It is found that a significant parameter is the point at which discharge is first observed as the voltage is raised (the discharge inception voltage). Related to this is the discharge extinction voltage, at which discharge ceases when the voltage is lowered. For studies of dielectrics electrically stressed over long periods, the latter is measured, but this would be prohibitively tedious and wasteful if carried out manually. Hence a servo-mechanism has been developed which automatically lowers the test voltage every five minutes to the value at which discharges cease, and then raises the voltage again to the test level. The envelope of the downward-going spikes thus shows the variation of discharge extinction voltage with time of application of stress. The interpretation of such records provides valuable information about the behaviour of discharges in all types of dielectric.

Impregnated Paper Capacitor Design

The results obtained in these researches on paper and impregnants, together with changes in the internal design arrangements, have enabled remarkable reductions in the size and weight of power capacitors to be achieved within recent years. For oil impregnated capacitors over the range of from 3 kvar. to 90 kvar. the volume for a given capacitance has been reduced from an average figure of 275 cu. ins. kvar. to 120 cu. ins. kvar. Over the same range the weight has been reduced from an average figure of 14 lb./kvar. to 6 lb. kvar.

Another design development is the high voltage unit capacitor. These units are normally built for a standard voltage of 2.4 kv. with a capacity of 25 kvar. These units are then arranged in a bank, with series parallel connections to give any combination of voltage or kvar. which may be required.

Corresponding developments have occurred in the design of the smaller impregnated paper capacitors, commonly used in electronic circuits. Such capacitors can be enclosed in aluminum cans or in protective plastic cases.

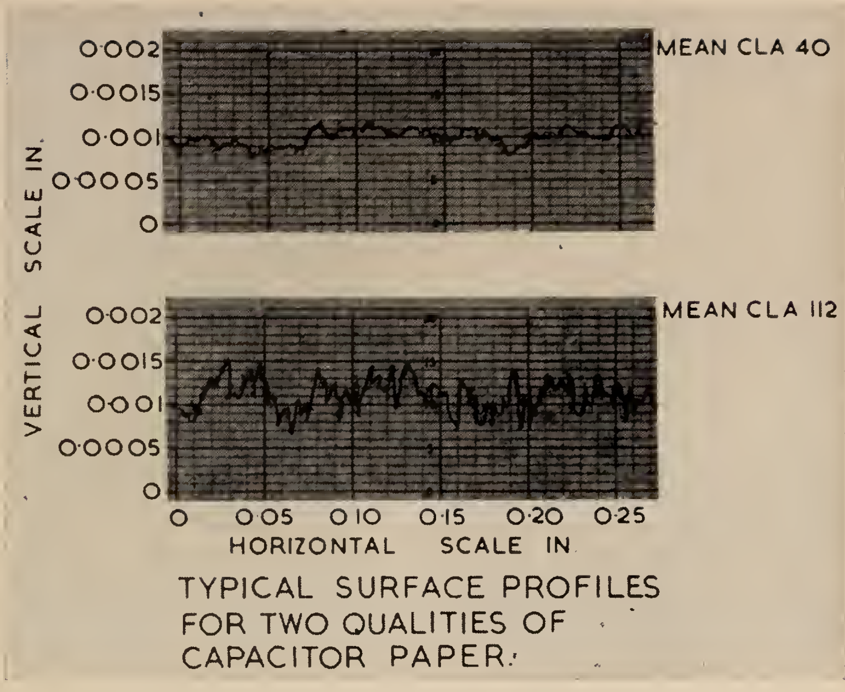

Fig. 2 Typical surface profiles for two qualities of capacitor paper.

SYNTHETIC POLYMER FILMS

Several of the various types of synthetic polymer films developed over the last decade possess attractive features as capacitor dielectrics, particularly for radio capacitors, where material costs are less significant than with large power capacitor banks. Some of the properties of the more important polymer films are listed in Table 1.

Apart from the electrical properties, the two most important properties determining the suitability of a polymer as a capacitor dielectric are its softening temperature, and the minimum thickness in which the film is available in continuous lengths, suitable for capacitor winding.

Polystyrene

Polystyrene is an excellent low loss dielectric available in high quality uniform film. With polystyrene and other synthetic films molecular orientation can be induced by stretching the film to upwards of 50% more than its original length. When released the film does not return to its original dimensions, but remains "set" in its extended length, with the molecules oriented and lying along the direction of extension. The film remains in this stretched and oriented state until it is heated to slightly above the softening temperature. Dis-orientation then takes place and it returns to its original length.

This property of orientation is utilised in the winding of polystyrene and other synthetic film capacitors. The winding is carried out with the polystyrene in the oriented state. After this the winding is "heat-shrunk" by heating it to just above the softening temperature. The film then contracts, thus producing a tightening of the winding of the film and stabilisation of the capacitance. Well-constructed polystyrene film capacitors compare very favourably in performance and cost with silvered mica capacitors. The rather low softening temperature limits their use to temperatures up to 70°C.

Polystyrene film capacitors possess the property of holding their electric charge to a phenomenally high degree. A group of three standard 1µF polystyrene capacitors charged to a potential of 500 V, and then kept in a sealed container, have been found at the present time, after six years, to retain more than 85% of their original charge.

Polyethylene

Polyethylene film is comparable in price with capacitor paper tissue, but it is not available in Britain in a thickness less than 18 micron (0.75 mil). It is only, therefore, attractive for high voltage capacitors.

Irradiation of polyethylene by high voltage electrons causes cross-linking of the polymer chains, resulting in improved electrical and mechanical properties at elevated temperatures. While normal polyethylene is only suitable for use at temperatures up to 80°C, irradiated polyethylene can be operated up to 120°C, and, if oxygen is excluded up to 150°C or above.

Electron irradiation is carried out by means of a two million volt particle accelerator of the *Van de Graaff* type. Irradiation of polyethylene causes luminescence.

Terylene

Polyethylene terephthalate (Terylene) film sold commercially as *Melinex* or *Mylar*, is very attractive as an alternative capacitor dielectric to paper, in all respects except cost. It has a high electrical and mechanical strength, a relatively high softening temperature, and it is available in thicknesses down to 6µ (0.25 mil). A 500 V Melinex film capacitor is about equal in size to a 300 V paper capacitor.

Teflon

Polytetrafluoroethylene (P.T.F.E. or *Teflon*) has excellent dielectric properties combined with a high

Table 1. Synthetic Polymer Films

Material	*Permittivity (1 K c/s)*	*Loss Tan. (1 K c/s)*	*Max. Safe Operating Temp.(°C)*	*Minimum Thickness (Microns)**	*Dielectric Strength (Volts/Mil)†*

Teflon	2.0	0.0002	200	6	1000

*1 Micron = 10^{-3} mm = 0.04 Mil † For Min. Thickness softening temperature, and it is hence suitable for high temperature, low loss capacitors. The material is originally made as a latex suspension, and a special technique has been developed for preparing uniform thin films. The P.T.F.E. latex is dip-coated on to a thin aluminum foil in a film whose thickness is controlled by surface tension and the coating is subsequently heat-treated and sintered by passing through an electric furnace. Laboratory apparatus used for this work is shown in Fig 3. This results in a uniform P.T.F.E. film of thickness down to 6μ (depending on the coating speed and conditions), deposited on the aluminum foil, from which it may be subsequently stripped if required. The slide shows reels of P.T.F.E. film made by the process. P.T.F.E. film capacitors are now available commercially, particularly to meet stringent Service requirements for guided missiles, etc., including an operating temperature of 200°C.

METALLISED CAPACITORS

The capacitors considered so far all have solid aluminum foil electrodes. Because of the presence of pin-holes, conducting particles, or other weak spots in the dielectric tissue or film, it is essential to use two or more thicknesses of dielectric film to eliminate local breakdown. As there are mechanical limitations on the minimum tissue and film thicknesses available, this means that it is often necessary to use a thicker dielectric than is needed to withstand the electrical stress over the bulk of the material. The capacitance per unit volume is proportional to the inverse square of the dielectric thickness, so that the physical size of a capacitor of a given value can be reduced by a factor of 4, by using only one thickness of dielectric film instead of two. This can only be achieved by introducing some method to eliminate the weak spots in the insulating film.

The metallised capacitor construction provides such a method. The solid foil electrode is replaced by a thin layer of metal, deposited by vacuum evaporation or other means. A pair of single metallised dielectric films are wound together to form the capacitor, the electrode connections to alternate layers of metallising being made by spraying on to the ends, and soldering on terminals. After winding and heat treatment (if required), and prior to service, the capacitor is subjected to a gradually increasing d-c. voltage. This causes local breakdown at any weak spots in the dielectric, but the energy of the local internal coronae is sufficient to evaporate and oxidise the thin metal layer in its vicinity, thus terminating the breakdown. After clearing, the capacitor is conservatively rated at a working voltage of one half of the maximum clearing voltage applied. Should any further faults develop in service, these will be similarly cleared by the operating voltage, so that the electrical failure is virtually eliminated by the "self-healing" property of the capacitor.

Vacuum Metallisation

A great deal of research and development work has been carried out on the metallisation of paper and of various polymer films. Vacuum metallisation plant used for this work is illustrated in Fig. 4.

In vacuum metallisation the basic principle is to melt the metal in a vacuum which is hard enough (about 10^{-4} mm. Hg) so that the mean free path of the atoms evaporated from the molten surface is sufficient to carry the atoms on to the paper or film where they are deposited and adhere. The film is metallised continuously. It passes from the supply spool, over rollers to the first crucible, where a very thin monatomic layer of silver is evaporated on to it. (Fig. 5). This forms a sensitising layer for the subsequent evaporation of the main metallised layer from the second crucible. In the initial work zinc and cadmium, which have relatively low boiling points, were used, but more recently techniques have been developed for the continuous evaporation of aluminum directly on to lacquered paper or film. Aluminum is preferable, since it is less chemically active, while its oxide, formed during the "clearing process", has excellent dielectric properties in its own right. After applying the metallised layer, the film passes over a pair of metal rollers, and the resistance square of the metal film is measured between these. This specific resistance is monitored, and it is maintained at a uniform value regulating the speed of the motor driving the film across the evaporation crucible. The film is then wound on the "take-up" spool, contact rollers being used in handling thin films liable to crease or be frictionally electrified.

The vacuum metallisation technique has been successfully applied

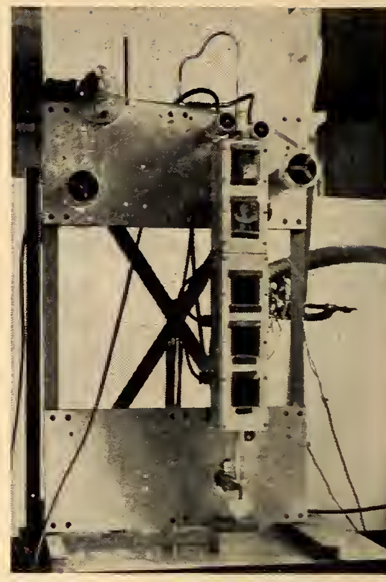

Fig. 3 Apparatus for P.T.F.E. latex dip-coating of thin aluminum foil.

to paper, polystyrene, polyethylene, Terylene and P.T.F.E. With paper a thin layer of lacquer is applied before metallising, to prevent penetration of the metal vapour into the pores. Provided the evaporation conditions are properly controlled, no difficulty is experienced with thermo-plastics such as polystyrene and polyethylene, although the temperature of the metal vapour (1400°C for aluminum) is greatly in excess of the softening temperature of the plastic. A cold water jacket in contact with the top surface of the plastic film assists in eliminating damage to the film by the hot vapour.

Metallised Capacitors for D.C.

Metallised capacitors are particularly suitable for D.C. application in radio circuits. They are not suitable for frequencies above 50kc, since the resistance of the metallised layer and the spray connections then contribute appreciably to the loss factor of the capacitor.

Metallised paper capacitors, of the same capacity and working voltage as conventional capacitors, are smaller in size due to the type of construction. This is again apparent when one compares metallised capacitors made from plastic films of various thicknesses, with a silvered mica capacitor.

Metallised Capacitors for A.C.

Although metallised capacitors were originally developed for d-c. applications in radio circuits, they have attractive potentialities for a-c. power capacitors, and these are being actively studied. Any doubts about the "self-healing" properties of metallised paper capacitors under a-c. conditions were completely resolved by a rather spectacular experiment. A metallised paper capacitor winding of 18μF, was connected to a 400V, 50c/s supply, in series with a current meter and fuse. While on voltage a steel nail is driven through the capacitor winding. Due to the rapidity of the "clearing" action no change could be observed in the meter reading, either during or after the insertion of the nail, and the capacitor continued to function satisfactorily. It should therefore be possible to develop metallised paper capacitors for a-c. applications, equivalent in performance and life to normal impregnated paper capacitors, but considerably reduced in physical size.

CERAMIC CAPACITORS

The Ferroelectrics—Barium Titanate

The high permittivity of ceramics, based on the ferro-electric material, barium titanate, form an important group of dielectric materials for use particularly in miniature radio capacitors.

Barium titanate is a ferro-electric material, in which the molecular dipoles are aligned in domains, just as in a ferro-magnetic material the molecular magnets are aligned in domains. Such domains impart a high permeability to a ferro-magnetic material; in a ferro-electric material they produce a high permittivity.

There are several similarities between the dielectric behaviour of a ferro-electric substance and the magnetic behaviour of a ferro-magnetic substance. Thus the permittivity of pure barium titanate is about 1500 at normal temperatures, rising to about 7000 at 120°C. Above this so-called *Curie* temperature, the material loses its ferro-electricity, since the domain structure is destroyed by thermal vibrations, and the permittivity falls rapidly with increase in temperature. A similar effect occurs with a ferro magnetic material, which loses its high permeability when heated above its *Curie* temperature.

High Permittivity Ceramics

For some capacitor applications, the permittivity-temperature characteristic of barium titanate, with a practically constant value of 1500 at normal temperatures is adequate.

Higher permittivities, and hence larger capacitance/unit volume, can be obtained by shifting the high permittivity region near the *Curie* point to the normal temperature region. This can be achieved by the addition of other titanates, notably strontium titanate, to the barium titanates, forming mixed titanates whose *Curie* point lies at lower temperatures.

These characteristics are too sharply peaked for most capacitor applications. The characteristic can however be flattened by suitable additions, notably the stannates and the zirconates to the titanate ceramics.

High-Permittivity Ceramic Capacitors

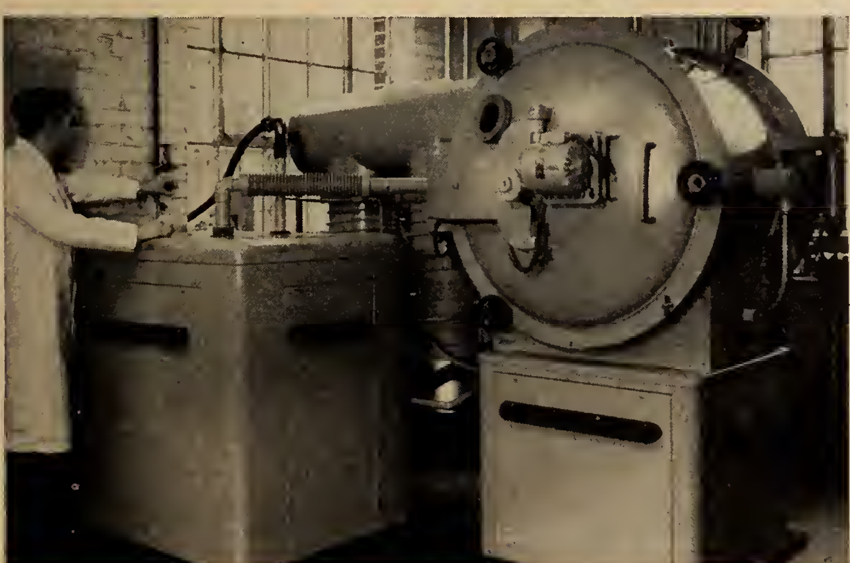
Due to the high permittivity, a large capacitance/unit volume is achieved with low voltage miniature ceramic capacitors. These ceramic capacitors are particularly suitable for use in h.f. radio circuits, when low loss and high stability of capacitance are not essential. More than 40% of all capacitors used are ceramic types.

Although most ceramic capacitors operate at relatively low voltages, a special high-density high-permittivity ceramic, with a breakdown strength of over 80 kv./cm. has been developed for high voltage applications. An experimental 5500 pF ceramic capacitor was designed to operate at 25 kv., and tested up to 80 kv. without failure, with the equivalent impregnated paper capacitor which it replaces. The ceramic disc is embedded in epoxy resin to eliminate surface tracking, and it is held in a protective cup of phenolic resin.

Other Ceramic Capacitors

Apart from the high-permittivity titanate ceramics, ceramics based on titanium oxide (rutile) and magnesium titanate/barium titanate mixtures, which have permittivities of about 90 and 36 respectively, form an important class of capacitor dielectrics. Being non-ferro electric, these materials have a low dielectric loss. They are particularly suitable for use in high-frequency capacitors, either at low voltages in radio receiver and similar circuits, or at high voltages in transmitters or other high frequency power applications.

Fig. 4 Plant for vacuum metallisation of paper and polymer films.



ELECTROLYTIC CAPACITORS

Like the oil-impregnated capacitor, the aluminum electrolytic capacitor has maintained its traditional place in the components field. During the last decade substantial improvements in design and technique have, however, been made, and the reliability and performance of the modern aluminum electrolytic capacitor are greatly in advance of its pre-war counterpart.

Aluminum Electrolytics

Research has been carried out on the various phases of aluminum electrolytic capacitor fabrication. In the manufacture of electrolytic capacitors the surface of the aluminum is often first etched. This is because the effective surface area on which the capacitance depends, of the rough surface, due to the hills and valleys, is greater than that of the polished surface. One of the most significant advances has been the development of an improved method of etching, called "ripple etching", producing additional increase in the capacitance/unit area of the formed foil. In ripple etching an alternating current is superimposed on the normal direct current used for the etching. By suitable control of the a-c./d-c. ratio and of the a-c. frequency, capacitance magnifications of up to 12 times at a forming voltage of 500 v. and correspondingly increased magnifications at lower forming voltages are achieved.

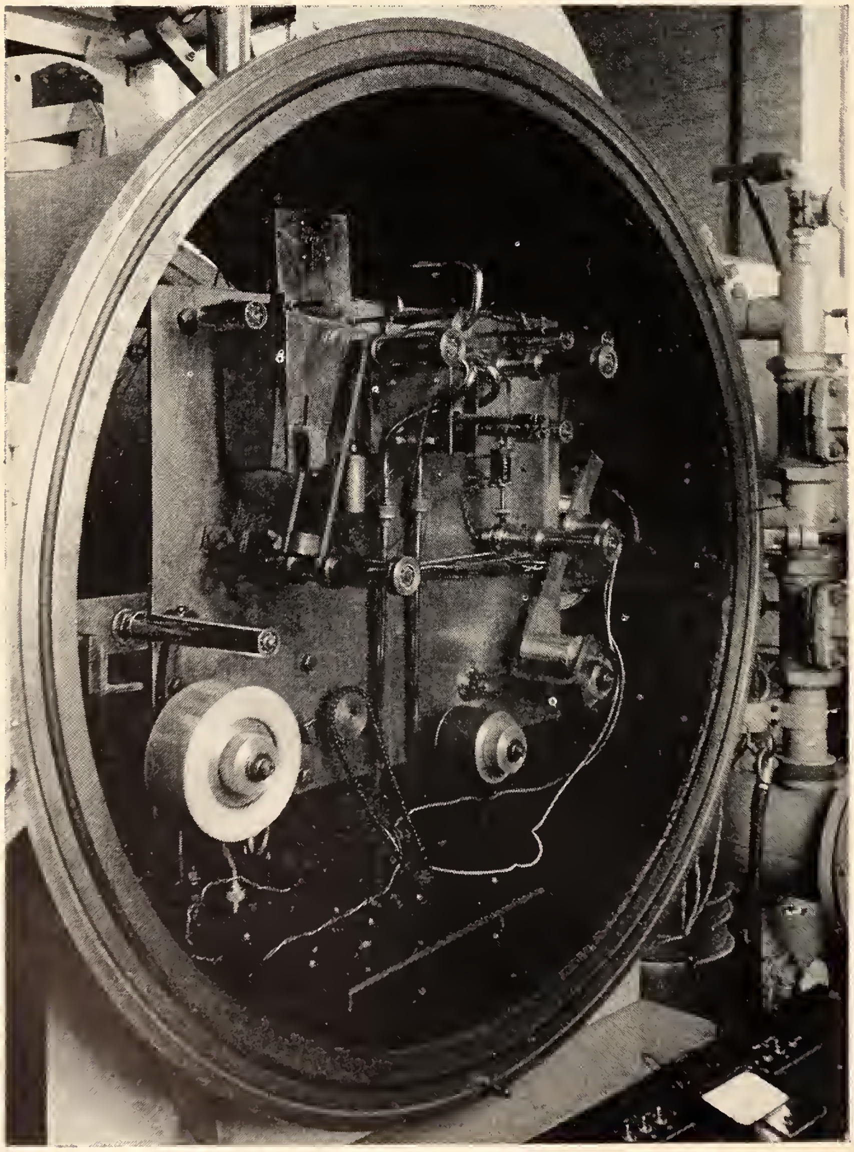
A range of miniature aluminum electrolytic capacitors, has been developed for use at low voltage in transistor circuits. Also, a group of special high-grade aluminum electrolytics, known as *Superlytics*, incorporating the results of recent researches, have an electrical performance and insulation resistance comparable with impregnated paper capacitors.

Tantalum Electrolytics

The post-war availability of tantalum has led to the development of the tantalum electrolytic capacitor. Tantalum and its oxide are much more chemically inert than aluminum and its oxide, and tantalum electrolytic capacitors have improved electrical performance and life compared with aluminum electrolytics.

It has been found that a major improvement in the uniformity and stability of the capacitor is produced by electro-polishing the tantalum foil prior to formation.

Fig. 5 Internal view of vacuum metallisation plant.



CAPACITORS FOR PRINTED CIRCUITS

One of the most important recent developments in the electronic industry has been the introduction of printed wiring circuits. These printed circuits, etched from the copper foil and supported by an insulating base material, can be mass-produced, and they lend themselves readily to mechanised methods of circuit assembly. A wide range of capacitors have been developed specifically for use in printed circuits.

MINIATURE CAPACITORS FOR TRANSISTOR APPLICATIONS

The metallised capacitor, the high permittivity ceramic capacitor, and the electrolytic capacitor, each represent techniques for the miniaturisation of components, by increasing the capacitance/unit volume. The development of transistors, as alternatives to electronic valves, has intensified the demand for miniature capacitors operating at low voltages of 5-50 v. The satisfaction of this demand involves ingenious new techniques in capacitor design.

Metallised Lacquered Foil Capacitors

The metallised lacquered foil capactitor represents a further stage in the miniaturisation of the metallic plastic film capacitor. The construction consists of a 6 micron aluminum foil, each side of which is coated with a thin lacquer of dielectric, from 1 to 6 micron thick. One edge (A) of the aluminum foil is then etched back 1-2 mm. by immersion of the rolled foil in a hydrofluoric acid solution. The thin lacquer layers on each side of the foil adhere to each other after the etching, thereby insulating the edge of the foil. One of the dielectric coatings is then metallised by vacuum evaporation, leaving the unusual insulating margin along the other edge (B). The coated metal foil, is then wound in a single roll to form a capacitor. Electrical connection is made to the metallised electrode along edge (A) by metal spraying and soldering. Similar connection is made to the aluminum foil electrode along edge (B), using ultrasonic soldering for connection to the aluminum. The capacitor is then "cleared" electrically, to eliminate any weak spots in the insulation, by the application of a gradually increasing

d-c. voltage up to twice the working voltage.

The metallised lacquered foil construction is applicable to any dielectric that can be applied as a lacquer to the aluminum foil. Among the materials successfully used in this manner are Desmodur/Desmophen lacquer polystryrene, polyethlyene and polytetrafluoroethylene.

A related miniature capacitor development is the metallised aluminum oxide capacitor developed from the electrolytic capacitor. In this type, the dielectric consists of a thin (0.5 to 1μ) layer of dry aluminum oxide, formed electrolytically. A metallised layer is evaporated on to the oxide surface, forming a capacitor with the very high capacitance of about 0.1μF/sq. in. The electrical properties of the metallised aluminum oxide capacitor may be used either in flat film, wound or stacked form.

Solid Tantalum Oxide Capacitor

The most recent miniature capacitor development is the solid tantalum oxide capacitor. This type has been evolved from the sintered tantalum electrolytic capacitor, which consists of a formed, porous block of tantalum, coated with oxide, and used with a sulphuric acid electrolyte. The corrosive nature of this electrolyte is a disadvantage of this type of capacitor.

In the new development, the formed porous tantalum block is immersed in a manganese nitrate solution, which is heated and thus decomposed, depositing semi-conducting manganese dioxide in the pores of the body. The surface of the block is coated with graphite, sprayed with metal, and a soldered lead attached as the cathode terminal.

The solid tantalum oxide capacitor has the highest capacitance/unit volume of any type (up to 10,000μF/cu. in. at 5 v. d-c.), yet its electrical performance is superior to electrolytic or other comparable capacitors, for potentials up to 35 v.

CONCLUSIONS

The sections of this paper reveal something of the multiplicity of types of capacitors that have been developed to meet diverse requirements and applications.

To summarise and present a clearer picture of the whole situation, Table 2 sets out the main features and properties of the 17 types of capacitors mentioned in this paper. It will be noted that of the 17 types considered, 10 are in large-scale commercial production. The remaining 7 which are still under development, are designed to replace or to supplement existing types, or to meet new and more stringent requirements.

Each new application or requirement as it arises is a challenge to the capacitor scientist and engineer. Progress over a wide field is rapid and there is little doubt that the future needs of the great electrical and electronic industries will be met.

MEASURING HUMAN MOTIONS for DESIGNING MACHINES

G. Nadler, *Head of the Department of Industrial Engineering*

J. Goldman, *Assistant Professor of Industrial Engineering*

Washington University, St. Louis, Mo. U.S.A.

FIFTEEN YEARS have seen overwhelming changes in engineering. The technology has improved, scientific frontiers have been pushed forward, new principles and concepts have emerged and of equal importance, the engineer has become aware of and started to assume responsibilities for the human being.

This awareness represents a significant stride forward for the professional stature of engineering. It is now considered necessary to attempt to fit the surroundings and equipment to the human being. It is difficult to state from where this new trend has come, but certainly new information from psychology and physiology has helped much. Social awareness of human values has become prevalent in executive thinking. In addition, labor unions have helped focus attention on the human being. Regardless of the source, everyone agrees that this awareness is a good step, and should even be expanded.

Of the many activities important in engineering, one concerning design is related to this awareness: the design of machines and equipment to fit the human being. Western civilization is known for its ability to design equipment for extremely advanced functions and performances. However, some of these designs have been literal monsters in relation to the human use of the equipment.

Part of the reason this condition has existed is related to the lack of information available to help the machine designer in his work. The most important unsolved problem is to determine what happens in the performance of work. This question should be answered for uses in the general and specific senses: (1) identifying and formulating general principles, and (2) attempting to test and/or evaluate specific designs of machines or equipment. There have been some general principles and specific techniques available in the field of industrial engineering. These have been rather broad and gross, not providing the type of information really required as indicated above.

This is a serious engineering problem and affects the general tendency of engineers to be more conscious of the human problem. This problem is one for which engineers and engineering principles are needed for arriving at a reasonable solution.

Fundamentally, the question of determining the performance of an individual using a particular piece of equipment is the same as asking what are the individual's motions at that particular design. Most research tools, like kymograph, motion pictures, and chronocyclegraph, have resulted in little additional information for the machine designer. The problem then becomes one of measuring the motions to provide enough information for the engineer to fit the classical definition of work, concerning the motion of a point of application of a force.

In effect, this means that the velocity, acceleration, deceleration, position in space, distance and time of a motion must be measured. It has not been possible to measure these factors for human motions until the UNOPAR (Universal Operator Performance Analyzer and Recorder) was developed. With the above information, it will be possible to obtain all information about what happens in the performance of any motion or series of motions.

Development of UNOPAR

In designing a new device for making these measurements, certain factors had to be considered. The measurements must be three dimensional; any attachments to the body member studied must be small and light; any device developed must be capable of being used under actual working conditions; the range of velocities might be rather small (0 to 10 feet per second); the range of acceleration and deceleration could be quite large; and so forth. By exploring the application of electronics in this problem, a suitable solution, the UNOPAR, has been obtained.[1]

Initially, there were a number of possible measuring techniques which could conceivably fulfill some or a great number of the aforementioned requirements. After careful consideration, it was decided that the Doppler effect with sound as the radiation medium presented the fewest formidable obstacles for successful development of a work measuring device.

Fundamentals of the UNOPAR

The operating frequency of the UNOPAR was chosen at 20,000 cycles per second which is above the threshold of hearing at normal levels of intensity. This frequency helps overcome the interference problem from other noises within a factory or laboratory and would not disturb the performance of the operator. The sound emitting source (speaker) must be attached to the body member (wrist, finger, elbow, etc.) which is to

1. J. Goldman, "Development and Testing of an Electronic Method for Determining Acceleration, Constant Velocity and Deceleration of Body Motions," Doctor of Science Dissertation, Washington University, St. Louis, Mo., Aug. 1955.

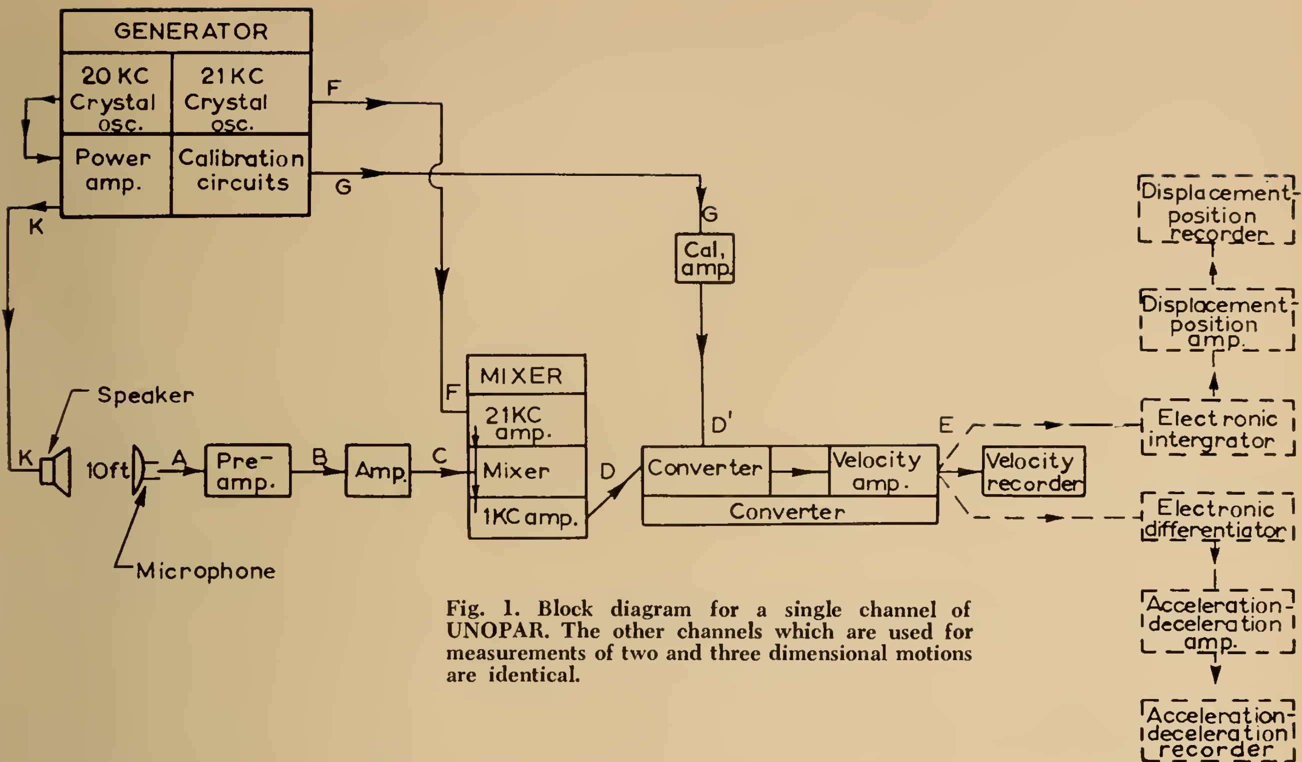

Fig. 1. Block diagram for a single channel of UNOPAR. The other channels which are used for measurements of two and three dimensional motions are identical.

be studied; however the size of this source is at present smaller in diameter, thinner and lighter than an ordinary wrist-watch.

Three microphones, oriented in three planes, with the directional axis of each perpendicular to the directional axes of the others, are utilized to measure motions in the three planes. Each microphone receives its component portion of the sound waves emitted from the speaker attached to the body member moving towards or away from the microphone. This system provides a variable reference orientation, since the three microphones can be rotated in any position as long as their orientation with respect to each other is fixed. This flexibility makes it possible to circumvent obstacles to the path of transmission and to permit use of overhead space in industrial situations.

Because of the Doppler effect, a transmitted source of sound (speaker) that is in motion relative to a stationary receiver (microphone) provides an increase or decrease in frequency of sound waves at the receiver which varies directly with the velocity of the source. Motions toward the microphone will increase the frequency received, and motions away will decrease the frequency received.

Fig. 2. The new specially designed Lorenz Electrostatic Speaker is only 1" in diameter, ¼" in thickness and weighs less than one ounce. It is shown with a regular watchband and the two small wires used to operate it. The UNOPAR speaker is being worn on the wrist of the operator being studied.

To minimize the error which can be caused by the moving speaker not remaining in the direct axis of each stationary microphone, the motion of the speaker is assumed to be confined within a one yard cube and the microphones are placed 10 feet away from the centre of this cube. The maximum possible error of measuring the velocity and time (the two basic measurements made with UNOPAR; the other measurements are made mathematically and electronically treating the two basic measures) will not exceed 1% of true value. Because (1) almost all work activity is usually performed with a one yard cube, (2) the size of the cube and the distance of the microphones from the cube can be increased (with the appropriate adjustments in UNOPAR) if desired, and (3) it is possible to orient this cube in any manner to encompass the motions in an operation, this error problem becomes virtually non-existent for practical purposes.

Operation of the UNOPAR

The basic operating procedure of the UNOPAR begins with the generation of the operating frequency of 20,000 cycles per second (by crystal controlled oscillator at 20.000 k.c.). As is indicated in the block diagram (Fig. 1) this 20 kc. signal is sent through a power amplifier to the speaker. Most of the research work performed to date has been done by moving a speaker rather than by attaching a speaker to a moving body member. This has helped in learning more thoroughly about the potentialities of UNOPAR. In the near future actual body motion tests will be performed. If more than one body member is to be studied, a different frequency signal would be used for each member involved.

At the present time the Lorenz electrostatic speaker (Fig. 2) is being utilized in the experimental work. Present speaker developments indicate the actual size of the speaker will be reduced to the size of a thick nickel or quarter. This size will make it possible to study any type of physical work, because the speaker will not hinder the operator in any way.

The perpendicular vectors of the frequency changes are received by the three microphones. The block diagram (Fig. 1) shows only one microphone and its corresponding circuit; the same circuity would be used for the other two microphones. When the speaker is in motion, the frequency of the sound received at the microphone will be 20 kc. per second plus or minus the Doppler difference caused by the motion of the speaker. Since the voltage level of the received signal is low (175 micro-volts), it is sent through a preamplifier attached to the microphone stand (Fig. 3). From here, the signal is sent to an amplifier section of the UNOPAR electronic relay rack. This amplifier has seven tuned amplifier stages.

The 20 kc. signal, plus or minus the Doppler difference frequency, is mixed with a 21 kc. reference signal (generated by a crystal controlled oscillator of 21.000 kc. control). From this mixing, a 1 kc. signal, plus or minus the Doppler difference frequency, is obtained. This is the usable signal for conversion to voltage. It is sent through two tuned amplifier stages to the converter chassis.

The converter circuit is arranged to provide a d-c. voltage output directly proportional to the frequency of the input signal. The resultant d-c. voltage is therefore directly proportional to the velocity of the speaker.

The d-c. voltage for each plane of motion is sent through an amplifier to the three velocity recorders. Each amplified d-c. voltage is also sent to an electronic differentiator, whose output voltage is proportional to the acceleration and deceleration of the speaker. Each of these signals is sent to an acceleration-deceleration recorder. Each amplified *velocity* voltage is also sent to an electronic intergrator whose output voltage is proportional to the displacement of the speaker. Each of these signals is sent to a displacement-position recorder. Direction of the motion is determined from the voltage variations above or below the voltage output of the one kc. zero velocity signal input. A larger voltage indicates a motion toward the microphone, and a smaller voltage indicates a motion away from the microphone. The three records for a given measurement unit can be combined into an absolute total by electronic vector summation.

The calibration circuit is designed to generate sine wave signals of the proper frequency and voltage to check the velocity and acceleration maximum displacement values, and the zero adjustment of all of the electronic equipment.

Fig. 3. Dr. Goldman makes the final alignment of the Altec-Lansing high frequency microphone in preparation for making a measurement with the UNOPAR. The self-contained preamplifier unit is attached to the microphone stand.

A 12 channel d-c. oscillographic recorder is used to plot the individual vectors of velocity, acceleration-deceleration, and displacement-position. The summation vectors of velocity, acceleration-deceleration, and displacement-position are also plotted on this recorder. The recorder is capable of plotting information at a constant synchronously controlled maximum speed of 125 mm. per second (5 inches per second), thus providing an accurate timing record for every motion and the above information.

Future Development of the UNOPAR equipment

The present electronic equipment and recorders are fairly large. De-

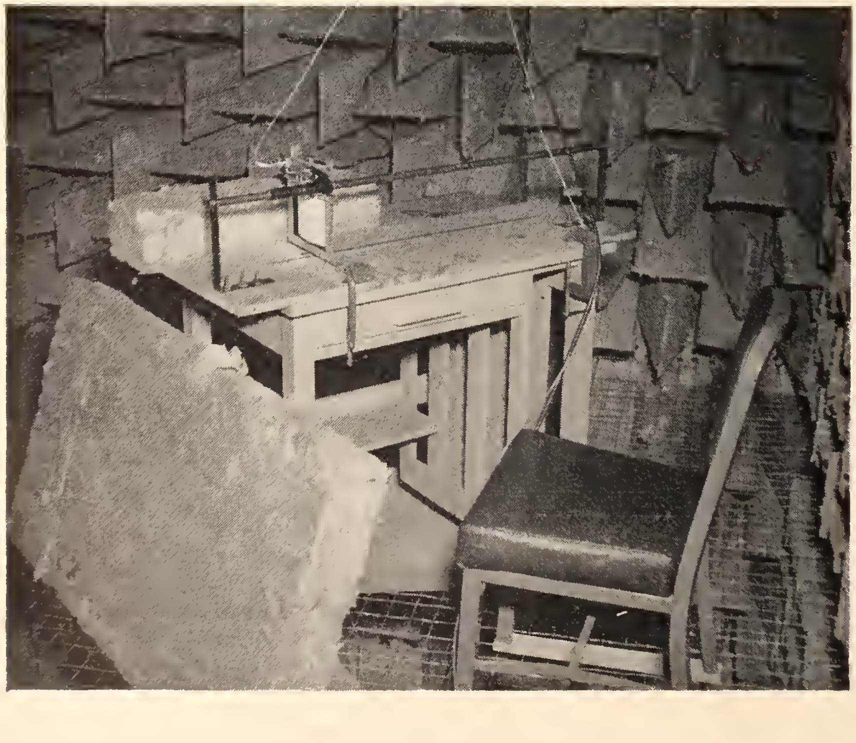

Fig. 4. Original verification apparatus used to check the validity and accuracy of the UNOPAR measurements. Note the small accelerometer (connected to the black wire) firmly attached to the same rigid frame as the test speaker, to insure that motions of the speaker and accelerometer were identical. Entire test apparatus is shown inside the anechoic chamber where the validification tests were made.

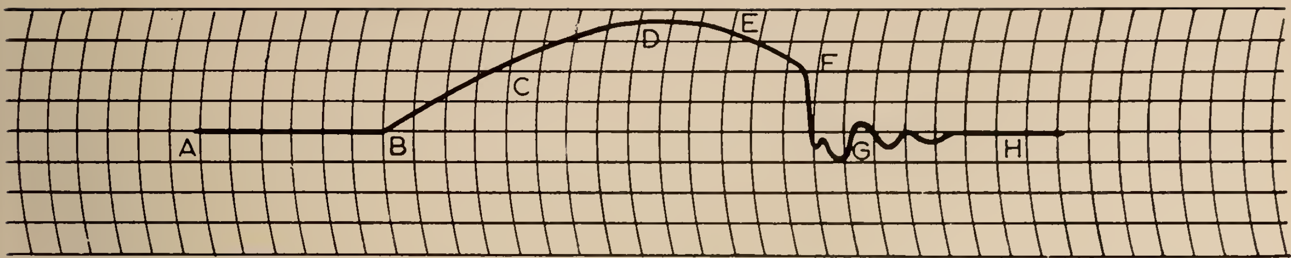

Fig. 5. Facsimile of a section of the UNOPAR velocity vs. time tape on which is recorded the one plane motion of the original test speaker. In this motion the hand moves the speaker from rest, over a known distance and strikes the front end brace of the test apparatus (Figure 4) to check the transient response of the system. The straight line section of the tape between points A and B shows zero velocity (center line of chart is zero) indicating the hand at rest. As the hand began to move the speaker down the rod, the velocity charted increased rapidly from point B to C to D. The changing velocity along this section of the curve (slope) is the acceleration portion of the motion. At point D, the velocity reaches its peak. The curve is not flat (does not remain at a constant velocity) on top but changes smoothly from its rising characteristic (acceleration) to a falling one (deceleration) as the hand begins to slow down (D, E, and F) before striking the end support. The speaker struck the barrier at point F and the velocity dropped immediately. Slight rebounds (damping) of the hand and speaker frame are indicated by the wavy motions of the curve at Point G. The straight line at point H indicates that the hand had come to rest again. This motion was recorded with the tape running at the fastest speed of 125 mm./sec. Therefore, each large division between the curvilinear vertical lines on the tape represents a time interval of 0.000665 minutes. The time interval for the performance of this motion is easily and accurately computed.

velopment of the equipment indicates there will be a substantial reduction in the amount, size and weight of the necessary components. At the present time all the electronic equipment must be in operation when measurements are to be made. However, in the near future a 3 channel magnetic tape-recorder will be introduced into the circuit, between the mixer amplifier and the converter chassis. One channel of the tape-recorder will be utilized for each one of the three planes. The inclusion of the tape-recorder makes UNOPAR a much more versatile measuring device, since only a small part of the electronic equipment need be present at the operation when measurements are being made. The tapes can be taken back to an office or laboratory and studied at a later time at the leisure of the analyst. Magnetic tapes provide a simplified and compact system of storing information, a much more practical way of utilizing UNOPAR, and an easy method for referring to any motion for new measurements or repetitions of the measurements.

Another problem to be solved concerns handling, processing, and interpreting the great mass of data provided by the UNOPAR. At the present time, all the information is plotted in graphical oscillographic form. Each motion made by the operator provides data of velocity, acceleration, deceleration, displacement, position, and time. A digital computer would greatly facilitate handling and interpreting these data and performing any mathematical manipulations desired. Since the information from UNOPAR is in analog form (a continuous plot as every motion occurs), a conversion has to be made.

At the present time, the plotted curves are measured visually using a specially developed UNOPAR tape analyzer, and these measurements are punched into a digital computer input card. This requires a great deal of time and effort. To reduce greatly this additional work, the output of the UNOPAR can be fed directly into the analog-to-digital electronic converter. The output information from the converter takes the form of punched cards or magnetic tape suitable for input purposes to the digital computer. This proposed system for data handling is now in the preparation stage.

Reliability of UNOPAR measurements

Tests for the reliability of UNOPAR measurements were made for a one plane motion (there is no criterion for a three plane motion) with an accelerometer as the criterion source. The test-speaker apparatus is shown in Fig. 4. The test was made in an anechoic chamber. This was done to eliminate all extraneous noises and spurious reflections which might interfere with the accuracy of test measurements. The speaker and accelerometer were rigidly mounted on a frame for the one plane motion.

Chi-square and correlation techniques were used to check the size and shape of UNOPAR and accelera-tion-deceleration plots with the similar plots from the criterion accelerometer. Chi-square probabilities of 0.99 and above and correlations of 0.99 and above were obtained, indicating excellent fits for the two sets of curves. Additional verifications were made by calculating the standard deviation for percentage of error from the accelerometer plots for the maximum (peak) velocities, maximum acceleration-deceleration values, and time for a series of motions. For velocity, the standard deviation was 1.08 percent; for acceleration-deceleration, 2.17 percent; for time for velocity, 1.06 percent; and for time from acceleration, 2.79 percent. These results indicate excellent measurements from UNOPAR (there is evidence that indicates part of most of the errors obtained were due to the mass action of the accelerometer, not to UNOPAR).

A sample of the type of information available from UNOPAR is shown in Fig. 5. The motion was performed on the test set-up of Fig 4, and the motion was stopped by the support at the end of the track. The velocity plot in Fig. 5 shows the direct response of the device to a motion of this type. This was a critical test of the transient response of the system since the speaker was brought to zero velocity almost instantaneously. Another illustration of a velocity curve from UNOPAR is shown in Fig. 6. This plot is from a research project currently in progress.

Uses of the UNOPAR

Because the UNOPAR provides the measurements of actual human performance, many uses and benefits can be expected in the industrial situation. Other disciplines which make studies of human being performances will be able to use such a device. A brief review of some of the problems UNOPAR can help solve and the possible uses of the UNOPAR is given below.[2]

2. For a more complete discussion see the following: G. Nadler, **Motion and Time Study**, New York: McGraw-Hill Book Co., 1955, pages 417-428; G. Nadler, "Electronics in Work Measurement," Proceedings, 6th Annual Conference, American Institute of Industrial Engineers, 1955; J. Goldman and G. Nadler, "Electronics for Measuring Human Motions," **Science**, Vol. 24, No. 3226, pages 807-810, October, 1956; J. Goldman, op. cit., page 85.

1. Work Simplification and Measurement. This is an important area in which information valuable to the machine designer would be obtained. Many problems confront the analyst in this area. What is a motion? How is it performed? What are correct classifications of motions? What effect does one motion have on another? What is the sequence of motions? What is the proper method of performing a job? How can an operator's performance be measured? What is the effect of mechanical or difficulty factors on operator's performance?

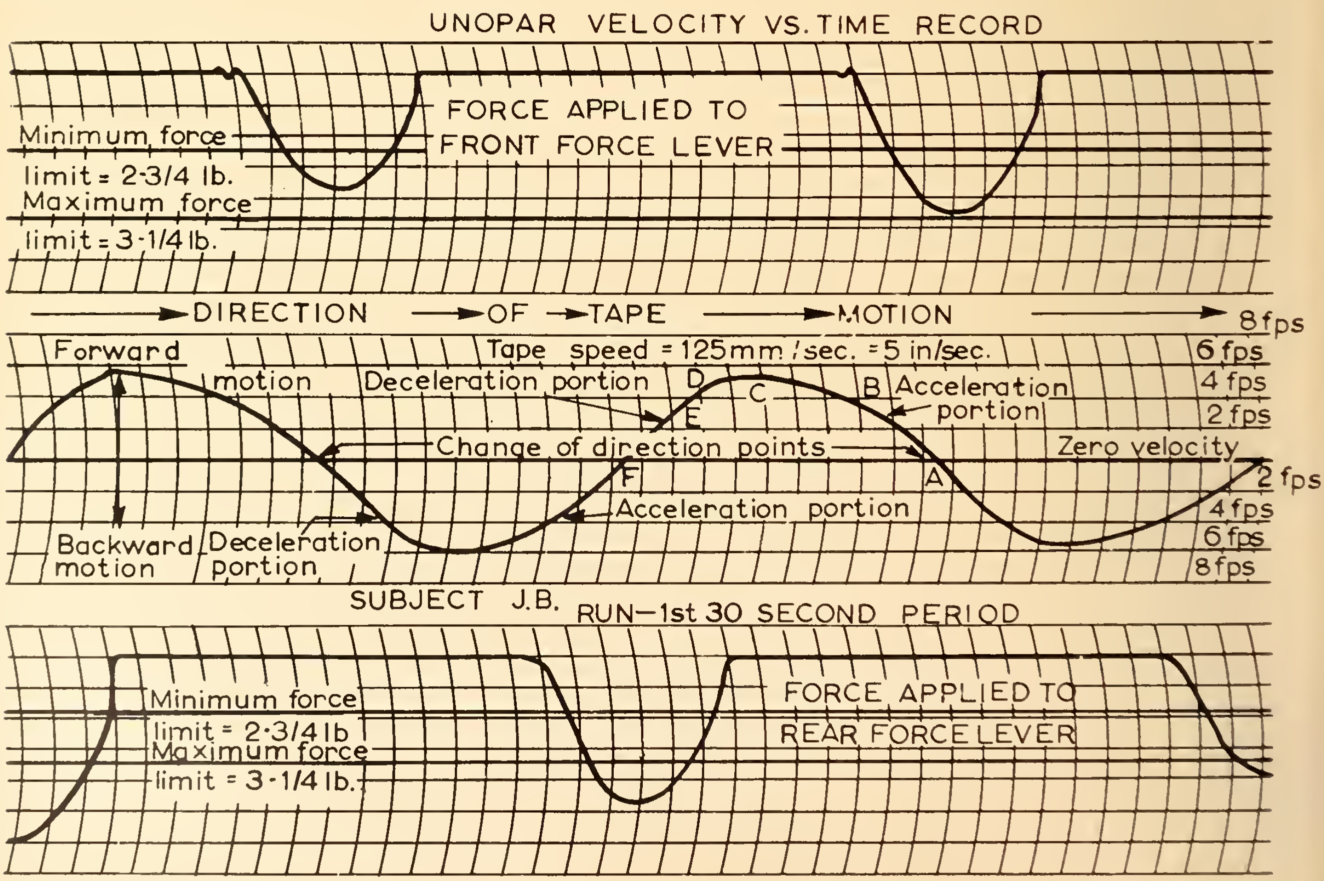
2. What is fatigue? Engineers are accustomed to the word fatigue in relation to materials. Now it has become important to learn about fatigue in relation to human beings to assist in design of equipment. Little is known about this subject, and getting the information about motions that UNOPAR provides will produce further advances in this area.

3. Psychological activities. There are many areas in psychology which will eventually provide information for engineers. Since psychology deals with why people do the things they do, it becomes important to correlate this information with work performance records. Certainly the UNOPAR information on work will be highly valuable for such purposes. In addition, UNOPAR information will be helpful in selecting the right people for the jobs or equipment to be used, and for training them for the work to be done.

4. Physiological activities. Just as in psychology, there will be need for UNOPAR information for physiologists. The physiologists deals with the physical functioning of the body, and of course, this is highly related to the work performance itself. It will be possible for physiologists to learn the relationship between work and the functioning of muscles, heart rates, oxygen consumation, and so forth.

5. Other engineering activities. Materials handling depends on people to move material, drive trucks, operate hoists and push dollies. Automation will depend on information concerning man's abilities and capabilities under nonrepetitive work situations. Production control requires information on scheduling which is dependent on time standards. With UNOPAR delving into

Fig. 6. Facsimile of a section of the UNOPAR tape record taken from a current research project being performed for the Office of Naval Rcsearch. The UNOPAR velocity vs. time record is shown on channel 2 (center) of this tape and a force measurement is shown on channels 1 and 3. This research project was undertaken to study the effects of learning on the performance of a job. The job was one of learning to apply a certain force (within gvien tolerance limits) at both ends of a 19 in. motion. A resume of a typical cycle shows that the motion starts (point A) at the front end of the test table after a force has been applied to a force lever at this end. The subject moves with a rapidly increasing velocity from point A to B and then to the peak velocity at point C where he begins to slow down in anticipation of striking the rear force lever. The jog in the curve (sharp deceleration) at point D indicates that contact with the force lever has been made (see also point D') and subject then decelerates to zero velocity when he thinks that the terminal force has approached the assigned value. An observation of the actual terminal force applied to the rear force lever ,point F") shows that the subject exceeded the upper tolerance limit for this cycle. The subject is signaled that he is within the tolerance force range by a buzzer which sounds whenever a force is within the acceptable limits. The subject then begins the return cycle to the front force lever (from point F).



the fundamental structure of work, many engineering activities will benefit.

6. Other branches of science. Biomechanics is interested in the relationship between man and machine, and much of their work depends on information concerning what an operator does and the time or pace for the performance. Physical education is directly concerned with motions, motion paths and learning more about what an athlete does in his performance. The effects of mental illness on the performance of the job would help find where such persons might be profitably utilized. Physically handicapped persons could also be studied to find information about their usefulness. Military possibilities are many. What is the proper load and distribution of load for a soldier charging across a field? What does a jet pilot do in operating his controls?

This list of possible uses of UNOPAR could be expanded greatly since many applied sciences deal with human beings. A complete understanding of what a person does and how he does it will, when this is needed, greatly contribute to the most effective results in the various disciplines.

Although the UNOPAR has not developed complete information on human performance, it is apparent that this tool will greatly assist the engineer in his functions for the future. Certainly, this tool should make the engineer even more aware of his responsibilities for proper design for human use of equipment.

ECOLE POLYTECHNIQUE

(Continued from page 52)

120,000 volumes can be stored in the shelves.

At the west end of this floor are storage cabinets for maps, and at the opposite end is a secondary reading room which can accommodate 48 persons. In addition there are some thirty well-lit tables along the outer wall at which publications can be consulted.

The two floors of the library are also linked by an electrically-operated elevator.

Classification of Publications

As already mentioned, the main classification of publications is by the universal decimal system, but certain exceptions are made to facilitate reference to particular subjects.

The central reference file has cards for each item by name of author, by title of publication, and by subject. All these are listed alphabetically and, in the case of titles, regardless of the original language of the article. However, the pertinent information is in French.

Dictionaries and similar reference volumes, which are not issued on loan, are kept in separate shelves with adjoining reading tables.

Books are loaned only to teaching staff, students, and graduates of Ecole Polytechnique, with the exception of inter-library loans, but other interested persons are allowed to consult material in the library.

MATERIALS TESTING DEPARTMENT

The study of the mechanical properties of materials at Ecole Polytechnique has been subdivided. The materials testing department studies ferrous and non-ferrous metals and alloys, woods and plastics. Other materials such as concrete, bricks, etc., are the province of the civil engineering department.

The department provides basic introductory studies, postgraduate work, and research work by personnel members, both in the fundamental and applied fields which may lead to improved industrial applications. Many published reports of the work of this department have already made it widely known in North America, France, and Britain. Further advances are anticipated, and the new quarters, which almost double the previous facilities, will be most helpful to that end.

Facilities

The main room in the department contains all the test machines for static and dynamic tension, impact, torsion, and hardness. Extensometers, dynamometers, and precision instruments for mechanical, optical, and electrical measurements are enclosed by glass partitions, together with testing machine accessories and calibration equipment.

A smaller room houses several fatigue-testing machines, most of which were designed and built in the department's workshops. Tests can be made over a wide range of geometry and environment conditions for tension, compression, torsion in uni, bi and triaxial fatigue sollicitation.

High-temperature studies are carried out in other rooms equipped with furnaces and apparatus for analysis and the observation of crystalline structure. A 65 kw. furnace fitted with hydraulic pumps and controls is used for creep studies at high temperatures and pressures on 7 ft. long, 1½ in. wall thickness pressure vessels.

Another room is equipped for photoelasticity measurements, and an important feature is the workshop in which the various test pieces are machined. A photographic darkroom completes the laboratory installations.

A separate concrete room near the laboratory is used for plastic fatigue testing on model pressure vessels, 4 ft. long, ¾ in. wall thickness.

Other Features

A portable crane is provided for handling heavy loads, and a large door allows trucks to enter. All dividing partitions in the laboratory are glazed above a height of three feet from the ground, to give all-round visibility. An insulated double ceiling is provided to prevent the noise of machines reaching the library, which is immediately above the laboratory.

3500 TON UNIVERSITY OF TORONTO BUILDING MOVED 250 FEET

R. M. Bremner, P.Eng., A.M.I.C.E.,
in charge of construction and planning at the University of Toronto.

AN UNUSUAL engineering project was undertaken last summer at the University of Toronto. The building which houses the Faculty of Forestry was moved two hundred and fifty feet to a new foundation. The main reasons for this move were to:

(a) Provide a clear site for an extension to the existing McLennan Laboratories — construction of this extension will be started in the spring of 1959.

With the Forestry building in its old position the extension to the McLennan Laboratories would be 'U' shaped and involve the construction of an additional five hundred feet of external wall. The 'U' shape and other complications made it difficult to plan a satisfactory layout of laboratories and lecture rooms.

(b) Preserve Baldwin House.

A 'U' extension would necessitate the demolition of one of Toronto's oldest and finest residences. Until acquired by the University in 1923, Baldwin House was the residence of Ontario's Lieutenant Governors.

(c) Extend the facilities of the Department of Forestry.

The increased enrolment of students and the demand for better post graduate courses had taxed existing facilities. An extension was required to the existing building but no space was available as a result of the plans for the McLennan Laboratories.

(d) Maintain facilities for 1958-1959 classes.

Construction of a new Forestry building would take about eighteen months and for this period Forestry facilities would be disrupted; the University did not relish this delay and inconvenience. The estimated cost of new construction was $600,000.—a factor which was also given much consideration.

Tenders were called, at the beginning of May 1958, for the building move, new foundation and extension. These tenders showed a saving of 55% against the cost of new construction and thus a contract was let, early in June 1958, with Hartshorne and Nicholas Associates, a firm of experts in this type of work.

The Forestry building is a 30 year old three storey brick and stone structure. Exterior and interior brick walls are bearing walls, while floors and roof are reinforced concrete beams and slab. The main concrete floor beams, which are at 14 ft. 6 in. centres, span 21 ft., in a north-south direction, between the 2 ft. thick external walls and the 1 ft. 6 in. thick brick bearing walls of the central corridor, running east-west. The central corridor, which extends the full height of the building, is 8 ft. wide.

The overall sizes of the building are:

Length (east-west)	84 ft.
Width (north-south)	57 ft.
Height (basement floor-roof)	55 ft.

The estimated dead weight of the structure above the "break point" for moving was 3,500 tons. (The "break point" occurred approximately 3 ft. below the finished first floor level).

Work was started on the building at the end of June 1958. Holes were cut through the walls of the structure to accommodate seventeen 14 in. x 16 in. x 142 lb./ft. wide flange needle beams which were inserted through the building in a north-south direction. Under these seventeen beams a further four beams were inserted in an east-west direction and thus a grid of steel beams was formed which supported the structure when being jacked and moved.

The top flanges of the upper steel needle beams provided support for 8 in. x 6 in. oak secondary needle beams which in turn supported walls, ends of existing concrete beams and other points in the structure. These oak needles also acted as cushions under points of bearing. The layout and wedging up of these oak needles required much skill and care for these members were the only ones in direct contact with the structure.

The difference in level between the existing first floor and the final first floor was 6 ft. (see Fig. 1). This "lift" was planned in three sections:

(1) The structure was jacked up 3 ft. 6 in. along the north side and 3 ft. along the south side. The whole structure was, therefore, on a 6 in. tilt from north to south.

(2) Inclined track beams laid under the support grid were given a rise of 1 to 120 in a northerly direction. About 2 ft. was gained on these inclined tracks over the 250 ft. move.

(3) When the building was over the new foundation it was levelled off and then jacked up the remaining 6 inches.

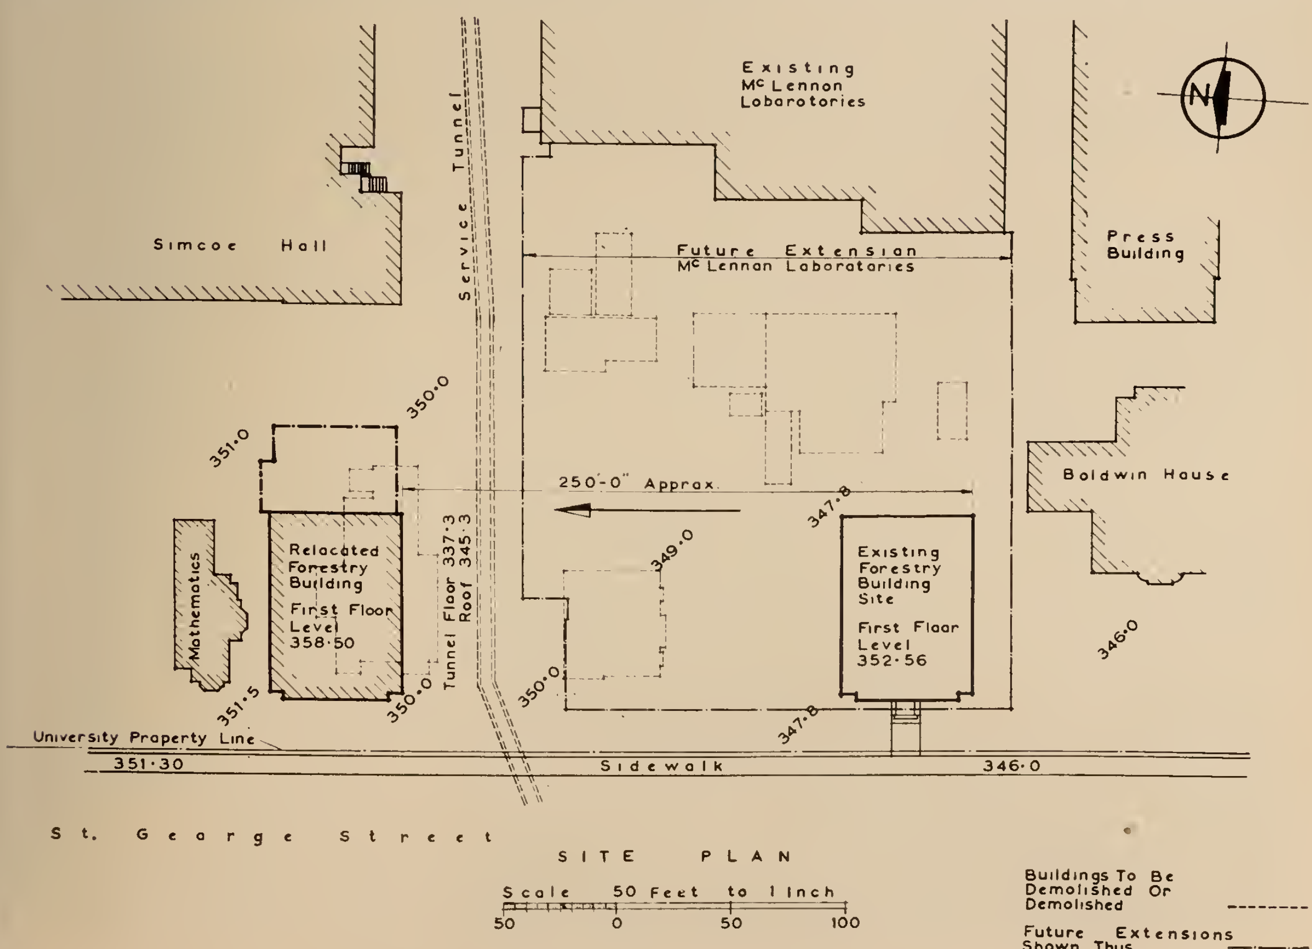
Forty-eight 100-ton Duff-Norton hydraulic jacks, with a rise of 6⅛ in., were used to jack up the structure. The jacks were arranged in four lines corresponding to the support beams running in the east-west direction. Each line of jacks was worked to definite sequence and no line of jacks was more than ⅛ in. ahead of the other. In this way the structure was jacked up as evenly as possible with all lines of jacks taking their share of the load.

It took about one day to re-set the jacks and build up cribbing after each 6⅛ in. rise. As the building was raised the efficiency of the jacking crew decreased since they were obliged to work from staging. (Fig. 2 shows the layout of jacks and cribbing when the building was raised about 18 in. and explains the reason for keeping the height of the initial lift to about 3 ft. 6 in.)

On completion of initial jacking the tilt of the building was about 1 to 120. The ground slopes up 24 in. from the old site to the new site (see Fig. 1) therefore the tilt of the building approximated to the slope of the ground and the track beams. A much more positive bearing was thereby obtained between the track beams and steel support frame and costly shaped packers were eliminated.

Before the building was moved and in order to provide additional bearing between the track beams and the steel needle beams a further four 14 in. x 16 in. x 142 lbs./ft. wide flange beams were inserted through the structure in an east-west direction. Eight sets of track beams were then run in north-south under the steel needle beams. A track beam comprised one 14 in. x 16 in. x 142 lb./ft. wide flange beam vertically on top of another with a 2½ in. diameter mild steel roller sandwiched between the flanges. The rollers were 2 ft. long and at 15 in. centres. All track beams were tightened up against the steel needle beams to ensure positive bearing and a 60 ft. length of track was continued, at the rise of 1 to 120, outside the structure and blocked with 8 ft. x 6 in. x 8 ft. oak baulks to distribute the loads from the tracks to the ground. The estimated ground pressure under the track beams was about 1¼ tons/sq. ft. which is a con-

Fig. 1. Plan of the area involved; showing existing Forestry building site, relocated forestry building and ground levels over the land traversed.



servative bearing pressure for the hard brown and grey clay strata under the move area.

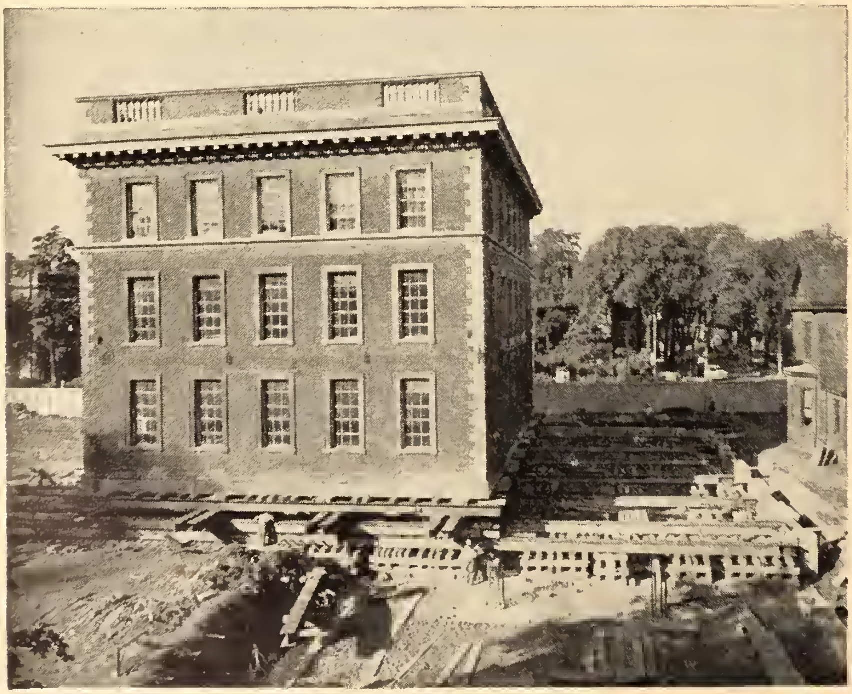
The maximum settlement observed on the track beam for a 60 ft. move was 1¼ in. while the relative settlement between individual tracks was no more than ½ in. The support beams of the structure appeared to adjust to these relative differences with no excessive strain imposed upon the structure.

Power for the move was obtained from two Mack Diesel trucks, each of 260 horsepower. Each truck had a 25 ton Silent Hoist winch mounted on the rear. Cables from the winches were arranged through a 6 line system of return blocks attached to various points of the steel support frame under the structure. The end cable of the six line system was anchored to a "dead man" in the ground. For the first 120 ft. of the move the trucks were positioned to pull the building towards them but for the last 130 ft. of the move they were arranged so as to move the building away from them. The two truck positions involved a simple rearrangement of cables from the winches, structure and anchor. (Fig. 3 shows the building just over the new foundation. Notice the steel beam at the end of the track beams being used as an anchor).

Preparation for each 60 ft. move took about one week, whereas the actual move took about 7 or 8 hours to complete. It was very important to maintain a balanced pull on each winch as the structure moved. Varying tensions on the cables tended to slide the structure off line and when this occurred the rollers would "fight" or bind each other. The structure was therefore moved in increments of 5 ft. and after each increment the rollers were trued up and re-centred. When the structure did move off line a correction was made by splaying the rollers in the direction of the required adjustment.

Fig. 2. The jacking crew at work: At this point, the building was being raised a further 18 in. and it was necessary for the men to work from staging.

Fig. 3. Here, the building has come to rest over its new foundation after moving 250 ft. from the old site.



The structure was relocated on the 23rd September and student classes in Forestry commenced on the 29th September. Underpinning was carried out while classes were in progress. The total time for the moving of the structure was 12 weeks while the new basement and extension was completed at the end of December 1958.

There was no structural damage to the building as a result of the move although a small sum of money was spent to tuck point parts of the exterior where the mortar joints to the brick and stone had spalled off.

This type of project is common in the United States particularly where highways are constructed through built-up areas. There appears to be no limit to the size or type of structure moved for the author has heard of 12 storey public buildings being relocated to preserve the structure and facilitate economic throughway construction. Some of these structures have been moved while the occupants still used all the facilities of the building and pursued their normal business day. The economy of moving a large structure varies with other circumstances but perhaps we may pause in the future to consider the possibilities of this technique.

A TYPEWRITTEN GRAMMATICAL WORD COUNTER

Jules O'Shea, Jr.E.I.C.,
Canadair Services Ltd.,
Pilotless Aircraft Division, Boeing Airplane Company,
Seattle, Washington., U.S.A.

This paper describes a simple electronic circuit counting exactly the number of grammatical words in a text as soon as they are typewritten. Such a device has already been constructed and has been described by the author.[1] Subsequently a public demonstration was given at the 1957 Annual Students Night of the E.I.C. Since that time the circuit has been completely redesigned and the previous limitations no longer exist.

As input or sensitive device, the first counter required complicated mechanical switches for sending pulses sequentially (as indicated on fig. 1) to the control unit. These were not commercially available and required tedious adjustments. Also this configuration resulted in poor accuracy at speeds higher than about 50 words per minute.

To obviate these shortcomings, the present counter uses only D.P.D.T. and S.P.S.T. switches which are fastened rigidly under the keyboard of the typewriter. This improvement has been possible after a new all-electronic circuit had replaced the previous one.

Definition

Since the computer proposed herein counts words, we must therefore define a word for our particular application. Any dictionary word (simple or compound), proper names, numbers, (regardless of the number of digits) can be detected and counted by the computer. Hence, a word is not a mere stroke average; the pronoun *I* for instance, must count just as heavily as the noun *antidisestablishmentarianism.* Moreover, the words are counted *grammatically;* the computer sees no difference between a simple word like *cat* and a compound noun like *brother-in-law.*

To sum up, let us say this special purpose computer has been programmed to solve the equation:

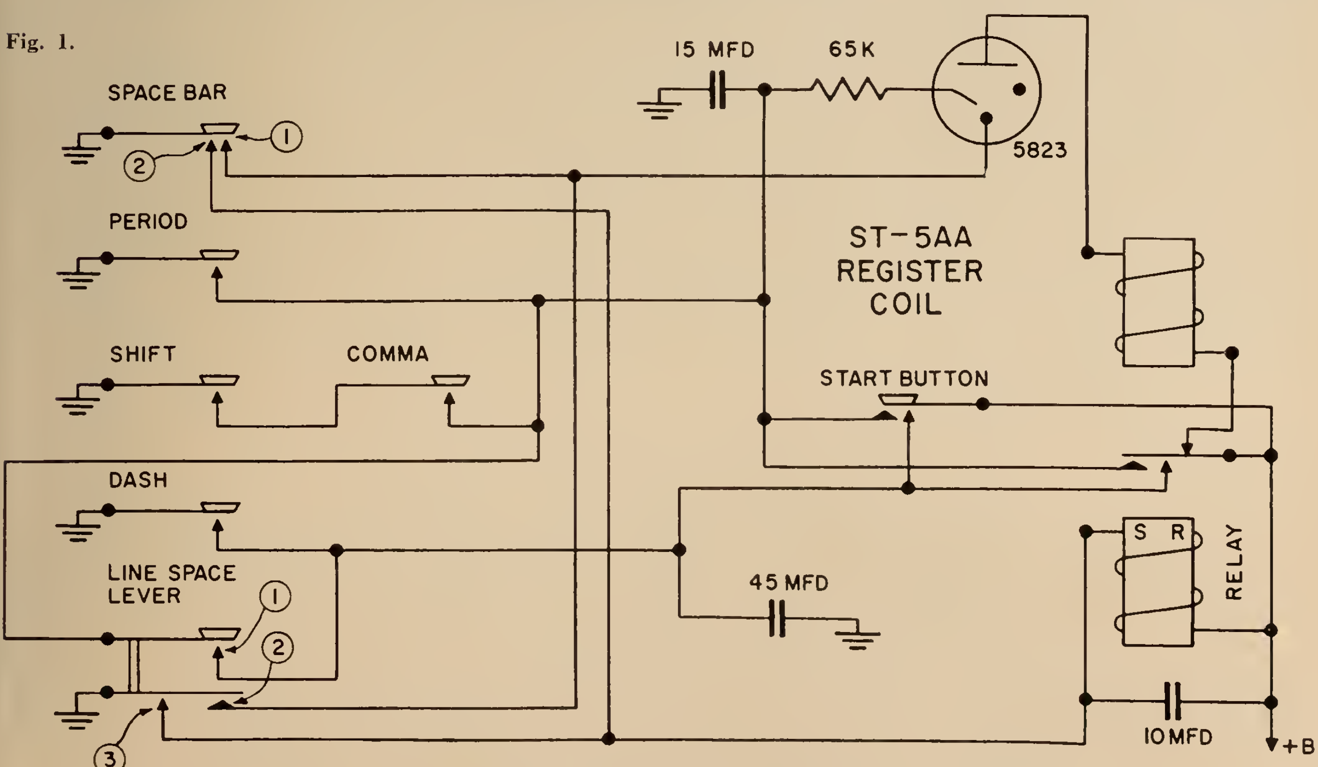
$$W = (S) + \frac{(S_s)}{2} + (L\text{-}L_h).$$

This equation infers that W, the number of words in a text, must be the number of times an electro-magnetic counter is energized by the computer circuit. Current (d-c pulse) flows through the register coil after either one of three predetermined conditions has occurred: (S) when the space bar is depressed between the words, ($S_s/2$) when the space bar has been depressed twice after a sentence, (L-L_h) when the line spacer lever has been actuated at the end of a line (L) which is not terminated by a hyphen (L_h).

A more detailed explanation for this setting will follow under the heading *Description.*

Since the switches are rigidly fastened to the keys, we have a built-in program. Therefore if one

Fig. 1.



GRAMMATICAL WORD COMPUTER

wishes to simulate another equation for "W", a mere relocation of the switches solves the problem.

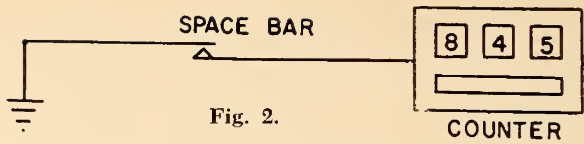


Fig. 2.

Description

The easiest solution to the problem of counting words printed by a typewriter seems to place a normally open S.P.S.T. switch under the space bar (fig. 2). Thus, every time a word is printed, the typist makes a space and contacts close the coil circuit of an electro-magnetic counter adding one to the total. However, it is a common office practice to leave two spaces at the end of a sentence and it follows therefore, that by using the single switch circuit, the last word of any sentence is counted twice. To remove this difficulty, we need four additional switches and a memory (fig. 3). The memory is a bistable circuit which stays on until it receives a pulse from the switches connected to the *gating bias,* then it turns off and must be re-set.

One of these switches performs two functions: it is operated by the period key and it also sends a pulse to the memory when an exclamation mark ends a sentence, since this punctuation mark necessitates the use of the apostrophe and the period keys sequentially. The other two switches are in series: one is actuated by the shift key and the other, by the comma key since both have to be depressed simultaneously to print an interrogation mark.

Therefore, according to fig. 3, the *memory and gate* circuit has no output after a period, an interrogation or an exclamation mark has been typed, and it stays off until the space bar is released after the first space. A switch then resets the memory (we shall see later how this is done). The second space after the sentence then triggers the counter and the last word is thus counted.

The circuit of fig. 3 requires further improvements. At the end of a line, the typist uses the line space lever and not the space bar. Therefore, when a word terminates a line, another switch (fig. 4) thereafter called *line space lever switch* closes the counter circuit and registers the word. Often only one or a few syllables of the last word can be printed before changing the line. Then the line space lever switch must *not* energize the counter.

Fortunately, in such a case, a hyphen tells the readers the word is not completed, hence a switch under the hyphen key can turn off a second memory (completely independent from the first one) and this prevents the line space lever switch from actuating the register. It also contains a re-set control as in the previous case. Finally, since both circuits now control the same register, they are linked together as shown in fig. 5.

This figure presents two rectangles marked memory and gate. These two functions take place in a one-tube circuit.

This circuit (fig. 6) performs the memory function from *partial-ionization* of the gas between plate and cathode of a glow discharge tube. In this manner the information is never lost unless intentionally erased.

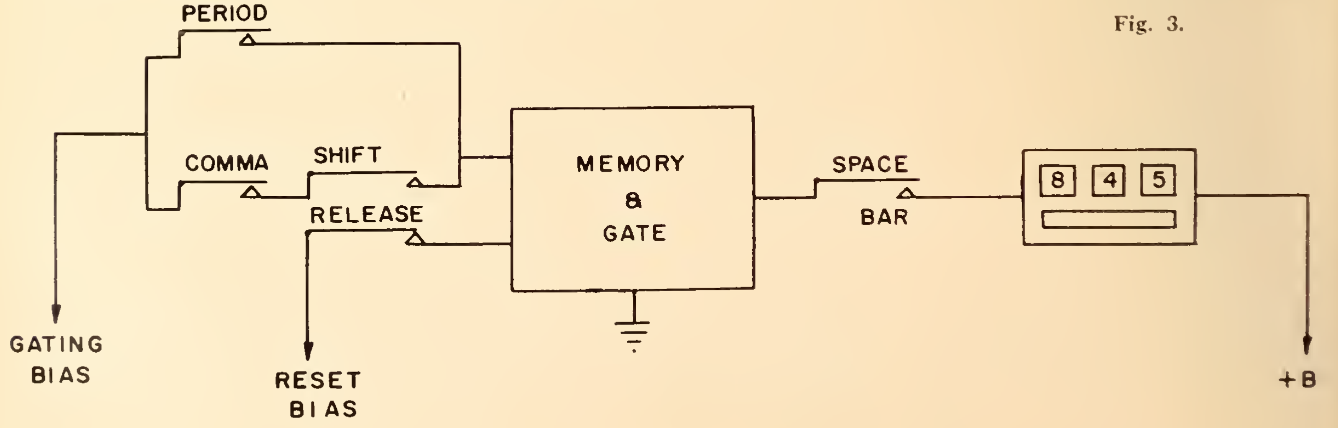
If switch S_1 momentarily applies a positive voltage on the starter, a small current flows through the tube and R_1. If S_3 is subsequently closed, a relatively large current (register coil d-c resistance being many times smaller than R_1) energizes the counter because the gas in the tube was already ionized. Only S_2 can interrupt the conduction of current in the tube; by-passing the current momentarily, the gas deionizes and the tube stops conducting as long as starter potential remains below break-down voltage. Although S_3 closes while the tube stays in this state the register cannot count. R_2 only prevents floating voltages to appear on the starter. (Note that a normally closed S.P.S.T. between R_2 and plate could have served the purpose of S_2 by cutting off the tube current momentarily).

In the actual computer (fig. 7), two of these circuits are connected in parallel to function as the two *memory and gate* of fig. 5. Switch S_2 now becomes, in circuit V_2, the *hyphen* switch. In circuit V_1 there are two ways for deionizing the triode: depressing the *period* switch alone or the *shift* and *comma* switches simultaneously.

The trigger switch S_3 of fig. 6, becomes in V_1, the S.P.S.T. contacts of the *space bar* while, in V_2, it becomes the S.P.S.T. *line space lever* switch. But the re-set switch S_1 is replaced by a more intricate means to send a positive pulse to the starter. As already explained, the triode deionizes after a punctuation mark, then the typist has to make two spaces. The computer uses the first one to restore ionization and the second one to energize the register; the S.P.S.T. contacts of the *space bar* switch, when depressed, charge capacitator C_1. When the space bar is released at the end of the *first space*, the capacitor thus brings the starter electrode to a high potential and ionizes the gas which then remains ionized because of R_1 (C_1 may discharge). When the space bar is depressed for the second consecutive time the S.P.S.T. contacts of the switch can now energize the counter since the tube is conducting.

The switch marked *release* is actuated, every time a symbol is printed, by a lever releasing a latching mechanism so that the carriage advances one stroke to the left. This is a dual-

Fig. 3.



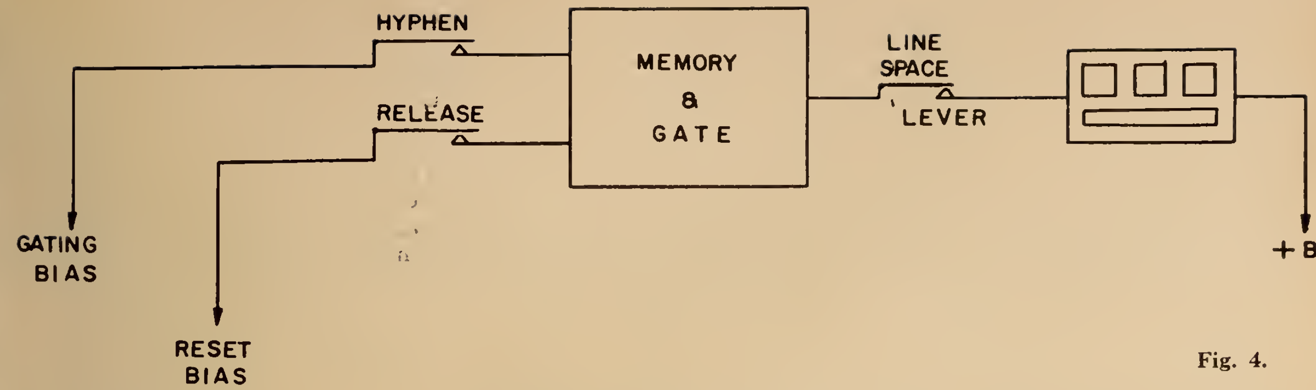


Fig. 4.

purpose re-set switch.

First when typing decimal figures, the period between the digits would have prevented the number to be counted as a word while depressing the space bar after this number because only the re-set would have been done then. Second, the hyphen between the parts of a compound word (or the dash replacing parentheses) deionizes the gas in triode V_2. But, since this hyphen has no relation with the end of the line, the *release* switch re-sets V_2 before the end is reached.

Conclusion

The reader who compares both circuits will easily discover the numerous advantages of the new computer over the previous one. Among the more obvious improvements he is likely to note the greater mechanical simplicity, the indefinite storage capacity and the faster time response. Hence, no speed limitations are encountered when a human person operates the typewriter (max. speed allowable by the counter 600 counts per minute).

Other improvements which might perhaps be overlooked are the following: a decimal number now counts as a word and a compound noun at the end of a line can be detected while, in the first computer, neither was counted. The re-set being done after the printing of any symbol (except the punctuation marks) cancels out the effect of punctuation marks when they are not followed immediately by a space or a change of line.

Typist mistakes such as erasures and strike-overs are relatively few and do not affect the counter as long as the space-bar stays at rest position. Therefore the typist should take care to use the tabulator key for paragraph indentation. Since there is no switch under this key, these spaces will not be registered as words. While existing rules are respected, no error should result.

The circuit should have a long trouble-free life because there are no filaments to burn out, no mechanical parts to wear out, nor critical circuits to adjust periodically. The only electro-mechanical component, the

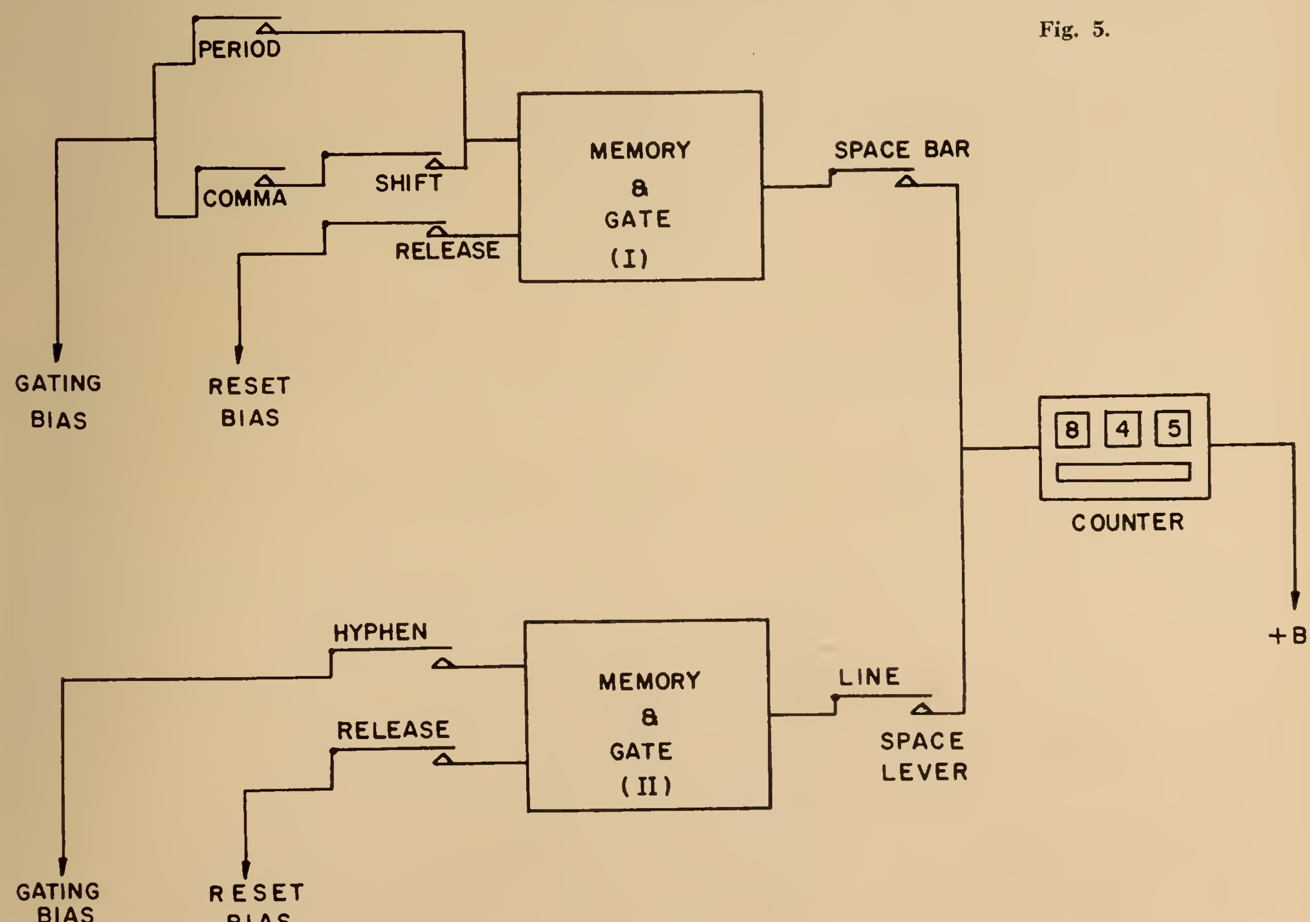

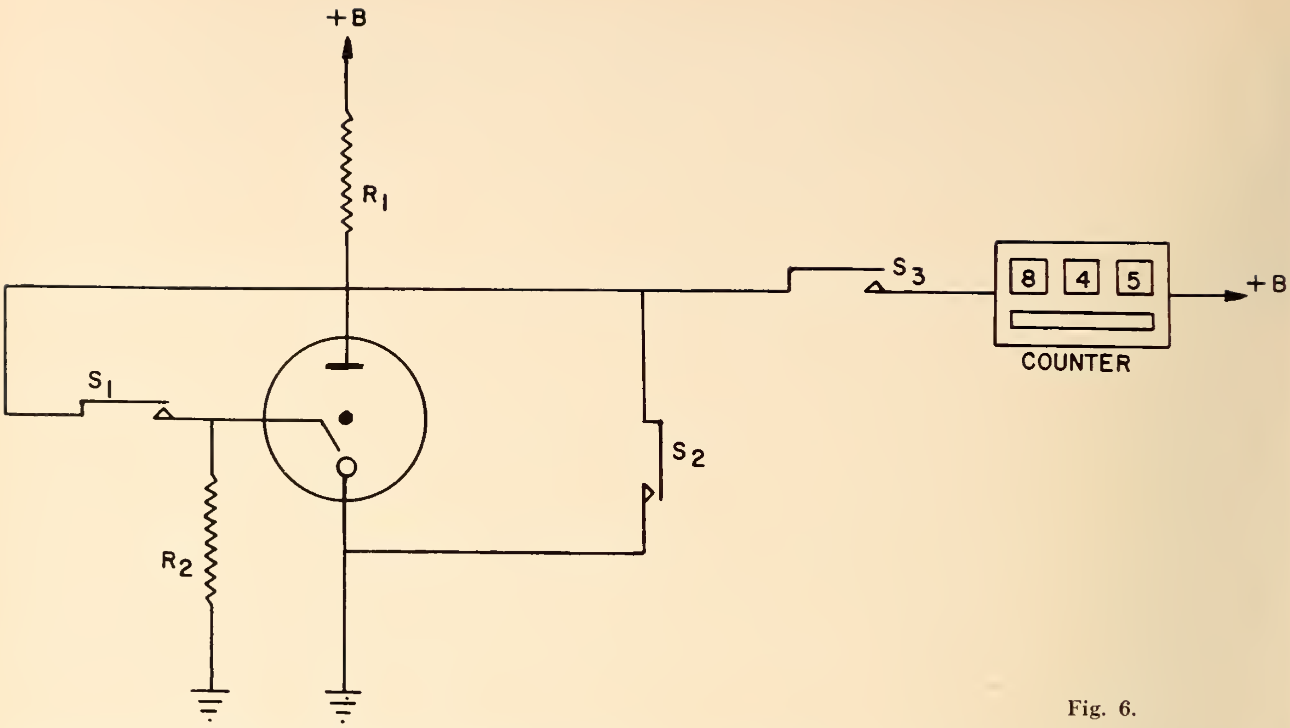

Fig. 6.

counter, shows no failure after more than three years of operation. The power supply is a standard semiconductor voltage-doubler which can be plugged in any 115 VAC outlet; no regulation is needed.

Potential users are governments and corporations employing many typists: the personnel office could evaluate at a glance the skill of a candidate or use the device for impartial promotion of actual employees. Newspapers and magazine publishers who pay articles on a per word basis would find it a very convenient and inexpensive way for counting words. The teletype and telegraph companies could also take advantage of this small counter. Last, but surely not least: the business colleges would thus be able to provide direct incentive for their typewriting students.

CONSTRUCTION OF FOUNDATIONS

for

VERNON NARROWS BRIDGE

R. J. McTavish, Jr.E.I.C., *Field Engineer*
Dravo of Canada Limited, Toronto, Ont.

IN CONSTRUCTING a by-pass for Highway 11 around the town of Huntsville, the Ontario Department of Highways is eliminating the last bottleneck for traffic moving north from Toronto to North Bay. Travel through the District of Muskoka, one of Ontario's leading summer and winter resort areas, will thus be more pleasant. At the present time it is not uncommon for summer weekend traffic to be stalled for several miles on either side of the Huntsville swing bridge over the North Branch of the Muskoka River. The major structure of the by-pass, a four lane bridge over the Vernon Narrows, clears the water by 17 ft. and thus eliminates the need for a swing or lift bridge on the by-pass.

Vernon Narrows connects Vernon Lake to Hunter's Bay, forming the source of the North Branch of the Muskoka River. Although the bridge span at the Narrows is only about 700 ft., the nature of the river bottom presented difficult construction problems. The contractor had available portable floating construction equipment which proved to be most suitable for the project. The award for construction included the building of eight reinforced concrete piers and two abutments to support the nine structural steel spans and reinforced deck which will make up the completed bridge. Support for the piers is provided by pipe pile driven to rock through an average of 55 ft. of silt, clay and gravel.

Fig. 1. Set-up for testing pipe pile. Sheet pile cell was placed on top of cofferdam undergoing test and filled with 450 tons of sand and gravel. Jack inside the test cell transmitted load to piling.

Two phases of the assignment presented more than usual problems. These were construction of the below-water portion of the piers and load-testing of the pipe pile. Solution of these problems called first for careful examination of the plans, specifications and boring results.

Each pier base is made up of two tripod pipe pile supports with reinforced concrete caps, tied together by a reinforced concrete strut. Specifications required the 18-inch-diameter pipe pile to be driven with an open end to rock, cleaned out and a four-foot tremie plug placed in the bottom. The plug was to be driven out either three feet or to a refusal of 40 blows per inch at 15,000 foot pounds per blow. After this, the casing was to be dewatered and filled with concrete. The reinforced concrete for the caps and strut was to be placed "in the dry."

The specifications also required two of the pipe piles to be test loaded with 400 tons each for a period of 24 hours. Borings indicated that the depth below mean water level to bed rock varied from 57 ft. to 92 ft., with the water varying from 6 ft. to 13 ft. in depth. Overburden on the bed rock was indicated to be very soft for most of its depth.

Thus, the basic requirements for the pier base construction were:

1. A support frame or system of leads from which the pipe pile could be positioned and driven.
2. A dewatered area for placing the caps and struts.
3. A method of testing the pipe pile with 400-ton loads.

To fulfill these requirements, the contractor decided to use a circular steel sheet pile cofferdam for each tripod and cap, and a double-skin form for the connecting strut. Circular cofferdams require a minimum of interior cross bracing, and in this case provided an unobstructed work area. In addition, this type of coffer could be adapted to allow for a 400-ton test setup and would support a timber frame to hold and guide the pipe pile into position.

Construction procedure for each pier base was laid out as follows:

Set and drive the sheet pile for two 21-ft.-diameter cofferdams. Excavate within each coffer to a depth of ten feet below the bottom of the pier cap and fill this area with granular material.

Set pile driving frame on coffers and drive pipe pile to rock.

Clean out pipe pile, place and drive plugs, and place concrete fill in the pipes.

Place bracing rings in coffers and dewater.

Place circular pier cap forms and pour concrete.

Remove forms and pull sheet pile.

Place waterproof strut form, dewater and pour concrete.

Remove strut form and begin construction of the above-water portions of the pier.

Details of Pier Base Construction

FA-6 steel sheet pile in 30, 40 and 45-ft. lengths was used for the circular cofferdam construction. Enough sheet piling was delivered to the job site to permit the simultaneous construction of six cellular coffers. The sheet pile was set around a wooden template floating on four 45-gallon fuel drums. Four 4-ft. by 4-ft. by 3-ft. plain concrete blocks provided anchorage for the template.

Fig. 2. Driving pipe piles with a diesel pile hammer. Pipe pile positioning and driving frame was 16 ft. square by 16 ft. high and secured to top of sheet pile cofferdam by chains tightened with loggers' load binders.

Fig. 3. Ferrying concrete from shore to piers. Concrete was mixed on shore, transferred via shuttle car to four bottom dump concrete buckets on cable-operated ferry.

After setting, the piles were driven to grade by a Delmag D-5 diesel pile hammer. Since the original river bottom was generally below pile cap elevation and too soft to support any load, the material within the coffers was replaced with granular fill to a depth of 10 ft. below the pile caps. This insured against settlement of the pile cap forms and concrete.

The pipe pile positioning and driving frame, constructed of 12-in. square and 10-in. square timbers, was 16 ft. square by 16 ft. high and could be lifted easily onto the top of a cofferdam by either of two floating rigs at the site. Once in place, the frame was secured to the sheet pile by chains tightened with loggers' load binders. The cross beams for supporting the individual pipe pile during driving were similarly installed. 18-in.-diameter pipe pile, in lengths up to 85 ft., were slung above the centre point and lowered into position through the frame by a floating Lima crane with a 100-ft. boom. The piles were driven to rock by a Delmag D-12 diesel pile hammer operating in swinging leads.

After the pipe piles were driven, the driving frame was removed and the material inside the piles was cleaned out to rock by compressed air. The air was supplied from two connected 150-cubic-ft. air receivers fed by an Ingersoll-Rand 600 compressor. An 80-ft. long, 4-in.-diameter "blow pipe", connected to the air receivers through

100 feet of air hose and a 4-in., quick-opening gate valve was inserted into the material within the pipe pile. When the pressure in the receivers built up to 110 pounds per square in., the valve was opened and the resulting quick release of a large volume of compressed air forced the material up out of the pile. When pressure dropped to 35 pounds per square in., the valve was closed and the whole operation was repeated.

On an average, cleaning out an individual pile took less than an hour with this method. Clay, silt and sandy gravel were forced out easily, but a little more difficulty was encountered with the large chunks of stone just above bed rock, many as large as 1 ft. long and 4 in. in diameter. Special safety precautions had to be taken to protect men and equipment, for some of these stones were hurled as high as 80 ft. into the air.

Great care was taken to insure a clean bottom well founded in rock for these pipe piles. Tremie concrete plugs were then placed in the piles and driven to their required penetration by the D-12 hammer, acting through a mandrel from the top of the pipe pile. This mandrel was a 10-in. bearing pile with a 17-in.-diameter by 24-in. driving head at the bottom. The 10-in. pile was supported laterally from the pipe pile by means of 17-in-diameter plates welded to the flanges of the mandrel at 20-ft. intervals. With the plugs in place, the piles were dewatered by a No. 35 Ingersoll-Rand air pump, which was lowered into the pipe as the water receded. Finally, the piles were filled with concrete.

Next step was to place the cofferdam bracing rings and dewater the coffers. Each ring consisted of four layers of 2-in. wood, cut into 4-ft. segments and laminated to form a circular frame 4 in. smaller in diameter than the inside diameter of the coffers. The rings were wedged into place with timber wedges and the coffers were dewatered with a 6-in. pump. The pipe piles were then cut to grade and the granular material levelled at the proper elevation to receive the cap forms.

These circular wooden forms were constructed of horizontal wales of laminated 2-in. segments cut to proper radius, vertical 2-in. x 8-in. planking at 10-½ in. centres, and ¼-in. plywood lining. A hinge was built into one side of each form with a lock rod diametrically opposite at the strut location. Here the form was extended 12 in. in the shape of the strut to form a projection which would facilitate waterproof sealing of the strut form. To guard against settlement, the cap forms were supported both by the granular fill and by two beams spanning the top of the cofferdams. Two cap forms were fabricated for the job, so that each form was used eight times. After removal of the cap forms, the sheet pile was pulled by an air-

Fig. 4. "Blowing out" pipe pile after driving. An 80-foot-long "blow pipe" connected by hose to air receivers was inserted into the material inside the pipe pile. When pressure in the receivers built up to 110 pounds per square inch, gate valve was opened and sudden release of compressed air hurled rock and other material up to 80 ft. into the air. Cleaning pile to rock took about an hour.

Fig. 5. Form work on one of the eight reinforced concrete piers. Plastic cover was devised to provide protection from freezing temperatures.

operated pile extractor.

The double skin strut form was placed in halves, then pulled together and sealed by tightening the cables. Rubber strips built into the form sealed against the concrete projections of the pile caps. A tongue and groove arrangement of the two segments forced together made the bottom seal. Placing of the reinforcing steel and concrete followed dewatering of the form.

Construction Equipment Used

Two floating rigs were used on this contract — a standard type C-10 Whirler with a 65-ft. boom and a 20-ft. jib, and a 703SC Lima with a 100-ft. boom. Each crane was fastened to the deck of a 50-ft. square barge through two 36-in. WF beams. Each barge was constructed of 63 hollow steel cubes that had been shipped to the job in strings of nine and assembled at the site. These cubes measured 5 ft. x 7 ft. x 5 ft. A similarly constructed barge, which was 50 ft. long x 30 ft. wide, was used for material handling.

Pile driving was accomplished by two Delmag diesel pile hammers, a D-5 and a D-12, and a McKiernan Terry E-4 extractor pulled the sheet pile. The cofferdams were dewatered by a 6-in. C.M.C. diesel-driven pump and kept dry by several quarter-horse-power electric sump pumps. Two Ingersoll-Rand 600 C.F.M. rotary compressors provided the air needed for pile extraction, concrete plant operation, blowing pipe piles and, in the winter months, elimination of ice in the working area.

Concrete was mixed in a one-cubic-yard Smith mixer after the material was weighed in a 50-ton-an-hour Blaw Knox batcher. The mixed concrete was transferred via shuttle car to four Johnson-Dravo bottom dump concrete buckets on a cable-operated ferry, which operated between the shore and the various pier locations.

During the winter the work area was kept relatively free of ice by forcing compressed air through small holes in a 1-½ in. plastic hose laid on the bottom of the Narrows. The bubbles forced the warmer, denser water from the bottom to the surface where the combination of agitation and increased temperature prevented ice from forming.

Pipe Pile Tests

The specification calling for testing of two pipe piles with 400-ton loads represented twice the design load of 200 tons per pile. After 24 hours of

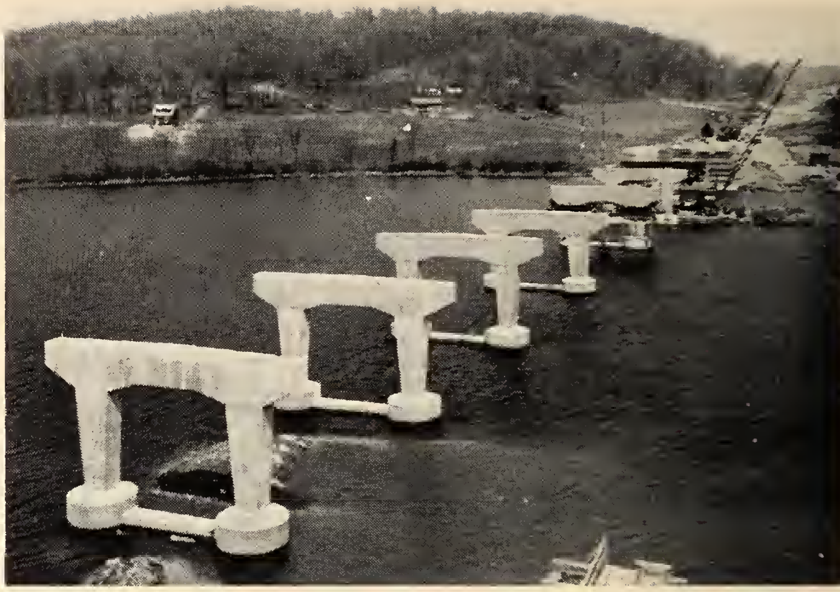

Fig. 6. Overall view of Vernon Narrows Bridge just before completion of piers.

load application, if the net deflection of a pile was less than ½ in., the pile was to be considered safe.

Before pile driving was started, the resident engineer indicated the pipe piles to be tested. Installation of the cofferdams and pipe piles was then carried out as previously outlined, except that longer sheet piles were used for the coffers.

After the pipe piles were filled with concrete, granular fill was placed to a level of 1 ft. above water, inside the cofferdam containing the test pile and to 9-½ ft. above water in the partner coffer. Two 33-inch WF beams tied together as a unit, and a 500-ton hydraulic jack were then set inside the test coffer. Next a 2-ft. thick concrete slab, reinforced top and bottom with No. 9 bars at 6-in. centres, was poured 8-½ ft. above the fill. It was held in place by clip angles welded to the sheet piling at the level of the bottom reinforcing mat. Bolts were embedded in the bottom of the slab to support the 33-in. beams.

An additional sheet pile cell was then placed on top of the cofferdam and held in position by bolted connections located at every sixth sheet. After removal of the falsework and support form for the 2-ft. slab, the beams and jack were set in position, and 450 tons of fill were loaded into the upper cell by clam-shell bucket. Before the test loading began, a 70-ton jack was placed between the test coffer and the partner coffer to resist the horizontal component of the 500-ton jack reaction. The 70-ton jack acted between the 2-ft. slab in the test coffer and a 1-ft. slab of plain concrete poured on top of the granular fill in the adjacent coffer.

As the 500-ton jack was operated, the test load was transmitted to the pile. This was done in 50-ton increments at one hour intervals until the full 400-ton load had been applied. An extensometer, calibrated in thousandths of inches was used to take settlement readings before and after each load increment. The maximum load was kept on the pile for 24 hours, with deflections recorded every hour. At the end of this time, the load was removed in 50-ton decrements over a 15-minute period, with rebound readings taken after each decrement.

Under the 400-ton load, the two piles settled an average of .70 of an inch. After 24 hours of full load, the figure was .75 of an inch. But when the load was removed, the reading was .15 of an inch. Thus the net settlement was only .15 of an inch, compared to the allowable settlement of .50 of an inch.

After completion of the test, the top cell and slab were dismantled and the beams, jack and granular fill removed, so that construction of the pile cap could be completed.

Erection of the Vernon Narrows Bridge was carried out under the supervision of the Ontario Department of Highways. Consultant for design of the bridge was T. O. Lazarides, Lount & Partner of Toronto. J. E. Boyer was superintendent for Dravo of Canada Limited.

THE DEVELOPMENT OF AN ELECTRONIC DETECTOR OF FLAWS IN PAPER

M. P. MacMartin
N. L. Kusters
National Research Council, Ottawa, Ont.

Companies which manufacture and sell high quality paper, such as bond paper or book paper, must be very careful that defects such as small dirt spots or shiny marks in the paper do not reach the customer. At present the paper is checked by visual inspection one sheet at a time. A considerable number of measurements have been made to determine what characteristics of paper at a flaw are different from those of good paper, in order to determine which characteristic is most suitable to be used by an automatic detector to give a fairly reliable indication of the presence of the flaw. The method of detection should be suitable for checking paper travelling at several hundred feet per minute without marking or damaging the paper. On the basis of these tests an electronic flaw detector has been built.

The electronic flaw detector measures variations in the amount of light reflected from the paper, by means of photomultipliers. Lenses focus the light reflected from a small area of the paper up into the photomultipliers. Rotating mirrors in the path of the light beam swing the beam so that the spot being looked at travels across the paper. The size and shape of the spot is defined by an aperture in the optical system. Variations in the light reflected from the paper produce electrical pulses from the photomultipliers, which are used to actuate the sorting mechanism. Mercury vapour lamps illuminate the paper where it is scanned. The present model can check paper at up to 300 feet per minute, but could be modified to operate at a higher speed if necessary.

In a paper mill, great care is taken to make sure that the finished product is of as high quality as possible. In spite of all the precautions, defects do occur, such as dirt or holes in the paper. If the paper is to be used for such things as advertising folders, photographic sheets, or good quality books these defects cannot be tolerated, and must be removed. The present method of doing this is to sort every sheet of paper by hand. The process is slow and tedious, and consequently is expensive when one considers that the output of a company is measured in tons of paper. Furthermore, the girls who do the sorting can let factors such as fatigue or boredom influence their work.

An automatic flaw detector, which could pick out the defective paper with a fair degree of reliability, but faster and more economically than it can be done by hand, would be an advantage to the paper industry. The requirements of such a flaw detector are that it should be suitable for installing on an existing paper processing machine in a paper mill, and must operate at the speed at which the paper is going through the machine. On a typical fine-paper cutter this speed is of the order of 300 feet per minute. The flaw detector must be able to pick out the worst flaws reliably, and should be able to detect as many as possible of the less serious defects. It must operate more economically than the present system.

TYPES OF FLAWS

There are many different types of flaws which may be found in fine paper. Some of the defects may seem insignificant, but they spoil the appearance of good paper, particularly if there are many of them. Others may be rare, but should be watched for continually since they might cause trouble in printing operations. A few typical flaws are shown in Fig. 1.

Wrinkles

In spite of care in the manufacturing process, the finished paper may not be smooth, but may have obvious wrinkles, or just little 'waves' perhaps one-half inch apart.

Creases

One step in the treatment of paper in a mill is to put it through a calendar stack. Here the paper passes between smooth heavy rolls where it is subjected to a high pressure of several tons per square inch which gives it a smooth finish. If the paper runs into the calendar stack a little crooked, or if paper which has some wrinkles goes through, there is a good chance that some of it will fold over very slightly, and be pressed together. The result is that three layers of paper are passing through where one layer is barely able to go. The very high pressure breaks down the fibres of the paper and weakens the paper at this point. This is what is known in the trade as a crease. The paper may actually break and the crease then becomes a cut. The paper is much more liable to tear at this point, and may cause damage when it is going through a printing press.

Some creases are quite long, perhaps several feet. These usually extend along the direction of travel of the paper in the paper machine. Short creases, up to several inches long, may be at almost any angle, though usually not more than about 45° from the direction of paper travel. Since the paper has been folded slightly, it may be thicker at a crease than elsewhere, and a bump may be felt by sliding the hand across it.

Calendar Stamps

If a small piece of paper sticks to the calendar roll, it will leave its mark on the paper which is going through the roll, once every revolution. At the mark the paper is thinner and usually shinier than the rest of the paper. This defect is particularly annoying because it repeats at regular intervals along the web of the paper.

Dirt

In spite of great care in handling, it is possible for dirt to get on the paper. It may come on the paper after it has been made, or it may have been in the pulp. It is frequently in the form of small black or brown spots, which are quite noticeable on white paper. Even very small spots are bothersome if they come in groups, several spots on one sheet. Dirt is usually more opaque than good paper, and sometimes is thicker than the paper.

Colour Streaks

These defects apply to coloured paper, and occur if the dye has not mixed properly. The light reflection and light transmission characteristics of these are different from those of good paper, and are usually similar to those of dirt.

Holes

There may be holes in the paper perhaps an inch across, called slime holes, where the pulp was just a mixture of slime without the fibres necessary for strength. There may also be small holes, caused for example when a small piece of foreign material has come loose and fallen out of the paper. If, as is usual, the background is not the same colour as the paper, holes look like dirt.

Torn Edge

If the end of a roll of paper has been damaged, a piece at the edge may tear off when the roll is unwound.

Pasters

If the web of paper breaks or has been cut for some reason during the continuous processing then it is necessary to splice it, and this is done with a strip of sticky red paper. The web of paper is kept continuous, but the splice should be taken out before the paper goes to the customer. From the point of view of sorting paper, splices, or "pasters" as they are called, could be considered to be flaws. They are made red intentionally so that they are easily visible on white paper.

Table I

Defects	*Translucence*	*Reflectivity*	*Thickness*	*Strength*	*Smoothness*
Wrinkles.					x
Creases and Cuts	x		x	x	x
Calendar Stamps		x	x		x
Dirt.	x	x			
Colour Streaks . . .	x	x			
Holes.	x	x	x		x
Torn Edges.	x	x	x		x
Pasters.	x	x	x		x

A brief resumé of the above information is given in Table I. Some characteristics which may differentiate these flaws from good paper are indicated.

STATIC MEASUREMENT OF FLAWS

Table I shows some of the characteristics of flaws which may make detectable differences between them and good paper. The problem is to make a working model of a paper sorter which will operate while the paper is travelling at the normal speed, several hundred feet per minute, and will use some characteristic difference to detect the flaws. Initial tests, to determine what measurement on the paper will give the most reliable indication of the presence of serious flaws, are more easily done statically, using fairly small sheets of paper with typical flaws, so this procedure was followed.

An important consideration is that the method of measurement must not damage the paper. For example, some methods of measurement which were quite effective for detection of small cuts were not suitable to use because the paper was marked. Other factors to bear in mind are that the measurement must be done at a paper speed of several hundred feet per minute, on a machine with considerable vibration and without interfering with the normal operation of the machine. A device to make one type of measurement which would detect as many defects as possible would be much more useful than a device which would detect only one. The results of measurements of flaw characteristics noted in Table I, and also electrical characteristics, are outlined below.

Translucence Measurements

A light was placed above the paper, and a phototube was placed below, with an aperture between so that the light shone through only a small area of the paper. By sliding the paper around over the aperture and measuring the phototube current, the normal variations of paper density (or translucence) were measured. The defect was then placed over the aperture and the density compared with the normal paper density. The light transmission through good paper is not at all uniform, and in the paper tested the variation for each specimen was between 8 and 23 per cent of the average. The signals obtained from flaws were of the same order of magnitude, so it was difficult to distinguish between variations due to flaws and those which are normal in good paper.

Light filters were inserted between the light and the paper to see if there was any improvement. Some flaws could be detected slightly better, but others could not be detected quite as well, so the extra complication did not seem justified.

Reflectivity Measurements

Intuitively, one would expect that this would be the most reliable method of detecting flaws, since in most cases it is the visibility of a flaw which is objectionable.

The most sensitive setup is that which gives specular reflection, i.e. the paper acts as a mirror and reflects the light beam directly into the phototubes. A number of sheets of paper with five different types of flaws were checked. The results are shown in Table II, for two different positions of the light. In the first arrangement the light beam and the pickup beam were both at 45° from the normal, and in the same plane, so that the reflection was specular. The results are given in the second column of Table II. Then the light was moved to directly above, so the reflection was diffuse. The results are given in the third column of Table II. The figures given are the amount that the reflection at the defect differs from that of good paper, as a percentage of the value for good paper. The normal variations over good paper were two to four per cent of the average value.

Table II

Defects	Optical Setup	
	Paper	*Paper*
Wrinkles	13%	5%
Creases	24%	2%
Calendar Stamps	23%	11%
Dirt	45%	33%
Oil	35%	35%

It can be seen from the table that for most defects the system is more sensitive when the reflection is specular. It is easy to have specular reflection in a static setup, but more difficult if there is motion in the optical system. If a beam of light is swept along the surface of the paper it is important that the reflection should be either specular or diffuse, but not changeable. If the beam passes through a position of specular reflection, the sensitivity to defects rises, and also, in general, the total quantity of light reflected.[1] The resultant surge from the photo-electric pickup is very undesirable.

The angle at which the light strikes the paper has some influence on flaw detection. If the light shines directly down on the paper, the brightness per unit area is greatest for a given source power, and the phototube current is highest, which is an advantage, as will be explained later. If the light strikes the paper from a source near the paper level i.e. if it grazes the paper, it will throw shadows, and this is particularly advantageous for detecting creases and wrinkles. This is partly responsible for the large signal from wrinkles and creases, as shown in Table II, when using a light beam at an angle rather than straight down.

The size of the area on the paper which is being examined has an important effect on the sensitivity. If the human eye is looking at a large area, the brain can focus attention on a small spot, but a phototube looks at all its field of view uniformly. If it is necessary to focus attention on some small spot, the field of view must be restricted. The signal from a small flaw could be expressed as $E = R.S.$ where

- E is the signal from the defect, and is the difference between the output at the defect and the output away from the defect;
- R is the ratio of light reflected per unit area from a defect and from good paper;
- S is the ratio of the size of the defect (within the boundary of the photosensitive area seen by the phototube) and the size of the photosensitive area.

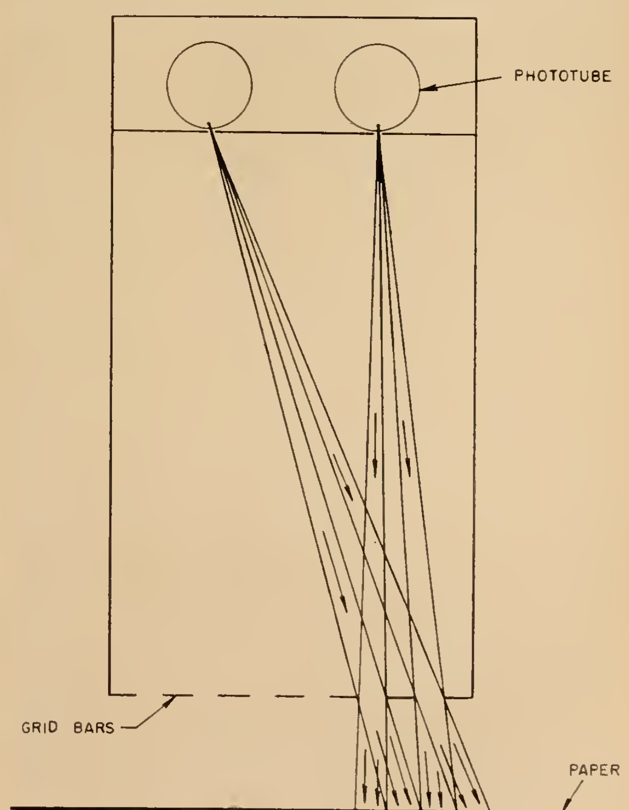
R is a constant for any given flaw, hence, for a maximum E, S should be as large as possible. For large defects $S = 1$ and for small defects S should be kept as close to 1 as possible. However, as will be seen later, in order to examine the whole of a sheet of paper, a large photosensitive area is advantageous. A reasonable compromise spot size is 1/64 square inch.

The value of R for any defect is rarely greater than one, that is, few defects reflect more light per unit area than does good paper. This applies particularly to coated paper which is usually fairly shiny. Hence a detector which could measure only reductions in the average reflected light would be satisfactory.

A test was made to compare transmitted light and reflected light for the detection of typical flaws in several sheets of paper. The signals in both cases were about the same, averaging about 12% beyond the normal level. However, the average variation in light reflected from good paper was 1.5% of the average level, while the average variation in light

Fig. 1. Typical Paper Flaws

Fig. 2. Petascope System



transmitted through good paper was 11%, the same order of magnitude as the signals. Therefore light reflected from the paper is much better than light transmitted through the paper for detecting small flaws.

The measurement of the light reflected from paper is the best method which has been found for detecting dirt or other defects where the value of R is significantly different from one. These include colour streaks and pasters, and also holes and torn edges if the background is different from paper, which is easy to ensure. Calendar stamps can be detected fairly well by this method. Stamps on uncoated paper are one of the defects where R is often greater than one. Unfortunately, small wrinkles and creases cannot be detected by reflected light, and other methods were tried to record these particular defects.

Table III

Type of Defect	Measured Characteristics					
	Translucence	Reflectivity	Thickness	Strength	Smoothness	Electrical Qualities
Wrinkles	No	Very Poor	No	No	Fair	No
Creases and Cuts	Very Poor	Poor	Poor	Poor	Fair	No
Calendar Stamps	No	Good	Very Poor	No	Very Poor	No
Dirt	Poor	Good	Poor	No	No	No
Colour Streaks	Poor	Good	No	No	No	No
Holes	Good	Good	Good	No	Fair	Good
Torn Edges	Good	Good	Good	No	Fair	Good
Pasters	Good	Good	Good	No	Good	No

Thickness Measurements

At a crease or cut, the paper is folded over and rolled together between the calendar rolls, so there may actually be three layers of paper at this point. If the creases are large, the thickness is greater than that of good paper, and they could probably be detected by a thickness gauge, but they can also be detected by other methods, e.g. by reflected light, just as easily. If the creases are small, there is usually some increase in thickness, but it may not be large. For example, paper which was 0.0045 inch thick was 0.0053 inch thick at a small crease. The thickness of the paper frequently is greater where some dirt has become embedded in the paper. For example, an easily visible piece of dirt may increase the paper thickness from .00325 in. to .00375 in. or even .0040 in. It is possible to build a thickness gauge which will detect this difference on a web of paper perhaps 60 in. wide running at 300 ft. per minute. However it is not easy and the precautions which are necessary to prevent the vibrations of the machine from actuating the detector are considerable. In addition, the machine operator must be able to thread the leading edge of the paper through the machine. Also some serious defects do not produce any significant change in paper thickness.

Measurement of Paper Strength

It seemed reasonable to try to use the characteristic weakness of the creases to locate them.

Applying tension from the edges across the paper is effective if the creases are near the edge, which they frequently are. It also tends to detect the long creases which run along the length of the paper, as they are stressed in their weakest direction. If there is enough tension to break most of the creases, even good paper is stretched slightly and this is not permitted.

A standard machine in a paper mill quality-control laboratory is a Mullin Tester. The paper under test is clamped in a ring with an inner diameter of about 1-1/8 in. and pressure is slowly applied to the circle of paper in the centre. The pressure at which the paper breaks is a measure of its strength. This could be used to detect a crease. For example, using one type of paper, the good paper broke at readings of 19 to 24-1/2, while at a small crease, it broke at 8 to 13-1/2. Hence, this is a good indicator, but unfortunately the paper is damaged at a reading of 12 or even less. Applying pressure by a rubber diaphragm and oil pressure, or by direct positive or negative air pressures or by a 1/2 in. ball on the paper, gave substantially the same results, but all these methods had to be rejected because they marked the paper.

Measurement of Smoothness by a Crystal Pickup

An ordinary record player crystal pickup was used with a 2-3/4 in. darning needle as the stylus. The crystal was placed on its side with the side of the needle near the point resting on the paper. As the paper slid past, a slight bump could be felt at a crease or cut, and this produced a very good signal from the crystal. On a test setup, using a piece of paper on a drum about 10 in. in diameter, this worked very well, and would pick out small creases and yet not mark the paper. However, anyone who tries to make a Hi-Fi set out of a paper machine will find that he is in trouble. The "rumble" and "wow" of the full size "turntable" is beyond hope and this promising method had to be given up. There are three other disadvantages: the output is partially dependent on paper speed which may be anything from zero to full speed; the crystals could not be placed closer than about 3/4 in. apart, and a crease along the length of the paper could possibly slide between two needles unnoticed; and it is difficult for the machine operator to thread the leading edge of the paper through without damaging the crystals.

Measurement of Smoothness by Vacuum Leakage

If paper is set on a smooth surface which contains a small hole which is connected to a vacuum system, the paper will block the hole, except for the air which may leak through between the paper and the surface. If the paper is very smooth, the leakage between the paper and the table should be small; but if the paper has a small ridge on it, such as might be found at a crease, one would expect the leakage to be larger, and this possible method of detection was examined. On smooth paper there is some correlation when measured statically. For example, on good paper the readings (in arbitrary units) were from 22 to 28, and the readings at a crease were from 28-1/2 to 34. However using the paper which did not have a smooth finish, the leakage at all times was fairly high, and the change in leakage due to a crease was only a small and unreliable amount more.

Measurement of Smoothness With Oblique Light

As mentioned previously the bump at a crease throws a shadow if it is illuminated from one side by a light barely above the surface of the paper. This is one of the better ways of detecting creases, but there are certain disadvantages. Since the light strikes the paper at a small angle, the illumination per unit area on the paper is low, even when using a bright light, and the sensitivity for other defects is low. Consequently, if light is to be used for detecting creases, it is not very satisfactory for detecting other types of flaws. Such a method is also sensitive to strain wrinkles which may appear when the paper is running over a roll. In spite of these defects, this method seems more satisfactory than any other that has been tried.

Measurement of Electrical Characteristics

If paper is tested by placing it between two electrodes, it is found that the conductivity and the dielectric strength of most flaws, except holes, are substantially the same as of good paper. Pieces of dirt sometimes have higher or lower values, but not sufficiently dependably to use this measurement as a method of detecting them.

A patent was issued in 1943 for a device which claims to detect flaws by a measurement of the dielectric constant.[2] However it is very difficult to get a consistent indication of dirt or any other flaws except holes by such a measurement. The main difficulty is that the measurement is of the structure of the paper which even for good paper is not at all uniform, and the variations of the dielectric constant over good paper are frequently greater than at a flaw.

SYSTEMS FOR DETECTING FLAWS IN MOVING PAPER

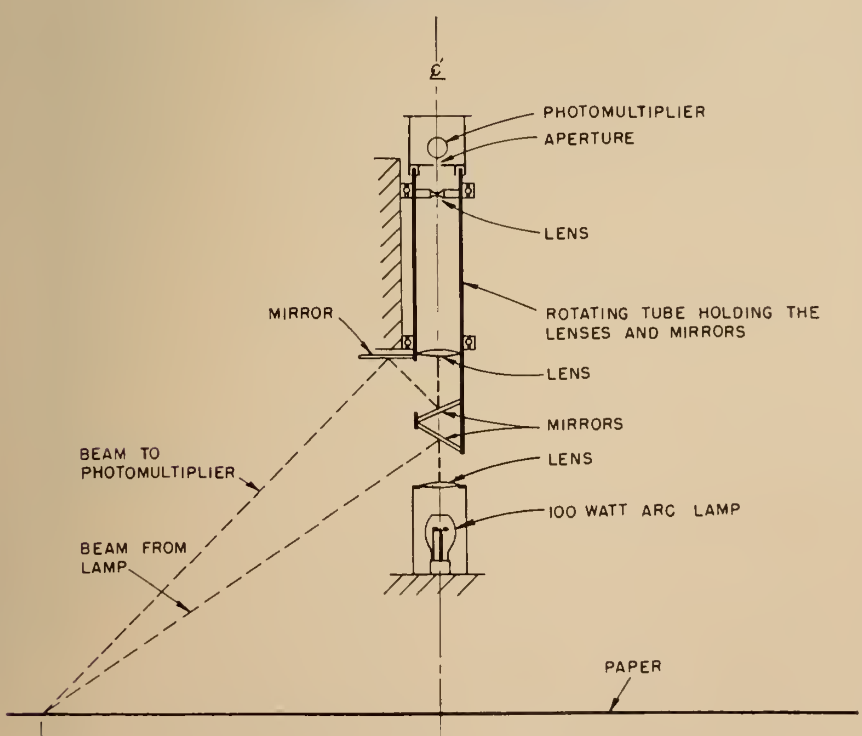
Before building a working model of a paper flaw detector, it must be decided which one of the above methods of measurement should be used. We now have more information than was given in Table I, and this is shown in Table III, which gives the relative merits of different measurements for detecting different flaws.

Reflected light appears to be the best for detecting the largest variety of flaws. Measurements of paper smoothness are best for detecting creases and cuts and wrinkles, but can detect little else. Since at least the larger creases can be detected by reflected light, this should be used. An arrangement which gives specular reflection has the highest sensitivity, but because of the difficulty of maintaining this during motion, it is better to avoid it and use diffuse reflection. The photo-electric pickup may look at a large area or a small area of the paper. Both methods have been tried and will be described.

Petascope System

In 1936 a photoelectric system was described for detecting flaws in paper in which the phototubes look at a large area of the paper.[3] Something basically the same was built. A sketch of this is shown in Fig. 2. The paper was uniformly illuminated over an area of inspection about 4 in. x 4 in. About an inch above the paper was a grid of opaque bars, 1/4 in. across and 1/4 in. apart. About 6 in. above this were two phototubes, placed so that each could look at only half of the lighted area, that which was not hidden by the bars, and the field of view of one phototube was exactly that masked off from the other. The bars were placed perpendicular to the direction of travel of the paper. Each time the paper moved forward 1/4 in. the defect would move from the field of view of one phototube to that of the other. If the light reflected from the spot was less than that reflected from good paper, then the output of each phototube went down slightly as the spot came into its field of view. The difference between the outputs of the two phototubes was a wave whose fundamental frequency was an easily calculated function of the paper speed, and a narrow pass band filter could filter out the desired signals, assuming that the paper speed was constant and known. The main disadvantage is that the flaw which should be detected is small compared with the area that is being viewed. For example, if a flaw is about 1/16 in. across, the area of the flaw is about 1/256 square inch, and the area being viewed by the phototube is about 1/2 x 4 x 4 = 8 square inches. The ratio of areas is over 2000:1, so that even if the viewed area was reduced by a factor of 10 the ratio of areas would still be 200:1. The result of this is that a large area with an insignificant change of reflection would give as great a signal as a small mark with a serious change of reflection. The unwanted signals have the same frequency as the wanted signals so that they cannot easily be filtered out. The system was most sensitive to spots which exactly filled the space between the bars, and was less sensitive to any other size or shape of spot. Another system showed considerably more promise, so the investigation of this system was dropped.

Fig. 3. Equipment for Circular Scanning



Scanning

The best results on the static tests for small defects in the paper were obtained using a phototube, which was focused on a small spot on the paper not much larger than the smallest defect, and which measured the light reflected from the paper. Since a random check is not good enough, i.e. it is necessary to examine all the paper, a multitude of photosensitive spots covering the whole width of the paper, or else some method of moving the photosensitive spot across the paper, must be used. If a multitude of areas are examined simultaneously the bandwidth of the associated electronic equipment is small, but a multitude of phototubes and amplifiers are required. If one spot is moved across the paper, one set of amplifiers is enough, but the bandwidth must be greater, the signal-to-noise factor will be decreased, and the problem will involve signal discrimination from the noise. This last method seemed preferable and is the method used in the final model.

Once it has been decided that the paper will all be covered by scanning with one small photosensitive spot, there are several variables which must be fixed, but which are mutually dependent, and dependent also on the maximum paper speed and width. These variables are: number of scanning units, size and shape of the scanning spot, duty ratio of the photoelectric units, and scanning speed. The compromise between these factors which can be arrived at determines the particular optical and electrical setup used. If it is assumed that the maximum probable paper speed is 300 ft./min., or 5 ft./sec., this gives some indication of the required scanning speed.

Television Camera

One type of scanning which should be considered is electronic scanning, such as is used in a television camera. In an Image Orthicon, a light image falls on the photocathode and an equivalent image of electrical charges builds up on the target which is just behind it. The information at any point on the target is sampled by the electron beam once each frame, i.e., once each 1/30 sec., and the charge on the target is neutralized during the time between scans. This is quite acceptable for T.V. since there usually is very little motion across the screen in 1/30 sec. However, at 300 ft. per min. a flaw 1/16 inch across moves 32 times its own width in 1/30 sec. The flaw shows up as a blurred streak instead of a spot, and the contrast at any point is far short of what it would have been statically. This means that the signal-to-noise ratio for the camera is about the same as for a photomultiplier, and since they cost considerably less, photomultipliers and mechanical scanning are preferable.

Circular Scanner

The circular scanner was constructed as shown in Fig. 3. The light from an arc lamp was focused by a lens and mirror on a spot on the paper. The same spot was focused by two mirrors and lenses, through an aperture, to a phototube. The tube which held the mirrors and lenses was mounted in bearings and rotated by an electric motor around an axis which was perpendicular to the paper, below. The spot of light described a circle on the paper and in the experimental setup the circle was about 3 feet in diameter. There was a fixed distance from the lenses to the object on the paper, so the optical system could always be exactly in focus. A 100-watt arc lamp produced a bright spot on the paper of sufficiently high intensity. There were no complications due to shifting angles since the angles between the paper, the light beam and the pickup beams were all constant. The system proved to be quite good for the detection of small spots and other flaws in a test setup.

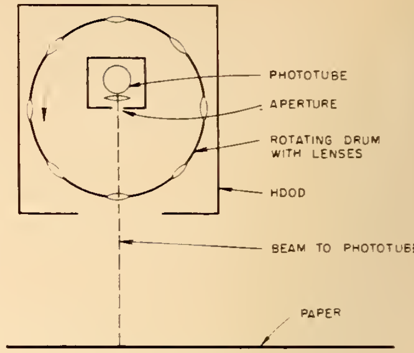


Fig. 4. Scanning System — Rotating Lenses

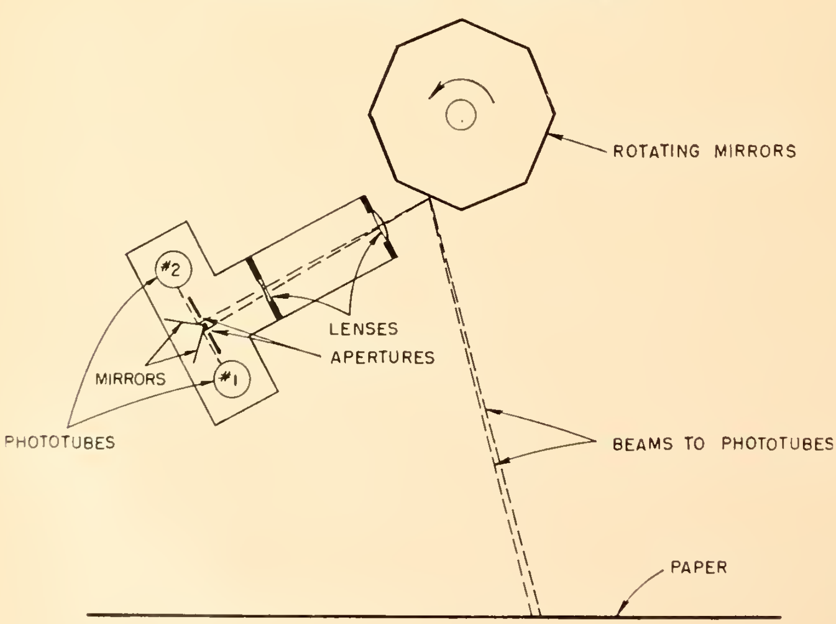
However, there were two serious defects. The photosensitive spot was about 1/4 in. long, and the rotational speed was about 1800 r.p.m., so the maximum paper speed was 1800 x 1/4 x 1/12 = 37-1/2 ft./min., which is about 1/8 of the required speed. Another and more serious defect is the fact that the total area scanned must be flat at all times, without strain wrinkles or flap. Anyone who has watched paper running between rolls in a paper mill, will realize that this is very difficult to obtain. For these reasons the circular scan method was dropped in favour of a line scan.

Linear Scanner

A machine which scans the paper along a straight line has the great advantage that the paper can be scanned where it is pulled tight over a machine roll. This should interfere very little with the normal operation of the paper processing machine. It is difficult to get a uniform illumination on the paper across its full width, but in spite of this, the linear scanner is the best of the methods tried. The model of the paper scanner which has been built uses a linear scan, and a description of this is given below.

Fig. 5. Scanning System — Rotating Mirrors



DESCRIPTION OF THE DETECTOR

Scanning System

Two possible methods of moving the scanning spot across the paper, i.e. swinging the beam of light from the scanning spot on the paper to the phototube, seemed feasible. One method is to rotate the whole optical beam.[4] A number of lenses can be mounted on the periphery of a light tight drum, which is driven by a motor. A phototube can be mounted inside the drum, but not attached to it, as shown in Fig. 4. As the drum rotates, each lens in turn sweeps the beam across the paper. This appears to be satisfactory if there is one phototube, but there are certain advantages

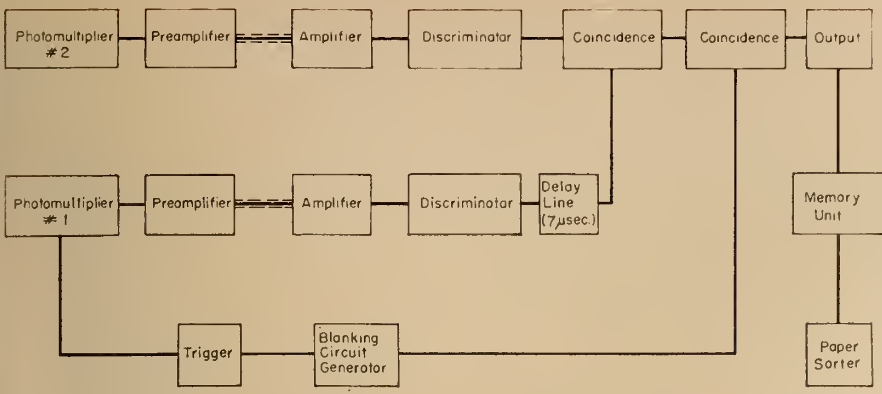


Fig. 6. Paper Flaw Detector — Block Diagram of Circuits

to be gained from using two phototubes, as will be explained later. In this case it is better to bend the light beam with mirrors. A number of mirrors on the periphery of a drum are placed in the beam path as shown in Fig. 5. As the drum rotates the mirrors swing the light beam across the paper. The drum has 8 mirrors rotating at 1800 r.p.m., to give 240 scans per second.

Illumination

The paper must be uniformly illuminated at the scanning spot all the time. There should be no variations due to changes of the spot position, or due to fluctuations of the light intensity. One method is to follow the scanning spot with a light spot from a d.c. arc light. In order to avoid variations due to changes in light beam angle at the paper when using a linear scan, it is easier to use fixed lights and illuminate the whole path along the paper. Using a row of reflector spot lights, it is not possible to get the output uniform enough, and the output shows a bump at every light. Fluorescent lights are efficient, but too low in intensity.

Two 3000-watt mercury vapour lamps are the most suitable. In order to get a light which does not vary with time, the lamps should be run from a d.c. supply, but they will not operate this way. They are run from a two-phase 60 cycle supply. This gives 240 peaks of light per second, one for every scan. In this way, with the same number of scans as light peaks, there is very little 120 cycle ripple in the output of the phototubes.

The 3000-watt lamps are suitable for getting a light which is uniform across the paper. The arc is 48 inches long. Plane mirrors perpendicular to the ends of the lights produce the effect of having a light source of infinite length, so the light on the paper is very uniform for about 52 inches. This is the maximum width that can be handled by one scanner. The lamps are placed about 18 inches above the paper, and elliptical trough reflectors reflect the light down to a line on the paper. Considerable heat as well as light is reflected down, and a mechanical baffle must be used to keep the heat off the paper when it is stopped. A disadvantage of the lights is that the light output is a function of both line voltage and lamp temperature, and electronic compensation must be made for any variations due to these factors.

Optical System

The optical system is shown in Fig. 5. Two lenses focus an area of the paper through an aperture to the photomultiplier. The aperture, which is directly in front of the photomultiplier, defines the size and shape of the scanning spot on the paper. In the discussion of a suitable size of the scanning spot, 1/64 sq. inch was said to be reasonable, and a spot 1/4 in. x 1/16 in. has been used. The narrow dimension should be about the same as the diameter of the smallest defect likely to be met, about 1/16 in. The long dimension of the spot, 1/4 in., depends on the maximum paper speed and the scanning speed. With 240 scans per second and a maximum paper speed of 300 feet per minute, each scan must cover 1/4 in., which is the required length of the scanning spot.

In order to discriminate between the signals and noise, an electrical coincidence is used, which requires two signals, exactly in phase, from two photomultipliers. If one optical beam is divided by a mirror which reflects 50% of the light into one photomultiplier and transmits 50% of the light into the other, the signals from both photomultipliers are exactly in phase, but each tube gets only 50% of the available light. If two separate beams are used, one must be slightly ahead of the other and an electrical delay must be used to bring the leading signals back into phase. However, each photomultiplier gets all the available light. This system seems preferable, and is being used.

Photomultipliers

Photomultipliers are used to convert energy from the light beam into electrical signals. Photo-transistors and solar cells are not suitable because they are sensitive to red and infra-red light, and they can not see many common defects which are not the right colour. Selenium cells respond too slowly to be useful.

As has been mentioned, one of the problems is to detect signals in noise. Most of the noise is produced in the photomultipliers, and it is important to keep this as low as possible. The conditions for low noise are a photocathode current as large as can be managed without saturating the output stages. To get the maximum photocathode current, tubes with high photocathode sensitivity are picked. Also the light intensity at the photocathode is made as high as possible. In order to get a reasonable depth of field in the optical system the aperture must be as small as possible, and this is another reason for high light intensity. The light requirements also are responsible for choosing two beams of light to the phototubes, and an electrical delay on one line, rather than splitting one beam between both tubes.

The second requirement of phototube operation is that the output stage must not be saturated. Tubes with low gain are picked for this application, and the supply voltage is kept as low as possible.

Electrical Circuits

The signal from the photomultipliers is about 80 volts during the time that the scan is on the paper, and nearly zero while it is off, but biased diodes hold the anode voltage near the 'on' value during the 'off' periods to reduce the large transient signals at the paper edges. Two photomultipliers are used. Each has a pre-amplifier, an amplifier, and a discriminator. The discriminator, a conventional Schmitt circuit[5] gives an output only if the signal is above a certain value. It passes pulse peaks which are due to flaws in the paper or due to noise in the phototubes. A 7-microsecond delay line in one channel, after the discriminator, brings the output of the leading tube back in phase with the other. The outputs of the two discriminators go to a coincidence circuit which passes a pulse only if a pulse arrives simultaneously from both channels. The probability is that coincident pulses are due to flaws in the paper rather than to random noise in the phototubes.

The output of this coincidence circuit contains pulses which are derived from the signals due to the edges of the paper. These are removed by a second coincidence circuit, or gate circuit, which requires a blanking square wave to come on just after the scan gets on the paper, and drop off just before the scan leaves. This square wave is produced in an auxiliary circuit as follows. The current in the photomultiplier suddenly changes as the scan comes on the paper, and this generates a voltage pulse, which triggers the square wave generator. This square wave holds the "gate" open while the scan is on the paper. The machine operator must adjust a calibrated dial, so that the width of the square wave matches that of the paper being handled. A block diagram of these circuits is shown in Fig. 6.

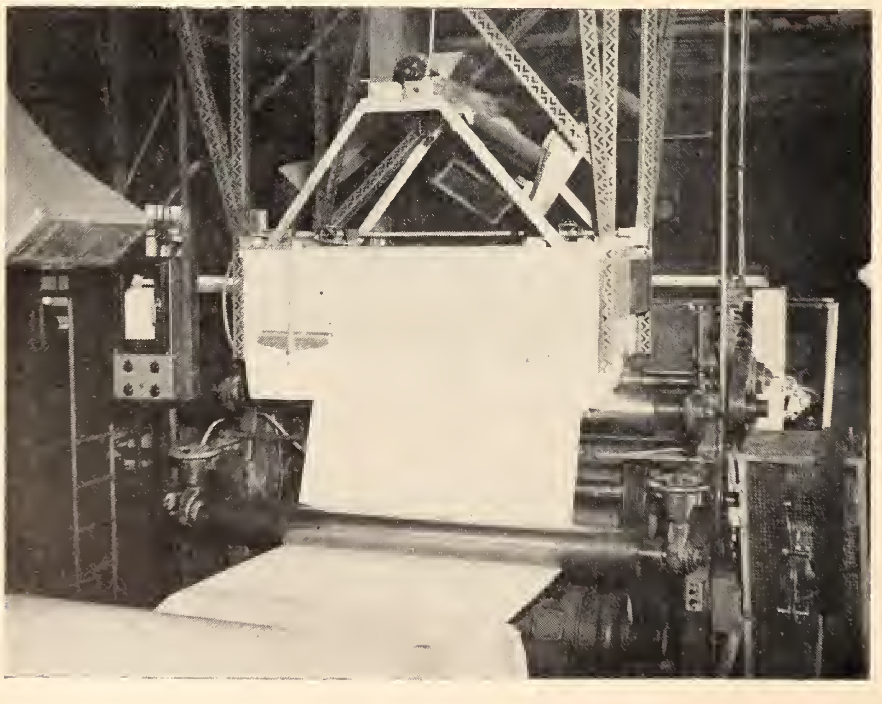
As has been noted before, the mercury vapour lamps are sensitive to variations of bulb temperature and line voltage. The light intensity changes approximately 3% for a 1% change in line voltage. As variations in the average output of the photomultipliers cannot be tolerated, the voltage at the dynodes of the photomultipliers is regulated by feedback to keep the output of the photomultipliers constant. Line voltage stabilizers improve the performance if variations of the supply voltage are large.

Final Model of the Detector

A flaw detector has been installed in a fine-paper coating mill. The scanner is set at the input to the cutter, which cuts the rolls of paper into sheets. The paper is scanned in a continuous strip, as it goes over a roll, but is sorted after it has been cut into sheets. A memory device remembers at which point on the roll of paper a flaw has been detected, and on what sheet the flaw is after cutting. This is necessary so that the sheets with defects can be removed some time after they are cut. The time delay is not constant, but depends on machine speed and sheet length.

The lights and their reflectors are enclosed in a box, suspended above the paper as it goes into the cutter, and are shown in Fig. 7. The rotating mirrors and the motor that drives them, the lens system, photomultipliers and preamplifiers are mounted on the top of the box, on a framework made of aluminum angle and channel.

Fig. 7. Paper Flaw Detector — Mill Installation — Scanning Unit



To the left of this scanning unit, as shown in Fig. 7, is the control box. This has switches for turning the electronic equipment off or on, dials for adjusting system parameters, and a recording meter which indicates whether the machine has been adjusted correctly or not. The bottom right dial setting controls the bias of the "Blanking Circuit Generator" shown in Fig. 6, and determines the length of the square wave from it. If this adjustment is correct, the "Blanking Circuit Generator" will generate a square wave which rises just after the scan has come on the paper and falls just before the scan leaves the paper. Signals from the photomultipliers can pass the gate or second coincidence circuit, only while the square wave is present, so signals from the edges of the paper or beyond are not permitted to reach the output circuit. The two upper dials control the level of the input to the discriminators in each of the two channels. These determine the sensitivity of the flaw detector. The recording meter indicates the number of pulses per unit time which come from each discriminator, which is an indication of the sensitivity of each. In the absence of any signals due to flaws in the paper, it shows the number of noise pulses which are able to pass each discriminator per unit time. Because there are two electronic channels and only one recording meter, the meter reads from each channel for alternate two and a half minute periods. The recording meter indicates the setting of the discriminators, and can be used as an indicator while setting the discriminator level. It is also a check on the drift of the machine and keeps a record of whether or not the operator is adjusting it correctly.

The control room contains the line switch, ballasts for the two mercury vapour lamps, transformers to provide two phase power for the lamps from the three phase line, and a transformer to provide 115 volts from 575 volts. A cabinet contains two chassis which hold the circuits, and the +300 volt and the −1400 volt power supplies.

Performance of the Detector

The electronic detector of flaws in paper will operate at paper speeds up to about 300 feet per minute, and will actuate a relay to sort the paper into two piles. It has been designed particularly for first grade paper which is normally sorted by hand. It will pick out most of the spots, marks, etc., which are serious flaws in this grade of paper. For example, when the sensitivity was set quite low, 6588 sheets were sorted by the machine and then resorted by hand. The machine picked out 342 sheets which contained defects. It missed 11 sheets which had defects which were not serious and missed 1 sheet which should have been removed.

It has certain limitations. It will detect only the larger creases and not the fine cuts. In order to be sure that it will detect all flaws, the setting must be over-sensitive. For example, in an order of paper with 3% defective sheets, the machine sorted out 10%. This means that the rejected sheets should be sorted again to reclaim the acceptable sheets. This is not serious since it is far cheaper to sort 10% of the paper than 100%, and even with hand sorting this must be done with double-size sheets to reclaim the good half of the sheets. Since it has been designed particularly for first grade paper, it is not ideally suited for sorting lower grades of paper. It rejects sheets with dirt marks, which may be acceptable for this type of paper, and if an order is particularly dirty the work of reclaiming the rejects is greater.

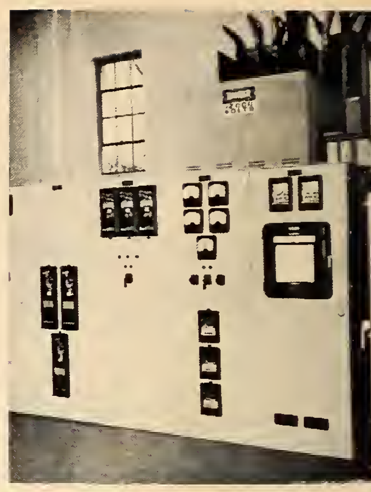
INSTRUMENTATION IN INDUSTRY

WATERWORKS AND SEWAGE



A 12 Kv. metal-clad structure at the McTavish Pumping Station.

IT WAS evident from remarks contained in the answers to the *Journal's* questionnaire that the concept of instrumentation as applied to automatic control and regulation of waterworks and sewage systems is in a very early stage of development in all but the largest centres. One or two respondants spoke of planned projects incorporating complete remote supervision, closed loop television supervision, automatic control of chemical feeds, automatic control of pressures and flow rates and a variety of automatic warning signals; but it was generally conceded in most cases that instrumentation involved the provision of fundamental parameters for manual operation and the provision of continual records of operation for operator's analysis.

The survey showed, however, that those responsible for waterworks and sewage in Canadian cities and towns are keenly interested in the latest developments in automation as applied to their field of activity. There was a great deal of interest expressed in automatic or semi-automatic control of pumps, filters, feeders and distribution systems through the use of various special sensing devices.

It is interesting to note from the literature on the subject that rapid strides have been made in recent years in the development of newer and better sensing devices, or transducers, which are essential to continuous automatic control work. The early experiments of Faraday, in which he tried to measure the flow of the Thames River by applying his theory of electromagnetic induction has been dusted off, and has resulted in very accurate and very versatile magnetic flow meters. In the transducer field, work is being done on a promising device to determine conductivity as it relates to coagulation reaction. A sensing device which relates fluoridation control to conductivity has also been developed, and many others are in various stages of investigation.

Those interested in the extension of closed loop, self-correction control systems realize that their success or failure is closely related to their ability to develop and provide simple, reliable sensing devices which can provide the necessary error signals for conventional and reliable servomechanisms. Increasing emphasis is being given to electronic control loops, as they minimize the problem of maintaining and replacement due to mechanical wear. An important factor in this trend has been the work done to improve reliability of electronic devices.

While there was little direct comment from those responding to the questionnaire, it appeared that the elaborate instrumentation used for fluorine feed into water supplies has functioned very satisfactorily in all cases, and the main comment seemed to relate to its high capital cost.

In all cases, emphasis was placed on the need for extreme simplicity, durability and ease of operation for all instruments used in water and sewage installations.

Power for Water and Sewage Plants

In most cases power requirements for plant operation was purchased from public utility power companies, but in several cases, and particularly in the smaller installations, some source of stand-by power was available.

Approximately 20% of those responding checked consumption of electrical power with their own instrumentation, and only four of those responding maintain separate steam plants for heating or power.

An interesting note with regard to steam is the use of steam provided as a by-product of sludge disposal in those plants utilizing or planning to utilize the atomized suspension technique or the high-pressure Zimmerman process. In each of these processes a wet combustion of the organic material present results in useful amounts of steam. The minimum solid content in the sludge must be 3-4% to support combustion, and the solid content should be more in the order of 6-8% to produce sufficient heat for power use. At least one plant has been built utilizing the atomic suspension technique, and some others are contemplating trying use of the Zimmerman process, which uses lower temperatures, but much higher pressures in its operation.

Uses of Instrumentation

As indicated in the introduction, very few plants in Canada are using fully automatic, self-regulated control systems, and therefore instrumentation is largely a matter of display and recording instruments. In those cases where servomechanism systems are used, pneumatic systems were indicated in more instances than electronic systems.

The most used application of instruments is to provide a continuous record of operations, followed by regulation of pressure or flow, achievement of better quality, provision of central supervision and economization in the use of fuel. In a few cases instrumentation was used to effect a reduction in the labour force, but this did not appear to be a major factor in waterworks and sewage plants.

The problems associated with waterworks and sewage plants almost invariably are reduced to those involving measurement of flow or pressure, provision of supervisory warning signals, and provision of records for analysis.

Who Determines Instrument Requirements

Most respondants determine their requirements through their own employees, but a considerable number use the services of consultants. As is usually the case, there is very often a combination of two, and about 20% of the organizations which replied, instrument requirements were determined largely through the services of firms supplying or manufacturing the instruments.

Specification of instruments is almost invariably handled by the waterworks engineer or his staff. The actual purchasing is also done by the engineering department in an overwhelming majority of cases, but in those which did not handle purchases in this way, there was a wide divergance in procedures.

Servicing of Instruments

Servicing of instruments is usually done by waterworks and sewage employees, or service is purchased as required, with approximately an equal number of respondants using each system. Only in about 10% of the cases reporting were service contracts with suppliers or independent companies used.

On the question of preventative maintenance programs, approximately one half have them, and one half do do not. There was no noticeable distribution among the replies, both large and small installations appeared on each group.

Most of those replying keep a stock of spare parts which has been built up through their own experience with various classes of instruments. The next most popular system for provision of spare parts was through lists recommended by suppliers of equipment, and this was considered to be very good, provided the supplier took the "long view" and resisted the temptation to increase contract figures with unnecessary material. Very few kept stocks of replacement units, and only two reported that they maintained no stock of spare parts for their instruments.

Special Features of Instruments

Most of those reporting stated that they were not interested in instruments incorporating optional plug-in features; only five respondants found such instruments suitable for their use. These represented larger installations, and probably are indicative of the fact that closed loop electronic control systems are not in general use at the smaller centre. The optional plug-in feature was found to be useful for maintenance, and for adaptability when changes or improvements are to be made.

In almost every case there was a preference for standard commercial lines of instruments, and in only a few cases did respondants show an interest in modifying standard lines to adapt them to their specific use. None of the respondants required instruments built to their own specifications.

In this group of organizations, as in almost all of the previous groups surveyed in this series, there was considerable emphasis placed on the need for simplicity and reliability. Respondants referred many times to the problems of training and maintaining adequate maintenance staffs, and of the new orders of magnitude of troubles, when they occur, in a plant which is fully instrumented. Apparently this is a factor which should be given serious attention by instrument designers; the users are willing to sacrifice a few orders of operational effectiveness in the interests of simplicity and reliability. They are afraid of gadgets and of systems which are hard to adjust, maintain or align.

The Financial Picture

Many organizations answering the questionnaire did not indicate whether they purchased or leased their instruments, but those that did indicated that, as might be expected, the great bulk of instrumentation is purchased outright. Total capital investment in instrumentation equipment ranged from under $3000 to over $500,000. Approximately one half of those reporting owned instrumentation in the range from $5000 to $25,000.

Annual maintenance costs varied widely among those reporting, from $35 to $50,000. Approximately one third of the respondants failed to answer this question, but it is interesting to note that the bulk of those who did, reported annual maintenance cost in the range from $500 to $5,000, and somewhere in the centre of this range would probably be the figure for a medium-sized plant.

Total capital investment in instrumentation during the past five years ran from $1,000 to $100,000. None of the very large centres reported this figure, and the $100,000 figure seemed about average for a city of 40,000-60,000 population.

General Comments

The excellent response to the questionnaire indicated a high level of interest in the subject of instrumentation in the water and sewage field. Some engineers expressed considerable dissatisfaction with the current rate of progress towards better instrumentation in many of the plants, and there was an expressed opinion which left the feeling that there will be a great deal of advancement in this field in coming years.

Specifically, in the field of water purification and distribution there is a great deal of interest in automatic systems to monitor the content of various organic and inorganic impurities, and to apply the correct degree of the appropriate remedy to maintain the water within pre-determined limits of purity. Automatic reversing and cleaning of the various high capacity filter systems now being developed, and automatic monitoring of chlorine and other chemical additions are only partly in hand, and there is much more work to be done. In distribution systems, there is interest in better automatic equipment to equalize pressure and control booster pumps, to provide warning and safety signals for leaks and flooding, and to control surges and fluctuations in large systems.

Sewage engineers are interested in better flow meters, pressure recorders, temperature recorders, and level recorders. They want automatically controlled sludge and circulating pumps, chlorine gas feeders, samplers, anti-foaming devices and samples.

Although most of Canada has no serious problem in water supply, there is one notable exception in southern Ontario where a lowering water table and increasing demand through increased industrialization and population is causing some concern. There is a good supply of fresh water available, but extension systems will be required to handle and distribute it, and there may be a day not too far in the future when the water table level will be maintained by a large percentage recovery of properly treated sewage. All of this points to more comprehensive and complicated water and sewage works, and seems to point to a bright future for advocates of advanced instrumentation in this field of activity.

ABSTRACTS

THE PERFORMANCE OF GALVANIZED (1 OZ./FT.^{2})* AND ALUMINIZED (ARMCO TYPE 1) STEEL SHEET IN VARIOUS CANADIAN ATMOSPHERES

THIS NOTE RECORDS the time to rusting of 1 oz./ft.^{2} (10 ¾ oz. in the trade) hot dip galvanized steel sheet and 0.040 in. Armco Type 1 Aluminized steel sheet in the atmospheres prevailing at six Canadian sites. The work was part of a large scale atmospheric corrosion test program undertaken by Aluminium Laboratories Limited in 1945.[1]

Galvanized steel sheet can be purchased with varying weights of zinc coating and it has been shown that its life depends almost directly on the thickness of zinc. The bulk of such galvanized steel sheeting sold in Canada is made to A.S.T.M. specification A 361-55T which includes provision for a triple spot check of thickness to a minimum of 0.90 oz./ft.^{2} and a single spot test minimum of 0.80 oz/ft.^{2} determined on an area of 5.06 in.^{2}. (ASTM A 90-53).

The material for testing was purchased from a Canadian sheet metal supply house in the form of flat sheet. It was cut into 6 x 8-in. panels for exposure. The zinc coating weight was determined by weight loss on stripping in inhibited hydrochloric acid and was found to be 1 oz./ft.^{2} (both sides). This corresponds to an average thickness of zinc of 1 mil. per side. A number of metallographic cross sections was examined under a microscope to determine uniformity of coating which was found to be in the range of 0.7 to 1.5 mil. with an average of 0.9 mil, in good agreement with the value obtained by stripping.

To check further the uniformity of coating a number of readings was taken with a *Drewitt* thickness gauge, which is equipped with a fine drill that penetrates the soft coating and stops on reaching the hard base metal. A dial gauge indicates the depth of travel (i.e. the thickness of coating). Five readings were taken on each side of six panels. The average thickness found was 0.95 mil, covering a range of 0.4-1.4 mil, which is in reasonable agreement with the results of other methods.

To prevent rusting of the bare steel at the sheared edges of the test specimens a quarter inch band of paint was applied by dipping. This included one coat of zinc chromate wash primer and two coats of aluminum-pigmented vinyl lacquer. This completely prevented edge rusting in all cases.

Five such panels were exposed at six Canadian test sites, all exposures being made over a period of about one year (December 1948 to February 1950). The specimens were held in porcelain insulators and faced south at an angle of 30° to the horizontal.

Single panels were removed from each site after varying exposure periods so that the progress of breakdown of the zinc coating could be followed. The main consideration was to ascertain as closely as possible the time period at which definite rust patches appeared, indicating loss of coating protection in these areas. The removal dates varied considerably from site to site for this reason, depending on the corrosivity of each location.

Shortly after these exposures were made, hot dip aluminized steel became available commercially and it was of obvious interest to compare the relative performance of the two coatings. A supply of Type 1 aluminized steel, produced by American Rolling Mills Company (*Armco*), was obtained, and sets of panels similar to those described for the galvanized sheet were exposed at the same six locations. This particular product is specified as having a 1 mil coating of an Al-Si alloy. The actual coating weight was determined by weight loss after stripping a panel in 10% NaOH and was found to be approximately 0.5 oz/ft.^{2} (both sides) which corresponds to an average thickness of 1 mil per side. Readings were also made by the *Drewitt* thickness gauge on five panels, the average thickness found over 10 measurements on each being 0.9 mil, ranging from 0.7 to 1.0 mil indicating a quite uniform coating. Exposures of aluminized panels were made from 1-2 years after the galvanized specimens had been set out. Single panels have now been removed from each of the sites, after time periods of 1, 2, 3 and 5 years. The fifth specimen will not be removed for 10 years or more, depending on its condition at each of the sites.

The table summarizes the time periods at which definite rusting first appeared on both galvanized and aluminized panels and the time periods to complete rusting of the upper surfaces, where this occurred. The test sites are listed in decreasing order of their corrosivity to the zinc

*1 oz./ft.^{2} (both sides) by actual measurement.

coating. Galvanized panels still remain on test at Kingston where no rusting has been observed to date.

On all panels the paint system on the edges is still providing excellent protection, the only breakdown occurring at the points of contact of the holding insulators. One point of general interest is that rusting of the galvanized coating on the upper surfaces started at the bottom of the panels and proceeded upwards. This effect is undoubtedly due to the runoff of moisture whereby the lower portions of the panel remain wet longer than the top areas.

Where rusting occurred on the Type 1 aluminized panels, it took the form of small pin point rust spots which appeared fairly early after exposure. However, in the ensuing period there has been little increase in corrosion and the aluminum is providing good overall protection to the underlying steel. The early appearance of these rust spots is due to a degree of porosity in the coating whereby micropores occur at which the steel rusts quickly. The aluminum surrounding these pores, however, provides cathodic protection and further damage is held in check. The main result is to detract from the appearance of the sheet without any serious corrosion or metal loss. More recently a second type of aluminized steel (Type 2) has been marketed which has a 2 mil coating of commercially pure aluminum on the steel base. Sets of specimens of this product have now been exposed at the same sites but no test results are available as yet. Indications are, however, that this is an improved product which solves the rust-spotting to which the first type is susceptible in some atmospheres.

The results clearly indicate that highly polluted industrial atmospheres are the most detrimental to galvanized coatings. Initial rust occurred in less than 3 years at Halifax, 3 years at Toronto and 3½ years at Montreal. These figures are in good agreement with the 3½ year life reported for a 1 oz./ft.^{2} coating exposed at Sheffield, England,[2] and with the A.S.T.M. average figure of 3½ years as the life of zinc coatings of similar thickness in a number of industrial atmospheres.[3] Longer protection for the base metal (approximately 8 years) was obtained at Vancouver because this site is only mildly industrial in nature. It is apparent that the aluminum coating has greatly superior corrosion resistance to industrial atmospheres.

It is interesting to note that the zinc coating performed somewhat better in a marine atmosphere giving protection to the underlying steel for over 7 years at Cape Beale. Marine atmospheres produce more pin point rusting of the aluminized sheet than industrial atmospheres but corrosion is still minor after 5-7 years.

In the rural atmosphere at Kingston, the galvanized panels are scarcely affected other than being darkened slightly after 8 years. Results of the A.S.T.M. tests to date show no failure of galvanized coatings of 1.5-3 .2 oz./ft.^{2} thickness after 23 years exposure to rural atmospheres.[3] The pin-point rusting of the aluminized panels which occurred early appears to have been almost entirely arrested and there is little increase in corrosion after 7 years over that present after 2 years.

INTERNATIONAL NEWS

BRITAIN

SCIENTIFIC AND TECHNICAL DEVELOPMENTS, as reported in *Commonwealth Survey,* March 17, 1959, are summarized as follows:

The 'Swallow' Aircraft Project

On February 23, 1959, the Minister of Supply, Mr. Aubrey Jones, announced in Parliament that he had made an agreement with the United States authorities and with Vickers for a joint research programme designed to prove the potentialities of the Swallow aircraft concept of variable geometry.

This principle, on which Dr. Barnes Wallis of Vickers has been working for some years, incorporates a pivoting system allowing the position of the wings to be varied so as to give the best characteristics for different speeds and phases of flight. Take-off and landing could be accomplished at slow speed, with the wings almost at right-angles to the fuselage; for high-speed cruising flight, the wings could be swept right back. It is thought that the design could be developed for civil or military aircraft.

The minister said that a series of tests and engineering studies would be undertaken, partly at Vickers, partly at the Royal Aircraft Establishment (Farnborough), and partly in US Government research establishments.

Progress with Flexible Barges

The flexible barge invented by Professor W. R. Hawthorne in 1956, and developed under the sponsorship of the National Research Development Corporation (NRDC), made its first commercial voyage in February 1959. It successfully delivered a cargo of 10,000 gallons of kerosene from the Esso refinery at Fawley, Hampshire, to Newport, Isle of Wight. Though experiments are in progress in Germany, this is thought to be the first commercial trip by this new form of transport for water-borne liquid cargoes.

The barge, which is an envelope made of nylon coated with synthetic rubber, was towed by a 45 horse-power launch and completed the 10-mile voyage in 2 hours, after which the cargo was pumped into storage tanks in 65 minutes. It was then filled with carbon dioxide and towed back. For commercial use it is intended to wind the vessel on to a reel and stow or tow it after discharge of the cargo.

These kinds of barges were originally intended for cheap ocean carriage of oil, but the emphasis is now shifting towards the carriage of liquids on inland waterways. Two vessels have been ordered for trials, one by an oil company and one by a shipping company. Both are for use in West Africa, an area better served by river than by road, and where such vessels consequently appear to be of great potential value.

The vessel used for the voyage was 100 feet in length, carried 40 tons of oil and cost just over £3,000. The company formed to develop the project, Dracone Developments Ltd., is now building one twice this length with a cargo capacity of 350 tons.

Improved Radar

In the debate on the Air Estimates on March 5, 1959, the Secretary of State for Air, Mr. George Ward, mentioned improvements which had been developed in radar. With present radar equipment, pictures could be taken which enabled airfields to be identified and runways accurately measured. With the improved equipment being developed for the Victor bomber, it should be possible, under favourable conditions, to make an estimate of the number of aircraft assembled on an airfield.

The Victors would be able to cover an area equal to the whole of the Mediterranean in a single radar reconnaissance sortie by one aircraft, and they could give a count of the total number of ships in the area. As another example, a radar map of an area of the size of the United States could be made in one sortie by only four aircraft.

The Isaac Newton Telescope

The Admiralty announced on February 23, 1959, that financial approval had been given to proceed with the construction of a large telescope known as the Isaac Newton Telescope, which will be erected in a special building in the grounds of the Royal Greenwich Observatory at Herstmonceux Castle in Sussex. This project was sponsored by the Royal Society.

The new telescope, which will have a 98-inch aperture, will weigh approximately 100 tons and be some 30 feet in length, will be the largest optical telescope in the United Kingdom. It will be used by visiting astronomers as well as by the staff at the Royal Greenwich Observatory, Herstmonceux, where the largest existing telescope has an aperture of only 36 inches diameter. The cost of the whole project, including erection and preparation of the site, is estimated at £660,000 at present prices, and will take 5 to 6 years to complete. Expenditure will be shared equally between the Treasury and the Admiralty.

British National Committee on Space Research

Britain's upper atmosphere research programme with the *Skylark* project, which has been the concern of the Royal Society's Gassiot Committee, will in future be a responsibility of the newly formed British National Committee on Space Research. This committee, which held its first meeting at the Royal Society on March 4, 1959, was set up to co-ordinate British research activities and to co-operate with the Committee on Space Research (COSPAR), formed by the International Council of Scientific Unions to arrange international collaboration on scientific experiments conducted in space. At its first meeting, the new national committee, under the chairmanship of Professor H. S. W. Massey, considered a report of British observations of earth satellites, and the theoretical work carried out on the motions of satellites in orbit.

A joint programme of upper atmosphere research with *Skylark*, arranged by the Gassiot Committee and the Ministry of Supply, began in 1958. The firing of *Skylark No. 5*, which reached a peak altitude of about 93 miles, on May 20, 1958, and *Skylark No. 6* on August 2, 1958, completed the initial phase of the development programme. The Gassiot upper atmosphere research programme began on April 17, 1958, when *Skylark No. 7* was fired. On June 19, 1958, *Skylark No. 9* was fired, on the occasion of the IGY World Rocket Interval, and reached a peak altitude of about 103 miles.

New Research Station for Scotland

It was announced by the Ministry of Supply, on February 17, 1959, that a research station to study the effects of the aurora on radio reception is to be set up on the site of a former radar station at Hillhead, near Fraserburgh, in Aberdeenshire.

This research, part of a programme of ionospheric studies, will be undertaken by the Stanford Research Institute of the United States, in collaboration with scientists from the Royal Radar Establishment of the Ministry of Supply. Observations will be made with a large parabolic reflector, about 140 feet in diameter, brought from the United States. The experiments are expected to start in the late spring or early summer, and will last one or two years. The cost will be borne by the Stanford Research Institute.

New National College of Agricultural Engineering

The Ministry of Education announced in February, 1959, that a new National College of Agricultural Engineering was shortly to be established by the ministry, near the National Institute of Agricultural Engineering at Silsoe, Bedfordshire, in co-operation with the agricultural industry.

GERMANY

THE NEW LINER "BREMEN", will go into service on the North Atlantic route later this year.

The new 32,000-ton "Bremen" is the fifth liner to carry this name in the past 100 years. Last year the Norddeutshe Lloyd shipping company decided to buy the old French troop transport ship "Pasteur" and convert it into a modern turbine-engined luxury liner, at total cost of $22.8 million. The new "Bremen" was refitted to carry 1,200 passengers. Among the particular features are 60,000 hp. engines, a single smokestack having smoke preventing equipment, and an air-conditioning system.

TOWN GAS FROM OIL. The Hamburg Gas Company, one of the largest municipal gas works in Germany, has effected useful combination of gas and oil. The company made 411 million cubic metres of town gas last year, of which 73 million cubic metres came from a new cracking-plant at Tiefstaack. For this purpose 47 million cubic metres of oil refinery gas was supplied by Esso of Hamburg-Harburg, a Standard Oil subsidiary. Another 8 million cubic metres of refinery gas were stored in an underground container at Reitbrook near Hamburg as a reserve for peak-hours.

Another cracking-plant at Boostedt in Holstein processed 1 million cubic metres of natural gas from the neighbouring oilfields of Plon and Barmstedt and made 2½ million cubic metres of town gas from it.

Other German gas works too have built crackers, or are planning to do so. Hamburg has started the second Lurgi cracker at Tiefstaack, and the plant can now make 800,000 cubic metres of gas a day.

AN ORE DRESSING PLANT, the second Krupp-Renn plant of this kind to be built in West Germany since the war is under construction at Essen-Borbeck. The plant, which will process low grade ores from Germany and abroad, is part of the West German steel industry's efforts to become gradually more independent of scrap supplies and to secure a steady supply of raw materials.

Called "Rennanlage Rhein-Ruhr", the plant is being constructed by Fried, Krupp, of Essen, and will be jointly operated by nine West German steel concerns. The first of its six kilns is to be ready to go into operation in mid-1959, the other five in 1960. The plant will eventually have an annual output capacity of from 420,000 to 450,000 tons of iron.

ITALY

PETROCHEMICAL PLANT. Construction began in March on a $95 million petrochemical plant being built by Montecatini at Brindisi. Estimated time for completion is three years.

With a planned capacity of 700,000 metric tons of chemicals per year, and storage tanks with a total capacity of 14,000,000 cu. ft., the plant will be the seventh and largest in the Montecatini group for processing hydrocarbons; the largest in Italy. In addition to several plastics, including polyethylene and Montecatini's new "MOPLEN" isotactic polypropylene, polymers for synthetic fibers, aldehydes, alcohols and organic solvents will be produced utilizing a minimum of 1,300,000 metric tons of raw materials annually.

The plant was described as a large scale translation to industrial application of concepts of stereospecific catalysis discovered by the Italian scientist, Professor Giulio Natta and developed by Montecatini.

A 1200-acre plot near Brindisi will serve as the plant site. Twenty miles of roadway and six miles of railroads will be built within the plant area to facilitate handling of raw materials and finished products.

A thermo-electric plant will also be built to supply the power requirements of the plant making it completely autonomous. An estimated 300,000,000 kw. hrs. of electricity per year — twenty times that consumed by the entire town of Brindisi — will be needed. The plant will use about 2,000,000 tons of steam annually. Upon completion, the plant will employ approximately 2500, with another 1500 employees engaged in activities directly related to its operation.

At least two thirds of the raw materials and finished products will be transported by sea, increasing the annual tonnage handled by the port of Brindisi by more than 1,500,000 metric tons.

Montecatini began its petrochemical activities in 1951. It operates petrochemical plants at Ferrara, Novara, and Terni.

VENEZUELA

CREOLE FOUNDATION PRIZE. A prize is offered by the Creole Foundation, in order to stimulate interest in research work related to Venezuela in the fields of natural, physical and social sciences. It is given for the best work on Venezuela in any branch of those sciences in accordance with certain rules.

It consists of the amount of $10,000, and a diploma, to be given to the author of the work selected through competition. It will be given every two years in Caracas, beginning October 17, 1960. Persons of any nationality may participate.

The works must be received by December 31, 1959, for the first competition. Copies of the regulations may be obtained by writing to the Embassy of Venezuela, The Roxborough, Ottawa, Ontario.

UNITED STATES

WHAT IS BEING DONE TO MAKE FLYING SAFER and more efficient, was described by the Air Transport Association in a recent Newsletter.

As part of its airways modernization program, the FAA is installing enroute surveillance radar with a 200-mile range. In adequate number, this long-range "eye" would have the ability to do much to increase air traffic capacity and air navigation coverage.

Long range radar has the potential to decrease delays in aircraft arrivals and departures, in addition to providing a better utilization of the airspace. Another important function of long-range radar is that it can help aircraft to avoid bad weather.

During the latter part of 1958, the CAA (prior to going over to FAA) and the U.S. Air Force's Air Defense Command set up a Radar Advisory Service to provide separation of civil jets from all other aircraft flying above 24,000 feet.

Essentially, the service employs the available FAA long-range radar, plus radar of the Air Defense Command network. FAA employees are used at the Air Force radar facilities to monitor the separation of civil jets from other traffic in the area.

Initially, this radar coverage was available only to jets operating in the Northeastern states and between New York and Miami. However, in late January of 1959 the service was extended to transcontinental routes. This means that as the scheduled airlines introduce jet aircraft into their transcontinental operations, radar advisory service will be provided.

A new FAA facility designed to centralize and speed up reports on near-miss incidents was recently announced by the FAA. The facility became effective on March 2.

Known as the Central Reporting Office, this new FAA facility will serve as a "clearing house" for all reports on near misses from FAA control stations around the country.

A joint civil/military program for studying ways to modernize the nation's aviation weather system was recently announced by the FAA. The program calls for establishment and execution by the Department of Defense, Commerce and the FAA of a unified research and development effort to produce a weather service system compatible with requirements of a modern system of aviation facilities.

"This would be a big step toward increasing the capacity and efficiency of the nation's air traffic control system," the FAA announcement points out.

Under the plan, the existing weather system and equipment development projects would be integrated with the Air Force semi-automatic system. Air navigation and traffic control developments also would be related. Initial step in the program would be taken by the Air Force.

Elements of a system under development by the Radio Corporation of America to increase driving safety on the nation's roads will be installed this year at the FAA's experimental center at Atlantic City to help solve the problem of jet-age air traffic at busy airports.

"Conceived as a means of sensing the presence of automobiles on a highway, the technique is adaptable with equal effectiveness to the detection of aircraft moving along runways and taxiways," an RCA spokesman said.

At the heart of the system is a series of wire loops and small detector units buried in the pavement along the path followed by aircraft on the ground. The FAA bureau of Research and Development envisions an eventual system under which an arriving airliner, for example, will be under electronic control from the time its wheels touch the runway until it is parked and discharging passengers.

The January, 1959 issue of Aircraft Industry Association's *Planes* said that the safety, efficiency and comfort of jet aircraft stand to be further increased by a revolutionary new liquid-cooled brake system utilizing what is called a "heat exchanger." This thermodynamic device is essentially a water boiler. A common anti-freeze mixture is circulated behind the friction surfaces of the brakes, picks up the heat, and transports it to the heat exchanger where it is transferred to water. Temperature buildup in the critical wheel and brake area is thus reduced by as much as 1,500 degrees.

Operating at low temperatures reduces the possibility of tire blowouts and brake failures. Brake noise and vibration are almost completely eliminated.

With today's high-speed, long-range aircraft, compass accuracy is of the first importance. A method of calibrating airborne compass systems has been developed under sponsorship of the USAF's Wright Air Development Center, Dayton, Ohio.

The Air Navigation and Traffic Control Division of the Air Transport Association has recently completed a study of some of the operational and technical characteristics, on a comparative basis, of the Decca and VOR/DMET navigation systems.

Copies of the study may be obtained by writing the Air Transport Association, 1000 Connecticut Avenue, N.W., Washington 6. D.C. Attn: Director of Information.

It is more than six times as safe to travel on U.S. scheduled airlines as to travel by automobile.

Private car and taxi fatalities during the five-year period ending 1957 (1958 figures were not yet available) were 2.7 per 100 million passenger-miles. Rate for the domestic scheduled airline industry was .42 for the five-year period ending 1958.

The airlines' safety trend shows continuous improvement. Fatality rate for the total U.S. scheduled airline industry was 2.55 per 100 million passenger-miles for the five years ending 1943. It dropped to 2.04 during the next five years. The rate was cut in half – to one fatality per 100 million passenger-miles–in the five-year period ending 1953. Statistics for the past five years (ending 1958) show an almost three-fold improvement, with the rate down to .38.

ISRAEL

RECENTLY ACQUIRED INSTRUMENTS now in operation at the Solar Physics Laboratory of the Technion bring the sun and its activities appreciably closer to earth for study.

Among the new acquisitions is a telescope fitted with a H-alpha filter. When fully installed it will enable the scientific viewer to observe, in hydrogen light, activities such as eruption flares on the surface of the sun. These are the phenomena which have a direct influence on the ionosphere level, which maintains radio wave propagations on the earth.

A coelostat solar spectrograph has been set up to measure turbidity in the atmosphere of the earth. This instrument displays a complete solar spectrum when aimed at the sun, and automatically follows the movement of the solar body in the sky. This equipment will serve as a basis for a survey aimed at measuring the penetration of various rays and will permit a check on the influence of these rays on public health and agriculture.

The equipment is located in the Albert Einstein Institute of Physics at Technion City. Plans are also now being made for an extension of the Solar Physics Laboratory on the roof of the building.

Prof. Kurt Sitte is head of the Division of Physics, and Assoc. Prof. Nathan Robinson is head of the Solar Physics Laboratory.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

THE ENGINEERING MANPOWER SITUATION

THE CANADIAN labour market for engineers in 1958 was affected by two important developments in 1957: firstly, the economic slackening after several years of sustained expansion and, secondly, the record net immigration of engineers into Canada.

According to the fourth professional manpower bulletin issued by the Department of Labour at Ottawa* the 1957 situation continued in the following year. The national economy did not expand at the 1956 rate, thus keeping down the rate of increase in demand for engineers. At the same time, the new supply almost reached the 1956 level. However, the most noticeable supply change in 1958 as compared with 1957 was the steep decline in the net immigration of engineers from the record level of the preceding year.

In early 1959 a general supply deficiency was no longer indicated, although universities and governments were still reporting great difficulty in recruiting engineers. Their lower salary scales compared with those in industry are probably the chief reason for this. Generally, demand and supply are fairly well balanced, but with a tendency towards a surplus, particularly of new and inexperienced engineers.

Net immigration of engineers is expected to be negligible over the next few years, whereas a large increase in the number of Canadian engineering graduates is foreseen. Expansion in the employment of engineers is expected to continue but at a much reduced rate. The moderate rate of economic recovery— in particular, of private investment—and probable changes in the defence program, are foreseen as limiting factors. A shortage of engineers might recur if there is any sharp expansion in economic activity, particularly if it is accompanied by a rise in private investment.

*"Recent changes in Engineering Manpower Requirements and Supplies in Canada"; Bulletin No. 4, January 1959, Economics and Research Branch, Department of Labour, Canada. Price 25 cents, The Queen's Printer, Ottawa, Ont., Canada.

The bulletin sums up the supply and demand situation for the periods 1955-57 and 1958-60 as shown in the following table.

Supply and Demand

	1955-57 (actual)	1958-60 (forecast)
Number of engineers graduating from Canadian universities	4,670	6,500
Approximate net immigration	3,285	500
Total new supplies	7,955	7,000
Net requirements	10,000 to 12,000	6,500

Upgrading

The two major sources of additions to the pool of engineering manpower are of course university graduates and net immigration: in 1958 graduates reached the highest number since 1951 while net immigration dropped to the lowest level in nine years.

A number of engineering positions are filled in Canada by men who have not obtained an engineering degree from a university. Some of these receive recognition by successfully passing examinations set by the appropriate provincial registering body. Others have neither qualified academically as engineers nor are they recognized by an engineering association, but they are considered as competent engineers at the professional level by their employers.

Only fragmentary information is available on the extent to which employers fill engineering jobs at the professional level with workers who have acquired their competency through work experience, periodic private study and informal learning. On the whole, they are an older group than the graduate engineers since they obtain their engineering status through years of informal training and experience. There are also probably a relatively large number of immigrants among them, including, for example, holders of Higher National Certificates from Great Britain.

There is some evidence that during a period of severe engineering shortages the number of non-graduate engineers increases, since employers will intensify the practice of upgrading and perhaps even reduce their hiring standards. Firms that have to build up their production schedules relatively quickly may find the experienced non-graduate engineer more immediately useful to them than the recent college graduate who, although possibly possessing greater potential, has to be trained for several months before being able to make any valuable contribution to the production process. An adequate supply of graduate engineers would probably have the opposite effect and reduce the willingness of employers to promote the non-graduate into a professional engineering job except for those who are outstanding in ability or experience.

On the recruitment side, an important new source of information has become available through the Department of Labour's Biennial Survey of Requirements for Professional Personnel, just completed. In the survey, replies were received from a very large proportion of Canada's employers of engineering and scientific manpower. The questionnaire contained a section on recruitment sources including upgrading. Employers were asked to indicate in quantitative terms the extent to which workers were upgraded to professional work level during 1956 and 1957 and on what basis. The returns showed that 339 were upgraded to professional status during the period and of that number, 41 had obtained a university degree subsequent to their original employment, 240 were upgraded by recognition of their experience and ability and 58 by obtaining membership in a professional association. The two latter figures combined were equivalent to 9 per cent of the total hirings of engineers and scientists during 1956 and 1957 by the employers surveyed. It must be remembered in this connection that this was a period of considerable shortage of engineers.

Employers' Expectations Change

Between 1956 and 1958 employers — especially in industry — considerably revised their estimates of their future requirement of engineers. In 1956 industry forecast an average percentage increase per year for 1956 to 1958 of 12.2 per cent, but in 1958 employers in the same sector predicted an annual increase of 5.1 per cent for the period 1958-1960.

Recruitment difficulties in 1954 and 1955 were reported by 61 per cent of employers in industry, 90 per cent of the colleges and universities, and 85 per cent of government agencies —compared with 22 per cent, 75 per cent and 58 per cent respectively reporting difficulties in 1956 and 1957. Employers in all three sectors expect this trend to continue: recruitment difficulty is anticipated by only 13 per cent of industrial employers, 61 per cent of the colleges and universities and 38 per cent of government agencies. Aeronautical engineering, followed by electrical, metallurgical and chemical engineering, were the fields reporting the greatest difficulty in 1956-1957, while mining, civil and geological engineering had the least. For expected recruitment difficulties from 1958 to 1960, three engineering fields stand far above the rest, namely aeronautical, electrical and metallurgical. These figures represent percentages of employers reporting or expecting difficulties, and are therefore subject to the limitation that one employer may be concerned with just a few engineering specialists while another's difficulties may arise from a need for dozens of engineers.

National Employment Service

National Employment Service figures are another clue to the changing labour market for engineers. Since the end of the Second World War, the Executive and Professional Division of the National Employment Service has been functioning as a nationwide employment exchange for executive and professional personnel, including engineers. Every month detailed statistics are available on the regular operations of the National Employment Service and these figures include, among other data, the number of applicants and unfilled vacancies at a given date. These statistics are broken down by region and occupation with data for engineers shown separately. To help assess the current labour market situation for engineers by means of these data, average ratios of vacancies to applicants in the engineering field for each year from 1950 to 1958 have been worked out. Examination shows that they range from 36 per cent in 1950 (or one vacancy for about three applicants) to 569 per cent in 1956 (or slightly more than five and a half jobs for every applicant), the second lowest ratio, 54 per cent, (or one vacancy for slightly more than two applicants) having been attained during 1958. On the basis of these figures, the period from 1955 to 1957, especially 1956, witnessed the greatest shortage of engineers of the nine years under review.

National Employment Service figures are also subject to limitations, but it is felt that they are reasonably meaningful in showing the general pattern of change in the labour market for engineers.

Since 1951, the National Employment Service has been surveying the major employers of professional personnel in Canada in order to obtain from them an estimate of the openings they expect to have the following spring for new graduates in different fields, including engineering. Except for 1951 and 1958, Canadian employers reported having more job openings for new graduates in engineering than the number of such graduates turned out by Canadian universities and colleges. The years 1956 and 1957 had the greatest number of job openings reported in excess of Canadians graduated from university in engineering.

Wages and Salaries

The trend of wages and salaries is generally assumed to reflect the changing relationship between supply and demand for labour. Increases in weekly earnings of workers as a whole and in engineering starting salaries followed each other very closely up to 1955. However, in 1955, 1956 and 1957 starting salaries for engineers rose at a much faster rate than industrial earnings. 1956 and 1957 were the two years when, as the preceding analysis indicates, Canadian employers experienced the greatest shortage of engineers since World War II. However, in 1958 starting salaries for engineers rose only slightly above the 1957 level while industrial earnings in general again increased significantly—confirming a relative slackening in demand for engineers.

Utilization of Engineers

The final section of the bulletin contains some pertinent observations on what may happen to the utilization of engineers when their supply comes into balance with demand or when an actual surplus develops:

"Employers finding it easier to obtain qualified engineers can afford to be more selective. They are in a position to hire and to retain on staff only the most efficient engineers for their enginering work. This in turn should result in a need for fewer enginers than would otherwise be the case. At the same time, still another result may occur when a fairly large surplus of engineers develops. The less efficient or less qualified engineer from the point of view of the employer, finding it more difficult to remain in or to obtain bona fide engineering employment, may, rather than join the ranks of the "out of work", accept jobs either without or with only a partial engineering content, thus leading to what could be considered to be "engineering underemployment" or "disguised engineering unemployment". A surplus of engineers in the labour market therefore may lead to contradictory results: the most qualified may be used more efficiently while the less able or less qualified may be used less efficiently. A surplus of technicians may also develop from this situation."

Such possibilities are seen as emphasizing the need to work toward successful job orientation by providing vocational guidance information and financial assistance to those students who, although most suited for an engineering vocation and desirous of entering such a profession, cannot afford to do so.

New Mining Industry

The first shipment of potash mined and refined in Canada was made to Canadian markets in March from the Saskatoon plant of Potash Company of America. Potash mining is a new Saskatchewan industry.

Mine and plant facilities costing $20 million, include the massive concentrator, crushing plant, warehouses, and general office.

Operating at capacity the plant will produce 600,000 tons of the finished product annually. The plant employs 200 people. Its annual payroll is in excess of $1 million.

Mining is carried on in a horizontal tunnel off the main shaft. A continuous miner is used in the mining operation. The ore is a mixture of potash, common salt and a small amount of clay.

FIRST UNIVERSITY NUCLEAR REACTOR

The opening of a privately owned atomic reactor at McMaster on April 10th places Hamilton's university in a unique position among Canadian institutions of learning. The nuclear reactor has clearly asserted its function as an instrument of peaceful research, and now takes its place as an academic installation in the quiet surroundings of the campus. The $2,000,000 project was financed by grants from Government of Canada research agencies, by the Hydro Electric Power Commission of Ontario and by contributions from private industry.

Housed in a circular (actually 15-sided) 72-foot high building, the 1000 kilowatt research reactor is of the "swimming pool" type, chosen for its inherent safety and adaptability to experimental work. The concrete, windowless reactor building is 82 feet in diameter with the lowest floor 17 feet below ground level. It has a firm foundation — a 140-foot wide, five-foot thick reinforced concrete slab which was poured in a single operation.

The reactor consists of a special concrete, tile-lined pool rising 35 feet above the experimental floor and extending through the second (operating) floor of the building. Its core—an array of thin sheets of aluminum and an alloy of uranium—is located 25 feet below the surface of the pool. One hundred thousand gallons of constantly purified water circulate around this core to provide a shield against radiation as well as remove heat and slow down the neutrons so that they can initiate fission in the U-235 atoms. Cadmium-lined boron control rods are used to draw off excess neutrons and regulate the fission process at the desired rate.

Core of fuel elements suspended from a movable bridge over the pool.

The availability of a nuclear reactor makes possible many research projects not previously feasible. For example, many of the most interesting radioactive nuclei are short-lived and can only be studied near the source. The properties of these nuclei can be more fully explored at McMaster.

Radiation produced by the reactor, or from radioisotopes produced in it, provides a fourth dimension for the chemist and chemical engineer. Chemical reactions are influenced by temperature, pressure and catalysts. Radiation, in many cases, acts like a catalyst and hence provides this fourth dimension. Chemists have studied the composition and behaviour of very large molecules to form long chain-like molecules which make up the plastics and synthetic rubbers. This process is called polymerization, and radiation is known to induce it at lower temperatures.

Mechanical engineers have studied engine wear and friction with radioactive piston rings. Neutron irradiation of the rings in a reactor yields radioactive iron. As the engine in which the rings are installed is operated, the weight of the iron that wears off may be detected down to 1/100,000 of an ounce by oil sampling.

The future holds promise for important studies in neutron diffraction by our physicists and metallurgists. This technique yields information about the structure of materials that will greatly assist in developing the new alloys and ceramics needed in this age of jet engines and rocket power.

Researchers in widely differing fields will be able to use the reactor. In addition to providing neutrons, gamma rays and isotopes to McMaster teams working in the physical and biological sciences, engineering and medicine, it will assist other research organizations wishing to develop new projects. It will also serve industry and aid in the teaching of nuclear science to students.

Building in the North

Special features of building in the Canadian North are dealt with in a new publication of the Division of Building Research, National Research Council, Ottawa. The technical paper "Building in Northern Canada"*, reports the recent quickening pace of construction in Northern Canada, demanded by mining development, the search for oil, and the decision to build the community now known as Inuvik, which will come into full use within the next year or two. Frobisher Bay will become a complete northern community, as a point on the Arctic trans-Atlantic air routes.

The factors that distinguish northern building from building elsewhere are the climate, the unusual terrain and the relative isolation of most building sites. Climate, the report explains, differs mainly in the duration of cold weather rather than in extremes of temperature, and the technical problems are not significantly different. But the climate does account for the short construction season, and for the presence of permafrost. And permafrost is a major technical consideration, requiring specific construction techniques in some conditions.

Distances, limited transportation facilities, lack of manpower, make the economic and logistic factors still more serious considerations.

Techniques, conditions to be expected, special northern requirements, transportation, supply, materials, and many other important points are discussed by authors R. F. Legget and H. B. Dickens.

Athabasca Oil Sands

The Alberta Technical Committee began meetings in April which will enable it to advise the Oil and Gas Conservation Board and the Alberta government on safety and other technical aspects of the proposed nuclear test in the Athabasca oil sands of Alberta.

Mr. S. Stewart, manager of the Canadian Division of the Richfield Oil Corporation, appeared before the committee to review the proposal. Dr. G. W. Johnson, test director of the Radiation Laboratory of the University of California, outlined for the committee results of five underground

---

* "Building in Northern Canada", National Research Council, Division of Building Research, Ottawa, Canada, 50-page mimeographed booklet, $0.75.

nuclear explosions which had been carried out under his supervision for the United States Atomic Energy Commission. He will furnish the committee with scientific and technical information on these tests for further study.

Dr. G. W. Govier is chairman of the Alberta Technical Committee; the members are Hon. A. R. Patrick, Grant MacEwan, H. H. Somerville, D. A. L. Dick, George Garland, C. G. Garvenor, Dr. H. E. Gunning, D. R. Craig, and A. S. Manyluk.

The terms of reference of the Committee are

- To review the procedure proposed and scientific data now available and requirements for adequate assurance that: there would be no surface breakthrough or fissuring to the surface; the bulk of the radio-activity produced would be adequately entrapped in insoluble form; and there will be no significant radio-activity contamination of the oil or gas or of underground water.
- To review the technical and scientific data which should be obtained, before, during and after the test, if the test is approved, and to review other relative materials.
- To advise the Oil and Gas Conservation Board and the provincial government on the entire proposal.

What Goes On

Columbia River Discussions

The International Joint Commission, meeting in Montreal on April 30 and May 1, made progress toward development of principles on the apportionment of benefits resulting from a cooperative development of the Columbia River.

The discussions were directed to clarification of principles. Technical officers will analyze the information developed, and the Commission was to meet again in a month's time.

Organic Cooled Reactor for Canada

Atomic Energy of Canada Limited has awarded to Canadian General Electric Company a $600,000 contract for a design study and associated development of a nuclear power reactor, to be known as OCDRE (Organic-Cooled, Deuterium-moderated Reactor Experiment).

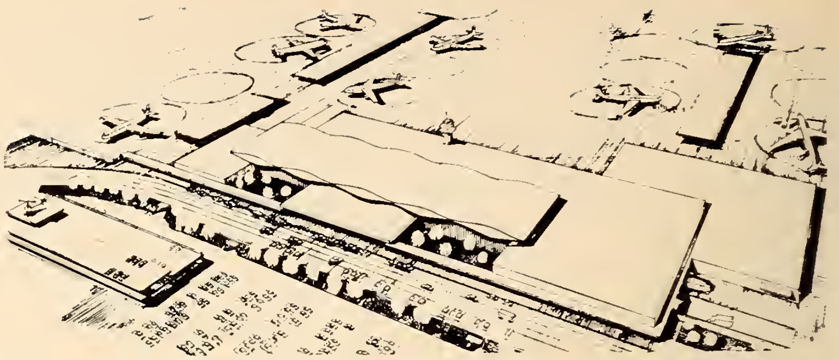
In this reactor, organic liquid, rather than heavy water, will be used to transfer heat from the uranium fuel to the steam generators. Heavy water is to be used as the moderator and the fuel will be natural uranium.

The growing interest in the use of organic liquids as reactor coolants is based on lower price, and the possible adaptation to small and medium size stations in more remote areas.

The decision to proceed with the design study resulted from discussions among members of the staffs of the Department of Northern Affairs, The Northern Canada Power Commission, and Atomic Energy of Canada Limited.

Organic coolants appear to offer means of reducing capital costs. Besides the saving in cost of the coolant, there is the additional advantage that a low pressure system can be used in the reactor, because organic liquid has a high boiling point. Organic liquids are much less corrosive than water at high temperatures and therefore more normal structural materials such as aluminum alloys could be used in the reactor.

On the other hand, organic liquids are affected by radiation and will require some continual replacement by fresh material. Furthermore, fuel costs in an organic-cooled reactor are likely to be higher than in a heavy water-cooled reactor.



Proposed terminal building for Vancouver Airport.

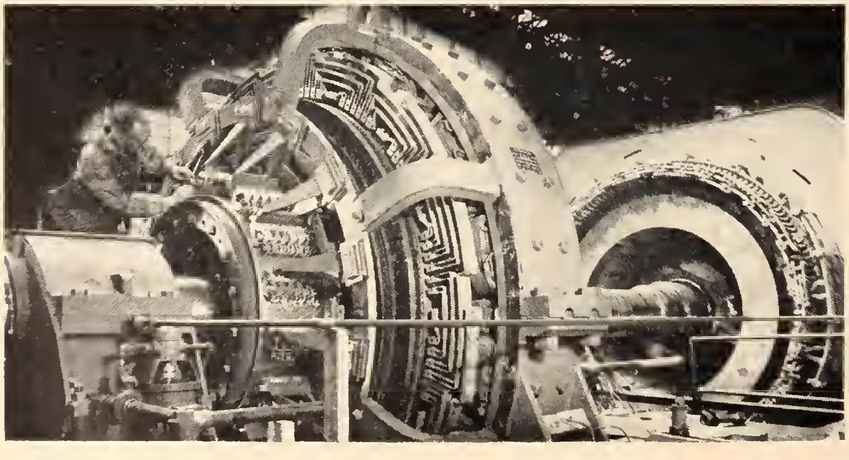
Vancouver Airport Proposal

The proposed $14 million passenger terminal for Vancouver's international airport is designed to cope with three times the traffic handled at Sea Island in 1958, according to a preliminary planning report submitted to the city. It provides 18 aircraft loading positions along two fingers connected by tunnel to the terminal.

Sealed construction is provided by the plan. Besides the main terminal building, the proposed layout includes an airport service building, cargo warehouse, airmail building, etc., and a hydrant refuelling system.

The design anticipates expansion beyond the forecast requirements for 1980, it is reported. B.C. Research Council supplied forecast data. Phillips Barratt and Partners, Vancouver, were the prime consulting engineers on design and cost estimate of the terminal facilities. Collaborating architects were Thomson, Berwick & Pratt.

Equipment for Dominion Foundries and Steel new 3-stand continuous hot-mill at Hamilton, Ont. The 12,000-kw. d-c set consists of three 4000-kw. generators and one 15,000-hp. synchronous motor.



JOINT REPORT of the COMMITTEES on CONFEDERATION

as appointed by the Canadian Council of Professional Engineers and The Engineering Institute of Canada

The President and Council,
Canadian Council of Professional Engineers.

and

The President and Council,
The Engineering Institute of Canada.

March 18th, 1959

Gentlemen:

Herewith for your consideration is the report of the Committees on Confederation—each as appointed by the Canadian Council of Professional Engineers and the Engineering Institute of Canada. This is a *joint* report.

The report is submitted in five parts—designated as Parts "A", "B", "C", "D", and "E".

The report has been approved by the Committees—each of which was appointed by your councils. Committee and sub-committee meetings have been conducted on a *joint* basis throughout

By way of explanation, comments in regard to the report are as follows:—

PART "A"—re-affirms the eight basic clauses of confederation as originally stated. These were approved in broad principle at the 1958 annual meetings of the respective councils. The only change in this part is found in Clause 8—where the assessment is raised to $6.25 from $6.00.

PART "B"—deals with the development of a budget considered to be adequate for the first or early years of operation of a new National Body.

PART "C"—this portion of the report deals with interpretation and/or explanation of intent—as interpreted by members of the joint committee and may be used for amplification of Clauses 1 to 8. It is anticipated that these explanations will be of assistance in understanding by those less familiar with the problems of Confederation.

PART "D"—this part deals with procedures for presentation and implementation of the recommendations of the report to the constituent members of Canadian Council of Professional Engineers.

PART "E"—this part deals with the requirement of presentation and implementation to the Council and members of the Engineering Institute of Canada.

With the presentation of this report, it is the belief of your committees that their terms of reference have been completed. However, if it should be the decision of your Councils to proceed further, your committees are prepared to assist in any way as they may be requested, to further the recommendations of this report.

Respectfully submitted on behalf of
CANADIAN COUNCIL OF PROFESSIONAL ENGINEERS
Committee on Confederation.

JOHN H. FOX, P. Eng., M.E.I.C.
Chairman

Respectfully submitted on behalf of
THE ENGINEERING INSTITUTE OF CANADA
Committee on Confederation.

IRVING R. TAIT, P.Eng., M.E.I.C.
Chairman

PART A

CLAUSE 1.

It is recommended that a new National Body combining the Engineering Institute of Canada, and the Canadian Council of the Associations and Corporation of Professional Engineers, be formed. The combination of these organizations will enable enlarged services to be rendered to the professional engineers of Canada.

CLAUSE 2.

Full Membership in the National Body shall be confined to members of the provincial and territorial associations and Corporation of Professional Engineers. There shall be no other way that full Membership may be obtained. There will be other grades of non-voting membership, such as Honorary, Fellow, Student, etc., as approved by the National Body.

CLAUSE 3.

The Council of the National Body shall be composed as follows: a president, and two vice-presidents (East and West) elected, the immediate past president, and representatives of the provincial and National bodies as follows: one representative appointed by the council of each of the provincial bodies, and additional representatives elected according to the membership of the provincial bodies; provinces with 301 to 5,000 members shall elect one additional representative; those with 5,001 to 10,000 members shall elect two additional representatives; and those with over 10,000 members shall elect three additional representatives. The elected representatives shall not be members of their provincial councils and shall be voted on by the full membership of their province. Such elections shall be conducted by the provincial bodies.

The first council of the National Body shall therefore be composed as follows:

President and two vice-presidents (East and West) elected.

Alberta	– 2 members	1 appointed by Council of provincial body and 1 elected at large—not serving on provincial council.
British Columbia	– " "	
Manitoba	– " "	
New Brunswick	– " "	
Nova Scotia	– " "	
Saskatchewan	– " "	

Newfoundland	– 1 member (appointed)
Prince Edward Island	– " "
Yukon	– " "

Quebec	– 3 members	–1 appointed by Council of provincial body and 2 elected at large—not serving on provincial council.
Ontario	– 4 members	–1 appointed by Council of provincial body and 3 elected at large—not serving on provincial council.

NOTE: The officers and representatives to be elected to the first council from the membership, shall be members of the present Engineering Institute of Canada, as well as members of their respective provincial bodies.

CLAUSE 4.

No decision by the council of the National Body shall be binding upon the members of the provincial bodies if such decisions in any manner concern the application of the provincial engineering acts or other provincial acts. They shall be binding in all other cases.

CLAUSE 5.

Branches will be established by the National Body at the request of a group of individuals of a community after such request has been processed and approved by the council of the appropriate Provincial Body. The branch charter and by-laws shall be approved and issued by the National Body after receipt of recommendation from the Provincial Body concerned. This will assure uniformity in the formation and operation of branches throughout the country. The branches will manage themselves in accordance with their approved charter and by-laws and will receive services both from their Provincial Body and the National Body.

CLAUSE 6.

It is recommended that a national journal be published.

CLAUSE 7.

Decision on the location of Headquarters of the National Body should not be a prerequisite to Confederation. Such decisions should be made the responsibility of the early councils.

CLAUSE 8.

The annual assessment shall be $6.25 per member.

PART B

Details of budget needs of a proposed new national engineering body to be formed by the confederation of THE ENGINEERING INSTITUTE OF CANADA and the CANADIAN COUNCIL OF THE ASSOCIATIONS AND CORPORATION OF PROFESSIONAL ENGINEERS.

1. STATEMENT OF AUTHORIZATION

The joint committees on confederation appointed a sub-committee to study the preparation of an operating budget for the proposed National Body and the amount of the assessment per member. This report has been prepared after a thorough study of the matter including an examination of the operations and the financial statements of the existing National Body.

2. BASIC DATA

(a) The proposed organization and budget is based on the present professional membership of approximately 32,000 members.

(b) The staff requirements are based upon continuing with one National Body the major services now provided by the Canadian Council of Professional Engineers and The Engineering Institute of Canada without duplication or overlapping of such operations and services.

(c) The organization and estimated budget are considered applicable only to the first or early years of operation. Enlarged services and programmes can be anticipated as the national organization develops, also an enlarged membership is certain so that the estimates herein may be considered as basic only.

(d) A simple organization chart is appended to this report —indicating what are considered to be basic or minimum staff requirements for the National Body.

(e) Fee accounting and collection will be handled by the offices of the Provincial Bodies;—(where the provincial membership does not warrant the support of an office staff these services will be rendered by the office of the National Body with the cost charged to the province concerned).

(f) Funds have not been provided in these estimates for the operation of a national journal. It is proposed that the Journal shall be operated as a separate entity and will be self-supporting.

PART B

3. BUDGET NEEDS

Building Accommodation:

(Based on an owned building)		
Operating expenses per year		12,000.00
Office expenses		
(a) Salaries —		
General Administration	26,000.00	
Divisional Administration	43,000.00	
Accounting, etc.	9,000.00	
Programmes, etc.	19,400.00	97,400.00
(b) Expenses — (Gen. & Admin.)		
Telegrams & Postage	5,000.00	
Telephones	2,500.00	
Supplies	9,000.00	
Audit	1,000.00	
Misc.	5,000.00	22,500.00

General Programmes

2 Council Meetings and 1 Annual Meeting	10,000.00	
3 Executive Committee Meetings	5,000.00	
Annual Meeting (deficit)	3,000.00	
Staff Travel	5,000.00	
Student Prizes	600.00	
Library—including salaries	13,000.00	
Conferences and Committees with other societies	5,000.00	
Pensions (staff)	5,000.00	
Conferences on Education	5,500.00	
Student activities	3,000.00	
President's Travel	4,000.00	
Sundry	1,500.00	60,600.00
CONTINGENCIES	5,000.00	5,000.00
TOTAL BUDGET		$197,500.00

Total Assessment per member—approx. $6.25 per year

JOURNAL PUBLICATION

Under this section all professional activities and the relations with other societies and professions will be administered.

Under this section activities will be carried out which relate to that of a technical professional society.

NOTE: *While not specifically indicated on the chart, monetary provision is made in the foregoing budget for librarians and building maintenance services as are now provided in the existing E.I.C. Headquarters.*

CONFEDERATION REPORT

PART C

CLAUSE 1.

The joint committee recommends that:

I. the charter of the Engineering Institute of Canada originally issued in 1887 be the basic charter for the New National Body. The constitution, by-laws, and objectives to be revised to meet the terms of the clauses of the agreement between The Engineering Institute of Canada and the Canadian Council of the Associations and Corporation of Professional Engineers.

II. the agreement for Confederation be drawn up between The Engineering Institute of Canada and the Canadian Council of Professional Engineers; each association and corporation to sign the final legal documents as constituent members of the Canadian Council.

III. the choice of name for the new body be left to the provisional council of the National Body.

The Provincial Bodies shall have complete jurisdiction over the administration of the Professional Engineers' Act within the province, which among other things embraces registration and enforcement of the regulations, protection of the public, and the maintenance of high standards.

The National Body shall have jurisdiction over matters relating to the dissemination of knowledge useful to the profession, which among other things shall include the holding of technical meetings and the publication of professional literature, assistance in matters related to education, public recognition of the profession at all levels both at home and abroad.

The National Body shall represent the profession in national and international matters when such representation is desirable, it being recognized at all times that the opinions and wishes of the Provincial Bodies shall be of prime importance in forming policy for such representation.

It is proposed that the new National Body will render enlarged services to its member engineers, through the carrying-out of the following aims and objectives:

(a) to develop and maintain high standards in the engineering profession.

(b) to facilitate the acquirement and the interchange of professional knowledge among its members.

(c) to advance the professional, the social and the economic welfare of its members.

(d) to assist in the development of uniform registration qualifications and examination schedules.

(e) to act in an advisory capacity in connection with legislative matters common to all of the professional provincial bodies.

(f) to enhance the usefulness of the profession to the public.

(g) to collaborate with the universities and other educational institutions in the advancement of engineering education.

(h) to promote intercourse between engineers and members of allied professions.

(i) to co-operate with other societies for the advancement of mutual or national interests.

(j) to encourage original research, and the study, development and conservation of the resources of Canada.

(k) to provide a forum for the discussion of problems common to all engineering bodies.

(l) to provide for the publication of a national Journal and technical and professional papers and transactions.

(m) to act as a recognized national voice speaking on behalf of all the professional engineers of our country.

PART C

CLAUSE 2.

The significant word in this clause is "full" before the word "membership". In essence this means that to be a Member (with a capital "M") of the National Body one must be a registered engineer.

Persons who are corporate members of the Institute on the effective date of the agreement, if not then registered engineers, will have a limited period (suggest five years) for the privilege of becoming full Members. Every effort should be made to get such corporate members to register and become full Members.

It is recognized that in some instances registration may not be a legal requirement, particularly for persons who have retired from engineering, and in others where a non-Canadian is concerned it may not be possible to obtain registration. Such persons need not be registered but their membership in the National Body would be distinguished from full Membership by a different membership classification.

Special provisions and classifications will be made for other members of the National Body such as Honorary, Life, Retired, non-resident in Canada, Students, etc. Further consideration should be given to the voting rights of such members.

CLAUSE 3.

(a) "Representatives elected according to the membership of the provincial bodies". This is interpreted to mean that representatives shall be elected by the members of the National Body within a province or territory.

(b) "Full membership of their province", is interpreted to mean the members of the National Body within the province.

(c) "Such elections shall be conducted by the provincial bodies". This phrase applies to the first election or appointment—subsequent elections would be held by the National Body.

(d) Clause 3 effects a democratic compromise for the election of the National council. It is designed to prevent the council from being unduly swayed by an overbalancing representation from any one province.

CLAUSE 4.

This clause is inserted to avoid any legal infringement by the National Body on any provincial legislation.

CLAUSE 5.

This clause provides for the establishment of local branches of the engineering profession in communities where required. It is understood that existing branches will continue their existence under the new organization without going through prescribed formalities.

It is recommended that every effort be made to merge or join together branches in any community where a branch of each organization exists at the time of confederation.

No specific provision is made in the joint annual fee for financing the branches. It is recognized that some such provision is necessary. It is suggested that the provincial bodies, when rendering the annual joint account for fees should include an item to cover branch membership.

CLAUSE 6.

It is understood that the National Body would publish a national engineering journal and in addition be responsible for the publication of transactions, and such technical papers as authorized by the Council.

CLAUSE 7.

In order to facilitate the organization and initial operation of the new National Body, the committee recommends that the staff of the organization be housed in the existing Engineering Institute of Canada building, on Mansfield St., in the City of Montreal.

CLAUSE 8.

This assessment will be made on the total membership of each provincial or territorial body, and is in addition to the provincial registration fee. This figure has been developed on the basis of the present number of registered engineers, i.e. 32,000. It should be noted that it does not include any provision for financial assistance to the branches.

This assessment will include a subscription to the national journal. (The present subscription to the Engineering Journal is $4.00 per year).

CONFEDERATION REPORT

PART D

**Implementation of the recommendations of the report of the committee on confederation to—
CANADIAN COUNCIL OF PROFESSIONAL ENGINEERS**

SUGGESTED PROCEDURES

1. That this report be reviewed and accepted by the Executive and council of the Canadian Council of Professional Engineers.

2. That this report be forwarded to the constituent Councils of the Provinces—for acceptance. It is recognized that procedures in all provinces are not the same, i.e. Provincial Councils may act for some associations while others may require reference to their membership.

3. That the Provincial Councils be requested to give enabling authority, to the next Canadian Council of Professional Engineers to proceed with the implementation of the terms of this report.

4. That such enabling authority, (para. 3.), be secured for the early appointment and establishment of a national provisional council to be known as "The Engineers Confederation Commission".

The duties of the "Commission" to be as follows:

(a) to draw up a constitution, by-laws, and legal details for the confederation of the Engineering Institute of Canada and the Canadian Council of the Associations and Corporation of Professional Engineers in conformity with the eight basic clauses laid down by the joint committee. Part "C" of this report is included as a guide to the Commission.

(b) The Commission will be bound by the terms of Clauses 1 to 8 of Part "A" of this report.

(c) The membership of the Commission to consist of a chairman and a vice-chairman, to be appointed jointly by the councils of the Engineering Institute of Canada and the Canadian Council of Professional Engineers.

(d) It is also recommended that the members of the commission be determined as follows:

Newfoundland, Prince Edward Island, Yukon Territories

One member from each of these areas to be appointed jointly by the provincial association council, and the Engineering Institute councillors of the **branches within the province.**

Nova Scotia, New Brunswick, Manitoba, Saskatchewan, Alberta, and British Columbia

One member to be appointed by the Council of the Association within the province designated. One member from each province to be appointed by the Councillors of the branches of The Engineering Institute of Canada in the province.

Quebec

Two members to be appointed by the Council of the Corporation. Two members to be appointed by the Councillors of the branches of the Engineering Institute of Canada in the province.

Ontario

Two members to be appointed by the Council of the Association. Two members to be appointed by the Councillors of the branches of the Engineering Institute in the province.

It will be noted that for the purposes of the Commission, the members are to be appointed rather than elected, and that only one Vice-Chairman is appointed.

The Commission is to be appointed for a term of one year —subject to extension or re-appointment for a further term, not to exceed one year.

Upon the installation of the first council, regularly constituted, the "Commission" shall be dismissed.

The first regularly constituted council is to be elected and appointed in accord with Clause 3—Part "A"—of this report.

Under this arrangement the "Note" at the end of Clause 3 —page 2—Part "A", becomes redundant and unnecessary and should be disregarded.

CONFEDERATION REPORT

PART E

Implementation of the recommendations of the report of the committee on confederation for the council of—
THE ENGINEERING INSTITUTE OF CANADA.

SUGGESTED PROCEDURES

1. That this report be reviewed and accepted by the Council of The Engineering Institute of Canada.

2. That after approval by the Council the report be submitted to all corporate members of the Institute with the ballot which was approved by the Council at its meeting in Toronto on January 31st, 1959, and accompanied by an appropriate covering letter from the president.

3. On receipt of a favourable ballot, Council appoint its representatives to the Engineers Confederation Commission.

The duties of the Commission to be as follows:

(a) To draw up a constitution, by-laws and legal details for the confederation of the Engineering Institute of Canada and the Canadian Council of the Associations and Corporation of Professional Engineers in conformity with the eight basic clauses laid down by the joint committee. Part "C" of this report is included as a guide to the Commission.

(b) The Commission will be bound by the terms of Clauses 1 to 8 of Part "A" of this report.

(c) The membership of the Commission to consist of a chairman and a vice-chairman, to be appointed jointly by the Councils of The Engineering Institute of Canada and the Canadian Council of Professional Engineers.

(d) It is also recommended that the members of the Commission be determined as follows:

Newfoundland, Prince Edward Island, Yukon Territories

One member from each of these areas to be appointed jointly by the provincial association council, and the Engineering Institute councillors of the branches within the province.

Nova Scotia, New Brunswick, Manitoba, Saskatchewan, Alberta and British Columbia

One member to be appointed by the Council of the Association within the province designated. One member from each province to be appointed by the Councillors of the branches of the Engineering Institute of Canada in the province.

Quebec

Two members to be appointed by the Council of the Corporation. Two members to be appointed by the Councillors of the branches of the Engineering Institute of Canada in the province.

Ontario

Two members to be appointed by the Council of the Association. Two members to be appointed by the Councillors of the branches of The Engineering Institute of Canada in the province.

It will be noted that for the purposes of the Commission, the members are to be appointed rather than elected and that only one vice-chairman is appointed. The Commission is to be appointed for a term of one year, subject to extension or re-appointment for a further term, not to exceed one year. Upon the Installation of the first council regularly constituted, the Commission shall be dismissed.

The first regularly constituted council is to be elected and appointed in accord with Clause 3—part "A"—of this report.

Under this arrangement the "Note" at the end of Clause 3 —page 2—Part "A", becomes redundant and unnecessary and should be disregarded.

Regional Conference, Sudbury

The first Northern Ontario Regional Conference, held in Sudbury, on April 25, gave the engineers of this region the welcome opportunity of meeting to hear discussions on the engineering future of Canada in the next twenty years.

With all the Northern Ontario branches participating, and with an invitation extended to all engineers and their ladies, the attendance of 150 was gratifying to the very active committee making arrangements for this first-of-its-kind conference in this region.

Consideration of Canada's future is obviously of interest to engineers, and it proved to be so as the technical meeting proceeded. Three speakers dealt with three different parts of the general picture:

Energy: Nuclear, Hydro-Electric, Carbonaceous, Solar, J. L. Olsen, Canadian General Electric Co., Kingston, Ont.

Transportation: Land, Air, Water, A. Lightbody, Assistant Manager of Research, and A. L. Bingham, Canadian Pacific Railways.

Defence, Maj. Gen. W. S. Macklin.

Mr. Olsen said that Canada's future lies in atomic power. The full capacity of carbonaceous fuels has almost been realized. Electric power has been utilized almost to capacity in the highly industrialized areas in Southern Ontario and Quebec. Solar energy is not sufficient in the northern latitudes. The only workable solution, in Mr. Olsen's opinion is production of energy by fission, atomic power. Every aspect is in Canada's favour, he said.

General Macklin had some critical comment to make on Canada's defence system. This was another thought provoking session dealing with the controversial defence decisions of the past five years and the necessary ones in the next twenty years.

Dr. Garnet T. Page, general secretary of the Engineering Institute, spoke at the evening banquet on the subject of Travelling in South America.

On the lighter side, there were many opportunities for the delegates to meet — at a luncheon, at the reception and cocktail party, and at the conference banquet. Climaxing the day there was the informal conference dance. The ladies accompanying the delegates enjoyed themselves immensely, with a program arranged by Mrs. F. A. Orange.

Credit for the success of the meeting is difficult to distribute. The support of so many members for this important project rewarded the efforts of the committee.

W. B. Ibbotson is the Branch chairman at Sudbury. R. P. Crawford was the conference chairman. Other members in charge of conference services were: W. J. Ripley, Jr., registration, T. C. Robertson, program, F. deStefano, welcome, R. H. Moore, speakers and special guests, P. R. McAdam, accommodation, F. Jackson, publicity. Representatives of the other E.I.C. branches on the committee were: W. A. Hogg, Sault Ste. Marie, and T. C. McNabb, North Bay. Notable for their assistance were P. F. Adams, C. A. MacMillan, F. G. Burchell, G. Charlap, and E. T. Querney.

Participating in the Sudbury Meeting: A. L. Bingham (left), A. Lightbody, J. L. Olsen, Maj. Gen. W. S. Macklin, and W. B. Ibbotson, branch chairman.

Dr. Garnet T. Page (left), a guest speaker, with Ralph Waddington of International Nickel, and F. A. Orange, E.I.C. councillor.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council in April 1959.

Member: H. Z. N. Argun, Toronto; E. Bernhardt, Montreal; E. L. Bowerman, Toronto; J. H. Dyer, Bell Island, Nfld.; J. K. Erskine, Montreal; H. L. Ferguson, Montreal; G. Fournier, Rimouski; E. C. Hale, Sturgeon Falls; J. W. Inglis, Vancouver; E. J. Johnson, Preston; W. Kalbfleisch, Ottawa; L. R. Kidman, London, Eng.; G. Koopmans, London, Ont.; D. I. MacMurchy, Toronto; I. Mansell, Montreal; F. W. Patterson, Niagara Falls; M. Reinbergs, Hamilton; M. Van Wijk, Arvida; C. S. Wiffen, Toronto.

Junior: R. J. Blake, Toronto; A. A. Boscariol, Windsor; V. P. Despatis, Montreal; R. D. Detwiler, Halifax; D. J. Dresselhuizen, Montreal; P. A. Hanley, Montreal; L. L. Hartford, North Bay; I. G. Holmes, Toronto; J. F. Schultz, Shawinigan; J. G. Spence, Kingston, Ont.

Affiliate: A. M. Hurley, Calgary.

Junior to Member: H. T. Floyd, Belleville; H. L. Isabelle, Montreal; D. C. Johnston, Ottawa; G. R. Leonard, Montreal; J. S. F. Ma, Toronto; M. Mindess, Toronto; D. W. Prendergast, Montreal; M. D. Robb, Edson, Alta.; D. H. Shields, Downsview; S. W. Shishakly, Montreal; R. R. Smith, Vancouver; J. A. Stewart, Hull; R. A. Williams, Victoria.

Student to Member: C. J. Macfarlane, Chalk River.

STUDENTS ADMITTED

University of Toronto: W. A. Adams, L. W. Argue, B. L. Barrett, D. R. Bonis, A. G. Carless, D. S. Davis, P. R. Ferris, G. A. Harris, W. Katarynczuk, R. G. Kraemer, P. G. S. Large, J. S. McGavin, G. L. A. Palinkas, A. Salumets, G. I. Tebbutt, J. D. Wilcox, C. C. Wilson, S. Yanchula.

St. Francis Xavier University: E. L. F. Anthony, R. G. Butler, F. Cianfaglione, W. J. Donovan, F. G. Doyle, J. H. George, P. I. Hurley, J. C. Joannette, W. V. Kukulki, M. A. Lafreniere, E. J. Poirier, P. E. Smith.

Acadia University: M. R. Bacon, R. M. Chown, D. E. Cushing, C. G. Hatfield, H. B. Hatt, M. Hon, A. R. McLaughlin, J. H. Oyler, J. I. Paul, C. W. Ploeg, K. C. Woo, C. E. Zwicker.

University of British Columbia: E. I. Dickson, R. E. Elcox, D. O. Haaheim, D. K. Holzman, G. E. Massey, M. A. Merlo.

University of New Brunswick: J. D. Ellison, W. J. Evans, D. M. Goss.

University of Alberta: B. A. Ellis, A. D. Turnbull.

McMaster University: H. J. Cox, F. A. Holik.

University of Western Ontario: S. G. Kennedy, F. J. Myslik, J. D. Ort.

Queen's University: L. S. Norman.

University of Sherbrooke: J. G. Bergeron.

Sir Geo. Williams College: P. Hawryluk.

University of Illinois: D. M. Shah.

University of Toronto: R. W. Millen.

A.P.E.B.C.: A. Canning.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Member: P. F. Proctor.

SASKATCHEWAN

Members: N. R. Dunne, W. J. Harper, T. C. Morgan, O. J. E. Wilson; **Junior:** D. M. Kent; **Junior to Member:** R. L. Frederick, J. W. Lukey, J. R. Mutch, J. H. Tims; **Student to Junior:** R. H. Billings, D. G. Bishop, A. D. Carlson, H. R. Daniel, H. G. Gilchrist, W. F. Maguire, E.C. Sherwin, J. J. Syrnyk; **Students:** J. A. Colgan, M. D. Glazier, E. D. Lidfors.

NOVA SCOTIA

Members: C. C. R. Bell, J. F. Lindsay, C. F. MacNeil; **Junior to Member:** H. W. Doane, R. N. Robertson, R. P. Whalen, K. D. Tuddenham.

MANITOBA

Member: S. C. Roberts.

Railway Engineering

The Institution of Civil Engineers, London, England, is now publishing monthly a publication entitled "Railway Engineering Abstracts". The civil, mechanical and electrical aspects of railway and other engineering are covered. The ordinary rate of subscription is £2. a year for 12 issues post free. Cost of single copies is 4s. 0d., post free.

Advertising the Engineer

Our April issue announced the first winners of certificates which The Engineering Institute of Canada now offers monthly for the best advertisement in *The Engineering Journal.* We confidently leave it to the independent judges to decide on the relative merits of advertisements directed to engineers in their own Journal. Meanwhile advertising addressed to other readerships is of prime importance to engineers when it has the opportunity to reflect their status in the community. That a well-conceived advertisement can serve our profession in this way has been admirably demonstrated by a number of prominent advertisers including General Electric, General Motors and Honeywell Controls. Among the advertisements that have recently been appearing in various Canadian publications the Honeywell Controls series, "Look to the Engineer", is especially commended. It is hoped that this trend in advertising will be encouraged by all who seek adequate recognition for the engineer's part in Canadian development.

The Canadian Conference on Education Issues a General Report and Program

THE 850 DELEGATES who attended the national conference on education held in Ottawa in February 1958 resolved that the conference organization should be maintained to work for the objectives outlined at that time. During its first year this organization has been chiefly occupied with determining the degree of public support for a widespread, completely voluntary effort; with a suitable organization structure; and finally with aims and objectives and a program.

The C.C.E. was created to bring laymen and educators together for an exchange of information and ideas at a time of crisis in education. Its purpose is to stimulate constructive public support for education in Canada.

Conference Widely Supported

Representatives of both French and English language groups—organized labour, business and industry, education, agriculture, women's associations and many other segments of society—direct the work of the Conference. The sponsors are 51 national organizations, representing some five million people. Canadian business and industry has contributed some $40,000 in the past year at the invitation of a finance committee headed by Mr. W. E. Williams, president of Procter and Gamble Company of Canada Limited. Daily and weekly newspapers, magazines, the C.B.C., private radio and television stations, the National Film Board, and those in the field of advertising have given assistance. As a result of a major advertising campaign 50,000 copies of the booklet "Crossroads" have been distributed during the year.

Aims

The Conference recognizes that responsibility for education lies at the provincial and community levels, and its general report and program, issued in March, indicates that most C.C.E. activity will take place at these levels. The program will be reviewed annually to ensure that the work reflects the changing needs of the nation and to endeavour to measure Canada's educational progress against those needs. This program is based on the following beliefs:

1. That constructive public debate and wide dissemination of information about education will contribute materially to the pub-

lic support necessary to the solution of the problems facing Canada's educators.

2. That everyone should have the opportunity to obtain the education he wants and needs within the limits of personal aptitude and ability.
3. That an essential responsibility of the citizen is to demand highly capable people to carry on the work of education and educational administration, and to provide them with proper buildings and facilities, so that they may use their professional training and ability to the best advantage of the community.
4. That Canadians, conscious of the vastness of their country, should work toward the elimination of the penalty which geography often places on education opportunity of those who live in rural and remote areas.

Trained Teachers

The Conference will therefore work to ensure that all teachers receive adequate training and prestige in the community, with commensurate salary levels and financial assistance for those in basic or advanced training. It will also seek improved conditions for rural teachers.

Adequate Buildings and Equipment

Efforts will be made to co-ordinate school site planning with other municipal planning, and to bring the student's technical equipment into line with that which he will use in earning his living.

Improved facilities will be sought for rural schools, and the advantages of wider use of educational television explored.

A Fuller Education

The Conference will also work for the introduction of English or French as a second language in elementary grades at as early an age as possible and for continued education to be made available to all who have the desire and capacity for it. It will seek the assurance that outstanding pupils in primary and secondary schools are encouraged to proceed to universities or professional schools.

More Money for Education

Other objectives in the program are the spending of a larger proportion of our national income on education, the provision of more scholarships, loans and bursaries and the expansion of research into all levels of education.

THE ENGINEERING INSTITUTE OF CANADA

OFFICERS 1958-1959

MEMBERS OF COUNCIL

President

J. J. Hanna, Calgary, Alberta

Past-Presidents

V. A. McKillop, London — C. M. Anson, Sydney — K. F. Tupper, Toronto

Vice-Presidents

Until May, 1961

C. V. Antenbring, Winnipeg
R. B. Chandler, Port Arthur
F. L. Lawton, Montreal

Until May, 1960

John B. Angel, St. John's, Nfld.
E. T. Buchanan, Grand'Mere
H. G. Conn, Kingston

Councillors

Representing Sister Societies

M. L. Baker, Halifax, N.S.
B. Chappell, Winnipeg, Man.
W. F. Hayes, Prince Albert, Sask.
K. W. Mitchell, Calgary, Alta.
Wm. J. Riley, Rosemere, Que.

Associations and Corporation

Information received through co-operation of the provincial organizations.

ALBERTA

Annual Meeting

The Association of Professional Engineers of Alberta held their 1959 annual meeting April 3-4 at the Palliser Hotel in Calgary.

Elected as officers at the time were C. A. Stollery, president; D. C. Jones, vice-president; Dr. G. W. Govier, past-president; councillors elected were Dr. R. N. McManus, W. D. Stothert, J. C. Scott, R. D. Hall, N. J. Allison, Dr. George Ford, W. A. Smith, B. F. Willson, P. M. Butler, F. A. Kidd, Dr. J. Spivak, W. D. Suitor, J. G. Dale, K. W. Mitchell, and L. A. Thorssen.

I. G. Finlay was elected registrar and J. F. McDougall, deputy registrar.

Dr. Gerald W. Johnson, guest speaker at the meeting, declared the feasibility of thermo and nuclear explosions for use in peacetime industry. He dispelled the fear of radioactive fallout surrounding such nuclear explosions through charts, slides and films of recent tests conducted at the Nevada proving grounds, where radio activity is captured and held underground or dissipated through the use of minerals.

Two projects Dr. Johnson hopes to see the Canadian government allow to go ahead are the production of a low viscosity oil from the Athabasca tar sands and the clearing of a channel harbour to be blasted out of solid rock near Cape Thompson in Alaska.

Two $200 bursary awards were presented by President Dr. G. W. Govier to University of Alberta students H. W. Webb and J. A. Allen for having achieved highest standing in their first year of engineering.

ONTARIO

C. T. Carson Addresses Meeting

If Canadian-made goods are to compete successfully in world markets with those produced in Europe and Asia, we must continue to increase productivity and at the same time, maintain high standards of quality, some 400 professional engineers were told recently.

Addressing a special regional meeting of engineers, C. T. Carson, P.Eng., of Windsor, Ont., past president of the Association of Professional Engineers of Ontario, said the professional engineer had an important role to play in meeting this challenge.

"In large degree, responsibility for production standards, efficiency, quality control and unit cost must be assumed by engineers," he told his audience. He added that new machinery, automated procedures, product design, plant layout and other developments which would contribute to increased efficiency lay in the engineer's domain.

"Unfortunately, we are not blessed with the density of population to provide a domestic-market profit cushion, and to reduce unit costs as are our industrial neighbours and competitors to the south," he stated.

"Also, we don't have skilled tradesmen willing to work at one-third the Canadian wage scale such as some of our competitors in Europe, not to mention one-tenth the Canadian wage scale paid to workers by the Japanese industrialist."

Mr. Carson warned that in the years ahead, Canada must overhaul its economy. He noted that in 1958, the Canadian standard of living declined for the first time in recent years.

"While wages were going up 1.8 per cent, prices increased 2.6 per cent. Gross National Product set an all-time record, but in the midst of the productive glow, half a million people were unemployed," he declared.

Mr. Carson said the manufactured goods increment must continue to gain "if we are to have any measure of full employment and general prosperity".

Referring to engineering universities, he said there was a growing need for quality rather than quantity in graduating classes, and noted that in recent years, the number of schools teaching engineering had increased to nine.

He called for elimination of "engineering wastage" where professional engineers are employed in sub-professional jobs. And he pointed out that the increased emphasis on productivity would help in solving the problem.

Secretary Treasurer Appointed

David L. Turner, of Toronto, has been appointed secretary-treasurer of the Association of Professional Engineers of Ontario.

Mr. Turner, a native of Vancouver, was formerly with Avro Aircraft Co. where he was employed as a senior stress engineer. A graduate in aeronautical engineering from the University of Toronto, he served in World War II as a pilot in the RAF Coastal Command.

Mr. Turner brings to his new position, five years of APEO committee work, having served on the company groups committee and the engineering technicians program. He served on the latter's certification board since its inception by the Association three years ago.

Certification of Technicians

The certification program for engineering technicians and technologists originated by the Association of Professional Engineers of Ontario in June, 1957, is now being adopted by the United States, it was announced recently by T. M. Medland, executive director of the A.P.E.O.

The National Society of Professional Engineers in Washington, D.C., has recommended to all of the state societies that they adopt the Ontario program. The only revision in the program would be made to fit U.S. standards of education.

Already the Wisconsin Society of Professional Engineers has announced it was immediately adopting the program. It is expected that other state societies will follow.

The A.P.E.O. was the first engineering body to set up a plan whereby engineering technicians are graded according to their training and experience into four categories. There are three grades of technicians and one of technologists.

The certification program was based upon the belief that it would encourage technicians to progress through the four grades to top proficiency, and would also serve as a means of defining the upgrading of technical employees.

"Technicians and technologists play a valuable role in engineering by assuming many of the non-professional duties of an engineer, thus permitting the latter to concentrate on full-time professional work," says Dr. Geo. B. Langford, P.Eng., Toronto chairman of the certification board.

At present there are between 900 and 1,000 certified engineering technicians and technologists in Ontario with certification being carried out at the rate of 75 new members per month.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

W. R. Stickney, M.E.I.C. died on March 4, 1959 at Toronto.

Born on December 1, 1911 in Elora, Ontario, he graduated from the University of Toronto in 1936 with a B.A.Sc. degree in chemistry later serving with Canadian Bridge Co. Ltd., Walkerville and Canadian Vickers Ltd., Montreal. For the past 12 years he had been chief welding engineer of the Canadian Welding Bureau.

N. J. A. Vermette, M.E.I.C. died on April 24, 1959.

Mr. Vermette was educated in Montreal where he attended the College Ste Marie and the Ecole Polytechnique.

From 1922 until 1927 he worked with the technical services department of the City of Montreal.

In 1927 he was named manager of the City of Shawinigan and in 1939 until his death was a civil engineer in charge of the provincial roads department survey division for Western Quebec.

He was active in youth organizations and from 1955 until this year was president of Verdun School Commission.

Thomas Maxwell Fyshe, civil engineer in mining promotions, died recently at his home in Toronto.

Born in Halifax, he received his education in Germany and McGill University where he graduated in science in 1905.

In 1940 he came to Toronto and was with the Nesbitt and Thomson Company Ltd., investment house in Montreal for a number of years. During the Second World War he was assistant to the oil controller for the Wartime Prices and Trades Board. For the past several years he had been with Brewis and White Ltd., Toronto mining securities firm.

He was a director of New Dickenson Mines.

William D. Neeland, M.E.I.C. died in October, 1958.

Born on May 21, 1912 in Moose Jaw, Sask. he graduated from McGill University in 1935 with a degree in geology and chemistry.

In 1929 he joined the Northern Development Company in Fort William, Ont. as chainman.

After working in various mining companies in Canada he joined the Royal Canadian Navy as Lieutenant from 1942 to 1945, returning as geologist with Kennco Explorations Ltd. in Toronto.

Mr. Neeland was consulting geologist and inspector of mines stationed at Flin Flon with the Department of Natural Resources in Saskatchewan and was best known in the mining world for his exploration and outline of the Steep Rock iron ore body.

H. B. Henderson, M.E.I.C. retired president of Cowin & Company Limited died on March 3, 1959.

Mr. Henderson who resided in Winnipeg from 1914 to 1957 was born in New York and graduated in engineering from Cornell University in 1894. He received his master's degree in mechanical engineering from MIT in 1896.

He was well known in the construction industry in western Canada and was a member of the American Society of Civil Engineers.

Arthur Edward McNicoll, M.E.I.C. died on October 11, 1958.

Mr. McNicoll was born in England on August 12, 1892 receiving his education at Royal Masonic School and the Montreal Technical school.

In 1916 he joined the Dominion Bridge Company Limited where was until the time of his death as design & general engineer for the company.

He was well known for the design of steelwork for many buildings in Montreal.

John H. Lapp, M.E.I.C. died on February 20, 1959.

Born on November 28, 1914 in Lincoln, Nebraska he graduated from the University of Nebraska in 1939 with his degree of Bachelor of Arts & Science in geology.

In 1940 he joined the Texas Company, Oklahoma City, Okla. as geologist.

In 1944 until 1954 he worked with various oil corporations in Canada and the United States.

He joined the Stanolind Oil & Gas Co., Regina, Sask. in 1955 where he was consultant geologist.

W. I. Elliott, M.E.I.C. died in December 1958.

Born on November 18, 1898 in Nova Scotia he graduated from Dalhousie University in 1923 with a degree in mechanical and civil engineering following which he joined the Canadian General Electric Company in Lynn Mass.

From 1926 to 1928 he worked with Byrne Mfg. Co. in Cleveland, Ohio and the Grazelli Chemical Company as draftsman.

In 1928 he joined Fraser Brace Engineering Company in Montreal where he was in charge of installing machinery and pipelines at the International Paper Company's plant at Three Rivers and worked on various railway projects until 1938.

Egon Alzner, M.E.I.C. died on February 28, 1959.

Born in Romania on October 21, 1905, he attended technical university in Berlin graduating in 1928 with a degree in mechanical engineering.

From 1929 to 1939 he worked with the Shell Oil Refinery in Romania.

In 1939 he was sent by Shell Oil Refinery on a special training trip to the United States, returning one year later to Romania where he was made technical manager for Shell Oil Refinery at H.Q. Campina.

From 1945 to 1949 he was mechanical engineer with the Military Government, Germany.

From 1950 until the time of his death Mr. Alzner was with Canadian Vickers Ltd., in Montreal where he was named chief estimator for the company in 1955.

Frederick Reginald Sharman, M.E.I.C. died on April 7, 1959.

Born on March 7, 1894 in Swindon, England, he graduated from Swindon & Wilts Technical Institute in mechanical engineering and from 1914 to 1919 served a mechanical engineering apprenticeship with the Great Western Railway.

After serving with the British Expeditionary Force in World War I, he spent the early years of his career working for the various railway projects.

From 1941 to 1946 he worked for the inspection board of U.K. & Canada as deputy inspector of Artillery Carriages and A. A. Mountings later being transferred to the British Admiralty Technical Mission as deputy inspector of Naval Ordinance. At the end of World War II, he was appointed chief district inspector to the contracts settlement board.

From 1946 to 1947 he joined the Waterloo Mfg. Co. handling technical sales of automatic oil fired boilers leaving there to work for the Aluminum Company of Canada as mechanical engineer to Demerara Bauxite Co. in British Guiana for the following two years.

Returning to Canada he was engaged by Canadian Car & Foundry Co. Ltd. in the engineering department from 1949 to 1950.

In 1950 he joined the Canadian International Paper Company as mechanical superintendent, Kipawa Mill.

J. Cecil McDougall, M.E.I.C. died suddenly on April 20, 1959.

Born in Three Rivers, Que. he graduated from McGill University in architecture and engineering and was a representative of McGill on the Montreal City Council.

He was president of the Province of Quebec Association of Architectures in 1926 and a member of Sir George Etienne Cartier Corporation.

At the time of his death he was consultant to the firm of Fleming & Smith, architects, where he had been a partner in the firm for a number of years.

Personals

V. A. M Robertson, M.E.I.C. of Sir William Halcrow & Partners, Consulting Engineers, has retired from the partnership but will remain as a consultant to the firm.

A. G. Asplin, M.E.I.C. (B.Eng. civil., McGill 1938) has been appointed president of Horton Steel Works, Limited, Toronto, Ont.

W. K. Gwyer, M.E.I.C. (B.A.Sc., civil., British Columbia, 1936) has become assistant general manager of the West Kootenay Power and Light Company, Trail, B.C.

A. G. Asplin, M.E.I.C.

W. K. Gwyer, M.E.I.C.

R. L. Weldon, M.E.I.C. (B.Sc., M.Sc., mech., McGill, 1917, 1920) has retired as president of Bathurst Power & Paper Company Limited, Montreal. He has been elected chairman of the board to the company.

C. W. West, M.E.I.C. (B.A.Sc., Toronto, 1915) has retired from the post of member of The St. Lawrence Seaway Authority.

Colin B. McMillan, M.E.I.C. (B.Sc., civil, Queen's, 1936) has opened his own office as a consulting engineer in Montreal.

William A. Williamson, M.E.I.C. (B.A.Sc., elec., Toronto, 1934) is an engineer, with N.B. Electric Power Commission, Fredericton, N.B.

R. L. Weldon, M.E.I.C.

F. W. Cranston, M.E.I.C.

Colin B. McMillan, M.E.I.C.

C. Arthur Miller, M.E.I.C.

F. W. Cranston, M.E.I.C. (B.Sc., mech., Queen's 1936) has been appointed vice-president of Industrial Advertising Agency Ltd, Toronto.

A. H. Mingail, M.E.I.C. (B.Eng., elec., Calcutta, 1942) has joined the Canadian Broadcasting Corporation in Toronto as an engineer in the network operations department.

A. E. Beazely, M.E.I.C. of Underwood McLellan and Associates Limited has been transferred from Calgary, Alberta to Saskatoon, Saskatchewan as engineer for the company.

Glenn H. Curtiss, M.E.I.C. (Master's degree in Business Administration, Toronto, civil, 1948, 1950) is now Vice-President of Stone & Webster Canada Limited, Toronto, Ont.

John F. Miles, M.E.I.C. (B.Sc., chem., Queen's, 1948) has been appointed assistant to the general superintendent of the Dominion Iron and Steel division of Dominion Steel and Coal Corporation Limited, Sydney, N.S.

W. Ralph Lewis, M.E.I.C. (B.Sc., B.A.Sc., elec., 1941, 1947) was appointed chief electrical engineer, Dominion Iron and Steel division, of Dosco, Sydney, N.S.

Robert Bezanson, M.E.I.C. (B.Sc., B.Eng., 1948, 1951) has been appointed mechanical and construction superintendent of the Seaboard Power Corporation Limited, Sydney, N.S.

John J. Laffin, M.E.I.C. (B.Eng., elec., Nova Scotia, 1947) has been appointed electrical engineer for coal operations of Dominion Steel & Coal Corporation Limited in Sydney, N.S.

H. C. Maitland, M.E.I.C. has been appointed assistant chief engineer of the Dominion Iron & Steel Division, Dominion Steel & Coal Corporation Limited, Sydney, N.S.

W. G. Ward, M.E.I.C.

Anton A. Goldes, M.E.I.C.

W. G. Ward, M.E.I.C. (B.Eng., elec., McGill 1942) has been appointed general manager, apparatus department, with Canadian General Electric Company Limited, Peterborough, Ont.

Anton A. Goldes, M.E.I.C. (B.Sc., civil, Waterstrand) formerly chief engineer with the Toronto firm of Yolles & Associates announces the establishment of A. A. Goldes & Associates, consulting engineers, Toronto, Ont.

H. Soloninka, M.E.I.C.

J. B. Mantle, M.E.I.C.

C. Arthur Miller, M.E.I.C. (B.A.Sc., mech., Toronto 1936) supervisor of cost studies, scheduling and standards, engineering department of Canadian Industries Limited, has been elected president of the American Association of Cost Engineers, New Hampshire.

H. Soloninka, M.E.I.C. (B.Sc., civil, Queen's 1951) has become manager of Haddin, Davis & Brown (Saskatchewan) Limited, Consulting Engineers.

J. B. Mantle, M.E.I.C., (B.E. mech., Saskatchewan, 1941, M.Sc., mech., Illinois, 1947) professor and head of the Department of Mechanical Engineering at the University of Saskatchewan is the chairman of the Saskatchewan Branch of the Institute.

Paul Riemer, M.E.I.C. (B.Sc., civil, Saskatchewan, 1947) assistant professor of civil engineering at the University of Saskatchewan has been elected chairman of the Saskatoon Section, E.I.C.

J. J. Schaeffer, M.E.I.C. (B.Sc., civil, Saskatchewan, 1946) is chairman for the Moose Jaw Section of the Institute. Mr. Schaeffer is with Underwood, McLellan & Associates, at Moose Jaw.

R. J. Genereux, M.E.I.C. (B.Sc., M.Sc., civil, Saskatchewan, 1951, 1954) planning engineer with the Saskatchewan Department of Highways at Regina, has been elected chairman of the Regina Section, E.I.C.

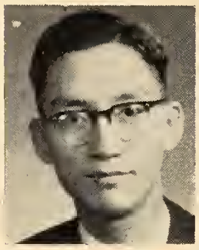
• PERSONALS

Dr. L. Austin Wright, HON. M.E.I.C., was elected president of the Quebec Division of the Canadian Arthritis and Rheumatism Society, of which he has been vice-president for four years. Also Dr. Wright has been reelected president of the Pointe Claire Memorial Library Association.

J. B. Morrow, M.E.I.C. has been working since July 1958 as an engineer for the National Sea Products Limited, Halifax.

William A. Arsenault, M.E.I.C. (B.E. civil, Nova Scotia 1938) is now supervising construction engineer with Quebec Cartier Mining, in supervision of railroad construction.

J. David Boulding, JR.E.I.C. (M.A.Sc., elec., British Columbia, 1959) is with the Electronics Laboratory of the Defence Research Telecommunications Establishment of the Defence Research Board in Ottawa as a Defence Scientific Service Officer.



Chung-Yen Chang, JR.E.I.C.

Ross Salmon, JR.E.I.C.

Chung-Yen Chang, JR.E.I.C. (M.A.Sc., civil, Toronto 1957) is a design engineer with the Hydro-Electric power commission of Ontario, Toronto, Ont.

Ross Salmon, JR.E.I.C. (B.Sc., mech., Queen's 1956) is now research assistant in the department of mechanical engineering at Queen's University, Kingston, Ont.

Stanley W. Young, JR.E.I.C. (civil, McGill, 1956) is located by H. G. Acres Company Limited in Warsak Colony, West Pakistan.

Walter Naumko, JR.E.I.C (B.Sc., civil, M.A.Sc., Manitoba, Toronto 1953, 1958) has been named project engineer, engineering division, with Hunting Technical and Exploration Services Ltd., Toronto.

G. E. Blair, JR.E.I.C. (B.E., mech., Saskatchewan 1957) is now design engineer with Beaver Engineering Co., Toronto, Ont.

Frank Barna, JR.E.I.C. (B.Eng., mech., (power & design) McGill, 1957) is now a power and fuel engineer, utilities division, with Edgar Thomson Works (Braddock) Pittsburgh district, a subsidiary of United States Steel Corp.

M. G. Colvin, JR.E.I.C. (B.A.Sc., civil, Toronto, 1951) chief engineer with the Canadian Kellogg Company Limited has been transferred to the company's Pan American branch in Mexico.

Charles W. Kingston, JR.E.I.C. (B.S.c., elec., New Brunswick, 1956) has been transferred from HMCS Dockyard Esquimalt to HMCS Crescent as electrical officer.

John E. Little, JR.E.I.C. (B.Sc., mech. Queen's 1957) is employed as an engineer (development work in thermodynamics, heat transfer, fluid flow) with the English Electric Company Ltd., Atomic Power Department, Leicester, England.

John A. Fuller, JR.E.I.C.

Austin A. Hills, JR.E.I.C.

John A. Fuller, JR.E.I.C. (B.A.Sc., mech., Toronto 1948) was recently appointed assistant general sales manager for Worthington (Canada) Limited, Toronto.

Austin A. Hills, JR.E.I.C. (B.Sc., physics, Queen's 1949) has been named chief engineer of the Aeronautical Division of Honeywell Controls Limited, Toronto, Ont.

• PERSONALS

Edgar G. Hazle, JR.E.I.C. (B.Sc., mech., Queen's, 1948) is now with Ferranti-Packard Electric Limited, Electronics Division, Toronto, Ont.

E. W. Lucht, JR.E.I.C. (B.Sc., chem. Alberta 1954) formerly a development engineer with the C.I.L. Ltd., at Edmonton is now a process engineer with the company.

Frank John Forbes, JR.E.I.C. (B.A.Sc., mech., Toronto, 1957) is assistant hydraulic engineer with the Ontario Department of Public Works, Toronto.

David G. McKay, JR.E.I.C. (B.Sc., mech., Manitoba, 1949) is a manufacturers agent for Emco Ltd., on Vancouver Island, servicing the commercial and industrial field.

A. A. Williams, JR.E.I.C. (B.Eng., civil, McGill, 1951) is the resident engineer for H. H. L. Pratley on the Canadian approaches of the Ogdensburg-Prescott Bridge, Prescott, Ont.

Howard H. Wyatt, JR.E.I.C. (B.Eng., elec., McGill, 1952) formerly of Montreal, has joined G. M Gest Ltd., Toronto, as manager of the Ontario electrical division.

John D. Brown, JR.E.I.C. (B.Eng., civil, Nova Scotia, 1957) is a student at Imperial College, London, England, under an Athlone Fellowship.

Gerard S. Lemire, JR.E.I.C. (B.A.Sc., civil, Polytechnique, 1951) is a sales promotion engineer with the Aluminum Company of Canada, Montreal.

R. H. Reynolds, JR.E.I.C. (B.Sc., elec., Alberta 1951) of Babcock-Wilcox and Goldie-McCulloch has been transferred from Calgary to Vancouver as manager of the Vancouver Branch.

M. G. Colvin, JR.E.I.C.

S. Lake, JR.E.I.C.

F. I. Morton, JR.E.I.C. (B.Sc., Eng. Phys., Saskatchewan, 1949) is on leave of absence from his position with the Department of Northern Affairs and National Resources, on a Colombo Plan assignment as a hydro development engineer with the Central Electricity Board of Malaya.

Gary N. Hesler, JR.E.I.C. (B.A.Sc., eng. & business administration) field engineer with the Square "D" Company of Canada Ltd., Montreal has been transferred to the Company's Ottawa office.

Eugene Motluk, JR.E.I.C. (B.Sc., mech. New Brunswick, 1957) is an engineer with the Burlington Steel Co. Ltd. in Hamilton, Ontario.

Jean Dupont, JR.E.I.C. (P.Eng., elec., Montreal, 1956) is working for Leblanc & Montpetit, Consulting Engineers, Montreal, Que.

Gordon Dysart, JR.E.I.C. (B.Eng., elec., McGill 1951) formerly of Donnacona, Quebec is now electrical engineer with the KVP Company Limited, Espanola, Ont.

S. Lake, JR.E.I.C. (B.Eng., civil, McGill 1955) has been appointed president and director of Secant Construction Company, Montreal, Que.

Robert L. Blackie, S.E.I.C. (B.Eng., mech., McGill, 1963) formerly of Montreal is now living in England.

Donald G. Delparte, JR.E.I.C. (B.Eng., civil, Saskatchewan 1958) has been appointed district engineer with the Saskatchewan Municipal Road Authority, Saskatoon, Sask.

Jean-Claude Hebert, S.E.I.C. formerly with the Canadian Broadcasting Corporation has left there to join a Consulting Engineer Bureau in Montreal.

knows the breaking point

Knowing the performance ability of steel plate structures, BEFORE THEY ARE BUILT, is the key to quality construction. This thoroughness of applied metallurgical research is why Horton fabricate the big and unusual contracts, many of a 'first-time' nature in Canada.

Applied metallurgical research—the pretesting of metallic qualities and building procedures under critical conditions—is a vital phase of 'Horton creative craftsmanship in steel'. It is in the hands of specialists.They work in a fully-equipped welding laboratory. Their uncompromising philosophy is, 'Leave nothing to chance. Test thoroughly all factors of final performance by simulating shop and field conditions prior to building the structure.'

The first step in 'knowing' is of a 'destructive' nature, testing base and welding materials, such as electrodes and flux. Breaking test welds under sub-zero temperatures on an impact machine to determine whether the weld and base material is capable of absorbing energy at low temperatures, is but one example. The result of this test—and many others—is the setting of pre-determined standards.

As fabrication commences, quality control systems progressively examine all phases of construction, maintaining pre-determined standards. On the finished structure,'non-destructive' tests such as radiography and others, are additional checks on quality. And, as final proof of quality, the vessel or tank may be tested beyond its normal working pressure.

No expert can foretell the strength of steel plate just by looking. But Horton, with their extensive facilities and skill, use all techniques for finding out. Whatever your requirements in steel plate—regardless of future code or specifications—Horton is ready to meet those demands—in new techniques, special alloys and clad materials. For information, or tenders, write our nearest office.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BAIE COMEAU

G. W. Scott, M.E.I.C., *Correspondent*

CANADA'S ATOMIC ENERGY PROGRAM was discussed by W. J. Bennett, executive vice-president and general manager of Canadian British Aluminium Company Limited, at a meeting on April 29, 1959.

In the speaker's opinion it would be at least 25 years before atomic power is likely to supersede hydro-electric power economically in places like the province of Quebec. This does not exclude the use of atomic power as a supplement to conventional sources of power in the near future, particularly where fuel transportation or transmission costs are high.

BELLEVILLE

D. A. Law, JR.E.I.C., *Correspondent*

C. E. CARSON, director of Imperial Oil, Toronto, presented his ideas on Energy and Progress on April 13, 1959 at the branch annual meeting.

Mr. Carson said that Canada, now traditionally known as a supplier of raw materials, is rapidly becoming an industrial nation, with an increasing demand for energy. With the power used per capita in the U.S.A. based on 100, Canada uses about 89% per capita, which is 6 times the world average. Projections have been made for 1980 at 2½ times the 1957 consumption. Mr. Carson also said that Canada has an abundant fuel supply for the foreseeable future.

Officers for 1959-60, elected at this meeting are: chairman, W. C. Benger, vice-chair., H. T. Floyd, secretary-treasurer, F. E. Moore, executive committee, T. J. McGaid, D. A. Law, W. G. N. Throop, E. Hilbig, V. L. Lewis, and W. T. Caniff.

BORDER CITIES

R. L. Kennedy, M.E.I.C., *Correspondent*

THE ADVANTAGES OF BEING AN ENGINEER were recounted at the meeting of March 19, by A. W. F. McQueen, president of the A.P.E.O., and president of H. G. Acres & Co.

Mr. McQueen was introduced by C. T. Carson, a classmate, and immediate past president of A.P.E.O.

THE LAW AND ENGINEERS was the topic which proved to be of great interest at the meeting of April 16. As presented by Judge Joseph A. Legris, judge of Essex County, Windsor, this was a general explanation of how the law affects a citizen. It was liberally sprinkled with anecdotes and humour.

Judge Legris is also an engineer.

At Border Cities meeting: C. T. Carson, A. W. F. McQueen, and Chairman J. Earl Dykeman.

CENTRAL BRITISH COLUMBIA

A. F. Joplin, M.E.I.C., *Correspondent*

WHAT THE LAW IS, and What You Can Expect from a Lawyer was the subject covered at the May 1, 1959 meeting. Speaker was P. Van der Hoop, of the law firm, Boyle, Aikens, O'Brian & Co., Penticton.

The history of English law, and the developing of case law, were discussed. There are duties placed upon the engineer in the exercise of his skill and knowledge, which the speaker described, giving examples.

M. L. Wade reported to the meeting on the plenary meeting held in Toronto. He also reported on a visit to Chalk River.

CHALK RIVER

C. E. Lawrence Hunt, JR.E.I.C., *Correspondent*

PRESIDENT K. F. TUPPER OF THE E.I.C. visited this branch on April 24. He addressed the meeting on the recent trip he and Dr. Page took to Russia in an attempt to arrange exchange of visits between Russian and Canadian engineers.

He gave his impressions of the engineering training in Russia and a brief description of living conditions in Moscow and Leningrad.

THE NEW EXECUTIVE for the 1959-60 season have been confirmed. They are: chairman, C. E. L. Hunt, sec.-treas., W. O. Findlay, program chairman, A. H. Wilson, membership, G. R. Fanjoy, and district representative, J. S. Flavelle.

CORNWALL

H. S. Johnston, JR.E.I.C., *Correspondent*

EDUCATION IN THE U.S.S.R. was the subject of a talk on April 15, 1959, by Alexei S. Tovstogan, second secretary of the Russian Embassy, Ottawa.

His audience of 92 was made up of members, ladies, and representatives of school boards, school inspectors and principals.

PETERBOROUGH

J. G. Hooper, M.E.I.C., *Correspondent*

LEONARD MARION was the speaker at the meeting of February 10 on the subject Hydro Electric Power Generation. Mr. Marion is a specialist at Hydro Electric Power Generation for Canadian General Electric Co., Peterborough.

Mr. Marion said that at the end of 1957 the United States was the greatest user of hydro-electric power in the world, and Canada was second, using 15% of world total or 8 times the world average. Of hydro and steam power Canada was second highest user per capita, following Norway and followed by U.S.A. In recent years which have seen a labour and materials costs increase of about 140 per cent, cost increase of Canadian built generators was 60 per cent due to improved technology and refinements. Reliability is important to avoid outages and loss of revenue.

EASTERN TOWNSHIPS

JEAN BOURASSA, JR.E.I.C., *Correspondent*

WALTER H. TREML, sales engineer, Viditon Corporation, Ottawa, was the speaker on April 17, 1959, his subject being A Down to Earth Approach to Aerial Photogrammetry.

He explained the difficulties encountered by the pioneers: relatively high cost of chartering planes, exacting performance required from cameras. Some

• BRANCH NEWS

applications of photogrammetry were illustrated by slides, as well as various instruments.

A buffet supper was served to the 46 members attending this meeting.

EDMONTON

I. G. Finlay, M.E.I.C., *Correspondent*

A NEW EXECUTIVE was elected at the annual meeting of April 23. S. R. Sinclair, chairman; J. Longworth, vice-chairman; executive members, C. R. McFadyen, A. W. Peterson, B. A. Ellis, D. B. Smith, I. G. Finlay, L. C. Moon, C. A. McNeill, A. Sandilands; secretary-treasurer, G. Hodge.

FREDERICTON

L. W. Smith, JR.E.I.C., *Correspondent*

THREE STUDENTS from the University of New Brunswick spoke at the meeting of April 20. They were Paul Como, of civil engineering, on Fredericton Traffic Problems, Possible Solutions; Allister MacLelland, of mechanical engineering, on Spark Erosion in Metal Processing; Paul Stewart, of electrical engineering, on Automatic Railway Signalling.

Paul Stewart was chosen as the winner of the speaking contest.

Election of branch officers took place at this meeting with the following results: chairman, W. L. Barrett; vice-chairman, H. E. Marshall, secretary, Eric Garland, treasurer, Carman Bliss, committee, John Burrows, Tim Bliss, and G. R. MacLaughlin.

LAKEHEAD

G. O. Hansen, JR.E.I.C., *Correspondent*

BRAIN STORMING TECHNIQUES were discussed on April 29 by R. F. Howsan, supervisor of industrial relations for the Fort William plant of the Canadian Car Corporation.

Brainstorming is a means of stimulating thought and action on problems that confront us. These methods have been used to solve many problems. One method is to assemble a small group of six to eight persons, to whom the problem is accurately described. Each individual, after a minute's thought gives his idea of a solution. These ideas are recorded and read back to the group, from the lot a master suggestion is adopted. The feeling of urgency in having to come up with an idea within a minute tends to overcome the fear of making a ridiculous suggestion.

McGILL UNIVERSITY

R. D. Hatfield, S.E.I.C., *Correspondent*

DR. K. F. TUPPER, president of the Engineering Institute spoke to some 300 students in a general meeting of the McGill University Undergraduate Society on February 27. Taking as his subject, The Engineering Graduate, Dr. Tupper emphasized the value of the young engineer's personality and general outlook on life as factors in his success in later life.

MONTREAL Junior Section

B. Michel, JR.E.I.C., *Correspondent*

THE ANNUAL MEETING took place on January 26. A review of the various committees was given, and of special interest were the results of a survey of the wants and needs of the junior membership.

A total of 403 answers were received. Of these, 33 per cent indicated preference for technical lectures in the member's own field, and 23 per cent a preference for non-technical lectures. Social activities were given second place.

Officers were elected, as follows: chairman, J. Dubuc, vice-chair., R. Walker, sec-treasurer, B. Lamare, councillors, D. A. Jackson, D. Pollock, L. H. Lafontaine, J. Tetreault, J. G. Garneau, P. Arsenault, B. Michel.

A MEETING ON FEBRUARY 16 featured a talk on Sporting Dogs by P. Ouimet and B. Lapper. An excellent film illustrated training of dogs for hunting.

THE MONTREAL-LAURENTIAN AUTOROUTE was discussed by A. O. Mathieu, on March 16. Mr. Mathieu, chief engineer of the Autoroute, gave technical information and details of the operating organization of the autoroute.

• BRANCH NEWS

Student Guidance

J. A. Randle, M.E.I.C., *Correspondent*

Two FORUMS are held each year under the sponsorship of the student guidance committee. One is for the English speaking students and one for French speaking students.

On February 12, at E.I.C. headquarters, W. A. Marshall, M.E.I.C., spoke on Careers in Engineering. On March 15, at Ecole Polytechnique, Bernard Lachapelle spoke on "Expose General sur la profession d'Ingenieur". Mr. Marshall is president of the Dominion Structural Steel of Montreal and Mr. Lachapelle is in charge of special services for the Corporation of Professional Engineers of Quebec.

At a question period, the students are invited to question the speaker and other engineers who join him for this part of the meeting.

NIPISSING AND UPPER OTTAWA

D. J. Thornton, S.E.I.C., *Correspondent*

THE ANNUAL MEETING of the branch was held on April 15, 1959.

These officers were elected for the coming year: chairman J. M. Rosborough, vice-chairman, T. H. Chapman, executive committee: C. A. Hellstrom, D. Cunningham, P. Rebin, H. Staniforth, D. W. Briden, G. M. Goodreid. The secretary-treasurer was to be appointed by the new executive.

Three members of the branch gave short addresses on their occupations. Richard Booy of Canadian International Paper Company, Temiskaming, spoke on Canada's Second Oldest Electrolytic Chlorine Plant; B. W. Kelly, of Dupont of Canada, North Bay, on The Manufacture of Commercial Explosives, and R. S. MacLennan, a consulting engineer, on Municipal and Town Planning.

DATES TO REMEMBER

AUGUST 11, 12, 13, 1959

NOVA SCOTIA TECHNICAL COLLEGE

50th Anniversary Reunion

For information write Box 811, Halifax, N.S.

NOVA SCOTIA TECHNICAL COLLEGE

Donald Kelly, S.E.I.C., *Correspondent*

AT THE RECENT ANNUAL MEETING of the Student Society, Donald Kelly was elected president for the coming year.

NORTHERN NEW BRUNSWICK

S. K. Henry, JR.E.I.C., *Correspondent*

E. J. LUTZ, spoke at a meeting on April 25 on The Growth of Canada, tracing the history and economic growth since Confederation. Mr. Lutz is a former manager of the Bank of Nova Scotia, at Newcastle, N.B.

This was a general meeting of the branch, at which nominations of officers for the year 1959-1960 were presented. The result was the following slate of officers: chairman, P. J. Delicaet; vice-chairman, V. G. MacWilliam; sec.-treasurer, Peter Dallien; executive, G. A. Bird, P. E. Desserud, R. E. Haines, R. A. Cameron. The annual meeting was announced for May 29, at Bathurst, N.B.

• BRANCH NEWS

OTTAWA

D. R. Grimes, M.E.I.C., *Correspondent*

G. W. STEAD spoke at a meeting of April 2 on the subject of Ice Breaking in the St. Lawrence. Mr. Stead is Director of General Marine Services Branch, Department of Transport.

Icebreaking prevents flooding in the Montreal area, and is also used to aid spring and fall shipping. The ice conditions this spring were the worst in 25 years. Some of the Department's problems and methods were described.

THE FOURTH ANNUAL ARCHITECTS-ENGINNEERS DANCE was held on March 19. About 160 architects, engineers, and their wives were received by Mr. and Mrs. John S. Watt, chairman of the Ottawa Branch, and Mr. and Mrs. Darcy Helmer, chairman of the Ottawa Chapter, Ontario Association of Architects.

PETERBOROUGH

J. G. Hooper, M.E.I.C., *Correspondent*

CHAMPAGNE DINNER DANCE was the third annual ladies' night event. It was held at Kawartha Golf and Country Club on Friday, April 24, 1959.

The menu was in the French manner. L. H. Mensforth was in charge of arrangements.

SASKATCHEWAN

W. A. Friebel, M.E.I.C., *Correspondent*

THE SASKATOON SECTION acquired on March 20, at its annual meeting a new executive by a new procedure. An elected committee has become the ex-executive.

The officers are: chairman, Paul Riemer, vice-chairman and treasurer, Dick Strayer, secretary, Fred Catterall, publicity, Vern Friebel, committee members, Morris Cherney, Roger Dupuis, Tom Greenaway, Don Kelly, Nick Peters, ex-officio, Ernie Cole and Bob McCullough.

G. HONDEGORD, of National Research Council, Saskatoon, spoke at the meeting of April 18, giving a commentary on the film "Setting Fires for Science".

The N.R.C. division of building research is continually conducting fire experiments, and as a result the national building code has been changed.

SARNIA

Murray Waghorne, M.E.I.C., *Correspondent*

THE CANADIAN AIRCRAFT INDUSTRY was considered by a meeting of the branch on February 17. M. D. Willer, Sales and Service Manager, Avro Aircraft Ltd., Toronto, was the speaker. After a review of the history of aviation in Canada, the present mature state of the industry was demonstrated by a coloured film covering the development of the Avro Arrow.

CAPE BRETON

H. M. Aspinall, M.E.I.C., *Correspondent*

BRIAN HANSON, of Imperial Oil Co., Sydney, N.S., was the speaker on April 29, and his subject was Lubrication Oils.

He outlined development of desirable properties in lubricating oils, detergent, anti-corrosion additives, etc. A small engine was used to demonstrate the acidic property of exhaust gasses and the use of proper oils to prevent corrosion.

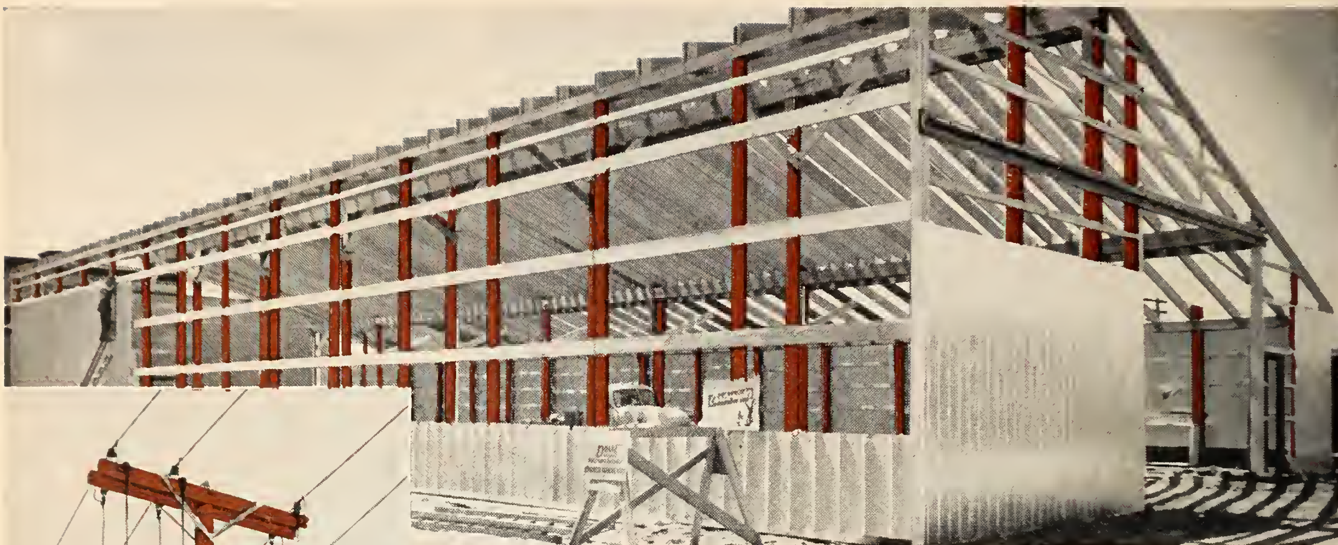
CARLETON UNIVERSITY

Thomas A. West, S.E.I.C., *Correspondent*

ROCKETRY presents problems which must be overcome before space travel becomes feasible. A paper was presented on March 27, by Dr. John Hart, associate professor in the Department of Physics, Carleton University, in which the human engineering aspect was examined. Design for the needs of the human body, and for extreme accelerations offer difficulties, which the speaker treated in an interesting and humorous talk. The constitution of the Engineering Society was considered, and passed by a majority vote on March 16.

ELECTIONS TOOK PLACE on April 7, with these officers elected by acclamation: president, Fred King, vice-president, Keith Stoodley, social convenor, Alan Webster, Tours and talks convenor, Elihu Edelson, secretary-treasurer, John Roll, public relations officer, Tom West.

Vancouver Branch. E.I.C. president and general secretary, K. F. Tupper and G. T. Page, on a visit to the R.C.S.M.E. at Chilliwack, B.C. In the picture, seated: Mrs. Page, Mrs. Heslop, Mrs. Tupper, Mrs. Carson, Mrs. Davy; standing: Mrs Boivin, Lt. G. Boivin, Mrs. Freeborn, Col. R. J. Carson, Prof. W. Heslop, Dr. Tupper, Dr. Page, Commodore A. C. M. Davy, Mrs. Wyld, Capt. R. C. Wyld, and Major F. R. Freeborn.



Pressure treated poles make low-cost, durable pole type buildings possible.

• BRANCH NEWS

SAULT STE. MARIE

R. J. Saunders, S.E.I.C., *Correspondent*

FORESTRY ENGINEERING was discussed by J. Lockwood, district forester, Dept. of Lands and Forests, Sault Ste. Marie, on April 10, 1959.

Growth of the forestry profession since the thirties was pointed out by the speaker, and the foresters' work in nurseries, fire protection, public relations, timber rights, and logging management. More foresters are needed to insure the forest economy, Mr. Lockwood said. There must be cooperation between the forester, the government and industry.

WINNIPEG

P. M. Abel, JR.E.I.C., *Correspondent*

THE DEAS ISLAND TUNNEL was described to a branch meeting on March 19, by N. D. Lea, vice-president, Foundation of Canada Engineering Corporation Limited.

The subject matter was the paper published in the April issue of the Journal, and was illustrated by slides and film.

A PLANT VISIT was arranged for April 16. Members visited the new Griffin Steel Foundries Ltd., in Transcona, Manitoba, with members of the Illuminating Society.

Civil Section

H. B. McLenaghan, JR.E.I.C., *Correspondent*

REGULATION of Lake Winnipeg and Lake Manitoba for flood control was outlined by Ed Kuiper, former chief engineer of the Lakes Winnipeg and Manitoba board at the January meeting of the civil section.

The flood control investigations included a control dam on the Assiniboine River, a cut-off channel from the Assiniboine to Lake Manitoba, deepening of the Red River channel in the vicinity of the St. Andrews rapids and also a diversion channel of the Seine River to the east around Winnipeg. The latter method of control was concluded to be the most advantageous and economical.

R. M. DILLON, M.E.I.C., spoke on February 12 on the subject "Some Aspects of the Design of Structures of the South Perimeter Route of the Metropolitan Winnipeg By Pass, Trans Canada Highway". Mr. Dillon is a structural director, M. M. Dillon & Co., Consulting Engineers, London, Ont.

The Assiniboine River Bridge substructure has four piers and two abutments carried on spread footings founded on hardpan. The superstructure is a composite design consisting of all welded structural steel built up girders carrying a 7½-inch reinforced concrete slab.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*TRANSISTOR TECHNOLOGY: VOLUME II

Part one discusses the technology of materials with special emphasis on silicon. Part two deals with the principles of device design beginning with diodes, and continuing with triodes and the more complex multiple junction switching devices and tetrodes. Chapters follow on radiation sensitive devices, field effect devices, and on noise behavior. The book concludes with the design implications of surface phenomena. (F. J. Biondi, ed. Toronto, Van Nostrand, 1958. 701p., $19.00.)

*TRANSISTOR TECHNOLOGY, VOLUME III

This, the latest volume of an extensive work, deals with the preparation of junctions; fabrication technology, including such processes as etching, alloying and diffusion, photoengraving techniques, and procedures for making contacts; information on measurement and characterization; laboratory and field use reliability. The material is equally divided between that of a general nature and that which is specific to germanium and silicon. (F. J. Biondi, ed. Toronto, Van Nostrand, 1958. 416p., $13.50.)

*DIGITAL TECHNIQUES FOR COMPUTATION AND CONTROL

A survey of the basic techniques used for digital computation and control, including code arithmetic, logical networks, multiplexing, conversion, data reduction, digital process control, two-terminal relay circuits, counting techniques, digital computers of all types, computer programming, digital differential analyzers, and combined analog-digital equipments. Descriptions of components and available commercial equipments add to the value of the book. (M. L. Klein and others. Pittsburgh, Instruments Publishing Co., 1958. 394p., $6.00.)

*PHILOSOPHY OF STRUCTURES

Discusses the basic concepts of advanced structural design as developed by Torroja, including such factors as the nature of stress in different types of structures; the proper use of materials; structural elements; design of retaining structures, roofs, floors, bridges, and aqueducts; construction methods and their influence on design and cost; the role of calculations and experimental stress analysis; the function of the designer in the construction enterprise. (E. Torroja. California, University Press, 1958. 366p., $12.50.)

*MODERN MATERIALS: ADVANCES IN DEVELOPMENT AND APPLICATIONS, VOL. 1

This volume, which is the first in a series, covers a variety of materials and the recent developments in connection with them: zirconium; the semiconductors, germanium and silicon; ceramic engineering materials and their applications; insulating papers for high voltages; glasses required to withstand strong irradiation in nuclear engineering; synthetic rubbers for special purposes; new areas of wood as a structural material; organic and inorganic fibres. (H. H. Hausner, ed. New York, Academic Press, 1958. 402p., $12.50.)

*THE TRANSURANIUM ELEMENTS

The author begins with the discovery of plutonium in 1940 as the result of the bombardment of natural uranium with deuterons in a cyclotron. He then discusses the chemical properties of the actinide elements, ranging from thorium to Mendelevium. The concluding portions of the book are concerned with the nuclear properties of the transuranium elements and the possibilities for new elements. A volume in the Atoms for Peace presentation set. (G. T. Seaborg. Reading, Addison-Wesley, 1958. 328p., $7.00.)

*U.S. RESEARCH REACTOR OPERATION AND USE

Studies the research reactor as a means of providing a strong source of neutrons and gamma rays for physical research, irradiation testing, and producing radioactive isotopes. The principal emphasis in the book is on the advantages and disadvantages of different reactors and on the costs of acquiring and operating a research reactor facility. Each type of research reactor is described in detail and analyzed in relation to specific needs. A volume in the Atoms for Peace presentation set. (J. W. Chastain, Jr., ed. Reading, Addison-Wesley, 1958. 366p., $7.50.)

*URANIUM ORE PROCESSING

A description of the technology utilized in extracting uranium from its ores. The book covers preliminary treatments like roasting and physical concentrations, leaching with acid or alkaline reagents, separation of the pregnant leach liquor from the unwanted solid gangue, and recovery of the uranium product from the solution, principally by ion exchange and solvent extraction. Six typical plants are then analyzed in considerable detail to illustrate these processes. The book concludes with minor sources of uranium ore such as shale, lignate and phosphate rock. A volume in the Atoms for Peace presentation set. (J. W. Clegg and D. D. Foley, eds. Reading, Addison-Wesley, 1958. 436p., $7.50.)

*TOOLS FOR MACHINE LITERATURE SEARCHING

An extensive work which represents the results of a considerable amount of experimentation over the past five years. The book is presented in four parts, of which the first two deal with machine literature searching systems in general and their basic underlying principles. In the third part, procedures developed by the authors are given for analyzing, encoding, and searching of record information. The concluding section consists of a semantic code dictionary with directions for its use. (J. W. Perry and A. Kent. New York, Interscience, 1958. 972p., $27.50.)

ROCKET TO THE MOON

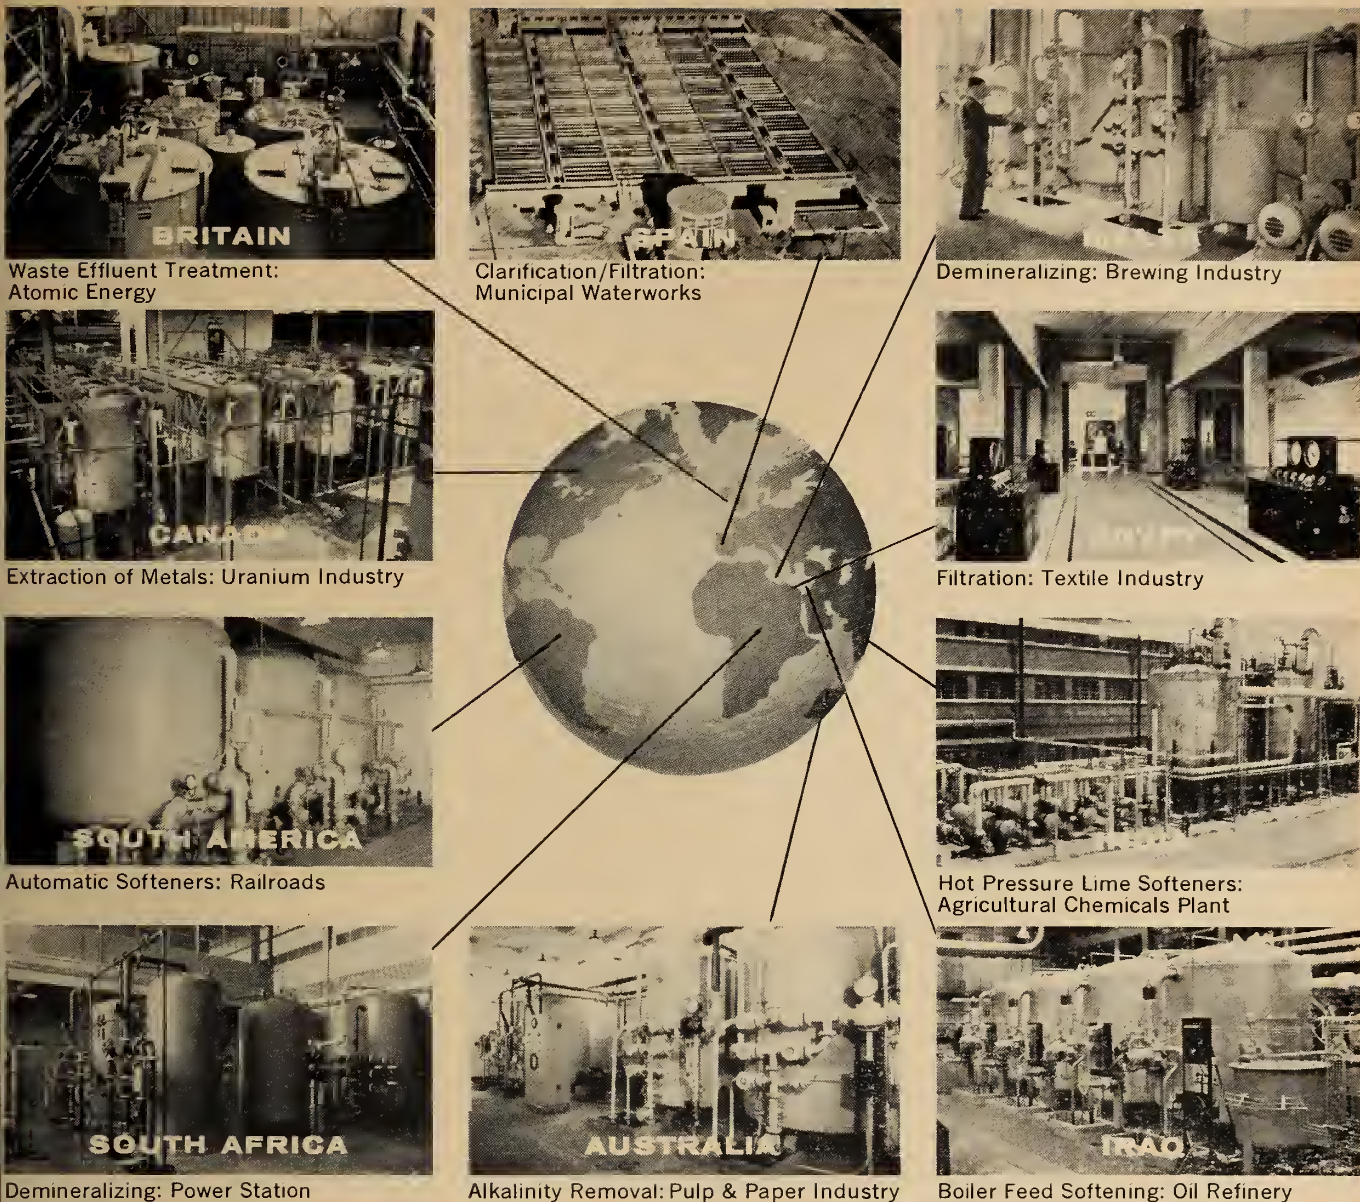
A compilation of ideas, thoughts, facts, guesses and assumptions on man's conquest of the moon, and the possible effects of that conquest. The authors, Americans, are convinced that it is possible to reach the moon, and critical of their country's space policies. They include information on the accomplishments of both the U.S. and the U.S.S.R. in this volume, intended primarily for laymen. (E. Bergaust and S. Hull. Toronto, Van Nostrand, 1958. 270p., $5.95.)

*SYMPOSIUM ON EFFECT OF OZONE ON RUBBER

Papers on various facets of the effect of ozone attack on rubber, particularly polybutadiene rubbers and elastomers. Also considered are preventatives such as chemical antiozonants, and the use of waxes. These papers were presented at a meeting held in St. Louis, Mo., in 1958. (Philadelphia, American Society for Testing Materials, 1958. 130p., $3.75. Stp. 229.)

*CHEMICAL PROCESSING OF NUCLEAR FUELS

An introduction to the problems of chemical processing of the fuel after it



BRITAIN
Waste Effluent Treatment: Atomic Energy
SPAIN
Clarification/Filtration: Municipal Waterworks
Demineralizing: Brewing Industry
Extraction of Metals: Uranium Industry
Filtration: Textile Industry

Hot Pressure Lime Softeners: Agricultural Chemicals Plant
SOUTH AFRICA
Demineralizing: Power Station
AUSTRALIA
Alkalinity Removal: Pulp & Paper Industry
IRAQ
Boiler Feed Softening: Oil Refinery

has been irradiated in a reactor. Following introductory materials, the major part of the book deals with aqueous processes, including solvent extraction, ion exchange, and precipitation processes; and with non-aqueous processes including distillation of metals, extraction by liquid metals, fluoride volatilization, and separations based on chemical reactions. Concluding sections deal with effluent disposal and fission product recovery, and with trends in nuclear fuel processing. (F. S. Martin and G. L. Miles. Toronto, Butterworth, 1958. 242p., $7.50.)

°GLOVE BOXES AND SHIELDED CELLS FOR HANDLING RADIOACTIVE MATERIALS

Papers dealing with radiation shielding which are based mainly on British practice. Part one is concerned with unshielded boxes and discusses safety, general design and manufacture, constructional materials, decontamination, layout in laboratories, provision of inert atmospheres, handling of polonium, operations with gaseous materials, and large scale operations. Part two deals with shielded cells, and discusses shielding calculations, viewing and handling equipment, design of shielded cells as well as operations on beta-ray emitters, plutonium, multicurie caesium sources, and irradiated fissile materials. These papers comprise the proceedings of a Symposium held at Harwell, England, in 1957. (G. N. Walton, ed. Toronto, Butterworth, 1958. 515p., $16.80.)

°A HANDBOOK ON TORSIONAL VIBRATION

An extensive work which gives formulas, design procedures, specifications and methods relating to torsional vibration conditions of engines and machines. The four major divisions presented encompass preliminary calculations and measurements, evaluation and prediction of torsional vibration stresses, design and operation of various devices for limiting vibration, and instrumentation. Each subsection on design procedure or testing is self-contained so as to provide maximum usability of the handbook. (Comp. by E. J. Nestorides for the British Internal Combustion Engine Research Association. Toronto, Macmillan, 1958. 664p., $18.70.)

°FINE PARTICLE MEASUREMENT

A discussion of the important techniques currently used in research laboratories for the measurement of size, surface and pore volume. The basic principles, construction and use of apparatus, methods of data analysis, applications, and limitations are given for such techniques as automatic scanning, the fixed-time method, the Hauser/Lynn method, gravimetric analysis, and liquid-phase sorption. An extensive biliography of approximately 400 references is included. (C. Orr and J. N. Dalla Valle. Galt, Brett-Macmillan, 1959. 349p., $10.50.)

°SCALE-UP IN PRACTICE

A unified review of the various aspects of pilot plant problems. Among the topics discussed are the factors justifying the operation of pilot plants, a review of scale-up theory, simulating operation of processes and equipment with computers, the hazards involved, the process and business economics of scale-up, and organization. (R. Fleming, ed. New York, Reinhold, 1958. 134p., $4.50.)

°WATER POWER ENGINEERING

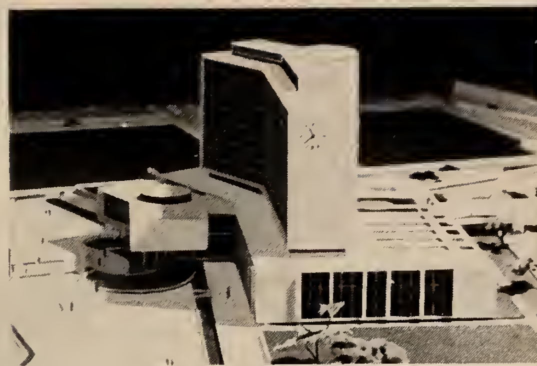
Begins with a survey of the water power industry and such aspects as planning, underground power stations, geological factors, and the relationship between water and nuclear power. The main types of turbines are then studied with stress on full scale and model tests and on cavitation. Such electrical problems as insulation, high voltage transmission, voltage regulation, and cables are also considered. (R. Hammond, Galt, Brett-Macmillan, 1958. 302p., $10.00.)

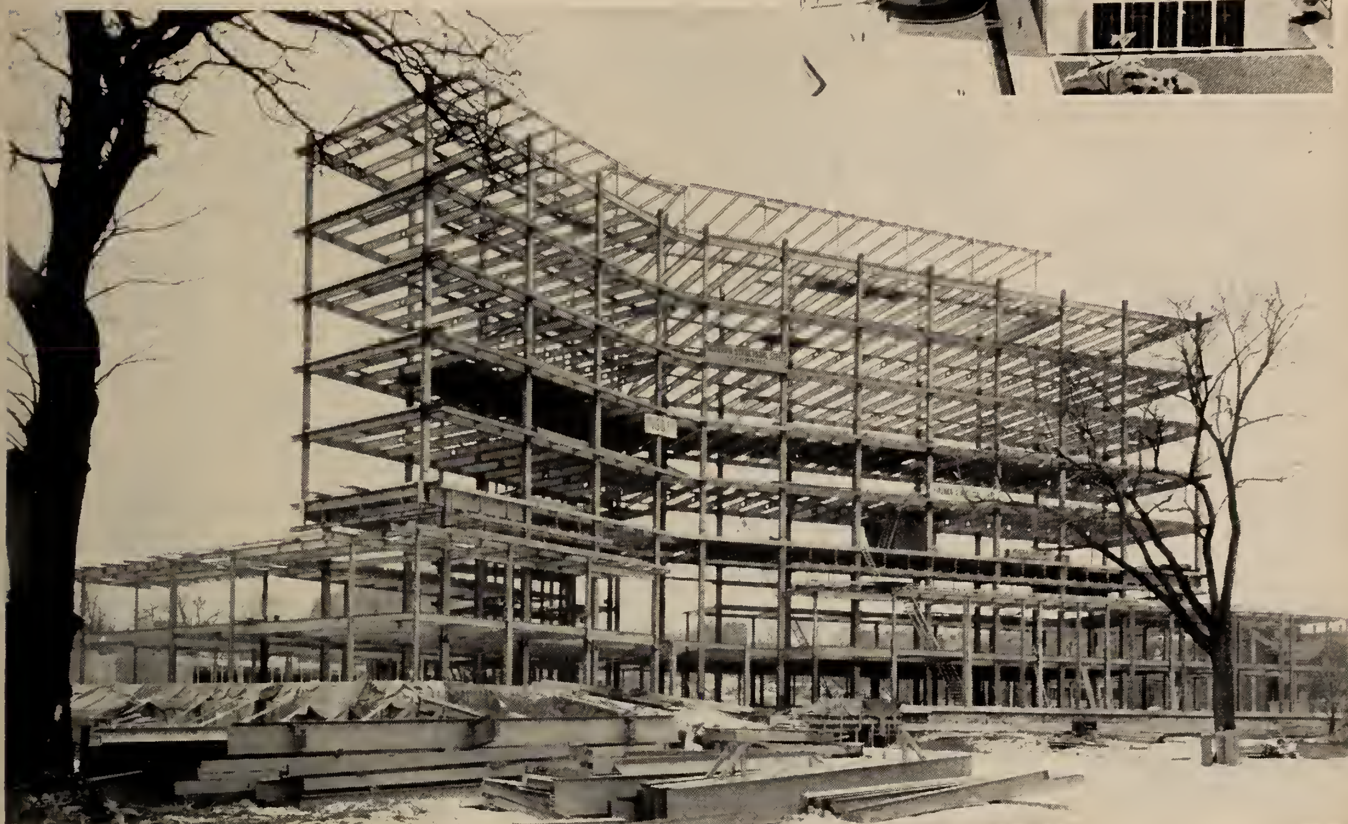
°GAS CHROMATOGRAPHY 1958

Twenty-eight papers are presented and divided into three sections dealings with theoretical and experimental aspects of gas chromatography, recent trends and new developments in techniques and apparatus, and various applications of gas chromatography. These papers comprise the proceedings of the second symposium organized by the Gas Chromatography Discussion Group and held in Amsterdam in May, 1958. (D. H. Desty, ed. Toronto, Butterworth, 1959. 383p., $13.00.)

°PHYSICAL LAWS AND EFFECTS

A compilation which provides a brief description of approximately 100 familiar and unfamiliar laws and effects, an indication of their expected magnitude, and references to further sources of information. The book is intended as a source of useful concepts in research de-





• LIBRARY NOTES

velopments, and among the varied topics included are the Barkhausen effect, luminescence, Bremstrahlung radiation, Curie-Weiss law, thermoelectric effects, memory metals, stress-strain effects, etc. (C. F. Hix and R. P. Alley. New York, Wiley, 1958. 291p., $7.95.)

*ELEMENTS OF ENGINEERING STATICS

Covers the problem of equilibrium, equilibrium of simple planar systems, equivalence of force systems, simple structures, sliding friction, work and energy methods, and equilibrium of simple spatial systems. The techniques of vector algebra are employed to develop rigorously the fundamental theorems, results, and methods of statics and to apply these to the solution of engineering problems. An extensive appendix consists of problems to illustrate the principles of the text. (H. Deresiewicz. Toronto, Oxford, 1958. 124p., $3.75.)

*AMERICAN POWER CONFERENCE. PROCEEDINGS, VOLUME XX

Papers dealing with varied aspects of the generation, transmission, and utilization of power. Among the topics discussed are steam and gas turbines, water technology;. hydroelectric power; nuclear power development; industrial plants; central stations; transformers; extra-high voltage systems; distribution equipment; fuels; heating, ventilation and air conditioning; computers and network analyzers. (Chicago, Illinois Institute of Technology, 1958. 748p., $8.00.)

*A HISTORY OF TECHNOLOGY, VOL. V: THE LATE NINETEENTH CENTURY, c.1850—c.1900

The importance of applied science and its effect on manufacture and production in the latter half of the nineteenth century is the outstanding theme of the present volume which concludes the series. Also considered is the social effect of scientific industry upon the lives of individuals. Topics presented include primary production, prime movers, the chemical industry, transport, civil engineering, and manufacture. (Ed. by C. Singer and others. Toronto, Oxford, 1958. 888p., $25.50.)

*MECHANICAL ENGINEERS' HANDBOOK, 6TH ED.

This new edition of a standard handbook previously edited by Lionel S. Marks, covers virtually every aspect of mechanical engineering. Theory, standards, and practice are compiled by over 90 persons, each a specialist in the area covered. Substantial revisions or additions include sections on numerical analysis and computing machines, vibrations, aerodynamics, jet propulsion, atomic power, automobiles, instruments and controls, railway engineering, corrosion, turbo compressors and gas turbines, lubricants and lubrication, and welding. (T. Baumeister, ed. Toronto, McGraw-Hill, 1958. Various pagings, $23.40.)

STANDARDS RECEIVED

ASTM standards. American Society For Testing Materials, 1916 Race St., Philadelphia 3, Pa.

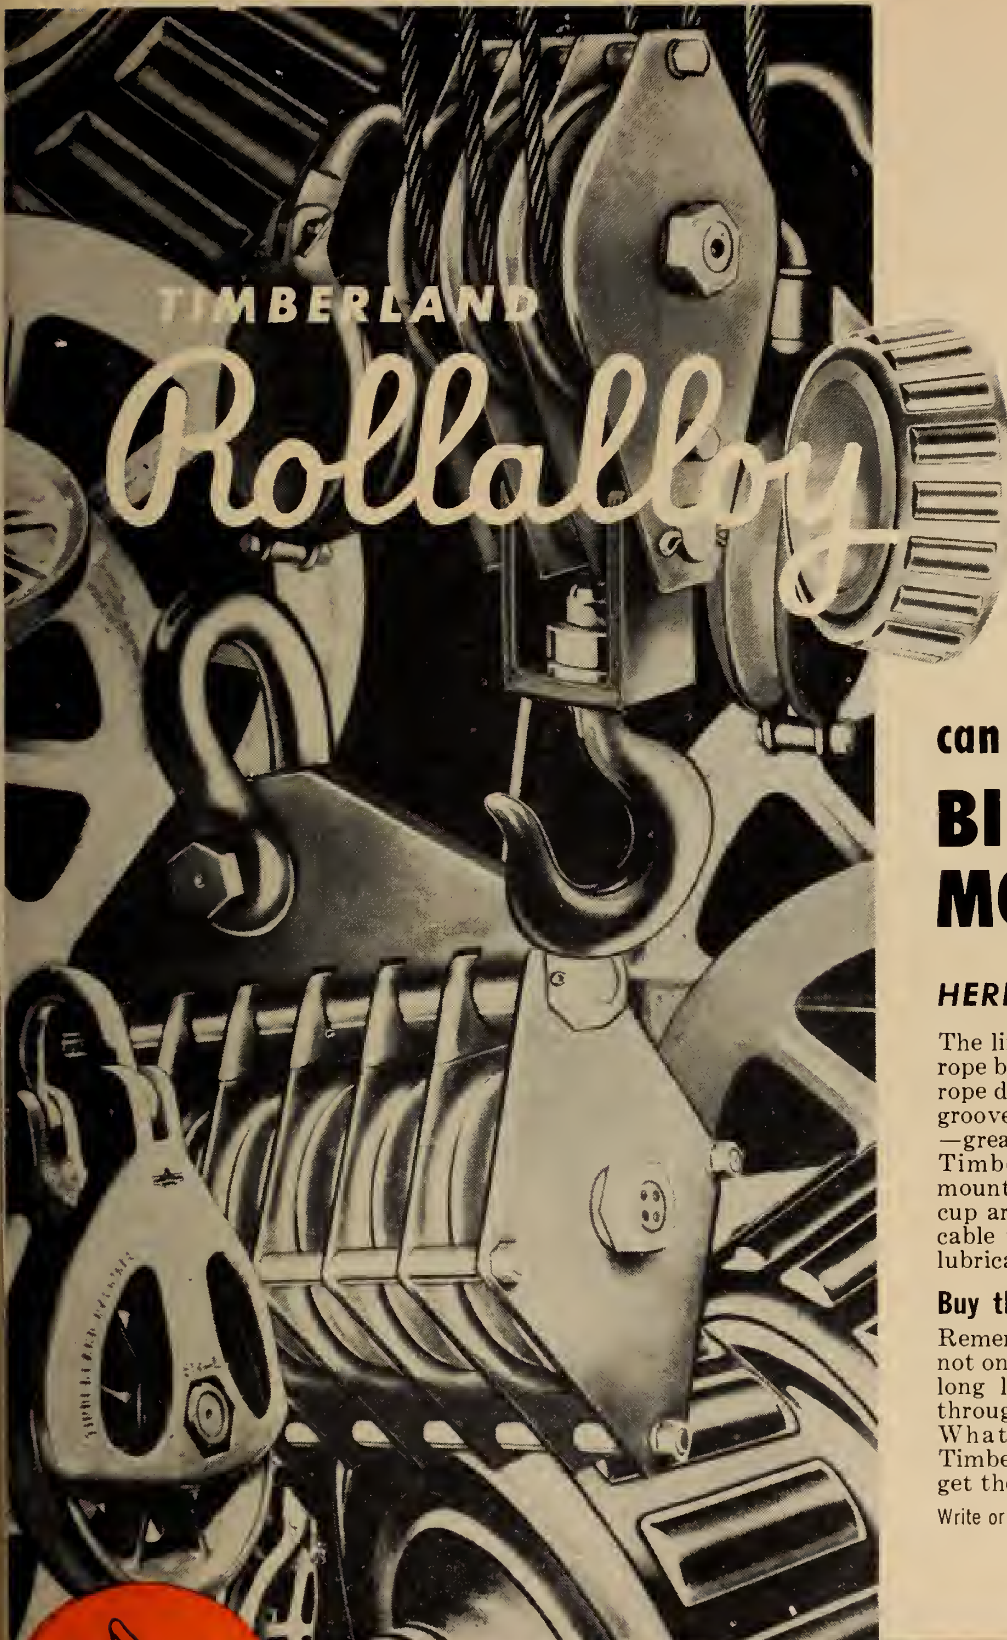
ASTM standards on cement. $3.50
ASTM standards on soaps and other detergents. $3.50
ASTM standards on textile materials. $7.50

*BOOK OF ASTM STANDARDS, 1958

The triennial compilation of ASTM Standards, expanded in this edition from seven to ten parts occupying 13,600 pages. A total of 2,450 standard specifications, methods of test, definitions of terms, and recommended practices are included in the various sections which deal with ferrous metals specifications; non-ferrous metals specifications; methods of test for metals; cement, concrete, mortars, road materials, waterproofing, soils; masonry products, ceramics, thermal insulation, sandwich and building constructions, acoustical materials, fire tests; wood, paper, adhesives, shipping containers, cellulose, leather; petroleum products, lubricants, tank measurements, engine tests; paint, naval stores, aromatic hydrocarbons, coal, coke, gaseous fuels, engine antifreezes; plastics, electrical insulation, rubber, carbon black; textiles, soap, water, atmospheric analysis, wax polishes. The volumes are available separately. (10 vols. $116.00.)

Canadian Standards. Canadian Standards Association, 235 Montreal Rd., Ottawa 2.

A31-1959: Code for modular coordination in building. $1.00
A145-1959: Rubber floor tile. 75c
B131.11-1958: Universal cast iron pipe



BLOCKS

can save you

BIG MONEY

HERE'S HOW!

The line grooves of Timberland wire rope blocks are flame-hardened. Wire rope does not mark these grooves . . . groove retains its surface and shape —greatly extending wire rope life. All Timberland Rollalloy blocks are mounted on roller bearings. Housings cup around the sheaves and prevent cable fouling. Require only seasonal lubrication.

Buy the Block that pays for itself

Remember—these quality features not only ensure maximum safety and long life but return real dividends through savings in wire rope costs. Whatever your requirements, a Timberland engineer can help you get the proper blocks for the job.

• BRANCH NEWS

(Continued from page 123)

The Pembina Overpass is a four span structure founded on precast piles driven into hardpan. The superstructure is also a composite design.

The Red River Bridge is similar in design to the Assiniboine bridge. It is a seven span structure, 848 feet long with three river piers carried on spread footings resting on hardpan.

The last structure also under construction is known as the Gladstone Overhead. This structure was to be completed June 1959.

SAGUENAY

H. C. Perreault, JR.E.I.C., *Correspondent*

J. W. L. Duncan, project engineer, electrical, Aluminum Company of Canada Ltd., Arvida, spoke at the meeting of March 17 on the Chute-des-Passes project.

This was a general description of the project to its present state. Slides were used to show topography and the general dimensions of the intake section, supply tunnel, underground powerhouse and discharge tunnel. The electrical features, especially the generator governors and transmission line were described.

UNIVERSITY OF SHERBROOKE

Bernard Vigneux, S.E.I.C., *Correspondent*

The student section is now officially established, with officers as follows: president, Andre C. Hamel, vice-president, Marc Gagnon, secretary, Bernard Vigneux. There are 35 new members.

On the occasion of the Faculty's first Ritual of the Calling of an Engineer, the guests were Dr. K. F. Tupper, E.I.C. president and Dr. Garnet T. Page, general secretary. Twenty-two students received the engineer ring. The president took this opportunity to present the E.I.C. student prize to Gilles Henault.

Jacques Lemieux, director of studies, Science Faculty; Gilles Henault, winner of E.I.C. bursary; Gaetan Cote, vice-dean; and President K. F. Tupper.

Student Night was held on March 20, at which four students gave papers: Sounding by Helicopter, Robert Leblanc; Puits Filtrants, Yvon Nadeau; Effects of Electricity on the Human Body, Gilbert Luneau; Power Plant, Charles Lebreque.

The program during the year has included many films, a talk by Rev. Fr. Adelphe, M.S., titled, "Science". The program will be concluded with a formal dance to mark the first graduation of the Faculty of Engineering of the University of Sherbrooke.

UNIVERSITY OF WESTERN ONTARIO

Paul Ruppel, S.E.I.C., *Correspondent*

The first annual banquet of the Undergraduate Engineering Society was held on March 12, with 140 students and faculty members present.

Guest speaker was Harry Hallworth, treasurer and general manager of the copying productions division of Minnesota Mining and Manufacturing of Canada Ltd.

Prof. S. L. Lauchland, head of U.W.O. engineering science, was made an honorary member of the Society on this occasion. Another highlight was election of officers, as follows: chairman, Paul Vellinga, secretary, George Steele, treasurer, Jim Savage, publicity director, Paul Ruppel, sports director, Howard Kagawa, and director of professional relations, Bob Frank.

The graduation dinner was on March 26, 1959, when members of the graduating class heard guest speaker E. V. Buchanan predict tremendous advances in engineering in the next few years, and an expansion of engineering opportunity unparalleled in history.

• OTHER SOCIETIES

Calendar

United Nations Educational, Scientific and Cultural Organization: International Oceanographic Congress to be held in New York from August 31 to September 12, 1959.

UNESCO is cooperating with the sponsor, the American Association for the Advancement of Science (1515 Massachusetts Ave., N.W., Washington 5, D.C.)

International Association for Hydraulic Research: eighth congress, Montreal, to be held during the week of August 24, 1959.

Information from J. E. L. Roy, c/o Quebec Hydro-Electric Commission, 107 Craig St. W., Montreal 1, Que.

The Building Exhibition: The 1959 Building Exhibition, London, England, November 18 to December 2, 1959.

Steel Founders' Society of America: fifty-seventh fall meeting, The Homestead, Hot Springs, Va. September 21-22, 1959.

The National Society of Professional Engineers: annual meeting, Commodore Hotel, New York City, June 17-20, 1959.

Canadian Electrical Association: sixty-ninth annual convention, Manoir Richelieu, Murray Bay, Que., June 24-26, 1959.

American Welding Society, New York, N.Y.: fall meeting, Sheraton-Cadillac Hotel, Detroit, September 28-October 1, 1959.

Columbia University: Department of Industrial and Management Engineering announce the eighth utility management workshop, Arden House, July 26-August 7, 1959.

The Institute of Radio Engineers: fourth annual IRE Canadian convention and exposition, Automotive Building, Exhibition park, Toronto, October 7-9, 1959.

IRE convention offices are at 1819 Yonge St., Toronto.

Science Council of Japan: second world conference on earthquake engineering, Tokyo and Kyoto, Japan, July 11-18, 1960.

Information about the program, about participation and attendance is available from the Science Council, Ueno Park, Taito-ku, Tokyo, Japan.

Ontario Water Resources Commission: sixth industrial waste conference, Honey Harbour, Ontario, June 15-17, 1959.

American Meteorological Society: national meeting, San Diego, California, June 16-18, 1959.

International Council for Building Research: Congress 1959, will take place on September 21-25 in Rotterdam, The Netherlands.

Further information can be obtained from The Congress Secretariat c/o Bouwcentrum, Postbox 299, Rotterdam.

Canadian Red Cross Society: National Water Safety Week, June 14-21, 1959.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

The four page, 2-colour (black and blue) insert of the Northern Electric Company Limited in the March issue of this "Journal", pages 31-34, was judged the best from the view-points of Accuracy-Information-Attraction. The jury consisted of 50 subscribers; five from each province.

The advertisement was planned and produced by Foster Advertising Limited, Montreal. The artist is Maurice Picard, Montreal, and Northern Electric's advertising manager is E. H. Woodley.

The certificate was presented to Mr. Woodley, by the General Secretary, Garnet T. Page, at a luncheon at the Engineers' Club, Montreal. A copy of the certificate was presented to Mr. Frank B. Thompson of Foster Advertising Limited.

Readers' response to requests for their services as jurors is most encouraging. During the first four months of the year a monthly average of 42 (out of a total of 50) completed questionnaires have been received. This co-operation is greatly appreciated by the Institute and the advertisers. The results of the judgeing will provide industrial advertisers with a guide as to the type of advertisement which is the most useful and attractive to Canadian engineers.

NORTHERN ELECTRIC CO. LTD. WINNING INSERT

This illustration is a monotone reproduction of the 4-page insert which readers selected as the best advertisement in the March issue, from the view-points of Accuracy, Information and Attractiveness.

The advertisement appeared on page 31-34. The actual advertisement was printed on offset, dull finish, stock, in black and blue.

You *can have your accounting done for you* *on* IBM **ELECTRONIC COMPUTERS** *at the* **IBM** *Service Bureau*

IBM Data Centre, Don Mills Road, Toronto.

IBM Service Bureau prepares our insurance renewals and gets them out earlier than we can ourselves.

It's confidential! IBM does our accounting, and from experience we know they keep our records in strict confidence.

The IBM 705 did some exhaustive calculations for us . . . calculations which could not possibly have been made by manual methods.

IBM electronic computers, with their tremendous capacity and lightning speed, have been added to our Service Bureau facilities, supplementing the wide range of punched card accounting machines which are at your service.

Companies, large and small—governments, scientific, statistical and research bodies—whose needs are not sufficient for them to own electronic equipment, can have their data processing done for them at our Service Bureau.

The IBM Service Bureau will do practically any accounting or statistical job that may be required: performing recurring jobs on a regular basis, helping through peak loads, or doing special computations that may be far too intricate or time-consuming for other methods.

Can IBM Help You in Your Business?

Telephone or write our nearest office and a qualified IBM representative will be pleased to explore the possibilities with you, confidentially.

• LIBRARY NOTES

(Continued from page 132)

***ENTWURF UND BERECHNUNG VON STAHLBAUTEN; VOL. I: GRUNDLAGEN DES STAHLBAUES**

The first volume of a series on the design and calculation of steel structures covers the following: steel as a building material; riveted, bolted, and welded connections; numerical solutions in statics; bending and torsion of beams; stability problems — buckling and collapsing; vibration; and the determination of optium dimensions and characteristics of structural elements. (F. Stussi. Berlin, Springer-Verlag, 1958. 577p., 55.50 DM.)

***THEORIE UND BERECHUNG DER STAHLBRUCKEN, 4TH ED.**

In dealing with the theory and design of steel bridges the author first discusses the fundamentals of elasticity and plasticity. He then develops the theory of plates and of girder grillages, and reviews the stability problem with special attention to buckling. The rest of the book is devoted to modern design methods for highway bridges, solid-web girder bridges, lattice girder bridges, arch bridges, suspension bridges, and compound bridges. The book is intended for the structural engineer as well as for the student. (A. Hawranek, rev. by O. Steinhardt. Berlin, Springer-Verlag, 1958. 426p., DM 66.)

***PLASTIC DESIGN OF STEEL FRAMES**

In addition to presenting simple plastic theory and methods of plastic analysis, such secondary design considerations as the influence of shear force, axial force, and buckling are reviewed. Using plastic analysis as a base, design procedures are given for proportioning building connections with particular reference to welded connections. A special feature is the chapter on "Design Guides" which provides in chart form the analysis and design procedures and the secondary design guides presented in this book. (L. S. Beedle. New York, Wiley, 1958. 406p., $13.00.)

MECHANICS: PART I: STATICS, 2ND ED.

Following an introduction to statics and dynamics, the resultants of force systems and the equilibrium of force systems are presented as are structures, distributed forces, and friction. A chapter is devoted to the principles of virtual work and shows the type of problems for which this method is superior. Full use of graphic procedures is made whenever they are of advantage, and problems are included which emphasize practical engineering situations. In this edition some of the chapters have been rewritten and many new problems have been added. (J. L. Meriam. New York, Wiley, 1959. 393p., $5.00.)

***ADVANCED MECHANICS OF FLUIDS**

An advanced sequel to the editor's earlier work, "Elementary Mechanics of Fluids". The goal of the present volume is the development of research methods, so that the theoretical approach is given primary emphasis. Among the topics discussed are irrotational flow, conformal representation of two-dimensional flow, laminar motion, turbulence, boundary layers, and free-turbulence shear flow. (H. Rouse, ed. New York, Wiley, 1959. 444p., $9.75.)

***HIGH TEMPERATURE WATER SYSTEMS**

Intended for engineers and contractors this volume contains data used successfully in high temperature water systems. Design, specification, installation, application, and economics are presented in detail. Specific aspects discussed are pressurizing, boilers and expansion tanks, system control, circulating pumps, valves, piping, and process and space heating. A feature is the complete treatment of the design of a typical system. (O. S. Lieberg. New York, Industrial Press, 1958. 211p., $7.75.)

***MECHANICAL PROPERITIES OF NON-METALLIC BRITTLE MATERIALS**

Papers which attempt to devise reliable methods of measuring the mechanical properties of non-metallic brittle materials, and to explain the reasons for their observed behavior. A variety of materials is studied such as coal, glass, rocks, ceramics, and concrete. Topics covered include strength in compression, tension, bending, and shear; elasticity and creep; dynamic loading, impact, and fragmentation; action of tools, with particular reference to coal. These papers constitute the proceedings of a conference held in London in 1958. (W. H. Walton, ed. Toronto, Butterworth, 1958. 492p., $12.75.)

***CONSTRUCTION MANAGEMENT AND SUPERINTENDENCE**

Examines the complex division of duties, responsibilities, and procedures among the owner, the architect, and the contractor. In part one the author covers the details of construction management. Using specific examples he deals with contracts and sub-contracts, changes of contracts, purchasing and deliveries, cost records, job office control, and the records necessary to keep track of hiring and discharging workers. Part two describes how to supervise each of thirteen trades to see that the plans and specifications are followed from start to finish. Included are subgrade work, concrete work, masonry, roofing, lathing and plastering, floor finishing, and painting. (W. C. Ross. Toronto, Van Nostrand, 1958. 238p., $8.25.)

***THE PETROLEUM CHEMICAL INDUSTRY 2ND ED.**

A description of the major products and the basic chemistry of the processes used, along with an indication of their commercial possibilities. New chapters have been included on the history of the petroleum chemicals industry and on statistics and economics, while many of the chapters have been enlarged and rewritten. (R. F. Goldstein. Toronto, McClelland and Stewart, 1958. 458p., $20.00.)

***DYNAMICS OF FLIGHT: STABILITY AND CONTROL**

The underlying principles and techniques of the dynamics of flight are presented. Incorporating recent developments, the author covers static and dynamic stability, transient and frequency response, feedback systems and automatic controls, dynamics of missiles, machine computation, and mathematical aids. In addition material on inverse problems and on flight through turbulent air is included. Automatic control theory is approached from the aeronautical engineer's viewpoint, while machine computation is approached from the standpoint of the machine user rather than the computing specialist. (B. Etkin. New York, Wiley, 1959. 519p., $15.00.)

***MANUAL OF STRUCTURAL DESIGN, 4TH ED.**

A manual providing a wide variety of tables and methods of calculation used in structural design. This edition contains entirely new information on concrete joists, slabs, flat slabs, stirrups, concrete columns, footings, and retaining walls. The steel beam tables are entirely revised and new tables have been added on long span joist, compound sections, and fireproofing. (J. Singleton. Topeka, Ives, 1957. 272p.)

***BASIC GEOLOGY FOR SCIENCE AND ENGINEERING**

A systematic development of physical geology with particular emphasis on those principles suitable for engineering application. Among the topics discussed are soil materials, physical and chemical properties of rock materials, soil forming processes, streams, shoreline processes, ground water, wind deposits, and crustal deformation. A considerable number of tables and graphs have been included. (E. C. Dapples. New York, Wiley, 1959. 609p., $9.50.)

***COMPACT HEAT EXCHANGERS**

A comprehensive treatment of compact heat transfer surfaces, including tube banks, plate fin surfaces, finned tube surfaces, and screen and sphere matrix surfaces. Analytical solutions are considered for abrupt contraction and expansion pressure-loss coefficients, laminar-flow heat transfer in circular and rectangular tubes, and the effects of temperature-dependent field properties on heat transfer and flow friction. A chapter is devoted to heat-exchanger performance theory, developed around the effectiveness versus number of heat-transfer units. Use of the data and theory is illustrated by sample problems. (W. M. Kays and A. L. London. Toronto, McGraw-Hill, 1958. 156p., $6.90.)

MEET THE AUTHORS

The late Sir Claude Gibb, KBE, FRS, Hon. M.E.I.C., chairman and managing director, C. A. Parsons and Company Limited, Newcastle-upon-Tyne, England. (*Graphite in the World Nuclear Power Program*).

Born in Adelaide, Australia, Sir Claude Gibb graduated from the South Australian School of Mines (Adelaide University) and later did post-graduate study at London and Durham Universities to obtain his doctor's degree. In the first World War he was a pilot in the Australian Flying Corps and in the Second World War he was Director General, Armoured Fighting Vehicles and chairman of the British Tank Board.

He started his industrial training as a fitter at the Heaton Works of C. A. Parsons and Company Limited, rising rapidly to chairman and managing director, which position he held at the time of his death.

In 1945 he was honored by the King with a knighthood for his war work and in 1956 was made Knight of the British Empire for his outstanding contribution to the development of atomic power.

We are indebted to **Mr. H. B. Topham**, director and general manager of the Anglo Great Lakes Corporation Limited, for preparing this paper for publication in *The Engineering Journal*. Mr. Topham was personal technical assistant to the late Sir Claude Gibb for twenty years.

N. W. Radforth, professor of botany, McMaster University, and **Jean Margaret Evel**, organic terrain studies, National Research Council and Defence Research Board (*Mobility on the Muskeg Frontiers*).

Mr. Radforth was born in England and emigrated to Canada in 1920. He graduated from the University of Toronto in Honour Biology in 1936 and began teaching in that university in 1939. In 1946 Mr. Radforth was appointed as head of the department of botany, McMaster University and became the first director of the Royal Botanical Gardens, Hamilton. Recently he was awarded a Royal Society of Arts (London) silver medal for a paper on peat in Canada and Britain and its economic implications.

Jean M. Evel

Miss Evel was born in Hamilton, Ontario and received a B.A. from McMaster University in 1948 in botany and zoology.

From 1948-1952 she participated in floristic studies of counties bordering the north shore of Lake Erie for the Ontario Research Council. She has held her present position since that time.

A. C. Blue, M.E.I.C., chief, mechanical section, and **E. M. Scott**, M.E.I.C., assistant manager, both of the engineering and construction division of The Manitoba Hydro-Electric Board (*Special Features of the Brandon Generating Station*).

Mr. Blue graduated from the University of Toronto in 1921 with B.Sc. joining the Manitoba Hydro-Electric Board in 1956 after many years of experience with other firms.

Mr. Scott graduated from the University of Manitoba in 1946 with B.Sc. in electrical engineering. He served three years as chief, electrical section, engineering and construction division before being appointed assistant manager of the division in 1959. He has served also as chairman of the electrical section of the Winnipeg branch of the Engineering Institute of Canada.

P. A. Pasquet, M.E.I.C., chief project engineer, thermal division, A. C. Shamess, M.E.I.C., director of Electrical engineering and **W. P. London**, M.E.I.C. chief engineer, thermal division, all of H. G. Acres & Company Limited (*Special Features of the Brandon Generating Station*).

Mr. Pasquet graduated from Queen's University in 1942 with a B.Sc. in civil engineering and joined his present employers immediately.

Mr. Shamess, graduated from the University of Toronto with a B.A.Sc. in electrical engineering in 1946, serving with the R.C.A.F. prior to his graduation. He joined his present employers in 1949.

W. P. London graduated from the University of New Brunswick with B.Sc. in 1934. He was employed by the New Brunswick Electric Power Commission and the Bathurst Power Company before joining his employers' firm in 1941.

G. E. Waters, M.E.I.C., supervising engineer, plant department, Canadian Broadcasting Corporation, (*C.B.C. Television Network Program Delay Centre*).

Mr. Waters was educated in England and worked with the B.B.C. (except for the World War II years). He came to Canada and since 1953 has been with the C.B.C. He is a member of the Institution of Electrical Engineers and of the Corporation of Professional Engineers of Quebec.

J. B. Bryce, M.E.I.C., Hydraulic engineer, Hydro-Electric Power Commission of Ontario, (*Head-Loss Coefficients for Niagara Water Supply Tunnels*).

Mr. Bryce graduated from the University of Toronto in civil engineering in 1935 and obtained his M.A.Sc. degree in hydraulic engineering in 1936. After graduation he joined the Ontario Hydro and became hydraulic engineer in 1953. From 1938-40 Mr. Bryce was with the National Research Council's hydraulic laboratory. He also serves on International St. Lawrence River Board of Control.

(At time of going to press no information was available on Mr. R. A. Walker, the co-author of this paper).

A. M. Lount, M.E.I.C., consulting engineer, A. M. Lount and Associates (*The Use of Electronic Computers in the Field of Civil and Structural Engineering*).

Mr. Lount graduated from the University of Toronto in 1946 with a B.Sc. in civil engineering. He worked seven years for Ontario Hydro Commission and with the engineering division of Pre-Stressed Concrete. He formed partnership with Dr. Lazarides in 1953 and in May 1957 formed his own firm, A. M. Lount and Associates.

T. Blench, M.E.I.C., professor of civil engineering University of Alberta (*River Engineering as a College Course for Civil Engineers*).

Professor Blench received his B.Sc. with 1st Class Honours in civil Engineering and mechanics from the University of Glasgow, 1927.

With Irrigation Branch, Public Works Department, Punjab, India, 1927-48 Professor Blench became director of irrigation research. He served in India from 1942-45 being in charge of Air Force Works Research and Development Section. In 1948 he joined University of Alberta staff, and also carries on a consulting practice.

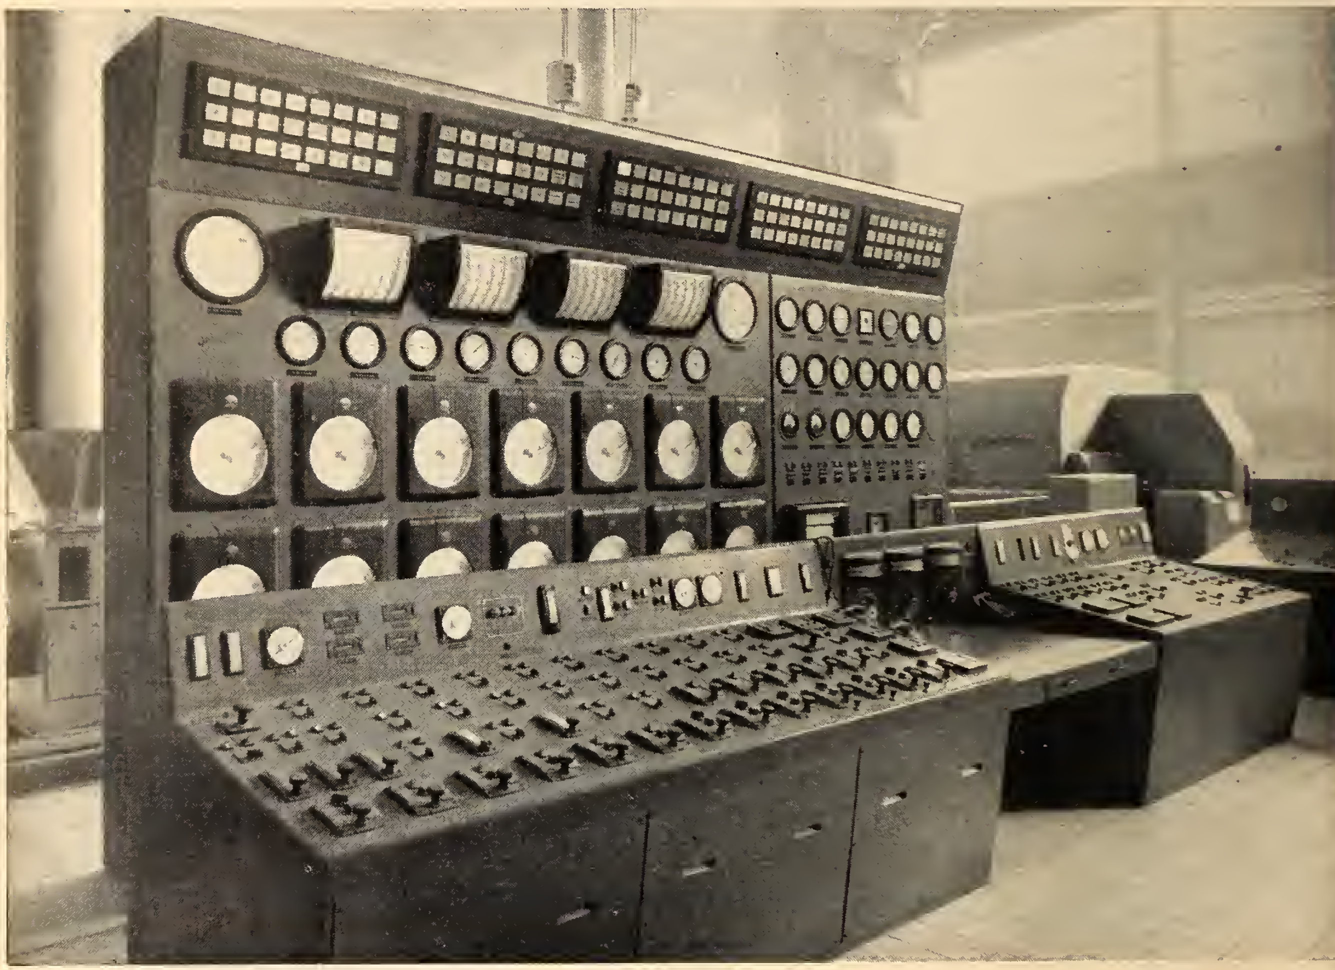
R. L. Duke, section engineer, mill industries, and **L. R. Hulls**, application engineer, Canadian Westinghouse Company Limited (*Magnetic Amplifier Control for Reversing Hot Mill Auxiliaries*).

Mr. Duke was born and educated in Vancouver, graduating from the University of British Columbia with B.A.Sc. in electrical engineering in 1941. He worked as an engineering apprentice for Canadian Westinghouse Company Limited and in 1943 became a section engineer.

L. R. Hulls, was born in Britain, graduated from Manchester University in 1943 in physics and electrical engineering. On graduation he worked with Signals Research Development Establishment until in 1949 he became chief of industrial electronic section at English Electric Company. He has held his present position since 1955.

BAILEY at Queen Elizabeth Power Station

Saskatchewan Power Corporation, Saskatoon, Sask.



Bailey vertical panelboard and miniaturized control console (foreground) comprise the "brain centre" of the boiler plant.

At the Saskatchewan Power Corporation's Queen Elizabeth Power Station, Bailey Meter Company Limited was selected to supply the following equipment.

Bailey Combustion Control System — controls the burning of natural gas, fuel oil or pulverized coal in each boiler according to plant load and maintains optimum Air-Fuel ratio regardless of fuel selected.

Bailey Three-Element Feedwater Control Systems — control rate of feedwater flow in proportion to plant load and maintain water levels constant in each drum.

Bailey Steam Temperature Systems — maintain constant steam temperature by superheater inlet condenser type control.

Bailey Boiler and Turbine Metering Equipment — indicate and record boiler and turbine operation.

Consulting Engineers: Hanright and Company Limited, St. Catharines, Ontario.

GRAPHITE IN THE WORLD NUCLEAR POWER PROGRAM

The late Sir Claude Dixon Gibb, K.B.E., FRS, HON. M.E.I.C.

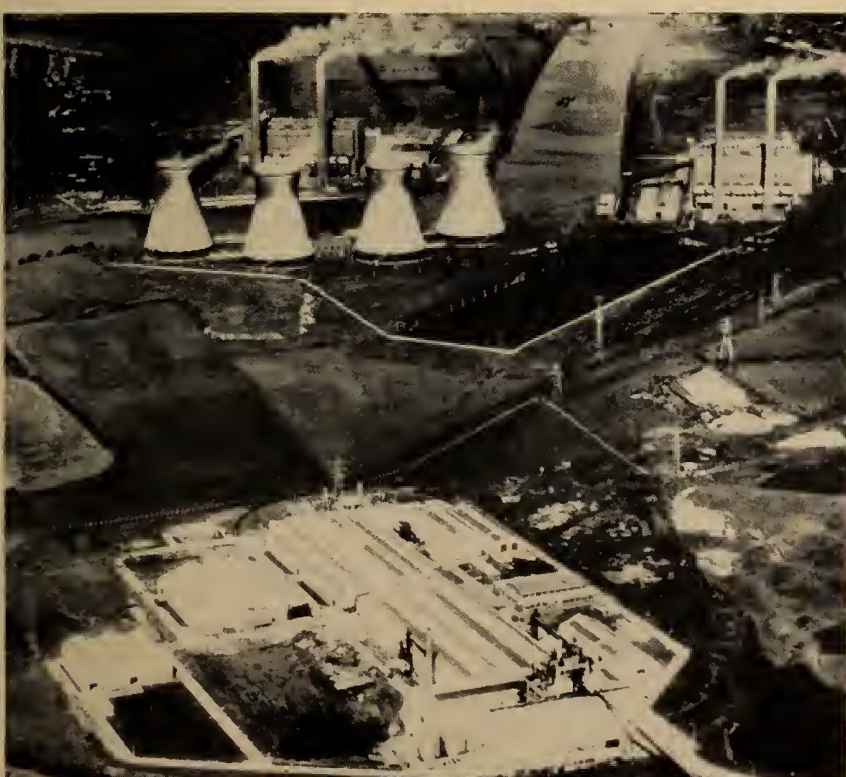
Chairman and Managing Director,
C. A. Parsons and Company Limited,
Newcastle-upon-Tyne, England.

The following paper was in an advanced stage of preparation by the late Sir Claude Gibb at the time of his death on January 15, 1959. He was writing it for presentation at the 1959 Annual General and Technical Meeting of the Engineering Institute of Canada.

Through the kindness of Mr. H. B. Topham, a colleague of the late Sir Claude for more than twenty years, the paper was completed and presented as scheduled at the 1959 Annual Meeting.

The Engineering Journal is privileged to bring to its readers this paper, by one of the world's most distinguished engineers.

Fig. 1. Aerial view of graphite plant including Stella North and South power stations.



A MERE ELEVEN YEARS separated the terror of Hiroshima and the potential blessing that Calder Hall offered to the world.

Devastation in 1945 demonstrated the power of the atom. That power is now tamed and turned to the benefit of mankind. The heat generated when fission takes place in an atom has been controlled and means found to extract, and then use it to raise steam for driving turbo generators for the production of electricity.

Almost every schoolboy today knows that one in every 140 parts of uranium metal is the isotope U_{235}, the remainder being U_{238}. The U_{235} atom is capable of splitting and in so doing a neutron detaches itself and, if it hits in its path another U_{235} atom, a further fission occurs releasing two neutrons which, under controlled conditions, can create further fission, each time creating energy which appears in the form of heat.

If the neutron from the U_{235} atom hits a U_{238} atom, then a new substance U_{239} can be formed called Plutonium which in itself is fissile, i.e. is capable of splitting and releasing one or more neutrons which thus could maintain the chain reaction or continuous controlled fission.

If uranium be specially prepared so that it consists wholly of the fissile isotope U_{235} there would be so many neutrons available to generate heat that only minute quantities could be arranged together, or else the rate of the chain reaction would release so much energy as to create a bomb effect. Natural uranium metal with only one part in 140 being fissile is entirely harmless and safe and can be handled in large quantities without fear of any bomb effect developing. Wholly enriched uranium is extremely dangerous, while in between those two extremes there can be an almost infinite range of enrichment from the entirely safe to the very dangerous.

Enrichment

Enrichment is uranium which has had the percentage of the fissile isotope U_{235} artificially increased by man. This can be done in several ways, e.g. by ultra high speed centrifuging whereby the non-fissile heavier isotope U_{238} is separated from its lighter but fissile companion U_{235}. But the method almost universally used is to prepare uranium hexafluoride which becomes a gas at a moderately high temperature which then is pumped through successive stages or cells where the inlet and outlet to the cell are separated by a porous membrane which allows the lighter U_{235} isotope to diffuse through at a faster rate than the heavier U_{238} and by doing this in series a great many times, eventually it is possible to produce material that is almost entirely U_{235} and therefore wholly fissile. Such material is extremely expensive, being costed at so much per gram, because of the high capital cost of the plant required and the huge quantities of electricity consumed in driving the compressors to maintain the uranium hexafluoride gas in the circuits.

It will be evident to engineers who, quite early, learned in life that "you can't get 'owt for nowt" that if you start with 140 pounds of natural uranium which would contain about one pound of the fissile isotope U_{235}, and, after passing this through the enrichment plant, you finish up with one pound of U_{235} separated from, instead of mixed with, the non-fissile and powerwise almost useless U_{238}, the amount of potential energy available is precisely the same except that that potential energy now weighs one pound instead of 140 pounds. But a very large amount of energy in the form of electricity has been used to concentrate the potential energy in the uranium.

Fig. 2. Unloading of coaster at quayside.

More Potential Power

The advantage of enriched uranium, — even if it is only slightly enriched, — is that more neutrons and therefore more potential power can be contained in a given volume. If, for example, with natural, i.e. non-enriched uranium, an output of 200 M.W. electrical can be obtained from a reactor core say 40 feet in diameter, then an output at least double that should be possible from the same core if instead of 0.07% of U_{235} in the fuel we could enrich 0.14%, i.e. double the amount of the fissile isotope. That reactor core has to be surrounded by a biological shield of the equivalent neutron absorbing capacity of say 9 feet thick of concrete. Hence the use of enriched fuel (uranium) enables a greatly increased output to be obtained from a given quantity of shielding concrete and a reduction in the cost of other equipment.

Fig. 3. Silos.

Cost Analysis

It will be obvious that if the cost of the electricity used in the enriching process plus the capital charges of the necessary plant exceeds the saving in capital charges due to reductions in construction size and costs of the enriched fuel reactor, then there is little or no advantage in enrichment. Only if electricity costs are extremely low and the enrichment plant has a very large throughput is it likely that a nuclear power plant using enriched fuel could compete economically with an indigenous fuel in most countries.

An inherent disadvantage of a natural uranium fuelled reactor is that the number of neutrons available for fission per pound or per ton of uranium are so few that neutron economy is of the utmost importance, but also, the minimum quantity of uranium necessary to maintain the essential chain reaction is quite large and such a reactor becomes increasingly economic as its output increases.

There is a minimum output below which the reactor cannot function and for very small outputs enriched fuel is essential.

Heavy Water

When fission occurs, the neutrons travel at great speed, exceeding the speed of light in fact, and to increase the chances of the neutrons splitting another fissile atom they must be slowed down by what is called a moderator. There are several moderators, the most efficient being heavy water since the number of neutrons captured by heavy water is the smallest of known moderators and therefore the all important neutron economy is a maximum. The whole of the Canadian research and development effort into efficient nuclear power production is based upon the use of heavy water as the moderator.

Beryllium or beryllia (the oxide) is another good moderator but is expensive and in short supply as well as being somewhat difficult to handle because of possible toxic effects.

Hydro carbons of the benzene ring family such as diphenyl or terphenyl are known as organic moderators and although suspect for a long time because of their known polymerisation under irradiation, it is now known that this effect is not necessarily so serious as to preclude their use. Active research is proceeding into the use of organic moderators but it seems likely that their use in a reactor would introduce complications which would appear to be undesirable.

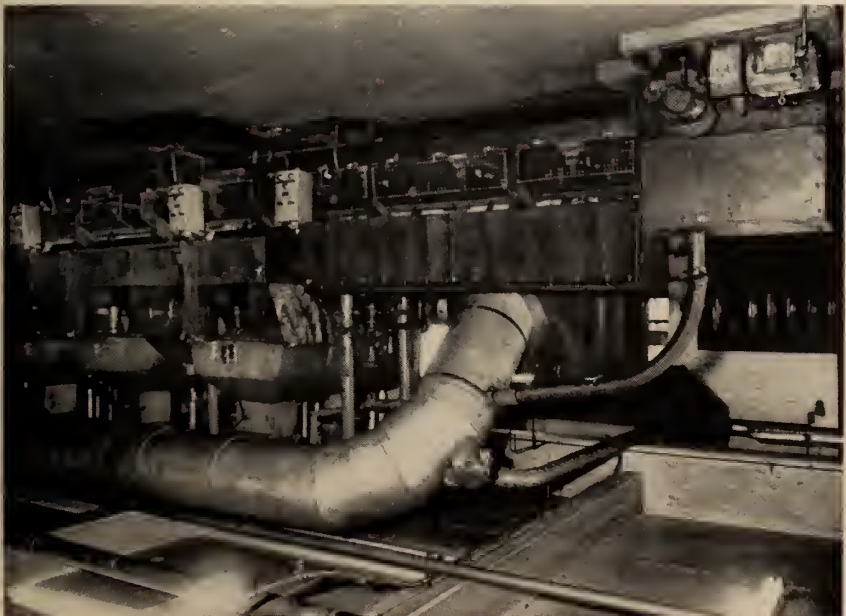
Demineralised light water is another possible moderator but with this the neutron capture is so high as to require the use of enriched fuel.

Fig. 4. Batch Weighing Control Board.

Graphite

Still another choice as a moderator is the carbon atom in the form of high purity graphite. Graphite as a moderator has advantages and disadvantages. Its disadvantage is that it captures many more neutrons than heavy water or diphenyl although less than light water. Its advantages are that it has considerable strength as a structural material even at very high temperatures and that it is relatively low in cost. Heavy water costs some $70,000 per ton against about $1,800 per ton for graphite machined to the shapes and sizes required for a reactor. But the weight of heavy water required purely as a moderator for a given electrical output is so much less than the weight of graphite that the moderator total cost with heavy water may not be that much above graphite as to be at least balanced by the greater neutron economy achieved. With heavy water the minimum output of a reactor fuelled with natural uranium is appreciably lower than with graphite.

Fig. 5. Batch Mixers.



When, in Britain, in 1948, the feasibility study that led to Calder Hall was begun, it was realised that the highest neutron economy would be achieved by using heavy water as the moderator. The only available source of heavy water at that time was the United States of America although small supplies were being produced at Trail, B.C., and in Norway.

Availability of both heavy water and dollars at that time had to be weighed against the disadvantages of graphite. Beryllium was not available; diphenyl was suspect, and light water demanded enriched fuel which was not available. The decision was taken to adopt graphite as the moderator for Calder Hall, and although tenders were invited for three fully commercial nuclear stations in Britain before Calder went critical or was known to be a success, those further designs were also to be graphite moderated.

The urgent need for Britain to find a fuel supplementary to coal or oil was and is so great that with enriched fuel unavailable and heavy water too costly in dollars to be considered, the nuclear power program had perforce to be based upon graphite and natural uranium.

Sixteen Reactors

Under construction in Britain today are sixteen graphite moderated reactors, eight at Calder Hall and Chapel Cross optimised for the production of plutonium with electricity as a by-product and two each at Berkeley, Bradwell, Hunterston and Hinkley Point, the latter eight being optimised for electricity production with plutonium as a by-product. The total electrical output of the sixteen reactors is 1,680 mw. nett. The cost of the nuclear power stations already on-load or under construction exceeds $600 million and is an indication of the faith we have in Britain in the graphite moderated type of reactor.

Reactor designers and research workers in Britain, however, are by no means neglecting the possibilities of the heavy water or organic moderated reactors for both small and large outputs of electrical power. For small outputs of say 20 to 30 mw. where natural uranium, graphite moderated reactors are both uneconomic and unsuitable, the heavy water moderated gas-cooled reactor is regarded as extremely promising.

But the potential of the graphite moderated gas-cooled reactor for large outputs is so great that attention in Britain is being devoted largely to their future development particularly in ways to further reduce capital costs which form such a large part of total generating costs.

GRAPHITE PRODUCTION

Only graphite of the highest possible purity is suitable as a moderator. Minute traces of boron for instance would so increase neutron capture as seriously to impair neutron economy and lead to an increase in reactor core size and the amount of uranium fuel charge. The maximum neutron cross section capture which can be tolerated is 4.0 millibarns but a figure as low as 3.75 can be obtained regularly if the utmost (and expensive) precautions are taken in the selection, transport and processing of the raw materials.

The moderating or slowing down of fast neutrons is a function of the mass of the graphite. Hence a greater volume of low density graphite is required than for high density material and thus maximum density is required to reduce the overall reactor core dimensions and thereby reduce capital costs. A minimum density of 1.70 is specified for British 'A' grade graphite but in fact an average density of 1.75 is achieved in large scale production while 1.78 to 1.80 can be reached by adding an extra impregnating and baking operation. It is however a question of economic balance between the saving in overall reactor costs excluding graphite and the additional cost of increasing the density.

Structural Strength

Graphite, as engineers generally think of it, in the natural or flaked form when used as a semi-dry lubricant, is useless for a reactor moderator. A graphite reactor core for an output of say 250 mw. electrical will be some 45 ft. in diameter and over 30 ft. high. It will be built up from bricks approximately 8 in. square by 30 to 36 in. long. And it will operate at a temperature approaching 1000°F. in the centre of the core. Hence considerable structural strength is necessary.

The three essentials therefore for reactor quality graphite are:—

a) Highest possible purity.
b) Maximum density that is economic.
c) Adequate structural properties.

The requisite physical properties can only be obtained by employing a structure which is interlocking and not laminar as is flaked or natural graphite. Furthermore, natural graphite as mined has so many impurities as to be useless without very expensive separation operations.

The graphite used in reactors is a

Fig. 6. Cooler in Mill Building.

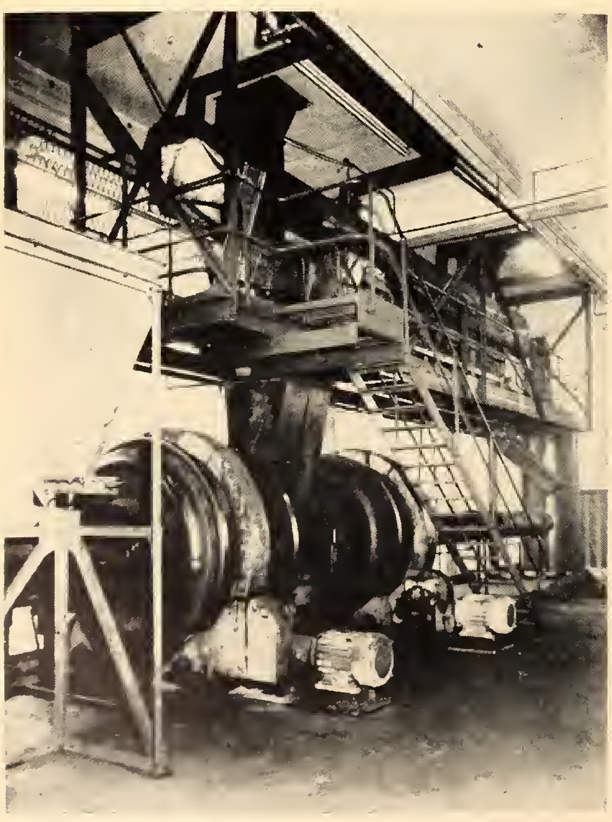


Fig. 7. Extrusion Press.

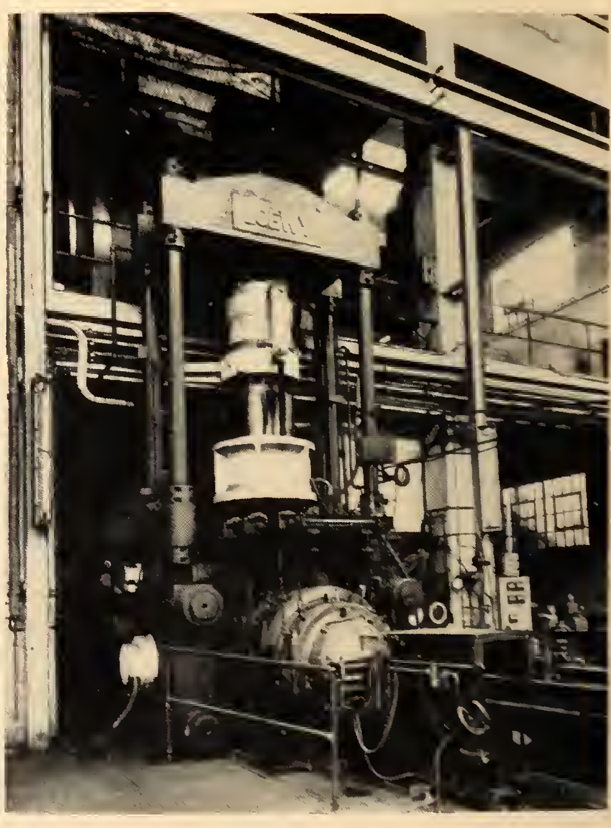

synthetic type, produced from high purity petroleum coke and equally high purity low ash coal based binder pitch. The transition stages from these raw materials to the finished product call for considerable science in selection, grading and control, but at least an equal amount of art in the shape of extensive manufacturing experience.

When the British Government in 1956, announced their extended nuclear power programme based upon graphite moderated gas-cooled reactors, there was only one source of supply in Britain for reactor quality graphite and this source was inadequate to meet the quantities which would be required. The United Kingdom Atomic Energy Authority decided to extend the factory of the existing producer and to provide an alternative supply source.

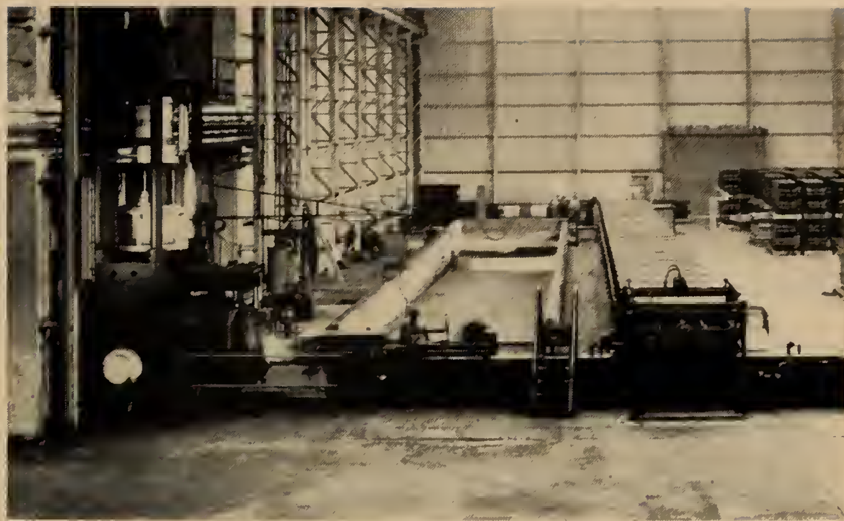

Fig. 8. Extrusion Bay.

New Factory

The description which follows is of the new factory built as the alternative supplier.

It will be obvious that *The Nuclear Power Plant Co. Ltd.*, a consortium of eight companies especially experienced in one or other portions of a complete nuclear power station, had a special interest in the availability and quality of the graphite required for reactor cores. Hence four of those eight member companies agreed to provide staff and much of the finance necessary to construct and operate a graphite factory, but, to buy time because speed in getting into production was essential, they would need technical assistance in design and early operation.

The Great Lakes Carbon Corporation of U.S.A. had graphite factories at Niagara Falls, New York State, and at Morganton, North Carolina and, although these factories produced commercial grade graphite, they had prepared limited quantities of reactor quality material. *The Great Lakes Carbon Corporation* had, during 1955, considered the possibility of building a graphite factory in Europe to meet a market there for electric steel furnace electrodes and other commercial graphite demands. Discussions between the interested British companies and the *Great Lakes'* executives indicated the likelihood of reaching agreement speedily on a basis for cooperation in design, construction and operation.

When producing nuclear graphite to a very rigid specification it was obvious that some rejected material would arise. Additionally, some of the high purity coke used as packing material during the baking cycle in producing artificial graphite can only be used once in case it receives any contamination, yet that packing coke may well be suitable as raw material for producing commercial grade graphite. So also would be rejected nuclear graphite. Hence the decision was taken to consider the economics of a factory capable of producing 10,000 long tons a year of nuclear graphite plus 5,000 tons a year of commercial grade graphite.

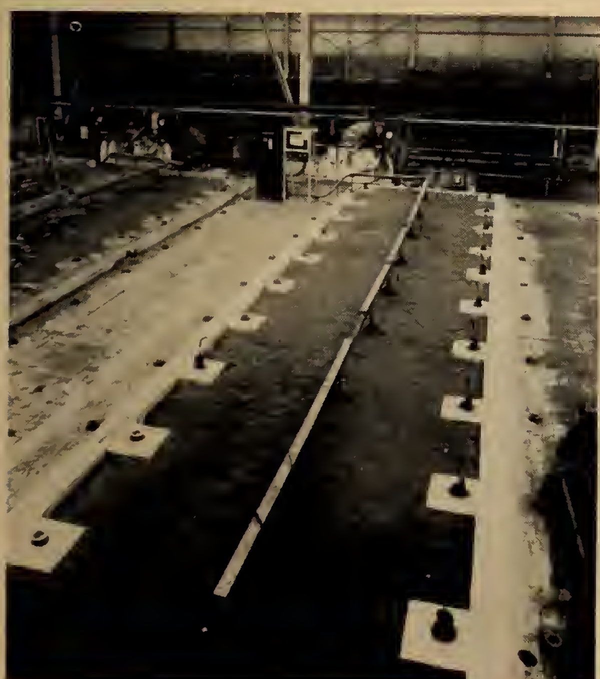

Fig. 9. Baking Furnaces

New Company

The economic study made showed that such a factory was just about the minimum output that would be competitive, and agreement was reached between the U.K.A.E.A.; the *Great Lakes Carbon Corporation* and the four British firms to proceed at once. A new British company was formed called *Anglo Great Lakes Corporation Ltd.*, and construction began in February, 1957.

The selection of a suitable site was extremely difficult. Since no petroleum coke is produced in Britain, that major raw material would have to be imported and hence sea or river access was desirable to reduce handling costs. Much of the finished product would have to be delivered long distances and therefore rail access was desirable.

Large quantities of electrical power would be used at a very high annual load factor, but with considerable phase unbalance at frequent intervals

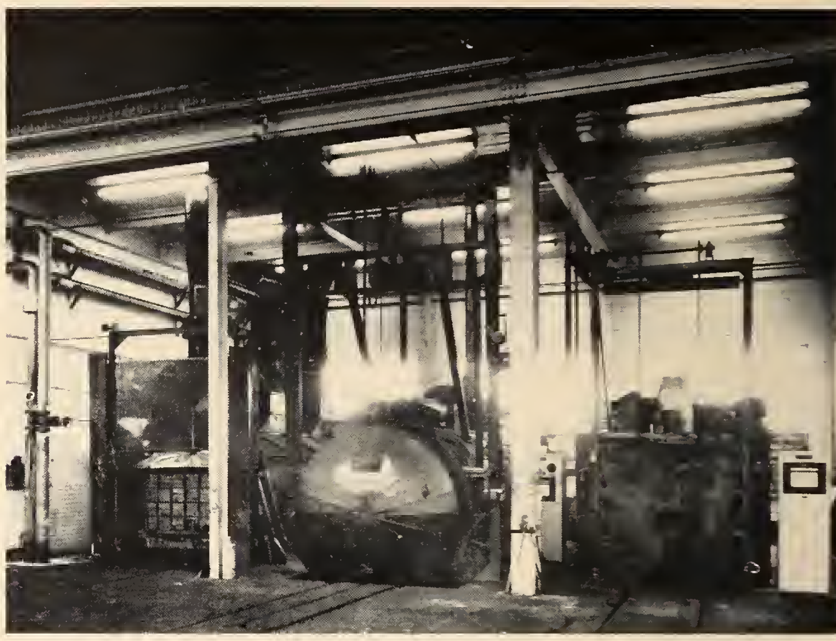

Fig. 10. Impregnators

because the graphitising furnaces are each single phase. Finally, the factory emits some smoke with pitch fumes and thus should not create a nuisance to a residential area. On the other hand, a staff of over 300 would be required and these must not have too far to travel.

Newburn Haugh

The only site fulfilling all these requirements was adjoining the Stella North generating station of the Central Electricity Generating Board and had been reserved by them for possible extensions. Since, however, the majority of the nuclear graphite to be produced would be used in the Generating Board nuclear power stations, they agreed to release the site for the erection of the graphite factory. Fig. 1. shows an aerial view of the completed plant at Newburn Haugh, some five miles west of Newcastle upon Tyne, with Stella North generating station and its four cooling towers on the north side of the River Tyne and Stella South generating station on the south or left bank of the river. Stella North has four 60 mw. turbo generators and Stella South five 60 mw. units. The two stations are interlinked at 132 kv. and are connected to the 275 kv. super grid running north to Scotland and south to Yorkshire. Hence a double circuit 132 kv. connection direct from Stella North, a matter of only 1,000 yards provides adequate safeguards for continuity of supply to the graphite factory which is important.

RAW MATERIALS

The petroleum coke is received in bulk by sea and unloaded by a grab mounted on a dockside crane. Fig. 2. shows a Dutch coaster being unloaded at the wharf of the *Anglo Great Lakes Corporation*. The grab delivers the coke into a hopper attached to the crane and travelling with it, and, by an electric vibrator, is passed to conveyor belts which take it to the primary crusher and thence by a third conveyor to the top of ten reinforced concrete storage silos, Fig. 3. where a cross conveyor delivers to the silo selected. Continuous sampling is done at this point.

The binder pitch at present is delivered by rail but consideration is being given to the possibility of delivering it in bulk by a coaster to the coke wharf. At all stages in the design of the factory, the truism that "handling adds nothing to the value of the product but does add to the cost" was always in mind and bulk handling of the pitch is a potential means of reducing manufacturing costs.

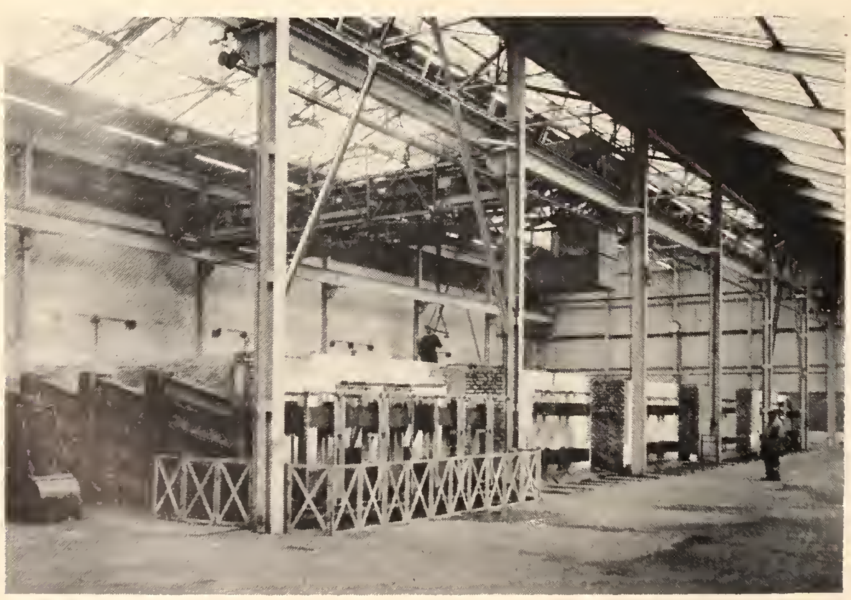
The relatively low melting point impregnating pitch is delivered in sealed containers by road.

THE PROCESSES

The petroleum coke after going through the primary crushers en route to the silos is drawn from the bottom of the appropriate silo and part of it is crushed before being sized on vibrating screens. The remainder is passed by chute to a Raymond type pulverising mill, to be reduced to flour size and conveyed to one of a series of bins each containing one of a range of particle sizes.

Depending on the density required and the duty for which the graphite is needed, the quantity of each particle size range is selected by the Technical Superintendent by a combination of science and art. Long experience has shown that there is a considerable scale effect between laboratory or pilot plant results and full scale production tests. Although high quality scientists are employed in the research laboratories both for quality control of raw materials and of finished product and for continual research into improved techniques, there is always the necessity for the production man to make adjustments

Fig. 11. Graphitising Furnaces.



in manufacturing techniques based upon a long experience. There is no direct road from laboratory to full scale operation.

The binder pitch similarly is prepared by crushing but as the pitch must be thoroughly mixed with the coke and, in effect, wet the coke, the pitch is crushed to a fairly uniform fineness yet larger than powder to assist handling.

Electro Pneumatic System

At the *Anglo Great Lakes* plant, the weight of each particle size and the weight of binder pitch having been selected, the actual weighing and distribution to the next process is done automatically by an electro-pneumatic system. The control board for this is shown in Fig. 4. Considerable difficulty was experienced in securing uniform and accurate batch weights at start-up due to the choking of filters with coke flour, i.e. coke passing through a 200 mesh sieve. Changing the type of filter and increasing their size was most effective and the amount of material lost in batch weighing is about one half of one percent and appreciably less than occurs when scale car weighing.

Each batch of coke and pitch after weighing is delivered to a heated mixer where the temperature is raised sufficiently to ensure the coating of each coke particle with pitch and a thorough mixing. Fig. 5. shows a part of the two rows of mixers.

The mixers discharge onto a band conveyor at a temperature which gives the batch a consistency rather like very stiff putty. Were it extruded to shape at this temperature, damage and deformation in handling would occur. The "mix" is therefore passed through a cooling mill, Fig. 6. and, at the appropriate temperature, loaded into the extrusion press, shown in Fig. 7. Temperature and consistency control at this stage is of great importance with experience playing a much bigger part than science. No one temperature will give satisfactory results in shape maintenance over varying cross sections.

The extrusion press drum is trunion-mounted so that it may rotate into three positions. Midway between vertical and horizontal it receives the charge of the mixture from the cooling mill. Next, in the upright position, a tamping ram consolidates the mixture and finally, in the horizontal position, the main ram extrudes the material through an electrically-heated die. The press is equipped with interchangeable reducers, so that a full range of dies may be used to produce either square bricks of nuclear graphite or cylindrical electrodes for steel furnaces.

Fig. 12. Power Transformers.

Green Stock

The extruded material as it leaves the die is of "cheese-like" consistency, which may be cut to required lengths by travelling shears before being transferred to a cooling belt. When cold the material, now known as green stock, is closely examined to make sure that its density, resistivity and general physical properties are up to specification.

Exceptionally fast steel works' cranes, arranged at two levels, are used to transfer batches of the green stock from the extrusion bay, shown in Fig. 8. to the baking bays, Fig. 9. where it is then loaded into muffle type furnaces for baking at about 1,000°C.

In the baking process the binding pitch in the green stock loses its volatiles and is reduced to coke. For this operation the bricks are loaded vertically into the baking furnaces and to prevent distortion and assist conduction of heat they are packed tightly with petroleum coke. The heating and cooling cycle in the baking furnaces takes about two weeks.

Baked stock is lifted out of the baking furnaces before it is cold onto a cooling belt at the end of which is a wire brushing machine to remove any loose packing material adhering to the surface. A further close inspection is then made to check density, resistivity and any visible signs of cracks or distortions.

The density of the material may then be increased, if required, by impregnating with a petroleum pitch. Fig. 10 shows a vacuum pressure impregnator designed to reduce the air pressure to within one or two millimeters from perfect, and shows that the baked stock, which has been heated to over 200°C. enables the pitch to penetrate fully into any voids caused during the previous baking process. Whilst immersed in pitch the vessel is subjected to a pressure of over 100 lbs. per square inch.

To obtain higher density for nuclear graphite it may be given further baking and impregnating treatment, though with diminishing returns for each successive cycle.

Furnaces

The last operation is to change the amorphous carbon sections into crystalline graphite by heating it to a temperature of at least 2,800°C. in a muffle furnace. The stock is mechanically handled from the baking bay into the graphitising bays where it is placed into one of thirty electric resistance furnaces, a group of which may be seen in Fig. 11. The furnaces are arranged on each side of heavy busbars to which they may be connected by specially designed switches mounted on cranes which traverse pressurised busbar chambers. Graphite furnace transformers feeding the busbars, which are single phase, are carefully controlled to take a balanced load from duplicate 132 kv. power lines supplying two power transformers, Fig. 12.

A special feature in the production of nuclear graphite is the maintenance of exceptionally clean conditions at all stages of manufacture and in maintaining the freedom from contamination, which is the prime concern in the selection of raw materials. Efficient dust control is maintained together with regular vacuum cleaning of the entire factory. The contamination, which could be picked-up from handling equipment, furnaces and

MOBILITY on the MUSKEG FRONTIERS

Norman W. Radforth, *Department of Biology, Hamilton College, McMaster University, Hamilton, Ont.*

Jean M. Evel, *Organic Terrain Studies, National Research Council and Defence Research Board.*

THERE ARE SIGNS — fixed and commanding — that exploitation of the petroleum potential of northern North America may either end abruptly or plunge the oil industry into a type of financing that contemporary economics will label prohibitive. The reason? Muskeg, better designated Organic Terrain. On the present frontiers of exploration in the northlands, this type of terrain is no longer a new acquaintance and indeed no longer casually impedes. There are few places where it does not present a barrier to operations. To surmount this barrier imaginative engineering skill has been combined with two new studies — Terradynamics and Palaeovegetography.

Imagine extensive beds of peat frequently heavily charged with water as liquid or ice. If this is conceived as covered above by special but varied vegetation and below by mineral soils differing as to properties, and the whole complex characterized by special physiographic circumstances—then the meaning of Muskeg will be basically understood. It follows naturally that Muskeg is best described as Organic Terrain.

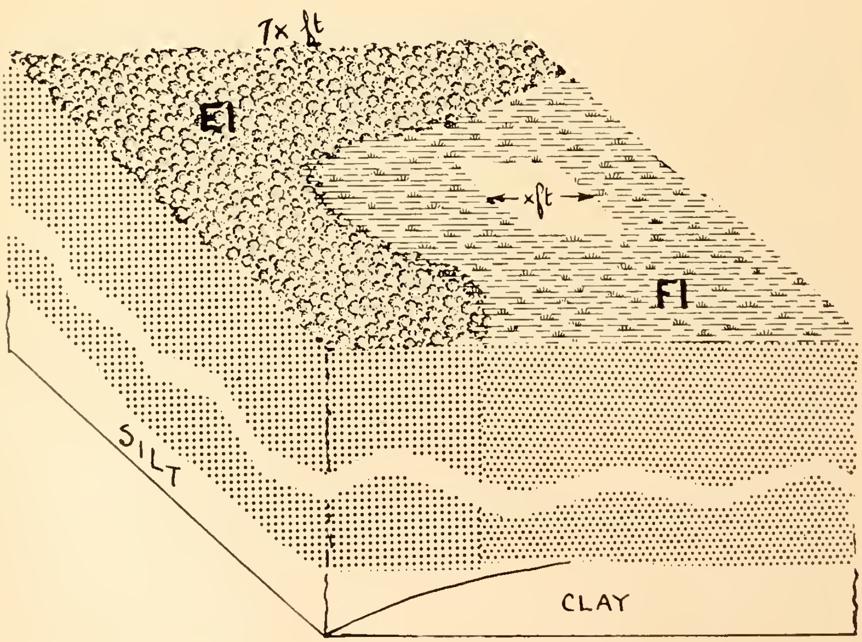
The interpretation of the history and structure of the ancient (fossilized) vegetation, the predominating component of the terrain contributing to the peat, is known as Palaeovegetography. It is a new study which probably would never have arisen had it not been for the fact that Organic Terrain exhibits a wide range of difference.

It is these differences that have precipitated the other new discipline known as Terradynamics,[1] the study of accessibility over organic terrain and the design of new vehicles pertinent to this study.

When considered in the light of research, organic terrain has not revealed itself as a disorderly medium, problematical though it has proved to be. Identification of its most frequently encountered types is dependent on recognition of only nine major categories of vegetation cover.[2] These are designated by letters A to I and almost invariably occur in combination. The latter are known as cover formulae, a few common examples of which appear in Fig. 2. Thus, an example of organic terrain like that shown in Fig. 3 can be completely defined as to cover type on the basis of formulae. The values of the letter symbols are transcribed largely in terms of plant stature, structure disposition and degree of woodiness.[2]

In recording the kind of cover it is important to indicate the area and shape of the sample of terrain under consideration. Fig. 1 shows two types

Fig. 1. Diagram showing space relationships for two major muskeg types. Note that sampling (e.g. small area in F 1) in arbitrarily selected areas (e.g. the outer limits of the diagram) must take into account cover formulae delineation.



of cover designated by cover formulae EI and FI. If the area selected for study is that shown as having the dimension *x* feet as its width, the quality and properties of the muskeg for which it would be symbolic would differ from those for which EI prescribes, and differ again were the area to overlap from FI into EI. In the case of FI, the peat would be constructed of a non-woody, fine-fibrous material existing with a high proportion of soft granules having no special shape. Where there is EI cover, it would represent peat structure also rich in non-woody fine-fibrous material, but with an abundance of woody particles much more resistant to compressional forces than are the shapeless (amorphous) granules. A transition condition occurs where the two cover types merge.

Only two types of structural condition are shown in Fig. 1. There are 16 that occur frequently. Each is characterized by its own set of properties. Besides these there are other features, for example, topographic ones, which are often diagnostic. Thus, where there is a peat of relatively coarse structure as compared to that beneath FI, it is often the case that ridges and mounds occur in the surface. In the spring these contain mounds of ice, producing a condition known as knolling.

The real key to relationship among surface cover, topography and peat category is found in a more specialized aspect of Palaeovegetography. It utilizes discreet microscopic units known as microfossils, biological indices that provide the means for historical and spatial sequence in the peat. Extensive study of these indices of organization has facilitated techniques of prediction concerning the structure of the terrain, and because of this circumstance, much information about a given expanse of organic terrain can be provided in a muskeg laboratory without reference to actual field experience.

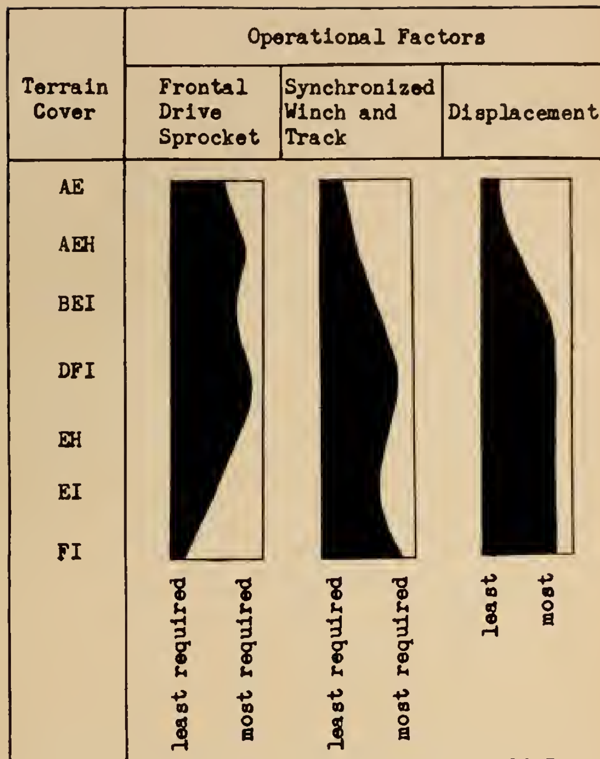


Fig. 2. Some common examples of cover formulae.

Fortunately, air-photo coverage is now available for the vast areas of organic terrain in the north. Now that it is known in general terms what cover formulae mean in relation to peat structure, stereo-pairs or mosaics of photographs showing ground cover can be used to predict structural conditions in the terrain. The highest altitude at which interpretation and prediction has been attained is at 30,000 ft. Obviously, at high altitude, cover formulae as they are known on the ground or at low altitude, appear to merge and any initial design that they effected gives rise to a new order of pattern. Detection of pattern, significant with reference to cover formulae, is a study in itself. The technique of detection has been explained elsewhere.[3, 4] Its application is essential if selection of route or any engineering development or operation in organic terrain is contemplated.

Usually route selection presupposes some knowledge of the fundamentals of Terradynamics. On the other hand, the latter is dependent upon the disclosures of Palaeovegetography. Thus, mobility on organic terrain is never adequate unless prescription for it is based on modern terrain interpretation. Indeed, failure is certain when the mechanical aids designed to achieve optimum mobility are carelessly and indifferently applied with respect to the type or types of muskeg encountered.

Fig. 3. Shown here is a typical example of organic terrain which, like all other categories of terrain, can be defined as to cover type on the basis of formulae.

Operations on muskeg reveal terrain variability of such unusual order that engineers and contractors are confronted with problems of a compound nature. A given vehicle operating adequately in one kind of muskeg and doing the work assigned to it will usually either fail or fall short of requirements on another kind of muskeg. There are now at least three types of vehicles that will successfully negotiate 90% of the terrain with EI cover shown diagrammatically in Fig. 1. The 10% that they will not negotiate is often so distributed as to effectively terminate an operation such as the construction of a road from an air strip to a drilling site or even delivery of supplies (for example, cement) where off-the-road access has been planned. For the FI cover the same vehicles would successfully traverse approximately only 50% of the terrain.

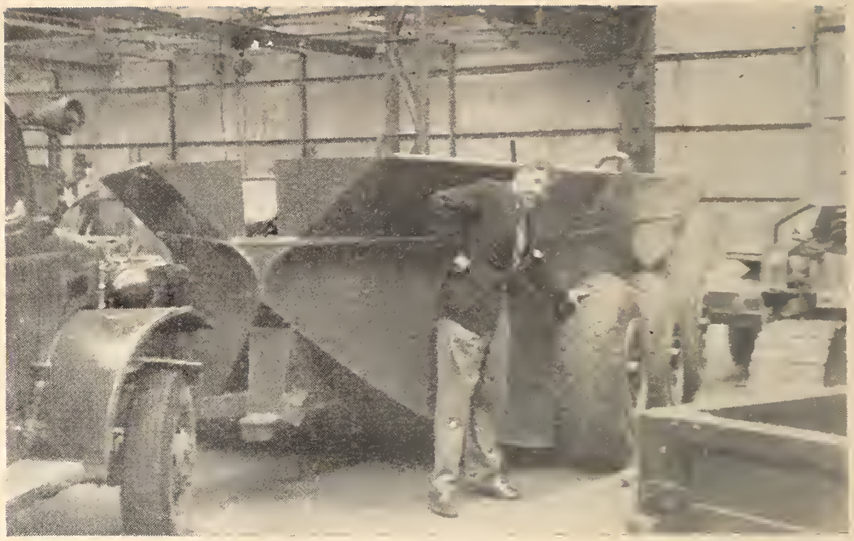

Fig. 4. A powered slipe. Note the aeroplane-type wheels which give greater buoyancy when the vehicle is on hard ground.

The reason for failure is usually twofold. One is that local terrain interpretation has not been adequate and the operator is uninformed or ill-advised. The other is that vehicle design is not sufficiently broad in its scope to accommodate for the diverse terrain conditions. It is a misconception that failure is always the direct result of a vehicle or vehicles sinking out of sight in the muskeg. Sometimes they sink only one or two feet and cannot be extricated either because of their own mechanical inadequacy or by reason of the fact that no device is available for pulling them out. Often it is not vehicle subsidence that limits an operation. It may be a characteristic terrain irregularity. Ice-knolling and irregular margins of peat plateaux are examples of this. The former condition is not only difficult to traverse, it is extremely hard on the drive and suspension mechanism of the vehicle. It is most devastating during the period April to June when the peaks of the knolls are at their highest amplitude (2-3 ft.). Distance between peaks is such that frequently the weight of the machine impinges on too few points on the tracks. This is accompanied by high frequency of impact of the track surface against the peaks. Because of this, steering is difficult and acceleration rate is constantly changing. The operator must be alert with the brakes and gears and must anticipate any embarrassment that might arise in manoeuvrability, especially if he is driving an articulated vehicle or if centre of gravity is inappropriate to terrain character. The degree of pitch that might be expected should be considered relative to characteristics of the cargo being transported or to the nature of the project under development.

Fig. 5. Here, a non-powered slipe is being drawn behind a powered unit: loads of up to ten tons can be hauled in these slipes.

Perhaps the best way to assess how much difficulty will arise in a given operation is to construct spatial diagrams appropriate to degree of limitation of terrain features and those mechanical features of the vehicles which the terrain will critically affect. An example of this suggestion is shown in Fig. 2. When these diagrams are placed side by side the general effect of the factors involved can be qualitatively compared for each terrain type to be traversed. In Fig. 2, two mechanical features and one operative effect imposed by the terrain are appraised for seven common terrain types. Normally, in any operation, at least these seven cover formulae would be encountered.

It is sometimes held that where the frontal drive sprocket is a design feature of the track vehicle there are distinct advantages. To be effective, the sprocket is so situated as to produce an inclined surface of track which meets obstacles in the terrain. A track approach angle therefore moves ahead of the vehicle facilitating elevation in the front of the vehicle. Also, with frontal drive, the lower run of track relaxes to the contour of the obstacle, thus affording maximum area of contact with the obstacle. This in itself assists traction and promotes uninterrupted progress. In addition, there is less likelihood of cutting the muskeg mat with the approach angle, and this is to be encouraged.

When the terrain mat is cut, even if as a result the vehicle does not completely subside, there is a good chance that it will lose traction, and winching will then be necessary. Where this situation arises, there is a high possibility of the condition worsening unless the speed of the tracks, which are kept rotating in the hopes of recovering traction, is approximately synchronized with the speed of the winch. Without this feature the vehicle noses down or up depending upon the speed relationship between the winch and track. This may result in unfortunate distribution of pressure and a change in ground pressure relations that may encourage subsidence.

Further examination of Fig. 2 shows that displacement brought on by subsidence is variable depending upon the type of muskeg as reflected in the type of cover. Note however, that of the seven types listed, displacement can be expected to be high in five of them. Even in the two remaining types, some chance of critical subsidence can be expected. The diagram expresses the relative frequency of subsidence to expect, not the amount of subsidence appropriate to each cover type. Therefore, it may only be said that where frequency of subsidence is high the degree of subsidence is apt to be great.

For muskeg with cover type AE the chances of displacement being frequent or considerable are very slight. Also, the need for synchronized winch and track speed is not essential. However, travel is much facilitated, as is manoeuvrability when a frontal drive sprocket is provided for in the design of the vehicle. Under the topographic conditions in this type of muskeg, angle of pitch for the vehicle can be expected to be high.

Accommodating mechanical features of vehicles to terrain requirements will not always make them faster. Usually it means that success in a given operation will be achieved as far as trafficability is concerned. An exception is when DFI occurs. Here, frontal drive sprocket, nearly synchronized winch and track speed are both highly desirable and often, in the opinion of the authors, essential. The need to accommodate for displacement is great. But if these requirements are met, speed of travel will be maximum and DFI is an excellent medium for travel.

Where EI and FI are concerned, displacement expectancy is very high. Indeed, it is in muskeg such as this that complete subsidence can be expected. With EI muskeg, extreme subsidence can be diverted if the frontal drive sprocket is incorporated as a design feature of the vehicle. For FI, this feature is not essential because the peat matrix is uniformly lacking in elements that can afford a means of traction once the upper surface of the mat is broken.

In the north generally, there are very large tracts of EI and FI cover. Although with modern muskeg transport equipment traverses and road construction can be achieved, it is not the normal situation to find that more than one or two passes can be made over exactly the same route. This has meant that the principles involved in Terradynamics have suggested a new type of design for transport where extensive EI and FI occur or where a traverse over this type of terrain is perhaps short but critical and used continuously.

The type of vehicle so far developed is known as a *Powered Slipe* (Fig. 4). It possesses aeroplane type wheels but these are only for buoyancy on hard ground when the vehicle is not progressing in muskeg Power is applied to a three-quarter inch cable anchored at either end or, for convenience, at intervals of about a mile. The cable is drawn in over the forward part of the hull of the slipe onto a capstan-type winch and run out behind the vehicle.

This method of travel depends upon buoyancy and never on traction. The breaking of the mat was discovered to have facilitated travel. Haulage of five to ten ton loads can be achieved in non-powered slipes (Fig. 5) drawn behind the powered unit.

The Slipe Haul system of travel in the far northern reaches of muskeg shows great promise. It is cheap; the cable is the road, and it can be salvaged when no longer required.

GRAPHITE *(continued from page 49)*

packing materials must always be kept very small. The boron content, for example, must be less than one-tenth of one part in a million. Some idea of the need for these precautions may be gathered from the fact that reliable test results were impossible after a laboratory analyst changed his make of hair cream.

Grade 'A' Graphite

Seventeen months after the first bulldozer arrived on the site samples from a furnace load of completed graphite blocks were tested in a reactor by the United Kingdom Atomic Energy Authority. They were found to be of acceptable quality as Grade 'A' nuclear graphite and in addition met all physical and chemical tests. Since then experience gained in producing blocks for the first two nuclear reactors has confirmed that the original design and technique had been successfully applied. The product has been remarkably consistent with a capture cross section lower than had been anticipated for production material.

An intensive research and development program covering new materials, processes and methods of manufacture is being carried out to reduce the total cost of nuclear graphite in a reactor. Already promising results gained with the pilot plant have been confirmed by larger scale production. This work is especially important for the more advanced types of graphite moderated reactors now being planned.

Preliminary Studies

THE BRANDON Generating Station of The Manitoba Hydro-Electric Board consists of four 33-mw units designed for throttle steam conditions of 600 p.s.i.g., 825° F, and operating with a cooling tower to provide condenser cooling water. In view of the modern trend to large units operating at high steam pressures and temperatures, and considering the climatic conditions at Brandon with their effect on cooling tower operation, it is of interest to review the factors which afforded the selection of the site and the equipment.

The Manitoba Hydro-Electric Board supplies most of the power for the Province of Manitoba, and is responsible for providing new generating capacity as required to meet the demand. The power for the City of Winnipeg is distributed by the City of Winnipeg Hydro-Electric System, part of it being supplied by The Manitoba Hydro-Electric Board and the balance being generated in the City of Winnipeg Hydro-Electric System's own hydro and thermal plants.

The power for the Province of Manitoba outside of the City of Winnipeg is generated and transmitted by The Manitoba Hydro-Electric Board, but is distributed by the Manitoba Power Commission. For the purposes of system planning and operation, the two generating systems referred to above can be considered as a single entity.

Preliminary studies for the Brandon Station, which were carried out by The Manitoba Hydro-Electric Board and their consultants, were based on this conception. At the time these studies were made, the power generating capacity of The Manitoba Hydro-Electric Board and the City of Winnipeg Hydro-Electric System consisted of approximately 566,000 kw in hydro units on the Winnipeg River, and a 50,000 kw thermal station in Winnipeg. The bulk of the generating capacity was located at the eastern end of the system within approximately 60 miles of the Ontario-Manitoba boundary.

The study of the system indicated that the load could be divided into two basic blocks; the east block centred near Winnipeg and the west block extending from Portage La Prairie to the Saskatchewan border. Since the hydro sites, both developed and potential, are generally east and north of Winnipeg, it was apparent that there would be some advantages in locating the first thermal station near the centre of the western load block. A survey of the load distribution in this area indicated that the load centre was approximately 20 miles north of the City of Brandon.

Power transmission studies indicated that the generation of power in the Brandon area not only increased the stability of the system, but due to reduction of transmission losses, increased the net power available from the system. In fact, these studies showed that a 30 mw. unit at Brandon would be equivalent to a 40 mw. unit on the Winnipeg River.

A consideration of possible fuels indicated that lignite from the Estevan area of Saskatchewan would be most advantageous, and this factor also tended to favour the Brandon location over sites further east. Since that time, natural gas has become available, and under some conditions can be used to advantage, but the extent of its ultimate use will depend on the relative prices of natural gas and Saskatchewan lignite and the availability of gas.

It was realized that the Brandon site was not ideal with regard to the availability of cooling water since it would be dependent on the Assiniboine River. Unfortunately, the flow in this river is extremely variable, recorded flows ranging from a maximum of 23,000 cu. ft. per second to a minimum of 7 cu. ft. per second. A plant with a capacity of 132 mw., as was considered for Brandon, requires approximately 150 cu. ft. per second of circulating water. A combined cooling system using river water when available, and a cooling tower when required, was considered. However, this would have been more expensive than a closed system using the cooling tower at all times, and the added expense could not be justified. Moreover, since minimum river flow occurs in winter, it would still have been necessary to operate the cooling tower during extremely cold weather conditions. A closed system was therefore selected.

A review of the existing and predicted loads, both in the western area of the province and in the system as a whole, indicated that the Brandon Station should be designed for an installed capacity of approximately 132 mw. or a net output of about 120 mw. For comparison purposes, plants consisting of four 33 mw. units, three 44 mw. units and two 66 mw. units were studied. Many factors must be considered in selecting the optimum unit size to meet the system requirements. These include system reliability, the increase in firm system capacity, capital cost, fuel cost, and operating and maintenance costs.

The increase in firm system capacity, resulting from the installation of a 120 mw. plant at Brandon, varies with the size of the units used, and the results of the comparison are interesting and are listed in Table I.

Table I
Increase in Firm System Capacity

No. of Units	*Size of Units*	*Increase Over Existing System*
4	33	142 mw
3	44	126 mw
2	66	99 mw

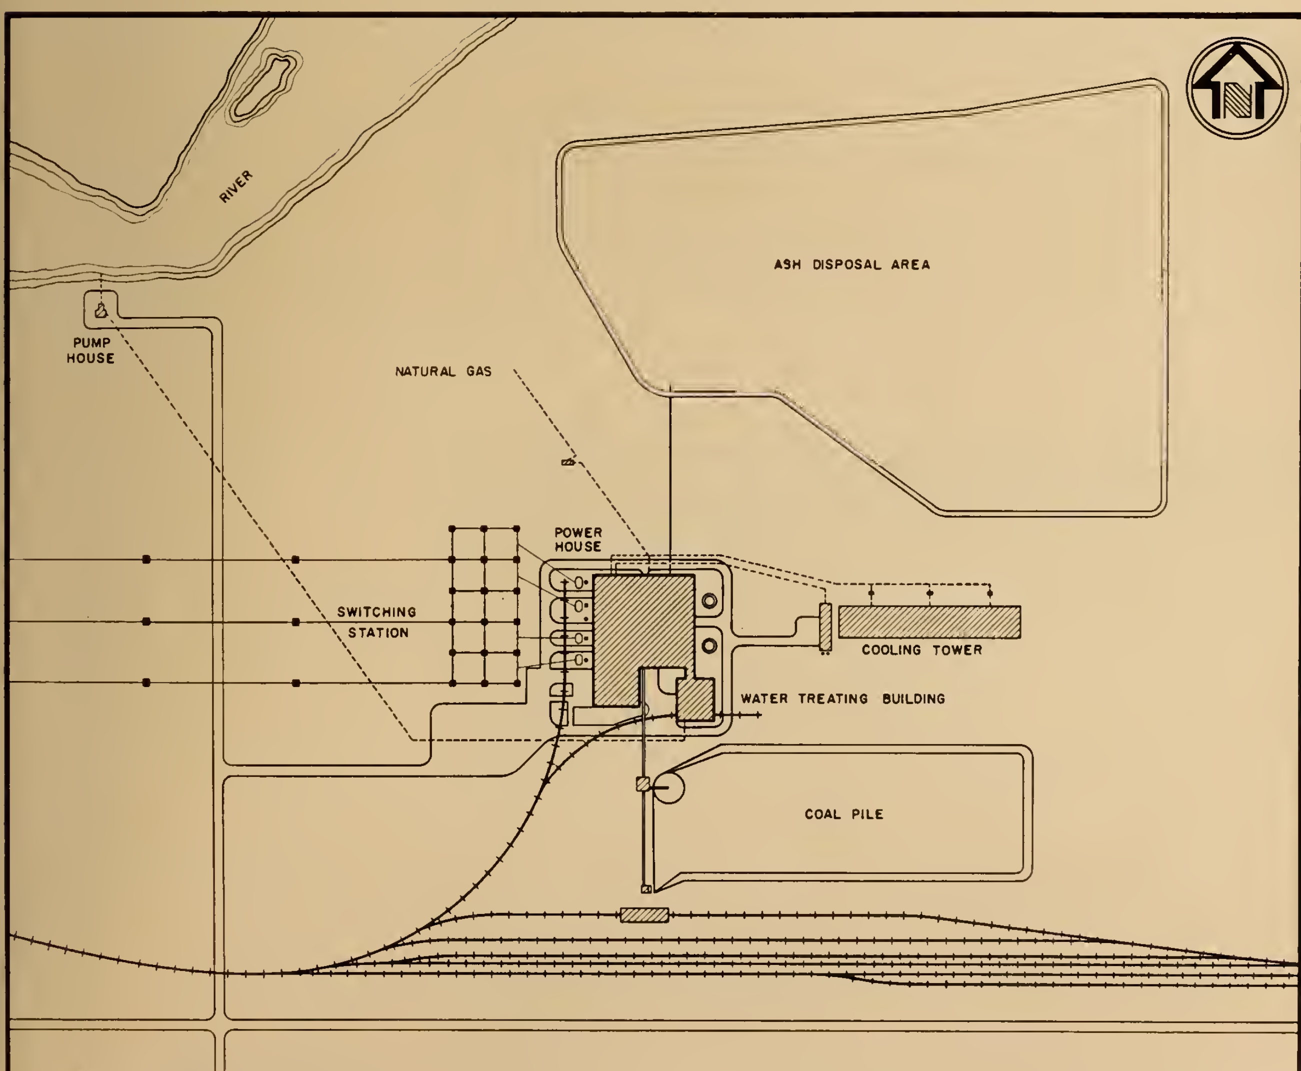
The increase in firm system capacity represents the increase in demand which the system can meet with the selected degree of reliability. The evaluation of this increase involves probability calculations with regard to forced outages of any one or more units in the system in conjunction with system peak demand studies. Although the trend indicated in Table I is normal since the required amount of reserve capacity is generally a function of the size of the units, the increase in firm system capacity is unusual since, in the case of the 30 mw. units, it exceeds the total capacity of these units. Although many factors are involved in the calculations, the main ones which resulted in the unusual increase in firm system capacity are:

(1) — Reduction of transmission losses.

(2) — Increase of the firm capacity of the hydro plants by providing more flexibility of operation, thereby permitting a more advantageous use of the available water storage facilities.

Studies of the system loads indicated that whereas the system load factor is approximately 57%, the expected average lifetime capacity factor for the Brandon Generating Sta-

Fig. 1. Brandon Generating Station—plot plan.



tion would be considerably lower or about 35%.

Detailed estimates of the total capital cost, fuel cost, and operating and maintenance costs were prepared for each of the three proposed unit sizes. The total annual cost per kilowatt increase in firm system capacity was then calculated. These calculations indicated that the optimum installation would consist of four 33 mw. units.

Further studies, which also involved comparison of capital cost, fuel cost, and operating and maintenance costs with turbine inlet steam conditions of 600 p.s.i.g. 825° F, 850 p.s.i.g. 900° F, and 1,250 p.s.i.g. 950° F, indicated that a plant operating with a turbine inlet steam pressure of 600 p.s.i.g. 825° F would be most economical for this installation.

General Description of Plant

The Brandon Generating Station is located on the south bank of the Assiniboine River, approximately 3 miles east of the City of Brandon. The arrangement of the site and location of the main buildings, cooling tower and switchyard is shown on Fig. 1. Fig. 1-A shows the general appearance of the office section and south side of the plant. Since the prevailing winds are from a westerly direction, the cooling tower is located on the east side of the main plant in order to reduce the spray nuisance.

The plant is designed on a unit basis, each unit consisting of a Metropolitan-Vickers turbine generator and condenser with a peak design rating of 33 mw, a Combustion Engineering-Superheater boiler with a design capacity of 325,000 pounds of steam per hour, and auxiliary equipment. The turbines are of the single cylinder impulse type with three extraction points and a single shell 2-pass condenser. The generators are of the hydrogen cooled direct-connected type, are designed to operate at 3,600 r.p.m., and are equipped with gear-driven exciters. The hydrogen system is designed for operation at a pressure of 15 p.s.i.g. at full load.

The boilers are of the tangentially fired type, designed for operation with either pulverized fuel, natural gas, or fuel oil. To date, only pulverized fuel and gas burning equipment has been installed, although there is provision for lighting off with light oil. Superheat control is provided by burner tilt, and attemperators have not been included.

The transverse section of the plant, Fig. 2, shows the relative location of the main equipment for each unit. Fig. 3 shows plans of the station at the operating floor and ground floor level. It may be noted that the arrangement of the equipment follows conventional lines. One departure consists of the provision of a totally enclosed central control room located on the operating floor between Units 2 and 3.

The plant feedwater heating cycle is shown on Fig. 4, and includes only three stages of heating. The cycle consists of two low-pressure closed feedwater heaters without drain coolers, but with a drip pump on the lowest pressure heater and a deaerating heater at the highest extraction pressure. This cycle, although not common for units of this size, has several advantages. It provides a reasonably high feedwater temperature and an acceptable efficiency while requiring a minimum amount of piping and controls. It is inherently simple and stable and, therefore, suitable for widely fluctuating load conditions and for two-shift operation. Furthermore, due to the relatively low average capacity factor anticipated for this plant, the extra cost of cycle improvements by the inclusion of additional heaters could not be justified economically. It should be mentioned that the operation of deaerating heaters at relatively high pressures as is done in this case presents a problem in maintaining sufficient net positive suction head to the boiler feed pumps under fluctuating load conditions. This problem, although beyond the scope of this paper, must be anticipated and provided for in the design of the plant, or the flexibility of the operation of the plant may be seriously impaired.

Fig. 1a. General appearance of office section and south side of Brandon generating station.

Water Supply System

As stated earlier, the fluctuations of flow in the Assiniboine River are such that a cooling tower is required. Since the evaporation rate in the cooling tower is approximately equal to the evaporation rate of the boilers, a considerable amount of make-up water is required. In the Brandon plant the cooling tower make-up water is obtained from the Assiniboine River. Unfortunately, the river water is very hard, with a degree of hardness varying between 200 p.p.m. and 900 p.p.m. The use of this water without treatment would result in rapid scale formation on the cooling surfaces of heat exchangers and condensers and in the cooling tower. This effect would, of course, be rapidly aggravated by the increased concentrations resulting from evaporation in the cooling tower. The system, therefore, includes a cold process lime softening plant in which all make-up water is treated. The system includes two reinforcing concrete treating basins, two lime feeders and slaker units, one soda ash feeder, one miscellaneous chemical feeder, control equipment and instrument panel. The system has a ca-

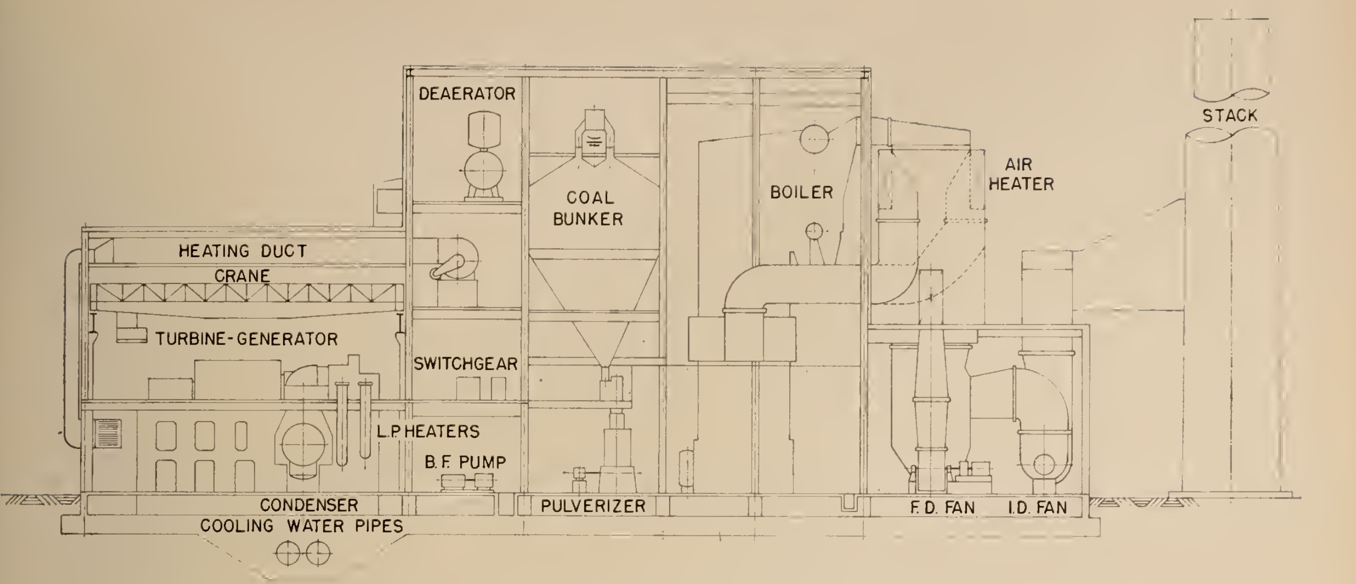


Fig. 2. Brandon Generating Station—transverse section.

pacity of 3,000 U.S.g.p.m., and is designed to reduce the calcium hardness to 35 p.p.m. and the magnesium hardness by 10 to 20%. The operation of this water softening system requires the use of relatively large quantities of chemicals, and storage bunkers are provided with capacities as listed in Table II.

Table II
Chemical Storage for Water Softening Plant

Chemical	*Capacity*	*Volume*
Pebble lime	130 tons	4,200 cu. ft.
Soda ash	42 tons	2,100 cu. ft.
Alum	60 tons	2,100 cu. ft.

In order to reduce costs, these chemicals are purchased in bulk, and a pneumatic car unloading system is provided to transfer the materials from the box cars to the storage hoppers.

Sulphuric acid and metaphosphate are used to control the corrosive and scale forming properties of the water, and to protect the cooling tower lumber against delignification. Although the water softening equipment is not unusual in design, it is probably the largest installed in a generating station in this country, both with regard to capacity and to the hardness of the water.

Demineralizing equipment is used for the treatment of boiler make-up. This was selected in preference to evaporators, partly because of the lower total operating costs and partly because of the expected intermittent plant operation. Demineralizing equipment unlike evaporators allows continuous production of make-up irrespective of plant or unit load.

Water from the Assiniboine River has a fairly high sodium content, averaging approximately 130 p.p.m. equivalent calcium carbonate. The possibility of sodium leakage seemed, therefore, to rule out the use of single stage demineralization. Consideration was given both to mixed bed demineralizers and to an *alternating series* arrangement. However, the system finally selected consisted of two complete lines of exchangers, each consisting of primary cation, primary anion, secondary cation and secondary anion units. A vacuum deaerator is installed ahead of the demineralizing equipment in order to protect both the demineralizing beds and the demineralized water piping from oxygen attack. Consideration was given to locating the deaerator between the primary and secondary units in order to take advantage of the reduction of chemical consumption due to the removal of carbonates at this point, but the added cost of making the deaerator corrosion-resistant could not be justified.

Cooling Tower and Circulating Water System

The cooling tower was supplied by Foster Wheeler Limited, and is of the induced draft type with 24 cells. Each cell is approximately 32 ft. square and 39 ft. high, so that the overall dimensions of the tower are 385 ft. by 70 ft. Each cell is provided with an exhaust fan with a capacity of 360,000 c.f.m., and provisions are made to operate these fans at half speed and in the reverse direction. The tower is designed for a water flow of 75,000 U.S.g.p.m. at an inlet temperature of 112° F, outlet temperature of 82° F with a wet bulb temperature of 72° F.

The optimum size of cooling tower and condenser combination was determined from economic studies. In making these studies a wide range of sizes of cooling towers and condensers was selected, and complete performance characteristics were worked out for each. The amounts of energy produced at each circulating water temperature were calculated, and from detailed estimates of capital costs of equipment, cost of pumping power and the cost of energy produced for each combination, the total annual cost for fixed charges, power and fuel was determined. As a result of these studies, a cooling tower as described above was selected with a ground area of .186 sq. ft. per kilowatt.

The condensers have an effective condensing surface of 15,000 sq. ft. per unit or approximately .455 sq. ft. per kilowatt. Both the cooling tower ground area and condenser surface are somewhat smaller than normal, but this again is the result of the low plant load factor and fuel cost.

The circulating water system consists of a closed loop with circulating water pumps pumping the water from the cooling tower sump through the condensers and back to the top of the cooling tower. The hydrogen coolers and turbine oil coolers are connected in parallel with the condensers. The four circulating water pumps have a capacity of 19,000 U.S.g.p.m. per pump against a total head of 65 ft. These pumps are located in a pump house adjacent to the cooling tower, and two 60 in. diameter buried steel pipes are provided for the water supply and return system.

The total number of circulating water pumps required at any one time depends on the load on the units and circulating water temperatures as determined by the wet bulb temperature. Under some conditions it is possible to operate all units at full load with only three circulating water pumps, whereas under other conditions it may be advantageous to operate the four circulating water pumps even though the station is operating at less than the rated capacity.

The circulating water pumps may be started and stopped from the central control room, and valve position interlocks are provided to protect the equipment. Valves are also provided to permit isolating sections of the cooling tower, and the cooling tower fans are controlled from the central control room.

Lignite Handling and Burning

As mentioned previously, the Brandon Station has been designed primarily to burn lignite from the Estevan area of Saskatchewan. The characteristics of this fuel as used for design purposes are given in Table III.

Table III
Characteristics of Lignite

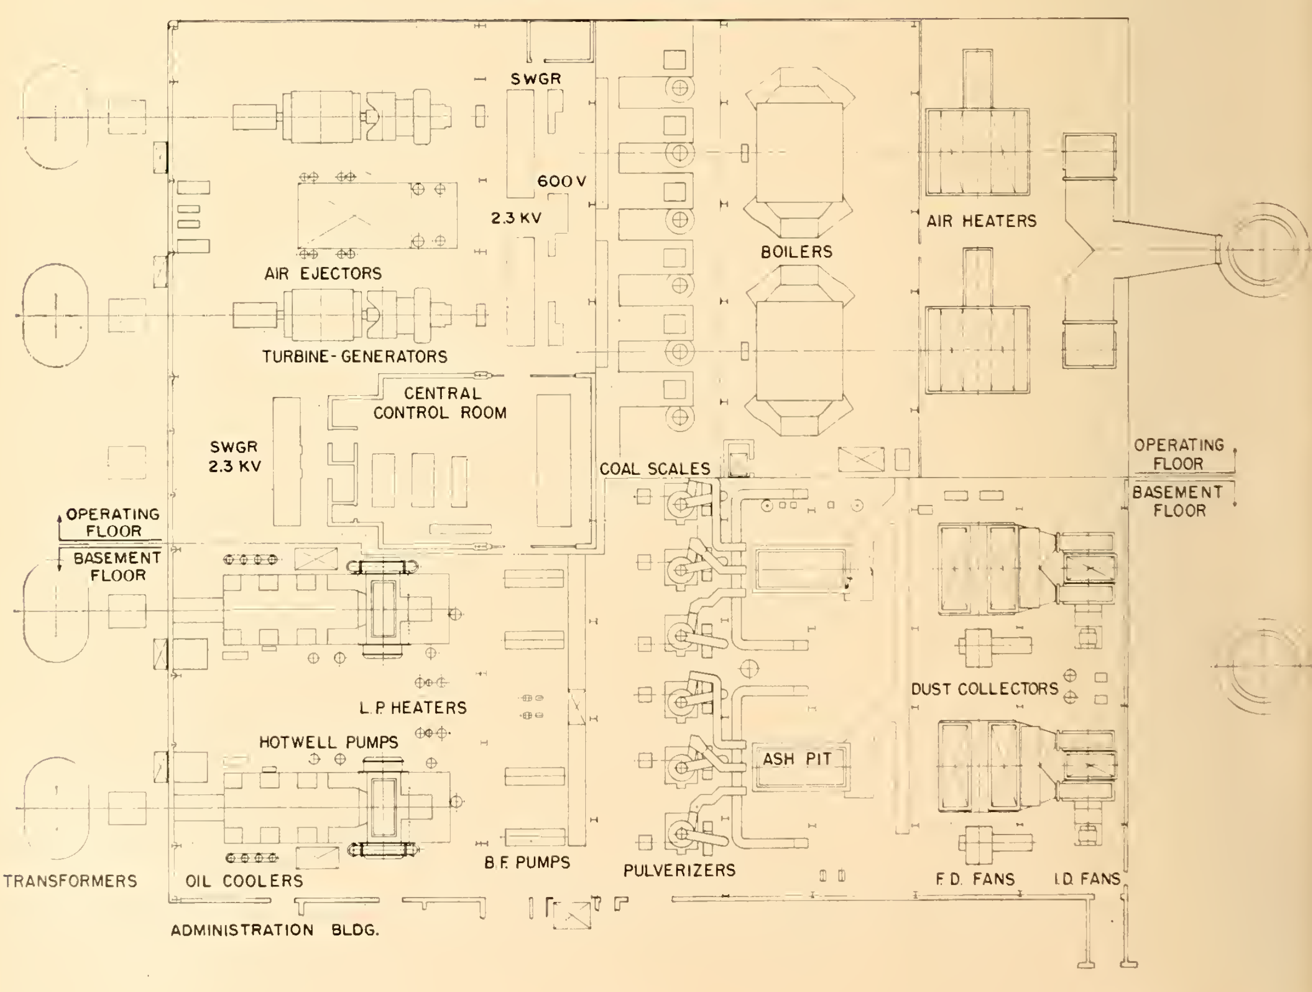
	Normal	*Worst*
Moisture	33.5	40.0%
Volatile material	26.0	21.5%
Fixed carbon	32.0	26.5%
Ash	8.5	12.0%
	100.0	100.0%
Sulphur	—	0.7%
Btu per pound (as fired)	7,100	5,900
Ash softening temperature	—	2,050° F
Grindability (Hardgrove)	55	50

It will be noted that this fuel has a very high moisture content and a correspondingly low heating value. Practically all of the moisture is in the *inherent* form. Surface moisture in the fuel is usually quite low and, in fact, the dust problem is somewhat greater with Saskatchewan lignite than with more usual fuels.

While at the time when the Brandon Station was designed there had been considerable experience in the use of Saskatchewan lignite on travelling grate and spreader type stokers, very little information was available on its use in pulverized fuel installations. The information that was available seemed to indicate that it presented no special difficulties although its behaviour was in some respects different from other fuels.

With bituminous coals it is generally necessary to supply air to the pulverizers at a temperature sufficiently high so that all of the moisture in the coal can be evaporated and the coal-air mixture delivered to the burners at a temperature of 150-160°. If this were true of lignite an extremely high air temperature would be required. However, information obtained from plants burning North Dakota lignite indicated that this fuel could be pulverized and burned

Fig. 3. Brandon Generating Station—plan.



quite satisfactorily while still retaining the greater part of its inherent moisture. The coal-air mixture in such installations may leave the mills at temperatures of 110-120° F.

Approximately at the time these units were purchased, tests were carried out on several car loads of Saskatchewan lignite in the plant of a power and light company at Aurora, Minnesota. The results of this test, which were reported in the December 1954 issue of *Combustion,* served mainly to confirm what was already known about the burning of lignite, and provided much of the detailed performance information on which the design of the Brandon boilers was based. No difficulty was experienced during the test in changing over from bituminous coal to lignite nor was any difficulty encountered in operating the pulverizers at maximum capacity with the pulverized fuel retaining as much as 26% moisture. There were some indications that fouling of the furnace walls took place somewhat more rapidly than with bituminous coal, but this did not appear to be a serious difficulty.

Due to the somewhat greater experience with this type of equipment, some consideration was given to the installation of spreader stokers at Brandon. However, this would have meant either that stokers of unusually large size would be required or that two boilers per turbine would be needed. Neither of these alternatives seemed particularly attractive, and since the information available indicated no real problems in the burning of pulverized lignite, the decision was made to install pulverized fuel units.

The units installed are quite conventional and include three bowl type mills per unit supplying tangential burners. Furnaces were designed for a heat release of about 90,000 B.t.u. per sq. ft. of furnace envelope. Provision was made for the installation of furnace wall soot blowers, but these were omitted from the initial installation with the thought that they could be installed later if experience proved them necessary. Air heaters were designed to supply air to the pulverizers at 620° F, and this was thought to be adequate for satisfactory pulverizer operation. However, provision was made for the installation of ductwork to permit hot gas to be withdrawn from the furnace bottom and mixed with the primary air if this should prove necessary or desirable.

Low heat content of the lignite

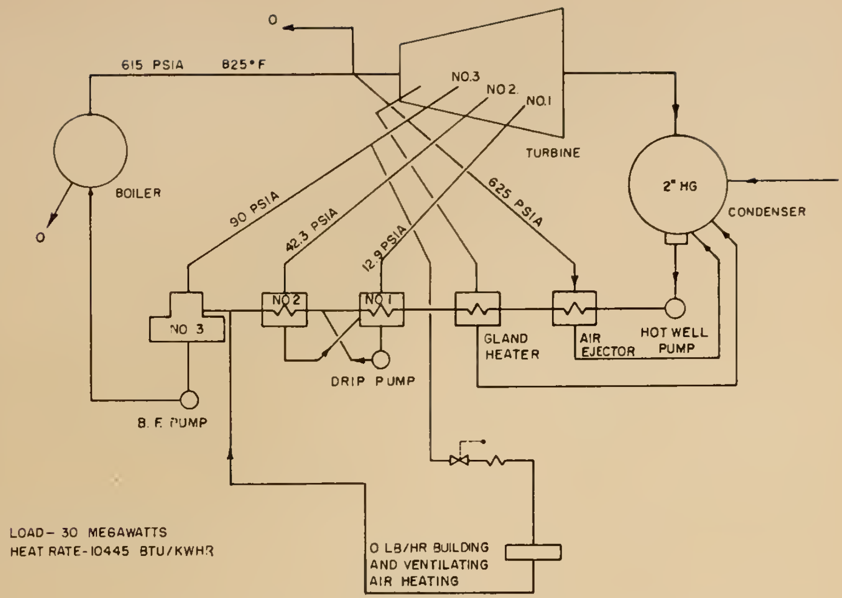


Fig. 4. Brandon Generating Station—cycle diagram.

necessitated the provision of an unusually large coal-handling system and bunkers. Based on a maximum daily load factor of 80%, the estimated maximum coal consumption is 2,400 tons per day, and the coal conveying system is designed for a capacity of 400 tons per hour, thus providing for one-shift operation of the coal-handling system.

All the coal is brought in by rail in bottom dump cars, and a car shaker is provided to expedite the unloading and facilitate handling of frozen coal. A stocking-out conveyor permits the stock piling of coal. Coal in the stock pile is handled with conventional mobile equipment such as bulldozers and carry-all scrapers. The coal bunkers have a capacity of 3,000 tons which is sufficient for 30 hours operation.

Centralized Control Room

All the main controls for the four units, switchyard, and common auxiliaries are located in the central control room on the operating floor between units Nos. 2 and 3. This room is air conditioned, and care was used in selecting materials and construction to reduce the noise level as far as practical.

No attempt has been made to provide for complete remote control of the plant. However, sufficient instruments are installed to permit the control room operator to direct operations in the plant by means of a *PAX* telephone and paging system. Such an arrangement permits a considerable reduction in operating staff since operators outside the control room need not be stationed in fixed locations, but are available to carry out duties in any part of the plant as directed by the control room operator. The reduction of staff is believed to be more than sufficient to pay for the added cost of centralizing the controls in this fashion.

The boiler and unit control panel is of the walk-in type with all control switches and manual controllers on the bench section forming an integral part of the panel. Furnace flame viewing television units, drum water level indication, annunciators, as well as all the necessary indicators are located on the vertical front portion of this panel. Three miniature recorders for each unit for steam-flow air-flow or gas-flow air-flow, drum level and steam temperatures are also located on the front portion. All recorders which are not required for normal operation are located on the back of the panel. Fig. 5 shows the front of this panel.

This arrangement has several advantages. The space required for the instruments and controls is reduced to a minimum as may be noted from the fact that the instruments and controls for four units and the common auxiliaries are grouped on a panel with a total length of 31 ft. 1½ in. Also, this arrangement permitted shipping the panels with all instruments and control relays, etc., completely piped and wired to terminal points at the bottom of the panel at a considerable reduction of field installation time and cost.

The combustion controls are of the conventional pneumatic type.

Although it is not possible to start up a unit from the central control room, most of the necessary controls have been provided for normal operation. These include controls for starting or stopping of boiler feed pumps, condensate pumps, fans, pulverizers, igniters, etc. Boiler purge interlocks and other safety features have been incorporated in the system to ensure safe operation under all reasonable conditions. Initially, coal failure alarms were provided which operated from the mill coal feeders and the coal scales. Recent experience has shown that a satisfactory indication of flame failure can be obtained from furnace draft, and the fuel systems have been interlocked with the furnace draft.

Heating and Ventilating System

The heating and ventilating system for a steam power station has two main purposes:

(1)—To maintain comfortable temperature conditions for the operating personnel.

(2)—To provide combustion air to the units.

The two functions may be treated separately in which case air for the forced draft fans may be brought in directly from the outside, heated and delivered to the unit while a separate system provides heat and ventilation for the plant; they may be combined in such a way that the forced draft fans withdraw air from the building and provision is made for introducing an equivalent amount of air at the proper temperature into the building; or some combination of the two schemes may be adopted. At the Brandon Station the second arrangement, combining the two functions, is used. Its advantages in producing more uniform building temperatures, due to the large volume of air passing through the plant, was felt to justify the somewhat greater cost.

The arrangement of equipment is indicated on the cross section and includes fresh air intakes at a point just above the turbine room roof, recirculated air intakes at the top of the boiler room and plenum chambers, heating coils and fans supplying air to the turbine room. From the turbine room some of the air passes across the building to the forced draft fan inlets and some flows upward to the recirculated air intakes.

Heat when required is supplied primarily by steam heating coils taking steam from the top extraction point on the turbine. Since the fans and heating coils are arranged on a unit basis, condensate from these coils can be returned directly to the main unit condensate system.

When all main units are shut down or operating at very low loads, the pressure at the turbine extraction point is not sufficient to supply the necessary heat, and it is necessary to provide some alternative source. In the Brandon Station a hot water heating boiler operating at atmospheric pressure is used. As compared to a steam boiler this has a number of advantages. Most important are:

(a)—Such a unit can be operated safely and completely automatically without attention from the operating staff.

(b)—By using hot water as the medium for distributing heat to the units that are out of service, cross connections between the steam and condensate systems of different units can be avoided.

When one or more turbines are in operation, it is more economical to supply all of the heat from these units rather than from the heating boiler. To permit this to be done, hot water converters are provided. supplied with steam from the turbine extraction.

The office section of the plant is heated by means of the same hot water system that supplies the main plant.

To provide additional ventilation in the summer period, a number of roof ventilators are installed in both the turbine room and boiler room.

Station Electrical Features

Fig. 6, shows the essential features of the plant. There are four main voltage levels utilized, which are broadly broken down as follows:

13,800 volts — Generator output voltage.

2,300 volts — For heavy auxiliary motor drives.

550 volts — For lighter duty auxiliary motors.

110/220 volts — For lighting and small auxiliary motors under $\frac{1}{4}$-horsepower.

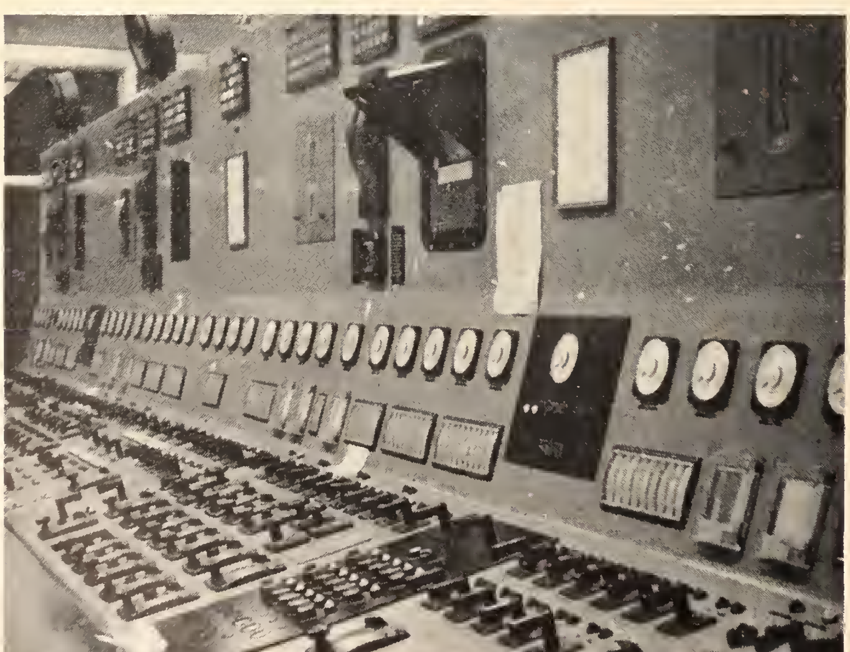
The main generator voltage is stepped up to 115 kv. for connection into the high-voltage distribution system. Provisions were made in the original design for additional 115 kv. lines and for a future 230 kv. expansion without major modifications to the existing layout.

In normal operation all unit auxiliaries are supplied with power by the unit, and auxiliary power requirement with the unit operating at full load represents about 6.5% of the generator output.

Alternators

For purposes of design it was considered that the generator and its associate step-up transformer would be considered a unit. Although the generator output voltage is 13.8 kv., it is immediately stepped up to 115 kv for utilization or distribution in the switchyard. The turbines and

Fig. 5. Front of boiler and turbine control panel.



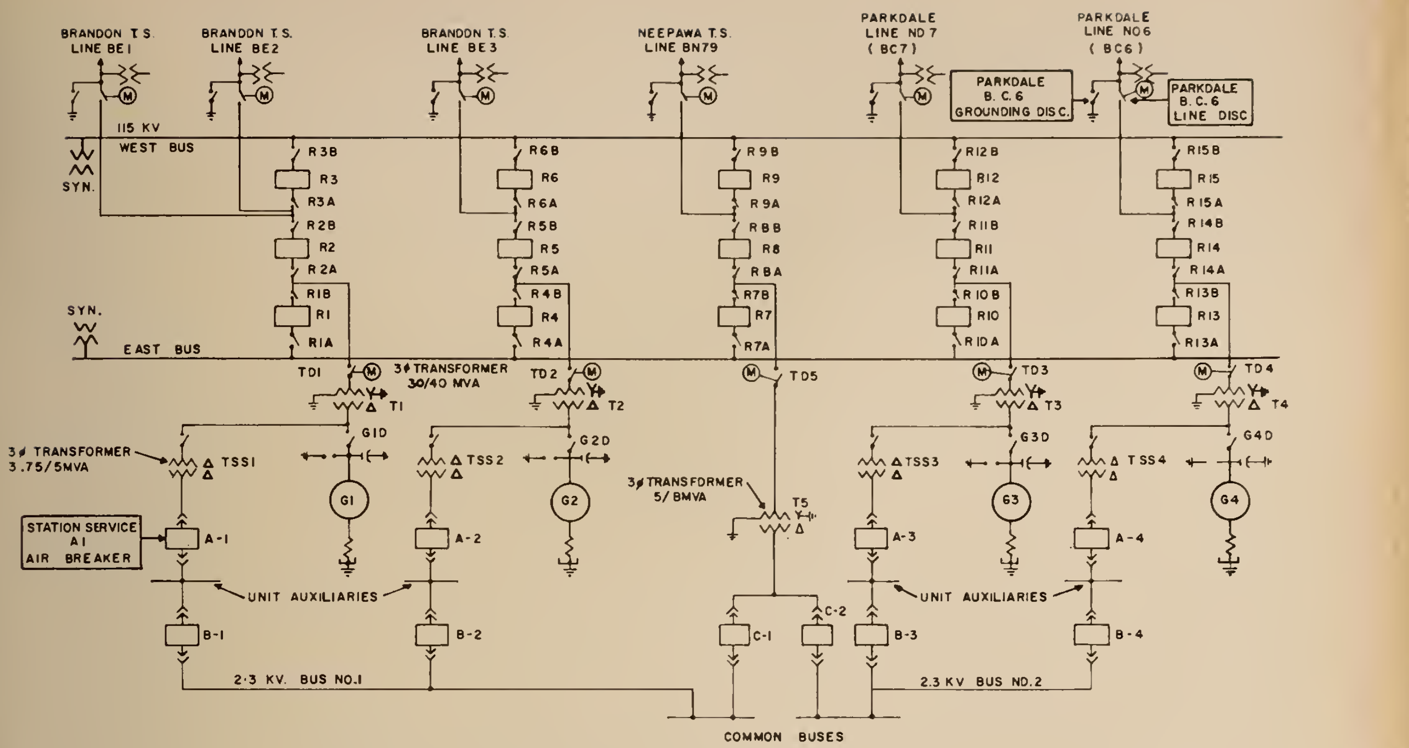


Fig. 6. Brandon Generating Station—electrical single line diagram.

alternators have a rating of 33,000 kw. The unit main transformers are three-phase transformers rated at 30,000-40,000 kva. The output of the unit transformers is connected to the high-voltage bus. The switchyard itself is termed an element and one-half bus which is becoming extremely popular on this continent because of the ease with which various elements may be removed from service for maintenance. The schematic diagram covering the high-tension features of the switchyard are also covered on Fig. 6.

The short circuit ratio of the Brandon generators is 0.8 which is common for machines built in this country, but a short circuit ratio of 0.5 is more usual in machines of European design. A short circuit ratio of 0.8 results in a low reactance machine and inherently greater system stability. Network analyzer studies indicated this to be desirable.

The high-voltage breakers located in the switchyard were among the first high rupturing capacity air blast breakers manufactured in Canada. At the time of purchase this type of high-voltage breaker was the only one manufactured which had the protective current transformers built into the breaker. This resulted in a considerable saving in switchyard structural steel. The rupturing capacity of these breakers is rated at 3,500 mva. with a total interrupting time to arc extinction of 5 cycles.

As with any station of this type, the design of the excitation system for the generators must tie in closely with system features. The voltage regulators associated with the generator exciters at Brandon are of the continuously acting static type. In this particular case, magnetic amplifiers were used to control the generator terminal voltage conditions through exciter auxiliary *boost* and *buck* windings. It was found that by adopting this type of control that pilot exciters were not required, at a considerable reduction in equipment and cost.

Generator Protection

The relay protection for the generator is generally consistent with that found in plants of this type on this continent and consists of the following:

(a)—Overvoltage protection
(b)—Voltage restraint overcurrent protection
(c)—Differential protection
(d)—Field ground protection
(e)—Reverse power protection
(f)—Negative sequence protection
(g)—Loss of field relay protection.
(h)—Station ground protection.

There are also two other types of relaying in connection with the voltage regulator such as underexcitation limit relay and a discriminating relay for protection of the generator and the system in case of a potential fuse failure on the regulator system.

Transformers

There are two types of transformers employed at the Brandon Generating Station. These are oil-filled, fan-cooled outdoor transformers and air-cooled indoor types.

The oil filled types were employed for the main unit transformers and the unit auxiliary transformers. Except for the two supplying the circulating water pump house, all step-down transformers from 2,300 v. to 550 v. and from 550 v. to 110 220 v. are of the air cooled type, and are located inside the power house where temperatures are relatively constant. The two 2,300 500 v. step-down transformers supplying the circulating water pump house are of the oil filled type.

Auxiliary Power

The induced draft fans, forced draft fans, boiler feed pumps, pulverizers, and other unit auxiliaries are supplied from the generator output on a unit basis. Obviously it is necessary to start the unit with power obtained from a station service or start-up transformer. This start-up transformer also supplies such common services as the circulating water pumps, cooling tower fans, coal-handling equipment, etc. This means that after a unit is supplying power it is necessary to *throw over* the unit auxiliaries from the start-up source to the unit source. This is accomplished at the Brandon Generating Station by the *dead transfer method*, so that when one source is tripped off there is a 45 cycle time delay before the second source is closed in to re-energize the motors. It has been proved by tests that after a 45 cycle delay the residual voltage due to the running motors has sufficiently decayed to allow a smooth restart-up to occur. This method of transfer makes a transfer scheme extremely flexible in a station of this type, and keeps the system relatively simple as no synchronizing of power sources is required.

There is, however, the inherent problems of drop out of low-voltage magnetic motor starters with the delayed transfer method. This problem was overcome by use of *latched in* starters so that the motor contactors remain closed during the transfer and all motors are re-energized automatically.

Remote Control

The water treating and coal-handling equipment are not controlled from the central control room, but rather are controlled from local control centres located within the water treatment building and crusher house respectively. The controls for all 550 v. auxiliaries located within the main plant have been centralized in the central control room using a 120 v. a-c. control voltage.

All 2,300 v. motors are controlled by means of the 250 v. d-c. station battery. As mentioned previously, there are several remote buildings containing motor drives whose operation are dependent on general plant conditions and which it is desirable to control from the centralized control room. In order to overcome the excessive voltage drops encountered by using a-c. control voltages, it was decided to use the station battery voltage of 250 v. d-c. for the control of all motors in remote buildings. This remote control covers such items as the raw water pumps, the cooling tower fans, etc.

One interesting feature is the control of the cooling tower fans. There are 24 fans on this tower, each capable of being run at slow speed and fast speed forward, and at a slow speed only in the reverse direction. Since the circulating water system is arranged to supply water to the cells in groups of four, the fan controls are also arranged in the same groups of four. In this way only six control switches are required in the central control room, although indicating lights are provided to show the fan speeds and the total number of fans in operation. Controls are provided at the cooling tower to permit individual control of each fan for maintenance or other purposes.

Station Batteries

The main station battery has an output voltage of 250 v. d-c. used mainly for circuit breaker control. There is also a stand-by battery of the same capacity, and throwover facilities are available to use the standby battery as the station battery, if required.

Emergency lighting and essential auxiliaries are also carried by the station battery in case of a-c. failure. This lighting is sufficient to permit plant operation on failure of normal lighting services. A 48 v. battery is also provided for annunciation purposes.

Communications

The plant has been equipped with an internal *PAX* telephone system for communication within the plant. This system can be tied in by use of a carrier system on the transmission lines for communication with the Winnipeg office. In conjunction with the *PAX* system is a paging system by which any telephone within the plant can be used to issue operating orders.

Operating Experiences

The first unit of the Brandon Station went into service in November 1957, and the fourth and last unit was commissioned in September 1958. Operating experiences to date have disclosed no serious difficulties.

Although there was some fear in the beginning that lignite might be difficult to store because of its tendency to catch fire by spontaneous combustion, this has not proved to be a problem. By compacting the coal carefully when it is put into storage, the tendency to overheat can be completely eliminated. Some minor difficulties were encountered in the early days due to the pile being formed with sides that sloped too steeply to permit proper compaction, but these difficulties were eliminated by simply decreasing the angle of the slope.

Lignite does tend to catch fire if left too long in the bunkers, and care must be taken to see that the storage time does not exceed about two weeks. Due also to its tendency to overheat in the bunkers, a considerable amount of gas is evolved and thorough ventilation of the space above the bunkers is required. This ventilation serves the further purpose of reducing the dust problem which has proved to be quite severe with the fuel encountered to date.

In its burning characteristics lignite has produced no real surprises. The major difficulty to date has been that the furnace tends to foul up rather rapidly with the result that steam temperatures during preliminary operation were excessively high, and there was a tendency for deposits of the bonded type to form in the superheater and convection zone. However, wall soot blowers have now been installed and by frequent operation of these blowers, it is possible to maintain clean surfaces in the furnace. When this is done the other difficulties disappear.

The fly ash from lignite has an unusually strong tendency to adhere to air heater and dust collector surfaces. In the case of the air heaters this has resulted in poorer performance than would be expected with other grades of fuel. In the dust collectors deposits have been experienced on the tube sheets and at the outlet cones of the collecting tubes. To avoid deposits in the latter location the outlet cones have been removed. This probably has the result of reducing the dust collector efficiency to some extent, but this is not considered serious.

As was to be expected, operation of the cooling tower in winter is not without its problems. Winter temperatures in Brandon are below zero most of the time, and fall to 30 below for about 2½% of the time. This results in severe icing, and the problem is aggravated by the intermittent nature of the load that the plant is required to carry.

The cooling tower fans are arranged for two-speed operation and can be reversed for de-icing purposes. While it has been possible by reversal of air flow, by closing the louvers over part of the intake area, and by varying the number of cells in operation, to keep the formation of ice more or less under control, the labour involved has been considerable. Furthermore, cooling water temperatures have been higher during the winter months than would be desirable. It is expected that further experience in cold weather operation will develop ways and means of improving these conditions.

CBC TELEVISION NETWORK PROGRAM DELAY CENTRE

G. E. Waters, P.Eng., A.M.I.E.E., *Supervising Engineer, Plant Department, Canadian Broadcasting Corporation, Montreal, Que.*

This paper discusses the geographical problems which prompted the Canadian Broadcasting Corporation, at the beginning of 1956, to undertake the project of providing a center along the coast-to-coast microwave network at which television programs could be delayed and later re-broadcast. Decisions which had to be taken regarding the quantity and layout of the equipment required are discussed, together with the problems attendant upon a double replay at closely spaced intervals.

The performance of the system is assessed, insofar as this is possible with equipment which has been in use barely six months, and mention is briefly made of the staff requirements for such an installation.

INTRODUCTION

IN A LAND as vast as Canada, problems arise in radio and television network operations which are not met in geographically smaller countries. Canada spans the North American continent from Newfoundland (longitude 55°W) to Vancouver Island (longitude 125°W)—a distance of approximately one fifth the circumference of the earth at the 49th parallel—and thence still further westwards to the Yukon (longitude 135°W).

Consequently, in Television Network operations a program' timing problem becomes apparent since there is a total time difference between Newfoundland and Vancouver of four and one half hours, which in

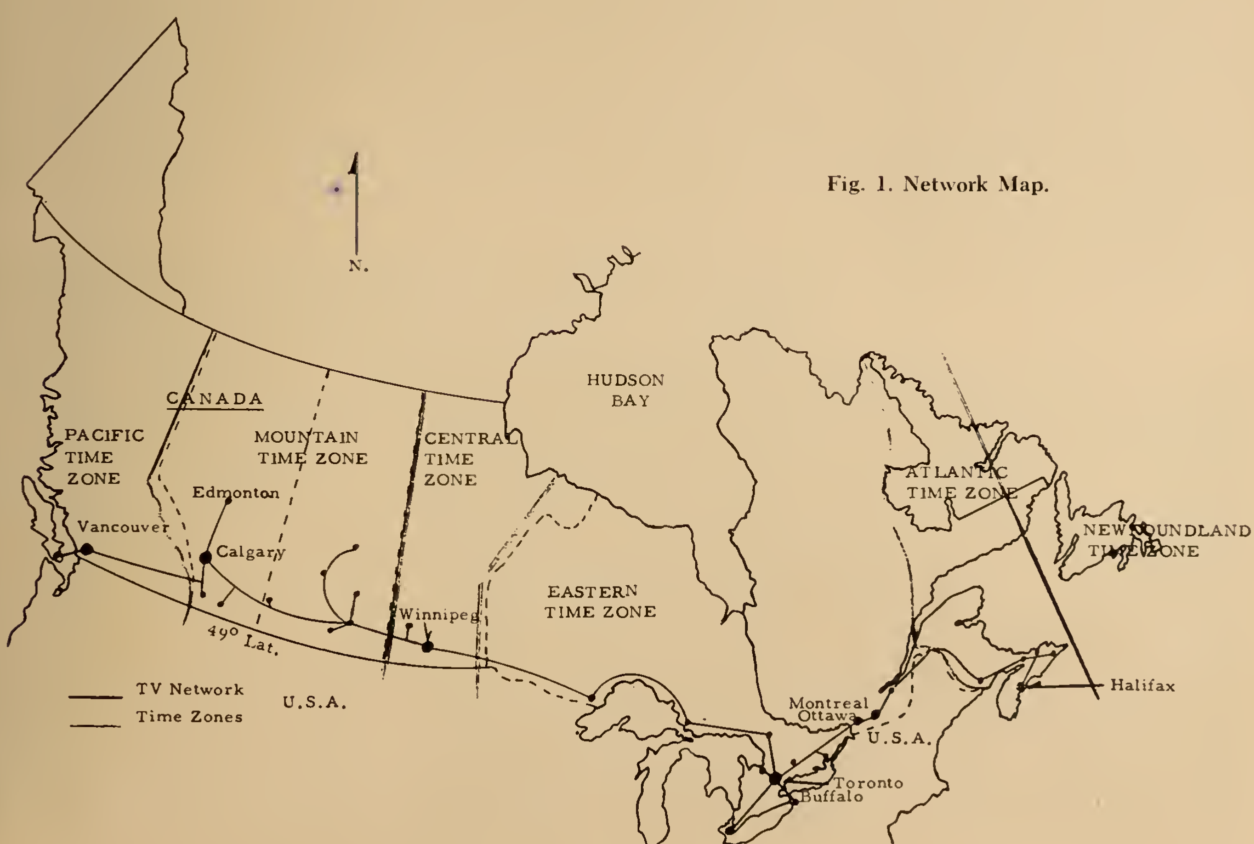

Fig. 1. Network Map.

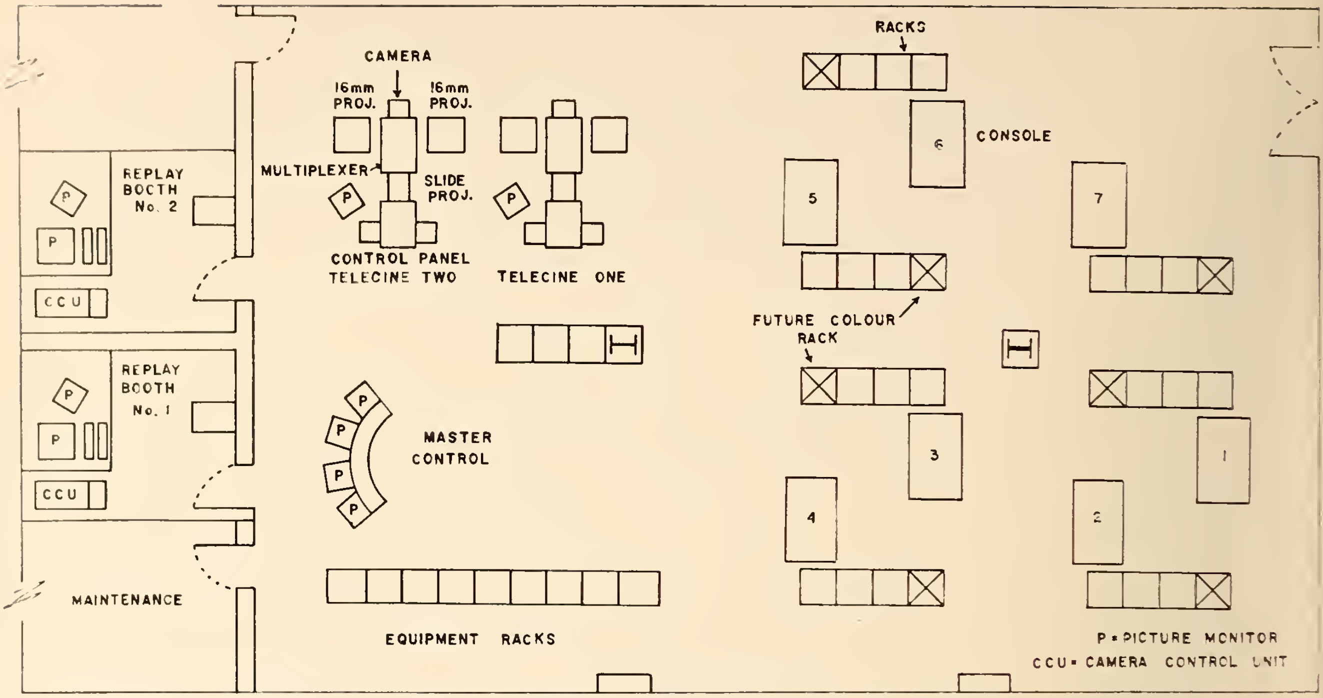

Fig. 2. Equipment Layout.

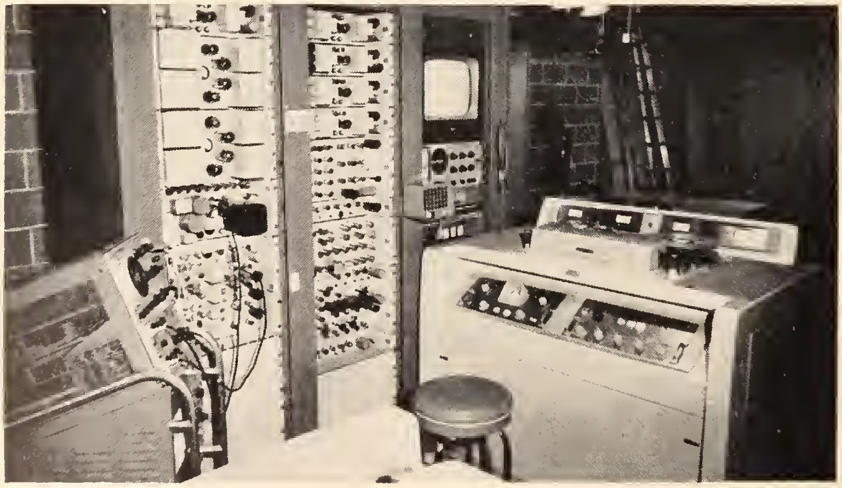
turn is divided between six time zones (see Fig. 1).

The majority of the English language television programs carried on a network basis originate in Toronto, and this is also the point of entry into the Canadian network for programs originating in the United States. Because of this, for the purposes of program timing all zones westwards are referred back to Toronto (i.e. Eastern Standard) time. The Maritime Provinces on the east coast are one hour ahead of Eastern Standard Time, while Newfoundland is one and one half hours ahead. The major problems arise when programs are fed westwards along the microwave network as far as Victoria, British Columbia, where the time is three hours behind Eastern Standard Time. Clearly, any future extension of the network into the Yukon will compound the problem by an additional one hour time difference.

In order to compensate for these time zone differences it is desirable to provide some method of recording programs. This would permit a program being aired at, say, 8 p.m. in the Eastern Time Zone (the peak evening viewing period) to be rebroadcast at 8 p.m. in the Mountain Time Zone (two hours later) and also at 8 p.m. in the Pacific Time Zone (three hours later). This point assumes considerable importance when viewed in the light of the saleability of air time to sponsors of the bigger commercial *spectaculars*.

Fig. 3. Video Tape Recorder.



To complicate matters still further, the timing pattern outlined above is subject to variation during the summer months, since stations in the Province of Alberta remain on Standard Time, while most stations in Saskatchewan and British Columbia change to Daylight Saving Time by advancing their clocks one hour. Further variations arise during the fall when western Canada has reverted to Standard Time while eastern Canada remains on Daylight time until the end of October. During this latter period, delays of three hours for the Mountain Time Zone and four hours for the Pacific Time Zone must be provided.

Alternative methods of providing the required delay

It was with the foregoing complexities of program timing in mind that thinking proceeded in the early part of 1956, directed towards possible methods of providing the required time delays. At that time the only proven and practical method of recording television programs for subsequent rebroadcast was by film—i.e. the well-known kinerecording system. Provisional plans were drawn up for a system incorporating kinerecorders, rapid film processing facilities and rebroadcast by means of a telecine film chain. From the start it was apparent that such a system would be complicated, unreliable and expensive to operate. In addition, studies indicated that it would only just be possible to operate with a minimum delay of two hours between recording and rebroadcast.

In April 1956 the Ampex Corporation of California demonstrated a prototype video magnetic tape recorder and it was immediately apparent that herein lay the solution to television network delay problems. Nevertheless almost two years were to elapse before the prototype video tape recorder had been developed into a production machine capable of being integrated into a television system.

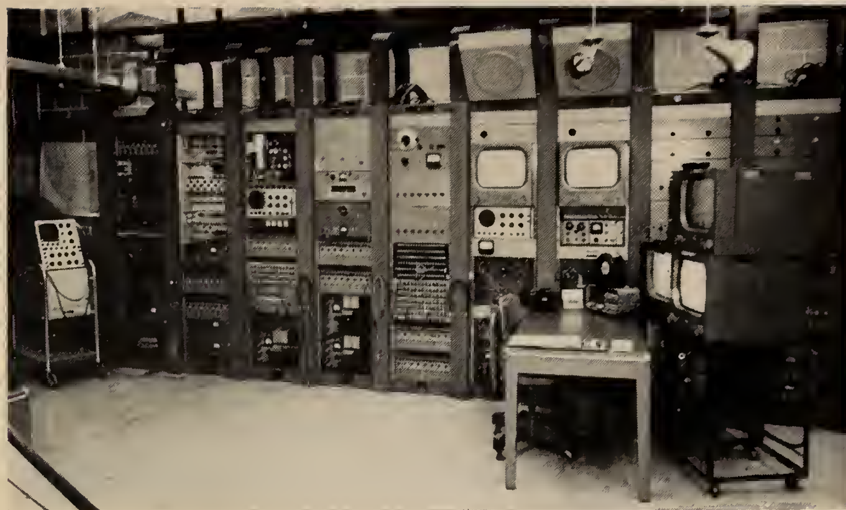


Fig. 4. Test Facilities in Master Control.

Selection Of Delay Centre Location

Meanwhile, the management of the Canadian Broadcasting Corporation had been making a detailed study to determine the optimum location of the proposed TV Network Delay Centre. Problems of capital cost, running costs, duplication of Network facilities, staffing, etc. were all considered and eventually the City of Calgary, in Alberta, was decided upon as the most suitable location. Reference to the network map will show that Calgary is located on the main microwave network at the junction of the northern leg to Edmonton with the western leg to Vancouver.

Thus it was decided to set up a Television Network Delay Centre which would be a vital part of the Canadian Television System, and in January, 1958 some 5000 sq. ft. of space was leased in the newly completed Alberta Government Telephone building in Calgary for this installation. This proved to be a happy choice, since power and lighting were available and the air conditioning equipment was already installed; furthermore, the TV Network microwave operating centre in Calgary was housed in the same building, three floors above the space leased for the Delay Centre.

Building work began in mid-February 1958 and was completed by the 1st of April, when installation of the technical equipment commenced. The operational target date was already fixed for July 1st, 1958, at which time the last section of the microwave network from Calgary to Vancouver would be completed and ready for use.

Equipment Layout and Installation

In planning an installation of this nature—the first of its kind in the CBC system, some problems concerning equipment layout presented themselves. At first it was thought to be desirable to isolate pairs of machines in separate rooms, and similarly to have the Master Control located in a room of its own. However, after considering such factors as sound isolation, personnel supervision, partitions and so on, it was decided to locate all terminal and recording equipment in one area, but to so arrange the layout that partitions could readily be provided later if required. This layout is shown in plan view in Fig. 2.

Fig. 5. Replay Booth.

Seven Ampex VR1000 video tape machines have been installed; six of these were operational for the commencement of the service on July 1st, 1958, the seventh coming into service a few weeks later. Six tape machines are essential for the continuous recording and double replay required to feed approximately fifteen stations on this section of the network. The seventh machine is provided as a standby in case of failure of any of the six in service.

Each video tape machine is provided with both audio and video monitoring facilities. Incoming network, and audio and video test signals are fed to all machines at all times. Pushbutton selection of the desired feed is made at the individual machines.

As received from the manufacturer, much of the equipment was mounted in standard 19-in. equipment racks. In the light of previous experience it was deemed advisable to relocate the equipment in racks specially designed by the CBC engineering staff to provide improved and controlled ventilation of the equipment. Fig. 3 shows a close up of one of the video tape recorders and its associated equipment.

Two telecine chains have been installed, and each chain comprises a vidicon camera, two 16 mm film projectors and a 2 in. x 2 in. slide projector. These chains are intended primarily as a safeguard against network failure anywhere between Toronto and Calgary. Should a failure of an hour or more occur, then both the two hour delay network and the three hour delay network must, each at the appropriate time, be fed with a standby film program. Additionally, an appropriate slide may be inserted in the outgoing feeds to either of the two networks to cover short breaks, programs underrunning, etc.

Special test facilities, shown in Fig. 4, installed at the delay centre include a multiburst Frequency Generator, Window Generator and Stairstep Generator. These signals, together with the familiar Indian Head pattern derived from a monoscope are used for testing both networks.

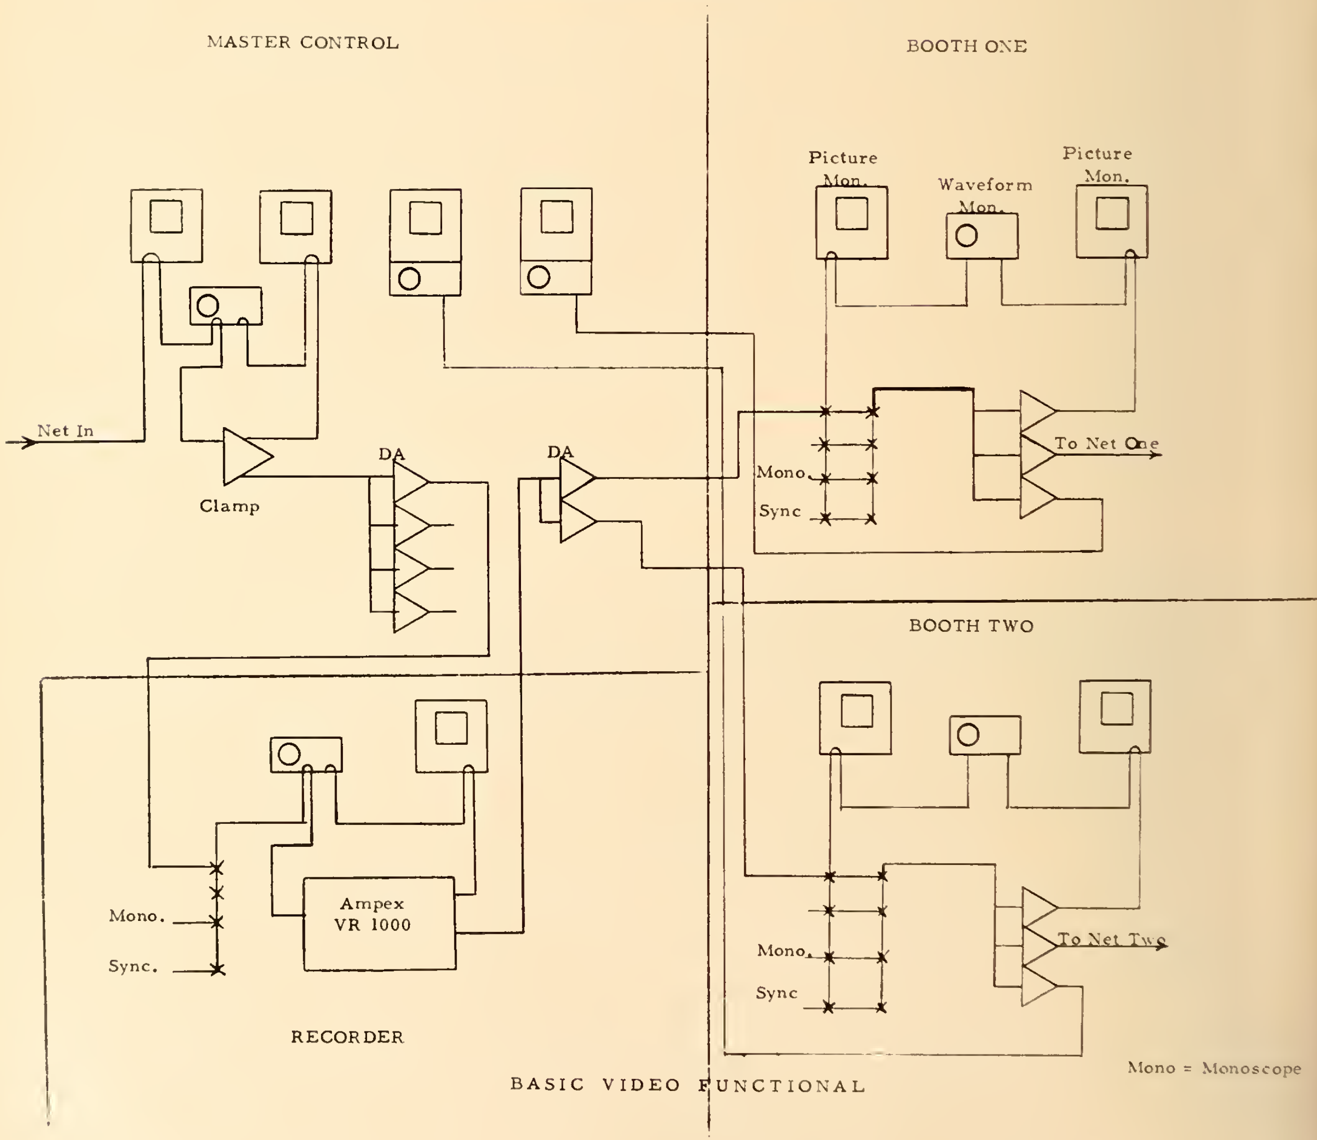
Stabilizing or line clamp amplifiers are available at the Master Control position in order that any degradation of the incoming video signal may be corrected before the signal is fed via distribution amplifiers to the Ampex video tape recorders. Similarly, the audio signals from the network are fed to a line amplifier incorporating a VU meter to permit adjustment of incoming audio signal level.

A high grade picture monitor and a waveform monitor are bridged across the incoming line, which is terminated in the stabilizing amplifier. A picture monitor and a waveform monitor are also fed from the monitoring output of the stabilizing amplifier prior to being fed to the video tape recorders. Picture smearing, for example, may be apparent on signals being received from the network and it is imperative that such a condition be observed and promptly rectified; monitoring both before and after the signal passes through the stabilizing amplifier gives the Master Control operator an immediate clue to the source of such trouble.

Two synchronizing signal generators with changeover facilities have been provided, although their function is of a secondary nature, since the video tape recorders derive their sync pulses from the incoming signal. However, the telecine chains, monoscope and test signal generators require locally generated sync pulses.

Locally generated sync pulses are fed to each video tape recorder to perform two functions. One function is to provide a reference timing signal for accurate replay of the re-

Fig. 6. Functional Diagram of System.



corded programs. Although the 60 cps power line frequency is normally sufficiently accurate for controlling replay speed, occasions have arisen when violent fluctuations of supply frequency in Calgary have caused the tape machines to lose tracking, with consequent disintegration of the picture. For the second function a sync signal is fed to one position of the input selector switch of each tape machine so that on completion of a recording the input may be switched to record only sync pulses for a short period. This ensures that on completion of the replay of a program sync is continued. As an additional safeguard, the sync signal is also fed to the replay booths for switching to the network during station breaks.

Two replay booths are provided adjacent to the Master Control position; these booths have facilities for switching between program sources —i.e. the seven video tape machines, telecine, test signals and sync. Since all the tape machines replay non-synchronous signals, mixing and fading between machines cannot be carried out and it was not, therefore, necessary to provide such facilities in the booths. Simple relay type switches are employed. Each replay booth is equipped with a picture monitor and a waveform monitor for monitoring the outgoing video signal, while a VU meter and loudspeaker provide similar facilities for the audio component of the program. These audio and video monitoring facilities are duplicated for preview purposes. No audio console is provided as each incoming feed to the booth is a complete program fed at the standard level (for video tapes) of + 4 VU and audio selection is accomplished by relay switching, the relays being actuated by a 24 volt supply controlled by additional contacts on the video switcher. By appropriate acoustic treatment the booths have been made suitable for critical subjective monitoring of the outgoing program audio quality, and this is one of the most important functions of the booths. Fig. 5 illustrates the operating position in a booth, showing the equipment installed.

In order to ensure accurate program timing, a crystal oscillator clock unit which delivers a 60 cps frequency has been installed. The secondary clocks are fed from the crystal-derived 60 cps supply via a 30 watt amplifier. A receiver permanently tuned to station WWV, is also installed to provide a constant check on the accuracy of the clock system.

Fig. 7. Master Control Monitoring Facilities.

An office type intercom provides communication between Master Control, the two booths, the seven video tape machines and the two telecine chains. The intercom equipment located in the two booths and at the Master Control position are master stations, the remaining positions being outstations.

System Performance

The video tape machines have been found to meet the manufacturer's specifications adequately, the frequency response being within ±3 db to 2.5 megacycles and approximately 10 db down at 4 megacycles. The low frequency tilt is less than 2%.

The signal to noise ratio of the video recording equipment is approximately 32 db (peak to peak signal to rms noise). Differences in video heads give rise to some variations, with a trend towards receiving quieter heads from the Ampex Corporation as the heads are returned for renewal.

The linearity of the system is adjustable by means of a white stretch circuit incorporated in the processing amplifier. The incoming signal passes through one stabilizing amplifier and one distribution amplifier before being fed to the recorder. On replay the signal passes through but two distribution amplifiers and a relay switcher before being fed back to the microwave network.

The frequency response of the stabilizing amplifiers is essentially flat to 8 megacycles. By the observance of good engineering practices the performance of the system (external to the recorders themselves) is more than adequate to pass the network signal, having a bandwidth of 4.2 megacycles, to the recorder and to feed the replayed signal back to the microwave network without any deterioration beyond that introduced by the recorder. A functional diagram of the video system external to the recorders is shown in Fig. 6.

Audio response is flat within ±3 db from 50 cps to 10,000 cps from network input to network output, including the recording process.

Normal Operation

As mentioned earlier, the Calgary centre delays programs two hours for the Mountain Time Zone, and three hours for the Pacific Time Zone. The signals are received from Toronto over approximately 2000 miles of microwave network and recorded on one of the Ampex machines. Normally, only one half-hour is recorded per machine, following which a second machine takes over for the next half hour. This may seem surprising in view of the fact that an Ampex video tape recorder is capable of recording programs up to one hour in length. A problem, however, is introduced when two replays are required spaced only one hour apart. It will be apparent that, if a one hour reel of tape is used, the beginning of the second replay will approximately coincide with the end of the first replay. Even allowing for the 90 seconds station break, insufficient time is available for rewinding, cueing, etc. before the reel is replayed a second time.

From the foregoing it will be clear that two machines are required for continuous recording and two more for continuous replay. A third pair

HEAD-LOSS COEFFICIENTS for NIAGARA WATER SUPPLY TUNNELS

J. B. Bryce, M.E.I.C., *Hydraulic Engineer*
R. A. Walker, *Assistant Hydraulic Engineer,*
The Hydro-Electric Power Commission of Ontario.

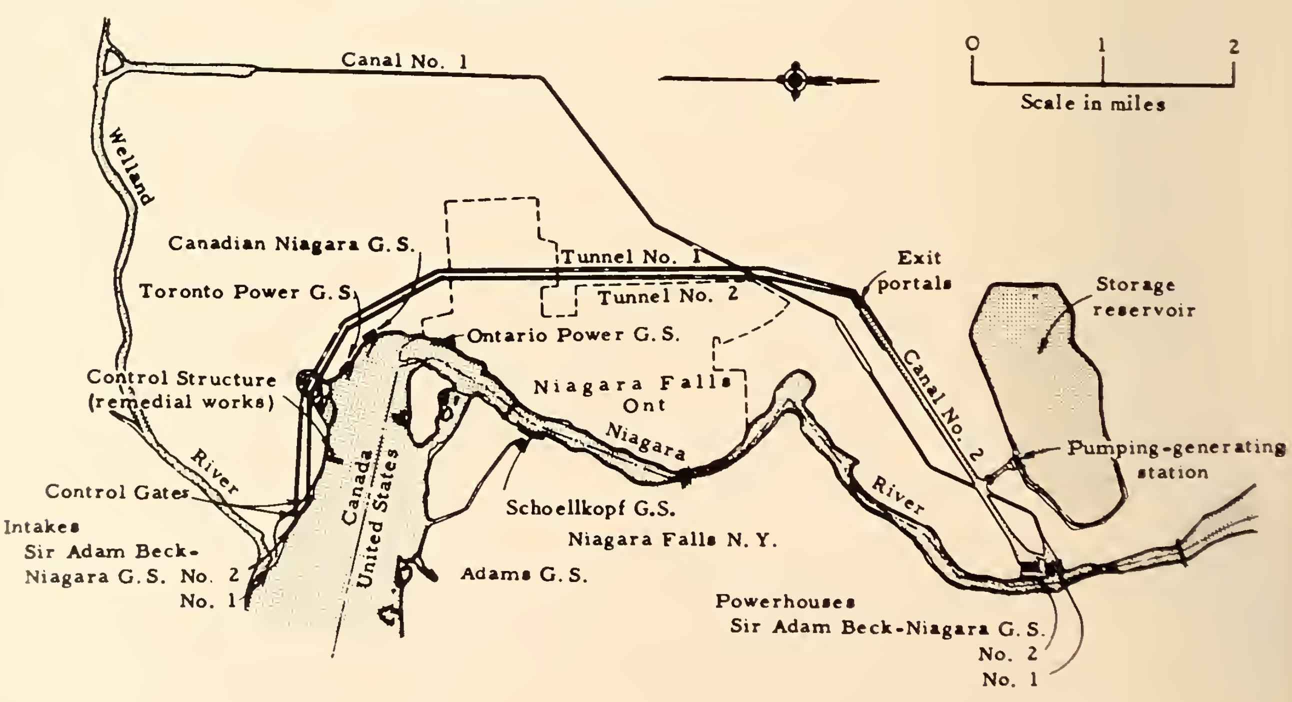
Introduction

Two large tunnels convey the water supply for the Sir Adam Beck-Niagara Generating Station No. 2 from intakes on the Niagara River, some two miles upstream from the falls, to a canal leading to the powerhouse forebay. The tunnels are each approximately 5½ miles long, are concrete lined, and have a finished diameter of 45 ft. During construction 15 piezometer openings were provided in each tunnel to enable tunnel performance, roughness coefficients, and bend loss coefficients to be determined for comparison with design values. The tunnels came into operation in 1954 and a series of field measurements were made to determine the performance of both tunnels. This paper describes the tunnels, the provisions made for field testing, the test procedures, and the results obtained. A comparison with design values is given also.

General Description of Niagara Water Supply System

In Fig. I is shown the general arrangement of the water supply facilities for Ontario Hydro's Sir Adam Beck-Niagara Generating Stations Nos. 1 and 2. The original supply facilities for the Sir Adam Beck-Niagara Generating Station No. 1 (formerly known as the Queenston Development) consisted of an intake on the Niagara River at the juncture with the Welland River, and an open power canal, designated canal No. 1, leading from the Welland River to the generating station. A maximum diversion in excess of 15,000 cfs is carried by this canal system. The

Fig. 1. General plan of Niagara water supply system.



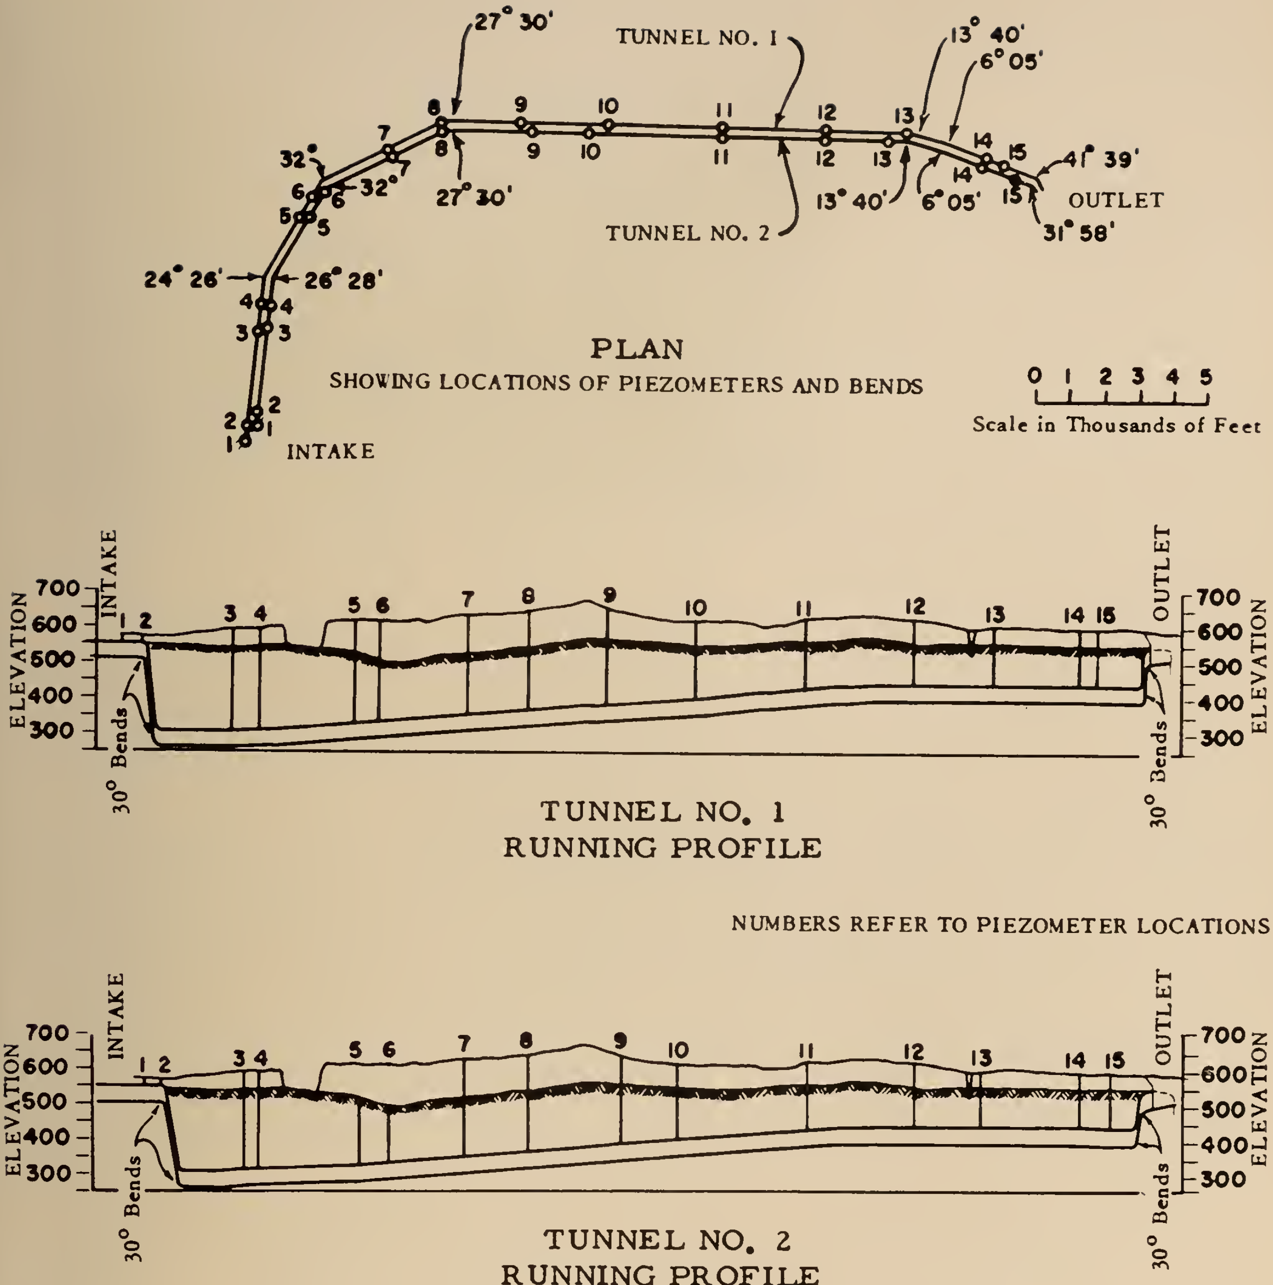


Fig. 2. Plan and running profile of tunnels showing Piezometer locations.

passage of the 1950 treaty between Canada and the United States made possible a redevelopment of Niagara Falls, and the Sir Adam Beck-Niagara Generating Station No. 2 was constructed adjacent to the No. 1 station.

The water supply for the new development is obtained from the Niagara River through two submerged gathering tube intakes located some two miles upstream from the falls and downstream from the original intake at the Welland River. After leaving the intakes, the water supply is conveyed approximately 5½ miles by two large tunnels which discharge through an outlet structure at their downstream ends into an open canal, canal No. 2, which conveys the flow about 2¼ miles to the No. 2 plant forebay. Canal No. 2 crosses the original power canal at the same grade and water level about ¾ of a mile upstream from the forebay, and both forebays are interconnected near their downstream ends. The pump storage plant draws its water supply from canal No. 2 just upstream from the canal crossover. The new water supply facilities can divert a maximum of about 48,000 cfs.

Description of Tunnels

The tunnels were driven through rock at a bore of 51 ft. and were lined with concrete to a finished diameter of 45 ft. The tunnels are parallel to each other on 250 ft. centres, and the geological formation of the area required that the tunnels be generally about 250 ft. below the surface. Tunnel No. 1 which follows the outer course of the river is about 28,800 ft. long, and tunnel No. 2 which follows the inner course is about 28,100 ft. long. In Fig. 2 is shown a plan and running profile of the tunnels.

The alignment of the tunnels required 11 bends in tunnel No. 1 and 10 bends in tunnel No. 2. The one bend less in tunnel No. 2 was due to the ability to combine one horizontal and one vertical bend into one composite bend near the outlet. Based on preliminary experimental work, an R D ratio (radius of curvature to diameter) of 5 was selected for each bend to minimize losses. The locations and deflection angles of the bends included between piezometers are given in Tables I and II.

The concrete lining for the tunnels was poured in two stages, the invert and the arch. The invert portion, forming the bottom segment of 60°, was shaped by a steel screed, wood floated, and steel trowel finished by hand. The arch, which constituted the remaining 300°, was made in one continuous pour around retractable, movable, oiled steel forms, 50 to 85 ft. long. Joints between adjacent pours were first sawn to a ¾ in. width and then filled with a quick setting cement mortar, and any projecting circumferential edges were ground to a 45° bevel. In Fig. 3 is shown a photograph of a portion of tunnel No. 2 with the lining complete.

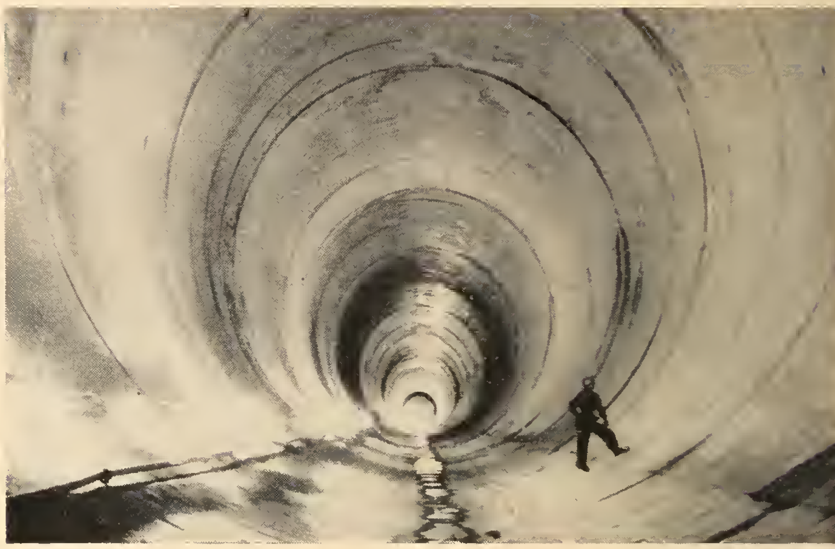

Fig. 3. Interior view of 45 ft. diameter Niagara tunnel No. 2 near downstream end with concrete lining complete.

Design Considerations

In the design of large water supply tunnels such as those provided at Niagara, an accurate knowledge of the roughness coefficients and the bend loss coefficients is of the utmost importance. For a particular flow capacity, the size of the tunnels depends upon the coefficients selected, and the accuracy of the selection governs whether or not the expected flow capacity will be realized. In selecting the roughness coefficient for the Niagara tunnels, it was found that very little data was available on tunnels of these dimensions. A formula proposed by Mr. F. C. Scobey, Consulting Engineer, which was based on an analysis of many tunnels, was considered most applicable and was used for the design.

It was found also that very little comprehensive bend loss information was available for large tunnels. As the alignment of the tunnels was such that a relatively large number of bends was necessary, it was considered that reliable information was required to determine the R D ratio for the bends that would produce a minimum head loss, and to determine the bend loss coefficients themselves. Accordingly, comprehensive experiments were carried out on a 6 in. pipe to determine bend loss coefficients for a range of R D values and deflection angles, and in Fig. 5 the results of these experiments are shown. While it was expected, due to the scale factor, that the bend loss coefficients in a 45 ft. tunnel would be somewhat less than those in a 6 in. pipe, it was felt that the results would be relative and would provide comprehensive and conservative values for design.

Due to the lack of field data on losses in large tunnels, it was felt very desirable to provide permanent means of measuring the losses in the completed tunnels. This would enable the performance of the tunnels to be determined, the loss coefficients to be checked, and would provide a means of detecting any change in performance over a period of time. Accordingly, provision was made for such measurements.

Provision for Field Testing

During construction of the tunnels, 12 in. diameter holes were drilled from the ground surface to the tunnels at approximately 500 ft. intervals along the centre line of each tunnel and were lined with 10 in. diameter steel pipes. These holes, which were used to supply concrete for the tunnel lining, offered an excellent opportunity for the measurement of pressure head in the tunnels. It was decided to convert 26 of these holes, 13 in each tunnel, into piezometer wells. In addition 4 piezometer wells, 2 in each tunnel, were installed near the inlet ends. The locations were chosen such that the pressure head could be measured, insofar as possible, at approximately 40 diameters downstream from each bend, 5 diameters upstream from each bend, and at selected points on the long straight section of each tunnel. The locations of these piezometer wells are shown in Fig. 2, and the details of a typical piezometer installation in Fig. 4. While it was recognized that a piezometer ring would have been superior at each point, the considerable number of necessarily more complex installations were not considered to be practicable.

Description of Testing Equipment

To determine the pressure head at each piezometer, special gauges were constructed to measure the vertical distance from the top of the 10 in. well pipe to the water surface in the well. A weight, suspended on graduated insulated conductor cables, was lowered from the top of the well to the water surface. From the bottom of the weight extended two electrical contacts which completed a circuit when they touched the water surface. An ammeter and battery at the ground surface completed the equipment, the ammeter indicating when the contacts touched the water surface. The elevations of the tops of the well pipes were carefully determined by precise levelling from project bench marks.

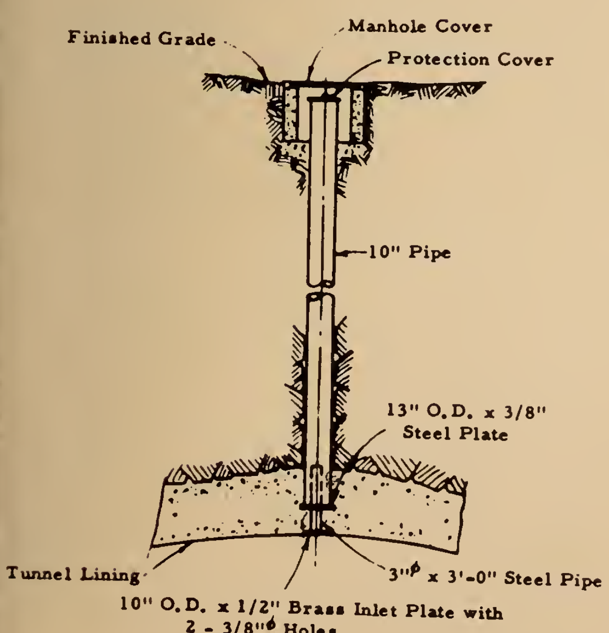

Fig. 4. Details of Piezometer installations.

Test Procedure

In June of 1954 the No. 1 tunnel came into service, and during September and October of that year 5 tests were made on the tunnel at discharges ranging from 13,350 cfs to 24,050 cfs. The test procedure used was to stabilize first the plant forebay level which governed the discharge through the tunnel. When steady conditions had been achieved, measurements of water level in all the piezometer wells were made, and the discharge through the tunnel was measured by current meter in the canal downstream from the tunnel. Each test was of approximately 3 hours' duration, the time necessary to make the current meter measurement. Water levels in the piezometer wells were measured at 5-minute intervals. Using the data obtained in these tests, a discharge calibration of the No. 1 tunnel was obtained by plotting the measured discharges against the measured fall between piezometers 2 and 13. The results of this plot are shown in Fig. 6, where the consistent nature of the relationship between discharge and fall may be noted. It is considered that this relationship provides a sensitive and

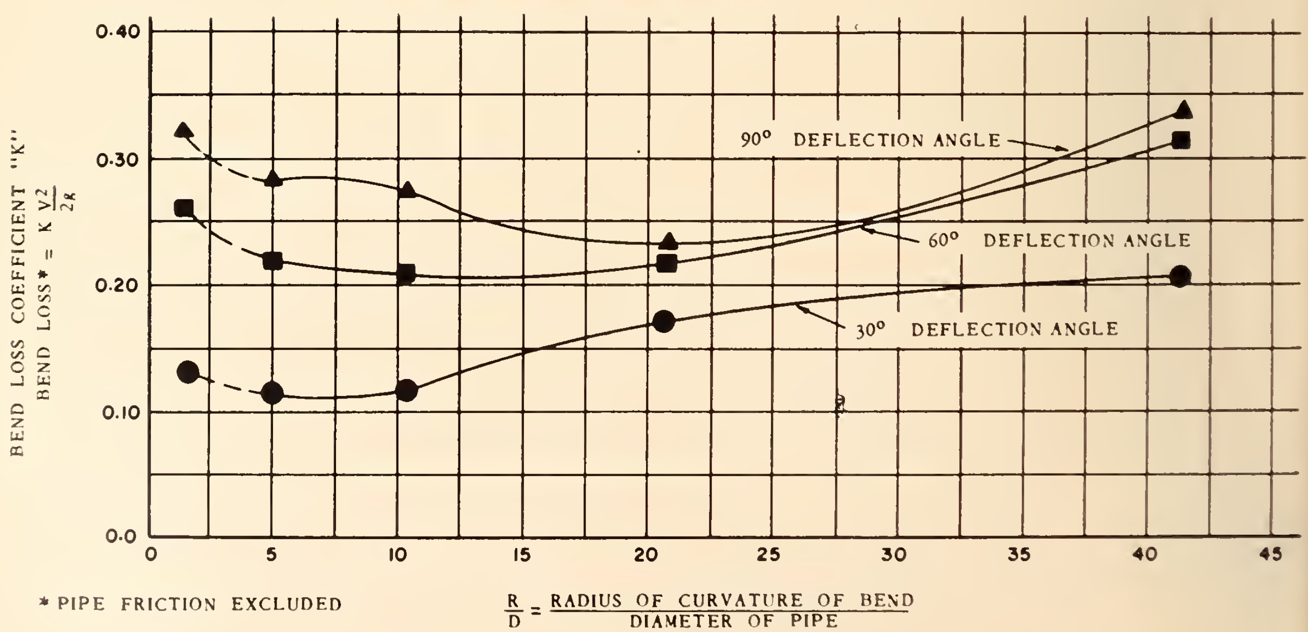
satisfactory meter of the No. 1 tunnel flow.

Tunnel No. 2 came into service during October 1954, and a test with both tunnels in operation was made in November 1955. Sufficient gauges were not available to measure the water levels simultaneously in the piezometer wells of both tunnels. Accordingly, measurements were made first on tunnel No. 1 at 5-minute intervals for 2 hours, and then similar measurements were made on tunnel No. 2 for an equal period. It was planned that during the test the discharge through both tunnels would be measured by current meter in the No. 2 canal downstream from the

Fig. 5. Bend loss coefficient curves from tests on a 6 in. steel pipe.



tunnels. The No. 1 tunnel discharge would be then determined from the fall-discharge relationship obtained in the No. 1 tunnel tests, Fig. 6, and the No. 2 tunnel flow by subtraction. Unfortunately it was found that with both tunnels in operation at the low forebay level, the velocities in the downstream canal were too high for accurate current metering. A secondary method of obtaining the discharge, that of metering the No. 1 canal flow and subtracting it from the total plant discharge, also proved unsatisfactory, as velocities in the No. 1 canal were again too high for accurate current metering. Therefore, no accurate measurement of the No. 2 tunnel flow was obtained. From the approximate measurements that were made, it appeared that the No. 2 tunnel was carrying about the same flow as the No. 1 tunnel. Based on the assumption of equal flows in both tunnels, results have been computed for the No. 2 tunnel for comparative purposes, but these must be con-

sidered as estimates only.

Method of Computing Head Loss Coefficients

The tunnel gauges were so located that 3 reaches did not contain bends and were considered sufficiently downstream from the preceding bend to permit true friction losses to be obtained. Insofar as possible all these reaches were used in the computation of roughness coefficients. For each test the average water surface elevation in each piezometer well and the head loss between wells were determined. The average head loss per thousand feet was computed from the total head loss and the total length between piezometers in the straight sections. Computations were then made for each test of the roughness coefficient n in the Manning formula:

$$V = \frac{1.486 r^{2/3} s^{1/2}}{n}$$

and the roughness coefficient f in the Weisbach formula:

$$h_f = f \frac{L}{D} \frac{V^2}{2g}$$

where:

V = average tunnel velocity in ft. per second.

r = hydraulic radius of tunnel in ft.

s = mean slope of hydraulic gradient.

h_f = loss in head due to friction in ft.

L = length of tunnel reach in ft.

D = diameter of tunnel in ft.

g = acceleration due to gravity in ft. per second per second.

For each test, using the roughness coefficients determined from the straight sections, the friction loss between piezometers in the reaches containing bends was computed, and the bend loss determined by subtracting this friction loss from the measured total head loss between piezometers. For each bend loss thus obtained, computations were made of the bend loss coefficient K in the formula:

$$h_b = K \frac{V^2}{2g}$$

where; h_b is the head loss in feet due to the bend only.

Test Results

In Table III is summarized all the measured data obtained during the tests on the tunnels. The levels for piezometer No. 1 are not included in the table as this piezometer is located near the outlet from the intake and is not relevant to these tests. When the tests were carried out it was found that certain of the piezometers were plugged or partially plugged and were obviously not yielding the correct water level, and these also have been omitted from the tabulation.

The results of the roughness coefficient computations appear in Table IV where the values of n and f are given for each of the tests. Tabulated also for each test are the tunnel discharge and velocity, the average friction loss per thousand feet, and the Reynolds Number. In Fig. 7 the values of f obtained from the tests are plotted on a Reynolds Number base on the chart adapted from *Friction Factors for Pipe Flow* by L. F. Moody, A.S.M.E. Transactions, November 1944. The purpose of this plot is to compare the roughness of the Niagara tunnels with that to be expected from theoretically smooth pipes, and to indicate the relative roughness of the tunnels.

For tunnel No. 1 the average value of n obtained for all the tests was 0.0120. Although the Scobey formula was not similar in form to the Manning formula, the predicted losses for the test conditions would produce an

THE USE OF ELECTRONIC COMPUTERS IN THE FIELD OF CIVIL AND STRUCTURAL ENGINEERING

A. M. Lount, M.E.I.C. *Consulting Engineer,*
A. M. Lount and Associates, Consulting Engineers, Toronto.

The rapid development of the use of electronic computers in the field of civil and structural engineering has been one of the most fascinating developments in recent years. The progress has been such that it has become important that engineers review their methods and approach to problems in the light of the possibilities inherent in this new tool.

Aided by our public newspapers and popular magazines, we have tended to accept in the past the stereotyped concept that the electronic computer can only be operated by experienced scientists, mathematicians or physicists, and could be applied to only the most complex of problems. In truth such concepts are far from reality and retard the practical application of these modern tools to everyday problems.

The main purpose of this paper is to show how the electronic computer can, in fact, be applied to the most common and prosaic of tasks.

Let us begin by putting the computer in its proper place in relation to the engineer. In his excellent book on this subject, Mr. MacCracken of the General Electric Co. made the observation that the computer should not be regarded as an electronic brain but rather as a high-speed moron. This emphasizes the main point that the computer is the servant, not the master. It has to be told, it cannot tell. It bears the same relationship to the engineer as does the slide-rule, the desk calculator, the transit, and the aerial photograph. These are all means by the proper and judicious use of which the engineer can better and more efficiently perform his tasks.

Section I—Basic principles

It is necessary to understand the fundamental principle of computer operation in order to fully appreciate the applications of this tool. A short introduction is therefore necessary for the benefit of readers not familiar with these fundamentals.

The computer is essentially a piece of equipment capable of adding, subtracting, multiplying, dividing, and storing information. The operations are carried out automatically in accordance with a set of instructions given it beforehand. A commonly used analogy is the post office analogy. The procedure can be likened in a rather crude fashion to a post office sorting room. Fig. 1 shows a sketch of such a room together with the corresponding computer diagram. On the right is a set of pigeon-holes in which are located data or other information. On the left is an instruction board on which are listed in precise detail the instructions to be followed by the postal clerk. In the middle is a table on which the clerk can perform the tasks assigned to him.

The pigeon-holes are all numbered. These numbers are called, naturally enough, addresses. The first instruction may tell the clerk to clear the table. The second tells him to go to slot no. 1 and to add the contents to what is on the table. He does this by going to the slot, copying what is in it, and taking this information to the table. Since the table is clear, the information on the table is now the same as that contained in slot no. 1.

The third instruction tells him to go to slot no. 2 and add the information to the table. This is done as before and now, since the table previously contained the information in slot no. 1, it now contains the sum of the information in slots no. 1 and no. 2.

The fourth instruction tells him to take the answer from the table and store it in slot no. 3. The last instruction tells him to stop. This is necessary, since, in the case of the computer, the operating medium is unable to make any decisions on its own and would become either very confused or very worn out searching for a non-existent instruction.

The operation of the computer is similar. However, the instructions are carried out at speeds almost beyond our comprehension. The speed of different equipment varies from about 200 operations per minute for the smaller slow-speed equipment to 40,000 operations per second for very high-speed equipment.

Section II—Vocabulary

A certain addition to our regular engineering vocabulary is necessary to enable us to discuss computer applications in simple terms.

The words *accumulator*, *memory* or *control* are readily understood from Fig. 1. The accumulator is obviously a place where the actual numerical operations are carried out by means of accumulating the information. The memory is, of course, where numbers are stored until required. The control directs the operation. The address is the number which locates the slot in the memory. The memory may consist of magnetic drums, cores or tapes. Some portions of the memory may be easier to reach or faster in use than others. Such portions are referred to as *high-speed memories* or *immediate access memories*. Other portions of the memory may be quite slow to use and are not so readily accessible. These are called *remote or secondary memories*.

The instructions given to the control are called the *program*. The operation of feeding the *program* into the machine is called *program input*. This is the means by which the machine is activated to work on an actual problem.

The data may be fed into the machine by means of punched tape, punched cards, magnetic tape, or it may be typed directly by means of an operator. This whole phase of the operation is called *input*.

Correspondingly, the means by which the machine released the information computed by it is called *output*. Often the machine can compute far faster than it can get rid of the information it has computed. In such a case the problem is *output limited*.

Some may wonder about the terms *digital* and *analog*. The computers described in this paper are all digital computers. They operate on the basis of numbers of digits. Analog computers operate on the basis of analogous circuits or measurements (i.e. slide-rule) and results are measured in physical terms from such circuits, i.e. voltage drops. A typical analog computer operation is a network analyser, such as used by many power authorities to determine network properties.

Fig. 2 shows a typical analog computer. Note its size and the board by which the properties of the internal circuit can be adjusted.

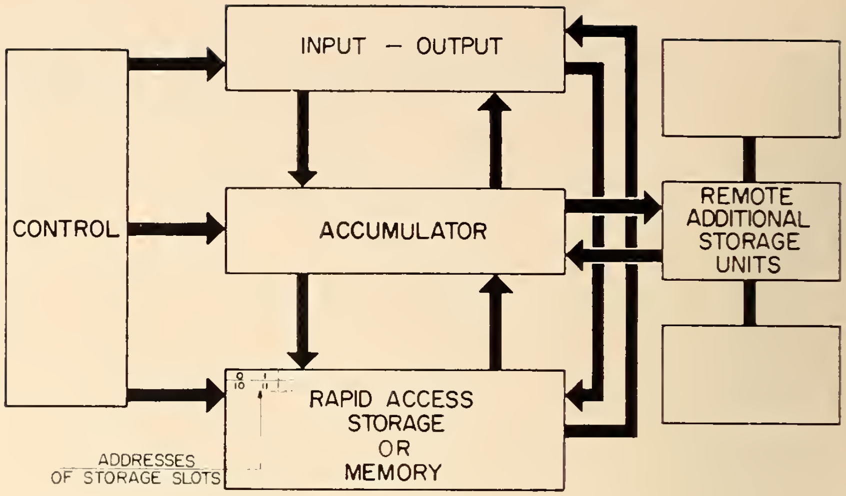

Fig. 1. Sketch showing post office "analogy".

Fig. 3 shows a typical digital computer. This computer is an IBM 650, a medium-speed computer operating at about 2400 operations per second. (0.67 ms add 12-17 ns X ÷)

Fig. 4—a slow-speed digital computer—Burroughs Electrodata 101.

Fig. 5—Univac II, a high-speed digital computer.

Fig. 6—IBM 704—a very high-speed digital computer.

Fig. 7 — Bendix G-15-D — a medium-speed computer.

Fig. 8—LGP 30—Royal McBee.

All digital computers operate on the same basic principles. Therefore, while the mode of operation of each machine may differ, the philosophy behind their use remains constant.

The balance of this paper is concerned with the program itself or, in other words, the instructions given to the machine for the execution of a particular series of operations for a given problem.

Section III—Civil Engineering Applications

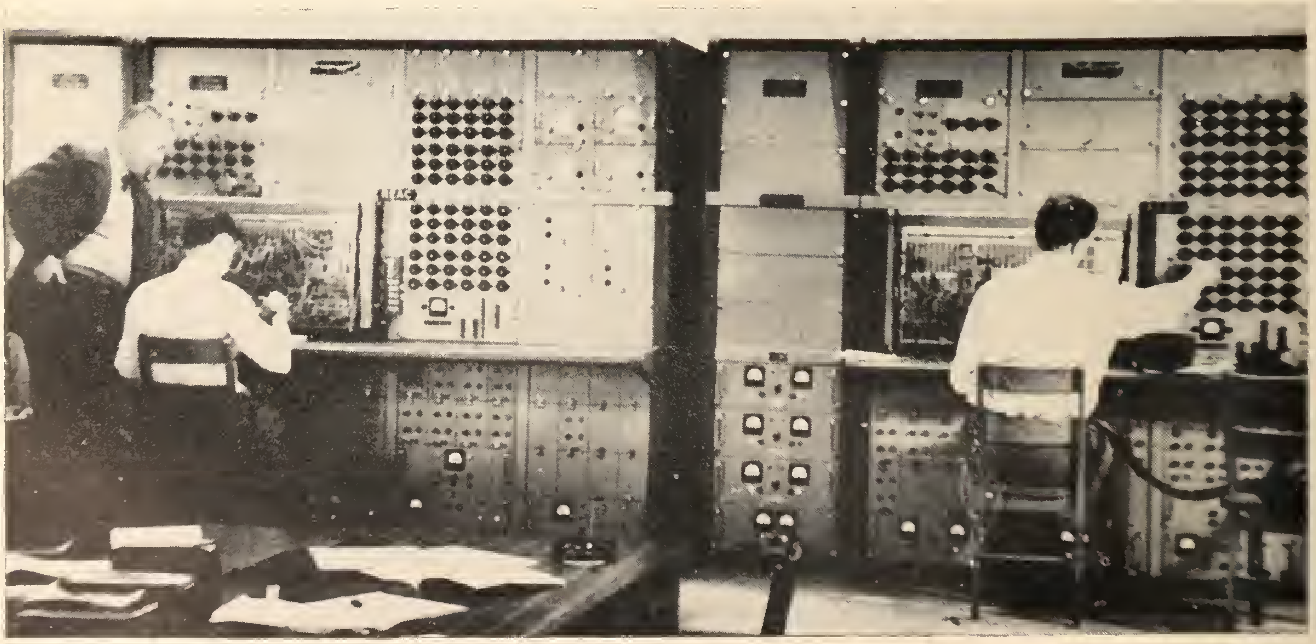
The three major fields of application in civil engineering are:

a) Earthwork
b) Structures
c) Hydraulics and Hydrology

a) Earthwork

The application of electronic computers to earthwork computations is probably the most widespread application to date. In this field the com-

Fig. 2. Typical Analog Computer (REAC).



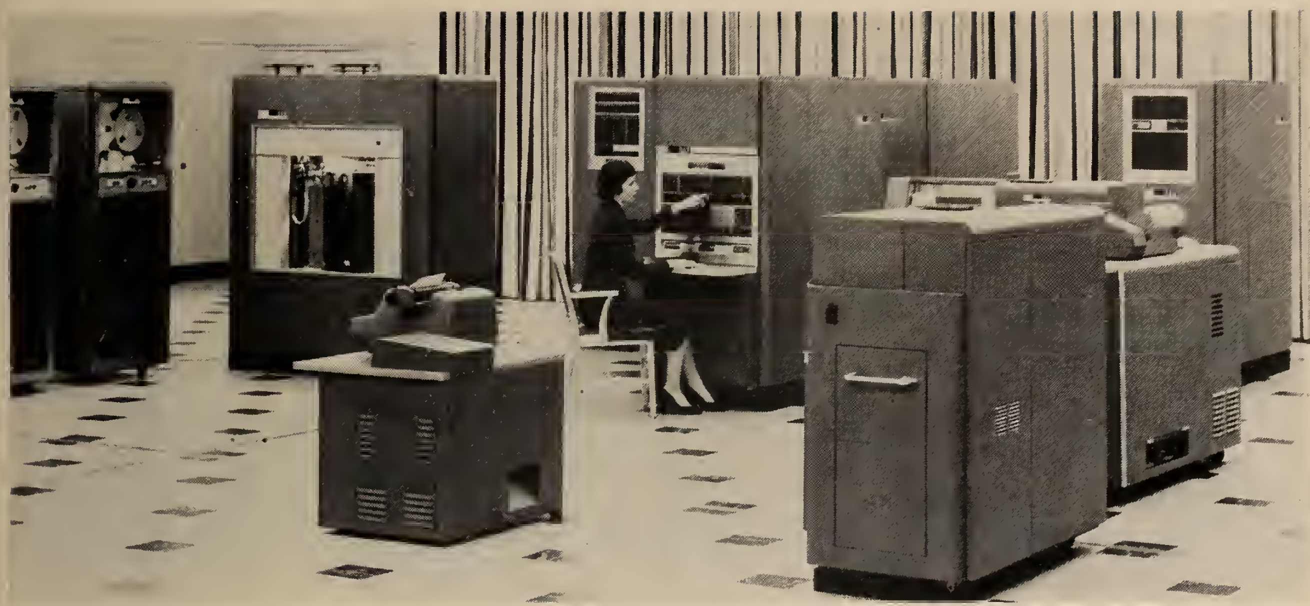


Fig. 3. I.B.M. 650 Computer.

puter has shown itself capable of performing in a few hours work which normally would have taken several men several weeks or months. The simplest application is, of course, the straight volume calculation, such as used on highways or for borrow pits. In these applications the computer is used to rapidly determine the volumes of earth that have been moved or that would be moved in accordance with a certain plan.

This is, of course, one of the earliest applications of the computer in the civil field. However, a more sophisticated use of the computer has begun to develop. As an example of this we may cite highway earthwork quantities. At first, the original cross-sections and the profile and template of the finished roadway were fed in as data into the computer. The computer then calculated the quantities of cut and fill material required for a certain stretch of road. It also could calculate the accumulated difference or the mass-haul diagram.

The computations are so rapid that it becomes soon apparent that one bottleneck is the mere handling of data. Problems very frequently become limited by input capacity and the time required to place the data into the computer becomes by far the largest part of the computation time. This, of course, is a most inefficient way to use high-priced equipment. Therefore, the idea has been conceived of marrying the electronic computer with aerial photography, and this has been done most successfully in at least two or three instances. One such program developed by a firm called Photronix, Inc. of Columbus, Ohio, determines from the aerial photographs the cross-sections of the road. The stereo-plotter transforms automatically the data into a form suitable for acceptance by a computer. In this manner, the amount of work required in data input is minimized. This procedure is also followed by McElhanney, McRae, Smith & Nash of Vancouver, B.C.

This is one of the most interesting consequences of the advent of electronic computers. Engineers are apparently not satisfied with merely being relieved of the drudgery of carrying out computations. They immediately set about to find additional work for themselves to do. As a result, they produce computer programs which do far more than could have been possible manually. They devise means whereby they not only determine the volumes of cut and fill and the excess of one or the other over a certain stretch of road, but, in addition, they have developed means which will automatically balance volumes of cut and fill by profile adjustment. The final end result is therefore the optimum grade calculated electronically directly from aerial photography. The accuracy of such results is better than 1%, a figure consistently achieved in Ohio and Indiana. This has been so successful that contractors have begun to quote better prices on computer calculated quantities than on manually computed quantities since they have found them to be more reliable. This reliability is, in fact, one of the major advantages of the computer. Once a program is established and is checked out for a given problem, we can be sure that the results produced by that program will be accurate. The element of human error is at least minimized, if not completely eliminated.

The Ohio program mentioned previously selects the optimum vertical alignment on a given horizontal alignment for a given highway. It will do this for either single or dual lane roads. It will even vary the vertical alignment in each individual lane in order to produce optimum conditions.

The Massachusetts Institute of Technology has developed a computer program which not only determines optimum vertical alignment but also selects optimum horizontal alignment. This is done from aerial photography using a grid of elevations taken over a given terrain. In this case the electronic computer is used not only to select the optimum vertical elevation, but also the optimum horizontal routing to produce the most economical overall route considering physical terrain conditions only.

At this point the engineer's new role becomes apparent. In the past he has been often used in operations involving considerable amounts of drudgery, thus occasioning a considerable waste of talent and manpower. In his new role, however, he will not have to make monotonous calculations but he is going to have to be most careful that the results achieved by the computer have real meaning. He must assess factors not included in the data supplied the computer, see whether they can be or should be considered by it, and make allowances for such considerations in his interpretations. The engineer must be careful not to accept computations for more than what they are, namely additional data on which he can make a considered engineering judgment. He must make sure that the necessary social elements, such as the routing of the highway through suitable areas, are taken care of. He must make sure that the information being fed to the computer is not based on invalid assumptions. He must make sure, in other words, that the answer is not only correct from the mathematical point of view, but also correct from other engineering and social-political aspects. Some of these aspects and different points of view can be themselves expressed in the form of a program and given to the machine itself. In other words, in the MIT program it would be quite possible to limit the possible road locations and to weigh the cost of obtaining access rights, etc. It is possible to feed in terrain data, such as whether the ground is rock, muskeg, clay or sand. Naturally, as the problem becomes more and more complex, it is going to be necessary for the engineer to pay far more attention to the validity of his basic assumptions in relationship to the problem under study.

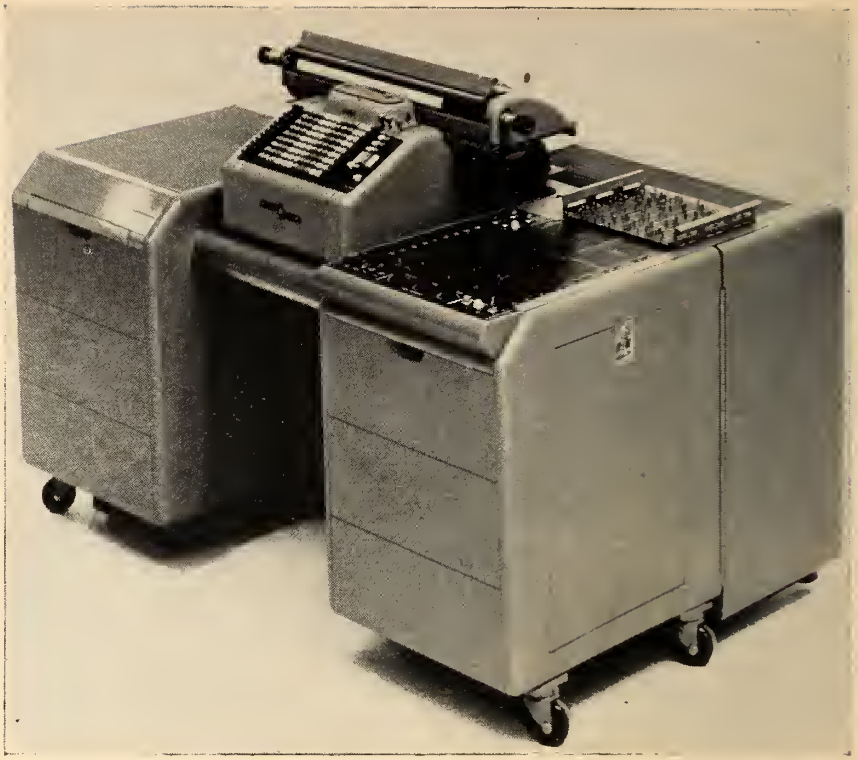

Fig. 4. Burroughs Electrodata 101.

Questions have been raised about the validity of old and standard approaches to some problems. For instance, are we really achieving minimum cost by balancing cut and fill or by balancing cut and fill modified by material factors? Is it not actually the fact that the fill and the cut material themselves, except that taken from a borrow pit under royalties, costs nothing? It is the cost of excavation, transportation, back filling, and compacting that involves the expenditures. Therefore, is it not better to analyse the design of a road in terms of the means by which that road is going to be constructed? We know that hauling material uphill is more costly than hauling material downhill. We know that certain types of material and excavating equipment cannot operate at the same speed or with the same capacity as others. The conditions of the ground over which the equipment works is also of importance and can be made a part of our cost considerations.

There is a term that is useful in discussing computer application, and that is *mathematical model.* This word is self-explanatory and represents a wholly mathematical reproduction of a particular problem. On such a model we can perform operations, we can study the effects of certain variables, and we can make

Fig. 5. Univac II—High Speed data processing Computer.

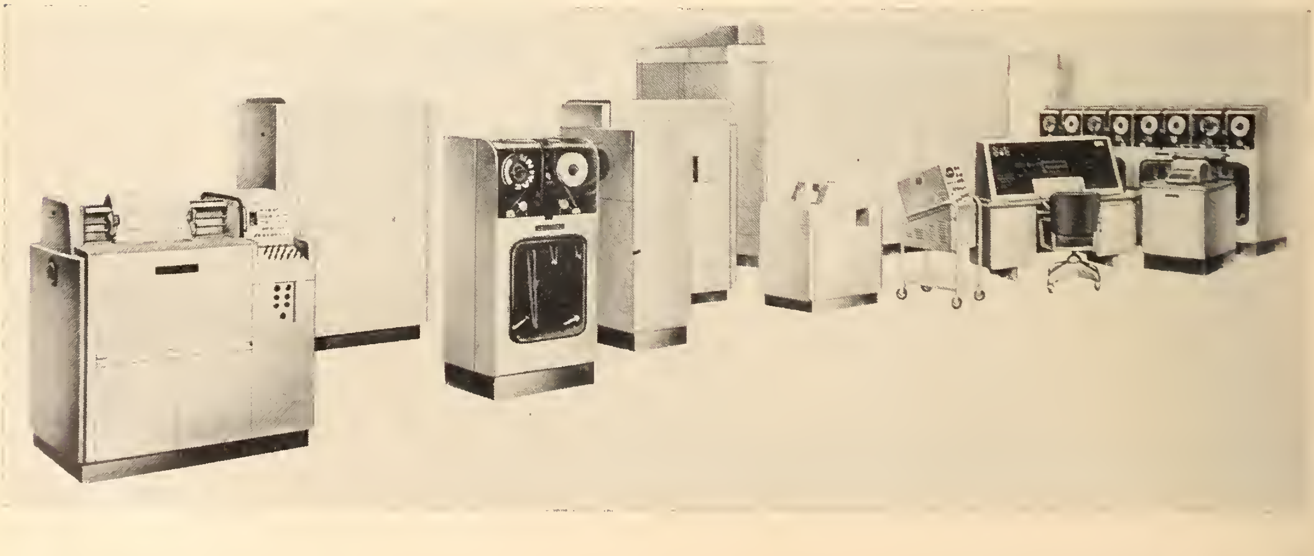

Fig. 6. I.B.M. 704 High Speed Scientific Computer.

a complete re-study of cost. The main advantage of such a model is that it can be altered readily and that the cost of production of the model, provided that it falls within a certain general pattern, is usually trivial.

b) Applications to Structures

The application of the electronic computer to structures is somewhat of a paradox. In a particular sense, probably no field of computer applications has been as thoroughly studied and as thoroughly developed as the structural application field. The aircraft industry has made use of electronic computers for structural computations for several years and stress analysis has become a major function for the computers in the aircraft field. We mentioned the word paradox because insofar as civil engineering is concerned, there has been little use made of computers to date. There appears to have been very little migration of information between the two fields. This is due in part to the fact that in the aircraft industry the computations carried out have been of such complexity that manual operations were out of question. Therefore it became quite natural to turn to the electronic computer, since the initial cost of solutions was not a major consideration. The relationship of weight to strength bears a very much greater importance in the aircraft field than it has in the past in the structural field. Therefore, the need and the essential requirement is for thorough analysis.

In structural design the cost of program development cannot usually be amortized on a given operation. It is therefore necessary to reuse a program several time to justify its existence. Medium-speed computers have now reduced programming costs albeit at the expense of slightly higher operating expenses.

With the increasing availability of medium-speed computers in the lower cost ranges and increasing familiarity of engineers with the potential of the computers, rapid progress is beginning to be made in this field. Later on in this paper we will discuss in detail a particular application of electronic computer to the design of a multiple rigid frame.

c) Hydraulics and Hydrology

The electronic computer has been used successfully for years by such organizations as the Ontario Hydro and the US Corps of Engineers for hydraulics and hydrologic calculations. The computer with its high speed is well adapted to the tedious and repetitive calculations that are associated with several hydraulic calculations, such as open channel flow and surge tank calculations.

The application of the electronic computer to the field of hydrology is beginning to be more widespread. In particular, the US Corps of Engineers has made successful application of electronic computers to hydrographs, water reservoir flows, and flood control problems in general. It is now quite feasible to develop a mathematical model of a watershed and to investigate very thoroughly in a pre-hydraulic model stage, if you wish to call it that, the possible effects on a watershed of certain improvements.

Finally, we have the application to general miscellaneous items, such as surveying, planning coordination, estimating traffic analysis, etc. In this field the computer has been successfully applied to asimuth observations, geodetic calculations, closure of traverses, layout of highway slope stakes, layout of interchange ramps, layout of curves, etc.

It can also be used in overall planning, scheduling, and coordination of projects. In other words, the entire schedule of a project of a civil engineering nature can be put on to a computer and various combinations of timing for various phases of the work can be studied in relationship to their effect on overall cost. And in similar fashion the computer can be used to produce cost estimates far more detailed than previously possible simply by virtue of being able to take into consideration more variables.

Section IV—Application to a particular problem

We will now discuss the application of the computer relative to a particular problem. The problem we will select for initial discussion is the calculation of influence lines on a five span bridge structure. The structure under question will have variable moments of inertia and each of the spans can be of different length. An experienced designer, who is doing this type of work all the time, will probably be able to make a calculation of this type in a few days. However, in the average design office a designer of this calibre is not usually free to devote his entire time, for even one day uninterruptedly, to one problem of this type. It has been found after careful survey of conditions in several offices that a problem of this nature will usually involve expenditure of at least $100 of direct payroll cost. This, with a normal overhead, works out to an actual job cost of the order of $200. Not only this, the time of an employee is tied up usually for about a week if we include the original design and the checking involved. There is also considerable and understandable reluctance to recalculate for a different set of conditions should any variations be found desirable. This is not so much due to the cost element as it is due to the time element involved in the design of the structure.

Let us suppose, that it is decided to apply an electronic computer to this particular problem:

1) **Problem statement.** To determine the moments at the supports and at mid-span for a load travelling across the entire bridge structure, load positions to be considered at the centre of each tenth point of each span. In addition, influence lines will be required for the reactions at each of the supports.

2) **Methods of computation.** Many methods of calculation could be used. In general, these may be classified into three broad categories:

a) Classical three-moment equation
b) Slope deflection
c) Moment distribution

Fig. 7. Bendix G 15 D Computer.

The first factor that needs to be considered is that the solution of simultaneous equations is not a difficult or lengthy problem for an electronic computer. Within certain limits imposed by economics, electronic computers can solve large numbers of simultaneous equations. The smaller computers can handle equations of the order of 29 x 29 and the larger computers equations up to 250 x 250.

The second consideration is that since the initial cost of programming will be very large in comparison to the operation cost, it is desirable to keep it to a minimum, provided that the operation expense does not suffer accordingly. Therefore, we tend to avoid methods such as moment distribution which will require elaborate planning at the program stage. This is where the three moment equation or slope deflection may, in certain cases, have an advantage over moment distribution. It is simple to set up a problem in concise terms using these methods. It must be remembered that the engineer does not participate in the individual stage or the computation. The computer cannot make decisions for itself. Therefore, all the possible situations that may arise must be thoroughly preplanned. And it is quite feasible in moment distribution to have certain situations arise which, under normal circumstances with manual operations, would not lead to any difficulties, but which, however, could lead to trouble on computer work. The engineer can exercise his judgement in deciding on the number of cycles to carry distribution. On applying this method to the computer he must predetermine the various situations that may arise and tell the computer what to do under the circumstances.

The three-moment equation approach has the advantage that it can be very simply stated in terms of the various properties of each individual span and the load position. This makes it possible to plan repeated cycles of calculation which are known as *loops*.

We thus see that moment distribution, while an admirable method for manual use, is not necessarily the

Fig. 8. Royal McBee LGP 30.

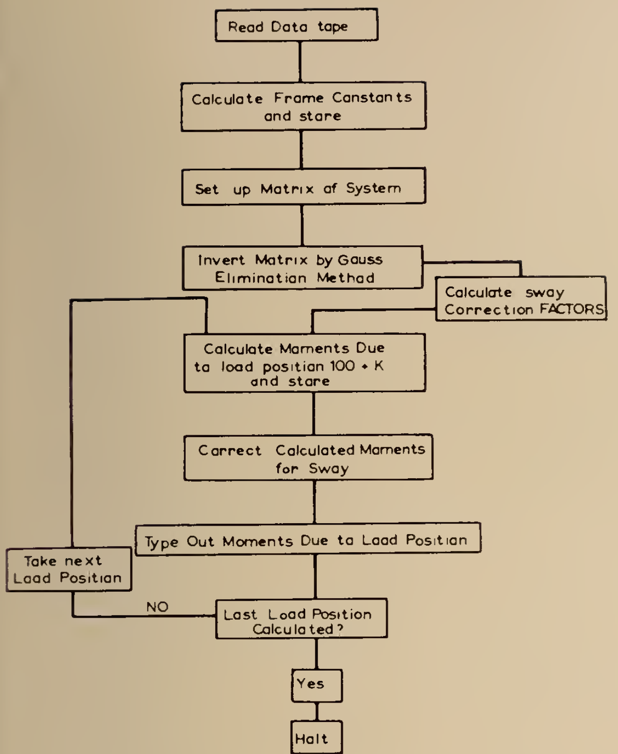

Fig. 9. Typical General Flow Sheet—Influence Line Program.

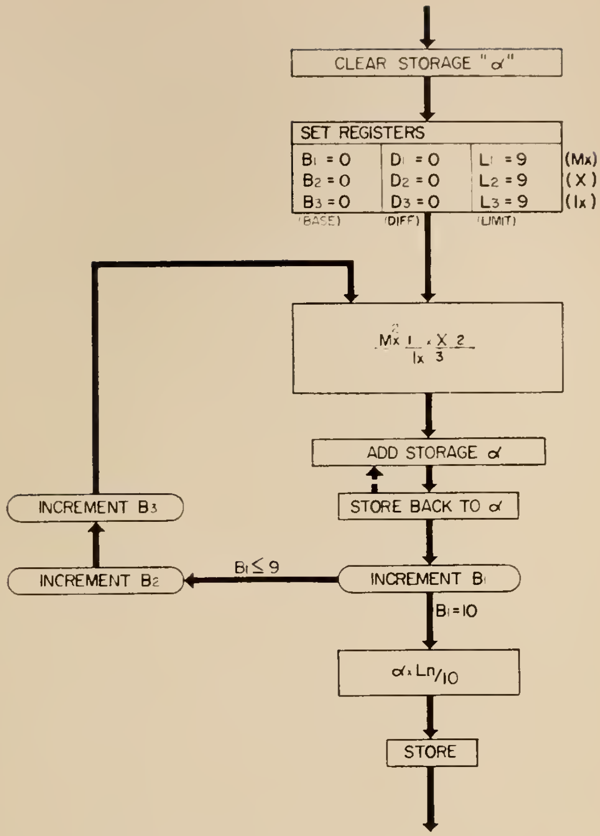

Fig. 10. Portion of detailed flow sheet.

solution for the computer. When putting a problem on the computer, it is often necessary to return to very first principles in order to achieve optimum results. We should caution the reader, however, that for large regular frames a form of moment distribution can be used to good effect.

3) **Selection of mode of operation for computer.** Having determined the method of calculation and having stated the problem, now it is necessary to select the computation medium and the means of operating that medium. For reasons previously discussed, insofar as the structural analysis is concerned for a problem of this nature, which is not going to be repeated a very large number of times, a medium-speed computer is usually the most economical. For the problem that we are discussing we have selected a Bendix G-15 computer which would be used as a means of demonstrating the method of solution.

There are several ways in which the computer can be operated. Each individual instruction can be given to the machine in what is known as *machine language*. When writing a program in this language it is necessary to detail to the very last step each individual operation. This means that to program such a simple operation as a multiplication, it is necessary to load the necessary portions of the rotating magnetic drum, tell the machine to carry out a certain number of operations, make the necessary transfers right or transfers left to take care of the decimal point location, and to replace the results in the proper storage slots in the proper sequence. There are many advantages to this type of programming which is known as *machine language programming*. Full advantage can be taken of the tremendous speed of the machine and this method is ideal for obtaining maximum efficiency out of the machine on short multi-reused problems. Fortunately, for the average application, it is neither necessary nor advisable to adopt this mode of operation. There are what is known as *interpretive routines*. These interpretive routines take very simple instructions, such as multiply, add, divide, subtract, etc. and convert them by means of the machine itself into a series of instructions to the various portions of the machine for the execution of the actual instruction. In this manner the programmer need not be concerned in detail with what is going on inside the equipment. It is true that a large amount of flexibility is lost and the actual operation of the program is considerably slowed down. This, however, must be balanced against the great simplification of programming and therefore the reduction of cost of the programming. There are different types of interpretive routines available to the programmer depending upon the circumstances. Some interpretive routines can eventually be converted to machine language by means of specially prepared computer programs. Such programs are called "compiler programs". It is well to remember, however, that very elegant procedures and highly efficient machine use almost inevitably depend on careful machine language planning.

Having selected a mode of computation, a flow-sheet is prepared. Fig. 9 shows a portion of the flow-sheet for the problem in question. This sheet is self-explanatory. This is a general flow-sheet, in other words a portion of the general attack on the problem. This outlines the method of solution to be used and can readily be followed by an engineer not at all familiar with the computer itself. This is a stage at which the program should be given the most critical appraisal not only by the programmer himself but also by all who are concerned with the eventual use of the program. It is at this stage that the validity of assumptions and methods must be studied. It is at this stage at which the scope, nature, and the extent of the program can be studied and therefore its usefulness assessed.

Fig. 10 shows a detailed flow-sheet. This flow-sheet takes the previous more general one and breaks it down into individual operations which will have to be carried out on the machine. As you will see, this is in considerable detail. On this chart a simple loop is shown. This particular computer has what is known as *index registers*. These are simple counting devices that enable us to determine the number of times a certain operation is repeated. Thus, in going through the computation shown on the board, we go through the additional multiplication loop once, the index register is increased by one, we go through the loop again, and the process being repeated until such time as the number of times for which the register has been preset is achieved. Once this number of operations has been completed, the computer proceeds to the next portion of the calculation.

Fig. 11 shows a portion of the final coded problem. This is the coded section for the detailed portion shown previously. We have standard code numbers for each individual operation. At the bottom of the picture you will see a description of some of the code numbers.

4) **Debugging.** After the coding is completed, the problem is now ready for the computer. First of all, this coding should be thoroughly checked. This particular problem involved 1600 instructions. It is almost impossible to avoid making some sort of error in coding. In fact, the recognition that the human element is subject to error is fundamental to computer applications. It is necessary to check out the program at every stage. This check-out is known as debugging. There are many classes of errors, such as:

a) Improper operation. Such an improper operation may be, for instance, division by zero. This is an obvious impossibility for the computer and therefore the computer rejects it.
b) Error in assignment of code numbers or address.
c) Typographical errors.

The above errors are usually detected by the simple reason that the computer refuses to operate, or produces results that are obviously in error.

Other errors are of a much more subtle nature. In a loop calculation of the type previously described, it is necessary to provide a means of getting out of the loop, otherwise the computer will not stop. Finally, it is necessary to check out a type problem to make sure that the right answer is being obtained.

Fig. 11. Typical Coding Sheet (Interpretive routine coding).

Notes	*Location*	*Oper. Code*	*Address*	*K*
$M_x = 580 - 589$, $I_x = 510 - 519$, $X = 420 - 429$ } storage locations	Stored α in 600

	122	.	.	
	.	.	.	
	.	.	.	
	.	.	.	

Debugging can often be by far the most costly part of the whole programming operation. It is one that requires careful attention on the part of the engineer and programmer, careful, logical thinking, and, above all, patience. However, there is one consolation, and that is, once a program is written, checked out and operating correctly on one problem, it will operate correctly on all other problems of the same type. As long as the human operator does not make a mistake, it is virtually impossible for the machine to do so. If the operator does make a mistake, a properly prepared program will detect it.

5) **Operation.** The operation of a prepared program is extremely simple. One needs only load the program tape into the machine, then load the data for an individual problem, and set the machine into operation and the desired results will be forthcoming, after the elapse of a certain length of time. The actual operation of the machine for a given problem is the simplest part of the whole operation. And obviously, where a problem is to be repeated many times the cost of programming and development costs associated with it are soon recovered.

Fig. 12 shows the portion of the output from a program for the calculation of a multiple span bridge with variable moment of inertia. The output in this particular case is in what is known as *floating decimal form*. This is a means that provides a neat compact arrangement and provides for the correct location of the decimal point. Fig. 13 shows a typical array of figures in floating point decimal form. This output mode is not essential and results can be obtained usually at a slight increase in program cost in fixed point form.

6) **Cost comparison.** It has been found that for the above problem the program development costs were about $3,500.00. It is anticipated that this and the related programs for the four and three-span bridge structures will be reused as much as 200 times over the next two years. This means that the amortized cost per use will be on the order of $17.50. On top of this, the machine operation cost for each time works out to approx. $48.00. This means that a five-span bridge of this type can be analysed on a computer of this type for a cost of approx. $65.00 total.

7) **Possible savings on higher speed equipment.** If higher speed equipment such as IBM 704 or Univac II were to be used, the operation cost would drop sharply. Once a program has

been formulated, i.e. written in terms suitable for lower speed computers, it is often quite feasible to make a conversion to the highest speed equipment. But since the rates per hour of the larger machines can be anywhere up to 20 times that on a slower machine, it is easy to see that the debugging costs could very easily climb. Also input-output time must be considered. The question of economics at this point is whether the repeated use of the program would justify the increased cost of the further speed possible on the higher speed equipment.

In general, it can be stated that the more repetitive the problem and the longer or more tedious it is, the more one should consider the use of very high-speed equipment. For problems that will not be repeated too often and for problems of a fairly complex nature it is often desirable to use a medium-speed computer so that the programming costs do not become excessive. It is very true that on high-speed equipment some extremely high-powered programming methods are available. It is still true, however, that an undetected logical error in the flow-charting will very rapidly consume a lot of time on high-speed computing equipment. A minute of silence costs far more at $750 per hour than at $40.

Section V—New Theory

As discussed above, the methods of computation used on a computer must be selected so that they can make maximum use of the possibilities inherent in the computer. For instance, moment distribution was designed for manual operation, particularly manual operation with the slide-rule.

The computer has a different base of operation. In all fields of engineering, for instance, we have seen a shift in the methods of calculations used as a result of the introduction of electric desk calculators. Similarly, with the advent of the electronic computer we are going to see a shift and a development of methods particularly suitable for use on electronic computers. An example of such a shift is in the methods of computation of rigid frames. There is not time in this particular paper to dwell at any length upon this particular phase of the problem; a short example will suffice. The author has developed a method which combines certain of the advantages of moment distribution with certain of the advantages of the three-moment equation system as applied to electronic computer solution.

The basic theory rests on the principle that prior to loading all joints are considered to be frozen. After loading fixed moments are produced at the ends of each span. All the joints are then released simultaneously and obviously a correction is then applied to the fixed end moment previously obtained. An important principle at this point is that it is only this correction moment which causes rotation of the joints. Therefore the correction moment can be solved for using the three-moment equation. This means that it becomes possible in a multiple rigid frame to provide an absolutely general solution for the frame irrespective of the loading. This is done by applying successively to each individual joint a unit unbalance. Once this is obtained, we can prepare a table or store in suitable computer address locations the effects at every joint of a load which would produce a fixed end moment of x_n at any point in the frame.

This method produces a rather interesting type of simultaneous equation, namely one that consists of either four or three elements along a diagonal form in the matrix of the equations. Since we know that all equations for this type of problem will be in the same general form, it is possible to evolve a special solution of the simultaneous equations which is a good deal more efficient than an universal matrix inversion formula or the usual Gauss elimination for the solution of the equations.

Sidesway in the frame is taken care of in the same manner as in moment distribution. It is unfortunately not possible in the scope of this paper to

Fig. 13. Use of floating point notation to determine decimal position.

Numbers in floating point decimal		*Numbers in fixed point decimal*

52.12345	=	12.345
53.12345	=	123.45
54.12345	=	1234.5

discuss this approach in detail. It is mentioned here merely to point out that with the electronic computer a revision in our approach to problems is going to become necessary in order to take maximum advantage of the computer. It will be essential to re-examine our approach to engineering problems in the light of the facilities which are offered us by the electronic computer.

Section VI—Economics of computer applications

In the problems and applications mentioned above the electronic computer has demonstrated that it can achieve substantial savings in design costs for earthwork calculations, structural calculations, hydraulic calculations, traffic control problems, and a multitude of other cases. Moreover, it can be shown that there is a far more important side to the problem than this. Quite irrespective of the design costs, overall economies can be achieved by the means of much more thorough analysis and study of a given problem than was heretofore possible. In estimates of cubic yard cost for a particular earth moving job the method whereby that cost was derived will have to be studied. And in the course of studying it, attention will be focused upon the efficiency of the means for executing the work. Greater attention will therefore be brought to bear by the engineer on the means of executing his work and consequently greater efficiency will be the outcome. Initially, there is no doubt that the computer will be viewed with a certain amount of suspicion by those who feel that it may do the engineer out of work or that we all may become robots or machines of some kind. Actually, the author's own feeling is that the contrary will be true. He feels that the computer will remove the drudgery of calculations from the shoulders of the engineer and therefore will enable him to be free for much more creative thinking than he has been in the past.

Section VII—The future

As far as the future is concerned, it is difficult to predict what the acceptance of the computer will mean over the next five or ten years. It is safe to predict, however, that the automatic design of standardized or semi-standard structures will become common. A so-called semi-standardized structure is a structure designed for a particular application in which a structure of any particular type will be tailor-made to an individual job and yet will bear a general family relationship to other structures. As an example of this, the author has developed a program which will design a complete bridge and detail the structure, complete to the preparation of bar lists. The analysis of this structure involves some of the procedures mentioned before. In addition, it determines the optimum dimensions of the structure for a given loading condition so that the minimum cost is achieved. The cost being based, in this case, upon the price of concrete, the price of reinforcing steel laid, and the cost of form work. In addition to this, the dimensions and quantities for the given structure are calculated together with the elevations of the bridge deck to conform with the road profile. The computer program will prepare an accurate bar list for the individual structure.

Future developments, as mentioned before, are hard to predict. It is, however, quite feasible that the computer will undoubtedly become essential in the planning of all major projects involving a close scheduling of materials, careful inventory control, and careful manpower planning. Job cost controls are an obvious application of the computer in the contracting field. The extension of the idea of preparation of bar lists to other types of structures will mean that we will be freed from the drudgery of the preparation, checking and rechecking of these necessary but very tiresome accessories to construction. These developments must, of course, be individually measured in terms of the economic justification of the expense involved in setting up the necessary programs and routines to handle the work in question. However, these are economic limitations in which each case will have to be considered on its own merits. Insofar as the practical feasibility is concerned, the limitation is merely the limitation of the imagination on the part of the engineer himself.

C.B.C. TELEVISION NETWORK *(continued from page 67)*

is required for the second continuous replay, while as previously noted, the seventh machine is available as a spare in the event of electrical or mechanical breakdowns.

It will be observed that no provision has been made for duplicate recording and replay to guard against any failure resulting in loss of a recording. Such an insurance would double the requirement for operational machines. In spite of this, some duplication of recording is undertaken as and when machines are available.

Readers who are familiar with the Ampex VR1000 recorders will be aware that there is no positive method of monitoring during the recording process to ensure that the picture being seen is in fact being recorded on the tape. The recording process is based on the use of a frequency modulated RF carrier. During the recording process the RF signal at the output of the modulator is supplied to two paths, one being directly to the recording head and the other path being via a demodulator to a picture and waveform monitor. This system provides a check on the electronic circuitry of the recording system but unfortunately provides no check of the recording head.

During replay, control of the waveform and amplitude of the signal derived from the tape is provided. The signal is fed to the booth where after switching, it is fed via a Distribution Amplifier to the microwave network for onward transmission. No stabilizing amplifier is provided in the output of the booth for two reasons. In the first place, it was considered desirable to minimize the amount of equipment in the signal path following the recorder; secondly, absence of a stabilizing amplifier puts control of the waveform and amplitude in the hands of only one person, namely the tape machine operator. The intercom system permits the booth operator to call the attention of the tape machine operator to any incorrect condition of the output waveform.

Three programs are being handled simultaneously—one incoming and two outgoing. In order to maintain close liaison with the microwave network operator, all contact is made through the operator at the Delay Centre Master Control. To facilitate this, the Master Control operator is provided with picture, waveform and audio monitoring facilities for all programs simultaneously. This operator also maintains the fault log. See Fig. 7.

No editing of tape recordings is undertaken, chiefly because of the limited time available, but also because an additional tape recorder is required for such an operation. Editing is not normally required, however, since only completed programs already on the network are handled.

The basic number of operators required by the system is six, allocated on the basis of one operator to each pair of Ampex recorders (three in all), one in each of the two replay booths, and one at the Master Control position. This, of course, does not represent the total staff, since provision must be made for shift work, holiday reliefs and so on. In addition, some maintenance staff is required. Approximately twenty technicians, plus supervisory staff, are employed at the Delay Centre.

Emergency Operation

It will be recalled that two telecine chains are installed, each consisting of a vidicon camera into which are optically multiplexed two 16 mm projectors and a 2 in. x 2 in. slide projector. When the occasion arises to play film to the network the Ampex machine operator for the appropriate time zone replay performs the functions of projectionist. The booth operator, having the vidicon camera control unit adjacent to the operating position (see Fig. 6) carries out the function of camera control operator.

Results

Speaking generally—and bearing in mind the limited time which the equipment has been in use as of the date of writing—the results obtained have fully justified the decision made in 1956 to go ahead using video tape recorders as the means of delaying TV network programs. One is inclined to ponder upon the possible course of events had video tape recorders not made their appearance and had this project proceeded on the basis of a kinerecording system.

Acknowledgements

Thanks for permission to publish this paper are due to Mr. W. G. Richardson, Director of Engineering, and Mr. J. E. Hayes, Chief Engineer, both of the Canadian Broadcasting Corporation.

Thanks are also due to Mr. J. Carlisle, Plant Engineer, of the CBC, under whose general supervision this project was executed, and to Mr. P. Corio and Mr. P. Mundie for their invaluable assistance.

NIAGARA WATER SUPPLY TUNNELS *(continued from page 74)*

average *n* of 0.0114. It is considered that this comparison indicates satisfactory agreement between the formula values and the test results.

Computing the individual bend loss coefficients for each test on tunnel No. 1 indicated an undue variation in the value of *K*. However, by averaging the individual bend loss coefficients for all the tests more consistent results were obtained. These average values of *K*, and the values determined for tunnel No. 2, are shown on Fig. 8 where the bend loss coefficients are plotted against the deflection angles of the bend. Shown also is a mean bend loss coefficient curve which was derived from the average overall bend loss between piezometers 2 and 14 for all tests. This method was used to minimize the possible errors in measuring the relatively small losses at each bend. For comparison purposes, the bend loss coefficient curve obtained from the tests on the 6 in. pipe for an R D value of 5 is included in Fig. 8.

Discussion of Results

From Table IV it may be noted that the roughness coefficients obtained for tunnel No. 1 are quite consistent. Although the discharge used for tunnel No. 2 can be considered an estimate only, it would appear that the roughness coefficient for that tunnel is of the same order as for tunnel No. 1. It is believed that the No. 1 tunnel roughness coefficients are reliable, as the straight portions used in their determination were of considerable length and consequently the friction loss was large in relation to any probable error in piezometer level measurement. The discharge measurements also were considered to be satisfactory, their consistency being indicated in Fig. 6. Inspecting Fig. 7 it may be observed that the values of the roughness coefficients obtained are quite low and not much above those that would be expected from a theoretically smooth pipe. The relative roughness is also very low and it is considered that the surface smoothness achieved is most satisfactory.

The results of the bend loss tests were somewhat disappointing. From the tests on the 6 in. pipe, it was found that extreme accuracy and precision were required to obtain consistent values. This is basically due to the fact that the bend loss is a relatively small quantity obtained as a difference between two relatively large quantities, i.e., the total loss between piezometers and the loss due to friction. Any small error in either of the larger quantities has a large percentage effect on the resulting bend loss and on the bend loss coefficient. It would appear that the precision of the measurements was not sufficient to produce consistent bend loss values. It is possible that a piezometer ring, rather than a single piezometer, might have produced more satisfactory results. However, the results do indicate the order of the bend loss coefficients, and it is believed that the mean curve is a reasonable estimate of the actual losses due to the bends. Comparing these results with those obtained from the 6 in. pipe tests, it appears that the tunnel bend losses are approximately 60% of the 6 in. pipe values.

Conclusions

In terms of diameter and length, the Niagara tunnels are among the largest water supply tunnels in the world. A considerable effort was made to provide minimum loss bends and a smooth internal surface in view of the large economic value of maximum discharge capacity. It is considered that the results of the tests indicate a very satisfactory performance from this standpoint, the overall discharge capacity being almost identical to that assumed in the design. As little performance data is available for tunnels of this size, it is hoped that the results reported herein will be of interest and will add to the knowledge on this subject.

Acknowledgments

In the carrying out of the tests and the analysis of the results, the writers wish to acknowledge the very able assistance of Ontario Hydro's hydraulic testing staff. Particular mention should be made of Mr. G. L. Ball, who supervised the testing work, Mr. E. K. Beam who carried out the current meter measurements, and Mr. J. M. Spratt who carried out many of the computations.

RIVER ENGINEERING AS A COLLEGE COURSE FOR CIVIL ENGINEERS

T. Blench, M.E.I.C., *Professor of Engineering, University of Alberta. Consulting Engineer.*

The author believes that the absence from civil engineering curricula of any effective instruction in river behaviour produces as serious national consequences as would the absence of soil mechanics. Within the limited space available he outlines reasons for this belief, and the possibilities of removing the deficiency.

The fundamental principle of river self-adjustment

STATED exceedingly briefly the fundamental feature of rivers that move non-cohesive material along their beds and have sides that are erodible is that they tend to adjust themselves to average breadths, depths, and slopes that depend on (a) the sequence of discharges imposed on them (b) the sediment load acquired by them from catchment erosion and erosion of their own boundaries and (c) the resistance of their cohesive banks to erosion. Geologists and specialist engineers, especially those who have had to deal with irrigation canals carrying sediment, have been generally acquainted with this principle for at least half a century and the specialist engineers have known satisfactory fundamental quantitative laws for some 30 years. Of course there are some rivers with entirely rigid inerodible boundaries and they do not self-adjust.

Typical engineering errors consequent on ignorance of the principle of self-adjustment

It would obviously be unfair to use specific instances to illustrate the misfortunes that have befallen engineering projects conceived in ignorance of the principle of self-adjustment. Accordingly the author has invented some hypothetical cases based on true life to demonstrate how ignorance of very simple phenomena, nearly all well known to geologists and specialists, can lead to major errors and even catastrophes in large civil engineering projects; resemblance between these cases and any real project is purely coincidental.

Case A

Province 'B', downstream, persuaded Province 'A', upstream, to agree to its building a dam on a river that flows from 'A' to 'B'. The dam ponded water right up to the boundary where A had a small town, upstream of which was a fertile alluvial plain. 'A' believed that the lake would be an amenity for the town and that the river upstream of the lake would continue to run as usual. Actually, within twenty years the town had to be abandoned because it became waterlogged and subject to enhanced high flood levels, and the enhanced waterlevels could be felt 20 miles upstream by farmers who suffered flooding, waterlogging, and deposition of river detritus on their good land. Apparently 'A' 's engineers who recommended acceptance of the proposal did not know the sediment load of the river, or that a delta would form, or that a river cannot run horizontally through a delta or anywhere else, or that artificially flattening the slope of a self-adjusting river causes deposition of load and a return to the original slope, or that the ultimate fate of the project (if left to itself) would be a reservoir full of sediment and a river running parallel to the old one at a height equal to the height of the dam above its old bed.

Case B

Country 'B', downstream, persuaded country 'A', upstream, which had rivers 'X', 'Y', 'Z' in common to divert river 'X' into river 'Y' for the benefit of irrigation in 'B' and, in return, country 'A' could have all the water rights of river 'Z'. The scheme was worked out entirely in terms of acres of irrigation and kilowatts of power without any consideration of what might happen to the rivers. When 'X' was diverted into 'Y' the latter started to erode its banks and to drop its levels. Within 20 years the breadth of the belt in which the river meandered had increased 50% over some 40 miles of river length, with consequent loss of agricultural land, the river had degraded up to 10 ft. in places, the products of enhaneed erosion had filled a reservoir in a canal system, an irrigation barrage had to be built to meet the rights of riverain dwellers who had been left high and dry by the receding river, and major repairs had to be made to a dam spillway that had suffered severe undercutting because of the same degradation. In this case 'A' 's engineers who recommended acceptance of the proposal did not know that, relatively, a big river adjusts itself to have a big meander belt and a flat slope.

Case C

A new highway crossed many meandering rivers. The bridge designers had river crossings surveyed and fixed the foundations of the piers at a certain number of feet below the river bed levels discovered at each pier site on the day of survey. Ten years later many of the high bed levels at piers had become low, and vice versa, many bridge piers and abutments had been propped up by masses of stone revetment and a few had been washed out by floods because stone had not been dumped in time. Many of the approach banks had had to receive expensive stone protection because the rivers had moved over to hit the roads some distance from the bridges and run along them; in one case a flood had gone right over a road and started a new river a mile away from a bridge. Here the engineers did not know that the *nature* of meandering rivers is to change course cyclically.

Case D

Without making measurements of sediment load at all stages of flow a high dam was built to store water for irrigation. After 10 years it was found that the reservoir had lost 15% capacity because of sediment deposition and was therefore no longer a guard against the once-in-20-years drought. All the settlers had occupied the irrigated area under the impression their reservoir would last forever, there was no other site for a large dam, and removal of the sediment mechanically was found to be quite uneconomic. Here the engineers had no knowledge of the rate at which deltas can form from heavily laden rivers, or perhaps imagined that deltas might form in the dead storage instead of at the entry of river into lake.

Case E

Engineers put the large spillway discharge of a reservoir down an old steep creek that had never carried more than a trickle. The original drop over the spillway was 15 ft. After 50 years the drop was 70 ft. and the spillway had been replaced by a chain of drops, each one having been made in the hope that there would be no more retrogression of levels. Here the engineers did not know how to relate discharge to the slope that nature required for it in a given soil; probably they did not even know there was a requirement.

Case F

In a system of unlined irrigation canals (controlled rivers actually) the engineers designed all the big channels to steep slopes so that cut and fill would balance, and all the small distributing ones to flat slopes so as to gain command of the fields. After 10 years they had had to protect all the bridge piers on the big channels, which had insisted on cutting down to flatter slopes, and had to face the perpetual cost and nuisance of annual sediment clearance of all the small channels which insisted on depositing their sediment load in an effort to obtain enough slope to carry it along. The engineers did not know about self-adjustment, and therefore did not know how to design the channels to carry their load to the fields and avoid erosion or deposition.

i.	Damage to agricultural land resources	$50 million
ii.	Damage from sedimentation in reservoirs	$50 million
iii.	Maintenance or impairment of capital value of drainage enterprises	$17 million
iv.	Maintenance of irrigation projects	$10 million
v.	Maintenance of harbours and navigable channels	$12 million
vi.	Water purification resulting from turbidity	$ 5 million
vii.	Sedimentation damages partly or wholly included in flood damage estimates	$20 million
viii.	Other damages (highways, railways, pipelines etc.)	$11 million

Cost of sedimentation in the U.S.A.

Naturally there is no good record of the costs, in different provinces or countries, of errors such as just described. An interesting assessment of the annual cost of sedimentation in the U.S.A. is contained in the welcoming address to a Federal Inter-Agency Sedimentation Conference of January 1948 (proceedings edited and prepared for publication by the U.S. Bureau of Reclamation). The author's personal guess is that most of the sedimentation could have been foreseen, and that this would have meant important differences in schemes actually executed. The assessment did not pretend to be anything more than an attempt to estimate the order of magnitude of annual cost with the object of demonstrating the importance of sedimentation, so the reader should not use the condensed breakdown (above) of annual costs in any other sense without reading the whole of the address:

An interesting statement re item (ii) is relevant to case (D) of the preceding section. It reads:

"The estimate is based essentially on the annual cost of fully maintaining the services now provided by these reservoirs through construction of additional storage or equivalent facilities as needed, plus the net losses if replacement is not possible. Additional storage must be provided in many drainage areas when 15-40% of the capacities of existing reservoirs are depleted. Often the supplementary storage will cost 2-10 times as much as the initial storage per acre-ft.".

Another interesting statement re item (i) is relevant to case (A). It reads:

". . . it should be borne in mind that sedimentation damage to agricultural land is cumulative, whereas floodwater damage is recurrent. For example: On a given piece of valley land which is overflowed on an average once in 5 years, sufficiently to produce a total crop loss, the loss is one-fifth of the potential net return. Take the same piece of land, however, and allow channel aggradation to raise the water table under the land so that crops cannot be grown at all, and the loss of return every year is 5 times as great".

Finally:

"Because the effects of many forms of sedimentation are slowly accumulating, however . . . because sedimentation is not generally spectacular like a flood, which is here today and gone tomorrow, leaving catastrophe in its wake . . . the true significance of the sediment problem has not been generally appreciated, even in the engineering profession, much less among laymen".

Importance of river knowledge in North America

The engineer's tremendous scope for construction in contemporary North America permits him to commit far greater errors than have occurred elsewhere. For example, the irirgation barrage system on the Indus and its tributaries that started late last century and has continued progressively to date has shown (Ref. 2) that every barrage results in the river upstream rising slowly but surely to the ultimate condition of parallelism with itself at a higher level fixed by the mean increased elevation at the barrage. (Changes of discharge and sediment distribution alter this simplified statement somewhat, but do not affect its general applicability to the present article.) The raising by the barrages, which were not intended for storage, was only a few feet in each case, there were no cities in the flood plains, the economy was somewhat primitive, and India and Pakistan now understand the phenomenon thoroughly and make future plans to allow for it. In North America engineers have thought nothing of damming rivers comparable in size and sediment load to heights of several hundred feet, there are cities or towns in some of the flood plains, the economy is far from primitive and, so far as the author can discover, engineers generally are unaware that there can be a sediment problem at all—some countries do not even conduct routine sediment surveys to find where there is a problem and the implications of some surveys do not seem to have been appreciated. (Of course, the trouble from a 100 ft. high barrage is not ten times that from a 10 ft. high one since a valley cannot rise faster, by deposition, than the rate corresponding to the total amount of sediment available for deposition). The interested reader will find, in Refs. 3 and 4, further examples that unfortunately do not separate the effects of wrong engineering from wrong soil conservation policies of the remoter past.

Engineering ethics in water disputes

Engineering and political ethics in water disputes is far too touchy a subject for generalization, but it is vital to a province's or country's interests, so the author will risk some personal observations. He has seen major water disputes either as a species of cold war or a tough game in which certain fouls are disbarred but the general idea is to beat the other side; he has also seen lifelong friendships between engineers fade away when they have found themselves on opposite sides in a water dispute. Under no circumstances would it be considered ethical for a member of one party to let moral scruples about outwitting the other cause him to divulge information that would interfere with the outwitting process. For example, in Case 'A' an engineer of Province 'B' who knew exactly what his province's proposals would do to damage Province 'A' if they were accepted could not be expected to inform Province 'A' about it although, so the author believes, he would be morally compelled to inform his own negotiators. And, in view of the possibly tremendous effects from wrong decisions, this brings us to the need for a country or province to have engineers to advise its negotiators (as *The Engineering Journal* has mentioned previously), and to be quite sure that these engineers are expert in river hydraulics (which is not taught in colleges).

Removal of ignorance of river behaviour

In the author's opinion ignorance of river behaviour is not universal; the trouble is that it is the prerogative of the civil engineers who build and plan water projects. If these civil engineers could cooperate with suitable geologists or specialist engineers, major errors would probably disappear. However, despite sincere efforts such as demonstrated by the Inter-Agency Sedimentation Conference, there are large practical difficulties. One is to find who really are the few suitable geologists and specialists. Another is to obtain effective cooperation between people whose experiences and outlooks are poles apart. Another, in our world of large insulated departments of central governments (most major water projects have to be central government ones if for no other reason than the refusal of rivers to recognize provincial boundaries) is to translate agreements amongst a few experts at a technical level up to a policy making level where similar agreement is possible; quite different departments of a government may divide amongst themselves aspects of river work that a scientist would say are vitally interlinked; e.g. soil conservation, dam building, navigation, diversions for irrigation and power, hydrologic studies, geomorphic studies, irrigation canal construction and running. On the whole the author, while heartily supporting cooperation between agencies, is of the opinion that the only effective solution is to offer civil engineering students the opportunity to study appropriately designed courses in river engineering, just as they now study soil mechanics. Then the civil engineers who plan and construct will know the principles affecting the rivers with which they interfere, and will be able to assess the magnitude of the consequences of these interferences.

Need for text books

River science might be classed as *geologic* because its phenomena cannot be studied adequately without world-wide coverage over periods of time comparable with a man's lifetime. Therefore, expertness cannot be acquired from personal experiences alone; reading the experiences of others is essential. But the subject is broad enough to receive contributions from workers of quite different outlooks, training, and abilities and, like all new sciences, abounds with apparent (often unreal) controversies; hence uncoordinated literature can be exceedingly difficult for a reader unacquainted with several branches of science and lacking critical ability. Therefore a coordinated text is needed to set out basic facts, develop equations representing observed quantitative correlations, explain them dynamically, apply them to practical problems, and give references to outstandingly useful or important literature. The author recently published a condensed but comprehensive text (Ref. 1) as a sequel to a previously privately published one, in the belief that a first book acts rather like a dam breach causing a flow of knowledge out of all proportion to its size.

Special Outlook needed by the river engineer

According to the writer's engineering and teaching experiences the school and college training of the engineer, engineering physicist or mathematical physicist usually leads to the subconscious beliefs that:

i. All physical phenomena meriting attention develop in a time comparable with that required for one physics or engineering laboratory exercise.

ii. Sufficiently complex mathematics removes the errors arising from the idealising assumptions of rigid body dynamics and rigid boundary hydrodynamics and is, in fact, a perfect substitute for physical knowledge.

It is exceedingly difficult to convince a person with this outlook of a host of facts that would be regarded as commonplace by a geologist or an agriculturist. For example, he would not believe that (a) a building placed on top of a wet clay cliff in 1958 might finish at the bottom during the next wet cycle of, say, 1998 because the layout associated with the building increased the water entering the subsoil, (b) the least time needed for observations of the relation between bed and side seepage of canals in the field, and the causes of seepage, is one year; and lack of intelligible results within three months is no reason for abandoning observations, (c) a tube-well irrigation scheme may deplete the water table so much in ten years that lift will be trebled and the wells will be drawing highly saline water (d) sediment-clearance of a channel will not stop sediment from entering from the catchment and redepositing. And, of course, he will repeat the errors of cases A-F in-

(*continued on page 95*)

MAGNETIC AMPLIFIER CONTROL FOR REVERSING HOT MILL AUXILIARIES

R. L. Duke, *Section Engineer, Mill Industries Section.*
L. R. Hulls, *Application Engineer,*
Canadian Westinghouse Company, Limited, Hamilton, Ont.

This paper discusses in general terms the various performance requirements for the drive and control of auxiliary equipment associated with a reversing hot mill, and shows how magnetic amplifier regulators may be used to advantage to produce systems with the required high standard of performance.

Operation of the Reversing Hot Mill

When rolling either ingots into slabs or slab into plate the hot steel is passed back and forth between the work rolls of the mill. The thickness is successively reduced at each pass by an appropriate adjustment of the mill screws which control the separation between the work rolls. In order to avoid rolling material of non-uniform thickness it is imperative that the operation of adjusting the screws be carried out in the small time interval between passes when there is no steel between the work rolls. On the side of the mill at which steel is entering, the metal is carried on a series of regularly spaced horizontal table rolls which turn with a peripheral velocity approximately equal to the velocity at which the metal is entering the mill. A similar arrangement of table rolls on the exit side serves to convey the metal away from the mill.

The characteristics of the hot rolling process are such that the metal emerges from the mill at a velocity which very nearly equals the peripheral velocity of the work rolls. Since the steel cannot accumulate in the mill the volume of steel per unit time entering the mill must equal the volume per unit time leaving the mill. The velocity of the steel entering the mill will depend upon the rotational speed of the work rolls and the reduction in thickness being achieved. Thus if V_2 feet per minute is the exit velocity and d_2 inches is the exit thickness then if d_1 inches is the thickness of the steel entering the mill the entering velocity V_1 feet per minute will be defined by the following equation.

$$V_1 = V_2 \times \frac{d_2}{d_1} \qquad \ldots.(1)$$

On reversing the mill the functions of the tables on the exit and delivery sides are interchanged and it is evident that the table speed will have to be re-adjusted to conform to the requirements of equation 1 if there is to be no slippage between the table rolls and the metal. A convenient arrangement for the control of the table drives matches the table roll speed to that of the main drive and introduces an appropriate draught compensation signal to reduce the speed of the group of tables which are entering the steel into the mill.

It will readily be appreciated that once the metal has emerged from the mill at the completion of a pass the function of returning the metal to the mill is completely dependent upon the table rolls. Anytime during which steel is not between the work rolls of the mill represents a non-productive period in the cycle of operation. Successful design of hot mill drive and control equipment is to a large extent dependent upon the minimisation of the non-productive interval between passes. Delays in reversing the table drives are by no means the only cause of lost time between passes. At the end of each pass the mill screws have to be adjusted and the steel must not be allowed to enter between the work rolls until the screws have moved to produce the required separation for the next pass. Side guides are required to centre the metal on the tables before entering the mill and again, this centering operation must be achieved with a minimum of lost time. On blooming mills manipulators and fingers for turning the metal are required to operate between passes.

In a manually controlled mill reduction of lost time will, to a large extent, depend upon the skill of the operator, however, poorly designed auxiliary drives and control will place a very definite limit on productivity which cannot be exceeded by the operator. In automatically programmed mills the operation does not depend upon the human element and in these cases the efficient utilisation of the mill will be critically dependent upon the operational characteristics of the auxiliary drives.

A considerable number of auxiliary drives with their associated regulators and control, are necessary to ensure the satisfactory operation of the modern reversing hot mill. For example, regulators are required for mill tables, feed rolls, side guides, mill screws and edger screws. In a comparatively simple installation some fifteen or more regulators would be required for the proper control of the mill auxiliaries. Since failure of any one of these may render the mill inoperative, reliability and simplicity cannot be too strongly emphasized in the design of the equipment. Magnetic amplifiers operating from a separate 400 c/s supply have been successfully used for the regulation and control of these auxiliary drives. The size and arrangement of the drive motors used in this application require d-c. generators with a capacity of 200 kw. or less. With machines of this rating it becomes economically feasible to excite the generator fields directly from magnetic amplifiers. This arrangement eliminates the need for an interposing exciter and provides a very simple design which has associated with it all the advantages of static type equipment. This basically simple type of regulator has been successfully applied, with slight modification to all types of reversing mill auxiliaries, however, for the purposes of this paper the table roll drives have been selected as being a typical example of the application of magnetic amplifiers in this field, and the detailed discussion which follows has been restricted to this topic.

Limitations on Table Roll Acceleration

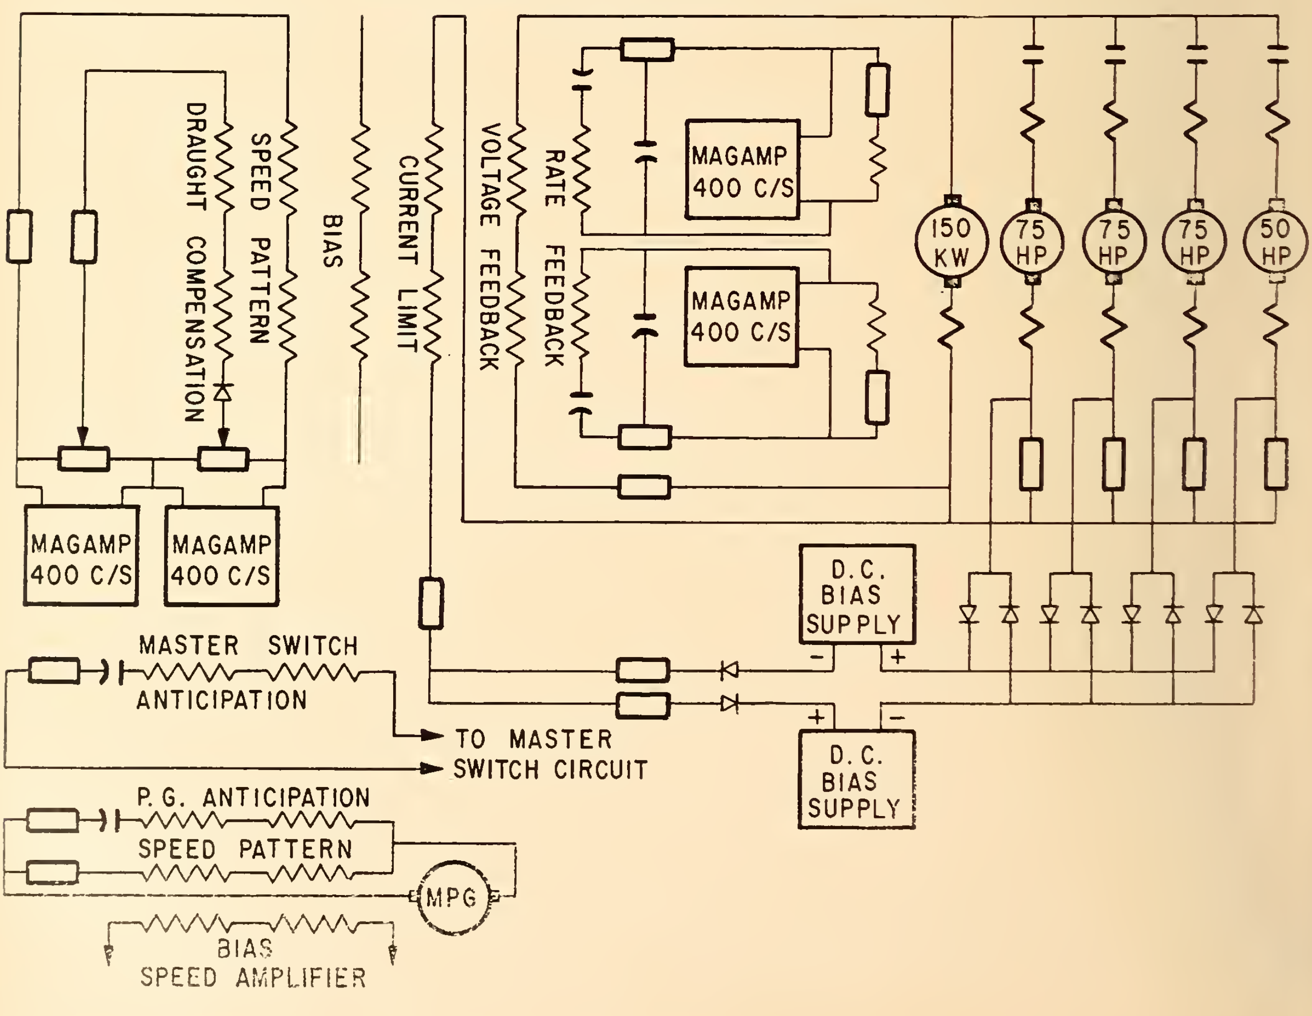
The table roll drives can only accelerate the metal at a rate which is uniquely dependent upon the coefficient of friction between the metal and the table rolls. The exact value of the coefficient of friction is difficult to determine, but taking a somewhat conservative estimate of 0.25 then the maximum acceleration possible without slippage is 480 ft. per minute per second. A hot mill reversing from base speed forward to base speed reverse in 1½ seconds may well be accelerating the metal at a rate of 450 ft. per minute per second and in such cases the question of slippage on the table rolls due to non-uniform acceleration may become important.

As well as being a factor limiting the maximum acceleration of the metal, slippage is also undesirable in so far that excessive slipping causes unnecessary wear on the table rolls.

The Table Roll Drive Regulator

Control of table roll speed is exercised by regulation of the table roll generator voltage. A voltage regulator gain of approximately 10 produces a system with adequate accuracy. At first sight it might appear that precise regulation of the table roll speed would be desirable, and certainly this is the necessary requirement if there is to be no slippage between the table rolls and the metal. However, it would be extremely difficult to achieve a precise speed match and even if this were possible the control equipment would be both complicated and expensive. The first difficulty arises in determining the precise speed of the metal entering and leaving the mill. There will always be some extrusion effect which will result in the metal leaving the

Fig. 1. Table roll voltage regulator and speed amplifier.



mill at a velocity slightly in excess of the peripheral speed of the work rolls. Unless an exact draught compensation adjustment is made every time the screwdown setting is changed, the entry speed of the table rolls will be in error even presuming that the exit speed is accurately known. Normal rolling practice is to set the draught compensation at some intermediate value which will provide a satisfactory comprise for all passes in a particular schedule. During the early passes the metal is almost continually accelerating or decelerating, very rarely running at a constant velocity for an appreciable period of time. In terms of regulator performance this would mean that the speed regulator would have to follow a rapidly varying input signal with no transient error. In general it may be said that precise speed regulation would present considerable difficulties in terms of regulator design and it is doubtful even if an accurate speed match were obtainable, if this would provide any significant advantage to the mill operator.

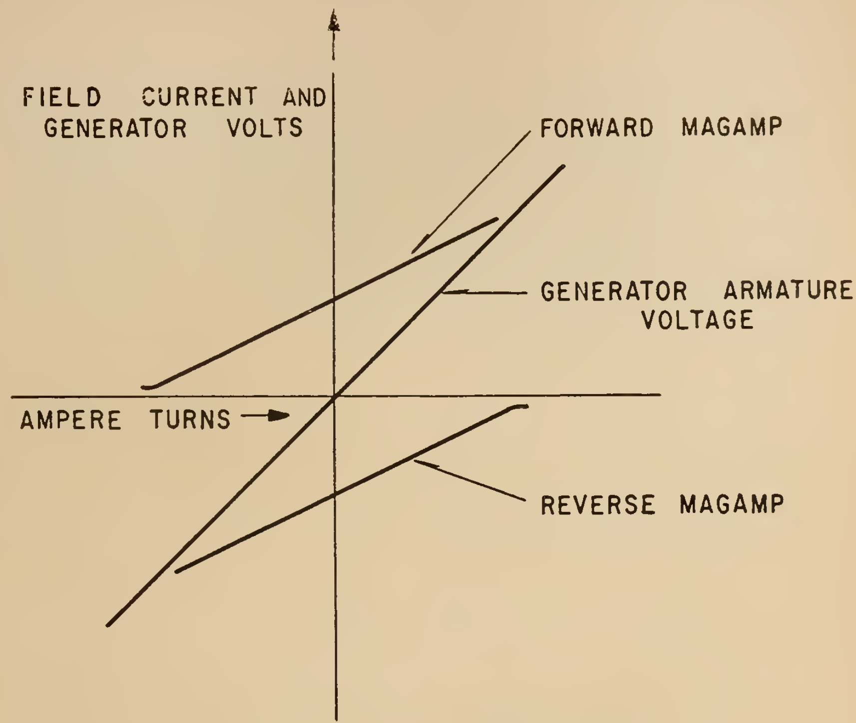


Fig. 2. Magnetic amplifier characteristics.

The voltage regulator with a gain of 10 could be expected to result in a system which will have a speed droop from no load to full load which is approximately equal to the speed droop of the table roll motors. Under steady-state conditions (i.e. constant speed) the motors will only be lightly loaded, the large torques being required only for accelerating and decelerating and, therefore, the drooping characteristic of the motors and their associated armature resistors is unlikely to seriously impair the accuracy of the speed match on the longer passes when the mill attains a constant rolling speed. The basic magnetic amplifier regulator is shown in schematic form in Fig. 1. The arrangement is a simple two delay regulator comprising the magnetic amplifier delay and the generator field delay. Two magnetic amplifiers are used to provide push-pull operation, thus enabling the polarity of the generator armature voltage to be reversed without using contactor switching. The characteristics of the two magnetic amplifiers are shown in Fig. 2, which illustrates how the combined reversible characteristic is obtained from the two individual unidirectional magnetic amplifiers. A typical arrangement is shown in block diagram form in Fig. 3. The overall open loop transfer function for the system is:

$$\frac{7}{(1 + .05S)(1 + 2S)}$$

The characteristic equation can be written down by inspection as:—

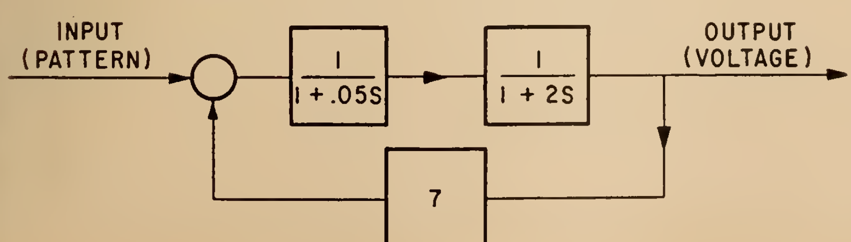
$$.1S^2 + 2.05S + 1 + 7 = 0$$

$$S^2 + 20.5S + 80 = 0$$

Hence the resonant frequency of the system will be $\sqrt{80}$ radians per second or 1.42 cycles per second. The damping factor will be 1.15 hence the system will be satisfactorily stable, being slightly overdamped in this case. The rise time will be approximately 0.25 seconds which is sufficiently fast in comparison with 1.5 seconds base speed reversal time of the mill with which the tables have to keep pace.

In arriving at this conclusion to confirm the adequacy of the speed of response it must be remembered that for large changes in speed the rise time will be reduced since the magnetic amplifiers will saturate thus placing a limit on the maximum voltage available for forcing the generator field. In practice there is always a tendency for the acceleration of the mill to reduce as it approaches its maximum speed and, therefore, the tables are not required to maintain a constant acceleration over their full speed range. In practice no difficulty was encountered on this account even when the maximum forcing allowable was somewhat under 50% of the full excitation voltage. In practice the table drives are required either to operate from a signal proportional to mill speed or from an independent master switch. In the case of the master switch step signals are applied to the voltage regulator. Under these conditions it is necessary to supply current limit protection to maintain the maximum armature currents within a safe value and prevent the motor overloads from

Fig. 3. Table roll voltage regulator—block diagram.



being tripped out when accelerating or decelerating. There is not the same definite requirement for current limit when operating from signals proportional to mill speed as the speed changes involved in this case are limited to the maximum acceleration of the main drive. However, the table motors are usually selected so that the maximum permissible armature current is used for acceleration and deceleration and on this account it is desirable to have current limit protection to prevent the possibility of overload tripping during speed changes. As more than one motor is connected to the generator it becomes necessary to use a selective type of current limit circuit so that no matter which motor happens to be operating at a limiting value of armature current it will feed a current limit signal to the regulator to change the generator voltage in such a way as to reduce the current flowing.

This selective type of current limit circuit is shown in Fig. 1. Current limit action will commence as soon as the voltage across any one armature resistor exceeds the potential of the bias supply. The individual rectifiers connected to each armature resistor prevent current circulating between the circuits and they permit only the rectifier connected to the resistor with the greatest potential drop to conduct. Current will then flow through the series blocking rectifier to produce the desired signal in the magnetic amplifier control winding. The purpose of the blocking rectifier is to prevent any current flow through the winding due to the bias supply alone. An additional set of rectifiers and a bias supply is provided to give current limit protection for either direction of current flow through the armature circuit.

If the drive were run at full speed and an increasing load torque gradually applied to the motor, the motor speed would reduce slightly by virtue of the speed droop in the motor until the armature current increased to a value where current limit action starts. As the load is increased the drive will slow down and armature current will increase until under stalled conditions the current will have increased to a value which is sufficient to produce a signal in the magnetic amplifier winding which almost completely counteracts the effect of the signal in the pattern winding. The higher the gain around the current limit control loop the less will be the increase in current between the value at which current limit starts and the value at which the drive stalls.

In practice it was found necessary to introduce a rate stabilizing loop around the magnetic amplifier in order to obtain a gain which was high enough to provide a sufficiently small difference between the stall current and the value at which current limit started.

The tables are matched to the speed of the mill by maintaining the table roll generator voltage proportional to the voltage generated by a tachometer driven by the mill stand drive motor. The simple idea of feeding a pattern signal from the pilot generator to the voltage regulator is inadequate for practical purposes, as tables controlled in this way will always tend to lag behind the mill speed during periods of acceleration and deceleration. In order to overcome this tendency of the tables to lag behind the mill it is necessary to feed an anticipatory signal to the table generator voltage regulator. This may take the form of a rate of change of pattern signal, or a transient pulse initiated from the main mill master speed control switch or a combination of both. The circuit incorporating this feature is shown in Fig. 1. In order to avoid the complication of using individual anticipation circuits on every table drive regulator a speed amplifier has been introduced to amplify the signal from the mill stand tachometer generator, and provide a common output which is fed to all regulators. The speed amplifier comprises two push-pull 400 c/s magnetic amplifiers which permit the incorporation of the two rate circuits on the input side, thus avoiding the necessity for duplicating these circuits on every individual regulator. A separate output is taken from the speed amplifier through a blocking rectifier, which allows a draught compensation signal to flow in the table drive regulators for only one polarity of speed amplifier output. The polarity of the speed amplifier is dependent upon the direction of rotation of the main mill drive and it is, therefore, possible to arrange for the draught compensation signal to effect only those tables which are entering metal into the mill. Hence it is necessary to use two blocking rectifiers connected with opposite polarity such that one rectifier serves the tables on the entry side and the other on the delivery side.

Conclusion

Auxiliary drive regulator circuits of the type discussed in this paper have been operating for a period of approximately two years on a reversing 2 HI hot mill at Hamilton, Ontario. The low maintenance record on this particular installation has done much to substantiate the claims made for the advantages of this basically simple magnetic amplifier arrangement and the satisfactory performance obtained has confirmed the validity of the theoretical considerations which formed the basis of the regulator design.

of a Series

INSTRUMENTATION IN INDUSTRY

FOUNDRIES AND STEEL MAKING

THE SURVEY of instrument usage in Canadian foundries and steel making industries showed a strong basic reliance upon the skill and experience of operators using manual methods, but there was a strong undercurrent of interest in automatic instrumentation evident among those replying to the *Journal's* questionnaire. In those cases where advanced instrumentation control systems had been investigated and installed, it appeared that the techniques used— and the results obtained — were equal to, or in advance, of those used in other parts of the western world.

The most commonly used systems appeared in temperature control devices, continuous casting devices, pressure and air control devices and in general furnace control. While these areas of activity are often interrelated, the control of temperature by automatic regulation of the fuel-air mixture is so widespread that it appears to be considered a necessary economic measure by most of those replying, and therefore it commands a separate mention in any report on instrumentation usage in this country. Since heat is the ever-present factor in foundries and steel making plants, it is not surprising to find systems ranging from simple on-off regulators providing two or more preset "fuel-air" mixtures to fully integrated electronically controlled loops which continuously monitor the product of combustion — or the product of the furnace, and adjust the air-fuel mixture for most efficient operation at any given time. The most general control loop appears to be combination electrical-mechanical in nature, with the error signals being transmitted to an amplifier as an electrical signal, which in turn drives a control motor activating a valve in a pneumatic servo loop adjusting the air supply. The great reliance placed on hydraulic servos in the industry at the present time seems to rest firmly on the requirement for a robust and trouble free mechanism which is extremely reliable, and which is not apt to appear too mystifying to the average operator. While it is true that many electronic systems are now made to be extremely reliable, most users appeared not too happy with the requirement for additional links such as relays, syncros for remote control, etc. Since it is not practical to drive servo-motors larger than about ½ h.p. directly from power amplifiers, it is axiomatic that relays and other transfer methods must be used, and a lot of the respondents did not like the idea.

Instrumented continuous casting is being successfully carried out by at least one of the organizations reporting, and the results are considered to be excellent. The instrumentation used is not complex, and represents a practical compromise on the problems associated with isolating and controlling a set of very complicated operating variables such as molten and solid metal temperatures, molten metal levels, casting machine speed, cooling water temperature and flow rates.

Operations having to do with pressure and air flow are commonly associated with furnace control and efficient production of high quality products with reduction in waste. A great deal of interest was evident in the application of tuyere control to blast furnaces which is being used at a number of installations on this continent. By properly regulating the flow of air to the tuyeres surrounding the furnace, a more uniform product is produced, and the elimination of hot spots caused by clogged tuyeres and channelling results in longer furnace life.

The ideal situation sought in the industry calls for fully automatic operation of the furnace cycle, including automatic detection of hot spots by the use of thermocouples or other appropriate transducers, variable charging rates to automatically eliminate hot spots when they occur, control of physical properties of air and other gases used in the process by continuous monitor, analysis and regulation of the flow, and control of quality through continuous analysis of output gases and automatic adjustment of the various raw materials used to charge the furnace.

Common Problems in Automation

Some of the more serious difficulties encountered in realizing these goals have been problems associated with accurate analysis of furnace gases, the need for better temperature transducers and mounting racks, and the need for a wider range of rugged, reliable servo loop components which can stand the abuse of long life in a hot, dusty, gaseous environment.

Many respondents indicated that they were unable to obtain a range of standard control components in this country, with the result that a very large part of the instrumentation for automatic or semi-automatic control is imported, or merely assembled in Canada. Most of those who mentioned the quality of the control engineering services offered by Canadian firms, however, were well pleased with the quality of these services.

They did, however, mention the usual problem of not being able to interest many qualified designers and manufacturers in the limited volume of work available. In many cases, the dollar value of the job is so small that it cannot support development costs, and the only alternative is to turn to imported goods and services.

While not a direct subject of the *Journal's* survey, it is interesting to note in the trade magazines the increasing mention of automation activities in foundries and steel making in the Soviet Union. Apparently it has been appreciated that their only hope of attaining the high rates of production programmed under their various plans is to make an all out effort to advance automation technology and many of their recent installations require very little human attention.

Power and Steam

None of the respondents develop electrical power for their own plant, but 75% of them check consumption of purchased power with their own instruments. Steam plants are used for heating only, and most of the larger companies run a fairly small steam plant for this purpose.

Uses of Instrument

The most commonly used instruments were those designed to measure and regulate temperature in various parts of the production process. As might be expected, such temperature instruments cover a wide range, but the most general types are used for the measurement of molten metal, and are of the pyrometer or thermocouple type. A large number of recording instruments are used, especially in those cases where instrumentation has advanced to the stage where there has been a sizeable reduction in the labour force. The recorded parameters are generally used to provide information for manual correction of processes, or as an aid in laboratory analysis of operating conditions. There were a few reports of self regulating servomechanism loops, mainly to control such things as pouring rates of pouring ladles, air-fuel mixtures — especially on oil fired furnaces — and in raw material fabrication processes. One firm holds slab heat for a planetary rolling mill between closely controlled limits by use of instrumentation, and the same plant has a fairly elaborate system of warning and safety devices designed to minimize danger to the equipment and to operating personnel.

The most commonly quoted purpose for instrument installations was to achieve better quality. The next most important purpose was to provide a continuous record of operations, while less important purposes were to provide supervisory or warning signals, to reduce skill requirements in the labour force, and to regulate pressure or flow. Economy in fuel consumption was another important purpose of instrument installations.

Who Determines Instrument Requirements?

In all of the companies responding to the *Engineering Journal's* questionnaire, company employees are primarily responsible for determining the company's instrument requirements. However, approximately 25% of the companies also used the services of manufacturers of instruments, and in the case of one of the smaller ones, this was the only instrument engineering service used. One or two respondents indicated that they also rely on independent consultants for the determination of their company's requirements.

Purchasing

This industry was less unanimous than others canvassed in the specification and recommendation of instruments to be purchased by the engineering department. While engineering departments still have the greatest say in the brands and types required, there were a number of firms which place this responsibility with the production department. They felt that the persons who use the equipment should have most to say in its procurement—provided, of course, that engineering performance specifications are met.

This questionnaire result requires careful interpretation however, since 85% of the respondents represented small firms with total investment less than $5,000,000.00 The larger firms show the standard pattern whereby instruments are completely specified by the engineering department, and are purchased under their direct supervision by a purchasing department which exercises little control other than to obtain the instruments at the most advantageous price.

Servicing

A wide range of servicing schemes were used, with about equal favour shown to servicing by company employees and the purchase of a service contract from the supplier. One respondent contracts for all his service requirements from an independent serviceman, and in two other cases the service requirements are purchased as required without benefit of contractual arrangements.

Preventative Maintenance

All but one of the firms replying to the questionnaire indicated that they operate a preventative maintenance scheme for their instruments. This is the most unanimous result obtained on this question to date, and seems to indicate that the foundry and steel making industry regard preventative maintenance programs as good business procedure. One of the reasons for such thinking is evident in the repeated reference to the continuous nature of most of the processes, and in the high cost of failures when they occur. While not directly stated, there was a fair amount of reference to the fact that many of the operating personnel regard highly instrumented systems as something of a mystery. Therefore, they are reluctant to delve into even the most simple failures, and instruments which operate without service failures build up confidence and operator moral. These factors all add up to an almost unanimous decision that preventative maintenance programs are a desirable thing, and well worth the money they cost.

Spare Parts Policy

Most companies in this industrial group—90% of those responding — keep a stock of spare parts built up through operating experience. Only one of those replying utilized the recommended spare parts list issued by the manufacturer, and this was not used exclusively—it was combined with the practice of maintaining spare parts built up from "experience lists". Only one of the respondents—one of the larger firms in the country—kept a limited stock of complete replacement units.

There was very little general interest in instruments incorporating optional plug-in features—in fact only one firm indicated that they were particularly suited to their needs. However, it is significant that this firm is one of the most highly automated in the country, and their expenditures on instrumentation was considerably higher than any of the others reported. Plug-in features are especially appreciated in electronic servomechanism systems where power supplies, amplifiers, and adapters may be easily replaced with serviceable units when trouble occurs. This considerably improves the maintenance problem, especially where non-technical operators are concerned. The modification of performance characteristics by the use of various adapters is an important secondary advantage of plug-in units, and is especially helpful when there is a large amount of automatic equipment installed in a plant. To obtain optimum advantage, however, it is necessary to design along certain basic lines, or the advantages of interchangeability of amplifiers, power supplies, etc. will be lost.

What Type of Instruments are Supplied?

The *Journal's* questionnaire has observed a common denominator on this point — practically all users want standard lines of instruments which they can adapt directly to their use, preferably without modification. While this is a very understandable objective, especially when one observes the cost of designing to specification, it may not yield the best results in all cases, and there is probably a field of activity here for a low-overhead instrument service which can supply tailor-made systems at prices not too far above those of standard lines. The resulting improved performance must outweigh the advantage of simplified servicing implied in the preference for standard products.

Statistics on Instrument Costs

All but one of the respondents purchases instruments outright, and in that case 2% of instrument requirements are rented as required. Capital investment in instruments varied widely and ranged from $5,000.00 to over $500,000.00. The majority of those reporting were smaller firms, and only two were in the "over $500,000.00" category for capital investment in instrumentation.

Most respondents indicated their annual maintenance costs for instruments to be in the $3000.00-$5000.00 range. One firm spends approximately $75,000.00 per year on maintenance and there were two in the $30,000.00-$40,000.00 per year range.

The general trend in this industry appears to be to seek rapid recovery of money invested in new instrument installations, and in most of the cases reporting it was stated that recovery of capital cost must be accomplished.

RIVER ENGINEERING *(Continued from page 88)*

definitely, firmly convinced their consequences are inexplicable accidents that will not recur. If he does happen to feel he needs advice he is more likely to ask it from a mathematician than from a geologist. Yet his basic trouble is that he has never had to think about the relatively slow and complex processes of nature such as concern geologists, agriculturists, geneticists, bacteriologists and a host of other scientists whose work gives them the time-sense he lacks.

College instruction

Fitting instruction into a college program is an administrative problem differing among universities and countries. In countries whose schools provide a standard of English, mathematics and physics that does not need to be supplemented in the colleges, the introduction of a couple of new courses at undergraduate level probably poses no problem. The writer is of the opinion that, however river engineering is introduced, it should be accompanied by a separate course in geomorphology to ensure (if nothing else) that the engineer acquires a timse-sense appropriate to phenomena he will encounter in dealing with natural channels and with various important field problems of soil mechanics. Further, he prefers it to be taught according to the system of Ref. 1 which does not rely on assumptions to which rigid-boundary hydraulics is applied but, instead, depends on dynamically satisfactory equations derived by observing actual channel self-adjustment in the field; that is, he prefers the approach of classic physics, via observations of facts, their correlation, and then the explanation and use of equations expressing the correlations.

At the University of Alberta ten years ago the elements of river engineering were taught in the undergraduate irrigation engineering course that dealt with project design (and not application of water in the fields). Now river engineering, considered as basic and applied mobile boundary hydraulics, is a post-graduate course for students majoring in hydraulics, but is taken by a fair number of soil mechanics graduates. The non-mathematical type of hydraulics student takes geomorphology in addition, and the mathematical type is advised to take it if he intends to become a practising river engineer. Advanced mathematics is not needed for river engineering except, of course, to the extent that it can be used by all students of science to improve their ability to think precisely.

Canadian Developments

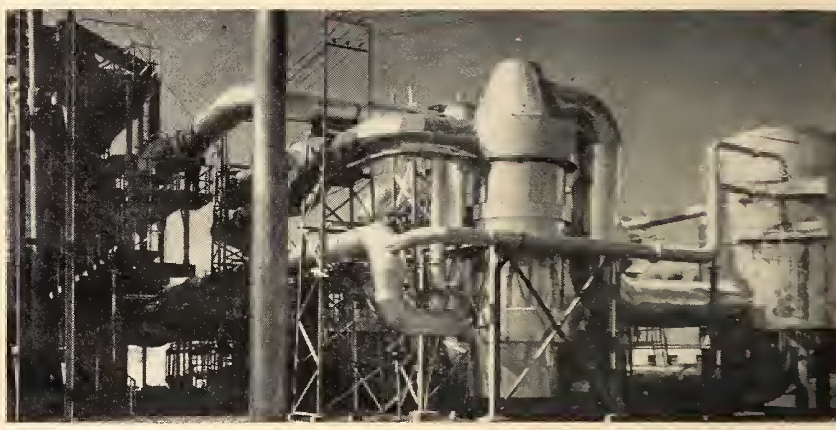
NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Industrial Advances

C-I-L Developments

The new $2 million ammonia oxidation unit for the production of nitric acid at the explosives works of Canadian Industries Limited at Beloeil, Quebec, contains advanced features in its control mechanisms and in its means of utilizing heat and waste gases given off in the reaction. A turbine driven by waste gases provides part of the power for the air compressor. The new unit went on stream late in 1958, designed for C-I-L by Chemical Construction Company.

In the process, filtered air is compressed to about 100 lbs. per sq. in. in a two-stage compressor. The air is mixed with vapourized ammonia and the mixture is passed through a platinum gauze catalyst. The hot gases resulting — mainly nitric oxide at about 900 degrees C. — flow through a series of heat exchangers and are further cooled and partly condensed in a cooler condenser.



Converters containing a vanadium catalyst are part of C-I-L's sulphuric acid plant at the explosives works, Beloeil, Que.

Dominion Tar continuous tar distillation plant, Hamilton.

The gases are fed in at the bottom of the absorption tower, where they are met by a flow of air that oxidizes the nitric oxide to dioxide. Water is fed in at the top. The interior of the tower contains a number of trays through which the nitric dioxide passes to become absorbed by the water to form acid. The concentration of the acid increases as it descends from one level to the next until, at the bottom, it is drawn off at 60 per cent strength.

Waste gases, which are not absorbed, are heated and piped back to drive a turbine which provides a portion of the power required by the air compressor.

Concentrated nitric acid is produced by dehydrating the 60 per cent acid with concentrated sulphuric acid and vaporizing the nitric acid from the mixture. The nitric vapor is condensed to produce an acid of about 98 per cent strength.

At Beloeil, also, a new million dollar sulphuric acid plant went into production in 1958. Designed and constructed by Chemiebau Canada Limited, the outdoor-type plant manufactures acid from sulphur by means of the contact process.

Hamilton Tar Plant

The new plant of the Coal Tar Products Division of Dominion Tar and Chemical Company Limited, at Hamilton, is the first continuous tar distilling plant in Canada. The plant receives coal tar, a by-product of the coking operation in steel plants, and produces distillates and coal tar pitches.

In this new operation, crude tar containing one to three per cent water is heated in the convection section of an oil fired tube heater and again in a trimming heat exchanger to 200°C and fed to a twelve plate dehydrating column, where water and light ends in the benzene, toluene, xylene range are removed as overhead. The water is decanted to waste treatment and the light oil pumped to storage.

The dry tar from the bottom of the dehydrating column is pumped back through the radiant section of the tube heater and flashed into the bottom of a 27 plate fractionation tower. The overhead from this tower is in the solvent naphtha range and contains the tar acids and cumerone-indene resins. Two side draws are taken, one containing 70-75% naphthalene and the second, oils boiling in the creosote range. Heat is recovered from the creosote fraction by exchange with the feed tar.

The column operates at 50 mm of mercury with vacuum provided by a two stage steam ejector. The melting point of the pitch residue in the bottom of the column is controlled by the temperature of the feed tar and the creosote draw-off. The products are pumped to storage.

The first section of the plant went into operation in October, 1958, with formal opening in May 1959. Engineering and construction were by Canadian Badger Company Limited.

Asbestos-Cement Pipe Plant

Quebec's first plant for the manufacture of asbestos-cement pipe was officially opened in May, at Montreal East, Que.

Automatic control plays an important role in the manufacture of asbestos-cement pipe here. Selected types and grades of asbestos fibre are automatically weighed, blended and dispensed into a fiberizer designed for treating asbestos fibre. Simultaneously, portland cement and silica are weighed and blended. All three components through electronic controls merge into a common blender. The dry mixed ingredients then flow to the wet conveyor where water is introduced, thence into the stock in the form of a slurry of uniform consistency.

Slurry feed is closely controlled from the stock chest to the pipe machine vat where it is picked up by the cylinder and transferred to the felt in the form of lamina.

Heavy steel mandrels of the correct diameter are automatically fed into the machine to receive the build-up of laminations under pressure. Lamination thickness and pressures are closely controlled to provide an end product which is uniform in structure. A feature of this machine is calendaring of the wet pipe.

After an initial set in the pre-curing oven, the mandrel is extracted revealing a rigid asbestos-cement pipe. Additional curing is achieved in the final pass of the pipe through the oven to the take off point.

From the pipe making machine the pipe is laid in specially designed bogies and placed in one of three autoclaves where it is subjected to an atmosphere of live, high-pressure steam.

Two Ontario Developments

Plate and Structural Steel Limited, have acquired a new plant, as a step in a planned program of expansion. *DuPont of Canada Limited* have begun production of polyethylene film at its new extrusion plant at Whitby, Ont.

Dominion Foundries Expansion

Dominion Foundries and Steel Limited, Hamilton, Ontario, will install a third Oxyton plant with capacity of 150 tons of oxygen per day.

The company first started operation of the oxygen steel making process in 1954. It now has three 60-ton capacity furnaces, employed on a rotation basis. The current $15 to $20 million expansion program will increase ingot ton potential from 750,000 to one million tons annually by the fall of 1959. Hot rolling and cold rolling facilities are also being enlarged.

Union Carbide Polyethylene Expansion

The third major expansion of polyethylene production at Montreal East is announced by Carbide Chemicals Company, Division of Union Carbide Canada Limited. With the new facilities the plant will have an annual polyethylene capacity of over 65 million pounds. Construction has commenced and completion is scheduled for early 1960. The second expansion phase has just been completed.

Iron and Steel Smelter in B.C.

Consolidated Mining and Smelting Company of Canada Limited, announced in April that construction will start immediately on Western Canada's first iron and steel smelter at Kimberley, B.C. The smelter will be the first stage in an integrated iron and steel operation costing in excess of $20 million.

It will produce pig-iron, steel ingots and rolled steel products. Its capacity will be more than 100,000 tons of steel per year. It will employ over 200 men.

The first stage will be sintering and furnace-feed facilities for a capacity of 100,000 tons of steel per year and one electric furnace of capacity of 36,500 tons of pig-iron per year, with production scheduled for early 1961.

A second larger furnace and oxygen blown converters for the production of steel ingots together with fabricating facilities will follow in the near future.

The Company's reserves of iron tailings from the Sullivan Mine at Kimberley now amount to 15,000,000 tons of recoverable iron. This raw material will be available to the new project in the form of a high-grade iron oxide containing over 60 per cent iron. These iron reserves, the company's power resources on the Kootenay and the Pend-d'Oreille river, the proximity of coal, coke and limestone in the Crowsnest Pass Area, constitute a unique combination of the materials needed for electrothermic production of iron and steel.

The Consolidated Mining and Smelting Company announced in March it will build a $5 million plant at Calgary to produce urea, a chemical which has fertilizer, animal feed and industrial uses. Completion is scheduled for mid-1960.

B.A. Oil Expansion

British American oil will expand the capacity of its Nevis, Alberta gas conservation plant from 15 to 25 million cubic feet of raw gas daily. The plant will process the B-A and Imperial Oil share of production from the nearby Nevis wet gas field.

The expansion will include inlet facilities, amine gas treater, amine liquid treater, refrigeration units, liquid treating and fractionation units, sulphur recovery and boiler plants.

Contracts have been awarded to Poole-Pritchard for construction of the sulphur and boiler facilities, and to Brown and Roote for construction of the hydro-carbon facilities. The expansion is scheduled for completion this fall.

Partnership in Technology

Canadian Vickers Limited, Montreal, have come to agreement with an American company, to fabricate in Montreal, and deliver throughout Canada, materials developed by Knapp Mills Incorporated, New York City.

Vickers will also produce diverse chemical processing equipment, for use where highly corrosive liquors or chemicals must be contained or where radioactive corrosives must be processed and shielded.

Canadian Engineers in Pakistan

The Warsak hydro-electric power project in Pakistan, located on the Kabul River, consists of four hydro-electric generating units, each with a capacity of 55,000 horsepower. It will supply energy to a 45,000 square mile region, and will irrigate 100,000 acres of territory.

H. G. Acres, consulting engineers of Niagara Falls, Ont., are doing the engineering. Construction started in the fall of 1955, and now employs 156 Canadians and 10,400 Pakistani. Canada's contribution to the project under the Colombo Plan is reported to be $36 million.

C.N.R. Photo

The Seaway. First Month of Operation

During May, 1959, the first complete month of operation of the St. Lawrence Seaway, 2,243,450 tons of cargo were carried through the St. Lawrence River canals, according to a preliminary statement of toll traffic issued by the Canadian and United States Seaway authorities. This volume of cargo was being transported by 980 vessels, the aggregate gross registered tonnage of which was 2,898,800. As compared with May 1958, when the 14-foot canals were in operation, the increase in cargo was 741,360 tons, or 49 per cent.

Listed in the first table are the cargo statistics for the month of May and cumulative from the opening of navigation:

ST. LAWRENCE SEAWAY—MONTREAL TO AND FROM LAKE ONTARIO
(tons, 2000 lbs.)

May, 1959	*Upbound*	*Downbound*	*Total*
Bulk cargo	700,500	1,300,950	2,001,450
General cargo	84,700	157,300	242.000
Total cargo	785,200	1,458,250	2,243,450
May, 1958			
Total cargo	457,593	1,044,497	1,502,090
Increase %	71.5	39.6	49.3
Navigation Season— April and May, 1959			
Bulk cargo	812,006	1,507,950	2,319,956
General cargo	124,856	231,900	356,756
Total cargo	936,862	1,739,850	2,676,712
April and May, 1958			
Total cargo	615,017	1,479,658	2,094,675
Increase %	52.3	17.6	27.8

During April this year, traffic on the Welland Canal was well below normal due to the later opening, and the persistence for some weeks of ice in the upper lakes. This situation has had an unfavourable influence on the comparison of the cumulative figures for 1959, as compared with those for the previous year.

To the end of May this year, 1370 vessels had entered the canal, gross registered tonnage being 5,740,305.

The cumulative figures reflect the later opening of navigation in 1959. To the end of May this year, 1173 vessels, having gross registered tonnage of 3,449,325, had entered the new Seaway canals.

WELLAND CANAL
(tons, 2,000 lbs.)

May, 1959	*Upbound*	*Downbound*	*Total*
Bulk cargo	636,100	2,255,300	2,891,400
General cargo	45,150	160,100	205,250
Total cargo	681,250	2,415,400	3,096,650
May, 1953			
Total cargo	528,325	2,212,640	2,740,965
Increase %	28.9	9.2	13.0
Navigation Season— April and May, 1959			
Bulk cargo	859,052	3,045,800	3,904,852
General cargo	70,713	250,750	321,463
Total cargo	929,765	3,296,550	4,226,315
April and May, 1958			
Total cargo	776,151	3,336,516	4,112,667
Increase %	19.8	—1.2	2.8

Welland Canal

Cargo tonnage for the Welland Canal for May, 1959, was 3,096,650, exceeding that of the corresponding month last year by 355,685 tons, or 13%. The number of vessels which entered the canal was 1022, of 4,102,000 gross registered tons.

The cargo figures for the month of May, are listed in the second table, with cumulative figures from the opening of navigation.

University News

University of British Columbia

Prof. David M. Myers, head of the department of electrical engineering at the University of Sydney, Australia, has been appointed dean of the faculty of applied science of the University of British Columbia.

Prof. Myers will take up his duties on January 1, 1960. He succeeds Dr. Henry C. Gunning, who is now a consulting geologist for the Anglo-American Corporation in Africa.

Prof. Myers is a native of Australia, and a graduate in engineering from University of Sydney. In 1938 he was awarded the degree of doctor of science in engineering for contributions to the science of computing. Meanwhile he had done post-graduate work in Manchester, England, and at Oxford University. From 1939 until 1949 he worked with the Australian National Standards laboratory, in the electrotechnology division of the Council for Scientific and Industrial Research. He joined the University of Sydney in 1949. He was president of the Australian Institution of engineers in 1958.

Carleton University

Dr. D. F. Coates, M.E.I.C., director of the School of Engineering, Carleton University, went into industry in June.

His successor at the University is Dr. Ruptash, B. Eng., M.S., Ph.D. from Rensselaer Polytechnical Institute, Troy, N.Y.

Dr. Ruptash is originally from Alberta, a graduate of the University of Alberta. He obtained masters and doctorate degrees at the University of Toronto in aeronautical engineering. He taught at the University of Wichita before going to Rensselaer.

This September the University is to move to the new campus on the Rideau River, where the third year of the engineering course will be offered for the first time.

University of Alberta

A degree course in mechanical engineering is to be offered by the University of Alberta. The first class will graduate in 1960. Dr. George Ford, M.E.I.C., graduate of Alberta, will head the new department. Dr. Ford received a Ph.D. degree in mechanical engineering at Stanford university in 1948, specializing in the field of applied mechanics; he joined the staff of the university in 1942. Two years ago he was named professor of applied mechanics.

The decision to establish a department was made after an exhaustive study to determine the need for such a new course and of modern trends of university curricula in this field.

The work of the new department will be centred around two major areas of specialization, applied mechanics and the basic science of thermodynamics; heat transfer theory, fluid mechanics and the applications of these to the design of mechanical equipment, will be included in the thermodynamics area, while statics and dynamics, vibrations, advanced strength of materials, elasticity and application of these basic sciences to machine design problems will be included in the applied mechanics field.

Other staff members will include D. Panar and D. W. Sadler and W. Johnson and C. M. Rodkiewicz, Dr. J. Duby and J. S. Kennedy. Students will be admitted to the course at the beginning of their third year. The first such group was accepted in September 1958.

McMaster University

The University begins a new phase this fall with the opening of the new engineering building. Construction of the building was completed in early May and represents the largest single project in the university's $13 million expansion program. Degree courses in engineering were first offered at McMaster two years ago when enrolment was restricted to 50 students per year. The new building is designed to handle a first-year enrolment of 170 students and a total student body of 550 in all years of engineering. Four-year degree courses are offered in chemical, electrical, mechanical and metallurgical engineering and in engineering physics. Civil engineering will be added this fall.

Highway Developments

Standards for Traffic Control Devices

The Joint Committee on Uniform Traffic Control Devices for Canada, meeting in Ottawa early in May, agreed on more than 200 sign standards, as well as standard signals and procedure. These standards will be published in a manual by Canadian Good Roads Association this year and implementation by governments is expected to follow. Standardization from coast to coast has obvious advantages.

Two features stressed are: visual impact of signs, and extensive use of graphic symbols. Sign wordage is greatly reduced. Striking examples are those signs prohibiting turns — black arrows enclosed in green circles, pointing out the direction in which traffic may proceed. Written messages will be included in the signs only until drivers have had a chance to become familiar with them. The signs are larger than those now in use and considered more striking because of the arrow symbols. There is a symbolic, five sided school house sign. The Trans-Canada Highway will be marked with a white maple leaf on a green background. There is also a civil defence route marker.

The manual recommends standardization of all traffic signs according to size, shape, colour, dimensions, symbols, wording and lettering. The new signs will have dimensions that have multiples of six. They are classified according to functions they fill: regulatory signs, warning signs and guide signs.

The manual contains the first national code for the design and use of traffic signs, signals and pavement markings ever proposed in Canada. The committee, established by C.G.R.A. in co-operation with the Institute of Traffic Engineers was supported by the ten provincial governments, eleven municipalities, agencies of the federal government and several national associations. Ninety-seven traffic men worked for three and a half years on the standards.

Alberta Highway Program

The province of Alberta has voted $32.5 million dollars for main highway construction, $3 million to complete the Trans-Canada Highway and $4 million to commence re-construction of the Mackenzie Highway. Federal government co-operation in the last two items is expected.

One of the major projects being undertaken in this year's program is the continuation of the divided four lane highway south of Nisku. The divided four lane highway completed last year between Airdrie and south of Red Deer is considered one of the most modern highways on the continent.

(Canadian Developments are Continued on Page 139)

INTERNATIONAL NEWS

CZECHOSLOVAKIA

THE INTERNATIONAL TRADE FAIR to be held at Brno, September 5 to 20, 1959 will have engineering exhibits from thirty countries. Many firms whose names are well known internationally will be represented, while other exhibits will be collective or national efforts.

Czechoslovakia's engineering industry has become the foremost of its industries, having developed most quickly since 1945.

Some noteworthy anniversaries being celebrated this year are: 100 years of the SKODA trade-mark; the 145th anniversary of the first Brno Engineering Works; seventieth anniversary of the engineering works at Kralovo Pole.

ITALY-FRANCE

THE MONT BLANC TUNNEL has been under construction since last autumn, and is to be finished in 1961.

To a point 8,200 feet below the summit of Mont Blanc, the tunnel will be driven four miles from Entreves in Italy and three miles from Chamonix in France. Tunnelling, starting at 4,631 ft. above sea level at Entreves, will fall steadily at a gradient of 0.25 per cent; from 4,179 ft. at Chamonix it will rise at 2.4 per cent; the two gradients will meet at 4,583 ft., near the centre of the mountain.

Last April, the face was advancing at about 13 ft. a day from the Italian side. Drills are operated from a three-storey jumbo.

The excavated section will be 861 sq. ft., and the finished section will be 775 sq. ft. The road surface will be reinforced concrete, with width of 23 ft., built 11 ft. above the invert of the driven tunnel. On both sides of the road there will be a pavement 27½ in. wide and 8 in. above the road level.

Other facilities will be 16-ft. long lay-bys at every thousand feet, man-size "escapes" at 330 ft. intervals, telephone links with tunnel entrances, international road signs, illumination controlled by photo-electric cells, good ventilation.

Two pipelines under the road will carry new telephone and telegraphic links between Italy and France.

At completion in 1961, the Italian and French companies responsible for the project will form one company of equal holdings to handle the administration of the tunnel for 70 years. Then it will become the joint property of France and Italy. The total cost for the project is £11.7 million.

The 7-mile route will cut the Paris-Turin and Paris-Milan routes by 137 and 194 miles respectively. It is expected to become a major industrial and a popular tourist route between Northern Europe and the Mediterranean.

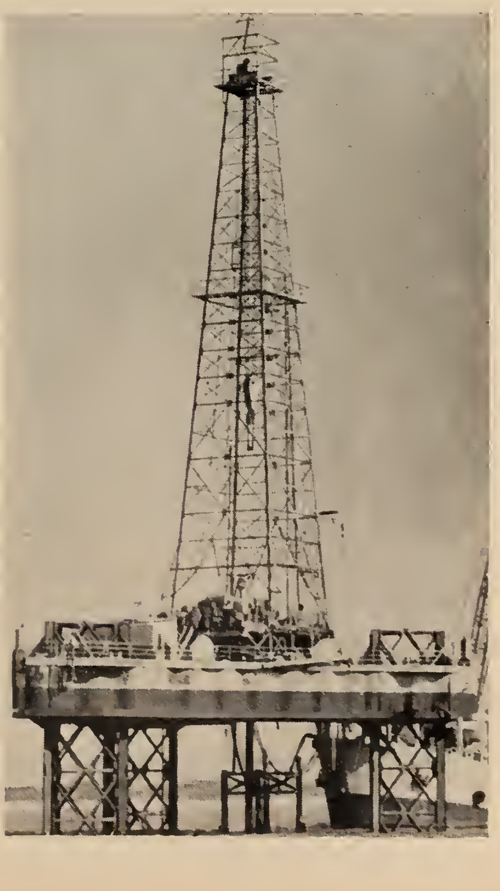
Tolls will be levied on each vehicle. Estimated annual traffic is 264,000 cars, 24,000 coaches, 49,000 motor bicycles and 15,000 trucks, together carrying 1,500,000 passengers and 75,000 tons of freight.

Abstracted from *Engineering*, April 17, 1959

USSR

ATOMIC ELECTRIC POWER, G. V. Yermakov, Chief Engineer of the Atomic Power Administration of the USSR Ministry of Electric Power Station Construction, in an interview with a Moscow correspondent said that the first section of the second atomic, electric power plant in the Soviet Union began operation in September 1958. The first section has a

A 1000-TON "PORTABLE ISLAND" on a tow-voyage across the Atlantic from the marine facilities of R. G. Letourneau, Inc., Vicksburg, Miss., U.S.A., travelled through 75-foot seas at times. It was installed by the Italian company SAIPEM off the coast of Gela, Sicily, in the Mediterranean, and is used to drill for off shore oil. The triangular hull measures 120 ft. by 115 ft. with a depth of 15 ft. The island can raise itself above the water.



capacity of 100,000 kw. and the station's total capacity will be 600,000 kw.

The third atomic electric power plant is going up in the Urals. It is based on the idea of producing super-heated steam by the reactor itself. The uranium-graphite reactor here has two groups of working channels. The super-heated steam goes to the turbine straight from the reactor. And the efficiency of the installation reaches 37 per cent.

The designed capacity of the fourth atomic electric power plant which is going up in Voronezh region is 420,000 kw. It will have two double-water circuit reactors. These reactors will use ordinary water at a pressure of 100 atm. as a neutron moderator rather than graphite.

The fifth atomic plant, of a similar type, will be erected in Leningrad region. In addition, fast neutron reactors are being designed in the Soviet Union, with the coefficient of fuel reproduction exceeding 1. A 50,000-kw plant of this type will be built on the Volga.

In the construction of atomic power plants great attention is paid to biological protection which absorbs the harmful radiation. The site is selected on ground containing thick layers of waterproof clay. Such conditions prevent radio-active substances from the underground installations from polluting local water streams. The sites are fenced off from residential sections and industrial enterprises by a sanitary protective zone which is an additional guarantee of safety for the population. The walls, floor, and ceiling of the main hall of atomic stations are made of solid concrete up to three metres (10 feet) in thickness. Simultaneously with the concrete work, large, metal biological protection structures—steel doors and iron protective slab-plates — are installed.

JAPAN

TOKYO'S NEW TV TOWER is 1,092 feet high. This new landmark was completed at Shiba Park in 1958 for the Japan Television Tower Company, at a cost of $7.5 million. It is topped by a 246-foot television antenna.

Because Japan is subject to frequent earthquakes and typhoons, the tower's stability under these hazards was planned by Dr. Tachu Naito, professor emeritus of Tokyo's Waseda University School of Technology.

Its primary purpose is to act as a platform for multi-service antenna for transmission of electric waves in a variety of frequencies. As many as six TV stations and 58 radio stations are to make use of the antenna unit. In addition police and fire departments and newspapers are expected to use the tower for radio communications.

ATOMIC ELECTRIC POWER GENERATING PROGRAM will be launched under a dual system involving British and American reactors.

The Japan Atomic Power Co. will buy an improved British Calder Hall type of reactor of 150,000 kilowatt capacity.

A 10,000-kw. test power reactor has been ordered from the General Electric Company for installation at Tomai-mura, in Ibaraki Prefecture, the Japanese Atomic Energy Research Institute has announced.

Work was to start on the reactor in April. It will cost about $8.6 million, and will be fueled by enriched uranium to be imported from the United States.

THE NETHERLANDS

COOPERATION IN MANUFACTURE OF PLASTICS is planned by Dutch and British interests. What is being considered is the joint foundation in the Netherlands of an enterprise for the manufacture of urea formaldehyde moulding powders, melamine formaldehyde moulding powders, urea resins and melamine resins.

COLOUR TELEVISION apparatus for medical purposes is being supplied by N. V. Philips' Gloeilampenfabrieken to the pharmaceutical firm of Smith, Kline and French, Philadelphia, U.S.A. The installation consists of a combination of three television projectors each of which reproduces on the screen one of the basic colours red, green and blue. The projection of these three colours over each other results in a perfectly accurate colour picture it is said.

THE LEADING HOISTING GEAR and conveyor factory of the country, N. V. Machinefabriek Hensen, is to build a new engineering works.

The manufacturing program now comprises the construction of various types of hoisting gear and conveyor plants such as cranes for shipbuilding yards, luffing cranes for harbours and various other types of crane, longitudinal and transverse slipways, sluices and barrages with the appurtenant mechanical and electrical operating machinery, and passenger and goods lifts.

THE METAL INDUSTRY has succeeded in the last five years in increasing its production-apparatus regularly. About thirty percent of the Dutch labour force now works in this branch of industry and the same percentage applies to the part the industry plays in the total Dutch industrial production.

UNITED STATES

DIRECT CONVERSION of nuclear reactor energy into electric power was reported on April 7, 1959, by The University of Michigan and Los Alamos (N.M.) Scientific Laboratory.

Robert W. Pidd, professor of physics at The University of Michigan, said the process would cut by perhaps one-half the present cost of building power reactors. It would also tremendously reduce fuel deadweight loads now necessary to propel a rocket into space and enable satellites to have a small but comparatively powerful and long lasting source of electricity with which to telemeter data back to earth. The process would also have great significance in submarine propulsion.

Electric power is obtained from a nuclear reactor containing a uranium carbide source surrounded by a plasma or electrified gas made from cesium. When the reactor is turned on, atomic fission causes the uranium to have such an energy release that it turns white hot. At this temperature a large electric current is produced and is then transmitted by the gas to a collector from which it can be put into use. The technique is called a plasma thermocouple. It eliminates virtually all but the nuclear reactor in the production of electric power from fission. Boilers, turbines, gas condensers and dynamos will not be necessary. But it will be some time before a commercial reactor could be constructed.

The simple device consists of: the source of power, a rod about ¼-in. in diameter and ¾-in. long, containing uranium carbide; this is suspended in the centre of the small cell and surrounded by cesium gas. When the assembly is lowered into the core of a reactor, the neutron flux activates uranium fission heating in the centre of the can, while the flow of reactor coolant around the outside of the can drops the temperature of the cesium plasma. The essential requirements of a thermocouple thus are met, and electricity is produced.

THE SEVENTY-THIRD ANNUAL GENERAL MEETING

THE TORONTO BRANCH was host for the seventy-third annual meeting of The Engineering Institute of Canada, June 8-9-10. Members, their wives, and guests of the Institute in the Queen City found nothing lacking in the hospitality extended by the Branch chairman, Professor A. C. Davidson, and Toronto officers and members.

The amenities of the improved Royal York Hotel, with its attractive new public rooms named and decorated after the Provinces and Territories of Canada, were especially welcome in view of the extreme heat out of doors. Moreover the busy schedule was itself more than sufficient inducement to remain inside. The coordination of Institute business, professional discussion and social events into a program of such variety and interest reflects great credit on the Toronto Committee, under the chairmanship of Whit Davis. Mrs. W. A. Hutchison and Mrs. A. C. Davidson organized the ladies' program.

Each morning for the ladies there was the coffee get-together which is a popular feature of the annual meetings, and on Monday this was followed by a morning drive around the city, lunch at The Old Mill, and an afternoon visit to the renowned James Gardens and Hyde Park Gardens. On Tuesday the ladies lunched at the Royal Canadian Yacht Club, where a bridge demonstration was afterwards arranged for them.

The ladies also paid a conducted visit to the exhibit specially installed in the hotel for this meeting by Atomic Energy of Canada Limited, and many of them were present at the film "Atomic Energy in Canada" which was shown in the ballroom on Sunday evening.

The Program

The Committee on Confederation met on Saturday afternoon and reported to Council the following day. Other Institute business was taken up on Sunday morning when the Branch Officers convened. Delegates and observers from all parts of Canada attended this conference to discuss ways and means of improving service to the Branches and cooperation between them throughout the country.

Council also met on Sunday, and the Committee on Technical Operations assembled in the afternoon. The Annual General Meeting was held on Monday morning, and the following day the new Council of the Institute met for the first time. A report on the Annual General Meeting will appear in an early issue.

The Committee on Engineering Education and the Students' Conference both assembled on Monday. Many of the out-of-town students were accommodated at Hart House, where University of Toronto students entertained student delegates to dinner on Sunday evening.

Authors' Breakfasts each day provided an opportunity for the authors of technical papers to meet the chairmen who were to preside at their sessions. Thirty-nine technical papers were presented, and on Wednesday the final session was devoted to a panel discussion on the economic aspects of the St. Lawrence Seaway. For the first time in Institute history, the technical program was organized and run by the Committee on Technical Operations, and consensus was that their efforts were successful and well appreciated.

At dinner on Monday, June 8th, the office of president of the Institute for 1959-60 was given into the hands of John Jeffery Hanna of Calgary by the retiring president, Kenneth F. Tupper of Toronto.

The inauguration of a National Committee on Professional Development Programs was marked on Tuesday when this committee assembled for the first time at an Annual General Meeting.

The Association of Consulting Engineers of Canada followed their custom of associating their meeting with that of the Institute, and held their annual meeting and annual dinner on Tuesday.

At luncheon on Wednesday President K. F. Tupper presented medals, prizes and certificates of honorary membership to engineers representing practically every area of Canada.

The annual banquet on Wednesday evening, with K. F. Tupper presiding, was followed by a presidents' informal reception and the annual dance. The new president, vice-presidents and councillors of the Institute were formally introduced at the banquet, in the presence of representaitves of all three Canadian Services and of eighteen Canadian and American sister societies. His Worship, Nathan Phillips, Mayor of Toronto, was present at the banquet with Mrs. Phillips as honoured guests of the Institute.

President Tupper also announced the retirement of Miss May McLaren, a senior member of the Headquarters secretarial staff, who is leaving the Institute at the end of June after an association of more than forty years. On hearing this announcement all present rose and gave Miss McLaren a standing ovation.

Quo Vadis?

The wit that framed the observations of Professor Marcus Long, speaker at the banquet, served only to sharpen the focus of his appeal for some attention to the humanities in the education of the engineer. The choice of a distinguished philosopher to speak on this occasion epitomized the spirit of the 1959 meeting, and his wisdom evoked that of other voices on the preceding days. On Monday Dr. Tupper had suggested that as we build and staff the schools of engineering the schools of philosophy should also be enlarged. Earlier still, at the very outset of the meet-

EIC

ANNUAL MEETING

TORONTO 1959

At dinner on Monday evening retiring President K. F. Tupper delivered his farewell address and formally handed over the gavel to President John Jeffrey Hanna.

The new Council holds its first meeting. Below: the retiring Council.

Dr. Lillian Gilbreth with Dagny Vidinsh, a 1959 engineering graduate and at 21 almost the youngest student delegate.

The newly-formed Professional Development Programs Committee. Left to right: J. Walsworth; W. E. Lardner; A. Missakian; K. R. Crean; E. T. W. Bailey (Chairman); W. A. M. Filer; W. O'Reilley; D. Stephenson; M. Truemner; K. Anderson; H. Lightbody.

HONOURS AND AWARDS, 1959

These awards were presented during the annual meeting to those recipients who could be present.

HONORARY MEMBERSHIPS

Randolphe William Diamond, Trail, B.C.
David Arnold Keys, Deep River, Ont.
Roy Aubrey Spencer, Saskatoon, Sask.
John Bertram Stirling, Montreal, Que.
James Alfred Vance, Woodstock, Ont.

SIR JOHN KENNEDY MEDAL

Richard Edgar Heartz, M.E.I.C., Montreal, Que.

JULIAN C. SMITH MEDALS

Norris Roy Crump, M.E.I.C., Montreal, Que.
J. Alphonse Ouimet, M.E.I.C., Ottawa, Ont.

GZOWSKI MEDAL

Raymond Edward Grout, Montreal, Que.
John Arthur Thomas, Montreal, Que.

LEONARD MEDAL

Lazure Eruant Djingheuzian, Ottawa, Ont.

PLUMMER MEDAL

Robert Owen King, M.E.I.C., Ottawa, Ont.

DUGGAN MEDAL AND PRIZE

William Cumming Leith, Montreal, Que.

ROSS MEDAL

Frederic Lewis Lawton, M.E.I.C., Montreal, Que.

ROBERT W. ANGUS MEDAL

Lawrence Milton Boyd, M.E.I.C., Montreal, Que.
Walter Scott McIlquham, M.E.I.C., Montreal, Que.

The Branch Officers met under the chairmanship of Professor A. C. Davidson.

Retiring President K. F. Tupper chats with D. O. Turnbull, President of the Canadian Council of Professional Engineers.

Rendezvous for the banquet. Left to right: Mrs. Marcus Long; E. R. Davis; Mrs. K. F. Tupper; Professor Long; Mrs. Davis; Dr. Tupper.

Conversation piece: Left to right: Mrs. E. C. Luke; Mrs. Garnet Page; Mrs. K. F. Tupper; Mrs. J. J. Hanna.

Dr. Tupper with representatives of the three Services: Colonel W. A. Capelle of the Canadian Army; Group Captain C. L. Ingles, R.C.A.F.; and Commodore H. G. Burchell, R.C.N.

His Worship, The Mayor with the two presidents. Left to right: the new president and Mrs. J. J. Hanna; Dr. and Mrs. K. F. Tupper; Mr. and Mrs. Nathan Phillips.

ASME Honours Canadian

H. S. Van Patter, M.E.I.C., vice-president and director of Dominion Engineering Works Limited, Montreal, recently was elected a Fellow of the American Society of Mechanical Engineers.

To mark the occasion, a luncheon was held at the University Club, Montreal, on April 22, with Dr. R. E. Heartz, M.E.I.C., HON. MEM. A.S.M.E., in the chair. Dr. L. Austin Wright, HON. M.E.I.C., MEM. A.S.M.E., presented Mr. Van Patter to the meeting and outlined his long connection and many activities with The Engineering Institute of Canada.

Logan Kerr, M.E.I.C., of Philadelphia, himself a Fellow of A.S.M.E., gave a short account of Mr. Van Patter's accomplishments in the field of engineering and of administration, pointing out that during the period of his services with the Dominion Engineering Works as design engineer and administrator the company has produced 13.5 million horsepower of hydraulic turbines. He referred also to the valuable experimental work done by Mr. Van Patter on turbine pumps and cavitation.

Dr. Heartz then presented the certificate of Fellowship to Mr. Van Patter, making reference to the many satisfactory transactions he had had with Mr. Van Patter and his company.

In response, Mr. Van Patter disclaimed the credit for the many achievements which had been mentioned by the three speakers. He gave credit for all of these to the company and to the many excellent people who had been associated with him throughout his almost forty years of connection with the Dominion Engineering Works Limited.

In conclusion, the meeting expressed to Dr. Heartz its appreciation of his thoughtfulness in bringing the group together to mark this interesting occasion.

S. Logan Kerr, M.E.I.C., and H. S. Van Patter, M.E.I.C., and Dr. R. E. Heartz, M.E.I.C.

The Royal Canadian Engineer Museum at Camp Chilliwack, B.C.

An abstract of an article by Capt. J. S. McGivern, S.J., M.B.E., C.D. R.C.A.Ch.C.(R.C.)

When the Royal Canadian Engineer Museum placed a military exhibit, or museum in miniature, in the Pacific National Exhibition last year, many people wondered about the parent Museum. This was not very surprising, for the history of this museum goes no further back than July, 1956. At that time, *The Canadian Sapper* headline read, "R.C.E. Museum Becomes a Reality".

It had been a long-felt want and many proposals and plans had in the past been made. But it was not until July 1956 that more strenuous efforts could be exerted. Under the encouragement of Colonel R. J. Carson, C.D., now commandant of the School of Military Engineering, and the enthusiastic cooperation of many other officers, plans for the Museum progressed rapidly. At that time a Museum Board was established, consisting of Col. Carson, Major Burgoin, Capt. Blake, and R.S.M. Sininger.

The first place set aside for the start of the Museum was the former Roman Catholic Chapel. The Army had built a new chapel for Catholic personnel and on August 15, 1956, the new building was taken over and the first service held there. This left the old chapel available for the R.C.E. Museum.

One of the first projects of the Museum was to try to illustrate the motto of the Royal Canadian Engineers: OBIQUE QUO FAS ET GLORIA DUCUNT. As the word 'FAS' normally in its original latin means 'divine right', it was considered appropriate to combine the old R.C. Chapel and the first Protestant altar used in Camp Chilliwack, as the shrine on which to place the Books of Memory containing the names of those Engineers who died during World Wars I and II. The altar was flanked with the Corps Flag, the Union Jack, the Canadian Ensign, and the last flag flown over the Royal Canadian Engineers' ships. In the centre, above the altar, the picture of Her Majesty Queen Elizabeth was placed.

Soon after this, exhibits began to come in. The Museum was finally set up in January 1957 in the old chapel and was opened to the Corps of the Royal Canadian Engineers by the Honorary Colonel Commandant of the Corps, Brigadier J. L. Melville, C.B.E., M.C., E.D., in May of that year. On August 8, 1958, Sir Ouvry L. Roberts, G.C.B., K.B.E., D.S.O., former Quartermaster General of the British Army and an Honorary Colonel, Commandant of the British Royal Engineers, opened the Museum to the public. Present on that occasion were a number of descendants of the British Royal Engineers who pioneered in British Columbia a hundred years before. The Museum is now open to the public every Wednesday evening, from seven to nine o'clock, and on the first and third Sundays of each month from three to four-thirty. The number of visitors is steady but by no means extraordinary as yet.

The biggest problem is that of continued growth. Unless it continues to have new and interesting exhibits and a place to show them, the R.C.E. Museum could become a stagnant and dormant thing. However, it is still continuing to receive new and interesting material from both the First and Second World Wars, though the influx is not as great as in the earlier days.

The R.C.E. Museum was formally opened by General Sir Ouvry Roberts, left, with Major A. S. Millen aud Col. M. Turner (at back).

However, we know there must be a great deal more material kicking around in attics or buried in trunks. We are particularly looking for badges, regimental flashes, medals and uniforms. The writer would like to urge everybody to continue to help us expand. If you find things that might interest us, please do not hesitate to contact the Museum staff.

One of the best helpers in the Museum is Mrs. Bateson, who has a special project at the moment — a Sergeant's Exhibit. It consists of uniforms and hats or caps of sergeants during the past sixty or sixty-five years.

Recently the Museum was presented with a complete set of Bruce Bairnsfather's "Fragments of France". There are also two original drawings of this World War I artist.

Brigadier J. B. Bishop, O.B.E., C.D., has commented "A military museum, over and above the intangible values of preserving the history and traditions of the Army, provides an educational value to all military personnel in the maintenance and display of equipment, material, and related items which have played a part in the history of the Canadian soldier. They give evidence of technical development, traditions, and an esprit de corps, of an army that has captured the admiration and respect of all nations".

M.E.I.C. at Atlantic Congress

James A. Vance, M.E.I.C., was one of the delegates from Canada to the Atlantic Congress, which was held in London, England in June. Mr. Vance was a member of the Committee on Resources and Underdeveloped Areas in the Atlantic Countries.

The discussions were attended by 650 political and business representatives from the member nations of North Atlantic Treaty Organization.

Chairman and head of the Canadian delegation was Henry Frank Jones, LL.B., M.P.

Consulting Engineers Annual Meeting

The annual general meeting of the Association of Consulting Engineers of Canada took place at the Royal York Hotel, Toronto, on June 9, 1959, the chairman being C. C. Parker, P.Eng., of Hamilton, Ont. Members from all parts of Canada were present and the Consulting Engineers Council of the United States was represented by its president, Ralph M. Westcott, of Los Angeles.

In his report for 1958, Immediate Past-President John G. Frost stated that the Canadian Association of Consulting Engineers has been admitted into the membership of FIDIC, the Federation Internationales des Ingenieurs Conseils.

Among the reports presented was that of the Committee on Tariff of Consulting Fees. Its chairman, Edgar A. Cross, of Toronto, referred to a study being made of fee structures in the various provinces and he expressed the intention to shortly submit proposed revisions which will be designed to more adequately meet the changing conditions in the various fields of consulting practice.

The meeting was followed by the annual dinner of the Association which was attended by members and their wives. Among the guests were Immediate Past President K. F. Tupper and Mrs. Tupper, and President-Elect J. J. Hanna and Mrs. Hanna, Engineering Institute of Canada; Ralph M. Westcott, Los Angeles; Maurice Payette, president, Royal Architectural Institute of Canada; J. E. Harrington, President, Canadian Construction Association, and Mrs. Harrington; A. W. F. McQueen, President, Ontario Association of Professional Engineers, and Mrs. McQueen; R. A. Frigon, Department of Trade and Commerce of Canada; and D. O. Turnbull, President, Canadian Council of Professional Engineers.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

John William Porter, M.E.I.C. died early in 1958 in Winnipeg, Manitoba.

Mr. Porter was born in Aberdeen, Scotland on October 15, 1877 and was educated at Gordon's College, Aberdeen. He served a five year pupilage with P. M. Barnett, chief engineer with the Great North of Scotland Railway.

Mr. Porter came to Canada in 1902 and joined the C.P.R. in Montreal.

In 1905 he became resident engineer with the C.P.R. in Toronto and in 1915 became chief engineer with the Hudson Bay Railway. In later years he was a consulting engineer, with W. C. Arnott & Co., in Winnipeg.

C. D. McAllister, M.E.I.C. of Saint John, N.B., died on March 20, 1959.

Mr. McAllister was with the Federal Department of Public Works where he was assistant chief engineer of the New Brunswick division.

He represented Canada as secretary on the Canadian contingent to the joint U.S.A., Canada committee on the Passemaquoddy hydro power project and was also a warden for the Engineering iron ring ceremony.

Until the time of his death he was active with several community organizations.

Mr. McAllister was a graduate of University of New Brunswick, class of 1918.

W. E. Warburton, M.E.I.C. retired city engineer of Penticton, B.C., died on March 28, 1959.

Born on March 1, 1893 in Charlottetown, P.E.I., he received his engineering education at Kings College, N.S., and at McGill University.

After serving in World War I, from 1914 to 1918, he joined Green Bros. & Burden, B.C. as instrument man. In 1921 he became assistant engineer with Nelson Sewer Construction and from 1925 until 1941 served on various construction projects.

Mr. Warburton opened his own construction company in 1946 and in 1947 became city engineer with the City of Penticton, B.C. where he was until his retirement.

A. R. Holmes, M.E.I.C., died on February 24, 1959, at Windsor, Ont.

Born at Hantsport, N.S. on July 18, 1872, he graduated from King's College, N.S., in 1895, with a bachelor of engineering degree.

After graduating he worked as draftsman and structural engineer with various construction and railway projects.

He was secretary-treasurer for seven years with MacKinnon, Holmes & Company Limited, Sherbrooke, Que. and later, president of Archibald & Holmes Limited, Toronto. He continued to work in engineering in Toronto, latterly with Allward Gouinlock, Architects, and with the Bell Telephone Company. He went to Windsor in 1958.

T. Frederick Francis, M.E.I.C., of Toronto, Ont., died May 8, 1959.

Born in Moncton, N.B., he started his career with the C.P.R. in 1907. He later returned to university and graduated from McGill in 1915 as a civil engineer.

After serving in World War I as a member of the Railway Corps, he returned to Canada and rejoined the C.P.R. where he supervised construction in western Canada.

He was responsible for construction work on the Rogers Pass and Connaught tunnel near Revelstoke.

Mr. Francis retired two years ago as construction engineer with the Ontario Department of Highways. Since his retirement he had been consultant on Trans Canada Highway work near Revelstoke.

Victor S. Chestnut, M.E.I.C. died on April 27, 1959, at St. John, N.B.

Born in Toronto, he received his degree in engineering at Toronto University in 1912. He was employed for five years in construction of the Welland Canal.

From 1919 until 1924 he was on the staff of Saint John Dry Dock Company Limited. He went to Ontario then to work on elevator construction at Midland, and later on the designing staff of the Welland Canal.

In 1930 he returned to Saint John as port engineer. He retired in 1953.

J. N. Stinson, M.E.I.C., died on April 3, 1959, in Ottawa.

Born at Toledo, Ont., he graduated from Queen's University in 1914 with the degree of bachelor of science in civil engineering.

Upon graduation he joined the National Parks Branch of the former Department of Interior. In 1949 he retired from the civil service where he was supervising engineer of the Engineering Division of the Department of Mines and Natural Resources.

George Percival Wilbur, M.E.I.C. died suddenly on May 5th, 1959.

Born at Victoria Harbor, he received his education in Toronto and in 1909 began his career with Polson Iron Works in Toronto.

In 1913 he joined Dominion Bridge Company Limited where he became successively chief draftsman, contracting engineer and sales manager and in 1951 he was elected vice-president and general manager for the company.

He retired from the company in 1956.

Ewart Greig, M.E.I.C. chairman of the board of Union Carbide Canada Limited, died May 18, 1959 in Toronto.

Born and educated in Toronto, Mr. Greig joined the National Carbon Division of Union Carbide in 1919 where he was appointed vice-president and general manager in 1942. Upon formation of Union Carbide Canada Limited in 1954, M. Greig was made first president of the company and was elected board chairman in 1956.

He was active in the management of CKNC in Toronto, one of Canada's first radio stations established by National Carbon in the early 1920's and then taken over by the Canadian Radio Commission.

Arthur John Gayfer, M.E.I.C. died on March 6, 1959, at Kelowna, B.C. He was born on January 25, 1877 at Uxbridge, England. He came to Canada in 1898.

Mr. Gayfer served in Belgium and France during the first world war as a major and as chief engineer of the Twelfth Battalion Light Railway Troops.

After forty-two years of service with the Canadian National Railway Company, he retired in Calgary, before going to Kelowna. His work had been mostly on location and construction of eastern and western lines.

E.I.C Annual General Meeting, 1960

Royal Alexandra Hotel, Winnipeg, Man., May 25-26-27.

Personals

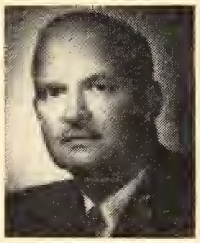
A. E. Cameron, M.E.I.C. (B.Sc., mining, 1913, M.Sc., McGill, 1914, D.Sc., M.I.T. 1926) was awarded the honorary degree of Doctor of Engineering recently at the Nova Scotia Technical College. Dr. Cameron is the former president of N.S.T.C.

J. H. Mowbray Jones, M.E.I.C. (B.A.Sc., mech., Toronto, 1927) received an honorary Doctor of Engineering degree at the recent Nova Scotia Technical College convocation. Mr. Mowbray Jones is vice president of Mersey Paper Company, Liverpool, N.S.

Jack Morris, M.E.I.C. plant manager of Courtaulds (Canada) Limited, Cornwall, Ont., has been elected to the board of directors of the company.

J. W. Macdonald, M.E.I.C. (B.Sc., elec., Nova Scotia, 1931) formerly assistant chief engineer, has been appointed chief engineer of the Nova Scotia Light and Power Company Limited, Halifax, and its subsidiaries.

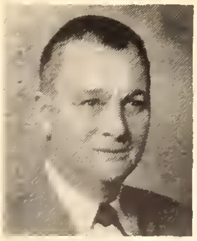
J. W. MacDonald, M.E.I.C.



Jack Morris, M.E.I.C.

Albert G. Ley, M.E.I.C. (B.Sc., elec., Nova Scotia, 1930) has been made superintendent of the thermal division with the Nova Scotia Light and Power Company Limited, Halifax, N.S.

W. G. Macdonald, M.E.I.C. formerly chief engineer, has been appointed executive engineer with the Nova Scotia Light and Power Company, Limited, Halifax.



Albert G. Ley, M.E.I.C.

W. G. Macdonald, M.E.I.C.

Dominion Bridge Company Limited reorganization has resulted in a number of senior management appointments, including these:

W. Herbison, M.E.I.C. has been appointed works manager in the Montreal Branch.

P. G. A. Brault, M.E.I.C. (B.Sc., McGill, 1921) has been named chief engineer, structural division (Montreal).

C. J. Pimenoff, M.E.I.C. (B.Sc., M.Eng., McGill, 1931, 1932) is assistant chief engineer, structural division (Montreal).

H. J. Leitch, M.E.I.C. (B.Sc., McGill, 1926) has been named sales manager, structural division (Montreal).

A. M. Bain, M.E.I.C. (B.Sc., civil, Manitoba, 1928, M.Sc., McGill, 1929) has been appointed chief engineer, platework division (Montreal).

W. G. Peacock, JR.E.I.C. (B.Eng., civil, McGill, 1949) is appointed sales manager of the platework division (Montreal).

D. J. Lewis, M.E.I.C. (B.Sc., civil, Queen's, 1924) is manager of contracts, platework division (Montreal).

H. L. Ferguson, M.E.I.C. has been appointed chief engineer of the mechanical division.

F. Block, M.E.I.C. (mech. engineer, Vienna, 1921) is chief engineer of the boiler division.

J. M. Dyke, M.E.I.C. (B.A.Sc., mech., Toronto, 1943) is manager of contracts, boiler division.

J. R. MacKay, JR.E.I.C. (B.Eng., mech., McGill, 1951) is in charge of sales of water tube boilers and steam storage schemes in the Boiler Division.

R. M. Robertson, M.E.I.C. (B.Sc., civil, McGill, 1920) manager of operations at Lachine, Que. has retired after many years with the company.

D. E. Perriton, M.E.I.C. (B.Sc., mech., McGill, 1922) has been appointed manager of contracts, for the mechanical division.

Herbert F. Schmelz, M.E.I.C. (Polytechnique Institute of Vienna, Austria, 1936) formerly of Montreal, has been appointed director of engineering for Industrias Metalicas and its allied plants in South America.

George L. Houghton, M.E.I.C.

Ernest F. Wilson, M.E.I.C.

George L. Houghton, M.E.I.C. (Higher Nat. Cert., Mech., 1946) has been elected second vice president of Racey, MacCullum and Associates Limited, Toronto.

Ernest F. Wilson, M.E.I.C. (B.A.Sc., Aeronautical, Toronto, 1949) has been made a representative of Linde Co. division of Union Carbide Canada Ltd., for Toronto and Eastern Ontario.

H. W. H. Casperd, M.E.I.C. (B.Sc., civil, London, 1928) has been appointed chief field engineer with the Foundation of Canada Engineering Corporation Limited, Toronto.

H. G. Ambrose, M.E.I.C. (B.A.Sc., mining, Toronto, 1942) has been appointed assistant general manager of V. D'Ambrosio and Company Limited, Toronto.

H. G. Ambrose, M.E.I.C.

H. W. H. Casperd, M.E.I.C.

Earl Dokken, M.E.I.C. (B.Sc., mech., Saskatchewan, 1944) is general manager of Redi-Mix Ltd, Moose Jaw, Sask., and also president and general manager of Inland Construction Ltd., Moose Jaw.

Kenneth C. Cox, M.E.I.C. (M.Sc., civil, Lehigh, 1939) was recently elected vice-president of Dravo of Canada Limited, Toronto.

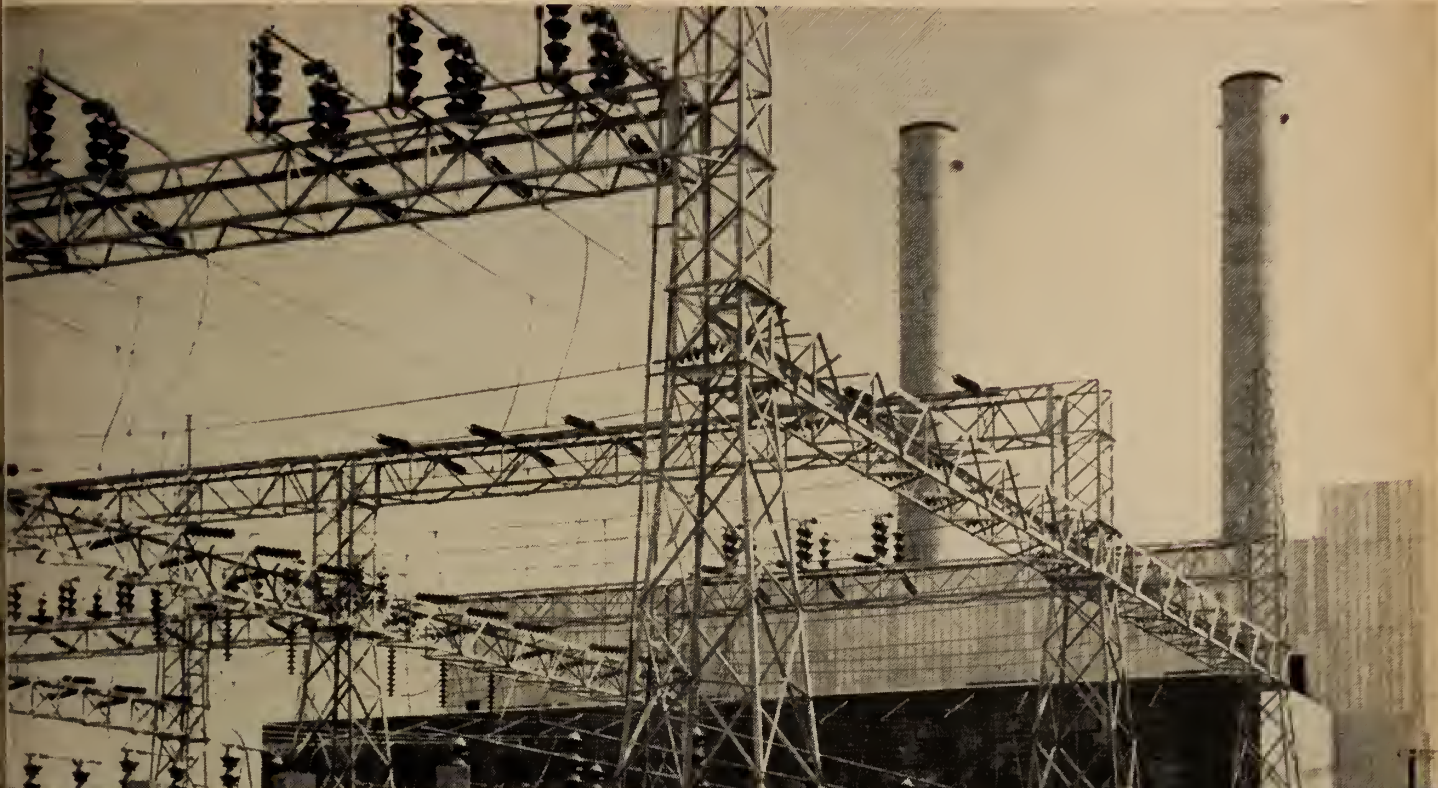
Earl Dokken, M.E.I.C.

Kenneth C. Cox, M.E.I.C.

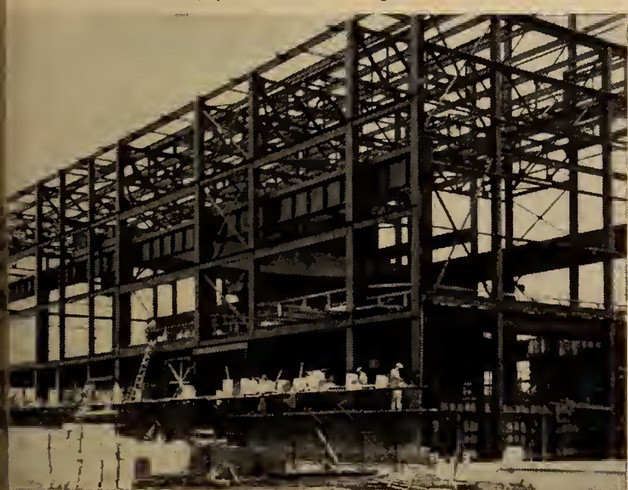
A. K. Piercy, M.E.I.C. (B.Sc., mech., Saskatchewan, 1942) has been appointed chief engineer of Alpha Manufacturing Company Limited, Winnipeg.

William L. Fraser, M.E.I.C. (B.A. Dalhousie, 1915, B.Sc., McGill, 1917) has been appointed Ontario Hydro's director of the St. Lawrence Power Project.

DOMINION BRIDGE



ba Bridge crews erect and place into position 60″, 48″, 30″ and 24″ pipe for the cooling water.



ork for the main building. All three buildings contain a total of 2100 tons of structural steel.

Brandon generating station switchyard showing galvanized steel structure:

At Brandon Generating Statio

Manitoba Hydro Electric Board's Brandon generating statio has a structural steel frame. The station has increased th system's capacity by 132 M.W. and comprises four 33 M.W hydrogen cooled steam turbo-alternator sets.

For this project, Dominion Bridge fabricated and erecte the structural steel for the principal buildings and Manitob Bridge supplied a considerable amount of the steelwor used throughout the plant.

Contracts included 2100 tons for the powerhouse, adminis tration building and fuel bunkers: approximately 1300 ton of miscellaneous steel structures for use within the buildings a 500 H.P. packaged unit scotch dry back heating boiler extensive steel pipework for the cooling water, and th galvanized steel structures in the switchyard.

MANITOBA BRIDGE

PERSONALS

D. B. Annan, M.E.I.C. (B.Sc., Queen's, 1940) is assistant director of military sales at the De Havilland Aircraft of Canada Ltd, Downsview, Ont.

Kenneth R. Bullock, M.E.I.C. (B.Eng., elec., McGill, 1952) formerly of Ontario has joined the Anaconda Wire & Cable Company, Hastings-on-Hudson, N.Y.

John Greenaway, M.E.I.C. is now application engineer with the Alpha Manufacturing Company Limited, Winnipeg.

G. H. Wood, M.E.I.C. (B.A.Sc., civil, Toronto, 1917) has recently retired as district engineer with the Department of Northern Affairs and National Resources, Ottawa.

A. C. Ridger, M.E.I.C., has been named special assistant, engineering division of Cominco Engineering, Trail, B.C.

N. D. Heaslip, JR.E.I.C. (B.A.Sc., chem., British Columbia, 1951) has been made supervisor of the high explosives department, of Canadian Industries Limited at McMasterville, Que.

R. Keith Jamieson, M.E.I.C. (B.A.Sc., M.Sc., civil, British Columbia, Manitoba, 1952, 1957) has been appointed engineer-Missionary under appointment to Angola, Africa with The Board of Overseas Missions, the United Church of Canada.

R. A. Phillips, M.E.I.C.

J. A. Dubuc, JR.E.I.C.

R. A. Phillips, M.E.I.C. (B.A.Sc., British Columbia, 1939) of Canadian General Electric Company Limited, Montreal is the chairman of the Montreal Branch of the Institute.

J. A. Dubuc, JR.E.I.C. of James H. Wilson Limited, Montreal has been elected chairman of the Montreal Branch of the Institute.

D. G. McKay, JR.E.I.C. (B.Sc., mech., Manitoba, 1949) formerly with Emco Limited, Calgary, Alberta is now self employed as a manufacturers agent in Nanaimo, B.C.

H. W. R. Gibney, JR.E.I.C. (B.A.Sc., mining, British Columbia, 1950) has been appointed method study technician, mines division of The Consolidated Mining and Smelting Company at Kimberly, B.C.

William Fredenburg, JR.E.I.C. (B.A.Sc., mining and geology, Toronto, 1949) field engineer with The General Engineering Company Limited, Toronto, has lately been located at Viburnum, Missouri.

Edger D'Souza, JR.E.I.C. (B.Eng., elec., Syracuse, 1950) has joined Quebec-Telephone in Rimouski, Que., to work in the plant extension group of the engineering department.

Raoul Verret, JR.E.I.C. (B.A.Sc., civil, Polytechnique, 1952) was recently appointed director for European operations for Werner Associates Inc., management consultants, New York.

R. H. Nutt, JR.E.I.C. (B.A.Sc., mech., Toronto, 1952) is working with the Pioneer Saw Limited, Peterborough, Ont. as a project engineer.

Kui Yuen Kwong, JR.E.I.C. (B.Eng., civil, McGill, 1957) has been made structural engineer with Pak C. Kwong, M.Arch., in Hong Kong.

Maurice Malo, JR.E.I.C. (B.Eng., mech., McGill, 1950) is now combustion and development engineer with Volcano Ltd., St. Hyacinthe, Que.

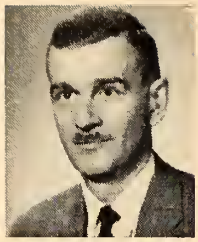
R. J. Kavanagh, JR.E.I.C. (B.Sc., elec., New Brunswick, 1953) lecturer at the University of Toronto has been awarded a National Research Council postdoctorate overseas fellowship at Imperial College, London.

• PERSONALS

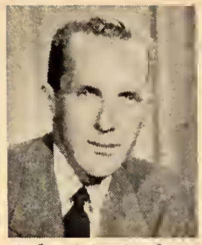
Edward W. Thorne, JR.E.I.C. (mech. eng., I.M.E., 1954) is an engineer with Spade Contractors, London, Ont.

R. M. Dunton, JR.E.I.C., (B.Eng., mech. McGill, 1949) of Dominion Engineering Company Limited, Montreal, has been appointed chief engineer of the press, mining and rubber departments.

K. L. Pinder, JR.E.I.C. (McGill, 1951, 1952, Ph.D., Birmingham, 1954) is in the research department of Dow Chemical of Canada Ltd., Sarnia, Ont.



R. M. Dunton, JR.E.I.C.



John M. Epplett, S.E.I.C.

G. D. McKenzie, JR.E.I.C. (B.Sc., mech., Manitoba, 1957) has become research and development engineer of Alpha Manufacturing Company Limited, Winnipeg.

Reginald S. Wallace, JR.E.I.C. (B.A.Sc., civil, 1956) is a field engineer with the Department of Transport, Air Services Branch, Toronto.

Paul Imbeau, JR.E.I.C. (B.Sc., mech., Laval, 1957) is an industrial engineer with Vincent Casson, P.Eng., industrial engineer and management consultant.

John M. Epplett, S.E.I.C. (B.Sc., civil, Queen's, 1958) is on the sales engineering staff of the bailey bridge department of Contractors Service Limited, Toronto.

Alex Grecoff, S.E.I.C. (B.Eng., civil, N.S.T.S. 1958) is a field engineer with the Pentagon Construction Company, Montreal.

Corrections

Names appearing under these two pictures in the Personals section, May issue, pages 133 and 137 were reversed in error. The pictures are repeated here, correctly captioned:

Max Deitch, JR.E.I.C.

C. K. Lockwood, M.E.I.C.

Mistakes were made also in the setting of names under these pictures in the section "Newly elected officers of the Institute", May issue, pages 127 to 128. The pictures are correctly identified, as follows:

A. S. Mitchell, M.E.I.C.

P. W. Gooch, M.E.I.C.

T. N. Davidson, M.E.I.C.

W. A. Mitchell, M.E.I.C.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute

and abstracts of the papers presented at their meetings

CENTRAL B.C.

Report of the Western Field Secretary, A. C. M. Davy, M.E.I.C.

IN PENTICTON ON MAY 1ST there was a joint dinner meeting of the Central B.C. branches of the Institute and the Association of Professional Engineers of B.C. About 30 people were present, some from as far away as Revelstoke and Kamloops.

Some thought has been given to the possibility of holding one or more joint meetings with nearby branches. They have concluded that joint meetings with Vancouver or Vancouver Island branches are not practical, but that a joint meeting with the Kootenay Branch might be worked out. Further study is to be given to this project.

An extremely interesting field trip was being arranged to the Rogers Pass section of the Trans Canada highway in later June. This is described immediately below.

A. F. Joplin, M.E.I.C., *Correspondent*

A FIELD INSPECTION of the Rogers Pass Route of the Trans Canada Highway in Glacier National Park was planned for June 26.

The party was to go on the Friday morning to Glacier, B.C., have lunch at the Federal Department of Public Works Camp, and then inspect the works and construction in the area.

Returning to Revelstoke, they were to take part in the dedication of a plaque. This is a joint project of the Central B.C. branches of the E.I.C. and the Association of Professional Engineers of B.C. It commemorates the pioneer engineers and especially Major A. B. Rogers, who was in charge of construction of the Canadian Pacific through the mountains, 1880-1885.

Two speakers were scheduled for the dinner meeting, later the same day. They are: P. Schaerer of the National Research Council, on "Avalanche Control", and R. K. Coates, P.Eng., engineer in charge of construction of the T.C.H. through Glacier and Revelstoke National Parks, whose subject is "Location through Rogers Pass".

CORNWALL

H. S. Johnson, JR.E.I.C., *Correspondent*

JOHN T. GEOGHEGAN, finishes division manager, DuPont of Canada Limited, Toronto, spoke at the meeting of June 2, on the subject, "The Hues You Choose and Use".

Colours and qualities of paints were discussed by Mr. Geoghegan. The thin finish on a car is expected to, and usually does, stand up to all extremes of temperature and weather conditions and usage. For best results, the speaker suggested that a reputable brand of paint be used according to the manufacturer's recommendations.

Colour, he said, has a definite psychological effect. The most preferred colours are blue, red and green. Colour can change the character of a room, for instance. Colour is an important factor for purposes of advertising and traffic and safety signs. The visibility and attention values of colours for these purposes is well known.

EASTERN TOWNSHIPS

Jean Bourassa, JR. E.I.C., *Correspondent*

THE ANNUAL MEETING and Ladies' Night took the form of a buffet supper on May 30 at the Club Sociale de Sherbrooke. The meeting was followed by a dance.

The newly elected officers of the branch are: chairman, J. C. Davidson; vice-chairman, J. P. Champagne; councillors, W. K. Baldwin, Michel Normandin and R. V. Planck. The new secretary is A. H. MacLean of Moulton Hill Rd., Lennoxville.

FREDERICTON

John Burrows, M.E.I.C., *Correspondent*

AN INFORMAL GATHERING was held on May 11, 1959 at which the Branch entertained members of the graduating class of the University of New Brunswick.

HAMILTON

C. A. McCurdy, JR.E.I.C., *Correspondent*

FIRESTONE TIRE AND RUBBER COMPANY, Hamilton, was host to a group of branch members on May 14, for a guided tour of the tire plant.

An afternoon coffee break was provided in the company cafeteria before the tour commenced. The tour then covered the manufacture of tires from the storage and curing of the raw rubber to the final inspection of the finished product.

Hamilton. J. L. Harbell, R. H. Stevenson, E. W. Hill, C. A. McCurdy, during an inspection visit to Firestone Tire and Rubber Company.

Hamilton officers, R. H. Stevenson, P. J. McNally, and R. C. Mitchell.

AN EXECUTIVE MEETING was held on April 9, 1959. R. H. Stevenson, vice president was appointed chairman to fill the unexpired term of H. E. Seely who had been transferred to Toronto. P. J. McNally was appointed vice-chairman and J. M. Skinner was appointed an executive committee member. At the same meeting three members were appointed to the national committee of the professional development program: W. A. H. Filer, K. R. Crean, and J. A. Walsworth.

LAKEHEAD

G. O. Hansen, JR.E.I.C., *Correspondent*

LEOPOLD NADEAU, general secretary of the Canadian Council of Professional Engineers spoke at the meeting of May

Plated U.F.G. beauty is apparent in these fine products. Case of the Westclox Pocket Ben by Western Clock Company, Ltd., and fishing lures by Lucky Strike Bait Works Ltd. are outstanding examples of low-cost fine finishes obtained with U.F.G. Brass Strip.

Noranda makes an extensive range of copper and brass strip and sheet to meet a wide variety of drawing, spinning, stamping and engineering applications. Because so many different characteristics can be "built into" copper alloys you can meet almost any product or production requirement with ease. Regardless of the material you are now using, it will pay you to discuss your strip and sheet needs with the Man From Noranda... chances are he can show you new ways to use copper alloys to better advantage.

Noranda Copper and Brass Limited

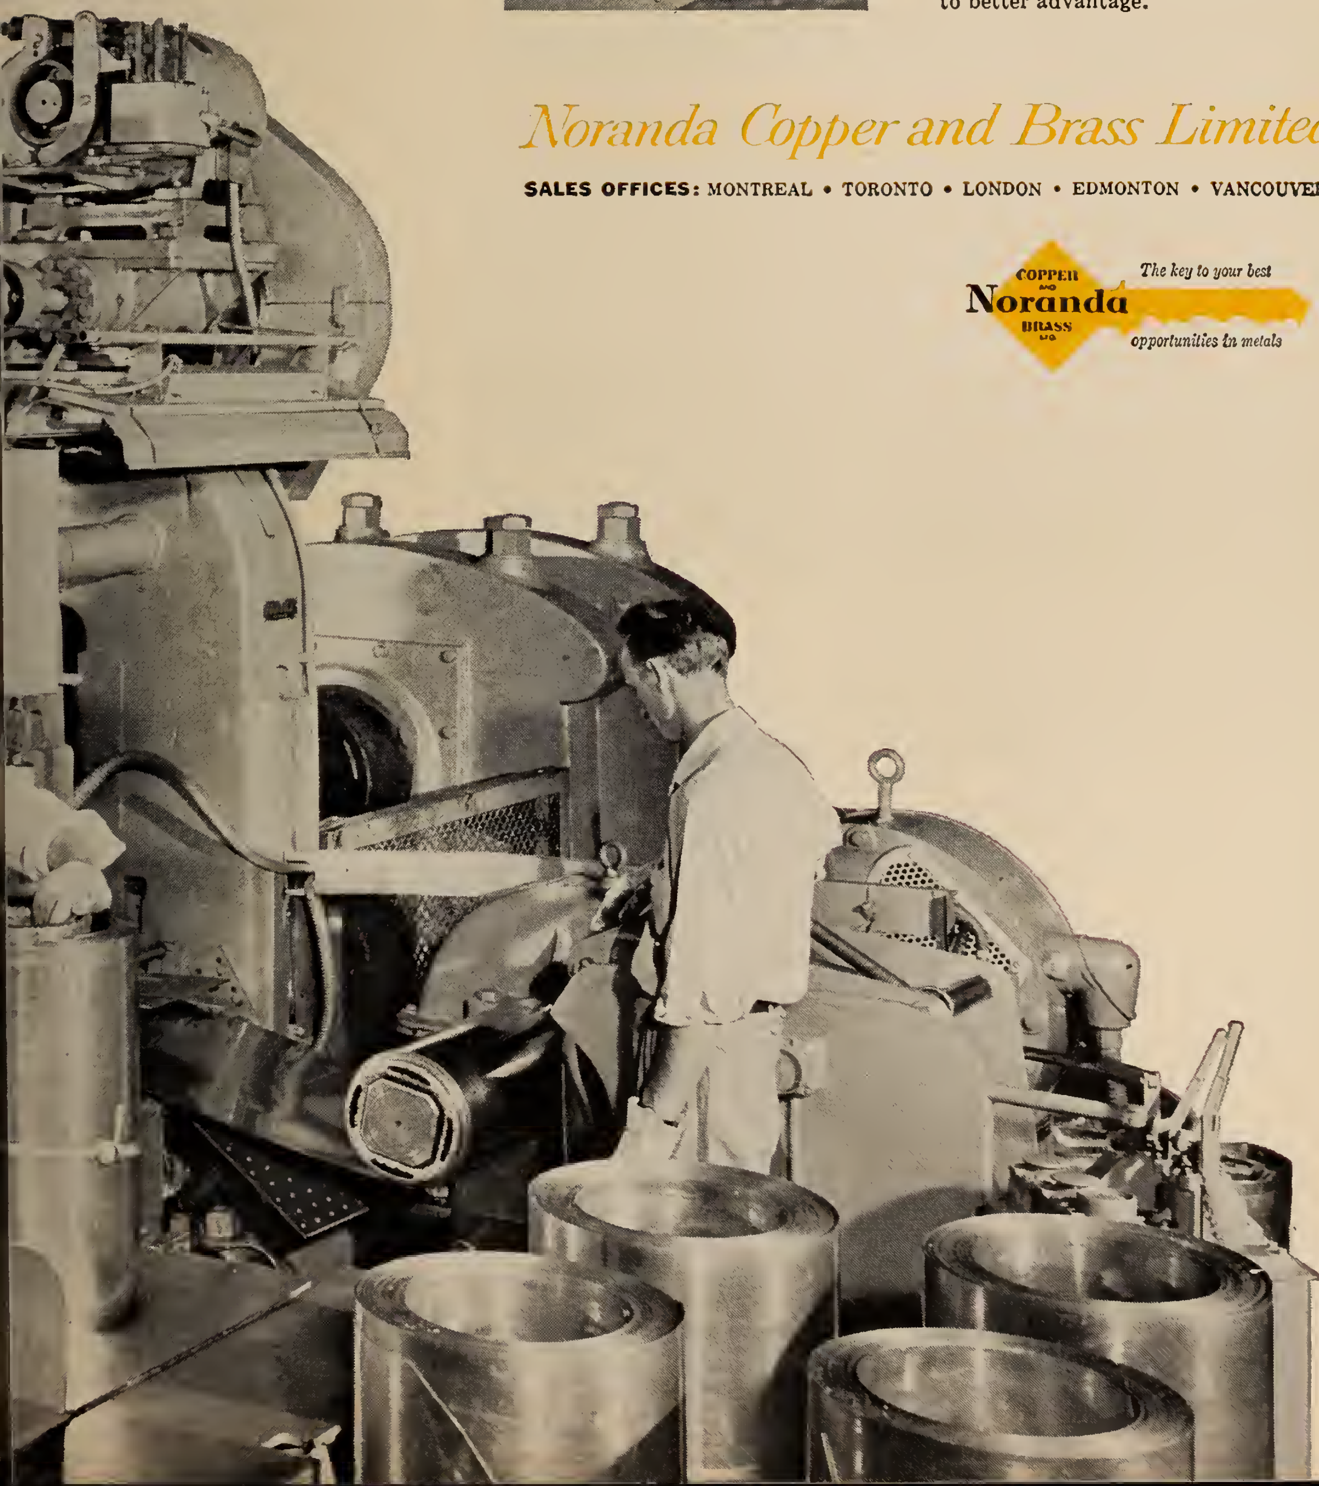
COPPER AND BRASS Noranda LTD.
The key to your best opportunities in metals



25 on progress of Confederation. Mr. Nadeau gave a brief history of engineering organizations in Canada. Mr. Nadeau said that with eleven professional societies spread across Canada, with their particular problems and viewpoints, it is difficult to arrive at a constitution agreeable to all. Unanimous agreement is necessary before confederation can be accomplished. However, Mr. Nadeau said definite progress is being made and in the course of time there will be confederation.

NIAGARA PENINSULA

E. C. Little, M.E.I.C., *Correspondent*

THE LADIES AUXILIARY of the Niagara Branch met for the first time at a tea on April 30 at the Niagara Falls Club. Some 65 ladies responded to the invitations that had been sent out.

Mrs. Lilian Robertson, Secretary of the Toronto office of the E.I.C. was guest of honour, and spoke on the aims of similar groups that had been formed in other districts.

AN EXECUTIVE DINNER was held on May 7 and the counting of the ballots resulted in the following members being elected for 1959-60; chairman D. O. D. Ramsdale; vice-chairman, E. D. Denham; past-chairman, D. A. Barnum; executive, R. T. Bailey; W. D. Tanner; H. S. Lundy; H. Jones; W. J. O'Reilly; W. J. Smith; A. Zahavich.

THE ANNUAL MEETING and Ladies Night was held on May 21.

Officers of the Women's Auxiliary are: president, Mrs. D. A. Barnum, vice-president, Mrs. E. C. Little, program convenor, Mrs. P. E. Buss, secretary, Mrs. D. O. D. Ramsdale, treasurer, Mrs. W. J. O'Reilly.

THE 6TH ANNUAL PROFESSIONAL ENGINEERS' BALL will be held at Prudhommes Garden Centre on the Queen Elizabeth Way at Vineland, on Friday, September 25, 1959.

Mart Kenney and his orchestra will provide the music. There will be a floor show consisting of two novelty acts. The plan is for the reception and cocktails at 6.00 p.m., dinner at 7.00 p.m., and dancing at 9.00 p.m.

R. T. Bailey is chairman of the dance committee; J. H. Travers (41 Rivercrest Drive, St. Catharines, Ont.) is publicity director.

OTTAWA

D. R. Grimes, JR.E.I.C., *Correspondent*

THE MUSKEG PROBLEM IN CANADA was the topic of a paper by I. C. MacFarlane of National Research Council at the luncheon meeting of May 7, 1959. Mr. MacFarlane is in the Soils Section of the Division of Building Research. There were about 60 members present.

Mr. MacFarlane defined muskeg as terrain made of living vegetation underlain by peat. Muskeg creates many engineering and economic problems. The petroleum industry has already spent $100 million dollars more than normal expenses for exploration in muskeg country.

Considerable research is being undertaken on this problem especially on the interpretation of muskeg from aerial photographs. The problem of transportation across muskeg is being attacked by the development of vehicles and by research into new and improved road construction methods.

E. B. EDDY COMPANY played host to the Ottawa Branch on May 14 when about 60 engineers toured the paper mill at Hull, Quebec. Three paper machines were in operation including the modern "Yankee" paper machine. This machine produces paper for serviettes and towelling in a continuous sheet 149 inches wide at a rate of 2,000 ft. per minute. The paper mill produces enough paper to encircle the globe, every two days, it is said.

AIR VICE MARSHAL C. L. ANNIS, O.B.E., CD., addressed a joint meeting of the E.I.C. and the Canadian Aeronautical Institute on May 21 with more than 100 engineers present. The topic he discussed was "Some Aspects of Canadian Aeronautical Development over a Half-Century".

Air Vice Marshal Annis emphasized the important role played by Mrs. Alexander Graham Bell in organizing and financing the Aerial Experiment Association in 1907. This association composed of Canadians and Americans added greatly to the interest taken in design and construction of aircraft in Canada and the U.S.

After some good years of initiative in design of aircraft adapted to Canada's geographical and climatic conditions, by 1923 the situation had changed. The producing aircraft industries in Canada now belonged to foreign parent firms. As a result, any research and development took place either in England or the United States. The Canadian industry was left to modify or make do with whatever aircraft the parent firms produced. During the second war, however, the financing of the design and development of aircraft shifted from private enterprise to government. The number of industries shrank and the development of original Canadian products began. Air Vice Marshal Annis concluded that great advances have been made in the original design and development of a particular aircraft by one Canadian firm. He said, however, that Canada's main effort has been the production and not the development of aircraft.

PETERBOROUGH

J. L. Olsen, JR.E.I.C., *Correspondent*

COL. SERGE STUKEN, M.E.I.C., Director, Engineering Services, spoke at a meeting on May 4, 1959 on the subject of "Canadian Arsenals".

He developed the progress of the Crown Company, now known as Canadian Arsenals Limited from the time in 1945 when a number of World War II munitions plants were grouped together.

The Company acts to supplement Canadian industrial capacity, but it is an association of six major Divisions. It has ten plants in Ontario and Quebec, and is capable of producing the ammunition, small arms, optical instruments and military radar which are required by the Canadian armed forces.

Colonel Stuken described the extent of the Company's operations, the precautions in handling high explosives; the mechanization of various operations concerned with the filling of projectiles and the assembling of ammunition. He also talked about the manufacture of the 7.68 mm. automatic rifle.

PORT HOPE

D. A. Runciman, JR.E.I.C., *Correspondent*

J. W. McMillan, director of personnel development, Canada Packers Limited, Toronto, spoke on March 18 on the application of psychology to management placement. Mr. McMillan divides psychology to academic, social and industrial divisions. He illustrated the use and application of the industrial psychology with examples from his personnel experience. He discussed the use of E.I.M.F. (early identification of the management function) and the group appraisal system.

SAINT JOHN

Harley K. Larsen, JR.E.I.C., *Correspondent*

Tuesday, May 19, a large group of members and ladies attended a dinner meeting at the Riverside Golf and Country Club. The meeting was arranged by the Professional Development Committee.

Harley K. Larsen, was the speaker. He showed two sound and technicolor movie films which were supplied by the Foundation Company of Canada. The film "Arctic Adventure" illustrated life in the Arctic and construction of the DEW Line. "Partners in Progress" showed the various large construction projects and services that the Company engineers have been recently associated with in Canada. Mr. Larsen also showed coloured slides illustrating his own experiences in the Arctic and in the Azores. Souvenirs of his travels were exhibited, such as mounted polar bear hides, Eskimo carvings and sealskin work.

ST. MAURICE VALLEY

Eric A. Love, JR.E.I.C., *Correspondent*

The patent system in general and in particular Canada's system were described by Gordon Asher of the Canadian Patent Office at a meeting on March 25 in Three Rivers.

The rules and regulations of patent application can be obtained for a nominal sum from Ottawa, the speaker said. His remarks on employer-employee relationship as regards inventions were of interest to all present. One of the most interesting statements was that "patents cannot be suppressed. If they are not worked compulsory licenses are given". There was a lively question period.

Industrial relations was the subject of a paper given on April 23 by J. J. Gagnon, director of personnel relations Aluminum Company of Canada.

For best results, Mr. Gagnon recommends that people be treated as individuals in their place of work. Skill and talent are required in industrial relations, beyond just common sense. People

want to know where they are going, and this is accomplished by good communication and information.

Personnel interest should be the business of top executives and interest should be stimulated in subordinates. Mr. Gagnon touched briefly on union problems including the internal problems facing some unions today.

TORONTO

D. R. Abbey, M.E.I.C., *Correspondent*

Dr. L. E. Jones, of the University of Toronto was the speaker on April 9. His subject was "The Supercharger". He started with the simplest of pumping devices used in early times and traced the development through the years. Viewing a pump as a device for transforming energy from a convenient source to a fluid, Dr. Jones showed how each type of pump was capable of transmitting energy of specific characteristics such as high pressure, high velocity, or high flow volume.

In addition, he had a wide range of displays and demonstrations by which he illustrated both ancient and modern pumping devices.

Dr. Jones is an associate professor in the Department of Mechanical Engineering.

Professor D. A. MacRae, Professor of Astronomy, University of Toronto and David Dunlap Observatory, was the speaker on April 23.

Dr. MacRae outlined how radio astronomy developed from recent research performed on shortwave. In investigations of static interference, it was found that some interference was coming from outer space.

Classic optical methods of astronomy are limited by the transparency of space which is limited in certain directions. Radio astronomy is unlimited in range but does have problems of resolution and signal collection the same as optical astronomy.

The speaker described the construction and operation of the 85 foot antenna at Leydon, Holland, and the 250 foot antenna in Manchester, England, and he explained some of the specific contributions made by this new branch of astronomy.

A plant visit to Hinde and Dauch Paper Co. of Canada Ltd., attracted 150 members on May 7.

This plant, located in Toronto, produces boxboard for use in manufacture of containers, and has one of the fastest board machines on the continent. During the tour, the members were able to follow the process from the pulping of scrap paper to the finished board, as well as the testing facilities for both the board and the finished containers.

NEWS OF THE

Information received through co-operation of the provincial organizations

CANADIAN COUNCIL

D. O. Turnbull Elected President of National Body

Donald Orton Turnbull, P.Eng., a native of Rothesay, N.B., has been elected president of the Canadian Council of Professional Engineers.

Since 1944, he has headed his own company, Turnbull and Scott Limited, in Saint John, N.B. which specializes in the design of marine structures and industrial buildings.

Donald Orton Turnbull, P.ENG.

Don Turnbull received his education at Rothesay Collegiate; Bishop Ridley School, St. Catharines, and Royal Military College from which he graduated in 1929 with an engineering degree.

In his early career he worked for Canadian Industries Ltd., and the Department of Marine, Hydrographic Service. Then he joined the Foundation Company of Canada as a job engineer on the reconstruction of the King Edward Pier in Montreal harbour. Later, he supervised construction of the breakwater at Liverpool, N.S., and the Alexandra Pier at Montreal harbour.

In 1939 he joined the Royal Canadian Air Force and became a navigator and navigation instructor. He was appointed the first chief ground instructor upon the formation of the RCAF's Central Navigation School, and later headed a technical development group at Air Force headquarters. He retired in 1944 with the rank of squadron leader, and formed his own consulting practice in Saint John.

He has served as chairman of the Saint John branch of the Engineering Institute of Canada and as councillor of the Institute, and he is also a member of the Consulting Engineers of Canada. He served as mayor of his hometown, Rothesay, and represented it on the County Council.

He is a director of Eastwood Industries Ltd., member of the advisory committee of Eastern Trust Company, and president of Turnbull Real Estate Company.

BRITISH COLUMBIA

The Continuing Obligations of the Engineering Graduate

Editorial reprinted from *The B.C. Professional Engineer,* April 1959.

In the next month, the Engineering Profession will welcome into its ranks more than 200 graduates in engineering from the University of British Columbia. Many of this group will leave the province, at least initially, to take up their first positions in engineering. Some will proceed with post-graduate education, either at the University of British Columbia or at other universities outside the province and the country. We hope that the great majority of these will return.

The profession owes a certain obligation to these young graduates. They have now completed the basic part of their academic training and for most of them, at least, there remains only to learn how to apply these principles, they have learned in theory, to actual practice. It is up to the senior members of the profession to assist them when assistance is needed, and to give them guidance. This assistance may take the form of constructive criticism but should always be available. Each junior engineer should be made to feel that there is some more senior engineer to whom he may turn for advice and guidance when necessary, and it is a responsibility that senior engineers in companies employing new graduates must accept.

Not only, however, is there an obligation upon the profession, but the graduate himself must accept certain responsibilities. His obligation is threefold. First of all, to himself; secondly, to the profession; and finally, to the community. These are not necessarily in order of importance.

The Graduate's Interests

It is incumbent upon a graduate in his own interests to ensure that the experience which he gains is such that his talents will be developed completely. He must realize at the outset that the experience that he gains in the first ten years after university will have a very important bearing upon his success in the approximately thirty years of professional life after that. He should weigh, then, any position he accepts in the light of the experience that he is going to gain in that position, should not allow any slight monetary gain to persuade him from accepting the position which will be most rewarding in experience. If he finds that, in the position which he accepts, he is not getting the experience which he expected to get, or, which is best suited to him, he would be doing himself and his employer a favour if he sought other employment which would give him the experience he wishes. He should look carefully at this, however, before changing positions and seek the guidance of a more senior engineer. He may find, for example, and it is usual in younger engineers, that he is developing but that he set his sights a little high. This is a good thing, and is to be encouraged, but he should not expect his employment to be just a training ground for him. It is important, too, that the graduate develop and maintain an interest in his work. He must always be learning and if he finds that he no longer needs to study to keep up with his work, then he had best take a good long look at himself and at his job, because he is not developing at the rate that he should.

Duties Towards Profession and Public

The graduate has an obligation, as well, to the profession. Upon graduation, he has spent approximately seventeen years in academic pursuits. He must now assure his elders that he is competent to practise, and he must do this by first of all learning by experience to put the principles he learned in university into actual practice, and then by presenting his credentials to his elders, so that he may be accepted by them into the profession. Regardless of whether he be in British Columbia or in any province in Canada, he should, as soon as possible after graduation, obtain registration as a professional engineer.

He should study the Code of Ethics of the profession and uphold that code, for therein are contained the rules of conduct by which he must live his professional life. He should be proud of his profession, and should serve as a good example to the public of the members of his profession.

Finally, the engineer has an obligation to the community. This obligation is last only chronologically, and not in importance. The graduate engineer must, in his early years after graduation, expend his major effort in getting himself established and in developing his own professional life. Once he has been established, however, he must lend his talents to the community at large and take an active interest in community affairs, such as education, civic affairs and welfare activities. He has received the benefit of the higher educational system in our country, and he must be prepared to pay back some of the dividends.

News of Other Societies

Steel Fabricators Meet

The largest meeting of the Canadian Institute of Steel Construction in the history of C.I.S.C. was held on May 22 and 23, 1959, at the Seigniory Club, Montebello, Que., with over 230 people attending. Mills were well represented, both Canadian and American, in addition to all Canadian steel fabricators.

These officers were elected at the meeting: president, W. A. Hepburn, vice-president, John T. Hepburn Ltd., Toronto; vice presidents, G. E. Ellsworth, president, Toronto Iron Works Limited, Toronto; E. A. Ford, vice-president, marketing division, Dominion Bridge Co. Ltd., Montreal; R. Raitblat, president, Standard Iron and Steel Company of Canada Ltd., Montreal; honorary treasurer, F. R. Murray, manager, Truscon Steel Company of Canada Ltd., Montreal.

General manager of C.I.S.C. is D. C. Beam, M.E.I.C. There are three regional engineers.

Committees of the C.I.S.C. reported to the annual meeting. President W. A. Hepburn reviewed the past year. Its 49 fabricator-members employ 18,000 Canadians and have total assets in excess of $350 million. He expects the Institute's activity in the next 12 months to surpass that of the last year. This, viewed with the brighter business forecast, reflects the vitality of the industry as a whole.

Some of the subjects dealt with in papers on the program were: Public Relations for the Steel Industry, by Wallace Harper, Assistant Executive Vice President, American Institute of Steel Construction, Inc., and

Competing materials — a Challenge to Management, by Robert E. Willmot, Sales Manager, Structural Shapes, Bethlehem Steel Co.

Chemical Institute Conference

The Chemical Institute of Canada held the 42nd annual conference at Halifax, N.S., May 25-27, 1959.

In the technical program speakers reported on recent advances in chemistry and chemical engineering. Some of the topics were: manufacture of basic petrochemicals; advances in cancer research and diagnosis of virus diseases with the aid of new techniques of tissue culture; "science fairs" as a means of encouraging the work of high school students in science; methods of codfish preservation; the program of outdoor testing sites to study weathering of building materials; the uses and handling of fluorine; storage of strontium-90; new work on metabolism using radioactive carbohydrates; dietary supplements which prevent formation of kidney stones in cattle; use of low grade Canadian ores to replace imported ores to make ferro alloys for steel manufacture; advances in cancer research due to new techniques of tissue culture; crude oil as raw material for petrochemicals.

The C.I.C. annual awards to members of the chemical industry were announced and presented (where possible) at the annual meeting.

Fellowship in the C.I.C.: awarded to twenty nine chemists and chemical engineers, from twelve cities. They were: S. D. Cavers, G.G.S. Dutton, R. Stewart, H. G. Khorana, Vancouver; S. A. Brown, E. J. Wiggins, Saskatoon; S. G. Davis, Edmonton; M. Cohen, W. H. Cook, R. J. Cvetanovic, O. E. Edwards, D. S. Montgomery, Ottawa; R. M. Butler, C. T. Steele, J. L. Tiedje, G. A. Olah, W. H. Arison, Walkerville; W. E. Grummitt, Chalk River; S. E. Jack, J. K. N. Jones, Kingston; R. H. Pearce, London; A. L. Tosoni, Toronto; H. Favre, D. A. I. Goring, A. Sehon, A. Taurins, Montreal; A. Cholette, I. Cameron, Quebec.

C.I.C. Medal: awarded annually for outstanding contributions to chemistry, this year to Richard H. Manske, director of research, Research Laboratories, Dominion Rubber Co. Limited, Guelph, Ont.

Ogilvie Fellowship: — first award made to Robert R. Matsuo of Winnipeg, for research in cereal chemistry.

Montreal Medal: — presented in recognition of significant leadership to Thorbergur Thorvaldson of Saskatoon, former dean of the College of Graduate Studies, University of Saskatchewan.

Officers Elected

E. Gordon Young, Director, Atlantic Regional Laboratory, National Research Council, Halifax, N.S., was elected president of the Chemical Institute for 1959-1960. William N. Hall, president, Dominion Tar and Chemical Co., Limited, Montreal was elected vice-president. Newly elected councillors taking office at this meeting, to complete the slate of 36 councillors, were: A. C. Cuthbertson, Sackville; B. A. Fairbairn, Drummondville; W. M. Campbell, Chalk River; B. A. B. Clark, Toronto; C. Sivertz, London; H. V. Kidd, Brandon; B. H. Levelton, Vancouver; M. R. Feely, Toronto; Paul E. Gishler, Edmonton; K. J. McCallum, Saskatoon; C. E. Coke, Montreal.

Calendar

Institute of Power Engineers. 1959 Canada Power Show, October 1-3, Toronto, Ont.

Mexican Society of Soil Mechanics. First Panamerican Conference on Soil Mechanics and Foundation Engineering, University of Mexico, Mexico City, September 7-12, 1959.

Societe Francaise de Metallurgie (25, rue de Clichy, Paris (9e)). Journées Métallurgiques d'Automne, Paris, October 19-24, 1959. Gas in Metals is the theme.

British Interplanetary Society. Tenth congress of the International Astronautical Federation, Church House, Westminster, London, August 31 to September 5, 1959.

International Council of Societies of Industrial Designs. Congress, Stockholm, September 16-18, 1959.

Associate Committee on Soil and Snow Mechanics of the National Research Council, Canada. Thirteenth Canadian Soil Mechanics Conference, at Nova Scotia Technical College, September 10-11, 1959. Information from E. Penner, Division of Building Research, N.R.C., Ottawa 2, Ont.

Canadian Good Roads Association. Annual Convention, September 22-26, 1959, Vancouver, B.C.

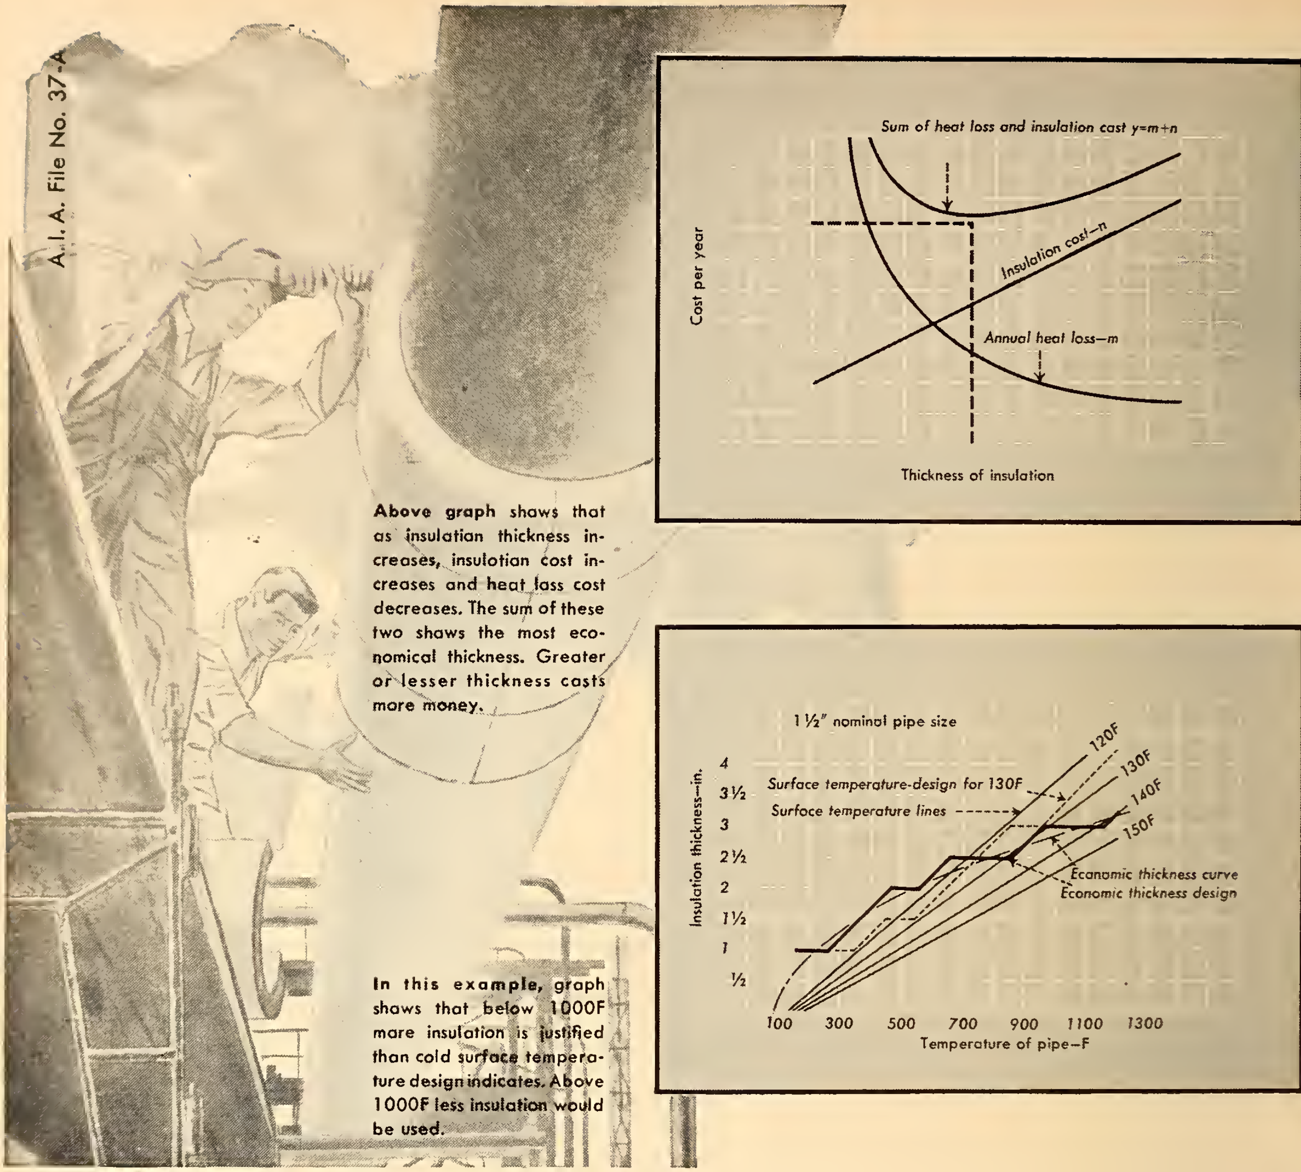
Massachusetts Institute of Technology. Two-week summer program on "The Shear Strength of Soils"; August 31 to September 11, 1959.

Community Planning Association of Canada. National Planning Conference, September 13-16, 1959, Sheraton Mount Royal Hotel, Montreal, Que.

American Meteorological Society. Conference on Stratospheric Meteorology, Minneapolis, Minn., August 31, September 3, 1959; Conference on Weather Modification by Artificial Means, August 27-29, 1959, Denver, Colorado.

McGill University. Seminar on Arctic and Stratospheric, Meteorology, July 27 to August 7, 1959, Stanstead College, Stanstead, Que., Enquiries to Prof. F. K. Hare, McGill University, Montreal.

A. I. A. File No. 37-A



Above graph shows that as insulation thickness increases, insulation cost increases and heat loss cost decreases. The sum of these two shows the most economical thickness. Greater or lesser thickness costs more money.

In this example, graph shows that below 1000F more insulation is justified than cold surface temperature design indicates. Above 1000F less insulation would be used.

"COLD SURFACE" CRITERION WASTES MONEY!

How J-M engineers determine economic insulation thickness

to give you more for your insulation dollar

Over-all cost of the operation should always be the determining factor in selecting insulation thickness. Yet, millions of dollars have been wasted because of rigid adherence to the cold surface temperature method. When Johns-Manville insulation is applied, J-M engineers carefully determine which thickness will provide the greatest operational savings. And this "economic thickness" is usually more (or less) than the cold surface method indicates.

Here's how it works. The annual cost of the heat loss through the insulation is plotted for various thicknesses. Also plotted is the annual cost of insulation. A third curve is then drawn as the sum of heat loss and insulation cost. The economical thickness is found where this third curve reaches its lowest point.

To arrive at the above figures in a given instance requires the following: 1. Cost of heat production per million Btu; 2. Rate of heat loss through insulation in Btu per unit area per hr; 3. Annual hours of operation; 4. Applied cost of insulation per unit area; 5. Rate of amortization and required return on the insulation investment cost. Items 2 and 4 are available from the insulation manufacturer; others are normally supplied by the plant engineer.

For more complete information, call or write Dept. IA, Canadian Johns-Manville Co. Ltd., Port Credit, Ontario. Ask for reprint of technical article "Select Economic Insulation Thickness."

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***EXPANSION MACHINE FOR LOW TEMPERATURE PROCESSES**

Following a brief history of the development of engines for refrigerative purposes, there is a discussion on low temperature refrigeration systems; engines and turbines for gas liquefaction, and expansion engines in low temperature systems. These systems are considered in relation to their application to many low temperature processes. (S. C. Collins and R. L. Cannaday. Toronto, Oxford, 1958. 112p., $2.00.)

***THE CONTEMPORARY CURTAIN WALL: ITS DESIGN FABRICATION, AND ERECTION**

A manual covering various aspects of curtain wall systems. It analyzes and evaluates the walls, their functions and malfunctions, component parts, materials and installations. Tables and lists give known data on insulating efficiency, fire resistance, dimensional stability, and similar factors. Pitfalls are pointed out, known solutions outlined, and accepted good practice specified. Many drawings are given to show construction details, and photographs are included to illustrate contemporary examples of the curtain wall. (W. D. Hunt. New York, Dodge, 1958. 462p., $12.75.)

***CONSTRUCTION ACCOUNTING AND FINANCIAL MANAGEMENT**

Proper accounting and management procedures are related to the basic operational patterns of the construction firm. Topics discussed are prejob procedures, purchasing policies, change orders, vouchering, control of receipts and disbursements, classification of accounts, financial statements and reports, auditing, insurance, and business machines as well as other aspects. Practical reasons are given to indicate why procedures that are standard in other businesses are either not used or are sharply modified. (W. E. Coombs. New York, Dodge, 1958. 490p., $12.85.)

***THE ANALYSIS OF GRID FRAMEWORKS AND RELATED STRUCTURES**

Presents a practical method of calculating the distribution of bending moments, deflections, etc., in a variety of structures such as bridge decks, interconnected beams, cantilevers, and arches. The first part deals with commonly occurring structures which can be analyzed by means of plotted coefficients, while the second is an analytical section containing the derivation of these coefficients and the application of the method to more complicated problems which cannot be solved in general terms. A concluding section describes experimental work on model and large scale structures which provide confirmation of the accuracy of the methods described. (A. W. Hendry and L. G. Jaeger. London, Chatto and Windus, 1958. 308p., 50/-.)

***DYNAMICS AND NONLINEAR MECHANICS**

The first part of the book surveys modern analytical progress in the treatment of problems relating to the dynamics of rigid bodies and celestial mechanics. The second part outlines the current knowledge of the analysis of non-linear oscillating systems, and discusses general methods, methods of approximations, oscillations in nearly linear systems, and relaxation oscillations. Volume II in "Surveys in Applied Mathematics". (E. Leimanis and N. Minorsky. New York, Wiley, 1958. 206p., $7.75.)

***MATHEMATICAL ASPECTS OF SUBSONIC AND TRANSONIC GAS DYNAMICS**

The author is concerned with a limited part of the theory of compressible fluid flow: two-dimensional steady potential flows. Mathematical methods are emphasized rather than the physical problems themselves, and the "applications" of fluid dynamics as a source of mathematical concepts are stressed. Particular attention is paid to existence and uniqueness questions for subsonic and transonic flow problems. Volume III in "Surveys in Applied Mathematics". (L. Bers. New York, Wiley, 1958. 164p., $7.75.)

***SOME ASPECTS OF ANALYSIS AND PROBABILITY**

Presents four aspects of the subject. The first is functional analysis and includes topological linear spaces, Banach algebras and group representations. This is followed by a survey of combinational analysis which deals with methods of enumeration, theorems on choice, and the existence and construction of designs. The concluding sections cover abstract harmonic analysis and recent advances in probability theory, including sums of independent random variables, general random elements and functionals of random functions. Volume IV in "Surveys in Applied Mathematics". (I. Kaplansky and others. New York, Wiley, 1958. 243p., $9.00.)

***NUMERICAL ANALYSIS AND PARTIAL DIFFERENTIAL EQUATIONS**

The first portion of the book deals with recent developments in numerical analysis, which is viewed by the author as a means of devising and evaluating numerical techniques for computers. Emphasis is placed on Russian contributions to this field. The second part studies the work which has been done in linear partial differential equations since 1953. Methods are given which are applicable to wide classes of equations, and in most cases results are stated in the form of definite theorems for the sake of easy reference. Volume V in "Surveys in Applied Mathematics". (G. E. Forsythe and P. C. Rosenbloom. New York, Wiley, 1958. 204p., $7.50.)

LE BRUIT DE FOND

The first of a series of electronics books to be issued by this publisher, this volume deals with background and random noises. The authors commence with basic experiments in the field, the work of Schottky and Nyquist, and basic laws.

Other topics covered include sound transmission in passive and active networks; noise index; photoelectric cells, and amplification by secondary emission, semi-conductor noise; mathematical representation; information theory and the calculation of probabilities. References for additional reading add to the value of this very useful volume. (P. Grivet and A. Blaquiere. Paris, Masson, 1958. 495p., 6,500 fr.)

CALCULATEURS ANALOGIQUES REPETITIFS

Concerned with the problems of repetitive differential analysis, the first part of the book discusses theory, the principles of solving mathematical problems with differential equations by the analog method. The second section is concerned with the elements of the calculation, and complete installations. Particular attention is paid to nonlinear equations. The last section discusses applications of this type of computer in the solution of ordinary differential equations and integral equations, and high-speed computing techniques. There is a useful bibliography. (Rajko Tomovic. Paris, Masson, 1958. 186p., 3,000 fr.)

• LIBRARY NOTES

PROBLEMS DE GEOLOGIE SOUS-MARINE

As the author points out, knowledge of the floor of the ocean is important for laying of cables and pipe-lines, development of harbours, disposal of radio-active wastes, etc. The first section of the book considers the geology of the "Précontinent", the area of the Continental Shelf, its geology, its boundaries, and sedimentary deposits. The second section covers the area more immediate to the shore, cliffs, coastlines, estuaries, and sandy beaches. (Jacques Bourcart. Paris, Masson, 1958. 123p., 980 fr.)

°ETUDE D'UNE PLAQUE RECTANGULAIRE RAIDIE PAR DEUX POUTRES DE RIVE

A theoretical and experimental study of the resistance to stress of thin rectangular plates reinforced by parallel supporting beams. The problem is first studied mathematically and a formula for determining the deflection and bending of plates under vertical loads is obtained. The second part describes an experimental study on the basis of this formula, utilizing a steel model. The results of the theoretical and experimental studies are then compared. Number 7 in the series Cahiers de la Recherche Théorique et Expérimentale sur les Matériaux et les Structures. (Z. Hashin. Paris, Eyrolles, 1958. 141p., (2,795 fr.)

ROCKET PROPELLANTS

The author is manager of the Special Projects Section of the Southwest Research Institute's Department of Chemistry, and in this volume he presents the history of rocket fuel development, and basic information of today's rocket propellants. It includes information on the composition, manufacturing methods, and performance details of solid- and liquid-propellants used in rockets, and on propellant burning, ignition and igniters, and the rockets using each kind of fuel. There are also chapters on safety in manufacturing, quality control, and the future of propellants. Bibliographies are included in each chapter. (F. A. Warren. New York, Reinhold, 1958. 218p., $6.50.)

CHEMICAL ENGINEERING PRACTICE, VOLUMES 5 AND 6

These two volumes continue the discussion of chemical engineering operations and processes involving fluid systems begun in volume 4.

Each chapter is written by an expert. Volume 5 deals with the transportation of gases and liquids; high pressure vessels; vacuum production; liquid-liquid systems; and distillation. Volume 6 covers liquid-gas systems; fluidization and fluidized beds; multicomponent gas systems; liquid-solid systems, leaching, colloids, filtration, centrifuging; solid-vapour systems, sublimation and vacuum freeze drying.

The series will be completed in twelve volumes. (Ed. by H. W. Cremer. Toronto, Butterworth, 1958. v.5, 695p. v.6, 600p. ea. $17.50.)

TEN STEPS INTO SPACE

A series of semi-technical lectures on astronautics sponsored by the Franklin Institute in 1958. The lectures covered the history of space travel; the principles of rockets and rocket fuels; satellite instrumentation; satellite orbits; the Explorer; the atmospheres of Venus and Mars; space medicine; space travel. The authors are all experts in their respective fields. (Philadelphia, Franklin Institute, 1958. 202p., $4.00.)

THE DETERMINATION OF NITROGEN IN STEEL

Another of the special reports issued by the Iron and Steel Institute, this report is concerned with the two methods in use for determining the nitrogen content of steel. The first section deals with chemical determination, and describes the methods employed, results obtained on the steels examined, a discussion of the results, and a proposed standard method.

The vacuum-fusion method is considered in part two, the factors affecting the accuracy of the method, and a

Goodyear announces

Green Seal

multi-V belts

- exclusive 3-T Cords
- dimensional stability
- 40% higher H.P. rating
- heat resisting
- oil resisting
- static conducting

GOODYEAR IS FIRST to solve the biggest problem in belting multiple drives—mis-matching is now a thing of the past! GOODYEAR HY-T V-BELTS bearing the GREEN SEAL provide new dimensional stability . . . now for the first time *matched belts stay matched.*

GOODYEAR HY-T V-BELTS are sinewed with Triple Tempered (3-T) Cords made by Goodyear's exclusive process that brings synthetic cord to its peak of greatest strength and stability, to provide 40% higher H.P. ratings than ordinary belts.

Goodyear's 50 years of experience is available to you through the Goodyear Technical Serviceman. Contact him at—Moncton, Saint John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver, or Head Office, New Toronto.

THE GREATEST NAME IN RUBBER

• LIBRARY NOTES

discussion of the results, and the two methods are compared. There is a special section dealing with the chemical determination of nitrogen in ferrochromium. Many of the results of the tests are presented in tabular form. (London, Iron and Steel Institute, 1958. 146p., 37/6.)

*PILES, CULEES ET CINTRES DES PONTS

This study of the piers, abutments, and arches of bridges begins with a short essay on the aesthetics of bridges. It then discusses piers and abutments and their resistance to various kinds of stress. A section on their erosion follows based on studies of the ruins of bridges. The main types of arches are then decribed and the book concludes with a study of the materials used in bridge construction including wood, concrete, and metals. (J. R. Robinson. Paris, Dunod, 1958. 316p., 3,600 fr.)

SURVEY OF MINES, 1959

This 408-page basic reference book reports that Canadian mining is preparing for greater mineral demands of expanding industry throughout the world.

It provides details on all active mining companies in Canada as well as thousands of others, and includes 22 pages of up-to-date maps of important mineral areas, an eight-year price range of stocks, mineral production tables going back to 1858.

Beside data on Canadian mines, the book also includes stock commission rates, lists of milling plants and metal prices. (Financial Post, Toronto, 1959. 368p., $4.00.)

*ELASTICITY AND PLASTICITY

A study of the mathematical theories of elasticity and plasticity, stressing modern trends in analysis. Emphasis is placed on the contributions made by Russian authors to this field, and extensive bibliographies are given. Volume I in "Surveys and Applied Mathematics". (J. N. Goodier and P. G. Hodge, Jr. New York, Wiley, 1958. 152p., $6.25.)

ENGINEERING LAW, 5TH ED.

Many textual revisions have been made in this edition, and citations of recent judgements added. The chapter on "Professional Engineering" has been moved to the beginning of the book, and chapters have been added on legal problems in mines, oil and gas wells, and pipe lines, public utilities and public health. The aim of the book is to present a simple treatment of the legal aspects of engineering undertakings and responsibilities. Most of the judgements cited are based on common law, and only occasional reference is made to the Quebec Civil Code. (R. E. Laidlaw, C. R. Young and A. R. Dick. Toronto, University Press, 1958. 461p., $6.95.)

KEMPE'S ENGINEERS YEAR BOOK

This sixty-fourth edition has, as usual, been thoroughly revised, and the sections on flow metering and mechanical testing, refrigeration, and paints rewritten. Additional material has been added to many of the seventy-nine chapters, including that on Mechanics which now includes the fundamental formulae dealing with motion of missiles and satellites, and escape velocity. Practically every branch of engineering is covered. (Ed. by C. E. Prockter. London, Morgan Bros., 1959. 2 vols. 85/-.)

BETON PRECONTRAINT. T.2 CONSTRUCTIONS HYPERSTATIQUES

The first volume of Guyon's well-known work on prestressed concrete was concerned primarily with general problems. This second and final volume deals primarily with beams and beam assembly, and certain types of slabs.

In the first part of the book the applicable elastic methods of design are discussed in relation to the calculation of beams, arcs, etc. The second part is a critical examination of these elastic methods, and their results compared with those obtained by other methods. The final chapter presents a method of calculation of breaking point. (Y. Guyon. Paris, Eyrolles, 1958. 818p., 9684 fr.)

UNIVERSITY MATHEMATICS, 2ND ED.

Intended for a first-year course in pure mathematics, this volume covers all branches with the exception of projective geometry. The material is taken from the syllabus of the London University science degree. Many worked examples are included, as are the answers to the problems found at the end of each chapter. (Joseph Blakey. London, Blackie, 1958. 582p., 35/-.)

*NOMOGRAPHY

Discusses the methods of constructing nomograms along with a thorough presentation of the underlying theory. Except for two chapters, only a knowledge of analytical geometry is required. Topics covered include determinants, projective transformations, matrix multiplication, more than three variables, empirical nomography, Kellogg's method, and nonprojective transformations. (L. I. Epstein. New York, Interscience, 1958. 134p., $4.50.)

THE WORLD ALMANAC, 1959

The amount of information in the Almanac is, as usual, amazing. The events of 1958, both U.S. and worldwide, are reported. The usual information is included on sporting events, chronology, population and geographical statistics, etc. No library should be without it. (Ed. by H. Hansen. New York, World-Telegram, 1959. 896p., $1.50.)

*FIELD INSPECTION OF BUILDING CONSTRUCTION

Following a discussion of the job of the inspector, several chapters cover

• LIBRARY NOTES

various phases of construction: the preliminary, foundation, structural framing, intermediate, and finishing stages. Because of the complex problems of inspecting concrete work, a special chapter is devoted to these materials. Responsibilities are defined and explained for such matters as quality of materials, quality of workmanship, coordination of work by different trades, schedules, storage of materials, provision of utilities and services, safeguarding of work in place, and safety precautions. (T. H. McKaig. New York, Dodge, 1958. 352p., $9.35.)

°HYDROLOGY FOR ENGINEERS

Emphasizes practical, well-tested methods for the application of hydrology in engineering. Techniques are stressed which utilize correlation methods and eliminate judgment to the maximum possible extent. Topics covered are weather, precipitation, streamflow, evaporation and transpiration, groundwater, runoff, streamflow routing, frequency and duration studies, sedimentation, and application of hydrologic techniques. (R. K. Linsley, Jr. and others. Toronto, McGraw-Hill, 1958. 340p. $9.20.)

°NUCLEAR ENGINEERING HANDBOOK

A comprehensive survey of nuclear theory and of nuclear engineering principles and techniques. Aspects covered include nuclear data, nuclear physics, experimental techniques, reactor physics, radiation and radiological protection, control of reactors, fluid and heat flow, reactor materials, chemistry and chemical engineering, nuclear power plant selection, mechanical design and operation of reactors, and isotopes. The material is presented on a practical level for engineers interested in the industrial uses of nuclear energy. (Ed. bv H. Etherington. Toronto, McGraw-Hill, 1958. Various paging. $25.00.)

°MAN THE MAKER

A history of technology and engineering in which power resources, transportation, communication, metallurgy, textiles, glass, chemical technology and some aspects of civil engineering are covered. The inventions of prehistory, of the Ancient East, the Greeks and Romans, the Arabs, the Middle Ages, the sixteenth and seventeenth centuries, the Industrial Revolution, and the modern era are also discussed, as are the relationships of the inventors to each period. (R. J. Forbes. New York, Abelard-Schuman, 1958. 365p., $5.00.)

°ELECTROMECHANICAL ENERGY CONVERSION

The fundamentals of analytical dynamics are used to establish a base for understanding the interactions in an electro-mechanical system. The first part of the book stresses dynamics, interconnected systems, and feedback control theory, while the second part gives detailed and specialized treatments of transducers, commutator machines, induction machines, and synchronous machines. To illustrate the unity that exists in the analysis of machines, a two-phase model of an electric machine is developed and its equation of motion derived and used in all the machine analyses of later chapters. (D. C. White and H. H. Woodson. New York, Wiley, 1959. 646p., $12.50.)

°THE POTENTIAL THEORY OF UNSTEADY SUPERSONIC FLOW

A systematic survey of aerodynamic forces which result from unsteady motion of the structural components of high speed aircraft. Beginning with a discussion of the basic equations of potential flow in their exact and approximate forms, the author develops the available methods of solution, and applies them to typical supersonic wing, slender body, and wing-body combinations. Illustrative calculations are given for harmonic motions such as occur in dynamic stability and flutter problems, and also for transient motions as in gust entry. (J. W. Miles. Toronto, Macmillan, 1959. 220p. $7.65.)

°ANALYSES OF INDUSTRIAL OPERATIONS

Case studies that show the actual application of quantitative methods to the analysis of industrial operating problems. The studies included are arranged according to method of analysis, and sections are given dealing with applications of linear programming, other programming applications, waiting line applications, total cost and value models, and applications of incremental analysis. The studies selected are intended to illustrate the simplifications, assumptions, method modifications, data needed, action, and results associated with operations analyses. (Ed. by E. H. Bowman and R. B. Fetter. Homewood, Ill., Irwin, 1959. 485p., $9.55.)

°SEMICONDUCTOR ABSTRACTS—VOLUME IV—1956 ISSUE

This volume covering the literature of 1956 and some of 1955, has been expanded by the inclusion of abstracts of unpublished papers presented at meetings of the American Physical Society and the Electrochemical Society. Abstracts are arranged by subject area and cover germanium; silicon; carbon, selenium, and other elemental semiconductors; intermetallics; sulfides, selenides, and tellurides; oxides; halides; organics; theory. An author and subject index is provided. (Compiled by Battelle Memorial Institute. New York, Wiley, 1959. 456p., $12.00.)

EMPLOYMENT SERVICE

SITUATIONS WANTED

MECHANICAL ENGINEER, Jr.E.I.C., B.E., 1951, age 37, married, veteran. Seeks position requiring initiative, organizational ability, dependability, and with opportunity for advancement. Experience includes planning, design, layout, estimating, development, production supervision. Presently employed in pulp and paper industry but will consider other. Located Atlantic Province. File No. 4025-W.

PROFESSIONAL MANAGER, M.E.I.C., P.Eng. (Ont.). B.A.Sc. (Mechanical), M.B.A., Canadian born, age 38. Presently employed senior management level. Desire general management or senior industrial sales position. Presently located Central Canada but willing to locate anywhere. Your confidence respected and full resume supplied. File No. 5549-W.

MECHANICAL ENGINEER, M.E.I.C., age 34, married. Varied experience including project, maintenance and mechanical design engineering in several fields. Seeks change to interesting position where past experience could be best utilized. Would prefer to locate in or near Montreal or Vancouver, or in Ontario, but other locations considered. A detailed resume of experience and technical qualifications etc., is available upon request. Located Prairie Province. File No. 4659-W.

CIVIL ENGINEER, N.S.T.C., 1951, Jr.E.I.C., P.Eng. Que., married, 37 years, bilingual. Three years' experience in general contracting, one year in smelter construction, four years marine and industrial design and construction and eight years' pre-graduate experience in hydro-electric and heavy industrial construction. Desires responsible position with consulting engineering firm or general contractor as resident or project engineer. Available upon reasonable notice to present employer. Presently located, Central Canada. File No. 5035-W.

PROJECT ENGINEER, Jr.E.I.C., P.Eng., (Ont.), B.A.Sc., (Mech.Eng.), U.B.C., 1951, age 37, married, two children, Canadian. Presently employed, Latin America, returning Canada August, 1959. Eight years petroleum refinery, petrochemical plant experience, including equipment inspection; piping, vessel, structural design involving programming of selected problems for a high speed digital computer; development of major refinery expansion projects. Seeks position with responsibility, good prospects for advancement. Located Scotland. File No. 5126-W.

MECHANICAL ENGINEER, P.Eng., Jr.-E.I.C., Grad.I.Mech.E., age 28. Experience includes five years comprehensive training rubber industry. Special purpose machine design, plant layout, two years gas turbine, fuel equipment. Also project and field engineer on diversified hydraulic schemes, construction and research. Presently design, estimate engineer, plumbing, heating, ventilating systems. Seeks permanent position in small or medium development organization. Presently located Central Canada. File No. 5456-W.

EXECUTIVE CIVIL ENGINEER, M.E.I.C., A.M.I.C.E., M.A. Cambridge, English born, Canadian citizen, 36, married, one child. 15 years' heavy construction, engineering experience in Canada, U.K., Africa, United States, Middle East. Presently in top construction management position. Particular experience in water, hydro dams, road work. Desires association with company engaged or contemplating construction or engineering, West Indies, Caribbean, Central, South America, for assignment on long term basis. Ambitious energetic, seeks position with executive ability requirement, corresponding compensation. Resume, references on request. Located Central Canada. File No. 5521-W.

MECHANICAL AND MARINE ENGINEER. P.Eng., M.E.I.C., M.I.E.S., M.I.Mar.E., experience: organization, administration, University Courses both subjects. Many years Naval, Merchant ships experience, including Salvage operations. Certified First Class Foreign-Going, Steam, Diesel. Good knowledge contractual work, supervision tests, trials, repairs, new construction, workshops. Actual technical experience most types boilers, turbines, turbo-electric, diesel, diesel-electric, diesel hydraulic. Resume of experience and education sent on request. Located Central Canada. File No. 5534-W.

ENGINEERING PHYSICIST, Jr.E.I.C., P.Eng., (Alta.), U. of T. 1956 Geophysics. Aged 26, single, present location Prairie Province. Three years' experience in seismic exploration business. Also some experience in other geophysical methods. Mathematically inclined and desires challenging position in research or the field of applied mathematics. File No. 5552-W.

B.Sc. IN MECHANICAL AND AGRICULTURAL Engineering, Jr.E.I.C., P.Eng. (Ont.), age 33, married. Experience in agricultural implement design; process air systems including compressor design, ducting, and instrumentation; equipment selection, plant layout, optical alignment, and engineering specifications; supervision of draughting, manufacturing, and installation. Desires position in mechanical design, industrial engineering, or consulting. Locate anywhere, Toronto area preferred. Present location Central Canada. Available on short notice. File No. 5554-W.

CIVIL ENGINEER, Jr.E.I.C., B.A., B.A.Sc. (Laval), Prof. Eng. Que., 1955, bilingual, married, varied engineering and some administrative experience, seeks employment with industry or consulting firm. Present location: Eastern Quebec. Willing to relocate anywhere in Quebec. File No. 5572-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.), McGill, 1951, age 34, veteran, single. Experience with large electrical manufacturer. Four years as manufacturing engineer. At present in design field. Business Administration studies. Seeking challenging position. Location preference Toronto or Montreal. File No. 5576-W.

GRADUATE CIVIL ENGINEER, S.E.I.C., B.Eng., age 27. Experience: 1 year lecturing — demonstrating, civil engineering courses. 1 year structural steel design and reinforced concrete design. 1 year structural steel and reinforced concrete construction. Located — Central Canada. File No. 5577-W.

CHEMICAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.), B.Sc., Queen's 1955, age 27. Three years' supervisory experience in nuclear reactor operations. Desires development work. Returning to Canada at the end of August, after a year in the U.K. Detailed resume on request. File No. 5581-W.

GRADUATE MECHANICAL ENGINEER, Jr.E.I.C., age 35. Specialized in ship power plants, speaks French and Italian fluently, good knowledge of English and German. Seeks permanent position in Canada. Presently working as senior design engineer in a leading Swiss manufacturer of boilers and industrial, domestic furnaces. File No. 5583-W.

ELECTRICAL ENGINEER, Jr.E.I.C., P.Eng., N.S.T.C., 1951. Single, age 39. Applicable experience (5) years' service and maintenance on power apparatus, electronic controls. Post graduate automatic control studies at McGill University. Naval artificer during war. Would desire appropriate position, temporary or permanent in Canada. Present location Central Canada. File No. 5587-W.

ELECTRICAL ENGINEER, P.Eng. (Quebec) with sound background in communications, automatic instrumentation and data processing seeks to join consulting firm engaged in industrial, power development, electrical or communications work. Particulars and references on request. File No. 5589-W.

MECHANICAL ENGINEER, S.E.I.C., graduate University of Saskatchewan 1957, age 24, married, one child. Experience consists of 2 years with the armed forces as a construction engineering officer. Work includes supervision of all engineering maintenance, operation, new construction, alteration of buildings, facilities and services. Desires position in heating and ventilation field or administrative field where an engineering background would be an asset. Present location Maritime Province. File No. 5590-W.

CHEMICAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.), McGill 1955, age 26, married, Canadian. Presently employed in Latin America, returning to Canada August 1959.

THE ENGINEERING INSTITUTE OF CANADA

This service is operated for the benefit of members of the Engineering Institute of Canada and for organizations employing engineers.

SITUATIONS WANTED

Advertisements are inserted free of charge for members of all classes. Maximum length is 60 words, and repeat insertions must be separately requested in writing for each desired appearance.

SITUATIONS VACANT

Rate: Six dollars per column-half-inch per insertion.
Replies to advertisements should be addressed to the file number, Employment Service, 2050 Mansfield Street, Montreal. Interviews with the Employment Service may be arranged by calling VI 2-5078 at the above address.

CANADIAN DEVELOPMENTS *(Continued from page 100)*

Refrigerants in Construction

The use of refrigerants to freeze a subsurface area and thus avoid danger of subsidence was adopted in a Canadian National Railway project in Montreal. The job consisted in removal of a 140 ft. length of centre supporting wall and two roof arches inside the central station end of the Mount Royal rail tunnel, erection of a single reinforced concrete arch in their place, and rearrangement of some 1,800 feet of track.

To avoid danger to foundations of adjacent large buildings, soil stabilization by mechanical refrigeration offered technical advantages. In an area measuring 80 ft by 50 ft., comprising some 80,000 cu. ft. of unstable soil below street level, the Foundation Company of Canada, acting as contractor to the C.N.R. installed an intricate system of inter-connected pipes. The system carried ten tons of refrigerated methanol solution, freezing the ground to a depth of 18 to 20 feet. Before excavation and during work on the tunnel, the methanol flowing through the pipes was cooled by Freon 12 fluorinated hydro-carbons to a temperature of 10 degrees below zero F.

Moncton Classification Yard

Canadian National Railways has called for tenders for construction of a diesel shop at the Moncton hump yard. Measuring 263 feet by 340 feet, the diesel repair and service installation will be patterned on similar shops in Montreal and Edmonton.

The $15 million electronic classification shop yard in Moncton will be the eastern installation in the C.N.R. chain of new freight marshalling yards.

Steel Pile Cell Dock

Uncommon use of steel sheet pile cell dock construction in the Great Lakes has succeeded, it is reported.

An L-shaped dock constructed by Dravo of Canada Limited, Toronto, at Millhaven, Ont., for Liquefuels Limited, has three 35-foot diameter mooring cells, connected by structural steel walkways. A 450-foot berm allows access from the shore. The walkway and berm carry a 10 inch fuel pipeline to unload tankers.

The Millhaven tank farm, which has a capacity of 500,000 barrels, has a direct line leading to the adjoining Terylene plant of Canadian Industries Limited.

Westinghouse Scatter System

Canadian Westinghouse developed the long-range communication system — super-high frequency "scatter" communication equipment which is being supplied to the U.S. Air Force for use in the Bomarc project. This is part of $10 million contract awarded the Westinghouse Electric Corporation in the U.S.

Canadian Westinghouse is also supplying to the U.S. Air Force scatter commmunications equipment which will go into service in a tactical system.

Correction!!

A mistake was made on page 90 of the May issue of *The Engineering Journal*. The sentence reading, "Hudson Bay Mining & Smelting closed early in 1958, but it is expected to re-open early in 1959." should have read: "Britannia Mining and Smelting closed early etc., etc."

CORRECTION from February issue of *The Engineering Journal* concerning **K. D. Sheldrick.** *(see author's page).*

In 1942 he joined the Canadian Army, serving in R.C.E.M.E. in the regular army until 1946, and in the reserve from 1950 to 1958. In 1958 he retired as Commanding Officer of the 3rd Technical Regiment R.C.E.M.E., C.A. (Militia) with the rank of lieutenant colonel.

In 1946 he returned to the Bailey Meter Company.

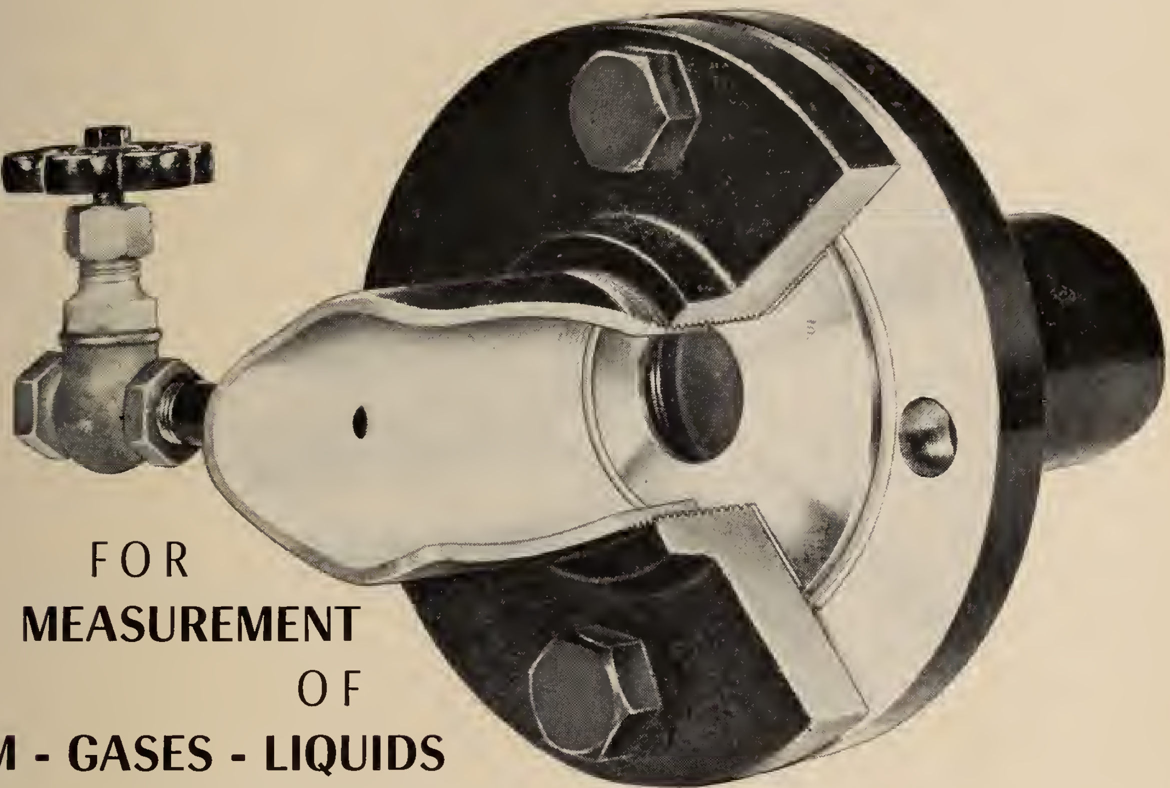
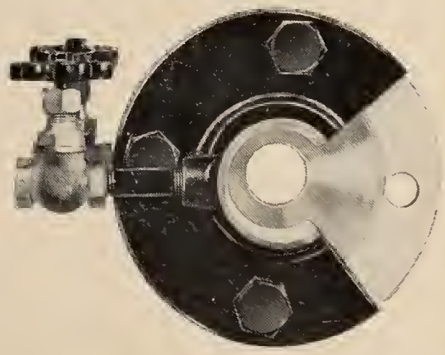
TRANSACTIONS

VOL. 3, No. 2 JULY





ANNUAL GENERAL MEETING

(*Continued from Page 103*)

ing, Past-President Ira Macnab had described the move to confederation as the biggest interpretation of what engineering is and what it stands for. And Professor Long's appeal had been anticipated by that alert octogenarian, Dr. Lillian Gilbreth, Hon. M.E.I.C., addressing student delegates the day before. Aware that the intensive development of engineering knowledge and techniques imposes a need for earlier and more thorough specialization, Dr. Gilbreth stressed the importance of finding the right girl to marry and delegating to her some of the responsibilities in the human relations field. Rather more seriously, she concluded that there is really just one answer: lifelong learning.

On the eve of the ballot on confederation the profession was undoubtedly taking stock of itself. The societies that speak for the engineer contemplate the prospect of their fusion with an evident awareness that this union is for adults only. And the attainment of majority, for the group as for the individual, implies much more than mere self-administration. With maturity comes social responsibility.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

A jury consisting of fifty readers of the *Journal*, voted the Imperial Oil Company four-colour insert the best in the April issue from the viewpoints of ACCURACY - INFORMATION - ATTRACTION. It appeared on pages 33 and 34 of the issue.

The readers who served on the jury were selected so that all provinces would be represented.

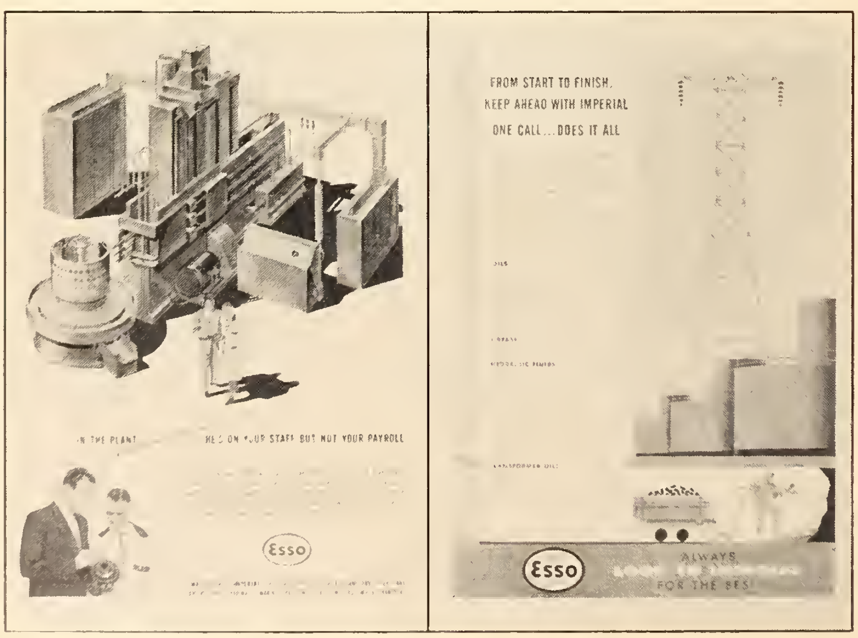
Each month the *Journal* mailing lists are used for the selection of names of jurors — five names are selected, at random, from each provincial listing. The selectees forward their votes to E.I.C. Headquarters by mail.

The number of completed returns by the jurors has been consistently large since the award of certificates was commenced at the beginning of this year The latest returns bring the average monthly number to forty-two.

It is the belief of the Institute that this method of judging advertisements in the *Journal* will be of value to the readers as it will give the advertisers a clear indication as to the type of advertisement most useful and attractive to Canadian engineers. The Institute is grateful for the co-operation of all readers who have served as jurymen.

WINNING IMPERIAL OIL ADVERTISEMENT

The Imperial Oil four-colour, two-page advertisement was judged the best in the April issue from the viewpoint of ACCURACY-INFORMATION-ATTRACTION. A certificate to that effect has been awarded to the Company. The advertisement was prepared and placed by the Toronto office of Cockfield Brown and Company.



E.I.C. ELECTIONS AND TRANSFERS

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on May 15, 1959.

Member: J. L. Ballantyne, Montreal; F. A. G. Dreville, Montreal; G. G. Hatch, Toronto; C. S. Kindersley, Calgary; D. C. McMillan, Moose Jaw; W. A. Orr, St. Catharines; A. V. Price, New York; J. A. Smith, Montreal; D. C. Stephens, Toronto; J. G. Trimble, Montreal; K. R. Warren, Jamaica; G. E. Waters, Montreal; G. L. White, Montreal; L. M. Yarberry, Montreal.

Junior: D. M. Buchanan, Montreal; C. J. Chang, Montreal; G. Lahaise, Montreal; E. V. Leon, Montreal.

Affiliate: W. A. Young.

Junior to Member: A. E. Benn, Montreal; L. R. Boutilier, Sydney; J. R. Burton, Cornwall; W. M. Campbell, Kingston; C. H. Murdoch, Montreal; W. Naumko, Toronto; W. W. Popiel, Winnipeg; W. J. Smith, Welland.

Student to Junior: W. Larson, Montreal.

STUDENTS ADMITTED

University of New Brunswick: W. M. Sherrard.

University of Alberta: R. D. Cameron, J. D. Mathews, S. B. Mellsen.

St. Francis Xavier University: D. J. G. Heroux, J. M. Tremblay.

Dalhousie University: D. A. Athanassopoulos, H. M. Leonard.

University of Toronto: F. E. Collins.
McGill University: G. B. Allan.

University of Manitoba: C. E. Lamont.

St. Mary's University: L. H. McIntyre.
Nova Scotia Technical College: J. C. Martin.

University of Western Ontario: J. H. Shortreed.

University of Sherbrooke: A. Giguere.

Imperial College, London, Eng.: D. G. T. Rees.

Student of C.P.E. Quebec: P. Lukas.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Member: A. Van Raalte; **Junior to Member:** D. M. Norum.

SASKATCHEWAN

Members: R. E. Bradfield, W. A. Burgess, C. J. Cameron, T. L. Carey, R. A. Purvis, W. A. Seedorf, P. M. Tyman; **Junior to Member:** B. H. Hamilton, R. S. Lang, A. Masuk, A. I. Reed, K. H. Wu; **Student to Junior:** G. C. Burns, D. G. Delparte, G. Goos, K. C. Lukawitsky, V. E. Worobey, J. E. Zuk; **Students:** M. Kotsakis, E. B. Lotochinski, D. R. Unroe.

NOVA SCOTIA

Member: R. W. Archibald.

MANITOBA

Member: V. W. Chorley.

• LIBRARY NOTES

(Continued from page 135)

***DIE HEBEZEUGE. VOLUME 1: GRUNDLAGEN UND BAUTEILE, 5TH ED.**

First of a three-volume set, this book deals with the basic components of cranes, hoists, etc., with the fundamental analysis and design of crane frames, and with the electrical equipment for hoisting machinery. Components covered are cables, chains, hooks and slings, shafts and bearings, brakes and couplings, gears and drives. Subsequent volumes will cover cranes and other types of hoisting machinery in greater detail. (Braunschweig, Friedr. Viewig and Sohn. 360p., 48.80 DM.)

***CIVIL ENGINEERING CONSTRUCTION**

Primarily concerned with construction problems rather than design. The section on plant covers such equipment as excavation and earth-moving, deep-drilling, tunnel work, blasting, hoisting and conveying, pumping and dewatering, pile driving, diving and air-lock equipment, and concreting. This is followed by a section on construction methods that deals with open excavations, shafts and tunnels, foundations, coffer-dams and caissons, timber and concrete construction, steel structures, bridges, roads, and river works. The concluding section deals with planning and organization of the project. (J. A. Antill and P. W. S. Ryan. Toronto, Ryerson, 1957. 626p., $15.00.)

***THE DESIGN OF PRISMATIC STRUCTURES**

Based on articles published in "Concrete and Constructional Engineering", this volume contains additional matter to make the analysis of pitched-slab prismatic structures more complete. Aspects discussed include prismatic structures of one span, multiple-bay structures, continuous prismatic structures, prismatic structures with sloping ends, and slabs with small angular change. In addition to the theoretical considerations applicable only to such structures, use is made of methods of calculation developed for other branches of structural engineering. Some of these methods include solution by relaxation, column analogy, moment-balance, and a method of combining bending and direct thrust. (A. J. Ashdown. London, Concrete Publications, 1958. 85p., $2.10.)

***ACOUSTICS, NOISE AND BUILDINGS**

A guidebook to the technical problems of acoustics from the standpoint of both the engineer and the architect. It discusses the behavior of sound in rooms; the design of rooms for speech and for music; the design of radio and TV studios; the design of high quality speech-reinforcement systems; sound insulation and noise control, including criteria and practice; sound measurement and calculation. (P. H. Parkin and H. R. Humphreys. Toronto, B.B.S., 1958. 331p., $14.00.)

***MECHANICS—PART II: DYNAMICS, 2nd ed.**

Among those aspects of the subject covered are kinematics; kinetics; force, mass, and acceleration; impulse and momentum; and periodic motion. Appendices deal with vector methods and moments of inertia. In the present edition of this work various changes have been made to make the book more useful. Greater distinction is made between absolute and relative motion analysis in the chapter on kinematics, and greater emphasis is placed on the formulation of problems in particle kinetics by means of the differential equation of motion. In the treatment of work and energy a new section on virtual work is included which not only helps in solving certain types of problems but provides a stepping stone to advanced theory. (J. L. Meriam. New York, Wiley, 1959. 420p., $5.00.)

***NOISE IN ELECTRON DEVICES**

The papers contained in this collection are the result of a course on "Noise in Electron Devices" which was held at the Massachusetts Institute of Technology. They cover the general problem of noise due to thermionic emission, the general circuit aspect of noise in microwave tubes, some of the detailed engineering solutions to the problems encountered in the design of low-noise traveling-wave tubes and space-charge control tubes, semiconductor noise, noise behavior of semi-conductor diodes and transistors, and the principles of low-noise transistor circuit design. In general stress is placed on basic physical phenomena and mathematical theory rather than on detailed design techniques. (L. D. Smullin and H. A. Haus, eds. New York, Wiley, 1959. 413p., $12.00.)

***SEMICONDUCTORS**

A thorough survey of the physical chemistry and fundamental physics of semi-conductors, with emphasis throughout on basic principles and phenomena. Following a general discussion of the subject, the authors deal with the physical chemistry of semiconductor systems, the relationship between the chemistry and the electrical and optical properties of a number of semiconductors, and the properties associated with semiconductor surfaces. Heavy emphasis has been placed on germanium and silicon, primarily because they are much better understood than other semiconductors. (N. B. Hannay, ed. New York, Reinhold, 1959. 767p., $15.00. American Chemical Society Monograph Series Number 140.)

***QUALITY CONTROL AND INDUSTRIAL STATISTICS, Rev. ed.**

The basic principles and procedures of statistical quality control are presented. Beginning with a section on the fundamentals which covers probability, frequency distributions, and sampling, the author continues with sampling inspection and control charts. The concluding part discusses statistical theory pertinent to industrial research and includes the estimation of lot and process characteristics, the theory of comparisons, analysis of components of variance, regression, analysis of covariance, and design of experiments. In this edition practically all of the material has been revised and expanded. (A. J. Duncan. Homewood, Irwin, 1959. 946p., $10.80.)

***THE RADIO AMATEUR'S HANDBOOK**

A new edition of a well-known reference work which contains practical information on various phases of radio communications, including receivers and transmitters of various power levels. Special methods of communication such as single sideband and radioteletype are also treated. The theory and practice of mobile radio equipment is thoroughly covered, and includes the fundamentals of transistor power supplies. A special feature is the section on vacuum tube characteristics which provides one of the most complete listings of characteristics and tubebase diagrams available. (West Hartford, American Radio Relay League, 1959. 584p., $3.50.)

***MECHANICAL DESIGN AND ANALYSIS**

The major part of the book consists of wide and recent selection of industrial case studies in machine design. The author's intent is to relate the text to specific design situations where the problem precedes the theory, and may be solved in a variety of ways. An analysis pertinent to each problem is given, providing a clear and coordinated background. Review material for the most part has been omitted, but certain topics which may not have been included in more elementary texts have been covered. These are limit dimensioning, materials to match job requirements, and repeated stress effects. (R. R. Slaymaker. New York, Wiley, 1959. 418p., $9.50.)

***JET PROPULSION ENGINES**

Presents the principles and problems encountered in combining components to form a complete engine. Following a discussion of the basic concepts common to most types of engines, the turbojet, turboprop, ramjet, the intermittent jets, and the solid propellant rocket engines are then considered in turn. The various sections on these engines examine those problems peculiar to each involving performance, control, testing, installation, and matching the various components. Similar analyses are presented for two of the hybrid types, the ram rocket and the jet rotor. Finally the use of atomic energy in jet propulsion and other future prospects are considered. (High Speed Aerodynamics and Jet Propulsion, Volume XII. O. E. Lancaster, ed. Toronto, Saunders, 1959. 799p., $23.00.)

• LIBRARY NOTES

°DESIGN OF PHYSICS RESEARCH LABORATORIES

Papers dealing with various aspects of design, including problems in the planning of research laboratories, trends in the design of American industrial research facilities, services and facilities from the user's point of view, buildings and services from the viewpoint of laboratory maintenance, and research on the design of laboratories. Numerous illustrations are included. The papers were given at a symposium held in England in 1957. (The Institute of Physics. New York, Reinhold, 1959. 108p., $4.50.)

°GUIDED MISSILE ENGINEERING

The basic principles and engineering techniques of various scientific fields are reviewed with particular emphasis on their application to guided missile design. Various sections of the book cover such fields as guidance theory, aerodynamics, electronics, airframe performance, computer systems, radio and radar, and flight simulators. Systems engineering aspects are stressed throughout the book which attempts to place in perspective the relationships between specialized fields and overall missile design. (Ed. by A. E. Puckett and S. Ramo. Toronto, McGraw-Hill, 1959. 497p., $11.50.)

°HEATING, VENTILATING, AND AIR CONDITIONING GUIDE, 1959

A revised edition of a standard handbook which covers environment, comfort, and physiological principles; heating and cooling loads; room heating and cooling methods and equipment; air systems and equipment; steam and water systems and equipment; heat generating methods and equipment; refrigeration, spray apparatus, and sorbents; controls, instruments and motors; and industrial systems. Five new chapters have been added on high temperature water systems, the heat pump, evaporative apparatus for heat rejection, evaporative air cooling and humidification, and snow melting. In addition extensive changes have been made throughout the volume. A feature of the guide is the extensive references provided with each chapter and a separately paged buyer's guide of over four hundred pages. (New York, American Society of Heating and Air-Conditioning Engineers, 1959. 768p., $12.00.)

°ROCKETRY AND SPACE EXPLORATION

Following a brief, non-technical explanation of the operation of rockets, a complete history of their development is given. The book begins with the origins of rocketry in the 1930's and continues with the Axis war rockets of World War II, and such post-war developments as the Atlas, Titan, Thor, Nike, X-15, Sputniks, Vanguard and Explorers. Concluding chapters deal with the efforts made towards international cooperation in astronautics, and with the work of such societies as the American Rocket Society and the British Interplanetary Society. (A. G. Haley. Toronto, Van Nostrand, 1958. 334p., $8.00.)

°SYMMETRICAL COMPONENTS

Presentation of the theoretical and practical aspects of symmetrical components as a means of determining the performance of electrical apparatus under unbalanced loads. The methods for calculating short circuits in computing currents and voltages in polyphase systems during fault conditions are explained in detail while other applications of symmetrical components are examined, including regulation, stability, and relaying problems of electric power networks. Stress is placed throughout the book on the use of mathematics and the corresponding physical interpretation as a means of achieving mastery of the subject. (G. O. Calabrese. New York, Ronald, 1959. 464p., $12.00.)

°MATERIALS FOR ROCKETS AND MISSILES

Presents typical engineering data on lightweight, high temperature materials. Existing metal and ceramic materials are surveyed and those materials which are expected to become available during the next few years are indicated. Materials are compared according to their chemistries and selected physical properties such as density, coefficients of thermal expansion and conductivity, elastic moduli, and impact strength. New material fabrication processes, including high temperature brasing, chipless production, and unconventional machining techniques are also covered. Sheet, wrought, and cast alloys with iron, nickel, and cobalt bases are covered, as are wrought and cast alloys of aluminum and magnesium, titanium alloys, cermets, molybdenum alloys, and ceramics. (R. G. Frank and W. F. Zimmerman. Galt, Brett-Macmillan, 1959. 124p., $4.50.)

°THE DESIGN OF LAND DRAINAGE WORKS

Papers on a variety of aspects of flood protection and alleviation, groundwater level control, water conservation, irrigation, and protection of low-lying land against the sea. They are intended to provide a concise reference for everyday use by design engineers, and include such topics as flood hydrographs, hydraulic calculations for channel improvement schemes, flow in alluvial channels, fluming for land drainage works, tidal outfalls, automatic radial sluice gates, land drainage pumping stations, and earthen flood banks. Each paper is accompanied by explanatory notes that serve both as an introduction to the paper and as a means of supplementing the information contained in it. (R. B. Thorn. Toronto, Butterworth, 1959. 235p., $7.00.)

°RELIABLE ELECTRICAL CONNECTIONS. PROCEEDINGS OF THE THIRD EIA CONFERENCE, 1958

The latest developments in the design and application of electrical connections are discussed. The results of investigations are given in thirty-two papers dealing with fixed connections, disconnect connections, soldered connections, pressure connections, wire-wrap connections, welded and ultrasonic connections. Several papers cover aspects of connections in relation to printed circuits. (New York, Interscience, 1958. 286p., $7.75.)

°FILLER METALS FOR JOINING

A presentation of the factors influencing the choice of a filler metal for any given metal joining situation. All of the recognized ferrous and nonferrous joining metals for welding, brazing, and soldering are discussed. Available materials are discussed in terms of applicability, mechanical properties, and degree of availability. The major portion of the book is devoted to arc welding electrodes, while the remainder deals with such topics as automatic welding of mild and low alloy steels, the new iron powder electrodes, recent developments in nonferrous metals, surfacing, and tungsten electrodes. (O. T. Barnett. New York, Reinhold, 1959. 244p., $7.00.)

°WELDING OF PLASTICS

The physical and chemical properties of individual plastics presently used for welded construction are discussed in relation to their use in chemical and allied processing. The various techniques of welding used are also discussed, and detailed procedures are given accompanied by suitable illustrations. Features of the volume include complete corrosion resistance tables and a concise guide to the choice of an appropriate plastic construction material. Two complete chapters are devoted to design considerations as they affect welded construction, and to testing and evaluation. (J. A. Neumann and F. J. Bockhoff. New York, Reinhold, 1959. 279p., $7.25.)

°FUNDAMENTAL ASPECTS OF REACTOR SHIELDING

Stress is laid on the fundamentals of the subject, specifically the factors affecting the permissible radiation levels, the sources and characteristics of the radiation to be shielded against, and how bulk shielding measurements are made. The book concludes with a detailed analysis of the calculations necessary to determine, theoretically or empirically, the attenuation of neutron and gamma rays in shield materials. Although certain related fields such as radiation biology and nuclear physics are considered, a background knowledge on the part of the reader is assumed. (H. Goldstein. Reading, Addison-Wesley, 1959. 416p., $9.50.)

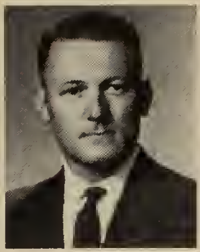
MEET THE AUTHORS

W. H. Sanders, manager, data communications and control, The Hydro-Electric Power Commission of Ontario (*Headquarters Computation Centre for Ontario Hydro).*

Mr. Sanders graduated in engineering physics at the University of Toronto in 1950. In 1955 he was appointed to a study team to report on the feasibility of electronic data processing and upon completion of the study was made responsible for the specification of input equipment and the design of error detecting techniques. He has held his present position since 1958.



S. J. Crossman, supervisor, design of teletypewriter switching systems, The Bell Telephone Company of Canada *(Headquarters Computation Centre for Ontario Hydro).*

Mr. Crossman was born and educated in Toronto, graduating from the University of Toronto in 1951 with a B.A.Sc. in electrical engineering after serving with the R.C.A.F. in the communications field. He was loaned to the Western Electric Company for a year during the installation and testing of the Distant Early Warning Line in Alaska and the Yukon.

On returning to The Bell Telephone Company he took part in the engineering of the Mid Canada Early Warning Line.

He is a member of the Corporation of Professional Engineers of Quebec and the Association of Professional Engineers of Ontario.

John Rywak, member, Scientific Staff, Northern Electric Research and Development Laboratories, Belleville, Ontario, *(Headquarters Computation Centre for Ontario Hydro).*

Mr. Rywak is a graduate in Electrical Engineering of the University of British Columbia. After service with the Royal Canadian Air Force he joined the Northern Electric Company in 1950 and during his service with this Company has been responsible for some ten patent applications.

Mr. Rywak is a senior member of the Institute of Radio Engineers and a member of the Association of Professional Engineers of Ontario.

At time of going to press no information was available on **Mr. H. Ross W. Davis** a co-author of the paper, *(Headquarters Computation Centre for Ontario Hydro).*

Dr. J. T. Hugill, M.E.I.C., M.B.E., manager, field operations and construction, L'Air Liquide (*A Large Capacity Oxygen Plant for Copper Refining*).

Dr. Hugill was born in Calgary, he graduated from Royal Military College and served with Canadian Army Overseas in chemical warfare. He was awarded M.B.E. in 1945 and joined L'Air Liquide in 1946.

Dr. Hugill is a Fellow of The Chemical Institute of Canada; a member of The American Chemical Society; The American Institute of Chemical Engineers and is a registered professional engineer in Quebec.

W. G. H. Holt, M.E.I.C., general manager of the mechanical division, Dominion Bridge Company Limited. *(Design and Erection Features of the Vertical Lift Bridges for the St. Lawrence Seaway Authority.)*

Mr. Holt graduated from the University of Toronto in 1936 as a mechanical engineer and began his career with the Dominion Bridge Company at Lachine where he gained experience in the mechanical drawing, design and sales offices, as well as in the production department. He was appointed Mechanical Engineer, Eastern Division in 1954, the position he held until his recent appointment this year.

He is a member of the Corporation of Professional Engineers of Quebec and The American Iron and Steel Engineers.

R. F. Scott, M.E.I.C., assistant professor in civil engineering, California Institute of Technology, *(Oil Tank Sites Preloaded by Well Point System).*

Dr. Scott was educated at Glasgow University, Scotland before coming to the United States to study and carry out research at M.I.T. He worked for two years for the Arctic Construction and Frost Effects Laboratory of the U.S. Army Engineers and in 1957 came to Canada to take up employment with Racey, MacCallum and Associates, Ltd. as divisional soils engineer. He is an associate member of the American Society of Civil Engineers.

P. E. Cavanagh, vice president, Premium Iron Ores, Montreal *(Processing of Low Grade Iron Ore Using Natural Gas or Petroleum).*

Mr. Cavanagh graduated from the University of Toronto in 1937 with a B.A.Sc. in Metallurgy. He worked with the Steel Company of Canada, Hamilton, for five years and with Allan B. Dumont Laboratories, Passaic, N.J. for three. He was with the Ontario Research Foundation for nineteen years, five of which he directed the Department of Engineering and Metallurgy.

Mr. Cavanagh has presented papers through all major societies and sat on committees such as A.I.M.M.E., A.S.T.M., and A.S.M. He has also been on U.N. Committees.

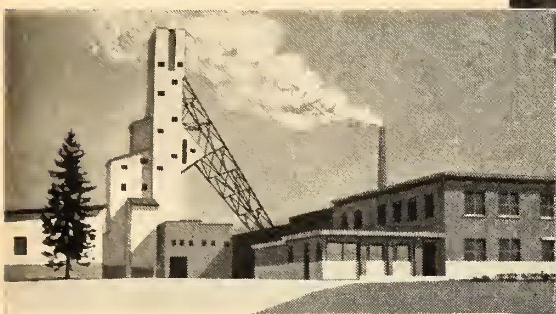
OMITTED FROM JULY ISSUE

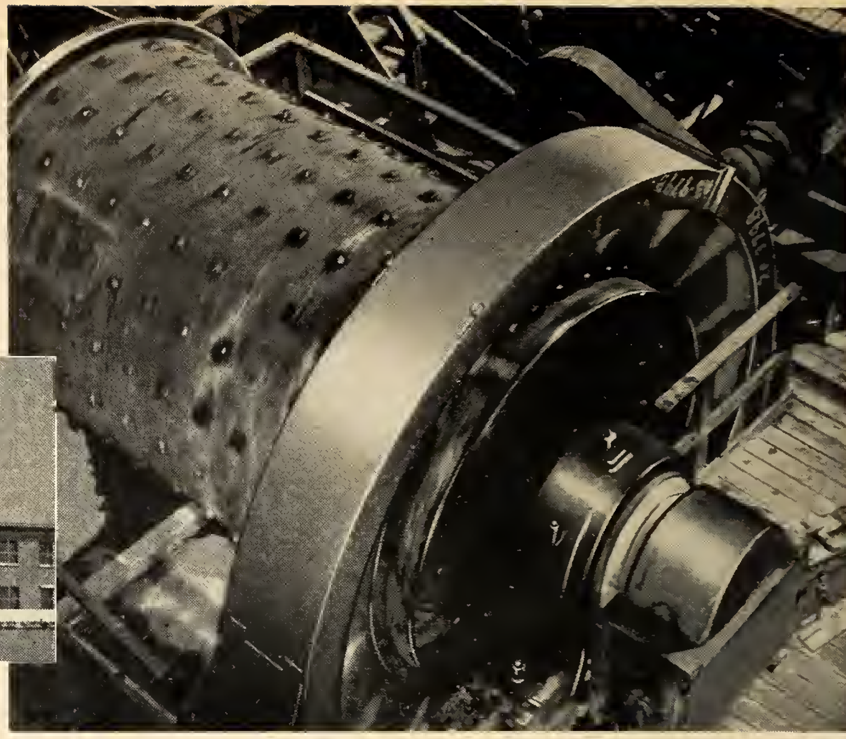
R. A. Walker, assistant hydraulic engineer, (studies) The Hydro-Electric Power Commission of Ontario *(Headloss Coefficients for Niagara Water Supply Tunnels).*

Mr. Walker graduated from the University of Toronto in 1943 with B.A.Sc. in mechanical engineering. He served as demonstrator in hydraulics at the University of Toronto 1943-44 and almost two years in the Royal Canadian Navy as engineer officer. In 1946 he joined the Hydraulic Department of the Ontario Hydro as junior engineer. In his present position he has charge of hydraulic field tests on turbines and structures, hydraulic resource estimates, storage regulation studies and hydrometric office and field investigations. He is a member of the Association of Professional engineers of Ontario and an associate member of the American Society of Mechanical Engineers.

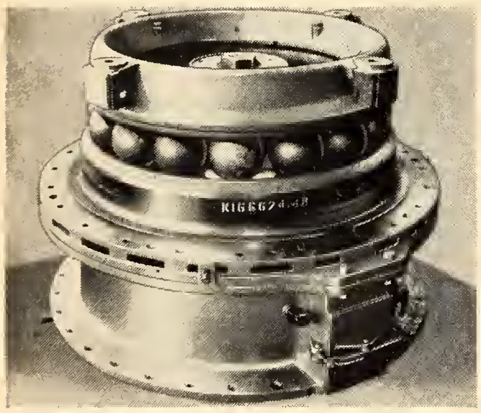
Our cover picture shows the interior of the main product pumphouse at the Hamilton Tar Plant of Dominion Tar and Chemical Company Limited, (Coal Tar Products Division)

Kerr-Addison Gold Mines, Limited, replaced forged steel grinding balls with Ni-Hard cast iron grinding balls in this ball mill shown at right, resulting in a saving of 20.1% in overall wear . . . cutting costs 14.8%.





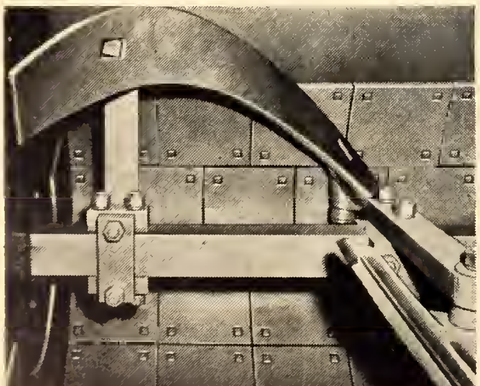
NI-HARD*cast iron cuts costs and reduces wear in abrasive applications



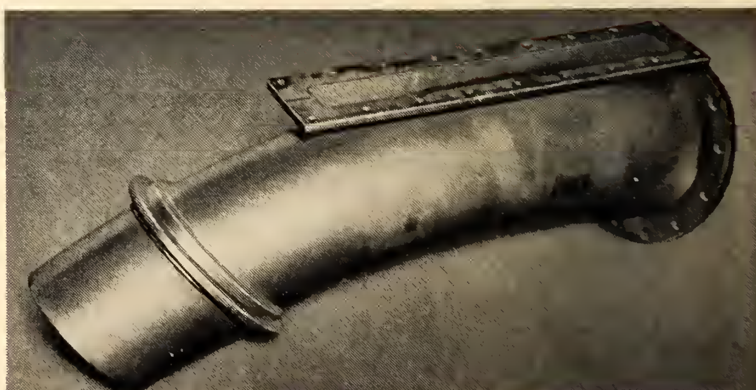
Ni-Hard grinding rings used in this coal pulverizer outlast white iron three to five times.

Ni-Hard is a nickel-chromium white cast iron with high abrasion resistance. It has many money-saving, wear-saving uses in mining, power, cement, ceramics, paint, dredging, coal-coke, steel, foundry and other industries—where abrasion is a problem.

**Trade Mark*



Ni-Hard paddles and liner used in cement block mixing machines give better than six to one service life over previous abrasion resistant material.



This cement slurry elbow of Ni-Hard cast iron replaced original equipment which had failed after three months' service. The Ni-Hard elbow is still giving excellent service after five times the service life of previous material.

HEADQUARTERS COMPUTATION CENTRE FOR THE H.E.P.C. OF ONTARIO

The Design of the Data Communication Network

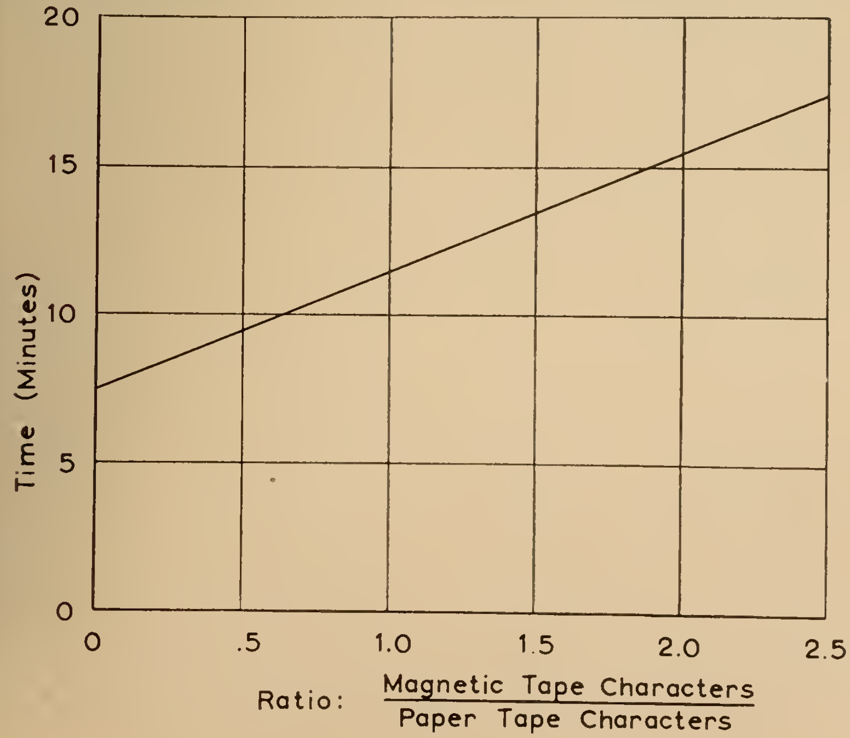
W. H. Sanders.

Manager, Data Communications and Control Dept., The Hydro-Electric Power Commission of Ontario.

THE ONTARIO HYDRO is a public utility which produces and distributes electric power throughout the Province of Ontario. There are two distinct phases of operation; the first is the provision and delivery in wholesale quantities of electric power to municipal utilities and large industrial customers, the second is the distribution of power to the ultimate customer. The distribution of power in most municipalities is conducted by municipal utilities. In rural areas and in a small number of municipalities, the Ontario Hydro operates and administers the distribution facilities.

For administrative purposes, the Province is divided into nine regions and the regions are subdivided into 103 rural operating areas. While the administration of the system is decentralized, certain areas of data processing are handled on a centralized basis.

Chart 1. Time required to convert 900 ft. of paper tape to magnetic tape (excluding handling time).



In August of 1955, the Commission authorized the establishment of a team to study Electronic Data Processing. The report of this study team recommended that the Commission centralize and integrate its data processing, enter the field of electronic data processing using a large-scale digital computer, capture input data on five channel punched paper tape at the initial recording (where economically possible) and transmit this information by wire to the data processing centre. The reports of the system were to be printed on high speed printers in the processing centre and mailed to the Area and Region offices.

The original concepts concerning the application of electronic computing machinery to commercial data processing followed two divergent paths, the information machine and the production machine. The study team recommended that the latter concept be used and that information be ordered prior to processing. The data would enter the system mechanically as a by-product of initial recording in a form not requiring further human intervention without destroying administrative and financial controls. Area offices would require the facility to enter data into the processing system and to produce a legible record. These offices would then transmit the information to their respective Region offices. The transmission of information in these nine networks would be one-way.

Due to the large number of Area offices, compared to the number of Region offices, and the fact that 90% of the original data is numeric, economy could be obtained by limiting the Area office to the entry of numeric data and requiring the Region office to enter all alphabetic data. This would be feasible providing the scheduling problem created by requiring alphabetic data to be mailed to Region offices could be overcome. The Region offices would be equipped with tape-reading typewriters to print out data contained in the tapes received from Area offices. This arrangement would provide the Region staff with the facilities to audit the accuracy of data forwarded to Head Office by exercising quality control using a statistical sampling basis, and to assure that only legitimate data is handled and that all data is processed. These offices would then relay information to the data processing centre.

The final stage in the data communication network would be the conversion of information from the medium of punched paper tape to the medium of magnetic tape.

Design of the System

The design of our data communication network was influenced by the need to maintain the concepts of decentralized administration, the capabilities of the basic input devices and the paper tape to magnetic tape converter, and the requirement for the detection and correction of errors.

One of the primary functions of an Area office is to provide customers with service. If this function was not to be disturbed, data transmission would be random rather than stringently scheduled. Information would have to be identified as to particular process involved and sorted prior to processing. This sort could be carried out on the computer or prior to entering the computer. If it were sorted on the computer, all data would have to be converted onto magnetic tape before any data could be processed. If the sort occurred before the conversion to magnetic tape, certain data could be given preferential treatment in the conversion to magnetic tape and one class of data could enter the processing system while another class was undergoing conversion. Data which was late in arriving in the processing centre could by-pass the normal conversion procedure and enter the central computer in time for processing. It would be possible to use more than one scheme of conversion to magnetic tape. This would permit error detection on the paper tape converter and thereby start correcting procedure at an earlier point in the processing cycle, and would reduce the time required for conversion and the time required to initially read the magnetic tape on the computer. It was decided to allow the Area offices to transmit data in a random order and to sort the data prior to conversion to magnetic tape.

The numeric input device in our data processing system is a Monroe duplex auto-punch. Numeric data can usually be segregated into data which identifies and data which quantifies. To detect errors in the keying of data, the identifying data carries along with it a check digit. This check digit has the property that the identifying data, including the check digit, is some multiple of seven. All identifying data is accumulated in one register of the machine and totalled at the end of each section of a message. Quantitive data is accumulated in the second register and also totalled at the end of each section of a message.

Prior to the transmission of the message, the totals of both registers are checked, the identifying data totals are checked for divisibility by seven, while the quantitive data totals are checked by accounting controls, i.e., total cash reported as collected from customers agrees with the total cash deposited in the bank. After these checks have been performed, the message is transmitted. If an error was detected, a correction message is prepared which, in the computer processing, will delete the item in error and insert the correct information. Since the paper tape message was prepared as a by-product of the initial recording, all correction messages must not only adjust the computer processing, they must also adjust the original hard copy to complete the information on file in this office and thereby facilitate the auditing of accounts.

Provision has also been made to correct information within the message if the error is detected either before the motor bars of the auto-punch have been depressed or after the motor bar is depressed but before the message is terminated. In the latter case, the procedure is similar to that of a correction message.

Errors in the transmission of data from the originating office to the data processing centre in which a decimal character changes to another decimal character are detected in the initial computer run by comparing the arithmetic sum of the data received with the transmitted sum. Identifying data which is common to a number of items of data, such as the particular process involved, date and originating office, is not entered into the accumulating registers. The ease with which keying and transmission errors can be detected is dependent upon the redundancy of the data. To protect that numeric data in which errors are not easily detected, the redundancy is increased by the insertion of the 9's complement. In this way, the information is duplicated without the use of the same keying configuration.

To detect the loss or gain of characters during the transfer of data to the computer and to simplify the control mechanisms on the input machines, the format of messages is strictly controlled. To detect the loss or gain of a character in the body of a message, it was decided to transmit information in groups of 60 characters, each group to fill one line of printing on the page printers. This, in turn, meant that the length of a line of printing was predictable and could be automatically controlled. During the time required for the

Table 1. Format Control.

No. of words in item of information	*Total No. of possible combinations of word lengths*	*Total No. of acceptable combinations of word lengths* — *Area × Region Network*	*Region × H.O. Network*
I All possible combinations of word lengths			
1	20	6	12
2	200	28	56
3	600	48	96
4	1200	72	144
II Excluding those combinations where any word contains less than 3 characters			
1	16	4	8
2	128	15	30
3	384	24	48
4	768	30	60

carriage to automatically return one or two characters could be received. If these characters are non-printing characters, there is no loss of information on the printed copy. If the characters are printing characters, over-printing will occur, a condition easily detected by visual inspection.

The auto-punch was designed to punch one function code character preceding the digits entered in the keyboard and another function code character following these digits. These additional characters are used to identify which motor bar was depressed and to control the paper tape to magnetic tape converters and the monitor page printers. The function code characters, following the entry of information in either register of the auto-punch, are non-printing characters.

Within the body of a message, each line of printing must contain an integral number of entries into the accumulating registers and each line contains 60 characters. To reduce the time required for transfer of information to the computer, the auto-punch is equipped with two switches which determine the number of digits to be punched when information is entered into one of the two registers of the machine.

Format control places a restriction on the number of possible combinations that can be transmitted. (See Table I). It provides a fast visual check that the operator has correctly set the input machine and characters have not been lost or gained in the transmission of data. It is also possible by visual inspection to detect the large majority of errors where decimal character changes to other than a decimal character.

One of the problems encountered in the transmission of information is the receipt of a blank character. All monitor page printers will space on a blank. If the blank is an additional character, spacing will distort the format and is easily detected, but the substitution of a blank for another character is not easily detectable by a fast visual inspection. All receiving points are equipped with blank detectors. When a blank is received, the transmission of the message is stopped and the message is retransmitted.

Data is not only sorted by the particular process involved, it is also sorted by whether it is numeric or alpha-numeric, and use is made of the paper tape to magnetic tape converter to detect illegal characters. In a parity check, one half of the total number of possible coding combinations is legal and the other half

illegal. In the paper tape to magnetic tape converter, this restriction does not apply. Any code combinations can be declared legal or illegal.

During the conversion of numeric messages, those characters which can be produced on the auto-punch, together with three characters required to indicate the end of data on a magnetic tape, are legal and are converted. All other characters are considered illegal, and the conversion stops. The paper tape is marked and the remaining paper tape is processed through the converter to detect errors in this section. The paper tape is returned to the communication operators for correction.

In the conversion of alpha-numeric messages, 60 of the 64 possible code combinations are considered as legal and this form of detection cannot be applied. Excluding the blank characters, two of the remaining 62 characters cannot be obtained on the alpha-numeric input machine, and are considered illegal combinations. One of these two characters is a function code on the numeric input machine. This arrangement prevents the bypassing of the illegal character tests when converting numeric messages.

Data is organized in the Univac system in fixed word lengths. The paper tape to magnetic tape converter changes the organization of data from the variable word format on paper tape to fixed word format on magnetic tape. The speed of conversion is a function of the ratio of the number of magnetic tape characters to the number of paper tape characters. (See Chart I). It is obvious that the length of time required to convert a given message and the length of magnetic tape produced can be reduced by employing more than one conversion scheme on numeric messages. Messages are therefore sorted by the system employed to convert messages to the medium of magnetic tape.

The format of data on magnetic tape can be controlled by a sequence of one, two or three characters. On the assumption that an error can produce any of the 64 characters, the more important functions of the converter are controlled by two or three characters in sequence. Two characters are used to activate the start convert function and three characters are used to activate the stop convert function.

In the initial computer runs, the format of the information on magnetic tape is checked, totals are checked against the detailed data and the indicative data is checked for divisibility by seven. The validity of the information is also checked when the computer performs a calculation or posts the information to its files. If an error has occurred, the office that originated the data is notified and takes the necessary action required to correct this condition.

Description of Equipment and its Operation

Each Area office is equipped with a Monroe duplex auto-punch, a sevens calculator, and a tape transmitter. Numeric messages are prepared on the auto-punch, the totals of each register are checked, and the paper tape is inserted into the gate of the transmitter. If an error was detected by checking the totals, the error is isolated and a correction message prepared. The transmitter is automatically started by the control equipment in the Region office when the gate is loaded and automatically stopped when the message has been transmitted. If a break occurs during the transmission, the transmitter stops, the tape must be repositioned to the start of the message and the transmitter reset. Messages are numbered sequentially through a 00 to 99 cycle and are filed. At any point in time, the originating office has on file the previous 90 messages. The first message transmitted each morning indicates the message number of the last message transmitted the previous day.

Each Region office is equipped with an automatic sequencing device, an on-line and an off-line Lorenz page printing reperforator, and a transmitter. The sequencing device automatically interrogates the Area offices until it locates an office which has loaded its transmitter, the transmitter is started and the message is received in the form of page printed copy and paper tape. The message is checked for number sequence and format. If acceptable, the paper tape is inserted into the transmitter for transmission to the data processing centre. After transmission, the paper tape is destroyed. (The hard copy received is then referred to the Region office staff to check that the appropriate authorization has been obtained and that the proper accounting distribution has been made.)

If a break occurs, an alarm is sounded, the sequencing device steps to the next Area, and the paper tape received from the first Area is destroyed. If an error occurs in the format, the paper tape is destroyed and the Area requested to retransmit the message. If on retransmission the identical error occurs, it is assumed that the original tape is in error. If the error is such that the message can be converted to magnetic tape, the message is transmitted, otherwise the Area is requested to prepare a new message. In the former case, the data processing centre is informed that the message transmitted is in error. The off-line Lorenz machine is used to prepare alphanumeric messages based on information received from the Area office.

Region offices follow procedures similar to those in effect in the Area offices for the preparation of messages. Each morning the Region operator prepares a message for transmission to the processing centre based on a sequence control card which lists the number of messages from each location sent to the processing centre the previous day.

Information is received in the data processing centre on page printers and on typing reperforators. The format is checked in a similar manner to that used in the Region office. Since sequence checking of messages is no longer practicable, the messages are tabulated by the type of message and the originating office. When sufficient tape has accumulated on the reperforators (150 ft. to 200 ft.), it is removed and the tape is inserted into one of two readers on the sorter. The sorter reads the paper tape and recognizes the double character start code, the four decimal digit message classification, and the triple character end code. Under the control of a switching panel, one of seven punches is energized and the message reperforated. One sorter can handle the output of between six and seven incoming lines due to its speed of operation and the nature of the data sorted. The sorter, which operates at eight times the speed of the incoming lines, was designed to initially recognize 50 different classifications of data.

If the total of the messages in each classification is of equal length, then a 49-way sort could be accomplished by reading each message twice. The effective speed of the sorter would be equivalent to four incoming lines. By means of the switching panel, any number of message classifications can be directed to any particular punch. Use is made of the fact that, in a given day, the total of the messages in each classification is not equal in length, by operating the sorter such that each punch is used for the same length of time. This reduces the volume of traffic requiring a second sort and effectively increases operating speed of the sorter. If the four decimal digits after a message start code are not a legal combination, the message is directed to an error punch which is associated with a transmitter and page printer. Prior to removing the paper tape from a punch, a special message is passed through the reader and directed to the punch. This message will identify the end of data on magnetic tape. A similar message is used prior to punching the first data message on a roll of tape to indicate the start of data on magnetic tape.

One reel of paper tape is then converted to one reel of magnetic tape. An error on a reel of paper tape requires the isolation of the error, its correction and a rerun of the conversion process. A reel of paper tape contains approximately 100,000 characters and each sorter processes approximately 10 reels of paper tape a day or 10^6 characters. An error frequency of 1 in 10^6 in the sorter will produce one error a day, and therefore the correction and reconversion of a reel of paper tape.

The sorter is equipped with message counters on each punch and on the reader. At the end of the processing day, the tabulation of incoming messages by message classification is agreed to the message counters on the sorter, while the tabulation of incoming messages by originating office is agreed to the control messages received from the Region offices. The initial run on the computer totals the number of messages on each input reel of magnetic tape and these totals are agreed to the sorter counters.

The hard copy from the page printers is used to post a manual control. Controls have been built into the computer system based on information received by the computer. The manual control checks that all information received over the communication network was processed and that all messages rejected from the system due to error have re-entered the processing system. In certain circumstances, the manual control will indicate those offices which have not prepared messages required for a particular process.

Communications Between Regional Offices and the Head Office and the Tape Sorting Operation

S. J. Crossman. *Supervising Engineer, Teletype Switching, The Bell Telephone Company of Canada, Montreal, Quebec*

THE DATA Communication System of the Hydro Electric Power Commission of Ontario provides the means of transmitting data from the H.E.P.C. area offices throughout Ontario via the nine regional offices to the head office in Toronto, sorting it into categories, converting it from paper tape to magnetic tape and processing it by a Univac computor. The system also provides for the transmission of administrative traffic from the head office to a number of the regional offices.

The portion of the transmission system between the area offices and the regional offices is provided by the telegraph companies and is described in another paper. The portion of the transmission system between the regional offices and the head office and the sorting of the information in categories is provided by the Bell Telephone Company and this is the portion of the system described in this paper. The electronic circuitry which performs the sorting operation is described in detail in another paper.

Transmission from Regional Offices to Head Office

At each of the nine regional offices, the data is available in the form of five level perforated paper tape. A No. 14 transmitter distributor accepts the paper tape and transmits the data in the form of electrical pulses over telephone company telegraph facilities to the head office in Toronto at the rate of 75 words per minute. At the head office, each circuit is terminated in a No. 14 receiving only typing reperforator and a No. 28 receiving only page printer.

The No. 14 typing reperforator reproduces the five level perforated paper tape containing the data and also types the data on the tape for identification purposes. The typing reperforators are mounted on drawer type shelves, stacked three in a cabinet. Each drawer also mounts a power-driven tape winder to wind the tape as it is perforated. Each tape winder is equipped with an individual visual and a common audible alarm to indicate when approximately 200 ft. of tape has been wound. This length was decided upon as being a convenient length for sorting. The typing reperforators are also equipped with individual visual "low tape" alarms to indicate when the supply roll of tape to the reperforator has been perforated.

The No. 28 page printer produces a printed page copy of the data being received. This page copy is scanned by an operator to check for transmission errors and is later discarded. By suppressing printing on several characters, a format of blocks of typing separated by blank spaces is obtained, which lends itself to a quick visual check. Each page printer is also equipped to light an individual visual alarm when a "blank" character is received. The "blank" character is not used in the transmission of data and is the character usually introduced by a "hit" or an "open" in transmission path.

Data Sorting Operation

The five level perforated paper tape being produced by each typing reperforator contains data from a number of area offices and one regional office. This data includes several types of information, such as meter readings, pay-roll, stock, etc. For economic reasons, it is desirable that the computor have one type of data programed into it for a given period and so it was decided that the data would be sorted into general categories before the programing operation. The *tape sorter* was designed to meet this requirement. It performs the sorting operation by accepting perforated paper tapes from the typing reperforators, with each tape containing several types of information, and producing several perforated paper tapes, each of which contains only the type or types of information selected by the operator. These output tapes are later converted into magnetic tapes for programing into the computor.

The *tape sorter* sorts the data at a rate of 600 w.p.m. The teletypewriter circuits from the regional offices are transmitting data at a rate of 75 w.p.m. so that a *tape sorter* unit will sort the output of seven or eight circuits without introducing an accumulating delay. Two *tape sorter* units were installed to handle the traffic from the nine regional offices and to provide for growth.

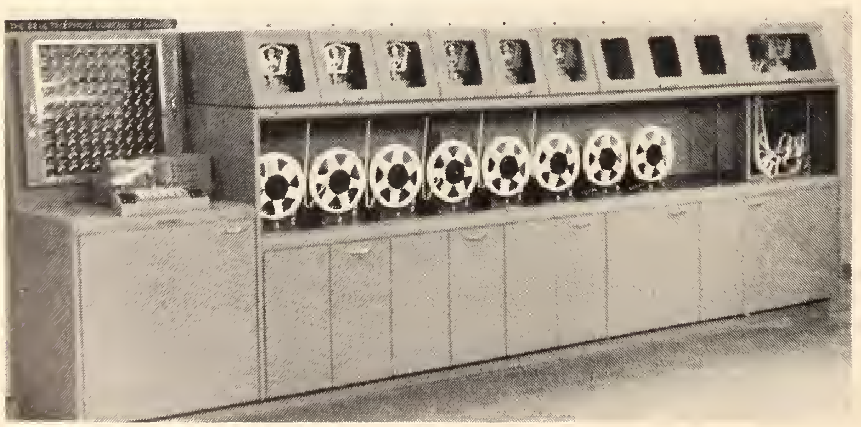
Each *tape sorter* is a self-contained unit mounting a 600 w.p.m. double gate tape reader with two associated tape unwinders, nine 600 w.p.m. tape reperforators or punches with associated high speed tape winders, a tenth 600 w.p.m. tape reperforator with an associated No. 14 transmitter distributor, the electronic control equipment, a control panel of one hundred selector switches and the required power supplies, all in a sheet metal cabinet 14 ft. long, $2\frac{1}{2}$ ft. wide and 5 ft. high. The reperforators are mounted on the top deck of the cabinet and covered with a common hinged cover to reduce noise. The tape winders are mounted on a lower deck under their associated reperforators. The electronic control equipment is mounted in the bottom of the cabinet in a pull-out framework. The tape reader and the control panel of switches are mounted at one end at a suitable height (see Fig. 1).

The input device of the *tape sorter* is the 600 w.p.m. double gate tape reader. The transmission through the *tape sorter* is on a six parallel path basis to accommodate the five level code plus a "control" level. Each path consists of several stages of storage termed "shift registers". As the information is stepped through these "shift registers" in succession, it provides a means of electronically looking at a number of consecutive characters in a message at any given instant. A visual display of the signal in each storage register is provided as a check of operation. The output devices of the *tape sorter* are ten 600 w.p.m. tape reperforators or punches. The sorting is done by automatically selecting the appropriate reperforator to terminate the transmission path through the *tape sorter*.

The *tape sorter* could be built to recognize codes of any number of digits. For this application, it was built to recognize four digit codes which have the first two digits between 00 and 99 and the last two digits assigned to verify the first two. At present, it is equipped to recognize 50 such codes. The codes are assigned by a simple strapping on a terminal board. Space was provided to allow the *tape sorter* to be equipped to recognize 100 codes.

The control panel consists of 100 nine position switches arranged in ten rows of ten for easy locating Each switch corresponds to an

Fig. 1. Tape sorter.



assigned four digit code and the nine positions of each switch correspond to first nine output reperforators. The programing is done by setting each of the "code" switches to a selected reperforator position. By this means, any one or more of the fifty types of messages as identified by an assigned code, can be directed to any one of the first nine output reperforators. Any message not identified by one of the assigned codes is automatically directed to the tenth or "error" reperforator.

The sorting operation is performed by taking a 200 ft. reel of perforated paper tape from one of the typing reperforators which terminate on incoming circuit from a regional office and placing it in one of the two centre unwind tape reels located adjacent to the reader of the *tape sorter*. As the reader is equipped with two input gates, the tape can be loaded into the idle gate and it will be read automatically when the tape being read by the other gate is spent. The spent tape is stored in a bin under the reader. Each message in the tape begins with the characters "Figures D", immediately followed by the four digit code which identifies the type of information contained in the message. Each message ends with at least three "carriage return function" characters. As the reader reads the tape, it steps the information through the shift registers. When the electronic control circuitry recognizes that the last two shift registers contain the "Figures D" combination, it knows that the four preceding shift registers now contain the four digit code identifying the message. It reads the code and connects to the transmission path the output reperforator programed by the control switches to receive messages identified by that particular code. When the electronic control circuitry recognizes that the last three shift registers contain the three "carriage return function" characters indicating the end of the message, it prepares to disconnect this reperforator. Upon receipt of the "Figures D" characters heading the next message, it disconnects this reperforator and connects the appropriate reperforator in accordance with the new code. The reader and each output reperforator is equipped with a Veeder Root type counter to indicate the number of messages that have passed through that unit.

The output tape from each of the first nine reperforators is wound on an associated power driven tape winder which can wind up to approximately 1,000 ft. of tape. Each reperforator is equipped with an audible and visual "low tape" alarm to indicate when its 1,000 ft. supply roll of paper tape has been perforated and rewound on the associated tape winder. The rolls of perforated tape are removed from the tape winders by the operator and are stored in suitably designated film type cans until they are to be read by the "paper tape to magnetic tape" convertor. The messages they contain will then be transferred to magnetic tape which will be programed into the Univac computor.

A power driven tape unwinder is provided which will hold the 1,000 ft. rolls of output tape from the sorter. This allows the output rolls of tape to be rerun through the input reader of the *tape sorter* to facilitate a resorting operation.

The output tape of the tenth or "error" reperforator is fed directly into a No. 14 transmitter distributor and the messages are transmitted automatically at 75 w.p.m. to a No. 28 page printer located at the supervisor's desk for investigation. The spent tape is stored in a bin under the transmitter distributor.

Transmission of Administrative Traffic

Outward transmission of administrative traffic from the head office to a number of the regional offices is being provided by using full-duplex teletypewriter facilities between these points. Full duplex operation permits the transmission of information in two directions simultaneously over the telegraph facility. In this case, administrative traffic can be sent out from the head office to the regional office while data is being sent in from the regional office to the head office on the same facility. At the head office, one gate of a No. 1 multiple gate transmitter distributor is assigned to the outgoing side of each full duplex facility. A No. 1 multiple gate transmitter distributor is a unit equipped with three independent transmitting gates on a common base and driven by a common motor which provides a more economical arrangement than individual No. 14 transmitter distributors when a number of transmitting units are required. At the head office, the administrative messages are prepared in tape form and inserted in the appropriate gate of a multiple gate transmitter. At the regional office, the receiving side of the full duplex facility is terminated in a No. 28 page printer which produces page copy of the message.

Miscellaneous

At the head office, one gate of a multiple gate transmitter is used to send into a room circuit terminated by a No. 14 typing reperforator and a No. 28 page printer. The arrangement is used for tape checking purposes. Additional items of teletypewriter equipment are provided at the sorting centre for maintenance spares and all items of line equipment and facilities appear on a jack panel to facilitate patching and interchange of units. A double-beam oscilloscope and a transistor test set are the only pieces of special test equipment required for maintenance in addition to the usual test meters and teletypewriter maintenance tools.

The Tape Message Sorter

John Rywak

Northern Electric Research and Development Laboratories, Belleville Branch; Belleville, Ontario

IN THE FEW years of semiconductor history, development of switching circuits largely has been directed towards high speeds as demanded by the computer designers. The relatively slow speeds of data handling suitable for general industrial uses have not attracted as much attention. Perhaps the tendency is to look for semiconductor applications in fields where up to now large quantities of vacuum tubes have been used. Computers, of course, are in this category.

The tape message sorter is an industrial application of semiconductor logic circuits. It was first developed for the Bell Telephone Company of Canada and installed at the Ontario Hydro Electric Power Commission's computation centre in Toronto. Coded data is received at the centre from the various regional offices on the normal 75 word per minute teletypewriter facilities. Because the computer does not have provision for sorting or categorizing of the data prior to processing, a separate sorting machine was required. Furthermore, since there are several incoming lines the sorting has to take place at a considerably faster speed to keep up with the traffic.

The tape is manually removed from the receiving apparatus, of which there are several, and fed into a tape reader. The reader, operating at 600 words per minute, inserts the coded data intact into the sorter where the messages are identified and directed to one of several reperforators which make new tape. Each reperforator, or punch, can be assigned to accept one or more categories of data. If there are more varieties of messages to be sorted than there are punches available, any punch can be assigned to accept the surplus and the new tape then can be sorted. Since the message identification code is always reproduced on the new tape, any number of resorts is permissible.

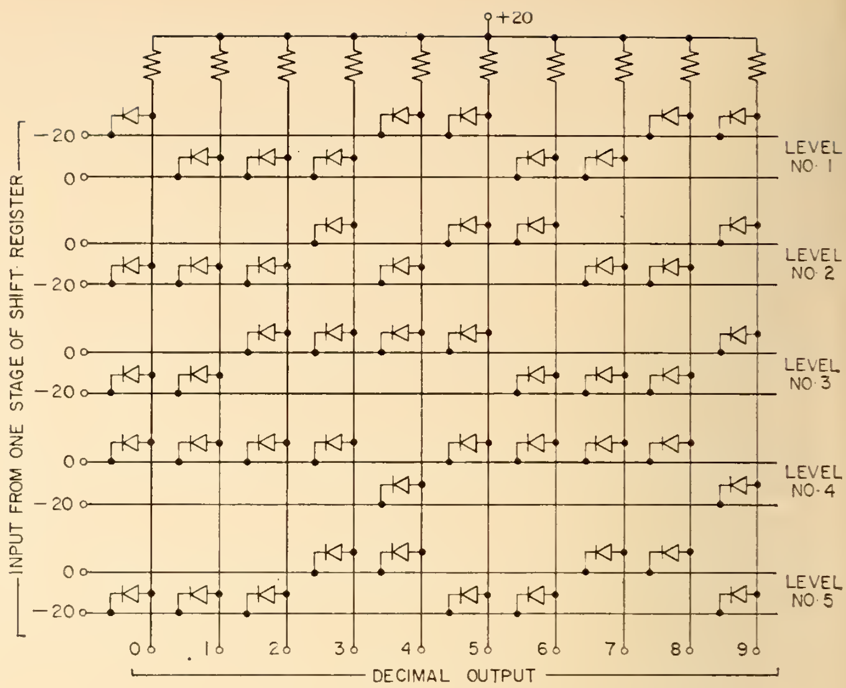


Fig. 1. Diode conversion matrix

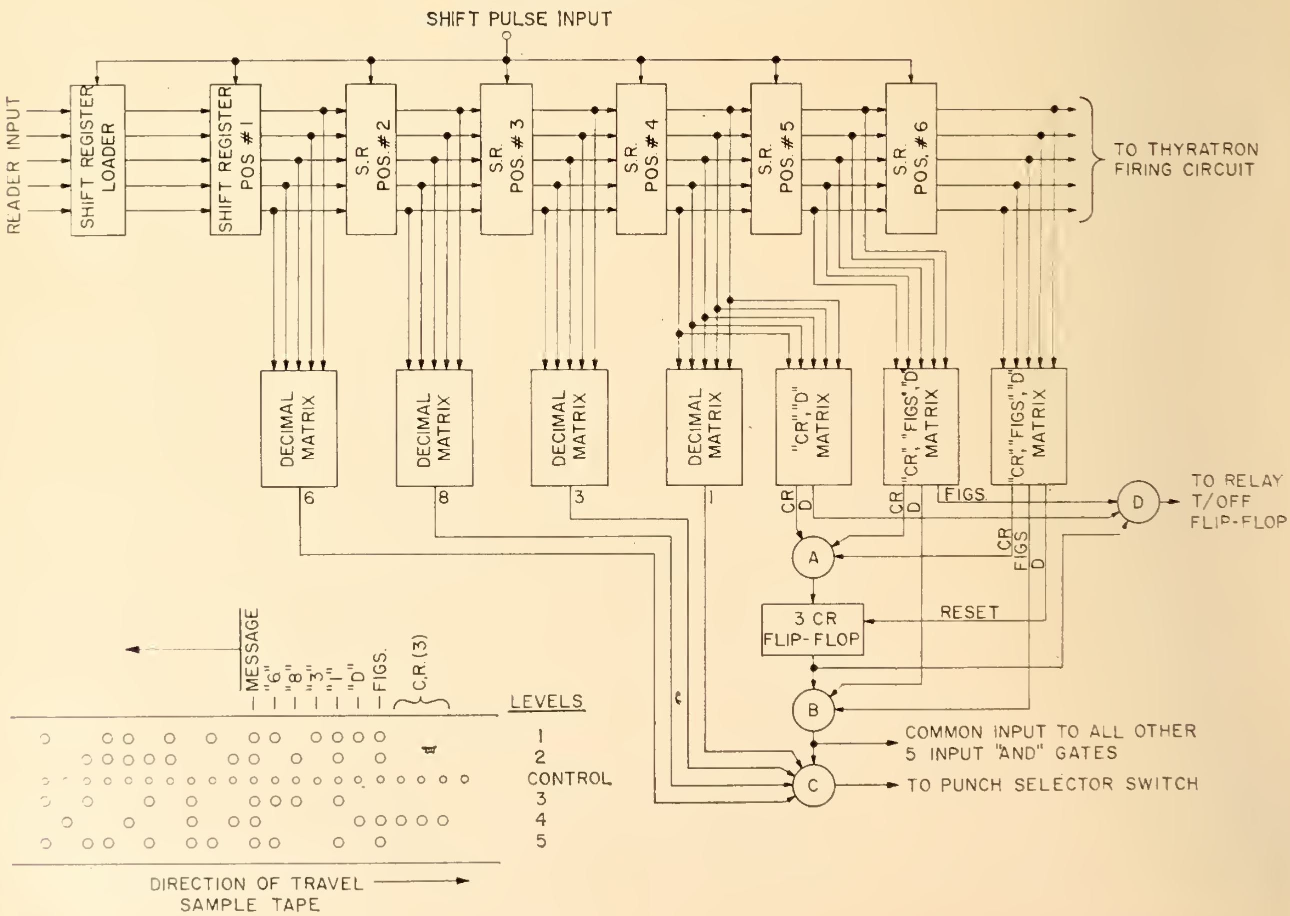
Some general problem considerations

Because the six character code by which a message is identified has to be reproduced by the selected reperforator, it is necessary to direct the

Fig. 2. Block diagram of route selection logic



message through a form of delay for a six character duration, so that the appropriate punch can be selected during this delay period prior to read-out.

Since the punches require 120 v. for operation, it was necessary to use relays for punch selection. But because relays require an appreciable portion of the character interval for their operation, an auxiliary storage of one character duration was necessary, which comes into effect only during message switching.

Although facilities for eight reperforators only were required, it was necessary for the circuits to be flexible enough for addition or deletion of reperforators without affecting the general operation of the sorter.

Keeping constant phase relationship among punches is difficult. Mechanical coupling could be provided, but the system would not permit easy exchange of punches or stopping of a given punch while others were running. Therefore, it was required that the readout circuits could be brought under control of any punch, in any order, with any phase relation between reader and punches.

It was necessary that the read-out and all the selecting and switching functions be performed while the tape is being read-in at a constant speed. That is, the tape should not stop during route selection and switching. It was also desirable that the facilities for circuit adjustments be kept to a minimum.

The following sections of the paper describe in some detail the more important circuits and the functions they perform. Space does not permit

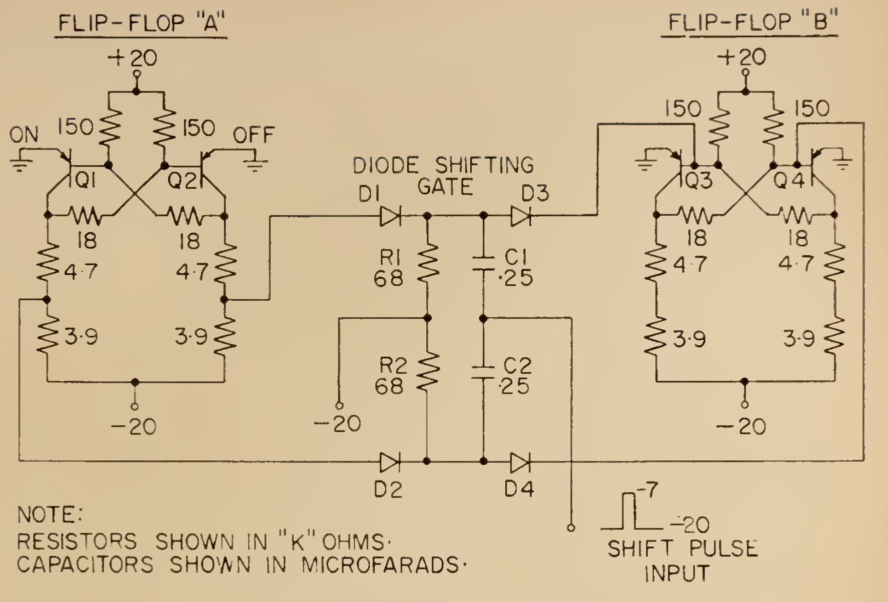


Fig. 3. One state of shift register

a complete description of all circuits, but it is hoped that the coverage given will be sufficient to give the reader some appreciation of the operational philosophy of the tape message sorter.

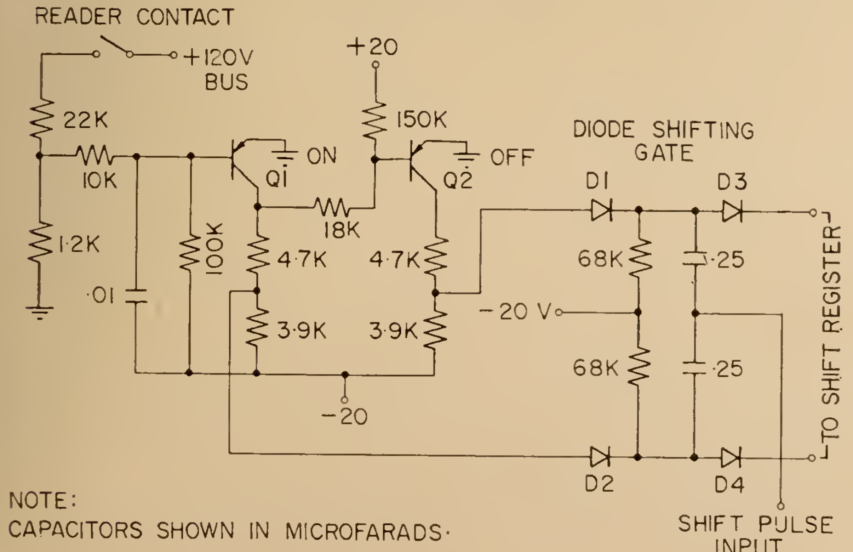
Route selection

The complete message identification code consists of the symbols "Figs" and "D" followed by two numerals which are followed by the 99 complement of the two code numerals, e.g. code number 13 would be "Figs D 1386". Since there is a finite probability of such a combination occurring within the body of the message itself, a further stipulaiton was made that only that code combination would constitute a beginning of a new message that was preceded by at least three carriage return symbols. Furthermore, the carriage return symbols need not be immediately ahead of the identification code group.

Since all information is in the form of the five level teletypewriter code, some method of conversion into decimal was necessary. A simple and reliable form of conversion was achieved with a diode matrix shown in Fig. 1. The five levels of input are provided by the five flip-flops constituting one stage of the shift register. As may be observed in Fig. 1, the flip-flop of level No. 1 is in opposite state to the flip-flops of the other four levels. This is the tape code representation of the numeral "3". It may be observed in the example that bus bars of all the decimal outputs are at -20 volts except bus "3" which is at zero volts. A similar diode matrix was constructed to recognize the symbols "Figs.", "D", and "CR" (carriage return).

In Fig. 2 the flow of information is from the tape reader on the left, through the shift register to the thyratron firing circuit on the right. As may be observed, when a group of three or more "CR" characters go through the shift register, the outputs of the last three matrices will energize the three-input *and* gate "A" which will trigger the 3-CR flip-flop. This flip-flop will provide a steady d-c. input to *and* gate "B". Hence, when the next set of characters "Figs" and "D" are located in shift register positions six and five respectively, the last two matrices will provide the remaining two in-

Fig. 4. Shift register loader



puts to *and* gate "B", the output of which will provide one input to all five-input *and* gates "C". A separate gate "C" is allocated to each identification code. In the example in Fig. 2 only one gate "C" is shown and it is wired into the decimal matrices to recognize numerals 1386. Therefore, when characters "Figs., D, 1, 3, 8, 6" are located in positions 6, 5, 4, 3, 2, 1, respectively of the shift register, *and* gate "C" will produce an output which will trigger the selected relay flip-flop causing that specific tape reperforator (or punch) to be connected to the Thyratron Firing Circuit.

The end of any given message is recognized by the location in positions 5 and 4 of the shift register, the characters "Figs" and "D", respectively of the next succeeding message. These two pulses, plus the output of the 3-CR flip-flop provide the necessary inputs to *and* gate "D", which will then set the relay turn-off flip-flop causing the system to be brought to its initial state in preparation for the new message following.

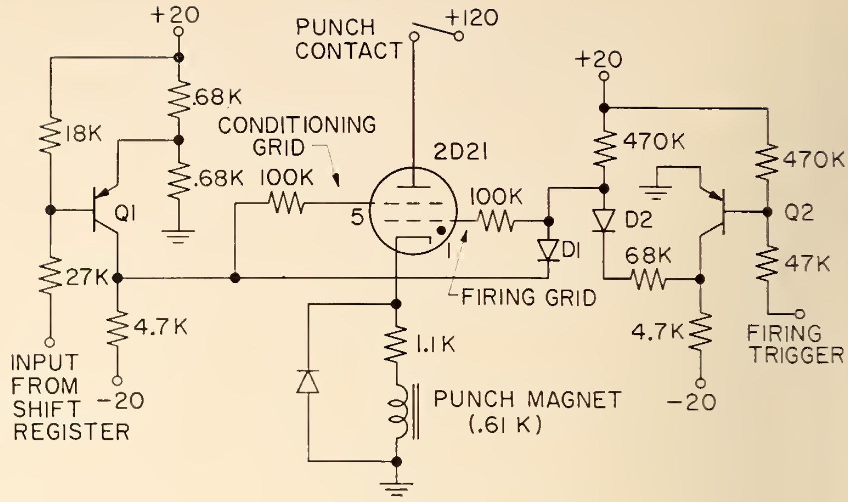


Fig. 5. Thyratron firing circuit

Shift register

As explained previously a delay or temporary storage of six character duration is required so that the complete identification code may be recognized and the appropriate route selected before the message (and the code preceding it) may be read out. A common type of shift register, consisting of five parallel rows of flip-flops, and each row containing six stages, is used to produce the delay. The five rows are required to accommodate the five-level teletypewriter code. Actually, a sixth level is necessary to control the stepping of the tape, but this is satisfactorily accomplished with a single flip-flop (control flip-flop).

A two-stage shift register is shown in Fig. 3. It consists of two flip-flops interconnected by two diode shifting gates. Transistors are driven into saturation when *on* and are cut-off by about two volts when *off*. Let it be assumed that in Fig. 3 transistors Q_1 and Q_4 are *on* and transistors Q_2 and Q_3 are *off*. Capacitor C_1 will charge up through diode D_1 to -17.1 v. and C_2 will charge up to -10.9 v. When the common junction of C_1 and C_2, which normally is at -20 v., receives a shift pulse of about 13 v. amplitude Q_4 will be cut-off by C_2 acting through D_4. Q_3, of course, will be turned *on* by the action of Q_4. Since with the application of the shift pulse the junction of C_1 and D_3 will only rise to -4.1 v., the shift pulse will not interfere with the operation of Q_3. Flip-flop "B" now is in the state that flip-flop "A" was before the application of the shift pulse. The 68K resistors R_1 and R_2 provide a discharge path, for the capacitors, of a somewhat lower resistance than the reverse resistance of diodes D_3 and D_4. Without R_1 and R_2 the leakage currents, through D_3 and D_4 would charge C_1 and C_2 to —2 v. and 0 volts respectively, causing D_1 and D_2 to be biased in reverse direction and thus disabling the shifting operation.

Shift register loader

The transfer of information from the shift register loader into the first stage of the shift register is identical with the interstage transfer. In Fig. 4 a "0" is represented when Q_1 is *on* and Q_2 is *off*. This is the circuit's normal standby state when the reader contact is open. When the reader contact is closed, representing a "1", Q_1 is cut-off and Q_2 turned *on*.

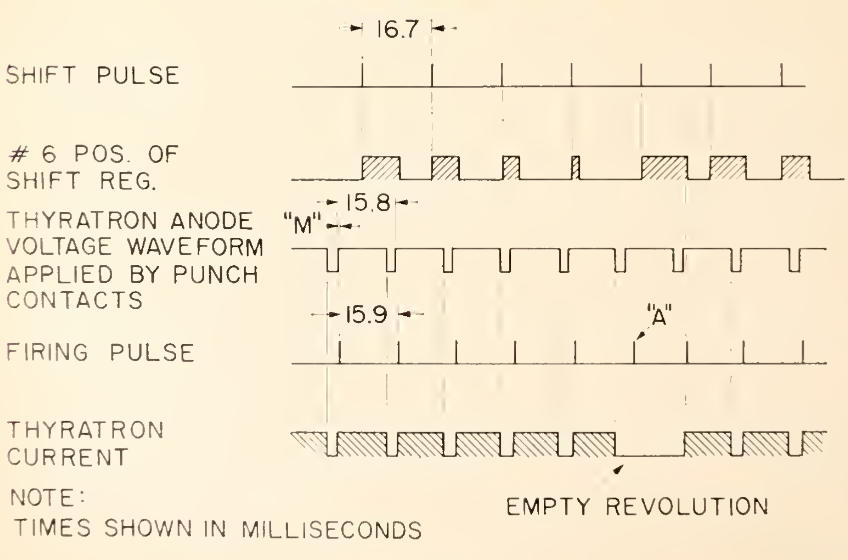
The shift pulse occurs about 4 milliseconds after the contact closure. This interval is necessary to accommodate slight differences in operating synchronism of the other reader contacts, bouncing of contacts, and the charging of the capacitors in the shifting gate. The integrating action of the capacitor in the base of Q_1 serves further to suppress the effects of reader contact bounce.

Thyratron firing circuit

The perforator magnets require 100 ma. at 120 v. for their operation. Since no transistors were yet commercially available that would handle such a load it was necessary to use thyratrons.

Normally thyratrons are fired by vacuum tubes or other thyratrons

Fig. 6. Thyratron operating wave forms



where large signal-voltages are available. In transistor circuits the pulse magnitudes are only about 15 to 20 v., far from sufficient to reliably trigger dual grid thyratrons by employing conventional circuit methods. Fig. 5 shows a circuit arrangement whereby a dual grid type 2D21 thyratron is satisfactorily operated for anode potentials from 115 to 140 v. The improved performance is obtained by using a diode gate in the control grid circuit.

Transistor Q_1 receives its input from the last stage of the shift register. When Q_1 is saturated the collector potential is about +8 v. and when it is cut-off the collector is at about -19 v. The collector of Q_1 provides the conditioning voltage to grid 5 of the thyratron. It may be observed that when this voltage is at -19 the potential of grid 1 (the firing grid) is also at -19 v. because of the location of diode D_1 in the circuit. Therefore, a firing pulse appearing at the collector of Q_2 will have no effect on grid 1 because of the blocking action of diode D_2. However, when the collector of Q_1 is at +8 v., diode D_1 will be reverse biased, allowing grid 1 to remain at about -15 v. Hence, when the firing pulse arrives, Q_2 will be saturated, allowing grid 1 to rise to about +3 v. and causing the thyratron to be ignited.

In the message sorter a set of 6 thyratrons is used, one for each of the 5 character levels, plus one for the control or stepping magnet. A firing pulse is simultaneously applied to the number 1 grid of all six thyratrons, but only those thyratrons will fire that have a conditioning potential on grid 5. The conditioning potentials are determined by the information in the last stage of the shift register. The control thyratron receives a conditioning voltage every

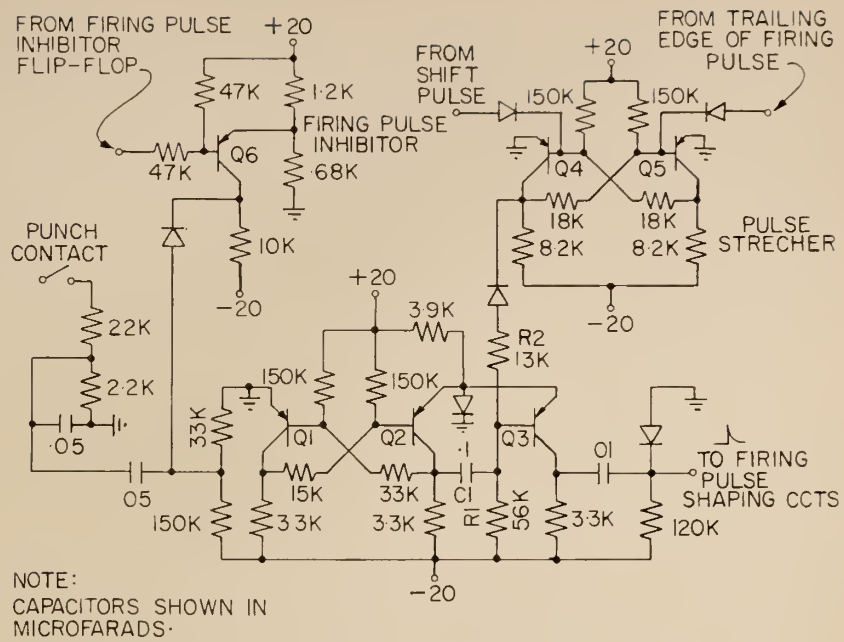


Fig. 7. Firing pulse delay

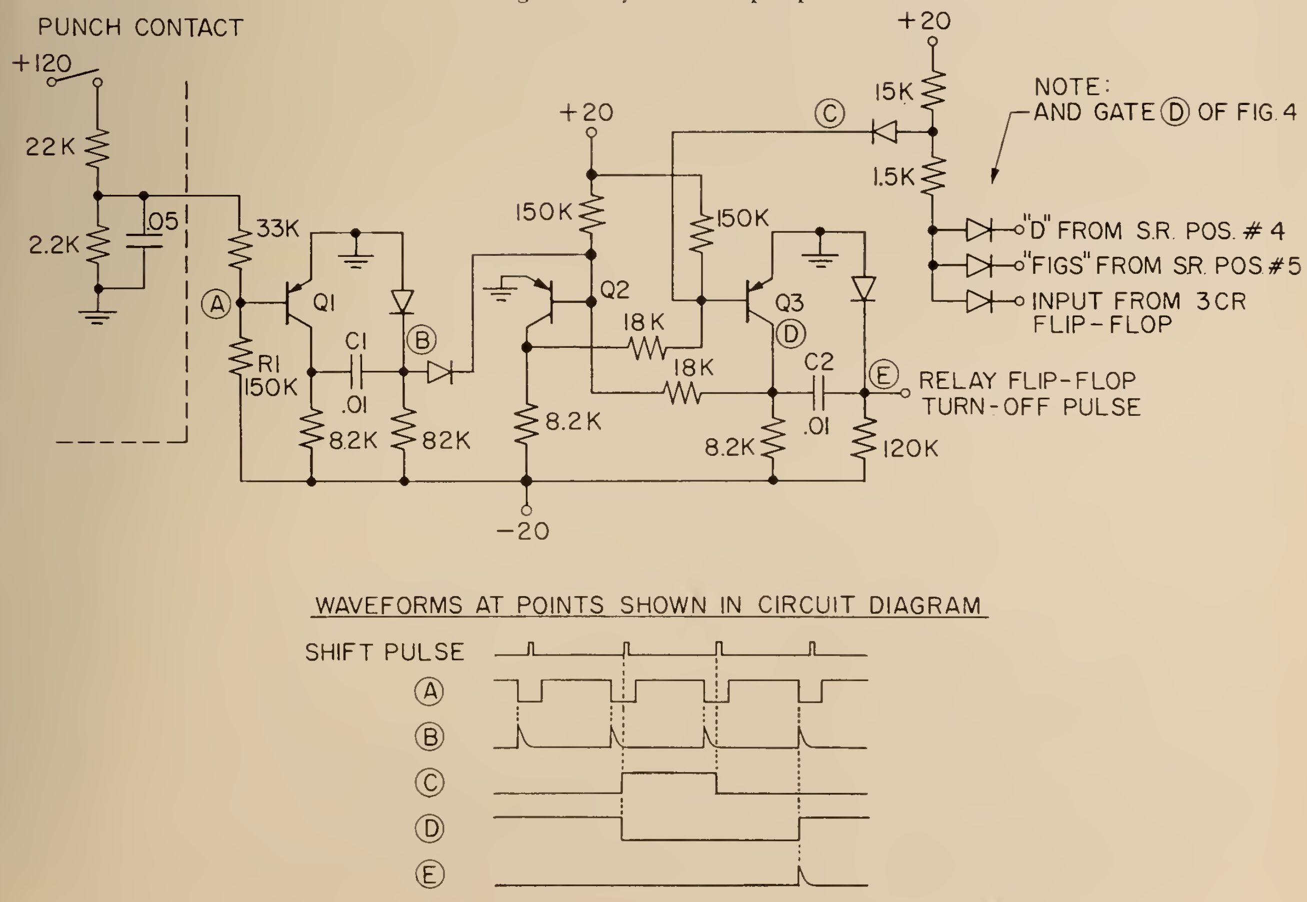
Fig. 8. Relay turn-off flip-flop.



time the tape reader reads a character, thus permitting the new tape to be stepped along the same number of times as the tape that is being read. The thyratrons are extinguished by the opening of the punch contacts which are in series with the thyratron anodes.

Speed differential of read-in and read-out

Although the tape is read at constant speed by the tape reader, the actual message information to any specific punch comes in at irregular intervals. Even if only one punch were involved, there would still exist the problem of precise synchronization of the punch speed with the reader speed.

The method used in the sorter to overcome this difficulty was to operate the punch at about 5½% higher speed than the reader and arrange for the punch to interrogate the output stage of the shift register and whenever information would be present, the thyratrons would fire and the last stage of the shift register reset to zero. Every eighteen revolutions of the punch mechanism the punch would catch up to the reader, hence no new information would be present for the punch to receive, so the punch would make one empty revolution to waste the accumulated surplus of time.

To perform the control function the time interval ("M" in Fig. 6) between punch contact closure and the thyratron firing is made continuously variable. That is, as the punch is catching up to the reader this time interval is increasing by about 0.1 millisecond per revolution until the time the actual overtake occurs. At that time the punch will make one empty revolution, but the next immediate firing will take place about two milliseconds sooner than it would have occurred if the punch were still behind the reader. This sudden shortening of the time interval "M" ensures that the information is extracted from the last stage of the shift register sufficiently early so that there will be no interference, during overtake, between read-out and read-in. The 2 millisecond shortening of the time interval between the end of the empty revolution and the next thyratron firing is the total accumulated time during the eighteen preceding operations. The timing waveforms are shown in Fig. 6.

The sequence of events as shown in Fig. 6 are as follows: The shift pulse inserts information into No. 6 position of the shift register, which in turn places a potential onto the conditioning grid of the thyratron. Punch contacts close, applying potential onto the thyratron anode, and after an interval of time "M" a firing pulse occurs igniting the thyratron. The trailing edge of the firing pulse erases the sixth position of the shift register leaving it ready for the shift pulse to insert new information. The thyratrons are extinguished by the opening of the punch contacts which remove the anode potential.

It may be observed that when firing pulse "A" occurs, new information has still not arrived into shift register position No. 6, hence the thyratrons will not fire and the punch proceeds to make an empty revolution.

The delay interval "M" between the rising edge of the anode voltage and the firing pulse is produced by a monostable flip-flop which is triggered by the application of the voltage to the anodes. This firing pulse delay flip-flop is shown in Fig. 7. During standby, transistors Q_1 and Q_3 are *on* and Q_2 is *off*. When a rising pulse turns Q_1 *off*, it in turn causes Q_2 to turn *on* which, through capacitor C_1, causes Q_3 to be cut off until the charge on C_1 leaks away through resistor R_1, allowing R_1 to turn Q_3 *on*. The action of Q_3 then turns Q_2 *off* and Q_1 *on*. It can be seen that if Q_4 of the Pulse Stretcher is *on* resistor R_2 will have small effect on the discharge time of C_1. However, if Q_4 is *off*, as when turned off by the leading edge of the shift pulse, R_2 will essentially be paralleling R_1 causing a more rapid discharge of capacitor C_1. This means that the time interval "M" in Fig. 6 will be minimum.

Since the Pulse Stretcher is flipped in one direction by the leading edge of the shift pulse and in the reverse direction by the trailing edge of the firing pulse, the time interval "M" will be longer at each successive cycle of operation because Q_4 will be spending less and less time in its off state.

Auxiliary store switch-over

Due to the flow of messages through the sorter being continuous, i.e. the beginning of a given message immediately follows the last carriage return of the preceding message, precautions had to be taken during switching from one punch to another that no information be lost. As has already been explained, only one set of six thyratrons is used in the sorter and the six magnets of each punch are connected through relay contacts to the thyratron cathodes, one punch at a time. So when a new message arrives, the relay of the punch that was being used has to be de-energized and the relay of the new punch energized. Actually, a turn-off pulse is supplied to all punch relay flip-flops and the code of the new message then selects and energizes the appropriate punch relay flip-flop for the new message. This same turn-off pulse also energizes the error punch relay flip-flop so that should the code of the succeeding message be unrecognizable, it would proceed to the error punch. But if the new code is recognizable and it causes one of the punch relays to be selected, the same turn-on pulse causes the error punch relay flip-flop to be de-energized.

Because the operate time of relays is a substantial percentage of the time interval between the characters of a message, one extra stage of shift register is provided to act as a temporary or auxiliary storage into which the new message will go during the switchover period. When the switchover has been completed, the new punch will extract the information from this auxiliary store, and continue to do so, until the occurrence of the first coincidence between the shift pulse and firing pulse. At the time of this coincidence, there exists an accumulation of two milliseconds of time which normally would result in one empty revolution of the punch (as has been explained earlier), but instead, this first coincidence is used to trigger the switchover circuits back to their normal operating position. That is, the punch will begin to extract information out of the sixth position of the shift register. The two milliseconds of accumulated time provide sufficient time for the switchover to take place and circuits to stabilize for the new or normal mode of operation.

Relay flip-flop turn-off

The relay flip-flop turn-off pulse is required at the conclusion of the last character of the last message or, stated another way, when the characters "Figs." and "D" of a new message are located in positions 5 and 4, respectively, of the shift register. Of course, only that set of "Figs.", "D" must be recognized that has been preceded by a minimum of three carriage returns.

In Fig. 8 Q_2 and Q_3 form a flip-flop with one input being derived from Q_1 and the other input from the *and* gate on the right. This *and* gate is designated as "D" in the flow diagram of Fig. 4. It may be observed that when the punch contact is closed transistor Q_1 is cut-off and capacitor C_1 charges up to 20 v. When the contact opens, waveform (A), resistor R_1 causes Q_1 to saturate causing a positive pulse, waveform (B), to be injected into the base of transistor Q_2. This train of positive pulses keeps the flip-flop turned *on* in one direction until it is set by the output of the 3-input *and* gate which will produce a positive pulse only when the 3-CR flip-flop has been set and "Figs." and "D" are in shift register positions 5 and 4 respectively. Transistor Q_3 will then be turned *off* and Q_2 will be turned *on* causing capacitor C_2 to be charged to 20 volts (waveform D). Therefore, when the next positive pulse of waveform (B) resets the flip-flop (Q_2 to *off* and Q_3 to *on*) a differentiated positive pulse will be produced at (E) as shown on the schematic by the waveform (E). This is the turn-off pulse that is applied to all relay flip-flops simultaneously, causing the error relay to be energized and the other relays de-energized.

Inhibition circuits

Although all punches operate at synchronous speed, the phase relationships of the perforating mechanism are random, and since the electrical contacts on each punch are part of the perforating mechanism, the last character of a given message is extracted on the command of the then operating punch, while the first character of the succeeding message is extracted on the command of the new punch. Because the message information is coming in at a constant speed, it would be possible at times to miss the first character of a new message because a complete cycle of operation was not available when the new punch became connected to the thyratron output.

The electrical contacts on each punch are connected in series with a set of contacts of the respective relays. It is, therefore, impossible to determine whether the first application of the thyratron anode voltage (immediately after switchover) is the result of the closure of the punch contacts or relay contacts.

To make certain that the firing pulse delay circuit is triggered by the closure of the punch contacts only, an inhibit circuit is provided to disable it for a period of time slightly in excess of the time it takes for the relay to become fully operated. The Firing Pulse Inhibitor Circuit is shown in Fig. 7. This circuit receives its input from the Firing Pulse Inhibitor Flip-Flop (not shown) which is triggered into inhibition by the relay flip-flop turn-off pulse and restored by a monostable flip-flop, whose time interval is about two milliseconds longer than the energization time of the relay. This restoring monostable flip-flop is triggered by the output of gate "B" shown in Fig. 2.

A similar arrangement is provided for inhibiting the turn-off pulses from the sixth position of the shift register during the time that a new punch is extracting information out of the auxiliary store. The restoration of this circuit is initiated by the coincidence of the firing pulse and the shift pulse.

Conclusions

A disadvantage of transistors in equipment where mechanical contacts are used for current interruption is the accidental triggering of flip-flops by transients. Precautions have to be taken for ensuring good ground connections and suitable isolation of noise-producing circuits. In tube circuits the operating voltages are several times those in transistor circuits, hence larger transients can be tolerated. It was for this reason that it was necessary to design a monostable flip-flop with a positive standby state similar to a bistable flip-flop.

It may be observed that the manner in which the data was handled is quite general. This means that although the present circuitry is handling five-level teletypewriter data, it can easily be expanded or compressed to handle other forms of binary coded data. The present sorter recognizes six-character message identification codes. This, too, can very easily be changed. For example, because the route selection is performed without interruption in the incoming messages, the sorter can be directly applied to perform automatic routing of digital data in a switching centre.

The power consumption of the electronic portion of the sorter is quite modest. Except for the six thyratrons, dissipating an average of 37 w., the rest of the circuits, which contain over 250 transistors and over 1000 diodes, dissipate 27 w.

Because of the low voltages required by the transistor circuits it was very practicable to use all semiconductor power supplies and regulators. Hence, no provision for circuit adjustments was necessary and reliable operation was achieved for a-c. line fluctuations between 105 and 125 v.

Communications Between HEPC of Ontario Area Offices and Regional Offices Using the Autoscan System

H. Ross W. Davis

Canadian National Telegraphs Engineering Department

THE PRIMARY data gathering networks of the Ontario Hydro's Data Processing Communications Network are provided by the Canadian National Telegraphs. These networks connect one hundred area offices to their associated regional offices, of which there are nine.

Each area office is equipped with

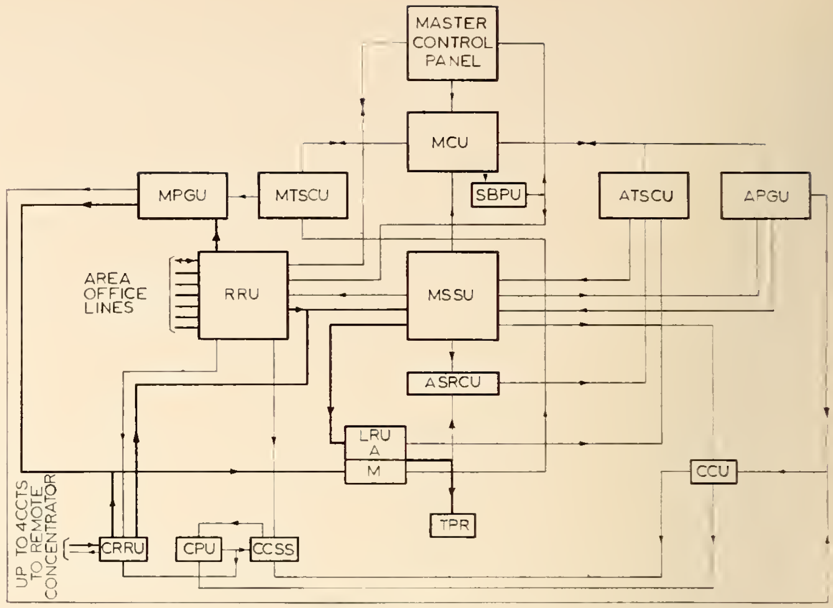

Fig. 1. Block diagram of the Autoscan System.

a Model 14 Transmitter-Distributor which transmits 5 unit tapes at a speed of 60 w.p.m. to the regional offices. In addition a Transmitter Control Unit is provided at each location which is controlled by pulses transmitted from the regional office. Figs. 6 and 7 illustrate the equipment provided at area office locations.

The regional offices are equipped, in general, with two teleprinter machines each equipped with a transmitter distributor and a reperforator attachment. These machines can be used for on-line or off-line operation. When used on-line the reperforator punches a tape and the teleprinter monitors the transmission and prepares page copy.

To facilitate the gathering of data from a large number of offices automatic area office selection by the regional office was desirable. This lead to the development of a selector system which provides considerable flexibility of operation called *Autoscan*. In general each Regional Office is equipped with an *Autoscan* selector.

Autoscan can be operated in two main modes; automatic sequential scanning, and manual. The circuitry of these modes of operation are essentially independent and can be so arranged. However, for ease in operation they are interconnected by control circuitry which enables *Autoscan* to be preconditioned at any time to change its mode of operation without interfering with traffic being received. This results in a saving of operator's time since there is no need to hover over the equipment waiting for the correct time to operate a control.

When automatic sequential scanning is employed a step switch steps to positions to which lines of the area offices are connected. When the step switch steps to a line a start pulse is transmitted to the area office and, if tape has been placed in the transmitter, transmission commences. A traffic sensing unit upon detecting idle line conditions causes the step switch to step to the next line position. There are various stepping rates of the step switch which are described later.

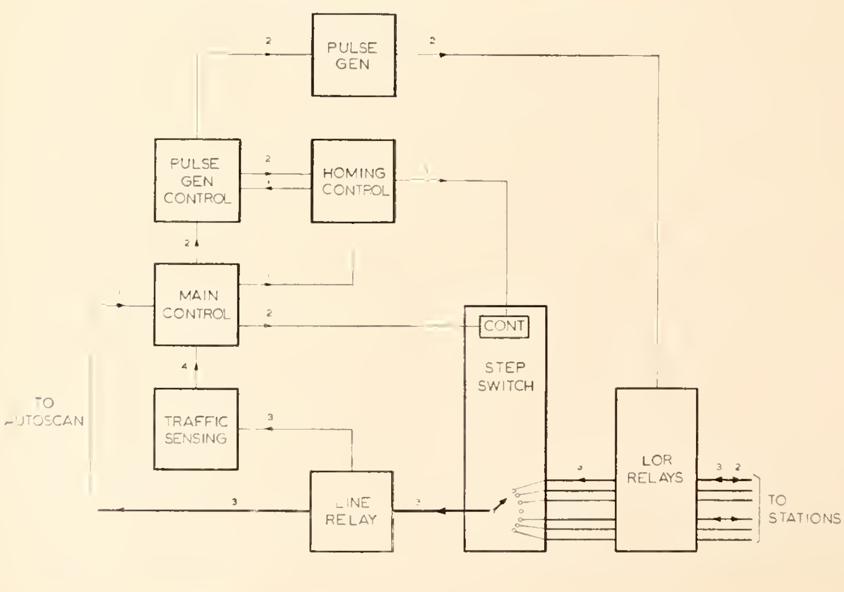
A very useful feature of *Autoscan* is its automatic-manual operation. The name of the operation appears to be contradictory, however this feature permits Autoscan to be manually conditioned at any time to select a station out of the automatic sequence and then automatically revert to automatic sequential scanning when traffic from this station has ceased. The desired station will not be selected by *Autoscan* until traffic, being received at the time the equipment was conditioned to select the desired station, ceases.

In the manual mode of operation, stations are selected by the momentary operation of a station button.

Priority may be given to a station. If the transmission of a particular station is required without delay the equipment is conditioned to select the desired station and the stop button is operated. This operation causes the remote transmitter to be stopped. *Autoscan* then immediately selects the desired station and its transmission is received. This feature is necessary since some station transmissions may be very lengthy.

A special feature required by the Ontario Hydro was a blank character detection circuit. Blank characters are not normally inserted in tapes prepared by the area offices and must not be present in tapes transmitted to the computer centre. The teleprinter is equipped to space on reception of a blank character. This feature is provided so that blank characters can be detected in the monitor copy. In addition the teleprinter is equipped with a set of contacts which

Fig. 2. Block diagram of the Autoscan Concentrator.



close when a blank character is received.

These contacts are wired to the *Autoscan* unit which transmits a stop pulse to the remote transmitter when they operate. The remote transmitter is then stopped and an indicator lamp and audible alarm indicates the situation to the regional office operator who then follows a prescribed procedure. In the meantime, however, the *Autoscan* selects the next station.

Autoscan provides complete indication of the mode of operation and the station being selected or transmitting. Push buttons are employed extensively which have internal illumination for indication purposes. Two types of lamp operation are employed, flashing and steady illumination. The flashing lamp indicates the station which *Autoscan* has been manually conditioned to select, while traffic is being received from a sequentially selected station whose lamp is steadily illuminated. Upon completion of this traffic the lamp of the station is extinguished and the manually selected station lamp then ceases flashing and is steadily illuminated.

Due to the fact that the Area Offices are well dispersed "party-line" operation of stations is not practical. This factor permitted the use of relatively simple control equipment at the area offices and necessitated the development of the *Autoscan* concentrator.

In certain locations it was possible to extend the lines of several area offices to a central point which was equipped with an *Autoscan* concentrator.

A full-duplex telegraph facility connects the *Autoscan* concentrator to the *Autoscan* in the regional office. This results in considerable economy of telegraph facilities for without the *Autoscan* concentrator one telegraph facility per area office would be required between these locations.

Autoscan

Twenty-four stations can be connected to the *Autoscan* Selector equipment either directly or by means of *Autoscan* Concentrators. Provision is made for operation to four *Autoscan* Concentrators.

Autoscan is composed of two main assemblies. A sloping front control panel is situated on top of a cabinet assembly.

Control Panel

Push buttons having internal indicating lamps are used extensively.

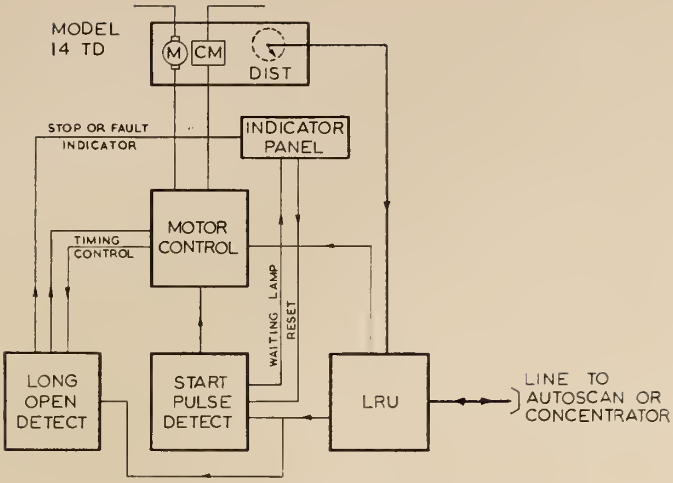


Fig. 3. Block diagram of the Station Equipment.

The following control buttons are provided:

Designation	Indication	Operation
automatic	green	momentary
manual	red	1. momentary — automatic manual 2. lock-in — manual
send stop	blue	momentary
alarm cut-off	white	1. momentary-release audible alarm 2. lock-in-prevent audible alarm
area office	amber	momentary operation

Cabinet Assembly

The circuitry of the *Autoscan* is housed in a cabinet below the control panel. This cabinet has doors on the front and back for accessibility to all parts. Fig. 4 shows the interior of the cabinet as viewed from the front.

For ease of maintenance and production plug-in sub-assemblies are employed extensively. Three shelves in the cabinet mount 13 plug-in units. A four shelf mounts components such as the battery distribution panel, capacitor bank and line resistor bank.

The following sub-assemblies are employed:

1.	Master control unit	MCU
2.	Relay register unit	RRU
3.	Master step switch unit	MSSU
4.	Line relay unit	LRU
5.	Automatic traffic sensing & control unit	ATSCU
6.	Automatic pulse generating unit	APGU
7.	Automatic step rate control unit	ASRCU
8.	Concentrator relay resister unit	CRRU
9.	Concentrator control unit	CCU
10.	Concentrator pulsing unit	CPU
11.	Concentrator control step switch unit	CCSSU
12.	Manual traffic sensing & control unit	MTSCU
13.	Manual pulse generating unit	MPGU
14.	Signal battery pulsing unit	SBPU

Switches are also provided on the control panel to apply a-c. to the rectifiers and teleprinter motors, and for teleprinter selection for on-line use. When one of the two teleprinters provided at the regional office is selected for on-line operation the other is terminated for off-line operation.

The following sub-assemblies are identical: automatic and manual traffice sensing & control units; automatic and manual pulse generating units; signal battery and concentrator pulsing units.

All relays in *Autoscan* are plug-in types. With the exception of the line relays, which are standard type 255A relays, the relay windings have a resistance of 10,000 ohms and are operated by a 7.5 ma current.

Trigger tubes, type 5823, are used for timing circuits. The voltage supply used for their igniter circuits is regulated to ensure stability of operation.

Three standard rectifiers supply power to the *Autoscan* and the two teleprinter machines. One of these rectifiers supplies 120 v. for step switch operation. The other rectifiers supply ± 75 v. to *Autoscan* and also supply power to the teleprinter.

Autoscan Operation

A detailed description of the operation of *Autoscan* circuitry would be very lengthy. This paper will therefore provide a simplified description of the operation.

A block diagram of the circuitry of the *Autoscan* selector is shown in Fig. 1.

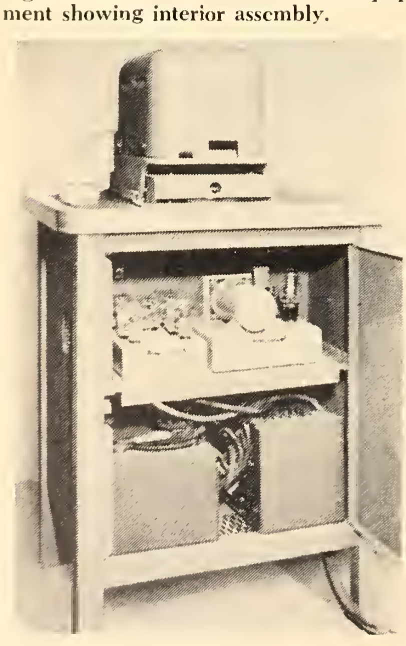
Sequential Scanning

After applying power to the *Autoscan* and teleprinter selected for receiving transmissions from the area offices, the momentary operation of the automatic button on the control panel conditions the *Autoscan* for sequential operation. The mode of operation is indicated by the illumination of this button.

The master step switch (MSS) in the *Autoscan* then commences to scan the lines of the stations connected to it under control of the automatic traffic sensing & control unit (ATSCU).

The lines of the stations are maintained closed when they are in the idle condition. When the MSS steps to a line of a station, the station's push button on the control panel is illuminated. The automatic pulse

Fig. 5. Rear view of area office equipment showing interior assembly.



generator unit (APGU) sends a one second start pulse to the remote station by operating the LTR relay associated with the line in the relay register.

If tape has been placed in the transmitter at the remote station its transmitter control unit (TCU) is conditioned to recognize the start pulse. When it is detected the TCU energizes the motor and clutch magnet of the transmitter and transmission of the tape commences.

The line relay in the *Autoscan* unit repeats the signals received from the station to the teleprinter machine, the ATSCU and also to the automatic step rate control unit (ASRCU).

Master Step Switch Stepping Rates

There are four stepping rates of the MSS.

Five Second Rate

The MSS steps one step every five seconds over closed lines provided that it has not passed its home position twice without receiving traffic.

When the MSS steps to a line a one second start pulse is transmitted. The ATSCU then causes the MSS to step after four seconds of idle line condition.

Two Second Rate

If the MSS steps to a position of an open line the ATSCU steps the MSS to the next line one second after the one second start pulse is transmitted.

Thirty Second Rate

If no traffic is received from stations connected to *Autoscan* for one complete rotation of the MSS from home position to home position the ATSCU is conditioned by the automatic step rate control unit (ASRCU) to step the MSS at thirty second intervals.

However once traffic is received from a station *Autoscan* immediately reverts to its 5 second stepping rate.

Fast Stepping Rate

The MSS steps over unassigned positions at its natural rate under control of its interrupter contacts.

Selection of Concentrated Offices

Autoscan is equipped for operation to four concentrators. The selection of a line to a particular concentrator is accomplished by the concentrator relay register under control of an LTR relay of the relay register which can be operated by either the MSS when sequential scanning of stations is used or by an RR relay of the

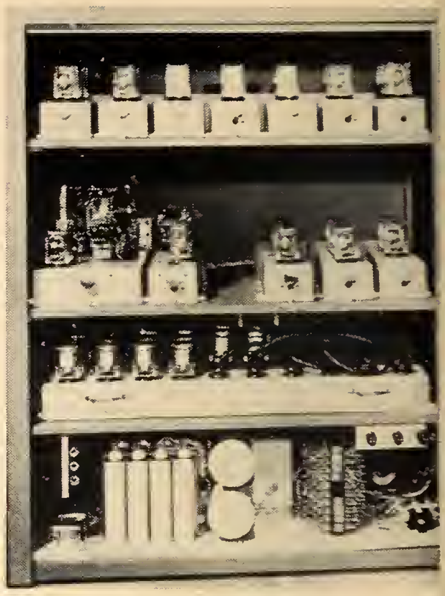


Fig. 4. Autoscan selector: interior assembly.

relay register which is controlled by the station push button when manual station selection is employed.

The LTR Relay of the Relay Register

1. Operates a relay in the concentrator control step switch.
2. Marks the concentrator control step switch.
3. Operates a relay in the concentrator relay register which connects the full-duplex circuit to the concentrator of the office being selected to the transmitting and receiving circuitry of *Autoscan*.

When the concentrator control step switch arrives at its home position a signal is transmitted to the remote concentrator which causes its step switch to be homed.

Pulses from the concentrator pulsing unit step the concentrator control step switch to the position marked by the LTR relay of the relay register. These pulses are also transmitted to the concentrator and they drive the concentrator step switch to the same position as the concentrator control step switch of the *Autoscan* unit.

The lines of the stations connected to the concentrator are connected to the concentrator step switch. When the concentrator step switch comes to rest on a line the pulse generator of the concentrator transmits a start pulse to the station.

After a period as described in "Master Step Switch Stepping Rates" the master step switch steps to the next position.

Automatic-Manual Station Selection

When *Autoscan* is in the automatic

mode of operation provision is made to condition *Autoscan* to select a desired station out of sequence. This is called automatic-manual selection.

To condition the equipment to select a station out of automatic sequence the manual button is momentarily operated. This operation causes the master control unit to apply pulsing signal battery to the manual button lamp, and extinguish the automatic button lamp.

The desired station's button is then momentarily operated. This causes the RR relay associated with the station button, in the relay register to operate. This relay applies the pulsing signal battery to the lamp of the station button.

When the ATSCU detects that traffic, being received while the above operations were performed, has ceased, it causes the master control unit to transfer control to the manual traffic sensing & control unit and the manual pulse generator unit.

In the case of directly connected station circuits the MCU also applies battery to the LTR relay of the relay register which transfers the station line from the MSS to the manual line relay via the manual pulse generator unit. Contacts of the MPGU transmit the one second start pulse to the remote station.

If the station selected manually is a concentrated station the LTR relay performs the functions outlined in the description "Selection of Concentrated Offices" however the receive line of the full-duplex circuit to the concentrator is transferred from the MSS to the manual line relay by the operation of a relay in the concentrator relay register.

The indicator lamp of the manually selected station ceases flashing when the station is selected and is steadily illuminated.

When traffic from this station is completed the MTSCU causes the MCU to revert the system to sequential station selection commencing with the station that would have been selected if the sequential pattern had not been interrupted. The manual button lamp is extinguished and the automatic button lamp is illuminated indicating the change.

Manual Station Selection

When fully manual station selection is desired the manual button is pushed and locked in this state by turning it. This prevents the MTSCU from restoring the system to its automatic mode of operation.

Upon completion of current traffic the system will be conditioned for manual selection of offices.

This mode of operation permits the selection of a single station at one time.

Stop Feature

Traffic received from individual offices on a data circuit can be quite lengthy. If an error is detected in the transmission from a station which would necessitate the tape to be corrected and retransmitted the regional office operator can stop the remote transmitter by the operation of the stop button. This can save considerable time. The *Autoscan* will then select the next station in the sequence.

If an operator wishes to give immediate priority to a station, the station is manually selected and the stop button is operated which causes the remote transmitter to be stopped and the transmission of the desired station will commence without delay.

The operation of the stop button causes either the manual or automatic pulse generators to transmit a one second stop pulse to the transmitting station. Upon detection of this pulse the transmitter control unit at the station causes the motor of the transmitter to be stopped and an indicator lamp is illuminated.

The tape is then corrected, if necessary, and replaced in the transmitter. The operation of the Reset button reconditions the transmitter control unit to detect a start pulse. A waiting lamp indicates that the TCU is thus conditioned.

Autoscan Concentrator

The *Autoscan* concentrator consists essentially of eight control circuits as are indicated in Fig. 2.

The step switch is always homed prior to station selection to ensure that it is in step with the concentrator control step switch of the *Autoscan* unit.

It is driven by the pulses generated by the concentrator pulsing unit of the *Autoscan* unit.

When it comes to rest on a line position the pulse generator of the concentrator transmits a start pulse to remote station.

The traffic sensing unit of the concentrator prevents the stepping of the step switch during transmission from a station.

If a stop pulse is received from the control office the pulse generator of the concentrator transmits a one second stop pulse to the transmitting station causing its transmitter to be stopped. The step switch will not step however since it is disabled by the traffic sensing circuit.

If the circuit between the control station and the concentrator is lost during transmission the transmitting station is stopped in the same manner.

Station Equipment

Each station is equipped with a model 14 transmitter-distributor which is mounted on a table. On shelves in this table are mounted a line relay unit, a transmitter control unit, and rectifiers. The equipment arrangement is illustrated in Fig. 5. Fig. 3 is a block diagram of the circuitry.

In the idle state loop current is maintained. Power is applied to the transmitter control unit (TCU) when tape is placed in the transmitter via its tape sensing pin. The waiting lamp on the table is then illuminated indicating that the circuitry is conditioned to detect a start pulse.

The TCU detects various open circuit conditions. In the idle state a pulse less than 0.75 seconds has no effect, however, a pulse of 0.75 to 1.25 seconds causes the TCU to start the motor of the transmitter and after a slight delay operate its clutch magnet. The tape is then transmitted to the control station.

Prior to transmission, a pulse longer than 1.25 seconds causes a fault lamp to be operated. Transmission will not take place if this occurs. A reset button is provided which when operated restores the TCU to its waiting condition. If the line is open the fault lamp will again be illuminated. The operator must then follow prescribed procedures to have the condition rectified.

During transmission the TCU will detect an open circuit condition which exceeds 0.75 seconds. When this occurs the transmitter is stopped and the fault lamp is illuminated. If this condition is caused by the reception of a stop pulse the operation of the reset button will restore the TCU to its waiting condition which is indicated by the waiting lamp.

If the transmitter has been stopped due to the reception of a stop pulse it may be due to either the control station detecting errors in the tape or due to the control station giving priority to another station. Operational procedures are necessary to clarify the situation.

Comments

The *Autoscan* system was designed

A LARGE CAPACITY OXYGEN PLANT FOR COPPER REFINING

J. T. Hugill, M.E.I.C., *Manager, Field operations*
Engineering and Construction Division
L'Air Liquide, Montreal, Que.

This paper describes in detail the largest tonnage oxygen plant in the British Commonwealth, a 330 ton per day unit built for the INTERNATIONAL NICKEL COMPANY OF CANADA, at Copper Cliff, Ontario. The reasons for erecting a unit of this size are considered briefly. Factors governing the design of the equipment and the choice of a cycle for the low temperature process are discussed at length, also the importance of low power consumption and long continuous operation. The process is discussed completely with respect to operating temperatures and product analyses. An engineering flow sheet is included. Mention is made of some of the design difficulties and the solutions adopted. Operating problems, techniques and plant control are covered. The paper is illustrated with photographs of the unit and some of the pieces of equipment which comprise a tonnage oxygen plant.

THE AUTOGENOUS flash smelting of sulphide ore has been considered in much detail for the past sixty years. As early as 1897 Bridgeman proposed a reverberatory furnace in which the sulphide ore would be smelted using the heat generated from the combustion of the ore itself[1]. It had been proposed by Norman[2] and others that oxygen could be used for autogenous flash smelting of copper and copper nickel concentrates and in 1945 the International Nickel Co. of Canada started miniplant tests. The success of these tests, the fact that low cost tonnage oxygen plants were now a commercial possibility and the good prospects for marketing sulphur, led Inco to start pilot plant tests using oxygen at 95-99% from a small 5-ton per day oxygen plant. The pilot plant was operated for two years and confirmed the economies of the oxygen flash smelting process[3]. From the pilot plant studies Inco developed the basic specifications for the oxygen plant which were a minimum capacity of 300 tons per day of pure oxygen delivered at a minimum purity of 95% and at a pressure of 25 per sq. in. gal. The overall power consumption was not to exceed 370 Kw./ton, excluding oxygen compression, and the plant must be able to run continuously for at least 12 months.

Oxygen Plant

At the time that INCO decided to go ahead on full scale operations there was only one tonnage oxygen plant in operation with a capacity equal to their requirements and two plants of larger size were under construction. Several plants had been built in Europe prior to and during World War II but all were under 100 tons day capacity, few produced oxygen at 95% purity and none ran continuously for periods longer than 8 months. The power consumption figures on existing plants indicated a wide variation, with no clearly defined basis for the figures.

Low power consumption was the major factor affecting the process design. Fortunately a plant of about one third the capacity of Inco's was being built by Air Liquide for the Dutch State Mines in Holland, which also had to meet this requirement and it was decided to use a somewhat similar process for the low temperature equipment on the Inco plant. However in scaling up the plant by a factor of three, many design problems occurred which necessitated some new approaches and resulted in what were, at that time, some radical solutions. Another factor which affected design was the decision to use as much automatic and remote control operation as possible to reduce manpower requirements. Up to this time all air separation plants, large and small, were entirely hand operated with the exception of the regenerator reversing valves.

Description of Cycle

A great deal has been published over the past ten years on tonnage oxygen plants, their advantages, basic principles of operation and the use of the *Frankl* regenerator in low temperature separations. The process design adopted for the Inco plant has some unique features which are not present in any other tonnage oxygen plant at present in operation and some pieces of equipment whose successful operation led to their continued use in more than a dozen tonnage plants built since.

The simplified flow sheet of this plant operating on the Oxyton cycle is shown in Fig. 1. In view of the previously published detail it is proposed to confine the description to those parts of the plant which are of process interest and were new developments in low temperature separation. The rest of the cycle will be dealt with only insofar as it forms part of the overall plant.

The plant consists of five main groups; the air compression and purification group, the regenerator section consisting of a pair of nitrogen regenerators and a pair of oxygen regenerators, an auxiliary circuit, the distillation columns with associated coolers and the expansion turbines.

The total air requirements for the plant are drawn into the air intake located at the top of the building and an air filter, and compressed in a two-stage Ingersol Rand centrifugal compressor. (Fig. 2). The compressor is driven by a 6000 hp. Synchronous Motor through a speed increasing gear. The air is cooled in a water wash tower. Due to the frequent high SO_2 concentration in the air around the plant two towers were provided on the original design in case of excessive corrosion developing. This has not proved to be a problem so the second tower has become a large separator. A shell and tube aftercooler is also provided in parallel and can be used during initial start-up and during defrosting operations when it is desirable to have a lower moisture content in the air.

The air, now at a pressure of 70 lb.

per sq. in. gal., is divided into two streams, 94% of the volume going to the regenerators and 6% to the booster compressor. The smaller portion of air, termed the auxiliary cycle, is further compressed to 160 lb. per sq. in. gal., scrubbed with 10% caustic solution to remove CO_2, dried in a desiccation battery and admitted to one of a pair of reversing warm exchangers. This stream is cooled to -105° F. by flowing counter current to a stream of waste nitrogen, passed through a final desiccation over silica gel and liquefied in a second exchanger. This exchanger or liquefier serves also as the reheater for the stream of high pressure nitrogen used in the turbo expanders. The liquefied air is flashed to the high pressure distillation column.

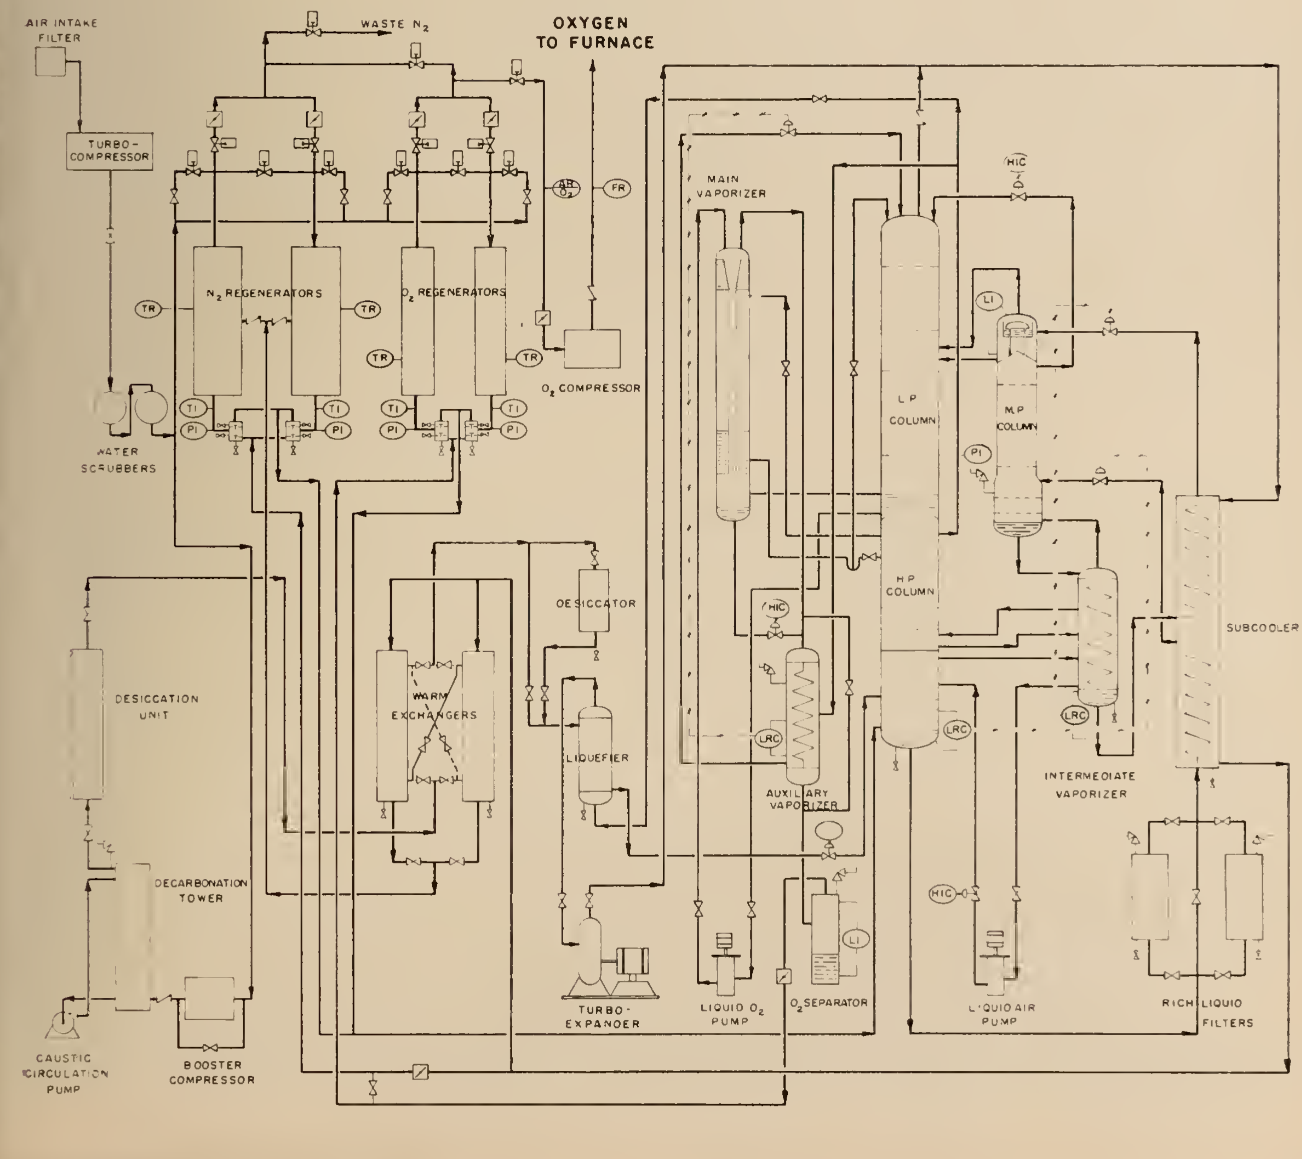
Regenerators

While the regenerators have been discussed previously, some new details of construction should be mentioned. In order to meet the A.S.M.E. Code for low temperature operation, carbon steel could not be used. There remained stainless steel or the new 8% nickel steel developed by Inco for this application. Based on economic reasons the latter material was chosen. Due to the size, fabrication of the 9 ft. diameter aluminum pancakes for the nitrogen regenerators presented some problems and special procedures were used to fasten the successive windings of crimped ribbon. In designing the spacers between pancakes consideration had to be given to the effect of one pancake piled on top of another and the whole subject to flexure on the outer edge due to the reversal of flow and the tendency to droop under their own weight. If not carefully installed the outer winding would tear off at an ever increasing rate and eventually no upper pancakes would be left. A specially shaped hold-down spider is placed on top of the last pancake. It is tightened by jack screws in the dome of the regenerator. These jack screws have to be tightened at successive intervals during the first few months of operation.

The main stream is cooled by direct contact with the precooled aluminum packing in one nitrogen and one oxygen regenerator—at the same time the packing in the other pair is being cooled by the separated products. The streams are reversed on a predetermined time cycle, the reversing double port valves being operated by solenoid controlled air operators actuated through the automatic cycle timer. In order to keep the oxygen purity steady there is a short purge period at each reversal when the product stream from the oxygen regenerators is blown to atmosphere.

The reversing valves on the top of the regenerators which can be

Fig. 1. Flow sheet of 300 ton/day Oxyton.



seen in Fig. 3 are standard double port design with a pressure drop of less than 10 in. water. Like the rest of the plant the size requirements put them in a special class. The low pressure nitrogen valves are 36 in. in size and each valve weighs over a ton. Special neoprene sealing rings had to be installed on the seating surfaces to withstand the wear caused by opening and closing every 3 minutes and at the same time provide absolutely tight shut-off. After the initial problems with seats and sealing ring they have completed over 2 million cycles without serious trouble.

During its passage down the regenerators the moisture and carbon dioxide are deposited on the pancakes and the air leaves the regenerator dry and CO_2-free at a temperature of -270°F. A system of check valves controls the flow of the high and low pressure streams. These check valves had to be especially designed for a very low pressure drop and at the same time be able to stand rapid opening and closing every three minutes. They are of cast stainless construction with specially treated high alloy springs. Part of the check valve assembly for the nitrogen regenerators is shown in Fig. 4.

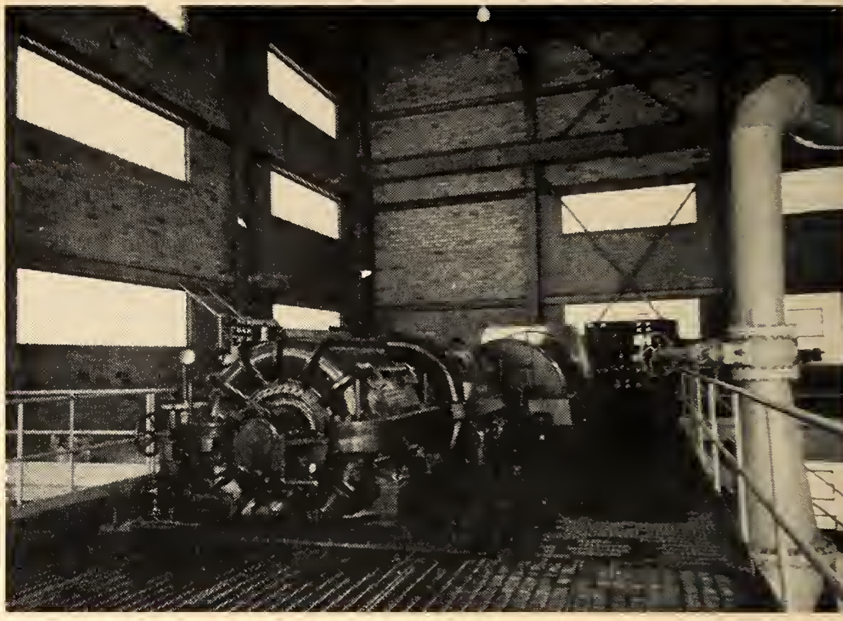


Fig. 2. Air turbo blower.

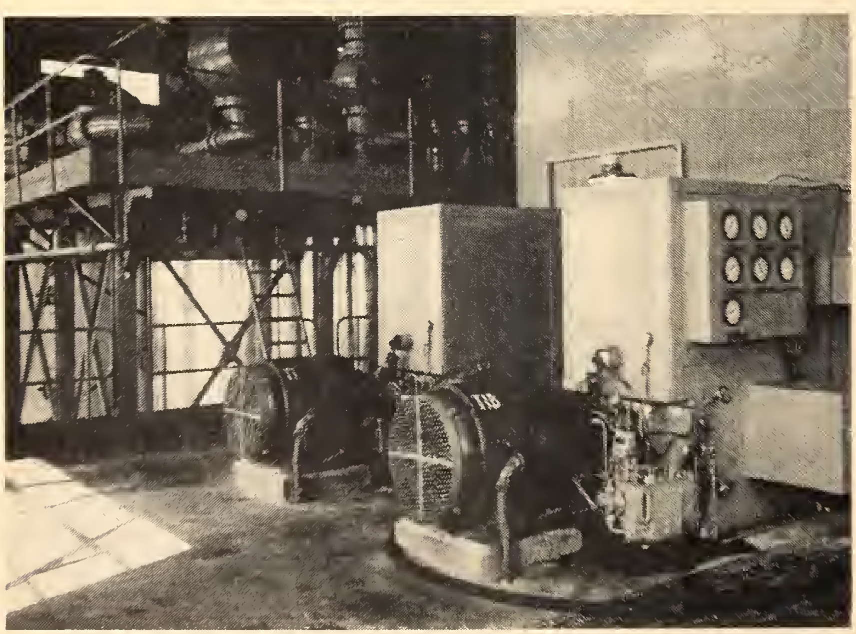
Distillation Column

The cold dry air from the regenerators and the liquid air from the liquefier provides the feed for the distillation column. The distillation section consisting of three columns, two vaporizers and a subcooler is the most interesting. It is this section which differs in many aspects from the conventional air separation plant. It has been shown[4] that for each mol of pure nitrogen removed in the column overhead, the minimum reflux ratio at the feed plate must be 0.91 mols. This reflux is produced in the main vaporizer or overhead condenser at -290°F at a pressure of 68 lb. per sq. in. gal. One method of reducing the power consumption necessary for air separation is to make the process less irreversible. This can be done if another condenser is provided operating at a higher temperature of -286°F. At this level the minimum reflux ratio is 0.715 mols and hence there is a saving of 0.195 mols on the amount of nitrogen which must be condensed by the overhead condenser. The energy thus saved is used in the second or medium pressure column to produce a further separation. A larger volume of nitrogen is then available for the turbo expanders to produce the required refrigeration.

Fig. 3. Regenerators and turbo expanders.



An examination of the flow sheet is necessary to follow the operation of the distillation columns and how they are inter-related. As stated above, the feed to the high pressure (hp.) column enters at 68 lb. per sq. in. gal. with 94% in the vapor state near its dew point, and the balance as liquid air. A separation takes place into pure nitrogen at the top and a bottoms product called rich liquid containing about 37% oxygen. The nitrogen is condensed in the main vaporizer and part of this condensed nitrogen is withdrawn to provide reflux for the low pressure column. The bottoms liquid is withdrawn, passed through one of a pair of silica gel filters, subcooled by the gaseous nitrogen product and flashed to the medium pressure (m.p.) column at 30 lb. per sq. in. gal. Here a further separation is made to give another pure nitrogen stream and a bottoms containing 55% oxygen. The m.p. column bottoms flow down through the tubes of the intermediate vaporizer at a temperature of -294°F and thereby condensing a part of the vapor stream from an intermediate tray in the hp. column. The intermediate vaporizer acts as a condenser for the lower portion of the hp. column and simultaneously a reboiler for the m.p. column—the 4° temperature difference being available from the differences of operating pressure and the differences in composition. The intermediate vaporizer works in a similar fashion to the overhead condenser of the hp. column (termed the main vaporizer) which is also the reboiler for the low pressure column. The m.p. column bottoms product, after subcooling, is flashed to 5 lb. per sq. in. gal. into the overhead condenser. This liquid, boiling around the tubes, provides the refrigeration to condense the reflux nitrogen inside the tubes by exchange of latent heat. Some of the condensed nitrogen is flashed to the top of the low pressure column for reflux. The liquid not vaporized, and the vapor, enter as feed to the middle section of the low pressure column. In the low pressure column the final separation of the oxygen product occurs.

Fig. 4. Regenerator check valve assembly.

The design and construction of the main vaporizer and the intermediate vaporizer presented the biggest problems in the low temperature section of this plant. In conventional air separation units, and in fact all units up to this time, the main vaporizer (or condenser-reboiler) was located between the two columns, serving as the top of one and the bottom of the other. The intermediate vaporizer could be installed between the 6th and 7th trays in the high pressure column with the tubes open at each end providing the connecting liquid and gas passages. With a unit of 300 tons/day size, handling 30,000 scfm of air, it is almost impossible to use a conventional design. Because of the small (5.5°F.) temperature difference between oxygen boiling at 5 lb. per sq. in. gal. and nitrogen condensing at 65 lb. per sq. in. gal., the depth of the liquid oxygen bath is limited to about 4 ft. To provide the surface necessary, the diameter of the tube sheet would have to be so large that fabrication would be difficult and its installation between the columns would be a major problem. This same situation exists to a lesser degree with the intermediate vaporizer. The problem was solved by redesigning the main vaporizer completely, making it a falling film type. By pumping the liquid oxygen from a sump in the bottom of the low pressure column, the vaporizer could be erected alongside the high and low pressure columns. These columns could then be mounted one on top of the other. In the case of the intermediate vaporizer the condensed liquid air is pumped from the bottom of the shell side back to the hp. column. The pumps used for this purpose are standard vertical centrifugal pumps with specially designed packing, a 40 in. shaft and a totally enclosed impeller. Pumping liquid oxygen or liquid air at temperatures of -280° to -300° F. near the boiling point, presented some difficulties. Quite a few headaches were experienced before satisfactory packings and bushings were developed.

Fig. 5. MP column overhead condenser tube nest.

The medium pressure column condenser is about the maximum size which can be fabricated on the conventional design. It contains over 12,000 ½ in. tubes with a 5 ft. diameter tube sheet. Fig. 5 shows the tube bundle of this condenser during construction, indicating clearly the magnitude of the tubing operation. Compared with the tube bundle of the main vaporizer shown in Figure 6 on a newer design principle and with approximately 2½ times the duty, it will be seen that there is a big difference in the number of tubes and the diameter and thickness of the tube sheet.

For safety considerations an additional vaporizer is added below the main vaporizer, through which most of the oxygen product is withdrawn as a liquid. It is vaporized against condensing nitrogen and combined with the gaseous portion withdrawn from the main vaporizer, goes through a separator and out of the plant via the oxygen regenerators. A slight excess of liquid oxygen is sent through the auxiliary vaporizer so that liquid oxygen washes down to the bottom of the tubes and into the separator. This liquid is purged at frequent intervals, depending on the concentration of impurities in the oxygen. The condensed nitrogen is flashed to the low pressure column as reflux, the flow being controlled by automatic liquid level control. The main features which result in safer operation using the film type recirculation vaporizer and an auxiliary vaporizer have been very thoroughly covered in previous papers[5]. It is interesting to note however that at the time this design was conceived and the plant was constructed, the industry as a whole was not entirely aware of the extreme importance of this phase of oxygen plant operations.

The gaseous oxygen product leaves the oxygen regenerators via the automatic valves and flows directly to the suction of the oxygen turbo blower. This machine incorporates special features for oxygen service such as stainless steel rotor, special seal labyrinths and fully automatic control. The oxygen is compressed to 25 lb. per sq. in. gal. and is carried by a 6000 ft. steam traced pipeline to the copper furnace.

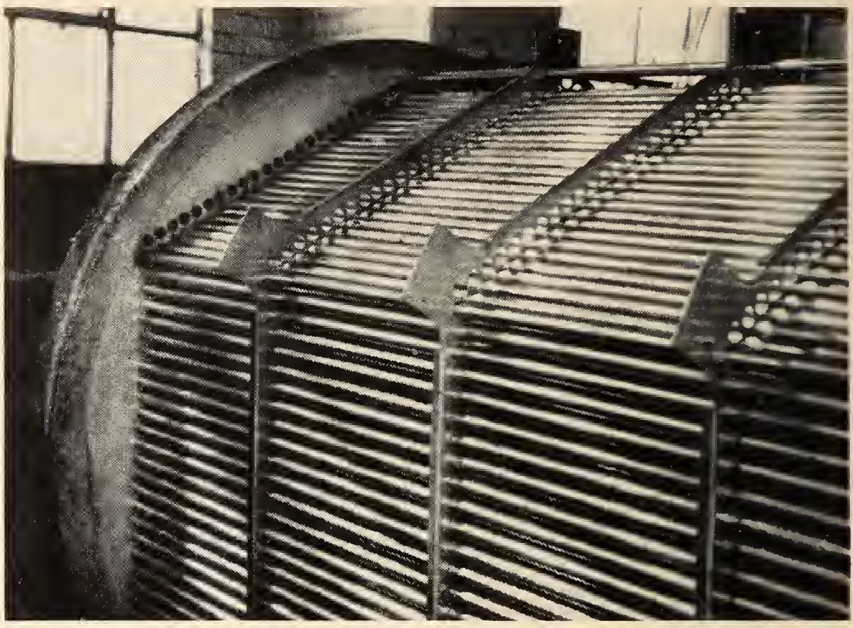


Fig. 6. Main vaporizer tube nest.

Fig. 7. Main control panel.

Like all chemical plants where heat is involved in the process, air separation plants have heat losses. It is perhaps peculiar at first glance to discuss heat losses for a process operating at or near -300° but B.t.u.'s are B.t.u.'s whatever the level. To avoid some confusion, the term refrigeration is normally used. The losses of heat or refrigeration are divided more or less equally into those due to warm end temperature differences and those due to radiation. Careful design of the heat exchange equipment can reduce the warm end losses. Oxytons normally operate with a 5°F. temperature difference between air feed in, and separated products out. By very close grouping of the various vessels and piping and enclosing the whole plant in a sheet metal box and packing this box with specially fabricated mineral wool, it is possible to keep the radiation losses to a minimum.

To compensate for these losses all low temperature separation plants must have a source of refrigeration supply. In some smaller air plants this can be provided from the Joule Thompson effect by expanding cooled air from a very high pressure of 3000 lb. per sq. in. gal. to a final low pressure of 70 lb. per sq. in. gal. The main feature of the Oxyton, namely low power consumption per ton of oxygen produced, would be defeated if the air had to be compressed to any pressure higher than absolutely necessary to carry out the separation. While Joule Thompson refrigeration is used to a small extent by expanding the various liquid streams from a higher to a lower pressure, it represents only a fraction of the refrigeration necessary. The considerations governing Joule Thompson effect refrigeration and refrigeration from an expansion engine or turbine have been covered in some detail in a previous paper[6].

The main source of refrigeration in this plant is provided by expanding nitrogen, removed from the top of the high pressure column, in an axial flow turbo expander. This nitrogen stream, reduced in pressure from 65 lb. per sq. in. gal. to 3 lb. per sq. in. gal., joins the low pressure column overhead and leaves the plant via the sub-coolers and nitrogen regenerators. Two expanders are installed, permitting rapid cooling of the plant during start up by using both in parallel and providing a spare machine during normal operation. They have a single wheel and run at a speed of 10,000 r.p.m. The energy produced in normal operation is 130 kw. and is absorbed by driving a wound rotor motor as a generator. The power recovered is sufficient to drive all the auxiliaries, namely soda pump, cooling water pumps, water circulation pumps and plant lighting. The volume required by the turbo expander varies from 26-28% of the total air feed. This variation depends on the atmospheric temperature, rich liquid filter reactivation, cold desiccator reactivation and the existing pressure drop across of the regenerators due to accumulation of CO_2 and water. Control of the volume through the expander is achieved by changing the number of operating nozzles in the nozzle ring. The adiabatic efficiency is 72%.

Mention has been made of radiation losses and insulation requirements. As radiation is a function of surface area, the casing for the low temperature equipment — termed a cold box — must be of minimum size. Connecting piping and vessel location must be very carefully studied in order to achieve this. The casing consists of a structural steel framework on which are fastened light gage metal panels. The edges of the panel are gasketed and sealed to prevent any air or moisture leak inward. The whole inside of the box is filled with mineral wool packed to a controlled density of 15 lb. per cu. ft. In addition to the mineral wool insulation some of the vessels, in which the operating temperature approach that of the condensation point of air, are individually insulated with 3 in. of foam glass applied direct on the vessel. An exception to the totally enclosed cold box method of insulation is the insulation provided for the regenerators. In this case each vessel is separately insulated with three layers of Zerolite blocks, each layer being 4″ thick and covered with a vapor seal. A thin aluminum sheet is wrapped around the outside to protect the block from damage and preserve the vapor barrier.

Except during initial start-up when the main air compressor is on manual, the plant can be entirely operated from the control panel. All valves used in normal operation are air operated and automatic liquid level and automatic analysis control is used whenever possible. The control panel is shown in Fig. 7. The necessary gas analysis, performed by the operator to check the analyzers, is carried out in front of the control panel so that he does not need to leave the area. A small laboratory is provided adjacent to the control area where routine tests are made.

Considerable care was taken in choosing a location for the plant with reference to smoke and fume concentrations from the Inco refinery. The site chosen is more than a mile away, on the prevailing upwind side of the main plant. Careful acetylene anaylsis of the liquid oxygen in the separator is carried out by the operator and regular checks are made by the control laboratory on the liquid oxygen and the rich liquid. The plant location is such that the Oxyton received the cleanest air possible, however impurities control is not relaxed.

The test runs on this plant, proved that it has an average capacity of 330 tons/day with an average power consumption of 350 kwh./ton. The unit has run for as long as 2½ years without a major defrosting (deriming). The shut-down periods, of necessity, have to be tied to the flash furnace operation and with one exception are every 15 to 18 months. Two operators per shift can run the plant very easily and handle all normal shut-downs and start-ups. When power failure shut-downs occur the plant can be restarted and on stream in less than 2 hours.

It had been predicted many years ago that large capacity air separation plants would eventually be utilized in the chemical and metallurgical industry. With the successful *on stream* operation of the Oxyton at Copper Cliff, on a somewhat larger scale than had been hitherto attempted, this prediction has come true. The whole process of oxygen plant, copper flash smelting furnace and liquid sulphur dioxide plant represents a big advance in technology in the metallurgical industry, each part being a necessary requirement for the proper development of the others.

HEADQUARTERS COMPUTATION CENTRE FOR THE H.E.P.C. OF ONTARIO

(continued from page 59)

to meet the Ontario Hydro's requirement for a system to collect data from area offices automatically on a sequential basis.

The automatic-manual and manual modes of selection provide considerable flexibility in operation. The ability to condition the equipment to change its mode of operation without interferring with current traffic results in a saving of operator's time.

Dependability is ensured by the independance of manual and automatic circuitry. In addition the use of plug-in components and plug-in sub-assemblies enables service to be quickly restored in the event of a component failure.

The stop feature enables priority to be given to a station and also permits an operator to stop a station sending incorrect tapes or tapes containing errors thus reducing the waste of machine time. No provision was made to indicate to the remote station the reason for the stopping of the transmitter since the HEPC has an order phone circuit. However, it would be possible to provide indications to show that the station was stopped due to the control station giving priority to another station, or due to detecting incorrect tapes or tapes containing errors.

Design and Erection Features of the Vertical Lift Bridges for the St. Lawrence Seaway Authority

W. G. H. Holt, *M.E.I.C., General Manager, Mechanical Division*
Dominion Bridge Company Limited, Montreal, Que.

THERE ARE twelve crossings of the new St. Lawrence Seaway; five are vertical lift bridges, three are high level highway bridges, two are rolling bascule bridges, and two are bob-tail swing spans. This paper deals with the vertical lift spans only and these may be located on the map shown. The names of the sites working upstream from the Montreal harbour to Lake St. Francis are: Lower St. Lambert, Upper St. Lambert, Caughnawaga, St. Louis and Valleyfield. These lift spans were all constructed in or close by existing bridges over either the St. Lawrence River or the Beauharnois Canal.

Early in 1955, after having decided upon the general types of bridges for the different crossings, The St. Lawrence Seaway Authority requested assistance from the Dominion Bridge Company to design vertical lift bridges for the C.P.R. crossing of the new canal at Caughnawaga, such technical assistance to include an investigation and report on the relative merits of different operating mechanisms. These services were subsequently extended to include the design of the two crossings of the St. Lambert Lock and to assist in the design of the operating machinery for the St. Louis and Valleyfield crossings of the Beauharnois Canal. The structural design of the last named bridges, as well as the electrical design of all bridges, was carried out by Authority engineers.

As it had been nearly twenty-five years since a major lift bridge had been built in Canada, it was decided that it would be wise to visit similar bridges both in this country and the United States before starting any detail design work. Representatives of the Authority, the Canadian Pacific Railway and the designers participated in this study. First, several lift bridges on the Welland Canal were inspected, mainly to learn what difficulties had arisen in operation and maintenance, since they were built twenty-five years previously. Secondly, several lift bridges in the vicinity of New York City were inspected to investigate the merits of a recent type of lifting machinery. Finally a trip was made to Cleveland where some of the most recently designed bridges were still under construction.

The first major decision which had to be made was whether "Span-Drive" or "Tower-Drive" type of lifting machinery should be used.

With "Span-Drive", the operating machinery is located in a house, mounted on the movable span, and the span is raised or lowered by means of uphaul and downhaul ropes, anchored respectively to the top and the bottom of the tower legs. Any out-of-level of the four corners of the span may be easily corrected by adjustment of the uphaul and downhaul ropes through simple worm take-up devices. This system, which had been used for some fifty years, had proven entirely satisfactory on the vertical lift bridges of the Welland Canal.

The "Tower-Drive" was first developed some twenty years ago in the United States. In this system, the drive machinery is mounted on the tower tops and is coupled through gearing to the counter-weight sheaves. The span is raised or lowered by rotating the counterweight sheaves, so there are no uphaul and downhaul ropes. Originally the problem of maintaining uniform levels at the four corners of the span presented serious difficulties because it was difficult to machine the four counterweight sheaves the same diameter. Also the level was entirely dependent upon the friction between the counterweight ropes and sheaves. Subsequently, to overcome these difficulties special electrical circuits were developed. For a-c wound rotor drive motors, synchronizing control was provided; and for Ward Leonard drives, various forms of speed regulating equipment were provided. After a great deal of investigation, it was decided to adopt the "Span-Drive" type as the cost was lower for bridges of the length required for the Seaway.

One of the troublesome things

about the existing "Span-Drive" bridges was the operating ropes running horizontally from sheaves at the four corners of the span to drums at the centre. Because the ropes could not run through all the posts and diagonals of the trusses, the machinery house had to be placed on top of the span which is very unsightly. Also these ropes tended to drip lubricant on the top chords. To overcome these drawbacks, the drums were placed near the four corners of the span and driven through bevel gearing by a line shaft located down the middle of the span from a central machinery house below the top chords. The line shaft took the place of the horizontal ropes.

The deliberations above did not concern the Upper and Lower St. Lambert bridges for the Canadian National Railways as these bridges had a much shorter span. They only cross the 80 ft. width of the St. Lambert lock while the other three cross the 250 ft. and 200 ft. widths of the canal reaches. The Canadian National Railways' experience with their lift bridges over the Lachine canal had been very satisfactory since they were built fifteen years ago so they decided to use a similar design. In this case, the drive machinery is at the centre of a trussed bridge between the tops of the towers and the span is operated by uphaul and downhaul ropes running over sheaves to anchor points on the span and counterweights respectively. This design also readily lent itself to twinning the lock at a future date.

At this stage, the designs, drawings and specifications for the respective bridges were started and the following sections describe the various parts in detail.

STRUCTURAL

One of the peculiarities of these five lift bridges was that there were four entirely different arrangements of railway tracks and roadways. Only two bridges are alike in this respect. The various arrangements may be seen in the accompanying cross-sections of the bridges.

Lower and Upper St. Lambert Bridges

Two lift bridges were built at the St. Lambert lock in order to avoid interruption of rail and road traffic and to reduce to a minimum interference with Seaway traffic. The lower bridge replaced the south end span of the Victoria bridge and crosses the canal at an angle of 76° 32′ at a point adjacent to the downstream lock gates. The upper bridge crosses the canal at right angles at a point near the upstream lock gates and functions as a by-pass route. Rail and road traffic will normally travel over the lower bridge but when it is raised, the traffic will be by-passed over the upper bridge.

Both bridges are designed so that an additional lift bridge can be added, if a twin lock is ever built.

The cross-section of the lower bridge was governed by the existing format of the Victoria Bridge which consists of double tracks on 13 ft. centres flanked by two 16 ft. roadways cantilevered outside the trusses, all on a .77% grade going down to St. Lambert. The bridge structure was also designed so that the railway grade could be raised in the future, if and when, Victoria bridge is rebuilt. The base of rail would then be nearly 9 ft. higher than it is at present, and the new grade would be .19%. The roadways of the rebuilt bridge would probably cross the canal above the navigation clearance line, so provision has been made in the design for the future removal of the roadways from the lift span with a corresponding modification of the counterweights. The spans of the lower bridge are of the deck plate girder type 107 ft. 7 in. long.

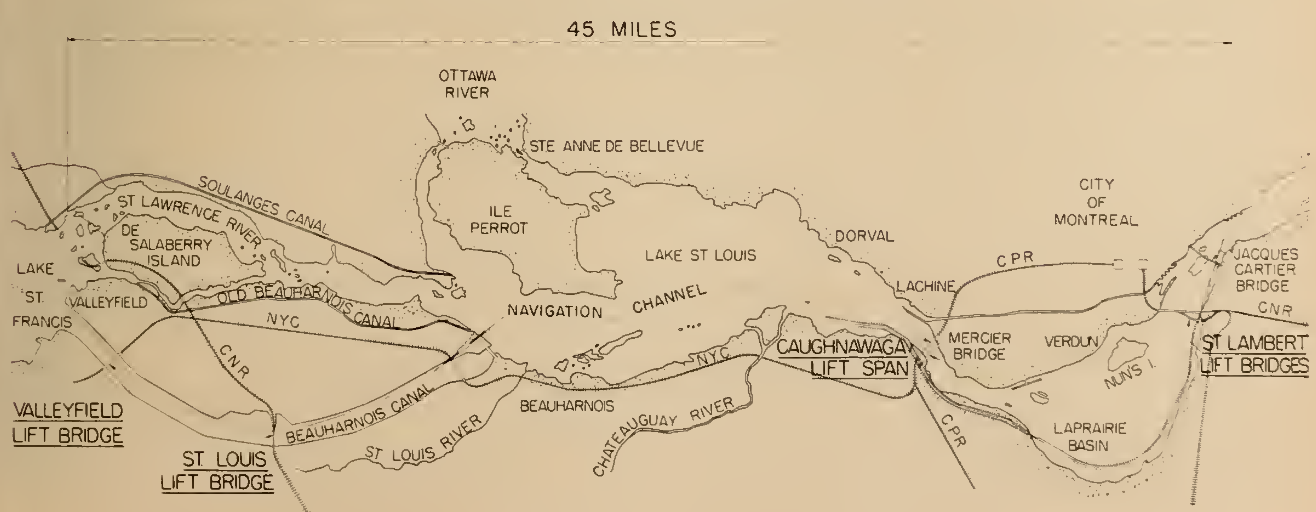
The upper bridge, although it will carry the same traffic is quite different in cross-section. It carries the double tracks on a level grade twenty feet above the roadways. The lift span is therefore a double deck trussed structure 31 ft. 6 in. centre to centre of trusses and 96 ft. long. The two tracks are on 13 ft. centres, laid on a steel deck supported by cross beams. The roadway portion consists of four separate 12 ft. lanes, two inside the trusses, and two cantilevered outside.

Both lift spans have portal girders supported and braced by "A" frames. The counterweight and uphaul operating ropes are attached to the portal girders. They are also arranged to carry future trolley wire systems in case the railway is electrified.

The structures are designed in accordance with the C.S.A. Railway Bridges Specification S1-1950 and the C.S.A. Highway Bridges Specification S6-1952. The railway live loading is Cooper's E60 for both bridges. The roadways of the lower bridge are designed for one 13½ ton truck per lane plus 30% impact. This loading represents the maximum capacity of the existing Victoria bridge roadways. The upper bridge roadways are designed for one H2O-S16.1952 truck per lane plus 30% impact.

The pier members for both bridges are of the dished disc type. The bearing surface of that portion of the pier member assembly that is at-

Fig. 1. Sites of the five vertical lift bridges.



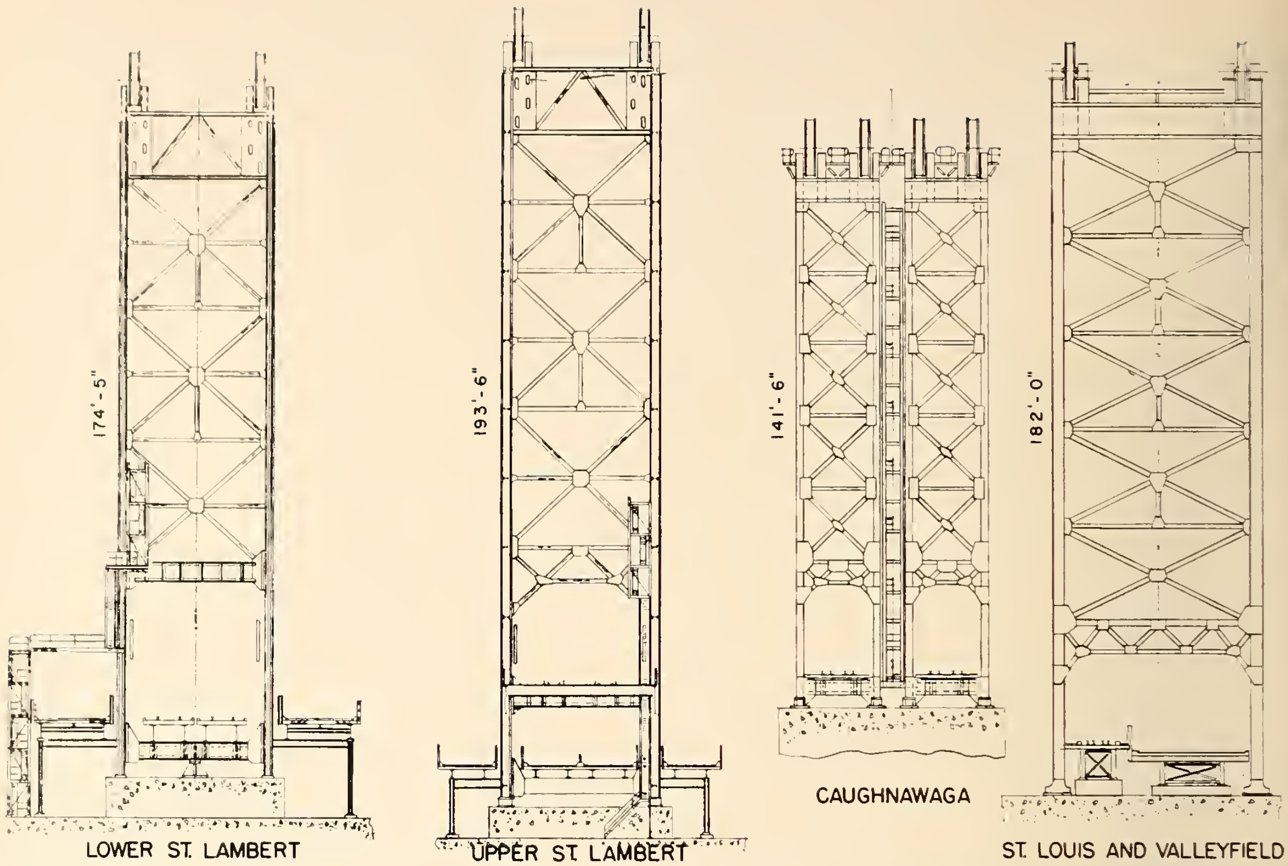


Fig. 2. Cross Sections of the bridges showing the various arrangements of railway tracks and roadways to suit existing bridges. Dimensions shown are from bottom of tower leg to centreline of counterweight sheave.

tached to the lift span consists of a hard bronze plate that can slide on the pedestal part of the assembly which is bolted to the foundation concrete. Although the pier members normally carry live loads only, they are also designed to carry both dead and live loads at 50% increased unit stresses for the emergency condition of the counterweights in the jacked position, with no stress in the counterweight ropes.

For the upper lift span, guide shoes are provided at each corner in the plane of the bottom chord. They engage guide angles located on the centre of the outside faces of the main posts of the tower structure. Jaw type guide castings are used at the fixed end which position the span both laterally and longitudinally during its vertical travel. The guide shoes at the expansion end position the span in the transverse direction only. Guide shoes are placed in a similar arrangement at each corner of the span, in the plane of the top chord. These guides position the span in the lateral direction only. The running surfaces of all guide shoes are fitted with renewable bronze wearing plates. The guides on the tower posts are so arranged that all running clearances are reduced to ⅛ in. during the last two feet of span travel, as it seats. The wind reactions from the top deck of the lift span are delivered to the tower structure by means of the upper guide shoes, so that it was not necessary to provide end portal bracing on the lift span. Because the lower bridge is a plate girder structure, it has only one set of guide shoes, located in the plane of the main lateral bracing system.

A centering device located at the fixed end consisting of a pin supported by the lift span framework, engages a hole in a plate supported by a fixed portion of the structure, and centres the span both laterally and longitudinally. This device also resists the longitudinal wind and tractive forces. Centering devices of the tongue and slot variety, are located at the expansion ends of the lift spans to center the bridge laterally to plus or minus 1/32 in. to ensure proper mating of the rail-breaks.

The counterweights consist of steel boxes filled with concrete. They are rectangular in cross-section and are each 10 ft. wide by 7 ft. deep and 34 ft. long. They have balance block compartments on top with removable panel covers. Each counterweight is guided by four bronze guide shoes, which engage guide angles supported in the bents and towers.

A built-in system of links and pins located in the overhead bridge structure makes it possible, by a series of jacking procedures, to suspend the entire counterweight from the overhead bridge if it becomes necessary to change counterweight ropes, or for any other maintenance reason.

The total weight of the movable span is 596 tons for the lower bridge and 532 tons for the upper bridge. The normal lift of the lower bridge is 96.5 ft. and of the upper bridge 100 ft. which is needed for a 120 ft. vertical clearance for the Seaway. A 3 ft. overtravel in excess of 120 ft. clearance was also provided.

The tower structures of both bridges are similar and some parts are identical. The general principle of framing is similar to the C.N.R. vertical lift bridges over the Lachine canal.*

An overhead bridge carries the machinery house at the mid-span

*(Refer: Engineering Journal, July 1946, Page 415.)

point, and is supported at one end by a bent, and at the other end by a rectangular tower, which gives longitudinal stability to the entire structure. The present arrangement as seen in elevation has a lopsided appearance, however, the tower is designed for the addition of another overhead bridge and bent, at the time a future twin lock is built. The complete structure would then be more symmetrical, and not unlike the Lachine canal bridge.

The south approach span for the upper bridge is, except for its length, similar to the lift span, and is identical in many details. It is designed so that it can be easily converted into a lift span if the twin lock is built.

The total length of the lower bridge structure is approximately 258 ft. being equal to the length of the Victoria bridge span which it replaced. The total length of the upper bridge project is 314 ft.

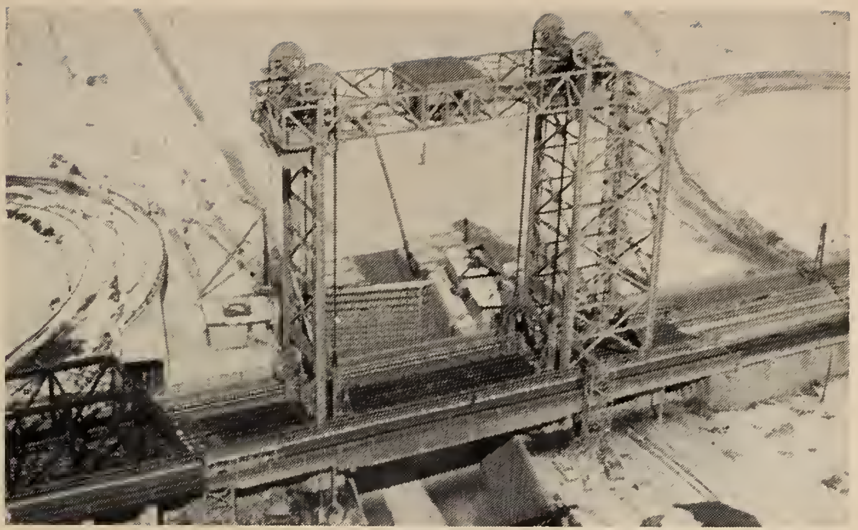

Fig. 3. Lower St. Lambert lift bridge which replaced the south end span of the Victoria bridge. It is located just downstream from the lower lock gates of the St. Lambert lock.

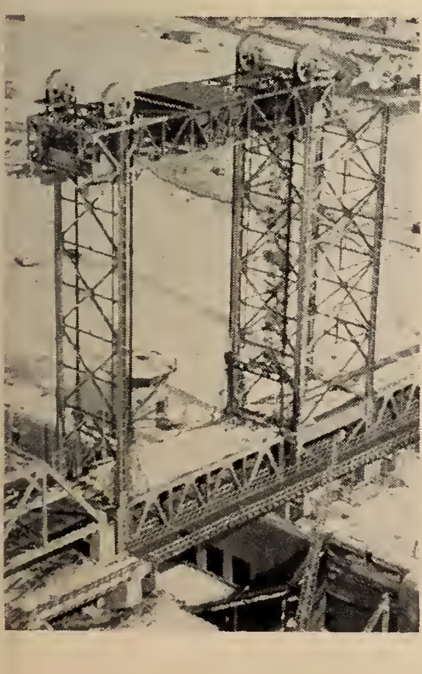
Caughnawaga Bridge

The two tracks of the Canadian Pacific Railway cross the 250 ft. wide canal at an angle of 59°. They are 27 ft. centre to centre, lie on a grade of .5% and are carried separately on twin vertical lift spans. The two spans are offset a distance of about 16 ft. in the longitudinal direction, because of the skew crossing.

Twin spans were built in preference to a single double track structure. The main reason for using twin spans was because they provided greater flexibility of railway operation. If one span were inoperative because of accidental or mechanical causes, the other could carry the traffic during the emergency. The railway has provided crossovers between their tracks so that either bridge may carry both northward and southward traffic.

Fig. 4. Upper St. Lambert lift bridge will be used to by-pass traffic when the lower bridge is raised. It is located just upstream from the upper lock gates of the St. Lambert lock.



A cost analysis was made to determine the economy of using low-alloy steel, in the lift span trusses and floor system, and in the tower main posts. This analysis indicated a small saving in material cost but it was largely offset by increased shop costs due to the use of two kinds of steel in the same structural components. Because the estimated saving was not large enough to be significant, and also because the railway expressed a preference for the use of medium structural steel as it is easily weldable in case emergency repairs are required, it was decided not to use low-alloy steel.

The main trusses of the lift span are 19 ft. centre to centre and have a total length of 322 ft. They are 45 ft. deep at the centre and provide space for the machinery house between the railway clearance and the top lateral bracing system. The ties are supported on 42 in. deep plate girder stringers spaced 8 in. apart. Special contraction joints were placed in the stringer system at the third points to prevent tension stresses being induced in them. Perforated plates were used instead of lacing on structural members, where practicable, for ease of maintenance and good appearance.

Double web girders 5 ft. deep join the two trusses just above the railway clearance at each end of the span. The counterweight ropes are attached to these girders, at each corner of the span.

The structure is designed in accordance with the C.S.A. Railway Bridges Specification S1-1950. The railway live loading is Cooper's E70.

The lift span fixed-end pier members are in the form of a jaw type weldment attached to the span. As the span seats, this jaw engages a pin located in a pedestal weldment bolted to an extension of the base slab on which the main tower post seats. These pier member units accomplish the final longitudinal centering of the lift span during its last two inches of travel, and when the span is closed, they carry all the longitudinal wind and tractive forces. The expansion-end pier members are made of weldments of the rocker type. They are spring loaded to ensure that the rockers will be vertical when the span seats.

The span guide shoes are similar to those described for the Upper St. Lambert Bridge.

To ensure perfect lateral mating of the rail-break assemblies, centering devices were provided under the end floorbeams at each end of the span. These "tongue and slot" weldments centre the lift span laterally to ± 1/32 in. during the last 2 inches of travel, as it seats.

Each counterweight consists of a rectangular steel box, 11 ft. 9 in. thick, 16 ft. wide and 40 ft. 3 in. high, filled with concrete. The ⅜ in. thick skin plate is supported by systems of horizontal and vertical ribs, giving an unsupported panel approximately 4 ft. square. The plate is designed for the hydraulic pressure from wet concrete at the time the box is being filled. A system of struts in two directions gives rigidity to the panelling. A grillage of timbers, attached to the bottom of the counterweight, act as a buffer, in case the counterweight should strike the deck of the bridge due to accidental overtravel of the lift span. The upper portion of the counterweight box consists of a compartment for the placing of concrete balance blocks. This block storage space is weathertight and is entered by means of a trap door. Each counterweight is guided by four bronze guide shoes, which engage guide angles supported on the tower bracing.

The total weight of each movable span is 955 tons. Because the base of rail is some 48 ft. above high water, a normal lift of only 78 ft. is required for the 120 ft. vertical clearance needed for the Seaway. A 3 ft. overtravel, in excess of the 120 ft. clearance, was provided.

Each tower supports two 15 ft. counterweight rope sheaves at an elevation some 141 ft. 6 in. above the pier top. The front tower posts are vertical and each pair carry the dead load of one half of the lifted span and one counterweight, as well as being subjected to bending loads from the lift span guide shoes, and wind overturning forces. These were built up of plates and angles to form an "H" cross-section. The tower back legs are essentially parabolic in outline and are relatively slender. The bottom portion of the tower acts as a 66 ft. span bridge with the same type of deck as is used on the lift span.

Fig. 5. Caughnawaga twin lift bridge which provides flexibility of railway operation. Cross overs were provided between the two tracks approaching from either side so that if one span is damaged all trains can use the remaining span.

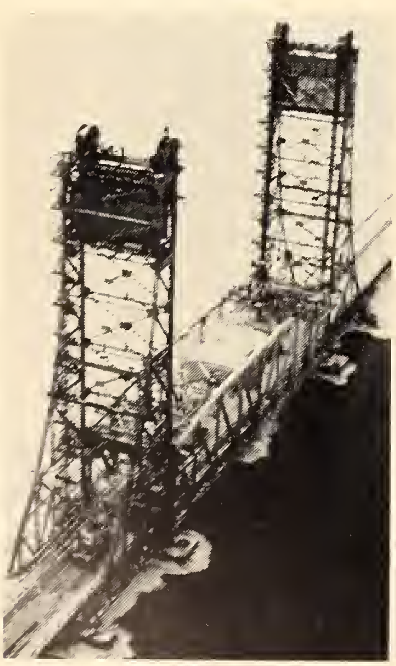


Fig. 6. St. Louis lift bridge which replaces two spans in the north end of the St. Louis bridge.

Girders are incorporated into the longitudinal faces of the tower, a short distance below the bottom of the counterweights when they are in their upper position. Temporary beams can be laid across these girders from which the counterweight may be jacked, and supported temporarily, if and when it becomes necessary to renew counterweight ropes. The fixed end of the balance chains are also supported on a transverse beam framed to the towers.

Deck plate girder approach spans, 55 ft. long, flank the towers at both ends of the project, to give the approach embankment room to spill around a buried type of abutment pier.

The total length of steel structure is 577 ft.

St. Louis and Valleyfield Bridges

The St. Louis and Valleyfield bridges both cross the Beauharnois canal at right angles and are level. They span an opening 199 ft. 6 in. wide between two piers flanking the Seaway channel. Provision was made when building these bridges about thirty years ago for the future installation of lift bridges. In succession there was a 75 ft. span, two 100 ft. spans, and then another 75 ft. span. The piers for the 75 ft. spans were made wide so that towers could be erected over them. The two 100 ft. spans were anchored in such a manner that they could easily be removed, the extreme ends resting on the wide piers for the towers, and the mating ends on a temporary pier. The new lift span replaces the two 100 ft. spans and their centre supporting pier.

Each of these bridges carries a single railway track and a double lane roadway. In cross section they look alike but there are slight varations due to different railway loadings and roadway widths. The roadway on the St. Louis bridge is 18 ft. wide and on the Valleyfield bridge 28 ft. wide. The truss centres are respectively 43 ft. 10 in. and 49 ft. 8 in.

In both cases all material in the trusses on the railway side, except gusset plates and stiffening angles, is of ASTM A-242 low alloy steel.

These two structures are designed in accordance with the C.S.A. Railway Bridges Specification S1-1950, the AREA Specification for Movable Bridges (Valleyfield only) and the C.S.A. Highway Specification S6-1952. The railway live loading at St. Louis is Cooper's E60 and at Valleyfield Cooper's E70. The roadways are designed for a live load of H20-S16 plus 30% impact or U-100 per lane.

The various structural parts of both these bridges such as the pier members, span and counterweight guides, centering devices and towers are similar to the Caughnawaga bridge and need not be described again. The counterweight box dimensions are 11 ft. 9 in. thick, 14 ft. 6 in. high, by 40 ft. 7 in. wide at St. Louis and 46 ft. 5 in. wide at Valleyfield.

The total weight of the St. Louis span is 1212 tons and the Valleyfield span 1402 tons. A normal lift of 113 ft. 6 in. and 114 ft. 6 in. respectively is required for the 120 ft. Seaway clearance. A 3 ft. overtravel, in excess of the 120 ft. clearance, was again provided.

Each tower supports two 15 ft. counterweight rope sheaves at an elevation 182 ft. above the pier top.

The total length of each of these lift bridges is 370 ft. including the original 75 ft. spans beneath the towers.

MECHANICAL

The mechanical parts of all the bridges were designed in accordance with the C.S.A. Provisional Specification for Movable Bridges (First Draft).

Counterweight Ropes

The counterweight ropes for the St. Lambert and Caughnawaga bridges were all cut from a special Grade 110/120 steel wire rope, 1⅞ in. in diameter, 6 x 19 construction, with an impregnated hemp centre. A breaking strength of 320,000 lb. was specified, and this figure was included in the requirements as the minimum value to be shown by any full size destruction tests.

The requirements for prestressing were to stretch the rope gradually to a tension of 48,000 lb., a load safely over the maximum value likely to occur in service, and also a value which would not squeeze out the lubricant used in their manufacture. This load was held for a period of time until no appreciable stretch was observed. The tension was then gradually released to about 11,000 lb. and again brought up to the marking load of 32,000 lb.

The metallic area of each rope was calculated to be 1.45 sq. in., and a factor of safety of 10 was required on the direct tension, thus giving an allowable unit of 22,000 p.s.i. The bending stress induced by passing the rope over the 15 ft. sheave was assumed to be:—

$$.7\,Ed/D \quad \text{where} \quad \begin{aligned} E &= \text{modulus of the wire} = 28{,}500{,}000 \\ d &= \text{diameter of each wire} = .121 \text{ in.} \\ D &= \text{diameter of the sheave} = 180 \text{ in.} \end{aligned}$$

This being equal to 13,400 p.s.i., therefore, the maximum allowable combined unit stress was 35,400 p.s.i. This gave a factor of safety of 6.2, the specified allowable being 5.

The counterweight ropes were calculated on the basis of equal distribution of weight between the four corners of the span. The St. Lambert bridges have twelve ropes per corner and the load in each rope is 24,800 lb., with a direct tension unit of 17,100 p.s.i. This was well under the allowable, but the ropes were designed to be the same as will be used on a possible future and larger span when the lock is twinned. The Caughnawaga spans have sixteen ropes per corner and the load in each rope is 29,800 lb., with a direct tension unit of 20,600 p.s.i.

The counterweight ropes for the St. Louis and Valleyfield bridges were designed and prestressed in a similar manner but required rope 2⅛ in. in diameter. These spans have sixteen ropes per corner and the load in each rope is 45,300 lb., with a direct tension unit of 26,600 p.s.i.

Counterweight Sheaves

The counterweight sheaves are all 15 ft. in diameter and four in number for each span. They were fabricated by forming and welding together A.S.T.M. A.373-54T. structural steel plates. Rough turned forged steel trunnion shafts were inserted into the sheave webs and arms, and were integrally welded into place. By using this construction, the sheaves were much lighter than if they were cast. Also time and labour was saved over the conventional cast steel sheaves where the hubs have to be bored and key-seated, and the shafts fitted by either heating the sheave or cooling the shaft. The

Fig. 7. Counterweight sheaves with integral trunnions fabricated in welded steel.

sheaves were stress relieved before machining.

For the counterweight sheaves steel cast pillow blocks, heavily bushed with phosphor bronze, were seated on structural members at the top of the towers. Deep reservoirs, with plate steel lids, were cast integral with the bearing covers for storing grease.

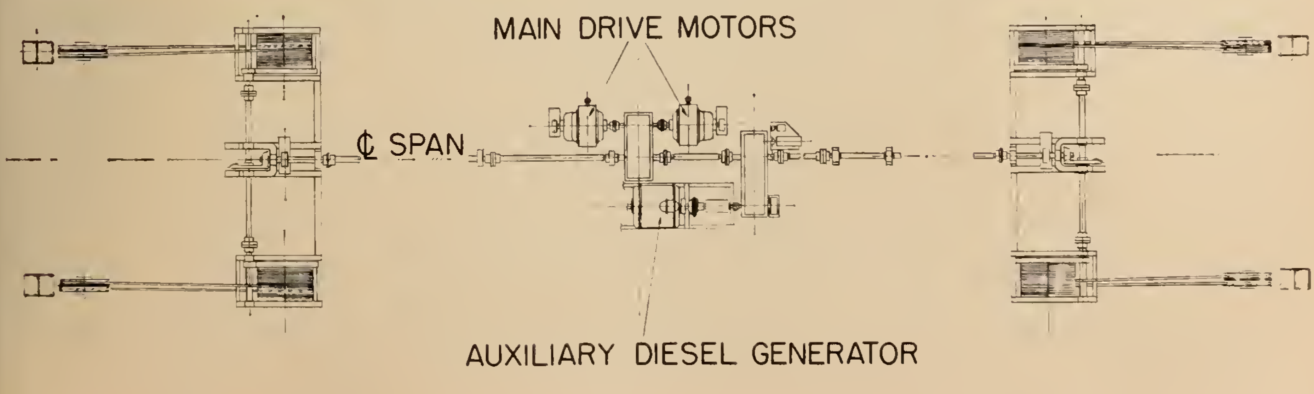
Grease channels were machined in both the trunnion shafts and the bushings. Pressure grease fittings were supplied for the bushings which allows the journals to be lubricated independently to facilitate starting up atfer a winter shutdown.

The use of rolling type bearings was considered but the extra cost of them over bronze bushed ones was decided to be too high considering the many years trouble-free service given by the bronze type on the Welland canal bridges.

Balance Chains

Weight was supplied in the form

Fig. 8. Machinery layout at Caughnawaga showing main drive machinery at the centre, and the operating drums at the ends, of the span.



of chain links to balance the weight of the counterweight ropes, as they move over the sheaves from the span side to the tower side and vice-versa.

On the St. Lambert bridges, one end of each balance chain is connected to the counterweight and the other end to the movable span. These chains hang down outside of the railway track clearance limits, and in order to prevent any encroachment, due to swing of the chain from wind or other causes, the lower part of the chain passes around a flanged wheel which is secured to a structural post. The weights of these wheels are carried by the chains and the connections to the post are such that the wheels have a free vertical motion to take care of variations in the length of chains due to differential temperature changes or wear. The chains are made of cast iron blocks and links connected together by steel pins, the weight being approximately the same, per foot length, as one group of counterweight cables. The counterweight of these bridges was theoretically equal to the weight of the span.

The Caughnawaga, St. Louis and Valleyfield spans have a different type of balance chain to that described above. This chain hangs in the form of a catenary, under the counterweight, one end being attached to the counterweight and the other end to the tower at a point slightly above the mid-point of the span travel. This makes the effective length of the chain half the length of the unbalanced counterweight ropes. To maintain a theoretical balance at all positions of travel the main counterweights are lighter than the span by an amount equal to the weight of the counterweight ropes and the balance chains are twice the weight of the counterweight ropes. The chain consists of cast iron blocks, with lugs, connected together with steel pins.

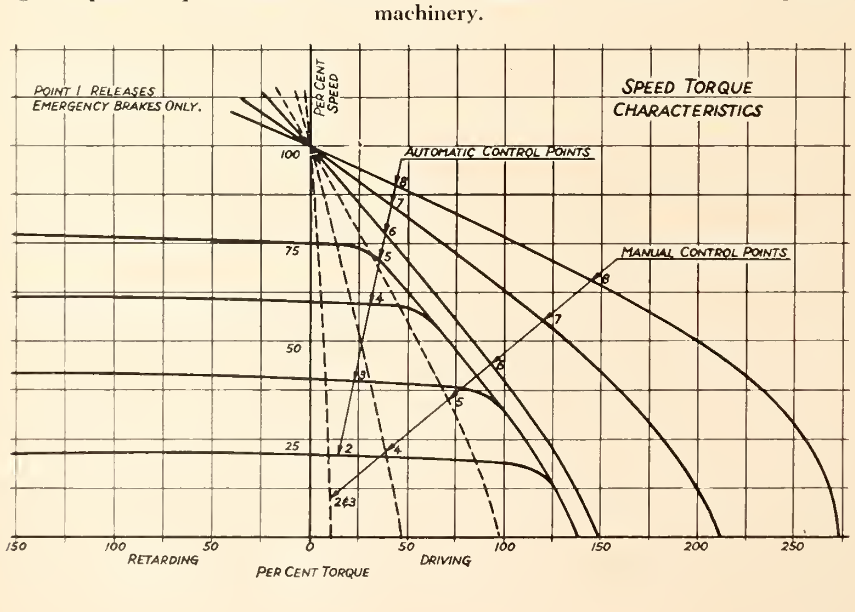
Span Locks

In order to insure proper seating of the spans, a locking device is provided at each corner of each span. The locks consist of a toggle lever type mechanism and are so designed that the contacting arms or hooks, of which there is one to each lock, are swung outwards and downwards (as on the St. Lambert spans) or outwards and upwards (as on Caughnawaga, St. Louis and Valleyfield spans) in the driving operation until they bear against special brackets on the span or the towers as the case may be. As the toggle straightens under this power stroke the hooks can develop enough pressure to force the span down tight on to its shoes and so line up the rails and roadways vertically.

On the St. Lambert spans these locks are mounted on structural steel girders anchored to the tower piers. The hook locks down on brackets on the movable span floor beams. They also have another function to perform. These spans to all intents and purposes have no dead load reaction, and as the bridge shoes are placed inside the cantilevered roadways, an overturning moment can occur when one roadway is loaded and the other unloaded. The span locks are mounted close to the bridge shoes, and are designed to resist this overturning load, as a static condition.

On the Caughnawaga, St. Louis

Fig. 9. Speed torque characteristics of the automatic a-c. control of the operating machinery.



and Valleyfield bridges, transverse struts are placed at the ends, parallel to the lifting girders and in the plane of the top chord upon which the span lock mechanism is mounted. The hooks bear up against special brackets mounted on the front legs of the towers.

Operating Machinery

The operating machinery for the St. Lambert bridges is located in weatherproof steel machinery houses on the overhead structure. Each set of machinery consists of four grooved drums of welded steel construction, two on the upstream side and two on the downstream side of the bridge. Each pair is driven by a common cross shaft, which has a pinion at each end meshing with gears on the drums. The cross shaft is driven at the centre by means of a double herringbone gear rolling bearing reducer coupled to the two 150 hp. motors.

There are eight operating ropes for each span, one uphaul and one downhaul at each corner, each 1¼ in. in diameter, 6 x 19 construction. One uphaul rope and one downhaul rope is wound on and anchored at opposite ends of each drum. The four uphaul ropes lead from the underside of the drums over large guide sheaves, at the corners of the overhead structure, to the span. The four downhaul ropes lead from the topside of the drums, over guide sheaves and are attached to the counterweights. To raise the bridge the operating machinery and ropes exert an upward pull on the movable span, and to lower the span, an upward pull on the counterweights. The operating ropes are anchored to the span and counterweight by a self-locking worm and take-up drum. The ropes are pre-tensioned by applying torque to the worm shaft and are prevented from loosening due to the self-locking feature of the worm and worm gear.

A gas engine is fitted to the machinery on the lower St. Lambert bridge only, for emergency purposes. It consists of a vee-eight 75 hp. gasoline engine connected to the machinery cross shaft through a spur gear rolling bearing reducer and clutches. A friction clutch and a slip type coupling is inserted between the engine and the gear reducer and a sliding jaw type clutch and reversing gear is incorporated in the reducer.

Thrustor operated brakes are mounted on the back end of each motor and also, at each end of the drive cross shaft.

The Caughnawaga, St. Louis and Valleyfield bridges have the operating machinery installed on the lift spans. Four, double pitch, grooved welded steel drums are attached just below the top chords of the trusses, one at each corner near the ends of the spans. They are connected to the machinery at the centre by means of transverse and longitudinal shafting through suitable spur and bevel gear reductions all turning in bronze bushed bearings. The longitudinal cross shaft is driven at the centre by means of a double herringbone gear rolling bearing reducer coupled to two 150 hp. motors at Caughnawaga and two similar reducers coupled to four 150 hp. motors at St. Louis and Valleyfield.

Fig. 11. Railway girder span is being lifted into place at Lower St. Lambert showing second track in readiness for trains.

Fig. 10. 109 ton tower derrick used to construct the lower St. Lambert bridge.

There are sixteen operating ropes for each span, double ropes being supplied at each corner for each of the uphaul and downhaul motions. The ropes are 1 in. in diameter at Caughnawaga and 1¼ in. in diameter at St. Louis and Valleyfield, 6 x 19 construction. The uphaul ropes, in pairs, lead from underneath the drums around large deflector sheaves, up the tower face to guide sheaves at the top and then to the self-locking take-up drums fixed to a cross-girder at the top of the towers. The downhaul ropes, in pairs, lead from the top of the operating drums, over large deflector sheaves down towards the base of the tower and thence to the take-up drums fixed to the tower legs.

An auxiliary diesel generator was supplied for each of the Caughnawaga, St. Louis and Valleyfield bridges. The diesel engine, with reversing gear, was mechanically connected to the main drive shaft by a helical gear rolling bearing reducer. A friction type clutch was placed between the engine and the gear reducer and a jaw clutch was inserted at the drive shaft.

Thrustor operated brakes are mounted on the back end of each motor and also at each end of the longitudinal shaft.

Pneumatic Buffers

Air buffer cylinders are installed, on all bridges, to check or cushion the end of the downward vertical movement of the lifted spans. The piston rods have an adjustable end piece of hardened steel which bears on plates anchored to the piers. The exhaust air is piped through a control needle valve and an oil fog lubricator to the rod end of the buffer cylinder. This means that the cylinder walls are sprayed with oil each time the buffer operates. A steel compression type spring is also fastened on the outside around the piston rod to ensure that the piston falls into operating position.

Rail Breaks

Manganese steel rail breaks of the sliding wedge type were provded at the St. Lambert and St. Louis bridges. These reciprocate horizontally by means of an electric motor driving, through a worm gear reducer, levers and links which form a self-locking toggle, thus fixing the rail wedges against movement from the wheels of the train. A slightly raised part lifts locomotive and car wheels as they pass the rail gap thus minimizing noise and impact.

At Caughnawaga and Valleyfield the rail break design is similar to some recent ones installed in the United States. There are no sliding parts, the rails being lapped together at the breaks. They practically eliminate noise and impact and allow trains to travel at full speed.

Operating Torques and Speeds

The specifications called for these bridges to be raised and lowered in a normal operating time against the forces caused by:—

(Case A) Friction, inertia, rope bending and wind.

In a period of time somewhat slower than normal against the forces caused by:—

(Case B) Friction, inertia, rope bending, wind and an additional unbalanced force caused by ice.

The table shown gives these forces as applied to the operating ropes of the various bridges.

The St. Lambert bridges are designed to open in 90 sec. normal time, 15 sec. being allowed for the rail and span locks, leaving 75 sec. to raise the bridge 96 ft. 6 in. This corresponds to a speed of 1.49 f.p.s at the operating ropes. The Caughnawaga bridge is designed to raise a distance of 78 ft. in 75 sec., a speed at the operating ropes of 1.2 f.p.s. The St. Louis and Valleyfield bridges are designed to raise a distance of 114 ft. 6 in. in 75 sec., a speed at the operating ropes of 1.64 f.p.s. Using suitable gearing, the torques in ft.-lb. at the motor corresponding to the rope forces, at the various bridges were calculated. These are also shown in the accompanying table.

Motors of 150 hp. running at about 860 r.p.m. were selected as suitable machines to provide the above torques. The maximum torque required by the motor would be Case "B" starting. With a voltage drop of 10% the maximum starting torque would be 270% of the normal torque.

Brakes

There are four thrustor operated brakes fitted to the machinery for each movable span of the St. Lambert and Caughnawaga bridges and six for each movable span of the St. Louis and Valleyfield bridges. The units on the back end of the motors are the decelerating brakes and the units on the drive shafts are holding or emergency brakes. These latter brakes are about half torque and have a time lag so that normally they do not come on until the machinery has stopped.

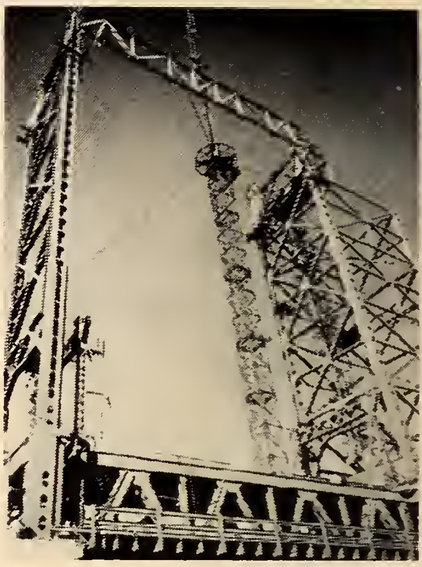


Fig. 12. 20 ton tower derrick used to construct the upper St. Lambert bridge.

Fig. 13. Falsework upon which both the Caughnawaga spans were constructed, one after the other.

ELECTRICAL

The success that has been attained in more recent years in operating a-c. wound rotor induction motors at subsynchronous speeds with good stability encouraged a search for an a-c. drive suitable for lift bridge operation. The development of saturable reactors and the applications of magnetic amplifiers led to schemes particularly suitable to bridge operations. Investigations showed that an a-c. drive employing wound rotor induction motors could be built to satisfy the operating requirements at a moderate capital cost. The decision was therefore made to use a-c. drives at 500 v., 3 phase.

A scheme controlling each winding of a two circuit motor was supplied by Canadian General Electric Co. Ltd. for the Caughnawaga bridges. An unbalanced voltage scheme was supplied by Canadian Westinghouse Co. Ltd. for the remainder of the bridges.

Speed control is entirely automatic for both schemes. Each speed point on the master switchsets up a reference voltage. A tachometer generator is geared into the drive and generates a voltage which is compared with the reference. This comparison is fed to magnetic amplifiers for regulation of the control equipment to maintain the drive at the reference speed. Once a speed is set by the operator, the equipment is automatically controlled to hold that speed regardless of whether the load requirement is a high or low torque, motoring torque, or braking torque. In the normal raising or lowering of a span, the speed should be a maximum for most of the travel to reduce the time of operation. However, in the nearly open and nearly closed positions, the speed should be reduced to approximately 20% of maximum speed. At each of these positions, a limit switch has been provided to set up a reference speed of 20% regardless of the position of the master switch. A second limit switch operates at each extremity of travel for the final stop and application of electric holding brakes. After the limit switch operates to set up a reference speed of 20%, a centrifugal switch is included in the circuit which stops the motion if the speed is not reduced in a reasonable time.

The control for both the two circuit motor scheme and the unbalanced voltage scheme is essentially static and employs few contactors. The use of saturable reactors not only eliminates many contactors but also provides nearly stepless speed and torque control. In addition, the transition from a low torque to a high torque or vice versa is done without shock. It is anticipated that the period for maximum torque change will not be less than 0.2 sec. The period for modern d-c. adjustable voltage control is about 0.3 sec. and this is usually accepted as the ultimate in smoothness. By contrast, the period for a wound rotor motor controlled by contactors and resistors is of the order of 0.01 sec.

Standby Generators

The standby diesel engine driven generators are unusual in that the generators are 25 cycle machines. It is not necessary in most bridge applications to supply standby equipment equal to normal capacity as a reduction in speed for emergency operation is quite acceptable. This results in a lower power requirement permitting the use of an engine generator set of reduced capacity and consequently reducing the cost. The reduction in speed in this case is accomplished by operating the equipment at 25 cycles. However, the voltage must be reduced to approximately 230 v. The arrangement may therefore be considered as an electrical speed changer. It is interesting to note that the automatic control equipment obains satisfactory operation of the motors when operating on 25 cycles.

Control Desks

The bridge operator controls all the operations from a desk type control unit which was designed specifically to facilitate and simplify the procedure. This unit contains the master switch, selector switches, push buttons, meters and other devices and instruments necessary for proper operation. Indicating lights show the position of the limit switches. A position indicator of the self synchronous type shows the height of the span. For the bridges where the normal operation is done from a control house separate from the bridge, a second control desk is supplied in the machinery house. This permits operation directly from the bridge if necessary or desirable.

Fig. 15. Floating span into place at the Valleyfield bridge.

ERECTION

Lower St. Lambert Bridge

As mentioned previously, the lower vertical lift bridge at St. Lambert replaced the south end span of the existing Victoria bridge.

At the start of the project, the highway traffic was diverted off the bridge. Railway traffic, however, was maintained at all times. In general both tracks were in use, but periods of single track operation were arranged to permit work on the structure supporting the other track. In general these periods were limited to 6 or 7 hours, although a few longer periods were required.

In view of the continuous heavy railway traffic and the existing truss to be removed, it was necessary that the main hoisting equipment be independent of the bridge structure. All the high lifting and heavy lifting for this project was done with a tower derrick standing on the floor of the lock.

A 150 ton guy derrick, with 202 ft. mast and 160 ft. boom was used. It was mounted on a 182 ft. steel tower standing on a dished disc bearing on the floor of the lock. The tower was guyed with four double guys at 90° to each other, while the mast had eight guys at angles governed by the roadway layouts. The derrick was rigged for 109 tons on this project. The location in the middle of the lock was necessary to reach both ends of the overhead structure from one set-up.

The cantilever roadways were removed using light cranes as soon as highway traffic was diverted. Then in order to dismantle the existing trusses, it was necessary to support each floor beam of the existing span for both dead load and live load. The four floor beams over the lock were supported on a 94 ft. steel truss span. There were three trusses, one on the centerline and one 13 ft. 10 in. each side of centerline, in order to permit removal of the floor beams half at a time. All field connections were high strength bolted. The remaining floor beams were each supported on three steel columns similarly located and braced with steel angles.

All the falsework was constructed about 2 in. clear of the existing trusses to permit free truss deflection. Load was transferred to the falsework by stopping all traffic, driving wedges at all points of support, and burning through the bottom chord of the existing trusses at the center. This period of about 3 hours was the only time that traffic was stopped on both tracks for more than a few minutes. As soon as the load was transferred to the falsework, the existing trusses were removed in as large pieces as possible by the tower derrick and two cranes.

Simultaneous with the falsework erection and truss dismantling described above, the bottom tiers of the towers were erected, with the tower base struts and lifting girders in between the old floorbeams ready to support the railway spans. The various railway girders were assembled at ground level into spans consisting of two girders, complete with bracing. In the case of the shorter spans, all the timber ties were installed in advance. In the case of the main lift spans only every fourth timber tie was installed in advance to limit the weight to 109 tons.

To permit erection of each span, traffic was stopped on one track right after the morning peak period. As soon as the rails were removed by the railway company, the existing ties, stringers, and half floor beams were removed by the cranes and tower derrick, following which the new span complete with ties was lifted into place. Typical time for the shorter spans was about 6 hours. For the lift spans about 11 hours were required, as falsework had to be removed to clear the deep girders and the remainder of the ties had to be placed.

As soon as portal struts of the towers were erected, Bailey bridging was suspended from them extending the entire length of the overhead structure. The Bailey bridging was covered with a 12 in. timber mat 36 ft. wide. The principal purpose of the mat was to protect passing trains from any bolts, pins, or other light objects which might be dropped from above. In practice it also proved useful as a working platform for laying out light steel for the structure above.

The remainder of the superstructure, including towers, overhead trusses, machinery, counterweight sheaves, counterweight boxes, counterweight concrete, and auxiliary counterweights, was then completed with the use of the tower derrick. Because of the great capacity of the tower derrick, whenever possible sub-assemblies were assembled and in many cases riveted on the ground before raising, to minimize the amount of high work.

Erection of the tower derrick started in September, 1957. Load was transferred to the falsework in December, 1957 and the first railway girder span was erected in January, 1958. The lift span was first operated in August, 1958 and final adjustments were made in November, 1958. Highway traffic was rerouted onto the span early in September, 1958.

Upper St. Lambert Bridge

As no traffic was involved the erection of the Upper Vertical Lift bridge at St. Lambert presented no unusual problems. With the exception of the lift span trusses, all steel up to the level of the third tier was erected with mobile or crawler cranes. To avoid the use of falsework in the lock, and for ease in riveting, the lift span trusses, weighing 55 tons each, were assembled in a horizontal position in the bottom of the lock and hoisted into place with a 75 ton pole. The erection of the upper portion of the superstructure was completed by means of a 20 ton tower derrick standing on the lift span railway deck. The approach span was erected by crawler cranes with the use of a single timber falsework bent.

Erection of the Upper Bridge started in May, 1958 and final adjustments were made in December, 1958.

Caughnawaga Bridge

A notable feature of the erection of these lift spans was the fact that

falsework was erected for the downstream span only. The upstream span was erected first on this falsework and then rolled into its final position, as described in detail below.

The close proximity of the existing railway line was the principal reason for the decision to build falsework for one span only. The toe of the embankment line at the level of the bottom of the channel extended into the area which would have been occupied by falsework for the upstream span. The difficulty of framing falsework on the side of the embankment, as well as the economy of erecting falsework in one position only, led to the decision to false work the downstream span only.

The falsework consisted of six timber bents 77 ft. high at 53 ft. 8 in. centres supporting the floorbeams at the bottom-chord splices of the span, and founded on concrete pads at the bottom of the channel. Four steel beams between each pair of bents supported the intermediate panel points.

In general, all steel for approach spans, towers up to the top chord level, and lift spans was done either with crawler cranes or with a 40 ton locomotive crane operating on the track. The south approach girders were erected as soon as piers were complete, thus giving access for the erection of the southeast tower. Erection of the southeast tower trusses, with overhead bracing omitted, gave access for the locomotive crane to the falsework. Due to the longitudinal component of the motion of the upstream span in rolling from the falsework to its final position, the southwest and northeast towers could not be started until after the translation was complete. The locomotive crane filled in the floor system and bottom chords of the upstream span starting from the south and working towards the north. Then the web members, top chords, overhead framing, and machinery were filled in working from north to south. The northwest tower and the north approach spans were erected by crawler crane independent of the lift span sequence.

When the riveting of the upstream span was substantially complete, it was ready for translation to its final position, which was 27 ft. laterally and 16 ft. 3 in. longitudinally, or a total movement of 31 ft. 6 in. Because of this skew translation it was necessary to have a separate runway for each corner of the span. Each runway consisted of four 85 lb. rails laid on timber cribbing. In order to clear the anchor bolts on the piers, it was necessary to raise the entire span about 2 ft. This was accomplished by the use of two 224 ton jacks and a short welded needle beam at each corner, thus permitting installation of the twenty wheel truck and completion of the runway.

Power for the translation was supplied by two 300 ton jacks with 4 ft. runout working against a weldment which was advanced and clamped to the rails at the end of each stroke. The horizontal movement took about 6 hours. When translation was complete, the span was jacked down onto its own pier members.

On completion of the translation operation, the downstream lift span was erected in its final position on the falsework using the same procedure as for the upstream. Simultaneously, the southwest and northeast towers were erected up to the top chord level.

All lifing for the upper portion of the towers except for the 42 ton counterweight boxes which required special rigging, was done by two 20 ton tower derricks, one standing on the pier at each end between the backlegs of the tower for each track.

Framing of timber falsework was started in July, 1957. First steel was erected in August, 1957. The upstream span was translated on December 30th, 1957. Railway traffic was diverted onto the spans early in June, 1958, and the spans were first lifted using auxiliary power early in July, 1958. Final testing was delayed until January, 1959, when 60 cycle power was available.

St. Louis and Valleyfield

As already mentioned these lift bridges took the place of two 100 ft. spans in each of the existing bridges and the towers were erected over two existing 75 ft. spans. Both bridges were close over the water level of the Beauharnois canal which made floating operations practical for taking out the old and putting in the new spans. Actually the existing spans had been floated out and in again many times as this was the only way the dredges which have been working in the canal for the past thirty years could get through.

There was railway and highway traffic to contend with on both bridges although its density was quite low. As far as the railways were concerned only freight trains used the bridges and during construction there was never more than a few hours delay. As the highway traffic was very light on the St. Louis bridge it was closed down for a period of three months except for the odd week-end. The highway traffic at Valleyfield was only delayed a few minutes at a time except the day when the new span was floated in.

The two lift spans were erected, complete with all machinery and electrical control equipment, on the north shore of the canal between the two bridges and about a mile from the Valleyfield bridge. The bank of the canal was first dredged to give enough draft for the barges to be used to float the spans and then falsework was constructed upon which the spans were erected. The two spans were placed end to end and a stiff leg derrick travelling on rails worked back and forth on top of the falsework during their construction. While the spans were nearing completion work commenced at the two bridges. First the piers were drilled for the large tower anchors. Due to the arrangement of the existing steelwork, it was only possible to complete one tower before the span was floated in. The north tower at St. Louis and the south tower at Valleyfield were erected first. Derricks mounted on creepers which travelled up the front legs of the towers were used for this work. The new lift spans were now readied for floating in. Two partially submerged barges were placed under a span at about quarter points and pumped out to raise it on blocking off the falsework. While this operation was going on, the 100 ft. spans to be removed from the bridge were being lashed together for floating out on barges. The floating out of the old spans and the floating in of the new one took approximately 6 hours at each bridge. Tugs and motor launches were used to manoeuvre the barges. Finally the south tower at St. Louis and the north towers at Valleyfield were erected. While the towers were being constructed at Valleyfield a protective covering of 12 in. x 12 in. timber was placed over the roadway and railway to prevent small objects from falling on traffic. This was not required at St. Louis as highway traffic was blocked off on working days. The centre piers which supported the old spans were not removed until after the lift spans were in operation and could be raised well clear for this operation.

Erection of the lift spans on falsework started in February and was completed in October, 1958. The first tower at each site was started during August and the spans were floated into place in October. The second tower at each site was started in November and the spans were first lifted in March, 1959.

Summary

A general idea of the relative size of these five lift bridges can be had from the foregoing descriptions and illustrations. However, in order that the reader may make a more detailed comparison the table showing quantities is included. The cost erected for the five bridges (superstructure only) was over 15 million dollars.

It was not the author's intention to go into a great deal of detail in this paper but to give enough information so that a good general knowledge of the bridges would be available to anyone interested.

The building of these bridges was carried out under the jurisdiction of Messrs. A. G. Murphy, Chief Engineer; S. Hairsine, Electrical and Mechanical Engineer; and R. W. Willis, Chief Structural Engineer; all of the St. Lawrence Seaway Authority: Mr. R. H. Findlay, Consulting Mechanical Engineer, to both the Seaway Authority and the Dominion Bridge Co. Ltd.: Messrs. C. A. Colpitts, Chief Engineer, Canadian Pacific Railway; A. C. Johnston, Chief Engineer, Canadian National Railways; and F. H. Simpson, former Chief Engineer and C. E. Defendor, Chief Engineer, New York Central Railroad; and their respective engineering staffs. Their considerate advice was very much appreciated by all contractors.

The author wishes to acknowledge the special debt he owes to Messrs. H. W. Buzzell, J. Smith, S. A. Craig, and H. D. Kennedy, all of the Dominion Bridge Co., Lachine, for their generous help during the preparation of this paper.

DISCUSSION

C. C. PARKIN of Toronto commented on the use of "Span-Drive" operating machinery in preference to the newer "Tower-Drive" machinery. He thought that, for the longer spans, "Tower-Drive" machinery would offset higher initial costs by greater operating economies. He also asked why the stand-by machinery for several bridges was designed to operate at half normal speed.

The author replied that initial economy studies had indicated that the "break-even" point between "span-drive" and "Tower-Drive" occurred at a span length of about 400 ft. It was the author's opinion that the trend is back to "span-drive" for economic reasons, except for very long spans. In reply to the question on stand-by bridge operation, he pointed out that modern power sources are very reliable and emergencies seldom happen. However, when they do, the location of the bridges in question are over open reaches of canal where traffic delays of short duration are not liable to be one of economie compromise.

W. G. Swan of Vancouver discussed the economics of "span-drive" as against "Tower-drive", and pointed out that tower mounted machinery becomes more competitive for lower lifts, where problems of "skew" and "cant" of the lift span becomes less critical. He also pointed out that there is a generous safety factor to prevent slippage of the wire ropes on the sheaves for "tower-drive" which is a friction type drive. Insofar as actual design was concerned, he pointed out the very large friction forces of approximately 50% of the total power requirement resulting from the use of phosphor bronze plain bearings on the sheaves instead of anti-friction bearings.

The author referred to difficulties in keeping the end floor beams level with friction drive, and the need for special error adjusting couplings to remedy this defect. He admitted that there had been a great deal of controversy about plain bearings versus anti-friction bearings, but stated that there was a large difference in initial cost and that in practice power savings would be less than one would expect. He referred to the actual operating costs of the C.N.R. Lachine Canal lift spans, which use anti-friction bearings to illustrate this point. He also pointed out that plain sheaf bearings are self healing, whereas anti-friction bearings are not.

W. H. M. Laughlin commented on the welding of sheaves, and asked if special techniques had been used. He also commended the erection engineers for the successful application of a number of ingenius methods.

The author replied that the welding procedures used to fabricate the counterweight sheaves was similar to that used by any large weldment of comparable size. He added, in reply to a question from Mr. Laughlin, that there had been slightly over 260 drawings of various types for each bridge.

S. Hairsine of Montreal discussed the basic design and said that proven features of older bridges on the Welland Canal and elsewhere had been retained, with new innovations being added as refinements rather than as radical departures. He pointed out that manual control had been retained for most part with optional automatic control to slow the span and creep it into the final limits of travel both raising and lowering. He also pointed out that the emergency power equipment was diesel powered rather than gasoline powered and that some compromise had been made between operating requirements and economic consideration in each case.

OIL TANK SITES PRELOADED BY WELL POINT SYSTEM

Ronald F. Scott, M.E.I.C.

formerly Divisional Soil Engineer,
Racey, McCallum & Associates Ltd., Toronto Division,
now Assistant Professor of Civil Engineering
California Institute of Technology
Pasadena, California, U.S.A.

When a soil investigation showed the existence of poor subsoil conditions at the Fort William Marketing Plant of Imperial Oil Limited consideration was given to several different types of foundation for the support of large oil tanks. The most economical was found to consist of preloading the ground by a combination of lowering of the water table by means of well points and fill surcharge. A well point system and surcharge were installed at each of the two tanks to be constructed in 1958, and fill surcharge only placed at two further tanks to be constructed in 1959. In two and one-half months of operation the combined loads on the underlying clay layers resulted in a settlement of over one foot out of a total predicted movement of two and one-half feet. The article describes the installation and the results which were obtained.

Description of Site

AT FORT WILLIAM, Ontario, several bulk oil and gasoline storage tanks with diameters ranging from 100 to 134 ft. are to be built, together with associated warehousing, pumping and distribution office facilities.

In the past the tanks which now exist at the site were constructed on top of piles driven to a depth of 40 to 50 ft. in the underlying soil. Notwithstanding the pile foundation, settlements have taken place under these tanks, the floors of which in some instances are badly rippled. No record is on hand of any borings which may have taken place in order to determine the soil conditions for construction of existing tanks.

When the new expansion was being planned, a soil investigation was carried out with the following results.

The site, as shown in Fig. 1, which is a photograph taken prior to construction operations, is level but is only one or two feet above the elevation of adjacent Lake Superior. Areas in which it is proposed to carry out future tank construction are mostly covered with fairly dense bush 5 to 6 ft. in height. From the general appearance of the site and previous experience at similar locations in the Lakehead area, it was felt that the subsoil would be composed of normally consolidated post-glacial lacustrine sediments, probably in the form of varved clay. The investigation confirmed this opinion.

From the ground surface to a depth of approximately 24 ft. the soil uniformly consists of a sandy silt or silty sand containing a few thin layers of a silty clay. This soil is underlain to a depth of about 75 ft. by varved clay deposits, the upper 15 ft. of which consist of a highly plastic dark grey clay. Below the upper layer of material was found a reddish-brown silty clay of much lower plasticity, 35 to 40 ft. in thickness. The average properties of the soil and the idealised soil profile assumed for the calculations are shown in Fig. 2 from information supplied by a number of boreholes. All boreholes were terminated at approximately 80 to 85 ft. depth in a primarily granular soil composed of a clayey sandy gravel. Information very generously supplied by the Ontario Hydro-Electric Power Commission indicated that this granular soil extends to a depth of about 130 or 140 ft. below ground surface, where bedrock is encountered.

Settlement Calculations

Consideration was first given to the most economical method of construction which would involve building the tanks directly on a normal gravel pad placed on the stripped ground surface. For the purpose of a settlement analysis, the subsoil was divided into four layers with soil properties as indicated in Fig. 2.

Since recent research has indicated that the values of relative density given by split spoon correlations are probably too low, especially near the ground surface, relative density measurements were actually carried out in the upper layer of silty sand which is cohesive enough to enable this to be done. These measurements gave a relative density of about 80% to this layer, compared to relative densities of about 40% obtained by the split spoon sampling technique.

Consolidation tests were carried out on representative samples from the two compressible clay layers and the results are summarised in two curves, shown in Fig. 3.

The possibility of complete failure of the tank must be considered first and, to this end, the ultimate bearing capacity of the underlying soil is estimated. A 134 ft. diameter, 48 ft. high tank was studied. When full of water (the normal testing procedure), the bearing pressure underneath the base of such a tank will be approximately 3000 lb. per sq. ft. This bearing pressure will be spread out or reduced before reaching the underlying soft, plastic clay. A spread of 30° to the vertical gives a bearing pressure on the surface of the clay layer of approximately 2300 lb. per sq. ft. Current soil mechanics literature indicates that the ultimate bearing capacity of a large circular footing on soft clay is approximately equal to 6 times the cohesive shear strength of the clay. With a cohesive strength of 500 lb. per sq. ft., the ultimate capacity of the upper clay layer is computed conservatively to be 3000 lb. per sq. ft. Consequently the factor of safety against complete failure of the underlying soil is computed to be at least equal to 3000/2300 or about 1.3, based on the shearing strength determined in the field vane measurements.

In spite of the conservative nature of the assumptions on which the analysis was based, it was felt that such a factor of safety was sufficiently low to require a reduction in height of the proposed tanks from 48 ft. to 40 ft.

The subsoil in its present condition is in a state of equilibrium under existing overburden pressures only, and any additional load such as an oil tank will certainly cause the soil to compress and consolidate. This compression will take the form of instantaneous elastic and plastic movements of the silty sand layer, and elastic plastic, and time consolidation settlements in the underlying clay and silty clay layers. Calculations of the settlement amounts due to each of these causes were carried out for a 40 ft. high tank, filled with water, although actual settlements would of course be due to varying levels of product.

From previous experience and the measurements of the relative soil density of the silty sand, it was concluded that settlement due to elastic and plastic effects in the sand layer would amount to about 3 or 4 in. The amount of settlement due to the immediate deformation of the underlying clay layers was calculated from the properties of the clay, as evidenced in the laboratory tests. The computations indicated that the plastic and elastic settlement of all the underlying clay layers would be of the order of 5 in., most of which would take place in the highly plastic upper clay layer.

The remaining settlement would take place over a long time as the result of the consolidation of the clay and silty clay. Calculations based on laboratory consolidation tests indicated that consolidation would yield a total settlement taking place over a period of years of about 1.8 ft. Thus, an immediate settlement due to compression of the upper layer of sand and to movements in the clay under

the tank, would amount to approximately 8 or 9 in., while the consolidation of the underlying clay layers would add 1.8 ft., leading to a total movement of about 2.6 or 2.7 ft. Because of the uniformity of soil conditions encountered in the various boreholes, it was felt that there would be a very good chance of this settlement occurring uniformly under each tank.

The lower than customary factor of safety (even of a 40 ft. high tank) and the large settlements expected made it undesirable to construct the tanks directly on a pad on the ground surface. Accordingly, cost estimates were prepared of the various methods of building suitable tank foundations. From these cost considerations and because of the uncertainty inevitably associated with the behaviour of soil under superimposed loading, careful thought was given to the possibility of preparing the site by preloading. Preloading is now a familiar way of preparing poor sites since several accounts have been given of the method in which large amounts of fill were placed on the foundation area, in order to induce settlement before the erection of the proposed final structure. The consolidation which takes place under the preloading has also the effect of increasing the shear strength of the underlying soil.

As the result of this consideration, the author recommended that the soil at the site be preloaded in two ways: by placing a layer of fill on top of the stripped natural ground, and by installing a ring of well points around each of the two areas to be occupied by future tanks. Since these recommendations were adopted, a fuller description of the well point preloading system is given in the next section.

Preloading

The effect of well points or wells in causing settlements to adjacent buildings during construction operations has frequently been noticed in the past. These settlements have led to considerable damage in many cases and are a great inconvenience during construction. The lowering of the water table changes the effective weight of the soil through which the water table is lowered from its buoyant unit weight to its normal wet unit weight. Thus, the effective stress imposed on the underlying soil layers is increased by 62.4 lb. per sq. ft. for every foot that the water table is lowered. If the underlying soil is a compressible material, such as in the present circumstances, consolidation and surface settlements will ensue.

At the Fort William site the lowering of the water table a distance of approximately 20 ft. would impose an additional stress on the underlying clay layers of approximately 1250 lb. per sq. ft.

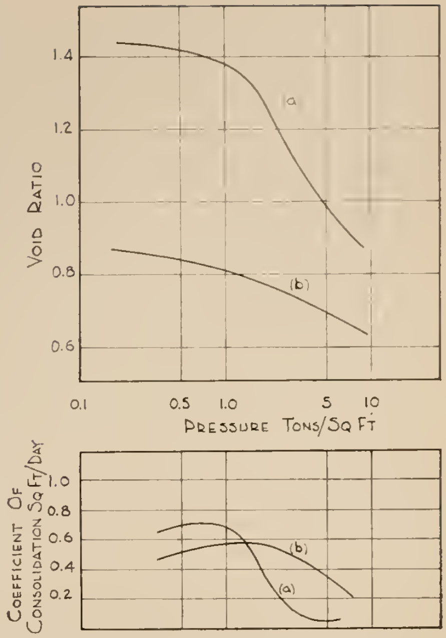

Fig. 3. Average consolidation characteristics of the two principal clay layers.

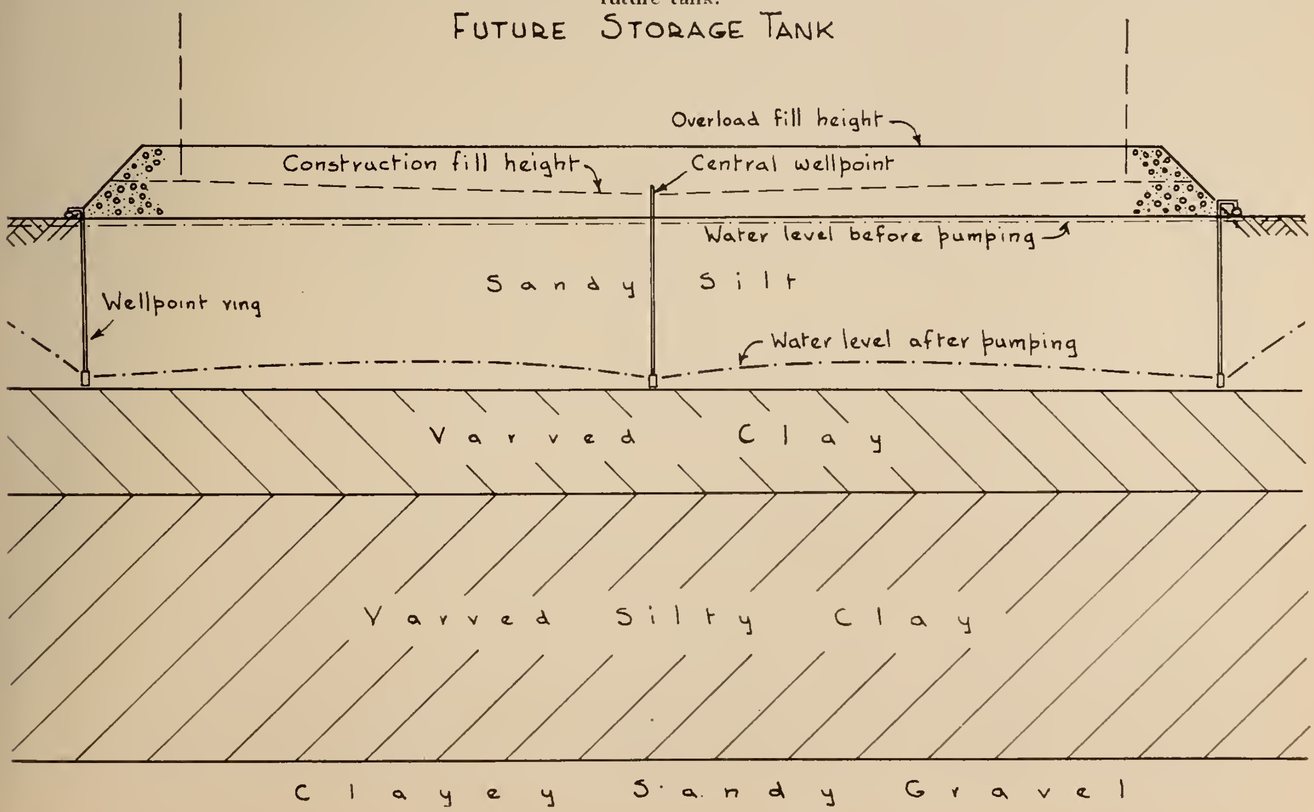
In addition to the actual settlement achieved, the information supplied on the properties of the soil during consolidation and on the nature and type of settling which the soil underwent, would be of value

Fig. 4. Diagram showing soil profile graphically together with approximate layout of wellpoints and their relation to the future tank.



in the erection of all the other oil tanks in the area and would enable specific recommendations to be made in future regarding their construction, filling, and maintenance.

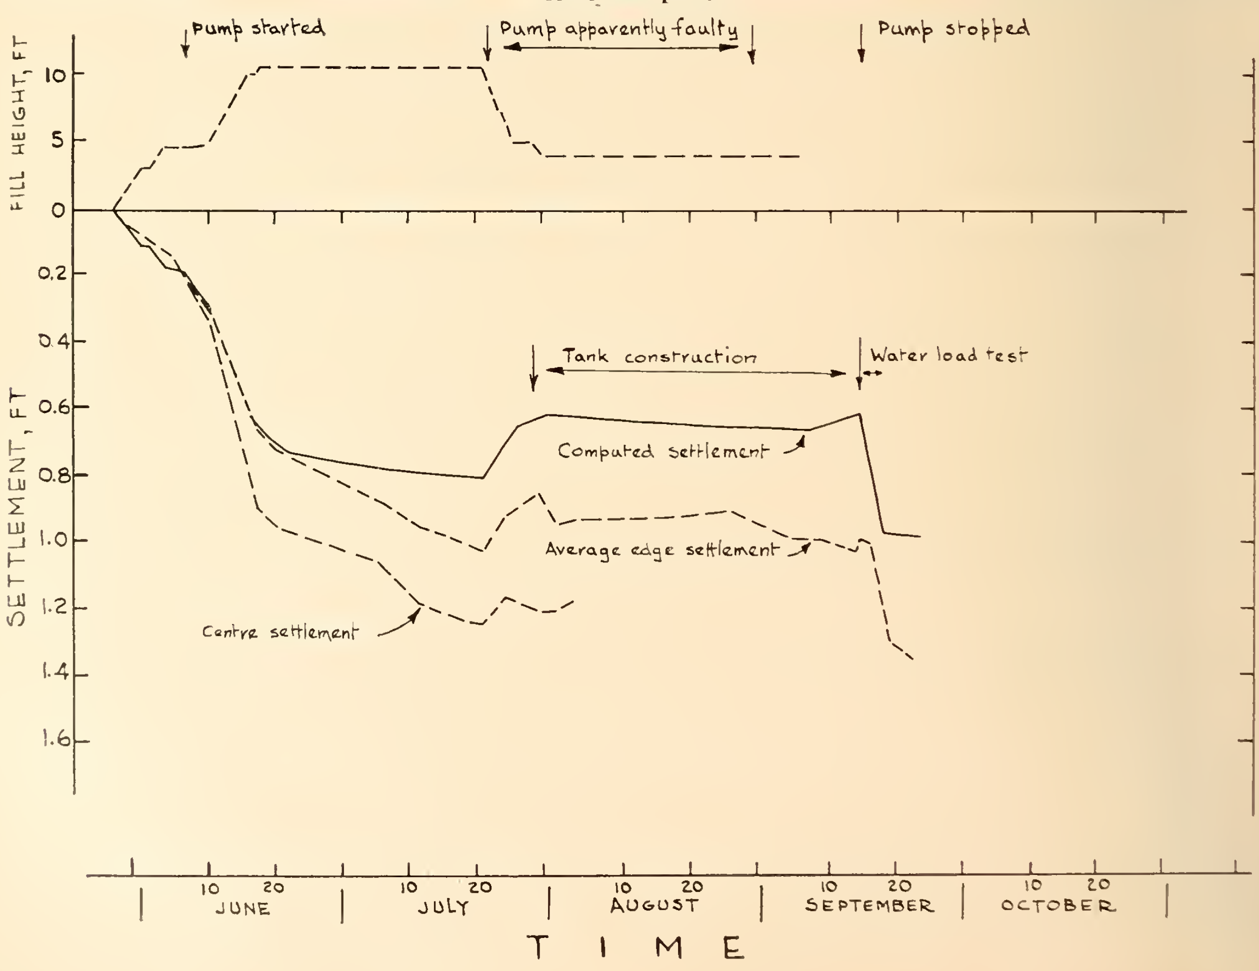
Compared to preloading by fill, the well point system has the advantages of flexibility and ease of installation, operation, and removal. The marshy conditions at the site would also be improved by the drainage.

A trial installation of about 12 well points was set up around the middle of May, 1958, for the purpose of ascertaining the feasibility of draining the fine-grained sandy silt layer. When they proved to be successful, two complete rings of points around 100 and 134 ft. diameter tanks were installed under the author's supervision. The system was set in operation at the larger of the two tanks on 6 June, 1958, and at the smaller tank on 13 June, 1958. Fig. 4 is a drawing of the layout of the well points at one of the sites and the actual installation is shown in Fig. 5.

It had proved possible to obtain substantial quantities of good quality fill material locally, and the filling work proceeded at alternate sites as the well points were installed. The site was first of all stripped of the surface layer of approximately 1 ft. of organic matter and vegetation, and a 6 in. to 1 ft. thick sand pad placed on the surface. On top of the sand pad five settlement plates at each site were located, four at the cardinal points of the compass, and one in the centre of the tank area.

Fig. 5. Filling operations in progress at larger of two tanks. Part of wellpoint installation can be seen in left foreground. Pipe sticking out of fill is one of the settlement points.

Fig. 6. Plot of the settlement of the large tank versus time. The solid line shows computed settlements based on average soil properties and one dimensional consolidation; the dashed lines show actual settlements given by the four edge and one centre settlement point.



Zero readings were established at these settlement points and fill was raised to a height of 10 ft. at each site by 18 June, 1958.

Results of Preloading

The calculations of preloading settlement expected were based on the soil properties measured during the consolidation test, and this requires a brief discussion.

The laboratory consolidation test is carried out on laterally confined samples to which the load is applied at right angles to the direction of layering of the soil. Porous stones are supplied above and below the sample, which allow the water to be squeezed out of the soil in a vertical direction. The calculations of the time which any particular degree of consolidation may be expected to take are based, therefore, on the permeability of the soil at right angles to the soil layers or varves in the present case. However, in the natural soil the application of the load at the surface of the ground may be expected to expel water from the voids of the clay both vertically and horizontally. It is difficult to take this into account in settlement calculations. Therefore, the estimates are based on vertical drainage only and on those properties of the soil obtained from the vertically drained laboratory consolidation tests. It has been found that the final amount of settlement can be predicted with reasonable accuracy by these methods, although the time predictions are generally incorrect.

In the present case, computations based on the laboratory properties of the soil indicated that 6 to 9 in. of total settlement might be expected in 3 months of preloading. Considering the natural three-dimensional process, it was therefore felt, with a certain amount of confidence, that the actually occurring settlements would probably exceed 1 ft. in a 3 month period.

Settlements were measured approximately twice a week at the various settlement points at both tanks, from the beginning of filling and well pointing operations. Fig. 6 is a plot showing the various stages of filling, the initiation of well point operation and the progress of settlements at one tank site. For comparison on this diagram, the computed average settlement curve for the actually observed load application is shown. It will be seen from this figure that the estimate of the elastic and plastic behaviour of the soil was apparently very nearly correct, but that the amount of movement attributable to consolidation proceeded, as expected, at a more rapid rate than theory predicts.

Fig. 7. View of site near completion of construction of new tanks, in middle distance. Between tanks and at extreme right of photograph can be seen preloading fill for two tanks to be constructed in 1959. The wellpoints have been discontinued at the larger of the two tanks and water can be seen at the ground surface.

To such a degree did the increased settlement occur, that a careful scrutiny of the movements at the middle of July, 1958, indicated that it would be possible to begin removing the surcharge fill at the beginning of August, 1958, so that construction of the tanks could be got under way by 15 August instead of 15 September, 1958, which was the date originally recommended. This was carried through and fill at both sites was removed to leave approximately 4 ft. thick gravel pads (the extra thickness being left to allow for future settlements) by the end of July, 1958. The fill removed was added to fill already placed at future tank sites which will be preloaded by the fill only for a period of approximately one year. Construction of the tanks proceeded and the final condition of the site at the end of construction is seen in Fig. 7.

From the behaviour of the tanks during the preloading process a curve was predicted and plotted for the progress of settlement as it should occur during the water load test. One such prediction was made for each of the two tanks constructed since the preloading had indicated slight differences between them.

Settlement observations were taken three times a day during the process of filling the tanks with water, which occupied four days for the larger of the two tanks and two days in the case of the smaller. The results of the water test agreed very well with predicted settlement values and were considered eminently satisfactory. As a result of the behaviour of the tanks during the preloading process and during the water test, predictions have been supplied regarding the probable future behaviour of the tanks when loaded with final product. The best estimate that can be made at present is that each of the two tanks will settle about 0.3 ft. immediately on filling and about another 0.6 or 0.7 ft. in the next year after filling. This amount of movement may be compared with originally predicted settlements of about 2.6 or 2.7 ft. total for each tank.

On the basis of preloading behaviour the smaller of the two tanks may be expected to settle differentially about three inches across the diameter of the tank in a determined direction. The future behaviour of the two other sites which have been preloaded by the application of fill only has also been worked out and information regarding future movements has been supplied.

Acknowledgments

The wholehearted co-operation of all Imperial Oil engineers concerned with this project, in particular Mr. L. Grime of the Toronto Office and Mr. L. Haberman of the Winnipeg Office, the Site Engineer, is acknowledged with appreciation. The success of the well point installation is due in part to the efforts of Mr. H. Ruddy and Mr. G. B. Wheeler of George W. Crothers Limited in Toronto.

The original soil report incorporating stability and settlement calculations was written by Mr. B. F. Welsh, while later computations were checked by Mr. J. J. Schoustra, both of Racey, MacCallum and Associates.

PROCESSING OF LOW-GRADE IRON ORE USING PETROLEUM AND NATURAL GAS

P. E. Cavanagh, *Vice-President,*
Premium Iron Ores Limited, Montreal, Que

THE NECESSARY foundation for industrializing any country is a basic steel industry. Canada is in the midst of changing from an agricultural to an industrial economy. The Canadian iron and steel industry has developed tremendously in the last twenty years, and will continue to do so.

The basic requirements for steel production are iron ore and metallurgical coke. The industrial heart of Canada lies in southern Ontario and Quebec. In this area, there was no Canadian iron ore, or Canadian metallurgical coke, available twenty years ago. The Dominion Steel & Coal Co. operations in Sydney, Nova Scotia, were based on local coal and iron ore from Newfoundland. Apart from this operation, all steel produced in Canada twenty years ago was made from imported American coal.

The recent discovery and exploitation of very large iron ore deposits in Canada has made available in Canada huge tonnages of iron ore. The production from presently operating Canadian iron ore mines is many times greater than can be utilized by the Canadian steel industry. Steel production in Canada is determined by the markets for steel in Canada which are dependent on the size of the population in Canada. The Canadian steel industry will grow vigorously as the population of this country grows. The excess iron ore, which can be produced above that useable in Canada, will be and should be exported from this country.

It is obvious that Canadian organizations should thoroughly investigate all possibilities of exporting Canadian iron ore in the most profitable form. If it is possible, profitably, to partially process iron ore to metal in Canada before export, this should be done. The primary requisite for such a plan is a market for the partially processed product. A second necessary factor in the study of such possibilities is the existence of commercially proven processes for producing metal from iron ores using fuels available in Canada.

New Technical Developments

Two major technological advances affect the present situation in Canada.

1) *Iron Ore Concentration.* It has been conclusively demonstrated on a very large commercial scale that low-grade iron ores of certain types can be ground, magnetically concentrated, agglomerated by sintering or pelletizing, and sold at a profit.

In the concentration of low-grade iron ores, there are several techniques in use for obtaining a rich, fine, concentrate of iron oxide. This fine material cannot be fed to the standard blast furnace, but must be agglomerated by sintering or pelletizing. These processes consist in heating the fine material to a point just below the fusion temperature, about 2,200°F. In the sintering process, a bed of fine material is fused into sinter which has the appearance of clinkers left after burning coal. In the pelletizing process, the fine concentrate is rolled into small balls and then heated.

There is no major application of oil or gas fuels in the sintering process except for ignition of the bed, which contains sufficient coke to support combustion.

In the pelletizing process, oil or gas can be used as a heating fuel. Fuel consumption in the pelletizing process ranges from about 500,000 B.t.u. per ton of pellets produced to a maximum of about 850,000 B.t.u.

The problem of concentration of magnetic low-grade ores which consist of magnetite crystals in waste rock, is relatively simple.

Where the iron oxide occurs wholly or partly as hematite, there are several methods of recovering the hematite. Probably the most dependable process is to convert the hematite to magnetite and then recover the iron oxide by magnetic separation. The feasibility of this procedure depends strongly on the price of available fuels. To heat the ore to reaction temperature of between 1,200°F and 1,500°F, and to provide suitable gas for reducing hematite to magnetite, requires the supply of between 450,000 B.t.u. and 1,500,000 B.t.u., depending on the type of fuel used and the process and equipment chosen to carry out this magnetizing roast.

2) *Direct Reduction.* It has been conclusively demonstrated on a large commercial scale that iron metal can be produced directly from iron ore without the use of metallurgical coke. Natural gas, oil, and electric power can be substituted for metallurgical coke. The resulting iron metal can be sold at a profit to steel making plants if the price of these fuels is sufficiently low. The market for such metal is small and uncertain at present.

Direct reduction of iron ore to metal is carried out by heating the iron ore, which is a mixture of oxides of iron, to a temperature of about 2,000°F and then contacting it with hot reducing gas. The reducing gas, which is carbon monoxide or hydrogen, or a mixture of the two, removes the oxygen from the iron oxides, leaving metallic iron. The rate of this reaction depends on several factors. The higher the temperature and pressure, the richer the reducing gas in carbon monoxide and hydrogen, the greater the rate of supply of gas to the ore, and the greater the surface area of ore exposed to the gas, the faster will be the speed of reaction.

A large number of direct reduction or sponge iron processes have been developed. Only a few of these have reached commercial production. The fuel requirements for the more interesting and practical of these processes are listed in Table I.

Reduction can be carried out at low temperature, in which case the metal is obtained in sponge form and is not melted. Alternatively, the process can be carried out at much higher temperatures, in which case molten metal is produced.

For true comparison of fuel requirements of the first type of process, the energy required to obtain metal in the same state must be determined. This means that, if solid sponge iron is produced, it should be melted and carried through to molten iron, which can be cast into pigs for true comparison to the fuel requirements for producing such products as pig iron from blast furnace.

In order to describe and compare the more interesting and commercially proven processes, they can be classified as follows:

Bases for Comparison of Processes

The processes to be considered can be classified as follows:

1. Standard Recognized Methods—blast furnace, electric pig iron furnace.
2. Commercially Proven Processes—HYL, R-N, Krupp-Renn, Tunnel Kiln.
3. Pilot Development — H-Iron, Strategic-Udy.
4. Initial Stages of Development—Jet-smelter, cyclosteel process, McDowell process, Esso-Little process, U.S. Steel Nulron process.

Plant and production costs for Class 1 processes are known and predictable on the basis of past performance of existing plants. Class 2 processes are sufficiently proven so that reliable plant cost estimates and production cost estimates can be made. Class 3 processes are under development and plant costs and production costs provided by the organizations concerned are not proven. Class 4 processes are not worth detailed economic studies at the present time, since no reliable plant costs or production costs can be provided.

Fuel Requirements

The major difference between the processes under study is in the type, amount, and cost of fuel and power required to carry out reduction of iron ore. For plants fed with the same grade of iron ore and making the same products, the only differences in production costs that are possible are due to differences in prices of suitable iron ores and of fuels and power. Differences in other items of cost of plant operation will make only minor differences in the final cost of the product.

Table I

Approximate Fuel Requirements of Processes Operating on 65% FE Pellets

NB—All processes producing cast pigs from molten metal. Melting of sponge iron in special electric arc furnaces required 400 KWH = 1,360,000 BTU

Process	*Type of Fuel and MM BTU Equivalent*				*BTU Consumption Millions*	
	Carbon	*Oil*	*Natural Gas*	*Electricity*	*Gross*	*Net**
Blast Furnace	20.3	—	—	0.03	20.3	14.5
Electric Pig Iron	13.0	—	—	7.6	20.6	16.0
Strategic-Udy Koppers	12.6	—	—	4.9	—	17.5
H-Iron—oil	—	20.0	—	1.92	—	22.0
—gas	—	—	16.24	1.8	—	18.0
Tunnel Kiln	17.5	3.3	—	1.66	22.4	21.0
H.Y.L.—oil	—	26.4	—	2.68	29.0	22.3
—gas	—	—	18.7	1.36	20.1	16.2

Descriptions of Processes

Only the essential features distinguishing processes from one another will be described.

A. Processes Producing Pig Iron

Blast Furnace—In the well known blast furnace, iron ore is charged to a large shaft furnace along with the required coke and limestone for smelting the ore and slagging off impurities. Molten metal may be cast into pigs of *pig iron* which has a high carbon content of over 3%.

Electric Pig Iron Furnace—The Tysland-Hole furnace is now a well proven and standard process with special application where electric power is low in price and the market to be satisfied is about 500 tons of iron per day. In effect, part of the coke used in the blast furnace is replaced by electrical energy to provide the required energy necessary to smelt iron ore in any furnace, or combination of furnaces. Less coke is therefore used per ton produced and this may be a weaker and poorer grade of coke because the bed of ore in the furnace is not nearly so deep as in the standard blast furnace. The molten metal produced is similar to the product from the blast furnace and can be cast into pigs of iron in the same way. The rich exhaust gas from the furnace can be used as fuel and credited to the smelting process.

B. Processes Producing Low Carbon Iron

Direct reduction processes produce sponge iron. In order to be easily marketable at a high price, it is recommended that sponge iron be melted in auxiliary furnaces to produce low carbon iron at under 1% carbon and then cast into small pigs of metal. This metal would contain less than .02% each of all other elements in the preferred specification. Such a high purity product cast into small pigs weighing 5 to 7 lb. has been christened *Canadian Iron.*

This product can be produced by melting sponge iron, if special electric arc melting furnaces are added to the plant and fed with sponge iron along with carbon and slagging additions to make a low carbon molten metal which could be tapped intermittently. No attempt is made in the furnace to refine the iron to make steel. The product is intended for remelting and refining in steel-making furnaces.

In cases where the sponge iron produced by the direct reduction process contains more than 5% silica, i.e., when pellets or ore are used, it is preferable to crush and grind and magnetically concentrate the sponge iron before melting. The preferred maximum silica content for sponge iron to be melted is 2%.

A special process under this classification is the Krupp-Renn rotary kiln process. The product is liquid metal which solidifies in small pellets and can be marketed in the form of low carbon iron nodules or luppen.

In this process, low-grade high-silica ore, which is not amenable to concentration by other methods, can be fed to the kiln along with fine coal and sufficient limestone to provide the special acid slag required for the process. The iron ore is reduced and the silica slagged off. The metal becomes liquid but the slag remains a thick, viscous mass in which the iron is suspended. When discharged from the kiln, the slag containing the luppen is crushed and the luppen recovered magnetically. Due to the reduction conditions in the Krupp-Renn kiln, the iron luppen are high in sulphur which enters the iron from the coal. Except in most unusual cases, the luppen cannot be considered as feed for steel-making furnaces, but are used as feed for blast furnaces. The intended application of the Krupp-Renn process is therefore as pyrometallurgical ore-dressing process for lean high-silica ore.

C. Processes Producing Iron Briquettes

Direct reduction processes produce sponge iron which can be crushed, if necessary, then ground and magnetically concentrated to produce a fine iron powder preferably containing at least 95% total iron and less than 1% silica. This fine iron powder with no binder added can be compressed in a hydraulic ram to produce briquettes of iron with a relatively high density of between 5 and 6. Fine carbon can be added to the iron powder before briquetting to give a desired carbon content in the resulting briquette.

D. Direct Reduction Processes Making Sponge Iron

As explained previously, it is not recommended that sponge iron be sold as produced but that it be further processed by briquetting or preferably by melting and casting into pigs.

HYL Process—This process has been in commercial operation for three years at Monterrey, Mexico, producing 200 tons per day of iron. The unit under construction will produce a further 500 tons per day of iron. Four reaction vessels are provided. This is a batch process. The vessel is loaded with iron ore, pellets or sinter, closed with a gas-tight top, and then hot gas is passed through it to raise it to reduction temperature and to begin reduction into metallic iron. After the initial stages of reduction, the flow of reducing gas is changed so that gas from the next vessel, which is now the primary reduction vessel, passes through the partially reduced ore. When reduction is complete, the gas flow is again changed so that fresh, cold, reducing gas enters the vessel which now contains hot sponge iron. The sensible heat in the sponge iron is used to pre-heat the reducing gas which goes to primary reduction. The fourth stage of the process consists of emptying the vessel of the batch of cold sponge iron and reloading it with fresh ore. With four vessels, each holding 105 tons of ore, production is 500 tons of metal per day when using a rich pellet.

Reducing gas is supplied in the present plants by reforming hot natural gas over a nickel catalyst with high pressure steam. A satisfactory reducing gas can also be made by partial combustion of naphtha with oxygen followed by reforming of the gas with steam. Provision of the required reducing gas from oil is considerably more expensive than the production of gas from natural gas at an equivalent price per million B.t.u.'s.

A 150,000-ton per year plant, with four vessels, is considered as a unit, since four vessels are necessary for an efficient cycle.

Wiberg-Soderfors Process — This direct reduction process has been in use for over fifteen years in Sweden in commercial production. There are now seven furnaces in operation, the largest of which produce about 50 tons per day of metallic iron. Rich lump iron ore, pellets, or sinter are fed into the top of a shaft furnace. The descending ore meets a rising current of reducing gas at a ratio of 2 carbon monoxide to 1 hydrogen. Hot gas entering the bottom of the shaft performs final reduction. Partway up the shaft, three-quarters of the gas is removed from the shaft and recycled through an electrically heated carburetor containing coke. The remainder of the gas continues on up the shaft to perform pre-reduction and preheating of the ore. The recycled gas is brought back up to reaction temperature and CO_2 and H_2O are converted back to carbon monoxide and hydrogen in the carburetor. This technically excellent method gives the lowest fuel consumption of any direct reduction process.

The process can also be operated by making the reducing gas by partial oxidation of fuel oil, followed by passing the resulting gases over a bed of hot coke. When this plan is followed, the real technical advantage of the Wiberg-Soderfors process is lost. The proper location of this process is in areas having very cheap electric power. The price of fuel oil would have to be extremely low to make the process economically feasible when based on fuel oil.

The R-N Process—This process has been developed by Republic Steel and National Lead Corporations and has been in pilot commercial operation in Alabama for over two years. Minus half inch or finer iron ore is fed to the kiln, along with coal having a controlled percentage of volatiles and limestone to pick up sulphur and phosphorus. The kiln is fired with gas or oil and there are air inlets along the length of the kiln to control combustion throughout the length of the kiln. Excellent control of gas composition and temperature is obtained. Temperature is sufficiently low so that no slagging or melting of the gangue or iron takes place. The discharged mixture of limestone, coke, and sponge iron is crushed and magnetically separated.

Coals with exactly the right specifications are rare so that in most cases it is necessary to provide a char plant to give a reactive char with the right percentage of volatiles.

Tunnel Kiln Process—This method is included mainly for comparative purposes and for future reference. The method of packing iron ore along with coke and limestone in a sealed ceramic container or *sagger* and then passing it through a brick kiln has been in successful commercial use for producing iron powder for many years. Although the plant cost is very low, the labour requirements are very high. When the plant is mechanized to cut down on labour requirements as at Oxelosund, Sweden, the plant cost is no longer very low.

H-Iron Process—Although this process is still in the early pilot development stage, it is included because it is designed to treat fine concentrates without pelletizing or sintering. The fine concentrate is fed to a pressurized vessel where a fluidized bed is maintained by a flow of reducing gas high in hydrogen at about 500 pounds per square inch and 900°F (480°C). The gas is recycled, water vapour removed, and fresh hydrogen added to the gas stream. Reducing gas may be produced from fuel oil by partial oxidation and subsequent treatment.

The first commercial unit for 50 tons per day of iron powder will be operating shortly at the plant of a certain steel company. It appears likely that the capacity of this plant which will produce iron powder will not be as high as it would be if it produced sponge iron. Operation of this unit should prove whether or not fine sponge iron can be produced from a fluidized bed of fine iron ore concentrates on a commercial scale.

Strategic-Udy-Koppers Process — This process, which is also an initial pilot operation, is a modification of the electric smelter technique. The exhaust gas arising from smelting of an ore-coke mixture is passed through a rotary kiln where it performs pre-reduction of the ore. The hot partially reduced ore is charged to a special type of electric smelting furnace. The entering charge is therefore at about 1,700°F (925°C) and is reduced to some desired extent. Power consumption in the electric smelting furnace is therefore less than in the standard electric smelting furnace. In addition, the furnace is not run with a submerged arc which results in somewhat different smelting conditions.

From experience with electric pig-iron furnaces in the past, it seems probable that the maximum degree of pre-reduction that will prove profitable and technically feasible is about 30% on a rich ore. This is estimated to give a power consumption of 1,400 kwh. per ton of iron, according to the company's own figures. On a lean ore, pre-reduction may be as high as 50% without undue technical difficulties or excessive cost in pre-reduction.

As stated before, the major differences between the processes studies lie in the fuel requirements. Table I shows the approximate fuel requirements of these processes when operated on 65% Fe pellets. Total heat requirements to produce a final produce in the form of cast pigs from molten metal are included. Compared on the basis of net B.t.u. consumption, the blast furnace provides a convenient yardstick while the net consumptions of the *Strategic-Udy Koppers* and *H-Iron* processes must be looked at as preliminary estimates based on the first stages of pilot operations.

It is interesting to compare the production costs of all these processes on the same basis and for the minimum profitable plant size.

Assuming that the same iron ore is used in all cases, and that the required plant to produce 150,000 tons per year of molten iron is provided in all cases, then the approximate cost of producing one gross (or metric) tons of iron will be:

1. Iron Ore Required	about $25.00
2. Fuel and Power—see Table I	—
3. *Cost of all other materials plus labour, supervision, repairs, and maintenance $19-21.50 (say)	$20.00
4. Capital charges, depreciation, etc. at 15% $10-12.00 (say)	$11.00
5. Cost of production above fuel cost	about $56.00

except in the case of the 300,000 ton per year blast furnace, where Item 3 will be approximately $12.00, and Item 5 about $48.00.

To this approximate cost, the local cost of the required quantity of fuel for the process as shown in Table I must be added to give the total production cost.

These costs are not meant to be exact, but are approximately correct. Even relatively major changes in the cost and quantities of the material and services required will not result in any major change in these processing costs. The only major variable in the total costs is the cost of suitable fuel.

The cost of sponge iron from the direct reduction processes will be about $20.00 below these costs for molten iron.

Conclusions

The cost of the required plant to produce molten iron from iron ore by any of these direct reduction methods is higher than the cost of a present day blast furnace operating in the cost efficient, modern, manner possible.

It is also evident that the cost per ton of molten iron made by any of these processes is higher than the cost of blast furnace pig iron when the blast furnace is located in a large market area where coal is relatively cheap.

Neither of these observations are at all surprising, but there has been a great deal of misunderstanding of the role and application of direct reduction processes, due to comparison of the production cost of sponge iron to the cost of pig iron. This is not a true or valid comparison.

The proper and profitable application of direct reduction processes is in locations where oil or gas are available at lower prices than the equivalent quantity of metallurgical coke, and where the market to be served is relatively small—at less than 1,000 tons of iron per day.

Although this condition exists in many locations in the world, the supplying of such markets under these conditions is, above all, today a Canadian problem of paramount importance.

At the present time, if rich ore, at more than 65% Fe, or an iron ore concentrate at more than 65% Fe, are available at a price of 20c per unit of iron or less and if oil or natural gas are available at 35c per million B.t.u. or less, a thorough investigation of the possibilities of direct reduction of iron ore is justified.

THE OIL AND GAS INDUSTRY

THE PETROLEUM industry may be divided into four generalized phases of operation: (1) exploration and production of crude oil and gas; (2) movement of crude materials to processing centres; (3) processing (refining) of oil and gas; (4) storage and distribution of refined products. Phases (2) and (4) involve the common factors of moving materials by pipeline or by ship, rail, and road tanker.

Instrumentation is essential to all these phases, but this article will deal particularly with the processing industry, which is among the leading users of advanced control instrumentation and recording equipment.

The specialized instruments used for the discovery and investigation of sub-surface formations, and for the logging of drilled wells are outside the scope of the present series of articles. At the other extreme of the industry, the distribution of products (except by pipeline) involves mainly conventional metering instruments.

Refining and pipeline operations will be dealt with separately.

PETROLEUM PROCESSING

The processing, or refining, of crude oil basically involves the physical and chemical separation, breakdown or synthesis of constituents to obtain the required end-products. Processes are mainly continuous and operate up to high temperatures and pressures. Furthermore, there is an increasing tendency towards the elimination of intermediate storage of products between different processes. There is thus a complex system of product streams between, for example, distillation, cracking, and reforming units, all of which must be fed at the right conditions of flow-rate, temperature, pressure, and level.

Instrumentation is therefore essential both to record and to control accurately the many process variables involved. Similar conditions prevail in the removal of impurities from natural gas in gas-processing plants, which also involve continuous chemical processes.

Reason for Instrument Installation

Though replies to a questionnaire on instrumentation in refining processes varied slightly in emphasis between individual companies, the main purpose of instruments is probably the control of process variables, with almost equal weight being given to improvement of quality, centralized supervision of operations, reduction of labour force, and economy of fuel consumption. This is to be expected, since the goal of a refinery is maximum quality with optimum efficiency, and hence an approach to completely automatic control, with a minimum of human intervention.

Uses of Instruments

As already outlined, instruments are needed in a refinery (or gas processing plant) to measure and control temperature, pressure, flow, and levels in vessels. Instruments are usually grouped in a central control room, though complex installations or those that have gradually been extended may have several control centres.

The transmission of signals from measuring instruments to the recording and control equipment is very widely done by pneumatic systems, but there is an increasing tendency to use electronic methods, which are becoming at least equally reliable and have better response and flexibility of application. This trend will probably be very marked in the future as transistor techniques are developed.

Electronic systems already have a point in their favour in Canada, particularly in the Montreal refining centre with its very cold winters, since pneumatic systems must be very carefully dried and lines frequently have to be steam or electrically traced for cold-weather operation.

Who Determines Requirements?

Replies to this question indicate that most companies with petroleum refining facilities determine their own instrument requirements, though in some cases the staff of an affiliated company may be involved. A petroleum refining company may depend on a research and development company within the overall organization for technical advice during the installation of new plant. At the same time, certain engineering companies specialize in the construction of refineries for the petroleum industry, and their advice on instrumentation may be used in some cases. Also, certain process units, such as catalytic cracking and reforming, are installed under licence from the company that developed them originally. Many specifications have to be followed closely, but there is latitude in the choice of the actual instrumentation used.

Who Buys the Instruments?

Practically all replies to this question showed that the engineering department is mainly responsible for specifying the types of instrument to be used and the source of their supply. Some of the individuals concerned may be members of the plant operating and maintenance departments. Even though the purchasing department may make the final order from a particular supplier, this is influenced by engineering recommendations.

• INSTRUMENTATION

Servicing systems

All respondents indicated that their own staffs are mainly responsible for servicing instruments, though a small proportion of service requirements may be met by independent contract or as required from outside sources. These are probably mainly concerned with specialized equipment.

Preventive Maintenance

Since continuity of operation, and particularly continuity of control of variables, are essential in the refinery the breakdown of components must be minimized. Consequently there is a tendency for most operators to use preventive maintenance programs for instruments. This is borne out by the replies to the questionnaire, though a few exceptions are recorded. Rather than repair a defect in an instrument, which may later develop a different fault, it is often preferable to remove complete units and overhaul them at leisure while replacing them with a standby unit. This is usually very convenient with electrical units which can be removed and plugged in quickly. Others, which cannot be removed without affecting the process, are maintained at regular plant shut-down periods or by pre-arrangement with operating staff if more frequent overhaul is indicated. The experience of several large operators indicates that preventive maintenance can reduce or eliminate unscheduled process interruptions, minimize replacement stocks, reduce costs, and distribute the maintenance work load evenly.

A large refinery adopted preventive maintenance for over 1450 instruments (including air regulators, large pressure gauges, etc.) at a cost of less than $500 for additional office equipment for keeping records, and carried out the program with five mechanics and a foreman. Clerical time was only six hours a week.

Spare Parts Practice

Preventive maintenance records usually indicate what spare parts are most likely to be required, so it was not unexpected to find that most companies keep a stock of spare parts based on experience. However, when starting without particular experience of certain instruments, the manufacturers' recommendations may be followed for an initial period. This does not mean that the makers' suggestions are frequently changed, since experienced refinery personnel often collaborate closely with the instrument manufacturers in the development of equipment best suited for process plant conditions.

Standard or Special Instruments

Partly because of the co-operation between operators and instrument makers, there exists a wide range of standard equipment for refining processes, and probably the great majority of instruments specified are standard models. However, experience or special requirements may call for units built to a company's own specifications or modified from standard. This specialization could possibly increase as research and development investigations into advanced process control produce new ideas in instruments. However, in the long run, the prototype special instrument of today will become another standard for the refineries of the future.

All companies who replied to the questionnaire buy their own instruments outright.

Statistics on Instrument Usage

Nearly 90 per cent of the respondents gave figures for capital investment in instrumentation. Of these, about 40 per cent indicated over $500,000, the same proportion in the range $100,000 to $500,000, and the remainder in the range $25,000 to $100,000. The same percentage of replies about capital investment in instruments during the past five years showed a range from $20,000 to $1,-500,000, the second highest reported figure being $1,250,000. Only slightly more than one-third of the companies gave figure for annual maintenance costs, and these ranged from $30,000 to $100,000.

The figures could be taken to indicate that investments in instrumentation are high in this section of the industry, but that maintenance can be relatively economical. It should be remembered that, although total refining capacity in Canada has increased rapidly in recent years, major capital investment in new or extended facilities by individual companies is not usually on a regular annual basis, but consists of a series of large steps taken over several years. Thus, a company that had no major refinery expansion in, say, five years might show a low capital investment in instruments during the period (for replacement and minor modifications), whereas another company with a smaller total investment in facilities could show a much higher investment in instruments in the corresponding period because it had added large new facilities.

PIPELINES

Although pipeline operations were not covered by the present questionnaire, they rely considerably on instruments and controls. There are now nearly 20,000 miles of main lines for transmission of oil, gas, and products across the country, with an additional 45 per cent expansion announced for the foreseeable future. This does not include the many smaller feeder lines in the fields and the rapidly growing network of gas distribution lines from main arteries to many communities.

Microwave radio provides multichannel communications for control and supervision of long lines from central dispatch points. Automatic flow-control systems, using feedback amplifier principles, are used to control unattended pumping stations. Details of products, levels, flows, motor loads, and many other variables are telemetered to control centres where they are indicated or recorded. Motors, pumps, valves, and other equipment are remotely operated and controlled from the supervisory centres.

ADVANCED CONTROL

The ultimate goal in both pipeline and processing operations is computer control. Computers have already been used for pipeline feasibility studies and the determination of optimum pipe sizes. Eventually, computers may be used for integrated control of pipeline systems.

In processing operations, one aim is to have a computer determine and maintain optimum conditions, through controls, taking into account factors such as catalyst deterioration.

Before these goals are satisfactorily reached, much remains to be done in the improvement of accuracy and sensitivity of instruments for measuring both physical and chemical variables. At present these are the limiting factors in the development of control.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

H. R. H. THE PRINCE PHILIP, HON. M.E.I.C ADDRESSES SCIENTISTS AND ENGINEERS

H.R.H. The Prince Philip spoke to scientists and engineers at a luncheon held in Toronto on June 29, 1959

I would like to say how much I appreciate your invitation to address you today. It would have been more appropriate, I think, if you had addressed me. Every now and then I get invitations of this sort and while I consider them a great honour I always try and get out of them in order to avoid the labour of trying to concoct something sensible to say. The course between platitudes and controversy is a rocky one, as most people who speak in public very soon find out.

However, in this particular case things are a little bit different because I think it's about time some more was said about the very solid and spectacular developments and achievements which have taken place in Canada in recent years.

There is hardly any field of science, engineering or technology in which Canada cannot show some outstanding example. Canadian medical and nuclear scientists have done and are still doing work out of all proportion to the numbers of people involved. The aeronautical engineers have fully lived up to the early courage and ingenuity of their predecessors who designed and built and Mr. McCurdy who flew the Silver Dart fifty years ago. I don't suppose any country in the world has made such phenomenal progress in the development of their natural resources, or taken such trouble to try and make the new towns which will provide the work people for these developments into satisfactory human communities.

Perhaps the most dazzling achievement of all is the cause of our present visit to Canada — the completion of the St. Lawrence Seaway for ocean going ships. There is much more to this than the very considerable engineering accomplishment. I think this project demonstrates the tenacity and strength of purpose of the Canadian character. Years of delay and frustration never discouraged and never deflected the purpose of those people who had the vision and the ambition to connect the centre of this continent to the oceans which are the commercial highways of the world.

Canada and the Commonwealth

It is this combination of technical ability with the qualities of foresight and enthusiasm which has made all these things possible. It is characteristic therefore that far from being content with commercial success at home, Canada also accepts her responsibilities as a member of the British Commonwealth of Nations.

In Feburary of this year I visited an undertaking of quite exceptional interest. At a place called Warsak in the North West Frontier Province of Pakistan a party of 150 Canadians are helping their fellow members of the Commonwealth to construct a dam 235 ft. high and 750 ft. long — a power station to produce 240,000 Kw and an irrigation system for 120,000 acres on the Kabul river. The project was initiated under the Colombo Plan and apart from the practical help in the way of technicians and experts Canada is also contributing some fifty million dollars to the project.

This is only one example in the growing pattern of inter-Commonwealth co-operation and help. It has long been recognized that the wealthy individual has a moral obligation to help those less fortunate than himself. In case this obligation should ever be forgotten most governments have established a system of taxes as a reminder.

Obligations between Nations

The same obligation is now recognized to exist between nations. It is recognized that an explosive situation will inevitably develop if the gap between the 'have' nations and the 'have-not' nations grows too big. At the moment international taxation is confined to supporting international agencies. The major work of direct assistance is done by the voluntary contribution of individual governments both in cash or in kind. Cash by itself is seldom enough. Know-how, technical skill, and experienced scientists and engineers are the means by which the well-off can help the less well-off.

But one thing further is necessary if this sort of help and co-operation is to be really effective and this point is made very clearly in the Koran where it is said "Verily, God Almighty does not improve the condition of people unless they themselves strive for it". From what I saw in Pakistan they are striving for it with a whole heart.

Looked at this way the project at Warsak is much more important than the purely civil engineering undertaking. Its real value lies in the fact that it is in essence a civil and electrical engineering university. The project is in fact providing courses of instruction for every one of the 8,000 men employed, from truck drivers to engineers, from plant managers to designers. The total value of this Canadian contribution to the improvement of conditions in Pakistan is impossible to calculate and it is certainly very much greater than the cost in pure money to Canada.

I know perfectly well that there are wonderful opportunities here, I know that there are any number of projects waiting to be tackled but it is worth remembering that the same is true of the underdeveloped countries of the world. The gap between the 'haves' and the 'have-nots' will steadily widen with catastrophic results unless the more fortunate nations singly and in co-operation make a real attempt to bring them along the path to a higher standard of living.

Many people pay lip service to the ideals of better international relations and many people seem to think that this can be achieved simply by talking. In fact much more is achieved by nations working together to complete solid, practical projects for the benefit of those who most need it. Warsak is the most convincing proof of this fact and therefore it is my hope that we shall see many more Warsaks in the years ahead.

Mr. Chairman, I am most grateful for the opportunity to pay tribute to Canadian science and engineering. I wish you every success in your future undertakings.

South Saskatchewan River Project

Everything involved in the construction of the South Saskatchewan River Project is big. The dam will be the largest rolled-earth fill dam of its kind in Canada and one of the larger ones in the world. It will rise above the present floor of the river 210 feet and will stretch across the river valley for a distance of almost three miles.

The diversion works associated with the dam to contain the flow of the river while the main fill is under construction, consist of five tunnels, twenty feet in diameter and averaging 4050 feet in length. After the dam is completed these tunnels will be converted so that they can be used to deliver water to the power generating station and to regulate the flows in the river below the dam.

The spillway location utilizes a natural depression created by Coteau Creek which flows in the South Saskatchewan River just below the main fill. The overall length of the spillway will be 17,000 feet of which 8,000 will be approach channel, 3,800 feet concrete control structure and 6,000 feet exit channel. The spillway will have a discharge capacity of 265,000 cubic feet of water per second to take care of any future flood conditions that might be expected to occur.

An auxiliary earth dam will be built at the divide between the Qu'Appelle Valley and Aiktow Creek which flows into the South Saskatchewan River, to control the flow of water from the main reservoir in the Qu'Appelle Valley. This will involve the building of a dam 90 feet high, 9,000 feet long and 700 feet wide at the base.

Construction: Ten contracts, totalling approximately 6¼ million dollars were awarded from October, 1958 to June 1, 1959. Tenders for the con-

• **Canadian Developments**

struction of Embankment, Stage 2 closed recently and the contract was awarded to Piggott Construction Co. Ltd., in the amount of $6,983,437.50. This brings the total of all contracts to approximately 13 million dollars.

The following summary outlines the construction activity on the South Saskatchewan River Project to June 1, 1959.

Access Roads: Two contracts totalling $341,149.60 were awarded to cover the construction of two access roads referred to as the east and north access roads. The east access road includes approximately twelve and one-half miles of road from Provincial Highway 19 to the damsite, while the north access road covers approximately sixteen miles of road extending from Provincial Highway 15 to the damsite and including access roads to the site.

Construction work on the East Access Road was started on September 5, 1958 and was completed early in 1959 by Evans Construction Co. Ltd., Saskatoon. Taylor Brothers of Regina started construction of the North Access Road in April. Progress has been satisfactory and approximately 50 per cent of the contract is complete.

Processing Aggregate: Work on this contract in the amount of $812,030.00 covering the production of six hundred and twenty-one thousand tons of concrete aggregate had not started. The contractor, McNamara Limited of Edmonton, Alberta, is actively employed setting up and testing the processing plant. Stripping of the stockpile area has been completed and it was expected that the processing plant would be in operation by June 15.

Headquarters Services and Buildings: Four contracts amounting to approximately $1,000,000 have been awarded for the purpose of providing Headquarters Services and Buildings. In general this work includes the construction of water, sewer and street systems, a well-point water supply system; and a pumping plant with appurtenant equipment to serve the construction headquarters. The contract for the headquarters buildings calls for the construction of forty housing units and five headquarters buildings.

Construction work was started on the headquarters buildings by Smith Bros. and Wilson of Regina, Saskatchewan, during December 1958. It is now estimated to be 95 per cent complete. Construction of services is being carried out by Beattie Ramsay Construction Company of Regina and work is progressing satisfactorily.

Construction Bridge: The construction of this bridge was divided into two separate contracts, namely the bridge substructure and bridge superstructure, totalling $1,285,225. The contract for the substructure was awarded to Foundation Company of Canada Limited, and called for the construction of four river piers and an abutment structure. The work has now been completed.

Bird Construction Company Limited were the successful bidders for the bridge superstructure which covers the supply and placing of structural steel, concrete deck and approach abutments. Completion date is scheduled for March 15, 1960.

Embankment, Stage I: This contract in the amount of $2,941,380. covers the construction of the embankment at the east abutment to elevation

1750 feet and involves approximately 8,000,000 cubic yards of material. Perini Limited of Toronto, Ontario, was the successful bidder and work commenced on March 25, 1959. The contract calls for this work to be complete by August 1, 1960. To date satisfactory progress has been made which consists mainly of stripping borrow and foundation areas, irrigating borrow pits and placing of compacted embankment.

Embankment, Stage II: This contract in the amount of $6,983,957.50 covers the construction of the embankment at the west abutment and involves approximately 18,000,000 cubic yards of material. Tenders closed on May 28, 1959 and the contract has been awarded to Piggott Construction Limited of Saskatoon.

Manitoba Flood Control Projects

Manitoba government engineers have started surveying alternate inlet locations for the 26-mile long Greater Winnipeg floodway designed to eliminate flood damage in the metropolitan area.

The $60-million project was one of several recommended by the Royal Commission on Flood Cost-Benefit. The other projects recommended, and now being studied by the government, include:

— A dam on the Assiniboine river near Russell

— A dam on the Assiniboine river near Holland

— A diversion from the Assiniboine river into lake Manitoba leaving the river near Portage la Prairie.

The Holland dam is being considered as a possible alternative to the Portage diversion.

Built in combination the flood control projects would almost completely eliminate flood damage in the Red and Assiniboine river valleys but not in the Upper Red River valley in the province. Further study will be given to control projects for this area.

Greater Winnipeg Floodway. The proposed floodway will have a capacity of 60,000 c.f.s. It will have a channel base width of 500 feet with slopes varying from six to one in clay areas to three to one in sand and gravel areas. The average depth will be about 35 feet but will vary along the course of the floodway from 24 to 67 feet. The plans call for acquisition of sufficient land to permit the excavated material to be deposited in a spoil bank on either side of the floodway.

A control structure will be required just below the floodway inlet on the Red River and an adjoining dike will have to be built running westward. Deposited material will provide a similar dike east of the river on the side of the floodway nearer the city. This dike and control structure will make it possible to raise the floodwater elevation upstream from the floodway and thus increase the flow through the floodway.

At the floodway's outlet a drop structure will be provided to discharge the flow in the floodway to the lower river elevation without causing erosion. The Seine river will be diverted permanently into the floodway.

In addition to these control structures there will have to be several highway and railroad bridge crossings as well as a crossing over the Greater Winnipeg aqueduct.

Russell Dam. This proposed dam costing $6.5-million, will be an earth-fill type with a concrete spillway, with top length of 3,600 feet and height of 78 feet above river bed.

The reservoir will extend upstream 56 miles from the dam and have a full surface area of 22,000 acres, a capacity of 450,000 acre-feet at spillway level and a full design level of 600,000 acre-feet. This reservoir would allow cutting off a flow of 15,000 c.f.s. for a 20-day period, in the Assiniboine. It would be of value in conserving water in dry years.

Portage Diversion. The proposed 18-mile long channel would leave the Assiniboine river, near Portage and run generally northward into Lake Manitoba. It would be a combination open channel and diked floodway, with a designed capacity of 25,000 c.f.s. The estimated cost would be $8,750,000.

An earth-fill and concrete control structure would be required in the Assiniboine river, and a concrete weir at the inlet of the floodway, and several drop structures along the course.

The weir would make it possible to keep water out of the channel when the natural flow of the river was less than 10,000 c.f.s. But when flood conditions existed in Greater Winnipeg a control dam across the river would make it possible to divert the complete flow on the Assiniboine into the diversion channel until the capacity of the diversion was reached. Beyond that point the gates on the dam would be lowered to maintain a constant capacity flow in the diversion channel.

Hand in hand with the proposed diversion is a project designed to regulate the level on Lake Manitoba. The Fairford river enlargement plan will allow water to be drained into Lake Manitoba from the Assiniboine river without causing unduly high water on the lake. It would consist of enlarging the existing Fairford river outlet channel to allow greater flows out of the lake during heavy inflow periods. A control structure in this channel would help maintain a satisfactory minimum elevation during periods of low inflow. The estimated cost of this enlargement will be about $1½-million.

Holland Dam. The Holland dam is still under investigation as a possible alternative to the Portage diversion. Its contemplated capacity could be two or three times that of the Russell dam but the practical design capacity is dependent on the results of the foundation investigation presently underway.

The Royal Commission also considered the possibility of widening, deepening and straightening the existing Red River as an alternative flood control measure. But to provide the same measure of protection as will be afforded by the floodway this kind of work would cost about $132-million — more than double the cost of the diversion.

The three major flood control projects on the Red and Assiniboine rivers are designed to provide protection to Greater Winnipeg for floods up to 169,000 c.f.s. below the confluence of the two rivers.

University News

University of Toronto

A new engineering course will be started at the University of Toronto in the autumn. It will be called Industrial Engineering, and is expected to meet a growing demand.

Those taking the course will study certain aspects of the various traditional branches of engineering and then concentrate on applied mathematics as their field of specialization.

A three year study of the course in Engineering and Business has brought a decision to discontinue it. Students desiring this training are advised to enrol in one of the conventional engineering courses and then to invest two additional years doing graduate work in business administration.

INTERNATIONAL NEWS

SWEDEN

A LARGE NEW SHIPYARD will be completed in 1962, at Gothenburg, the first clearing blasts having been made in March of this year.

Planned for "indoor" building of ships up to 100,000 tons on the assembly line principle, and featuring a series of advanced technical systems, the yard is being constructed by the Götaverken shipbuilders. Its annual capacity is planned at about 200,000 tons d.w., and it is estimated that building time for a 40,000 ton tanker will be reduced to 20 weeks. The aim is modernization of the shipyard's facilities, and the cost will be $30 million.

Starting from the completely mechanized plate yard at the far end of the plant, the material will proceed on roller lanes to plate and profiling workshops, welding shops and further on to the large assembly hall. Here the hull, stern first, is assembled in sections weighing up to 200 tons. Gradually, as new sections are added, the hull moves on rollers into one of the open-air building docks, each measuring 300 by 46 by 10.6 metres, where installation of machinery and other equipment is performed from dockside plants. The ship would be completed and ready for her trial run only two weeks after the prow has left the assembly hall —where the stern section for the next ship can immediately be put on the roller lane. The dock is filled with water and the finished ship is simply towed out.

The large width of the building docks, 46 m. will make it possible to build two 20,000 ton tankers simultaneously in the same dock. This ensures efficient use of the production facilities.

A NEW PULP QUALITY for papermaking, produced by a novel process pioneered by Stora Kopparberg, has been launched on the market. Known as "Stora 59", it is a bleached sulphite pulp made from pine wood. The principle of the process is that the wood is cooked in two stages, each with definitely different pH conditions. In the first stage the wood is impregnated and partly sulphonated with an almost neutral cooking liquid, while in the second stage the removal of the lignin is performed under acid conditions.

In order to obtain a highly soluble bisulphite, a sodium-base was chosen, as it makes for less hydrolytic destruction of the valuable hemicellulose components in comparison with the conventional sulphite process. Furthermore, it makes possible the grading of the quality characteristics of the pulp over a much wider range.

Confederation Ballot

Ballots were mailed to 10,835 corporate members whose fees were recorded as "paid" at close of business, June 4, 1959.

The ballot was closed at 5:00 P.M. July 3rd and the results recorded by the scrutineers are as follows:—

"Yes" votes	3,628
"No" votes	192
Spoiled ballots	2
Unidentified	15
Total	3,837

Miss May McLaren Retires

E.I.C. Staff Pays Tribute

The E.I.C. staff held a farewell dinner for May McLaren on June 30. This was the day on which Miss McLaren's many years of service with the Institute were completed, with her retirement.

The whole staff took part in this tribute to a co-worker whom they have loved and admired. But, remarkably, for all the implications of sadness the dinner turned out to be a gay affair, a good party for a really grand person.

For there was no prospect of inactivity for Miss McLaren. She was starting out almost immediately on a month-long trip to San Francisco, Los Angeles, and the Grand Canyon. And there were suggestions of absorbing activities, also, after her trip.

General Secretary Garnet Page started the very informal after dinner talk with a toast to the guest of honour. Dr. Austin Wright was present, and being the person best able to tell the story of May McLaren's long and important service to the E.I.C. he did this effectively. People close to Institute work have known or guessed how deeply she was involved. But, largely unknown to the membership, her unfailing assistance to the general secretary made many projects possible. Dr. Wright mentioned some of the projects on which her help had been invaluable—over and above a large share of responsibility for the routine of the Institute operations, and for the welfare of the staff.

The staff presented two gifts to May: a clock-radio which they hoped would entertain and please, and a purse of money which they asked her to use according to her own inclination.

Miss McLaren (left) received her gift from friend and co-worker Miss Maudie Abraham, of headquarters.

Miss McLaren gave a talk that was really entertaining. She spoke about the four general secretaries she had worked with, the many friends she had made among the members and their wives, and the travelling she had enjoyed.

ASME-E.I.C., Calgary

Calgary, Alberta was chosen as the location of the June meeting of the Boiler and Pressure Vessel Committee of the American Society of Mechanical Engineers. It was held on June 1-3, 1959, with headquarters in the Palliser Hotel.

The Calgary Branch of the Engineering Institute sponsored this meeting on one of the very few occasions when the ASME Committee of some 80 members has held its regional meeting in Canada.

The purpose of these meetings is to hear and consider suggested changes in the ASME Code, and to discuss and interpret specific cases. The agenda included meetings of sub-committees on non-destructive testing, on welding, on power boilers, on heating boilers and on unfired pressure vessels, as well as the main committee on boiler and pressure vessels. Among the decisions reached was one permitting wider use of castings in nuclear reactors covered by the Boiler and Pressure Vessel Code. If confirmed by letter ballot, the ruling will be issued in the near future.

It was an extremely successful session. The Canadians offered their guests many social events, including a western barbeque and entertainment, sponsored by the province, the Calgary Branch of the Institute of Power Engineers and the ASME.

Planning and arrangements for the program were carried out by P. S. Grant, M.E.I.C., and Neil Carr, M.E.I.C., chairman and vice-chairman of the committee on arrangements, and Gerald Coughlin, president of the Calgary Branch of the Institute of Power Engineers.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on June 7, 1959.

Member: S. G. Beckett, Toronto; H. R. Brand, Jamaica; P. W. Breithaupt, Toronto; G. R. Cook, Niagara Falls; K. J. Lee, Toronto; A. F. Provenzano, Vernon; R. G. Regimbal, Copper Cliff; K. G. Richardson, Toronto; H. K. Sandlos, Sarnia; T. Smith, Sarnia; J. W. Wilde, Toronto.

Junior: N. F. Budgen, Winnipeg; T. J. Flint, Sarnia; W. H. Harley, Toronto; P. G. R. M. Waddell, Ottawa.

Affiliate: C. G. Lenihan, Vancouver.

Junior to Member: D. E. Morrison, Toronto; R. J. Nesbitt, Lauzon; R. W. Rogers, New Westminster.

STUDENTS ADMITTED

University of Toronto: P. J. O'Higgins, A. H. Tilt, J. A. Underwood.

University of Alberta: D. J. Winkel.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Member: R. D. Meeres; **Junior to Member:** A. G. Swanson; **Student to Junior:** W. N. Hasegawa.

NOVA SCOTIA

Members: A. F. Goodwin, J. J. Hernon, G. R. Oulton, J. F. Vajda; **Junior to Member:** G. E. J. Blaiklock, D. C. Menchions, J. R. Soy.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Abstracted from the *Bulletin* of the CPEQ, May, 1959.

The Annual General Meeting

The 1959 annual general meeting of the Corporation was very well attended: about 150 members were at the morning session and attendance rose close to 300 in the afternoon.

Committee Reports

As announced previously, a morning session was held this year for the exclusive purpose of discussing the reports submitted by the various Corporation Committees. These reports were received but held for discusion at a forthcoming meeting of Council.

In connection with the report of the Remuneration Committee, some explanations were provided on the background of the Report on Salaries. It was reported that the figures quoted in the Report were obtained through a survey in which twenty-eight Quebec firms and some sixty-five Ontario firms participated. The figures shown in the Report were representative of salaries actually paid by these firms.

The Report of the Committee on the Advancement of the Employee Engineer drew much interest. It was reported that the Committee had produced a form of employment agreement for possible use as a guide to individual engineers and had recommended to Council that this form be made available to the membership. It was pointed out, however, that the Committee did not find it appropriate at this time to recommend that the use of written agreements be encouraged by the Corporation. Council agreed with these views and a form of agreement prepared by the Committee is to be made available as soon as it is reviewed by the legal adviser.

The Committee on Consulting Practice recommended in its report that Consulting Engineers be treated as a distinct group in the Code of Ethics and also that the title "Consulting Engineer" be defined either in the Act, By-Laws or Code of Ethics. A revision of the Tariff of Minimum Fees was also recommended by the Committee.

Regular Business

In the afternoon session, Council's Report for 1958 as distributed to the membership in printed form was discussed and approved. Likewise, the Treasurer's report appearing as an appendix to Council's Report was approved.

Some members commented on the fact that eligibility to our Group Life Insurance Plan is restricted to members below age 60. It was felt that there should be a higher age limit so that older members may join the plan. It was pointed out, however, that premiums at all ages would have to be raised substantially if the age limit were extended.

ALBERTA

Annual Meeting—Committee Reports

Abstracted from *The Alberta Professional Engineer*, June 1959.

Giving the Chair to C. A. Stollery (the Vice-President) Dr. G. W. Govier, in his capacity of Chairman of the Acts and By-Laws Committee, outlined the work that his committee had done, and indicated in detail the changes in the wording of the Act that had been approved by Council. These changes allowed for the separate designations of Engineers, Geologists and Geophysicists (Council had rejected the suggestion that Scientists be registered). An "eminent persons" clause, accepted by Council by a majority of one, was the subject of some discussion, and the clause was rejected by a vote of 62 to 42. The amended Act will go before Legislature next session.

Reports from Committees on Counselling and Education, Discipline, Enforcement, and Consulting Practice, were unanimously approved.

The Public Relations Committee report was presented by Mr. J. Longworth, who described to members the aims of his Committee: to promote, both inside and outside the Association, pride in and recognition of the Association's work. The Committee, to this end, had formulated a ceremony for the presentation of membership certificates (the first ceremony was held in Edmonton on January 23, 1959), had instituted a new and improved seal, and had distributed copies of the new information booklet "The Engineer and His Profession." Liaison with University students continued through the annual luncheon held this year on March 21 and, with the approval of Council, arrangements were to be made to present meritorious high school students with slide rules. Association news and opinions had been transmitted to reading members by the five published copies of The Alberta Professional Engineer. Mr. Longworth concluded by expressing his appreciation of the Association's Public Relations Counsel, McConnell-Eastman Ltd.

In his Committee's report on Engineer's salaries, the Chairman Mr. T. D. Stanley indicated that the small number of replies to the questionnaires (barely over 50%) seemed to imply that members were perhaps not very interested in the survey. Mr. Stanley endorsed the new Salaries booklet and felt sure that the membership would approve of it. He also presented curves indicating the results of the earnings' survey.

The report from the Special Committee on Mechanical Engineering at the University of Alberta was happily introduced by Dr. Govier, who told the meeting that the establishment of a degree course in Mechanical Engineering had just been announced by the University President, Dr. W. H. Johns. The meeting applauded this news and the appointment of Dr. George Ford as Department head.

MANITOBA

Record Attendance at Annual Dance

Four hundred and seventy-eight people, the largest turn-out ever, attended the Association's Annual Banquet and Dance at the Royal Alexandra Hotel. From the opening cocktail party through the banquet and on to the dancing, the large crowd enjoyed themselves thoroughly.

All branches of the profession were well represented with large groups coming from the Manitoba Civil Service, the Manitoba Hydro-Electric Board, the construction industry and the consulting fields. President Les Wardrop hosted members of his firm at the gathering.

Councillor, R. E. Chant, P.Eng.

The election of Professor R. E. Chant to the Association Council at the annual meeting adds another chapter to the very colorful career of one of the well-known members.

First Lady Engineer

At the last session, the Provincial council unanimously concurred to accept Mrs. E. Kuiper (nee Minka Van der Schaaf) into the Association. This is the first time in the history of the provincial organization that a lady has been admitted as a member. This welcome precedent could not have been set by a more charming lady.

Mr. Edward Kuiper, her husband, is a well known member of our Association. They have five children who were born in three different countries.

Personals

Dr. R. L. Hearn, M.E.I.C. (Toronto, '13) has been appointed deputy chairman of the board of British Newfoundland Corporation Limited in Montreal.

Robert J. Askin, M.E.I.C. (Queen's '23) of Abitibi Power & Paper Company, Limited has been appointed executive vice-president (development, engineering and services) for the company in Toronto.

M. Neil Hay, M.E.I.C. (Queen's '23) works manager of the Aluminum Company of Canada Limited, Kingston, Ontario, has retired after many years of service with the company.

E. R. Smallhorn, M.E.I.C., (McGill, '23), consulting engineer, has been elected mayor of Senneville, Que.

M. S. Fotheringham, M.E.I.C., (Toronto '31), was awarded the International Nickel Company of Canada, Limited, platinum medal during the annual dinner of the Canadian Institute of Mining and Metallurgy in April. Mr. Fotheringham is president and general manager of Steep Rock Iron Mines, Limited, and vice-president and director of Premium Iron Ores Limited.

D. O. D. Ramsdale, M.E.I.C., (McGill '33), manager of transformer department, English Electric Co. of Canada Ltd., was elected chairman of the Niagara Peninsula Branch of the Institute, at the Branch annual meeting.

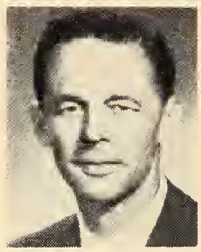
Robert J. Askin, M.E.I.C.

D. O. D. Ramsdale, M.E.I.C.

A. H. Pask, M.E.I.C. (Manitoba, '35) has been appointed chief engineer with the Greater Winnipeg Gas Company.

F. W. Cranston, M.E.I.C., (Queen's '36) has been appointed a vice-president of Babcock-Wilcox and Goldie-McCulloch Limited, and will retain responsibilities related to his present position as general sales manager. An incorrect reference to this appointment was made in the June issue of the *Journal*, for which the editors sincerely apologize.

W. O. Horwood, M.E.I.C. (McGill, '37) of International Equipment Company Limited is the general sales manager for the company's Montreal office.



W. O. Horwood, M.E.I.C.

William S. Allen, M.E.I.C.

Dr. G. G. Meyerhof, M.E.I.C. (London, '38) has accepted an invitation by the National Research Council of Canada to become a member of the Council's Associate Committee on Soil and Snow Mechanics. He is head of the department of civil engineering, Nova Scotia Technical College, Halifax, N.S.

F. A. Davis, M.E.I.C. (Queen's, '40) of Foundation of Canada Engineering Corporation Limited is division engineer with the petroleum and petroleum chemical division in Toronto.

William S. Allen, M.E.I.C (Queen's '43) has been elected to the board of directors of Racey, MacCallum and Associates Limited, Montreal. He is executive engineer, Toronto division.

E. F. J. Clark, M.E.I.C. (Toronto, '47) has recently been made manager of the Toronto sales office of Canada Cement Company, Limited.

J. Brown, M.E.I.C. of Dominion Structural Steel Limited, Toronto, has been appointed assistant to the president.

H. J. T. Patterson, M.E.I.C. (McGill, '48) has been appointed Montreal district sales manager for the Dominion Structural Steel Limited.

C. Peter Jones, M.E.I.C., (British Columbia '48), partner in the firm of Read, Jones, Christoffersen, Vancouver, is the chairman of the Vancouver Branch of the Institute, having been elected at the recent annual meeting.

A. G. Watt, M.E.I.C., has been appointed manager of the structural division of the Saint John Dry Dock Co. Ltd., East Saint John, N.B.

H. J. T. Patterson, M.E.I.C.

C. Peter Jones, M.E.I.C.

Rear Admiral (E) Brian Roff Spencer, M.E.I.C., chief of Naval Technical Services, (R.N. Engr. College, England, '49) has been appointed to the board of directors of Canadian Arsenals Limited.

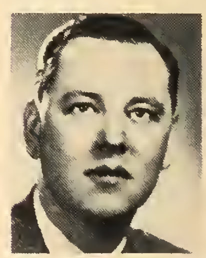
R. Kenneth Robertson, M.E.I.C. (McGill, '49) is the general manager of the Quebec division of Cooksville-Laprairie Brick Limited.

W. E. Dowbiggin, M.E.I.C. (McGill, '50) has recently been appointed manager, gas products, of Linde Company in Alberta.

D. McNicol Lowe, M.E.I.C. has been appointed resident engineer for Foundation of Canada Engineering Corporation Ltd. on the St. John's harbour improvement project at St. John's, Newfoundland.

Kaljo Tammik, M.E.I.C. (Sweden, '57), formerly of London, Ontario, is now assistant to general manager with Walsh Canadian Construction Company Limited in Montreal.

Gordon F. Coates, JR.E.I.C. (Alberta, '48) has been appointed manager of the highway division, Mannix Company Limited, Calgary.



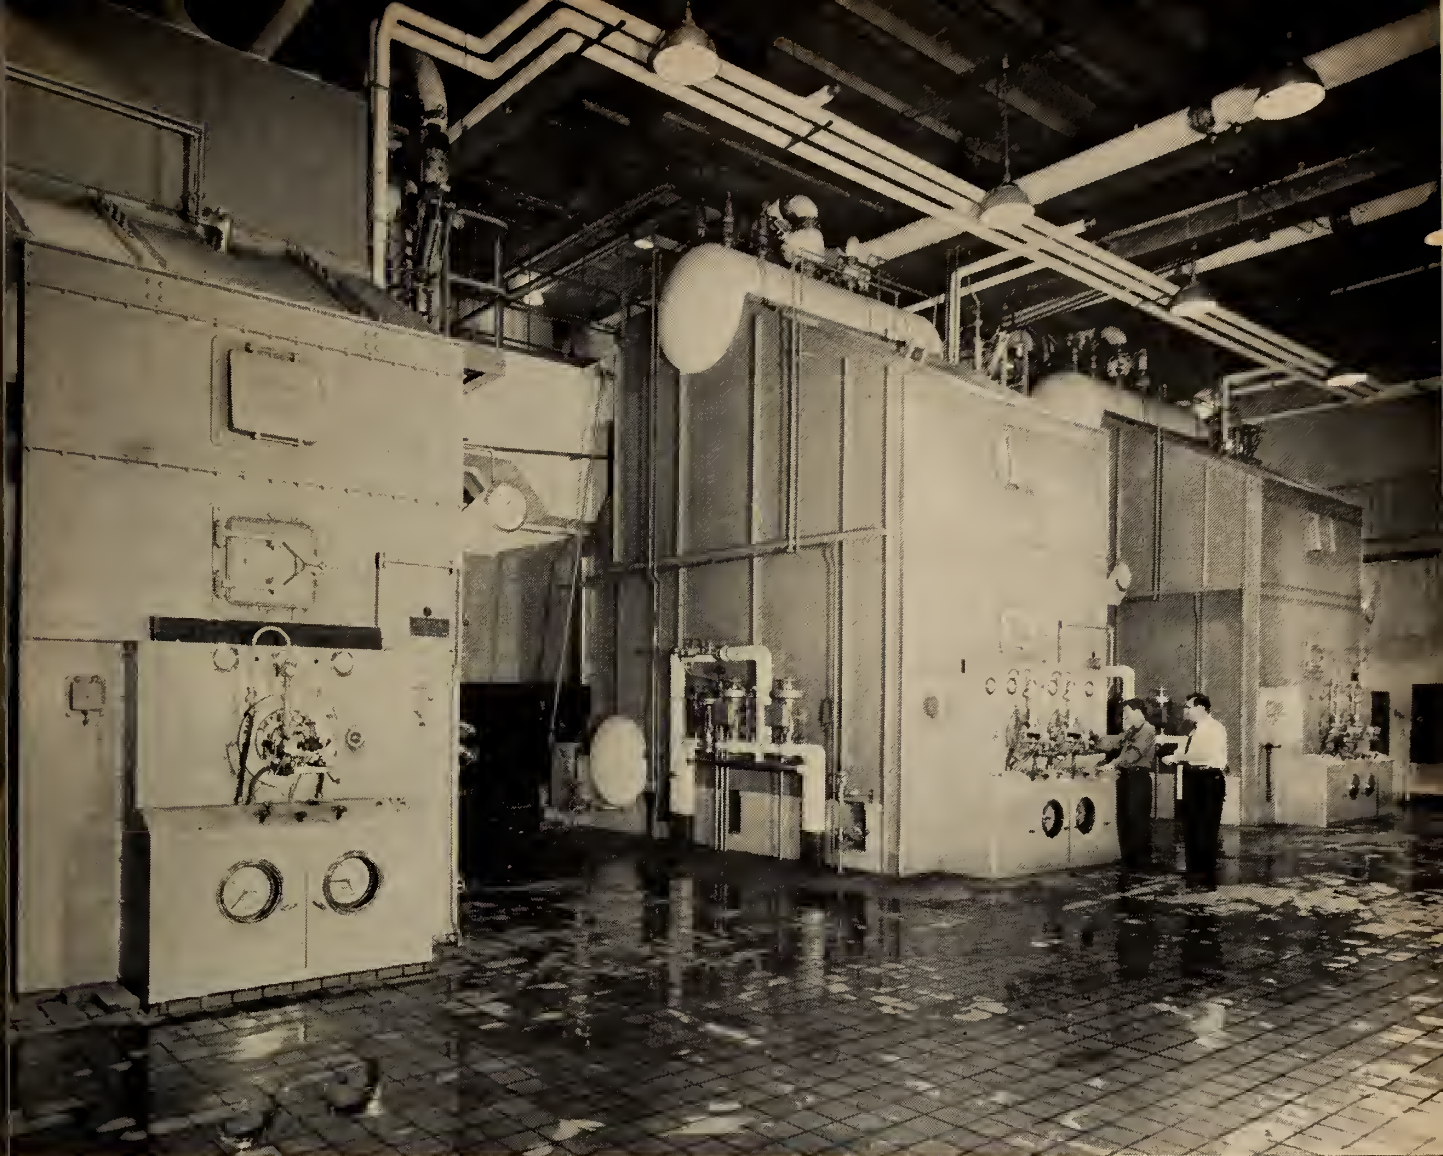
J. Brown, M.E.I.C.

R. Kenneth Robertson, M.E.I.C.

S/L N. B. Flavin, JR.E.I.C. (Alberta, '50, Mass. '59) has completed his masters degree at Massachusetts Institute of Technology. He is now at Air Force Headquarters in the Directorate of Systems Evaluation, Ottawa.

W. E. Dowbiggin, M.E.I.C.

E. F. J. Clark, M.E.I.C.

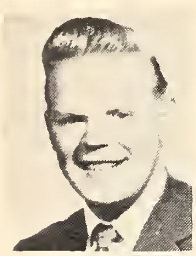


Marcel Lapierre, JR.E.I.C. (Ecole Polytechnique, '50) has been made assistant manager of the industrial sales department for Hydro-Quebec.

John R. Challis, JR.E.I.C. (Toronto '51) formerly of Montreal has joined the staff of Kilborn Engineering (1954) Limited, Toronto as resident engineer on projects in the St. Catharines, Ont. area for the St. Lawrence Seaway Authority.

D. A. Young, JR.E.I.C. (Manitoba, '52) has been appointed secretary of the Foundation of Canada Engineering Corporation Limited in Montreal.

Richard M. Girling, JR.E.I.C. (Saskatchewan '57) is resident engineer with Haddin, Davis & Brown Limited, Edmonton, Alberta.



Gregory Dewhurst, Jr.E.I.C.

H. A. L. McGuire, S.E.I.C.

Gregory Dewhurst, JR.E.I.C. (Saskatchewan '57) of Honeywell Controls Limited, Calgary has transferred to the industrial division sales and service for the Calgary and Edmonton areas.

F. E. Roy, S.E.I.C. (Manitoba, '58), formerly at Avro Aircraft Limited has accepted a position with the Department of National Defence, inspection services, in Ottawa.

H. A. L. McGuire, S.E.I.C. has been awarded a scholarship in engineering from the Foundation Company of Canada Limited and will continue his studies at the Nova Scotia Technical College.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Hugh Robertson, M.E.I.C., died on February 24, 1959.

Born on June 6, 1886 in Helensburgh, Scotland, he graduated from Technical College, Glasgow, Scotland.

During the early part of his career he assisted in the design of various bridges and steel buildings. From 1908 to 1912 he was resident engineer on the construction of roads, sewers and various buildings in Scotland.

In 1912 he became draftsman and transitman with the C.P.R. at Montreal and Toronto and in 1913 to 1915 he was a transitman of the C.P.R. in Toronto. Later he worked in the Canadian Inspection Company, with the Ontario Hydro Electric Power Commission and with the Ontario Department of Highways.

In 1950 he was bridge engineer with the Department of Highways in Ontario.

Col. C. Arthur Scott, M.E.I.C., British Columbia commissioner of the Canadian Red Cross died on April 4, 1959. He had been commissioner for fifteen years.

During World War I, he served from 1915 to 1919 as an officer with the Queen's Own Rifles.

Before coming to British Columbia in 1944 from Toronto where he was born, Colonel Scott was national field directoı of the Red Cross. From 1940 to 1942 as overseas commissioner with headquarters in London.

He designed and carried out the construction of the Canadian Red Cross Hospital at Taplow. The first civilian Red Cross blood donor service was set up under his supervision in B.C. in 1947.

Earlier, Colonel Scott was a roadway engineer for the city of Toronto.

Claud Norris Rands, M.E.I.C., president of Rands and Associates, died on June 2, 1959, at Regina, Sask.

Mr. Rands was born in Portsmouth, England. He graduated from London University. During World War II he served as a lieutenant in the RNVR. After coming to Canada in 1951 he headed Rands and Associates, a geological consulting firm in Calgary and Edmonton.

Mr. Rands was an active member of various organizations and a Fullbright Fellow to the U.S.A. to carry out postgraduate research in sedimentology.

Gordon Reed, M.E.I.C., president of the Quebec branch of the Canadian Handicrafts Guild, died on March 27, 1959 in St. Sauveur, Quebec. He was a practising architect in Montreal.

Born on September 17, 1895 in Ottawa, Ontario, he attended Lower Canada College and McGill University. He graduated in 1922 with a B.Sc. degree in civil engineering.

During both World Wars he served with the Royal Canadian Army, retiring with the rank of Major.

Mr. Reed was vice-president of the Historical Sights and Monuments Commission of Quebec, and a member of The Quebec Association of Architects and the Royal Architects Institute of Canada.

Correction

Egon Alzner, M.E.I.C., whose death was reported in June, 1959 issue, was a graduate, 1928, from Technische Hochschule in Munich where he received the title of Diplom Ingenieur in mechanical engineering. He later studied for a year at the Technische Hochschule in Charlottenburg, Berlin. On this information about graduation the *Journal* item was inaccurate.

E.I.C. Annual General Meeting, 1960

Royal Alexandra Hotel, Winnipeg, Man., May 25-26-27.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

The two-page insert of Canada Wire and Cable Company Limited, pages 157-158 of the May issue of the *Journal* has been voted the "best" in that issue by a jury of fifty readers. Judging was based on ACCURACY - INFORMATION - ATTRACTION. This is the second time this Company's advertising has been voted "the best in the issue" since the award of certificates was commenced in January of this year.

The insert is printed in four colours on the front and in black and red on the reverse side. The copy on the front page covers a special cold chamber in the advertisers' development laboratory in which samples of wire and cable were tested for flexibility at -100°F. On the other side there is a description of the "Vertozone" continuous vertical vulcanizing process designed to improve ozone resistance of high voltage cables.

The advertisement was prepared and placed by Walsh Advertising Company Ltd., Toronto.

CANADA WIRE AND CABLE WINS SECOND AWARD

The Canada Wire and Cable Co. Ltd., two page, four colour, insert was voted the best in the May issue from the viewpoints of ACCURACY-INFORMATION-ATTRACTION.

MEET THE AUTHORS

R. L. Clark, Commissioner of Works, The Municipality of Metropolitan Toronto *(The Humber Sewage Treatment Plant)*.

Mr. Clark graduated in engineering from the University of Toronto in 1937 with a B.A.Sc. He worked as mechanical superintendent of the Consumers' Gas Company of Toronto, held the rank of flight-lieutenant with the R.C.A.F. as a navigator during the first part of the war and later was a construction and maintenance engineer on the Northwest Staging Route in the Yukon and Northwest Territories. In 1946 he joined the engineering ranks of the City of Toronto and was appointed Cimmissioner of Works of the Metropolitan Corporation in July 1956.

Y. DeGuise, M.E.I.C., assistant chief engineer, regional operation division, Quebec Hydro *(The Beauharnois No. 3 Development)*.

Mr. DeGuise graduated from Ecole Polytechnique in Montreal in 1937 and completed the Canadian General Electric Company two-year test course in 1939. He worked for Provincial Hydraulic Service of Quebec until 1945 when he joined Quebec Hydro. He was resident engineer at Beauharnois plant from 1947 to 1951 and superintending engineer of generating stations 1951-1953. He has held his present position since 1954.

From 1943-1955 he also lectured in water power engineering at Ecole Polytechnique.

Mr. DeGuise is a member of the Corporation of Professional Engineers of Quebec, American Institute of Electrical Engineers and other electrical societies.

C. Forest, M.E.I.C., assistant chief engineer, power development division, Hydro-Quebec *(The Beauharnois No. 3 Construction and Development)*.

Mr. Forest obtained his B.A. in 1936 from Montreal University and graduated from Ecole Polytechnique in 1941. From 1941 to 1943 he was with the Civil Aviation Division of Department of Transport. From May 1943 he was field engineer on the Beauharnois canal until 1946, with Beauharnois Light Heat & Power and Hydro-Quebec. In 1946 and 1947 he was field engineer on Beauharnois No. 1. From 1948 until 1952, resident engineer on Beauharnois No. 2. In 1952, superintending engineer of construction in the Montreal head office of the power development division of Hydro-Quebec. In 1953, Mr. Forest was transferred to Bersimis Lac Casse project as assistant project manager. In 1954, Mr. Forest came back to Head office as special assistant to the chief engineer, in 1956 became general superintending engineer of construction and in 1958 assistant chief engineer.

A. J. Bachmeier, head of the gas dynamics section, and **R. A. Tyler**, senior research officer, both of the division of mechanical engineering, National Research Council *(A Gas Turbine Power Plant for Locomotives)*.

Mr. Bachmeier is a graduate of the University of Saskatchewan and has been with N.R.C. since 1946.

Mr. Tyler is a graduate of the University of London and joined the N.R.C. Council in 1947.

J. Featonby, designer, **E. S. Moore**, designer and **D. C. MacPhail**, director, all of the division of mechanical engineering, National Research Council *(A Gas Turbine Power Plant for Locomotives)*.

Mr. Featonby worked for Armstrong Siddeley Motors Ltd., Coventry, England, before joining the N.R.C. in 1948.

Mr. Moore worked for D. Napier & Son, Alton, London, England before he joined N.R.C. in 1949.

Dr. MacPhail is a graduate of the University of British Columbia and came to N.R.C. in 1948 from the Royal Aircraft Establishment, Farnborough, England.

R. J. Kennedy, M.E.I.C., department of civil engineering, Queen's University *(Littoral Drift in Lake Ontario Harbours)*.

Professor Kennedy graduated from Queen's University in 1941 with honours and the medal in civil engineering.

During the years 1941 to 1946 he served with the R.C.E. and was awarded the military cross at Arnhem in Holland.

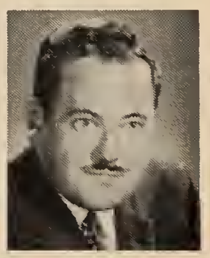
From 1946 to 1948 he was teaching at Queen's University then spent a year at the State University of Iowa on the J. Waldo Smith Hydraulic Fellowship of A.S.C.E. Returned to Queen's where he has been on the staff to date. Professor Kennedy has been supervisor of the Pulp and Paper Research Institute of Canada for project RC-12 since 1952. He was awarded the R. W. Angus medal of the Engineering Institute of Canada in 1958.

A. Brebner, department of civil engineering, Queen's University *(Littoral Drift in Lake Ontario Harbours)*.

Dr. Brebner graduated from the University of Aberdeen, Scotland in 1947 and received his doctoral degree there in 1952.

During the Second World War he served as pilot in the R.A.F. Dr. Brebner was on the staff of the Kent Rivers Catchment Board and taught at Aberdeen University. Since 1957 he has been a member of staff at Queen's University.

Dr. Brebner is an associate member of the Institution of Civil Engineers, a member of the International Association for Hydraulic Research and has published numerous papers on structural and hydraulic topics.



N. R. Grover, M.E.I.C., supervising engineer plant department, engineering headquarters, Canadian Broadcasting Corporation *(C.B.C. Studios 7 and 42 Video and Audio Facilities)*.

Mr. Grover was born in Saskatchewan and obtained his early education there. During the World War II he flew with the R.A.F. Ferry Command. In 1945 he joined the Canadian Broadcasting Corporation.

He received his B.Sc. from Sir George Williams College in Montreal.

Mr. Grover is a member of the Corporation of Professional Engineers of Quebec.

At time of going to press no information was available on **Mr. S. G. Anderson.**

Our cover picture shows the Humber Sewage Treatment Plant, Metropolitan Toronto, near its completion. In the foreground are shown final settling tanks with the return sludge pumping station on the right. Behind the aeration tanks is the blower building and head house. To the left are the two primary sludge pumping stations.

THE HUMBER SEWAGE TREATMENT PLANT

R. L. Clark, *Commissioner of Works*
The Municipality of Metropolitan Toronto

BY AN ACT of the Provincial Legislature in 1953, The Municipality of Metropolitan Toronto was established, to provide certain essential services for thirteen adjacent municipalities. This action culminated nearly three years of discussions, hearings, and intensive studies of existing conditions by the Ontario Municipal Board, and eight months of research and consideration by a Government Committee.

The Metropolitan Area comprises approximately 153,000 acres, with a population of 1,429,000 according to the most recent tabulation. It is 24 miles across in an east-west direction with a north-south depth of close to 12 miles.

Services for which the new Corporation became responsible were: water supply, sewage disposal, housing, education, arterial highways, metropolitan parks, certain welfare services, transportation, finance, assessment, administration of justice, and over-all planning.

Immediately prior to incorporation, many of the member municipalities, shown in Table I, were inadequately served with sanitary drainage and sewage treatment facilities.

The City of Toronto System for the most part was the combined type with sewage being treated at the North Toronto and the Main Sewage Treatment Plants. The former plant, which also accommodated the Town of Leaside and the Village of Forest Hill in addition to small areas from the Township of North York, was treating an amount of sewage well above its designed capacity, but was still producing a reasonably good effluent. The latter plant was treating practically 90% of the sanitary flow originating within the City's boundaries and was providing primary treatment with approximately 50% of the suspended solids being removed.

The Pharmacy Sewage Treatment Plant was accepting the sanitary flow from the western portion of the Township of Scarborough, providing approximately 50% removal of the suspended solids. This particular unit, although recently enlarged, was rapidly becoming overloaded. A large number of septic tanks for individual properties were in use.

The Township of East York was operating two plants, namely, Todmorden and Danforth Park, each of which was severely overloaded, providing only 55% removal of the suspended solids.

The Township of North York had six small sewage treatment plants, each of them providing 87 to 94% removal of solids; nevertheless, accommodating only 50% of the population and a very small area in relation to the Township's acreage. They were rapidly becoming overloaded due to development in their tributary areas. A seventh plant (Don Mills) was under construction by a development company with the approval of the Township. Small sections of the Township of North York were served by connections to the sanitary systems of the Townships of East York and York, the City of Toronto, and the Town of Weston, which were providing sewage treatment accommodation through agreements. An extensive portion of the population in the Township of North York was served by septic tanks which were proving to be unsatisfactory in many cases, due to soil conditions.

The Weston Sewage Treatment Plant had been enlarged to accommodate the Town of Weston and portions of the Townships of Etobicoke and North York. Although it was providing moderately good treatment at the time, it was obvious that the rapid development in the areas of North York and Etobicoke would soon create serious overloading.

The Rockcliffe Plant served a concentrated population in the Township of York but, due to its limited size, was providing only 40% removal of the suspended solids.

Swansea Village Treatment Plant was accepting more sewage than it could accommodate, with the result that only 48% of the solids were being recovered.

Table I

Area Municipality	*Acreage*	*Population* 1951	1958
Township of East York	3,747	64,616	68,319
Township of Etobicoke	27,312	53,779	121,720
Village of Forest Hill	739	15,305	19,936
Town of Leaside	1,126	16,233	16,409
Village of Long Branch	750	8,727	11,026
Town of Mimico	500	11,342	14,401
Town of New Toronto	659	11,194	11,912
Township of North York	44,588	85,897	200,185
Township of Scarborough	45,012	56,292	168,281
Village of Swansea	682	8,072	8,972
City of Toronto	22,287	675,754	658,420
Town of Weston	622	8,677	9,485
Township of York	5,050	101,582	119,966

(See Fig. I)

Sanitary sewage from the southern portion of Etobicoke Township was handled at the recently constructed Etobicoke Sewage Treatment Plant, situated on Mimico Creek near the lake front. This area was only partially developed, and the plant was providing efficient treatment. However, development in the tributary area was proceeding at a very rapid rate, and there was every indication that extended facilities would have to be provided. Small areas of the Township drained to the Mimico and Long Branch Systems under agreement.

New Toronto and Mimico were accommodated by the Union Sewage Treatment Plant situated in the Town of Mimico. Due to the inlet flow containing extensive amounts of industrial waste, this plant had been severely taxed for a number of years.

The Long Branch Treatment Plant served the Village of Long Branch, a small section of the Township of Etobicoke, and limited areas in Toronto Township, and was accepting sewage beyond its capacity with unsatisfactory results.

Evidence indicated that each Area Municipality had endeavoured to assist its neighbour in acquiring sanitary drainage accommodation for its residents, but the existing sewage plants and trunk sewers-deemed escapacity required if all citizens were to be provided with accommodation. In addition, many of the sanitary trunk sewers in the Area Municipalities were of insufficient size to permit drainage from one Municipality into its neighbour system to any extent. There had been no adoption of a co-ordinated master plan for sewage plants and trunk sewers deemed essential for the development of a satisfactory Metropolitan sewerage system.

The numerous overloaded sewage treatment plants which discharged their respective effluents to the various rivers located throughout the Metropolitan area, or directly through outfall sewers to the lake, were causing rather severe pollution in Lake Ontario, from which the water supply for most of our residents was derived.

The foregoing will serve to illustrate the situation with regard to sanitary sewerage facilities which existed when the Metropolitan Council first convened in early 1954 for the purpose of providing the thirteen Area Municipalities with essential services.

Capital Works Program adopted to provide adequate sanitary drainage for the Metropolitan Area

A capital works program designed to provide the Metropolitan Area with

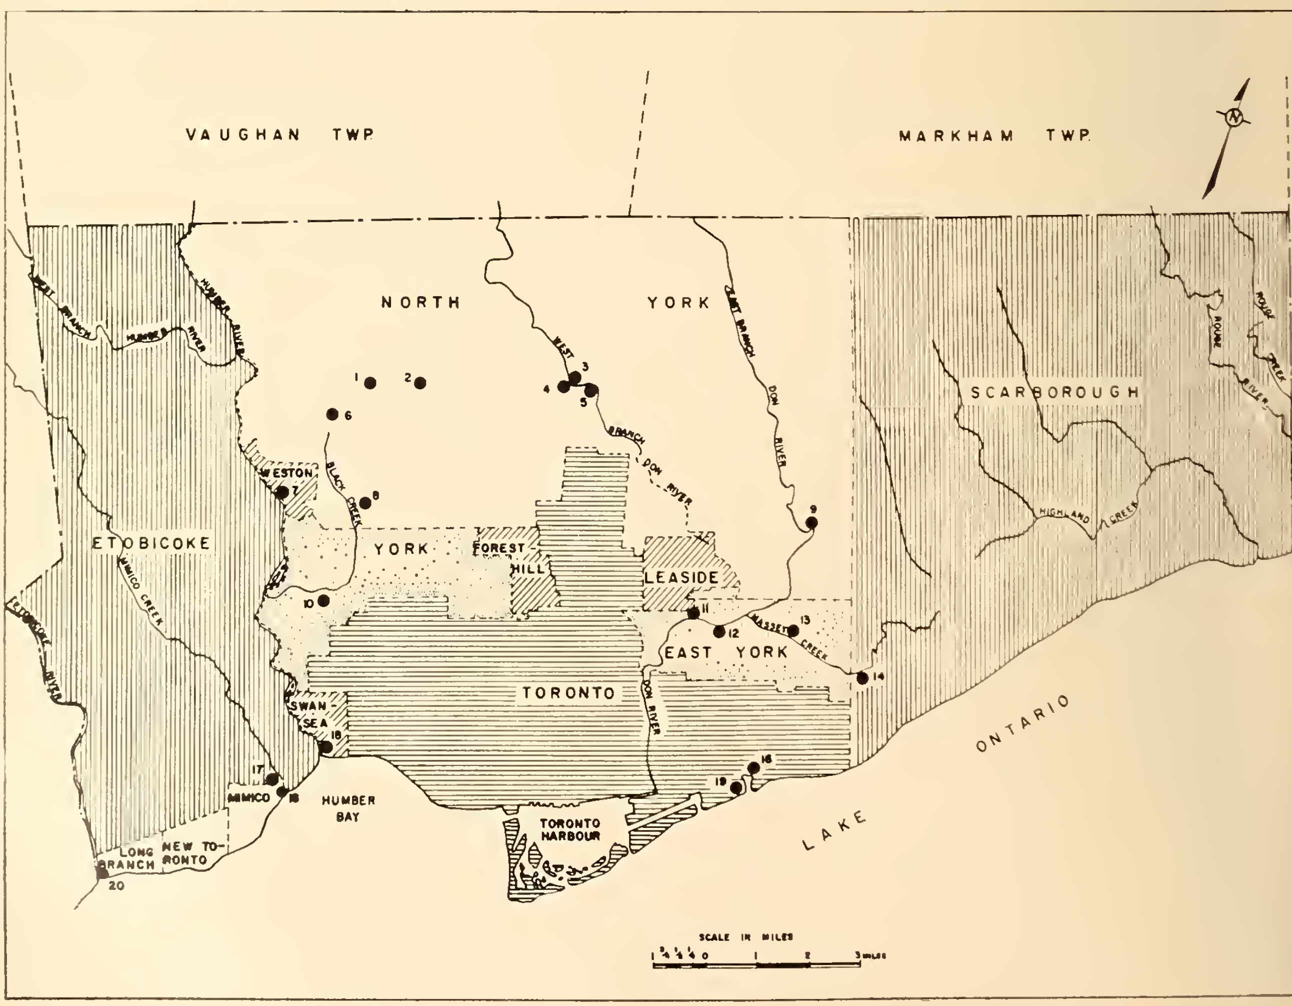
LEGEND

Metropolitan Toronto Boundary —— . ——
Sewage Treatment Plant - - - - - -
Municipality Boundary ●



adequate sewage treatment plants and sanitary trunk sewers to convey the sewage to them, was adopted by Metropolitan Council in its first year of operation — it being planned to conform with the recommendations made in a report, dated January 30, 1954, prepared by Messrs. Gore and Storrie, Consultants, outlining sewage disposal requirements necessary to adequately service all thirteen member municipalities.

In general, the scheme embraces major treatment plants at the mouths of the larger rivers in the Metropolitan area, with sanitary trunk sewer systems extending northerly from each plant for collection purposes. Extensions and improvements to certain existing plants are also included. The estimated cost of the over-all program, including plants and sewers, is $90 million.

The major plants under construction—planned in all cases to remove 90 to 95% of the suspended solids and biochemical oxygen demand — and their initial capacities, are set out in Table II.

Table II

Plant	*Daily Capacity being provided*
Highland Creek (new plant)	4,000,000 gals. per day*
Main Plant (Ashbridge's Bay) (Enlargement and Improvement)	120,000,000 gals. per day
Humber (new plant)	50,000,000 gals. per day*
Long Branch (new plant)	To be decided
Glendale (Extension)	3,000,000 gals. per day
Weston (Extension)	6,700,000 gals. per day

*Provision made for extensive enlargements when required.
(See Figs. 1 and 2 for location of the plants and associated sewers.)

The pollution control program being carried out by Metropolitan Toronto is comparable to any instituted to date on this continent. One of the more important facets of this work is the establishment of a new treatment plant at the mouth of the Humber River and its associated trunk sewer development, to which this paper is devoted.

In developing the Capital Sewerage Works Program for the Metropolitan Corporation in 1954, the consulting engineers found that conditions in the Don and Humber Rivers were totally unsatisfactory. The bacterial counts in the lower portions of the rivers were exceedingly high, and there were excessive quantities of suspended solids and oxygen demand. Obviously, the pollutional load had been increasing rapidly with the post-war expansion. To limit the bacterial count in these streams to the maximum recommended by the Ontario Department of Health, i.e. an mpn* count of 2400 per 100 millilitres, elimination of all normal disposal of sewage effluents was imperative.

Accordingly, this situation dictated that any plant constructed at the mouth of the Humber River must serve a complete trunk sewer system extending northerly therefrom to the northern Metropolitan boundary, with all existing inadequate plants within the watershed being eliminated.

The consultants, to estimate the degree of treatment required at the new plants, carried out extensive research on the various water intakes along the shore of the lake and on the lake currents. Results of the study decreed that any plant built within the Metropolitan boundaries must be based on supplying complete treatment.

*most probable number

Engineering Appointment

With some of the general principles established respecting the Humber Drainage System and the type of plant to be provided, Metropolitan Council appointed James F. MacLaren Associates in April 1954 "To supply all engineering services incidental to the development of the project to accommodate and treat the sanitary drainage from the entire Humber River watershed within the geographic limits of the Metropolitan Area as designated by the Corporation." In carrying out its commission, this firm decided to consult with the firm of Alvord, Burdick and Howson of Chicago, Illinois.

The initial authorization defined the general limits of the tributary area, but detailed analyses of the existing sewerage systems and their planned development within the various municipalities concerned were to be conducted to ascertain the actual limits to be served eventually.

Functional sketches with approximate estimates of cost were to be made for review and endorsement at the outset of the engineering assignment.

Population in Tributary Area

The watershed of the Humber River and its tributaries within the limits of Metropolitan Toronto embraces an area of 34,200 acres representing six municipalities, namely the western part of the Township of North York, practically all of the Township of York, the Town of Weston, the Village of Swansea, a major portion of the Township of Etobicoke, and a large percentage of Wards 6 and 7 in the western section of the City of Toronto. Early studies of the areas tributary to the proposed treatment plant indicated that they were somewhat more extensive than the watershed proper, due mainly to the existing sewerage systems in the various included municipalities, which at certain points had been extended beyond the watershed's limits.

In the case of the Township of Etobicoke, it became obvious that the existing trunk sewer discharging sewage for treatment to the Etobicoke Plant would have to be diverted to discharge its flow to the new Humber Plant, and that at such time it would be desirable to similarly divert the sanitary waste from the Towns of New Toronto and Mimico. It also appeared realistic to provide for sewage flows from a very limited area of the watershed beyond the northern limits of the Metropolitan Corporation, to ensure that no future sewage treatment plants would be established on the Humber River or its tributaries within, say, one half-mile of the Metropolitan limits.

From these studies, it became evident that the ultimate area contributing sewage to the Humber Plant would be close to 50,000 acres, or about one-third of the land area within Metro. The ultimate resident population to be accommodated by the Plant would approximate 800,000. Fig. 2 indicates the tributary area and the main interceptor sewers that were planned in the initial report to convey sewage to the proposed plant.

Review of existing land use in the tributary area and the zoning plans for the undeveloped districts indicated that nearly 45% of the district would be utilized for residential development, 2% for commercial pursuits, 20% for industrial purposes, 17% for roads and 16% for parks, schools and utility rights-of-way. Ultimate density of the residential area was calculated to be 39 persons per acre, as against a future density in the whole area of 16.3 persons per acre.

Analysis of actual development in the tributary area indicated at that time (1954) that it had a population of 304,000, or 38% of the estimated ultimate, with the greatest concentration being in the two wards of the City, previously mentioned, and in the Township of York, which accounted for two-thirds of the existing tributary population.

Densities in the Townships of Etobicoke and North York were less than three persons per acre, indicating that practically all future growth could be expected within their limits.

Data assembled on expected growth in the tributary area indicated a conservative population increase of 15,000 a year; accordingly, it was assumed its final population would be attained by the year 1990. In the four years which have elapsed since this study was made, the population increase within the area confirms the initial assumption.

Design Flow and Strength of Sewage

Two methods were employed to determine the anticipated tributary flow, initially and ultimately, from the area to be served. On one basis, actual unit flows of sewage on an acreage basis were computed from water consumption figures according to residential, commercial and industrial uses. Such figures were then applied to existing and ultimate land use areas to determine the estimated flow.

As a confirmation, the sewage flow each hour of the 24 hour day over a one week period was gauged at existing sewage plants and in main trunk sewers. The flows determined from such gaugings were then compared with the results obtained by applying the aforementioned unit area flows to the development applicable in the area tributary to the gauging point. It was found that satisfactory co-relation existed between the two methods and, accordingly, the existing and ultimate flow conditions were established, provision being made in the latter figure for some future increase due to an expected increase in the per capita consumption of water.

Gaugings in 1954 indicated that an average flow of some 28 to 29 million gallons a day (or 96 gallons per day per capita) was originating from the planned tributary area. The b.o.d. of the sewage was calculated from the sampling data to be 530 parts per million, the suspended solids 310 parts per million, and the grease content 190 parts per million. These figures represented exceptionally strong sewage, which could be generally traced to the large flow from the tributary district of the City of Toronto. The flow from this district was found to be 12.5 m.g.d., of which 9 m.g.d. was derived from packing houses situated in the vicinity of Keele Street and St. Clair Avenue. The strength of the sewage for the whole area would have been approximately one-half that indicated if packing houses were discharging wastes of the strength found in domestic sewage.

In view of the existing and estimated population of the area, its calculated rate of growth and its present sewage flow and strength, it was determined that a plant initially capable of treating a daily average flow of 50 million gallons of raw sewage, from a population of 475,000 persons, be constructed, capable of treating sewage with an average b.o.d. of 260 p.p.m., a suspended solids content of 210 p.p.m., and a grease content of 75 p.p.m. Since the initial design population would be in existence by 1973, the layout was made in such fashion as to permit for enlargement to 100 million gallons capacity, deriving from the ultimate pre-determined population of 800,000.

Site Selection and Development

The location proposed for the Humber Sewage Treatment Plant was originally recommended in the Capital Works Program prepared by Gore and Storrie in 1954. It incorporated the existing Humber Valley Golf Course to the west of the Humber River and north of Queen Street Extension, in the district known as "Humber Bay."

Accepting the consultants' recommendation, Metropolitan Toronto purchased the Humber Valley Golf Course in 1955 comprising 89 acres, of which approximately 26 were located in the flats known as "The Marsh" alongside the Humber River. This site made it possible for sewage originating throughout the watershed to be discharged to the proposed plant by gravity sewers. Furthermore, it permitted discharge of any treated effluent from the site to the lake at a maximum distance from existing waterworks intakes.

A housing development bordered the acquired property on the southwest extremity, and Stonegate Road — a residential street with modern and expensive homes — constituted the northerly boundary. A large apartment development, recently established, was situated a short distance to the north.

Because the Golf Course site had originally been utilized as a source of clay for a brickyard operation, the contours of the ground varied radically in steep slopes from elevation 250 to 310. Two main ridges extended from west to east across the property, with slopes towards the river on the easterly boundary.

An extensive marsh adjacent to the river was a source of unsightly reeds, due to the apparent high organic nature of its contents. Normally, the marsh area is moderately dry when the river level is within its normal limits of elevation 244 to 248 but, on occasion, its level has been raised to approximately 260, as was the case during Hurricane Hazel. Instability of sub-soil in this region denied the use of 26 acres of the property for actual plant installations.

Initially, a provisional lay-out using a north-south axis, immediately west of the marsh area, was considered. However, it was abandoned in favour of an east-west lay-out paralleling the Queensway. The final proposal required expropriation of a further 26 acres located to the south-west of the original property, on which scattered residential development existed.

In planning the new lay-out, maximum separation of the plant from the developed areas was to be secured by construction of a high ridge (elevation 310) on the west and north sides of the site, which could be built with the large quantity of earth involved in the plant excavation work. It was further proposed that the main grade elevation throughout the site be established at 270, and that the greater portion of the hydraulic structures be set down at 260.

Establishment of the base grade for the site and the topography of the property indicated a total excavation of 1,000,000 cubic yards, of which approximately 300,000 cubic yards would be derived from the excavation for structures after the completion of rough grading. This quantity was deposited in the ridge and on the marsh. However, due to the instability of the latter, it could only be safely filled to an elevation of 260 and then only for half its width.

In order that the Corporation might proceed with construction in the location finally selected, an amendment to the official plan for the area was requested, since the Golf Course property was officially designated as *Green Belt*. This amendment understandably was declined, in view of the objections raised by neighbouring home owners to the construction of the plant. Accordingly, the Metropolitan Council appealed to the Ontario

Municipal Board for the desired amendment. Subsequently, the Board held a full hearing on the subject, carefully investigating each objection presented by the ratepayers and other affected Bodies.

Finally on June 22, 1955, the Ontario Municipal Board approved of the zoning amendment, thus permitting construction to proceed. In granting its approval, however, the Board placed certain limitations on the Metropolitan Corporation in the use of the site for the stated purpose and on the structures to be erected thereon. Basically, some of these limitations had already been suggested by the Metropolitan Corporation in its functional plans. The significant sections of the directive required that the Corporation utilize all the area of the property outside of the plant fixtures for development of landscaped park lands; and that a screen be made of tree planting around the plant periphery; and, insofar as practicable, the digestion tanks be located below ground level with sludge and other wastes being processed and handled in enclosed buildings.

The objections raised to the establishment of the plant on the Humber Golf Club site required a full review of all other practicable locations for the plant's establishment. At the time of the Board hearing, five alternative proposals were investigated in detail. However, it was concluded that of all the sites studied, the one at the mouth of the Humber River was the most feasible. This fact was based mainly on economy, for it was found that to construct the ultimate plant in any other area would entail at least two million dollars more expenditure.

Tributary Trunk Sewers

Before outlining plant facilities in detail, it may be helpful to review briefly the trunk system required to convey sewage to the plant. Referring to Fig. 2; sewage will be received from two main sources and one secondary source. The Humber River Sanitary Trunk Sewer — the largest of these — will extend northerly from the sewage plant along the west bank of the Humber River through the Township of Etobicoke and the Kingsway District some 19,000 ft. to the junction point of the Humber River and Black Creek.

This major sewer is at present under construction, the lower 3,000 ft. being under soft ground tunnel conditions requiring up to 15 pounds of air to control ground water, with the major section located in rock at an average depth of 70 ft. below surface level.

The tunnel varies from 9-ft. diameter at the lower end to 8-ft. 6-in. in the rock portion, and it has an over-all capacity of 400 cu. ft. per sec. An emergency overflow to the Humber River to prevent surcharging during times of extreme flood in the river will be built at the lower end.

Because complaints could be anticipated through construction of the sewer in the residential areas, no shafts were permitted in the rock tunnel contract; all entrances to the work being driven in adit from the bank of the river immediately above water level. Alternative tender prices were sought for carrying out construction with and without the use of explosives. The non-explosive alternative envisaged use of rock boring equipment which had been satisfactorily employed on the Oahe Dam in Missouri. When bids were received it was evident that the non-explosive alternative could be employed at substantially the same cost as would be required for normal blasting methods and, accordingly, this alternative was selected. Progress on the tunnel is now being made, using a Robbins rock boring machine for excavation at a net rate of 25 ft. per 24 hours, although some difficulty was experienced at the start in getting the mechanical equipment tuned up. Specifications call for a 12-in. unreinforced concrete wall with pressure grout to a minimum pressure of 80 p.s.i. being placed after the wall concrete has set.

At the junction of Black Creek and the Humber River two sanitary sewers extend further north; one, the Black Creek Sanitary, extends northerly along the line of Black Creek, intercepting flow from the York Township combined sewerage system up to a maximum of 2½ times the average dry weather flow and accepting packing house wastes, which are to be diverted from the City of Toronto sewerage system. (When this sewer is available, Rockcliffe Plant will be converted to provide storm water treatment to flows received from the York Township sewerage system during excessive runoff periods.) From Rockcliffe Plant, the sewer continues northerly in 60-in. to 48-in. diameter size to the Metropolitan limits, accepting flows along its length from various municipal systems including the diversion of flows now tributary to existing sewage treatment plants scheduled to be abandoned. This work is currently being expedited with completion planned for 1960.

The other sewer, known as the Etobicoke Sanitary Trunk, continues northerly from the previously mentioned junction point along the Humber River, accepting flows from municipal systems as it progresses up river to the Weston Sewage Treatment Plant (to be abandoned), at which point all tributary flows will be connected to the trunk. This sewer is at present being extended in sections up to the northern boundary of the Metropolitan Area. Coincidently with this work, the Townships of Etobicoke and North York are improving their sewerage systems to make the necessary connections thereto on a permanent basis.

The second main feature of the tributary system to the Humber Sewage Treatment Plant is known as the Queensway Sanitary Sewer, which extends westerly from the plant along the Queensway to Park Lawn Road and across Mimico Creek. It will intercept flows now tributary to the Etobicoke Sewage Plant and the Mimico-New Toronto Union Sewage Treatment Plant. Diversion of flows from these plants will permit the abandonment of the latter plant and utilization of the more recent Etobicoke Plant for a dewatering facility to serve the new Humber installation. The Queensway Trunk Sewer, established at a diameter of 66-inches, will be constructed in mixed face conditions through its lower section, altering to complete rock tunnel as it progresses upstream, with the sections to the west of Mimico Creek to be constructed in open cut. Work on this project is well under way.

A secondary, but third measure, in the diversion of flows for treatment at the Humber Plant calls for replacement of the obsolete Swansea Plant with a new pumping station capable of pumping maximum anticipated flows through a steel forcemain across the Humber River on the Queensway bridge to the new plant site.

The foregoing trunk sewers and intercepting devices represent the responsibility of the Municipality of Metropolitan Toronto. Sewers necessary to connect to this system are the responsibility of the individual municipalities concerned and, as previously noted, are being carried out in conjunction with the Metropolitan Corporation's program, so that a fully unified development can be in satisfactory operation by mid-1960.

Soil Investigations

Preliminary soil investigations on the Humber Golf Course indicated the overburden to be grey silty clay with 90 to 95% by weight passing a No. 200 mesh. Unconfined compressive tests indicated the bearing value was as low as 1000 lb. per sq. ft. and as high as 3,500 p.s.f., with the weaker soils occurring at depth. It appeared that such material would be extremely difficult to compact when wet, its moisture content varying from 12.6 to 25.6%, while its liquid limits varied from 21.0 to 38.3 and its plastic limits from 16.1 to 20.1%. No groundwater problems at levels above the lake surface were revealed.

The soil, being extremely variable in bearing capacity, was not attractive for support of the proposed structures, which despite low imposed unit loading would, nevertheless, be extensive. Fortunately, the underside of most proposed structures would extend below elevation 250, and laminated shale was encountered throughout the site at a depth varying from elevation 256 in the west to 238 in the east. It therefore appeared feasible to establish all major foundations on the shale rock which, although shattered especially in its top strata, was found to be adequate for the maximum imposed loading of 3,500 lb. per sq. ft.

Conditions encountered in the marsh area were entirely contrary to those prevailing on the remainder of the site and are of some interest. Fifty to eighty ft. of organic silt with little measurable resistance rested on a shale bottom. Obviously this material was inadequate to support the heavy structures, and it was questionable if it would support placement of fill. Since the marsh area was desirable as an excavation disposal zone to reduce off-site handling, extensive laboratory investigations were carried out to ascertain how far consolidation would occur if fill was placed in the area. It was feared that stability might be overcome sufficiently to cause the silt to shift and destroy the hydraulic capacity of the river. However, on review of all information, it was determined the area could be filled to a depth of 15 ft. over half its width with a settlement of 3 ft. resulting, being 90% complete after a period of 6 months. Careful filling during construction permitted this procedure to be followed, and no noticeable settlement occurred after the first six months.

Plant Features

As previously mentioned, complete treatment of the sewage tributary to the Humber Plant was mandatory for proper protection of waterworks intakes located within two to three miles of the plant outfall, and to protect adjacent beaches. This demanded 90% reduction of b.o.d. and suspended solids in the raw sewage and, during the summer months at least, post chlorination. Primary settling followed by secondary treatment based on the activated sludge process appeared to be the logical process to adopt in order to protect the receiving body to the extent required.

Operating results and experiences obtained from original plants at Milwaukee, Chicago and Indianapolis since 1925, together with experimentation and the development of the modern Chicago, New York, Cleveland, Philadelphia, Gary, and Columbus plants, were reviewed before making the final decision. Recent advances in design and improved operation methods have given added importance to the usefulness and flexibility of the activated sludge process. The options in sludge re-aeration, such as step aeration and biosorption, have further increased its attractiveness.

The final process procedure adopted for the plant comprises the following features:—

1. Trash Racks and Bar Screens;
2. Grit Chambers;
3. Pre-aeration Tanks;
4. Primary Settling Tanks with Grease Collecting Facilties;
5. Conventional Aeration Tanks designed to provide for Sludge Re-aeration and Step Aeration Facilities;
6. Final Settling Tanks;
7. Chlorination Facilities;
8. An Outfall Sewer to the Lake at depth;
9. Sludge Pumping Facilities to Digestion Tanks;
10. Sludge Digestion Facilities and Gas Storage Units;
11. Vacuum Filtration of Digested Sludge.

Centralized control will be achieved through incorporation of inlet structures, grit chambers, blower plant and administration offices in one building.

Having described in general form the pollutional control program, and especially the Humber project, the remainder of this paper will be devoted to detailed description of the various plant units.

Mechanical Screening and Inlet Facilities

The Head House contains the plant inlet facilities, including shut-off gates, screens and grit removal devices. Here the incoming sewage enters four separate but equal conduits, each controlled by a 7 ft. by 5 ft. sluice gate operated by an oil hydraulic system, in order that all flow can be shut off in the event of power failure or flood conditions in the Humber River.

Beyond these gates, the conduits become open channels, each approximately 11 ft. deep and 5 to 8 ft. wide, in which the screening devices will operate.

Each channel is equipped with a trash rack and coarse screen, similar to the New York practice. The use of trash racks with 15° slopes, each unit having mechanical cleaners discharging to tipping buckets, was considered expedient to protect the screens from damage due to floating debris. Bar spacing was set at 3 in.

Similarly, the bar screens were established with a 1 in. clear spacing, which was deemed sufficient to stop the passage of injurious material to pumps and other equipment further on in the plant process. The screens were set at an angle of 30° off the vertical to control the fall-back of material caught on the rakes. Raking mechanisms operate electrically, being actuated by either a time clock or a high water float control. All screenings enter tipping buckets.

With the foregoing spacings and maximum velocities through the screens limited to 2.5 ft. per sec., an average of 4 cu. ft. of screenings per million gal. should be recovered.

The possibility of grinding the screenings and returning them to the sewage flow was set aside in favour of daily disposal by a covered container capable of easy mounting on a truck.

Grit Removal

It is a well-founded concept that the heavy mineral matter carried in sewage, such as gravel, sand, cinders, ashes, coal and heavy organic matter, must be removed from the sewage flow as soon as possible to avert severe abrasive wear on internal plant pumps and equipment. It can also seriously affect the organic strength of the primary and biological sludges.

At the outset, 70% of the flow to this plant will derive from combined sewer areas where grit generally reaches the sewers in substantially greater quantities than from separate sewer areas. In addition, many miles of newly commissioned sewers, carrying sewage with an abnormally high grit content, will convey flow to the plant. For these reasons, facilities have been designed on the assumption that a grit content equivalent to normal combined sewage will be experienced in the initial years, although it is recognized that quantities should diminish as the new sewers become completely flushed and separation of some of the combined systems occurs.

Determination of the extent to which heavy material should be removed from the sewage is one of the main problems in grit chamber design. Also, present day practice dictates that grit be washed prior to disposal to reduce the putrescible content below 3% for odour control. Previous experience has been to collect 80% or more of the grit in sewage (i.e. that portion greater in size than 0.20 to 0.25 mm.) at maximum flow rates, thus effectively reducing abrasive problems in subsequent machinery while limiting organics in the grit to a reasonable level.

Three standard designs were considered for application to the Humber problem — (1) the straight-line rectangular tank with bucket type collector, (2) the aerated grit chamber, and (3) the square clarifier type. On review of the anticipated operating conditions which would prevail, two square clarifier type grit chambers were selected. These were located within the head house for odour control, and with classifiers to remove grit were substantially free of organic matter. Grit will be accumulated in tipping buckets and discharged daily to trucks for transportation to fill areas.

Pre-Aeration

Pre-treatment of sewage through the use of diffused air type pre-aeration tanks has become, in recent years, an increasingly attractive addition to many plants.

In the case of the "Humber", its inclusion was considered justified on the basis of (1) the control of odours, especially during warm weather and low flows; (2) the aid offered in the flotation of grease for subsequent removal in the primary settling tanks since grease is anticipated as a problem; (3) the protection of efficiency of the biological processes and the plant generally from shock industrial waste loads; and (4) a further safeguard against grit carry-over to mechanical equipment.

It was felt that retention time on pre-treatment should be set at not less than 60 minutes. In addition, it was deemed wise to utilize standard spiral flow type aeration tanks with diffused air equipment. To maintain a spiral flow velocity in the tank of approxmiately 2 ft. per sec., air diffusion at a minimum rate of 3 c.f.m. per lineal ft. of tank was necessary.

Primary Sedimentation

Primary sedimentation in modern activated sludge plants is standard practice as a multiple purpose unit designed mainly to reduce and regulate sewage strength and concentrate solids for disposal. The present day mechanically cleaned settling tank, however, is available in a number of shapes and sizes, each with its particular advantage.

The use of a circular settling tank (or square, which represents only a modification of the former) utilizing a horizontal rotating rake with ploughs moving sludge in the direction of rotation toward the base of the tank for removal, was given due consideration but was set aside in favour of a rectangular design. For this two alternative mechanisms were studied: (1) the bridge type with extended bottom scrapers and surface skimmer, and (2) the straight line drag type chain collector. The latter was selected finally, designed with surface return for scum and grease collection at dip troughs, primary sludge being concentrated for removal at the inlet ends. The inlets have been baffled to confine short circuiting, and a weir length established sufficient to confine overflow rates to prevent formation of strong outlet currents and subsequent inefficiency. To accommodate sufficient trough length within the tanks, all troughs were arranged parallel to the flow at the effluent end.

Cross-collectors at the influent end of each tank will concentrate sludge from each pair of tanks to a central point where it enters the suction side of piping connected to pumps located in the two primary sludge pumping stations. Each station is equipped with two 50 g.p.m. positive displacement sludge pumps, with vari-drive for discharging sludge at a continuous rate to the digestion tanks and one 300 g.p.m. plunger pump for handling sludge on an intermittent basis and for tank drainage. The stations also have grease separation vats for storage of scum discharged from the surface of each pair of tanks. The contents of these vats will be heated from time to time to permit separation of the grease from liquid matter, and the former will be conveyed by Moyno pumps to containers or directly to trucks for disposal. Normally, sludge based on a concentration of 6% will be removed at the rate of 83,000 gallons per 24 hours, while it is anticipated that scum will be recovered at the rate of 20,000 lb. per day.

Aeration

The activated sludge process was first discovered by Ardern and Lockett at the University of Manchester in England, some forty-six years ago. Although the first North American plant of this type was built at San Marcos, Texas, in 1916, the large scale plants at Indianapolis, Milwaukee and Chicago were not put into operation until the end of the twenties, when the process became more widely accepted as a means for the complete treatment of sewage. Since that time several process variations have been developed, but the original unmodified installations have proved to be among the most efficient and economical operating today.

Basically, the activated sludge process is a contact operation in which the formation of biologically active flocs or slimes of living organisms is promoted under aerobic conditions, for the purpose of transferring to the floc putrescible (principally finely divided and dissolved) substances. These substances are partially stabilized by biological activity, some of the soluble and stable end products being returned to the plant flow, while excess biological flocs and their stored impurities are more or less continuously unloaded as waste activated sludge. Determination of the aeration tank volume and the weight of sludge that must be returned to it, along with the required amount of air to support the action if the desired purification is to be effected on the daily applied load, represents a major problem in design.

Correlation of all factors at the Humber indicated that the secondary treatment section should be designed on a conservative activated sludge basis, but with complete facilities incorporated for step aeration or some form of sludge re-aeration. It was, however, decided to make hydraulic provision for carrying flows 50% in excess of the anticipated design maximum. By so doing, if it is found that sludge re-aeration methods can produce adequate removals at considerable saving of aeration tank volume, the tank capacity will not have to be increased substantially in the future enlargement. In view of the extensive research currently being carried out on activated sludge, it was considered unwise to design a plant of this capacity without permitting the ultimate in flexibility.

Spiral flow diffused air procedures versus high rate mechanical aeration was given serious thought, and the former method was selected. In calculations, a sludge loading of 0.30 lb. of b.o.d. per lb. of mixed liquor suspended solids was used, with the latter to be maintained at a mean of 1700 p.p.m. Three pass tanks for the inlet of settled sewage at the beginning of each pass, with return sludge to be admitted at the beginning of the first pass, were selected as optimum for the Humber condition.

Air supply was based on providing a maximum of 1000 cu. ft. of air per pound of b.o.d. to be removed with an additional 33% in standby. Coarse bubble diffusers were favoured, due to their flexibility in handling air quantities over a 4 to 1 range while maintaining a practicable head loss condition. Their adaptability to higher than anticipated sewage strengths and to sludge re-aeration procedures also played a part in their selection. Spacing at 14-in. centres along the tank wall, with 16 units being carried on one 4-in. diameter header, was deemed adequate.

Effluent spray systems are affixed to all tanks to give a surface spray at the rate of one-third gal. per linear ft. of tank to control foaming that has become prevalent of late in many cities.

All air supply piping is galvanized steel located on wye walls between the tanks, while connections to the 4-in. diameter diffuser headers are made through valved down pipes located at 18 ft. centres.

An aeration control gallery located wholly below ground level was established to house all piping and controls. Settled sewage to each tank is metered through 36-in. and 20-in. venturi tubes with flow to each of the three outlets to a tank being controlled through 36 in. butterfly valves, the proportion to each outlet being gauged by the resulting solids concentration within the tank contents at each location, as measured by a 30 minute settling test. Air is metered through venturi inserts to the wall headers, while return sludge is discharged through rate controllers in equal proportions to each tank.

Final Sedimentation and Return Sludge

The prime development in the design of final settling tanks, in recent years, has been the recognition that density currents and their effects must be carefully assessed. The initial theory of sedimentation bears no relation in importance to the problem of density currents, insofar as the design of Sewage final settling tanks is concerned. The work of Anderson at Chicago and subsequent work of Gould at New York have brought these problems to the fore.

As a result of their investigations, tank depths must be selected most meticulously, despite the apparent adequacy of present surface loading rates; and there must be a limiting ratio between flow length or distance from the inlet to the upturn of the density current and the tank depth, in order to confine density current velocities. The use of offset weirs, as practised at the Humber, should further relieve the problem of density currents.

In addition, recent experience indicates that for proper final tank operation, quick removal of the return sludge must be achieved to maintain it as fresh as possible. Its retention time should not be more than 40 minutes within the tank, and it should be as concentrated as feasible at withdrawal, to confine the hydraulic requirements of sludge return.

Present limitations of surface loadings at 900 gal. per sq. ft. per day on final tanks, replacing older criteria of 2 to 2½ hours' detention, are therefore only established to obtain sufficiently quiescent conditions in the final tank flow to permit activated sludge to settle out as rapidly as practicable—generally within 30 to 40 minutes.

Final tank shapes and sludge collecting mechanisms are identical to those offered for the primary settling tanks, with the exception of an additional induced suction type of unit usually applicable to circular or square tanks. Preference for the latter was established in view of the ready means available for dealing with overflow rates and density current problems.

Although the rate for moving return sludge is actually determined by the solids concentration to be carried in the aeration tank liquor and the settling characteristics of the return sludge, it is often set with liberal limits as a percentage of the design rate of sewage flow.

Accordingly, the return sludge pumping station has five vertical type direct connected mixed flow electrically driven pumping units, each rated for 10.25 m.g.d. against a total head from all causes of 13 ft. Three of these units are normally used for the return of activated sludge to the aeration tanks, providing a ratio of 10 to 70% of the average design flow in return sludge capacity. The additional two units are employed for aeration or final tank drainage; for the wasting of excess activated sludge to the primary settling tanks; and as auxiliaries for return sludge service. A 3.6 m.g.d. and a 1.5 m.g.d. vertical type centrifugal pump are included in this station to pump screened effluent at a total head of 160 ft. for the aeration tank sprays, the flushing water system and the chlorine solution lines.

All sludge is returned to the inlet of the first pass of each aeration tank, equalized delivery to each tank being maintained through a rate controller system, pneumatically operated.

Chlorination

Disinfection of sewage plant effluents by chlorination is an important factor in the protection of municipal water supplies and bathing beaches. Even in the case where complete treatment is provided, the stabilized effluent always has substantial bacterial counts, some of which could be the pathogenic type. Post chlorination is essential to ensure maximum safety.

Use of chlorine in some of the individual operations within the plant process is also desirable. When required, control of odours and improvement in the removal of grease and the settling of solids may be achieved by addition of the chemical to the incoming sewage (prechlorination). Slime growths in the effluent flushing system can be minimized by small daily dosages of the disinfection, especially during warm weather. It also may be necessary on occasion to chlorinate the supernatant liquor from the digestion tanks, if the solids concentration reaches abnormal levels. Control of bulking on an emergency basis by the addition of chlorine to the return sludge is not uncommon.

Dosage rates vary for the different applications. Pre-chlorination, post-chlorination and return sludge control, representing the highest sewage flows, demand the larger quantities of chlorine with dosages varying from 1 to 12 p.p.m. Supernatant liquor can be considered minor flow requiring 25 to 300 p.p.m., with slime control calling for a moderate range of 2 to 10 p.p.m.

Four 8000 lb. per 24 hour, manually controlled, mechanical solution feed, vacuum type chlorinators are to be installed initially, one assigned to each of the three points of high chlorine demand with the fourth as an auxiliary. A 2000-lb. per 24 hours capacity machine is provided for supernatant liquor and effluent flushing application. All units draw chlorine from one ton containers set on weigh scales through electric heater type evaporators. (It was found impracticable to arrange tank car delivery of chlorine.) Each chlorinator is equipped with a flow recorder designed for a 20 to 1 range. Automatic proportioning of chlorine is not required, due to the continuous variation in organic content of the receiving flow.

Precautionary alarms to detect chlorine leaks and a special ventilating system form part of the safety equipment.

Air Blowers, Engines, Heating and Electrical Systems

Air requirements of the activated sludge process and the pre-aeration systems, previously described, dictated an average supply of 40,000 c.f.m. for the initial design flow and 60,000 c.f.m. for maximum flow, with 33% of maximum capacity being provided in standby.

Accordingly, four 20,000 c.f.m. units, operating at 8 p.s.i., will be installed initially, Nevertheless selection of the type of blower to be used, i.e. centrifugal or rotary, did require considerable research. Both are used widely on this continent for sewage treatment service, the latter not being available in sizes larger than 20,000 c.f.m. at the indicated pressure. The latter were selected finally to match the speed of the engine drivers, the selection of which will be discussed later. Special snubbers have been employed on the blower units to obtain a low noise level.

Filtration of the air supply to the degree normally required for some types of diffusers was not incorporated in the sewage tanks, in view of the selection of coarse bubble diffusers. Air cleaning, therefore, has been restricted to the use of single stage automatic self-cleaning type filters, employing an overlapping panel curtain rotating through an adhesive bath.

Methane gas generated in the sludge digestion tanks has served as a fuel for heating boilers in sewage treatment plants for about 30 years, and to some degree it has been utilized for development of motive power. But its use for power purposes can only be justified on the basis that production costs are lower than those quoted by the electrical utility. Thus, an economic analysis of the Humber project was made, comparing cost of power obtained through gas or dual fuel diesel engines against purchased power. Such analysis took account of all building and equipment costs as well as operating costs. It was found that the greatest economy could be achieved by driving the large air blowers with dual gas engines, using gas generated within the plant.

Rates and standards of service quoted by the local gas utility indicated that the use of natural gas (1000 Btu rating) as an auxiliary to the sludge gas (600 Btu) on a gas cycle engine would be cheaper than utilizing oil as standby to sludge gas on a dual fuel diesel engine. Accordingly, the blowers are to be driven by 1000 h.p. dual gas engines, operating at the blower rating speed of 333 r.p.m. The combined assembly will be mounted on a vibration isolating spring mounting system to control noise and vibration within reasonable limits.

Heat recovery devices on the engine cooling and exhaust systems are the primary heating element for the digestion tanks and plant buildings. Heat for the digestion tanks is provided from the engine cooling system through a hot water system operating between 140 and 160°F. The low pressure steam heating system for the building derives heat from exhaust gas recovery units, with standby steam boilers being provided to supply either the building system directly or the digestion system through steam to hot water converters.

The blower room, heating plant, workshop and control room are located in the main building along with the Head House and the administration section.

Ventilation of the main building is planned to ensure that no gases or odours reach dangerous or obnoxious proportions, all foul air being directed to the air blower suctions on a controlled basis and discharged through the diffuser system in the aeration tanks for odour control.

The plant electrical supply is obtained from an adjacent 27.6 kw.-feeder of the Etobicoke Hydro Electric Commission, and is transformed through the plant's main substation to 2300 volts. From this point, buried 2300 volt cables in duplicate are laid to transformer stations in the main building and return sludge pumping station, with feeders emanating from these points to eight 575 volt motor control centres (provided with lighting transformers and 120/208 volt low voltage systems), located about the plant. A floodlighting system is included to facilitate 24-hour operation, and all structures and galleries are equipped with emergency lighting systems using nickel cadmium batteries. Electrical equipment within the digestion control galleries is explosion proof.

Plant Hydraulics and Metering

Satisfactory flow through plant elements requires a difference in elevation between the level of the incoming sewage and Lake Ontario—the receiving waters for the effluent—to provide for various hydraulic losses. These head losses will vary with the rate of flow, and the efficient operation of the plant relies in large measure on the skill with which the losses have been assessed. In general, the hydraulic analysis of the Humber plant was based on the following considerations: assuming the highest controlled level of Lake Ontario (Seaway); providing for maximum flow with one of each type of unit out of service; allowing for free discharge over all weirs under such conditions; anticipating the later duplication of the plant; and ensuring average velocities of at least 2 ft. per sec. in all structures preceding the aeration tanks and at least 1 ft. per sec. in all succeeding structures. Kutter's formula was used to determine losses anticipated in the open channels, while Hazen and Williams' work was employed to compute losses in the conduits. Standardized coefficients related to velocity heads were required to establish losses due to turbulence, obstructions, openings, and changes in hydraulic area. Loss of energy caused by flow momenta at juncture points was not overlooked.

Final review of all hydraulic determinations and assumptions indicated that 13.5 ft. should be left between the maximum water level in the inlet sewer and top water level in the final settling tanks.

Adequate meter equipment plays an important role in any large sewage plant—indeed, its absence can make operation extremely inefficient. The cost normally is less than 2% of the project.

A location for the metering of the raw sewage has been selected between the grit removal and pre-aeration facilities where a concrete venturi tube, square in cross-section, is being cast in the connecting conduit, its throat reducing to a square of 42 in. from an inlet size of 84 in. square. The throat will be bronze lined and differential will be measured by a mercury well type electric transmitter. Settled sewage entering each of the five aeration tanks passes through 36 in. by 20 in. venturi tubes, which record flow with the aid of pneumatic transmitters of the nozzle-bellows, forced balanced type. Return sludge to each tank is metered through a 20-in. venturi tube having a 16 in. butterfly valve installed in the throat, the flow into No. 1 tank being manually set and pacing to an equal proportion the flow to all other tanks. Air to each aeration tank is metered through venturi insert nozzles, and both return sludge and air primary devices are provided with mercury operated pneumatic transmitters.

A venturi tube with a mercury well operated pneumatic transmitter accounts for the volume of waste-activated sludge handled, and all primary and digested sludge is measured by calibration of the reciprocating pumps and recording their period of operation on a time chart.

All meters are equipped with visual dials and transmitters, which relay data to totalizing and recording charts on the central control panel being established in the Main Building. Statistics on digestion tank temperature, gas pressure and engine operation are also accommodated on this panel.

Outlet Sewer

Outlet sewers for plant effluent should terminate well below the surface of the receiving waters, in order to disperse the fluid as rapidly and uniformly as possible. They must be located with careful regard to prevailing currents and proximity to water works intakes and bathing beaches. Multiple outlet risers along the line of the submerged outlet can be an important factor in ensuring that the effluent does not reach critical lake areas in concentrated form.

The outlet pipe for this installation will be placed in Humber Bay, immediately west of the mouth of the Humber River. This location has been adopted after careful study of both surface and depth currents, soil borings and sounding information — all made through the use of floating equipment. The shore section of the 10 ft. diameter outlet has already been constructed in concrete lined rock tunnel from the plant site, some 900 ft. southerly to the Lake shore. The 10-ft. diameter marine section will be under way shortly, extending 2200 ft. into the lake and terminating in fifteen 4-ft. diameter outlet ports at a depth of 23 ft. below normal lake level.

Soil investigations indicated that rock level dropped sharply from elevation 230 at the shore to 153 at a point 600 ft. out in the lake. At

1400 ft. from the shore it commenced to rise again, reaching an elevation of 200 at the 2200 ft. mark. For the intermediate area, the overburden was composed of silty sand varying from extremely weak to well compacted material on an irregular pattern. Because of this condition, it was decided to fabricate the pipe of welded steel in 60 ft. lengths with special flexible marine joints, and lay it in a specially constructed sand bedding with a minimum cover of 5 ft. Such construction will not increase the loading on the supporting soil, and the flexible pipe will provide for any slight settlement or variation in the bedding. Alternative tenders, however, may be requested, using reinforced concrete pipe with subaqueous joints delivered in 16 or 32 ft. lengths.

An emergency 6 ft. diameter bypass into the Humber River permits the submerged outlet to be dewatered at any time for cleaning or inspection. An 84-in. diameter sewer has been constructed around the entire plant connecting to the outlet sewer, thus permitting diversion of excessive flows directly to the lake in emergencies.

The length and area of the outlet sewer will give 15 minutes contact time for post chlorination of the effluent, even at maximum flow.

Sludge Digestion and Disposal

The disposal of the solids removed as sludge from the primary and final settling tanks represents a separate and difficult part of the project. Being highly putrescible, this sludge could be a serious nuisance unless its disposal is satisfactorily accomplished. It must be rendered unobjectionable and disposed of rapidly to prevent excessive accumulation; such methods as may be employed preserving economy to the highest degree.

Any treatment to the sludge that excluded digestion could not be practised on the Humber site without the creation of unfavourable odours. Such odours would result in severe criticism from residents in nearby developed areas. In addition, the reduction of solids by 40% and the consequent decrease in the volume of sludge to be handled by later disposal methods, plus the value realized in utilization of sludge gas for power and heating purposes, made digestion in this instance almost mandatory. Through digestion above all else, sludge can be made sufficiently innocuous to be safely distributed in some form for soil rehabilitation.

Estimated sewage strengths predicted that at initial design 96,600 lb. of sludge on a dry basis would have to be pumped to the digestion tanks daily or, at 4.5% solids concentration, 215,000 gal. If solids loadings on the digestion tanks were to be restricted to 2.15 lb. (dry basis) per cu. ft. of digestion tank per month, then approximately 1,400,000 cu.ft. of volume was required.

To meet this requirement, six tanks are now under construction, each 110 ft. in diameter with 25 ft. side water depth. It is reasonable to assume that within 40 days sludge will be reduced in volatile content sufficiently to reduce the daily weight of solids for disposal to 61,000 lb. dry basis, and that this reduction will produce gas at the rate of 581,000 cu. ft. per day, representing heating value of 14,100,000 B.t.u. per hour.

The tank structures have been arranged for two-stage digestion, with the four Primary ones being in a continuous state of rapid digestion while the two Secondary units will permit separation of the sludge under quiescent conditions. Three of the Primaries are equipped with mechanical sludge mixers, the fourth having a gas recirculation system. With this arrangement, sufficient experimentation will be possible to determine if high rate digestion is feasible, in which case the initial tanks will be capable of considerable overload when planning future extensions. All primary tanks are designed with fixed covers, while the secondary tanks are fitted with gravity gas holders that will permit storage of 200,000 cu. ft. of gas at 7 in. pressure.

The tanks are arranged three abreast with a central control gallery. Raw sludge will enter the Primaries through spiral type hot water heat exchanges located in the gallery, and the tank contents will be continually circulated to maintain temperatures between 90 and 95° F. The introduction of raw sludge to the primaries automatically spills sludge from these tanks to the secondary units, from which supernatant liquor overflows to the plant inlet for treatment and from which digested sludge is pumped. Gas generated in each tank is metered and discharged either to the engines or the gas holders, depending on the pressure obtaining in the system. Automatic controls, pressure and vacuum relief valves safeguard the system against explosion.

Digested sludge withdrawn from the secondaries will be pumped with heavy duty plunger pumps through an 8 in. forcemain some 4000 ft. westerly to the existing Etobicoke Sewage Plant, which is to be converted to a dewatering facility as part of the Humber project.

The existing digestion tanks here will be utilized for storage of digested sludge passing through the forcemain mentioned previously, and the existing open tanks will be used for elutriation and sludge concentration purposes. Sludge from the elutriation tanks will be pumped to new vacuum filters for dewatering to 67% moisture content. The filters will receive sludge at the rate of 4.4 lb. (dry basis) per sq. ft. per hour, with application of 3% by weight of ferric chloride for coagulating purposes. Filter cake will be stored in hoppers for daily disposal by trucks to farm lands within a seven mile range. Incineration or heat drying facilities may be necessary on this site at a later date.

Calculations indicate that the disposal of digested sludge by elutriation, filtration, and truck haulage to farms would cost approximately $10.25 per ton (dry basis) including capital and operating charges.

Structural Features

The plant hydraulic structures are reinforced concrete, with design based on standard A.C.I. and National Building Code regulations. Anchors have been used to resist uplift from the relatively high ground water. These are formed of ¾ in. diameter double legged deformed bars, extending 5 ft. into drilled holes in the rock that were slushed full of neat cement grout after setting of the steel. These units were designed to resist a pull of 10 tons, but tests on the finished product have indicated that a pull of 30 tons can be made without failure.

Despite the length of the open tanks, no expansion joints were provided, partly because of the rock anchorage cost and risk of major leakage. As an alternative, temperature steel was increased to 0.5% of the net concrete area: corners, together with construction joints, were specially reinforced, on the assumption that temperature cracks would distribute with even spacing and few would support leakage of measurable amount. This procedure had been followed in some American plants with success.

Leakage tests on the new tanks at the Humber and the crack pattern that has developed have proved the

THE BEAUHARNOIS NO. 3 DEVELOPMENT

Y. De Guise, M.E.I.C., *Assistant Chief Engineer*
Regional Operation Division

Clement Forest, M.E.I.C., *Assistant Chief Engineer*
Power Development Division
Quebec Hydro-Electric Commission, Montreal, Que.

This paper deals with No. 3 Section of the Beauharnois Development, a project originated in 1929 and now nearing completion with construction of this third and final phase. A property of the Quebec Hydro-Electric Commission and situated some 30 miles west of Montreal, the completed Beauharnois Development will be one of the main sources of power supply for Canada's metropolis.

This submission on Beauharnois No. 3 includes its general features, hydraulic characteristics, evaluation of benefits to be derived from its generating units, general design considerations, equipment characteristics, construction procedure and methods.

ONE SHOULD not merely picture a huge powerhouse when considering the Beauharnois Development. Rather, the project embraces a tremendous development extending over 16 miles of territory, an enterprise involving the control of the St. Lawrence River which, for the first time in history, was dammed over completely for eventual total diversion into a man-made canal.

The Beauharnois Development utilizes the water power available on the St. Lawrence between Lake St. Francis and Lake St. Louis. Three series of rapids cause a drop in level of 82 ft. over a distance of 15 miles. Since the minimum flow of the St. Lawrence at Beauharnois will be maintained above 210,000 c.f.s. during high-load periods on the system, the primary potential power available will be over 1,600,000 continuous horsepower.

River flow is controlled at the outlet of Lake St. Francis by four dams extending across the St. Lawrence between three islands—(Fig. 1). Water is directed into the 15-mile canal excavated on the south shore, and returned to Lake St. Louis following an 80-ft. drop through the powerhouse.

Incidentally, the St. Lawrence River control works and remedial dams were described in detail by the late M. V. Sauer, M.E.I.C., in an excellent paper published in *The Engineering Journal* of December 1943.

The first two sections of the Beauharnois Powerhouse comprise 26 main units of approximately equal capacity (53-56,000 h.p.) and two auxiliary 8,000 h.p. units, providing a total of 1,425,000 h.p. Addition of the third section—Beauharnois No. 3—will increase the installed capacity to 2,161,000 h.p. with the ten units being installed or to 2,235,000 h.p. if a contemplated additional unit be added. The total length of the powerhouse is 2,843 ft.

The average daily production will be over 34,000,000 kwh. by 1961. This production can be appreciated better by comparison with its energy equivalent: a daily train load of coal comprising more than 300 cars of 50-ton capacity apiece!

Hydraulic Characteristics

Construction of the St. Lawrence Seaway and development of power in the International Rapids Section of the St. Lawrence have brought to the fore the opportunity of regularizing available flow. The problem, however, has proven to be very complex because of the multiplicity of conflicting interests. Two countries, the United States and Canada, are involved, with two different Provinces of our country, Quebec and Ontario. As a result, some degree of compromise was necessary to satisfy navigation interests, riparian rights and power requirements. Numerous criteria were suggested to protect all interests as much as possible, and a tentative regulation plan was proposed. This plan would bring the minimum outflow from Lake Ontario, the source of the St. Lawrence, to 190,000 c.f.s. in open water periods, and would limit the maximum discharge to 310,000 c.f.s.

Production of power at Beauharnois is governed not only by flow available in the river but also by the possibility of admitting into the 15 mile intake canal—under adverse ice conditions—the quantity of water required by hydraulic turbines. It is known quite generally that such difficulties have been experienced mainly because the total capacity of units installed increased more rapidly than did the enlargement of cross-sectional areas of the canal—(Fig. 3.) As a consequence, resulting water velocity has been higher than desirable for the formation of a smooth ice cover. Moreover, it happens frequently that frazil or shell ice accumulates in the cooling system of units before ice has consolidated on the surface. This has temporarily impaired normal output.

Considerable progress has been made in recent years in eliminating a substantial percentage of the reduction of power accompanying freeze-up conditions. Such results have been obtained mainly through:

(a). the use of ice booms installed at various strategic locations in the canal to prevent movement of ice sheet in areas adjacent to higher-velocity currents, the booms placed to facilitate formation of an initial ice cover.

(b). the installation of emergency sources of frazil-free water supply—either in the sluiceway adjacent to the plant or in the excavated area for Beauharnois No. 3 powerhouse.

Experience obtained from the latter expedient has contributed valuable information for the design of the cooling-water supply system for the third section of the powerhouse.

Evaluation of Benefits to Be Derived from Units of Beauharnois No. 3 Powerhouse

Beauharnois No. 1 and No. 2 powerhouses experienced serious limitations in power output for several years during ice-forming periods. Accordingly, genuine apprehension was felt about benefits to be derived from investment involved in the third section of the plant. Contributing also to this anxiety was the fact that the reduction in output generally coincided with peak-load periods on the system.

Based on latest information on the probable regulation plan to be adopted for Lake Ontario, a careful analysis was made of energy to be derived from each additional unit of Beauharnois No. 3. Borne in mind were:

(a). Limitations in flow that can be admitted into the canal during the winter season.

(b). Loss of power produced at the Cedars plant—dependent upon the same control works for its water supply—when diversion of flow into the Beauharnois canal does not leave at least 64,000 c.f.s. in the river.

The 95 years of recorded flows of the St. Lawrence were divided into nine 10-year periods, the last five being ignored for statistical purposes and the proposed regulation plan applied through that period.

The average yearly flows in each 10-year period were tabulated in order of magnitude and listed, respectively, as flow available 10%, 20%, 30% and up to 100% of the time. The nine averages were then used as the basis of an overall average yearly flow figure—again for 10%, 20%, 30% and up to 100% of the time.

The monthly distribution of flow, corresponding to the theoretical average yearly flows calculated above, was obtained by comparison with a year of similar flow average under the proposed regulation plan.

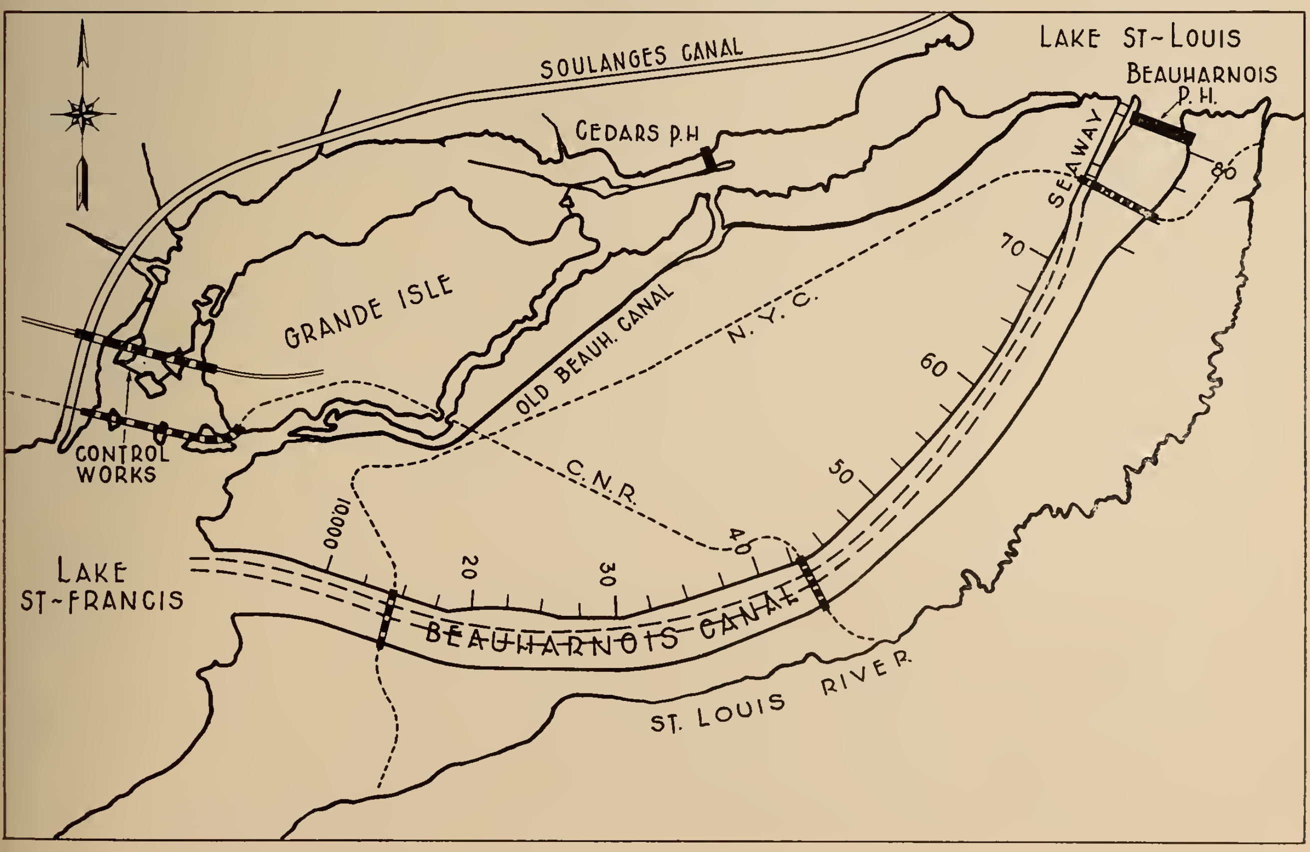
Table I gives the monthly flows used for assessing benefits to be expected during a given percentage of time.

Table II figures have been derived from the flows given in Table I. They show additional energy to be expected from the ten units of Beauharnois No. 3, bearing in mind the limitations previously mentioned.

It is very interesting to note that, considering flows available five years out of ten, the energy production at Cedars during the December 15-March 31 period—after Beauharnois No. 3 is in operation—will still be 57% of what it would have been without Beauharnois No. 3. Moreover, with Beauharnois No. 3 powerhouse in operation, Cedars plant winter production is 84% of its average annual production.

The next very important question was the quantity of firm power to be obtained from Beauharnois No. 3. There has been and still is some doubt

Fig 1. Beauharnois Development



about the number of units that can be utilized during the ice-forming period. Opinions vary from two to four. However, it is quite generally admitted that, after consolidation of an ice cover on the canal, the minimum guaranteed winter flow through the probable regulation plan (210,000 c.f.s.) could be utilized. This involves the first three units of this third section.

It must be borne in mind also that a good proportion of the energy to be available from Beauharnois No. 3 will be used to firm up the production of sister plants. Such plants include the nearly-completed Bersimis development, some 400 miles northeast of Montreal, and the proposed Carillon plant, on the Ottawa River, about fifty miles west of the metropolis. The ratio of average production to installed capacity at these three plants, as indicated in Table III, is less than Hydro-Quebec's annual load factor. In other words, these three stations cannot contract for power—at the usual load factor—to the extent of their installed capacity, unless energy is supplied from another source to counteract the lack of water available.

Other considerations contributed to the decision to install 10 units in Beauharnois No. 3 and provide space for an 11th:

(a). A majority of the 14 units in Beauharnois No. 1 has been more than 20 years in operation, four of them being 27 years old. Moreover, owing to their physical dimensions, the runners were cast in four sections bolted together and they have required more maintenance than conventional one-piece runners. It is usual to take a turbine out for major overhaul every eight to ten years, with an outage period of over three months. Applying the same assumption to turbines of Beauharnois No. 2 and Beauharnois No. 3, it is expected that — with their combined total of 36 units—four could be taken out of operation every year.

(b). Since it would not be economical to transmit reactive power from the Bersimis plants, any additional units at Beauharnois—for which no winter flow was available — could provide a substantial and flexible source of reactive power which would be economically preferable to installation of static capacitors in the Montreal area.

General Design Considerations

General agreement was reached on the following limitations in design:

(a). Avoidance of any radical change in architecture or superstructure construction unless a substantial saving—in the order of $1,000,000—would result.

(b). Allowable increase in spacing of units of not more than 10% as compared to existing installation—and no allowance for reduction—on account of required bulkhead stability.

(c). Maintenance of present elevation for roof, bulkhead, generator floor and crane rails.

(d). Permission for a change of plus or minus 4 ft. in turbine floor elevation to accommodate larger scroll cases associated with more powerful turbines.

(e). Retention of alignment of walls.

(f). Since the bulkhead and intake for the first four units had been built already with the powerhouse of Beauharnois No. 2 to provide a tie in the upstream earth dyke, it was agreed not to eliminate the possibility of a different design for the remaining units if the savings resulting therefrom could justify the added inconveniences. However, it was concluded that all ten units should be similar.

The major difference in the design of the powerhouse of Beauharnois No. 3 and the powerhouse of Beauharnois No. 2 lies in the type of turbine and the capacity and speed of units. Beauharnois No. 3 has propeller turbines of greater capacity and higher speed than the Francis-type turbines in Beauharnois No. 2. Consequently, draft tubes, scroll cases and generator foundations are quite different.

Individual hoists for headgates are provided for seven units to permit emergency lowering. Gates had been installed already for the first four units and individual hoists were not provided. Sump and sump pumps have greater capacity and the method of de-watering draft tubes is different.

Table II

% of Time	Annual Energy from Beauharnois I and II, plus Cedars	Annual Energy from Beauharnois I, II and III, plus Cedars	Annual net gain
10	10,454 × 10⁶ kwh	13,227 × 10⁶ kwh	2,773 × 10⁶ kwh
20	10,441	12,948	2,507

90	10,116	11,294	1,178
100	9,942	10,927	985
		Average:	1,832 × 10⁶ kwh

EQUIPMENT CHARACTERISTICS

Turbines Comparative cost studies led to the conclusion that the use of propeller-type turbines — as opposed to the Francis-type turbines in Beauharnois No. 1 and Beauharnois No. 2 —would permit a saving of at least $3,000,000. These turbines have a normal rating of 73,700 h.p. under a 78-ft. head and rotate at 94.7 rpm. Their outside diameter is 252 in. and six blades are bolted to the runner hub. The runners are of cast steel, with a layer of stainless steel over areas more susceptible to cavitation. Flow is controlled through 24 wicket gates. Draft tubes have an H D ratio of 2.62, about the same as for Beauharnois No. 1 and Beauharnois No. 2 plants. The low point of the draft tube floor is at Elevation 24.5, compared to Elevation 34 for units of the first two plants.

Governors Similar to the governors in the Beauharnois No. 2 powerhouse, they are of size adequate to supply sufficient oil to servomotors. It is possible to operate the turbine gates through a complete closing or opening stroke in a minimum of four seconds, with minimum oil pressure of 270 lb. per sq. in. in the tanks and an operating head of 83 ft. The governor head is capable of causing the relay valve to pass oil in the direction to effect a corrective movement of the turbine gates—in consequence of a speed variation of 5/100 of 1%.

Servomotors are provided with adjustable by-pass connections whereby the rate of closure may be retarded during the portion of gate travel, from slightly below speed-no-load position to fully closed position.

Generators Of vertical shaft, water-cooled type, the generators have direct connected main and pilot exciters. With a continuous rating of 65,000 kva at any power factor from 85% to 100% and rated at 13,800 v., their temperature rise does not exceed 60° C in the rotor and stator windings. They are capable of withstanding the runaway speed of the turbine—206 rpm.

The field winding is equipped with non-continuous damper winding, which gives a ratio of quadrature to direct axis subtransient reactance of not more than 1.5. Short circuit ratio is calculated to be 1.11 and exciter response ratio is at least 1.0 as defined by ASA standards.

Table III

	Installed Capacity kw	*Average Production kw*
Bersimis I	900,000	560,000
Bersimis II	625,000	300,000
Carillon (proposed)	625,000	285,000
TOTAL	2,150,000	1,145,000

RATIO: $\frac{1,145,000}{2,150,000} = 53\%$

The flywheel effect of the rotating parts is 78,000,000 lb. ft. squared and the thrust bearing will support 1,987,000 lb., representing the weight of rotating parts and unbalanced hydraulic thrust. Each generator is so constructed that it can be assembled or dismantled with the use of existing 200-ton cranes.

Coolers are so designed that, when operating at rated load, the difference in temperature between air leaving the coolers and water entering them will not exceed 10° C.

The multi-turn stator coils are insulated with continuously-taped Class B material and, by means of a vacuum and pressure process, are impregnated with a thermalastic compound.

The star-connected stator winding has two circuits per phase, distributed around the stator for split-phase differential current protection. It is a double-layer, top-connected, four-circuit winding with alternate poles in series and using three turns per coil.

Transformers, Breakers, Control Transformers are rated 40,000/65,000 kva - three phase - 60 cycles - 13.8/120 kv - type ONS-ONP - 55° rise.

The high-voltage winding is star-connected for grounded neutral system and has additional turns to compensate for regulation at 85% power factor, lagging, full load. Insulation is graded from 650 kv basic insulation level, at the line end, to 110 kv at neutral. Low-voltage winding is delta-

Fig 2. Aerial view—powerhouses 1, 2 and 3

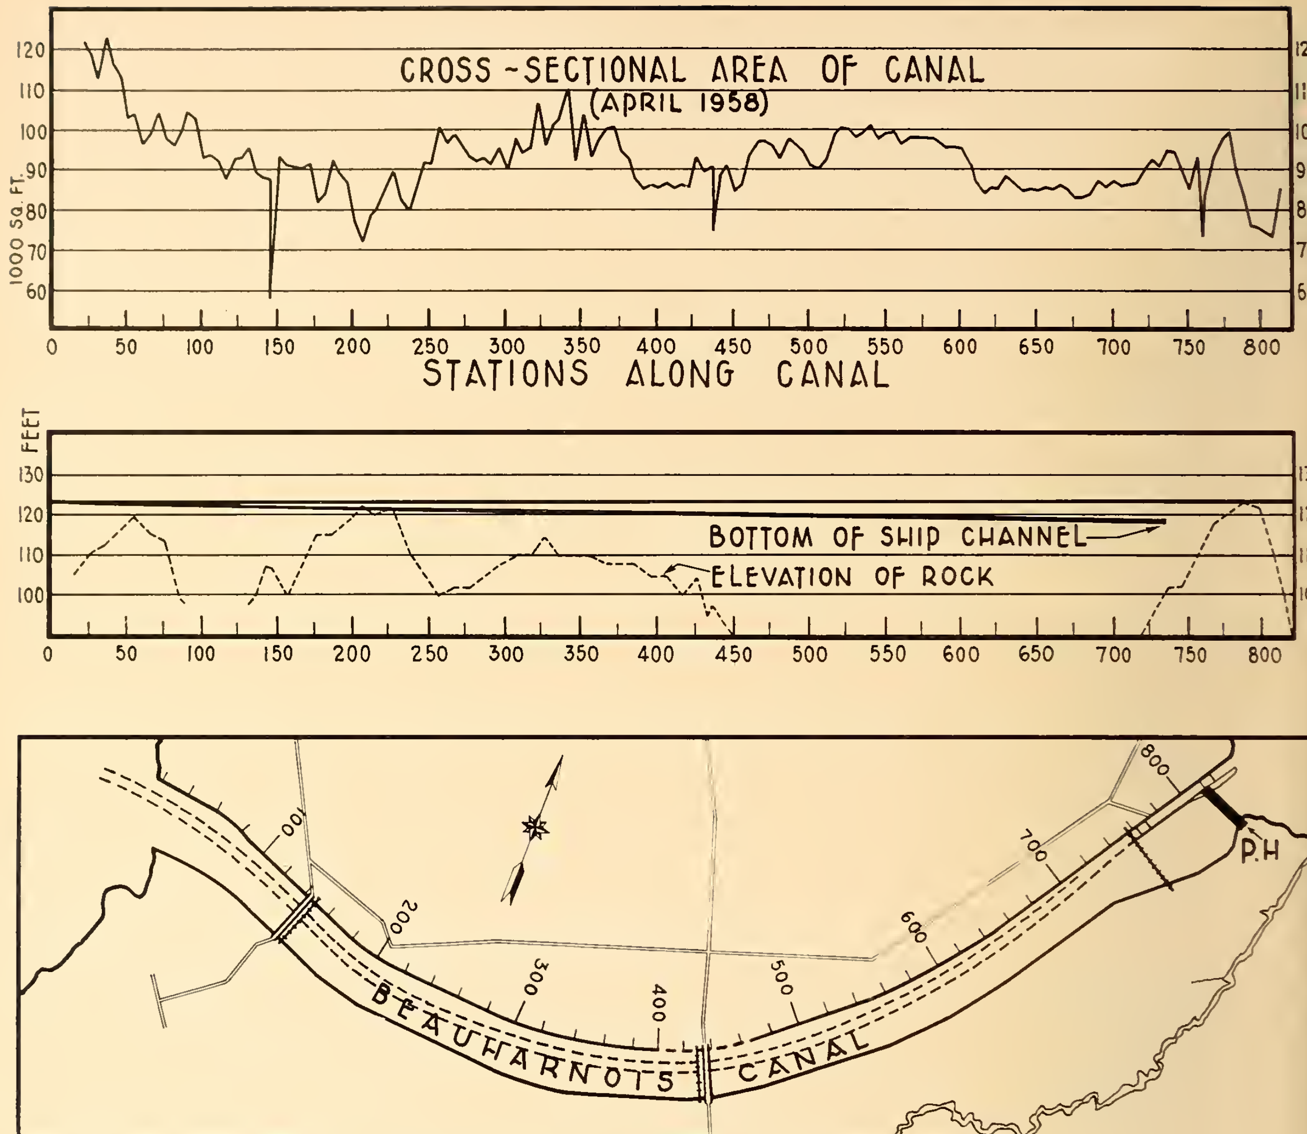

Fig 3. Cross-sectional area of canal

connected for operation on the 13.8 kv system.

Fin-type radiators are installed in groups on both sides of the transformer banks. Axial-flow, air-blast equipment is mounted on these radiators and automatically controlled by the temperature of the hottest spot in the winding.

The tank is of *Shell-form-fit* construction and designed to withstand full vacuum.

Power is taken from these transformers to the switching station near the tailrace through three-phase 5,000 mva oil-circuit breakers.

Control of units can be effected locally through duplex switchboards, each handling two adjacent units, as well as by supervisory means from the main Control Room in the Beauharnois No. 1 powerhouse.

Electrical Supply for Plant Auxiliaries Electrical station service provided for the Beauharnois No. 3 powerhouse consists mainly of:

(a). Two 1,500 kva-13,800 575 v., dry-type transformers which can be fed from two different power sources.

(b). One 575-v. distribution system to supply main auxiliaries.

(c). Six 112.5 kva-575 120 208 dry-type distribution transformers for lighting and convenience outlets.

It might be well to explain the 13,800-v. power supply and the 575-v. switchgear and distribution.

13,800 v. power supply. One of the sources of supply for plant auxiliaries is a 13,800-v. station service ring bus. Located in the Beauharnois No. 1 plant, it has supplied station service requirements for the Beauharnois No. 1 and Beauharnois No. 2 plants. The second source is a tap connection installed between two units, Nos. 23 and 24.

To simplify protection and prevent faulty operation, it was decided that the transfer from one source to the other would be performed manually. On the basis of previous experience in the Beauharnois No. 2 powerhouse, it is estimated that the units in the Beauharnois No. 3 plant will be able to operate from 20 to 30 minutes without station service power. That period of time should be sufficient to permit manual transfer.

This ring bus has proved a reliable system. It can be fed from two 7500 kva auxiliary units or from any other main unit from No. 1 to No. 16 inclusive. The present station service load is approximately 5,000 kva and, with the addition of the Beauharnois No. 3 powerhouse, it should not exceed an average of 6,000 kva, which is less than the capacity of one auxiliary unit. An extensive scheme of protective relays was completed recently on the ring bus so that defective equipment may be cleared in minimum time and with the least interference with plant operation.

Since physical and economic considerations dictated the use of power-cable connections to supply auxiliary power in the Beauharnois No. 3 plant, and because of the possibility of failure of cables and associated equipment, it was decided that the importance of such service justified a duplicate source of 13,800-v. power. Incidentally, the tap connection was installed between units No. 23 and No. 24 because of space available for tap-off equipment and because of existing provision in the isolated phase bus of these units.

575-v. Switchgear and Distribution — An air circuit breaker in the secondary of each transformer is connected to a main bus, sectionalized by a tie breaker. Six main feeders are connected to this main bus, three on each side of the tie breaker. Normally, each transformer will supply one-half the station service load. Should a fault occur in one of the transformers or in its 13,800-v. source, causing a marked decrease in voltage, the secondary breaker on the faulted transformer will open automatically. Following this action, the tie breaker will close, thus transferring the entire powerhouse service load to the other transformer.

A similar throw-over feature is included in each of the six distribution cubicles receiving power from two 1000-amp. bus ducts connected to one of the three feeders on each side of the above mentioned tie breaker.

Service Water System

An effort has been made to save the Beauharnois No. 3 powerhouse from the difficulties experienced by its allied units through frazil-ice blockage of the cooling water supply to generators and bearings. Success will mean improving the dependability of the system under all climatic conditions.

Essentially, the service water system must be planned so that piping, strainers and pumps are designed to provide an adequate flow of filtered water at prescribed pressures. It consists of four main component parts:

(a). Raw water intakes and header;
(b). Strainers;
(c). Filtered water headers;
(d). Fire protection and high-pressure system.

Raw Water Intakes and Header — The raw water header is a 16-in. pipe line, extending the entire length of the powerhouse. Its main purpose is to serve as a collector for the raw water intakes and divert it to strainers and other feeds.

Unlike previous installations, there are two different types of raw water intake. One consists of a standard 12-in. intake with a rough metal grid strainer and originating in the scroll case of each unit. Similar to the intakes installed in the Beauharnois No. 2 powerhouse, they have a capacity of approximately 7500 gpm at 20 psig and under operating conditions.

The second type consists of a 16-in. pipe extending along the side and near the bottom of the main water intake passage of units No. 31, No. 35 and No. 36. It is estimated that each of these intakes will have a capacity of some 10,000 gpm at 20 psig under operating conditions.

This second type of intake was installed to provide a source of water free from frazil ice during the winter months. During that period, cold air temperatures, winds, and water velocity in the power canal and open-water areas cause ice particles to be formed. These particles are carried in a state of suspension in water, their density varying from light to slush ice.

This frazil ice creates two problems in the water system. First, should the concentration be appreciable, it will clog the rough strainer at the intakes. Secondly, if the ice particles are much diluted in water, they will enter the water system and accumulate in the main water strainers which have a mesh of 12 x 12 x .022. The result in both cases is that a serious water shortage develops, impairing the cooling system.

Location of openings for the auxiliary intakes was selected on the basis of frazil ice soundings and the absence of icing conditions at the lower section of the trash racks. Sounding records indicated a negligible concentration of frazil ice at depths greater than 27 ft. On the basis of these findings, the above mentioned intakes were located at Elevation 101.3 — water surface elevation in the winter being 148.0 - 149.0 — and as near the bulkhead as possible.

Strainers — Three banks of strainers have been provided. One bank of two strainers is located between units No. 28 and No. 29, another of three between units No. 30 and No. 31, and space has been provided for a future bank of two between units No. 34 and No. 35. Each strainer has a capacity of 4300 gpm with a water head loss of 5 ft. Greater volumes can be obtained with correspondingly larger head losses and a lower degree of cleanliness.

Filtered Water Headers — Two 16-in. pipe lines are provided to distribute the filtered water at approximately 18 psig from the strainers to the unit cooling systems, fire pumps and accessories. Both of these headers will be interconnected with similar pipes in the Beauharnois No. 2 powerhouse. One of the headers extends into the Beauharnois No. 3 powerhouse to the second bank of strainers located between units No. 30 and No. 31. The other header extends the entire length of the powerhouse. The flow of water through these headers varies with climatic conditions, but approximately 13,000 gpm will be used by this powerhouse on an average summer day. The main feeds are the unit-cooling systems, each requiring 1000 gpm for generator cooling and 100 gpm for bearings.

Fire Protection and High-Pressure System — These headers are used mainly for sprinkler feeds to the units, flushing of strainers, compressor after-coolers, hose connections, deluge valves for mulsifyre systems on transformers and breakers, etc. . . .

Total water-cooling requirements, exclusive of protection needs, amount to over 20,000 gal. per min. for the Beauharnois No. 1 and Beauharnois No. 2 powerhouses, and to over 10,000 gal. per min. for the Beauharnois No. 3 plant.

Equipment Protection — Depending on type of fault, the following operations may take place:

(a). An alarm or signal will be given.

(b). The high-tension circuit breaker will open, the generator continuing to operate at speed-no-load.

(c). A multi-contact relay will cause high tension and field breaker to open, with the governor closing turbine gates and brakes bringing the unit to complete rest.

An alarm will ring, causing the irregularity to be indicated on an annunciator board under the following circumstances: whenever a ground develops in the stator winding or in the field circuit of the exciter or generator; whenever an abnormally high temperature is detected by thermal elements in the windings, bearings and oil wells.

The high tension breaker will open, with the generator operating at speed-no-load, whenever one of the following situations arises: an overload on the transformer accompanied by a voltage drop, an over-voltage on the unit, a 5% over-speed of the unit or a fault detected by bus differential relays.

The multi-contact relay will operate, bringing the unit to rest, whenever there is an unbalance in the split-phase circuits of the generator or in the current between generator and transformer; an overload in the generator accompanied by a voltage drop; an over-speed of 125%; high bearing temperature detected by thermometers; low oil pressure in the governor system; or formation of gas in the transformer tank.

Powerhouse Outgoing Lines — The output of units No. 1 to No. 22 inclusive—except for five or six generators used on local 13.2 and 44 kv systems—is directed to a switching station near the Beauharnois No. 1 tailrace by means of ten 115 kv lines, while the production of units No. 23 to No. 36 inclusive is fed into another switching station near the Beauharnois No. 3 tailrace by means of seven 115 kv lines. The two switching stations are interconnected by two 115 kv lines of 795,000 C.M., crossing the forebay.

From these two switching stations — of the double bus and transfer bus type — power is transmitted to the Hydro-Quebec system in and around the Montreal area.

We have attempted to outline problems encountered in realization of Hydro-Quebec's Beauharnois No. 3 project, and the measures taken to arrive at what we expect to be the best solutions.

Construction aspects of this development

The project was approved in the summer of 1956, the schedule calling for four units to be delivering power by the fall of 1959. Scanning the amount of work to be done in a short period of three years, no one can deny that this was a very tight schedule. The general contractor came in the field on August 1, 1956.

Table IV will give an idea of the huge quantities of materials and equipment we had to handle.

Table IV

1—*Excavation*	Earth in forebay	225,000 cu. yds.
	Earth in powerhouse and tailrace	165,000 cu. yds.
	Rock in powerhouse and tailrace	1,265,000 cu. yds.
2—*Dykes*	(a) *New Dyke*	
	Stripping borrow pits	15,000 cu. yds.
	Earth excavation	140,000 cu. yds.
	Rock excavation	200 cu. yds.
	Foundation Preparation	
	On rock	23,000 sq. yds.
	Under clay core	10,000 sq. yds.
	On natural ground	8,500 sq. yds.
	Rock fill	219,000 cu. yds.
	Impervious clay core	117,000 cu. yds.
	Transition material	108,000 cu. yds.
	Sand filter	13,000 cu. yds.
	Gravel	2,000 cu. yds.
	Overhaul	150,000 ton-miles
	(b) *Old Dyke*	
	Removal	1,000,000 cu. yds.
3—*Cofferdam*		141,000 cu. yds.
4—*Concrete*		220,000 cu. yds.
	Contact forms	1,440,000 sq. ft.
	Rock preparation	26,000 sq. yds.
5—*Reinforcing*		8,000 tons
6—*Structural Steel*		1,200 tons
7—*Bricks*		1,200,000 units
8—*Glazed Tiles*		250,000 units
9—*Floor Finish*		265,000 sq. ft.
10—*Units*	10—plus space for one additional	
11—*Head Gates*	14—each with its individual hoist (two per unit)	
12—*Trash Racks*	44—(four per unit in two sections each)	
13—*Draft Tube Gate, permanent*	two sets (four gates) steel. In addition, three sets of concrete stop logs for construction purposes.	
14—*Highway Bridge over Tailrace*	five spans of 90 ft. apiece four lanes four concrete piers of 45-ft. height	

Construction Services

There is nothing out of the ordinary about these services. An electrical substation was built with the necessary distribution facilities . . . fire protection facilities were installed where required . . . various buildings were re-adapted from Beauharnois No. 2 construction for stores, offices and shops for machinists, carpenters, pipefitters, electricians and other tradesmen . . . quite an elaborate heating plant and distribution facilities were made available for winter concreting.

Incidentally, the main pieces of construction equipment will be mentioned as we go along.

Cofferdam

Since the Beauharnois plant is not being built directly across the St. Lawrence River, there is no water diversion problem. Nevertheless, it was necessary to build a cofferdam to permit excavation of the tailrace in the dry. To meet schedule requirements, construction of the cofferdam had to be started in winter. The starting and completion dates were February 1 and July 2, 1957, respectively.

Located in the practically still water of Lake St. Louis, this cofferdam was built as a rock-fill dam with a clay blanket and rip-rap. This procedure proved to be much cheaper than the regular crib work used for Beauharnois No. 2.

The quantities involved were:

77,000 cu.yds. of rock from the powerhouse and tailrace excavation;
26,000 cu.yds. of gravel from the disposal of canal dredging;
30,000 cu.yds. of impervious material from the nearby borrow pits used for construction of the main dyke;
9,000 cu.yds. of rip-rap.

A 6-cu.-yd. Marion dragline did removal work in less than six weeks — November 10 to December 20, 1958.

It took some two weeks to remove the 25,000,000 gal. of water from the cofferdam by means of one 18-in. pump with a capacity of 8,300 gal. per min. and two 6-in. pumps with a capacity of 2,000 gal. per min. each. Working only part time, one of these 6-in. pumps kept the excavation dry thereafter.

Excavation

The Beauharnois Development sits on Potsdam sandstone, the worst property of which is its abrasiveness. Our experience during construction of Beauharnois No. 2, together with much study, decided us to use the oldest type of drilling equipment — the churn drill — for the main part of this particular work. The drilling required nearly 18 months.

Table V shows equipment and results obtained:

Some 943,000 lb. of nitrone and forcite 40% and 75% were used — the equivalent of 0.74 lb. per cu. yd. of solid rock. Short-period blasting caps were used, with periods from zero to 20.

Two 2,800 c.f.m. stationary air compressors supplied compressed air. One 3½-cu. yd. diesel shovel and one 5 cu. yd. electric shovel loaded the blasted rock into 10 dump trucks of 30-ton capacity, with a number of 2 and 2½ cu. yd. shovels being used also from time to time.

Disposal was made into Lake St. Louis for two purposes:

1. To provide the foundation for a new substation;
2. To increase the break-water required between the outlet of our tailrace and the outlet of the Seaway canal.

Grouting

Since the rock was almost horizontally stratified, the only treatment given was a little curtain grouting along the upstream face of the bulkhead, extending to a depth of 40 ft. Following excavation, the rock preparation consisted of removing loose pieces — they were plentiful in some places — and cleaning. The site was ready then for concrete to be poured.

Aggregate

No sand suitable for concrete had been found in the immediate vicinity during construction of Beauharnois No. 2 (1949-52) or during erection of Beauharnois No. 1 (1929-32). We encountered the same problem and duplicated the practice of making sand from the rock excavated at the same time as the crushed stone.

Contractors for the Seaway were preparing to build the Beauharnois Locks at that time. One company was required to supply all the contractors with all the aggregates needed for some 600,000 cu. yd. of concrete. The concrete for our smaller-sized walls and slabs demanded an aggregate whose maximum size was smaller than what the Seaway required. But we reached an agreement with this contractor whereby we were supplied with the full amount of every size required.

Batching Plant

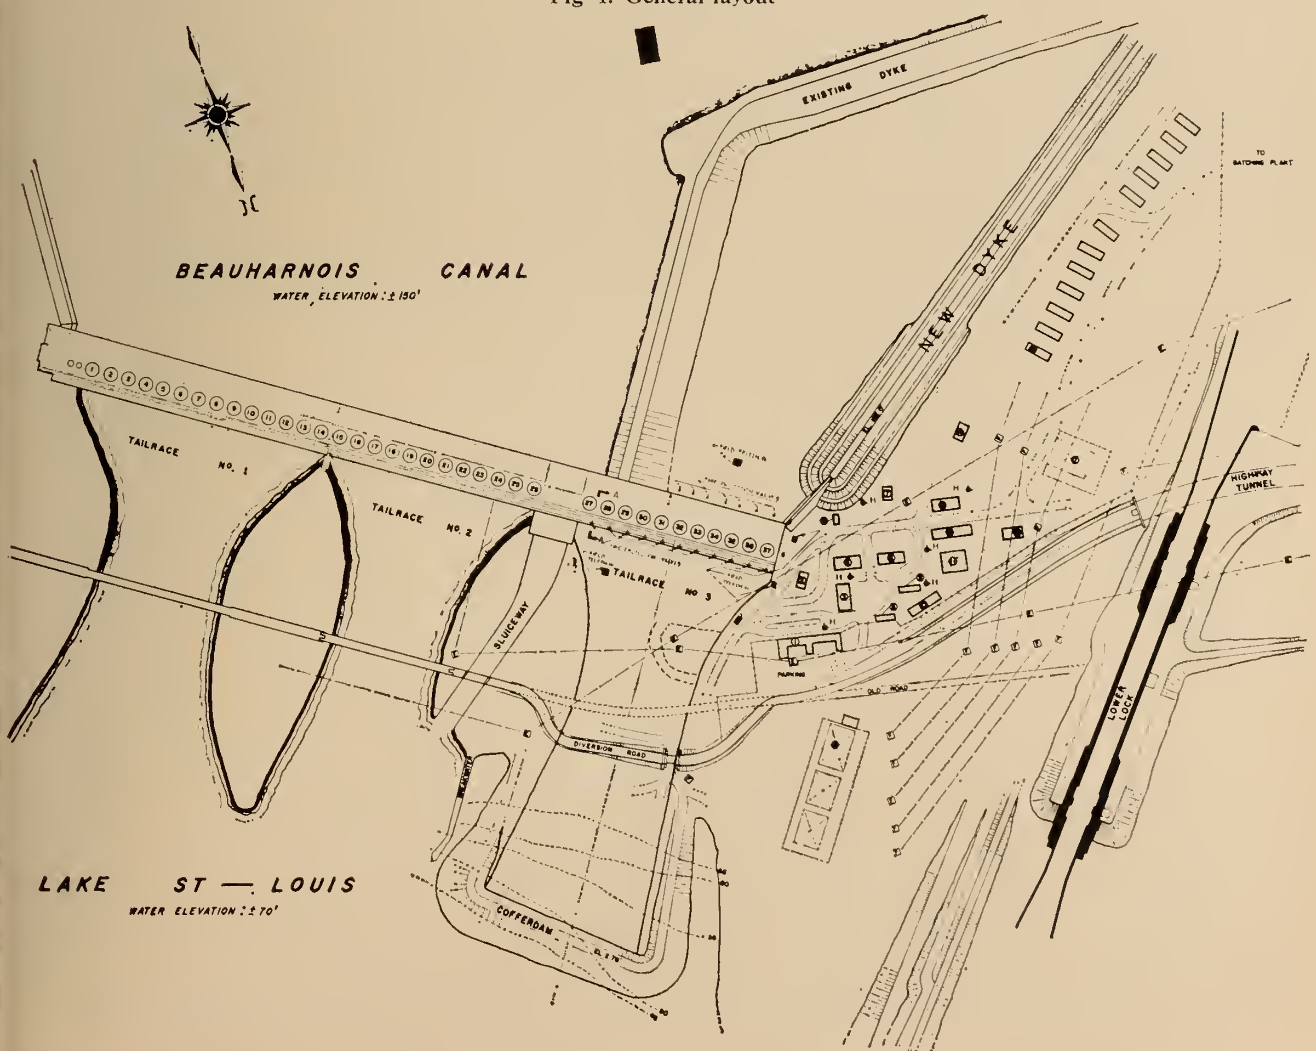
The aggregates were dumped into the supplier bin close to the crusher's stock piles. A conveyor took them from there to four compartments of a silo atop our batching plant. Two of these compartments had a capacity of 90 cu. yd. each, while the other two were of 116-cu. yd. capacity each. A fifth compartment — of 500-barrel capacity — was used to handle the cement to the weight

Table V

Equipment	*Size of bit*	*Drilling speed in ft. per hour*	*Footage drilled between sharpening*	*Footage drilled per bit*	*Total drilled*
4 churn drills.....	9 in.	4 ft.	8 ft.	592 ft.	46,500 ft.
2 Joy Challenger..	3½ in.	15 ft.	12 ft.	141 ft.	180,000 ft.
4 wagon drills....	2 in. and 1½ in.	25 ft.	16 ft.	+120 ft.	506,000 ft.

The maximum depth of excavation was 80 ft.

Fig 4. General layout



batcher, on which every size of aggregate was weighed also.

Bought in bulk, cement was delivered by truck from Montreal — a distance of some 30 miles — and placed in four silos. Two of these silos could handle 3,500 bags each and the other two had a capacity of 4,180 bags each. A special pump transferred the cement from these silos into the batching plant.

Our batching plant, incidentally, was built to accommodate four tilting mixers of two cu. yd. capacity. For this particular work, however, only two were installed, giving us an average production capacity of 80 cu. yd. an hour. This production could be increased to 100 cu. yd. per hour at peak.

Straight Portland cement was used, with an admixture to provide good plasticity and an air-entrained content of 3% to 5%.

The 28-day strength resistance was specified at 3,000 p.s.i. and was obtained by using 400 lb. of cement per cu. yd. of concrete when 3-in. aggregates were used. Once mixed, the concrete was discharged into a 12-cu. yd. hopper under the mixers.

Placing Concrete

Seven 15-ton autocar trucks, equipped with special boxes, brought the concrete from the hopper to the form work of the powerhouse. The hauling distance was less than one mile and the concrete was dumped into 3-cu. yd. laydown buckets. 2-cu. yd. buckets were used when the reach was too far for the equipment.

Placing equipment to handle these buckets comprised:

- One 15-ton truck crane;
- One 45-ton truck crane;
- One 15-ton stiffleg derrick on rails;
- Two twin-boom Gantry cranes of 6-ton capacity each at 100 ft. radius;
- A number of two and 2½ cu. yd. cranes.

For the last six scroll cases and generator piers and slabs, the powerhouse structure being built, crane and derricks from the outside are not practical, so we have gone to pumpcrete; but on account of harsh aggregate, to allow the concrete to flow through the pipe we are obliged to increase the cement content.

With that we are succeeding, but we have noticed that the abrasiveness of the aggregate is causing the pipe to wear very fast, and even with more cement we experienced delays due to plugged pipe, so we are using the overhead cranes of the powerhouse —when they are available—to place the concrete brought inside the powerhouse from the downstream bridge through a window.

All pours have been what might be termed small lift. The largest pour per unit was 1,700 cu. yd. with 1,200 cu. yd. as the second largest and the remainder under 800 cu. yd.

Formwork

With small lifts, there is no necessity for very heavy forms. We use small panels of 2 ft. 8 in. by 8 ft., made of a 2 in. by 6 in. frame and sheathed by ¾ in. plywood.

The walers were made of two — 2 in. x 8 in. and the steel tie rods were ⅝-in. The limit of rising speed was 4 ft. per hour for a temperature of 55°F. It should be explained here that we worked all year round, a circumstance that called for protection and heating during periods of freezing weather.

Such non-straight forms as the intake and draft tubes were of the dismantling type, the heaviest piece weighing five tons. Three sets of forms were built for the seven intakes and two sets for the 11 draft tubes.

Reinforcing Steel

The 8,000 tons of reinforcing steel were bought in lengths and sizes varying from 40 to 65 ft., with diameters ranging from ¼ to 1½ in. A bending machine shaped these straight bars to requirements. We used an average of 72 lb. per cu. yd. of concrete.

The Building

As explained earlier in this paper, Beauharnois No. 3 is the same type of building as No. 1 and No. 2. Such a heavy structure as Beauharnois No. 3 is needed to support two 200-ton cranes which handle rotor and shaft weighing 350 tons.

The usual procedure was followed for erecting steel and for laying brick and tile. Part of the brick, incidentally, was laid in winter time.

Powerhouse Handling Equipment

Our studies indicated that three 200-ton overhead cranes, already in use in the powerhouse, would be sufficient for the 39 units as far as maintenance was concerned. This was not really enough, however, for the construction period. Nevertheless, by scheduling the heavier lifts as accurately as possible, we proceeded with the work without too many difficulties and two much delay.

Three 150-ton gantry cranes were available on the bulkhead and no additional cranes were required because seven of the new units were equipped with individual hoists.

Trash Racks

As indicated on the cross-section, the Beauharnois powerhouse had no room for emergency gates or stop-logs. To meet any eventuality, the trash racks are designed to be sheeted — if necessary — to function as stop-logs. This is the reason they are so bulky. The opening at the racks is 1.8 times the opening of the gate, while the spacing of the cross bar is 6⅜ in.

Draft Tube Gates

Beauharnois No. 1 and No. 2 have the same draft tubes and the same draft tube gate-openings. Two sets of steel gates are used when repairing turbines in these two sections.

Sizes being different in Beauharnois No. 3, two other sets of draft tube steel gates were provided. Due to the schedule, however, two additional sets of concrete stop-logs were precast to permit work on four units at the same time. A third set was poured last January, as a result of which we are working on five units to have four of them completed during the Fall of 1959 and a fifth early in 1960.

Trashway

A small trashway — with a 4 ft. by 12 ft. overflow-type gate — had been provided in Beauharnois No. 1 on the east side of the units and was operating well.

After construction of Beauharnois No. 3, it was found that — with a 2,100-ft. bulkhead — trash was not all going to the east end. It was necessary to build a similar trashway at the west end of Beauharnois No. 3.

Tailrace Bridge

It was necessary to build a bridge over our tailrace as part of No. 3 highway between Montreal and Valleyfield. A boulevard at present links the town of Beauharnois with the suspension bridge spanning our Beauharnois No. 1 tailrace. A bridge of similar width — 28 ft. — also spans our Beauharnois No. 2 tailrace and spillway channel.

The Seaway Authority constructed a boulevard tunnel to connect with a Boulevard on the Melocheville side, while the Quebec Department of Roads was contemplating additional bridges over No. 1 and No. 2 tailraces. We were asked to build a four-lane bridge with a minimum width of two 22-ft. lanes separated by a 4-ft. curb. Another requirement was a 4½ ft. sidewalk on the downstream side.

The location of this bridge is such that we were not able to make it straight. A 3° 13′ 15″ curve was used. The piers were placed parallel to the flow on the curve of the road. The four welded girders per span were set on the tangent to the curve at mid span, while the floor beams, parallel to the piers, were placed on the girders with their ends on a straight line for each individual span. The floor beam overhang off the girders varies all along the bridge.

This bridge has five spans of 90 ft. apiece. They rest on piers 45 ft. high, 49½ feet long and 5½ ft. wide. The bridge was opened to traffic at the end of May 1958.

Forebay and Dyke

When Beauharnois No. 1 was built —up to and including Unit No. 14— the bulkhead of Units Nos. 15 to 18 was constructed to serve as an end wall to the west dyke of the canal. The eight head gates of these four units were put in place and the clay of the dyke rested against them. These gates were of the upstream skin type.

The same type of construction was used for Beauharnois No. 2. Four additional bulkheads were built with the same kind of dyke, a rolled fill clay protected by 3 ft. thick rip-rap on the water side. Since the gates were of the downstream skin plate type, a row of sheet piling was placed immediately upstream of them. Such construction offered no difficulties, with plenty of clay and with easy and cheap removal by means of our huge suction dredges.

With less clay available, no dyke to be removed later and no bulkhead needed for further extension, a completely different design was made for Beauharnois No. 3.

A concrete wall, acting as a dam, was built from the west end of the bulkhead towards the southwest. However, instead of having a cross wall with contreforts against which the dyke would butt — as on the east side of Beauharnois No. 1 — this wall was extended to be enclosed by the end of the dyke. This dyke was of the rolled fill clay core type, flanked by quarry-run rock from the tailrace excavation.

A row of drilled holes, extending 20 ft. under the upstream part of the clay core, was grouted to guarantee the water tightness of the rock. A wooden spillway was built to fill slowly the pond between the new dyke and the old one from Beauharnois No. 2. Some 300,000,000 gal. of water passed through the spillway.

Why did we proceed this way? There are three reasons:

1- To enable us to check the watertightness of our head gates;
2- To prevent any sudden pressure on our clay core dyke;
3- To permit control of the water in case of trouble.

The operation required five days — September 19-24, 1958. Subsequently, the 16 ft. by 16 ft. concrete slabs on the slope of the old dyke close to the powerhouse were removed by a crane, the 3-ft. thickness of rip-rap having been removed previously by a 6-cu. yd. dragline. In October 1958 the *Hydro-Quebec*, our 36-in. suction dredge, started to extract 400,000 cu. yd. of the 1,000,000 cu. yd. required and to clean that portion of the intake up-stream of the sheet piling which was against the gates. To help in this delicate work—there are four openings 13 ft. wide per unit —a monitor jet was used from the dredge and from the bulkhead to dislodge part of the hard-tamped clay. The remaining 600,000 cu. yd. are to be removed in the early summer this year.

A problem confronted us at the juncture of the Beauharnois No. 2 dyke and the original dyke. Since the old dyke comprised two small dykes with hydraulic fill between, we were obliged to drive six cellular cells linked together to assure stability. These cells were of 645 A7 steel sheet piles. They were removed only by the use of a very strong pile extractor and jet. Even with that, one of them remained in place. This removal task was completed in October 1958.

HUMBER SEWAGE TREATMENT PLANT *(Continued from page 63)*

wisdom of selecting the alternative procedure.

The digestion tanks were designed on normal ring tension procedures, and tenders invited on this basis. An alternative design for prestressed tanks was prepared, however, and reductions in price requested from tenderers if they desired to utilize this method. However, no interest in the alternative was shown.

Practically all superstructures incorporated standard design of structural steel, with only the blower room of the main building requiring special treatment since it embodies an 85 ft. span on a clear height of 45 ft., and must be equipped with a 10-ton crane operating at relatively high speeds.

Construction Progress and Costs

Project work commenced in September 1955, with award of the first rough grading contract, which was followed one month later by award of a second contract covering the shore section of the plant outlet sewer. In the spring of 1956, operations began on the final rough grading contract after homes in the southwest portion of the site had been demolished. All preliminary grading and the shore section of the outlet were finished by fall 1956.

Immediately after completion of the above work, contracts were signed for the supply and installation of return sludge pumps, for the effluent flushing pumps, and for supplying and installing air blowers, gas engines and auxiliaries.

In January 1957, the first general contract was awarded for construction of sedimentation and aeration tanks and related structures at the cost of $5,837,000. About the same time, arrangements were made for the supply and delivery of primary tank collector mechanism and of final tank mechanisms. The first general contract was completed in May 1959.

In January 1958, the contract was awarded for construction of the main building, digestion tanks and related structures.

Three sets of tenders remain to be invited, covering the supply and delivery of vacuum filter equipment; the general contract for construction of the dewatering building; conversion works at the Etobicoke Plant; and the placing of the outlet sewer beyond the shore line of Lake Ontario.

The Humber Sewage Treatment Plant is scheduled for operation before the spring of 1960; and the final cost, inclusive of lands, engineering and contingencies, will be in the vicinity of $17,500,000.

Construction commitments require that the Trunk Sewer Program at present underway along the Humber Valley be completed simultaneously with the plant.

A GAS TURBINE POWERPLANT FOR LOCOMOTIVES

A. J. Bachmeier, *Head, Gas Dynamics Section, Division of Mechanical Engineering*

J. Featonby, *Designer, Division of Mechanical Engineering*

D. C. MacPhail, *Director, Division of Mechanical Engineering*

E. S. Moore, *Designer, Division of Mechanical Engineering*

R. A. Tyler, *Senior Research Officer, Division of Mechanical Engineering National Research Council, Ottawa, Ont.*

Some of the gas turbine locomotive developments are reviewed in relation to operating experiences in various parts of the world.

In the light of this experience and of some of the characteristics of operation in Canada, certain lines of development seem in one or more respects to be attractive. In particular, it appears to be important to determine the practicability of relatively high power mechanical transmission. It is desirable for most types of railway service to evaluate a prime mover with better part-load fuel economy than is normally attained by the simple gas turbine, and a low idling consumption is essential.

These questions are examined and proposals are made

EVEN BEFORE the wartime advent of the aviation gas turbine, there was a good deal of interest in the possible application of this form of prime mover to railway use. In spite of the possible problems of noise and the difficulty of competing in fuel economy with the diesel engine, there has always been a strong incentive to reduce the number of rubbing parts and the whole lubrication requirement.

The comparatively recent availability on the market of a variety of excellent aviation engine materials and of improved cooling techniques greatly improve the performance possibilities of the gas turbine. This, in conjunction with the acquisition of design and operating experience in several places, is attracting steadily increasing attention.

This paper is intended to describe some of the advances and to set out certain developments which appear to make the gas turbine a potentially advantageous choice of machinery for locomotive use in Canada. The start of the present work owed a good deal to the encouragement of the late Mr. W. A. Newman, then Chief of Motive Power and Rolling Stock of the Canadian Pacific Railway, who laid great stress on the operating advantage of securing markedly increased power during severe winter conditions. This characteristic distinguishes the gas turbine from the steam or diesel engine. We have since had a great deal of assistance from both the Canadian Pacific and Canadian National Railways, especially information and guidance concerning operating conditions, some of which seem to be little known outside railway circles.

Existing Gas Turbine Locomotives

Table I lists locomotives which have been manufactured or definitely proposed so far. Of those listed a few have not gone past the design stage, but the total operational service of all the units built so far is becoming significant and is sufficient for a preliminary assessment.[1,4,5] It is worth noting that the first gas turbine locomotive operated in Sweden and consisted of a diesel engine exhausting into a gas turbine with mechanical transmission. The second locomotive was constructed by Brown Boveri and went into use on the Swiss Federal Railways in 1941. It employed electrical transmission very similar to that developed for diesel locomotives, and was dismantled in 1954 after it had covered about 230,000 miles.

The Sigma Renault development in France[2,3] makes use of a GS-34, S.I.G.M.A. free piston gas generator and incorporates a mechanical transmission (Fig. 1). Both of these features appear to be giving satisfactory service, and the Renault Company have followed this development with two or more locomotives similar to the first but of twice the power. One of these was expected to be in service before the end of 1958.

British operating experience has been related to two gas turbine electric locomotives, which started operation in 1952 and have accumulated about 300,000 miles each. In many ways they have proved suitable, but the over-all efficiency has been disappointingly low — less than 7% at the rail.[4] One of these, a Brown Boveri locomotive, has a heat ex-

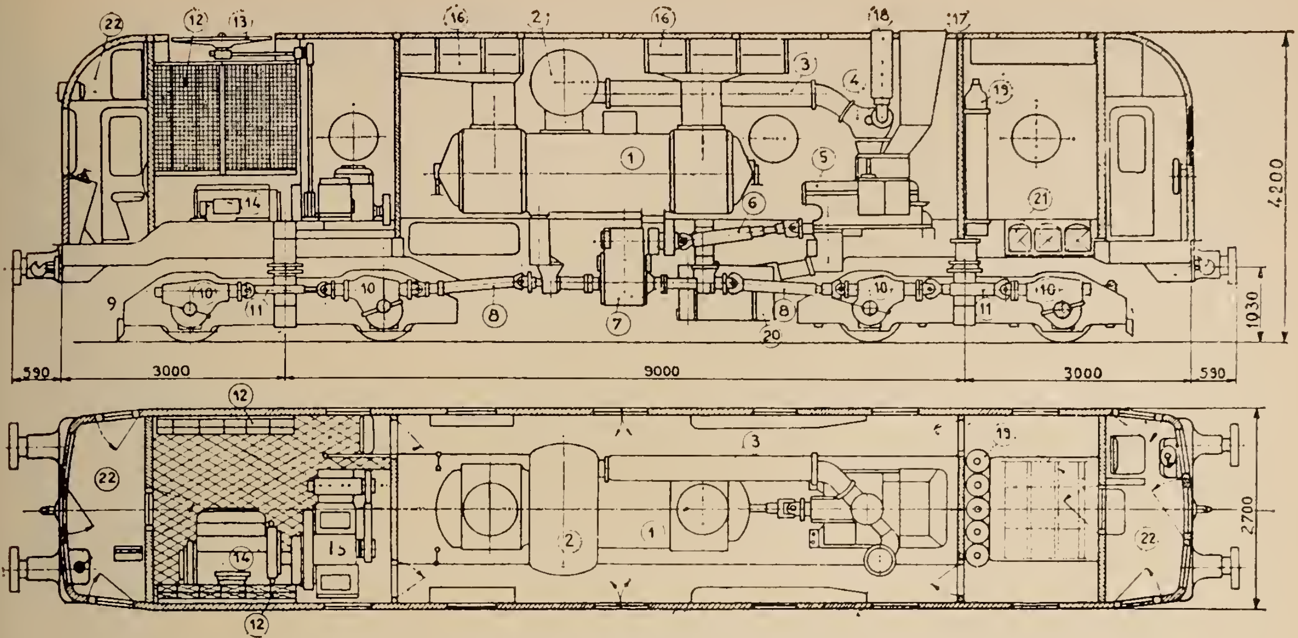


Fig. 1. Sigma Renault 1000-H.P. gas turbine locomotive (Free piston gas generator)

changer incorporated in the cycle but experienced some trouble from coking and subsequent fire, with the result that much of the service has been without the heat exchanger in operation. This locomotive is still in service between London and Bristol, but the other locomotive, of Metropolitan Vickers manufacture, was withdrawn from service rather more than a year ago.

By far the most extensive operational experience has been gained in the United States[5, 6, 7] where 25 locomotives manufactured by the General Electric Company, each developing in excess of 4500 h.p., have been in regular service since 1952 on the Union Pacific Railroad between Ogden and Cheyenne (Fig. 2). The generally satisfactory performance of these engines is attested by the fact that in 1957 the same railway placed an order for 15 additional gas turbine locomotives developing 8500 h.p. each, five of which are now in service.

In 1952 the Westinghouse Company also built an experimental locomotive with two turbines, developing a total of 4000 h.p. Extensive trials with both the Westinghouse and the General Electric locomotives were made on various United States railways in different types of service, but only the Union Pacific Railroad has extended the use beyond experimental service. It appears that the road and traffic conditions are ideally suited to the gas turbine locomotive characteristics, that is to say, there is a long haul at steady maximum load conditions, with the result that the turbine locomotives show to advantage in fuel economy and the maintenance costs. [6, 7]

In Sweden a second engine was built in 1954 using a two-stroke diesel engine as a gas generator with mechanical transmission: this engine has now accumulated 120,000 miles. In Russia a 1000-h.p. free-piston turbo-electric locomotive has been in service since 1956, and Czechoslovakia put into service in June 1958 a 3300-h.p. gas turbine locomotive, with mechanical drive to two three-axle trucks.[5]

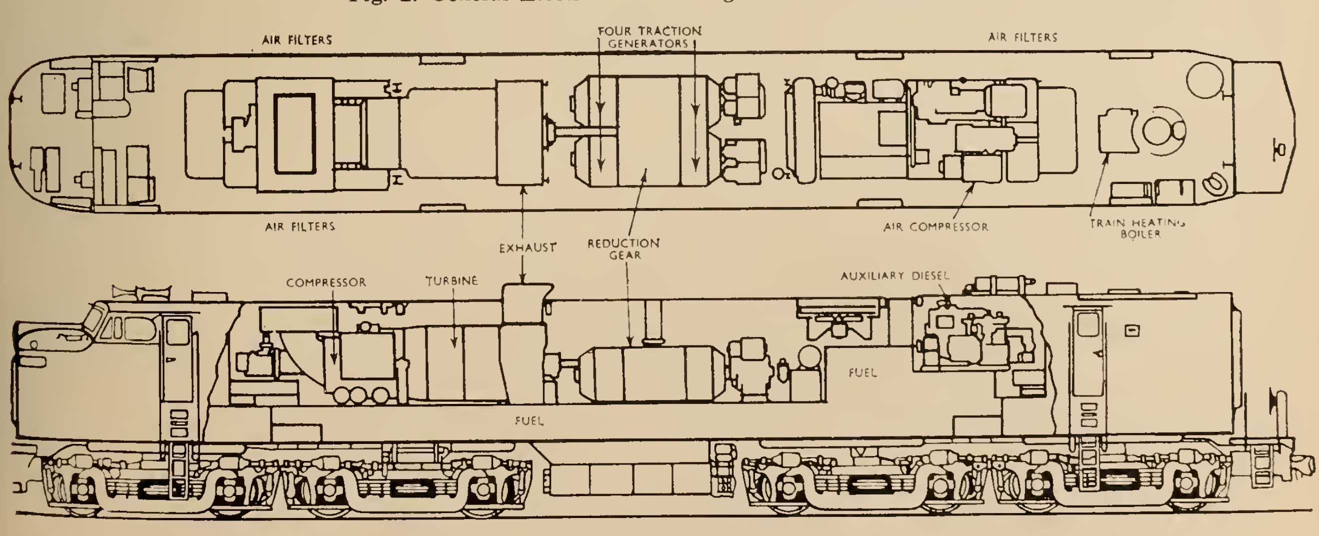

Fig. 2. General Electric 4500-H.P. gas turbine locomotive.

This unit incorporates a recuperative heat exchanger and is reported to be giving satisfactory service.

The Russian State Railways have also been experimenting with gas turbine locomotives of single shaft axial compressor and free piston compressor design.

In view of the difficulty of rivalling the thermal efficiency of the diesel engine except by using free piston gas generators, considerable attention has been directed to the possibility of burning cheaper fuel in the gas turbine than is digestible by a reciprocating engine.

Special reference should be made to developments aimed at the utilization of coal for locomotive gas turbines. Work sponsored by the Locomotive Development Committee in the United States with directly fired coal encountered severe blade erosion.[5, 8, 9] Although progress was being made in separating the ash, the work was suspended in 1958. In order to avoid ash erosion troubles, an indirectly fired coal burning arrangement has, since 1948, been examined at McGill University in Canada[10] and jointly by the C. A. Parsons and North British Locomotive Companies in Britain.[11, 12, 13] The latter project is well advanced and a prototype locomotive is nearly ready for preliminary trials. While the indirectly heated cycle removes the erosion problem from the turbine, it places a somewhat arduous demand on the heat exchanger which, for high power, becomes difficult to accommodate in the usually available space.

Mechanical Drive

In the diesel locomotive, the capabilities of a high efficiency prime mover are commonly matched to the starting and running demands through the intermediary of an electrical transmission system. Such an arrangement, employing direct current, provides wide choice of drive arrangement and of running characteristic, but implies a considerable inventory of high powered machinery and an inevitable loss in effective horse-power. Hydraulic transmissions have in recent years been made to transmit powers in excess of 3000 h.p.[14, 15] and now appear very appropriate for railway traction.

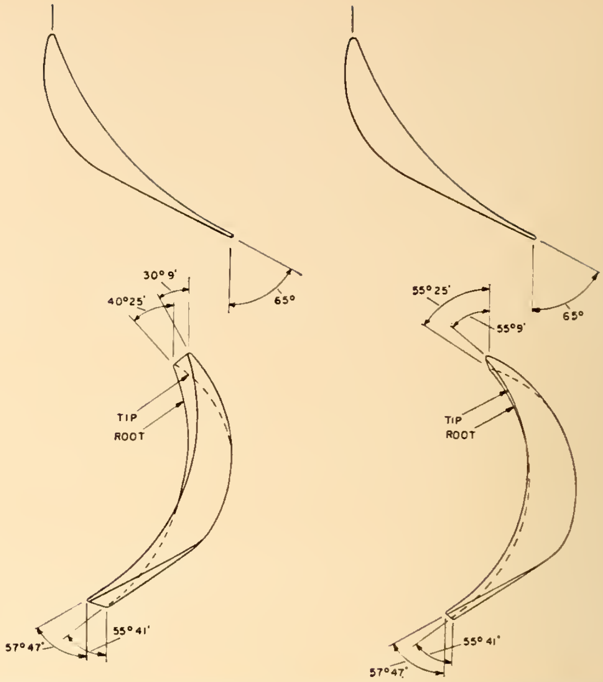

Fig. 3. Left—"Standard" stator blade and "Standard" rotor blade; Right — "Standard" stator blade and "High Torque" rotor blade.

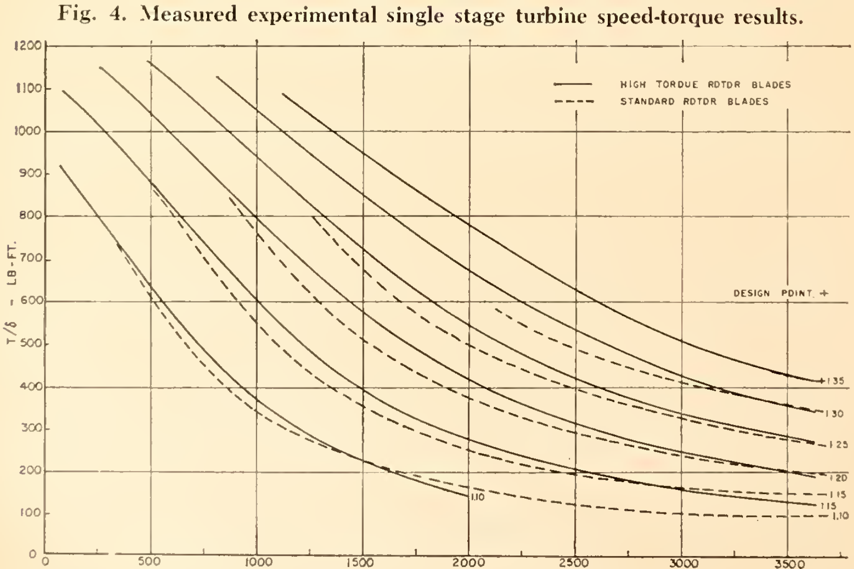
In contrast with the diesel engine, the gas turbine may have a torque at standstill of several times that at the design speed, so that it is analogous to the hydraulic torque converter and very appropriate for traction requirements. It seems to the authors that this feature is one of the main claims of the gas turbine for consideration as an important and economic locomotive powerplant. The distribution of power to a number of running wheels, so elegantly accomplished by electrical transmission, is however a severe problem worthy of very careful attention.

Fig. 4. Measured experimental single stage turbine speed-torque results.



Existing Arrangements

Of the locomotives listed in Table 1, two in France, one in Sweden, and one in Czechoslovakia use a mechanical drive; all employ bevel gears and cardan shafts with universal joints. The final drive of the recent Swedish engine is by means of side coupling rods. In this respect it is similar to the English Electric proposal, the gearing of which has been tested, and the Parsons-North British unit which has also been bench tested. On the other hand, it has been suggested that the most suitable arrangement for a geared transmission is to set the traction turbine shaft transversely—i.e. parallel to the running axles—thus allowing the use of spur or helical gearing.[16] The authors believe that the strength of this arrangement is highly appropriate to conditions in Canada, and gear assemblies of this kind are discussed below.

The main points to be made for

this form of gearing are the facts that it can be made to operate free of end thrust, and it is tolerant of variations in end location and centre distance, especially in comparison with the various forms of right angle drive gearing. Furthermore, it easily accommodates a face width adequate for impact, strength, and wear, and does so without complicating the manufacturing processes.

In the present instance, the proposed scheme of dealing with the various motions of the running axles relative to the main frame is as follows:

(a) Vertical and horizontal motions of axle boxes-coupling rods, and sliding couplings of the "Oldham" type;

(b) Lateral and pivoting motion of trucks — flexible water cooled gas joints.

These arrangements for accommodating the wheel motions involve mounting a traction turbine and its reduction gearing on each truck. Although a variety of centre plate layouts can be contrived, the best suggestion we have so far devised is to use a comparatively large ring surrounding the reduction gear case. In turn this arrangement would probably require forced lubrication to maintain the turning resistance at a satisfactory level, and it implies that trucks be dropped out complete with turbine, gearing, and the banjo surrounding the gear case, without breaking the centre plate joint.

Turbine Speed-Torque Characteristics

Some considerable testing has been directed towards establishing the range of torque available from typical traction arrangements over a range of rotational speed from design down to near standstill conditions.

In the present experiment, a single stage turbine of 20-in. hub diameter and 25-in. blade tip diameter was manufactured for this purpose with two sets of interchangeable rotor blades, each set designed for use with the same nozzles and design point conditions of pressure ratio (1.35:1) and reduced speed (N/θ = 3660 r.p.m.), but with differing design point incidence distributions along the blades. The first set of rotor blades employed conventional incidences on the blades, but for the second set the design point incidences were reduced by some 20° in an effort to improve the gas incidence on the rotos at standstill. It was hoped thereby to increase standstill torque.

The resulting blade sections are shown in Fig. 3. Owing to limitations on the available air supply for driving the turbines, coupled with relatively large losses in the exhaust arrangements in the test installation, it was only possible to cover a range of speed close to the design speed at the full design pressure ratio during the early testing on the conventional blading. Later improvement in technique allowed an extension of speed range at this pressure ratio during the testing of the so-called high torque blading, but the earlier results are still incomplete in this respect. No direct conclusions can yet be made therefore in the efficacy of the high torque blading at standstill conditions. The available results are shown plotted in Figs. 4 and 5 showing the variation of torque and efficiency with reduction of speed from the design point at various stage total pressure ratios for the two types of blading.

The chief points of interest which have been established are:

(a) There is no loss of efficiency or torque at the design point (expansion ratio 1.35:1, N/θ = 3660 r.p.m.) for the "high torque" low incidence blading relative to the conventional blading;

(b) There is a general gain in efficiency and torque down to about 20% design speed for the "high torque" blading, the maximum gain occuring at about 50% design speed;

(c) The range of torque available from standstill to design point speed at the design pressure ratio for the

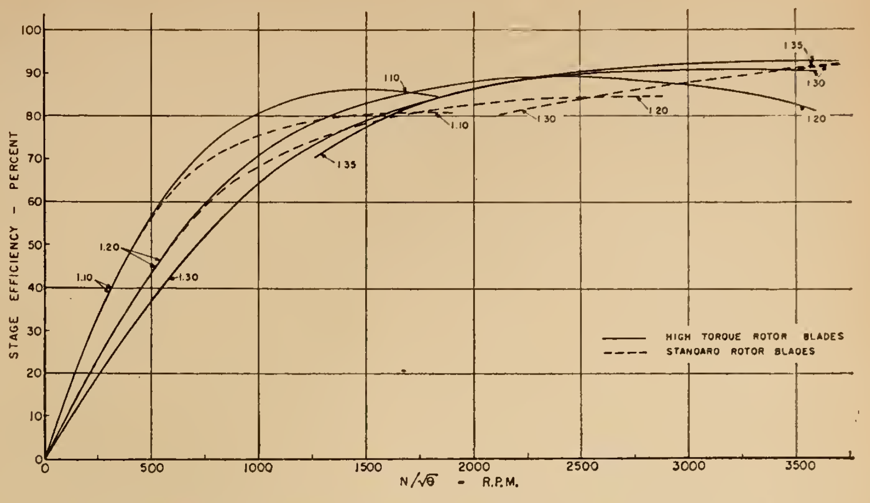


Fig. 5. Measured experimental single stage turbine speed-efficiency results.

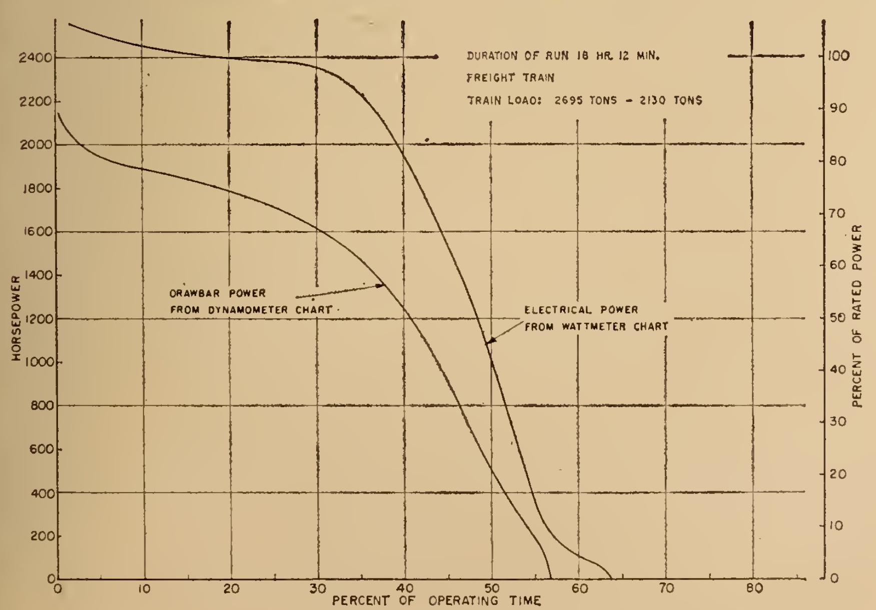
Fig. 6. Typical power variation in Canadian locomotive service.



"high torque" blading appears to be at least 3:1.

Proposed Arrangements

Having established the torque-speed characteristics obtainable from a simple traction turbine, it is next necessary to ascertain whether or not a final drive can be devised with the appropriate strength, reliability and running characteristics for the conditions in mind. The requirements have been taken to be:

(a) Transmission of 3200 h.p. through two trucks, with a maximum standstill torque of three times the value at the design point;

(b) Spur gearing only, with coupled axles;

(c) Individual axles or complete trucks to be easily removable;

(d) No gear changing other than simple reversing at rest;

(e) Axle loading 30 tons/axle.

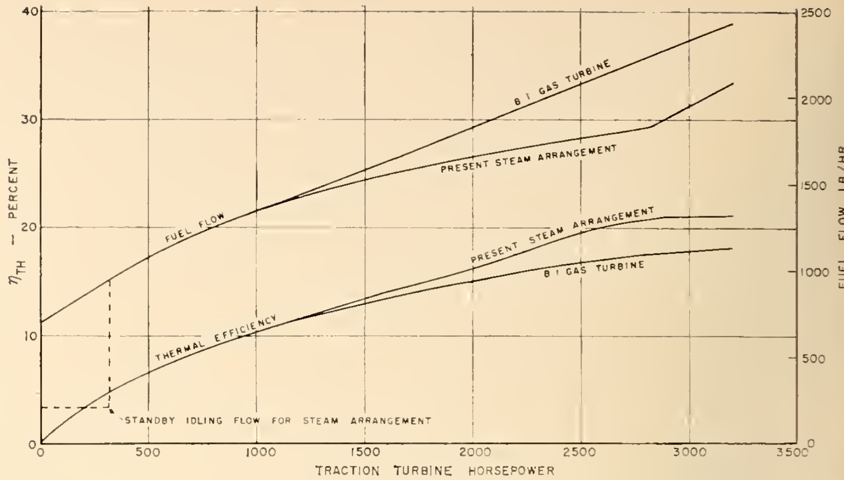


Fig. 7. Approximate part load variation of thermal efficiency.

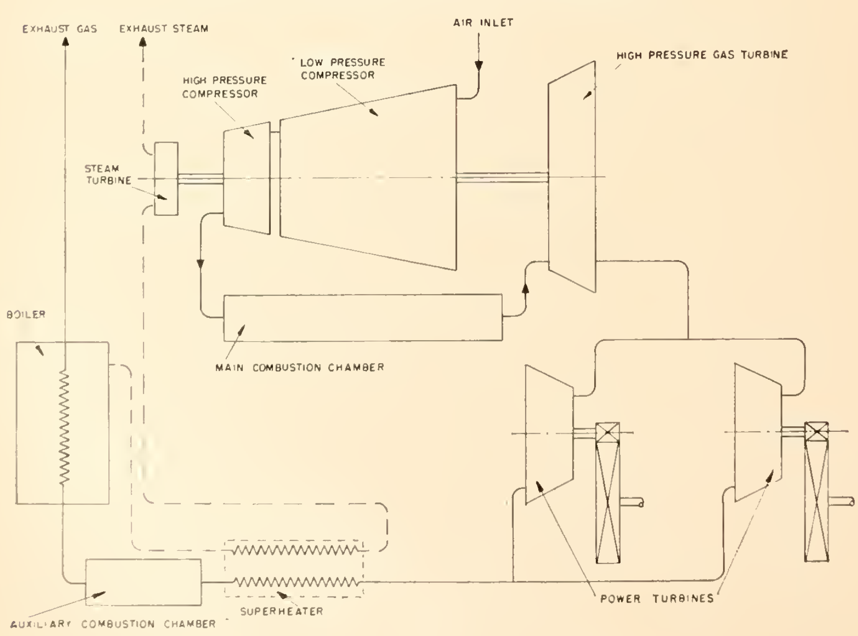
It appears to be possible to meet these conditions with a reasonably sturdy locomotive. With the above axle loading and a co-efficient of friction of 0.25, the maximum attainable tractive force at the rail amounts to 15000 lb./axle. Traction turbines of 3200 s.h.p. (design point) are capable of 40,000 lb. tractive force at 30 m.p.h. or 30,000 lb. at 40 m.p.h. With a static torque equal to three times that at the design point, the former would have a starting tractive force of 120,000 lb. and the latter 90,000 lb. At 15,000 lb. per axle, gearing for 30 m.p.h. aerodynamic design speed requires a total of eight driven axles, while gearing for 40 m.p.h. aerodynamic design speed requires six driven axles. In both cases the mechanical limit on speed has been taken to be roughly twice that at the design point, i.e. 60 m.p.h. and 80 m.p.h. There are two schemes, the first incorporating coupling of the axles of each truck by means of side rods, and the latter employing spur gearing with sliding couplings. In this connection the experience of the Swiss and the Swedish railways are to be noted. On the latter especially, the coupling rod and jack shaft type of drive is preferred for speeds up to 60 m.p.h.[17]

Load Variation in Actual Service in Canada

A considerable amount of data in the form of dynamometer and wattmeter charts, taken over the entire duration of several typical freight and passenger runs, were analysed to obtain some information on the kind of load variation encountered in service. It was not found possible to define a power-time relationship of general applicability, a wide variation existing between runs, particularly in passenger service. For freight service the results shown in Fig. 6 appeared to be as nearly representative as could be obtained from the data considered. Roughly the locomotive powerplant output was between 90% and 110% of rated load for 35% of the operating time, between zero and 90% for 25% of the operating time, and for 40% of the operating time no tractive effort was required.

Fig. 8. Gas turbine—steam cycle arrangement.



Use of Free Piston Gas Generators

The nearest gas turbine relative of the well established railway diesel engine is the composite system employing a reciprocating free piston generator to supply the hot gases to a power turbine. Attention has already been drawn to several existing locomotives of this type. Electric drive is of course possible with this arrangement and would employ conventional electrical traction gears. Free piston gas generators are also applicable to the form of mechanical transmission proposed and seem to be adaptable to high powers.

In comparison with the purely rotating form of gas turbine, the free piston system attains a considerably higher thermal efficiency. Whether or not it will prove more economical depends both on its ability to burn a cheaper fuel than standard diesel oil and also on the corresponding maintenance costs.

Suitability of Residual Fuel Oils

It appears likely that the frequent

occurrence of very severe boiler tube corrosion reported during the period between 1925 and 1940, and which was sometimes referred to as "catastrophic" corrosion, was in some cases at least due to vanadium attack. The phenomenon was at the time not understood, but it was clear that the attack was not consistent with corrosion rates normally associated with the sulphur or sodium constituents of the fuel. The intensive development of the gas turbine for industrial purposes which began immediately after World War II was slowed down considerably by similar troubles arising from the ash deposition and corrosion accompanying the burning of residual fuels. Bowden and Jefferson in 1949[18] described results obtained in a Parsons 500-h.p. experimental turbine in which compressore surge due to turbine blockage occurred after only 43½ hours' operation on residual fuel. The deposit was confined largely to the first three turbine blade rows and, on analysis, was found to be approximately 40% vanadium oxide. Lloyd and Probert[19] discussed the problem in more detail, and referred to what have since been recognized as the two practical ways to control vanadium troubles. The first is to regulate the combustion in such a way as to produce carbon "cenospheres" which trap a large portion of the ash and aid in scrubbing the remaining deposit from the blades. The second uses additives which convert the vanadium either to a compound which is not active or to one which will raise or lower the melting point and vapour pressure to a point where it is no longer a problem. Amgwerd[20] in 1949 studied the attack of V_2O_5 and of natural ash on a number of alloys over the temperature ranges 650-850°C, and found that the effect of V_2O_5 in promoting oxidation was very marked over the whole temperature range, and that the effect of natural ash containing 66% V_2O_5, 8.7% Na_2O and 12.7% SO_3 was even more vigorous. Later reports by Hughes and Voysey[21] indicate that there was relatively little damage to blading on the Parsons turbine during the fouling process. The corrosion rate is apparently very temperature-sensitive, and the operation of the Parsons plant at 550°C was below the temperature at which attack begins. Analysis of deposit on some of the nickel alloy blades which did show corrosion showed nickel oxide content of approximately 16% as compared with 4 or 5% in the original fuel ash, and a corresponding decrease in blade weight when the oxide and deposit had been removed. Bowden et al.[22] and Draper[23] present curves showing deposition rates and provide a list of suggested mechanisms which might account for the very rapid rates of build-up encountered. At any rate the process is regarded as a complex one in which a number of reactions are involved. They discuss in more detail than did Lloyd and Probert the two methods of reducing deposition by controlled combustion and by additives, and present curves showing the effect of various inorganic additives. Of these, SiO_2, ZnO, MgO and Al_2O_3 are the most effective in the order given and provided stable suspensions can be achieved, are quite promising.

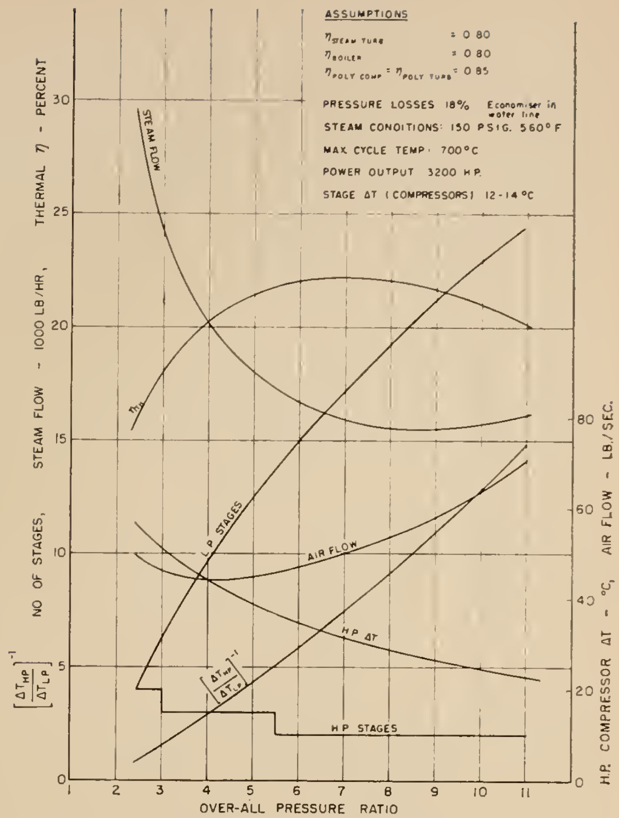


Fig. 9. Gas turbine —steam cycle selection of over-all pressure ratio.

Some deposits[19, 21, 24] do not appear to result in significant corrosion and will in fact wash or break off when the turbine is shut down.

Young et al.[25] describe a method of evaluating the corrosion resistance of blading materials, and Buckland and Sanders[26] describe a process for washing residual fuels where 90% of the sodium and a substantial portion of the calcium is removed. The addition of magnesium oxide to prevent the deposition of vanadium makes the fuel reasonably satisfactory for turbine operation. The authors point out that the addition of lead spoils the effect of the magnesium in inhibiting vanadium deposition, and that when sodium is present in quantities in excess of 10 p.p.m., the ratio wt. of sodium: wt. of vanadium should not exceed 0.3. For inhibiting the vanadium deposits, the ratio wt. of magnesium: wt. of vanadium should be at least 3.

Shortly after extensive oil discoveries in Western Canada, the National Research Council carried out a study of the composition of the various crude oils from Canadian sources and other large oil fields. Table II taken from References 25, 27 and 28 summarizes the results.

The freedom from vanadium and sodium of three types of Canadian crudes suggested that these would be ideal gas turbine fuels. To verify this conclusion a test rig was set up and 12 blades, 4 each of Vitallium, Inconel X and Nimonic 80, were exposed to the combustion products of Leduc bunker C at 700°C for 1000 hours. The results of this experiment are reported in Reference 29 and are essentially as shown in Table III. A conclusion to be drawn from these tests is that the fuel is indeed a satisfactory one, but actual turbine tests are being undertaken as further verification.

General Performance Considerations

The suitability of free power turbines for mechanical transmission (with associated freedom from the cost, losses and complication of elec-

tric drive), together with the availability in Canada of cheap residual fuels of low vanadium and sodium content, clearly indicates the possibility of some form of gas turbine powerplant for locomotive use.

Performance Obtainable with the Straight-Through Gas Turbine Cycle

It appears from various analyses that the simple gas turbine is capable at a turbine inlet temperature of 700°C of a reasonable full power efficiency — or at least of a competitive full power fuel cost when burning residual fuel oil. There are also in sight substantial improvements due to increased temperatures in conjunction with blade cooling. In particular, the practice of spraying water or other coolant on the turbine blading has already achieved considerable success in aviation engines[30] and is capable of cooling by several hundred degrees solid blades of conventional sturdy design[31, 32] with correspondingly enhanced full load efficiency.

On the other hand, conventional gas turbine arrangements of reasonable efficiencies at present temperatures imply the use of high pressure ratios requiring large numbers of expensive compressor and turbine blades and/or gas-to-air heat exchangers involving high metal temperatures, high grade materials, and bulk somewhat difficult to house in a locomotive. Further, the straight gas turbine arrangement suffers the severe disadvantage of very high fuel consumption at zero power output (Fig. 7), a condition shown in Fig. 6 to amount to about one-third of the total operating time between terminals. Under these conditions the fuel flow is of the order of 30% of the full load value, comparing very unfavourably with the corresponding diesel value of about 3%.

In addition, the duty of starting motors is not only arduous but must be discharged in a rapid, reliable and highly manoeuvrable way if operating people are to accept the practice of shutting down during yard and station delays, waiting on sidings for meets, and during coasting at zero power. It appears to us, therefore, that the gas turbine is not suitable for general locomotive usage unless the starting arrangements are so efficacious as to avoid any need for fast idling operation. In addition, it is extremely desirable to minimize the variation in the turbine disc and blading temperature in order to avoid repeated thermal shock and fatigue cracking.

The Gas Turbine—Steam Cycle

In an effort to eliminate the undesirable features of the simple gas turbine cycle, a number of arrangements involving more than one basic prime mover—diesel, steam and gas turbine — were considered. Of the schemes examined, the one set out in Fig. 8 and described in the following sections appeared to have certain distinct advantages and was finally adopted for detailed examination.

Cycle Arrangement

Heat exchange is introduced through a waste heat boiler with mild steel tubes and forced circulation and employing steam conditions common to locomotive practice. The energy recovered is returned to the cycle mechanically through a steam turbine driving a high pressure compressor of appropriate dimensions. The normal advantage of heat exchange in reducing the required pressure ratio for maximum efficiency, and hence the number of compressor stages, is thereby reinforced by a large reduction in air flow for a given power output, leading to reduced turbo machinery dimensions at the expense of introducing less critical (and also less efficient) steam turbine blading. Further, the presence of the steam driven compressor affords a method of maintaining a small flow of hot gases through the system to maintain rotor and casing temperatures and boiler pressure under standby conditions. In this way, the main gas generator can be effectively shut down with the energy capacity of the boiler available for a fast restart when required. This feature promises very low standby fuel consumption, and notwithstanding thermo-dynamic inferiority of steam-raising plant in comparison with an exhaust heat exchanger in a gas turbine cycle, and the implied operating problem of using water, the advantages of steam seem to accrue in the following ways:

(a) Recovery of some of the exhaust heat as steam enables the gas turbine cycle to be boosted directly or by means of a steam turbine compressor drive. Either method raises the cycle efficiency and also reduces the sizes and costs of both compressor and gas turbine parts;

(b) The considerable power available in the steam turbine alternative of (a) should accomplish agile starting of extreme reliability. Should a start be prevented by fuel system or ignition trouble, there is no prac-

tical limit to the number of subsequent attempts;

(c) Auxiliary power to maintain the lubrication, bearing and disc cooling, and turning gear of an idle gas turbine permits the "hot" parts to be kept hot and relatively free from thermal cycling and shock;

(d) A supply of steam is one of the simplest, cheapest, and most convenient ways of heating and atomizing bunker fuel oil and for train heating, where required;

(e) Recuperation of exhaust heat in the form of steam rather than combustion gas permits the heat exchange system to be constructed of mild steel rather than the more expensive stainless alloys;

(f) Partial duplication of auxiliary power supply driven by steam permits reduction of the necessary diesel or semi-diesel alternator set to a size which can be started by hand.

Fig. 9 illustrates the variation of efficiency and required air flow with over-all pressure ratio for the steam cycle considered here, assuming the high pressure compressor absorbs the whole of the available waste heat at the design point. Also plotted are the number of compressor stages required, the design point steam flow (water consumption), and the ratio of the high pressure compressor temperature rise to the low pressure compressor temperature rise. The latter factor has a bearing on the capability of the system for quick restarting from the standby condition and has a practically useful minimum limit. Consideration of the various factors illustrated by curves of this type led to the selection of an over-all pressure ratio of 4.5:1 with a steam driven compressor temperature rise of 35°C, the latter value being somewhat less than the maximum available to allow a margin for auxiliary steam requirements (including train heating) and reduced exhaust temperatures at low ambient temperatures. The maximum cycle temperature was set at 700°C.

In this arrangement the main operating procedures are envisaged rather as follows:

Stone cold to stand-by:

(a) Start auxiliary (semi)-diesel engine;

(b) Fill boiler with water or, if practicable, with hot water and steam from shop supply;

(c) Start auxiliary lubricating pump and main compressor turning gear;

(d) Light main and auxiliary combustion pilots;

(e) When steam is available, start steam turbine to turn high pressure compressor slowly as a forced draught fan;

(f) Turn on steam heat to bunker fuel, atomizing steam and, in cold weather, heat to water tank;

(g) Start steam driven alternator to protect superheater and to supply fuel pump, air pump, and main lights;

(h) Gas turbine heats nearly to running temperature, gas generator being turned over at 50 r.p.m.

Stand-by—Normal Running

As the main throttle is opened, the following series of automatic control adjustments is proposed:

(a) Steam turbine throttle opens and main combustion chamber temperature rises, with fuel flow limited by a rate of temperature rise control;

(b) As the main gas generator set reaches the required speed, the high pressure compressor speed adjusts automatically to use the steam produced, and the auxiliary burner adjusts to maintain constant steam pressure;

(c) Should the wheels slip, quick closing of the throttle is arranged to open a discharge on the gas generator exhaust, with automatic closing.

It is evident that an advantageous execution on the above lines would ameliorate very much the basic disadvantages of gas turbine machinery, but with the operating disadvantage of requiring water.

The thermal efficiency and air flow requirements of the gas turbine — steam cycle, and a straight gas turbine cycle have been compared for the same maximum temperature with various assumed system pressure losses and with no heat exchange.

There is marked improvement in the efficiency and reduced air flow of the steam assisted cycle-even at relatively moderate pressure ratios—over the "straight" system at an optimum pressure ratio of about 8:1. The selected design point values for the steam assisted cycle led to a 12-stage low pressure compressor, 3-stage high pressure compressor, 2-stage gas turbine driving the low pressure compressor followed by two 2-stage traction turbines in parallel. With careful attention to pressure losses throughout the system, an output of 3200 h.p. is expected from an air flow of 43.75 lb. sec. at a thermal efficiency of 21% (s.f.c. = 0.65 lb./h.p. hr.)

A study of a two-shaft gas turbine cycle of 8:1 pressure ratio and the same maximum temperature of 700° C indicated an air flow of 65 lb./sec. for the same output at an efficiency of about 18%. A total of 22 compressor stages and about 3000 compressor blades were indicated, compared with 15 compressor stages and 1900 compressor blades for the arrangement involving steam.

Approximate Part-Load Performance

In order to maintain the high pressure compressor at a speed appropriate to aerodynamic matching of the turbo machinery, it is necessary to augment the exhaust heat by combustion in an auxiliary burner before the boiler at ratings less than about 90% full load, depending on the auxiliary steam requirements. The required matching speed of the high pressure compressor is almost constant at the design point value down to about 10% full load. Some limited testing has been carried out on the existing boiler-steam turbine-high pressure compressor combination. A simulated standby idling air flow of 5 lb. sec. at 400°C (fuel flow about 10% full load) was applied to a completely cold boiler and the boiler pressure raised to about 100 p.s.i.g. The response of the high pressure compressor system at atmospheric intake to opening of the steam throttle was obtained with the rate of firing held constant at a level corresponding to idling fuel flow. The compressor system was able to accelerate to and maintain its governed design speed without increase of the heat supplied to the boiler. The behaviour of the actual locomotive arrangement with the low pressure compressor in position and direct connection on the gas side with the boiler represents of course a somewhat extreme extrapolation from these tests: examination of the capability of the steam turbine to start the whole system, the required initial boiler conditions for effective starting, and the required compressor management during starting, is now being made. Results from this work will establish the minimum heat supply necessary during stand-by periods to enable a rapid start to be made. On applying the results of Section 4, Fig. 6, to the fuel flow values of Fig. 7, one would expect the mixed cycle powerplant of 3200 h.p. rated output to consume 1200 lb. of residual oil per hour of operating time. For a diesel-electric powerplant of the same capacity the comparable consumption would be about 800 lb. (of diesel oil). The expected fuel consumption per operating hour of the straight gas turbine with mechanical drive is 1540 lb./hr. These figures are approximate and are summarized in Table IV which also includes an estimate for a free piston unit with mechanical drive. The relative costs would naturally depend on the unit prices of the fuels in question. Although the mixed cycle powerplant appears likely to show to advantage when burning bunker fuel at half the unit price of diesel fuel, it needs to be emphasized that fuel cost alone is only one criterion by which to make a sound comparison.

Table IV
Approximate fuel flows per operating hour
3200 H.P. to Wheels

Arrangement	*Idling fuel flow per hour idling*	*Fuel flow per operating hour*	*Fuel cost per lb.*	*Fuel cost per operating hour*
Mixed Cycle—Mechanical	210	1200	1c	$12.00
Straight Cycle—Mechanical	700	1540	1c	$15.40
Free Piston—Mechanical	240	700	2c	$14.00
Diesel—Electric	50	800	2c	$16.00

Variation of performance with Ambient Temperature

In common with the straight gas turbine, although to a reduced degree, the mixed cycle arrangement exhibits pronounced variation of output with ambient temperature. An increase of about 30% (i.e. 1000 h.p.) over the rated 3200 h.p. is expected for ambient temperatures in the neighbourhood of 0°F, at maximum gas generator r.p.m.

Traction Turbine Characteristics, and Available Tractive Effort

Some considerable testing has been directed towards establishing the range of torque available from typical single stage traction turbines over a range of rotational speed from design down to near standstill conditions. The curves of Fig. 4 show measured results for two arrangements tested. These results have been used to estimate the torque-speed relationship for the two-stage power turbines of the actual locomotive powerplant. With a conventional loading of 60,000 lb./axle and an assumed factor of adhesion of 0.25, an engine of 3200 h.p. requires eight drive axles if geared for a maximum service speed of 60 m.p.h. and six axles if geared for 80 m.p.h. For the powerplant considered here the power turbine design speed is 5200 r.p.m. and the wheel diameter is 48 in. At low ambient temperatures the maximum available stand-still torque is greater than that required to slip the wheels (at 60,000 lb./axle and 0.25 factor of adhesion), and partial throttle is required from standstill with progressive opening up to full throttle as speed is picked up, for maximum train acceleration. In practice the factor of adhesion with coupled axles might exceed the above assumed figures of 0.25 [14, 17].

Weight Changes Due to Fuel and Water Consumption

Apart from the problems of supply, the use of water in a locomotive implies a change in the weight on the wheels. In the present instance it is suggested that 3100 gal. of water (and all the fuel) be carried on the engine chassis and further water in a tank car or tender. The corresponding variation in weight on the driving wheels would entail greater risk of slipping with tanks empty, but the additional adhesion required seems to be within the margin ascribed to coupled wheels [11,13].

Construction of the Experimental Plant

In setting out the mechanical design of this experimental gas turbine, one object was to make a result reasonably ready for industrial exploitation and development and also appropriate for general railway application. Considerable effort has been made to incorporate various features such as ease of manufacture, simplicity and accessibility for maintenance, sturdiness, freedom from close tolerances and critical materials, and the need for special manufacturing facilities and services.

The compressor casings are split on the centre-line to allow convenient assembly and easy inspection of rotor and stator blades, the latter being easily removable in sections. With one exception the bearings are accessible directly by removing caps, and all but one are identical. The turbine casings are complete rings with the object of avoiding excessive distortion.

Built-up rotor construction with dovetails to hold the rotor blades is employed in the low pressure compressor, which with its turbine is carried on a single shaft in two large journal bearings. The high pressure compressor at present has three bearings.

The compressor blades are made of stainless steel of heavy section in an effort to ensure freedom from vibration and erosion problems. All blades in each compressor are the same and are cropped from stage to stage to provide the proper flow areas.

Mounting the high pressure turbine on the low pressure compressor shaft has the disadvantage of limiting rather sharply the space available for the turbine outlet diffuser. The arrangement shown on both the high pressure compressor outlet and the high pressure turbine outlet is, however, aerodynamically quite efficient, with a pressure recovery equal to about 90% of the gas exit velocity head. At this stage, treatment of the flow is no longer critical and bends may be introduced without serious loss. Duct velocities are kept low to minimize distribution losses, and turning vanes are employed where it appeared profitable to do so. The turbine rotor material is G18 B, the stator blades are Vitallium, and the rotor blades are Inconel X. While the cycle temperature employed does not demand materials of this standard, the fact that they are used allows one the possibility of increasing the maximum power without creating undue stress problems and at the same time ensuring a long component life.

The turbine blading in common with the compressor blading employs constant section profiles which can be generated by straight lines, thereby allowing maximum scope in the method of machining the profile.

Combustion takes place in a single metal chamber, with air cooled flame tube and liner, employing steam atomization. Ignition is obtained by means of a pilot torch burning diesel oil which can be lit by an electric spark or with a match. The torch burns only a fraction of a gallon per hour and remains lighted so long as the system is alive. The main burner, injecting bunker C fuel, can be shut down and relighted without difficulty.

Precise figures for combustion efficiency have not so far been obtained; but, on the basis of mass flow and temperature measurements, the combustion efficiency is estimated to be in the neighbourhood of 98%.

The steam boiler being used for the experiments is of LaMont forced circulation type with mild steel tubing, and incorporates an auxiliary combustion chamber which will be dispensed with if operation without it proves feasible.

Conclusions

The requirements of railway traction are generally met in a very capable way by the diesel engine which, when employing electric or hydraulic transmission, makes a very economical and flexible locomotive.

If the gas turbine is to compete with it on a comercially sound basis to any appreciable extent, the authors feel that all of its potential advantages must be exploited. These appear to be substantial and generally as follows:

1. The torque speed characteristic of the turbine makes it practicable to use simple mechanical coupling to the wheels with a potential gain in starting tractive effort due to improved adhesion, reduced capital cost, and reduced maintenance costs;

2. The inherent ability of the gas turbine to use low grade fuels is outstanding, and, together with the fact that the cycle is peculiarly adaptable to waste heat recovery, allows the possibility of substantial savings in fuel costs;

3. To achieve a saving in fuel costs it is necessary to provide the locomotive with an idling fuel consumption cost comparable to that of the diesel engine, and so ensure rapid reliable starts when required if operators are to take advantage of this feature.

The proposed design is intended to take some advantage of these possibilities. Further assessment will have to await additional tests and experience.

Acknowledgement

A great deal of the effort which has gone into this project came from other staff members of the National Research Council whose names do not appear. The authors wish specifically to acknowledge and express their appreciation for the co-operation and assistance of the staff in the Mechanical Engineering Divisional Shop where the turbine was to a very large extent manufactured; and to the design, engineering and shop staff of the Gas Dynamics Section for their co-operation and enthusiastic effort in bringing the project to its present state. They wish also to express appreciation to staff members of the two Canadian railways who have been most cooperative in supplying information and helpful in their suggestions, and to members of various industrial organizations for their general interest in the project and for their suggestions and comments on pertinent aspects of the proposed arrangement.

LITTORAL DRIFT IN LAKE ONTARIO HARBOURS

A. Brebner, A.M.I.C.E., *Assistant Professor of Civil Engineering,*
R. J. Kennedy, M.E.I.C., *Associate Professor of Civil Engineering*
Queen's University, Toronto, Ont.

THE PROBLEMS created by littoral drift—which may be loosely defined as the transport by waves, tides and coastal currents of littoral or beach material along the shores of large bodies of water—are present all over the world. The erosion of valuable land in some places and damage to channels and harbours by siltation in others occurs at greater or lesser rates wherever there are supplies of beach material and water with sufficient energy content to move them.

On the north shore of Lake Ontario the erosion at Scarborough Bluffs is well known and erosion at less spectacular rates does occur along much of the coast. Some idea of the magnitude of the siltation may be gained from the typical annual dredging figures given below.

Cobourg Harbour	31,700 cu. yd.
Port Hope Harbour	25,000 cu. yd.
Bowmanville (pleasure craft only)	1,650 cu. yd.
Oshawa	15,000 cu. yd.
Port Whitby	4,865 cu. yd.
Toronto Eastern Gap	36,000 cu. yd.

With the exception of Hamilton and Toronto the harbours on the north shore of Lake Ontario will not be able to accommodate ships of the Seaway draft. Since these smaller harbours hope to share in the increased trade which the Seaway is expected to bring, it is apparent that information will be required regarding the way in which any proposed changes would affect the annual maintenance cost and the beaches in the vicinity.

Fig. 1.

In some countries there is a particular agency or department charged with the study of these problems—in the United States it is the Beach Erosion Board. In Canada the Department of Public Works, which is responsible for the maintenance of most harbours, has long been aware of the problems but has not been able to devote much time to detailed studies. Toward the end of 1957 the Department asked the National Research Council for assistance, and in early 1958 the National Research Council Associate Committee on Waves and Littoral Drift was set up. The Committee has initiated a twofold program of basic investigation and field measurements using the facilities of the Department of Public Works, the National Research Council and Queen's University.

This paper deals with the question of littoral drift and the Committee's program under the following headings:

Source of Littoral Material.
Rate of Supply.
Mechanism of Transport.
Theory of Waves.
Wave effect.
Remedial Measures.
Program of Investigation.

Source of Littoral Material

Lake Ontario (Fig. 1) which has an area of over 7,000 sq. miles and a mean water level in the region of

246.0 ft. above sea-level occupies a limestone and shale basin formed in an early geological period which has subsequently been scraped out and enlarged by glacial action.

Outcrops of bedrock limestone occur frequently between Kingston and Presqu'ile, infrequently between there and Cobourg and not at all between Cobourg and Toronto. The overburden on this north shore consists of stratified silt, sand, gravel and boulder clay varying in depth from a few feet to many hundreds of feet. The contours are such that there are swamps at the shore in some areas and bluffs rising high above lake level in others, the Scarborough Bluffs for instance, reaching a height of nearly 200 ft.

Being of such a friable nature this unconsolidated material offers little resistance to erosion of any type and once eroded is the prime source of littoral material. A typical grading curve for soil taken from the bluffs to the west of Oshawa is shown in Figure 2.

The agencies involved in shore erosion are wind, surface drainage and wave-action, the latter being by far the most important. Having been deposited by erosion at the base of the bluffs and on the beaches near them, this material is then subjected to littoral processes. Since the material along the bluffs is very similar at all locations it is virtually impossible by mechanical analysis alone to state the exact geographical location of the source of any littoral material. However, the net direction of travel over long periods may be obtained from aerial photographs or surveys. Figs. 3 and 4 show the harbours of Cobourg and Port Whitby. At Cobourg the littoral drift is west to east as evidenced by accretion on the west side of the harbour breakwaters and depletion on the east. At Port Whitby the net littoral drift is from east to west as evidenced by depletion to the west of the harbour. Somewhere between Oshawa and Port Whitby there is a null point.

Littoral drift may be toward the east one day and toward the west another. The direction depends upon the direction of the wave motion while the rate of drift is some function of wave energy which in turn is related to the fetch and to the wind velocity. Thus the net drift at any point will depend upon the direction, duration and velocity of the winds and upon the fetch or distance which the waves travel. It seems that the prevailing south-west wind in the Toronto-Scarborough area does not cause as much easterly littoral drift as the less frequent south-east wind which has a longer fetch. Farther east, where the relative fetch distances are reversed, the direction on the net drift is also reversed.

It is sometimes suggested that currents caused by the Niagara River, which enters Lake Ontario from the south, caused the littoral drift to the west in the Scarborough-Toronto area. The authors have examined this theory and do not believe that it has any basis in fact.

A typical profile of the shore on the west side of Cobourg Harbour is shown in Fig. 5 along with grading curves of the beach material in Fig. 6.

It is interesting to note the excellent grading of the material as well as the change in mean particle size with distance from shore—the finer material being found in deeper water. Similarly graded sands found off the southern shore of Lake Ontario at one time were a source of material for construction purposes. Severe erosion on these shores was rightly or wrongly associated in the minds of many with the removal of this material. As a result—the authors understand—the State of New York now forbids the dredging of such material within its State limits.

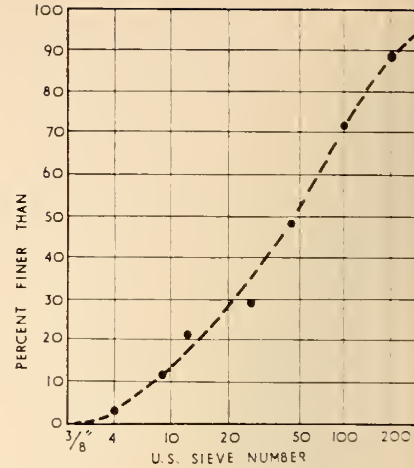

Fig. 2.

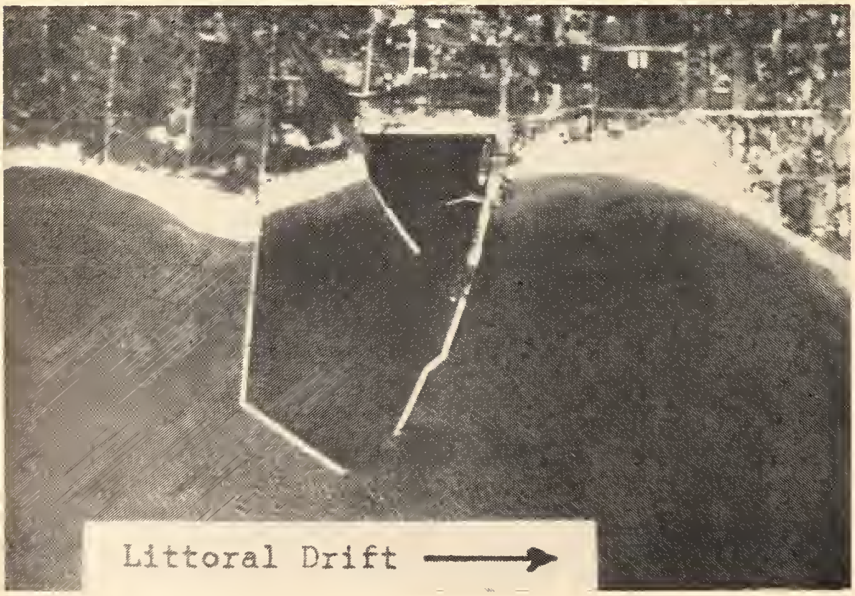
Fig. 3.



The Rate of Supply of Littoral Material

Since littoral material must be supplied from the shore, the rate of shore erosion is a measure of the rate of supply. Because the process of erosion is slow and the rate irregular, measurement can be made only by comparing surveys or aerial photographs taken over fairly lengthy intervals. In the case of the Scarborough Bluffs to the east of Toronto the erosion is reported to be of the order of 1 to 2 ft. per year. Since these bluffs are roughly 200 ft. high the average annual contribution must be about 300 cu. ft. of material per ft. of shore line. Assuming that a substantial proportion of the fines are carried out into deep water and lost, it is still evident that a mile of shore could supply the annual dredge at Toronto Harbours eastern gap, namely 36,000 cu. yd.

A sloping beach protects the shore behind it by dissipating part of the energy of the wave as it comes in. For this reason erosion proceeds faster during years in which high water partially submerges the beaches and allows a larger proportion of the wave energy content to be applied to the shores. If the new dams on the St. Lawrence make it possible to reduce the fluctuations in the level of lake Ontario, the rate of erosion in the future should be more uniform than it has been in the past.

Figs. 7 and 8 are reproductions of aerial photographs taken at Cobourg Harbour with an interval of 23 years between them. The lake level in Fig. 7, April 1931, was around 245.0, whereas in the summer of 1954, the date of Fig. 8, the level was around 247.5. The scale of these particular photographs is such that it is virtually impossible to derive quantitative figures for the rate of erosion. However, there is definite evidence of accretion to the west of the western breakwater.

The Mechanism of Transport of Littoral Material

The transport of sediment or littoral material may take place under the action of:

(a) tidal currents;
(b) river and estuary currents;
(c) wind driven surface currents;
(d) waves and the currents and movements generated by them.

As far as Lake Ontario is concerned tidal currents are negligible, and the Niagara River with its mean inflow of around 250,000 cfs. would appear to be quite incapable of causing any littoral transport on the north shore. (There is some evidence of density currents due to temperature gradients but—in the authors' opinion—none on the north shore, due to the Niagara River). Wind driven surface currents do not cause sufficient movement below the surface to give rise to appreciable transport of any sediment except perhaps very fine clay.

The main mechanism responsible for the movement of littoral material in Lake Ontario is wave action and its associated long-shore currents. Waves coming in at an angle to the coast line usually set up long-shore currents at the breaker zone, and such currents play a vital role in the transport of littoral material. Even the casual observer may note that waves coming in at an angle to a gravel beach carry pieces up the beach in an oblique direction and then roll them down again in a direction at right angles to the water line. Following such a zigzag path the coarse pieces are thus transported along the beach. It is easy to imagine that farther out the sand and finer particles stirred into temporary suspension by the waves are being moved in the same general direction by the long-shore current. However, despite the importance of the problem and the work which is being carried out on it in various parts of the world, the fundamental mechanism of this transport is still imperfectly understood.

Fig. 4.

As waves are the prime movers of littoral material it may be well to examine briefly the basic mathematical theories of wave motion which have been proposed.

The Theory of Waves

Waves in general may be regarded as being either of the oscillatory or translatory type. Oscillatory waves which originate in relatively deep water often acquire many of the characteristics of translatory waves as they move into shallowing water.

The variables involved in the description of water waves are defined below:

L = the wave length: the horizontal distance between similar points on two successive wave-crests measured perpendicular to the crest;

T = the wave period: the interval of time between the passage of two successive wave crests at a fixed point;

c = the speed or velocity of the wave: the speed with which an individual wave advances;

d = the depth of water measured in a vertical direction from the still water surface to the bottom;

H = the wave height: the vertical distance from the crest of the wave to the bottom of the succeeding trough;

d/L = the relative depth;

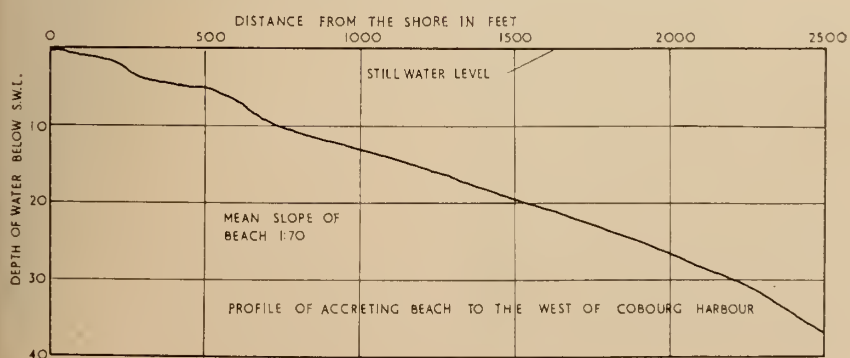
H/L = the wave steepness.

Oscillatory Waves

There are various theories regarding the form of the surface of oscillatory waves. The surface may be assumed to be sinusoidal (Airy), trochoidal (Gerstner) or sinusoidal with modifications (Stokes) which makes the wave crest more pointed and the troughs longer and flatter.

Irrespective of the wave form the velocity of the wave is given fairly

Fig. 5. Profile of Accreting beach to the west of Cobourg Harbour.



accurately by the expression:

$$c^2 = \frac{gL}{2\pi}\tanh\left(\frac{2\pi d}{L}\right)$$

since $C = \frac{L}{T}$ this can be written in the form

$$L = \frac{gT^2}{2\pi}\tanh\left(\frac{2\pi d}{L}\right)$$

and is plotted in Fig. 9 as such for various periods T ranging from 1 sec. to 10 sec.

It may be seen that in deep water, usually defined as depth exceeding one half the wave length $(d/L > 0.5)$, $\tanh (2\pi d)/L$ is sensibly equal to unity and hence c tends to $\sqrt{(gL/2\pi)}$ In shallow water, usually defined as depth less than 0.05 times the wave length $(d/L < 0.05)$, $\tanh 2\pi d/L$ tends to $2\pi d/L$ and hence c tends to $\sqrt{gd}$

It will be noted that the relationship for c, T and L contains no reference to wave-height H. However, using the Stokian wave theory the relationship for velocity can be shown to have the form

$$c^2 = \frac{gL}{2\pi}\left(1 + \pi^2\left(\frac{H}{L}\right)^2\right)$$

for the deep water case. Since in general the steepness H/L of the wave is small this additive term has little effect and so the approximate expression

$$c^2 = \frac{gL}{2\pi}$$

is usually sufficient for all practical purposes.

In a wave the particles of fluid are continually in motion. The particles of fluid in an oscillatory wave system describe closed elliptical orbits, the major and minor diameters of the ellipses depending on the relative depth in which the wave is travelling and the position of a particle relative to the still water level. If y is the depth of a particle below the still water level its elliptical path is given by:

semi-major horizontal diameter =

$$= \frac{H}{2} \cdot \frac{\cosh \frac{2\pi}{L}(d - y)}{\sinh \frac{2\pi d}{L}}$$

semi-minor vertical diameter =

$$= \frac{H}{2} \cdot \frac{\sinh \frac{2\pi}{L}(d - y)}{\sinh \frac{2\pi d}{L}}$$

For deep water that is $d/L > 0.5$, these reduce to circles of radius given by the relationship

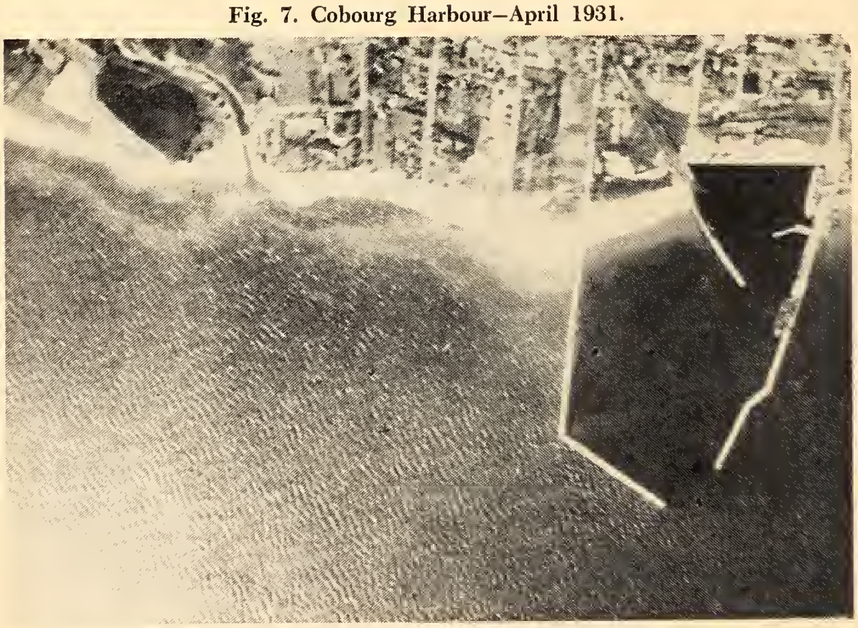
$$\text{radius at any depth } y = \frac{H}{2} \cdot e^{-\frac{2\pi y}{L}}$$

On the surface, $y = 0$, the orbital radius is $H/2$. At a relative depth, y/L, of 0.5 the radius of orbit is sensibly zero. Thus, in so-called deep water, the passage of a wave is unnoticed at depths greater than half a wave length.

For shallow water, that is $d/L < 0.05$, the elliptical orbits do not degenerate into circles nor die away with depth. At $y = d$, that is on the bottom, the particle oscillites backwards and forward in a straight line with a whole amplitude of

$$\frac{H}{\sinh (2\pi d/L)}$$

Fig. 7. Cobourg Harbour—April 1931.



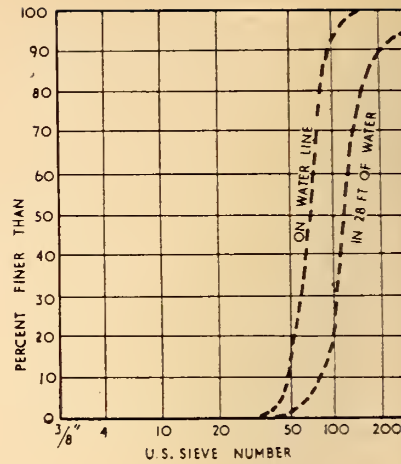


Fig. 6.

whilst on the surface the particle has a whole vertical movement of H and a whole horizontal movement of

$$\frac{H}{\coth (2\pi d/L)}$$

Thus oscillatory waves in shallow water and in the transition between deep and shallow are capable of carrying material into suspension and into oscillatory but not translatory motion.

Solitary Waves

The theory for the solitary wave supposes the existence of only one wave whose two limbs on either side of the elevated crest decrease rapidly in elevation away from the crest.

If y is the elevation of the waveform from the undisturbed level an infinite distance on either side of the crest the equation for the surface is given by

$$y = H \operatorname{sech}^2 \frac{x}{2b}$$

where H is the height of the crest above still-water level,

x is the horizontal distance from the crest on either side,

b is a function of the depth d and the wave height H given by various expressions of which the Boussinesq solution is quite adequate, namely,

$$b = \sqrt{\frac{d^3}{3H}}$$

The solitary wave in theory stretches its limbs to infinity on each side, but in practice it is found that to all intents and purposes the volume of water in the wave is contained in a length equal to about four times the depth on each side of the crest. Hence there is the possibility that a series of solitary waves in shallow water, the proper distance apart, could appear to be a train of waves but behave as solitary waves. Fig. 10 shows the profile of a typical solitary wave.

The motion of the water particles in a solitary wave is markedly different from the motion in an oscillatory wave. The solitary wave gives a horizontal movement which is sensibly constant at all depths and in this respect is similar to the oscillatory wave in shallow water. However, the solitary wave motion is not an oscillation but a forward movement or translation. The forward displacement as a solitary wave crest passes through the undisturbed water is given (approximately) by $4\sqrt{dH/3}$, the forward path being quasi-parabolic. This is explicable if one thinks of the particles moving forward with the crest and remaining displaced until the next crest passes through, since in a solitary wave there is no real trough to impart a backward motion.

Wave Energy

The energy contained in an oscillatory wave in deep water consists of potential and kinetic energy. It may be shown that the total energy contained in such a wave is given by

$$1/8 \cdot w \cdot L \cdot H^2$$

ft. lb. per ft. of crest length.

The total energy contained in a

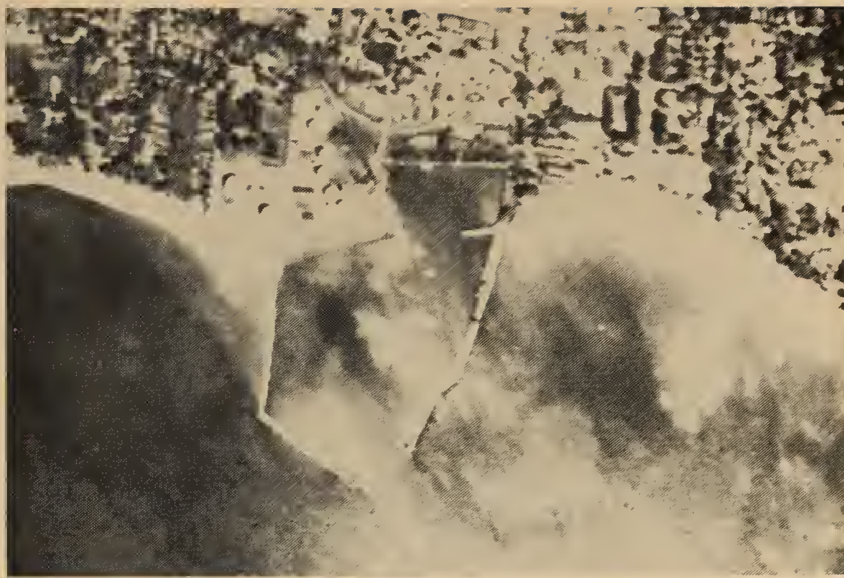

Fig. 8. Cobourg Harbour—summer 1954.

solitary wave also consists of potential and kinetic energy and may be shown to have a value given by

$$8/(3\sqrt{3}) \cdot w \cdot \sqrt{H^3 d^3}$$

ft. lb. per ft. of crest length.

As stated above, most of the volume of the solitary wave is located near the crest; the total energy content is even more concentrated, 98% of it being located within a distance equal to $2d$ on either side of the crest.

With the theory as background, the effect of waves upon the shore will now be examined.

Wave Effects

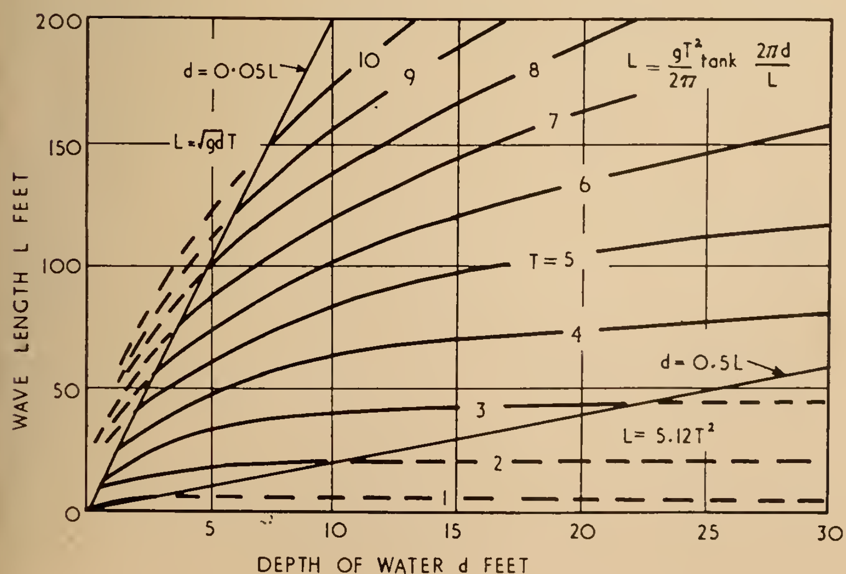
Oscillatory waves are normally generated in deep water far from shore by the action of the wind. The wave motion so generated moves shorewards, usually picking up more energy from the wind as it goes.

To an observer these waves in deep water appear to be rolling in towards the shore in a manner which suggests that any floating or suspended material would be carried with them. In fact the forward motion is far more apparent than real since, as has been stated, the water particles move in nearly closed circular orbits and have little or no net movement. As the waves move into shallowing water when the shore is approached they are effected somewhat by the resistance of the bottom and the circular orbits tend to be flattened into ellipses.

A storm wave of 4 sec. period in deep water on Lake Ontario, for example, would have a wave-length of about 80 ft. as shown in Fig. 9. Such a wave would not be felt on the bottom until the depth of water was less than 40 ft. As it continued shoreward in ever shallowing water it would be slowed down, with an accompanying decrease in wave length. Since the energy of the wave in deep water can be modified only by loss due to bed friction as it moves shorewards, the shortening of the wave length in shallowing water is accompanied by a steepening of the wave. At a depth of 16 ft. its length would be reduced to about 72 ft. and its height might be slightly increased (if there were no loss of energy the height would be increased by about $\sqrt{80/72}$, (or 5 %).

The total energy possessed by a wave in deep water has been stated

Fig. 9.



to be

$$1/8 \cdot w \cdot L \cdot H^2$$

ft. lb. per ft. of crest length. By mathematical analysis it may be shown that, to a first approximation, the energy transmitted forward from deep water towards the shore is one half of the total, namely

$$1/16 \cdot w \cdot L \cdot H^2$$

ft. lb. per ft. of crest length. Since the period of the wave is T sec. the energy transmitted per sec. is

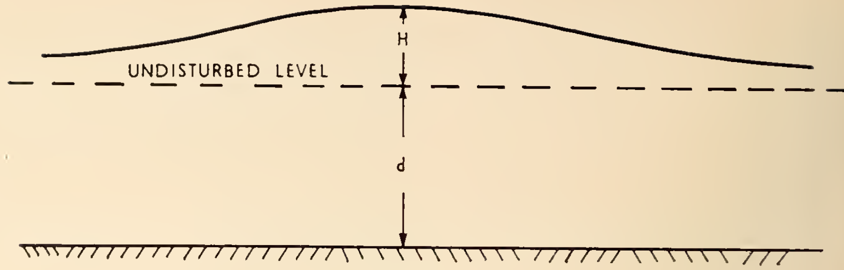
$$1/16 \cdot w \cdot (L/T) \cdot H^2$$

ft. lb./sec. per ft. of crest length. For the wave under discussion (T = 4 sec., L = 80 ft.) *the horse power* transmitted forward is

$$\frac{62.4 \times 80}{16 \times 4 \times 550} H^2 \approx \frac{H^2}{7}$$

per ft. of crest length. If this wave has a height of 4 ft. from crest to trough—a not uncommon height during a moderate storm—the power which must be dissipated is of the order of 2 h.p. per ft. of shore-line. It is little wonder that waves often damage marine structures since so much power is available.

As stated previously, the oscillatory wave, whose profile in deep water is approximately trochoidal, tends to become steeper as it moves into shallowing water and this is accompanied by a flattening out of the trough. In this way its profile becomes more like that of the so-called solitary wave. The 4 sec. period wave in a depth of 16 ft. would have a wave-length of about 72 ft. A solitary wave has been stated to have sensibly all its energy contained in a distance equal to twice the undisturbed depth on each side of its crest—in this case a distance of 32 ft.



PROFILE OF SOLITARY WAVE --DEPTH d TWICE WAVE-HEIGHT H

Fig. 10.

Thus solitary waves would act as such at any spacing greater than 64 ft. Since the crest to crest length of the oscillatory wave would be greater than this, namely 72 ft., it would seem reasonable to liken the action of the oscillatory wave in this depth of water to that of a solitary wave unaffected by the waves preceding or following it.

This postulation has been confirmed by some (but not all) laboratory experiments. It has been suggested that for any given depth of water and height of wave there is a critical period below which the motion is oscillatory and above which the motion is effectively translatory. If the actual wave-period is greater than this critical period the oscillatory waves may be expected to assume the characteristics of a sequence of solitary waves which give rise to pronounced forward displacement of bed material. This critical period may be shown to decrease with the shallowing of the water and also to decrease with increasing wave height for a given depth of water.

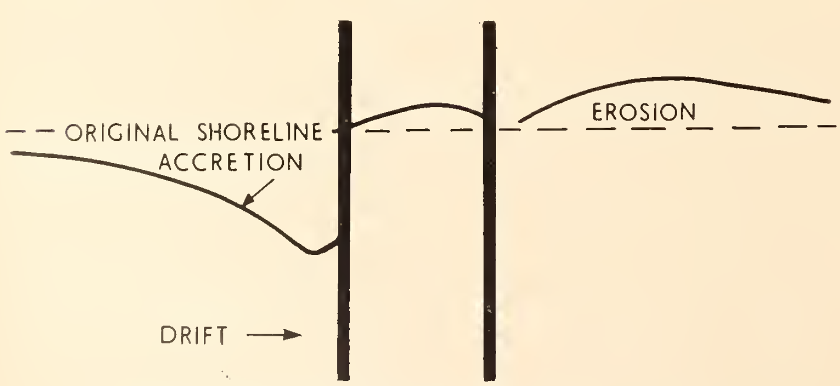
The translatory action would account for the deposits of sand found deep in the harbour areas. It is possible that a storm of a few days' duration, with long period waves acting as solitary waves when they reach the appropriate depth of water, is capable of giving rise to most of the year's deposit. In this connection it is worth noting information in the records of the Department of Public Works concerning the dredging of Port Traverse :

"Average re-dredging per year 1310 cu. yd. During the 1954 contract approximately 2,000 cu. yd. entered the channel during the dredging operations and the dredge was bogged down".

The direction of travel of a deep water oscillatory wave is determined by the wind direction in its generation area and to some extent by the winds farther along its course. If it approaches a sloping beach at an angle, it refracts—the portion of the wave reaching shallower water first slows up, tending to bring the crest into alignment with the underwater contours and the shoreline. As the wave proceeds into even shallower water the lower portion is increasingly retarded by the bottom while the crest becomes steeper and eventually falls forward or breaks, usually when the ratio of wave-height to depth is in the vicinity of 0.7. When the wave breaks an extremely confused and turbulent state of flow exists. The momentum of the breaking wave crest will carry the water up the shore along with particles of sand and gravel. The return flow usually occurs over a longer period, and, as it is not so violent there is a tendency for the heavier particles to remain farther up the beach. This gives rise to the grading of the material on the beach—the finer material being carried farther out.

Because the approaching waves do not usually refract sufficiently to break completely parallel to the shore, swash from the breakers has a component of velocity along the shore and consequently the beach material is carried up at an angle. It is brought back by the return flow in a direction more nearly normal to the shore-line, thus travelling in a zig-zag path along the shore by the process known as beach drift. Since the waves can attack the shore at any angle the direction of this motion in

Fig. 11.



TYPICAL EROSION ACCRETION PATTERN DUE TO A HARBOUR the breaker zone, where most of the littoral movement is thought to occur, may change frequently, but over a period of time there may be a net movement in a definite direction, evidence of which has been presented in Figs. 3 and 4.

It has long been thought desirable to relate the amount of littoral material moving past a given line normal to the shore, which under storm conditions might well be several hundred cu. yd. per day, with the energy or momentum of the oscillatory waves off-shore. Unfortunately an empirical relationship derived for one locations is apt to be incorrect when applied to another. From records of wave height, H, wave length, L and direction of approach to the shore (the incident wave making on angle α with the shore), the long-shore component of energy over a period of time may be computed. The rate of littoral drift may then be written in the form

Rate of Littoral Drift = Constant x L x H^2 x sin α. Unfortunately the so-called constant is far from constant and seems to be affected by some or all of the following factors:

(a). the size and density of the beach material;

(b). the slope of the beach;

(c). a term akin to Reynolds number since certain features of model work do not appear to agree with either larger scale models or prototype results;

(d). the temperature of the water and its viscosity;

(e). the relationship between the oscillatory and translatory nature of the wave prior to breaking.

The knowledge gained from laboratory and field studies will eventually lead to a more complete understanding of the items discussed above.

Remedial Measures

The formation of a beach at the base of eroding bluffs provides a partial barrier to further erosion since much of the energy of the oncoming waves may be spent before reaching such bluffs. Short of sheet-piling the perimeter of the lake the beaches form an indispensable and natural protection for the shores. Drifting of these beaches is inevitable, but so long as the beach is nourished by an amount equal to its annual loss it will maintain a sensibly stable state.

Off-shore breakwaters limit the amount of incident energy striking a beach and slow down the rate of drift in their shadow. Fig. 11 shows the off-shore breakwaters at High Park, Toronto and the accumulation of drift behind them.

Fig. 12. Typical erosion-accretion pattern due to a harbour.

Drifting material in the vicinity of a harbour is the prime source of silt or sand in the navigation channels; Fig. 12 shows the typical pattern at such a harbour. The rate of movement of sand on the updrift side of a harbour may be reduced by the use of groynes. This decreases dredging costs until the groynes fill up with drift material and the whole process starts to repeat itself. Unfortunately, during such a period movement will continue downdrift of the harbour and, since little material is being supplied, erosion of the beach and shore will result.

In lieu of groynes it is sometimes feasible to locate the harbour breakwaters so that the drifting material is carried out into deep water. Failing this it may still be possible, by suitable placing of the breakwaters, to limit the rate of deposition in the navigation channel to something that can be dealt with by occasional as against annual dredging. The rate of erosion of the shore downdrift of the harbour may be so slow that it is not objectionable. If, however, the rate of erosion is serious it may often be decreased by "nourishing" the beach. This nourishing may be achieved by mechanical dumping or by means of a by-passing plant which pumps sand from the updrift or accreting side of the harbour to the downdrift or eroding side.

The control of littoral drift in order to reduce or eliminate damage is often difficult and expensive. The decision on each proposed solution should be based on the ratio of the probable annual benefits to the annual cost.

Inherent in the difficulties faced by engineers in considering remedial measures for the harbours on Lake Ontario is the paucity of information on the following items:

(a). the type of material which moves as littoral drift;

(b). the quantities of material which move as littoral drift;

(c). the wave conditions causing the movement;

(d). the regions and depths where this movement occurs;

(e). the occasions and periods during which significant amounts are moved.

With a thought to the various remedial solutions which have been tried elsewhere, not always with conspicuous success, and the information required both from the field and from the laboratory for their implementation, the National Research Council Associate Committee is proceeding along the following lines with its program of investigation.

Program of Investigation

The field information required to plan remedial measures is

(a). long term wind records;

(b). long term wave records;

(c). long term records of the rate of movement of littoral material.

The information available consists of wind records for the Toronto and Trenton areas which indicate wind speeds and directions by only 45° sectors, aerial photographs and surveys of the shoreline indicating the amount of past erosion and records of the dredging carried out annually by the Department of Public Works. The

CBC STUDIOS 7 AND 42—
VIDEO AND AUDIO FACILITIES

N. R. Grover, M.E.I.C., *Supervising Engineer, Plant Department*
CBC Engineering Headquarters, Montreal, Que.

THE CBC'S most modern television studios are the two placed in service in October 1958. Technical facilities for Studio 7 in Toronto and Studio 42 in Montreal had been under installation and planning for nearly a year prior to their opening, and represent the latest in CBC engineering and operational concepts.

Both studios are located in new buildings constructed on property adjoining existing CBC plants. These buildings house, in addition to the studios, shops, storage areas, dressing rooms, makeup rooms and other ancillaries. Both studios have been initially equipped for monochrome, though space is available for conversion to color. Studio 7 in Toronto is 70 ft. wide, 90 ft. long and 40 ft. high. Studio 42 in Montreal is 70 ft. wide, 95 ft. long and 30 ft. high.

Since the video and audio installations for both studios are very similar, a detailed description of the facilities of Studio 42 Montreal will be given first, and later, items of interest which concern Studio 7 alone will be covered.

General

Fig. 1 shows the layout of Studio 42 Control Rooms. The complete length of one studio wall on the second floor level is occupied by the Lighting Control Room, the Announce Booth, the Audio Control Room and the Video Control Room. A video equipment rack area is located off the video control room.

Video Facilities

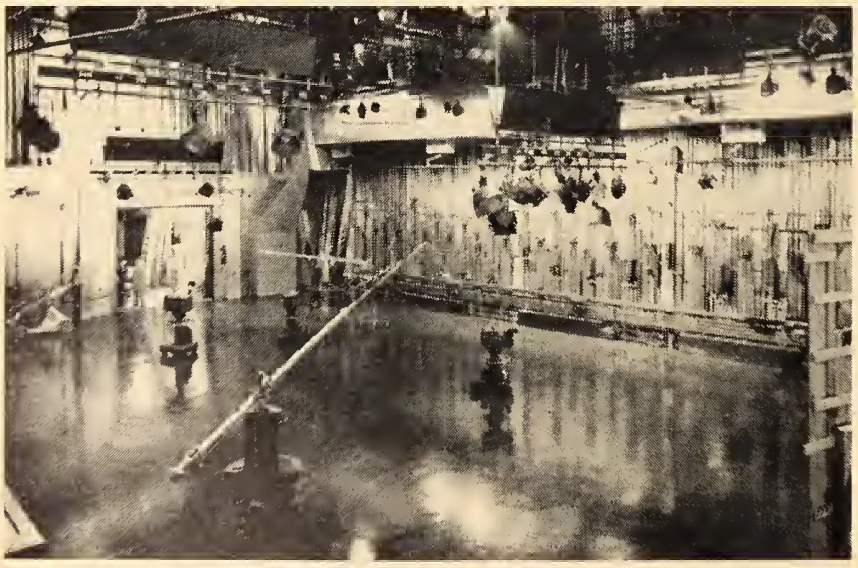
A production desk seating program production personnel, the technical producer and the video switcher operator, occupies the center of the room. In front of this desk is a large window to provide a view into the studio. Immediately below the window, in a well in the floor, are located 17 in. video production monitors which provide the production personnel with continuous monitoring of all cameras, telecine and two line inputs, as well as output, cue, mix and preview.

To the right of the production desk (see Fig. 2) are the camera controls, and on the left of the camera controls is a camera patch panel. Video equipment racks to the right of the production desk, and past the camera controls, house video patching facilities, video and pulse distribution amplifiers and test equipment. Other video equipment, including the video mixer, is housed in the racks which are further removed from the production area.

The camera patch panel is used to connect any one of the four camera controls to any of eight camera bulkhead connectors which are located around the perimeter of the studio (four spare positions can be filled later if required). The four cameras in the studio can thus be connected to the most convenient bulkhead connector and be routed via the camera patch panel to the desired camera control unit. Cable lengths from the patch panel to the bulkhead outlets have all been made the same length. This ensures that no matter where cameras are used in the studio there is no problem with regard to different timing in the video signals at the vision switcher.

For the present, four monochrome cameras have been provided. These

Studio 7 Interior



cameras can be equipped with either 3 in. or 4½ in. image orthicons. Provision is made for the addition of a fifth camera if required. Grating generator signals, fed to the camera controls, may be superimposed on the camera control picture monitor to aid in geometric alignment. The camera viewfinder is normally fed from the output of the camera control unit, but special feeds may be switched in by the camera control operator to assist camera operators in special effects. Picture weave for any camera may be selected and controlled from the vision mixer position. Weave effects are achieved by using an audio oscillator to modulate the camera line scan circuit.

As can be seen in Fig. 3, the output of each camera is fed to a bank of distribution amplifiers which provide feeds to production monitors, the vision mixer, picture match switching and spare outputs for any special requirements. Individual feeds from distribution amplifiers rather than looping or bridging feeds have been provided for the above and other facilities for two reasons. First, the looping and bridging of video lines, especially when the bridging point is far removed from the line termination, may introduce line discontinuities, with consequent reflections and high frequency loss. Second, looped lines do not lend themselves to the rapid replacement of defective equipment without affecting other facilities fed by the same line.

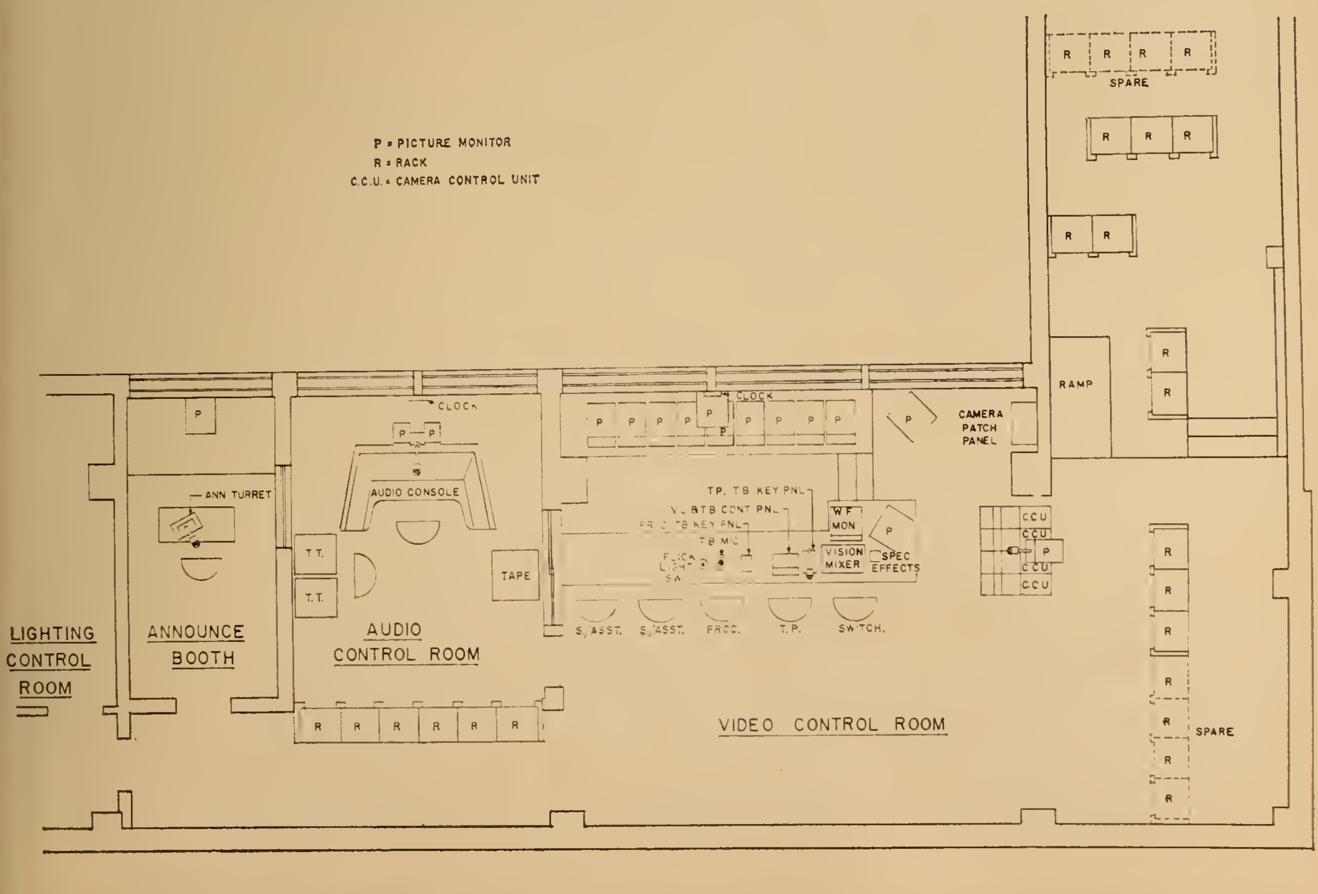
The picture match monitor located at the camera controls permits the visual matching of all cameras on one high quality monitor. Sequential viewing of camera outputs is obtained by push button controls at the camera control operator's position. This monitor can also be switched to a special pre-patched signal and to the studio main output. As with the camera control picture monitor, grating signals may also be superimposed on this monitor by a switch.

Equalized input lines from Master Control cater for telecine, other studios and remotes. These also are routed to banks of distribution amplifiers to permit multiple use.

The vision mixer comprises a control panel and two equipment racks. It will handle twelve inputs and provides one main output, a preview output and two mix outputs. Non-composite or composite, synchronous or non-synchronous signals can be accepted. The switching section of the mixer is a six level, 15 input 6 output video crossbar. One level is used for video switching and the remaining levels for tally, hold, lap-gap and sync non-sync switching. A big advantage in the use of a crossbar for video switching is the relatively low cost and small space required for quite comprehensive facilities. The crossbar itself is compact, and due to its low capacity presents no loading problem even when all video ouptuts are connected to one input. Because of the low loading effect only one standard input amplifier is required to feed each input and it is not necessary to provide isolated feeds to each input, output combination.

The top row of push buttons control the preview bus, and select the output to the production preview monitor and to the switcher operator's master monitor. Selection of any input or any of three "mix" feeds is possible on this bus. The master monitor can also be switched to output by means of the push buttons to the right of the preview buttons. The second row of buttons control the cut bus, and select the signal which is to be switched to the main output, the selection is as the preview bus selection, i.e. any input or "mix" feed.

Fig. 1. Studio 42 Control Room Layouts



The third and fourth row of buttons are known as mix 2 and route any input signal to a mixing amplifier, the output of which is controlled by the two quadrant faders to the right of these busses. The two push buttons between the Mix 2 busses and the fader arms will substitute a special effects unit for the mixing amplifier. The fifth and sixth row of buttons are known as Mix 1 and are similar to the Mix 2 busses.

As mentioned previously, the outputs from the two mixing amplifiers are routed to the "cut" bus as Mix 1 and 2. Additionally, the outputs of these two mixing amplifiers are fed to a third mixing amplifier which is controlled by the fader arms at the far right of the panel. The output of this third mixing amplifier appears at the cut bus as Mix 3. The output of the cut bus feeds a stabilizing amplifier which back porch clamps the signal to maintain correct black level and inserts a local or reconstituted sync/signal.

The toggle switches at the top of the control panel are set for synchronous or non-synchronous inputs as appropriate, and control sync insertion in both the stabilizing amplifier and switcher video monitors. The stabilizing amplifier controls are mounted on the upper right hand corner of the control panel and permit signal adjustment if necessary, though they are normally preset. Non-synchronous signals cannot be handled on the mix busses, but a fade of this type signal on the cut bus is possible by utilizing the stabilizing amplifier "Picture Fade" Control.

Input lines to the vision mixer are isolated from the slight capacitive effect of the crossbar by 6 db. resistive pads. The loss is made up in subsequent amplifiers.

One of the problems in any video switching operation is the avoidance of flashing or transients which may occur during the switch and which may be quite objectionable to a viewer. If it is arranged that there is an overlap of a few microseconds of the two signals being switched, the transition from one signal to another will be freer of objectionable flashing than if there is an actual finite break between the end of the first signal and the beginning of the second. The former type of switching is known as lap switching and the latter, gap switching. In many more complicated video switcher designs there is isolation between the various input output combinations, and no intraction can occur when an input already in use on one output bus is also switched to

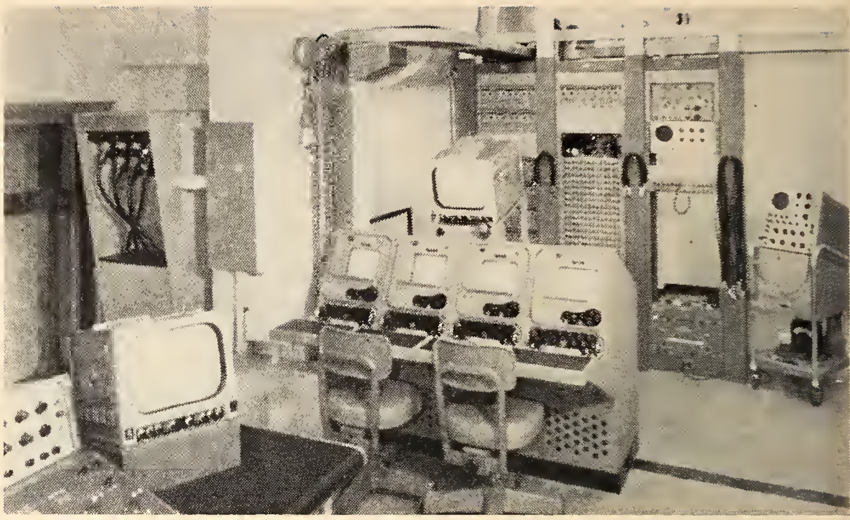


Fig. 2. Studio 42 Video Control Room

a second output bus. Consequently all busses are arranged for lap switching.

In the video crossbar system however there is no isolation between the various input output combinations. If all busses were arranged for a lap switching the selection of an input, on a mix bus for instance, which was already in use on the cut bus, could cause momentary crosstalk and transients. The problem is avoided in this vision mixer by the use of special control circuitry in the crossbar, which is so arranged that the bus which is routed to the switcher output at a given moment will always switch lap and therefore be transient free, while all other busses will switch gap. This arrangement works very satisfactorily since any transients occuring in busses not routed to the switcher output are not important.

The design of the mixer is such that is possible to:

1. Cut from any input to any other input;
2. Fade from any input to any other input;
3. Mix from any synchronous input to any other synchronous input;
4. Superimpose two, three or four synchronous inputs simultaneously;
5. Superimpose two synchronous inputs and a special effects:
6. Cut from any input to any super imposition;
7. Mix from one superimposition to another;
8. Fade from any input to any super imposition or special effect.

The main output from the mixer (see Fig. 3) is fed by and equalized line to Master Control. A second output feeds distribution amplifiers which are used to supply various monitors throughout the studio and the building. Failure of individual mixer components will not completely disable the mixer as patching facilities permit by-passing sections as required.

Video tie lines are provided from the video patch panel on the racks to convenient locations in the studio for cue and special effects purposes.

Pulse System & Sync Locking

There is no synchronizing generator in this studio. Drive, blanking and sync signals are supplied by lines from Master Control. The operation of Studio 42 is linked with the pulse distribution and sync-loc system of the Montreal TV plant. There are four sync generators in TV Master Control. These generators feed drive, blanking and sync signals to a six level 4 input 20 output video crossbar. The generator feeds are terminated at the end of the crossbar and bridging amplifiers are connected to each output. Push button controls in Master Control permit any telecine, or studio, or groups of telecines and studios, to be connected to any sync generator. Three of the sync generators are provided with sync-loc facilities, fed with stripped sync from input stabilizing amplifiers. With the above arrangement it is possible to operate the whole plant from one sync generator, or to sectionalize the plant into groups using different sync generators. An example of operation in Studio 42 could be as follows: Studio 42 and

Telecine 1 are switched to sync generator 1; Telecine 1 video, audio and intercom are patched to Studio 42. Variable delay lines in the pulse feeds in Studio 42 are adjusted to compensate for the time delay in the Telecine 1 feed. Telecine 1 may now be used as a synchronous input to Studio 42. Similarly, it may be arranged for any other local studio or telecine to be used by Studio 42. Should it also be required to use a remote studio, an outside broadcast, or a network program with Studio 42 on a synchronous basis, sync generator 1 is sync-locked to the remote signal, thus making Telecine 1, Studio 42 and the remote signal all synchronous. This sync system is extremely flexible and permits many special set-ups to be made with ease. Requirements for this flexibility arose from CBC operations which involve servicing two major French and English networks, Canadian insertions on American network programs and, in the case of Montreal, the programming of French and English local transmitters.

Audio Facilities

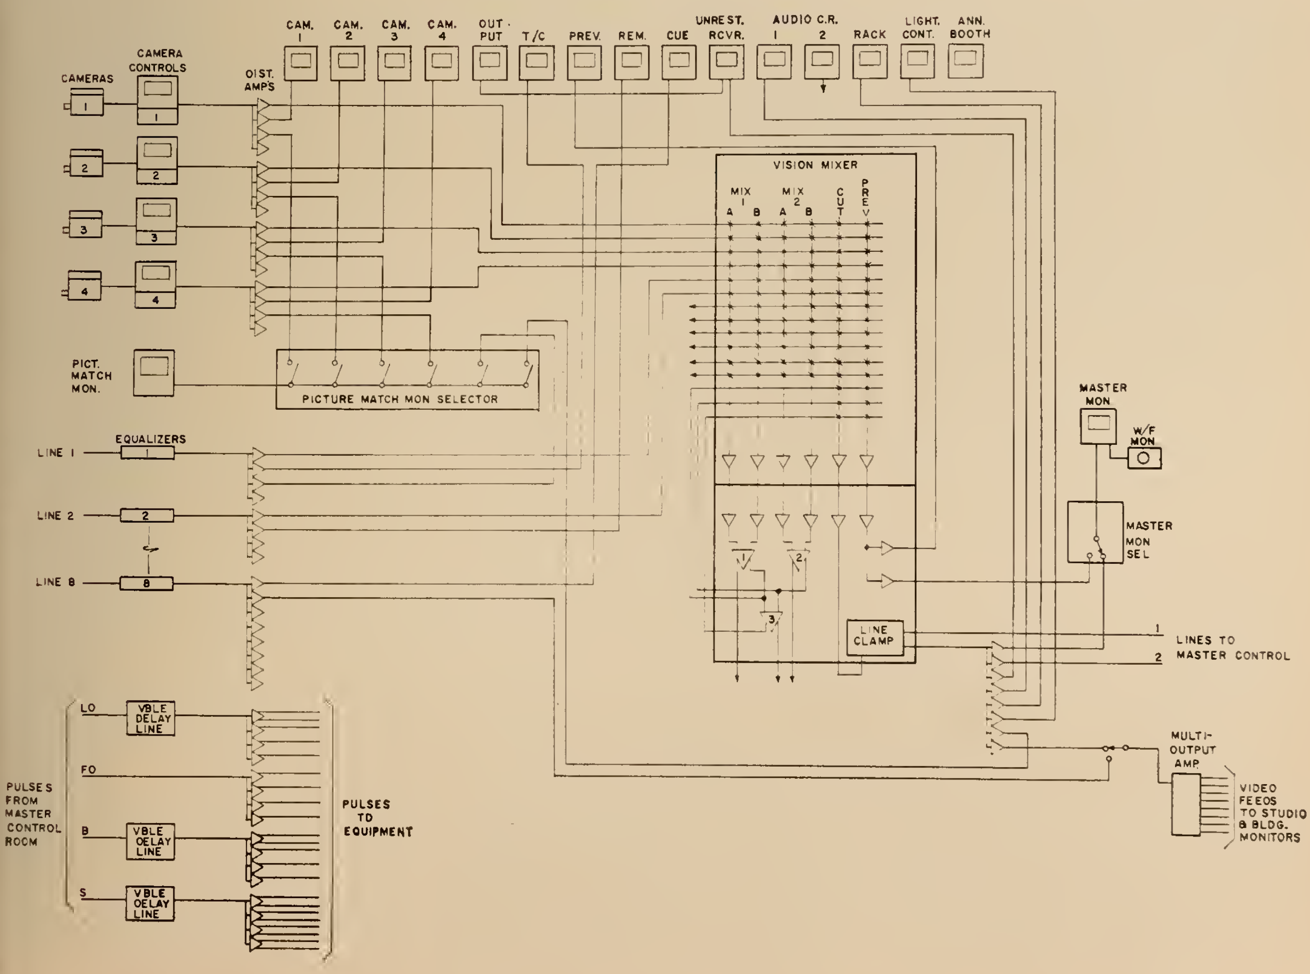
To the left of the production desk in the video control room and separated by a sliding window, lies the Audio Control Room. The audio console faces the studio, with a window to provide a view of the studio floor. Also in front of the audio console are two 8 in. video monitors and intercom facilities. Two turntables and one tape recorder/reproducer are located to the left and right of the console. Be- left of the Audio console and is hind the audio console, and forming part of the back wall of the audio control room, are the audio and intercom equipment racks.

The Announce Booth lies to the equipped with video and audio monitoring facilities and a control turret. The latter permits the announcer to switch his own microphone on or off as desired.

Fig. 4 shows the audio functional diagram. Thirty-eight microphone inputs, from conveniently located microphone connectors around the perimeter of the studio and from the lighting grid, terminate in the audio console. Two turntables and one tape unit feed into the console, from which position they may be stopped and started remotely. Six input lines from Master Control and ten trunk lines to the Studio audio patch panel are also available.

The audio console comprises the control console and two equipment racks. The control console houses terminals, potentiometers, transformers, pads, switches, jacks and "VU" meter, while the racks contain amplifiers and power supplies. The left hand wing houses a console patch panel which permits the patching of any microphone input, turntable, tape machine or line from Master Control into any of 32 console inputs. These 32 inputs are connected to 16 input preselect keys which are located just to the right of the jack panel. Through these input select keys it is possible to route, simultaneously, 16 of the 32 inputs to the 16 preamplifiers. Immediately below the input select keys are 16 submaster select keys. These keys permit allocating any or all of

Fig. 3. Studio 42 Video Functional



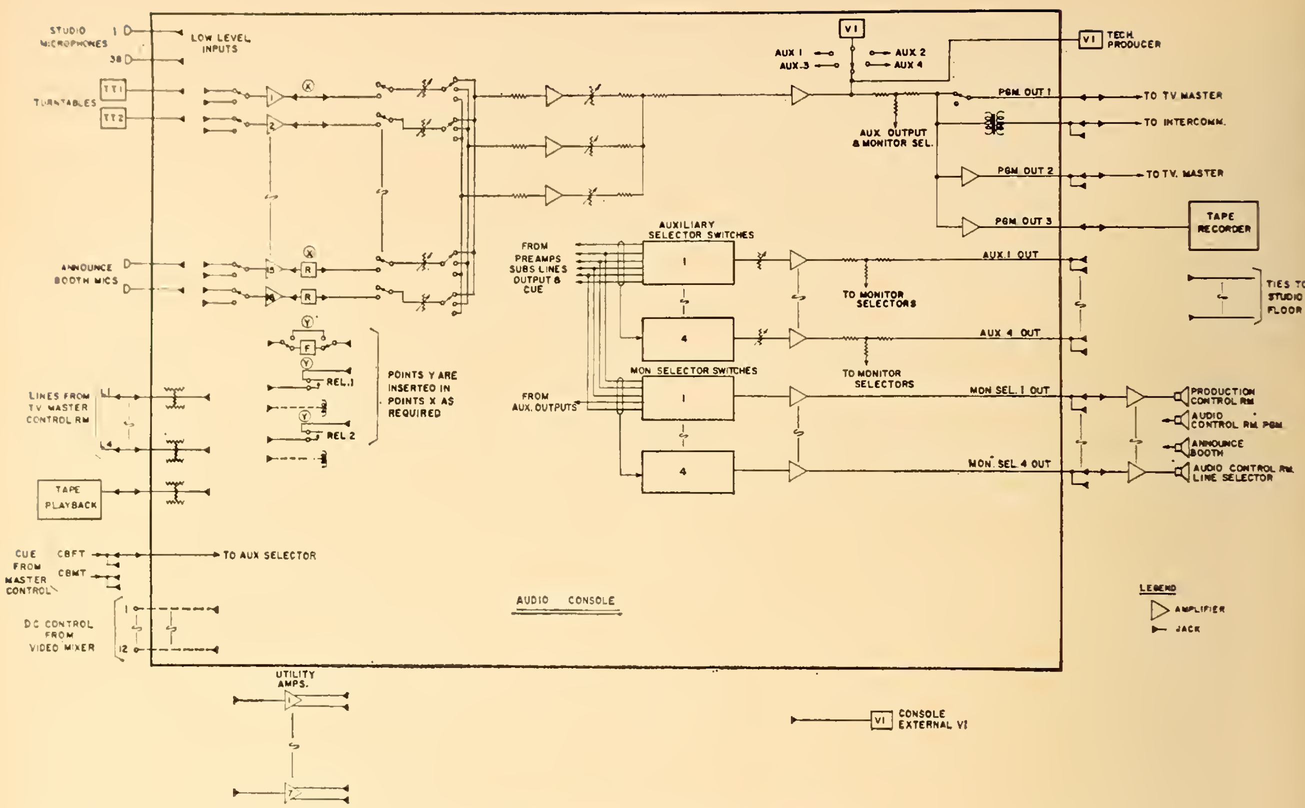


Fig. 4. Studio 42 Audio Functional

the preamplifier outputs to any one of three submaster controls.

The center panel of the console is the main operating area. The lower left and right sections house sixteen potentiometers and associated on-off keys which control the individual preamplifiers. The lower center section houses the three submaster controls known as red, green and amber. Above the submaster controls is a "VU" meter. To the right of the "VU" meter is the master gain control and the output key. To the left of the "VU" meter are the meter select keys which permit monitoring the various console outputs, and further to the left are high and low pass filter controls. The filters may be patched into any desired circuit and used for various effects.

Directly above each preamplifier potentiometer is a frosted glass window which permits the write-in of input designation. This window glows red, green or amber, depending on the submaster to which the particular preamp has been assigned. To the left of each pre-amp on-off key is a small pilot light which is illuminated when the key is on. At the same time, a pilot light associated with the input preselect key, on the left hand panel, is also lit, to warn that the channel is live. The preamp on-off key may also be operated so as to extend remote control of the channel to an announcer.

The right hand wing of the console houses auxiliary output and monitoring controls. There are four auxiliary outputs from the console.

Self-illuminated push buttons, on the right hand panel, permit the routing of any preamp output, any submaster output or the main output, through any auxiliary channel. A gain control is available for each auxiliary channel, and the console "VU" meter may be switched to any channel for signal level monitoring. The auxiliary outputs may be used to feed a reverberation facility, studio floor cue speakers, special recording feeds, public address systems and for other special purposes. The monitor speakers for the control room and studio are also fed from similar switches and gain controls on the right hand panel.

In order that audio inputs may be switched simultaneously with video for special purposes, two special relays have been included in the audio console. Microphones or other inputs can be patched through these relays and will be switched on and off as the relays are operated. Control of the relays may be routed by patching to any one of the video switcher input select buttons on the cut bus. With this arrangement it is possible to have both audio and video switched simultaneously by the vision mixer operator, and thus ensure the synchronism of sound and picture where complicated programming requirements might otherwise cause difficulty.

Intercom Facilities

One of the most important and the most complex of the technical facilities for a television studio is its intercommunication system. It is essential that a rapid flow of information and orders may pass between the control rooms and the multitude of people engaged in a television production. To achieve this end, several methods of intercommunication are used. Personnel, who must hear the producer at all times, are equipped with headsets if located on the studio floor, and with small loudspeakers if located in separate control rooms. They are connected at all times to the producers talkback microphone output. Such people are cameramen, the audio operator, the floor manager and assistants. In the case of the floor manager, a special one-way radio frequency intercom system permits him to receive the producer's talkback without being encumbered by trailing wires. He may talk back to the producer by using special wired intercom microphones, which are available about the studio and connect to the production control room speaker. Of course if the program is only in rehearsal he may talk back through one of the audio microphones. Regular two-way wired intercom headsets are also available for the floor manager, if required.

Other locations such as the studio floor, telecine, remotes, lighting control room and dressing rooms are switched into the general intercom system as the producer requires. The technical producer has facilities duplicating those of the producer, though all are on a switching basis.

The audio operator, also on a switching basis, has facilities for talking to the studio floor, the sound effects operator, the boom operator, telecine, the announcer and the production control room. The lighting operator can communicate with follow spot men and the production control room.

The camera operators have two-way intercom with the camera control operators and are connected to the production control room speaker. All intercom positions are also supplied with program sound, and just prior to the start of the program receive a sound cue from the program preceding. Individual automatic gain control amplifiers have been provided to control intercom microphone levels, and output amplifiers permit adjustment of headset and speaker feeds to standard levels. In addition, each headset and speaker is individually equipped with volume controls, permitting the user to adjust them to suit his own requirements.

Test Equipment

Audio test equipment consists of an audio frequency generator, a noise and harmonic distortion meter and an extended range "VU" meter.

Video test equipment comprises a video sweep generator, a multi-frequency burst generator, a staircase type linearity checker, a window generator, a grating generator and oscilloscopes.

Miscellaneous

The equipment racks used in this installation are a special CBC design, and are ventilated by four ducts which form the four vertical corner members of the rack. Cooled air from the studio ventilation system is fed to the ducts at the top and directed, by circular vents in the inner sloped side of each duct, against the front and rear of rack mounted equipment. Exhaust outlets are situated external to the racks in the ceiling, and remove the hot air from the racks before it can circulate in the room. Conventional room ventilation is also provided. Experience with this type of rack has shown a marked improvement in equipment stability and a reduction in maintenance requirements due to the reduced operating temperatures of equipment. One rack may carry equipment which dissipates up to 4.5 kw. As a satisfactory average it has been found that an airflow of 50 c.f.m. per duct of 50° air is suitable. The ventilation system takes care of an equipment heat load of about 25 kw. in the control rooms.

Video and pulse amplifiers are of the plug-in type, permitting rapid replacement in the event of failure. Additionally, patching facilities for the complete system are so arranged that defective components, whether video or audio, can be rapidly bypassed or replaced.

Hydraulically counterbalanced camera pedestals and a power operated crane, all equipped with a new type springless pan-and-tilt head, have been provided as camera mounts. The pan-and-tilt head is so designed that no matter in what position the camera is placed its center of gravity does not change height, and consequently the camera is always stable.

A new type artificial reverberation unit, which consits basically of a large steel plate with input and output transducers welded to it, has been provided in lieu of the usual reverberation room. Reverberation times varying from one half a second to over five seconds can be remotely selected by the audio operator. From limited experience to date this unit appears to be much more satisfactory than the rooms usually provided.

Studio 7 Toronto

As noted previously, the Studio 7 installation in Toronto is essentially the same as the Studio 42 installation just described. An additional facility provided in Studio 7 is a separate Sound Effects Room with special turntables, tape machine and small audio console. This permits recorded music and complex effects to be routed as a single input to the main audio console. In Studio 42, sound effects are usually obtained from the studio floor.

An interesting problem arose in connection with the Studio 7 video installation. The building in which Studio 7 facilities are housed is a separate unit from the main TV plant, and separated from it by about 100 ft. Two separate power entrances and watermain entrances serve the two buildings. Early in the project it was found that the ground potential between the two buildings was of such magnitude that when a video signal was fed by coaxial cable from one building to the other, the longitudinal noise voltage was on occasion so severe as to make the video signal unusable. Several avenues of investigation toward a solution were open, but the simplest appeared to be to prevent the difference in ground potential from inducing an unwanted voltage onto the video signal. Fortunately a device known as a longitudinal stop coil, produced by a British firm, was available for test. This stop coil consists of a coaxial cable about 100′ long wound in a toroidal form on a magnetic core. Stop coils have been placed in all coaxial cables joining Studio 7 to the TV Master Control, and entirely eliminate hum voltages up to approximately 10% of the video signal.

As noted above, Studio 7 is in a separate building to the TV Master Control, and all video audio and intercom circuits connecting the two locations are carried by a special messenger cable which joins the two buildings. Video and pulses are handled by two specially constructed cables each made up of ten coaxial cables with an overall covering of polyethylene. Audio and intercom are handled by two 26 pair telephone type cables also provided with a polyethylene covering.

Acknowledgements

In projects of this size it is obvious that dozens of individuals have played an important part in the design and installation work, and it would not be feasible to acknowledge their contributions individually. Thanks are due to Mr. W. G. Richardson, CBC Director of Engineering, for permission to publish this paper. and to the CBC Chief Engineer Mr. J. E. Hayes and the Plant Engineer Mr. J. Carlisle, under whose supervision the work was carried out.

SOME FUTURE DEVELOPMENTS IN THE TELEPHONE INDUSTRY

S. G. Anderson

SINCE THE ARRIVAL of nationwide network television in Canada, much has been said about our Trans Canada Microwave Network. This system known as the TD-2 Radio Relay System, operates in the 4000 mc band and is capable of carrying 3,000 telephone circuits or five 2-way T.V. network channels over distances of 4000 miles. Remarkable as this is, a system now undergoing trials operates in the 6000 mc band and will be capable of carrying up to 13,320 telephone circuits or six 2-way T.V. channels over distances of 4000 miles.

Looking further into the future, we know that if a stable extremely high frequency signal of say 50,000 mc could be generated and this propagated by some means between two points without undue loss, that a very large channel bandwidth can be obtained. This radio frequency carrier can be used to transmit a multitude of T.V. channels and many thousands of telephone circuits. (Table 1)

Both the TD-2 and TH Systems make the maximum possible use of the available frequency spectrum (i.e. 3700-4200 and 5925-6425), assigned by the Department of Transport. Now let us assume that equipment operating in the 50,000 mc band was available for use, add this to our table and see what circuit capacity we have in hand. Assuming the same percentages in frequency spectrum and channel spacing as for the TD-2 system, and assuming 25% of the available channels are held for protection purposes, we find 61 working channels available for message use. At 2200 telephone circuits per RF channel, this system would provide us with approximately 133,000 telephone circuits, or 61 2-way television channels. Even the most avid T.V. fan would consider this number of T.V. channels adequate.

The next question is: how do we transmit a 50,000 mc signal from city to city? Since this signal is too high in frequency to travel through the atmosphere without extreme attenuation, experiments are underway in the Bell Telephone Labs. to determine if this signal can be successfully transmitted down a hollow pipe or waveguide using a certain mode of propagation in the waveguide (TE01) . . . We can visualize our cities of the future connected together by a network of communication pipes with repeaters every 40 miles or so amplifying signals of 50,000 and perhaps 100,000 mc.

By utilizing the vast communications highway that is being established across the country, operators have been able to dial directly to numbers in distant cities in all parts of North America. Already in some parts of North America, telephone users are able to dial their friends in distant cities directly, without the help of an operator. With each succeeding year many more will be able to dial their own long distance calls to many of the 65 million and more telephones in Canada and the U.S.A.

The present type dial on your telephone operates equipment by interrupting a d-c. loop between your house and the telephone office at the rate of ten impulses per second. On long distance circuits however, it is not possible to provide d-c. paths to operate equipment and multi-frequency tones are employed.

With the multi-frequency pulsing system, six frequencies spaced 200 cycles apart from 700 to 1700 cycles are used. Two of these frequencies are used for each pulse and each pulse represents one digit. There are 15 pairs possible from a group of 6, and 10 of them are used for the digits 0 to 9 inclusive. One each is used for signalling the beginning and end of pulses. These multi-frequency tones can be sent out over the toll line by means of what we call sender equipment in the toll office. The operator causes this sender to function by pulsing into it with d-c. key buttons. Such senders store the pulses and re-transmit multi-frequency pulsing signals to the toll line at the rate of seven digits per second. (2L-5N number is transmitted in one second).

The average speed of keying by an operator is two digits per second, which is about twice the average speed obtained by the dial. This speed of keying along with the rapid transmission rate of these signals along the toll circuit, represents a large saving in operator and circuit usage time. The day may come when this little key set will replace the present dial on your telephone.

We are now thinking in terms of world wide communications. Late in 1956, the first Trans Atlantic telephone cable went into service between Europe and North America.

It provides 29 telephone circuits between London and New York, and six between London and Montreal. Seven of the New York and London circuits have been extended to continental network centers.

From Oban, Scotland to Clarenville, Newfoundland, transmission is over a deep sea submarine cable system. This link makes use of two cables, one for each direction of transmission. The cables are laid approximately 20 miles apart and they are 1,950 miles long, submerged at depths up to 2½ miles. 102 repeaters, 51 in each direction, are used to compensate for the cable attenuation. The repeaters are enclosed in flexible housings within the cable and were designed to pass through the ship cable laying machinery. At the same time they had to be strong enough to withstand the deep sea pressure of 6,000 lb. per sq. in.

From Clarenville, Nfld. to Sidney Mines, Nova Scotia, a single coaxial cable having a capacity of 60 circuits was laid. Sixteen repeaters were required in this section.

The idea of a submerged telephone cable is not new. Non-repeater telephone cables have been in existence for many years. The fact of great significance in the laying of this cable is that the 300 and some odd vacuum tubes and many other thousands of components must have a reliable life of at least twenty years, without maintenance.

Plans are underway to lay a British-Canadian cable having a 60 circuit capacity, and an additional cable to link Continental Europe with the U.S.A.

Miniaturization is of especial importance in the improvement of telephone service. When something smaller can do as good a job or better than the equipment it replaces, there are often important savings to be made, not only in material but also savings in space and power requirements. One of the best examples of this research is the work that has been done in the Bell Telephone Laboratories in the semi-conductor field, producing such items as the Solar battery, photo-transistor, and transistor-amplifiers.

The heart of the Solar battery is the *p-n* junction or boundary between different electrical conductivity types in a semi-conductor crystal. Light energy when it strikes a semiconductor will often split off an electron from its normal position in the crystal lattice, leaving a positively charged hole in the vacant space. Both the electron and the hole will then be available for the conduction of electricity—if they can be prevented from re-combining and thus neutralizing each other. The *p-n* junction provides a built in electric field, that pulls the electrons into the *n* or negative side of the junction, and the holes into the *p* or positive side before many of them recombine. The electrons and holes are said to be collected by the junction. With suitable contacts and leads to the two sides, the resultant current can be used in an external circuit.

There are five important facts about the Bell Solar battery that are really worth emphasising:

(1) It is an experimental device that converts sunlight directly into electrical power with no intermediate steps;

(2) It is at least fifteen times more efficient than the best previous solar energy converter, having an efficiency of 8% at present;

(3) It has no moving parts or corrosive chemicals and should last indefinitely;

(4) Its efficiency of conversion of available light remains essentially constant, even in poor light where other converters will fail;

(5) It charges the storage battery at constant voltage, and a solar battery-storage battery combination can thus average a steady power output day and night.

Semi-conductors can also be used as photo-conductive devices in which the conductance of a semi-conductor element is increased when the element is illuminated. This is a principle employed in the photo-transistor, and this little device is used in nation wide dialing in routing calls through offices. This routing information is registered on metal cards with holes in them, the cards to be selected in accordance with the digit dialed. The cards are stacked together and a light is shone on them.

Photo-transistors are used then to determine what light channels are blocked or clear, by causing the operation of a relay, thus supplying the routing information.

The transistor as an amplifier is essentially two *p-n* junctions located very close together. One junction (emitter) is biased by a battery in the forward direction; the other junction collector is biased in the reverse or very high resistance direction; and the small current which does flow is due only to the small number of minority carriers which are always present in a semi-conductor near the junction.

A very small signal in the emitter circuit will produce a corresponding current across the emitter junction. As a result, minority carriers (electrons) are emitted into *p* type base layer. Due to the dimensions of the base layer almost all emitted electrons will reach the collector junction before they find their way out to the contact at the base, or are lost by re-acting with holes. Since there is very little current flow in the collector circuit due to this high resistance, the introduction of the unattenuated signal from the emitter results in a large increase in power, and the energy of amplification is furnished by the battery B2.

Hence transistors have many advantages:

(1) They require practically no power to run, operating on 2 to 4 volts only. Thus in the telephone companies, where thousands of vacuum tubes are now used requiring larger amounts of power, the introduction of the transistor amplifier will represent large savings;

(2) They are very small in size, permitting miniaturization of components which represents a large saving in equipment space;

(3) They have a long life expectancy due to the fact that electrons are not being emitted from material as in the case of the vacuum tube.

City-wide personal radio signalling is a potential new service now being tested in the telephone industry. The system serves to indicate to a particular customer, perhaps a doctor or salesman, when his secretary or some other party is trying to reach him. The customer carries a small radio

Table 1

	Frequency Spectrum Mc	*D.F.S.*	*RF Channel Bandwidth*	*RF Channel Spacing*	*No. of RF Channels*	*RF Channels left for Message use*	*No. of Protection Channels*	*Telephone ccts/ch.*	*Total Message ccts. per system*
TD-2	3700—4200	500 mc	20 mc	40 mc	12	6	1	600	3,000
TH	5925—6425	500 mc	28 mc	29.6 mc	16	8	2	2200	13,320
TX	50,000—56,500	6500 mc	20 mc	40 mc	162	81	20	2200	133,000

receiver, completely transistorized and only slightly larger than a package of cigarettes, in his pocket or clipped to his belt.

On receiving a radio signal with the proper code, the radio will emit an audible tone of sufficient loudness to inform the user that he is being called. He then goes to a telephone and calls his office where he is given the message.

To call a customer the person dials a particular telephone number and is connected with a personal signal operator. The calling party gives the operator a four digit number which corresponds to the code associated with the radio receiver assigned to the called party. The operator then places this number into a memory system by setting up a series of four rotary switches. The codes set up on the switches are scanned and translated into components of four audio frequencies. The audio frequencies modulate a 250 watt A.M. transmitter which operates on one of the common carrier mobile frequencies.

When the radio frequency signal is picked up by the receiver, it is demodulated and the audio tones are used to energise a group of four vibrating reeds. If all reeds are energised, an audio oscillator is triggered and an alternating tone informs the customer that he is being dialed.

The units are small and light in weight and employ a single 4 v. battery.

It is estimated that ranges of about two to four miles from each transmitter will be obtained. To compensate for variations in radio propagation, any given code is transmitted three times.

There are also some changes in store for your telephone. At present there are long range plans underway in telephone laboratories to convert from a mechanical type dial switching to electronic type dial switching systems by extensive use of the transistor. This conversion will necessitate many accompanying changes, one of these will be the replacements of the familiar bell ringing signal by an electronically generated musical tone. At present 90 v. of 20 cycle power is required for ringing the present bell. A tone ringer superior in output to the conventional ringer and more pleasing to the ear has been designed through use of voice frequency tones of less than 1 mw. This employs a transistor amplifier and small speaker in the telephone set. By using different frequencies on the line and resonant circuits in the telephone, telephones working on a party line basis may be rung individually. Tests have shown that the musical tone can be heard at great distances and stands out above general room noise more effectively than the present bell.

Other changes in the telephone may include replacing the dial with a key punch. The hand set itself may eventually be replaced by a small microphone and speaker, permitting operation with the hands free.

We may in the future have a telephone that transmits pictures as well as sound. In the experimental models that have been developed, the pictures are 2 in. by 3 in. in size. Unlike television, a new picture is displayed every two seconds. The picture phone has been made possible by slowing down the rate of transmission of picture information, so that the required band width can be handled by conventional telephone circuits (300-3400 c/s). The illuminated area of cathode ray tube is made up of 60 lines, each line containing 40 dots. Thus a complete frame is made up of 2400 dots. If one complete picture is transmitted every two seconds, a bandwidth of 600 cycles is required.

In order to pass the low frequency components of this 600 cycle band over telephone facilities, this video signal is modulated on a 1200 cycle carrier, and produces a conventional A.M. double side band signal (600-1800 c/s). It will be possible for a caller's picture to be dialed like an ordinary telephone call, provided the switch (and there must be a switch) on the picture equipment is turned on at both ends of the line.

Today the telephone companies have a growing list of new users who are not people but electrical and electronic business machines. Such machines talk to each other at very high speed over long distances.

A data transmission device has been developed which has been an important step in the transmission of data over telephone lines. This device takes the information after it has been placed on a magnetic tape and transmits it over telephone facilities.

For example, a secretary in the headquarters of a power firm has a two page, thousand word document which must be delivered to an outlying office. The desk in front of her has an electric typewriter which produces type and magnetic tape for use in the subset. She establishes the call in a normal long distance manner, places the tape in the machine and transmits the thousand word document in less than a minute.

LITTORAL DRIFT *(Continued from page 91)*

only wave data available would be hind-cast records built up by tedious calculation from synoptic charts.

In an effort to determine some of the necessary facts it has been decided to gather data initially at two typical harbours, Cobourg and Port Hope. Complete hydrographic surveys have been made at each of these harbours and range lines established along which soundings are taken monthly in an effort to determine the rate of accretion or depletion. The measurement of waves has been achieved by setting up a pressure-cell recording device in 40 ft. of water 4,000 ft. off shore at Cobourg, with automatic recording in an instrument house on shore. This distance offshore was deemed necessary to avoid the reflections set up by the breakwaters nearer the shore-line. The pressure type wave recorder was designed and installed by the Instrument Section of the National Research Council and has been recording the wave action every three hours since last February. A recording wind gauge has also been installed at Cobourg to operate in conjunction with the wave apparatus.

A wave flume has been designed and constructed in the hydraulics laboratory at Queen's University. It is at present being used in a basic investigation of the transporting properties of various types of waves.

When sufficient field information about the wave characteristics, the rate of littoral drift and the rate of deposition in existing harbour channels has been accumulated, it will be possible to construct models of actual harbours and attempt to adjust the operation to reproduce existing conditions. Proposed changes such as deepening of channels or extension of breakwaters could then be tried out at the model scale in an effort to predict prototype behaviour before the changes are made.

INSTRUMENTATION IN INDUSTRY

CHEMICAL PROCESSING PLANTS

THE GENERAL requirements for controlling and recording instrumentation in the chemical processing industry are quite similar to those prevailing in the petroleum refining, gas processing, and particularly, petrochemical fields. Processing is here taken to cover the making of desired end-products by a continuous series of chemical and physical processes, usually in liquid or gaseous phases, rather than the intermittent batch processes or electrolytic methods used in the production of some heavy chemicals and dyestuffs, or the final blending of materials.

The processing industry could not function without the use of instruments to record and control such variables as temperature, pressure, flow rates, liquid levels. The efficiency of processing is further increased by the use of instruments for the continuous measurement of pH, chemical composition, specific gravity, and so on. Additional refinements may include the use of continuous measurement of corrosion within lines or vessels.

The complexity of instrumentation naturally varies with the size of the plant and the processes involved, but there is a notable trend towards full automatic control and the release of operators from routine checking to devote more time to improvement of production. Apart from the automatic operation of pumps, valves, feeders, etc., stream conditions can be constantly checked by such techniques as thermal conductivity, gas chromatography, and infra-red analysis.

Power Supply

The chemical processing industry in Canada relies almost entirely on main electrical power purchased from outside suppliers. In only a few cases is this supply checked independently by the user, though the individual circuits within the plants naturally have their own regulating and measuring systems.

Who Determines Instrument Requirements?

All companies that replied to a questionnaire on this subject have instrument requirements determined by a member of the engineering staff, frequently an instrument engineer. This is particularly the case where the company controls its own process design and has reason to keep information secret. Maximum efficiency may be better obtained by selection of individual instruments on their own merits, rather than going to one manufacturer for all requirements.

Who Buys the Instruments?

In nearly all cases covered by the questionnaire, the engineering department (usually an instrument engineer) has the responsibility of specifying the types of instrument required, but the order to the supplier is placed through the purchasing department.

One large manufacturer stated that the instrument buyer has to be familiar with the equipment and well qualified to evaluate competitive quotations. He attends training courses run by the instrument makers and visits their plants so as to acquire a good overall knowledge of what is available in the instrument field.

Servicing of Instruments

Replies to the questionnaire indicate that at least 90 per cent of replacement, service, repair, and recalibration of instruments is carried out by the processer's own staff. Exceptions noted include small plants that do not carry the necessary staff, but send instruments to the manufacturer for repair and recalibration, and certain cases of specialized instrumentation.

No specific data are available on the use of preventive maintenance throughout the industry, but it is probable that some form of preventive system is prevalent for the same reasons that it is used in the petroleum refining industry.

Maintenance staffs obviously vary with the size and complexity of the plant, and may consist of one instrument mechanic for a relatively small organic chemical processing plant. A more diversified organic chemical plant with an initial instrument installation costing over one million dollars maintains some 2,000 instruments: there are four instrument mechanics plus one man for regular shop repair and overhaul, and an electronic technician to service electronic equipment. In one large plant, operating under severe conditions, twelve mechanics are used on day shifts to maintain instruments which have an installed value of over $1.5 million.

Spare Parts Practice

Practice in handling spare parts again appears to vary with the type of plant and other conditions. Probably, the smaller and simpler the instrument installation, the less tendency there is to hold a stock of complete replacement units, though all replies indicate that some spare component parts are held for essential repairs and replacement.

Instrument Specifications

It appears to be general practice for the chemical processors' own engineers to specify the instruments to be used in an installation. The industry also generally uses 'standard' instruments, of which a wide range has been developed to meet the varied needs of the chemical processing techniques now in use.

• INSTRUMENTATION

Statistics on Instrument Usage

Capital costs of instrument installations vary widely with the size and complexity of the plants involved. It is difficult to attempt any comparison between capital investment in instruments and volume or value of product, since a relatively small output of one chemical product may have a high dollar value per unit, whereas another may be produced in much larger quantities for a smaller unit value. At the same time, there is no simple relationship between complexity of instruments, gross throughput of plant, and value of end-product.

Installed cost of instruments for a one-product plant (organic chemicals) might be of the order of $20,000 to $25,000, with an annual maintenance cost of four per cent to fifteen per cent of installed investment. A multi-product organic chemicals and resins complex with installed instruments to a value of just over $1 million reports an approximate breakdown of initial installed instrument cost as: one-third for raw materials processing and utilities; two thirds for chemical and resin processing. The question of recovery time for instrument investment is largely academic in the chemical processing industry, since most processes are virtually inoperable without certain basic recording and control instruments.

Types of Control

Opinion of chemical processers is divided on the subject of pneumatic versus electronic control systems. Generally, pneumatic controls have prevailed so far in the Canadian chemical processing industry, but the use of electrical transmission circuits and electronic controllers is now being more widely investigated. The main objection to electronic controls is the need for special precautions if they are used in potentially explosive atmospheres.

Advanced Instrumentation

As already mentioned, there is a growing tendency to incorporate refinements into processing plants beyond the basic essential control and recording instruments. In particular, it is now becoming possible to keep a constant check on constituents in process streams by the use of industrial-scale vapour-phase chromatography, infra-red analysis, and analysers for oxygen and combustible gases, plus pH measurements on liquids.

Ultimately it will be possible to feed such information, together with data on such variables as temperatures, pressures, flow-rates, levels, catalyst efficiency, etc., to a computer system which would regulate all the interdependent conditions to give maximum process efficiency far more rapidly and consistently than is possible with the intervention of human operators.

This degree of control has already been achieved on an experimental scale in a chemical plant in the United States.

J. B. Birks, B.A., Ph.D., D.Sc., F.Inst.P., A.M.I.E.E., reader in physics, Manchester University. (co-author of the paper, "Capacitor Developments in Great Britain", in our July issue).

Dr. Birks was Research Manager of British Dielectric Research Limited from 1954-57. He is the editor of "Progress in Dielectrics" and the author of 50 published papers.

We offer our sincere apologies to Dr. Birks for omitting this relevant information and stating his academic qualifications incorrectly in our earlier biographical note.

It was erroneously stated in the June issue of *The Engineering Journal* (Authors page) that Mr. R. M. Bremner *(3,500 ton University of Toronto Building Moved 250 Ft.,)* was in charge of construction and planning at the University of Toronto. Mr. Bremner is, in fact, an assistant in the department and the staff of *The Engineering Journal* apologize for any inconvenience or embarrassment caused.

WANTED

June 1959 issue of THE ENGINEERING JOURNAL

The Engineering Institute has received so many requests for additional copies of the June issue of *The Engineering Journal* that the available supply has been exhausted.

It will be greatly appreciated if readers who do not keep their copies on permanent file, will return them to the editorial office at 900 Sherbrooke Street West, Montreal, Que.

We offer our sincere apologies to Mr. C. C. Parker, whose name was misspelt in our August issue (Discussion on the paper—Design and Erection Features of the Vertical Lift Bridges for the St. Lawrence Seaway) by W. F. H. Holt, M.E.I.C.

Canadian Developments

1959 Coast-to-Coast Surveying

Mapping of Canada

The federal mapping and charting program for 1959 has been under way since May and will continue until November. The program will take survey parties to all ten Canadian provinces as well as to Yukon, Northwest Territories and coastal and inland waters. Included in the field survey force of more than 1000, there are 81 individual survey parties and 28 units of the Canadian Hydrographic Service.

Mines Minister Paul Comtois said that emphasis is being placed on the development of the northland. The objectives are: the long range purpose of providing Dominion-wide coverage in base maps and charts at various scales; and the short range objective of gaining knowledge of potential resources of minerals, water power and forests. Defence needs are also aided by the mapping and charting program.

Public Works

Harbour Improvement: The contract has been awarded at over $3 million to MacNamara (Quebec) Limited for a large harbour improvement project at Pointe-ou-Père, Quebec. The result will be a good winter port on the Quebec South Shore and better traffic facilities for the developing North Shore.

The improvements will include a widening of the existing wharf to 200 feet. There will also be an extension to the existing wharf, which will be 710 ft. x 75 ft., and new approaches on the east and west sides. Dredging of 54,000 cu. yd. is necessary for berthing and turning areas.

Bridges: Poole Construction Company of Calgary have received a $2 million contract to build bridges over the Pelly and Stewart Rivers, Y.T., and to improve the Yukon River Bridge at Carmacks.

The Pelly River and Stewart River bridges are on the Whitehorse-Mayo Highway, 160 and 220 miles north of Whitehorse respectively.

A bridge will be built between Campbellton, N.B., and Cross Point, Que., and a $2.9 million contract was awarded for construction of the superstructure has been awarded to the Canadian Bridge Division of Dominion Steel and Coal Corporation Limited, Walkerville, Ont.

The two provincial governments and the federal government are jointly financing the project, which will replace a ferry crossing and avoid a 26 mile drive around the Bay of Chaleur. Work is already progressing on the substructure.

Atlantic Provinces

Construction in 1959 in the Atlantic Provinces will exceed the 1958 program in volume, and approximately 11% more will be spent on construction than in 1958, according to a Canadian Construction Association report of forecasts.

All of the Atlantic Provinces with the exception of Newfoundland; will noticeably increase volume of construction bringing per capita spending for this purpose closer to the national average. The highest rate of activity is in New Brunswick, then Prince Edward Island and Nova Scotia.

Canada's $7.2 billion estimated program for 1959 will represent a small decrease from 1958, and a per capita spending of $415. The Atlantic Provinces volume of $499.6 million represents a $270 expenditure per capita.

Ontario Frequency Standardization

Ontario Hydro have completed the 10-year frequency standardization program ahead of schedule. Well over one million customers now receive 60-cycle in place of 25-cycle power. Estimated cost of standardization was $360 million. It is estimated that this outlay will be recovered in approximately 20 years through savings directly resulting from the change.

Work on Victoria Bridge

A 130-ft. girder-type span weighing 60 tons was put in place recently on Victoria Bridge, Montreal, by C.N.R. in an unconventional engineering job.

Trucks moved the span 2,000 ft. over the bridge to its final location. Later the span was lowered into place and old sections were removed.

The girder-type spans are required to replace two of the present truss-type spans, which must be removed to allow a diversionary rail and road route to be joined to the existing bridge structure. This is the fourth and final girder-type span to be installed in the downstream side. Next year, spans will be replaced on the upstream roadway, and later, on the rail route. Construction is to be completed in 1961.

Building in Winnipeg

The new head office of the Great West Life Assurance Company was formally opened in Winnipeg, Man., in June.

The building is on an 8-acre site. It is a T-shaped structure of 5 storeys with a 2-storey penthouse. Frontage on Osborne Street is 758 ft., depth is 283 ft., and height, 99 ft. Floor space is 219,000 sq. ft.; capacity is 1,600 persons (addition of five-storey wing will increase capacity to 3,200).

Piling consists of 198 caissons to hardpan bedrock, averaging 55 ft. below street level; 7,000 cu. yd. of concrete; 800 tons of reinforcing steel and 1800 tons of structural steel were used.

Year-round climate control is provided, and three 300-hp capacity oil fired units produce 30,000 lbs. of steam per hour for forced hot water heating through converters.

Turbine Export to U.S.

Dominion Engineering Company Limited of Montreal, is to supply ten Kaplan type hydraulic turbines, to be installed in the Wanapum Development on the Columbia River in the State of Washington. Each of the turbines will have a rated capacity of 120,000 hp., when operating under 80

• CANADIAN DEVELOPMENTS

ft. head at a speed of 85.7 r.p.m. They will be among the largest units of this kind in the world.

This is the company's debut into the U.S. hydraulic turbine market, though Dominion turbines are operating in Brazil, Russia, Ceylon, Pakistan and New Zealand.

Natural Gas Future

"Tremendous gas discoveries during the past year" in British Columbia were mentioned recently by Dr. George S. Hume, vice-president and chief geologist of Westcoast Transmission Company Limited.

Indications now are that British Columbia may have reserves in excess of 60 trillion cu. ft. of natural gas, while further large reserves may lie in the north, he said.

Requirements of 350 million cu. ft. per day for the current period will rise to 640 million cu. ft. per day in the 1962-63 period, and 835 million cu. ft. per day in the 1964-65 period, the company estimates.

Alberta Industries

Fibreboard Plant: The Province's first rigid fibreboard insulation plant, built at Wabamun by Fibreboard Manufacturing Limited, went into operation early in 1959, with an estimated eventual production value of $1 million annually.

A new industry at Fort Macleod manufactures an all-purpose winch and hoist called the Giant Hand. Production capacity is 25 to 30 units per day. The company plans to arrange national distribution of its product.

Inventors say it is the only tool of its kind made in Canada, and compares with imported models, though lighter in weight. With a weight of only 13½ lb., it has a lifting or pulling capacity of one ton.

Export of Mine Hoists

An American steel producer is buying Canadian Westinghouse mine hoists for a new iron mining development in Missouri. The hoists and braking system, slated for installation in 1960 (Koepe friction hoists and pneumatic disc braking system), represent the largest and first export to date of this equipment.

Westinghouse is also working on an export order for five giant power transformers for the Tacoa power project near Caracas, Venezuela. Shipment of the first is scheduled for September.

Nuclear Power Plant

A site is being sought for Canada's first large-scale nuclear power plant, and there is some interest in a site near Kincardine, on Lake Huron.

The agreement was reached in June, between Ontario Hydro and the Atomic Energy Control Board, that full scale work on a 200,000-kw. plant will be undertaken. The $60 million project is intended to be in service in 1964-65.

Ontario Hydro, who will staff the plant and buy the power generated, will eventually buy the plant for the Hydro system.

New TV Relay

The BBC Engineering Division has developed a system for transmitting brief television news picture sequences and other short television film sequences of up to one minute's duration over a circuit of the transatlantic telephone cable normally used for sound. These picture transmissions can be sent over the cable in both directions.

The development was first used to cover the visit of Queen Elizabeth to Canada, allowing swift transmission of departure and arrival pictures to Canada and to Britain. Films of the opening of the St. Lawrence Seaway by the Queen were also transmitted by the new system, the development of which makes use of an altogether new technique.

The process employs a slow-speed flying-spot film scanner, and uses the video signal from it to modulate a carrier for transmission over the cable. At the receiving end the signals are demodulated and used to operate a slow-speed film telerecording equipment.

Saskatchewan Industries

Steel Mill: Progress of the big rolling mill of Interprovincial Steel Corporation at Regina, points to completion of the $15 million mill on schedule, January 1960.

Gas Plant: Liquid Carbonic Canadian Corporation Ltd. has announced plans for the construction of a 750,000 industrial plant at a site adjacent to the Interprovincial Steel Mill, at Regina. The plant will supply oxygen to the steel mill through a direct pipe line, the mill using 1.5 million cu. ft. per month. The plant will also manufacture industrial gases.

Cement plant expansion: A $1 million expansion of its Regina plant is planned by the Saskatchewan Cement Company. This development will ensure adequate supplies of cement for the South Saskatchewan River project. Major portion of the expansion cost will go into the new grinding mill.

Potash Plant: Construction is being pushed ahead on the potash mine of International Minerals and Chemical Corporation (Canada) Ltd., near Esterhazy, Sask.

Investment is estimated at $20 million, with full plant capacity of 400,000 tons annually to be reached in Spring of 1961.

Foundry: A new foundry to cost $110,000 is under construction in Regina, establishing Norwood Foundry (Sask.) Ltd.

Steel Fabricating Plant: Construction was to start in July on the new Regina steel fabricating plant of Dominion Bridge Company Limited.

The $1 million plant is to be the start of a development which will see the company invest some $12 million in the Regina operation over the next 10 years. There will be five stages to the development.

Employment Statistics

The Department of Labour and the Dominion Bureau of Statistics in a joint release in July, reported that employment had reached an all-time record level in June, 1959. An estimated 6,053,000 persons had jobs, 201,000 more than in the previous month, and 174,000 more than the year before. The increase from May to June occurred almost entirely in the non-farm industries, the largest gains being in construction, logging and the distributive industries.

Statistics of Interest

Crude Oil Consumption: Consumption of crude oil in May, 1959 advanced to 20,824,187 barrels, placing January-May consumption nearly 17% over last year, at 108,928,568 barrels.

Carbon Steel: Net shipments of rolled carbon steel products in May rose to 347,763 tons, raising the January-May shipments 13.3% to 1,678,788 tons.

The consuming industries in May were mainly: building construction, 69,026 tons; pipe and tubes, 41,500 merchant trade products, 40,468; railway operating, 40,064; wholesalers and warehouses, 38,914; container industry, 33,163; automotive industries, 18,315; and pressing, forming and stamping, 17,190.

New Steel Wheel Plant

A $12 million fully automated steel wheel plant was opened in June in Montreal, when Canadian Steel Wheel Limited introduced a new industry to Canada.

The plant produces railway steel wheels — with diameter of from 24 in. to 50 in., and weighing up to 2,000 pounds each.

To provide the high-quality steel the melting shop is equipped with two 16-ft. diameter, 45-ton capacity, electric arc melting furnaces. A constant check is kept on the analysis of the steel as it is melted.

The molten metal is poured into a 50-ton capacity ladle and transferred by a 75-ton overhead crane to an ingot pouring car. This car moves the ladle over moulds set in a pit and the metal is teened down centre runners and up into clusters of five or six moulds. The ingots vary in weight from one to three tons. After a regulated period of time, the ingots are stripped from the moulds, transferred to the ingot breaking shop and broken into either three or four blocks. A conveyor system, incorporating scales for weighing the blocks, transfers them either into storage or to the rotary hearth furnace in the wheel forging and rolling shop.

The forging and rolling shop is capable of producing an average of 60 wrought steel wheels an hour, and a feature of the operation is that a permanent record is maintained of the product throughout each stage of manufacture from ingot to finished wheel.

Highly-mechanized handling equipment enables the entire forging and rolling operation to be controlled by only seven operators. The forging and rolling operations, taking only two to three minutes, make it possible to complete the whole cycle in a single heating of the block.

Blocks are heated to forging temperature in a rotary hearth furnace, 60 feet in diameter and capable of heating 40 tons of blocks an hour. In order to control the rate of heating, the furnace is divided into six zones in which temperature and furnace conditions are automatically controlled. The blocks are carried through the heating zones on the rotating hearth until the final zone is reached where the blocks are soaked to forging temperature.

An indicator dial connected to the

• CANADIAN DEVELOPMENTS

hearth shows the number and location of blocks — up to 348 — in the furnace, and a further record is maintained by the operator as part of the product control system. Automatic charging and discharging machines handle blocks in and out of the furnace. The discharging machine swings the blocks through an arc of 90°, passing them through an hydraulic descaler and depositing them on the lower slabbing die of the 6,000-ton forging press.

On the forging press, the block is first reduced to a flat disc between slabbing tools and then transferred by sliding tables to the forming dies. These dies form the hub and part of the web of the wheel, and displace metal to the rim to permit the rolling mill to complete the wheel.

The wheel rolling mill, of the horizontal type, forms the finished profile of the rim of the wheel and in doing so spins metal from the rim into the plate and permits the wheel to grow to the required size. This mill has two edging rolls and a back roll, each driven by separate electric motors and, in addition, two pressure and two guide rolls mounted in separate sliding carriages.

When rolling has been completed, a specially-designed machine removes the wheel from the mill and deposits it on the lower die of the 3,000-ton coning press. This press displaces the hub axially and cones the plate so that the wheel is now formed to its finished profile. All these operations are controlled from specially-designed consoles located in glass-enclosed air conditioned control booths.

After leaving the Forging and Rolling Shop, the wheels are transferred by roller conveyor to the heat treatment furnaces. Three car-type heat treatment furnaces, each nearly 90 ft. long, are fired by light fuel oil and are designed to give flexibility in heat treatment cycles.

University News

University of Toronto

Appointments and promotions in the Faculty of Applied Science and Engineering have been announced by the University of Toronto president, Dr. Claude T. Bissell.

Promoted to professor are: H. S. Ribner, aerophysics; W. F. Graydon, chemical engineering; M. W. Huggins, M.E.I.C., civil engineering; J. M. Ham, electrical engineering; I. W. Smith, mechanical engineering; and S. E. Wolfe, mining engineering.

Promoted to associate professorships are: W. H. Burgess, chemical engineering and A. J. Kravetz, electrical engineering.

Promoted to assistant professor are: F. B. Friend, applied physics and P. E. Burke, electrical engineering. Two newly-appointed assistant professors are: A. R. Straughen, electrical engineering and J. Schwaighofer, civil engineering.

University of New Brunswick

President of the University of New Brunswick, Dr. Colin B. Mackay has announced the appointment of Ira M. Beattie, M.E.I.C., as head of the department of civil engineering and the appointment of Chen-Chang Ting as associate professor of electrical engineering. Mr. Beattie has been acting head of the department since the retirement of Dr. O. E. Turner in 1957.

Assistant professors appointed are: D. A. George, electrical engineering; D. G. Blanchard, civil engineering and Dr. R. B. Banerji; who will lecture for the mathematics department and be in charge of the new digital computer.

INTERNATIONAL NEWS

United Nations

THE WORLD METEOROLOGICAL CONGRESS at its third session in Geneva this year was told that artificial satellites, rockets, balloons and other new devices could play a useful role in helping man learn more about the weather, but could serve most usefully in conjunction with continued normal observations from the surface and upper air.

The Congress is the legislative body of the World Meteorological Organization, a specialized agency of the United Nations with 100 member states and territories and with headquarters in Geneva. It meets once every four years.

The role of satellites was examined by W.M.O. President Andre Viaut (France). The need for international meteorological cooperation was stressed by the president, and the importance of its application to the well-being of mankind, especially to agriculture, aviation, shipping and civil engineering.

A SURVEY OF ENERGY DEVELOPMENT PROBLEMS issued earlier this year by the UN noted that the importance of energy as a basic factor in development is receiving wide recognition. However, it points out, several important aspects of energy development have been neglected, especially as regards economic problems in underdeveloped countries.

The report (Doc. E/3212), prepared by the UN Secretariat at the request of the Economic and Social Council, contains chapters on general energy problems, conventional fuels, non-conventional energy, electric power, and experience and problems in technical assistance. Early action was recommended on the following: appraisal of energy resources, analysis of long-term costs and prices of fuels and power in selected countries; the convening of UN seminars on economic aspects of energy development in underdeveloped countries, in the first instance on the economics of electrification; coordination of the various bodies rendering technical assistance to underdeveloped countries.

The increase in the use of petroleum and the decline of coal trade are mentioned as examples of revolutionary changes in the pattern of international trade. Energy imports are a consideration in most countries, though many are striving for self-sufficiency.

GERMANY

THE RESEARCH INSTITUTE for the Physics of Jet Propulsion in Stuttgart works on basic and applied research in the field of aviation and space travel. This is mainly done by work on the physical, chemical and technological fundamentals of the apparatus of jet propulsion, especially ramjet propulsion, chemical rockets and atomic rockets.

In the field of ramjet propulsion, theoretical work and physical experiments are being carried out as well as technical experiments on carbon hydrate fuelled ramjets.

The theoretical work mainly deals with the thermodynamic states of air and their carbon hydrate combustion gases at high temperatures; and with analytical experiments of thermochemic internal flow (which is done with the help of electronic computors). Other projects are concerned with compiling a technical measurement table for ramjet power plants in the whole field of application up to supersonic flight, into the ionosphere, and on the flight mechanics of ramjet space ships.

Similar experiments on the thermochemic external flow of ramjet power plants and cells serve mainly to ascertain the aerodynamic transformation of heat and the thermal boundaries during stationary flight at great heights.

The physical experiments on ramjets are concerned with molecular rays in the highest possible vacuum in order to get more information of the kinetics of primary chemical combustion and the possible effects of ultra-violet radiation during chemical reactions. Kinetics of reflection of air molecules on different kinds of solid surfaces is being studied also. This is done with special regard to those walls scarcely affected by boundary lays flow and the resulting possible shifting of the thermal boundaries during stationary flight at great heights.

The technical experiments are concerned with the development of smaller ramjet power plants especially for ramjet propellers and ramjet helicopter screws. Larger experiments are planned in the combustion canal, on the sled track, in the air and with supersonic ramjet power plants. The technical aims of these experiments are auxiliary power plants, smallest possible helicopters, and large area aerial defence missiles, as well as supersonic passenger aeroplanes.

In the large field of chemical rockets, theoretical work and experiments are being carried out on the physical and technical side of hot-water rockets. This work mainly deals with analyses of the economical developments of these rockets and drafts, and constructions for the application of hot-water rockets as an economic starting point. The physical experiments on models of hot-water rockets have been carried out in the size two sec./ton power of propulsion and have resulted in very interesting first measurements, e.g. up to 90-95% of usable yield of momentum.

The technical experiments deal with hot-water rockets of more than 200 sec./ton propulsion. The aims are to find special economical rockets with safe start, independent of climatic conditions for unmanned flying objects and manned supersonic aeroplanes.

In the field of atomic rockets extensive theoretical work is being carried out, and physical experiments are in course of preparation. They will deal mainly with production of very hot plasmas and the measurement of their characteristics: convection, radiation, current and heat transmission.

Abstract of News Letter of the Research Institute for the Physics of Jet Propulsion, No. 14.

UNITED STATES-CANADA

NAADC. The Minister of National Defence announces that the President of the United States, with the concurrence of the Canadian Government, has appointed General Laurence S. Kuter to replace General Earle E. Partridge as Commander in Chief, North American Air Defence Command, effective upon the retirement of General Partridge on July 31. Air Marshal C. R. Slemon, R.C.A.F., will continue in the appointment of Deputy Commander, North American Air Defence Command.

UNITED KINGDOM

THE UK STEEL INDUSTRY is described in a booklet issued in January 1959 by the U.K. Information Service.

Although the United Kingdom steel industry today consists of over 300 companies engaged in the manufacture of pig-iron, and in the subsequent processes of making, shaping and treating steel, the bulk of output is concentrated in 25 companies, which between them produce nearly 77% of the pig-iron and nearly 91% of the crude steel manufactured.

World iron ore reserves, it is reported, appear to be adequate for at least 300 years. In 1957, Britain used 32.7 million tons of iron ore, of which 17 million tons were obtained from home ore deposits and the rest imported. The most important iron ore reserves in Britain at present are the Jurassic ores.

To provide for regular and economic shipment of imports of iron ore, special ore-carrying vessels are in service. By 1963 there will be about 72 of these.

In 1957 the consumption of steel scrap amounted to 11.5 million tons, as compared with 12 million tons of pig-iron.

The industry's requirements of coking coal totalled 17.2 million tons in 1957; in addition about 5 million tons of other qualities of coal were consumed. The most important sources of high quality coking coal are the Durham and South Wales coalfields; others are in Lancashire and Scotland. The National Coal Board expects to be able to provide the 24 million tons of coking coal and blended coal, which the steel industry estimates as its annual consumption, by the 1960's.

Major Companies: As the outcome of a series of amalgamations during the last thirty years, the production of steel, though still divided between many often rather small plants, is now concentrated in the hands of some large concerns. Thus in 1952, six firms, operating thirty-two works in which steel was made, each had an output of over one million tons, and an output of 9.5 million tons in the aggregate; that is to say, 58% of total output. A further five firms, operating twelve works, had an aggregate production of over 3 million tons, or an additional 18% of the total. Eleven firms, then, accounted for just over three-quarters of the ingot output. Today, their share is probably even higher, the report states.

The Iron and Steel Board exercises general supervision over the industry. Late in 1958 about five sixths of the iron and steel capacity had been returned to private industry, with one-sixth in the hands of the Iron and Steel Holding and Realization Agency.

Production: Steel production in Britain increased steadily, from 12.7 million tons in 1946 to the record level of 21.7 million ingot tons in 1957. In 1958, mainly as a result of running-down of stocks in the hands of steel users, output dropped to 19.57 million ingot tons. Productive capacity for steel in 1959 is expected to reach 24½ million ingot tons. Blast furnace capacity has also increased greatly since 1945, and pig-iron production totalled 14.3 million tons in 1957, although in the following year output fell back.

In Britain today about 87% of total steel output is made in open hearth furnaces, about 7.5% by the Bessemer converter process and about 5.5% in electric furnaces.

Development plans have been carried out by all British steel companies. There is a development plan for a capacity of 27 million tons in 1962, this program to cost about 650 million up to that year.

U.S.S.R.

AUTOMATION IN A GIANT TIRE FACTORY is to be accomplished by means of a plant performance recorder. The plant, now being built in Russia by a consortium of British firms, will have monitoring equipment by The Digital Engineering Co. Ltd. The entire process of tire and tube making is to be monitored hourly and at the end of each shift, providing a classified summary of output of various components. All the counting equipment will be centralized and an office will be equipped with page printers where the hourly and shift production totals will appear coded according to size or type.

SWEDEN

A TURBINE RESEARCH and model testing laboratory has been put in use by Karlstads Mekaniska Werkstad at their Kristinehamn works, Central Sweden. The laboratory has been designed for all kinds of model tests with pump turbines and includes equipment for precision measurements by means of electronic devices to ensure full objectivity and reliability of the tests.

The new laboratory has three testing units. There is an open flume circuit with 4-metre head for testing complete waterpower plant models with a runner diameter of up to 500 mm. There is a high-pressure cavitation test tunnel especially built for pump turbines but also suitable to be used for tests with models of Francis and Kaplan turbines. The third unit is a cavitation tunnel for Kaplan turbines of conventional type and for testing various types of tubular turbines.

A NEW STARTING UNIT for jet aircraft known as "Air Partner" has been developed and launched on the market by Atlas Copco. The truck-mounted device is of the hot-air type and uses a screw compressor of special design. It is claimed the new unit will reduce the starting time to half, and that it can be operated for 10,000 hours without overhaul.

Month to Month

EIC Annual General Meeting

Minutes of the Annual General Meeting of the Engineering Institute of Canada held in the Concert Hall of the Royal York Hotel, Toronto, Ontario, on June 8, 1959, at 10.00 a.m. until Noon, and presided over by President K. F. Tupper, Toronto.

Notice of Meeting
The General Secretary read the notice of the meeting which had been circulated to the membership on May 1, 1959, with the E.I.C. Annual Report for 1958.

Confirmation of Minutes
There being no amendment or correction to be made, President K. F. Tupper declared the Minutes of the Seventy-Second Annual General Meeting of the Institute held on May 21, 1958, at Quebec City, Quebec, confirmed, and signed the Minute Book.

Nominating Committee For 1959
The General Secretary reported that the Nominating Committee for 1959 has been appointed, one member serving on it from each branch, with Mr. W. K. Gwyer, M.E.I.C. of Trail, B.C. as Chairman.

NOMINATING COMMITTEE 1959

Amherst, R. L. Alexander.
Baie Comeau, T. G. Rust.
Belleville, C. H. Lusk.
Border Cities, C. G. R. Armstrong.
Brockville, R. H. Wallace.
Calgary, A. W. Howard.
Cape Breton, C. N. Murray.
Central British Columbia, E. R. Gayfer.
Chalk River, H. V. Smith.
Corner Brook, K. Bulins.
Cornwall, J. M. Hawkes.
Eastern Townships, J. C. Davidson.
Edmonton, R. N. McManus.
Fredericton, I. M. Beattie.
Halifax, O. N. Mann.
Hamilton, L. C. Sentance.
Huronia, Ross MacKay.
Kingston, D. L. Rigsby.
Kitchener, M. A. Montgomery.
Kootenay, W. G. Small.
Lakehead, E. T. Charnock.
Lethbridge, C. S. Clendening.
London, D. D. C. McGeachy.
Lower St. Lawrence, J. R. Menard.
Moncton, L. R. Wadlyn.
Montreal, C. G. Kingsmill.
Newfoundland, J. P. Henderson.
Niagara Peninsula, C. G. Cline.
Nipissing and Upper Ottawa, T. H. Chapman.
North Eastern Ontario, William Kay.
Northern New Brunswick, R. C. Eddy.
North Nova Scotia, M. C. Wolfe.
North Shore Lower St. Lawrence, M. Storrier.
Ottawa, R. F. Legget.
Peterborough, B. Ottewell.
Port Hope, E. F. Marston.
Prince Edward Island, J. D. M. MacDonald.
Quebec, Paul Vincent.
Saguenay, C. C. Louttit.
Saint John, J. J. Donahue.
St. Maurice Valley, D. M. McKim.
Sarnia, Gordon W. Ames.
Saskatchewan, L. T. Holmes.
Sault Ste. Marie, F. H. MacKay.
Toronto, M. McMurray.
Vancouver, W. O. Scott.
Vancouver Island, Thomas Miard.
Winnipeg, T. E. Storey.
Yukon, J. R. B. Jones.
Chairman: W. K. Gwyer, M.E.I.C., Trail, B.C.

Honours, Prizes and Medals
The President announced that at its meeting held on April 18, 1959, the Council of the Institute voted unanimously that the following Honours, Medals and Prizes be awarded for the year 1959:

HONORARY MEMBERSHIPS
"Chosen from those who have become eminent in engineering or kindred sciences, and elected by unanimous vote of Council".

Randolphe William Diamond, B.A.Sc., D.Sc., recently retired as Director, Consolidated Mining and Smelting Co., Trail, B.C., and also as President of West Kootenay Power and Light Co. Ltd.

David Arnold Keys, B.A., M.A., Ph.D., D.Sc., Scientific Advisor to the President, Atomic Energy of Canada Limited.

Roy Aubrey Spencer, B.Sc., M.Sc., formerly Dean of Engineering, University of Saskatchewan, now Consulting Engineer, Saskatoon, Sask.

John Bertram Stirling, B.Sc., LL.D., President of E. G. M. Cape & Company, Montreal, Que.

James Alfred Vance, President, James A. Vance Company, General Contractors, Woodstock, Ont.

SIR JOHN KENNEDY MEDAL (1958)
"Awarded as a recognition of outstanding merit in the profession or of noteworthy contributions to the science of engineering or to the benefit of the Institute".

Richard Edgar Heartz, B.Sc., LL.D., M.E.I.C., President and Director, The Shawinigan Engineering Company Limited, Montreal, Que.

JULIAN C. SMITH MEDALS (1958)
"For achievement in the development of Canada".

Norris Roy Crump, M.E., D.Eng., D.C.I., LL.D., D.Sc., M.E.I.C., President, Member of Executive Committee and Director, Canadian Pacific Railway, Montreal, Que.

J. Alphonse Ouimet, B.Eng. (Elec.), M.E.I.C., President, The Canadian Broadcasting Corporation, Ottawa, Ontario.

GZOWSKI MEDAL
"For the best paper of the medal year on a civil engineering subject, "Civil" being used in the limited sense to indicate structural surveying and construction work generally".

Raymond Edward Grout, B.Sc., M.E.I.C., Chief Engineer, Electrical Divisision, The Shawinigan Engineering Company Limited, Montreal, Que.

John Arthur Thomas, B.A., B.Sc., M.E.I.C., Chief Engineer, Civil Division, The Shawinigan Engineering Company Limited, Montreal, Que.

For their paper: "Engineering Features of the Beechwood Development".

LEONARD MEDAL
"For papers on mining subjects".

Lazare E. Djingheuzian, M.C.I.M., Senior Engineer, Division of Mineral Dressing and Process Metallurgy, Department of Mines and Technical Surveys, Ottawa, Ont.

For his paper: "A Study of Operating Data from Ball Mines Operating in Quebec, Ontario and Manitoba".

PLUMMER MEDAL
"For papers on chemical and metallurgical subjects".

Robert Owen King, B.A.Sc., M.E.I.C., Defence Research Board, Department of National Defence, Ottawa, Ont.

For his paper: "The Production of Ethylene by the Decomposition of N-Butane; The Prevention of Carbon Formation by the use of Chromium Plating".

DUGGAN MEDAL AND PRIZE
"For the best paper dealing with the use of metals for structural and mechanical purposes".

William Cumming Leith, B.A.Sc., M.A.Sc., Mechanical Research Engineer, Dominion Engineering Works Limited, Montreal, Que.

For his paper: "Cavitation Damage To Metals".

ROSS MEDAL
"For papers on electrical engineering subjects".

Frederic Lewis Lawton, M.E.I.C., Chief Engineer, Power Department, Aluminum Laboratories, Montreal, Que.

For his paper: "Underground Hydro-Electric Power Stations".

ROBERT W. ANGUS MEDAL
"For the best paper on a mechanical engineering subject".

Lawrence Milton Boyd, B.Sc., M.E.I.C., Chief Engineer, Hydraulic Division, Dominion Engineering Works Limited, Lachine, Que.

Walter Scott McIlquham, B.Sc., M.E.I.C., Hydraulic Engineer, Dominion Engineering Works Limited, Lachine, Que.

For their paper: "Beechwood Kaplan Turbines—Hydraulic and Mechanical Features".

H. N. RUTTAN PRIZE (Western Provinces), JOHN GALBRAITH PRIZE (Ontario); Committees recommended no award this year.

ERNEST MARCEAU PRIZE (Quebec—French), PHELPS JOHNSON PRIZE (Quebec—English), MARTIN MURPHY PRIZE (Maritimes); No papers received.

Report of Council for the Year 1958
The General Secretary stated that the Report of Council for 1958 is incorporated in the Annual Report for 1958 which was circulated to the membership as a supplement to the April 1959 issue of **The Engineering Journal.**

Treasurer's Report, Report of Finance Committee, and Financial Statement
The Treasurer, Mr. T. W. Eadie, conveyed the apologies of Mr. Albert Deschamps, Chairman of the Finance Com-

mittee, for his inability to attend the meeting and present the Report of the Finance Committee and Financial Statement. Mr. Eadie stated that the statement of revenues and expenditures and the balance sheet for 1958 is presented in the Annual Report on Page 15, and has been circulated to the membership. It was therefore his intention to merely summarize the results on this occasion, as follows:

"Revenues in 1958 were $27,000 below the 1957 level—a $4,000 increase in membership fees and a $5,000 increase in investment income was offset by a drop of $36,000 in advertising revenues and sales. Expenses on the other hand increased by $54,000 to $595,000. This increase was spread over a number of accounts and, as the Chairman of the Finance Committee states on Page 3 of the Annual Report, reflected among other things an increased activity in the administrative field at both the local and international levels.

"There were no appropriations to building, contingency or publication reserves. There was a draw down from the pension reserve of $2,400. The year's deficit was $32,000 which had to be drawn from surplus, reducing the surplus from $86,000 to $54,000 and the assets from $462,000 to $430,000. A deficit on operations is always a matter of concern and has been receiving the continuing attention of the Finance Committee.

"While our budget for 1959 prepared at the opening of the year contemplated a possible deficit of $10,000 for the year 1959, the actual results to date suggest that a balanced budget may be achieved and you can be assured that the General Secretary and all members of the staff are working assiduously to produce revenues and to control expenses to this end."

Motion for Approval of Report of Council, Report of Finance Committee and Financial Statement, and Treasurer's Report For 1958

It was moved by Mr. J. W. Millar, seconded by Mr. R. Prescott, and carried unanimously, that the Report of Council, The Report of the Finance Committee, The Financial Statement, and the Treasurer's Report for 1958, be accepted and approved.

Committee Reports

The General Secretary reported that the Committee Reports are incorporated in the Annual Report for 1958 on Pages 16 to 23. It was moved by Dr. B. G. Ballard, seconded by Mr. J. S. Waddington, and carried unanimously, that the reports of the following committees be taken as read and approved:

Admissions
Harry F. Bennett Education Fund
Board of Examiners
Canadian Chamber of Commerce
Canadian Standards Association
Confederation
Life Members
Legislation
Papers
Policy
Prairie Water Problems
Professional Interests
Property
Publication
Student Policy
Technical Operations

Branch Reports

The General Secretary reported that the Branch Reports are incorporated in the Annual Report for 1958 on Pages 24 to 39. It was moved by Professor J. B. Mantle, seconded by Colonel W. A. Capelle, and carried unanimously that the reports of the Branches and the Ontario Division be taken as read and approved.

Business from the Annual Council Meeting

The General Secretary reported that no business had been referred specifically from the Annual Council meeting held on June 7, 1959, to the Annual General Meeting.

Confederation

The President stated that Council's report on Confederation is printed on Page 6 of the Annual Report for 1958. He invited Mr. T. Foulkes, Ottawa, Acting Chairman of the E.I.C. Committee on Confederation, to report to the Annual General Meeting in the absence of Dr. I. R. Tait, Chairman. Mr. Foulkes thanked the President for this opportunity to address the membership on the subject of the work of the Committees on Confederation, and reminded those present that a report of the E.I.C. Committees activities is presented on Page 18 of the Annual Report for 1958. Mr. Foulkes reported that the Council of the Institute at its meeting held in April 1959 approved the joint report of the E.I.C. and C.C.P.E. Committees on Confederation, dated March 18, 1959. At the same meeting, Council gave authority to the E.I.C. Committee on Confederation to instruct the General Secretary to proceed with mailing a ballot on the principle of Confederation at an appropriate time to fully pail-up corporate members. At the Annual Meeting of the Canadian Council of Professional Engineers held in Winnipeg on May 20 to 22, 1959, the members of that body also accepted the joint report, on the understanding that it would ask its constituent bodies to appoint members to the proposed Engineers' Confederation Commission (previously called a Provisional Council) and stipulated that its approval did not bind it to accepting the report of this Commission, but that this report should be submitted to the C.C.P.E. again for approval. On receiving advice of this action, the E.I.C. Committee on Confederation consulted with the President and requested the General Secretary and his staff to proceed with mailing the ballot to fully paid-up corporate members of the Institute.

This was done on June 4, 1959: the package consisted of a letter from the President of the Institute, the joint report of the E.I.C. and C.C.P.E. Committees on Confederation dated March 18, 1959, ballot paper, ballot envelope and return envelope. In anticipation of a favourable ballot from the membership, Council agreed at its Annual Meeting held on Sunday, June 7, 1959, that it would take preliminary steps towards the appointment of E.I.C. members to the Engineers' Confederation Commission. Mr. Foulkes emphasized that some members of the E.I.C. Committee on Confederation were present at the Annual Meeting and would be pleased to answer any questions or listen to suggestions which might be directed towards them. He said they would endeavour to give answers to the questions in the light of present documents, and to illustrate the spirit behind the documents. This was the first time that it had been possible to release copies of the joint report to the membership, and the Institute members are now being asked to vote on the report and to say whether or not they are in favour of the principle of Confederation as outlined in the report. The Committee felt it necessary to have a mandate from the membership on the principle of Confederation before undertaking the great amount of work necessary to draw up a final report and detailed plan of the organization. He therefore urged the membership to vote as they wished, but vote. This will enable the E.I.C. to continue negotiations with the C.C.P.E. in drawing up final documents for submission to the membership of the respective bodies.

The President thanked Mr. Foulkes for his report and informed those present that the subject of Confederation has been much discussed by Council throughout the year. Unfortunately, the Annual General Meeting is the only occasion each year when the membership as a whole can discuss it with Councillors and the members of the Confederation Committee. He therefore urged that there be a full discussion on the subject.

Past-President L. F. Grant, Kingston, stated that throughout these proceedings he had noticed a great deal of ignorance on the subject of Confederation. As Mr. Foulkes had said, this was the first opportunity that the general membership had had of seeing the proposals for Confederation. It was true that progress reports had been published in **The Engineering Journal** from time to time, and to that extent the members should know what was going on. Although this ballot commits the Institute only to the general principles of Confederation, there are certain aspects of it that are causing deep concern. One of these—and it might as well be faced—is the elimination of the branches. There is no provision for branches in the report: there is no provision for the money to operate the branches, and he wondered if at the Branch Officers' Conference, held the previous day, they had considered ways and means of operating branches without money from Headquarters. There had been a hope expressed that something would be done to enable the branches to continue, but it is very different from the system which has been sustained in the past. It had been repeatedly said "leave these things alone, they will all be ironed out". He submitted that it was too important a question to be left to the bare possibility of it being "ironed out".

Colonel Grant said that a similar though not identical question, is the lack of contact of the individual member with the new body. In the past a member has had this through a councillor at his branch. True that many councillors did not attend meetings, especially those for whom access was difficult. There were nonetheless very few branches that, at some time or another, had not sent a councillor to attend a meeting when a question of particular importance to them was to be discussed. He did not know what was the state of the other Associations, but in Ontario he had seen no machinery for the individual member to approach Council. He did not suppose that if a member did, his approach would be thrown into the waste basket, but the machinery to which the E.I.C. membership is accustomed does not exist there.

Colonel Grant expressed concern that the Canadian Council of Professional Engineers was not sending out a ballot on the principle of Confederation and that the E.I.C. was therefore "out of step" by doing so. It had always been a principle of the two committees that the two negotiative bodies should march in step but he did not think that this was now the case.

There were several proposals in the report which he did not like: he thought the tendency was towards centralization and domination by Headquarters. There are only two vice-presidents, and the number of councillors is much smaller. He did not intend to go into details but he trusted that branches would hold meetings on the report prior to voting, and that at that time they would consider the important points which he had raised—the most vital one being the apparent elimination of the branches. (Applause).

Mr. Leo E. Roy, Montreal, a member of the E.I.C. Committee on Confederation, said that he fully agreed with Colonel Grant's view regarding the importance of branches in the new Confederation. He believed that the members of the E.I.C. Committee on Confederation had investigated the matter very seriously and that there are many difficulties yet to be solved. He drew the meeting's attention to Clause 5 which he read together with the explanation of this clause. He thought this proved that the committee is aware of the situation regarding branches and urged that it be borne in mind that at present the vote is merely on the principle of Confederation. He was confident that the Engineers' Confederation Commission would be able to work out the problem of satisfying all members of the new organization if that meant having branches (Applause).

Mr. W. L. Hutchison, Toronto, said he wished to make one observation, namely, that as an ordinary member of the Institute he had found it exceedingly difficult in the past to keep informed on the work of the committee, which he was sure had worked assiduously. The points enumerated by Colonel Grant concerned him also, and he had several questions on the report. His greatest concern was the fact that members of the Institute had not had the opportunity to know some of the details behind the report and, as a result of this, might vote "No" and, in his estimation, reject something which should be considered seriously. He said that if the report were rejected at this stage, it will not be possible to resume Confederation negotiations for many years. He urged that, although it is too late to do anything about the present situation, the membership be kept better informed from now onwards of the activities of the Engineers' Confederation Commission, if it is appointed, so that if and when a final vote is taken on Confederation, the membership is fully aware

● E.I.C. — A.G.M. MINUTES

of what it is voting for. (Applause). Past-President J. B. Challies, Montreal, said he was against the whole proposal: he thought that the membership would find that the majority of the Past-Presidents are against it also. They felt that the representatives of the Institute on the joint committee had "swallowed the bait" of those who are so actively interested in Confederation, "hook, line, and sinker". There was no doubt about the fact that if Confederation goes through as it is set up now, the E.I.C. becomes a captive organization of the Provincial Associations. He asked what was being gained by it. When he was President of the E.I.C. twenty years ago there was one thing that he had learned, namely, that the members of the E.I.C. hoped that some day there would be a common membership between the Institute and the Associations but on a basis fair to the E.I.C. and not on the basis at present proposed. In his opinion the ballot which had been sent to the membership was irregular and illegal. It was received the day before the Annual General Meeting. The By-Laws state that the Council must be informed of any proposed change by October 1st and the membership twenty-one days prior to the Annual General Meeting. He asked whether there could be a more important change than the one envisaged by Confederation. He emphasized that there would no longer be an independent E.I.C.; instead it would be dominated by the Associations. He reminded the meeting that the Institute had helped with the formation of the Associations because the members of the Institute were almost unanimously in favour of a registration movement. He again emphasized that the Institute By-Laws require that any contemplated change or addition to them must be discussed both at an Annual General Meeting and by each of the Branches, and must be approved by Council. When a ballot goes out to the membership, it must be accompanied by a clear memorandum stating the arguments for and against the proposed change. The confederation report accompanying the present ballot was, he considered, the most complicated document he had ever seen.

Dr. Challies said that he did not like the idea of Confederation. Colonel Grant had made a very important point, namely, "what about the branches"? He asked whether the E.I.C. was just going to let the Associations say whether or not the Montreal Branch and the Toronto Branch, for example, could exist in the future. He considered that the whole scheme was "cockeyed" and he could not understand how it had come about—unless it had come about under cover. Dr. Challies said he had no wish to stand in the way of progress, but he did want this progress to be on a fair basis for the E.I.C. and on a basis that is worked out by the E.I.C. membership in accordance with the E.I.C. By-Laws. He understood that, generally speaking, at the most 45% of the members vote when a ballot is sent round. As the present ballot is to be decided by a simple majority, he did not consider that the vote would be representative of the Institute's membership. He understood that the membership of only one Association had voted on the report or would do so at this stage. He had quarrelled with Irving Tait on this issue and Dr. Tait had said "In one or two cases the provincial registration bodies would turn it down." Dr. Challies said that he did not want to sit by and wait for their decision: this was no answer to the problem.

He contended that the E.I.C. is dependent on its branches and that when the branches begin to realize what is going to happen under a new organization, they will not accept the Confederation proposal.

Dr. Challies said that although he was not in good health, he had made up his mind that if it was the last thing he did for the Institute, he would be present at this Annual General Meeting to warn the membership not to vote for this proposal. He asked if those present could imagine the Canadian Parliament being composed of representatives from the various Provincial legislatures. He was confident that many E.I.C. members did not understand the full implication of this proposal to the future of the E.I.C. In closing his remarks, Dr. Challies paid deep tribute to the gentlemen who have negotiated on the problem of Confederation. Although he was very much against the proposal, he appreciated the fact that those carrying out the negotiations on behalf of both bodies had worked extremely hard.

The President said he would like to try and assure Dr. Challies that, in his opinion, although he could be wrong, he did not think the present ballot was illegal for the reasons Dr. Challies had set forth. Dr. Challies replied that its legality might well be contested in court. The President emphasized that the present Confederation ballot did not promulgate anything. He regarded it merely as a vote which, if favourable, would permit another step of exploration to be begun.

In reply to some of the queries raised, Mr. Foulkes drew the attention of those present to Pages 10 and 12 of the joint report. Part "D" of Page 10 outlines the procedures to be followed by the Canadian Council of Professional Engineers. It will be noted that there is no provision in that procedure to submit the matter to the members of the Associations before appointing the C.C.P.E. members to the Engineers' Confederation Commission. On Page 12, Part "E" of the joint report, it is to be noted that the E.I.C. Committee on Confederation insisted in Item 2 that a report and ballot be submitted to the membership of the Institute, thereby preserving the democratic quality of its organization. The E.I.C. Committee members did not think it fair to ask permission to proceed with the details of trying to consummate the Confederation or joint body of engineers if the members of one constituent body were not in favour of the principle involved.

Mr. Foulkes said that there has been no secret about the proposal for Confederation. He emphasized this by reading extracts from the minutes of the 72nd Annual General Meeting of the Institute, concerning Confederation.

Mr. Foulkes stated that the clauses contained in the minutes of the special meeting of the Council held in Quebec City in May, 1958, had remained unchanged except for Clause 8 where the figure for fees had been altered from Six Dollars to Six Dollars and Twenty-Five Cents. He said the clauses had been published and had been available for a whole year for anyone on the membership to read and to ask questions about. The Institute had paid the expenses for councillors to attend two special meetings regarding Confederation — one held in Quebec City in May, 1958, and one in Toronto in January, 1959. In both cases a full report on the proposals regarding Confederation was either appended to or contained in the minutes. In addition the joint report of the Committees on Confederation, dated March 18, 1959, was discussed at the April meeting of the Council of the Institute, and a copy of it was appended to the minutes which were sent to councillors and branch chairman throughout the country. The officers therefore had every opportunity to present it to their executives and branch members, and to discuss it with them. He contended that the Institute is a democratic organization under its present method of representation, and that information regarding Confederation proposals had been passed on and made available to the membership. He admitted that when the ballot was mailed to the membership on June 4 it was the first time that a report on Confederation had been put in the mailbox of each individual member eligible to receive it. No change to the report had been made in the last twelve months. From Page 7 onwards the report comprised an attempt on the part of the E.I.C. Committee to interpret the clauses, and in this work the Committee had received a great deal of help from the General Consultant.

He informed the meeting that the E.I.C. representatives on the joint Committee on Confederation had received great cooperation from the representatives of the C.C.P.E., all of whom are also members of the Institute. He said there had been a spirit of "give and take" and that none of the policy had been dictated by paid servants of the professional bodies. He wished the meeting to know that, with the exception of the Institute's former General Secretary, there were no paid staff of the Associations, the Corporation or the Institute present at any of the joint meetings.

Mr. Foulkes agreed that the question of branches was one which required further negotiation and caused the E.I.C. Committee a great deal of concern. He stated that the Committee had been acting as the Institute's representative and on occasion asked Council for guidance. At the Annual Meeting of Council on June 7, 1959, they asked for ideas to improve proposed arrangements for branch operation under the new organization. The proposal regarding branch financing was the best that the Joint Committee had been able to agree upon so far. If this Annual General Meeting required something stronger than the proposal as it now stood, it was perfectly at liberty to inform the E.I.C. members on the Engineers' Confederation Commission of its wishes in this matter.

Mr. Foulkes explained that the Council members of the new organization would have the rank of a President or Vice-President of the Institute. For example, in Ontario where there is the greatest number of branches, some system of regional communication would be set up which would make it mandatory to keep in touch with the representatives of the branches. There was no reason why there should not be some regional councils. The business of running a national organization is not new — service clubs accomplish it and surely engineers can work out a suitable method of representation. The last thought that existed in the minds of those who had prepared the joint report was that the branches of the national body of engineers should be eliminated.

In answering Mr. Hutchison's question, Mr. Foulkes admitted that there may have been some lack of publicity. The reason had been that the E.I.C. and the C.C.P.E. were anxious to keep in step with one another. This was not possible if one body released a report on Confederation which might be embarrassing to the other; in the initial stages of negotiation it had been necessary to curb publicity until agreement had been reached. He thought it possible that publicity regarding any future negotiations may lapse into a period of quiet. He was of the opinion that the activities of the Engineers' Confederation Commission should be reported at every meeting of Council and releases on the status of negotiations be made in **The Engineering Journal**. (Applause).

Mr. F. A. Brown, Past-Chairman of the Saguenay Branch, said he would like to thank the members of the E.I.C. Committee on Confederation for their excellent work. He said they are all very busy men who have given up much of their time and he did not think the Institute could be better represented on the Joint Committee on Confederation. As a past-chairman of a Branch he liked the thought that the branches themselves would say whether or not they were going to exist under the new organization. They could not be legislated out of existence. If the agreement did not contain financial provision for them the branches will have to work out a system for themselves. He would like to see a strong national body, and that he had every confidence in the present Joint Committee on Confederation.

Professor C. G. E. Downing, Guelph, said that it appeared that the new national body would consist of members of the E.I.C. and the Associations and Corporation. He inquired about the status of engineers in the CIC, CIMM, or other Canadian engineering groups. It appeared that the membership in the new organization was mandatory, and he inquired what was envisaged for "associate members" such as are now supporting the E.I.C. but who are not members of an Association.

Mr. Foulkes recalled that when Mr. Herbert Smith evolved his "Plan for Unity" he had hoped that the CIC, CIMM, and other engineering groups would join with the CCPE and the E.I.C. in the formation of a national body of engineers. The CIC and CIMM said that only a portion of their membership were capable of being registered as professional engineers and that they would rather not enter into negotiation. If any members of their organizations were registered with the Association or enrolled in the E.I.C., under the proposed new plan they would automatically be members of the

• E.I.C. — A.G.M. MINUTES

new national body. Adequate provision has been made for "associate" or "affiliate" members and an explanation is given on Page 8 of the report, Clause 2. Mr. J. R. Rattie, Winnipeg, inquired how long it would be before Confederation took place. Mr. Foulkes replied that the proposal laid down that the Commission would be appointed for one year and provision was also made to extend its activities for a further year. There had been no definite date set for the completion of negotiations and Mr. Foulkes thought that if a favourable report and ballot were received the earliest date for Confederation would be 1961. Judging from the time it took to reach the present stage in negotiations he did not think that Confederation could be accomplished within one year. Mr. Rettie said that if this were the case the Winnipeg Branch was looking forward to being host at the Annual Meeting of the E.I.C. scheduled to be held in Winnipeg from May 25-27, 1960.

Mr. R. A. McGeachy, Sarnia, said that he had attended many Council meetings and he would like to stress that the gentlemen who have been negotiating on behalf of the E.I.C. are extremely honorable, that the whole joint committee is working for the best interest of engineers in Canada, and that there is no question of one body trying to undermine the other.

Professor L. E. Gads from Alberta said he presumed when he reached home after attending the Annual Meeting that he would receive his ballot in the mail and that he would mark it "yes" and mail it back to Headquarters. He said that he had been a member of the Edmonton Branch for about twenty years as well as a member of the Provincial Association, and he believed that he could be termed as "an ordinary rank and file member". He attended as many meetings of both the Association and the Institute as he could, and he had also attended Annual Meetings of the Institute and the Provincial Association, and believed that he had a reasonable understanding of the affairs of both organizations. He belonged to the 45% group that answers and returns ballots when they are sent out, and resented the implication that he, as an average member, was going to be so innocent as to be "led down the garden path" and assist in the dissolution of the E.I.C. just because he is not a member of the E.I.C. Council. He also resented the implication that the members elected to office had perpetrated something for which the membership would be sorry. He remembered the question of "unity" being discussed many years ago and even at that time some people almost came to blows on the question. He could see the implications of the proposal clearly enough to mark his ballot paper "yes" and he hoped this would give the Engineers' Confederation Commission an opportunity to work out details for a new organization and to present a clear picture of its plans to the membership in the future. (Applause).

Mr. R. F. Legget, Ottawa, stated that if the new Engineers' Confederation Commission were appointed when the result of the ballot was known, this Annual General Meeting might be the last one to which the E.I.C. Committee on Confederation was asked to report. Councillors knew that there had been few committees of the Institute which had devoted so much attention to the Institute's affairs. He considered it would be inappropriate to allow the meeting to close without moving a vote of thanks to the E.I.C. Committee on Confederation, under the chairmanship of Dr. I. R. Tait, for the splendid job they have done in the interests of the engineering profession of Canada. The motion was seconded by Past-President McKillop and carried by acclamation.

Report on Election of Officers

The President reported that a new President, three new Vice-Presidents representing Quebec, Ontario and the Western Provinces, and an appropriate number of councillors had been elected at the December 1958 meeting of Council in accordance with the By-Laws. These would be formally introduced at the Annual Banquet. He introduced to the meeting Mr. J. J. Hanna, Calgary, Alberta, the Institute's new President for 1959.

PRESIDENT

J. J. Hanna, Calgary, Alberta

VICE-PRESIDENTS

Zone A (Western Provinces)
C. V. Antenbring, Winnipeg, Man.

Zone B (Province of Ontario)
R. B. Chandler, Port Arthur, Ont.

Zone C (Province of Quebec)
F. L. Lawton, Montreal, Que.

COUNCILLORS

Yukon, N. Gritzuk, (Whitehorse)
Vancouver Island, P. F. Fairfull, (Victoria)
Vancouver, P. N. Bland
Central British Columbia, H. R. Hatfield, (Penticton, B.C.)
Kootenay, A. F. Brooks, (Trail, B.C.)
Edmonton, T. H. Newton
Saskatchewan, A. H. Douglas, (Saskatoon)
Winnipeg, Stewart Barkwell
Lakehead, D. B. McKillop, (Fort William)
Sudbury, F. A. Orange, (Copper Cliff)
London, A. L. Furanna
Port Hope, H. A. Gadd, (Cobourg, Ont.)

Newfoundland, C. H. Conroy, (St. John's)
Border Cities, W. G. Mitchell, (Walkerville)

Vote of Thanks

It was moved by Past-President L. F. Grant, seconded by Past-President Ross L. Dobbin, and carried by acclamation that a very hearty vote of thanks be accorded to the retiring President and Members of Council in appreciation for the work that they have done for the Institute during the past year. The President said that he would like to transmit this vote of thanks to the 1958 Councillors of the Institute. He stated that many of them have attended meetings at considerable personal inconvenience and that he appreciated the work undertaken by the individual Members of Council during the past year.

Mr. F. L. Lawton stated that, having on many occasions worked very closely with them, he would not like to let this opportunity pass without expressing his own appreciation, and he hoped the appreciation of the members, for the courtesy, efficiency, promptness, and co-operation of the General Secretary, Dr. Garnet T. Page, and his staff at E.I.C. Headquarters. (Applause). The President said he hoped that Dr. Page and members of the staff present at the meeting would take note of this sentiment and instructed them to convey it to the members of the staff not present.

Motion For Adjournment

It was moved by Mr. R. A. McGeachy, seconded by Mr. J. H. Budden, and carried unanimously that the 73rd Annual General Meeting of The Engineering Institute of Canada be adjourned.

The meeting adjourned at 12.00 Noon.

President: K. F. Tupper
General Secretary: Garnet T. Page
The Engineering Institute of Canada,
2050 Mansfield Street,
Montreal, Que.
July 22, 1959.

NATIONAL CONFERENCE ON PROFESSIONAL DEVELOPMENT PROGRAMS

Over forty delegates from across Canada attended the first national conference on Professional Development Programs June 9 at the Royal York Hotel in Toronto. The forum, held at the same time as the E.I.C.'s annual meeting, was a milestone in the efforts of young engineers to broaden their interest in non-technical subjects.

The newly formed National Committee on Professional Developments Programs undertook the organization of this conference as the first of their projects to bring together representatives of the twelve PD Programs in Canada and to interest those local branches which are not running programs in their work.

Set up in April, 1959, by the E.I.C. Council to assist local branches, the committee is chaired by Councillor E. T. W. Bailey, of Hamilton, and consists of a corresponding secretary from each branch and a small executive drawn at present from past members of the Hamilton, Niagara, and Toronto Program Directorates.

Delegates to the conference were welcomed by Dr. K. F. Tupper and Dr. Page. Dean C. Wandmacher of the Engineers' Council for Professional Development, which represents eight engineering societies in the U.S.A. and Canada, outlined activities going on in the U.S.A. in professional development. Doctor Tupper and Dean Wandmacher both paid tribute to the work of Col. L. F. Grant in starting the PD Programs in Canada as former president of the E.C.P.D.

Reports from twelve PD Programs across Canada showed enrolments ranging from 30 to 336. Program contents ranged from four-year integrated courses covering many fields (public speaking, the art of listening, business administration and finance) to detailed courses on single subjects such as law and economics. Some branches organize courses with little outside help; others work closely with local universities.

Address by Dean Mordell, McGill

Dean Mordell of McGill University opened the afternoon session, describing three essential requirements for a successful professional engineer — technical ability, the power to analyse a problem and to apply sound scientific principles to a wide range of technical problems; an appreciation of the broad view and an open mind to gain new knowledge; the ability to understand and communicate with other people, giving leadership when necessary. The university can only open an engineer's mind, not complete his education, Dean Mordell pointed out.

The university, the individual, and the profession all play a part in making the professional engineer, according to the dean. The profession is a community and the members owe it to the

FIRST TIME IN OTTAWA

OTTAWA REGIONAL

THURSDAY & FRIDAY

CHATEAU LAURIER

REGISTRATION • by special form as mailed to each member or by writing the treasurer of the Ottawa Branch, 2039, Prince Charles Road or during conference at the lounge facilities.

ACCOMMODATION • at the Chateau Laurier Hotel by the special form mailed to each member.

TECHNICAL PROGRAM • see details on opposite page.

TECHNICAL DISPLAY • Atomic Energy Display and photographic panorama of Ottawa district engineering achievements.

LUNCHEONS • two luncheon meetings featuring outstanding speakers, in the Ballroom. See details.

LADIES' PROGRAM • a special tour on Thursday afternoon and coffee party on Friday morning have been arranged by the Engineers' Wives Association.

RECEPTION • in the Drawing room for one hour prior to the dinner.

DINNER DANCE • dinner in the Ballroom from 7.30 to 9.30 p.m. The president, Mr. Hanna, will speak. From 9.30 to 12.30 p.m. the dance will be in full swing (informal dress).

CHATEAU LAURIER

NATIONAL CONFERENCE ON PROFESSIONAL DEVELOPMENT PROGRAMS

(Continued from page 114)

community to help those aspirants who are prepared to work hard to join the ranks of the profession. Giving a young man his iron ring at the ceremony of the calling of an engineer, welcoming him and then forgetting him, is not enough. It is an encouraging sign that many branches are organizing professional development programs to help the young engineer in this difficult transition from university to becoming a full-fledged member of the profession.

Dr. Lillian Gilbreth, world-famous engineer and author, made an appearance at the conference unexpectedly, and expressed her support for this type of program with its emphasis on the lifelong education of the engineer.

Discussion Groups

The luncheon table discussion groups brought up a variety of interesting questions concerning Professional Development Programs. Among them:

"A PDP course was not organized by our branch because of the diversity of opinions regarding the kind of course and subject matter." *Discussion:* It may be that what engineers want is the chance to discuss and think together on a variety of subjects to learn to express themselves. If this is so, the choice of subject matter is only of secondary importance.

"It was felt that there are sufficient night schools and colleges available to members, therefore we do not need a PDP " *Discussion:* In many places these courses are not available. Also, as Dean Mordell indicated, night schools and technical courses provide technological instruction rather than the broader training.

"There is a lack of junior members in the area." *Discussion:* More attention should be focussed upon getting employers to recognize the value of PDP. A certificate could be given to engineers completing the course. There could be more co-ordination with the local E.I.C. branch and more contact with upper levels of managers and employers.

"These various organizations offer similar courses to those offered by the universities."

Discussion: There are four main differences. The PDP offers much greater scope for participation. The PDP courses are broader and designed to awaken interest rather than to give complete knowledge. They are designed specifically to give courses in non-technical subjects to engineers. Fourthly, PDP can probably run courses more cheaply than can a university.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

Canadian Council

The Annual Meeting

Report abstracted from "The Professional Engineer", July, 1959.

The 22nd annual meeting of Canadian Council was undoubtedly one of the busiest and most productive meetings ever held by this organization. A record number of twenty-one formal reports were considered and many important decisions were taken. An unprecedented spirit of true co-operation was in evidence throughout the proceedings and the genial hospitality of the Manitoba Association contributed in considerable measure to the success of the meeting.

Most of the important problems concerning the profession were discussed and some of these are reported elsewhere in this issue. Other matters dealt with included the following.

Ethics—After two years of study, the committee submitted its final report and the proposed uniform Code of Ethics has been referred to the Associations and Corporation for consideration and study.

Federal Legislation—A report on current federal legislation was tabled and in order that Council be in a position to take action quickly if required, in connection with proposed new legislation, the Executive Committee was authorized to appoint a committee to deal with legislative matters at Federal Government level.

Salaries—The method of dealing with the question of engineers' salaries was fully discussed and the representatives from British Columbia reported that their Association, in the interest of uniformity, was now prepared to endorse the annual Report on Salaries of Professional Engineers by Levels of Responsibility as published by Canadian Council in 1958. It was therefore agreed that a new Report be published in 1959 with the seal of approval of all eleven Associations. It was unanimously agreed to continue the annual salary survey.

Amendments to Constitution—A number of amendments to the Constitution of the Council which were considered to be urgent to improve the efficiency of the organization and to regularize current practices were approved. These include the addition of a President who will not represent an association, to the existing eleven members of the Council, the President having the right to vote only when the votes of the members are equally divided; a new definition of the duties and responsibilities of the Secretary who will now use the title of Executive Secretary; an increase in the maximum assessment to $1.50 per member; the creation of an Executive Committee whose powers are determined by the Council; and a few other amendments of a minor nature.

Model Law—It was unanimously agreed that a committee be formed to prepare a Recommended Uniform Professional Engineer's Act for the assistance and guidance of the associations. This proposed Model Act is intended to serve as a guide with a view to attaining a uniform high standard throughout Canada.

Fees—A committee will be appointed to study the question of fees and consulting practice on a national basis. It is hoped that this step will assist in obtaining adequate and uniform schedules of fees and high standards of consulting practice in all provinces.

Engineers & Unions—The question of engineers and labour unions received considerable attention. Some associations would make it unethical for their members to voluntarily join labour unions while others feel that other methods should be used, such as assisting engineers employed in large organizations in making collective representations to management. Although all delegates agreed that it is highly desirable to keep professional engineers out of labour unions, no formal decision was taken.

Engineering Technicians—Several Associations reported considerable interest in this problem and a detailed report of the activities of the Ontario Association in this field was presented.

Counselling in Engineering—A detailed report of the activities of the various associations in this field was submitted by the Secretary-Treasurer.

Syllabus of Examinations—After years of study, the Committee on Revision of the Uniform Syllabus of Examinations submitted a report recommending substantial revisions to the Syllabus which is presently in use in all provinces.

Tariff Item 180e—A committee was appointed to investigate and study the problem of tariffs on the importation of engineering plans, drawings and specifications and to recommend to this Council any action that may be deemed advisable in the best interest of the Canadian economy and of our profession.

Council Officers Elected

Officers of Canadian Council for 1959-60, elected at the Winnipeg meeting were:

President: Donald O. Turnbull, P.Eng., Past-President of the Association of Professional Engineers of New Brunswick. Mr. Turnbull is engaged in consulting practice in St. John, New Brunswick.

Viçe-President: J. G. Dale, P.Eng., Past-President of the Association of Professional Engineers of Alberta. Mr. Dale is Manager of Customer Service & Utilization, Northwestern Utilities Ltd. in Edmonton, Alberta.

Executive member: W. L. Wardrop, P.Eng., President of the Association of Professional Engineers of Manitoba. Mr. Wardrop is engaged in consulting practice in Winnipeg, Manitoba.

Secretary-Treasurer: Leopold M. Nadeau, P.Eng., of Ottawa.

Canadian Council Office

Permanent office of the Canadian Council is now established at 77 Metcalfe St., Ottawa, in charge of Leopold M. Nadeau, executive secretary.

Personals

B. F. Lamson, M.E.I.C. (Queen's '12) of Proctor & Redfern, Consulting Engineers, Toronto, has been appointed special representative for the company's Niagara Peninsula area.

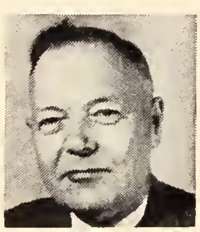
B. F. Lamson, M.E.I.C.

Ervin B. Parrag, M.E.I.C.

Ervin B. Parrag, M.E.I.C. (Budapest '26) well-known engineer has opened his own engineering consulting service in Montreal to be known as Ervin B. Parrag and Associates.

Douglas F. Hamelin, M.E.I.C. (California '29) has been transferred by Western Water Wells & Hamelin Drilling Ltd., Calgary, to the company's branch in Vancouver, where he will be manager of B.C. operations.

Douglas F. Hamelin, M.E.I.C.



J. Stuart Neil, M.E.I.C.

J. Stuart Neil, M.E.I.C. (Alberta '30) construction engineer with McColl Frontenac Oil, Calgary, has been elected chairman of the Calgary branch of the Institute.

Robert S. Stockton, M.E.I.C. (Colorado '95) of Spokane, Wash. recently received a distinguished achievement medal, the highest honorary award of the Colorado School of Mines.

Colonel Wm. S. Hunt, M.E.I.C. (McGill '36) has recently been appointed Canadian Military, Naval and Air Attache to Yugoslavia. Colonel Hunt was formerly electrical and mechanical engineer, Eastern Command, at Halifax.

W. L. McFaul, M.E.I.C. (Toronto '13) city engineer and manager of waterworks for the city of Hamilton, recently retired after many years of service.

Leslie Harold McManus, M.E.I.C. (Alberta '34) has been appointed Deputy Minister of Highways for the Province of Alberta.

D. C. Holgate, M.E.I.C. (McGill '38) formerly of Sault Ste. Marie is general manager of Dominion Bridge's Winnipeg Branch.

D. C. Holgate, M.E.I.C.

F. Allan Davis, M.E.I.C.

F. Allan Davis, M.E.I.C. (Queen's '40) has been appointed division engineer, Petroleum and Petroleum-Chemical Division, Foundation of Canada Engineering Corporation (Fenco), Toronto.

Dr. J. J. Green M.E.I.C. (Portsmouth '28) has been appointed chief superintendent of the Canadian Armament Research and Development Establishment, Valcartier, Que.

J. T. Dyment, M.E.I.C. (Toronto '29) chief engineer with Trans-Canada Air Lines, has been named a fellow of the Canadian Aeronautical Institute. The honour is for "notable and valuable contributions in aeronautical science or engineering."

John Campbell Sproule, M.E.I.C. (Alberta '30) of J. C. Sproule & Associates, Calgary, has been elected president of the Canadian Institute of Mining and Metallurgy in Montreal.

Robert L. Dunsmore, M.E.I.C. (Queen's '15), retired president of Champlain Oil Products, Montreal, and past president of the Montreal Board of Trade, was appointed chairman of the CBC Board of Directors on August 17. Mr. Dunsmore, whose new appointment is in effect until March 31, 1960, has been acting as chairman of the board since June, when CBC President J. Alphonse Ouimet became ill and Vice-President Ernest Bushnell went on vacation. Mr. Dunsmore up to this time has been chairman of the CBC finance committee.

F. Hugh Brennian, M.E.I.C. (McGill '44) is the new vice-president and general sales manager for Brencoat Sales Limited of Ville St. Pierre, Montreal.

H. W. Luckett, M.E.I.C. (Toronto '44) who heads the newly created Engine Sales Division of Sheridan Equipment, has been appointed Ontario distributor for Allis-Chalmers Engines.

Ben O. Baker, M.E.I.C. (Manitoba '40) has been appointed director of weapons research for The Defence Research Board in Ottawa.

Ben O. Baker, M.E.I.C.

R. A. Reid, M.E.I.C.

R. A. Reid, M.E.I.C. (McGill '42) has been appointed manager of manufacturing services at the Dominion Bridge head office in Lachine.

R. F. Martin, M.E.I.C. (Nova Scotia '42), city engineer with the St. John's Municipal Council, has been elected chairman of the Newfoundland branch of the Institute.

• PERSONALS

Emil J. Sanden, M.E.I.C. (Alberta '46) of the Alberta Department of Highways, has been appointed assistant chief engineer for the Province of Alberta.

V. E. McCune, M.E.I.C. (Alberta '46) has been named chief bridge engineer for the Department of Highways in the Province of Alberta.

D. E. Burnham, M.E.I.C. (Alberta '48) has been transferred by C.I.L. to the "Fabrikoid" plant in New Toronto, as assistant works manager.

Charles E. Garnett, M.E.I.C. has retired after forty years as president, and latterly as chairman, of Gorman's Ltd., Edmonton. He will remain a director of the company and devote his time to Edmonton Elevator Service of which he is president.

Kevin St. George, M.E.I.C. (N.S.T.C. '49), project engineer at Bowater's Newfoundland Pulp and Paper Mills, has been elected chairman of the Corner Brook branch of the Institute.

S. J. Medwadowski, M.E.I.C. (London '50) consulting engineer, is engaged in the private practice as a consulting structural engineering and in addition has been teaching and conducting research at the University of California.

D. W. Stairs, M.E.I.C. (McGill '48) is the new chairman of the Saguenay Branch of the Institute.

D. W. Stairs, M.E.I.C.

Ronald E. Pelkey, M.E.I.C.

Ronald E. Pelkey, M.E.I.C. (Saskatchewan '52), bridge design engineer with the Department of Highways and Transportation in Saskatchewan, has been awarded an Esso Good Roads Scholarship to the University of Illinois for postgraduate work in structural engineering with supplementary study in mathematics and soil mechanics.

John E. Rymes, M.E.I.C. (Manitoba '51) has been elected chairman of the Lakehead branch of the Institute. Mr. Rymes has been promoted to chief engineer, research and development, Canadian Car, Montreal.

Robert C. McDermott, M.E.I.C. (Toronto '51) has been appointed manager, Electric Products Sales, Eastern District, of Linde Company, division of Union Carbide Canada Limited, Toronto.

Alan J. Scott, M.E.I.C. (Durham '44) chief engineer of Consolidated Toronto Development Corporation has been elected president of the Urban Development Institute of Ontario.

B. W. Gilbert, M.E.I.C. (Toronto '48) of Linde Company, division of Union Carbide Canada, Toronto, has been appointed assistant manager, Gas Products Sales, Eastern District.

Dr. John L. Kearns M.E.I.C. (Iowa '54) has been appointed to the newly-established Abitibi Professorship in Engineering Science at the University of Western Ontario.

Alan J. Scott, M.E.I.C.

B. W. Gilbert, M.E.I.C.

Richard E. J. Putman, M.E.I.C. of Evershed & Vignoles (Canada), Toronto, has recently been appointed resident engineer, Western Canada.

L. R. Lauer, M.E.I.C. (Alberta '52) has been appointed sales engineer for the Toronto office of Canada Cement.

John E. Rymes, M.E.I.C.

Robert C. McDermott, M.E.I.C.

Richard E. J. Putman, M.E.I.C.

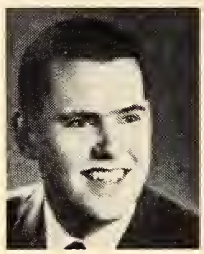
L. R. Lauer, M.E.I.C.

• PERSONALS

J. W. MacNeill, M.E.I.C. (Saskatchewan '58), formerly of Ottawa, has been appointed executive director of the South Saskatchewan River Development Commission, Regina.

J. W. MacNeill,
M.E.I.C.

J. W. Tremain, JR.E.I.C. (McGill '55) of Canada Cement, Ottawa, has been named sales engineer for the company's Edmonton office.



J. W. Tremain,
JR.E.I.C.

Reginald T. Giovannetti, JR.E.I.C. (Nova Scotia '52) has been promoted to plant engineer manager, Shore Establishments' East Coast Command, Department of National Defence, Nova Scotia.

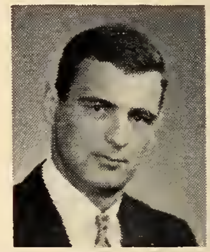
Reginald T. Giovannetti,
JR.E.I.C.

Arthur H. Abbott, JR.E.I.C. (New Brunswick '55) has taken a position with the Engineering Development branch of the Department of Public Works in Ottawa.

S. H. Phillips, JR.E.I.C. (Nova Scotia '52) has joined the Transport Department of The Toronto Star Ltd.

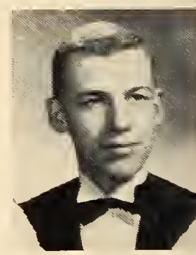
K. L. Currie, JR.E.I.C. (Queen's '56) has recently been granted a National Research Council Post-Doctoral Fellowship at Queen's University.

Jacques Charland, JR.E.I.C. (Laval, '57), traffic engineer with the Quebec Department of Roads. will do postgraduate work in traffic engineering at Yale University where he was awarded a Scholarship by the Canadian Good Roads Association.



Jacques Charland,
JR.E.I.C.

Bryan K. Johnston, S.E.I.C. (Manitoba, '36), resident engineer, Banff, Highways Division, Federal Department of Public Works, has been awarded a Standard Gravel Good Roads Scholarship to the Institute of Transportation and Traffic Engineering at the University of California where he will study for a master's degree in traffic engineering.



Bryan K. Johnson,
S.E.I.C.

Boris R. Hryhorczuk, S.E.I.C. (Manitoba '58), engineer with W. L. Wardrop & Associates, Winnipeg, has been awarded an Armco Drainage Good Roads Fellowship to do postgraduate work in city planning and traffic engineering at Yale University.

Desmond H. Annala, JR.E.I.C. (Queen's '57) is construction and waterworks engineer with the Public Utilities Commission of the City of Port Arthur.

J. E. Kean, JR.E.I.C. (N.S.T.C. '57) has left Canadian Standards Association Testing Laboratories in Toronto for the company's London, England office where his position will be that of electrical engineer.

S. E. Pearce, JR.E.I.C. (Queen's '48) of Canadian Westinghouse, Hamilton, has been named manager of their Mining, Petroleum and Chemical Section.

Arthur A. Sloane, JR.E.I.C. (Toronto '50) has become maintenance superintendent for North Star Oil (Refinery), St. Boniface, Man.

James G. Morrison, JR.E.I.C. (Nova Scotia '51) is general manager for Scotia Equipment, Halifax.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

HAMILTON

M. W. MacKenzie, JR.E.I.C., *Correspondent*

THE TENTH ANNUAL DANCE of the E.I.C. Hamilton Branch, will be held on Friday, September 25 at the Royal Connaught Hotel.

The committee announces there will be dancing from 9.00 p.m. to 1.30, with a midnight buffet.

R. T. Bailey is chairman of the dance committee which is anticipating a good crowd and a wonderful time.

KITCHENER

ON TUESDAY MAY 12, 1959, the wives of the executive met to discuss the formation of an E.I.C. Wives' Club. Mrs. Robertson of the E.I.C. Toronto Office, was present to answer questions and tell what the other wives' groups are accomplishing.

It was decided to hold a membership tea at the home of Mrs. Clare Leicht in Kitchener, on Tuesday, June 16, when one hundred ladies, wives of members of the branch, were to be invited to join the new club.

The following ladies agreed to act as an executive of the club: chairman, Mrs. L. J. R. Sanders, vice-chairman, Mrs. K. W. Kaye; Kitchener: Mrs. Walter Runge, Mrs. R. A. Dahmer, Mrs. W. Bobbie, and Mrs. Clare Leicht; Guelph: Mrs. F. H. Theakson and Mrs. G. E. C. Downing; Galt: Mrs. William Horner and Mrs. William Sheldon.

NIAGARA PENINSULA

J. H. Travers, JR.E.I.C., *Correspondent*

THE 6TH ANNUAL PROFESSIONAL ENGINEERS Ball will be held at Prudhommes Garden Centre on the Queen Elizabeth Way at Vineland, on Friday, September 25, 1959.

Publicity Director, J. H. Travers, promises these attractions:

- Music by Mart Kenney and his orchestra.
- A floor show, with two novelty acts
- Reception and cocktails at 6.00 p.m.
- Dinner at 7.00 p.m., dancing at 9.00 p.m.
- Cost, only $10.00 per couple.
- Refreshments.

OTTAWA

D. R. Grimes, JR.E.I.C., *Correspondent*

ELECTRONICS IN SOLIDS, SPACE AND SOUND was the subject of a demonstration lecture given on June 11, 1959, by Cyril N. Hoyler, manager of technical relations of the David Sarnoff Research Centre, R.C.A. Laboratories, Princeton, N.J.

The developments discussed and shown by Mr. Hoyler provide a dramatic progress report on the work of more than 250 R.C.A. scientists whose studies range over the broad areas of electronic materials, devices and systems. The results of this work lead to basic improvement and innovation in electronic techniques for the home, for industry, and for defense. Solid state electronics is the development and use of new solid materials within which electron action can be precisely controlled to achieve a variety of useful effects.

A NEW RECORD was established when 120 engineer golfers teed off at the Arnprior Golf Club on June 19, a fine sunny day, in the Fifth Annual Ottawa Valley Engineers Golf Tournament.

Participating in this tournament were members of the American Institute of Electrical Engineers, the Association of Professional Engineers of Ontario, the Corporation of P.E. of Quebec, the Canadian Institute of Mining and Metallurgy, the Chemical Institute of Canada. The E.I.C. Ottawa Branch was the sponsor for this year's tournament.

Hugh C. Brown was chairman of the 1959 committee, which included representatives from each engineering organization and three honorary members: Fred Wrangell, Blake Goodings, and Jack Melville.

The low gross prize was won by M. Ross of Ottawa with a score of 79; and the Quebec Corporation Trophy, emblematic of golf supremacy in Ottawa Valley Engineering circles, was presented to Mr. Ross by John S. Watt, chairman of the E.I.C. Ottawa Branch.

A. S. Lawson of Ottawa was runner-up, with a low gross of 80, closely followed by R. D. Watson of Deep River with 81. Some twenty prizes were presented at the dinner following the game.

Next year's tournament will be sponsored by the Association of Professional Engineers of Ontario.

SAULT STE. MARIE

THE E.I.C. WIVES' ASSOCIATION completed their first season in May. Organized in January, the group held a dinner in February, the annual meeting in March, and a social evening with a Chinese auction in May.

At the annual meeting officers were elected as follows: president Mrs. W. M. Hogg; vice-president, Mrs. G. L. Brown; secretary, Mrs. V. A. Graham; treasurer, Mrs. L. F. Mason-Tulby; chairman, publicity, Mrs. N. A. Paolini; chairman, membership, Mrs. A. D. Taylor; chairman, program and entertainment, Mrs. R. G. Sanders.

TORONTO

Harry Tryhorn, M.E.I.C., *Correspondent*

THE JOINT AREA COMMITTEE (a committee coordinating technical activities of Toronto branches of the E.I.C., the American Society of Civil Engineers, and the Institution of Civil Engineers) announces the fall program:

On October 22, 1959, E. G. Swenson of the National Research Council, will speak on "An Unusual Canadian Case of Cement Aggregate Reaction".

On November 19, 1959, W. E. Hickey, chief engineer, Foundation Co. of Canada, will talk about "Construction Engineering".

All meetings will be in Room E-21, Electrical Building, University of Toronto.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

DESIGN OF PLUMBING AND DRAINAGE SYSTEMS

This volume covers the basics of American plumbing design and practice, including plumbing codes, footing drains, water supply, cleanouts, etc. In addition it deals with some specialized topics, such as fire protection in tall buildings, services for research laboratories, motel systems, low cost housing projects, parking area drainage, animal quarter services and handling volatile fluid wastes.

The author of this detailed guide and reference book has had twenty years' experience in the field. (Louis Blenderman. New York, Industrial Press, 1959. 320p., $8.40.)

HANDBOOK OF AIR CONDITIONING, HEATING AND VENTILATING

The emphasis in this volume is on working data, and much of the information is presented in the form of tables, formulae, graphs and maps. The book is divided into eight sections, each of which has its own table of contents. There is also a detailed index to the whole volume.

The information given includes tables of heat losses from insulated pipe; heat losses through every standard type of window; data on steam flow in pipes; tables of heat losses from buildings; combustion data for fuels; design data for all standard pipe and tube, including plastics, etc.

Many experts have contributed to this Handbook, and the editor is the editor of Air Conditioning, Heating and Ventilating. (Ed. by Clifford Strock. New York, Industrial Press, 1959. irreg. paging, $17.00.)

*ELEMENTS OF PHYSICAL METALLURGY, 2ND ED.

Both the theory and practice of physical metallurgy are presented by treating current practical achievements in physical metallurgy as examples of fundamental principles. In this edition additions and revisions have been made throughout to bring the book up to date. The dislocation theory is introduced, while additional material on the electron theory of metals is given because of the increased importance of electric phenomena in semiconductors. A new chapter on phases in metal systems is also included. (A. G. Guy. Reading, Mass., Addison-Wesley, 1959. 528p., $9.50.)

INTRODUCTION TO ADVANCED DYNAMICS

An advanced undergraduate textbook, covering ideas of classical dynamics not usually discussed in courses on elementary mechanics, the emphasis being placed on basic principles. It deals with: Newtonian dynamics; Hamilton's principle and Lagrange's equations; central force motion; dynamics of a rigid body; oscillatory motion; Hamilton's equations and phase space; the Hamilton-Jacobi equation. References for further reading are included. (S. W. McCuskey. Reading, Mass., Addison-Wesley, 1959. 263p., $8.50.)

WATER TREATMENT

A concise practical survey of the methods of water purification and treatment now in use, intended primarily for industrial users, public health officials and swimming pool superintendents, although it will be of wider interest, especially the chapter on chemical and physical estimations.

The topics covered include collection and storage, filtration, chemical and other methods of treatment, effect of synthetic detergents, and mussel control. Although the emphasis is on standard British practice, the authors refer to papers published in other countries, notably the U.S.A., and these are listed in the four-page bibliography. (G. F. Mugele and A. Wiseman. London, Newnes, 1958. 141p., 21/-.)

ELSEVIER'S DICTIONARY OF NUCLEAR SCIENCE AND TECHNOLOGY, IN SIX LANGUAGES

Another of the multi-lingual dictionaries published by Elsevier, this volume contains over 4000 words in its basic list. The words are listed alphabetically in English, distinguishing British and U.S. usage, and defined. Corresponding terms in German, Spanish, French, Italian and Dutch appear on the opposite page. There is an alphabetical list for each language, keyed to the basic list. (Comp. by W. E. Clason. Toronto, Van Nostrand, 1958. 914p., $28.00.)

ELECTRICAL ENGINEERING: THEORY AND PRACTICE, 2ND ED.

Based on an undergraduate course, the emphasis is on the understanding of basic principles and processes, with equal attention given to the three major areas, circuits, machines and electronics.

In this enlarged edition, the section on electronics has been reorganized to include more material on the transistor and semi-conductor, and a new section has been added on magnetic amplifiers. Many more problems have been included. (W. H. Erickson and N. H. Bryant. New York, Wiley, 1959. 614p., $8.00.)

ELECTRONICS FOR EVERYONE, REV. ED.

Assuming no knowledge of electricity on the part of the reader, this volume explains in relatively simple language the history of electricity and its applications in condensers, batteries, coils and tubes, and later in radio, radar, television, both black and white and colour, x-rays, loran, satellite and missile electronics, electronic cookery, etc. There are many illustrations, and suggestions for further reading. (Monroe Upton. New York, Devin-Adair, 1959. 386p., $6.95.)

CONDUCTANCE DESIGN OF ACTIVE CIRCUITS

The techniques described in this volume for the use of conductance curves in the design of tube and transistor circuits have been developed over several years, and can reduce design and development time, and increase reliability. The topics covered include the basic principles; the problem of data presentation; design of simple circuits; impedance and power amplifiers; r-f and i-f amplifiers; special circuits; sine-wave oscillators; multivibrators and relaxation oscillators; mixers and detectors; transistor ampliers; high-frequency transistor circuits. There is a bibliography, mostly of periodical articles by the author, who is on the staff of the Ballistic Research Laboratories at the Aberdeen Proving Ground. (K. A. Pullen. New York, Rider, 1959. 330p., $9.95.)

*LINEAR STRUCTURAL ANALYSIS

A study of the equilibrium analysis of linear elastic structures. In this method the changes in geometry of the structures under load are sufficiently small to have

• LIBRARY NOTES

a negligible effect upon loads and their corresponding stress distributions, and the structural materials obey Hooke's law. This method of structural analysis is described in conjunction with linear matrix algebra techniques. Topics discussed include influence coefficients; indeterminancy; properties of matrices; computation; scale factors; stress resultant distributions, lack of fit and settlement; transformations; release system relations; flexibility matrix; and machine analysis. (P. B. Morice. Toronto, Longmans, Green, 1959. 170p., $7.00.)

°NUCLEAR ROCKET PROPULSION

Various aspects of the subject are discussed including heat transfer, structural analysis, fluid flow, thermodynamics, ballistic flight, reactor physics, and radiation safety. Many sections of the volume have applicability to all types of high-power density fission reactor design including mobile and ground power reactors. A feature is the detailed explanation, with examples, of the presently used methods of systems analysis. (R. W. Bussard and R. D. DeLauer. Toronto, McGraw-Hill, 1958. 370p., $11.50.)

DESIGN OF TRANSISTORIZED CIRCUITS FOR DIGITAL COMPUTORS

Written from the viewpoint of the circuit designer, the book is concerned with the design of transistorized digital computers and digital type circuits. Emphasis is on "worst-case" design techniques so that circuits can operate with resistors, voltages, transistor and diode parameters, simultaneously off their nominal values by the expected maximum tolerances.

Some of the topics covered include: basic building blocks in digital computers; diode gating; voltage-switching diode gate logic with transistor inverting amplifiers; direct-coupled transistor logic; design of flip-flops and delay multivibrators. (A. I. Pressman. New York, Rider, 1959. 316p., $9.95.)

CLASSIFICATION AND INDEXING IN SCIENCE

The flood of scientific literature appearing today has led many people to consider the use of machines for information retrieval, but as the author points out in his preface, behind every index or machine there must be an analysis of the subject matter.

This book discusses modern techniques of subject analysis, the construction of classification schedules, the classified catalogue (which is used in the Institute library), mechanical selection, indexing, and the future of information retrieval. (B. C. Vickery. Toronto, Butterworth, 1958. 185p., $5.50.)

INTRODUCTION TO STRESS ANALYSIS

A textbook for an introductory course in stress analysis, placing the emphasis on theory rather than empiricism. Some of the topics the author has included are: stress resultants in bars; stress and strain; uniform stress; flexure; shear stress; buckling phenomena; fatigue, creep, relaxation, etc.; plates and shells; strain energy; plasticity, elasticity and distortion. (C. O. Harris, Galt, Brett-Macmillan, 1959. 330p., $7.50.)

GENERAL CIRCUIT THEORY

Another in the series of Monographs on Physical Subjects, this book is a self-contained development of circuit theory. The emphasis throughout is on general relationships, and the text covers the general structure of circuits, general circuit theorems, linear passive four terminal circuits in the steady state, and in transients, and extensions to non-linear theory. (Gordon Newstead. London, Methuen, 1959. 144p., 15/-.)

°ELECTRONIC CIRCUIT THEORY

The authors' approach to electronics is based on circuit models so as to reduce the number of separate ideas and concepts required. In particular, piecewise-linear circuit models are used to convert a nonlinear circuit problem to a number of related linear problems. Thus, the mathematics of linear circuit theory can be applied to a broad class of physical circuits and systems operating in a non-linear manner. Models are devised to approximate the characteristics of diodes, triodes, pentodes, transistors, and other control devices, and graphical and geometrical interpretations of analyses are given. The effect of circuit and signal on device operation is shown by means of locus plots. Among the basic circuit functions considered are rectification and detection, waveshaping and amplification, and waveform generation. (H. J. Zimmerman and S. J. Mason. New York, Wiley, 1959. 564p., $10.75.)

°POWER PLANT THEORY AND DESIGN, 2ND ED.

A revised edition of the authors' "Steam Power Plants" that covers the entire range of power generating equipment, with particular emphasis upon the steam plant as the basic element. While giving principal attention to large central power station design, the book also discusses the smaller industrial plants, as well as gas, hydroelectric, and nuclear plants. Recent advances are given in the design of such equipment as cyclone furnaces, pressurized boilers and demineralizing equipment. The economic aspects of equipment selection receive increased emphasis and the proper selection of pipe sizes, insulation thickness, heater terminal differences, and station pressures and temperatures are fully discussed. (P. J. Potter. New York, Ronald, 1959. 710p., $10.50.)

°SYMPOSIUM ON SOLVENT EXTRACTION IN THE ANALYSIS OF METALS

Papers covering the following aspects: convergence of tie lines in ternary liquid systems and its application to liquid extraction; metals analysis with Thenoyltrifluoracetone; use of tri-n-octylphosphine oxide in analytical chemistry; 8-hydroxyquinaldine extractions applied to the analysis of metals; use of organic solvents in flame photometry. (Philadelphia, American Society for Testing Materials, 1958. s.t.p. no. 238. 54p., $2.25.)

°SYMPOSIUM ON RADIOACTIVITY IN INDUSTRIAL WATER AND INDUSTRIAL WASTE WATER

Because of the advent of nuclear power, new problems have been created in the field of industrial water techniques. Papers are presented which discuss problems in the reacior plant itself and in the associated water waste. Methods of analysis are described which include those for radiation hazards. (Philadelphia, American Society for Testing Materials, 1958. s.t.p. no. 235. 69p., $2.50.)

°SYNCHRONOUS MOTORS AND CONDENSERS

An introduction to the characteristics of synchronous motors and to the problems encountered in selecting the most suitable motor for a particular industrial application. In addition information is provided on associated starting and control equipment and on various aspects of protection for synchronous machines. A concluding section discusses synchronous condensers. (D. D. Stephen. Toronto, Ryerson, 1958. 500p., $12.00.)

SOVIET SPACE SCIENCE

Translated from the second Russian edition, published at the end of 1957, this book presents a good survey of astronautics, and although the emphasis is on Soviet achievement, the work being done in other countries is recognized.

With the emphasis on celestial mechanics and rocketry, the author discusses the laws of motion of artificial satellites, and their motion relative to an observer on the earth, construction and launching of a satellite, man in space, communication with the ground, the return to earth, artificial satellites of bodies of the solar system, and the use of artificial satellites.

The author, who commenced his career in France, has been concerned with astronautics for more than 25 years, and shows a great deal of knowledge of Western work in the field. (Ari Shternfeld. New York, Basic Books, 1959. 361p., $6.00.)

°FOUNDATIONS OF INFORMATION THEORY

An analysis of the mathematical theory of information. The author discusses the discrete channel with and without memory; the coding theorem for discrete channels without memory; the semi-continuous channel without memory; the binary symmetric channel. (A Feinstein. Toronto, McGraw-Hill, 1958. 137p., $7.50.)

ELECTRICITY AND MAGNETISM, 3RD ED.

The M.K.S. system of units has been adopted in this edition, necessitating considerable changes in the sections of the book dealng with electromagnetic and electrostatic theory, in addition to general revision throughout the book.

An elementary text, useful also for reference, the volume covers electricity and matter; effects of an electric current; magnetism; circuits; thermoelectricity; electrolysis; electromagnetism; measuring instruments; principles of electric machines; principles of electrostatics; elements of thermionics. (A. C. Hirst. Glasgow, Blackie, 1959. 438p., £2.)

FINANCIAL POST SURVEY OF OILS, 1959

According to this latest Survey, Canada's oil industry is going through a key period of consolidation which will set the pattern for future growth, and world events are pushing Canadian oil and gas into an increasingly important role. Details are given on active oil and gas companies in Canada, covering production, reserves, earnings, dividends, acreage interests and management. There are also special map sections and an eight-year price range of stock movements. (Toronto, Financial Post, 1959. 252p., $4.00.)

°SOLID STATE MAGNETIC AND DIELECTRIC DEVICES

An account of solid state devices and components using ferrites and titanates. The book begins with a classical treatment of magnetization and polarization and then proceeds to show the general application of these principles to electromechanical devices, small signal devices, ferrites at microwave frequencies, magnetic and dielectric amplifiers, digital techniques employing square loop materials, magnetic recording, and magnetic and dielectric measurements. Appendices discuss specialized aspects of the subject such as reciprocity in linear systems, magnetoresistance, and parametric devices. (Ed. by H. W. Katz. New York, Wiley, 1959. 542p., $13.50.)

THE ST. LAWRENCE SEAWAY

The first President of the St. Lawrence Seaway Auathority tells his inside story of the discussions and negotiations which went on between Canada, the U.S., and numerous other interested parties before construction of the Seaway began, and in its early stages, including the "battles" of the Montreal bridges and the tolls. He outlines the history of the earlier canals, the problems to be faced in building the Seaway, and how they were overcome. (Lionel Chevrier. Toronto, Macmillan, 1959. 174p., $3.50.)

THE ST. LAWRENCE SEAWAY

Professor Hills of the Geography Department of McGill University has written the story of the long chain of

● LIBRARY NOTES

events leading up to the construction of the Seaway and Power projects. He places the project in its geographical setting, and traces the early exploration of the system and early canals, to the end of the 14-foot canal era. He considers both the Canadian and U.S. views on the Project, and the work done before construction was started, and outlines the actual construction. In a final chapter he discusses the economic prospects of the Seaway, as distinct from the Power project which is an assured success. (T. L. Hills. London, Methuen, 1959. 157p., $2.50.)

SHIPS AND THE SEAWAY

In this book the general reader will find information about the Seaway, and the ships which sail it. The first section of the book describes the Seaway from the Gulf of St. Lawrence to the Lakehead, with a final chapter on measures taken to overcome the ice problem. The second section describes the ships of the different lines which will be using the Seaway, and the house flags and funnel colours of forty major shipping companies are illustrated on the end papers. (F. J. Bullock. Toronto, Dent, 1959. 115p., $3.95.)

*FAST REACTIONS IN SOLIDS

Deals with recent experimental investigations into the mechanism by which an explosion can be initiated in a solid, and in particular with the mechanism by which a crystal can decompose when subjected to heat, light, shock, or nuclear radiation. High resolution electron microscopy combined with electron diffraction is used to investigate the early stage of decomposition, and high-speed photography and fast electronic methods are employed to follow the rapid reaction. An important application of the subject matter is the accurate control of the burning of explosive materials. (F. P. Bowden and A. D. Yoffe. Toronto, Butterworth, 1958. 164p., $7.00.)

*SYMPOSIUM ON SOME APPROACHES TO DURABILITY IN STRUCTURES

Papers dealing with nonmetallic materials that are generally used in structures where weather plays a major part in the durability of the structure. The problems of variations of kinds of exposure and of associated moisture migrations are discussed. (Philadelphia, American Society for Testing Materials. s.t.p. no. 236. 67p., $2.50.)

*SYMPOSIUM ON ADVANCES IN ELECTRON METALLURGY

New and comprehensive techniques for the study of materials through the use of the electron microscope are described and include direct transmission electron microscopy, electron probe microanalysis, studies of the microstructure of age-hardenable and heat-resistant alloys, and improved techniques in specimen preparation and replication.

(Philadelphia, American Society for Testing Materials. s.t.p. no. 245. 120p., $4.00.)

°SYMPOSIUM ON CLEANING OF ELECTRONIC DEVICE COMPONENTS AND MATERIALS

Papers which discuss various aspects of the current knowledge concerning decontamination of electron devices, including both semiconductors and tubes. (Philadelphia, American Society for Testing Materials. s.t.p. no. 246. 220p., $6.50.)

°SYMPOSIUM ON BASIC MECHANISMS OF FATIGUE

Papers discussing the mechanisms of failure such as dislocations, internal friction, crytalline and structural changes, and surface disintegrations. In addition to clarifying the mechanisms leading to fatigue damage, the papers emphasize the statistical nature of the material behavior under cyclic loadings. (Philadelphia, American Society for Testing Materials, 1958. s.t.p. no. 237. 121p., $3.75.)

°AIR POLLUTION CONTROL

Presents the basic factors that should be considered in any air pollution control program. Beginning with an explanation of the effects of air pollution and the importance of meteorological variables, there follows a discussion of the nature and source of the more common air pollutants. Detailed consideration is then given to the methods of determining the amounts of various contaminants in the air, the most appropriate means of controlling emissions at the source, and the legal means available for control. Newer aspects such as the automobile exhaust problem and the hazards of radio-activity are also discussed. (W. L. Faith. New York, Wiley, 1959. 259p., $8.50.)

°AN INTRODUCTION TO CHEMICAL ENGINEERING

An introductory text that presents the fundamental concepts upon which chemical engineering is based. After preliminary material discussing chemical engineering as a career the authors discuss process variables, molecular units, compositions of mixtures and gases, PVT relations for gases, mixtures of gases and vapors, material balances, energy balances, and equilibria in chemical systems. (C. E. Littlejohn and G. F. Meenaghan. New York, Reinhold, 1959. 271p., $7.80.)

°FLUID-DYNAMIC DRAG, 2ND ED.

A comprehensive presentation of information on drag or fluid-dynamic resistance. The present edition has been extended to include the resistance of bodies in water, wind loads on buildings, and three new chapters dealing with aerodynamic drag at transonic, supersonic, and hypersonic speeds. Each chapter begins with theoretical aspects and provides references to fundamental papers on the subject. This is followed by diagrams, tables, and curves giving the known experimental measurements. Over 2000 references on the subject are included. (S. F. Hoerner. Published by the Author, Midland Park, New Jersey, 1958. 400p., $15.00.)

*REFRACTORIES BIBLIOGRAPHY 1947-1956

This volume continues the previous compilation which covered the period 1928-1947. Over 9,500 abstracts from the periodical literature and patents are included, and relate to the raw materials, manufacture, properties, and uses of refractories. Refractories in all phases of industrial use are covered, including glass industry, petroleum industry, and foundry refractories, as well as refractories for the iron and steel industry. Developments in high temperature materials are given particular emphasis. (Compiled by The Joint Refractory Committee of the American Iron and Steel Institute and The Refractories Institute. Toronto, Burns and MacEachern, 1959. 1822p., $9.50.)

*PLASTIC DESIGN IN STEEL

Methods are given for designing continuous steel structures on the basis of their ultimate or plastic strength. The chapters contained deal with plastic theory applied to bending, effect of axial load on bending resistance, shear and web crippling, bracing requirements, non-symmetrical sections, haunched connections, design of continuous beams, design of single span rigid frames, and design of multi-span rigid frames. (Toronto, Canadian Institute of Steel Construction, 1959. 93p., $4.00.)

*RADIATION HAZARDS AND PROTECTION

The nature of the radiation hazard is explained and the levels of radiation which are accepted as safe are presented. The authors then discuss the protective methods by which these safe levels can be attained, and the measurements that will show whether satisfactory conditions have been achieved. In a concluding section the radiological hazards arising from atomic warfare are examined, together with the protective measures possible. A considerable portion of the book is devoted to various types of instrumentation. (D. E. Barnes and D. Taylor. London, Newnes, 1959. 178p., 30/-.)

*INTERFERENCE BETWEEN POWER SYSTEMS AND TELECOMMUNICATION LINES

The problems posed by interference and their solutions are discussed at length in this monograph, which covers coupling between circuits, the characteristics of power systems that effect telecommunication systems adversely, the effects in telecommunication circuits arising from interference, telephone interference by induction at audio frequencies, variations in effects due to different types of power lines, and reduction of interference. An extensive bibliography is included. (H. R. J. Klewe. Toronto, Macmillan, 1958. 256p., $14.00.)

*CONDUCTION OF HEAT IN SOLIDS, 2ND ED.

This edition has been expanded to provide as complete an account of the subject as can be encompassed in one volume. To achieve this purpose, many new results have been added, and certain parts of the discussion have been extended, as is the case with heat generation, surface heating, geophysical applications, anistropic media, moving media, and substances with variable thermal properties. Three new chapters dealing with melting and freezing, integral transforms and numerical methods, as well as a number of new tables and text figures giving numerical information have also been added. (H. S.

(Continued on page 159)

Canmark Services Limited has been established to provide engineering sales and services across Canada. Formed by a group of 12 companies, of which Montreal Armature Works Ltd. is one, the new enterprise has headquarters in Toronto at 131 Bermondsey Road.

Piggott Construction Ltd. have placed an order of some 30 Caterpillar machines, including D9 and D8 tractors, scrapers and motor graders with Kramer Tractor Company, Ltd. The Piggott firm was successful bidder on Stage 2 of embankment work at the South Saskatchewan river dam project.

Quartzline lamps—The Canadian General Electric Company Limited have announced a new line of quartzline lamps which will be available first in 500-watt and 1500-watt sizes. The company's lamp department states that the growing line of pencil-thin tubular quartz lamps represents the first successful application of a repeating iodine cycle principle to lamp-making.

New Hardfacing Electrode—A new low hydrogen electrode, depositing a hardfacing weld metal of a new type is announced by ESAB Arc Rods Ltd., Montreal. It has, it is claimed, a very high degree of crack resistance with or without preheat.

Imperial Oil Limited have put out a revised edition of their booklet "Facts and Figures about Oil in Canada".

Atlas Asbestos Company Limited, manufacturers of "Turnall" asbestos-cement pressure and sewer pipe has released a 14-page guide to the writing of sewer pipe specifications. Available from any branch office of Atlas Asbestos Company Limited.

Hughes-Owens Co. Ltd., 1440 McGill College Avenue, Montreal, is the Canadian agent and distributor for optical instruments for the metal working industry manufactured by M. Hensoldt & Son, Optical Works, Wetzlar, Germany.

Public Works Contracts Awarded—Contracts involving expenditures totalling $5,993,610 were awarded by the Federal Department of Public Works during the month of May, 1959. During the month of June contracts awarded totalled $12,-863,810. The amount for new works in building construction and harbours and rivers engineering in May was $2,198,-802 and in June $7,585,266; for repair and maintenance of existing structures in May $270,520 and in June $1,-187,108; for the construction of highways and bridges in May $3,054,544 and in June $3,718,236; and for dredging in May $469,744 and in June $373,200.

Pirelli Cables, Conduits Limited appointment. Announcement has recently been made of the appointment of John J. Haines as technical representative for Pirelli Cables, Conduits Limited, attached to Head Office Sales Montreal.

HONEYWELL CONTROLS LIMITED AWARD WINNING INSERT

The four page insert shown above has been voted the best in the June issue by the fifty readers who were asked to judge the advertisements in that issue. The judging was based on ACCURACY—INFORMATION and ATTRACTION. Please turn to pages 33 to 36 of your copy of the June issue to see the actual advertisement.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

The fifty readers who were asked to judge the advertisements in the June issue from the viewpoints of ACCURACY – INFORMATION – ATTRACTION, voted greatly in favour of the four page insert of HONEYWELL CONTROLS LIMITED, which appeared on pages 33 to 36.

The winning insert, printed in yellow, red, and black, features HONEYWELL'S new "ElectriK Tel-O-Set System". The copy describes in a very concise manner how the system functions. The use of colour in the advertisement makes it very dominating.

The insert was prepared and placed by Cockfield, Brown & Co. Ltd. of Toronto. The person in charge of advertising at the Company is Mr. K. K. Warne, Merchandising Manager.

°ANALYSIS OF ELECTROPLATING AND RELATED SOLUTIONS, 2ND ED.

Over three hundred methods are given for the determination of principal constituents and impurities, together with chapters on sampling, and control of cleaners, the analysis of plating salts and of water, the physical and physicochemical methods of analysis, the preparation of standard solutions for volumetric analysis, and many tables. In this edition the text has been partially rewritten and forty new methods, mainly based on the use of ethylene diamine tetra-acetic acid, have been added. (K. E. Langford. Teddington, England, Robert Draper, 1958. 423p., $9.00.)

STANDARDS RECEIVED

ASTM standards. American Society for Testing Materials, 1916 Race St., Philadelphia 3, Pa.

ASTM specifications for steel piping materials. $6.00.
ASTM standards on wood, wood preservatives, and related materials. $5.50.

Canadian standards. Canadian Standards Association, 235 Montreal Rd., Ottawa 2.

MEET THE AUTHORS

Professor A. G. Christie, M.E.I.C., Johns Hopkins University *(Some Considerations in Steam Power Plant Design).*

A graduate of Toronto University in 1901, Professor Christie holds several honorary degrees, including M.E., Dr.Eng. and LLD. He has worked for Westinghouse Machine Company, Allis-Chalmers Company and Western Canada Cement and he has taught at Cornell University, the University of Wisconsin, and Johns Hopkins University (where he became professor emeritus in 1948). Professor Christie is consulting engineer for the Hydro Electric Power Commission of Ontario, the Manitoba Hydro Electric Board and the New Brunswick Electric Power Commission.

G. D. Mader, chief engineer, Nova Scotia Power Commission *(The Interconnected Power Systems of Nova Scotia and New Brunswick).*

Mr. Mader received his B.Eng. (civil) from Nova Scotia Technical College in 1945. He joined Atlas Construction Company as construction engineer and transferred to the Nova Scotia Power Commission in 1950. He is a councillor of the Association of Professional Engineers of Nova Scotia and chairman of its board of examiners.

N. S. Haines, M.E.I.C., civil design engineer, Candu Nuclear Power Station, Hydro-Electric Power Commission of Ontario *(Whitedog Falls and Caribou Falls Generating Stations — Hydro Electric Developments on the Winnipeg and English Rivers).*

Mr. Haines graduated in 1935 from the University of Toronto with the degree of B.A.Sc. in civil engineering. He has worked as a field engineer in Northern Ontario; as research assistant on the International Tribunal on Smoke Control; and as consultant on overseas hydraulic work. Since 1940 he has been with The Hydro-Electric Power Commission of Ontario working on the design and construction of hydraulic developments.

E. K. Akin, M.E.I.C., senior mechanical engineer, Nova Scotia Light & Power Company Limited, *(The First Cyclone Fired Boilers in Canada and Some Aspects of their Early Operation).*

Mr. Akin received his early education in Windsor, N.S. and attended Dalhousie University. In 1934 he graduated from Nova Scotia Technical College with a B.Sc. in electrical engineering. He joined the Nova Scotia Light and Power Company Limited in 1935 and became superintendent of their steam plant in 1939. In 1950 Mr. Akin was made senior mechanical engineer.

T. Ingledow, M.E.I.C., president, B.C. Engineering Company Limited *(138 kv Under Sea Cable Across Georgia Strait).*

Mr. Ingledow joined B.C. Power Corporation (B.C. Electric Co. Ltd.) as chief engineer in 1940; became executive engineer of the B.C. Power Corporation and was president of B.C. Eng. Co. Ltd. from 1954 to 1958, when he became president of the newly-formed company, B.C. & B.B. Power Consultants, in 1958.

A member and past president of the Association of Professional Engineers of British Columbia, Mr. Ingledow is also on the Defence Research Board of Canada.

George S. Cavadias, M.E.I.C., consulting engineer, Montreal, Que. *(A Method of Determining the Power Potential of Rivers with Many Reservoirs and Power Plants).*

Mr. Cavadias graduated in civil engineering from the National Technical University, Athens, Greece, in 1942 and worked on structural and hydro-power engineering before coming to Canada in 1950. He has worked with the Shawinigan Water and Power Company and the Department of Northern Affairs and National Resources. Mr. Cavadias recently obtained an M.Sc. degree from McGill and in August, 1959, established his own consulting practice in Montreal.

Winnett Boyd, M.E.I.C., president, Winnett Boyd Limited *(The Design of a Daniels-Boyd Nuclear Steam Generator for a 400 Mw (Net E) Power Plant).*

Mr. Boyd graduated from the University of Toronto in 1939 in mechanical engineering and did post graduate work at M.I.T. From 1940 to 1943 he was with the Aluminum Company of Canada in British Guiana, Montreal and Shawinigan Falls. As chief designer at A. V. Roe Canada Limited, he designed Canada's first two jet engines, the Chinook and Orenda. From 1951 through 1956 he was chief mechanical engineer with C. D. Howe Company Limited on design of the NRU reactor. Since 1957 he has worked on the Daniels-Boyd Nuclear Steam Generator and is now in practice as consulting engineer. He is a registered professional engineer in Ontario and Quebec and is a fellow of the Canadian Aeronautical Institute.

J. A. Paget, M.E.I.C., General Atomic Division, General Dynamics Corporation, La Jolla, California *(The Design of a Daniels-Boyd Nuclear Steam Generator for a 400 Mw (Net E) Power Plant).*

Mr. Paget graduated from the University of Toronto in 1946 with a degree in mechanical engineering. In 1952 he joined The C. D. Howe Company Limited, Montreal on the NRU project, later working with the Daniels-Boyd Reactor Group; in 1958 he was engaged on the CANDU steam generator design; and in August, 1959, he joined the John J. Hopkins Laboratory of General Atomic as a member of the research and development staff. He is a registered professional engineer in the provinces of Quebec and Ontario.

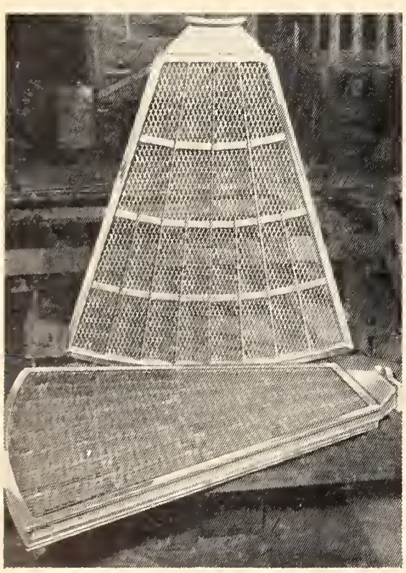
Paul Hamel, engineer, Atomic Products Section, Orenda Engines Ltd. *(The Design of a Daniels-Boyd Nuclear Steam Generator for a 400 MW (Net E) Power Plant).*

Mr. Hamel graduated from Ecole Polytechnique, Montreal, in 1942, in mechanical engineering and did post-graduate work from 1954 to 1956. Employed by the C. D. Howe Company in 1954, he worked on the NRU reactor. In 1957 Mr. Hamel spent six months at Chalk River studying reactor physics and the use of digital computers. From 1957 to mid-1958 he worked on the Daniels-Boyd Nuclear Steam Generator. He recently joined the Atomic Products Section of Orenda Engines Company, Malton, Ontario. Mr. Hamel is a registered professional engineer in Quebec.

Silver Falls Generating Station. Biographical notes on the authors of this paper will appear in the next issue of *The Engineering Journal.*

Incoloy tubing installed in a large furnace for converting ethane to ethylene. Very little tube maintenance or downtime required in spite of the 1500°F. temperature of operation. Tube wall temperatures are about 1700°F.

NICKEL ALLOYS withstand high resist corrosive processing and



Expanded Monel and Inconel metal for use as backing screens in disc-type filters in pulp and paper industry. Frame is fabricated type 316 or 304 stainless steel.

Three Inco Nickel Alloys . . . MONEL, INCONEL and INCOLOY . . . fulfill most requirements where high temperature and corrosion problems are encountered in chemical processing and pulp and paper production.

MONEL* is a strong, tough nickel-copper alloy that resists attack by many organic and inorganic acids, alkalies and salts. Monel has good mechanical properties, is easily fabricated and welded.

INCONEL* nickel-chromium-iron alloys have good resistance to oxidation up to 2100°F. and retain good mechanical properties at temperatures up to 1800°F. Excellent resistance to sulphur-free heat-treating atmospheres. Practically immune to embrittlement by carburizing or nitriding atmospheres.

INCOLOY* provides good strength characteristics and—like Inconel—good resistance to oxidation and other corrosive conditions at high temperatures. Incoloy also gives greater resistance to sulphur attack, green rot and molten cyanide salts.

POWER IN CANADA

Net Generation up 6.3% in first seven months of 1959

PRODUCTION of electrical power in Canada during the first seven months of 1959 continued to rise over the output for previous periods. Net generation as reported by Dominion Bureau of Statistics refers only to firms which generate at least 10 million kwh. a year, but these represented 99.1% of total production in 1957.

On this basis, net generation in the first seven months of 1959 totalled 59,414,323 Mwh. compared with 55,898,132 Mwh. in the same period of 1958, representing a gain of 6.3%

About four-fifths of this total was produced by power utilities, the rest by industrial producers. An approximate breakdown of net generation for the period January-July 1959 is:

Utilities	*% of total*
Hydro	74.3
Thermal	5.2
Industry	
Hydro	18.5
Thermal	2.0

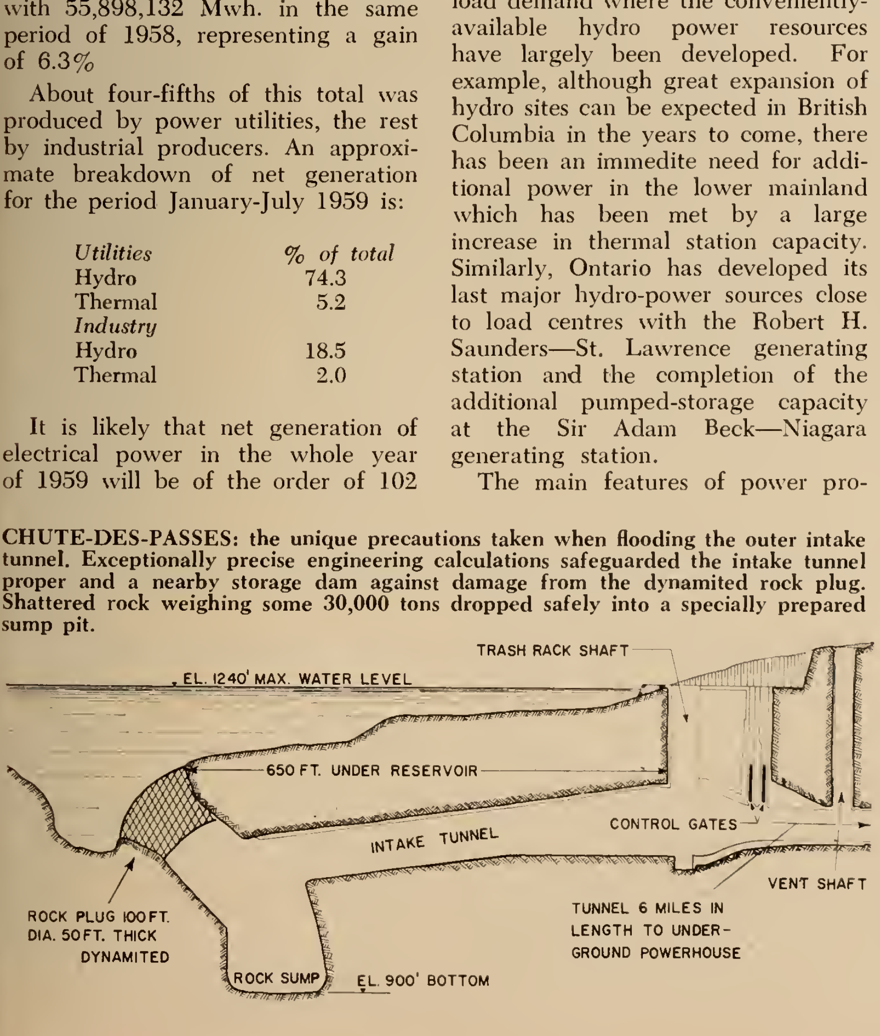
It is likely that net generation of electrical power in the whole year of 1959 will be of the order of 102 million Mwh., compared with the 1958 total of 96,743,717 Mwh.

Hydro/Thermal Generation

Installed capacity of water-power plants at the end of 1958 totalled some 22,470,040 h.p., and the total for thermal generating plants was about 3,660,000 h.p. The relative growth rate of thermal power expansion is increasing over that for hydro power because of the need to increase base load capacity in areas of high load demand where the conveniently-available hydro power resources have largely been developed. For example, although great expansion of hydro sites can be expected in British Columbia in the years to come, there has been an immedite need for additional power in the lower mainland which has been met by a large increase in thermal station capacity. Similarly, Ontario has developed its last major hydro-power sources close to load centres with the Robert H. Saunders—St. Lawrence generating station and the completion of the additional pumped-storage capacity at the Sir Adam Beck—Niagara generating station.

The main features of power production across Canada will be dealt with briefly by individual provinces and territories.

CHUTE-DES-PASSES: the unique precautions taken when flooding the outer intake tunnel. Exceptionally precise engineering calculations safeguarded the intake tunnel proper and a nearby storage dam against damage from the dynamited rock plug. Shattered rock weighing some 30,000 tons dropped safely into a specially prepared sump pit.



BRITISH COLUMBIA

At the end of 1959 in British Columbia there were 40 hydro-electric installations with an installed capacity of 3,287,505 h.p. in the category of stations with installed turbine capacity of not less than 2000 h.p. A further 510,000 h.p. was under construction, or planned for development.

Aluminum Company of Canada Limited had the largest single installation with 1,050,000 h.p. from seven units at the Kemano-Kitimat development in the northern part of the province. Expansion to the total potential of 2,400,000 h.p. at this site will take place when warranted by business conditions.

British Columbia Electric Company Limited will have two out of four generating units installed this fall at their Bridge River No. 2 site, which will add some 345,000 h.p. to the B.C.E. hydro capacity when completed in 1960. Total cost will be about $56.5-million.

In the thermal field, B.C. Electric will complete the 134,000 h.p. stand-by gas turbine plant at Port Mann this fall. Work is progressing on the Company's largest undertaking, the Burrard thermal station, which is a natural gas fired, steam-driven plant, of which the first 200,000 h.p. generating unit will be in service in 1961. Three others will be brought on line between 1961 and the end of 1964, and the plant can be expanded to house six units with a total capacity of 1,200,000 h.p.

British Columbia Power Commission is also actively expanding its resources. Most recently completed additions, which were officially commissioned on 2nd September 1959, are the 100,000 h.p. capacity Georgia gas-turbine generating station near Chemainus and the 35,000 h.p. Ash River hydro station near Port Alberni, both on Vancouver Island. The two plants raise the Power Commission's generating capability within the province to 600,000 h.p., which is estimated to be sufficient for demands until the early nineteen-sixties. A further expansion now under way is the addition of a 3000-kw. gas-diesel generating unit at Quesnel, which will boost the capacity of the station to 15,000 kw. This is part of an extensive expansion program of Power Commission gas-diesel and diesel generating stations at Prince George, Dawson Creek, Quesnel, Smithers, Chetwynd, and Alert Bay. The new unit at Quesnel is due to be in service by May 1960. The Commission serves many small centres in relatively remote areas and, at March 31, 1959, had 78 diesel and gas-diesel generating sets, including some 500-kw. mobile units, with a total capacity of 62,001 kw.

The overall picture of power generation in British Columbia in the future will be greatly affected by the ultimate results of negotiations and planning for the two controversial projects on the Columbia and Peace Rivers. Development of the Columbia has, as is well known, depended on lengthy discussions with United States authorities on such problems as downstream water rights. The Wenner-Gren group has had the backing of the B.C. Premier, Mr. Bennett, to develop its plans for production of a possible 4 million h.p. on the Peace River, but the Federal Government has taken the view that the project is not economically feasible at present, for want of a sufficient market. However, the future of these two great projects will be watched with much interest.

YUKON AND NORTHWEST TERRITORIES

The Northern Canada Power Commission of the Federal Government completed its 15,000 h.p. hydro installation at Whitehorse Rapids, Y.T., in 1958, and has plans for a further unit of 7,500 h.p. at this site. The Commission's other hydro sites are on the Mayo River, Y.T. (6000 h.p.), and Snare Rapids, N.W.T. (8350 h.p.). A second development on the Snare River, eight miles downstream from the present site, will have a capacity of 9,200 h.p.

Other major hydro plants are the 15,000 h.p. installation of Yukon Consolidated Gold Corporation on the Klondike River, which was developed between 1911 and 1935, and the Consolidated Mining and Smelting plant of 4700 h.p. at Bluefish Lake, Klondike River, N.W.T., which was installed in 1941.

Recent thermal plants include a 600 kw. unit at Fort Smith and a 150 kw. diesel unit at Inuvik (formerly New Aklavik).

There is a potential of some four-million h.p. on the Yukon and Nass Rivers under investigation by Northwest Power Industries Ltd.

ALBERTA

At the end of 1958 there were 12 hydro developments in Alberta with installed turbine capacites over 2000 h.p. The capacity of these totalled 310,510 h.p.

Calgary Power Limited operated eleven of these hydro plants (240,000 kw.) and present expansion consists of an additional 80,000 kw. at the Spray-Rundle plant, to be completed in 1960. Application has been made for construction of a dam and hydro generating plant on the Brazeau River (a tributary of the North Saskatchewan) 96 miles S.W. of Edmonton. At a cost of $45 million the initial capacity will be 150,000 kw., to be complete in 1964, though some power should be available in the Fall of 1963. The project will require the construction of a 10-million cu. ft. earthfill dam, two miles long, with a twelve-mile long canal to carry water from the 900,000 acre-ft. storage reservoir to the powerhouse.

Calgary Power's Wabamun thermal plant now produces 144,000 kw. from two units, using natural gas as fuel. An additional 150,000 kw. unit is scheduled for completion at this site by 1962. There is a reserve of 70 million tons of coal at Wabamun, which can be developed by strip mining, and eventually the thermal power plant will operate on coal, though natural gas will be replaced only as coal is economically available and will continue to be used for emergencies and as a pilot for coal-firing.

There is an interesting relationship between the growth of the oil and gas industry in Alberta and the growth of the electrical power demand in the Province. In 1947, the year of the Leduc discovery, Calgary Power supplied the oil industry with 2,089,400 kwh. of electrical energy (1.2% of the industrial load or 0.5% of the total load). In 1958 the supply had risen to 212,816,562 kwh. or 34% of the Company's industrial load (14.8% of total load). This great increase in demand for power by the petroleum industry has had a considerable effect on the planned expansion of the power industry.

The Canadian Utilities Limited are spending $2,680,000 on capital expansions during 1959, particularly for transmission line extensions. Other large expenditures are planned for the Company's northern subsidiaries, McMurray Light and Power Co., Yukon Electrical Co., Ltd., and Yukon Hydro Co. Ltd. (Whitehorse, N.W.T.). A 200 kw. diesel plant and distribution system was built in 1958 to serve the rapidly-growing oil centre of Swan Hills. During 1959, the Company is building a 150 kw. diesel generating plant to serve the community of Fort Chipewyan in northern Alberta.

SASKATCHEWAN

Saskatchewan had only two hydro installations at the end of 1958 with capacity of over 2000 h.p. The 106,500 h.p. Island Falls plant (Churchill River) of the Churchill River Power Company has an additional unit of 19,000 h.p. completed this year.

The big development in the province is the South Saskatchewan River project for which a 200,000 h.p. hydro-electric installation is planned.

Since the end of 1957, when there were 14 thermal generating stations in the over-2000 h.p. category, the Saskatchewan Power Corporation has added a 66,000 kw. steam turbine to its Queen Elizabeth station in Saskatoon and increased capacity of the Kindersley station by 20,000 kw. in two gas turbine units.

MANITOBA

Eight hydro-electric developments (over 2000 h.p.) at the end of 1958 had a combined capacity of 777,000 h.p. Of these four were operated by the Manitoba Hydo-Electric Board (562,000 h.p.), two by the City of Winnipeg (201,000 h.p.), and two by Sherritt-Gordon Mines Ltd. (Laurie River Nos. 1 and 2, each of 7000 h.p.).

The Manitoba Hydro-Electric Board is proceeding with the Kelsey hydro-station on the Nelson River in northern Manitoba, which will supply power to the International Nickel mining development at Moak, Mystery, and Thompson Lakes. Two 42,000 h.p. units are scheduled for completion in 1960 plus three more in 1961. When completed, this project will bring the normal winter generating capability on the Manitoba Southern Power System to over one-million kw., from 870,000 kw. in 1960 and 416,000 kw. in 1950.

The Board is making engineering investigations at the Grand Rapids site on the Saskatchewan River. The site has a potential of over 400,000 h.p. and is being considered for development with a head of 120-125 ft. Another program of investigation is under way at the Great Falls generating station to consider the advisability of increasing capacity from the present 132,000 kw.

The Board's thermal station at Brandon is rated at 132,000 kw. (see *The Engineering Journal*, July 1959) and was completed late in 1958. A further 132,000 kw. of thermal generating capacity will become available when the Selkirk station produces from its first stage in 1960. Provision has been made for further expansion of the Selkirk plant to a maximum of one-million kw.

The possibility of a four-million kw. system in Manitoba by 1980 has been considered, and this would probably include a capacity of one-million kw. at Selkirk and some two million from exploitation of the hydro potential of the northern rivers: about 300,000 kw. from the Grand Rapids site and the rest from sites on the Nelson River. The remaining one-million kw. might come from the Winnipeg River, where rather more than half this amount is now being developed. Actual development depends on the economics of the various forms of power generation, including that from nuclear energy.

In the field of transmission, the Manitoba Hydo-Electric Board has a project for a 150-mile 138-kv. line between Manitoba and Saskatchewan.

The 51,000 kw. capacity of the City of Winnipeg Amy Street thermal station will form part of the intergration of resources, both thermal and hydro, of the Board and the City, and investigations have been made towards integrating the resources of the northwest pool of Ontario Hydro and those of the industry in Manitoba.

ONTARIO

At the end of 1958 Ontario reported 105 hydro generating stations of capacity greater than 2000 h.p. for an installed capacity of over 7,080,000 h.p. By the end of 1959, when the last of the sixteen units at the Robert H. Saunders-St. Lawrence station is in service, a further 525,000 h.p. will have been added (for a total of 1,200,000 h.p. at the St. Lawrence project.

Most of the hydro development in the province is controlled by the Hydro-Electric Power Commission of Ontario (Ontario Hydro), with 67 hydraulic stations and a total capacity of 5,761,100 kw. Industry, particularly pulp and paper and some mining and smelting operations, accounts for a further capacity of over 637,000 kw.

Ontario Hydro progress in 1958 has been discussed earlier (*The Engineering Journal*, May 1959), and 800,000 kw. of new generation was added in that year. At the end of the year, work was in progress on nine stations: five hydraulic, three conventional thermal, and one nuclear-electric. As already mentioned, the Robert H. Saunders-St. Lawrence hydraulic station at Cornwall will be completed in 1959. Silver Falls generating station, on the Kaministikwia River about 30 miles northwest of the Lakehead, is scheduled to produce 45,500 kw. in September 1959. Red Rock Falls station, on the Mississagi River about 14 miles northeast of Thessalon, is scheduled for completion in 1961, when it will have a capacity of 38,000 kw. Otter Rapids generating station is being built at the lower end of a series of rapids on the Abitibi River and will produce 31,000 kw. when completed in 1961. A further 45,000 kw. capacity was added in 1959 to the existing 181,000 kw., Abitibi Canyon station, 50 miles northeast of Kapuskasing, the largest generating station in northern Ontario.

At the end of 1957 there were 13 thermal stations in the province of capacity greater than 2000 h.p. for a total capacity of 967,300 h.p. The largest of these is Ontario Hydro's Richard L. Hearn steam plant in Toronto, on which work is proceeding to increase capacity from 400,000 kw. to 1,200,000 kw. by 1960, at an estimated cost of $107,600,000. The new Lakeview station, on the shore of Lake Ontario a few miles west of Toronto, will be among the largest thermal-electric plants in the world. It is scheduled to begin operation in 1961 with one 300,000 kw. unit, and a second unit of the same size is to be added the following year. A total installed capacity of 1,800,000 kw. is planned for the middle 1960's at an estimated cost of $250 million. The third thermal station on which Ontario Hydro is working is that at Thunder Bay, at the mouth of the Mission River on the Fort William waterfront. Initial plans call for a single 100,000 kw. unit, to be in operation in 1961, but the site is large enough for the ultimate construction of a 1 million kw. station.

Nuclear Power

Canada's first nuclear-electric generating station is the NPD (Nuclear Power Demonstration) plant, now being built in co-operation with Atomic Energy of Canada Limited (A.E.C.) and the Canadian General Electric Company on the banks of the Ottawa River 150 miles northwest of Ottawa. Scheduled to be completed in 1961, the relatively small 20,000 kw. station will be operated and maintained by Ontario Hydro, who are also working with the Nuclear Power Plant Division of A.E.C. on plans for a 200,000 kw. nuclear plant known as CANDU (Canadian Deuterium Uranium). The objective is to produce electricity competitive with conventional thermal generation, and it is expected that power from CANDU will be fed into the Ontario Hydro system by 1965 or even earlier.

Other recent advances by Ontario, in addition to considerable expansion of transmission and distribution facilities, included the experimental extra high voltage transmission line, near Coldwater, for testing up to 600,000 volts. Completed in 1959, this is the first three-phase test line of this voltage in North America; the use of extra high voltage transmission will be the best means of carrying power over long distances, for example, from far northern hydraulic sites, and of integrating more fully the northeastern and southern Ontario systems. The second notable development was the introduction of an electronic data processing system in the head office in Toronto (see *The Engineering Journal*, August 1959).

Apart from the developments of Ontario Hydro, the Great Lakes Power Company this year started operation of the Cat Falls 30,300 h.p. hydro-unit on the Michipicoten River.

QUEBEC

The province of Quebec depends

almost entirely on hydraulic generation for electrical power. At the end of 1958, in the over-2000 h.p. category, there were 92 hydro installations with a combined capacity of some 9,784,000 h.p., compared with only seven small thermal stations (over 2000 h.p.) with a capacity of 36,584 h.p.

Many organizations are involved in the development of hydro-electric power, but the leaders are Hydro-Quebec, Aluminum Company of Canada Limited, and Shawinigan Water and Power Company in terms of installed capacity.

Hydro-Quebec (Quebec Hydro-Electric Commission) is proceeding with construction of the Bersimis II development on the Bersimis River, at which three units of 171,000 h.p. each are scheduled for completion in the last two months of 1959, and two further units for late in 1960. The 1,200,000 h.p. Bersimis I plant was completed in 1958. At Beauharnois, on the St. Lawrence River, the third and final section of the powerhouse is under construction with two out of eleven units of 73,700 h.p. installed. Completion is due in 1961, when the station will have a total installed capacity of 2,234,700 h.p.

The Aluminum Company of Canada had a capacity of 2,600,000 installed h.p. from five stations, including the 1,200,000 h.p. Shipshaw development, at the end of 1958. Now under construction is the new project at Chute-des-Passes, 150 miles north of the aluminum centre of Arvida, Saguenay District, where the first 200,000 h.p. unit was due to operate in September 1959. The further four planned units are scheduled for completion early in 1960, for a total capacity of 1 million kw.

The most recent development of the Shawinigan Water and Power Company is the 330,000 h.p. Beaumont plant, on the St. Maurice River, completed in 1958.

Several other developments are now under way. Quebec Mining Company has a 66,000 h.p. three-unit development on the Hart Jaune River scheduled for operation by late 1960. James MacLaren Company Limited is completing a two-unit 50,000 h.p. development at Dufferin Falls, Lievre River, and removing the existing 1500 h.p. plant in Buckingham from service. Hollinger-Hanna Limited is investigating possible development of 150,000 to 180,000 h.p. on the Aux Pekans River.

Quebec Department of Hydraulic Resources is continuing water power investigations on several rivers in the James Bay, Ungava Bay, and St. Lawrence River watersheds.

NEW BRUNSWICK

The New Brunswick Electric Power Commission reports hydro-electric power capacity of the province in 1959 at 194,030 kw. from ten stations, four of them operated by the Commission. Thermal capacity is given as 192,576 kw. from twelve stations plus diesel generator installations. The Commission's share of the total is rather more than one-half at 196,610 kw.

The Beechwood hydro station, completed with two 45,000 h.p. units in 1958, is designed for future addition of a further unit of the same size.

Latest addition in the thermal field is the new 50,000 kw. plant at St. John, which will serve, among other customers, the nearby Irving Oil refinery which is now under construction.

A feature of the power developments in New Brunswick is the interconnection of generating systems and extension of the new 138 kv. transmission grid. The five major pulp and paper companies operating in the province are partners in the reciprocal arrangement for distribution, and there is a tie-in with the Maine Public Service Company, which serves the northern part of the State. By March 1960 the systems in the province of Nova Scotia will be added to the power pool.

NOVA SCOTIA

Nova Scotia has the poorest water-power resources of the mainland provinces. Though 26 hydro stations of over 2000 h.p. capacity were reported at the end of 1958, the total capacity was only 168,290 h.p. Thermal generation reported at the end of 1957 amounted to 462,046 h.p. from eleven installations.

The Nova Scotia Power Commission has a hydro development on the Sissiboo River, consisting of two plants totalling about 15,000 kw., scheduled for completion by the end of 1959. Two sites on this river, capable of producing an additional 12,000 kw., will be built for completion in 1963. An investigation is underway on the hydro development at Wreck Cove, Victoria County, which is expected to have an ultimate capacity of 74,000 kw. Scheduled to go into service this fall is an additional 20,000 kw. unit at the Trenton steam station and, though additional thermal plants are not foreseen in the immediate future, long-term plans include two additional units at Trenton which would be rated at 75 Mw. and 100 Mw. respectively.

Nova Scotia Light and Power Company Limited will commission their 45,000 kw. No. 7 plant addition to the Water Street thermal generating station on 30th October 1959, which will bring the combined capacity of the Company's thermal and hydro facilities to 204,500 kw. A site has been procured, and engineering design is well advanced for a new thermal generating station at Tufts Cove, on the Dartmouth side of Halifax Harbour. The first unit will be in the 100 Mw. class and is scheduled for operation in 1963. The Company has also announced plans for the construction of two hydro-electric stations in the Annapolis Valley, at Alpena on the Nicteaux River and at Lequille. These will add 14,000 h.p. to generating facilities in the Valley. Lequille is scheduled for operation in 1961; Alpena in 1963.

PRINCE EDWARD ISLAND

Water power resources are negligible in Prince Edward Island, because of the small size of the streams. Less than 2000 h.p. of installed turbine capacity is developed at present. There are two major thermal installations, the principal one being the Maritime Electric Company steam plant at Charlottetown with 22,500 kw. capacity. To meet increasing demand for power, the Company is installing a new oil-fired boiler and 10,000 kw. generator at the plant site. The new 105,000 lb. hr. boiler is to be in use by september 1960, and the new turbo-generator by May 1961. A new central control room is to be included in the extension, and provision will be made for eventual automation of the plant and remote control of the company's sub-stations throughout the province.

NEWFOUNDLAND AND LABRADOR

At the end of 1958, nineteen hydro installations (over 2000 h.p.) were reported in Newfoundland with a total capacity of 361,750 h.p. Six thermal stations had a combined ca-

SOME CONSIDERATIONS IN STEAM POWER PLANT DESIGN

A. G. Christie, M.E.I.C., *Professor Emeritus*
Mechanical Engineering Dept.
Johns Hopkins University, Baltimore, U.S.A.

STEAM PLANTS that are designed today require large investments which are expected to be written-off during a service life of from 25 to 30 years. Consideration must therefore be given to desirable characteristics and elements of such new plants.

Large generating units

A common mistake in the design of new power plants is the failure to install large generating units. Equipment is purchased that appears to meet the immediate needs of the system. This practice disregards the fact that in twenty-five years at the present rate of growth, system peak demands will be over four times the present peaks. This rapid system growth soon makes the selected unit relatively so small and inefficient that it is held only for reserve and for occasional peak load service.

The advantages of large interconnected systems have been fully demonstrated. This recognition has led to the formation of power pools in various sections of the country with the objective of lessening the amount of reserve equipment of the interconnected system and of adding large highly efficient generating units to provide service to the whole pool at minimum cost. Agreements are made to share fixed charges of these large units and to adjust costs of kilowatt-hours delivered to each pool member.

Where hydraulic power plants with large storage reservoirs are elements of a system, large steam units can be added to carry base loads, leaving the hydro units to care for peak loads by short-time draw-down of storage. Experience has indicated that additional generating capacity for peak load service can often be added at such hydro plants at a lower cost per kilowatt of capacity than by any other peak load equipment. Present and future hydro plants should be analyzed with this object in mind.

The installation of large generating units, designed for operation at high steam pressures and temperatures, is justified by the preceding considerations. Large units can be purchased at a lower cost per kilowatt of capacity than smaller units. High steam pressures and temperatures lead to low heat rates; this is a desirable feature in view of expected increases in fuel costs. The same size of operating staff can serve a large unit as a small one, thereby reducing labour cost per kilowatt-hour. Maintenance charges per unit of output appear to be independent of capacity. Hence lower total generating costs can be expected of the large units when given base loading.

The operating records of large units have indicated high factors of availability and reliability which are as good as those of smaller units.

Large units can provide greater capacity on a desirable plant site than smaller machines. This is an important factor, for suitable power plant sites near large cities are becoming scarce. It is essential that available sites for future steam plants be purchased ten or more years in advance of their need. Otherwise such sites may be unavailable later.

High plant efficiency

Increasing mining costs combined with decreasing heat values per pound of coal, make it imperative that new units be highly efficient over their operating life. This indicates the use of as high steam pressures and temperatures as can be justified for the turbine considered.

Steam generators are operating with natural circulation at pressures up to 2400 psi. Forced circulation and once-through steam generators will probably be used in new high pressure plants generally with one or more stages of reheat. These may cost less when the usual large steam drum can be omitted.

Steam pressures considerably above the critical pressure of 3206 psia have been used in several recent new plants. Such high pressures increase the cost of boiler feed pump, economizer, evaporating surfaces, superheater, steam piping and the forward end of the turbine. The increased power required by the boiler feed pump absorbs a large portion of the gain resulting from the increased pressure.

Metallurgical difficulties appear at present to limit steam temperatures to about 1100° F. Higher steam temperatures at a given pressure would increase the cost of the secondary superheater, the high pressure steam piping and the inlet section of the turbine. On the other hand the energy required by the boiler feed pump would be reduced for a given generator output. Such advantages over increased pressures should encourage the development of new metals of moderate cost which are capable of withstanding higher steam temperatures. From an efficiency standpoint higher steam temperatures are more desirable than higher pressures.

Limited gains in efficiency are possible at the low temperature portion of the thermal cycle. Flue gas temperatures to chimneys are generally about 300° F. Steam generator efficiency is improved about 1% for 35° F. reduction in flue gas temperature. A reduction to 160° F. would result in a 4% gain in overall station economy and at no added cost to plant equipment other than such low pressure equipment as is necessary to effect this reduction in flue gas temperature. This substantial gain in efficiency deserves consideration in new steam plant designs.

Combinations of gas and steam turbines have been proposed and certain of these proposals have shown possible gains in overall efficiency. Such combinations may be used where natural gas or oil serves as fuel. The main difficulty with such combined plants is the inability of present forms of gas turbines to effectively use coal as fuel. When gas turbines can burn coal satisfactorily, there may be a more extended use of the combination of steam and gas turbines, probably with pressurized boiler furnaces.

Pumped storage of water has been revived as a means of improving system economics. Off-peak energy supplied by large highly efficient steam turbine generators at a low increment cost of operation, would be used to pump water to elevated storage ponds. This stored water is discharged later through hydraulic turbines to carry peak loads which would otherwise require added steam plant capacity and additional fuel. Pumped storage has been used overseas for more than fifty years. In the United States, the Rocky River plant of the Connecticut Light & Power Co. has operated for 29 years. No other pumped storage plant was built until recently. In considering pumped storage, overall efficiency and increasing fuel costs must be carefully analyzed. Experience indicates an overall efficiency of such plants of 60 to 65% due to losses in transmission lines, transformers, motors, pumps, pipelines, reservoir seepage and evaporation and electrical generators. As a consequence, where off-peak energy from steam plants is contemplated for pumping, increased fuel prices may soon make pumped storage uneconomical.

Fuels

Natural gas is burned at present as a fuel in some power plants. Extensive pipe lines to distant cities and increasing gas costs at well head will make this luxury fuel too expensive to use for generating electricity except during summer off-peak periods for gas.

The future use of fuel oil in power plants is also questionable. Improved cracking methods at refineries reduce the proportional amount of residual or "Bunker C" oils which have formerly been sold to power plants at low cost. Such residual fuels contain all the impurities in the raw petroleum. The contents of sulphur and other impurities may be so high that its use will be prohibited in certain areas.

Atomic power plants are being built in increasing numbers. Some time must elapse before experience indicates which system leads to lowest total production cost of electrical energy. It is apparent that for the next twenty years, steam plants burning fossil fuels will predominate in extensions to electrical systems.

The ash content of commercial coal appears to be increasing due to strip mining, the use of mining machinery and the recovery of coal from seams of lower quality. Excess ash can be removed in some cases by washing. High ash contents increase the freight charges in shipping coal. The location of a steam plant adjacent to a coal field deserves consideration particularly when cooling water is available and where distances from plant to loads are not great. Increased transmission line voltages and freedom from increasing freight rates on fuel, may make such a location profitable particularly if lignites or other low heat value coal must be burned. Such locations would probably be free from restrictive ordinances governing smoke, sulphur and other gaseous discharges from chimneys. The disposal of ashes should cost little in mining areas.

Attention must be given to the combustion of sub-bituminous coal and lignite that are abundant in certain sections. These formerly were troublesome to burn due to the difficulties in maintaining capacity in winter with high moisture in the coal, snow, ice and low outdoor temperatures. It is possible to burn such fuel in pulverized form when primary air is preheated to at least 700° F. or where the fuel is predried before entering a pulverizer. In Germany, furnace gases are introduced directly into Kraemer mills. The practice of introducing furnace gases with their sparklers into present types of American pulverizers has an element of danger that should not be overlooked.

Disposal of ashes as fill may become a problem during the life of the plant. Cost of haulage could be a significant item of operating cost. Some ash may be worth examination as a source of rare metallic elements.

Communities are becoming conscious of discharges of dust and gases from chimneys. Tall chimneys are desirable to provide wide dispersion of the gases. Dispersion is further improved by high gas velocities from the top of the chimney secured by the use of one or more orifices. The development of some automatic means to maintain high exit velocities from the chimneys at all loads is highly desirable.

Automation

While certain advantages may be gained by the use of some steam-driven auxiliaries such as boiler feed pumps, these require additional piping and must have the attention of operators as they are generally less easy to operate from a control centre than motors. Electrically driven auxiliaries are favored where central controls are installed.

All plant operations are generally under full control of the man in charge of the control room. The few other men on shift move around the plant to note and remedy any mechanical or electrical defects. While the present operating staff is more highly trained and better paid than operators in earlier plants, this large reduction in personnel has been a factor in maintaining low production unit costs.

Controlled operation requires the use of sturdy and reliable instruments of many types and these are undergoing steady improvement. There is still a need for simplification in the control room and for the elimination of instruments which contribute little to operating efficiency. An instrument that would give instant and continuous indications of overall plant efficiency would be a desirable addition to ensure highest operating economy.

Plant details

Large coal bunkers that contained 30 hours or more of coal supply have been carried at the top of the boiler room by heavy steel framing. Bunkers of 10 to 12 hours capacity with duplicate conveyors to take coal from outdoor storage piles, seems a better arrangement. Dust from such storage piles in built-up localities must be prevented by oiling or other treatment.

Plant may be outdoor, semi-outdoor or enclosed, depending on climatic conditions. Where plants are enclosed, walls of sheeting or panels have largely replaced more expensive brick or concrete walls. Many power stations have few outside windows and depend on artificial lighting and ventilation.

Steam generators have large radiant furnaces and rise to considerable height above basement floors. This construction generally requires a long steam pipe from the superheater outlet to the steam turbine inlet. Higher steam pressures and temperatures increase both the cost of such piping and its length since liberal bends must be employed to care for expansion of the thick pipes. Evidently the design of steam generators should be modified to decrease the length of the high pressure steam piping. Several schemes have been suggested: to turn the furnace upside down and fire from the top; to make the secondary superheater of the radiant sidewall type with its outlet approximately at the level of the turbine inlet; or, when floor space is available, to build the boiler on its side. The last form would save steel and would seem fitting for units of the "once-through" type.

Pressurized furnaces have demonstrated certain advantages but present problems in building large units.

Improvements in the design of evaporators and the use of oversized units have resulted in satisfactory supplies of feed water in moderate pressure plants. Demineralizers can furnish feed water free from mineral and gaseous impurities as needed by the highest pressure steam generators. Such equipment has not been made fully automatic and an operator is generally required to check water conditions in demineralizer and steam generator and to care for the regeneration of the resins.

Hydrozine and other non-metallic compounds are used in high pressure and once-through steam generators to control alkalinity of the evaporating water, in place of the sodium compounds formerly used.

Superheat temperatures are controlled by spray desuperheaters, by attemperators, by combined radiant and convection surfaces, by changing burner pitch in the furnace and by gas recirculation. Spray desuperheaters require pure feed water for the sprays. Attemperation by partial condensation of the entering steam or by cooling the steam between primary and secondary superheaters by heat exchange to boiler water, has proven satisfactory. Combinations of radiant and convection surfaces produce relatively constant superheat over a wide range of load. Changing burner pitch varies superheat by altering gas temperatures at the superheater. Gas recirculation sustains superheat temperature at light loads.

Operating experiences indicate that much can be learned about heat transfer in superheater sections, the proportioning of superheater surfaces and the control of final superheat temperature. Panel forms of superheater tubes, widely used abroad, are proving satisfactory.

Tempering of air to the air preheater is a problem where extremely low winter temperatures are experienced. Steam preheaters have frozen. Recirculation of preheated air increases the input to the forced draft fan. Radiation loss from the steam generator is employed in one plant to temper incoming air. There is need for a better method to temper air.

The removal of ash particles from the flue gases becomes of increasing importance due to the increasing ash contents in coal and to more stringent regulations on chimney discharges. If equipment is provided to cool the flue gases to 160° F. as suggested above, the dust must be removed before the gases reach this equipment. This may require the development of an electro-static precipitator that can function satisfactorily in hot gases. The equipment to cool gases to 160° F. must be suitable for washing periodically while the plant is at capacity and also easily cleaned during an outage. No commercial method has been developed for the removal of sulphur and nitrogen compounds from the flue gases.

Attention must be given with large turbine generators to small gains that may be secured from drain coolers and from counterflow sections in high pressure extraction heaters to take advantage of the superheat in the extracted steam. Boiler feed pumps have been placed beyond the highest pressure heater so that pump losses can increase the temperature of the feed water to the economizer.

An economizer element serving as the section to cool the flue gases to 160° F. may replace the first extraction heater after leaving the condensate pump. This combination would increase overall station economy.

Various attempts are being made to reduce the pressure losses between the last blade row and the condenser tubes and also in the tube banks. Aluminum tubes and tube sheets are being tried with fresh water. Rates of condensation in the condenser may be increased and the total cooling surface reduced by increasing the water velocity in the tubes above 6 or 7 ft. per sec. as now used.

Steam jets to produce vacuum have efficiencies of only 5 to 7%. Small steam pipes, often with reducing valves, are required with these jets, and it is desirable with high pressures to eliminate such piping. Two-stage heaters must be supplied with the jets to recover the heat in the discharged steam. Modern high speed dry vacuum pumps have many times the efficiency of the steam jets, which reduces their energy demand on the station. Increasing fuel costs will make the consideration of dry vacuum pumps desirable as fuel savings can soon pay for the extra cost of these pumps.

Many different types of condensers are available with varying arrangements of tubes, steam paths and water flow. Consideration must be given in the selection of a condenser to operating problems connected with tube fouling, reverse water flow, air cooling, and the condensate pump.

There is the problem of the utilization of the heat in the exhaust, which at present is generally discharged to waste in the cooling water. One Canadian city used this heat to modulate the temperatures of its water supply in winter so as to prevent freezing of distribution lines. The condenser cooling water was used in an industrial plant for space heating by regulating the vacuum according to the outside temperature.

A German city used condenser cooling water in its public baths. Some method should be devised to use at least a portion of the 50% of the heat in the fuel that is now thrown away in condenser cooling water.

Air-cooled condensers have been suggested for certain locations with a small water supply. These become unusually large and it is difficult to maintain a reasonable vacuum in summer time.

Cooling towers will be used more extensively where water supplies are limited. Large ground areas are required so that towers may be widely spaced to prevent recirculation. Chimneys on cooling tower outlets aid in lessening recirculation. The *evasé* cooling towers used in Europe, are so tall that recirculation seldom occurs. They can be placed closer together than towers of the current American type.

Consideration must be given to the effect of thermal stresses in turbine parts when high steam temperatures are used. It is desirable to provide for quick start-up and for rapid load changes from system disturbances. These problems are increased with reheat. Double casings in the high temperature sections of the turbines lessen the difficulties with thermal stresses.

Fluid-cooled stator coils permit the construction of larger electrical generators. High hydrogen pressures are employed for rotor cooling. Motor generator exciters permit preheating of rotor and rotor windings before reaching operating speed. This practice has lessened failures of insulation on rotor windings.

These paragraphs present some of the factors that should be considered in the design of steam power plants. New developments are made and practice changes so that other considerations may become more important in future years.

DISCUSSION

WE WISH to thank all of the people who contributed to the discussion of this paper for the time they have taken and for the helpful criticism offered.

Since a number of points were raised several times by different people, we should like to change the manner of reply from the customary one by speaking to each issue raised, rather than to each commentator.

Ability of turbine to burn Bunker C and the economics involved in relation to other prime movers

For our experimental work we have used the Bunker C oil directly from tank cars without any treatment except heating and filtering to remove particles greater than .015″. We have been able to turn the oil off and on at will with positive relighting even at subzero temperatures. Operation of the power plant has so far been entirely on Canadian residuals, and we do not expect to have significant corrosion trouble with these at a combustion chamber temperature of 700°C. However, if one were to burn residuals high in vanadium and sodium such as are available from the South American or Middle East fields, it is possible that additive treatment would be required to prevent deposition at this temperature.

The suggestion has been made that diesel engines, and especially free piston gasifiers, are equally capable of burning Bunker C fuel. Experience on marine and railway diesel engines has indeed shown that Bunker C may be burned cleanly at full power, but the saving in fuel has generally been accompanied by a corresponding increase in trouble and maintenance, with the result that reduction in operating cost, if any, has not been established. It is probable that free piston engines will burn Bunker C fuel quite satisfactorily at full power; but it is not clear that satisfactory operation over a range of loads is possible, especially if some gas generators of a set are to be shut down as an economy procedure at light loads. It appears also that the maintenance costs of free piston engines will exhibit the same trends as the diesel engine. These are issues that need to be resolved before one may claim a saving from burning Bunker C fuel.

It has also been suggested that a free piston type of engine disposes of the combustion chamber problems sometimes associated with gas turbines. While it is true that the problem of burning Bunker C in a gas turbine is real, it is difficult to see how it has been disposed of in the free piston engine, where it is associated with smaller injection nozzles and finely machined and closely fitted mating surfaces, which are highly susceptible to dirt, carbon and sludge. In practice, severe oil contamination and a two or threefold increase in wear of piston rings and cylinders has been encountered when burning Bunker C in reciprocating engines.

Capital charges, maintenance and repairs

We have not compiled figures for the cost in quantity of the experimental power plant described herein; but in the design we have paid some attention to details which seem to us to be especially important in the reduction of capital and maintenance costs. In terms of both capital and maintenance costs, the purely rotating gas turbine seems likely to show a considerable margin of superiority over both the diesel and free piston types.

Reliability, control and flexibility

We agree entirely with the comments that a locomotive power plant capable of replacing present diesel units must be superior in reliability and convenience of operation, and that the flexibility of operation achieved by multiple working of diesel units is indeed very satisfactory. While the proposed gas turbine output appears at present to be a useful one, it is quite possible to scale this type of unit for either larger or smaller power.

Transmission

We agree that the high reduction ratio involved in gearing a turbine directly to the wheels involves problems during shunting, slipping, etc., but are satisfied that they can be managed in a practicable way. The proposed arrangement with a two stage traction turbine allows one to couple directly to the wheels without a gear change. The free piston gasifiers with the higher pressure and lower temperature gases ease the problem of gas ducting, but on the other hand make a five or six stage traction turbine necessary which because of its poorer torque-speed characteristic requires either gear changing or electric drive to give satisfactory train operation. In the arrangement proposed, the gear box and turbine are carried as sprung weight and are therefore not subject to the most severe rail shocks.

Thermal efficiency and cycle potential

The efficiency of 21% given in the report makes adequate allowances for pressure drops and is, we feel, realistic for the arrangement set out. This will be reduced further by a transmission gear loss to give a net efficiency at the rail of 19%. The diesel engine is often credited with a thermal efficiency of 32%; but, in practice, it achieves more nearly 28%. Applying to this a factor of 80% for electrical and gear losses one finds the comparable diesel efficiency is 22.4%. The published efficiency of the free piston engine is 40% as a gasifier and this is reduced to 32% after putting the gases through a turbine. If the arrangement is used with an electrical drive, the rail efficiency is only slightly better than that of the diesel. If it is used with a mechanical drive, one finds that the starting torque of the five or six stage turbine necessary for existing gas pressures is not sufficient for good train handling and a two speed transmission with its additional complication is then necessary.

It should be emphasized that the proposed cycle was not arrived at merely for reasons of efficiency, but on grounds of general adaptability, simplicity and inherent capability for development. By suitable choice of the three basic design quantities available (overall pressure ratio, maximum cycle temperature and boiler size or effectiveness) the emphasis can be shifted among overall thermal efficiency, machinery size and cost, maintenance requirements, water consumption, etc., with a large degree of freedom, the main restriction involving the need to maintain nimble starting characteristics so that the essential feature of low consumption idling is retained. From an economic point of view, the optimum power plant is that with the lowest total operating costs comprising fuel costs, maintenance costs and capital charges. The present power plant, with moderate temperature and pressure ratio, represents a considered starting point which may well be close to a present optimum and also serves to provide experience indicating the directions in which progress must be made to reduce the total running costs to a minimum. As an example of the diversity of possibilities, an increase of maximum cycle temperature from the present level to 1000°C. may be utilized in at least three ways. Firstly without prejudice to the existing level of economy, the arrangement can be considerably simplified by the elimination of the entire low pressure compressor gas turbine system with considerable benefit to capital costs. Alternatively, both the present level of efficiency and pressure ratio may be maintained but the boiler considerably reduced in size with the resulting water consumption less than half the present level. Finally, the overall pressure ratio can be increased to 8:1 with the overall thermal efficiency increasing to values in excess of 30% and a resultant efficiency at the rail considerably greater than that possible from either the diesel or the free piston gasifier units as presently envisaged. In going to 1000°C. one could, for example, employ water spray cooling on the turbine blades which, in addition to improving the performance, could also afford protection against blade fouling and corrosion.

The fall off in power of the gas turbine as the ambient temperature rises is, of course, more pronounced than is the case in the diesel engine, but the corresponding increase in turbine power with a drop in ambient temperature seems to be the really significant feature because of the general railway requirement for increased powers in cold weather.

Starting from cold

The one hour starting time referred to in the report is for a completely cold engine and would be about the same for summer or winter conditions. While this is an appreciable time, the certainty of securing a start is inherent, a respect in which it invites comparison with either the diesel or the free piston engine under winter conditions. When the engine is in a roundhouse with steam available, the time required to bring the unit to low idle condition should be greatly reduced. From the low idle condition, the power plant is found to be very responsive and will give a performance in standing fuel costs, and time to full load about the equal of the diesel engine.

Dynamic brakes

In the report we have made no reference to dynamic brakes which have been found very useful in some regions but of little value in others. We have in mind an arrangement for dynamic braking using a water brake coupled directly to the traction turbines.

Simplicity

Mechanically the arrangement is clean. The use of a separate steam turbine is, we believe, an advantage which incidentally disposes of electrical energy storage and the use of direct current. Blowing the steam into the main gas turbine would eliminate one shaft, but would deny one of the benefits obtained from a two shaft machine. These appear to us to be considerable, particularly from the aspects of control and part load operation. There would also be an additional boiler corrosion hazard if one were to blow the wet exhaust gases through it.

Coal burning locomotive

The possibility of burning coal in a gas turbine locomotive is an intriguing concept but in practice is a much more difficult task than burning Bunker C. In addition to the problem of supplying fuel and avoiding erosion and corrosion problems, there is the added difficulty of "control" with a suitable response. For these reasons we believe the burning of coal in a locomotive can most advantageously come after some measure of success has been attained with oil fired machinery.

Water consumption

It is appreciated by the authors that the relatively large water consumption is an embarrassment, but the advantages accruing from the system proposed seemed to us worth the price. It is in fact this feature which differentiates between this proposal and a large number of others.

The boiler has sufficient capacity to supply the 6000 lb./hr. of steam for train heat in addition to the compressor work, and a pressure of 250 p.s.i. as suggested is practicable although we have chosen 150 p.s.i. with more superheat as being preferable for the engine itself.

We appreciate very much the suggestion that, with the rate of water consumption we have proposed, a tender supply of 10,000 gallons would ensure uninterrupted running over a railway division. While we foresee ways of reducing water consumption to a fraction of that now proposed (with elimination of the tender or extension of running to several divisions), we again draw attention to the special advantage of certain uses of steam. Apart from the questions of efficiency and fast starting set out in the paper, there are a number of other important implications. The storage and generation of starting energy as steam eliminates entirely the need for storage batteries, controls and a d-c. electrical system. The use of three phase alternating current with standard industrial squirrel cage motors seems to us to be an important advance in reliability, simplicity and cost.

THE INTERCONNECTED POWER SYSTEMS OF NOVA SCOTIA AND NEW BRUNSWICK

G. D. Mader, P.Eng., *Chief Engineer*
Nova Scotia Power Commission
Halifax, N.S.

THE INTERCONNECTION of the electrical power systems of Nova Scotia and New Brunswick is expected to be accomplished by March 1960. Participating utilities are the New Brunswick Electric Power Commission, the Nova Scotia Power Commission, and the Nova Scotia Light & Power Company Limited. The interconnection involves the construction of 105 miles of single circuit 138 kv. transmission line and the expansion and modernization of five substations, together with necessary relaying, metering, carrier control and communication equipment.

Fig. 1 shows the general service areas of the participants. The area served by the Nova Scotia Power Commission is divided by that of the Nova Scotia Light & Power Company. The New Brunswick Electric Power Commission is separated from the Nova Scotia Power Commission by the service area of the Canada Electric Company. For the purpose of the interconnection, the Canada Electric Company is considered as part of the Nova Scotia Power Commission's system. These two utilities have had an interconnection for some years and it is felt that this additional expansion can be more conveniently handled by one utility. Included within the interconnection agreement will be roughly 67% of the generating facilities of the two provinces. Private industry, municipalities, the Seaboard Power Corporation in Cape Breton and the Gatineau Power Company in northern New Brunswick supply the remainder.

The three participants are practically equal in size and their loads are approximately the same. At the present time the loads of both the Nova Scotia Light & Power Company and the New Brunswick Electric Power Commission are increasing at a somewhat greater rate than the load of the Nova Scotia Power Commission.

The interconnection of two or more generating systems always reduces the amount of generating capacity to be installed as compared with that which would be required without the interconnection. The amount of such reduction may be small or large depending on the interrelation of the various factors and characteristics of the interconnecting systems and the level of service reliability. The installation of the transmission facilities that are necessary to bring about the interconnection may or may not be justified. This fact can be determined only by a proper economic comparison of the alternate installation.

In May of 1957, engineers from the three participating utilities, together with other interested parties, conducted a series of loadflow studies on the Westinghouse a-c Network Calculator at Pittsburg to check performance of the interconnected systems and to get an indication of conductor size and voltage level requirements of the tie lines. These studies clearly indicated the interconnection technically feasible.

Subsequently, management set up an engineering committee composed of staff of all three utilities for the express purpose of determining the economics of the interconnection. From the data obtained at the Pittsburg studies, capital expenditure for tie lines, substations and related equipment was estimated at $4 million. It remained to be shown what capital savings could be effected because of reduced reserve requirements under interconnected operation.

Probability theorems were used to compare the reserve position of each utility with that of the proposed interconnected system for varying degrees of service reliability. This approach was necessary because none of the participating utilities had identical reserve policies. To compare the capacity required of one utility to carry out its load responsibility with the same degree of reliability as another would otherwise have been difficult.

Partial results of this study are shown in figs. 2 and 3. Fig. 2 is computed for a service reliability of

one day in five years, that is to say, with the amount of capacity shown there is a probability of not being able to carry the load (all or any part of it) of one day in five years or an outage probability of 0.2 days per year. Results for the four years, 1959 to 1962, are shown. Other years will be similar. Fig. 3 is plotted for the year 1961. The ordinate represents the probability of failure in days per year while the abscissa shows the installed capacity in megawatts. Note that as the reliability is increased (or the probability of outage is decreased) the installed capacity for separate operation increases at a far greater rate than that for interconnected operation, e.g., with a peak load on the system of 490 mw. and a reliability level of one day in five years, the interconnected system would require 52 mw. of reserve capacity. If, however, the utilities operated independently they would require a total of 224 mw. or roughly 4 1/3 times as much.

Fig. 1. Interconnected Utilities — areas served by generation.

The results of the study shown graphically in fig. 2 can be tabulated as in table I.

Estimating the capital cost of interconnecting existing facilities as $4 million and annual carrying charges as 7%; and the capital cost of capacity as $150 per kw. and annual carrying charges as 8%; then the annual dollar benefit is as shown in Table II.

Another result of this study was to show that on an interconnected basis, a reserve of approximately 12% of system peak would be required for an acceptable degree of service reliability. All three utilities have been carrying reserve approximately 30 to 40% of their peak loads because of established reserve policies.

After due consideration of the results of this study, the three utilities mutually agreed to proceed with the interconnection and directed the engineering committee to complete design of interconnection facilities. At the same time an operating committee was appointed to draft a suitable interconnection agreement.

Of necessity there has been close liaison between the engineering and operating committees. It was agreed in early discussion that the main purpose of the tie transmissions would be to supply reserve power between utilities in case of emergency. It was recognized that firm power interchange would in all probability require double circuit 220 kv. transmission which would nullify the economic benefits of the interconnection, at least at the present time. It was decided that in general the capacity installation of any utility would not be permitted to fall below the peak load of that utility. For this reason tie line flows would be restricted to a maximum of about the capacity of the largest unit on the system at the time.

The design of the interconnecting facilities was well advanced early in 1958. Final decision on conductor size and voltage level was withheld however, and no equipment orders were placed pending confirmation of the results of our studies by another network analysis which was undertaken in April of last year.

This study resulted in the final choice of a 138 kv tie line using a 556,600 circular mill ACSR conductor. Transformer types, sizes and tap range were established along with circuit breaker ratings, stability limitations and reactive requirements.

Loadflow studies were carried out to check operation on a maximum transfer of 100,000 kw. either from Nova Scotia to New Brunswick or vice-versa. This transfer appeared possible under emergency conditions; normal operating conditions may be lower than this level for some time.

Loadflows were also checked to provide operational data such as voltage levels, var flows and system losses.

The systems were checked for both steady state and transient stability in accordance with the best advice available regarding critical points of the interconnection. No particular technical problems were encountered.

The Engineering Committee have now decided on a uniform design for the entire interconnection. It is to be a steel tower line with double overhead ground wires and counterpoise where necessary. Power line carrier communication with provisions for

1961	490	714	542	172
1962	541	772	606	166

Table II

Year	*Capacity*	*Interconnection*	*Benefit*
1959	$1,080,000	$280,000	$ 800,000
1960	1,548,000	280,000	1,268,000
1961	2,064,000	280,000	1,784,000
1962	1,992,000	280,000	1,712,000

relaying, telemetering and supervisory control has been chosen for the entire link.

The choice of 138 kv. for tie line voltage was indeed a fortunate one since both the Nova Scotia Power Commission and the New Brunswick Electric Power Commission had some 138 kv. lines either under construction or in operation before decision was reached to interconnect. The Nova Scotia Power Commission had the section of line from Trenton to Onslow and from Onslow to Maccan constructed for 138 kv. but operating at 69 kv., while the New Brunswick Electric Power Commission had a considerable amount of their 69 kv. grid overlaid with 138 kv. transmission.

The three utilities have now all accepted in principle the agreement submitted by the operating committee. This agreement provides for the seting up of an administrative committee composed of one representative of each utility to: (a) Interpret the provisions of the agreement, (b) Consider load forecasts and schedule generation. (c) Supervise the operating committee.

The operating committee will be composed of one representative and an alternate from each utility and will be responsible for: (a) Scheduling of daily spinning reserve and daily placing of orders, (b) Scheduling maintenance, etc.

It is anticipated that the systems will always be operated in parallel and that a plan will be set up for frequency regulation. Kilowatt hours will be exchanged on a scheduled basis only, and spinning reserve will be allocated between the parties.

Reserve capacity limits for the interconnection have been established between a minimum of 10% and as close to a maximum of 15% as practicable. Each utility will be required to contribute a reserve capacity equal to its peak load times the percent reserve determined as adequate for pool operation or pay at the rate established in the Agreement to others carrying it. At the time a new unit is to be installed to retain the desired system reserve ratio, it will be the responsibility of the participant having the lowest reserve ratio at that time to install the necessary unit. Many alternate patterns of installation are possible under the terms of the agreement. Naturally any pattern will be under continuing review and adjusted as actual load conditions deviate from those forecast.

Peak loads shown are outgoing feeder peaks and installed capacity

represents net capacity after allowing for station service. It will be noted that for the three years 1959-61 system reserve is considerably above that which is necessary. This is because certain unit installations were committed before agreement to interconnect was reached. A condition of the agreement provides that no deficiency payments shall be made between parties unless or until the system reserve ratio drops below 15% or the reserve ratio of an individual utility drops below 10%. This would happen in 1962 if new capacity is not added at that time. From this year onward, utilities having a reserve percentage lower than the system reserve percentage will pay capacity deficiency payments to the utility or utilities having a greater than system percentage reserve.

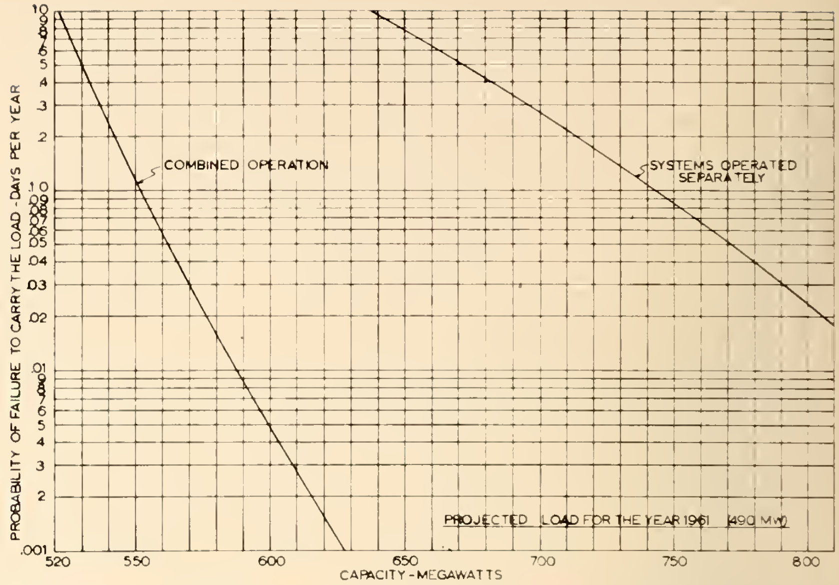

Fig. 3. Probable average frequency of occurrence of failure to carry the load for the year 1961.

The largest size thermal units at present operating in either Nova Scotia or New Brunswick are 50 mw. installations. The Nova Scotia Light & Power Company have two of these installed in their Water Street plant. The New Brunswick Electric Power Commission's Saint John plant will have a 50 mw. machine operating in 1961. The interconnection makes it possible, as well as economical, to bring into service in 1963 75 mw. units and in 1966 100 mw. units, which we feel would not have been advantageous with separate operation. It is interesting to note that decision to interconnect has already permitted deferment of additional units at Trenton and Tuft's Cove.

It is felt that the capital savings alone are sufficient to justify the interconnection. Other benefits come from the installation of larger units of better efficiency, exchange of surplus energy, and the opportunity of being able to postpone the installation of a new unit by purchasing a share in a large unit of a neighboring utility. This unit participation scheme could become one of the more valuable sections of the interconnection.

Possible future members of the interconnection could be the Seaboard Power Corporation in Cape Breton and the Gatineau Power Company in northern New Brunswick. Both of these organizations, although not as large as the three participating utilities, supply a substantial portion of the Maritimes load, and besides benefiting the interconnected system, should gain from it.

There exists at present a tie between the New Brunswick Electric Power Commission plant at Beechwood and the Flo's Inn Substation (Presque Isle) of Maine Public Service Company. The New Brunswick Electric Power Commission also has a number of ties in the northern part of the province with the different paper companies in that area. Both utilities in Nova Scotia have similar but smaller ties with industry and municipalities. Possible ties in the future may be with Prince Edward Island and through the New Brunswick Electric Power Commission to various utilities in Maine and Quebec.

New developments in the near future are a thermal station at East Saint John for the New Brunswick Electric Power Commission, one at Tuft's Cove (near Halifax) for the Nova Scotia Light & Power Company and a 74 mw. hydro installation at Wreck Cove (in northern Cape Breton) for the Nova Scotia Power Commission.

To sum up, we must say that we expect to derive greater benefits from the interconnection as it progresses and as the participating utilities become more familiar with the savings to be gained from one system operation. This of course will only come with the passing of years during which the individual participants will become more accustomed to group operation. We think that the savings and benefits derived from the first few years of operation will enable the participating utilities to see the advantages that can be theirs with a spirit of cooperation. We shall be able to achieve the savings of large system operation while retaining our independence.

As the load in the Maritimes increases so will the value of the interconnection, and we trust that this is only the first step toward better and cheaper power production in the Atlantic Provinces.

WHITEDOG FALLS AND CARIBOU FALLS GENERATING STATIONS

Hydro-Electric Developments on the Winnipeg and English Rivers

N. S. Haines, M.E.I.C., *Project Engineer*
The Hydro-Electric Power Commission of Ontario

TO MEET the increasing demand for power in its Northwestern Region as in all sections of the Province, it has been necessary for the Ontario Hydro to maintain a continuous program of development of new power sites. The following is a description of the development of two of these sites—Whitedog Falls on the Winnipeg River and Caribou Falls on the English River, which were constructed as a combined operation. The construction of Whitedog Falls Generating Station was authorized on August 8, 1955. Eight months later it became apparent that still more power would be required shortly to meet the anticipated demand, and the construction of Caribou Falls Generating Station on the English River was authorized.

In Ontario, the two main branches of the Winnipeg River are the Winnipeg flowing northwest from the chain of lakes that forms the boundary between Canada and the United States immediately west of the Great Lakes, and the English flowing from the northeast. Tetu Lake at the confluence of the two tributaries is the common tailwater of both the stations described. The combined outflow from Tetu Lake passes over Boundary Falls and continues as the Winnipeg River, emptying into Lake Winnipeg. The provincial boundary lies one mile below Boundary Falls. Downstream from Boundary Falls through Manitoba to Lake Winnipeg, the total head of about 256 ft. has been fully developed in six plants, each with an installed capacity to use about 30,000 cu. ft. per sec. (see Fig. 1).

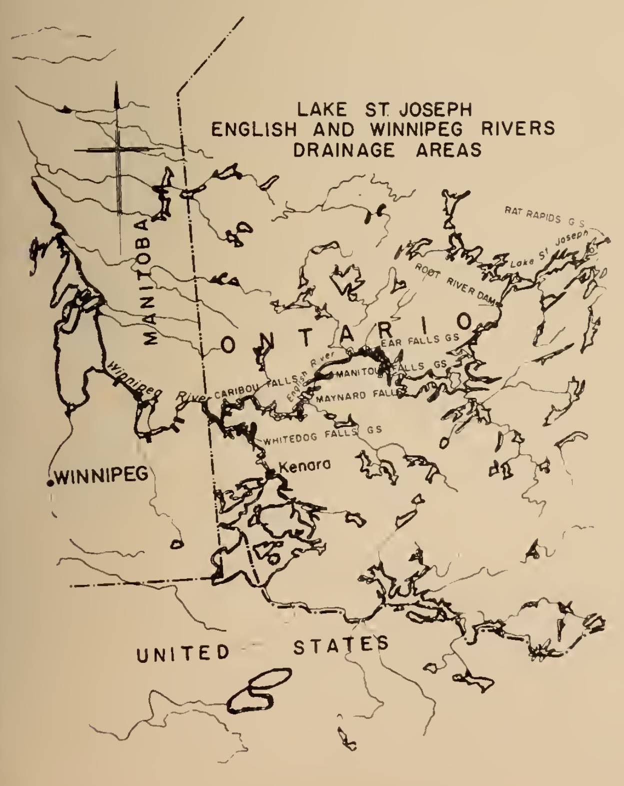

Fig. 1. Drainage area Winnipeg River.

Whitedog Falls is 17 miles north of Minaki, which is on the main line of the Canadian National Railway. The rated head is 50 ft. and the rated capacity 81,000 b.h.p. Caribou Falls is 17 miles farther to the northwest and has a rated head of 58 ft. and a rated capacity of 102,000 b.h.p.

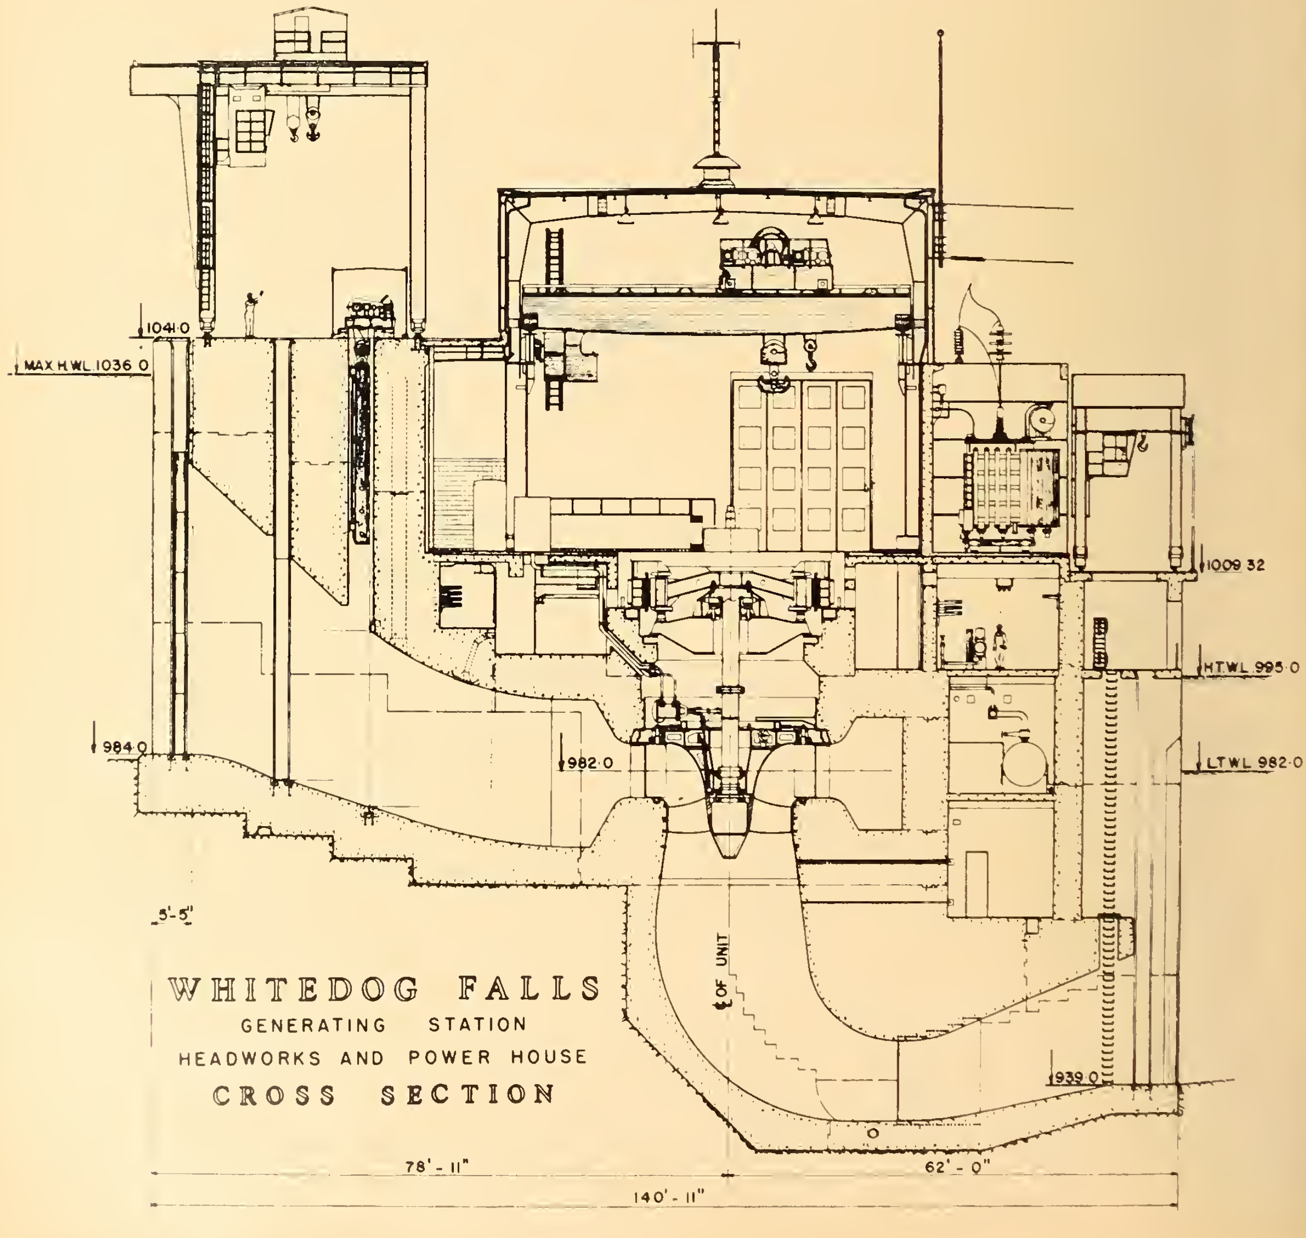
The Lake of the Woods, from which the Winnipeg River issues at Kenora, is an international lake, and its outflow is regulated by a control dam and four privately owned power plants. Under normal conditions responsibility for the lake levels and discharge is vested in the Canadian Lake of the Woods Control Board. Under conditions of extreme high or low water, this responsibility reverts to The International Lake of the Woods Control Board. The control works have a maximum discharge capacity of 50,000 cu. ft. per sec. and provide 4,990,000 acre-ft. of storage. The total fall in the Winnipeg River from below the Norman Dam at Kenora to the foot of Boundary Falls is about 54 ft.

Lac Seul, from which the English River issues at Ear Falls, is regulated by a control dam at its outlet. Responsibility for the regulation of Lac Seul is vested in the Lake of the Woods Control Board. This lake provides 4,530,000 acre-ft. of storage. Ontario Hydro operates the Ear Falls Generating Station at the control dam and about 20 miles downstream is located the recently constructed Manitou Falls Generating Station. The total fall in the English River from the tailrace at Manitou Falls to the foot of Boundary Falls is approximately 94 ft. This fall occurs as a series of rapids in the river section between intervening lake areas.

Preliminary Investigation

The original surveys of the various sites on the English River between Boundary Falls and Lac Seul were conducted by the Manitoba Hydrographic Surveys under the direction of the late M. C. Hendry, MEIC. In 1930 the Ontario Hydro and Dominion Government survey agencies expanded this information and secured topographic information on the Winnipeg River from Boundary Falls to Kenora. In 1951 an extensive survey was made of the Boundary Falls site to use the combined flow of both rivers in one plant under a head of about 50 ft. Studies made using this information indicated that development of Boundary Falls would be costly due to the extensive side dams and the clearing of large areas that would be flooded. The improved reliability of remote-controlled stations, with the resulting savings in colony costs that occurred at this time, now favoured the construction of multi-stage developments. In 1953 a survey of the upstream sites was undertaken to establish the best pattern for the development of the rivers. The pattern finally selected was to develop the full remaining head on the Winnipeg River at Whitedog Falls, the headpond of this plant to flood back to the tailwater level of the plants at Kenora. Since the tailwater of Whitedog Falls would be Tetu Lake, it was proposed to utilize the total fall by making channel improvements at Boundary Falls that would lower Tetu Lake. The pattern chosen for the English River was to develop 58 ft. of head at Caribou Falls site, which would also benefit from the channel improvements at Boundary Falls, and develop at some future date the re-

Fig. 2. Section Whitedog Falls powerhouse.



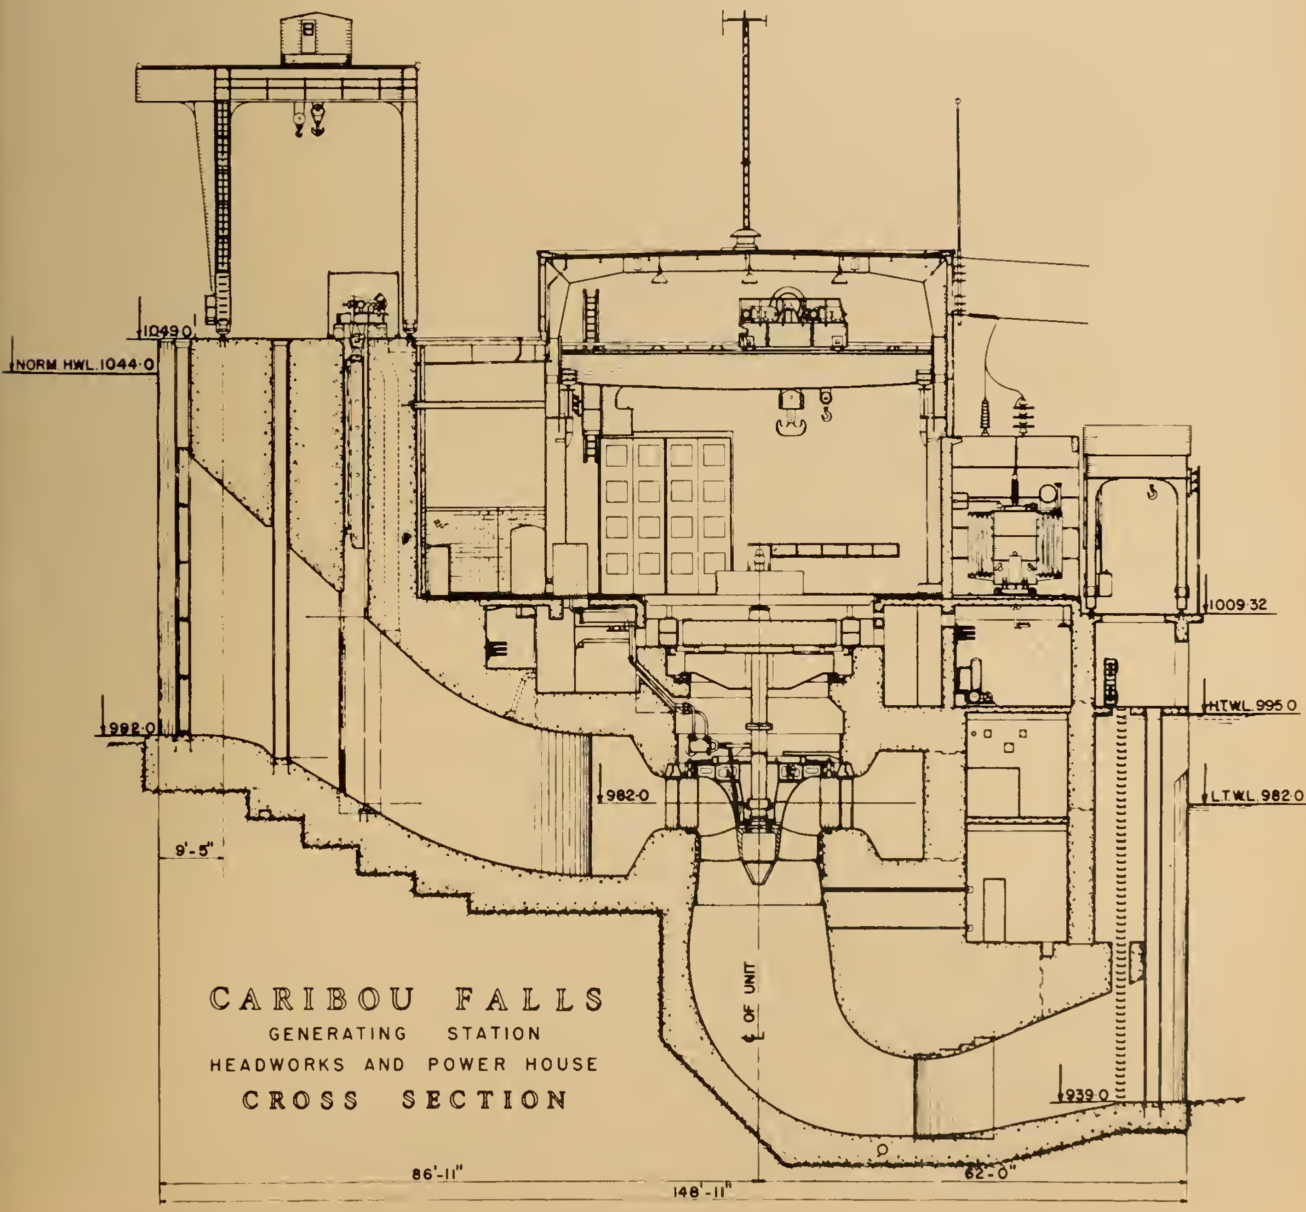
maining 36 ft. of fall on the English River at Maynard Falls.

Turbine Selection

The Northwestern System of the Ontario Hydro is not connected with the systems in the other section in the Province, but it is interconnected with the Manitoba Electric System, which contains both hydraulic and thermal stations, and thermal stations for the Northwestern Region were being considered. These conditions indicated that a low load factor plant would be advisable at Whitedog Falls. Also of a total drainage area of 27,170 sq. miles on the Winnipeg River, all but about 1,000 sq. miles were above the Lake of the Woods control dam, which has a storage volume of 184 acre-ft. per sq. mile of drainage area. The shape of the duration curve could therefore be varied to suit many conditions. The flow required on weekdays by the plants at the outlet of Lake of the Woods is constant, with the shutdowns during week-ends. The Whitedog headpond has an area of 33,000 acres, but since part of it is in a highly developed summer resort area, riparian owners would object to large fluctuations of water level. The present rule curve used by the Lake of the Woods Control Board produces a duration curve that would indicate an installed capacity to use a flow of 14,000 c.f.s. at Whitedog Falls at 60% load factor. An economic study showed that the incremental energy cost equalled that of thermal energy when the installed capacity uses a flow of between 16,000 and 17,000 c.f.s. The selection of this capacity was based on a duration curve of the Winnipeg River regulated for the maximum energy output such as might be desired when Ontario and Manitoba have developed substantial thermal-electric capacity. The studies indicated the economic limit of installation to occur with a maximum turbine discharge equal to the flow available 25% of the time. Under 50 ft. of head and at 88% efficiency, this gave a turbine output of approximately 81,000 b.h.p.

Maintenance conditions of a remote-controlled station such as Whitedog would indicate a smaller number of large turbines. Operating flexibility for maximum efficiency with varying flow conditions indicates a larger number of smaller

Fig. 3. Caribou Falls powerhouse section.



units. Five units similar to those previously installed at the Commission's Manitou Falls plant would meet the latter condition. The power was urgently needed, and units of this size could be procured without allowing much time for engineering and tests. On the other hand, the large number of units would require a longer installation period. Turbines of a size to develop this power under 50 ft. of head in one or two units were not in common use and considerable time would be required for engineering and model tests. A compromise was made and three units of 27,000 b.h.p. were decided upon. These units would have hydraulic characteristics similar to those at Manitou Falls and a physical size approximating the units at the Chenaux Generating Station built in 1950. It was known that such units could be procured within a reasonable time and preliminary estimates indicated some saving in cost as compared with a five-unit plant. The three turbines as purchased for the Whitedog Falls Generating Station were rated at 27,000 b.h.p. under 50 ft. head and at a synchronous speed of 105.9 r.p.m. Under these conditions the guaranteed efficiency was 90.3% and the discharge per unit 5,200 c.f.s.

Fig. 4. Whitedog Falls first stage unwatering.

Preliminary studies for Caribou Falls using similar basis and a duration curve for the English River indicated the use of two 46,500 b.h.p. units. To make the most efficient use of the water, Kaplan type turbines were considered. A further increase in the anticipated demand for power made the diversion of an average of 2,800 c.f.s. from the Albany River watershed to the English River desirable. This water would develop an additional 250,400,000 kwh. annually in plants already constructed on the English River or under active consideration. This increase in flow of 2,800 c.f.s. made the economic capacity of Caribou Falls larger, and three units of somewhat smaller individual capacity now appeared more appropriate. With three units and a large headpond it was felt that there was sufficient operating flexibility to use the water efficiently in fixed-blade turbines. Also an additional transmission line was being added to the Northwestern System, which would reduce the percentage of time that Caribou Falls Generating Station would be used for tie line load regulation. Kaplan type turbines were more expensive and the delivery time would be longer than for the fixed-blade type. The capacity chosen for the plant was 102,000 b.h.p. developed in three propeller type turbines at 34,000 b.h.p. each, under 58 ft. of head, with a synchronous speed of 112.5 r.p.m. and a discharge of 6,250 c.f.s. per unit. A duration curve prepared from English River flows plus the diversion from the Albany shows flow for this capacity to be available 25% of the time.

Similar units to those supplied for Whitedog Falls were provided, adjustments being made for the greater head and output. This proved to be a great saving in time and money as the turbines could be delivered within a minimum time and numerous parts were interchangeable between the two plants. Since the water passages and spacings were the same, the substructure drawings for Whitedog Falls could be revised and used for Caribou Falls (see Figs. 2 and 3).

The turbine analysis for both plants was based on synchronous speeds and settings which will allow operation under full gate without limitation of turbine capacity on account of cavitation restrictions at either rated head or maximum head. A band on the back or under side of the blades extending 24 in. in from the periphery was required to be coated with 1/8 to 3/16 in. of stainless steel as a further precaution against cavitation.

For both plants the generator capacity was based on the expected maximum output of the turbine rather than on a normal output of the machine based on its nominal rated capacity. The generator capacity chosen was such that when the turbine operates at maximum expected output, the generator will be operating at 10% over-rated capacity. The

Fig. 5. Whitedog Falls second stage unwatering.

transformer capacity was based on maximum turbine output less losses to the output side of the transformer.

Whitedog Falls Site

Above Whitedog Falls the Winnipeg River divided into two channels forming Whitedog Island. The north channel was small and under normal flows carried about 10% of the flow. The drop in this channel occurred as a series of rapids. The south channel, which carried most of the flow, passed through several rapids and swifts with the main pitch near the downstream end of Whitedog Island. The surveys undertaken in 1953 indicated two possible sites for the dam line. One site was at the extreme downstream point of the island, and the other slightly upstream at the foot of the main falls. On May 16, 1955, detailed surveys were commenced. The sites were investigated on a comparative basis by geological mapping, a seismic geophysical survey, and a limited amount of diamond drilling. Estimates were made as this information was received, while the investigation was in progress. These estimates favoured construction at the upstream site. The surveys and geological investigation were then concentrated on this site during the late summer and fall of 1955. The sites of two block dams required were also investigated; one at the head of the north channel, the other in a draw on Whitedog Island.

The overburden in the area consisted of alluvial clay overlying granular soils. The clay is more or less continuous except at points along the river bank or along flanks of rock outcrops where granular soils are sometimes exposed.

The underlying granitic type bedrock was exposed in the river channel and on both banks. Many surface slab fractures occurred but diamond drilling showed these did not extend to depth. The diamond drilling revealed that two zones of altered and fractured rock crossed the proposed dam line and these zones would require grouting. The altered zones were tight at greater depth.

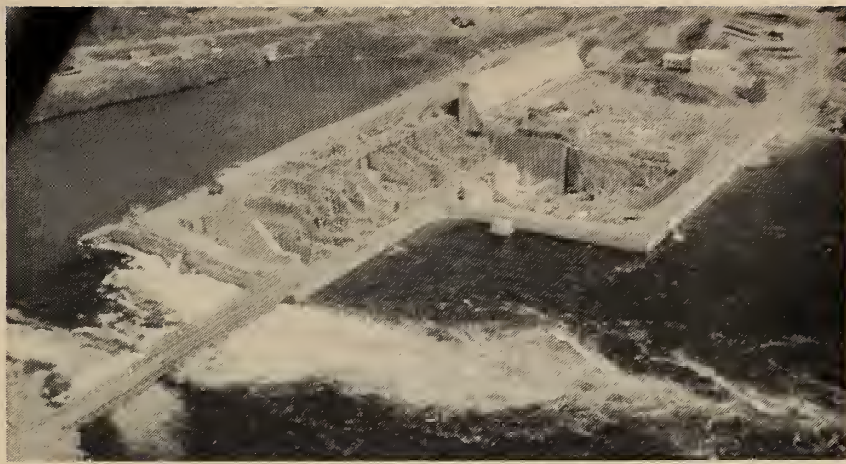


Fig. 6. Caribou Falls first stage unwatering.

Caribou Falls Site

Caribou Falls is located 8 miles east of the Manitoba border at the outlet of Umfreville Lake, which forms the headpond, and just upstream from Tetu Lake. The surveys of 1953 had indicated two possible dam lines at this site. One site was a short distance above the falls and the other was along the crest of the falls. Sufficient topographical and geological information was taken during the summer of 1955 to make comparative estimates of the two possible sites.

On the upper line granitic rock was exposed on the right bank and continued under the river. On the left bank outcrops of sedimentary gneisses were exposed, thinly overlain in places by shallow deposits of coarse brown sand formed by weathering of the rock. At the line along the crest of the falls the granite was exposed on the right bank and in the river section. The left bank was overburden composed of sandy silt overlain by a buff clay. This overburden extended back from the river about 1,000 ft., where there was a granite knob outcropping. A saddle between this outcrop and the gneiss outcrop on the upper dam line was filled with overburden and was possibly an old river channel. Estimates indicated the lower line along the crest of the falls to be the most economical. Further geological and topographical information was taken during the early summer of 1956 on the chosen dam line and on the sites of four block dams required. All the block dams were in rock saddles partly filled with the overburden typical of the area, that is, firm buff clay overlying dry sandy silt with perched water tables lying on the top of the clay, the top layer of which had a high organic content. Two of the block dams were on the right bank some distance from the end of the main dam. One on the left bank was near the end of the main dam and the other was 10 miles to the southeast between the English and the Winnipeg River watersheds.

Fig. 7. Caribou Falls second stage unwatering.

Description of Developments

Hydraulic studies indicated 1036 as a desirable normal headwater level at the Whitedog Falls plant. This allowed for 1 ft. of loss in the river channel back to Minaki after channel improvements were made at the head of the Whitedog Falls gorge to reduce the gradient loss through this constriction. The mean low tailwater was set at 982, with channel improvements required at Boundary Falls to achieve this. This elevation will vary with flow conditions. The hydraulic studies showed that high water during flood flow above Minaki would not be higher than in the state of nature. The structures were designed on this basis, with the powerhouse and the headworks located in the river channel near the left or southwest bank and with the erection bay on the shore side, as this was the direction from which the road would reach the plant. The gravity type bulkhead wall extends from the headworks to the 1041 rock contour on the left bank. On the right of the powerhouse is a short bulkhead section with a storage well for service gates. Beyond this is a sluiceway section with nine sluiceways and a log chute headblock. A further section of bulkhead wall ends in a wing wall and short core wall for connection with the earth fill dam which extends to the right bank.

All concrete sections of the dam and headworks were designed to elevation 1041 to allow 5 ft. of freeboard above the regulated high water level. The earth section was designed with a top elevation of 1044, providing 8 ft. of freeboard. It was known that the construction of Caribou Falls would begin in the near future and the access road to this site would have to cross the Winnipeg River. Therefore, the deck of the dam and headworks at Whitedog were designed with sufficient width for use as a single lane roadway.

All concrete sections of the dam and headworks were designed for the following load conditions:

1. Horizontal pressure on the upstream face due to water in the forebay at elevation 1036;

2. Horizontal pressure due to ice assumed to be 10,000 lb. per lin. ft. on concrete and 5,000 lb. per lin. ft. on steel gates, applied at elevation 1035;

3. Uplift on the base of the dam over two-thirds of the area assumed to be full head at the upstream face and decreasing uniformly to zero or to tailrace pressure, if any, at the toe;

4. The unit weight of concrete was taken at 145 lb. per cu. ft.

The controlling requirements for the top width of the bulkhead section was its future use as a roadway and the top width was made 16 ft. The bulkhead section was laid out to be poured in sections 30 ft. long. The highest pour was about 30 ft. Drains were provided near the upstream face at rock level and at horizontal and vertical construction joints, with plastic waterstops across the construction joints upstream from the drains.

The sluiceway section comprises 9 sluices controlled by steel gates. The clear opening of each sluice is 18 ft. in width and the sill is 25 ft. below regulated water level. The total discharge capacity of the sluices is approximately 74,000 cu. ft. per second. This was based on the present capacity of 50,000 cu. ft. per sec. at the control works at Kenora plus possible additions. Two of the sluice gates are screw operated from an overhead bridge. These two gates have a discharge capacity approximately equal to the plant flow and they can be remote controlled either from the powerhouse or from the Kenora control room. The remaining seven gates are operated by the headworks travelling gantry crane. Five of the crane-operated gates are designed for dogging in the fully open position. The remaining two gates located adjacent to the screw-operated gates are designed to be dogged at 6 ft. open and 12 ft. open, in addition to the fully open position. As there is no log driving on this reach of the river at the present, a log chute headblock only was installed and the opening was closed by a removable concrete slab.

Fig. 8. Whitedog Falls powerhouse construction.

The headworks forms part of the dam and is in line with it. The concrete setting and headworks for each unit was designed as a separate structure. An expansion joint extends from forebay to tailrace between each unit and between the units and the bulkhead walls. No reinforcing or ties were allowed to cross these joints. There are three openings in the headworks for each unit. Each opening is 15 ft. wide and is provided with racks and a headgate. Between the racks and the headgate there is a check for service gates. Each of the nine headgates has individual hoists. The lip of the intake at the upstream face is at elevation 1024 and the sill is at 984. This gives a suburgence of 12 ft. and a velocity considering the gross area at the racks of 2.9 ft. per sec. at rated load. The water passage continues at 15 ft. wide past the headgate. The headgate sill is at 977 and the lintel of the opening is at 1001, the velocity at this point under rated load being 4.8 ft. per sec.

Drains and plastic waterstops were required at all construction joints in the headworks, subject to water pressure. The headworks is connected to the powerhouse by a short transition section and is dependent upon the powerhouse to meet the stability requirements previously noted.

The design requirements for Caribou Falls Generating Station were the same as those at Whitedog Falls except that the head was 58 ft. rather than 50 ft. and the deck of the dam and headworks were not designed for use as a road. The area at the racks is the same and the velocity of the water is 3.47 ft. per sec. The headgate opening is 27 ft. high and the velocity is 5.14 ft. per second at rated load. The layout was very similar and the structures had the same relative location, except that an earth fill dam was required on the left bank at Caribou Falls. No core wall or wing wall was used and the earth fill was allowed to wrap around the end of the bulkhead section.

The draft tubes are of the elbow type and are skewed 3° 46′ 41″ to the left of the upstream and downstream centre line. Each unit has two openings with a 6-ft. wide centre pier.

The exit velocity is about 6.3 ft. per sec. under full load. The bottom of the draft tube is 48 ft. below the centre line of the distributor and it extends 62 ft. downstream from the centre line of the unit. The sill of the draft tube outlet is at elevation 939.0 and the lintel is at 957.0 on the centre line. The face of the lintel above the opening was marked on the drawings to be poured to exact dimensions so that the tailrace service gates could be sealed against this surface. Sufficient gates were provided to close all draft tubes from sill to lintel. The gates were to be placed before the tailrace was flooded and sealed at the lintel in the dry. This allowed the tailrace to be flooded before the units were complete. When it is necessary to unwater a draft tube for maintenance there are sufficient gates to close one unit from sill to above high tailwater level, and it will not be necessary to make a seal at the lintel although this has been done on occasion. The draft tube liner and throat ring are 17 ft. in diameter and extend about 10 ft. below the lower ring.

The concrete scroll case has a maximum internal diameter of 55 ft. and the units are spaced at 65-ft. centres. There is no lower stay ring on the turbine and the lower ends of the stay vanes rest on steel pads set in concrete. The scroll case floor was poured in three sections, two flat sections covering the full area, the cone around the unit being the third section. Cutouts were left for the embedded parts and these were grouted in later. The walls and roof were poured separately, the roof originally being designed to be poured in seven sections, but this was later changed to a single pour. All construction joints in the scroll case subject to water pressure were provided with drains and plastic waterstops.

The generators are umbrella type and the generator pedestals rest on the scroll case roof. Walls extending upward from the pedestal to the operating floor enclose the generator area. The only part of the generator above the operating floor level is the exciter and the permanent magnet generator for the governor.

The powerhouse superstructure is a rigid frame steel building, about 58 ft. wide and 260 ft. long including the erection bay. The building is covered with aluminum siding. The transformers are located on the downstream side of the powerhouse on the tailrace deck at operating floor level. Each transformer is surrounded on three sides with concrete flash walls, the upstream

Fig. 9. Whitedog Falls generating station.

wall forming part of the powerhouse wall and acting as a stiffener in the longitudinal direction. A lower steel frame structure to the right of the transformers and attached to the main building houses the metalclad switch gear.

The area between the generator room and the headworks opposite the erection bay and No. 1 unit contains the control room, meter room and temporary living quarters for operating and maintenance personnel. A penthouse on the roof of this area contains ventilation and air-conditioning equipment for the rooms below.

Electrical Equipment

Umbrella-type machines were purchased for both but the design of the supporting brackets was different, as was the location of the cooling coils, which results in different generator pedestals. This is the major difference between the substructures of the two powerhouses. The Whitedog generators are each rated at 24,000 kva., 13.8 kv., 3 phase, 60 cycle, 105.9 r.p.m., 90% power factor. The Caribou Falls generators are each rated at 28,500 kva., 13.8 kv., 3 phase, 60 cycle, 112.5 r.p.m., 90% power factor. Class B insulation was used by both manufacturers and the generators were designed to deliver their rated output without the temperature exceeding 60°C above ambient. The units are capable of operating at an overload of 15% in excess of their rated load without the temperature exceeding 80°C above the ambient. The ambient was assumed to be 40°C. The generators are cooled by a closed air system with air to water heat exchangers. Provision is made to bleed off ventilating air for powerhouse heating. The dampers for controlling the powerhouse heating air close automatically if the carbon dioxide fire protection system on the units is tripped. At Whitedog the generator air system is separated from the turbine pit by a steel plate membrane between the bracket openings. At Caribou Falls the generator pit is open to the turbine area. Each machine is provided with three current transformers on the neutral end of each phase located in the air housing. A primary balanced type current transformer for split phase protection is provided on the line side of each phase. Automatic high speed continuously acting voltage regulators of the static type are provided at each plant with motor-operated voltage adjusting rheostats.

The low voltage switching located on the downstream side of each powerhouse contains three breakers for the generator circuits and two for station service rated at 14.4 kv., 1,500 amperes, 1,000,000 kva. The circuit breakers are metal-enclosed air blast type. At Caribou Falls provision is made to add a breaker for the future supply of local power.

The step-up transformer banks at both stations consist of three single-phase oil-immersed forced air cooled transformers. The transformers at Whitedog Falls are rated at 25,000 kva., 13.5-138 kv. At Caribou Falls the rating is 27,500 kva., 13.5-138 kv. A spare transformer is provided at each station. The high voltage side of each bank is wye connected and the low voltage side is delta connected. Two station service transformers rated at 1,200 kva. are provided at each station. The high-voltage switching for both stations is located at Whitedog Falls. At Caribou Falls provision is made for transformers for future power requirements in the area. These transformers will be located outside the east wall of the powerhouse at the toe of the dam. The generators and switching can be operated from the control room in each station or from a central control room in the Kenora Transformer Station. The sluice gates are operated from the deck of the dam or Kenora Transformer Station. The headgates may be lowered by remote control but must be raised from the headworks hoist house. Contacts are provided so that full remote control of the headgates may be installed in the future if it is required.

Supervisory control equipment, operating via a power line carrier link, is utilized for remote operation of the plants. At present 41 operations at Whitedog Falls Generating Station and 25 operations at Caribou Falls Generating Station can be controlled from Kenora Switching Station. Supervision of equipment at the controlled stations is maintained by light indication on each control feature and approximately 90 alarm indications at each plant. Generator watts and vars are telemetered continuously, while 24 quantities are telemetered on an "as called for" basis.

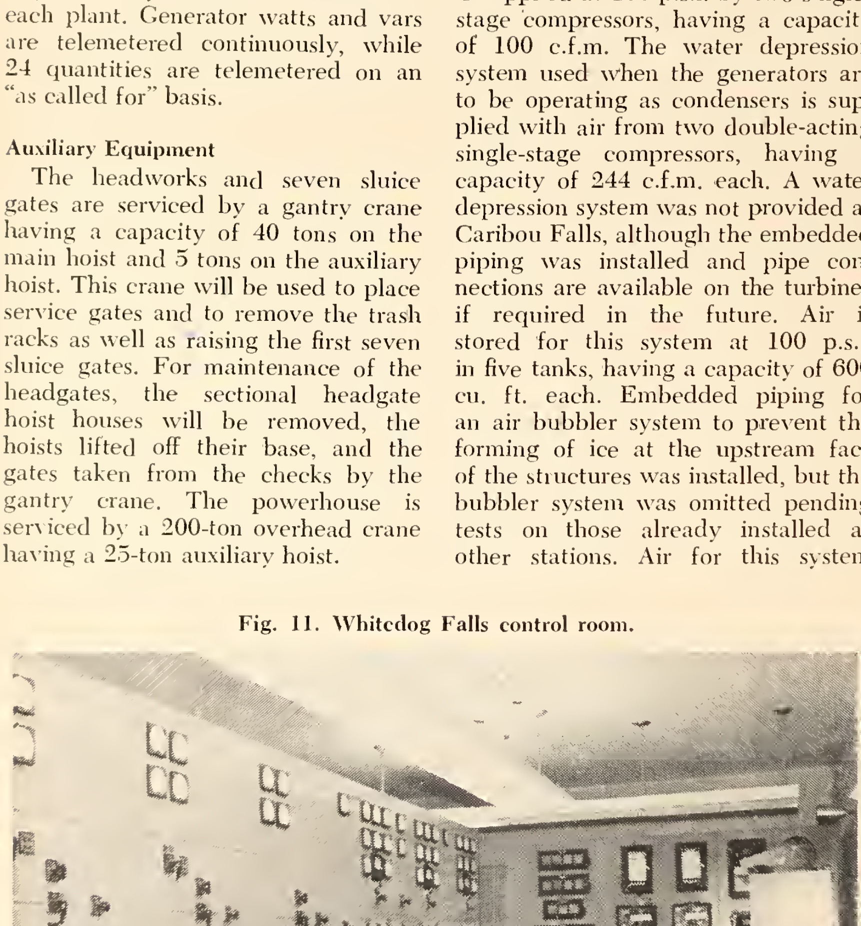
Auxiliary Equipment

The headworks and seven sluice gates are serviced by a gantry crane having a capacity of 40 tons on the main hoist and 5 tons on the auxiliary hoist. This crane will be used to place service gates and to remove the trash racks as well as raising the first seven sluice gates. For maintenance of the headgates, the sectional headgate hoist houses will be removed, the hoists lifted off their base, and the gates taken from the checks by the gantry crane. The powerhouse is serviced by a 200-ton overhead crane having a 25-ton auxiliary hoist.

The generators are protected by both water rings and a carbon dioxide fire protection system. Carbon dioxide fire protection is used for the oil filter room as well as the generators. The system is operated in the generators by thermocouples and by split phase relays. In the oil filter room temperature rate-of-rise devices are used to actuate the system. Water for fire protection is supplied by an electrically driven fire pump with a gasoline-driven pump as a back-up. Fire stands are provided through the powerhouse and the main transformers and station service transformers are protected by automatic deluge systems controlled by temperature rate-of-rise devices.

The governor air supply is from two double-stage air compressors, having a capacity of 38 c.f.m., delivered at 325 p.s.i. The station service air is supplied at 100 p.s.i. by two single-stage compressors, having a capacity of 100 c.f.m. The water depression system used when the generators are to be operating as condensers is supplied with air from two double-acting single-stage compressors, having a capacity of 244 c.f.m. each. A water depression system was not provided at Caribou Falls, although the embedded piping was installed and pipe connections are available on the turbines if required in the future. Air is stored for this system at 100 p.s.i. in five tanks, having a capacity of 600 cu. ft. each. Embedded piping for an air bubbler system to prevent the forming of ice at the upstream face of the structures was installed, but the bubbler system was omitted pending tests on those already installed at other stations. Air for this system would be drawn from the station service air supply.

Fig. 11. Whitedog Falls control room.



For unwatering the draft tubes, one deep well pump of 5,000 gal. per min. capacity under 85-ft. head was supplied. Leakage to the sump from the drainage system of the powerhouse is taken care of by two 500-gal. deep well pumps.

The tailrace deck is serviced by a 25-ton gantry crane for placing and removing tailrace gates. Operating on the same rails is a motor-operated transformer transfer truck, having rails on its deck to receive the wheels of the transformers as they are moved from the pockets. The transfer truck then moves the transformers to rails leading to the erection bay. The transfer truck is motorized for movement along the rails and to operate a hauling winch of the 9,000-lb. capacity to move the transformers out of their pockets.

Unwatering for Construction

The Winnipeg River at the Whitedog site had two channels, but the north channel was small compared to the south or main channel and the invert was high. Therefore, while the north channel took an increased share of the flow during construction, it was necessary to provide a by-pass for the water in the main channel where the powerhouse and dam were to be erected. A by-pass channel was cut in the rock on the north bank of this channel and four sluices with piers and floors were constructed before the rock plug at this upstream end was breached. The piers had checks for closure gates and were spaced so that the service gates for the permanent sluices could be used to make the final closure. When this structure was complete, the timber crib cofferdam around the powerhouse area was tied into the end pier. The diversion sluice piers were continued up to deck elevation of the dam. After the final closure, rollways were poured between these piers and they became part of the permanent sluiceway section. The four diversion sluices could discharge 4,000 c.f.s. each at elevation 1011.0. A deep section in the river bed downstream from the powerhouse provided a good tailrace channel but required a cofferdam of 60 ft. maximum height.

The English River at the Caribou site had a rather wide, flat bed, with rock forming the right bank. The unwatering scheme adopted was to push the river towards the right bank with the first stage cofferdam. The cofferdam enclosed the powerhouse area and the area for six closure sluices

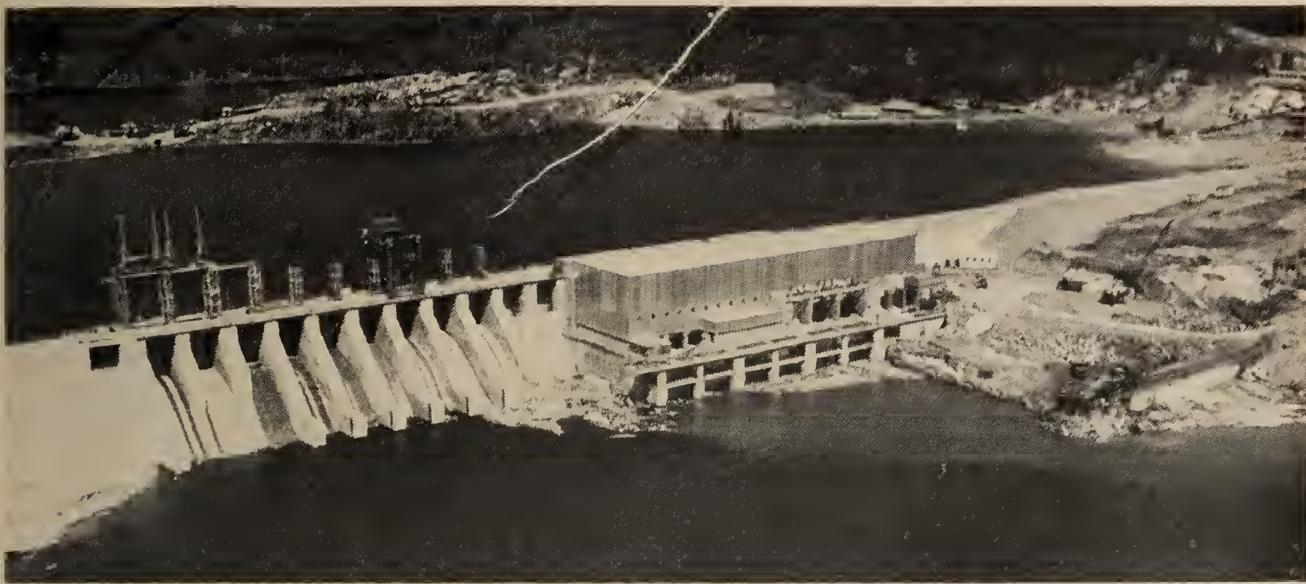


Fig. 10. Caribou Falls generating station.

similar to the four at Whitedog Falls. The cofferdam was arranged so that the powerhouse area would remain dry when the flow was through the diversion sluices and the area for the remaining sluices and the right bulkhead wall was unwatered by the second stage cofferdam. The discharge capacity at headwater elevation 1010 was 30,000 c.f.s. for stage one and 40,000 c.f.s. for stage two. Provision was made for extending the stage one cofferdam to elevation 1012.5 so that 40,000 c.f.s. could be discharged during this stage. The maximum height of the cofferdam was approximately 32 ft. This was on the upstream side.

Construction

Approval for construction of Whitedog Falls was received in August 1955. By early September, the road as located from aerial photographs was being traced on the ground and contract slashers were clearing the right-of-way. A base camp and siding was located at Pistol Lake on the Canadian National Railway 2.5 miles west of Minaki and connected to Minaki by a single lane road. Construction of the two-lane access road was pushed from a base camp and from two intermediate camps that could be supplied by water transport from Pistol Lake. Some supplies were moved in to the power site by barge, a start on the permanent camp was made, and footings were prepared for a Bailey bridge across the Winnipeg River upstream from the powerhouse dam to give access for the construction of the diversion channel.

Autumn rains followed by early freeze-up and heavy snow delayed progress on the road, and it was found necessary to push through a pilot road to bring in material for camp construction. The pilot road could not carry heavy equipment for bridging but early in January 1956 a cofferdam crew was established on the west side of the Winnipeg River in a rehabilitated survey camp, and supplied by barges as the swift water remained open all winter.

Throughout the winter, work continued on the road and heavy equipment was moved to the site over the unfinished road while it was frozen. The construction of the cofferdam continued using B.C. fir and local timber, and by March the Bailey bridge across the river was complete, so that rock from a quarry area on the left bank could be supplied to the cofferdams. By the end of March, drilling and excavation of the diversion channel was under way. Spring break-up caused considerable damage to the road and loads had to be reduced or carried during the night when the ground was frozen. In May a portable aggregate plant was at the site and screening and crushing of aggregates commenced; aggregate was stockpiled over 6-ft. diameter corrugated iron culverts, which were used for reclaiming tunnels. The natural gravel contained insufficient large sizes, and rock from the approach road excavation was crushed in a jaw crusher to make up the deficiency of coarse aggregate. A total of about 87,000 cu. yd. of material was stockpiled near the mixing site. An automatic mixing and batching plant was erected together with the conveyor belts to deliver the aggregate from the stockpiles to the storage bins. Bulk cement was received by rail at Pistol Lake and hauled by truck to a silo at the mixer. Concrete from the mixing plant was hauled to the power site by truck and placed in the forms direct, where possible. For inaccessible forms, concrete was pumped or carried by conveyor belts. Elephant trunks were used for distribution in the forms.

By the end of July 1956, the south bulkhead section had been poured, the diversion channel excavated, and the control piers in the channel poured. The upstream diversion plug was blown in August and by September 1st the water was flowing in the bypass. Due to the rock configuration at the bottom of the stream and to the depth of the river, completion of the main cofferdam and unwatering of the powerhouse site was slow. High flows in the river made the placement of toe fill difficult, and faults in the rock under the upstream cofferdam required grouting. By the time the cofferdam was made tight the water inside the enclosure had frozen, and it had to be removed as excavation rather than by pumps. Thus it was late 1956 before rock excavation could begin in the powerhouse area.

During the summer the work had continued on the bulkhead section and the camp had been completed to house about 800 men. Most of the buildings were prefabricated steel of various types and brands. The camp contained cafeteria, recreation hall and bowling alley, storage buildings, post office, grocery store, and houses for senior personnel. Junior personnel were housed in trailers. Married workmen were rented material to build their own houses according to plans provided. Serviced lots were provided on a rental basis for the houses and for those who wished to bring trailers. All buildings were serviced with electric power, sewage and water. Commission buildings and houses were supplied with heat from oil burning boilers, each boiler serving two or more buildings, depending on the size of the building and the heating unit.

Pouring of the bulkhead walls and sluiceway section continued during the fall and winter of 1956 and 1957. The first concrete in the base of the powerhouse for No. 2 draft tube was placed in March 1957. Bailey bridges were constructed across the powerhouse area and over the headworks area for the supply of materials and concrete. Intermediate footings for the powerhouse bridge were moved back and forth as the different pours were made, to avoid embedment of the footings of the permanent structure. This bridge in the powerhouse area was used to place the embedded parts for the turbines and was left in place until the main powerhouse crane was in service in September 1957.

During June and early July of 1957 the watershed of the Lake of the Woods received exceptionally heavy rainfall, and as the lake was nearly full from spring run-off it was necessary to discharge about 35,000 c.f.s. at Kenora. Considerable concern was felt for the cofferdams and the upstream cofferdam was raised. The flood was passed without serious damage, although several rather serious leaks developed.

Work progressed on a double shift basis throughout the summer and fall of 1957 in order to make up for the time lost in road building and unwatering. To further this end, consideration was given to pouring the scroll case roofs in one pour instead of in seven as is normal practice for units of this large size. Due to the density of the reinforcing and its complex pattern, considerable time would have been required to form the bulkheads for the sections and there would be a waiting period between pours in order to obtain the results desired from the multi-pour method. It was decided to pour No. 1 roof in one pour as an experiment, subject to the following conditions: Fly ash was to be used in the concrete to reduce the heat of the hydration and the shrinkage and to extend the initial set period; no cold joints were allowed and the differential pressure on the embedded parts of the turbine was limited to not more than that caused by 8 in. of fresh concrete; since the mixing plant contained only one two-yard mixer it was required that either an additional mixer be added or that the Caribou Falls plant be used as a standby, with the ready-mix trucks available to haul the concrete 17 miles to Whitedog. This procedure proved successful with only minor cracking of the concrete, and the method was adopted for the scroll case roof throughout the job. The area of the scroll case roof was approximately 65 ft. by 60 ft. with a 20-ft. diameter opening in the centre for the turbine pit. A total of about 875 cu. yd. of concrete was required for each roof.

By the time the weather became cold in the fall of 1957, the erection bay and No. 1 unit area were advanced far enough to be covered by a permanent superstructure, and the powerhouse crane was erected in this area. It was necessary to protect local areas of units 2 and 3 by tarpaulin covers and heat them with steam as the pours were made. Moving parts of the turbine and all generator parts were placed, using the powerhouse crane. Generator erection commenced in November 1957.

The final clean-up of the flooded area continued throughout the fall of 1957 when weather conditions permitted burning of brush. Work on the upstream channel improvements that had been interrupted by the high flows during the summer was completed shortly after Christmas. Fast water and cold weather combined to make this operation very difficult in winter time.

In October 1957 the river flow was about 13,000 c.f.s. and as the upstream cofferdam had been constructed to a height which would pass 35,000 c.f.s. through the four diversion sluices, the gates in one diversion sluice were placed and the rollway was poured for the permanent sluice. The volume required to fill the headpond was only about 13,000 acre-ft., but this had to be accumulated gradually so as not to withhold water from downstream plants. After the cofferdams were removed in late November, the Lake of the Woods Control Board were requested to slightly increase the discharge from the Lake of the Woods above that required by the Manitoba Plants. The remaining three diversion sluices were then closed one at a time, the gates being placed in each sluice as the water rose, so as to maintain a constant flow. As each sluice was closed, the permanent rollway was poured and the sills and gates installed. After the headpond level was above elevation 1011 (the sill elevation of the sluices) the discharge was controlled by the completed sluices. By February 11, 1958, the headpond was within operating range and No. 1 unit was ready for service. No. 2 unit was placed in service on March 25th and No. 3 on June 6th. Work on the finish floor, clean-up and painting continued during the summer of 1958.

Construction of Caribou Falls was approved in June 1956. Power requirements and river flows combined to force a very tight schedule. An immediate start was made on an access road that was an extension of the Whitedog access road. The extension commenced at the Bailey bridge crossing the Winnipeg River just above the Whitedog Falls. The road specifications were changed in order to speed up the work. Instead of grubbing and removing forest litter, the trees were close cut and excavation from the ditches was placed on the surface to form the sub-base. This was supplemented where necessary by fill from local borrow pits along the road without respect to type of material. The finished sub-grade was to be topped with 18 in. of granular material. Work on the road was carried on from the Whitedog Falls camp and from the Caribou end of the road, with an intermediate camp that could be supplied by barge. Tetu Lake, being the tailwater of both plants, provided an excellent water route from Whitedog Falls to Caribou Falls, and full use of this was made in the transportation of equipment and supplies until the road was passable. A temporary camp that had been in use for preliminary investigation was extended for use by road-building, cofferdam and camp-building crews. By New Year 1957, the permanent camp at Caribou was ready for occupancy, and the sub-grade of the road was complete with sections where the granular surfacing material had been placed. The clay sub-grade of the road had frozen hard and this was covered by a thin layer of granular material on the uncompleted sections. In this condition the road was used throughout the winter, and sufficient heavy equipment and supplies were brought in to cover the period in the spring when it was known the road would break up. During and after break-up, additional granular material was added where required and the road compacted. As the road proved serviceable in this condition the full 18 in. of granular material was not placed.

A mixing and batching plant containing two 2-yd. mixers was erected during the winter and sufficient coarse aggregate hauled from Whitedog Falls to supply the plant until aggregate crushed from the powerhouse excavation would be available. A large pit containing fine aggregate was located near the site. One section of this pit contained 20,000 yd. that would meet the concrete specifications for fine aggregate without screening. This material was placed in stockpiles for reclaiming, similar to that at Whitedog. The mixing plant was located so that concrete could be supplied direct to the forms by pumping or by truck. The sand was found to contain a natural air entraining agent which, combined with the additive used, entrained so much air that the pump would not work and had to be abandoned.

Cofferdamming progressed well during the winter in spite of extremely cold weather. The first-stage cofferdam consisted of a square enclosing the powerhouse area and an adjoining rectangle extending into the river with the upstream edge of the two in line. Construction of the upstream and downstream cofferdams was carried on simultaneously. As the upstream cofferdam was extended it was followed downstream by a causeway to the junction of the side of the square and the downstream side of the rectangle. When this point was reached, a corner crib was placed and two more working faces were available. It soon became evident that the rectangular section was crossed in an upstream and downstream direction by a ridge of rock which almost separated it from the powerhouse area. A temporary earth dyke was built on this ridge, allowing the powerhouse area to be pumped out and excavation to start well ahead of the completion of the first-stage cofferdam.

During the early spring of 1957, concrete was poured in the east bulkhead section and a Bailey bridge from the outstream end of the cofferdam to the west shore of the river permitted pouring to begin on the west bulkhead by the end of May. The first base slabs for the draft tubes were poured in August. By September the diversion sluices were ready for use and it was certain that final closure would be made during the spring of 1958 to catch the freshet. As water levels were low on the watershed and no fall freshet was expected to occur, the permanent rollways were poured in two of the six diversion sluices before flooding the diversion area. The four diversion sluices left open were in use by the end of September. Construction procedures were similar to those at Whitedog, except that a Bailey bridge was used in the powerhouse area only and none at the headworks. Steel columns were used as intermediate supports and these were imbedded in the final structure. The headworks were poured from the deck of the bulkhead section and from the deck of the adjoining headworks structure.

One of the major items in the construction of Caribou was the clearing of 18,800 acres of land to be flooded in the headpond, and the salvaging of approximately 27,000 cords of pulpwood from this clearing. The headpond extended some 30 miles along the river and intervening lakes, and had a shoreline of about 500 miles. Mosaics of the flooded area were made from aerial photographs and the flooded contour of 1044 was marked on these by photogrammetric means. The area to be flooded was divided on the mosaic into approximately 30-acre blocks. The clearing of each block was contracted to a group of three or four men, at a price per acre with an extra allowance per cord of pulpwood piled, when indicated. At one time nearly 400 men were under contract on this work. Areas cleared were measured for progress payments and final payment from aerial photographs taken at two-week intervals. The contractors were instructed to leave a few trees standing on the edge of their blocks to indicate the boundaries. These trees were easily identified on the aerial photographs and the areas for payment were measured by planimeter.

Water level gauges were set on different reachs of the stream by engineer's level and water transfer. Bench marks set on the flooded contour at convenient intervals by running level lines from the water's edge to the contour by engineer's level. The contour between bench marks was then run by hand level and marked by blazing the trees.

An operation extending over such a wide area presented a difficult problem in supply and supervision. During the open season supervisors used boats to visit the contractors and carried provisions ordered previously. When the river and lakes were frozen, light tractors and snowmobiles were used. Depots were established at conveniently located points around the headpond and stocked with the supplies for use during the break-up and freeze-up. Since nearly all the contractors used power saws, large stocks of gasoline and spare parts of the various makes of saws were necessary. For travelling during break-up a light punt driven by an airplane motor and propeller was found convenient. This machine could travel on either ice or water. The continuous engine maintenance required made these vehicles unreliable. During the break-up of 1957 a helicopter was retained for emergency use, and during times of high fire hazard daily airplane patrol was maintained.

By the autumn of 1957 cutting was complete, but the salvage of pulpwood presented a difficult problem. The areas where pulpwood was to be salvaged were small and were scattered over the whole flooded area, some very remote from the then existing river system. Some wood was removed by truck over the ice early in 1957 and some easily accessible wood was skidded to the water during the summer and towed to Caribou Falls, where it was trucked to rail at Pistol Lake. During the winter of 1957 and 1958 large amounts of pulpwood were hauled by truck to the lakes and placed in booms on the ice. In some inaccessible areas the 2-cord piles of pulpwood were banded with high-strength steel wire and allowed to float up when the water was raised. This procedure was only partially successful as the bundles had to be separated from other floating trash and collected into booms. In one area, which formed a nearly closed bay when the water rose, the muskeg at the mouth of the bay, complete with stumps, floated up and blocked the entrance to the bay.

Earth Fill Dams

The overall construction schedule required that all the earth fill dams be complete by the spring of 1958. This meant that the dams would all have to be constructed during the summer of 1957. The season during which earth fill dams may be constructed in this area is short, as the ground remains wet until late in the spring and heavy rains and frost may be expected in September. As some of the block dam sites had perched water tables, ditches were cut to drain two of these in the fall of 1956. Due to the topography and vegetable matter in the top soil, the drainage even with the ditches was very poor.

Sufficient earth-moving equipment to work at two sites at once was supplied well in advance, so that work could commence as soon as the sites were workable. Tests run on samples of the clay showed that while it would make good core material, it was subject to expansion on wetting, and heavy rock cover would be necessary to overcome the expansive effect. Rock was available at all sites and sufficient rock for loading and for riprap was drilled and blasted early in the season before it was possible to work on the clay sections.

Completion of the earth wing dam on the right bank at Whitedog Falls would facilitate delivery of material to the dam and powerhouse, as when it was complete, trucks could make a circuit over the dam without having to back off. The site was stripped to bedrock in early June and a bad fissure was found in the rock. The fissure was excavated down to sound rock and backfilled with concrete. The clay borrow pit was in a well drained position, but it was nearly the end of June before the water content was low enough to meet the specifications for good compaction. The clay core around the end of the concrete bulkhead and wing wall was compacted by hand rammers and the main section by smooth rollers and tractors. After the clay core was complete, the granular material and riprap were placed as convenient.

In July the sites of the west block dams and Goshawk dam for Caribou were stripped of vegetable matter and drained. These sites were allowed to dry, and work proceeded on the east block dam at Caribou and the west block dam at Whitedog. The Goshawk lake dam and No. 2 west block dam for Caribou Falls were the largest earth structures and required careful work. A soils testing laboratory had been set up in the field to control the borrow material and to check on the compaction of the material in place, as continued testing was necessary. Difficulty was encountered in draining the foundation and in maintaining proper moisture content of the fill. The natural water content of the material in the borrow pits was from 25 to 30%, varying with depth. The plastic limit was about 32% and the plasticity index about 47. Rains during the night would prevent work from commencing until late in the morning and during the day drying winds would make the addition of water necessary by 2:00 p.m., even though the material had been too wet in the morning. Although the clay beds were extensive, being part of the bed of prehistoric Lake Agassiz, the characteristics of the material varied greatly with depth and in different sections of the borrow pits. By September 6th, the clay cores of five dams were complete and the east wing wall at Caribou with its adjacent clay blanket was well under way. This blanket was necessary to seal the dam to the rock along the original river bank, where sand was exposed between the rock and the natural clay. This blanket also covered any punctures in the clay blanket made by construction activities. The placement of granular material continued throughout the fall and was complete in late November. Despite the fact that the dams had been designed to use local material, large enough deposits having proper grading in the natural state for filter material could not be located and it was necessary to crush and screen blending gravel for the filters and topping.

The block dam in the north channel of the Winnipeg River was left as long as possible to reduce the flow past the Whitedog powerhouse site. This structure was founded on exposed bedrock in the north channel of the river and was designed for winter construction without unwatering the site. Rock from a bluff on the bank was blasted into the stream and bulldozed to form a barrier of proper dimensions across the channel. Graded materials were then dumped on the upstream side to form a filter and an impervious blanket. Silty gravel and sand were used instead of clay, as these handled better in the cold weather. The impervious layer was then covered with riprap. The operation was successfully completed and there is very little leakage from this structure. It is believed that this small amount of leakage comes through fissures in the adjacent rock.

By March 1958, the dams and headworks for the Caribou Falls Generating Station were sufficiently complete to allow the headpond to be raised and final closure made. This operation required special study, as approximately 1,500,000 acre-ft. of water were required to fill the headpond.

In the summer of 1957 a canal and control works were constructed to divert water from Lake St. Joseph on the Albany River watershed to Lac Seul. During the winter of 1957 and 1958, as water was withdrawn from Lac Seul for power purposes on the English and Winnipeg rivers, water was diverted from the Albany River and stored in Lac Seul. By March of 1957, when the Caribou headpond was ready for filling, approximately 700,000 acre-ft. of water were available in Lac Seul for the filling operation. About two weeks before the closure commenced at Caribou Falls, the Ear Falls dam was opened to discharge this water at a rate of about 6,000 c.f.s. Two weeks was the time estimated for the water to traverse approximately 125 miles of river from Lac Seul to Caribou Falls. Closure was made in a manner similar to that at Whitedog, the same gates being used and the headpond being raised at such a rate that only water equivalent to that from the diversion was stored. As the spring progressed and the freshet started, close cooperation was maintained with the Manitoba plants downstream, so that any flow in the English River which when combined with that from the Winnipeg River would be in excess of their requirements would be stored in the Caribou headpond. While the spring freshet of 1958 was very low on the English River, a good run-off was received from the Albany River diversion and by July 8, 1958, the headpond at Caribou Falls was raised to operating level.

The downstream cofferdam below the powerhouse had been located by balancing the extra cost and time of building cofferdams against the added cost of excavating rock under water. The final location was such that about 15 ft. of rock under the cofferdam and tapering to nothing downstream had to be excavated. This rock was drilled fanwise from the dry side of the cofferdam and blasted before the cofferdam was breached. A timber barrier was placed near the cofferdam to prevent damage to the downstream side of the powerhouse and the transformers located some 150 ft. away. The blast was successful in breaking the rock and leaving the cofferdam sufficiently intact so that a dragline and trucks could work over the top of it for removal of the cofferdam and broken rock. The area within the cofferdam gradually filled with water and no material was washed towards the powerhouse. The No. 1 unit was placed in service on July 27, 1958, No. 2 on September 11th, and No. 3 on October 11th. Thus Caribou Falls Generating Station was completed and on the line in slightly over two years, in spite of the fact that it was located far from the sources of supply and 17 miles of access road had to be built to reach the site.

During the summer of 1958 channel improvements at Boundary Falls were carried out. This involved the removal of some 47,000 cu. yd. of

(Continued on page 95)

THE FIRST CYCLONE FIRED BOILERS IN CANADA AND SOME ASPECTS OF THEIR EARLY OPERATION

E. K. Akin, M.E.I.C., *Senior Mechanical Engineer,*
Nova Scotia Light and Power Company Limited
Halifax, Nova Scotia

THE cyclone fired boilers, which have a combined peak load capacity of 1,000,000 lb. of steam per hour, are known as Units Nos. 6 and 7 in the Water Street plant of Nova Scotia Light and Power Company, Limited, at Halifax, N.S. These boilers are unique in that they are the first of this type to be installed in Canada. In the range of operating pressure and temperature, they rank with the largest at present operating in this country, and in fact are the largest boilers in operation in the Maritimes.

No. 6 boiler, the first cyclone fired unit to be commissioned, went into commercial operation in October, 1957. Although this boiler did not run continuously during its early stages of operation, it did prove invaluable in bolstering system output and taking care of system peak conditions, particularly as water storages for the system's hydro plants were in short supply because of a prolonged spell of dry weather.

No. 7 boiler was put into operation in September, 1958, and since the steam mains for these two boilers are cross connected, it has been available as a 100% standby for No. 6 boiler.

The addition of these two cyclone fired boilers together with two turbo-alternator sets increases the plant capability by 100 mw. and represents the last phase of construction at the Water Street site. With the commissioning of No. 7 turbo-alternator, now scheduled for July or August of this year, the total plant capability will be 180 mw. This is supplemented by approximately 41 mw. of hydro capacity to make a total for the system of 221 mw.

Fig. 1. Exterior View of Plant overlooking Halifax Harbour.

Further expansion of the steam generating facilities of the Company will necessitate the development of the new Tufts Cove site, which is located on the Dartmouth or eastern side of Halifax Harbour.

History

At this stage it may be in order to review the development and growth of the present Water Street Plant. Fig. 2 shows the general plant arrangement.

Between the years 1944 and 1955, four turbo-alternator sets together with the necessary boiler plant to supply the steam for their operation, were installed at the Water Street site. These units were all designed for steam conditions of 600 p.s.i.g., 815° F. As will be seen from Table I, the last three of these units were installed at two year intervals in order to keep pace with the growing demand for electrical energy.

Table I

Turbo-Alternator	*Capacity K.W.*	*Commissioned*
No. 2	12,500	1944
No. 3	20,000	1951
No. 4	22,000	1953
No. 5	25,000	1955

During this same period approximately 21,000 kw. of hydro capacity was added to the system.

Early in 1954, with the system load growth still increasing at the rate of 10 to 12% per year, it became apparent that additional steam generating plant would have to be installed for operation in the fall of 1957. Having established that this was necessary to take care of the growing system requirements, the next step was to decide on such things as the steam pressure and temperature to be selected, the size of unit or units to be installed, and also the location for this additional plant.

With reference to plant location, studies were carried out in order to determine whether or not the additional capacity should be added to the Water Street Plant or if the new Tufts Cove site should be developed at this stage. The studies indicated many apparent advantages to remaining at the present site, and after due consideration it was decided to follow this course of action.

Over the years one of the principle aims of power utilities has been the production of electrical energy at the lowest possible cost. In this respect we need not look backward many years to note the tremendous strides that have been made in this direction. During the early 1920's, the average thermal plant required approximately 3 lb. of coal to produce 1 kwh. of electricity; by the early 1930's this figure had been halved, or reduced to 1.5 lb. of coal per kwh. Today a considerable number of plants are producing a kwh. for 1 lb. of coal or less and a few of the leading plants on this continent are producing a kwh. for as little as ¾ lb. of coal. It has been through the progressive thinking and foresight of power utility engineers and equipment manufacturers that such impressive savings have been made possible.

Today we are just entering the age of atomic power generation. Relative operating and capital costs of atomic plants as compared with similar costs of conventional plants burning fossil fuels, will to a large extent determine the rate of development and widespread use of this new method of power generation.

In some countries, the scarcity of fossil fuels and their relatively high cost will, of course, accelerate the rate of development of atomic plants.

However, over the next number of years many conventional plants designed to burn fossil fuels will be built and put into operation; and at the same time the better grades of coal required to fuel these plants will become scarcer and more expensive as time goes on. Therefore, larger and larger quantities of the poorer grades of coal will of necessity have to be burned for the generation of power.

The development of the cyclone furnace was, in part, brought about by the need for a furnace capable of burning a wider variety of poorer quality coals while maintaining efficiencies at least as high as other types of conventional coal burning units.

The Company has always been interested in the utilization of Nova Scotia coals and considered cyclone fired units should prove to be well suited for burning this class of fuel. Operating experience to date, although not completely trouble free, has proved that these units are well suited to burn Nova Scotia coals.

In selecting cyclone fired boilers for the final extension to the Water Street Plant, some of the factors influencing the choice, and from which it was hoped to derive some benefits in this particular application, are listed below:

1) The cyclone fired boilers would occupy less space than most other conventional types having the same capacity;

2) With few exceptions, the characteristics of Nova Scotia coals are well suited for cyclone firing;

3) Cyclone ash or slag is easier to handle and more readily disposed of;

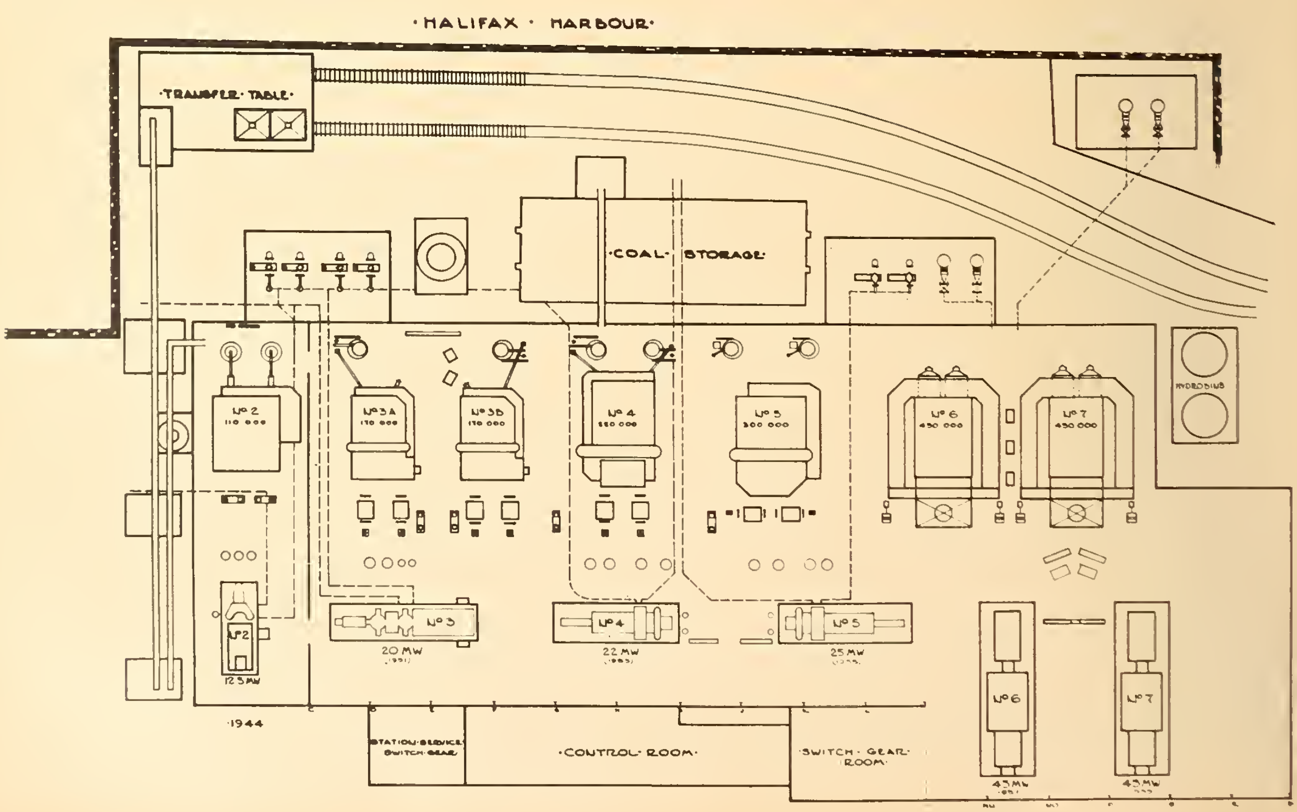
4) Less stack emission and possible elimination of dust collector equipment;

5) Since the coal is crushed and not pulverized, a considerable power saving results from the coarser preparation;

6) Safety of operation since the risk of furnace explosions is largely eliminated when burning coal;

7) Only two cyclone burners would be required as compared to 8 or 9 burners for pulverized fuel firing for

Fig. 2. Plan of Power House Arrangement.



a boiler of the same capacity;

8) Due to the smaller number of burners, cyclone firing is admirably suited to remote automatic control;

9) The heavy foundations required for pulverizers are eliminated as well as the pulverizers themselves, together with their driving motors, blowers and associated switchgear;

10) A considerable reduction in maintenance costs is expected due to a reduction in the number of moving parts and elimination of the pulverizers;

11) Cyclone firing offered possibilities of attaining efficiencies higher than other types of combustion equipment.

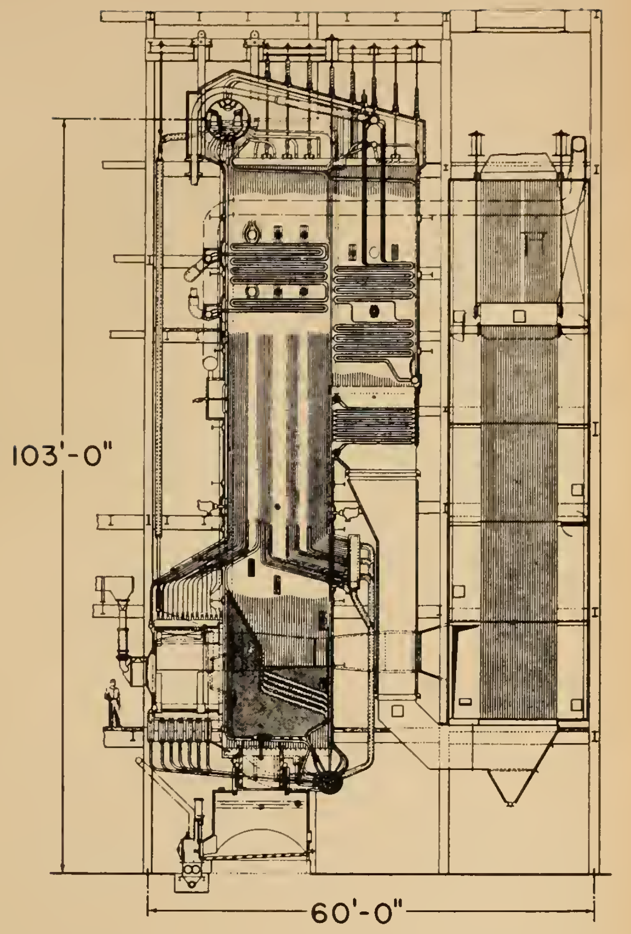


Fig. 3. Sectional Elevation of Boiler.

Boilers

A typical section through the boilers is shown in Fig. 3 from which you will note that the boilers are suspended directly from the building steelwork by a series of drum straps and hanger rods. Suspended in this manner, the units are free to expand radially and downward as the temperature increases. The distance from the centre line of the steam drum to the ground floor level measures 103 ft., and the total downward movement due to expansion between cold and operating temperature is of the order of 3½ in. This movement is taken care of by means of a water seal trough which is located between the neck of the slag tank and the furnace floor.

The steam generators are identical with respect to size and capacity, each having a continuous steaming rate of 450,000 lb. of steam per hour and a two hour peak rating of 500,000 lb. per hour. Specified steam conditions at the superheater outlet are 925 p.s.i.g., and 915°F. plus or minus 10°; this steam temperature being maintained for all loads above the control point of 225,000 lb./hr. In practice, a steam temperature 915°F. is usually maintained for loads down to about 180,000 lb. per hr. For the higher loads above the control point outlet steam temperature is controlled by direct injection of boiler feeder water into a venturi type attemporator. This attemporator is located in a section of 10 in. pipe connecting the primary and secondary superheaters.

Each boiler unit consists essentially of two cyclone furnaces, primary and secondary furnace, primary and secondary superheater with an inter-stage attemporator, economizer, air heater and chimney. The auxiliary equipment consists of two forced draft blowers per unit with inlet control dampers and outlet isolating dampers; spark ignited automatic oil lighters for the cyclones, and high level oil lighters and burners for quick starting or for two shifting operation, as well as two drag type coal feeders with variable speed drives for each unit.

In addition to the above equipment, each unit is provided with full capacity secondary air port bunker "C" oil burners and the necessary bunker "C" oil pumping and heating sets.

Since these two boilers have been designed for pressure firing no induced draft fans are required. However, this presents a problem in that all door openings and observation ports required for inspection purposes must be supplied with cooling and sealing air and also with an aspirating air supply. Air lock arrangements have been provided so that before any inspection doors can be opened, the cooling air supply, shut off; and aspirating air turned on to prevent hot gases from rushing out.

The cyclone furnaces (2 per boiler) are located side by side on the lower front wall of the furnace. They are made up from an intricate arrangement of bent tubes and headers and may be described as being fully water cooled, horizontal cylinders, 8 ft. in diameter by about 11 ft. long, into which fuel is fired. Figs. 4 & 5 illustrate the general arrangement of a cyclone furnace. The tube surfaces forming the inside surface of the cyclone are studded and covered with a refractory material as a base for slag adhesion. Crushed coal falls by gravity from the discharge end of the coal feeders and enters the vortex or outer end of the cyclone burner. High temperature primary air, representing approximately 15% of the total air required for combustion, enters the side of the burnerscroll at high velocity and imparts a whirling motion to the particles of coal, carrying them into the larger cylinders of the cyclone furnace. Here the whirling or centrifugal action of the coal air mixture is further increased by the secondary air flow which enters the cyclone tangentially at velocities of some 350 ft. per sec. The centrifugal force tends to throw the fuel particles to the cyclone walls where they are captured in the molten slag layer. The high temperature, high velocity air sweeps past the particles of coal embedded in the molten slag layer inside the cyclone furnace. In this way there is very rapid and intimate mixing of air and

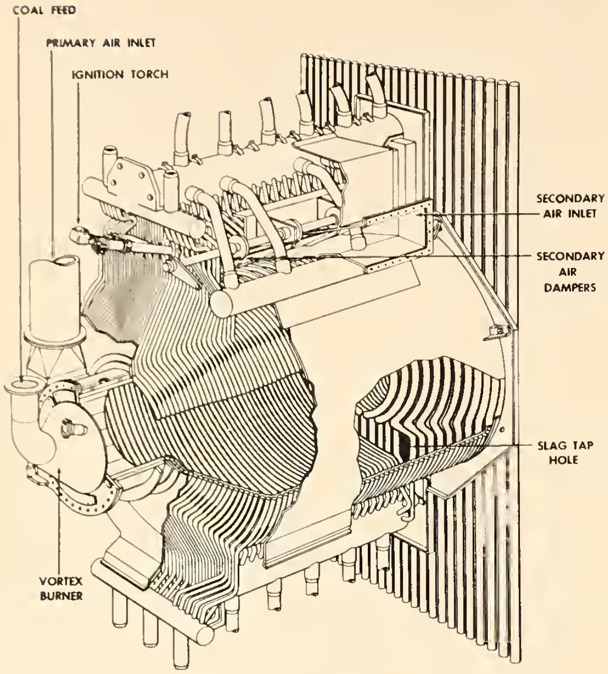

Fig. 4. The Cyclone Furnace.

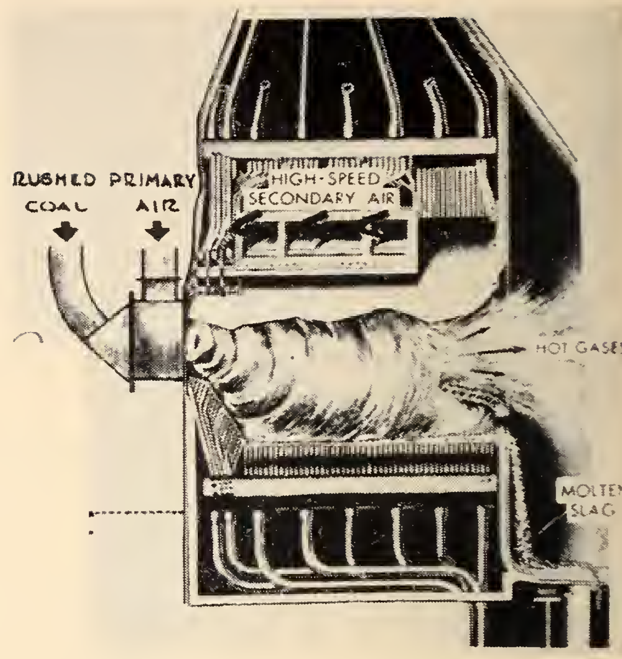

Fig. 5. A Section through the Cyclone Furnace.

the coal gases generated, and sufficient oxygen is very rapidly supplied to promote high speed burning. Heat releases at full load are of the order of 500,000 Btu. per cu. ft. per hr., and gas temperatures 3000°F. or higher.

The film of molten slag, covering the walls of the cyclone furnace, flows gradually toward the rear of the furnace, drains through a tap-hole, and continues downward to the slag pool on the floor of the primary furnace. From this point it passes through a water-cooled slag spout and is discharged to the slag tank filled with water.

During normal operation combustion is substantially complete in the cyclone furnace, the products of combustion pass through the water-cooled re-entrant throats and into the primary furnace. The re-entrant throat sections made up of studded tubes —illustrated in Fig. 6—are shipped to the job as assembled units and form a part of the main circulation of the front wall of the primary furnace. Again the primary furnace and screen tube sections are all constructed of studded tubes and coated with a refractory material. The purpose of this type of refractory covered construction is to present a surface which will maintain a molten slag cover and thus act like fly-paper in capturing and retaining any particles of coal or ash which come in contact with these molten surfaces. The screen tube section which is made up of four layers of staggered tubes on about 14 in. centers is likewise very effective in capturing any fly ash particles, since these studded tubes also present a sticky surface coated with molten slag.

The flow of gases from the cyclones on entering the primary furnace is deflected downward by the close spaced tube arrangement in such a way that the hot gases sweep over the furnace floor and thus keep the surface of the slag accumulated on the floor in a molten state. The gases then flow through the slag screen which separates the primary and secondary furnaces. The remaining ash particles which have escaped from the cyclone furnaces are nearly all trapped in the molten slag layer covering the primary furnace walls and the screen tubes.

After passing through the screen tubes the gases, in addition to being cooled by the close spaced furnace wall tubes, are also further cooled by three division wall platens projecting into the furnace in such a way as to divide the secondary furnace into four chambers. Since these division wall tubes are completely surrounded by hot gases their entire surface is utilized in heat absorption.

The hot gases rising up through the secondary furnace pass, at right angles, over the secondary or outlet superheater tubes. Thence, horizontally across the top of the furnace; then downward through the primary superheater tube bank and the economizer section. Both the primary and secondary superheater tube banks are arranged between headers in such a way as to be completely drainable.

Beyond the economizer, the flow of gases is downward through a section of ductwork to the bottom or inlet end of the air heater. From this point the flow is upward through the vertical tubular air heater which is constructed in two sections. The hot section contains 3381-2 in. tubes 54 ft. long, and the cold or outlet end contains 2949-2 in. tubes, 17 ft. long. The air heater has been divided into two sections to facilitate maintenance of the cold end where corrosion problems are most frequently encountered.

The gases leaving the air heater have been cooled to about 266° for full load rating on the boiler and the incoming air elevated to 560°F.

Table II gives some design data and the expected performance figures for coal firing.

The expected performance figures for coal firing have not as yet been substantiated by actual tests. However, various observations appear to indicate that the efficiency of these units will be close to the predicted values. Present plans are to carry out full scale tests shortly after the commissioning of No. 7 Turbo-alternator which is at present scheduled to go into operation this July.

Special Features

Some of the special features incorporated in the design of these steam generators merit special attention and will be discussed briefly in the following order:

(1) All welded construction;
(2) Pressure casing;
(3) Water Column TV and other water level indications;
(4) High level oil burners;
(5) Full capacity Bunker "C" Oil Burners.

All Welded Construction

Specifications for most large boiler and turbine units being installed today require that they shall be suitable for two shift operation and for quick start-up. Since these last two units represent a large percentage of the total system capacity it was mandatory that they should fall within this class and at the same time be capable of two shift operation without sacrificing anything in the way of reliability or availability.

Past experience has emphasized the fact that repeated cycles of pressure and temperature fluctuations such as encountered with two shift operation are a prime factor in promoting leaks in such items as flanged joints, boiler hand hole gaskets, and at tube expansions.

Table II Design Data

Maximum Continuous Rating Lbs./Hr.	450,000		
Peak Capacity 2 Hour Duration	500,000		
Design Efficiency %	90.06		
Design Pressure psi	1,100		
Operating Pressure (S.H. Outlet) psi	925		
Total Steam Temperature °F	915		
Number of Burners	2		
Diameter of Cyclone	8 ft.		
Coal	Nova Scotia		
Btu/lb. (as fired)	12,500		
Ash Softening Temp. °F	1,900		
Expected Performance			
Steam M Lbs./Hr.	100	225	450
Excess Air %	29	14	12
Coal M Lbs./Hr.	9.1	22.6	42.8
Flue Gas Entering Stack °F	200	229	266
Water Entering Economizer °F	355	355	415
Air Leaving Air Heater °F	400	461	560
Calculated Heat Losses % at M Lbs./Hr.	100	225	450
Dry Gas Loss	2.01	2.55	3.29

Unburned Combustible	0.10	0.10	0.10
Radiation	1.71	0.76	0.38
Unaccounted for	1.50	1.50	1.50
Total Heat Loss	9.82	9.48	9.94
Efficiency	90.18	90.52	90.06
Heating Surfaces			
Boiler and Furnace	35,783 sq. ft.		
Superheater	18,830 sq. ft.		
Air Heater	123,630 sq. ft.		
Economizer	7,280 sq. ft.		

As a preventive step in this direction the boilers were designed for all welded construction in the field, that is to say, the boiler drums and all headers were supplied with stub tubes strength welded in position prior to being stress relieved in the shops. Figs. 7 and 8 show a steam drum and various headers with stub tubes projecting. To erect the units, with this type of construction, it was only necessary to weld the various components together, thus tube expanding was 100% eliminated for the boiler pressure parts. As a further safe-guard from the point of view of reliability all hand hole caps were designed to be seal-welded in place.

As might be expected this feature of all welded construction has been followed throughout for both the main steam and feed water piping systems.

High Level Oil Burners

In addition to being suitable for two shift operation and quick start-up, a further requirement laid down in the specifications was that the boilers were to be capable of delivering steam at or close to full design temperature for hot starting the turbines. On a two shifting schedule where a unit is shut down each night and brought on the line again the following morning the actual steam temperature required initially will depend on the temperature of the turbine at the time of shut down, its rate of cooling during the night and the duration of the shut down. The average cooling rate for the high pressure turbine cylinder is usually about 25° F. per hour. The desired steam temperature for hot start-up is generally specified as not less than the temperature of the turbine casing and preferably up to 150°F. above this temperature.

This requirement has been taken care of by four high level oil burners which together with their lighters are mounted on the front wall of the boiler at an elevation about 10 ft. below the superheater tubes. These lighters are gang operated by remote manual control from the boiler operating console. From this location they can be projected into the furnace or withdrawn by air operated pistons, which in turn are controlled with electrically operated solenoid valves. As an operational safe-guard to prevent explosive mixtures of unburned oil and oil vapours from collecting in the boiler setting, each lighter is provided with a flame failure detector to warn the operator should a flame failure occur.

These burners are steam atomized and have a controlled firing rate which is adjustable from the boiler control console. As a further aid to controlling steam temperature,

Fig. 6. A view of the furnace front wall showing the re-entrant throats mounted side by side. Note slag tap opening.

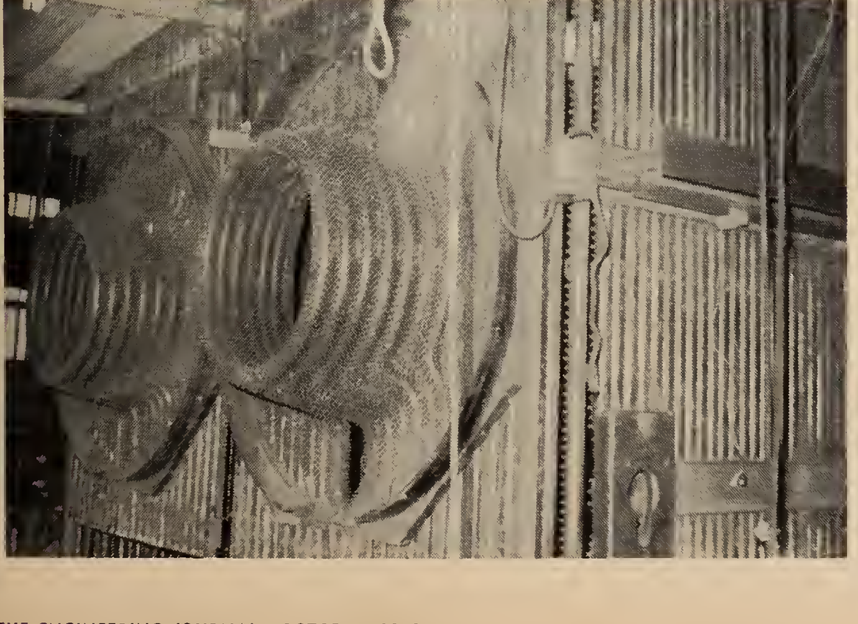

Fig. 7. A view of Steam Drum showing stub tubes projecting.

thermocouples are attached to the outlet ends of the secondary superheater tubes. A 24 point quick reading scanner records the tube metal temperature on a strip chart and also sounds an alarm should the temperature rise beyond a predetermined value.

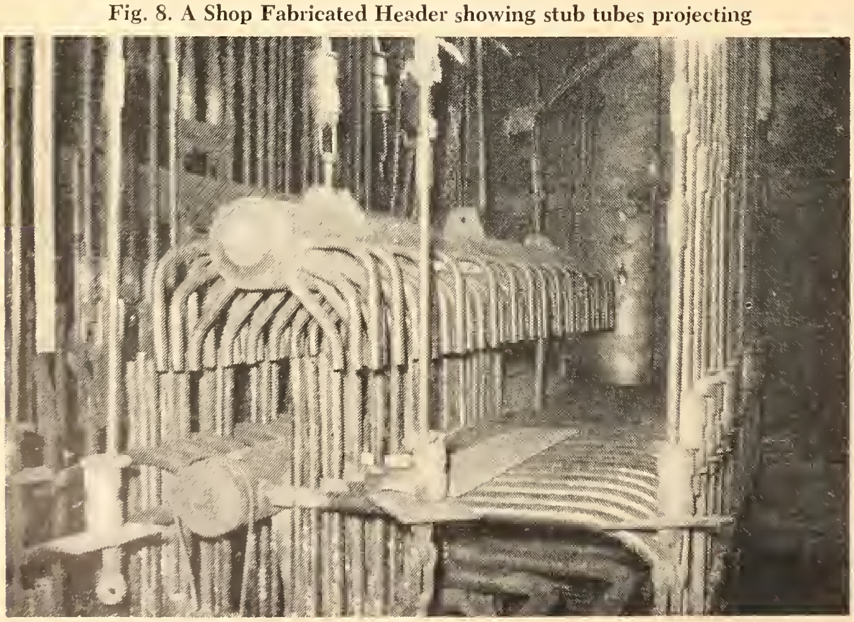
When the high level burners are in service it has been the practice to install portable thermocouple probes to measure and record the temperature of the gas entering the superheater. At present the chore of inserting and withdrawing these probes requires a boiler operator or an assistant. However, consideration is being given to providing retractable probes that can be inserted or withdrawn from the boiler console panel.

Pressure Casing

As previously stated these cyclone boilers have been designed for pressure firing; thus the forced draft blowers must provide all of the static pressure requirements for both the air and gas sides of the units, and all parts of the boiler casing are under pressure up to the stacks. Infiltration of air into the boiler setting is eliminated which results in a smaller volume of gas discharging to the stack with a corresponding reduction in heat loss.

Since these units operate under pressure they must be provided with a pressure-tight casing to prevent the escape of hot gases into the boiler room. This pressure-tight casing is made up of 10 gauge plate welded against the furnace and boiler tubes in such a way as to make a gas tight barrier. Construction details are such that ample allowance has been provided to take care of relative expansion. The exterior hot surfaces of the boiler are covered with an appropriate thickness of suitable insulating material to reduce heat loss to reasonable limits.

Fig. 8. A Shop Fabricated Header showing stub tubes projecting



Water Column TV and other water level indications

All operating personnel recognize the prime importance of close feed water control and the necessity of maintaining proper water level in the boiler at all times. Because of the importance of water level it is customary to have at least two and often three or more independent water level indications available to operating staff. These boilers have a water column with gauge glass mounted at both ends of the steam drum, and an instrument indicating and recording drum water level at all times. High and low alarm contacts have been incorporated in this instrument which in case of an abnormal water level condition initiate a flashing light signal on the enunciator panel and also sound an alarm.

In addition closed circuit television has been incorporated to show water level on a TV screen mounted on the boiler instrument panel. To give still further protection one water column on each boiler has been equipped with a high and low water level float mechanism, which for an abnormal water level condition blows a whistle and closes the contacts on a mercroid switch. These in turn initiate a flashing light signal on the enunciator panel and at the same time sound an alarm at the control panel. From the point of view of continuity of service the TV equipment has not been trouble free but rather has required some modifications and a considerable amount of maintenance. However, the operators do like this TV feature and it is considered a very desirable piece of equipment.

Secondary Air Port Oil Burners

The secondary air port oil burners, as is implied by their name, are installed through the front of the cyclone furnace and located in the secondary air port inlet as illustrated in Figure 9.

Due to their location they are cooled by the stream of high velocity secondary air flowing past them, and therefore can be left in position at all times regardless of whether coal or oil is being burned. In this location the oil burner is ready for immediate use in an emergency and can be put into operation very quickly.

These burners are rather simple in construction and are made up from a section of ¾ in. Type 310 stainless steel pipe or tubing; one end of which is plugged off and the pipe drilled along one side with a series of ⅛ in. holes to direct the bunker "C" oil into the furnace. No attempt is made to atomize the oil, since the velocity of the combustion air and the temperature of the cyclone furnace sufficiently accomplish this.

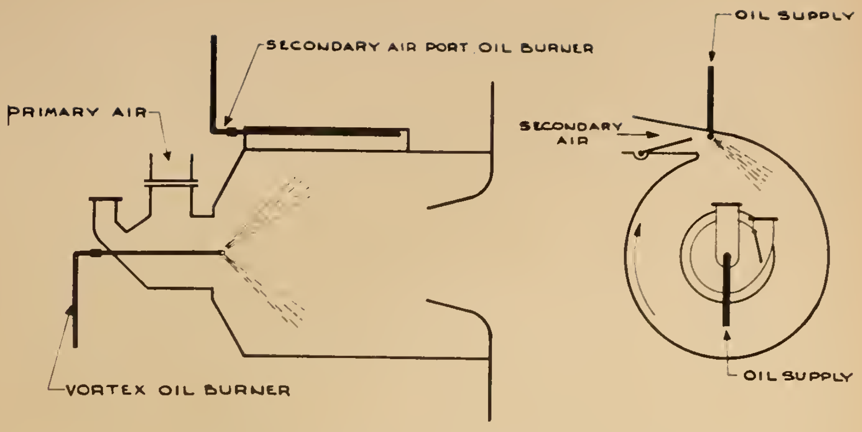


Fig. 9. Two Types of Cyclone Furnace Oil Burners.

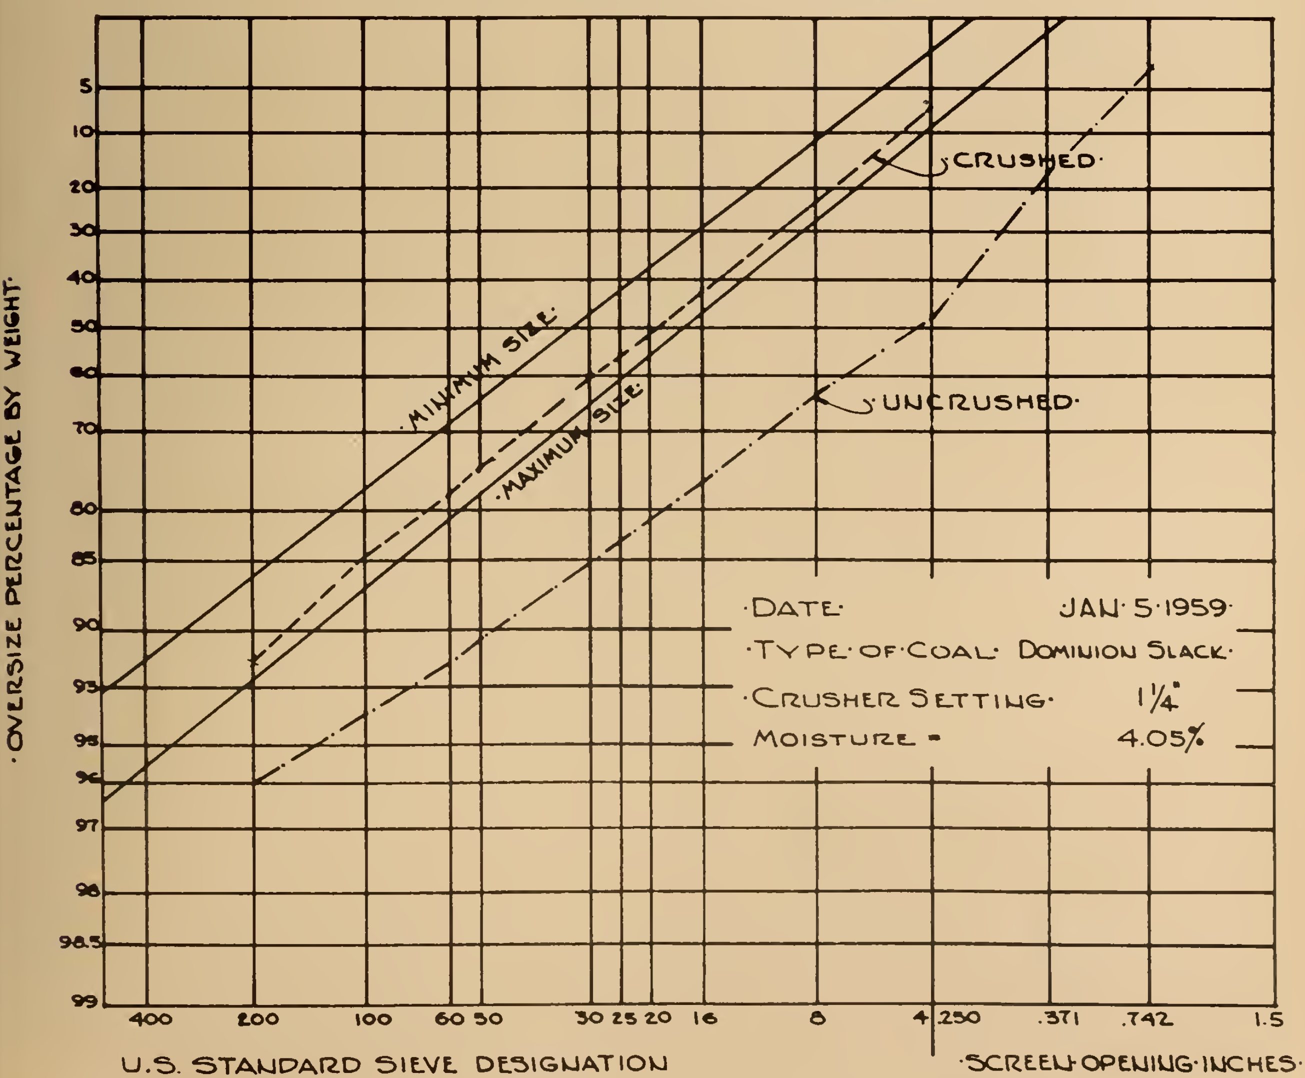
Fuel — Coal and Oil

Bunker "C" oil and Nova Scotia coal provide alternate sources of fuel for this plant. The oil deliveries are normally made by harbour fueling lighters and pumped directly into two oil storage tanks which have a combined capacity of 30,000 barrels. Space is available for an additional oil storage tank if this is found to be necessary.

The importance of oil as an alternate fuel cannot be too strongly emphasized due to the very limited coal

Fig. 10. Chart of Typical Sieve Analysis of Crushed Coal.



storage facilities at the plant site. Apart from a small coal storage silo having a capacity of only 2,000 tons, the only storage available is in the coal bunkers for the various boilers. For the most part the bunkers are sized to hold about 2 days' supply with the units operating at full capacity. Should the daily coal deliveries be interrupted for any reason there is no difficulty in converting to oil.

Coal which until a few years ago was delivered by water transport, is now delivered by rail. Due to local conditions namely, the relatively short rail haul and the fact that fewer handlings are required, this method of delivering has been found to be more economical than water transport.

All coal is delivered to the plant by rail in hopper bottom cars and unloaded into a track hopper. From here it is taken to the various bunkers by a series of belt conveyors having a rated capacity of 200 tons per hour.

On the way to the bunkers the coal passes through a rotary hammer mill type of crusher where it is reduced in size to give a graded product, 95% of which should pass through a No. 4, or ¼ in. size screen.

The boiler manufacturer has recommended that the coal for optimum firing conditions for the cyclone units should conform with Table III.

Fig. 10 shows a typical sieve analysis of a sample of crushed coal.

Coal Feeders

Fig. 11 shows the general arrangement of the coal feeder equipment between the bunkers and the cyclone furnaces (2 per boiler) which consists essentially of the following:

(1) A motor operated upper coal valve;
(2) A drag type coal feeder with variable speed drive, and a separately driven coal distributor;
(3) A motor operated lower coal valve.

All of these items of equipment are electrically driven and are controlled from the boiler control panel.

To protect the equipment and prevent plugging of the coal feeders it is essential that they be operated in a definite sequence. To insure that the proper sequence is followed the equipment is electrically interlocked as follows:

(1) A forced draft fan must be operating before a lower coal valve can be opened;
(2) A lower coal valve must be open before its corresponding coal feeder and distributor motors can be operated.
(3) Closing a lower coal valve shuts down the feeder and distributor motors;
(4) Loss of both forced draft-blowers shuts down the feeder and distributor motors and also closes the lower coal valves.

In operation the speed of the drag type coal feeders which are driven through a magnetic clutch arrangement followed by a reduction gear can be controlled either automatically or manually from the boiler control panel. As an aid to the operators in regulating the coal feeders, speed indicators have been provided to in-

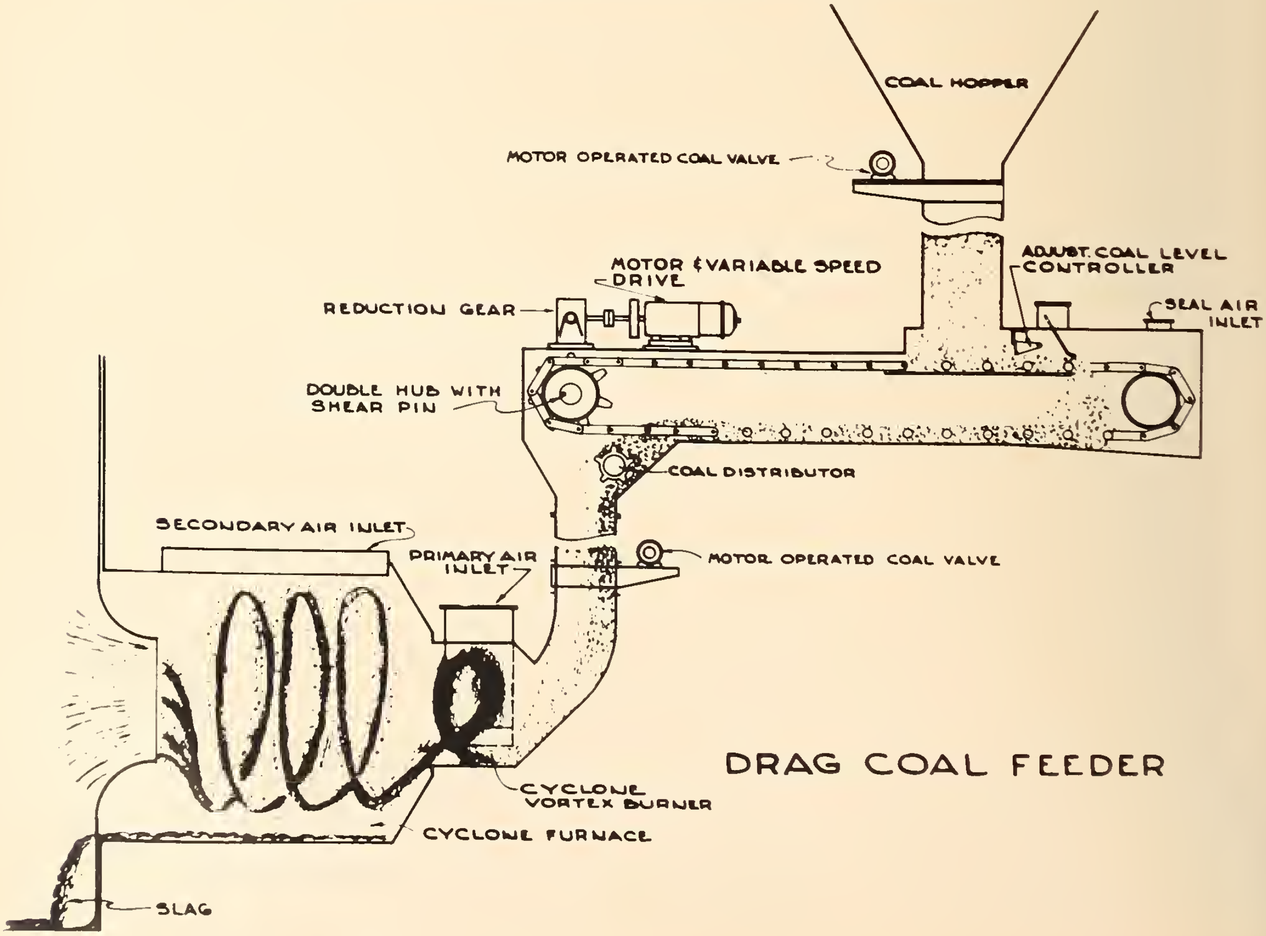

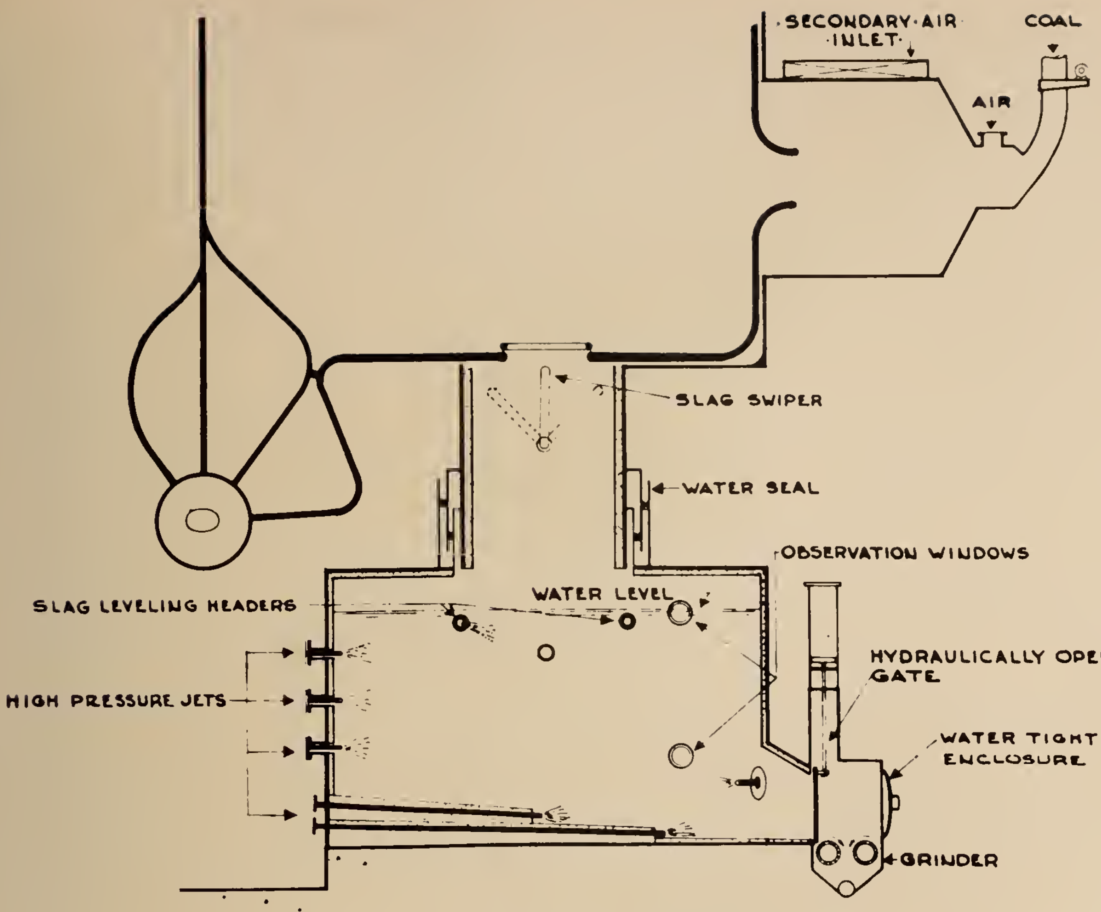

Fig. 12. Slag Tank Arrangement.

dicate the input speed to the reduction gear drives. In addition indicating lights have been provided to show the position of both the upper and lower coal valves.

One drag type feeder is used to supply coal to each cyclone, at a controlled rate in accordance with load requirements. The top flight of the drag feeder chain undercuts the column of coal flowing down the coal chute from the bunker. The movement of the drag feeder chain carries the coal toward the rear of the feeder passing under a levelling plate which is set to maintain a given depth of fuel and thus provide a uniform flow.

After passing under the levelling plate, the coal falls to the bottom of the feeder and is moved by the bottom flight of the chain to the discharge point. The fuel rate is determined by the speed of the drag chain which is controlled from the boiler operating panel. A motor driven rotary coal distributor is located in the discharge end of the coal feeder housing to assist in providing a uniform flow of coal by eliminating any avalanching tendency with dry coal or pulsating feed with wet coal.

Ash Handling System

Approximately 85% of the ash from the coal burned is collected in molten form and discharged to the water filled slag tank, which is shown schematically in Fig. 12.

This quantity represents the combined result of the slag collecting ability of the cyclone furnaces and the primary furnace. It follows that since combustion is virtually completed in the cyclone furnaces, the largest portion of the slag is therefore produced in the cyclones. The molten slag layer is continually added to as the incoming coal is burned out, and since the thickness of the slag layer tends to remain constant for uniform conditions of load, the excess slag flows to the rear of the cyclones and drains through a tap-hole to the primary furnace. From here the molten slag flows through a slag spout opening in the furnace floor to be collected in the water filled slag tank.

The molten slag on striking the relatively cold water is quickly chilled and breaks up into granular particles about the size of split peas or smaller. These granular particles have a vitrified appearance; they are shiny jet black in colour and have sharp corners.

The storage area in the slag tank of approximately 720 cu. ft. is designed to hold about 12 hours' accumulation of slag with the boiler operating at rated capacity. To distribute the slag evenly in the tank and prevent it from building up in a cone, two slag levelling headers having a series of high velocity water jets have been provided. Salt water, pumped from the harbour, is supplied to the headers which are located about 3 in. below the surface of the water in the tank, thus the high velocity jets keep the water very turbulent, preventing the surface water from becoming hot and at the same time encouraging disintegration of the slag.

The accumulated slag is removed from the tanks on a once per shift basis. Its removal is accomplished by a hydro-ejector arrangement which sucks the ash and water from the slag tank outlet. Salt water, pumped from the harbour, at the rate of 1300 U.S. g.p.m. and delivered to the hydro-ejector nozzle creates a vacuum for the ash removal operation.

The mixture of slag and water is delivered to either one of two hydrobins where the ash and water are separated. The slag falls to the bottom of the hydro-bins and the water builds up to the overflow level running to waste. Each hydro-bin has sufficient capacity to hold the slag produced over a 48-hour period by one boiler, operating at continuous full load.

Some of the Early Operating Problems and how they were overcome

During the initial stages of operation of the first cyclone fired unit, operation was attempted only during the day time and the unit was shut down each evening. This was partly to gain experience in starting and shutting down the plant and partly to insure that the plant was run only when there was close supervision by technical staff. In addition, it was necessary for the operating staff to gain some operating experience and become familiar with the new equipment before the burden of its safe operation could be placed upon them.

Acid Cleaning

The original plan was to operate the plant on medium loads for several months before acid cleaning the boiler. However, subsequent events changed this program. After about a week of intermittent operation of the boiler a leak developed in one of the 1½ in. O.D. cyclone furnace tubes. Investigation revealed that circulation was restricted in this tube due to blockage by foreign matter in the form of a gravel stone or pebble lodged in the inlet end of the tube. As a result of this discovery a very close internal examination was carried out of all boiler parts, particularly of all cyclone headers and tubes. A considerable quantity of foreign material was found which somehow had escaped detection during the preliminary boil out and clean up of the unit. In addition to the foreign matter, rusting and rust deposits were considered to be excessive, particularly in the two cyclone furnaces and, on the basis of this rust condition, it was felt necessary to acid clean the unit before attempting any further operation. The prearranged date for the official plant opening was now only three weeks away and—still more important — the additional capacity was needed to take care of system load requirements. The acid cleaning job was therefore commenced as soon as possible.

The cleaning job itself, which was carried out with utmost speed and under close supervision, went very well and good results were obtained in so far as removal of the rust coating was concerned. However, the acid cleaning resulted in other unforeseen difficulties developing and really proved to be the "acid test" since a series of leaks occurred following the acid cleaning. Without exception, the leaks occurred at welded joints in the boiler tubes. As near as could be determined, these leaks were due to the removal of small slag inclusions in the welded joints. In themselves the leaks were small and not too serious, however, the actual repairs ran into several time consuming operations since it was necessary, in each case, to cool down the boiler and drain the unit before repairs could be carried out.

Slag Removal

During the first weeks of operation, difficulty in removal of slag accumulations from the slag tank caused some concern and prevented continuous operation of the boiler. A number of forced outages were necessary in order to empty the slag tank and also for the purpose of carrying out various design changes and adjustments of the equipment. The general arrangement of the slag tank is shown in Fig. No. 12 which was referred to earlier.

During the slag removal operation, the hydraulically operated door is opened to permit the flow of water and slag from the tank to the water tight enclosure from where it passes through the clinker crusher, to be picked up by the hydro-jet and delivered to the hydro-bins. The agitator nozzles, located at various levels in the tank and designed to encourage the flow of slag from the tank, were not effective in complete removal of the slag. As water level in the tank dropped the pile of slag remaining would protrude above the water level; then the molten slag being continuously discharged to the tank would fall on top of the slag remaining and cause large clinker formations. Numerous arrangements of the agitator nozzles were tried with varying degrees of success. However, the final and complete answer to the difficulties was arrived at only after several months of operation. The solution proved to be the installation of 3 water jets in the floor of the tank, located in such a way as to undermine the pile of slag and carry it from the tank to the clinker crusher. As a further aid to operating personnel, two heavy glass observation windows were located in the side of the slag tank so that water level in the tank could be observed as well as the rate of ash removal. Slag removal has now settled down to be a straight forward and routine job, requiring 30 to 40 min. per shift.

Coal Feeder Troubles

The drag type coal feeders (which were described earlier under fuel handling) were responsible for some of the teething troubles during the early weeks of operation: the general arrangement of the coal feeders (2 per boiler) is illustrated in Fig. 11.

The top flight of the coal feeder chain in passing under the coal chute from the bunker, carries coal into the feeder. Most of this coal falls through the drag chain to the bottom of the feeder housing, however, a small quantity may stick to the chain links and be carried to the rear of the feeder. Chips of wood or foreign matter, which have got by the magnetic pulley on the coal conveyor system, often were carried to the rear of the coal feeder and then proceeded to wedge tightly between the drag chain sprockets and the bottom of the feeder housing. This results in the failure of a shear-pin which is designed to protect the feeder chain and drive from damage. Failures of this type happened so often that the bottom of the drag feeder housings were lowered to give greater clearance and thus prevent the wedging of small bits of foreign matter from causing a shear-pin failure. This was a step in the right direction and eliminated a great deal of the troubles. However, shear-pin failures still occurred, due to foreign material and other causes.

From the operational point of view shear-pin failures, resulting in loss of coal feed were looked upon as being very serious, particularly since the boiler operator would not know there was anything wrong until they started to lose steam pressure. By the time the operator located the trouble and determined which cyclone burner was out, it was often necessary to transfer 20 to 25,000 kw. of load. Needless to say, this type of failure suddenly caused large and undesirable pressure and temperature changes in both the boiler and turbine equipment. Alarms to indicate a coal stoppage to the feeders had been provided, however, they would not give an indication of a shear-pin failure.

A member of the operating staff came up with a very ingenious and simple idea to indicate a shear-pin failure. Since these new alarm indications have been provided, there has been a marked improvement in over-all operation. Should a shear-pin failure now occur, the operator knows immediately which feeder is in trouble, and since the secondary air port bunker "C" oil burners are always ready for use, the standard procedure is to switch over to oil burning immediately. A secondary air port burner can be brought on simply by opening one isolating valve. This change-over can be accomplished with little or no loss in steam pressure and without the necessity of reducing load.

Conclusions

The early months of operation of the cyclone fired units were not completely trouble free. However, the difficulties encountered, for the most part, have now been overcome and satisfactory solutions arrived at.

It was expected that, with this comparatively new method of burning coal, some initial teething troubles would be encountered, especially until such time as the operating staff had an opportunity to become familiar with the new equipment and had been trained in the new operating techniques.

A few of the early operating troubles have been discussed as well as how they were overcome. For the most part, operation has now settled down to be a routine job.

The following list records some of the observations made during the early months of operations of these cyclone fired units.

(1) The cyclone furnaces have proven to be well suited for burning most grades of Nova Scotia coal.

(2) The danger of furnace explosions for coal firing is eliminated, by the use of crushed rather than pulverized coal.

(3) The cyclone furnaces are suitable for operation with bunker "C" oil.

(4) The cyclone furnaces can be very quickly changed over from coal to oil firing as the secondary air port oil burner remains in position and ready for immediate use at all times.

(5) The maintenance cost of cyclone burners is considerably less than for pulverizer equipment. However, this saving is partly overcome by higher maintenance costs for the coal crusher hammers. Experimental work is still being carried out with various types of hammers, and with hardcoating materials to protect the hammer wearing surfaces.

(6) There is no dust problem involved in the handling and trucking away of the cyclone slag.

(7) On a few occasions, stack emission has been excessive due to faulty combustion conditions. and at other times, due to soot blowing operations. This matter is still under study.

(8) From an operational point of view, the boiler room staff like the cyclone units; they have found them easy and safe to start up and operate.

POWER IN CANADA *(Continued from page 62)*

pacity of 65,920 h.p. (end-1957).

United Towns Electric Company Limited is constructing a 1200 h.p. single-unit hydro plant at Pitmans Pond, New Chelsea Brook.

Iron Ore Company of Canada is expected to add a single 19,000 h.p. unit in 1960 to the existing development at Manihek Rapids, Ashuanipi River, in Labrador. Present capacity is 12,000 h.p.

British Newfoundland Corporation Limited and its subsidiary companies do not at present have any electric generating capacity, but they have water-power rights on about half the undeveloped rivers in Newfoundland, and on virtually all of the rivers in Labrador. The Hamilton River, in Labrador, has a proven potential of 4 million h.p. at one site and an estimated 2 million h.p. at other sites downstream.

At Bay d'Espoir, on the south coast of Newfoundland, there is a proven potential of 350,000 h.p. at one site. The Corporation plans to complete construction at this site of the first stage of 70,000 h.p., in two units, by 1962-3. Further stages, each of a single 70,000 h.p. unit, would be added as required to meet demand. Initial plans are to build transmission lines at 161 kv. from Bay d'Espoir to Grand Falls and Whitbourne.

Hamilton River power can be developed most economically by the "Channel Scheme", which would have a total installation of at least 4 million h.p. in a single powerhouse under a head of 1050 ft. Because of the difficulty of marketing such large blocks of power, various subsidiary schemes have been surveyed in the Hamilton watershed. These would enable demands of 50,000 h.p. to nearly 500,000 h.p. to be met. Initially it may be necessary to build one of the subsidiary schemes to meet local demand, and results are expected from negotiations with several potential customers, including mining interests in Labrador.

WHITE DOG FALLS

(Continued from page 84)

rock, some of which was under water. All equipment was transported to the site 17 miles by barge. This included compressors, 2½ yard draglines, heavy tractors and trucks, as well as necessary camp equipment and supplies. Where the rock to be removed was under water, staging was built and drilling was done through boiler pipes set in the rock. The work was carried out in three sections. First the upstream section, then the downstream, and finally the centre section. In carrying out the excavation in this manner, nearly all dragline work was in still water and a barrier was maintained across the new channel until the greater part of the rock was excavated. The underwater blasting was successful except for a small section near the upper end of the channel. This section was subsequently redrilled from a barge and blasted. The broken rock was later removed by clamming. The rock channel broke exceptionally smooth and the loss of head through the Boundary Falls reach is now only about 6 in.—it was formerly about 3 ft. 6 in.

Both projects were designed by the Ontario Hydro Engineering staff and constructed by the Ontario Hydro Construction Division.

138 kv. UNDERSEA CABLE ACROSS GEORGIA STRAIT

T. Ingledow, M.E.I.C., *President*
B.C. Engineering Company Limited
Vancouver, British Columbia.

THE COMPLETION of the submarine cable link between the lower mainland of British Columbia and Vancouver Island has been called a landmark in the development of submarine power transmission. This paper describes the basic considerations leading to the adoption of the 138 kv. interconnection, and the design, manufacture and laying of the cables.

The first circuit with five cables was completed in the summer of 1956. In 1958 an additional two cables were installed to provide two circuits, each capable of transmitting 120 Mw. with one cable as a spare. It is estimated that the cable link will be sufficient to meet the needs of the south Vancouver Island service area of the B.C. Electric Co. Ltd. until the late 1960's.

The British Columbia Electric Company Supply System

The service area of the British Columbia Electric Company shown in Fig. 1 covers the south western mainland of British Columbia and the southern part of Vancouver Island. The mainland of British Columbia is well endowed with indigenous power resources. It is estimated that more than 15,000 Mw. of hydro power still awaits development, while natural gas from the Peace River district is now available in the lower mainland. By contrast, the area served by the B.C. Electric Company on Vancouver Island contains no new hydro electric sites suitable for development. Furthermore, while the northern portion of Vancouver Island still has some undeveloped water power, it is anticipated that this will be needed to meet the region's own increasing electrical demands.

From load studies made several years previously, it had become evident that an additional source of power for the southern part of Vancouver Island would have to be provided during 1956. Actual and predicted one hour peak loads for the B.C. Electric Company's Vancouver Island system are plotted in Fig. 2 for the period from 1945 to the present time, with projected loads to 1970. This curve shows that during the past ten years an average load growth of 10% per annum compounded has been realized. During the winter of 1955/56 the one hour peak reached 75 Mw. thus practically equalling the system peaking capability of 76.9 Mw. detailed in Table 1.

A serious need was also developing for additional reserve capacity. All four units of the Jordan River hydro electric plant are served by a single wood flume making them particularly vulnerable to simultaneous outage. Also the old Brentwood steam plant contained 12 Mw. of inefficient units, some of which were due for retirement.

From Fig. 2 it will be seen that another 120 Mw. of electrical power would be needed over the subsequent six or seven years, allowing for the anticipated termination of contracts for purchased power.

Alternative Sources of Supply

Since additional purchased power from hydro electric sources in the northern part of the Island was not available, consideration was given to an oil or coal fired steam plant, a nuclear power plant, and an a-c or d-c submarine cable interconnection transmitting mainland hydro electric power to the Island. The cost of power from a modern 120 Mw. steam plant operating on Bunker C oil or coal at 60% load factor was estimated at about 8 mills per kwh. including fuel, fixed charges, operating and maintenance costs. Nuclear plants of that size were neither sufficiently developed at the time nor economically competitive. It was estimated that the cost of mainland hydro electric energy delivered to Vancouver Island over a 120 Mw. a-c submarine cable interconnection would be about 80% of that obtainable from a modern coal or oil burning generating station. The unit cost of transmission over the cable link itself would be little over 1 mill kwhr. when operating at 60% load factor. High voltage d-c transmission was also considered but rejected as uneconomical, and the limited practical experience with converting equipment at that time was deemed insufficient to justify its adoption.

The a-c interconnection scheme had other advantages. One block of reserve capacity would suffice for both Island and Mainland systems. The hydro electric plant on southern Vancouver Island was dependent on the run-off of one watershed only. In wet years, water was spilled, while in dry years an energy shortage sometimes occurred. The interconnection would allow the co-ordinated and efficient use of several watersheds having diverse run-off characteristics both on the Mainland and on the Island. There was no doubt that the high voltage a-c interconnection scheme was both feasible and economically attractive. The decision was taken to go ahead.

Route Selection

A map of the interconnection route from Tsawwassen Beach on the Mainland via Galiano, Parker and Saltspring Islands to Vancouver Island at Sansum Narrows is shown in Fig. 3. To determine the best route, exhaustive hydrographic surveys were carried out, soundings and accurate sea bed contours were taken, bottom currents measured and bottom samples collected. The profile of the route finally adopted is shown in Fig. 4 with submarine conditions summarized in Table 2.

Between Vancouver Island and the Mainland are a number of long narrow islands rising steeply from the sea bed. Bottom conditions generally are rugged; part sand or gravel, part rock, with abrupt changes in contour, and deep holes. Fortunately a part of the channel between Tsawwassen and Galiano was found to be covered with silt from the Fraser River, and offered a flat soft bottom except for a ridge of rock about two miles off the shore of Galiano Island. The cables take this route, and with the permission of the U.S. authorities pass through U.S. territorial waters for a distance of about 7 miles.

The channels between Galiano, Parker, Saltspring and Vancouver Islands are much less attractive from the cable laying point of view. However, a detailed survey of Trincomali Channel between Parker and Saltspring Islands revealed a small section which was satisfactory, involving a short 2.6 mile crossing. For the mile wide crossing of Sansum Narrows between Saltspring and Vancouver Islands an overhead span was utilized.

Ships anchors and trawling provide potential hazards to the cables in the congested coastal shipping lane. With the co-operation of the Department of Fisheries beam trawling was prohibited in Trincomali Channel but no trawling restrictions were imposed in the Strait of Georgia. To minimize the danger of damage from ships anchors, cable routes and landing sites were kept well clear of good anchorages.

Scheme of Development

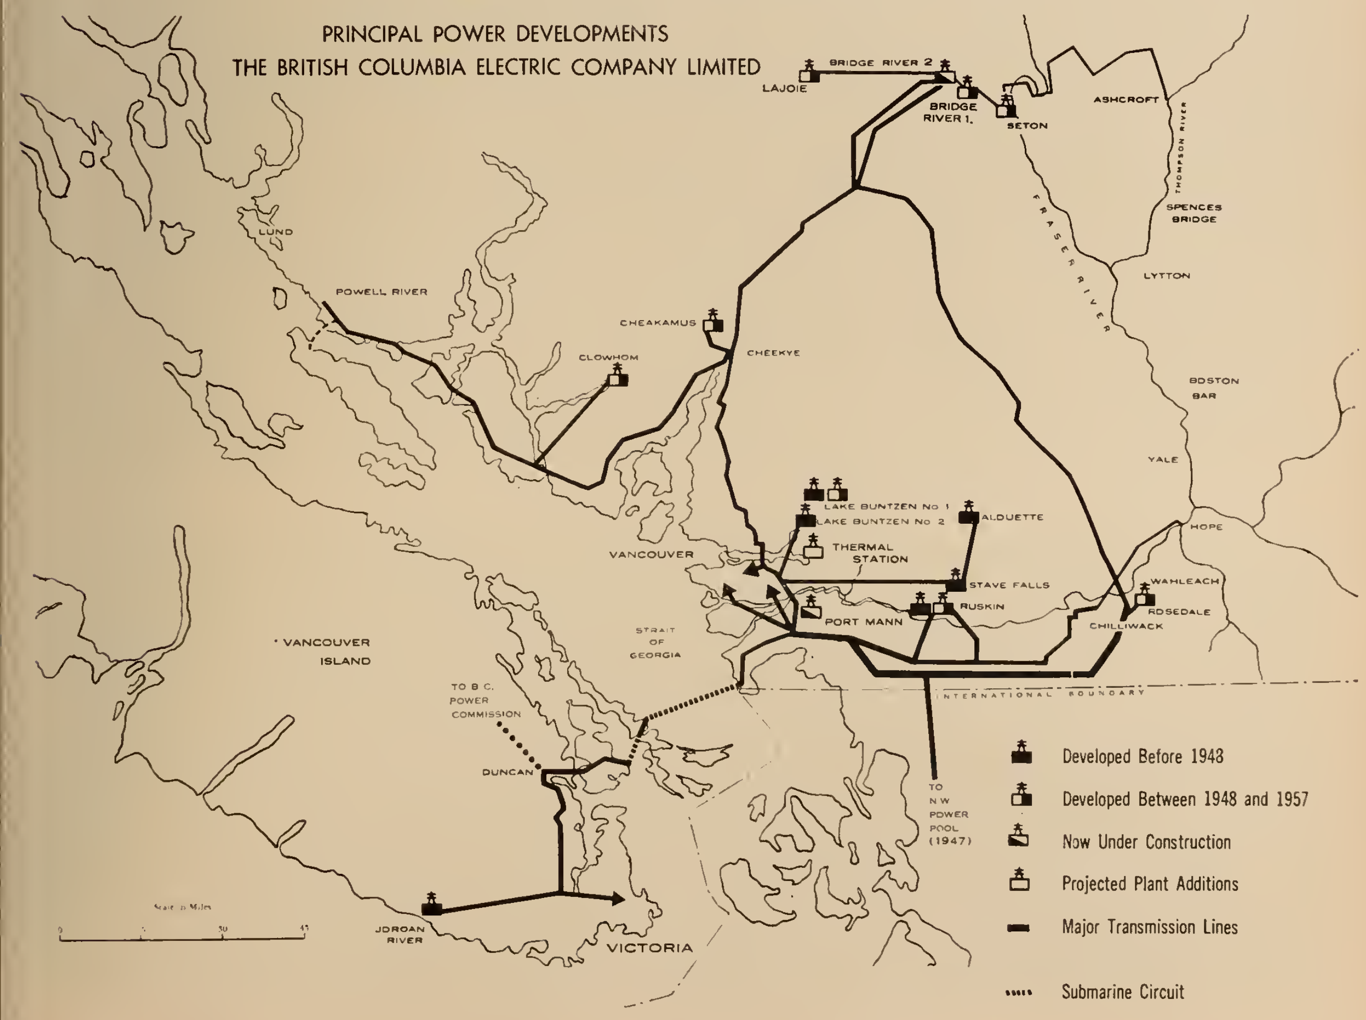
Under the first stage of the development in the summer of 1956 five submarine cables were laid across the Strait of Georgia and five across Trincomali Channel. Four of these cables were connected to the four conductors of the 138 kv. overhead line sections of the link. Three cables were used for the single three-phase circuit while the fourth circuit could be switched at the terminal station to replace any faulty phase. The fifth cable served as an additional standby.

The second and final stage of this development completed in 1958 involved the laying of another two cable links and the provision of another overhead circuit. Thus there are now seven cables and seven overhead conductors comprising two 120 Mw. three-phase interconnections with one common spare circuit.

Protection and Control

Both terminal stations are unattended and controlled by supervisory carrier-current equipment from the load dispatch centres in Victoria and Vancouver respectively. Two-zone impedance relays are used for phase protection, and high-speed directional ground-impedance relays for ground protection. A single-zone impedance back-up relaying system is provided to guard against failure of the primary relays and circuit break-

Fig. 1. Principal Facilities of the British Columbia Electric Company.



ers. In the event of a phase-to-ground fault the circuit breakers at the terminal station are tripped, and the spare circuit is automatically substituted for the faulted phase using motor operated switches. The Mainland circuit breaker is then reclosed, and the Vancouver Island system is resynchronized if necessary either manually or automatically, from the load dispatch centre in Victoria.

Communication and gas pressure alarm facilities are provided through the co-operation of the British Columbia Telephone Company. The low gas pressure alarms are signalled at the telephone exchanges closest to the cable terminals. An audible alarm is given together with two signal lights for gas failure and one light for circuit failure. Alarm conditions are reported by the exchanges to the B.C. Electric Co. Load Dispatch Centres.

Cable Design and Manufacture

The decision was taken to manufacture the cable in continuous lengths,[1] even though this meant installing special plant for its manufacture and handling. It was agreed that the use of joints involved uncertainties which could only be justified under conditions of emergency, although both rigid submarine joints for jointing two sections of cable at sea, and reconstructed joints to be made at the factory had to be fully developed. As it transpired, both types of joint were needed.

The decision to adopt the single-core gas-filled type of cable using pre-impregnated paper insulation[2] followed logically, this being the only practicable type which lent itself to continuous manufacture and could be developed for the duty required.

Table I

B.C. Electric Company—Vancouver Island System

One-Hour Peak Capability—December, 1955

Source	*Type*	*Peak Capability*
Jordan River plant	Hydro-electric	26.4
Diversion plant	Hydro-electric	1.5
Brentwood plant	Steam (oil-fired)	12.0
Purchased power		37.0
		76.9

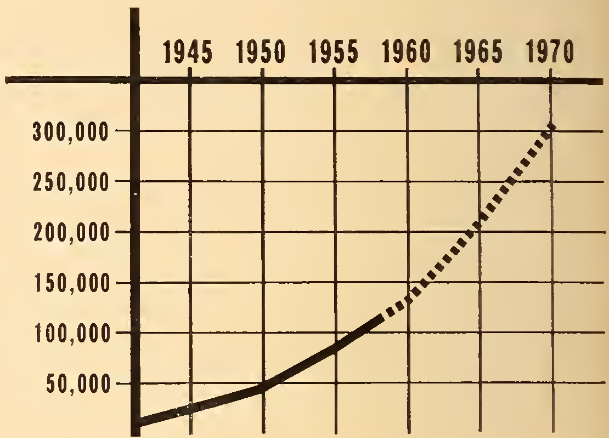


Fig. 2. British Columbia Electric Company — Vancouver Island System. Actual and Predicted One-Hour Peak Loads.

The cable was required to operate at 138 kv. 3-phase 60c/s, with a rating of 120 mva. The maximum external sea-water pressure would be 265 lb/in², and in order to prevent extensive ingress of water into the cable in event of damage, it was designed to operate at 300 lb./in² nitrogen gas pressure. Extensive laboratory tests followed by sea trials at approximately 100 fathoms, including laying, grappling and recovering the cable, led to the development of the final design summarized in Table 3 and illustrated in Fig. 5.

Meanwhile, the layout and design of the plant to manufacture the cable in continuous lengths was proceeding, with particular consideration being given to the methods of storing long lengths of cable between the various stages of manufacture. A diagram of the plant layout is shown in Fig. 6. Features of particular interest in the design and construction of the cable are as follows:

A. Conductor and Insulation

The cable was designed on the basis that all coiling would be in a clockwise direction. The outer layer of conductor wires was stranded right-hand, so as to contract in diameter under coiling, thus avoiding damage to the dielectric papers. The central duct was designed to provide the gas-flow channel; the clearance under the lead sheath, which is stan-

Fig. 3. Mainland—Vancouver Island Interconnection Route.

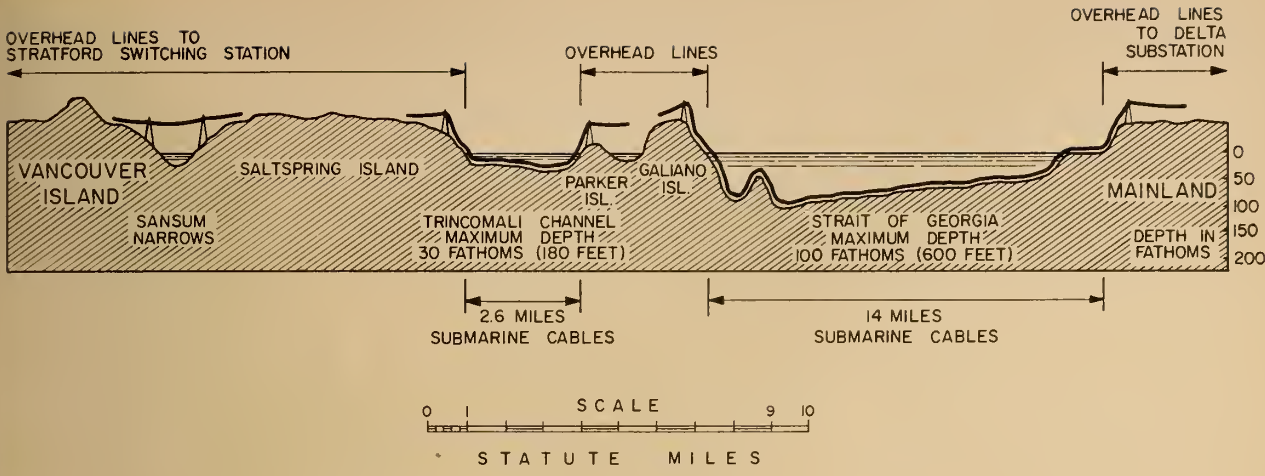

Fig. 4. Profile of Route.

dard practice in the case of land cables, is inadmissable, since at depths in excess of 40 fathoms the sheath would tend to deform under the external water pressure. Stranding of the conductor was performed on a standard floating-bobbin two-carriage machine.

The normal method of storing a long length of cable is to coil it on the ground, but this twists the cable through 360° for every turn of the coil. It was decided that twisting of the cable should be reduced to a minimum at every stage of manufacture except in its finished state, and that large power-driven horizontal turntables should be installed for coil-storing the cable between operations. A turntable was installed to receive and coil-store the conductor between the stranding and insulating machines. It was 24 ft. in diameter, designed to accommodate up to 25 miles of conductor of 1 in. diameter, and driven through an electronically-controlled magnetic coupling giving constant speed at any load. Owing to the difference in speeds between coiling down from the stranding machine and paying-off into the insulating machine, the drive was fitted with two gears and a 2-speed motor.

Insulating papers were applied with graded thicknesses and tensions in four reversed-lay sections by means of a rotating-cage type lapping machine of special design. As the paper applied to the cable was pre-dried and impregnated, special measures were taken to eliminate contamination and to control the moisture pick-up during any enforced long stoppages of the machine. The insulating machine was therefore fully enclosed with a drying plant to maintain the atmosphere within the enclosure at uniform humidity, which could be reduced to 3-4% in the event of a prolonged stoppage.

B. Alloy-Lead Gas Retaining Sheath

Alloy E was adopted for the gas retaining sheath, after careful study of the properties of alternative alloys, primarily because of its high fatigue resistance. The sheath was extruded on to the insulation by the lead press with a shrinkage of 30-40 mils diametrically to obviate distortion under external water pressure while the cable was being laid.

To allow continuous manufacture, it was essential for the plant to run continuously for 500 hours or more. From this aspect, the most vulnerable point in the whole production line was the lead press, where a stoppage of ten minutes would so damage the cable as to necessitate cutting it out. As a safeguard, the pumps and control console were duplicated, any necessary change-over being possible within a few minutes.

A special gamma-ray photographic unit was developed for measuring regularly the sheath thickness at four positions at right angles to each other, without interruption of production. The gamma-ray source was 2 curies of cobalt 60 in a heavily screened container with a remotely controlled shutter.

Since it was impracticable to synchronize exactly the insulating machine and lead press, an accumulator system was designed and installed between the two machines to store 130 yd. of cable. This enabled the lead press to run for up to three hours at normal production speed with the insulating machine stopped. In an emergency the lead press could run for up to 20 hours at reduced speed should a breakdown of the insulating machine require it. The accumulator consisted of a large 8-fall pulley system mounted horizontally. All the pulleys were 15 ft. in diameter and the spans of cable between the pulleys were supported by a system of rollers. A second turntable, 47 ft. in diameter was installed between the lead press and the reinforcing machine to accommodate up to 25 miles of cable.

C. Reinforcing and Armouring

The application of the reinforcing tapes, vulcanized-rubber anti-corrosive sheath, bedding, steel-wire armour and serving was carried out in tandem in machines driven from

Table II Summary of Submarine Conditions

Item	*Strait of Georgia*	*Trincomali Channel*
Length of Cable section	14.7 miles	2.9 miles
Maximum depth	100 fathoms (600 feet)	30 fathoms
Bottom conditions	Generally sediment, but with a ridge of rock parallel to and at a distance of 2 miles from shore.	Generally sediment
Peak of ridge	Ridge rises from 100 fathoms to 40 fathoms at the peak, and falls to 80 fathoms on the Galiano Island side.	
Currents	Surface: 4 knots average. Bottom: 1 knot maximum.	
Corrosion	No corrosion conditions due to organic or chemical sources.	
Marine life	No teredo present.	

a common backshaft.

The reinforcing tapes were applied with a right-hand lay (i.e. opposite-hand to the armour) in three layers, so that, under the tensile loads experienced during laying, their circumferential torque was opposed to and practically equal to that of the armour. This substantially reduced any tendency of the cable to throw loops on the sea bottom under certain conditions of laying and recovery.[3]

The anti-corrosion sheath, which protects the reinforced gas-retaining sheath against corrosion, consists of a homogeneous and fully vulcanized sheathing of natural rubber compound. It provides adequate insulation against the transient voltages approximately 10 kv.) which may be induced between the armour and the gas-retaining sheath in service.

After vulcanizing, the rubber sheath was tested at 20 kv. by two-spark testing units in tandem. These were interlocked so that voltage was applied only when the cable was moving. Failure of the rubber sheath automatically stopped the armouring machine to allow inspection and repair to be made.

Steel-wire armouring comprised galvanized steel wires applied with a left-hand lay to avoid locking during clockwise coiling. The optimum lay was determined, by experiment, as 12 times the pitch-circle diameter, to provide the desired coiling and handling properties consistent with minimum torsion under the tensile loads of laying. Much work was done on various aluminum alloys with the object of reducing the electrical losses in the armour. Although their normal electrical and mechanical properties were satisfactory, it was found that, under water, the abrasion resistance was much inferior to that of steel, and for this reason the use of aluminum wire armour was rejected and galvanized steel was adopted. The cable was transported from the capstan of the armouring machine by overhead gantry and coiled in the coiling shed in readiness for loading on to the cable ship.

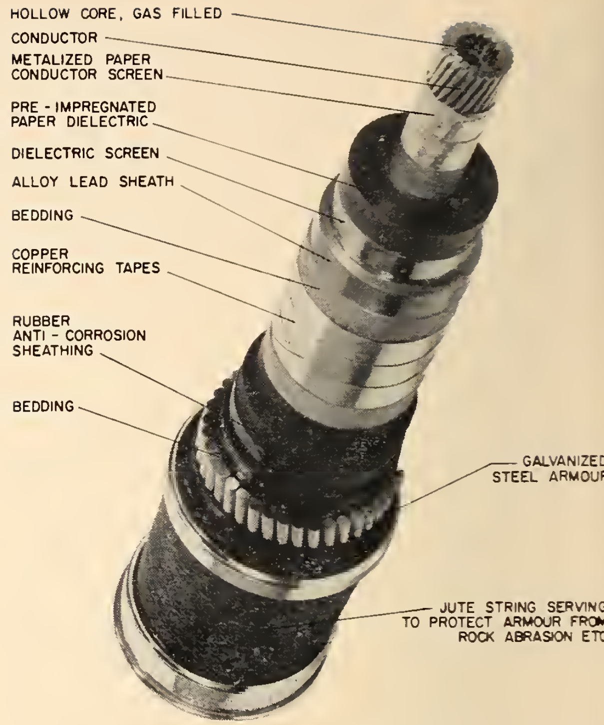

Fig. 5. Construction of 138 kv single-core gas filled cable.

D. Quality Control and Tests

It was not practicable to test the cable under high voltage a-c. conditions and full gas pressure, either during or on completion of manufacture, owing to the length involved and to the fact that full gas pressure could not be applied without impairing the flexibility and handling properties of the cable before laying. Consequently, rigid quality control and inspection at all stages was essential. High voltage d-c. tests and pneumatic tests at reduced gas pressure were carried out on the full lengths of cable in the lead-sheathed stage (No. 2 turntable) and the finished stage (coiling shed). At the start and finish of each length manufactured, lengths were cut off for complete testing and dissection to confirm compliance with the specifications. Performance tests include electrical stability, voltage surge, bending, coiling, and tests under external water pressure and internal gas pressure.

Cable Installation

A. Shipment

The five cable links comprising the first stage of development were shipped to site and laid by the cable ship "Ocean Layer".[4] This ship of 4,600 tons displacement had recently been completely fitted out with the most modern equipment and gear, and with an experienced captain and crew proved very suitable for the difficult job of installation.

Cable was loaded into the tanks of the "Ocean Layer" by a specially constructed overhead gantry 350 yd. long at a speed of about 800 yd. per hour. Fully loaded with approximately 3,900 tons of cable the "Ocean Layer" sailed for Vancouver and commenced laying operations there on the 16th of July 1956. For the second stage of the development in 1958, the unavailability of the "Ocean Layer" led to the charter of "H.M.T.S. Monarch", the largest cable ship in the world. Procedures developed for the first installation were utilized throughout and the cable laying operation followed a virtually identical pattern.

B. Landing Sites

Detailed surveys were made of the waters and bottom conditions surrounding the landing points. Storm records over a period of years were examined, and it was established that the effect of wave action could be adequately restrained.

The three island terminals of the submarine cable route are broadly similar, lying in small indentations on rocky coastlines with sufficient depth for the cable ship to anchor about ¼ of a mile off shore in 15-25 fathoms. After clearance and grading of these inlet sites, reinforced concrete cable chases were constructed from 5 ft. below low water to the pothead sites some 50 ft. above high water mark and 300-400 ft. distant. These were subsequently covered with concrete slabs. Additional protection for cables exposed at low tides was achieved by sleeving them with split articulated protectors of malleable cast iron.

The Mainland terminal at Tsawwassen Beach presented special problems since it had a sea approach over about 1½ miles of sandy shallows and on land a steep unstable bluff rising to a height of about 180 ft. This bluff was cut to a depth of about 30 ft. to reach a competent layer and a concrete cable subway 450 ft. long furnished with steps and cable racks was constructed leading to the potheads some 900 ft. from the high water mark. On completion the cut was filled and replanted to reduce the risk of subsequent movement.

C. Laying from the Cable Ship

The greater part of each cable was laid from the cable ship using established methods. To avoid the risk of looping or kinking the cable it was decided to lay it with a small residual tension on the sea bottom. The position of the touch-down point of the cable was calculated in relation to the position of the echo sounder in the ship, the shape of the suspended cable and the tension required at the dynamometer on the deck, to maintain the desired residual tension in the cable on the sea bottom. During laying, extensive records were kept from which it was confirmed that the cables had been laid closely in accordance with the planned requirements. Speed of laying was limited to approximately 3 knots which was considered the maximum at which the cable could safely be handled out of the hold and through the ship's machinery. During cable laying, the ship's navigating officers plotted her position at 4 min. intervals using suitably positioned markers on land and, in the Straits of Georgia, additional marker buoys with radar reflectors previously laid by the ship. Laying proceeded without incident except for one Trincomali Channel cable when the ship was carried at right angles to the route by an unexpected rip tide near Parker Island: the cable under heavy tension was bent to a radius of 15 in. around the bow sheave flange, and visibly flattened. During d-c. testing after laying the cable failed at this point and a submarine repair joint was inserted.

D. Laying From Cable Scows

The use of continuous cable lengths precluded laying shore ends separately and special attention was focused on the problems of getting the ends ashore. Scows or barges with shallow draught and large flat decks are used extensively in the Vancouver area and it was decided to adapt these local craft for laying cables from ship to shore. At the starting and finishing end moorings, around 2,000 ft. of cable had to be transferred to the scow except at the Mainland where a little over 9,000 ft. was needed; the weights involved being approximately 16 and 72 tons respectively. The required cable length was coiled on the scow adjacent to the laying ship. The scow then laid the cable from the ship to the shore. A power winch pulled the free end of the cable up the cable chase to the potheads.

The problems of handling the shore ends of the cables were studied using models and later a full-scale dummy scow and ship were constructed on land. As a result of this work a cable scow was designed with a reversible cable sheave mounted centrally on an A frame structure 25 ft. above the deck. The sheave was powered by a hydraulic variable speed gear also arranged for braking. A compression type cable brake was fitted to the stern so arranged that the cable could be lifted in and out and the brake removed in sections when necessary. A tunnel consisting of wooden ramps with a removable top plate was provided so that the cable could be paid out from under the remaining turns and remove the twist in the cable introduced during coiling. At the stern, a rounded apron was built up so the cable could be pulled off in almost any direction without too sharp a bend. The scow was equipped with winches for warping and cable handling. VHF radio and loud hailers, a compact galley and store below deck, and a navigation platform at the top of the structure completed the equipment.

Final trials were made in England in December 1955 using the "Ocean Layer" and the scow equipment described above mounted on a pontoon of suitable dimensions. The trials proved that the equipment and method was satisfactory and two wooden scows 90 ft. long by 34 ft. wide and about 230 registered tons were fitted out in Vancouver. Their crews were given extensive training prior to the commencement of the actual installation.

Table III Cable Construction

Component	*Radial thickness*	*Cumulative diameter*
Spiral steel duct (internal dia. 0.47 in)	0.030	0.530
Copper conductor 42/.105 in 0.35 in² (445,000 c.m.)	0.210	0.950
Metallized paper conductor screen	0.0105	0.971
Pre-impregnated paper dielectric	0.575	2.121
Copper-tape dielectric screen	0.003	2.129
Alloy E/B.S. 801: 1953) sheath	0.150	2.429
Reinforcement bedding	0.012	2.453
Tinned 1% tin-bronze reinforcing tapes (3 x 0.009 in)	0.027	2.507
Compounded cotton tapes	0.027	2.561
Vulcanized-rubber anti-corrosion sheath	0.120	2.801
Armour bedding	0.118	3.037
Single-wire armour, galvanized steel, 25-32 tons/in² tensile	0.232	3.501
Bituminized cotton tape	0.050	3.601
Jute serving	0.180	3.961

Fault Location and Repair

The location of electrical faults, in general, follows conventional practices. A method was also developed by the cable manufacturers for locating a submerged gas leak. From numerous tests carried out it had been shown that the pneumatic resistance of the cable was very uniform, and accurate formulae were derived relating gas flow to the feed distance. The method developed consists of a loop test using a sound cable, applying a common pressure, and measuring the relative gas flows. By applying the derived formulae the fault position can be calculated.

Means had to be developed for locating and cutting a faulty cable even in the deepest water since it would be impracticable to lift a bight of cable without cutting it. The test methods already referred to, used in conjunction with the record of cables as laid, would give a preliminary location which might be confirmed using Leader gear[5] and by towing a submarine search coil to pick up a signal injected into the faulty cable. Grappling for the cable would then proceed in this area using a specially designed grapnel containing a search coil (to confirm that the correct cable was in the prong of the grapnel) and an explosive charge to be fired from the surface for cutting it. The gas system previously described would limit ingress of water, and the two ends would be recovered separately for jointing-in the required new length of cable.

Gassing, Testing and Commissioning

The cables were charged with nitrogen to a pressure of approximately 10 lb/in² before they were loaded into the cable ship and were checked on arrival in Vancouver. Immediately after laying and before the terminations were made, the cables were tested at 276 kv. d-c. for 15 min. at atmospheric pressure. After the terminations had been made, the cables were gassed at a rate of 50 lb./in² per hour up to 350 lb./in² for a pneumatic overpressure test. The cables were then retested at 276 kv. d-c. for 15 min., and as soon as the circuit was available, line voltage was applied for a period of approximately 48 hours. The cables were brought down to their working gas pressure of 300 lb/in² and the pneumatic system was set to give the required warnings.

After all the cables had been subjected to these tests, the circuits were switched in on load without incident, and the spare cables were maintained at line voltage.

Conclusion

Since the submarine cable interconnection first went into service on September 25, 1956, it has been in continuous operation except for a few short outages for testing and overhead line maintenance. No operating problems have been experienced, except for some minor gas leaks at the terminal equipment, and some relaying troubles. These were remedied, and the interconnection has functioned satisfactorily and efficiently since. During unexpected outages of some hydro-electric plant on Vancouver Island, the submarine interconnection was also called upon to provide additional peaking power from the Mainland system. Thus the cable link has already accomplished its dual purpose of providing a standby as well as normal power supply for Vancouver Island, and the installation has proved to be a practical and economic engineering proposition.

Acknowledgments

The successful completion of the submarine cable interconnection described in this paper is due to the combined efforts of the B.C. Electric Company Ltd., the B.C. Engineering Company Ltd., the B.I.C.C. group of companies and other manufacturers and contractors involved. Special acknowledgment is given to the work of Mr. R. M. Fairfield, Director, British Insulated Callanders Cables Limited and Mr. D. T. Hollingsworth, Director and General Manager, British Insulated Callanders (Submarine Cables) Limited.

The author acknowledges their help with thanks and also the invaluable part played by oceanographers, surveyors, and by the personnel of the cable ships and other vessels.

Table IV Technical Data of Cable and Typical Performance Characteristics

Conductor area	0.35 in² (445,000 c.m.)
Weight in air	52.3 lb yd
Minimum permissible bending diameter	6 ft.
Minimum permissible coiling eye diameter	10 ft.
Maximum permissible twist	36° per yard
Maximum permissible tensile load	6 tons
Working voltage to ground	80 kv.
Current rating	500 amp.
Losses per 3-phase circuit	119 Kw per 1,000 yd.
Maximum conductor operating temperatures—	
In sea	50°C.
On land	70°C.
Cable spacing—	
Strait of Georgia	500 yd.
Trincomali Channel	250 yd.

A METHOD OF DETERMINING THE POWER POTENTIAL OF RIVERS WITH MANY RESERVOIRS AND POWER PLANTS

G. S. Cavadias, M.E.I.C., *Engineer*
Water Resources Dept.
Shawinigan Water and Power Company.

The power potential of modern hydro-systems is a complex problem and present methods of determining it are not entirely satisfactory.

The method presented in this paper is based on previous work by Don Johnstone and John W. Hackney and considers the total power production of the system as the basis for the computations. In addition to the total power potential of the system, the productions and the installations of the individual plants are also determined.

The paper gives the theoretical basis for the computations and includes an example of the application of the method to a typical hydro-system.

1. Introduction

MOST MODERN hydro-systems have interconnected plants which form an integrated system. The determination of the power and energy potential of such river systems is a complex problem.

The usual method of determining the power and energy potential of a river is to undertake a regulation study based on the available flow records. The standard tools for achieving this are the hydrograph, the mass curve and, in the case of remote storage reservoirs, analytical methods. In the case of interconnected systems the application of these techniques is usually based on the assumption that the flow is regulated for the "centre of gravity", which can be determined by some empirical formula.[1] This approach is generally inadequate for complicated systems such as shown on Fig. 3. On the other hand, if every existing reservoir and plant are considered separately in the regulation study[2] the calculations do not give the best combined output of the system.

Fig. 1

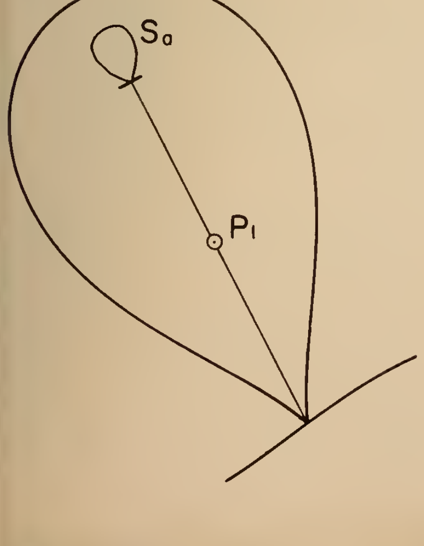

Fig. 2

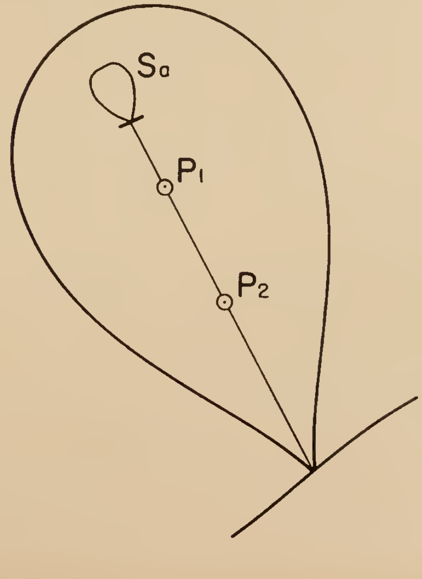

According to the method described in this paper, the power and energy potential of the river are determined by regulating the total power production of the system instead of the flow at a particular site. The proposed method is a generalization of the concepts introduced by Don Johnstone and John W. Hackney [3,4] and determines the following quantities:

(1) Total power and energy production of the system;

(2) Installations of the individual plants, based on a given prime system load factor.

2. Method of Regulation

2.1 Purpose. The purpose of the regulation study is to use a sufficiently long record of river flows to calculate the power and energy potential of a river system, under the following assumptions:

(1) Throughout the regulation, future run-offs are considered as known;

(2) The operation of the storage reservoirs is determined from the condition that the total power production should be as uniform as possible. This requirement is realistic if the mean monthly loads are approximately constant, or if the storage and pondage capacities are sufficiently large to

equalize the differences between daily and weekly water supply and power demand.

2.2 System with one Plant (Fig. 1). In the simple case of one reservoir and one plant, the average power produced during any month is:

$$k_1 d_a + k_1 f_1 = p \quad ..(1)$$

where

k_1 = kw. c.f.s. ratio for the plant P_1

d_a = discharge from storage S_a in c.f.s.

f_1 = Total uncontrolled run-off at Plant P_1 in c.f.s.

p = Monthly power production in kw.

Equation (1) can be written;

$$d_a + f_1 = (p/k_1) = R \quad ..(2)$$

where R is the regulated flow at the plant P_1. The regulation of the river is achieved by choosing d_a so as to make the regulated flow R (and consequently the power production p) as uniform as possible throughout the period of regulation.

Although for the case of one reservoir and one plant it is more convenient to use equation (2) in the computations, the more direct approach of equation (1) will be used for more complicated cases.

2.3 System with Two Plants (Fig. 2). For a river with two power plants P_1 and P_2, the monthly power production can be expressed as follows:

$$(k_1 + k_2)d_a + k_1 f_1 + k_2 f_2 = p \quad ..(3)$$

where f_1 and f_2 are the *total* uncontrolled run-offs at the plants P_1 and P_2.

Before equation (3) can be used as a bas's for the regulation study, the inflows f_a to the reservoir S_a are multiplied by $(k_1 + k_2)$. The "controlled power" $(k_1 + k_2).\,d_a$ is determined from the condition that the total power p should be as uniform as possible.

2.4 System with any Number of Plants and Storage Reservoirs (Fig. 3). The monthly power production p of the river shown on Fig. 3 can be expressed as follows;

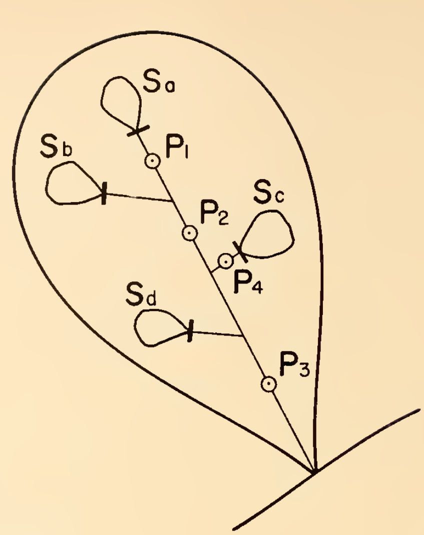

Fig. 3

$$(k_1 + k_2 + k_3)d_a + (k_2 + k_3)d_b + (k_3 + k_4)d_c + k_3 d_d + k_1 f_1 + k_2 f_2 + k_3 f_3 + k_4 f_4 = p \quad ..(4)$$

where

$(k_1 + k_2 + k_3)d_a + (k_2 + k_3)d_b + (k_3 + k_4)d_c + k_3 d_d$ = controlled power

and

$k_1 f_1 + k_2 f_2 + k_3 f_3 + k_4 f_4$ = uncontrolled power

Again, the "controlled power" for any month is determined from the condition that the total power p should be as uniform as possible.

3. Power Production of the Individual Plants

In applying the above method to systems with many reservoirs and plants, the same total power p can be achieved with many combinations of discharges from the individual reservoirs. The actual discharges are determined from the condition that, in addition to the *total* power, the power produced by each individual plant should be as uniform as possible.

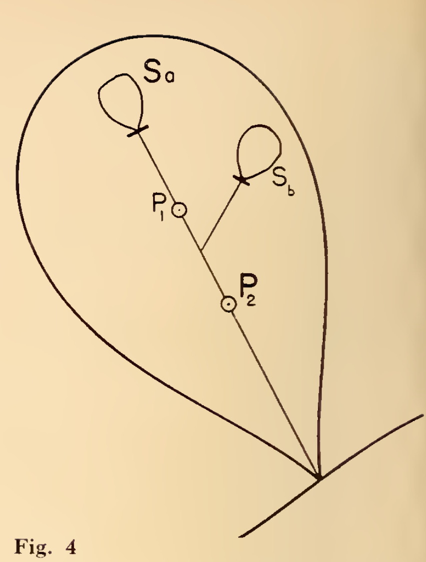

Fig. 4

In the case of the river shown in Fig. 4, we proceed as follows:

Total Power Production

$$p = (k_1 + k_2)d_a + k_2 d_b + k_1 f_1 + k_2 f_2 \quad ..(5)$$

Production of plant P_1

$$p_1 = k_1 d_a + k_1 f_1 \quad ..(6)$$

Production of plant P_2

$$p_2 = k_2 d_a + k_2 d_b + k_2 f_2 \quad ..(7)$$

Power draft from S_a

$$(k_1 + k_2)d_a = \frac{p_1 - k_1 f_1}{k_1}(k_1 + k_2) \quad (8)$$

Power draft from S_b

$$k_2 d_b = p_d - (k_1 + k_2)d_a \quad ..(9)$$

when p_d = total power draft from storages

For a given regulating period we have from equation (6)

$$\Sigma p_1 = \frac{k_1}{k_1 + k_2}\Sigma (k_1 + k_2)d_a + \Sigma k_1 f_1 \quad (10)$$

where

$$\Sigma(k_1 + k_2)d_a = \Sigma(k_1 + k_2)f_a + \Sigma(k_1 + k_2)\Delta S_a$$

and ΔS_a is the change in the storage S_a during the regulating period.

From the total production Σp_1 of plant P_1, we determine the monthly regulated power, taking into account the high values of the uncontrolled power $k_1 f_1$ for some months (usually in the spring).

The necessary additional conditions for the calculation of p_1 are established as follows;

Let p_d = Total power draft

$= p - k_1 f_1 - k_2 f_2$

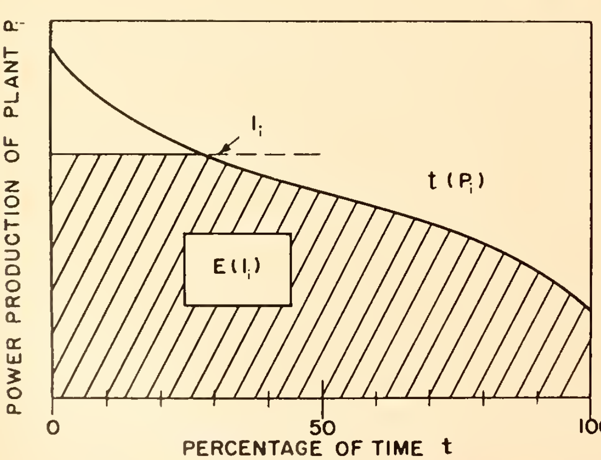
$= (k_1 + k_2)d_a + k_2 d_b.$

We have

$(k_1 + k_2)d_a \le p$ or $d_a \le p_d/(k_1 + k_2)$

and

min. $(p_1) = k_1 f_1 \le p_1$



ENERGY PRODUCTION CORRESPONDING TO INSTALLATION I_i OF PLANT P_i

Fig. 5

$$\leq k_1/(k_1 + k_2).\, P_d$$

$$+ k_1 f_1 = \max.\,(p_1) \quad ..(11)$$

The permissible monthly values of p_1 are also restricted by the storage capacities of the reservoirs S_a and S_b.

The details of the calculation of p_1 and p_2 for each month of the regulating period are carried out as in the usual case of regulation with remote reservoirs. For a full understanding of these calculations the example given at the end of this paper should be studied thoroughly.

This method of determining the power production of individual plants can be applied in the case of systems with many reservoirs and plants, provided that the plants can be considered in groups, the total number of which is equal to the number of storages in the system.

4. Installations of the Individual Plants

The calculation of the total installation, and the installations of the individual plants is based on the duration curves of p and p_1, p_2 . . .

4.1 Total Installation. From the duration curves of p we find the total primary power p_{90} corresponding to a suitable percentage of time (usually about 85 to 90 per cent). Assuming a prime load factor L for the system, we calculate the total installation from the formula:

$$I = p_{90}/L \quad ..(12)$$

4.2 Installations of individual Plants. The installed capacities of the individual plants can be determined from the following conditions:

(1) The sum of the installed capacities should be equal to the total installation

$$I_1 + I_2 + \ldots + I_n = I$$

(2) The sum of the energies produced by the individual plants should be maximum. This criterium can be stated in a more general way as follows:

The installations $I_1, I_2, \ldots$ should be such that the sum

$$F(I_1) + F(I_2) + \ldots + F(I_n)$$

is maximized where $F(I_i)$ is a suitable function of I_i, usually related to the economic losses corresponding to the installation I_i.

The second condition, in its simpler form, can be applied as follows for the calculation of the installations[5];

The energy produced by the Plant P_i (Fig. 5) with an installation I_i is:

$$E(I_i) = \int_0^{I_i} t(p_i)dp_i \quad (13)$$

where $t(p_i)$ = percentage of time corresponding to the power p_i.

The above conditions can now be expressed as follows:

(1) $I_1 + \ldots + I_n = I$

$E_1(I_1) + \ldots + E_n(I_n) = E$

(2) should be maximum

The condition for maximizing E is:

$$dE = \frac{dE_i}{dI_i}dI_1 + \ldots + \frac{dE_n}{dI_n}dI_n = 0 \quad (14)$$

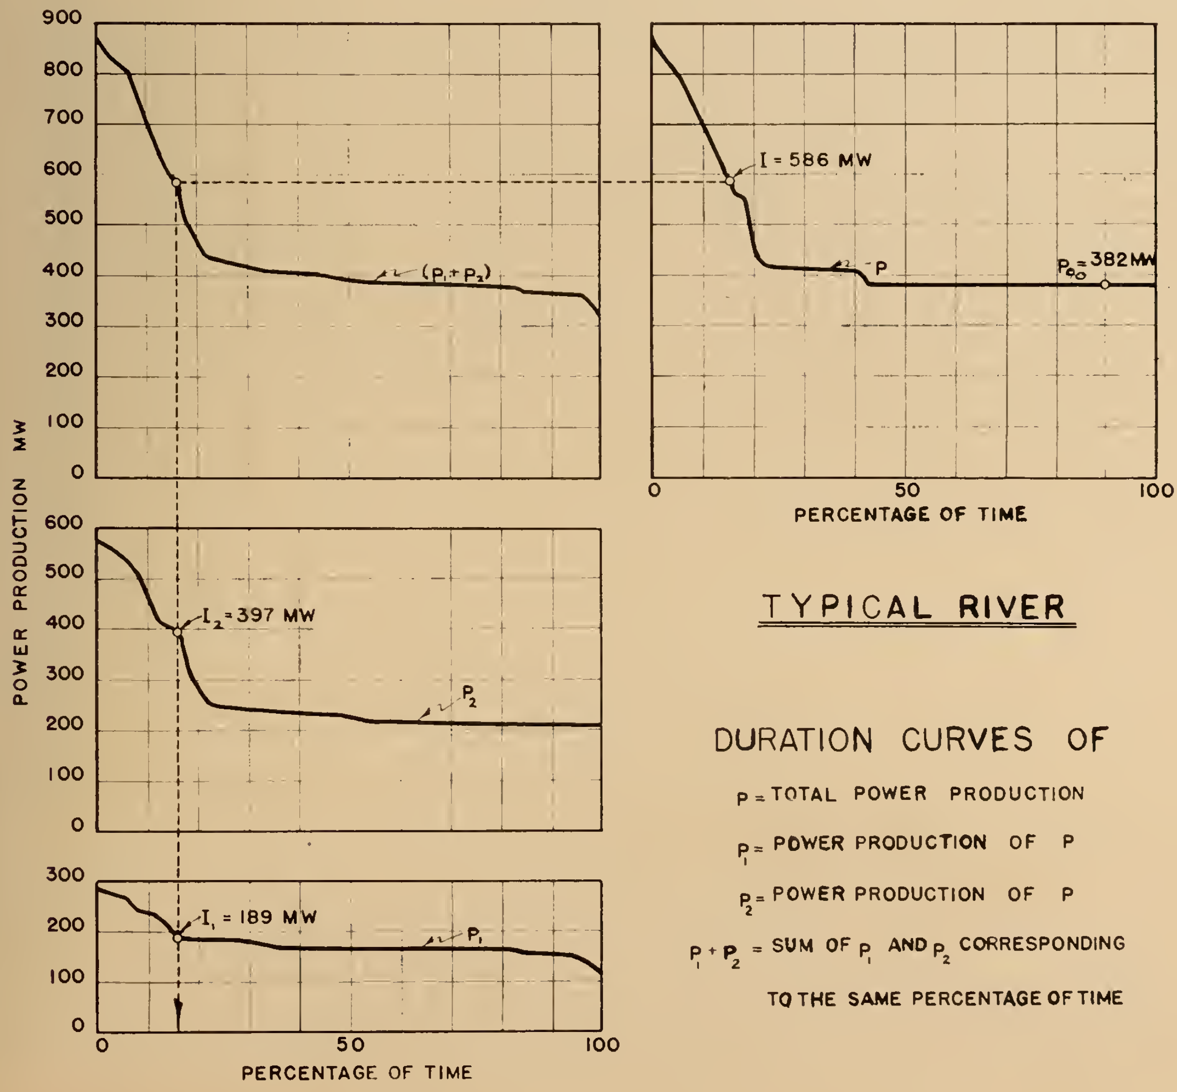
From condition (1) we have

$$dI_1 = -dI_2 - \ldots - dI_n.$$

Substituting in (14) we find:

$$dE = \frac{dE_1}{dI_1}(-dI_2 - \ldots - dI_n)$$

Fig. 6



$$+\frac{dE_2}{dI_2}\cdot dI_2 + \ldots + \frac{dE_n}{dI_n}\cdot dI_n$$

$$dE = \left(\frac{dE_2}{dI_2} - \frac{dE_1}{dI_1}\right) dI_2 + \ldots + \left(\frac{dE_n}{dI_n} - \frac{dE_1}{dI_1}\right) dI_n = 0 \qquad (15)$$

and because the differentials $dI_2, \ldots dI_n$ are now independent, we must have

$$\frac{dE_1}{dI_1} = \frac{dE_2}{dI_2} = \ldots = \frac{dE_n}{dI_n} \qquad (16)$$

But, from (13) we have:

$$\frac{dE_i}{dI_i} = t(I_i)$$

and therefore, the condition for maximizing E is:

$$t_1(I_1) = t_2(I_2) = \ldots = t_n(I_n) \qquad (17)$$

Equations (17), together with the equation

$$I_1 + \ldots + I_n = I$$

determine the installations $I_1, \ldots I_n$.

The calculations are carried out in the following way:

From the duration curves of $p_1, \ldots p_n$, we determine the curve of $(p_1 + \ldots + p_n)$ by adding together the p's corresponding to the same percentage of time (Fig. 6). From this curve, we read the percentage of time corresponding to the total installation I.

The installations of all plants correspond to this percentage of time and are found from the duration curves of $P_1 \ldots P_n$ as shown on Fig. 6.

Of course, before a final decision is made concerning the individual installations, consideration must be made of certain practical problems such as the consistency of installation in series of plants, necessary for the efficient use of the water during the time when water is being withdrawn from storage.

5. Example of the Application of the Method

5.1 Basic data for the typical river. The watershed of the typical river is shown in Fig. 4.

Heads

Head of plant P_1 = 805 ft.
Head of plant P_2 = 535 ft.

Total Head 1340 ft.

At 88% efficiency we have;

$k_1 = 0.0746 \times 805 = 60$ kw./c.f.s.
$k_2 = 0.0746 \times 535 = 40$ kw./c.f.s.

$(k_1 + k_2) = 100$ kw./c.f.s.

Storage Capacities

S_a = 11,000 c.f.s.-months
= 11,000 × 100 = 1,100 Mw.-mos
S_b = 7,500 c.f.s.-months
= 7,500 × 40 = 300 Mw.-mos

Flows

The inflows of the reservoirs, f_a and f_b, and the total uncontrolled run-offs at the plants (f_1 and f_2) are given in the regulation tabulation (Table 1).

5.2 Regulation Study. The total regulated power p is determined as in the usual type of regulation study. The drafts from the reservoirs S_a and S_b are calculated from the condition that, in addition to the total power production p, the production of each individual plant should be as uniform as possible. The details of the regulation study are shown in the regulation tabulation.

5.3 Installations of the Plants. After the completion of the regulation study we plot the duration curve of the total power production p (Table 2 and Fig. 6). From this curve we find that the power available 90 per cent of the time is p_{90} = 382 Mw. Assuming a load factor of 65 per cent, the total installation I = 382/0.65 = 586 Mw. From the duration curves of the individual power productions p_1 and p_2 we construct the curve of $(p_1 + p_2)$ as described in the text. From this curve we find that the total installation of 586 Mw. corresponds to 16.32 per cent of the time, and therefore the installations of plants p_1 and p_2 are 189 Mw. and 397 Mw. respectively.

The total energy spill (area under the curve $p_1 + p_2$ above 586 Mw.) is

$$\frac{(844+586)}{48} - 0.1632 \times 585 = 24.36$$

Mw. years.

or 24.36 × 8760 × 1000 = 0.213 billion kwh.

5.4 Power and energy potential of the typical river.

Total primary energy

382,000 × 8760 = 3.35 billion kwh.

Total energy under the duration curve of p:

21,547/48 × 8,760 = 3.93 billion kwh.

Secondary energy:

3.930 − 3.350 − 0.213 = 0.367 billion kwh.

Total installation .... 586 Mw.
Installation of Plant P_1....... 189 Mw.
Installation of Plant P_2....... 397 Mw.

5.5 Remarks on the Computations. The first step of the study is the computation of the power inflows to the reservoirs and the power plants. The repetitive nature of this computation justifies the use of punched-card computing machines, especially in the case of long flow records. After the power inflow columns are filled in the tabulation, the regulation study can be easily carried out with a desk calculator. The resulting total and individual regulated powers are then arranged in order of magnitude, using punched-card sorting machines. In this way, the time devoted to the regulation study by competent office personnel is kept to a minimum. In general the time spent in the engineering office for the completion of a study of total power production is not appreciably longer than required for a regulation study restricted to one power plant.

SILVER FALLS GENERATING STATION

P. R. Stratton, **P.Eng., A.M.I.C.E.,** *Project Superintendent*
C. T. Bath, **B.E., P.Eng., A.M.I.E.** (Aust.) *Construction Project Engineer The Hydro Electric Power Commission of Ontario*

The tunnel at Silver Falls is two miles long and was driven to 17 ft. 6 in. diameter; it will later be lined with 18 in. of concrete to a diameter of 14 ft. 6 in. Rock at the site was granite and paragneiss—generally fairly competent.

The equipment was all set up for a tracked operation, i.e., a one cu. yd. bucket capacity electric mucking machine, a number of 6 cu. yd. mine cars, a 7 drill main line jumbo, one 15-ton and two 10-ton locomotives.

An interesting feature of the tunnel driving was the construction of the two ancillary shafts, i.e., the 300 ft. intake shaft and the 200 ft. surge shaft. These shafts were excavated in three steps by a method believed to be new to Canada:

1) A pilot hole was driven from the surface to the tunnel;

2) A hoist was set up on the surface and used to support a cage for two men to drill a 6 ft. diameter pilot raise;

3) The shaft was slashed down to full size.

THE DEVELOPMENT of the Silver Falls site, where there is a difference of head of some 360 ft. between Dog Lake and Little Dog Lake, has long been considered attractive, and it became economically justified as a peak load plant following the development of all but one of the remaining hydraulic generating sites in Northwestern Ontario.

The general topography of the area, river flow records and an extensive geological survey established that the development would consist of an intake structure and shaft located on the south shore of Dog Lake and a single unit 62,000 hp. generating station at the upper end of Little Dog Lake, connected by a concrete lined 14 ft. 6 in. diam. hydraulic tunnel almost two miles long. In addition, there would be a surge shaft and tank located 900 ft. upstream of the powerhouse.

Concurrently with the preparation of engineering preliminary plans, estimates and field surveys, the construction planners developed their schedules and methods of operation. The tunnel would be driven with 3 ft. gauge track equipment from the penstock portal which was to be serviced by a track cut located outside the powerhouse excavation. Following Commission authorization to proceed on February 13, 1957, initial orders for materials and equipment were placed and field operations commenced early in April, 1957.

During the ensuing 6 months, 20 miles of road were built or regraded, 45 acres of shop and camp facilities were laid out and erected, and sufficient overburden and rock was removed to commence tunnelling operations from the penstock portal on October 8, 1957.

The geological survey, which included seismological and diamond drill investigations, indicated reasonably competent paragneiss and granite rock over the length of the tunnel and shafts, with the possible exception of a rock depression 1500 ft. from the intake.

The 3 ft. gauge track equipment used for driving the tunnel consisted of a main line 7 drill jumbo mounted on bogies, an electrically driven 1 cu. yd. mucking machine equipped with a loading conveyor, two 10 and one 15-ton diesel locomotives, and an assortment of used 5 and 6 cu. yd. ore cars, flat cars, dynamite and vent pipe handling cars.

The drill jumbo, which proved highly successful, was equipped with the latest type of hydraulic boom mounted screw feed drifter drills with 8 ft. aluminum shells. Both decks were equipped with three 3½ in. piston machines using 1¼ in. round lugged steel, the lower machines being underslung with offset booms. An additional 4½ in. machine mounted on a tripod boom and centrally located between decks was used for drilling the burn cut and square-up holes. The upper deck was provided with hydraulically actuated flaps, which when raised formed a platform 16 in. wide and 36 ft. long.

The jumbo was equipped with 6 in. and 4 in. air, water and drainage headers which were coupled directly into the tunnel service pipes by bull-hoses, the latter discharging drainage water from a vacuum pump located on the lower deck.

The hydraulic system was powered by two air motors, and the main's water pressure was boosted to 80 p.s.i. by a duplex air pump. Dynamite was handled to the upper deck by an elevator driven by a tugger hoist. Spare parts, including three complete drills together with oxy-acetylene burning equipment, were carried in purpose-made brackets on the jumbo.

The tunnel was excavated to a nominal bore of 17 ft. 6 in. diameter modified to a horseshoe shape to facilitate subsequent concrete lining operations.

The burn cut drilling pattern which was adopted consisted of two 4 in. or 3½ in. diameter cut holes with a blast hole in between them, a sweeper hole and six cut square-up holes, all 2½ in. diameter, and drilled off with the 4½ in. machine using 1¼ in. hexagon sectional "carborized" steel and series 600 tungsten carbide insert bits. The remaining holes, including the perimeter holes which were spaced 2 ft. 6 in. apart, were drilled off in blocks of ten by the six 3½ in. machines using 1¼ in. diameter round lugged carbon steel with detachable tungsten carbide insert 1⅞ in. and 2 in. D thread bits.

Average powder factors were:

5.1 lbs/cu.yd. for tunnel
8 lbs/cu. yd. for shaft pilot raises

and
2.5 lbs/cu.yd. for slashing down.

Each shift comprised a crew of 28 as follows:

Shift boss
Walking Boss
Jumbo Leader
9 miners 7} on jumbo
6 helpers 5}
2 motormen
2 switchmen
1 electrician
1 pipefitter
1 mucking machine operator
1 dumpman
1 drill mechanic
1 oiler

On day shift only, there were 6 additional personnel as follows:
1 track foreman
2 trackmen
1 labourer
1 powderman
1 pumpman

The tunnel alignment and grade was maintained by an offset centre line and concrete monuments, each face being marked up by an instrument man and chain man with a transit and radius chain.

Blasting was done electrically by a 220-v. circuit using 8 in. sticks of 1¼ in. diameter 70% driftite and 0 to 14 long period X-107A detonators with 20 ft. lead wires.

Each shift was supplied with up to 30 lengths of 8 ft. and 16 ft. and 8 lengths of 18 ft. round lugged steel with 2 in. and 1⅞ in. bits attached, together with 10 lengths of sectional steel with couplings, 2½ in., 3½ in. and 4 in. bits partly assembled.

At the outset and until January 3, 1958, first 12 ft. and then 14 ft. rounds were drilled off until the crews became fully conversant with the equipment and maintained the required cycle of a round per shift.

A bit testing programme established the make of bits with the best performance for the type of rock encountered. Including test bits, the overall footage obtained was 299 for the D series bits and 296 and 451 for the 4 in. and 2½ in. 600 series bits respectively. The bit life was considerably increased when the operation at the face became stabilized at 46 ft. per day and the steel shop techniques were improved and under better control. Thus for the latter two-thirds of the tunnel the bit life was 398 and 374 ft. respectively for the 2 in. and 1⅞ in. bits.

Likewise, the steel life figures showed a similar improvement, the 8 ft. increasing from 245 to 818 and the 16 ft. from 371 to 540.

The tunnelling crews received production bonus for average daily advances in excess of 28 ft. a day and although there were many occasions when the men would have preferred to break cycle and gain extra rounds, they were restrained from doing so in the interests of safety. The accident record of no fatalities and no serious injuries producing permanent disability justified this policy.

The average times spent on the various operations for each shift were as follows:

Drilling	2 hr. 30 min.
Loading and blasting	1 hr.
Exhaust smoke and lunch break	30 min.
Mucking, scaling and cleanup	3 hr.
Laying track, installing pipe, setting up jumbo and travelling time	1 hr.

The job operated on a 6-day, three 8 hr. shift basis with a scaling shift on the seventh day. The average rate of advance over the whole length was 40.5 ft. per day, but for the last seven months when 16 ft. steel was used the average was approximately 45 ft. per day.

Primers for all three shifts were prepared in advance by the dayshift powderman and delivered to the tunnel in compartmented containers as required.

Blasting was done electrically on a 200 v. circuit. The charge at the face was divided horizontally into two series, and by using a four-conductor cable for the last 300 ft. the two series were kept isolated until a disconnecting plug and socket 300 ft. from the face was closed. In this way induced voltages in the blasting leads could not cause circulating currents while the crew was in the vicinity of the face. The blasting cable, which was located along the spring line on the opposite side of the tunnel to the power cables, transformer stations and lighting circuits, ran from this point to the blasting stations locked switch. This was for the most part outside the portal, but was later moved inside the tunnel when tests proved the noise frequency level to be tolerable. The crew wore ear muffs when using the blasting station inside the tunnel. Loading was abandoned when lightning storms were imminent.

Immediately following the blast, the mucking machine was moved up to the face by the first muck train and proceeded to clean up the scattered rock whilst the smoke cleared.

We were fortunate in obtaining permission to dispose of 100,000 cu. yd. of tunnel rock in a nearby bay on Little Dog Lake, which kept the track grades down to 2% or less. This allowed us to haul up to twelve and eight loaded cars behind the 15 and 10 ton locomotives respectively. Some of the rock from the dump was crushed, screened, and washed to provide most of the coarse aggregate required for the project's 60,000 cu. yd. of concrete. The triple roll apron-fed portable crusher, which produced 1,000 tons a day, was equipped with an electro magnet for removing tramp iron.

The underground haulage system included four passing tracks 200 ft. long arranged in pairs at the third points along the tunnel, the first one of each pair being equippel as a servicing bay for the jumbo and mucking machine. The tunnel section was enlarged at the passing tracks, which, together with the transfer switch and transformer pocket slashes at 275 and 1100 ft. intervals respectively, were made on the fly without affecting progress at the face.

The ventilation system, which provided 15,000 c.f.m. of air on exhaust and 10,000 c.f.m. on blow, consisted of a 24 in. diameter spiral weld pipe in 40 ft. lengths, with banks of 4 contra-rotating axial flow fans at 2,200 ft. intervals. It proved very effective in that daily testing for noxious gases from diesel and dynamite fumes never showed a higher concentration than the limits specified by the Department of Labour. The pipes were transported and lifted into position on two flat cars equipped with cradled arms actuated by hand-operated hydraulic rams. They were suspended from the tunnel arch by ¼ in. diameter cable attached to two 18 in. eye bolts with expansion shells.

Power was supplied to the site at 13.2 kv. from Kakabeka D.S. A transformer station set up 700 ft. outside the portal transformed the 13.2 kv. star system to a 2.3 kv. delta system. A higher voltage than 2300 would have presented insulation problems, while at a lower voltage regulation would have exceeded acceptable values unless a large cable were used.

Power requirements were as follows:

a) *Ventilation* — Groups of four fans each 25 h.p. were set in the ventilation pipe at 2,200 ft. intervals. A bank of three 25 kva. transformers was used for each group.

b) *Mucking Machine* — Two motors had a total capacity of 130 h.p. Three 37½ kva. transformers were used. One 37½ kva. transformer was kept as a spare.

c) *Lighting* — 3 watts per ft.

d) *Electric Drainage Pumps* — 1½ in. and 3 in. had capacities of 1½ and 3 h.p.

All cables in the tunnel had to satisfy Mining Regulations. The main distribution cable was an armoured No. 2/0 size cable, rubber insulated, neoprene jacketed rated at 4 kv. The cable came in lengths of 1,100 ft., i.e., between transformer stations. Pockets for the transformer stations were slashed out during the tunnel driving so that all equipment could be set safely back from the rail tracks. Tunnel transformers were filled with non-inflammable liquid and had 4¼% taps for compensating voltage regulation.

Since no permanent equipment could be installed within 300 ft. of the face, a trailing cable 1,450 ft. long was required to cover the 1,100 ft. between transformer pockets plus this 300 ft. to supply power to the face. This cable was *type G*, neoprene jacketed for rough usage and rated at 1000 v. Voltage was transformed down to 550 v. at the input end of this line.

For lighting supply to the face a single phase 600-120/240 v., 5 kva. mobile transformer was kept 300 ft. back from the face. This was connected back to the 37½ kva. transformer by 1,100 ft. of *type W* neoprene jacketed No. 14 cable also wound on a reel.

For permanent lighting a 5 kva., 2400-120/240 v. transformer was installed every 1,100 ft. Each transformer supplied lighting 550 ft. behind and ahead of its position. Pin type sockets were used for the lifts in preference to pig tail sockets. The main current path was a two conductor, No. 2 PVC 600 v. cable surplus from other jobs and with the lamps being attached to shorter lengths of one conductor No. 12 PVC 600 v. cable spliced into the main cable.

During the winter, a 1,250,000 B.T.U. hot air oil-fired furnace, which was piped directly into the ventilating system, raised 10,000 c.f.m. of air 70°. This prevented a build-up of ice at the portal and considerably improved working conditions in the tunnel.

The compressed air supply from the central boiler and compressor house, which had an installed capacity of 3,300 c.f.m., was piped to the face through 12 gauge 6 in. diameter spiral weld pipe. The water supply and drainage system were conveyed in 14 gauge 4 in. and 6 in. diameter pipes. All three pipes were in 40 ft. lengths connected together by cast iron couplings with rubber seals, and carried along the left hand tunnel wall on purpose made triple rack pipe hangers.

Drainage water was pumped into the main line by 1½ in. diameter, 220 v. submersible pumps and four sludge tanks equipped with automatic 3 in. diameter 550 v. submersible pumps were located at 1,000 ft. intervals behind the face.

A blacksmith's shop was set up for threading, lugging and rehabilitating the 1¼ in. round carbon steel. This allowed us to make immediate changes in the length of our steel, ensured adequate supplies with a minimum stock in reserve and dispensed with heavy transportation costs to and from the suppliers in Eastern Canada. Final costs show that, including the write-off of shop equipment, steel costs were less than those for buying steel ready made: steel life was equal to or better than that of manufactured steel used in the initial stages. The four wing bits were removed from the steel, checked for gauge loss and insert failure, and then sharpened with a semi-automatic grinder or replaced as required.

In addition, the blacksmiths produced thousands of bull horn pins, pipe and cable hangers, track gauge spacers, scaling bars and mining gads.

The two shafts, namely a 200 ft. surge shaft and a 300 ft. intake shaft, were excavated by a relatively new method which was developed in Sweden.

A pilot or cable hole was first drilled from the surface to the tunnel. In the case of the surge shaft a churn drill was used to drill a 9 in. diameter hole. The rate of progress was slow and it wandered about 5 ft. off plumb. Most of this deviation however was in the last 20 ft. so that by the time several rounds were taken out the hole was near enough to vertical to allow the cage to be used in the next step. A 4 in. diamond drill hole was used for the intake shaft. It remained within 1 ft. of the vertical alignment and was drilled in a third of the time.

However, during the raising of the shafts it was found that there were two serious disadvantages in the 4 in. hole. Firstly, several rounds froze due to its inadequacy as a burn cut whilst preventing us from using a draw or vee cut, and secondly blowing smoke took five times as long.

A 5 ft. diameter steel cage was suspended on a wire rope passing through the hole from a geared down 75 h.p. electric mine hoist on the surface. Two men used the cage as a platform to drill and load each 8 ft. round of the 6 ft. diameter pilot raise, after which it was lowered to the bottom of the raise and stowed away for each blast.

The cage was hoisted to the face after the smoke had cleared, any loose rock being scaled down. It was then wedged against the sides of the raise by three spuds and six telescopic arms at the sides and the top of the cage respectively, the latter being used to support a moveable wooden drill platform.

Services — air, water communication lines, were paid out from below. After the pilot raise was completed, the shaft was slashed down to the finished 17 ft. 6 in. diameter in 10 ft. rounds from the surface by a 10 man crew using 6 jackhammers.

A second cage 5 ft. square with drawbridge style sides was used in its closed position for hoisting the men and materials, plugging the raise during drilling and loading, and in its open position for scaling and guniting.

Since the surge shaft was excavated concurrently with the tunnel, it was mucked out through a loading hopper and chute, whereas the intake shaft, which was started after the tunnel driving had been completed, was mucked out from the tunnel floor.

This method proved to be considerably safer and faster than conventional methods, and further application of the equipment would of course make the method even more desirable.

The rock in both the tunnel and shafts proved to be generally very good with little water seepage. Steel arch ribs were on the site to meet any emergency, but were never used. 2,000 Roof bolts up to 10 ft. long were required in the latter stages, especially under the rock depression previously mentioned.

Overlapping exploratory diamond drill holes were carried ahead of the face to antipicate adverse rock or

THE DESIGN OF A DANIELS-BOYD NUCLEAR STEAM GENERATOR A 400 MW. (NET E) POWER PLANT

Winnett Boyd, M.E.I.C., *President,*
Winnett Boyd Ltd., Montreal, Que.

J. Arthur Paget, M.E.I.C., *General Atomics Division,*
General Dynamics Corp., La Jolla, California.

P. Hamel, *Orenda Engines Limited, Malton, Ontario.*

A full description of the Canadian nuclear steam generator, suitable for use in a public utility power station and incorporating an active circuit, helium cooled, ceramic reactor of the general type first proposed by Dr. Farrington Daniels.

THE DANIELS-BOYD Nuclear Steam Generator (see Fig. 1) is a device which utilized the heat from uranium fission to produce high quality steam (2,400 psiG, 1,050°F.) for the generation of electricity in large public utility power stations. It has two major advantages over the other nuclear steam generators at present in operation or under construction. These are:

(a) The power output has been greatly increased in spite of reduction in size and/or complexity;

(b) The overall thermodynamic efficiency in the conversion of heat to electricity has been increased to 33½%.

Both these advantages stem from the high reactor core temperatures which have been made possible by eliminating from the core non-refractory materials such as metals. Because of this and other improvements, a nuclear power station incorporating a Daniels-Boyd Reactor (DBR) in its present form will produce electrical power in Canada at a cost competitive with that from the most modern coal-fired stations. Moreover the development potential of the DBR is such that power costs will decrease significantly as operating experience is gained, since the present design parameters are deliberately conservative.

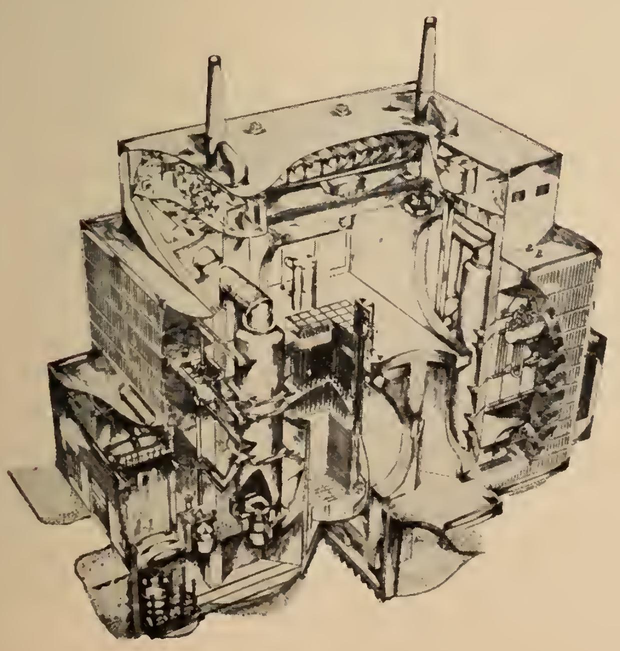

Fig. 1 Daniels-Boyd Nuclear Steam Generator.

Description

Superficially the Daniels-Boyd Nuclear Steam Generator greatly resembles the equivalent devices found in the English nuclear power stations now under construction, particularly those at Bradwell, Hunterston and Hinkley Point. In both designs the heat producing reactor core is contained in a steel sphere about 70 ft. in diameter filled with the primary cooling gas under pressure (200 psiA for Hinkley Point and 215 psiA for the DBR). In both also this so-called cooling gas (CO_2 for the English reactors, helium for the DBR) is circulated through the reactors and the heat exchangers or steam raising units where water is boiled and the resulting steam is superheated. The superheated steam is then used to drive conventional steam turbines coupled to generators. However, due to the low operating temperatures of the English reactors, the steam turbines associated with them are low temperature and pressure affairs and cannot therefore be built in the very large sizes required for modern public utility power stations. By comparison the most modern type of turbo-generator can be used in a power station incorporating a D-B Nuclear Steam Generator and we have, in fact, obtained a preliminary quotation on a suitable 450 Mw. unit.

The D-B Nuclear Steam Generator is based on the use of a mildly active circuit. This resulted from the reasoning that if a reactor is designed for a closed cooling circuit and appropriate scavenging,* then cladding or canning as it was originally called, can logically be eliminated. The canning tradition began with the early plutonium production reactors in which atmospheric air or river water was circulated for cooling. Thus fission products could not be allowed to get into these coolants which were subsequently discharged. Consequently all the fuel elements were canned. This was possible because with the low reactor temperatures which could be used, the cans could be made of relatively cheap metal which was reasonably compatible from the nuclear point of view and at the same time sufficiently corrosion resistant.

*See Addendum.

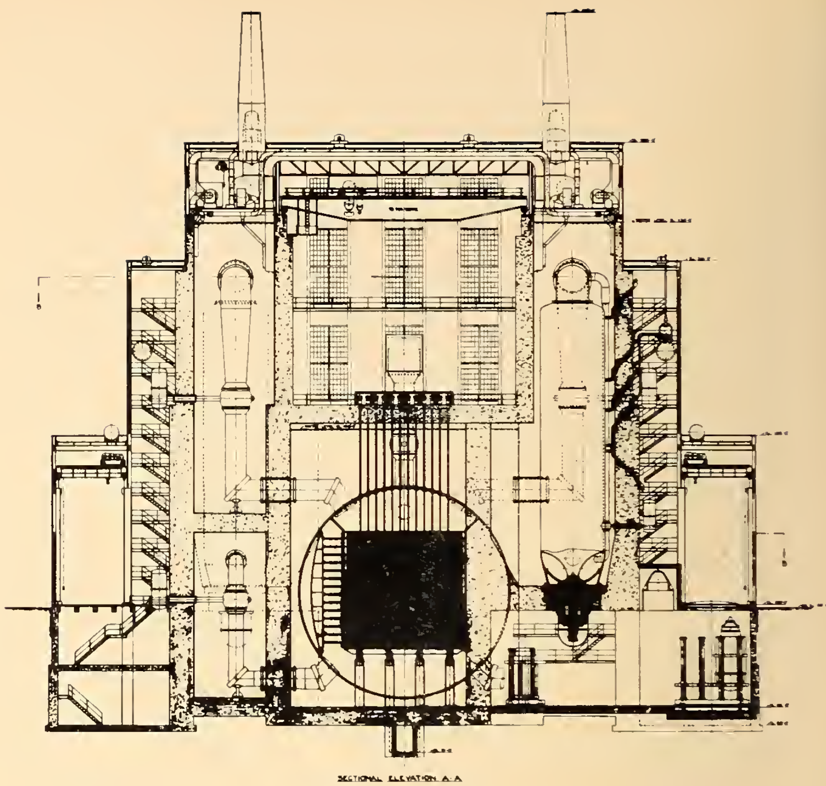

Fig. 2. Sectional elevation A-A.

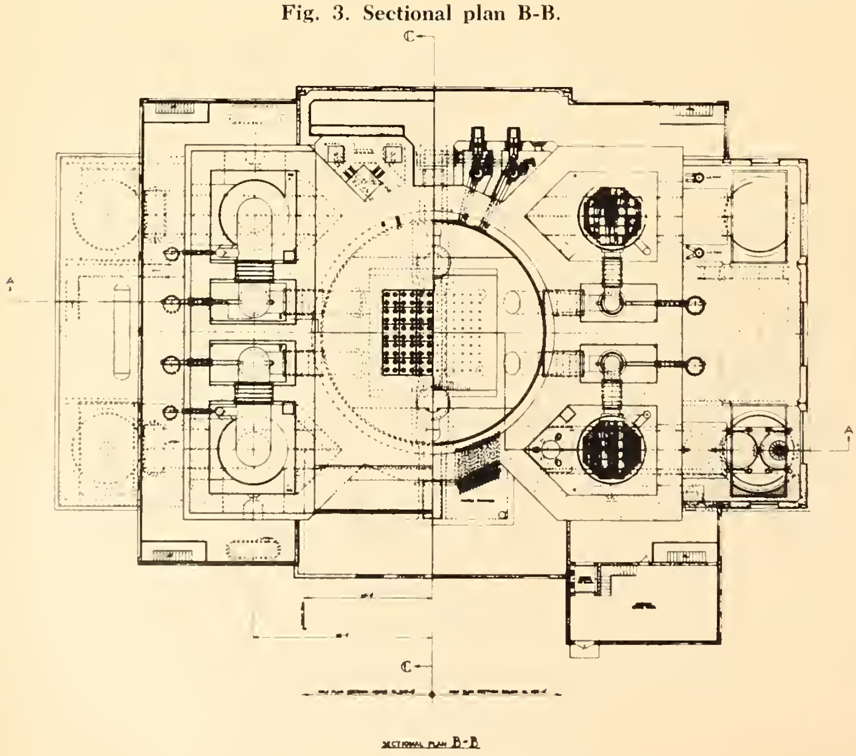
Transplanting of this canning philosophy into closed circuit high temperature reactors, and using of canning materials whose value exceeds that of the uranium fuel itself, is a peculiarity of existing power reactor designs which seems unlikely to survive in central station practice.

In fairness to the British it must be admitted that since the canning of the Calder Hall type fuel elements was required to provide the necessary cooling area, it was logical to use it to contain the fission products. But in a high temperature gas cooled reactor where the only reason for canning is fission product containment, we doubt that the practice will survive the test of time.

Fig. 3. Sectional plan B-B.



The use of even a mildly active circuit requires that the heat exchangers or steam raising units be shielded, that special provisions be made for servicing such things as the main gas circulators etc., that a continuous gas purification system* be provided, and that a system of fuelling be devised that requires the very minimum number of access openings into the active circuit. The high gas temperatures that are necessary to produce modern quality steam require special design provisions if the equipment in the gas circuit is to be fabricated from carbon steel. These were the problems that faced us when we set out to design the D-B Nuclear Steam Generator.

The heart of this generator is an approximately cubical shaped (actually 36 ft. long x 38 ft. high x 40 ft. wide), graphite moderated, uranium monocarbide fuelled nuclear reactor or "pile". (See Figs. 1, 2, and 3). The size chosen was the largest for which there was precedent, i.e. the maximum

*This becomes a part of the Scavenging System—See Addendum.

size that would fit into a 70 ft. diameter sphere. We found that the higher operating temperatures possible with such a pile would permit a heat output of 1,200 Mw. With modern turbine efficiencies this is somewhat more than enough for a gross electrical capacity of 460 Mw. which will give a net sent-out of 400 Mw. (E). The pile itself differs from the Calder Hall type by virtue of having horizontal rather than vertical fuel elements although it does have vertical cooling flow. This is the first and a very important novel feature of the design.

Horizontal fuel elements were chosen in preference to vertical ones because ceramic fuel elements are inclined to be brittle and thus cannot be easily loaded into the reactor from the top (in tension). The only alternatives therefore are vertical fuel elements with bottom charging or horizontal continuously supported fuel elements. We chose the latter as bottom charging machines seriously compromise the pile support structure and vice versa.

Fig. 4 shows that the pile itself is an assembly of the three basic types of graphite blocks. This results in a pile which has horizontal through-holes for the fuel elements, arranged on an 8 in. square lattice, with a series of vertical sinuous passages through which the cooling gas (helium) flows upwards from the bottom to the top. At regular intervals (32 in. centres), the moderating blocks have large vertical holes to accommodate 120 vertical control rods. The complete pile is prevented from collapsing outwards by a restraining structure, a portion of which can be seen in Fig. 2. This is assisted during operation by the positive pressure differential which exists between the outside and the interior of the pile. The fuel elements themselves, or slugs as they are called, (see Fig. 5) are pushed through the horizontal holes in the pile by the Charge-Discharge machines which will be described later.

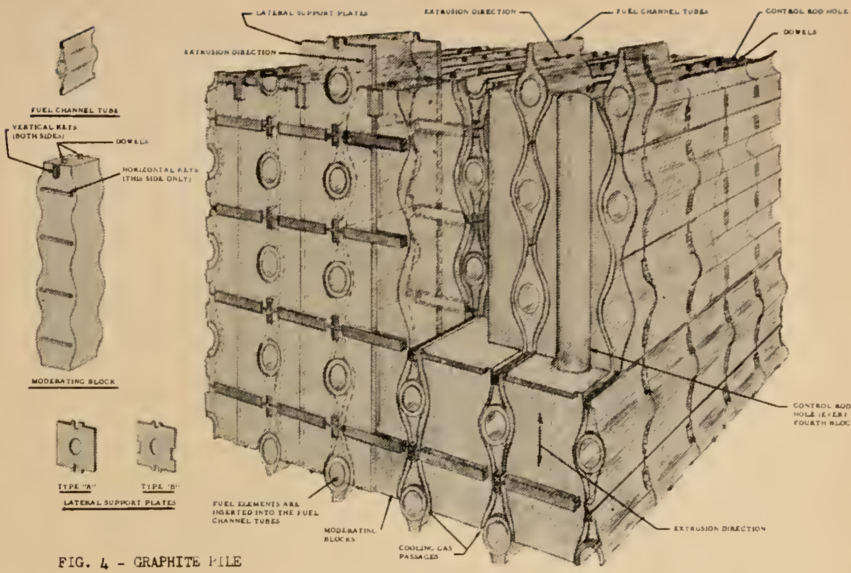


Fig. 4. Graphite pile.

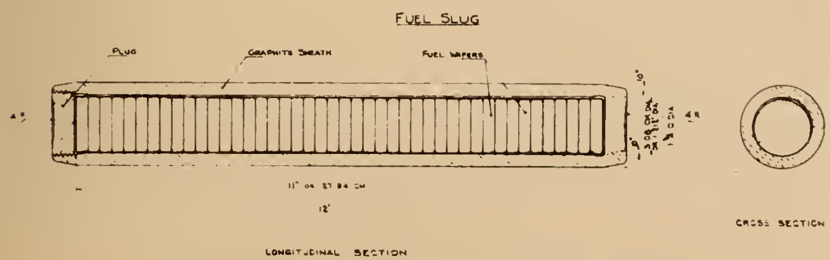
The fuel elements, which are 12 in. long and 1¾ in. outside diameter, are made of ¼ in. thick uranium monocarbide wafers contained in porous graphite sheaths. Obviously, differential expansion clearances must be provided between the fuel wafers and their sheaths as well as between the outsides of the sheaths and the horizontal pile holes into which the slugs are charged. However, this must be done without seriously affecting the flow of heat from the fuel wafers to the helium cooling gas on the outsides of the fuel channel tubes. It is accomplished by means of a rather simple arrangement which is the second and equally important novel feature of the design.

In Fig. 6, which is a cross section of two fuel elements in their fuel channel tubes, the fuel wafers are in the centres. They are surrounded by the graphite sheaths which in turn are surrounded by the fuel channel tubes. The helium coolant flows around the outsides of the fuel channel tubes from the bottom to the top. If the fuel wafers were truly circular and of a smaller diameter than the hole in the graphite sheath, then line contact between the two is all that could be expected. However, if the peripheries of the fuel wafers comprise the arcs of three circles, each having the same radius as the bore of the graphite sheath but with different centres, then each wafer must contact the bore of the graphite sheath for 120° of arc. As there are 44 fuel wafers in each slug, the average effect will be that the fuel wafers will contact the bottom third of the graphite sheath. Further, it will be appreciated that with this design, as large a clearance as required can be left at the tops of the wafers without adversely affecting the bottom contact.

A somewhat different arrangement is used to ensure good thermal contact between the outsides of the fuel slugs and the bores of the fuel channel tubes. The outsides of the fuel slugs are made circular while the bores of the fuel channel tubes have troughs machined in them which extend over the bottom 120° of arc. These troughs have radii equal to the outside radii of the fuel slugs. Thus the slugs will settle into the troughs and good thermal contact will result.

Heat transfer calculations based on this arrangement and using appropriate contact areas, film coefficients and material conductivities, indicate that adequate heat transfer will be obtained, that 75% of the heat flows through the lower half of the assembly with 25% going through the upper half, and that the maximum

Fig. 5. Fuel slug.



fuel temperature within the pile will be of the order of 2,900 °F. at full load with a corresponding fuel slug surface temperature of 1,800 °F.

Since the calculations for the above were made, information from Germany has indicated that the decrease in the thermal conductivity of uranium monocarbide with increased temperature is more severe than was first thought.* The data are as yet scanty but, if true, will necessitate some fuel element redesign to maintain the above low fuel element temperature. However, little difficulty is anticipated in doing this, and two possible solutions are the use of a graphite core inside an annulus of uranium monocarbide or the use of a mixed (cermet) fuel made of uranium monocarbide and graphite.

Having evolved a satisfactory high temperature pile design, the next task was to design a gas circuit which could cope with the high temperature gas coming from the reactor and direct it through appropriate steam raising devices or heat exchangers for the purpose of producing high quality steam. By examining Fig. 2 it will be noted that the gas flow in the main circuit is upward through the pile, through the ducts to the tops of the heat exchangers (each 21 ft. 6 in. I.D. x 90 ft. high), downwards through the heat exchangers, through the single stage centrifugal blowers and from thence back to the bottom of the pile.

The steam conditions decided upon were the highest that modern central station turbines can handle, i.e. 1,050 °F. and 2,400 psiG at the throttle. However, to get as large a gas temperature drop as possible through the heat exchangers (and an equally large rise through the pile) in order to keep the gas flow and thus the pumping power to a minimum, it was decided that a dual pressure system, similar to that employed at Calder Hall, was required. The steam conditions chosen for the low pressure portions of the heat exchangers were 950 °F. and 600 psiG. The estimated quantities of steam that can be produced are 2,132,000 lbs./hr. of H.P. steam and 1,180,000 lbs./hr. of L.P. steam.

To produce the above steam and yet keep the heat transfer area in the heat exchangers within reasonable limits, fairly high gas to steam (or water) temperature differences had to be used. Thus it was decided that the helium coolant should have a maximum temperature of 1,250 °F. and a minimum temperature of 450 °F.

This top gas temperature is well above the maximum to which carbon steel pressure vessels can be subjected, and as alloy steels could not be considered because of cost, the incentive to "invent" a suitable high temperature gas circuit obviously existed. It was reasoned at the outset that if carbon steel pressure vessels were to be used they would have to be internally insulated. The choice of internal insulating material was almost obvious, i.e. it had to be something that would not "foul" the pile if it "dusted". The only material that comes within this category is commercial carbon. While this material has the same excellent thermal shock resistance as graphite, it has a thermal conductivity only one tenth that of graphite and considerably below that of magnesia at the temperature at which it will be used.

Even with internal insulation the carbon steel pressure vessels would heat up if they were not externally cooled. At first it was thought that air cooling would be adequate but it was not long before the idea of

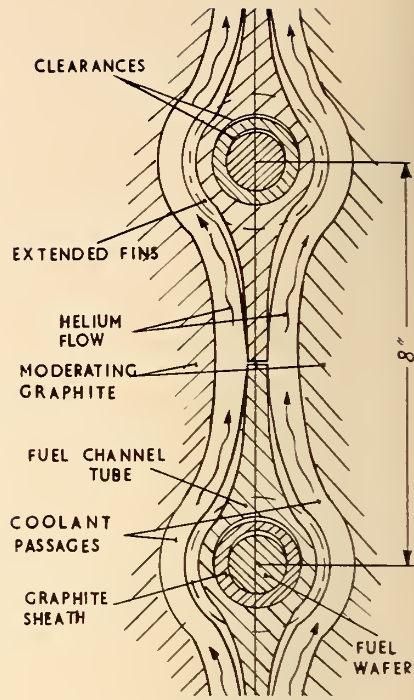


Fig. 6.

external water flooding was evolved. This came about logically and is the third novel and very important fundamental feature of the design.

With an active cooling circuit, the heat exchangers and ducts as well as the reactor itself must be shielded. This means that massive concrete shielding walls must be built around all these pieces of equipment. In short, the equipment will be housed in the equivalent of concrete tanks. Thus, it was reasoned that if these concrete tanks were steel lined (to prevent water leakage) and filled with water, the carbon steel pressure vessels would be adequately cooled with many other desirable results. One of the most important of these is that very uniform vessel temperatures can be maintained. This practically eliminates differential thermal expansion and the necessity for expansion joints in the ducts. This in turn means that the ducts do not have to be kept in one plane which results in a very compact arrangement. (See Fig. 3). This is best illustrated by stating that the building volume of a D-B Nuclear Steam Generator is somewhat less than that for the equivalent modern coal-fired boiler.

Another desirable result of this external water flooding is that it con-

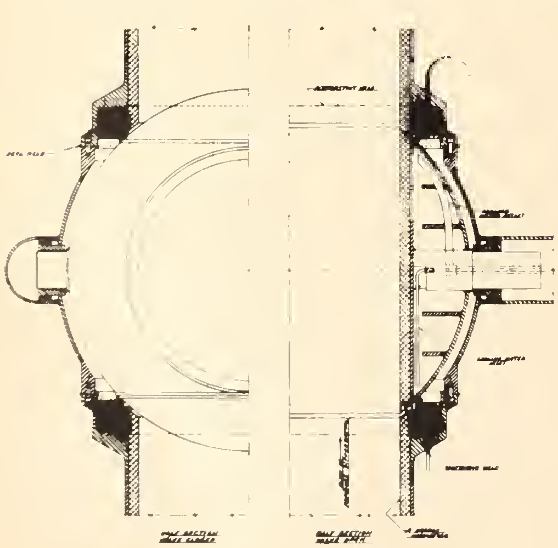

Fig. 7 Spherical helium valve.

*This has since been contradicted by a paper entitled "The Physical Properties of Uranium Monocarbide" by F. Rough (BMI) and C. A. Smith (AI) presented at the December 1958 meeting in Detroit of the American Nuclear Society which indicates that the thermal conductivity of UC improves above about 500°C.

tributes substantially to the shielding and completely eliminates the so-called "thermal shield" which in other power reactors is made of very thick steel or cast iron. Yet another is that the external water flooding permits the entire pressure circuit to be hydrostatically tested after it has been erected in place and prior to the "internals" being installed. This is a most important safety feature.

Many secondary advantages stem from this external flooding of the primary gas circuit. Among them is the fact that a higher internal gas pressure can be used. Another is that the main gas isolating valves can be of the spherical type with water cooled spheres and double seats (see Fig. 7). This renders them almost insensitive to the internal gas temperatures and means that still higher gas and steam temperatures are possible with this type of nuclear steam generator. Another advantage of the water cooling is that the actual pile support structure, which consists of hollow columns, box girders and box beams, can be internally water cooled. This structure can be seen in Figs. 2 and 10.

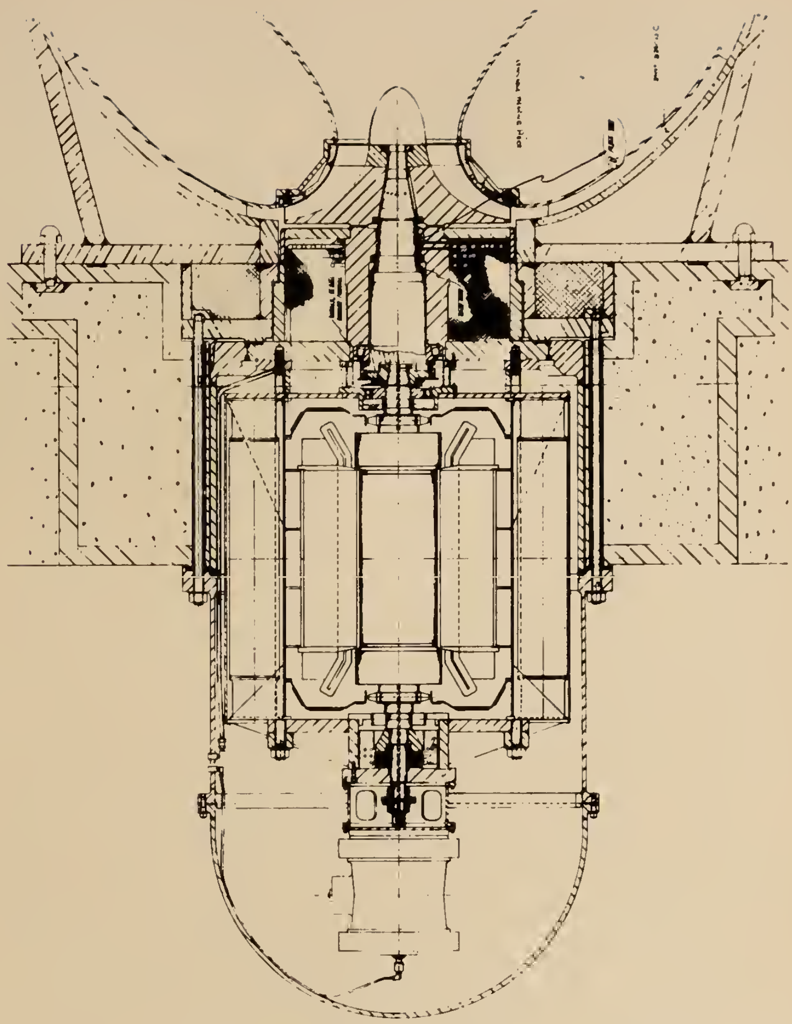

Fig. 8. Blower assembly.

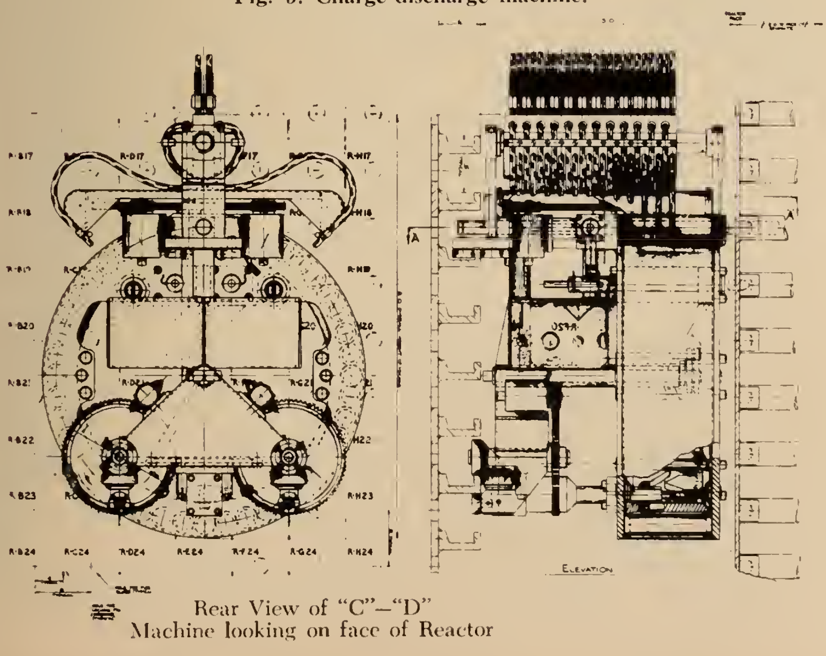
Because of the active circuit special attention had to be given to the design of the main blowers and their driving motors as well as to the various other items of equipment which penetrate the active circuit from the non-active regions. The main blowers, motors and pony motors are illustrated in Figure 8. It will be observed that they are completely "canned" assemblies. Active helium can be prevented from entering the motor cans, as well as all the other gas filled devices that protrude beyond the shielding, by continuously flowing purified helium into them. This helium will come from a purification system having a capacity of 200 cfm at 200 psiG. The helium pumps used in the purification system will be metallic diaphragm CORBLIN pumps which are made in France. These are very cunningly designed affairs in which the metallic diaphragms are relieved of any stresses other than their own flexural stresses. Thus they are available as compressors in standard sizes ranging from 60 cfm, 210 psiG in one stage to 18 cfm, 3,700 psiG in two stages. The company has also made a high pressure machine having a delivery pressure of 15,000 psiG.

The method of charging and discharging the fuel slugs that was evolved for the Daniels-Boyd Reactor is the fourth important fundamental feature of the design. In tackling the problem the premise used was that the number of openings into the active circuit must be kept to a minimum. Obviously the absolute mini-

Fig. 9. Charge-discharge machine.



mum is one. The next best is two and the system which we have evolved requires only three: two inlet and one discharge. The hearts of the system (for it has two to permit bi-directional fuelling) are the Charge-Discharge or C-D machines illustrated in Fig. 9. Each of these consists of a magazine, an indexing system, a ram, a frame and appropriate wheels. All of the motions in the C-D machines are operated by 500 psi helium. The machines themselves operate on horizontal static tracks built within the reactor pressure sphere (see Figs. 10 and 11) and incidentally, only static devices remain in the sphere. All the pieces of mechanism which might require maintenance are retractable from the sphere.

The C-D machines are lowered into the sphere on track equipped dollies which run on vertical tracks extending from the elevator heads as seen in Figs. 10 and 11 down to the bottom of the pile. Each of the elevator shafts is equipped with a spherical isolating valve having double seats and as large a sphere as is required for shielding when closed. Below each elevator head is a diametrically split lead gate with hose and cable slots. These gates are kept closed at all times except when the C-D machines are passing through. The entire elevator heads are removable and are internally shielded with lead to protect maintenance personnel. When in use they are surrounded with additional removable concrete shielding to protect personnel from the radiation emanating from "Hot" slugs.

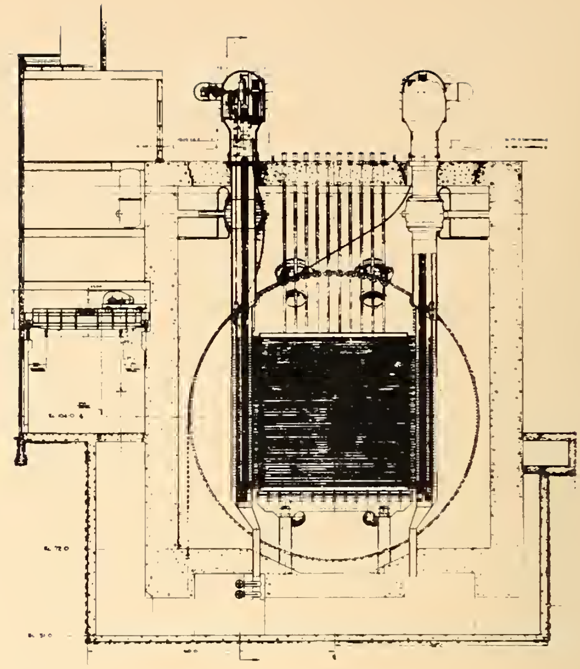


Fig. 10. Fuelling system.

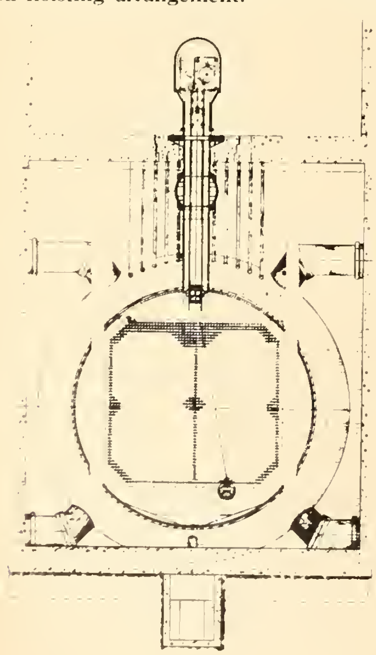
An interesting feature of the elevator heads is that there are no shafts or other dynamic devices projecting through them from the active circuit. This also applies to the rest of the reactor and it is the reason why we think that the helium system can be made gas-tight. All of the active circuit joints, with the exception of the maintenance joints, are welded. All of the maintenance joints are static and are located beyond the regions of high temperature and high activity. Thus organic gaskets can be used, and we have found that such joints can be made helium-tight. Finally all of these maintenance joints face purified rather than active helium. This is a desirable safety feature should small leaks actually occur in any of these joints.

One rather important feature of the Charge-Discharge system is the method of locking the elevator dolly onto the horizontal tracks within the reactor sphere. This is done in such a way that it cannot be unlocked until the C-D machine returns to it. The device is illustrated in Fig. 12 and depends on the fact that while the dolly locking mechanism is on the dolly, the key for it is on the C-D machine. Thus, when the C-D machine has moved away from the dolly along the horizontal tracks, the dolly cannot be unlocked and withdrawn.

In operation the fresh fuel slugs, which will be shipped in helium filled, solder sealed tins similar to English cigarette tins, are loaded into the C-D machines through helium filled atmospheric glove boxes and gas locks on the two elevator heads. Spent fuel slugs are discharged from the C-D machines in the elevator heads into turning devices and thence into discharge tubes. The spent slugs slide down these discharge tubes under the influence of gravity and end up in a spent fuel slug canning machine which is enclosed in a pres-



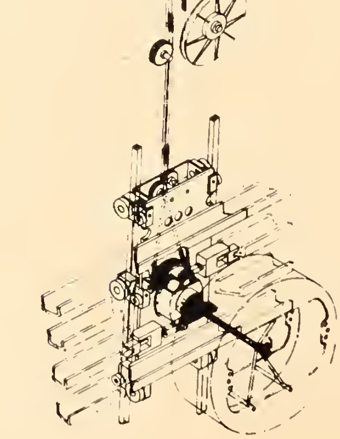


Fig. 11.—Below: Fuelling system.

Fig. 12.—Right: Elevator dolly locking and hoisting arrangement.

sure shell and operates in helium at pile pressure. In this machine the spent slugs are put into carbon steel containers (two to a container) which have end caps welded onto them. The filled containers are then discharged into a shielded flask through a helium lock. They are then transported by this flask to a surface decontaminating bath and after this operation is completed, they are put into a cooling pond for medium term storage before being sent to the chemical processing plant.

Nuclear Physics

While the engineering work on the overall D-B Nuclear Steam Generator was in progress, a series of calculations was made, with the aid of desk calculators and a Datatron digital computer, on the nuclear physics of the pile itself. Naturally, with the limited time and man-hours available, our accomplishments in this field were limited. We did, however, make calculations of optimum lattices, of the excess reactivity vs. temperature (see Fig. 13), of the effect of graphite purity and bulk density on initial reactivity (see Fig. 14) and of the probable burn-up that might be expected with this type of reactor.

It will be appreciated that because the Daniels-Boyd reactor is nothing more than a helium cooled heterogeneous assembly of uranium monocarbide and graphite (325 tonnes of UC and 2,540 tonnes of graphite) without any parasitic material, it will have as high a nuclear efficiency as it is possible to obtain with a high temperature, graphite moderated gas cooled reactor. This was confirmed by our reactivity and burn-up calculations. However, very modest enrichment was found to be necessary because of fission product poisoning and the net deterioration of the neutron reaction cross sections with temperature.

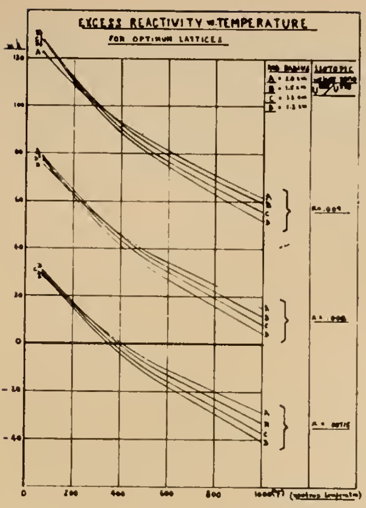

Fig. 13.—Left.

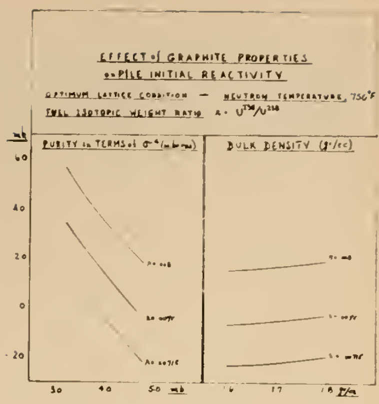

Fig. 14.—Above.

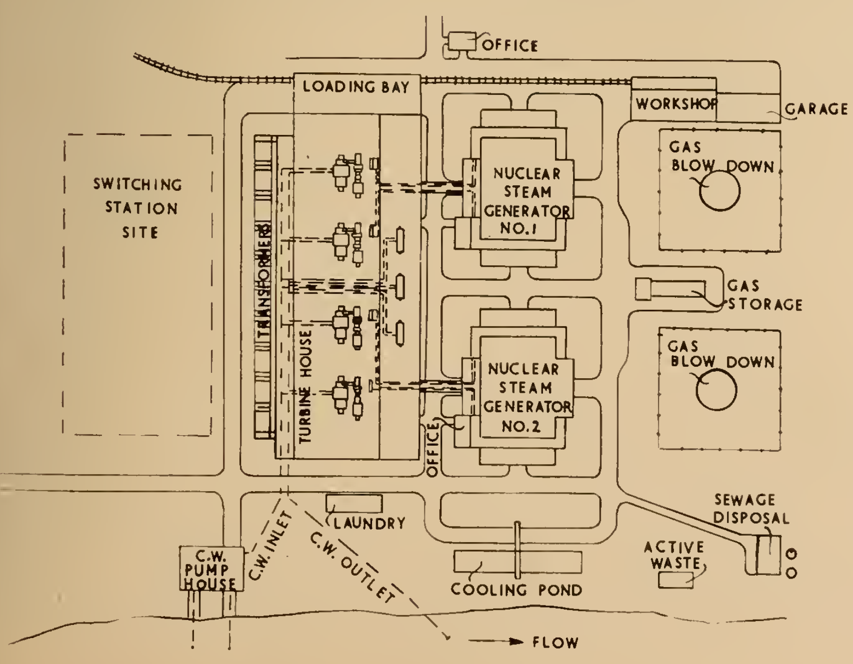
Although it was not possible to fully optimize the pile, it was calculated that for an optimum lattice with an 8 in. pitch and a fuel element diameter of 1¼ in., the isotopic concentration of U^{235} in the fuel would have to be increased to 0.75% for the reactor to remain critical after a cold, clean start. Also, preliminary calculation further indicated that a burn-up of about 4,200 MWD/tonnes could be expected with 0.8% initial U^{235} content and 9,800 MWD/tonnes with 1.0% initial U^{235} content.

Fig. 15. General arrangement of an 800 MW. nuclear power station.



Economics

Because of variations in accounting practices and financing charges, uncertainties about the cost of plutonium and similar uncertainties about the long term cost of uranium, it must be strongly emphasized that the power costs expressed in mills are not directly comparable with such cost figures produced by others.

In arriving at the figures quoted we used the following assumptions based on the most conservative practices used by the Hydro Electric Power Commission of Ontario:

Fixed charges 8½% per annum
Fuel inventory 4% per annum

An allowance of $1.00 per kilowatt per year was made for insurance and contingencies, and the operating cost was based on the figure of 0.90 mills per kwh. as given on page 128 of the Ninth Annual Supplement of the Federal Power Commission's Report F.P.C. S-127 on steam-electric plant construction cost and annual production expenses as applicable to the 500 Mw. Philip Sporn plant at Graham, W. Virginia.

In the absence of other data natural uranium was costed at the U.S. Atomic Energy Commission price of $40 per kilogram and enrichment costs were taken from the A.E.C. table of charges for enriched uranium.

A complete 400 Mw. station (see Fig. 15 which illustrates an 800 Mw. station) is estimated to cost $100 million or $250 per installed kilowatt. Of this amount $40 million or $100 per installed kilowatt represents site and plant costs equivalent to those of a coal-fired station less the boilers.

The remaining $60 million or $150 per installed net electrical kilowatt represents a preliminary approximation to the cost of the 400 Mw. (net E) Nuclear Steam Generator and its associated building and equipment.

A detailed engineering estimate indicated that the fabricating cost of each fuel slug would be approximately $21. According to one preliminary study that was made, the reactor will contain about 100,000 natural uranium slugs and about 8,000 enriched slugs. The following power cost estimate was based on this and is considered to be conservative.

A computer program, which would have determined the optimum relationship between burn-up and enrichment, was undergoing computer trials when design work was stopped. Also, detailed reactor cost estimates were well advanced at that time but experimental fuel element fabrication had not begun.

With these reservations the power cost shown in table I can be compared with about 7 mills per kwh. (based on the same costing assumptions) for the original R. L. Hearn station of the Ontario Hydro.

Also since preparing the original manuscript, it became apparent that our reactor arrangement is an ideal one for the incorporation of a gaseous and volatile fission product scavenging system. This, we found, could be added without compromising the reactor in any way and its basic design has now been completed.

Table I

Estimated Power Cost

	Mills per Kwh.
Capital charges at 8½% on $100,000,000 assuming 400Mw. Operation for 7,000 hrs. per year	3.030
Fuel inventory at 4% on $18,644,000	0.266
Fuel Costs	2.135
Spent Fuel Cans	0.042
Insurance and Contingencies—$1.00 Kw./year	0.143
Operation based on the Philip Sporn Station	0.900
TOTAL	6.516

This added feature, together with ceramic fuel, graphite moderation and helium cooling gives the Daniels-Boyd reactor great inherent safety. The vast heat sink of the graphite plus the very high melting point of the ceramic fuel renders the reactor almost completely immune to the effects of blower power interruptions and short time power excursions. In the very unlikely event of a structural failure in the main cooling circuit, a minimum amount of activity will be released to the atmosphere because the gaseous and volatile components of the fission products will have already been scavenged from the system and confined in separate containers.

On the other hand the type of gas cooled reactor now being built in the U.K. does not enjoy such safety advantages. This is due to the very small margin that exists between the operating and melting temperatures of their magnox canning. Such reactors will thus be more sensitive to blower power interruptions and short time power excursions. And in the event of a structural failure in the main cooling circuit, some of the magnox canning will most probably melt and as a result, release a portion of the concentrated fission products to the surrounding countryside. In spite of this however, the English consider their reactors to be sufficiently safe to build them in large numbers and without the American type of safety containment.

Conclusions

1. We believe that the only type of nuclear power reactor that will survive the test of time in the public utility power business, i.e. that will produce competitive power, is one which can generate steam at present day temperatures and pressures, can be made with the existing types of boiler making and heavy engineering machinery, can be made of present day engineering materials, can be safely operated by average plant personnel and *IS SELF-SUSTAINING (with appropriate chemical processing) AS FAR AS ENRICHMENT IS CONCERNED.*
2. The helium cooled, active circuit, graphite moderated, carbide fuelled, ceramic reactor appears to be the only type that will satisfy the above requirements.
3. The Daniels-Boyd Nuclear Steam Generator incorporates such a reactor and is an engineering contribution to the solution of the problem of economic public utility nuclear power.

DISCUSSION

of Technical Papers and Other Articles

Magnetic Amplifier Control for Reversing Hot Mill Auxiliaries
R. L. Duke and L. R. Hulls
Canadian Westinghouse Company, Limited, Hamilton, Ont.
The Engineering Journal, 1959, July, p. 89

W. G. Wright*

BEFORE embarking upon a specific discussion of the technical points raised in the paper, I would like to make one general observation. The authors' paper is an excellent example of the care and insight which electrical engineers must use in order to enable a piece of production machinery to deliver the goods. Time was, that provided you had a starter and enough horsepower, you were in business. Now the ultimate limit on production (and hence return on investment) may well be the performance of the electrical system. The present paper demonstrates this admirably and, I might add, very lucidly.

The Canadian General Electric has never been quite so ready as Canadian Westinghouse to use push pull magnetic amplifiers for direct excitation of DC generators. Instead we have preferred to use a rotating amplifier driven by small control magnetic amplifiers. Our reasons for this are as follows:

(1) In order to get two fully rated fields on the generator we usually end up with a more expensive generator which offsets any economy brought about by eliminating the rotating amplifier.

(2) The performance of both systems may be perfectly matched to the application but we believe that the rotating amplifier circuitry is simpler for an electrician to follow. Perhaps this is a matter of how the circuits are drawn. A three phase push pull magnetic amplifier circuit with all its attendant filtering may be quite complicated. However, it may be made to look simple if these devices are drawn as blocks with input and output terminals.

(3) Commutators and bearings present a maintenance problem on the larger machines rather than small rotating amplifiers. Thus the bearing and commutator difficulties really stay with you even though the main amplifier has been made static.

(4) Since we keep our control magnetic amplifiers small (about 75 VA) we can usually make them 60 cycle. Even if we do go to a higher frequency we are able to generate this by small frequency multipliers rather than supplying a high frequency generator.

The above is a brief review of a difference in viewpoint which has been going on for some time now. It's probably really due to our respective accounting systems and so will never be resolved.

I wonder if we will get in unison again when the power generators themselves are replaced by static devices.

In conclusion I would like to ask the authors to expand a couple of points which aroused my curiosity.

(1) Referring to the block diagram we see that the feedback has a gain of 7. A typical output voltage of a bloom mill auxiliary is 500 volts. This means the input pattern is 4000. This is a very large number if it refers to ampere turns. In other words, I am saying that with a total loop gain of 7 I would expect the feedback gain to be .1 and the forward gain 70.

(2) The speed amplifier is outside the regulating loop. Are these magamps biassed to their midpoint, and if so how do you ensure freedom from drift?

(3) A time constant of 2 seconds for a 150 Kw. generator having two fully rated fields seems somewhat low. Is there anything special about this machine such as small air gap or laminated frame.

* Specialist — Metal Rolling & Processing Engineering, Systems Application Engineering, Apparatus Department, Canadian General Electric Co. Ltd., Peterborough, Ont.

G. L. D'Ombrain*

Dr. G. L. D'Ombrain of the McGill University also raised two questions from the floor and the following is our interpretation of his queries.

1. How are time constants determined by calculation or by test?

2. Please elaborate on the step or steps taken from the open loop transfer function to the characteristic equation. Is the characteristic equation derived from the closed loop transfer function?

* Professor, faculty of Electrical Engineering and Chairman of the Department, McGill University, Montreal, Que.

R. B. Cornell*

I congratulate the authors on their paper. It describes an excellent method of controlling Reversing Hot Mill auxiliaries.

The importance of prompt reversal and fast acceleration of these auxiliaries can be appreciated when we note that the mill would make about 23 passes to reduce an ingot and this would require about 190 seconds. If the time required to reverse the ingot and return it to the mill was increased by only 1 second per reversal, it would add 23 seconds to the rolling time and decrease production by 12%.

On the slide, fig. 1, four motors totalling 275 hp. are shown connected to one 150 Kw. generator. The motors are selected to accelerate the rolls and the share of the ingot that is driven by those rolls. When rolling begins, the ingot may rest on only two rolls and these must have motors powerful enough to accelerate the rolls and the whole ingot.

The table section would probably have 15 rolls, and two of which could be called on to accelerate the ingot. Therefore, all of the motors are capable of the same output per roll, but only two of them are delivering full output.

The generator is selected to supply the acutal load and not the connected load. The difference between generator capacity and total motor ratings decreases for table sections farther from the mill because when the bar being rolled becomes long enough to reach these rolls, each roll would be supporting the same share of the bar.

*Engineering Department, Dominion Foundries and Steel Limited, Hamilton, Ont.

The Authors

The reasons given by Mr. Wright for using rotating exciters rather than push-pull magnetic amplifiers for generator excitation on reversing drives merit additional comment.

1. It is our contention that magnetic amplifiers feeding directly to generator shunt fields, provides a simple and reliable device. The slight additional cost of the two field windings is more than offset by the elimination of the field exciter. This not only eliminates an item that requires regular maintenance but also saves the purchaser from supplying the building space, mounting details, starter and wiring that must be furnished for installation of additional rotating equipment.

2. With regard to simplicity, a two delay system is inherently more stable than a three delay system and therefore requires little or no stabilizing feedback. Our practice is to use single phase MAGAMPS almost exclusively and experience has indicated that filtering circuits are seldom required. These factors permit the regulator to be designed for the ultimate in simplicity and ease of calibration.

3. Any DC machine requires regular maintenance regardless of size and a multiplicity of small machines can be more trouble than a few larger units.

4. The performance can be obtained with 60 cycle MAGAMPS but where a large number of systems are required the 400 cycle supply can be justified on the basis of smaller more economical reactors, improved characteristics, isolation from mill distribution voltage disturbances etc.

The following is in reply to specific questions by Mr. Wright.

1. The system analysis is not affected by the location of the gain in the closed loop. For the sake of simplicity it has been lumped in the feedback loop in the block diagram but in the physical system it is distributed essentially as indicated by Mr. Wright.

2. The speed amplifiers are biased to their mid-point as suggested and to ensure freedom from drift they are provided with voltage feedback, which was not indicated on the diagram in Fig. No. 1.

3. The auxiliary generators have solid frames, standard air gaps and do not include any special features to obtain a low time constant. They do, however, have a small amount of series resistance as shown in Fig. 1 and this has been included in calculating the generator time constant.

In reply to Dr. D'Ombrain's question the generator time constants are determined by calculation, with occasional checks from test figures. This procedure is adequate because, if a system design depended on exact value of time constant, it would be too critical for industrial application and would be abandoned in favour of a more flexible solution.

The answer to Dr. D'Ombrain's second question would be the subject of a separate paper and we would refer him instead to a standard text on the subject. One such reference is Chestnut and Mayer's book "Servomechanism and Regulating System Design" Volume 1, page 139 under the heading "Development of characteristic equation in terms of the transfer function".

Mr. R. B. Cornell's discussion requires no comment from us but we would like to thank him and the other discussors for their interest in the paper and their contribution to the meeting.

Littoral Drift in Lake Ontario Harbours

A. Brebner, A.M.I.C.E. and R. J. Kennedy, M.E.I.C.
Queen's University, Kingston, Ont.

The Engineering Journal, 1959, September, p. 85

Dr. S. D. Lash, M.E.I.C.* asked whether the problem had any fundamental solution applicable to all port conditions and situations or whether each port had a particular problem requiring solution.

Dr. J. A. Langford,§ commented that he had been working on the problem of erosion on the shores of Lake Ontario for many years and was glad to see some further work being done by the authors. He cautioned, however, against solutions which did not take into effect all conditions and in particular the solution of a harbour siltation problem which resulted in even worse erosion of the down-drift coast.

Mr. A. U. Sanderson, M.E.I.C.† commented that in his long experience of conditions in the Toronto region the worst erosion and drift appeared to occur during the winter storm periods. He was also of the opinion that viscosity played a major role in the rate of drift. Viscosity had an important bearing and wondered if the authors had considered the effect of building a breakwater sensibly parallel to the existing up-drift breakwater in an effort to create a venturi-flume effect which would give the littoral currents sufficient velocity to by-pass the harbour entrance.

Mr. R. F. Leggett, M.E.I.C.‡ wondered if the authors were correct in assuming that river flow into various lake-shore harbours had little effect in producing siltation.

Dr. W. D. Baines,# pointed out that the problem of littoral drift was one common to all Canadian shores, lake or ocean. Since conditions were often greatly different between such bodies of water due to the fetch distances involved the solutions themselves very often differed. He also wondered what was the real mechanism whereby littoral material did actually get inside relatively sheltered harbour areas.

Mr. J. E. Jarlan,¶ had forwarded a fairly lengthy comment which was read in part by Dr. Baines. Mr. Jarlan pointed out the importance of wind generated currents and the possible magnitude of wind set up. He added somewhat to the mathematical development of wave theory presented by the authors and stated that in shallow water the energy transmitted forward by a wave was approximately $H^2/3.5$ ft. lbs. per ft. of crest length compared to the figure of $H^2/7.0$ proposed by the authors for deep water.

Mr. Jarlan suggested that it would be interesting to have tidal or seiche recorders installed on Lake Ontario to determine the magnitude of the actual phenomenon. He mentioned also the desirability of studies of bed material movement using radioactive tracers and of wave characteristics using aerial stereophotogrammetry.

Dr. Brebner, replying on behalf of the authors thanked the meeting for the discussion raised. Mr. Jarlan had contributed a good deal of written material which the authors felt was very valuable. They had, however, since to their knowledge this was the first paper to the E.I.C. on this topic, tried to keep the material as descriptive and non-mathematical as possible. Dr. Brebner in closing replied briefly to all the points raised in the discussion.

INSTRUMENTATION IN INDUSTRY

Instrumentation in the Modern Boiler Room

THE STEAM boiler has a long history going back to the eighteenth century, but it is only in the last forty years or so that the efficiency of conversion of thermal energy has shown a remarkable, rather than a gradual, increase. Much of this increase in efficiency is attributable to improvements in overall control of the many variables involved. Hand-fired boilers were common in the 1920s; today it is possible for the largest units to operate at maximum efficiency by completely automatic control of all contributing variables.

Instruments and Applications

The degree of instrumentation of a boiler plant naturally depends on its size and operating conditions. Industrial installations range from small units for heating purposes only, to those for production of process steam, to high-efficiency marine propulsion units and those used for power production via multi-stage steam turbines. The fuels used may be gas, oil, coal (and similar solid fuels) or a combination of two or more of these.

Variables which may be controlled or recorded include: rate of fuel feed; rate of air feed; feed water flow; temperatures of fuel, air, water, and steam; flue gas temperature, constituent analysis, and smoke content; plus ancillary data such as fuel and water reservoir levels.

The purpose of control instruments is largely to obtain maximum efficiency automatically, or nearly so, by constantly adjusting air and fuel supply for economy in combustion, maintaining steam pressure, combustion and exhaust pressures, temperatures, and so on. Provision is also made for transfer between automatic and manual control, and the necessary safety factors such as recording of operating faults; for example, flame or draught fan failure.

Signals from local measuring instruments may be used for several purposes (to indicate, record or control) and, by feeding the one signal or series of signals to different computing relays, two or more control functions may be carried out. After selection, the resultant outputs are transferred to controls for the operation of valves, pumps, fans, and so on.

Both pneumatic and electronic transmission of signals for recording and control are in use, and a combination of methods may be found in one plant system. Research and development work is continuing towards improvement of electrical combustion control. One aim is a simple electrical power unit which can give the same speed and accuracy as the hydraulic or pneumatic power cylinder. An advantage of the use of electrical signals is their ready application to print-out and computing circuits.

Scope of Survey

Replies from operators of steam plants in a wide field of industries indicate that it is inadvisable to try to derive definite conclusions about instrument practice in the modern boiler room from a necessarily limited survey. The sizes of plant and degrees of instrumentation vary greatly, according to the steam requirements of the industry. However, some general conclusions can be reached.

The largest and most complex boiler installations are found in the thermal-electric plants of power utilities and of industries that develop large amounts of power for their own use, for example, some of the pulp and paper and mining companies. Other manufacturing industries, in general, use steam plants for heating, driving some auxiliary equipment, such as pumps and compressors, or as a source of steam used in manufacturing processes (e.g., petroleum, chemical, food processing industries). These installations may range from small package units to relativey large capacity installations.

Requirements and Purchase

All manufacturers covered by the survey determined at least some of their own instrument requirements. However, the many package boiler units now in use are generally provided with necessary control and recording equipment as part of the package. Additional instruments may be incorporated to suit the needs of the purchaser.

Specification of instruments and recommendation of choice of suppler was reported as almost entirely the resposibility of engineering, maintenance or production department, or a combination of members of these departments.

Servicing and Maintenance

Most companies reported using their own staff to service instruments, but it is apparent that there are many instances of the use of service by the supplier or other contractor, especially where instruments are mainly to be found in the boiler plant and there would be little additional need for a permanent instrument engineer or technician.

Some form of preventive maintenance appears to be the general rule for boiler plant instruments.

The great majority of replies stated that stocks of spare parts were kept as dictated by operating experience, though some combined this practice with partial adherence to suppliers' recommendations.

As might be expected, instruments used in these boiler plants are almost entirely standard types, and are usually purchased outright.

Instrument Costs

Capital investment in boiler plant instruments could not be judged properly from the survey, but other investigatitons indicate an installed direct cost of instrumentation at $0.35 to $0.75 (approximately) per pound of steam. The figures decrease with increasing unit size (in terms of pounds per hour of steam) and vary slightly with the type of fuel used. On this basis the cost of instrumentation for a 250,000 lb./hr. steam boiler works out at about $125,000 (at $0.50 per pound of steam). Some increase in cost of instrumentation and controls is to be expected as unit size increases, since larger metering and valve equipment, and more extensive metering equipment, are usually employed. A fairly high instrumentation cost is justified by the resulting improvement in efficiency of steam generation (figures of 6% to 9% of total plant cost have been noted).

SILVER FALLS *(Continued from page 108)*

water conditions through the section where the original geological survey indicated that the rock cover was less than 75 ft. Fortunately, neither conditions were sufficiently bad to warrant interference with our normal tunnel driving procedures.

Both the shafts and the tunnel will be lined with concrete, reinforced in low rock cover sections and terminating with steel liners near the surface. The surge shaft has already been completed and the 200 ft. tank is under construction. Towards the

The invert will be poured starting end of the tunnel driving, the invert curbs were excavated with a rubber tired backhoe and poured from two 8 cu. yd. truck transit mixers which had been remounted on bogie well deck cars.

At the present time, the tunnel is being washed down, the fan pipe is being removed, tights are being drilled and blasted, and the invert is being mucked out with a small bulldozer, the mucking machine and a shielded blow pipe.

at the portal and from a 700 ft. moving bridge containing a moving screen, a rail handling device, two pumpcrete machines, a delivery conveyor and a California switch. Steel invert forms will be fixed to the curbs by embedded screw anchors.

The arch will be poured continuously from the intake and using telescopic forms and a traveller. Finally, the lining will be pressure grouted in two stages and closures made at the penstock and upper elbow of the intake shaft.

DESIGN OF A DANIELS-BOYD NUCLEAR STEAM GENERATOR *(Continued from page 118)*

4. We believe that while many of of the detail features of the Daniels-Boyd Nuclear Steam Generator will undoubtedly be changed and improved upon in the course of time, it is as fundamental to the public utility nuclear power business as Stephenson's "Rocket" was to railroading.

Acknowledgements

We would like to thank Dr. Daniels, not only for allowing us to associate his name with our project, but also for his ever ready encouragement and advice. We would also like to thank all of our former colleagues who continue to give us their help, both moral and real. Especially we would like to extend our thanks to Miss Asselin for typing this manuscript.

Addenda

Since preparing the original manuscript some further calculations of power costs have been made. These are shown in table II and are qualified by the related notes, all of which are self explanatory.

Recently the Americans have been giving considerable thought to gas cooled reactors both with and without canned fuel elements. In a recent Oak Ridge report, the following very cautious conclusion was reached for a high density ceramic fuelled, helium cooled reactor with a fission product scavenging system and an *average fuel* temperature below 2500°F: "While one cannot conclude that a reactor plant of this type will not need containment, it is quite obvious that the activity in the gas is orders of magnitude (1000 times or thereabouts) less than had previously supposed and is generally *much closer* to the clean clad system than the hypothetical case of 100% activity in the coolant".

Elsewhere in this same Oak Ridge report (TID-7564) the conclusion was reached that a stainless clad, ceramic fuelled, helium cooled reactor "will yield a substantially safer system than (the one) employed by the British and that this system does not require containment". Thus, even in the country where containment is almost a tradition, it is admitted that containment is not required for gas cooled reactors with canned fuel elements and that it may not even be required for those with uncanned fuel elements if a scavenging system is employed.

Because of this we believe that it is not unreasonable to predict that after a truly unbiased and careful study has been made of the safety aspects of the high temperature, ceramic fuelled, helium cooled, graphite moderated reactor which is equipped with an effective gaseous and volatile fission product scavenging system, the conclusion will be reached that it is inherently the safest type of reactor possible and that it will definitely not require containment.

When this has been done, the way will be clear to capitalize on the many advantages of this type of reactor which will bring truly economic nuclear power within our grasp.

Canadian Developments

The agrarian economy of thirty years ago yielded to an industrial revolution that owed much of its impetus to the country's tremendous reserves of hydro-electric power. It was the fashion in those days to speak of this resource as largely untapped. This is no longer true. The more accessible and economic sources of water power have already been exploited. While considerable hydro-electric capacity is still being developed across Canada for initial output in the near future, relatively fewer new turbines will hum with the rushing waters. Thermal electric power is getting a toe-hold in Canada today, and it is the large unused deposits of coal, oil and gas that now command attention.

Thermal power

Perhaps for this reason the naming of the Queen Elizabeth Power Station at Saskatoon* is an especially apt reminder of Her Majesty's visit to us at this particular moment in our economic history. Coal, oil and natural gas are used at the new station, and burning these three competitive fuels has stabilized fuel costs without incurring any significant additional capital expense.

Design steam conditions are 850 p.s.i.g., 900° F. and each steam generator is designed to deliver 600,000 lbs. of steam per hr. continuously and 600,000 lbs. per hr. for 4-hour peaks.

Both turbines are of the two-cylinder-tandem type with direct-connected, 3,600 r.p.m. hydrogen cooled alternators. The boilers will operate at full load on any one or any combination of the three fuels.

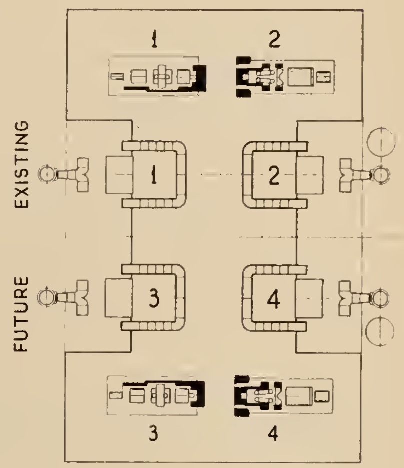
The plant layout is unconventional — the boilers will not be "in-line" but in a square formation with two turbine isles (see diagram). This layout allows a saving in building volume over the conventional arrangement.

Two sides of each boiler have been left exposed at the upper levels. There is no basement. Station auxiliaries such as pulverisers and feed pumps are at ground level. All important control and instrument panels are in a centralized location on the operating floor — not an isolated room.

All water requirements are pumped directly from the South Saskatchewan River. A buried steel pipeline delivers water direct from the pumphouse to the plant. A precast concrete pipe returns it to the river.

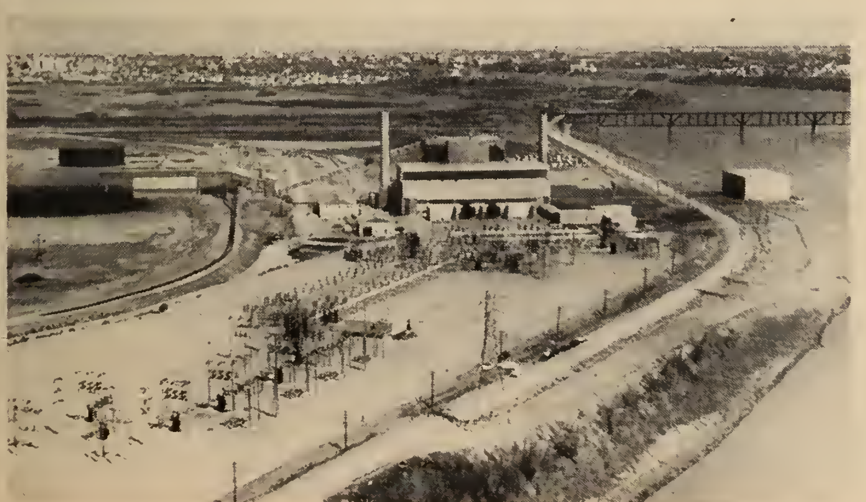
The coal-handling system consists of a rotary car dumper, belt and drag conveyors, Harding-type ball mills and other miscellaneous equipment. Provision has been made in the main building, pumphouse and fuel-handling plant for the addition of two further units of up to 100 Mw. capacity each.

With the completion of the present construction program, the Saskatchewan Power Corporation system will have reached a total capacity of over 500 Mw. by 1960, all of which is either steam or internal-combustion engine power. The Queen Elizabeth Power Station, therefore, represents 28% of that total.



Operating floor plan of the Queen Elizabeth Power Station shows the position of the ultimate four units and gives the H-shape of the building.

SET IN motion by Her Majesty Queen Elizabeth II July 22, the 141 Mw. Queen Elizabeth Power Station, situated on the South Saskatchewan River at Saskatoon comprises a switch-yard (foreground), coal handling plant (to the left) and the office block and pumphouse (to the right). The boilerhouse is on the far side of the building behind the turbine room and transformer bays.



Coal

A second large thermal plant is under construction near Estevan, Sask. — the Saskatchewan Power Corporation's Boundary Dam Generating Station. It gives an additional 60,000 kw. to the provincial power network.

The Boundary Dam Generating Station will double in size and power-output by 1960. The whole installation is similar in design to the Queen Elizabeth Power Station.

The Boundary Dam station was designed to make further use of the vast

* For full technical description of station see paper entitled "Saskatchewan River Generating Station" given before the Institute's Annual Meeting, June, 1957, by R. R. Keith, M.E.I.C., and published in The Engineering Journal, May, 1958. We are indebted to G. E. Cummings, Jr.E.I.C. and H. Kaldor, M.E.I.C. for the present information.

supplies of lignite coal underlying the Estevan area. Coal for the plant is being mined at the site.

A third 150,000 kw. unit is scheduled to be added to the Wabamun steam plant, located 42 miles west of Edmonton. The plant is adjacent to a 60,000,000 ton deposit of strippable coal and will in the future make use of it as fuel, although until now it has been burning natural gas.

Ontario Hydro's Lakeview Generating Station – reportedly the world's largest thermal-electric plant – will generate its first power in 1961. By about 1965 the six 300,000 kw. thermal generators will be in action producing 1,800,000 kw.

The plant is being built on the former Long Branch Rifle Range and an additional 25 acres of land reclaimed from Lake Ontario. Complete with enormous coal-storage yards, the station area will cover approximately 128 acres.

In full operation each of the six units will require over 100 tons of coal an hour. Thus provisions have been made for stock-piling 2,500,000 tons.

Oil and Gas

Canada's proven reserves of natural gas are in the vicinity of 23 trillion cu. ft. – about what the U.S.'s were 35 years ago. Her oil reserves appear to be almost limitless as recent strikes bring new fields to the fore in Alberta and oil drilling in the Yukon begins to spout returns.

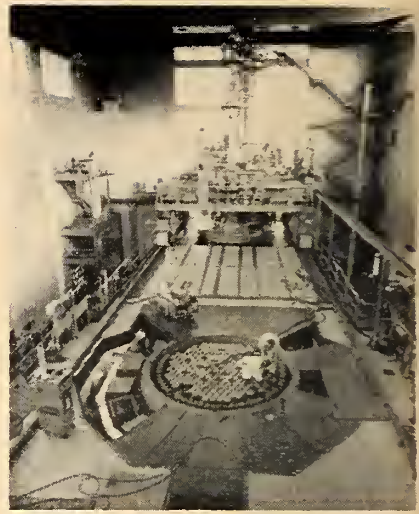
Drilling at Western Minerals Chance No. 1, 150 miles northeast of Dawson City, Yukon, and less than 200 miles south of the Arctic Ocean, brought gas and oil reserves to the surface in mid-August.

Ten thousand cu. ft. of gas per day was coming from the well at last report. Presumably it will take about two years to determine the actual extent of the resources and whether they merit commercial exploitation.

This gas-oil strike at Eagle Plain is the first in the far north since the Norman Wells Field discovery 300 miles to the southeast in 1920. The sedimentary sections in this area are comparable to the foothills and plains of central and southern Alberta, and there is good reason to hope that gas and oil reservoirs may exist in deeper horizons at the same wellsite.

The well at the time of the August discovery had a depth of 4,200 ft., 130 ft. of that giving gas and another 15 ft. of oil. The well eventually will reach 8,000 ft. in depth.

Alberta's Dick Lake field is also the site of a recent gas strike. A potential daily yield of 1.2 billion cu. ft. has been unearthed. The yield of this new 7,645 ft. well is four times greater than that of any of the other five wells in the area.



The NRU reactor at Chalk river is a triple purpose machine — it produces plutonium, makes radioactive isotopes and provides extensive facilities for research, engineering development and testing.

Nuclear Power

Ontario — **where the last 30 rivers** with hydro potential are being mapped and charted – where natural deposits of coal are negligible – has become the seat of nuclear power research in Canada. She not only needs to find a new power source to meet her needs as early as 1965, but within her boundaries lie extensive supplies of uranium waiting to be mined.

The Western provinces look to Ontario – the Maritimes watch her nuclear development with interest – all of Canada stands to benefit in the next three decades if the Ontario projects bring to light a method of power production by nuclear fission which is economically competitive with traditional hydro and thermal operations.

Atomic Energy of Canada has four nuclear power projects underway in Ontario.

The 20,000 kw. NPD-2 (Nuclear Power Demonstration) reactor at Rolphton is to be completed in late 1960 and will be hooked-up with Ontario Hydro generating stations by 1961. It will be fuelled with natural uranium oxide; cooled and moderated by heavy water.

CANDU (Canadian Deuterium Uranium), a $60,000,000 reactor which will generate 200,000 kw. (10 times NPD's output) is to be built on a 2,300 acre site on Lake Huron 9 miles north of Kincardine. It should be in full operation by the end of 1964.

The CANDU project represents a giant stride in Canadian nuclear research. This type of reactor, when perfected, should be able to operate on large baseload stations. Burning natural uranium at the rate of 8,000-10,000 Mw. days per ton, the heavy water cooled and moderated reactor is designed to reduce fuel costs considerably and eliminate the necessity of chemically reprocessing irradiated fuel.

NPD — Canada's first atomic power station.

OCDRE (Organic cooled, deuterium reactor experiment) is designed to fill two quite different functions. This type of reactor, it is hoped, could be used either in a small installation or in a 100,000 kw. project.

Since nuclear research is constantly concerned with finding a way to process uranium cheaply enough to make it a competitive power fuel, OCDRE has particular significance.

Organic liquid, rather than heavy water, is used as the coolant in this heavy water moderated reactor in an attempt to cut capital costs. With organic liquid, higher temperatures can be achieved with lower pressures. The reactor walls do not have to be so strong and building costs are diminished.

OCDRE is envisaged for certain small and medium sized sites in Northern Canada. Canadian General Electric has undertaken the contract for the 40,000 kw. plant.

Canadian Westinghouse is studying the field of small nuclear power plants. They will be necessary in Canada for two purposes — power for remote regions and a power booster for existing hydro stations.

So far the natural uranium heavy water moderated reactor appears inefficient in small sizes, and Canadians are investigating the pressurized light water or boiling water reactors used in the U.S. with enriched uranium fuel.

Both Manitoba and the Maritimes anticipate the need for new power stations of the 100,000-200,000 kw. magnitude by 1960. The utilities thus look with interest and concern upon these first nuclear projects in Ontario. Long after the rivers have been dammed and the coal beds mined there should still be uranium.

An atomic explosion may be used to release oil from the extensive deposits of tar sands in the Athabasca River region of Alberta. Heat and pressure can conceivably be used to crack the heavy hydrocarbons, making lighter products for normal crude oil production techniques to recover.

Between 200 and 300 billion barrels of oil are estimated to underlie the 17,000 sq. mi. surface area. The oil contained in the sand is highly viscous before recovery, but it cracks to a lighter form at relatively warm temperatures and does not readily return to its former state. Not all the hydrocarbon content of the tar sands will be recovered, but it is hoped that the return is adequate to compete with other liquid hydrocarbon sources.

Hamilton Falls, Newfoundland.

Hydro Power

Rivers still rush unharnessed in British Columbia and Newfoundland. These two provinces are perhaps the last in Canada to exploit their real hydro power potential. Eventually they too will be forced to turn to thermal or nuclear power — or both — to turn their turbines.

While the power of the rivers is tapped, coal, oil, gas and uranium deposits lie secretively under the great surface of the earth.

(Continued on page 188)

INTERNATIONAL NEWS

UNITED KINGDOM

Nuclear power stations are too expensive—says Sir Leslie Gamage, chairman of Britain's General Electric Company—and as a result the market for them will remain limited. Britain has a surplus capacity for atomic power station construction but the cost of building reactors is too great. Some people maintain that reactor construction in Britain could be made feasible by reducing the number of groups who are able to build reactors from the present five to three. Thus a bigger share-out of the limited demand would be available to offset gigantic research costs. Sir Leslie proposes, however, that the solution lies in finding the means to construct a less expensive reactor, thus automatically increasing demand. This will only be possible, he contends, when enrichment is available and plutonium technology is considerably advanced.

Britain's sixth nuclear power station, about to be built on the southeast coast of England, will export some of its electricity to France. The power will be conveyed by cable along the bottom of the English Channel. French hydro-electric plants, well over-stocked with electricity during the rainy seasons, can reciprocate by switching their output through the British grid.

The link-up, in operation by 1961, will be highly advantageous for both countries. Peak loads on the national grid systems occur at different times: while a full breakfast is being prepared in England, the French are making only coffee, and in the evening dinner is early in Britain, late in France.

Zeta I—the "Zero Energy Thermonuclear Apparatus"—has set up such a complicated pattern of behaviour that British scientists have decided to design a new machine to tell them more about Zeta's operation. Zeta, Britain's first step in an attempt to tame the H-bomb reaction and use its immense energy to drive power stations, must have stabilization of the great volume of electrical currents which are shot through it.

The new machine, **ICSE** ("Intermediate Current Stability Experiment"), will be much bigger than Zeta and have ten to twenty times its electricity-storage capacity. A glimmer of the research project's magnitude can be got from the fact that in order to make Zeta a paying proposition (that is, yielding far more power than is shot into it), temperature inside the machine must reach one hundred million degrees—hotter than the surface of the sun.

AUSTRALIA

The Snowy Mountains Scheme, Australia's enormous power and irrigation project of seven major dams, at least fifteen major power stations, 83½ miles of tunnels, and 330 miles of mountain aqueducts, is well underway.

In April power began to flow through 90 miles of transmission lines into the New South Wales Electricity System. The 320,000 kw. power station, 1,200 ft. underground, is now operating at full capacity.

54-kw. package power plant — "La Maignannerie" — on the Mayenne River (France).

NEW ZEALAND

A chain of ten hydro-electric stations on the Waikato River in New Zealand's North Island is nearing completion and will produce a minimum of one million h.p. of electricity. The 420,000 kw. station under construction at Benmore on the Waitaki River in the South Island will be the biggest hydro-electric station in the Southern Hemisphere. A third project—a geothermal station—is underway at Wairakei in the natural thermal area of North Island. The second station of its kind in the world, it will be producing 150,000 kw. three years from now and an additional 100,000 kw. eventually.

A shaft is being sunk in the west coast area of North Island as a result of several years' intensive prospecting by a combine of major oil companies. In addition, sizable deposits of shale oil are known to occur in South Island, Otago and Southland.

FRANCE

Package Power Plants designed by Electricite de France in cooperation with manufacturers of hydroelectric power equipment are now in operation on the by-pass canal of the Garonne River, on the Mayenne River, on the Maulde River, and on the Meuse River. They are composed of an electric generator in a sealed housing, driven by an axial-flow turbine of the propeller type. These package power plants, according to Electricite de France authorities, can be installed on pocket power projects as well as in larger installations as boosters.

Solar radiation is being collected and concentrated in large amounts at the Centre National de la Recherche Scientifique, Montlouis, France. Scientists have ascertained that while radiation on the surface of the sun equals 8 kw. per square centimeter, this same solar radiation by the time it reaches the stratosphere is only 0.135 kw per square centimeter. Their task, therefore, is to determine what can be done to recover some of that lost energy.

Scientists at Montlouis have been developing the "glass house effect" whereby the solar rays pass through a glass shield and are absorbed by certain substances on the earth. The glass shield then acts as a reflector for the rays emitted by the absorbent bodies after solar radiation has acted upon them. These rays from the absorbent bodies are much longer than those from the sun and thus give much greater temperatures.

Energy thus salvaged from solar rays and concentrated by further use of reflectors can be made to heat water, distill it, and heat air.

A large uranium oxide fritting plant which will produce two to three tons per month is now in operation near the Nuclear Research Center at Saclay. It is the forerunner of a much larger plant to be built near Paris when uranium oxide becomes more common as fissionable material in nuclear reactors.

The methods for manufacturing this material are strikingly similar to those for ceramics. The basic material, finely powdered uranium oxide, is first blended with an organic binder, then transformed into granules resembling soluble coffee. Powerful presses, exerting several tons' pressure per sq. in., compress these granules into small cylinders.

The cylinders are then placed in special kilns containing hydrogen and are brought to a temperature of 2,912 deg. F., fusing the granules into a hard, dense solid without altering the organic shape. After final inspection, the cylinders are encased in aluminum and zirconium containers and put into reactors.

202-kw. "Verdun" package power plant on the Meuse River (France).

A complex of atomelectric power plants, using natural uranium as fuel, graphite as moderator and carbon dioxide as cooling medium, is being built by Electricite de France on the banks of the Loire six miles north of Chinon. The heat absorbed by the carbon dioxide will be converted into steam to drive the classic generator units.

The project comprises three independent phases — the first producing 60,000 kw. of electric power; the second, 170,000 kw.; and the third, more than 250,000 kw.

Latest French hydro-electric power developments include the Kariba Dam on the Zambesi River; the multiple-vault dam at Migoelou in the Pyrenees; and the Saint-Vidian Dam on the Garonne, 37 miles from Toulouse.

SOUTH AFRICA

Export of uranium oxide in 1958 totalled 6,153 tons, according to the South African Minister of Mines. However, though the export totals for 1956-1958 show an increase of approximately 1,000 tons each successive year over the last, the figures for the first quarter of 1959 show a decline in export tonnage. In 1958 a total of $159,621,789 worth of uranium oxide (compared to 1957's $149,965,896) was exported to the United States, England, and Japan, most of it through the Combined Development Agency.

"Saint-Jory" pocket power project on the bypass canal of the Garonne River (France).

JAPAN

Japan's first nuclear power station is to be built at Tokai Mura, 65 miles northeast of Tokyo, for operation in 1963. The Japan Atomic Power Company has chosen the General Electric Co. Ltd. of England to build the station with the cooperation of 14 leading Japanese companies known as the First Atomic Power Industrial Group (F.A.P.I.G.).

The gas-cooled, graphite-moderated reactor will have an electrical output of 150 mw. The station, similar to the one built at Hunterston, Scotland, will be specially designed in order to ensure the safety of the installations under earthquake conditions.

UNITED STATES

A new electro-motive MU-60 peaking and reserve generating plant has been developed by General Motors Corporation. The 6,000 kw. plant is designed according to specifications laid down by public utilities companies in response to General Motors inquiries. It is portable, completely automatic in operation, unobtrusive in an outdoor setting, and can be installed for under $100 per kw. Its purpose is to supply a special power boost when the demand is at a peak.

The high-energy fuel program undertaken by Stauffer-Aerojet Chemical Company has not been affected by the recent cancellation of Air Force and Navy contracts to operate boron fuels production plants. The large-scale pilot plant at Sacramento, Calif., just completed, will begin operation immediately to develop low cost boron fuels.

The Fifth World Petroleum Congress held in New York in June drew more than 5,500 representatives from some 50 countries, among them D. S. Simmons, B.Sc., of the Engineering Institute of Canada.

INDIA

A symposium on power development

(*Continued on page 129*)

Month to Month

The Late Sir Claude Gibb Honoured

The Institution of Mechanical Engineers, London, dedicated a moment of silent tribute to the memory of the late Sir Claude Gibb on January 23. At this time, only eight days after Sir Claude's untimely death, the Institution was to have presented Sir Claude with the 1959 James Watt International Medal, awarded to "men who have attained world-wide eminence in mechanical engineering."

Sir Claude, an Australian, had made an outstanding contribution to the field of large power producing plants. It will be recalled that his paper "Graphite in the World Nuclear Power Program" was published posthumously in the July issue of The Engineering Journal.

Symposium on Reliability and Quality Control

The **Sixth Annual Symposium on Reliability and Quality Control in Electronics** is to be held at the Hotel Statler, Washington, D.C., on January 11, 12, and 13, 1960.

The symposium, initiated five years ago and sponsored by the IRE, AIEE, ASQC, and EIA, is founded on the belief that maximum reliability in electronics can only be had through research, education and free interchange of scientific knowledge and achievements. It maintains that this reliability is essential to our industrial and military organizations.

Symposium topics will include: New Mathematical Techniques; Contractual Implications; Cost Considerations; The Effect of Advanced Design and Production Techniques on Reliability; Reliability Training and Education; New Maintainability Techniques; System Aspects; Military Requirements and Specifications Now and in the Future; Reliability Prediction; New Production Techniques; Accelerated Environmental Testing; Life Tests; Failure Modes.

Increased Membership in Ontario Association

Membership in the Association of Professional Engineers of Ontario has reached 18,500, according to figures made public by their executive council in late August.

Objections to U.S. legislation

Objections to current U.S. legislative proposals regarding the Armed Services Procurement Act have been made by the National Society of Professional Engineers (U.S.A.) on the grounds that the legislation could "lead to competitive factors in the awarding of a contract for professional services."

Paul H. Robbins, executive director of the 50,000-member engineering group, testifying before the Senate Armed Services Subcommittee, emphasized that in order for the negotiation of professional consulting engineering services to conform to established practices and to professional ethics, the contracting procedure should follow two distinct steps: first, the selection of the consultant or firm deemed best qualified for the professional service required; second, the negotiation of a suitable fee with that consultant or firm.

International Congress for Bridge and Structural Engineers

The Sixth International Congress for Bridge and Structural Engineering, convening in Stockholm from June 27 to July 1, 1960, will cover six main topics: Basis of Structural Design; New Developments of Connections in Metal Structures; Steel Skeleton; New Developments in Bridge Building; Prefabricated Structures; and Important Progress in Bridge and Constructional Engineering and Composite Structures.

Engineers interested in attending the congress are asked to inform the Congress Secretariat, A.I.P.C., VI. e Congres, Box 14045 Stockholm 14, immediately.

Toronto Branch Organizes New Power Section

A newly organized power section of the Toronto Branch of the Engineering Institute will study the use of energy in all its forms.

Chaired by Dr. John Shotwell, assisted by Secretary-Treasurer Peter Killaby, the power-study group comprises men involved in every phase of the power industry — design, building, equipment manufacturing, fuel supplying, and operating.

° ° °

Montreal Section of the National Association of Corrosion Engineers, at Queen's Hotel, Montreal, November 10, "New Plastics and Their Properties".

NOMINEES FOR OFFICE

THE ENGINEERING INSTITUTE OF CANADA

The report of the Nominating Committee, as accepted by Council at its meeting held on September 12, 1959, in Saint John, N.B., is published for the information of all corporate members as required by Sections 19 and 40 of the By-laws:

VICE-PRESIDENTS

One to be elected for two years

Zone B (Province of Ontario)	Edgar A. Cross, Toronto, Ont.
Zone C (Province of Quebec)	Charles Miller, Baie Comeau, Que.
Zone D (Atlantic Provinces)	T. C. Higginson, Saint John, N.B.

COUNCILLORS

Two to be elected for three years

Montreal	Paul G. A. Brault R. A. Phillips

One to be elected for three years

Ottawa	John S. Watt
Toronto	A. C. Davidson

One to be elected for two years

Vancouver	W. G. Heslop
Edmonton	S. R. Sinclair
Lethbridge	R. D. Livingstone
Calgary	W. G. Sharp
Saskatchewan	J. L. Thompson
Winnipeg	N. S. Bubbis
Sault Ste. Marie	W. M. Hogg
North Eastern Ontario	(no nominee)
Huronia	Frederic Alport
Sarnia	J. E. Harris
Kitchener	L. J. R. Sanders
Hamilton	W. A. Dawson
Niagara Peninsula	Paul E. Buss
Peterborough	D. A. Lamont
Cornwall	B. T. Yates
Quebec	Georges Demers
Northern New Brunswick	F. W. Buckley
Moncton	C. L. Trenholm
North Nova Scotia	C. V. Campbell
Halifax	J. Douglas Kline
Cape Breton	W. A. MacDonald

News of Other Societies

New Publications

The Institute of Engineers, Australia, has launched two new publications in 1959: *Electrical and Mechanical Engineering Transactions* (first issue—Volume EM 1, No. 1, May, 1959) and *Civil Engineering Transactions* (first issue—Volume CEI, No. 1, March, 1959).

Canadian Agricultural Engineering (first issue—Volume 1, No. 1, January, 1959) is to be published yearly by the Canadian Agricultural Engineering Society.

Conference Schedule

American Society for Metals, Philadelphia, October 17-21.

Ninth Annual High Polymer Forum (cosponsored by the National Research Council and the Chemical Institute of Canada), Guild Inn, Toronto, October 19-21.

National Association of Corrosion Engineers, North Central Regional Meeting, Cleveland, October 20-22.

ASLE Lubrication Conference, Sheraton-McAlpin Hotel, New York, October 20-22.

Society for Experimental Stress Analysis, 1959 Annual Meeting, Pick-Fort Shelby Hotel, Detroit, October 21-23.

Computer Applications Symposium (sponsored by Armour Research Foundation), Morrison Hotel, Chicago, October 28-29.

Institute of Radio Engineers, Radio Fall Meeting, Syracuse, N.Y., October 31-November 2.

Midwestern Meeting on New Frontiers in Aviation, Hotel Lassen, Wichita, Kans., November 2-4.

International Rubber Technology Conference on Materials Handling (ASME, ACS, & ASTM participating), Shoreham & Plaza Hotels, Washington, D.C., November 8-13.

The Chemical Institute of Canada, Chemical Engineering Subject Division Symposium, Hamilton, Ont., November 9-11.

European Federation of Chemical Engineering, Technical Meeting on Laboratory, Measuring and Automation Techniques in Chemistry, Basle, Switzerland, November 10-15.

Automation Show and Conference on Materials Handling, New York Trade Show Building, N.Y., November 16-20.

INTERNATIONAL NEWS (*continued from page 125*)

in India early this year brought out the question: Why should India bother about hydro power stations when nuclear power can be expected in five or six years? However, Dr. K. L. Rao pointed out that nuclear power can not take care of a peak load and therefore hydro has an important place in India's power development. Also India must proceed rapidly now, and the next five years will be crucial to her development.

The main obstacle which Indian scientists and engineers face at the moment in this power development effort is their dependence on other countries for the mechanisms from which power projects are built. Even small switches must be imported from an outside source. Dr. Rao spoke of the 40 kw. generator being made at Baroda and suggested that even though it appeared insignificant beside a 300-million kw. unit being produced now in Russia, it was a triumphant step in India's course toward independent manufacture and development. He urged that the Bhopal Heavy Electrical Machinery project be rushed so that transformers, switchgears, and even generators would be made in the machine shop at Bhopal within the next four or five years.

SWEDEN

A gas turbine power plant said to be the largest in the world is nearing completion on the Island of Lucerna, off the city of Vastervik on the Baltic coast. Designed for a peak-load operation of about 500 hours per year, the station will produce 40,000 kw. It is thus considerably cheaper than conventional steam power plants and its construction costs have been 25% less.

Built by the Swedish State Power Board in close collaboration with two Swedish firms — Stal for turbines and Asea for electrical equipment — the new station will use bunker oil, 495 cu. ft. per hour. It is to be remote controlled from the transformer station at Vastervik.

Final plans for the next large water reservoir at Tjaktjajaure in Sweden's arctic country have been handed over by the State Water Board to the Water Court for acceptance. They call for raising the lake's water level some 100 ft. with a dam 1,450 metres long, 100 metres high.

The $48,000,000 project should be completed by 1967, producing 150-190 mw. and allowing an annual increase of 474 million kw. in the downstream power stations' production.

BRAZIL

A 40,000 h.p. hydroelectric power plant is in operation on the Rio Paranaiba at Cachoeira Durada, State of Goias. Eventually to be a 320,000 h.p. installation, the project was designed by the mixed capital stock company "Centrais Electrica Goianias" for the state capital, Goiania, and the new federal capital, Brasilia.

SOUTHEAST ASIA

Burma, Ceylon, Indonesia, and Thailand were the objects of extended research by the International Atomic Energy Agency this year. The agency set out to determine the needs and possibilities of power development in these countries.

The Union of Burma Atomic Energy Centre will set up a nuclear radiation laboratory by 1960-61. They hope to have a research reactor installed by 1963. Burma still has unexploited hydroelectric power sources but reserves of conventional sources of energy are low.

Ceylon's National Planning Council has created a Committee on Atomic Energy and anticipates a central atomic energy authority. Ceylon needs a thorough assessment of uranium and thorium resources. She has no proven reserves of coal and oil and her hydroelectric power reserves appear insufficient for the future. Projections of likely growth in demand for power suggest that by the late 1960's installation of a nuclear station might well be feasible.

An Institute of Atomic Energy is to be founded in Indonesia. At present all work is centered in Bandung, Bogor, Djakarta and Jogjakarta. Research reactors are contemplated for Bandung and Jogjakarta. The agency mission to Indonesia concluded that before plans be developed for exploitation of the country's resources, her scientific staff and experimental facilities should be enlarged. Indonesia does have reserves of oil, coal, gas and untapped hydroelectric power, so that her need for development of nuclear power is not as urgent as some other countries'.

The Thai Atomic Energy Commission for Peace is charged with the promotion, development and control of all peaceful atomic energy activities in Thailand. The Curtiss Wright Corporation of the U.S.A. has been contracted for the construction of a swimming pool reactor with a maximum output of 1 mw. It should be in operation by early 1963.

The Yanhee hydroelectric project, supplemented by thermal power fuelled with indigenous lignite, will meet Thailand's power demands in the immediate future. However, the northeast section of the country needs industrial development and is far from power sources, so nuclear research will have to supply answers for the future.

Personals

M. Murray Dillon, M.E.I.C., has retired from the presidency of M. M. Dillon and Co. Ltd., Consulting Engineers of London, Toronto and Ottawa. He has been appointed chairman of the board.

George E. Humphries, M.E.I.C. (Wolverhampton, Staffs. '11) is the new president of M. M. Dillon and Co. Ltd., Consulting Engineers of London, Toronto and Ottawa.

M. Murray Dillon

George E. Humphries

W. L. McFaul

W. L. McFaul, M.E.I.C. (Toronto '13) has been appointed special representative in the Hamilton area for Proctor & Redfern Civil and Consulting Engineers, Toronto.

J. F. Lester, M.E.I.C., has recently retired as chief location engineer in the Alberta Department of Highways.

H. J. Stephens, M.E.I.C. (Indiana '18) has been named chief location engineer by Gordon E. Taylor, Minister of Highways, to replace Mr. Lester.

E. V. Leipoldt, M.E.I.C., has been elected to the board of directors of Canadian ASEA Electric.

Stuart R. Muirhead, M.E.I.C. (Toronto '24) will join the Okanagan Telephone Company at Vernon, B.C., as assistant to the superintendent.

C. W. Sparrow, M.E.I.C. (Manitoba '28) has been made manager of operations and engineering of Saskatchewan Government Telephones.

F. Vernon Sturman, M.E.I.C. (Berlin '29) has been appointed vice president and general manager of Gross Machinery (Eastern) Ltd., Town of Mount Royal, Que.

Stanley Adam Stannard, M.E.I.C. (Warsaw Polytechnical '32) has been appointed to the faculty of Western Ontario Institute of Technology to teach electronic technology.

C. W. Sparrow

F. V. Sturman

Guy Savard, M.E.I.C. (R.M.C. '37) was recently appointed manager, Province of Quebec region, by Canadian Liquid Air.

Dr. George W. Govier, M.E.I.C. (B.Eng., B.C. '39; M.Sc., Alberta '45; Ph.D., Michigan '49) has been named dean of the faculty of engineering at the University of Alberta to succeed Dr. R. M. Hardy. The appointment was effective July 1.

T. T. Dobie, JR.E.I.C. (B.C. '48) has been appointed design engineer III of The Consolidated Mining and Smelting Company's engineering division, Trail, B.C.

B. F. Reimer, JR.E.I.C. (B.C. '48) has been made maintenance superintendent of the phosphate plant, Chemicals and Fertilizers Division, The Consolidated Mining and Smelting Company, Trail, B.C.

Major J. J. Eatock, JR..E.I.C. (Alberta '49) is with the Department of External Affairs, United Nations Military Observer Group (India & Pakistan) for the period August 1959 to August 1960.

N. H. Booth, JR.E.I.C. (B.C. '50) has been transferred from the engineering division of The Consolidated Mining and Smelting Company, Trail, B.C., to a special assignment on iron and steel studies.

R. W. Lockie, JR.E.I.C. (B.C. '50) is the new secretary-treasurer of the Vancouver Island branch of the Engineering Institute of Canada.

J. L. P. Limbert, JR.E.I.C. (B.C. '51) is the new acting maintenance superintendent in the Tadanac Department, Chemicals and Fertilizers Division of The Consolidated Mining and Smelting Company, Trail, B.C.

R. C. Hermann, JR.E.I.C. (B.C. '52) has been transferred by Northern Aluminum Company to Auckland, New Zealand on construction of an aluminum fabricating plant.

L. H. Fransen, JR.E.I.C. (B.C. '52) has been appointed maintenance superintendent at The Consolidated Mining and Smelting Company's Bluebell Mine, Riondel, B.C.

James R. Plummer, S.E.I.C. (Queen's '58) is working with a relief organization, on loan to the U.S. Operations Mission to Paraguay, for the construction of the Trans-Chaco Highway.

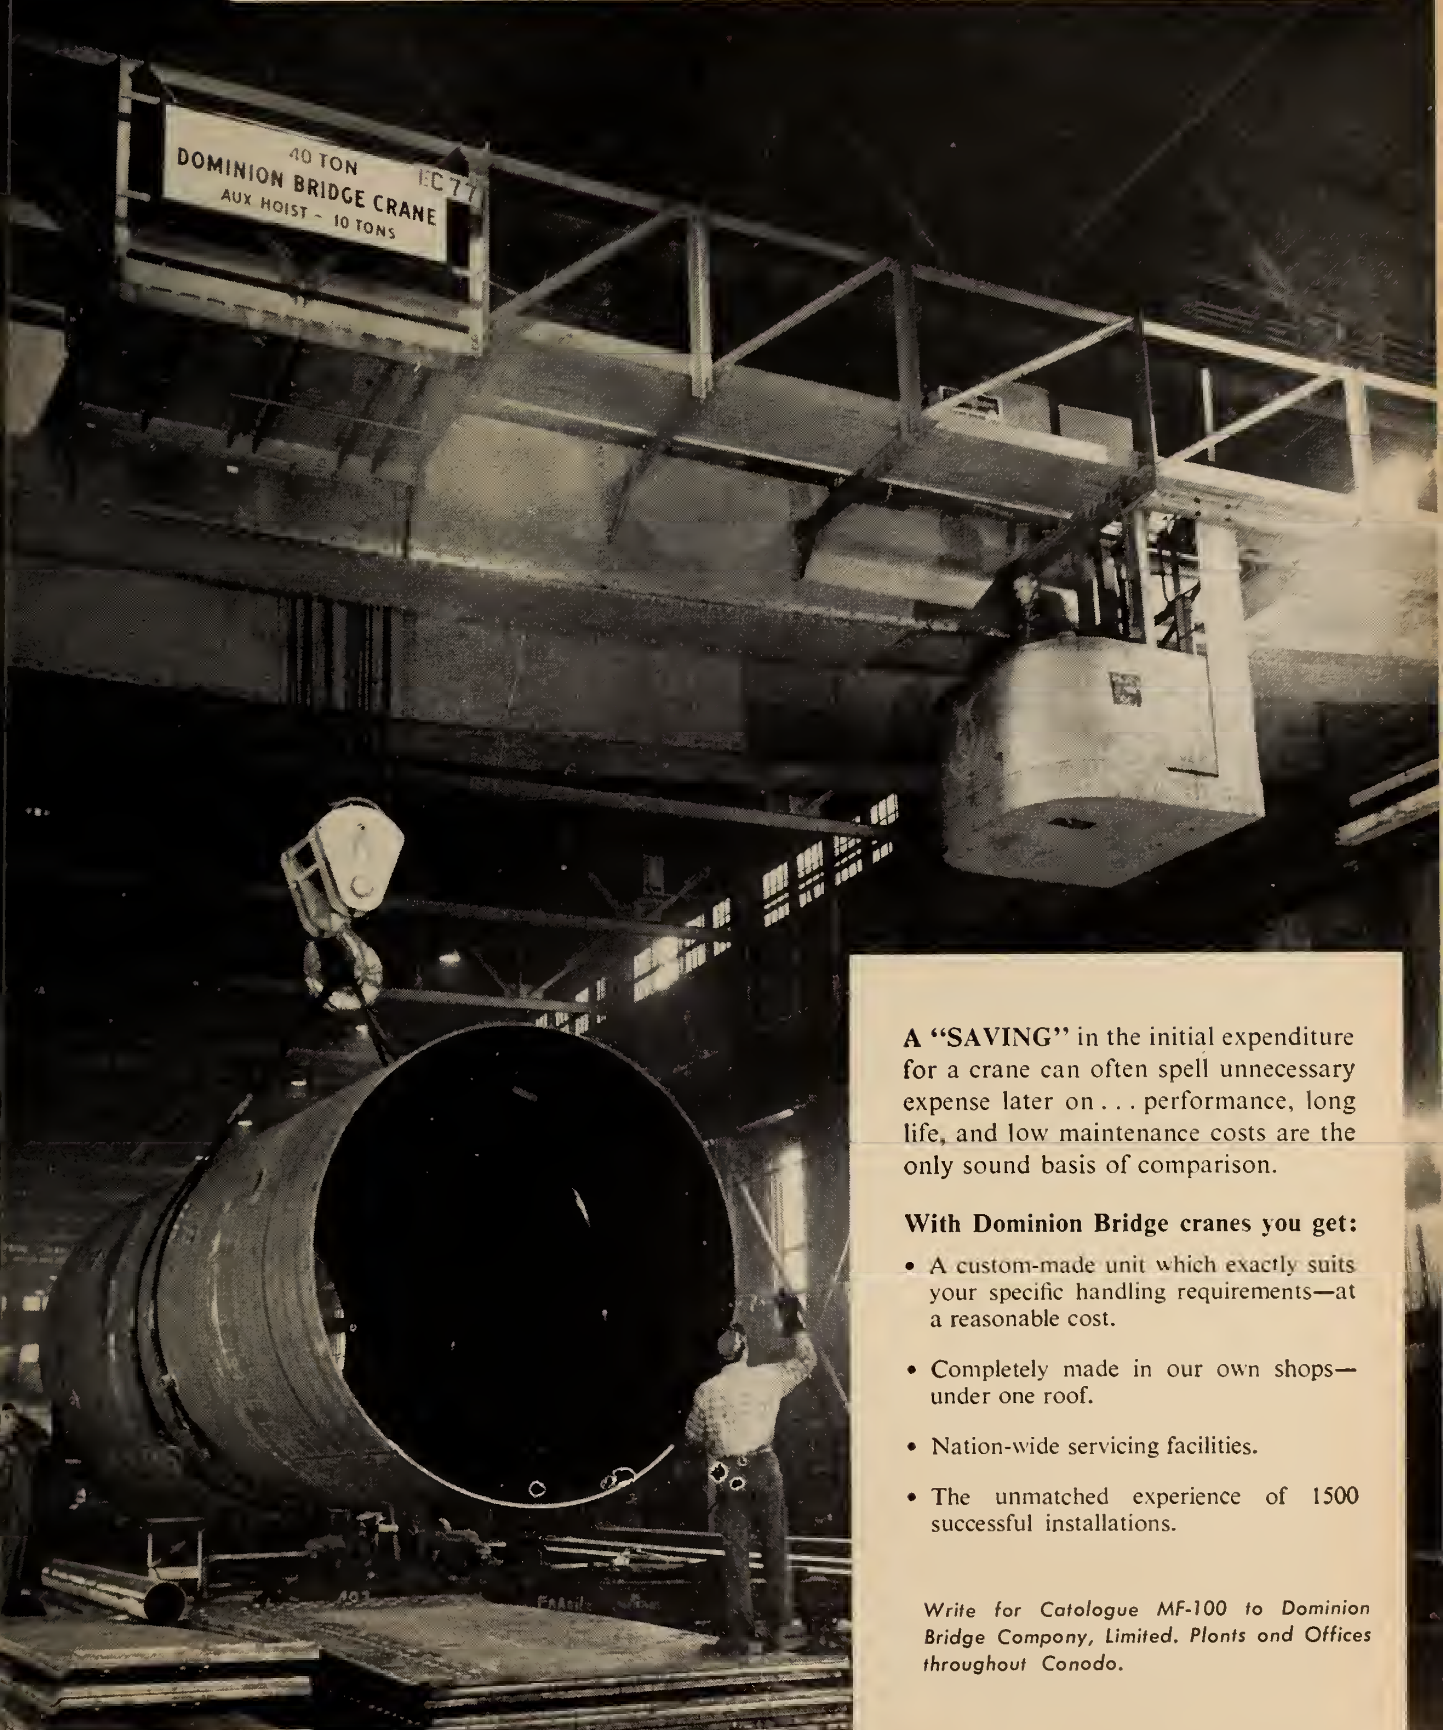
J. Edgar Dion, M.E.I.C., (McGill '26), formerly president of J. Edgar Dion & Company Ltd., management consultants, is now associated with Price Waterhouse & Co. and operating as J. Edgar Dion, consulting management engineer, Canada Cement Building, Montreal.

A. G. Macdonald, JR.E.I.C., (McGill '53) has joined Racey, MacCallum & Associates Ltd., Montreal, as an electrical engineering consultant. He has been with the Department of National Defence (RCAF), Ottawa.

G. M. Boissonneault, JR.E.I.C., (McGill '49) has been appointed assistant manager of the Shawinigan Water and Power Company's hydraulic resources department.

Howard D. Hamer-Hunt, M.E.I.C., has joined Messrs. Robert Jenkins & Co. Ltd., Engineers of Rotherham, Yorkshire, England, as site erection manager.

Investment or Expense?



A "SAVING" in the initial expenditure for a crane can often spell unnecessary expense later on . . . performance, long life, and low maintenance costs are the only sound basis of comparison.

With Dominion Bridge cranes you get:

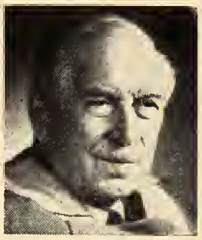
- A custom-made unit which exactly suits your specific handling requirements—at a reasonable cost.
- Completely made in our own shops—under one roof.
- Nation-wide servicing facilities.
- The unmatched experience of 1500 successful installations.

Write for Catalogue MF-100 to Dominion Bridge Company, Limited. Plants and Offices throughout Canada.

CRANES *by* DOMINION BRIDGE

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here



Charles E. Fraser, M.E.I.C.

Edmund Lancelot Miles, M.E.I.C.

Richard Francis Critchley, JR.E.I.C.

Charles E. Fraser, M.E.I.C., died at his home in Short Hills, N.J., August 23, 1959. He was 86.

Mr. Fraser was born in Montreal and received his engineering degree from McGill in 1899. In 1952 he was made an honorary life member of the McGill Graduates' Society and in 1954 the university conferred an honorary doctorate of science upon him for his outstanding work in engineering.

Moving to New York at the turn of the century, one of Mr. Fraser's early projects was the New York subway system planning. In 1908 he founded Fraser-Brace Engineering Co. Ltd. and acted as senior partner and chairman of the board until his retirement in 1955.

The company moved its operations to Montreal in 1911 and one of its outstanding achievements was the construction work on the Atomic Energy plant at Chalk River.

Armand C. Crepeau, M.E.I.C., dean of science at the University of Sherbrooke, which he helped to found, died on August 17, 1959. He was 75.

Born at St. Camille, Wolfe County, in 1884, Dr. Crepeau graduated from Laval University in 1909 as a civil engineer and land surveyor.

Dr. Crepeau began practising his engineering in Sherbrooke and represented Sherbrooke in the Quebec Legislature from 1924 to 1931.

A member of the Office of Directors of the Corporation of Land Surveyors of the Province of Quebec, Dr. Crepeau acted as its president from 1945 to 1948. He was also a charter member of the Eastern Townships branch of the Engineering Institute of Canada.

Before becoming first dean of science at the new University of Sherbrooke in 1954, Dr. Crepeau was engaged as a consulting engineer for the Hydro-Electric Commission of Ontario and later as engineer in charge of exploration work and surveying for the Department of Lands and Forests in Ungava (New Quebec).

Edmund Lancelot Miles, M.E.I.C., died September 1, 1959, in Montreal, at the age of 76.

Mr. Miles joined the consulting firm of Calt and Smith in 1909 and the following year became a junior partner in John Calt Engineering Co. Ltd. of Calgary.

Later he and John Haddin formed the firm of Haddin and Miles Ltd. of Calgary, Winnipeg, and Vancouver.

During World War I Mr. Miles was associated with the Department of the Interior in Western Canada and in Ottawa. He was engineer for the County of Victoria in Ontario from 1921-29 and in 1923 was elected a Fellow of the Royal Society of Arts, London. From 1930-38 he was manager of Standard Paving (Maritimes) Ltd. of Halifax and Charlottetown, PEI.

Mr. Miles acted as supervising engineer with the R.C.A.F. at Mont Joli Airport, Que. during World War II. He was with the Aerocrete Construction Co., Montreal, from 1945 until his retirement in 1953.

Earle Bedford Patterson, M.E.I.C., died on February 25, 1959, in Winnipeg, Manitoba. Mr. Patterson was born at Listowel, Ontario on February 22, 1883.

Upon leaving the Toronto School of Practical Science in 1909, he acted as assistant engineer at Point du Bois hydro-electric development and later as assistant engineer in charge of party for the Dominion Water Power Branch on their Winnipeg River power survey.

In 1912-13 Mr. Patterson worked as resident inspecting engineer at the La-Colle Falls Power Development of Prince Albert (Sask.). He later became assistant engineer for the Manitoba Hydrometric Survey.

Mr. Patterson was appointed resident inspecting engineer in 1930 for the Water Power Branch, Dept. of Mines and National Resources of Manitoba, at Seven Sisters Falls. In this capacity he oversaw construction of Northwestern Power Company's Winnipeg River project.

Richard Francis Critchley, JR.E.I.C., lost his life in a traffic accident at Burton-on-Trent, England, June 21, 1959. He was 26 years old.

Born in Regina on December 17, 1932, Richard grew up in Prince Albert and attended the University of Saskatchewan. He graduated in 1955 "with great distinction" in Mechanical Engineering. Richard was the recipient of the Association of Professional Engineers' prize for the "most distinguished graduate of the year in Engineering"; the Massey-Harris-Ferguson Award; and the Bowman Brothers' undergraduate award.

In 1958, after three years with Dominion Engineering Works, Montreal, he was awarded an Athlone Fellowship for two years' post-graduate study in England. While in England he did research with Vickers-Armstrong of Newcastle-on-Tyne and attended the Rolls-Royce Diesel Engine School at Derby.

Richard held a commission in the Royal Canadian Electrical and Mechanical Engineers and had been attached in that capacity to the Northumberland Hussars, Territorial Army, England.

J. Roy Freeman, M.E.I.C., died at his home in Moncton, N.B., April 18, 1959.

Born in Brighton, Ontario, April 14, 1887, Mr. Freeman graduated from the University of Toronto in 1912.

He was first employed by the Dominion Bridge Company, Montreal. From there he went to the head office of the Canadian National Railway at Moncton, where he worked until his retirement a few years ago. He was an authority on structural bridge work.

During World War I Mr. Freeman fought with the Ninth Heavy Siege Battery.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*MANPOWER AND INNOVATION IN AMERICAN INDUSTRY

This study attempts to explain the expansion in utilization of executives, managerial personnel, engineers, and scientists as a function of fundamental economic forces operating in modern society. It concludes that the greater employment of high-talent manpower is the consequence of innovation and of the pace of progress in American industry, and that this trend will increase as the economic growth of America increases. (S. E. Hill and F. Harbison, Princeton, N.J. Industrial Relations Section, 1959. 85p., $2.00.)

*AN OUTLINE OF PHOTOGRAMMETRY

Translated from the German, this text gives a reasonably concise presentation of the fundamentals, methods, instruments, and results of photogrammetry from a practical standpoint. Although German instruments and methods predominate, there is an attempt to cover achievements in other countries also. Topics discussed are terrestrial photogrammetry, serial photography, plotting serial photographs with simple equipment, rectification of single photographs, stereophotogrammetry, and applications of photogrammetry. (K. Schwidefsky. Toronto, Pitman, 1959. 326p., $13.00.)

*SYMBOLIC LOGIC AND INTELLIGENT MACHINES

The principles, methods, and purposes of symbolic logic and Boolean Algebra, on which the programming of computers and some other machines is based, are explained. The material on symbolic logic contains a considerable amount of comparisons and examples, as does the discussion on machines. The designs of both small and large machines are presented, along with the specific problems involved. The programming of automatic computers and complex devices such as robots completes the book. (E. C. Berkeley. New York, Reinhold, 1959. 203p., $6.50.)

*CAREERS AND OPPORTUNITIES IN ENGINEERING

The author indicates what personal traits and abilities are needed for success in various fields of engineering and discusses educational requirements and engineering courses. The actual work performed by engineers in different areas is described as are salaries and prospects for advancement. Also included is a brief history of engineering and a chapter on the opportunities for women. (P. Pollack. New York, Dutton, 1959. 140p., $3.50.)

*ELECTRONIC WAVEGUIDES

Papers dealing with such aspects as travelling wave tubes, dynamics of electron beams and plasmas, electron plasma oscillations, propagation in ion loaded wave guides, double-stress electron beam systems, boundary conditions at the surface of a slow-wave circuit, nonlinear O-type backward wave oscillators, space and time harmonics in electron beams, and high magnetic field submillimeter wave generators with parametric excitation. This volume comprises the proceedings of a symposium held in New York 1958 and is issued as volume 8 in The Microwave Research Institute Symposia Series of the Polytechnic Institute of Brooklyn. (Ed. by J. Fox. New York, Interscience, 1958. 418p., $5.00.)

*MOLECULAR SCIENCE AND MOLECULAR ENGINEERING

In this, the third and final volume in a series on modern materials research, the fundamental molecular properties of matter and their applications derived by molecular strategy are presented. Beginning with atoms and molecules, it continues with the behavior of charge carriers in gases, the formation and structure of condensed systems, dipoles and their spontaneous alignment in ferroelectrics and ferromagnetics, and ions and electrons in liquids and solids. Among the specific applications considered are gas-discharge and solid state devices, the molecular concepts producing masers and memory systems, transducers, transistors, parametric amplifiers and ion-exchange resins. (A. R. Von Hippel. New York, Wiley, 1959. 446p., $18.50.)

*CIVIL ENGINEERING HANDBOOK, 4th ed.

A handbook, written by various authorities, which covers mechanics of materials, stresses in framed structures, steel design, highway and airport engineering, water supply, sewage disposal, and other aspects of civil engineering. In this present edition new and expanded material appears on photogrammetric surveying, interstate highway system requirements, soil classification, flow in pipes and channels, stresses in continuous beams and frames, welded steel construction, and reproportioning concrete mixtures for air entrainment. (Ed. by L. C. Urquhart. Toronto, McGraw-Hill, 1959. 1184p., $20.15.)

*LOGICAL DESIGN OF ELECTRICAL CIRCUITS

Systematic treatment of Boolean methods for analyzing relay, diode, and vacuum tube circuits, particularly as used in the design of automation systems, computers, telephone dialing systems, and similar applications. Combinational circuits, sequential circuits, and shunt-down circuits are discussed in terms of Boolean algebra, and proven methods are given for simplifying circuits. Problems in the use of relays such as those relating to speed of operation and interference between units are described in detail. (R. A. Higonnet and R. A. Grea. Toronto, McGraw-Hill, 1958. 220p., $11.50.)

*PLASTIC ANALYSIS OF STRUCTURES

Presents the techniques necessary in the analysis of structures beyond the plastic limit, and the conditions under which a plastic analysis is appropriate. The first part of the volume treats in detail the application of plastic methods to frame-type structures whose principal strength lies in their resistance to bending, and discusses such topics as elastic plastic deformations, variable and repeated loading, and direct procedures of design. The second part is concerned with combined stresses in beams, circular plates, and circular cylindrical shells. (P. G. Hodge, Jr. Toronto, McGraw-Hill, 1959. 364p., $12.10.)

*THE PHYSICS OF ELECTRICITY AND MAGNETISM

The basic theory of electricity and magnetism is treated in a rigorous manner from the viewpoint of the physicist. A modern atomic approach is used to describe such phenomena as metallic conduction and the production of chemical and thermal electromotive forces. Topics discussed are charge, field, and potential; metallic conductors; dielectric materials; steady currents; electron levels; magnetic field and materials; alternating currents; and electromagnetic radiation.

A fully descriptive and mathematical treatment is given using vector notation and intermediate calculus. (W. T. Scott. New York, Wiley, 1959. 635p., $8.75.)

°THERMODYNAMICS

The fundamental laws and terms of thermodynamics are presented from an engineering perspective. Topics discussed include the first and second laws of thermodynamics; entropy; ideals gases; availability, irreversibility, and efficiency; reciprocating machines; power and refrigeration cycles; flow through nozzles and blade passages; thermodynamic relations and equations of state; combustion; equilibrium. Tables of thermodynamic properties are included in an appendix. (G. J. Van Wylen. New York, Wiley, 1959. 567p., $7.95.)

°THE ENGINEER AND PROFESSIONAL MANAGEMENT

An introduction to management functions for the engineer beginning his career. The book is divided into two parts of which the first deals with such non-engineering functions as promotion, finance, professional management, organization, marketing, advertising, purchasing and public relations. The second part deals with such semi-engineering functions as managerial accounting and auditing, cost accounting and statistical control, estimating, valuation or appraisal, engineering economy, and industrial technologic research. (H. Rubey. Columbia, Mo., Lucas Brothers, 1958. 299p.)

°NUCLEAR REACTORS FOR POWER GENERATION

Intended for engineers who are closely associated with the building and operation of nuclear power plants without necessarily being responsible for their design. An introductory section on world energy requirements in relation to nuclear energy programs is followed by sections on nuclear physics, types of reactors, materials, the physical basis of reactor design, safety and instrumentation, and applications and economics. (Ed. by E. Openshaw Taylor. New York, Philosophical Library, 1958. 144p., $7.50.)

°THE ATOM AND THE ENERGY REVOLUTION

A broad introduction to atomic energy and its industrial and social implications. The author discusses world energy resources and demand, new sources of energy, the atom and its energy, methods of releasing atomic energy, sources of natural materials for atomic energy development, the exploitation of atomic energy, and political and commercial organizations for atomic energy development. (N. Lansdell. New York, Philosophical Library, 1958. 200p., $6.00.)

°ANALYTICAL TRANSIENTS

Presents the more advanced aspects of network analysis. Considerable emphasis is placed on the Laplace transformation, and on the Fourier series as a logical basis for the Laplace transformation. Attention is given to the convergence of the series, the sampling theorems, and the Gibbs phenomenon. Also included are two significant chapters, the first of which deals with the behavior of linear systems of differential equations and the influence of discontinuous driving functions upon their solutions. The second

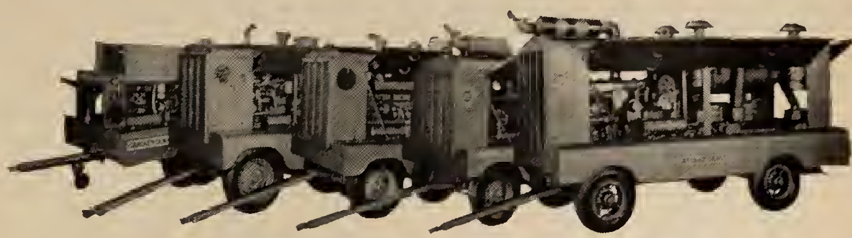
ONLY GARDNER-DENVER ROTARIES

Give you all these field-proved portable compressor advantages



Left to right, Models RP125, RP210, RP365, RP600, RP900.

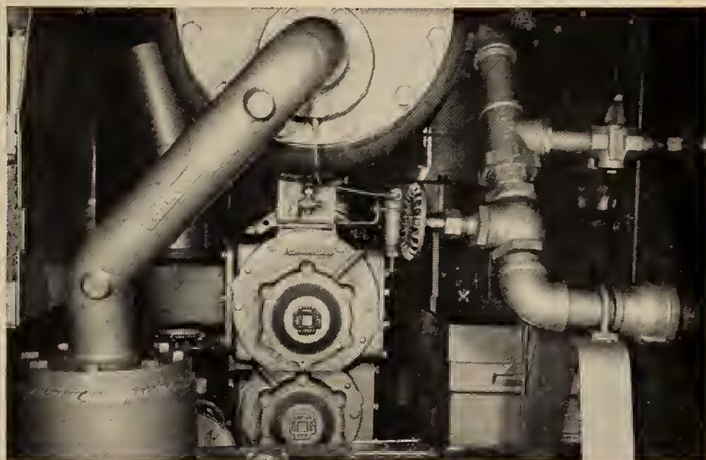
Safe, sure all-weather operation—water-oil cooling system keeps engine and compressor temperature constant.

Lubricated cold-weather starting—clutch allows compressor oil to be warmed before engaging compressor.

Positive flood lubrication—instantaneous oil flow not dependent on receiver pressure.

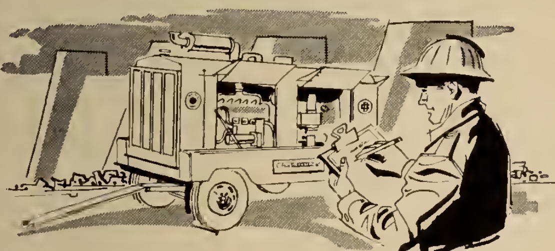
Fuel economy plus—exclusive Gardner-Denver "THRIFTMETER"® saves fuel, saves wear and tear on engine and compressor.

Simplified field maintenance—all compressor parts are easy to get to, making inspection and field maintenance faster and easier. See your Gardner-Denver distributor or write for bulletin.



The Gardner-Denver rotary requires no major dismantling job for inspection of working parts. Only a few minutes are required to remove the 12 cap screws to expose all the blades for routine inspection or replacement that assures trouble-free operation.

KEEPING TAB ON PROGRESS



At Gardner-Denver there's no substitute for men—our philosophy of growth for 100 years. Gardner-Denver engineers know your field from field experience . . . keep in constant touch with men and machinery . . . seek new ways of developing surer, safer, more productive equipment.

Gardner-Denver RP900's on Glen Canyon diversion tunnel job provide trouble-free air for all phases of this major project.

● LIBRARY NOTES

(Continued from page 138)

deals with stability, in which a general application of Sturm's and Routh's theorems is supplied. (T. C. G. Wagner. New York, Wiley, 1959. 202p., $8.75.)

*PACKAGE DESIGN ENGINEERING

Beginning with the basic fundamentals of static and dynamic mechanics, strength of materials, and stress analysis, the text continues with the design characteristics of the tension spring, rubber shear mount, solid cushioning, and canvas strap suspension systems. In addition the peculiarities of corrugated, sheathed crate, plywood, and metal shipping containers are discussed, as are the engineering fundamentals and design application of dehumidification and pressurization, vibration, and package test instrumentation. (K. Brown. New York, Wiley, 1959. 263p., $8.50.)

*ELECTRICAL ENGINEERING MATERIALS

The basic physical processes responsible for properties of materials are stressed in this volume, which contains sections on dielectric properties of insulators in static fields, behavior of dielectrics in alternating fields, magnetic properties of materials, conductivity of metals, mechanism of conduction in semiconductors, and junction rectifiers and transistors. Simple classical or semi-classical models are used to develop insight into the physical mechanisms described. (A. J. Dekker. Englewood Cliffs, N.J., Prentice-Hall, 1959. 208p., $8.00.)

*LINEAR NETWORK ANALYSIS

The foundations of network theory are developed in relation to steady-state and transient responses, time and frequency responses, and analysis and synthesis. Starting with basic fundamentals the authors continue with network synthesis, realizability conditions, and feedback and control systems. Specific aspects discussed include computation of network functions from any given real part, magnitude, or angle; integral relationships between real and imaginary parts; method of computing steady-state response for periodic driving functions; general treatment of classical filter theory; signal flow graphs from the point of view of directed graph theory. (S. Seshu and N. Balabanian. New York, Wiley, 1959. 571p., $11.75.)

*STATISTICS OF EXTREMES

Presents the theory of extreme values and rare events, and indicates how it may be applied to such problems as preventive measures against floods and droughts, calculating the risk involved in construction, and calculating the endurance of metals. A knowledge of calculus, analytical statistics, and prob-

(Continued on page 143)

● LIBRARY NOTES

(*Continued from page 140*)

ability theory are required, although in many instances graphical procedures are used to replace complicated formulae. The book covers order statistics and their exceedances, exact distribution and analytical study of extremes, the first asymptotic distribution and its uses, the second and third asymptotic, and the asymptotic theory of the range. (E. J. Gumbel. New York, Columbia University Press, 1958. 375p., $15.00.)

°THE MEASUREMENT OF POWER SPECTRA

Review of power spectra analysis for communications engineers, digital computer designers, and statisticians. The book is divided into two parts, the first dealing with the broad aspects of the subject, and the second with certain details and derivations.

Continuous records of finite length, equally spaced records, analysis, planning for measurement, and fundamental Fourier techniques are discussed. The present edition is reprinted from the "Bell System Technical Journal" with the addition of an index and a preface. (R. B. Blackman and J. W. Tukey. Toronto, McClelland and Stewart, 1958. 190p., $2.05.)

°THE MANY BODY PROBLEM

Papers presented at the School of Theoretical Physics of the University of Grenoble. Topics discussed include the perturbation theory of many Fermion systems; nuclear structure; many body systems; nuclear matter; collective and spurious degrees of freedom in nuclear models; the Bogoliubov canonical method and its application to nuclei; electrons, plasmons, and phonons; superconductivity; the hardsphere Bose gas and the method of pseudopotentials. (New York, Wiley, 1959. 675p., $15.00.)

°HEAT TRANSFER AND FLUID MECHANICS INSTITUTE, **1959.** Preprints of papers.

Papers concerned with current, fundamental research. Sections included deal with rarefied gas flows; magnetohydrodynamics; fluid mechanics and heat transfer; ablation, mass transfer, and separation; new and unusual research. These constitute preprints of papers given at the Institute held at the University of California in Los Angeles. (Stanford, Univ. Press, 1959. 243p.)

°ENGINEERING AND ORGANIZATION

The goals of engineering are defined and the standards by which its performance can be evaluated are established. The greatest portion of the book is concerned with the place of the engineering process within the over-all structure of an industrial enterprise, and discusses such aspects as management, product specification, budget, design, production, selling, buying, maintenance, and personnel. The author is primarily concerned with

● LIBRARY NOTES

fundamental principles as a basis for establishing standards, rather than with present-day practice. (E. Laitala. Toronto, General, 1959. 391p., $7.95.)

***HANDBOOK OF THE ATOMIC ENERGY INDUSTRY**

Provides a broad summary of the atomic energy industry throughout the world. Included are training and education; atomic structure; nuclear fuels and reactors; metals used in atomic energy; industrial, biological, and agricultural uses of radiation and radioactive isotopes; radiation hazards and protection; the handling of radioactive isotopes; radioactive waste disposal. (Ed. by S. Jefferson. Toronto, British Book Service, 1958. Various paging, $8.00.)

***DISPOSAL OF RADIOACTIVE WASTE**

Provides information relating to the basic data on which the safe limits for radioactive discharge are considered. Discusses the formation and nature of radioactive waste, the biological effects of radiation, discharge to the natural environment, and the treatment of airborne wastes, liquid effluents, and solid wastes. The problems likely to arise in the future and the means of coping with them are considered, as is the utilization of individual fission products. (K. Saddington and W. L. Templeton. Toronto, British Book Service, 1959. 102p., $4.50.)

***STATISTICAL QUALITY CONTROL**

Written for management personnel who wish to familiarize themselves with statistical quality control without the necessity of mastering the mathematical details of the technique. Following an introduction to the concepts involved and their place in management, the basic tools are then described including statistical concepts, process capabilities, statistical control charts, and statistical acceptance sampling. The book concludes with the methods used for investigations and their field of application and limitations. (D. H. W. Allan. New York, Reinhold, 1959. 129p., $3.50.)

***WORK MEASUREMENT**

The need for better planning is stressed in this volume which discusses the setting of work standards and how to use and maintain them. All phases of the work measurement program are presented: why work is measured and what it means to company personnel; the standard data approach; the economics of work measurement; the consultant's role; labor relations and work measurement. The methods and procedures described were developed from the first-hand experience of management consultants and industrial engineers actively engaged in the field of work measurement. (V. H. Rotroff. New York. Reinhold. 1959. 203p., $4.85.)

(Continued on page 146)

• LIBRARY NOTES

(Continued from page 144)

*THEORY OF BEAMS

Discusses the application of the Laplace Transformation method to the solution of the ordinary differential equations which occur in the theory of beams. Solutions are obtained for beams on two supports under various conditions of end fixing as well as for continuous beams both with rigid and elastic supports. In addition the author derives a solution of the differential equation of the elastic curve for the case of a beam with variable rigidity and defines the load function for this case. (T. Iwinski. New York, Pergamon, 1958. 85p., $3.50.)

*ANALYSIS OF LINEAR SYSTEMS

A detailed presentation of the two essential steps involved in the analysis of a linear physical system: the setting up of the mathematical equations that describe the system in accordance with physical laws, and the solution of these equations subject to appropriate initial or boundary conditions. In the formulation of the equations that describe a physical system, emphasis is placed upon electrical circuits. To deal with systems other than electrical, a chapter on analogous systems is included which treats in detail methods for drawing electrical circuits analogous to linear mechanical and electromechanical circuits. The Laplace transform method of solving linear differential and integrodifferential equations is stressed. (D. K. Cheng. Reading, Mass., Addison-Wesley, 1959. 431p., $8.50.)

*TIGNES

This group of papers by engineers connected with the work, covers fully the hydraulic installations of Tignes in the French Alps. The Tignes Dam, one of the highest in the world is described in detail, as are the problems encountered in its construction. The power plants at Brévière, Le Chevril and Ponturin, and the central plant at Malgovert are similarly treated. The book is profusely illustrated with photographs and diagrams. (Paris, Hoüille Blanche, 1958. 440p., 8000 fr.)

*STAUANLAGEN UND WASSERKRAFTWERKE. Teil 1: TALSPERREN, 2d ed.

Part I of a three-volume set on hydroelectric power plants, this volume gives a concise but comprehensive description and analysis of the various types of modern concrete gravity, arch and earth dams, with a wealth of illustrative sketches and photographs from existing installations. Auxiliary structures and equipment are also shown, and there is a bibliography of over 1200 items. Considerably enlarged from the previous edition. (Heinrich Press. Berlin, Ernst, 1958. 395p., 54 DM.)

*MASTGRUNDUNGEN FUR FREILEITUNGEN, FAHRLEITUNGSANLAGEN UND BAHNSPEISELEITUNGEN

A manual for the design of concrete pole foundations for high-tension overhead lines, trolley wire installations, and railway feeders. It provides a comprehensive treatment of the calculations involved in designing the most economical foundations, including numerous graphs for rapid determinations. (M. Suberkrub. Berlin, Ernst, 1958. 124p., 19.80 DM.)

*BEWEGUNGSFUGEN IN BETON- UND STAHLBETONBAU

Dealing with expansion joints in concrete and reinforced concrete construction, this book discusses the importance of such joints and gives more than 300 examples of the design and construction of buildings and other structures incorporating them: silos, tanks, swimming pools, bridges, harbor works, pipelines, roads, tunnel and mine structures, etc. (A. Kleinlogel. Berlin, Ernst, 1958. 272p., 34 DM.)

*DIE BERECHNUNG DER ZYLINDERSCHALEN

Following the opening chapter on the fundamentals of shell theory, the author devotes each of the subsequent chapters to the calculation of full or partial cylindrical shells under various conditions. Particular attention is paid to barrel roof construction. The author uses the "model-shell" concept as a basis. There are over 200 references in a selected, chronological bibliography. (A. Aas-Jakobsen. Berlin, Springer-Verlag, 1958. 160p., 22.50 DM.)

°THE DESIGN OF PRISMATIC AND CYLINDRICAL SHELL ROOFS

Simplified methods of design are given for prismatic and curved cylindrical shells of any geometric form, under varying conditions of loadings, support and continuity. The structure is split into compatible elementary structures, and these are designed by elementary methods based on the theory of structures. Approximation methods are applied throughout, and only a small number of linear equations have to be solved. Fully worked out examples illustrate the application of the methods described. (D. Yitzhaki. Amsterdan, North Holland, 1958. 253p., 42 guilders.)

°CIRCUIT THEORY OF LINEAR NOISY NETWORKS

Discusses a method of determining the single-frequency noise performance of an amplifier and its optimization. The properties of linear noisy networks that are invariant under lossless network transformations are analyzed. These invariants are determined for multiterminal-pair networks, and their physical interpretations in terms of a generalized "available power" are presented. The invariants are then considered for the special case of a linear two-terminal-pair amplifier, and are shown to establish a lower limit on its noise performance. Various ways of achieving this limit are presented for all classes of amplifiers, including those with negative resistance. (H. A. Haus and R. B. Adler. New York, Wiley, 1959. 79p., $5.00.)

°THE ALGEBRA OF ELECTRONICS

Reviews the mathematical principles involved in the solution of problems in the field of circuit theory and design. Starting with graphs of networks and the relation of Kirchoff's law to Ohm's Law, the author continues with loop-branch relations in tabular form, model analysis determinants, Laplace's expansion of determinants by cofactors, solution of simultaneous equations, and Fourier waveform analysis. Applications to specific problems are considered and include series tuned circuits, impedance matching, amplifiers, noise, and modulation, demodulation, and distortion. (C. H. Page. Toronto, Van Nostrand, 1958. 258p., $9.75.)

°DECISION-MAKING AND PRODUCTIVITY

The author attempts to show that major alternatives in industrial decision-making exist and have discernible effects on productivity. He also attempts to define some of the opportuniites that exist for accelerating the growth of productivity. The book is divided into four sections covering alternative methods for productivity growth, decision-making by the union, decision-making by management, and the effects of union and management decision-making on productivity. (S. Melman. New York, Wiley, 1958. 206p., $7.00.)

BOOK REVIEW

EARLY ENGINEERING EDUCATION AT TORONTO 1851-1919

Usually the record of current events which ultimately makes up a history, is not good enough to well serve the purpose. Histories as such are written by people who come after the events and who frequently have only the fragmentary and frequently inaccurate writings of an earlier people upon which to base their story. Such historians, too, are frequently biased so that their interpretations of the record may well vary from historian to historian, as can be seen readily in histories of nations and races.

Canadian engineers are fortunate that within their midst there is a man who has the patience, the understanding and the ability to seek out the early developments in engineering education in Canada and to do it before the events become obscured by the passing of time. Such a man is Dr. Clarence Richard Young, consulting engineer, educationalist, author and historian.

This volume is Dr. Young's latest publication. It is a fascinating and well documented story of the early thinking of Canadian educationalists on the question of providing a course of a technological nature in the Province of Ontario.

The story should be interesting to all Canadian engineers but in particular to those who passed through the halls of the "School" at the University of Toronto. Dr. Young has searched the written record for a multitude of details, and has drawn on his own knowledge gained from contacts with many of the pioneers in the field of education. The result is a story which is complete, accurate and readable. As the title suggests, it relates principally to the University of Toronto, but as well it includes many references to other Canadian universities and provinces.

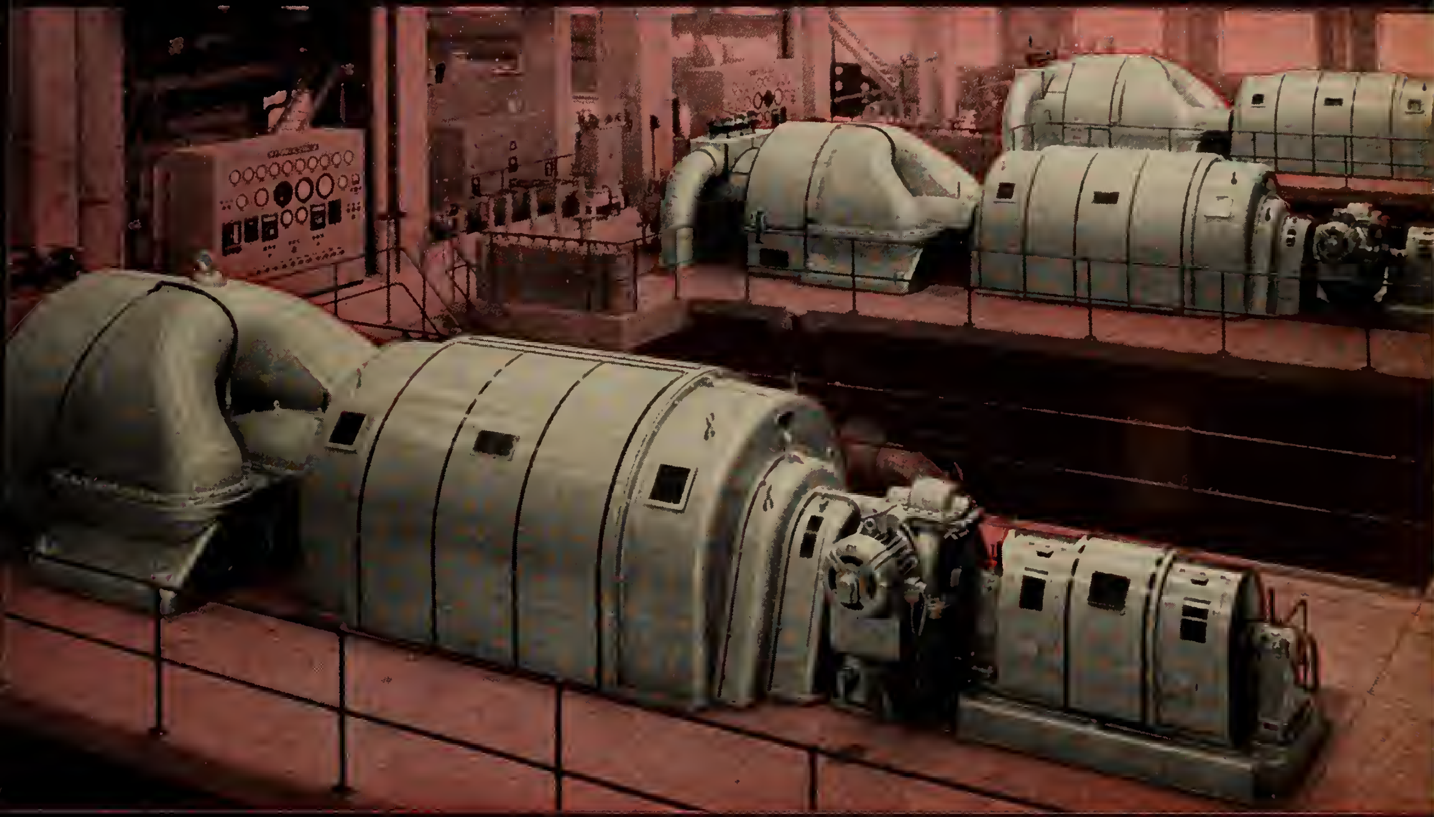
As would be expected, a history of this kind would have to be a biography of those stalwarts who fought hard and long for the establishment of technical education. Dr. John Galbraith, the founder of engineering education at Toronto, and his close associate, Dr. W. H. Ellis, have already been recognized as great men, but with the presentation of this detailed story of their struggles and success they grow even to greater stature. The profession is indeed indebted to them, and to Dr. Young for seeking out the story and presenting it in such excellent form.

Many other important early engineers are woven into the story such as Cumberland, Marshall, Herrick, Armstrong, Brydone-Jack, Cregan, Chapman, Fleming, Keefer, MacDougall, Thomson, Croft, Tyrrell, Stewart, Dawson and others.

Few members of the engineering profession in Canada write as well as does "C.R.". It is a delight to go through these pages, not only because the story is interesting but because it is so well told —and in such good English. It would

(*Continued on page 150*)

Power behind Scottish



• LIBRARY NOTES

(*Continued from page 147*)

make excellent required reading for any student or young engineer.

To illustrate the philosophy of some of the educationalists of those times, and their opposition to anything practical, Dr. Young quotes the president of King's College, of Fredericton, N.B. (now University of New Brunswick), who in 1851 said: "To those who would make the college a polytechnic institution we may not promise much more in the way of merely practical teaching; we must not listen to the cry that calls us from the pursuit of truth and virtue to the lower paths and grosser occupations of the multitude." What would he say if he knew that today practically fifty per cent of the enrollment at the University of New Brunswick is in engineering?

To show there were others not so narrow in their outlook, Dr. Young quotes from an editorial published in a local paper: "To be intimately and critically acquainted with the writings of the philosophers, historians, and poets of Greece and Rome is a luxury confined to the aspirations of the few—not a necessity for the many. The many of this fast and labouring epoch look for knowledge that contributes relief to the wants, and will meet the exigencies of the passing hour. Mental life in a new country cannot afford the time required to detect the subtleties of the Areopagitica, or to elaborate the conceits of a Sappho, or wade through the nonsense of a fabulous mythology. The present is overloaded with the practical."

In addition to being distinguished as an educationalist and an author, Dr. Young has served and been honoured by many organizations. He was president of The Engineering Institute of Canada in 1942, was made an honorary member in 1949, and received the Sir John Kennedy Medal in 1951. He retired from the deanship of the Faculty of Applied Science and Engineering at Toronto in 1949 after serving there for over forty-two years. Since then he has continued his consulting practice with great success.

"Early Engineering Education at Toronto 1851-1919" is a real addition to the all too limited volume of Canadiana. (Toronto, University Press, 1958. 152p., $3.95.)

L. A. WRIGHT, M.E.I.C.

PEACEFUL USES OF ATOMIC ENERGY, 2ND INTERNATIONAL CONFERENCE. PROCEEDINGS.
V.8, NUCLEAR POWER PLANTS, PART 1

The official Proceedings of the Second International Conference on the Peaceful Uses of Atomic Energy are now being issued by the United Nations. This eighth of thirty-three volumes covers sessions G-3, G-6 and G-7.

The first of these heard seven papers on experience with operating nuclear power plants in the United Kingdom, United States, France and the Soviet Union. The second session was concerned with the use of nuclear energy for purposes other than the generation of electricity, and included papers on the Russian ice-breaker Lenin, the U.S.A.'s N.S. Savannah, the Japanese submarine atomic powered tanker, nuclear propulsion for ships, nuclear energy for heating, and the use of nuclear energy in industry.

The third session heard reports on future construction plans for nuclear power plants in Canada, Czechoslovakia, France, Italy, U.S.S.R., U.K., U.S.A., Sweden and Belgium. This volume also contains a Catalogue of operating nuclear reactors. (Geneva, United Nations, 1958. 584p., $14.00.)

V.12 REACTOR PHYSICS

The sixty papers included in this volume represent the majority of those presented at the Conference on this subject. The three sessions covered were concerned with fast and intermediate reactors, liquid moderated reactors, and solid moderated reactors.

Specific topics discussed include fast reactor physics, fast, intermediate and coupled reactors, fast reactor safety, D_2O and H_2O systems for liquid moderated reactors, and beryllia, graphite and com-

• LIBRARY NOTES

posite systems for solid moderated reactors. (United Nations, Geneva, 1958. 767p., $18.50.)

°USINES DE DERIVATION

A treatise on hydraulic plants which utilize water diverted by means of canals, tunnels and pressure pipe lines. The first volume treats of water-intake systems, describing these from the point of view of climate, topography and fish protection. The formulas, equations and laws involved in calculating hydraulic construction are then discussed at length. The second volume covers forebays and pressure pipe lines with emphasis on prestressed high-pressure pipe. There are sections on water hammer, and surge tanks and the author ends the second volume with a discussion of underground hydraulic plants. (H. Varlet. Paris, Eyrolles, 1958. Two volumes. 4600; 4400 frs.)

°COST MANUAL FOR PIPING AND MECHANICAL CONSTRUCTION

The purpose of this volume is to help estimators to arrive at reliable figures as well as to provide plant maintenance managers and engineers with a means of checking estimates submitted to them. Following preliminary material on plant and service accounts, types of estimates, standard hours, direct costs, and pay statements, tables are presented on piping installation, mechanical construction, comparative unit-costs, and miscellaneous data. The tables provide unit costs calculated in man-hours, and therefore are not subject to constant changes in labor cost. (H. Herkimer. New York, Chemical Pub., 1958. 176p., $10.00.)

°TECHNOLOGIE DES REACTORS NUCLEAIRES, TOME 1 — MATERIAUX

An introduction to the fundamental concepts of nuclear technology. The effects of radiation on various materials are analyzed and classified. This is followed by a discussion of the behaviour of reactor materials, their mechanical properties and radiation damage, as well as the modification of physical properties or the formation of new substances. Nuclear fuels and non-fissionable materials provide the subject matter for seven chapters, while recent developments in uranium, heavy water, beryllium and cermets are described. (P. Ageron and others. Paris, Eyrolles, 1959. 567p., 6900 fr.)

°INTRODUCTION TO THE THEORY OF SOUND TRANSMISSION

Transmission of sound is discussed with specific application to transmission in the ocean. The fundamental relations and general theory underlying the theory of sound transmission are presented and then followed by transmission in shallow water, transmission in deep water, reflectivity, and attenuation. Mathematical derivations are developed in some detail, and physical explanations of theoretical results are given where possible. Modern advances are covered with particular emphasis on developments during the past twenty years. (C. B. Officer. Toronto, McGraw-Hill, 1958. 284p., $11.00.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Granular materials. Size determination

Review and evaluation of methods of particle size analysis, by R. F. Pilgrim. Ottawa, Dept. of Mines and Technical Surveys, Mines Branch, 1958. IC 106. 25c.

Industrial manpower

Training and recruitment of skilled tradesmen in selected industries in Canada 1951-1956. Ottawa, Dept. of Labour, Economics and Research Branch, 1957. 25c.

Instruments

British instruments; directory and buyers' guide, 1959. London, Scientific Instrument Manufacturers' Association, 1959.

Roads and streets

Flexible pavement design — research and development 1958. Wash., Highway Research Board 1959. (Bulletin 210) $1.20.

Subsurface drainage of highways and airports. Wash., Highway Research Board, 1959. (Bulletin 209) 50c.

Snow

Factors affecting snowmelt and streamflow; a report on the 1946-53 Cooperative Snow Investigations at the Fraser Experimental Forest, Fraser, Colo., by W. U. Garstka, and others. Denver, U.S. Dept.

(Continued on page 155)

of the Interior, Bureau of Reclamation, 1958. $1.25.

Soil mechanics

Annual report of the Canadian section of the International Society of Soil Mechanics and Foundation Engineering for year ending June 1958; including membership list of the Canadian section, prepared by C. B. Crawford.

Proceedings of the fourth Muskeg conference, March 11, 1958. Ottawa, National Research Council, Associate Committee on Soil and Snow Mechanics, 1958. (Technical Memoranda nos. 54 and 55.)

Stabilization of soil with calcium chloride, annotated by F. O. Slate and A. W. Johnson. Wash., Highway Research Board, 1958. (Bibliography 24)

Schools

Legal liability of school boards and teachers for school accidents, by R. L. Lamb. Ottawa, Canadian Teachers' Federation, Research Division, 1959. (Research study no. 3)

Aerodynamics

Effect of standing vortex on flow about suction aerofoils with split flaps, by P. Mandl. Ottawa, N.R.C., 1959. (Aeronautical report no. LR-239.)

Aircraft

Note on the minimum power required for flight at low airspeeds, by R. J. Templin. Ottawa, N.R.C., 1959. (Aeronautical report no. LR-245).

A preliminary analysis of the penalties associated with piercing a wing torsion box with a grid of holes, by A. H. Hall. Ottawa, N.R.C., 1959. (Aeronautical report no. LR-236.)

Analysis of a cantilever beam developing an isoplastic response under impact at the tip, by A. H. Hall and V. L. Saxon. Ottawa, N.R.C., 1959. (Aeronautical report no. LR-237.)

Beams and girders

A survey of residential post-and-beam construction in greater Vancouver, 1957-1958, by V. F. Lyman. Ottawa, N.R.C., Division of Bldg. Research, 1959. (Technical paper no. 70.) 50¢.

Canada. Northwest Territories

Potentialities of the Northwest: an engineering assessment, by R. F. Legget. Ottawa, N.R.C., Div. of Bldg. Research, 1959. (Technical paper no. 65) 25¢.

Computers

Transfer-function discovery on the pace analogue computer, by J. H. Milsum. Ottawa, N.R.C., Div. of Mechanical Engineering, 1959. (Mechanical engineering report MK-2)

Construction industry

Modular co-ordination cuts design and building costs, by S. R. Kent. Ottawa, N.R.C., Div. of Bldg. Research, 1959. (Technical paper no. 58). 10¢. The technological properties of brick masonry in high buildings, by P. Haller. Ottawa, N.R.C., 1959. (Technical translation no. 792)

Fires and protection

Fire research and fire prevention; proceedings of a conference held October 1-3, 1958 in Ottawa. Ottawa, N.R.C., Div. of Bldg. Research, 1958. (Bulletin no. 2.) $1.50.

Hydroelectric power plants

The Stornorrfors power plant, by T. Nilsson. Stockholm, Swedish State Power Board, 1959. (Blue-white series, no. 19E).

The Swedish state power administration, by L. Fritz. Stockholm, Swedish State Power Board, 1958. (Blue-white series 20)

Metals and alloys

The behaviour of fine copper-nickel alloy wires with negative temperature coefficients of resistance, by W. Wiebe. Ottawa, N.R.C., 1959. (Mechanical engineering report MS-100.)

Soil mechanics

Heat and moisture transfer in closed systems of two granular materials, by W. Woodside and J. B. Cliffe. Ottawa, N.R.C., Div. of Bldg. Research, 1959. (Research paper no. 77.) 25¢.

Heat transfer in a moist clay, by W. Woodside and C.M.A. de Bruyn. Ottawa, N.R.C., Div. of Bldg. Research, 1959. (Research paper no. 79.) 25¢.

Soil engineering problems on the Quebec-North Shore and Labrador railway, by K. B. Woods, R. W. J. Pryer, and W. J. Eden. Ottawa, N.R.C., Div. of Bldg. Research, 1959. (Technical paper no. 72). 25¢

Tubes

Tube and semiconductor selection guide, 1958-1959, comp. by Th. J. Kroes. 2d rev. ed. Eindhoven, Holland, Philips, 1958. $1.50.

Vibrations

Human sensitivity to vibration, by D. T. Wright and R. Green. Kingston, Queen's University, 1959. (Report no. 7.)

Wind tunnels

Boundary layer transition on a 10-degree cone in the N.A.E. 30 - X 16-inch wind tunnel, by J. van der Bliek. Ottawa, National Aeronautical Establishment, 1958. (Laboratory report LR-232). Drag measurements on agard model 'A' in the N.A.E. 30- X 16-inch wind tunnel and comparison with other data, by J. A. van der Bliek. Ottawa, National Aeronautical Establishment, 1958. (Laboratory report LR-233.)

Notes on half model testing in wind tunnels, by J. A. van der Bliek. Ottawa, National Aeronautical Establishment, 1959. (Laboratory Report LR-235.)

REPRINTS ISSUED BY DOVER PUBLICATIONS, NEW YORK

Advanced calculus; a text upon select parts of differential calculus, differential equations, integral calculus, theory of functions, with numerous exercises, by E. B. Wilson. 1958. 566p., $2.70.

Computational methods of linear algebra, by V. N. Paddeeva. 1959. 245p., $2.15.

The dynamics of particles and of rigid, elastic, and fluid bodies; being lectures on mathematical physics, by A. G. Webster. 2d. ed. 1959. 588p., $2.60.

Elasticity, plasticity and structure of matter, by Dr. R. Houwink; with a chapter on the plasticity of crystals by Dr. W. G. Burgers. 2d. ed. 1958. 368p., $2.45.

Guide to the literature of mathematics and physics including related works on engineering science, by N. G. Parke III. 2d. rev. ed. 1958. 436p., $2.49.

An introduction to Fourier methods and the Laplace transformation, by P. Franklin. 1958. 289p., $1.65.

Introduction to symbolic logic and its applications, by R. Carnap. 1958. 241p., $2.05.

Linear groups with an exposition of the Galois field theory, by L. E. Dickson. 1958. 312p., $2.15.

Meson physics, by R. E. Marshak. 1958. 376p., $2.15.

Theory of functionals and of integral and integro-differential equations, by V. Volterra. 1959. 221p., $1.95.

The value of science, by H. Poincaré. 1958. 147p., $1.50.

CHIEF ENGINEER. Large Toronto Structural Steel Fabricator and Erector is seeking an experienced engineer with outstanding capabilities who has held a position of responsibility. This key position offers an excellent opportunity for advancement to a man who has considerable experience in the design of buildings and bridges. Applicants must have professional standing in the Province of Ontario. Salary commensurate with ability. Replies held in confidence. Please write to us giving detail of age, education, experience to File No. 6823-V.

CIVIL ENGINEER with experience in construction and municipal works required by Buildings and Grounds Department of a University in Western Canada. Duties to include estimating, supervision of construction, assist in planning of operations, maintenance and expansion of buildings and utilities. Salary range $6600 - 7800, pension and other benefits. File No. 6833-V.

STRUCTURAL ENGINEER required by expanding Edmonton firm. Work would consist of designing and client consultation with opportunity for executive appointment. File No. 6834-V.

GENERAL SUPERINTENDENT REQUIRED by general contractor in Eastern Ontario City. This man must have a proven record of performance on building contracts in excess of one million dollars and be capable of directing the work of several job superintendents with the utmost economy. Applicant must be capable of dealing with architects and engineers and settling matters with considerable dispatch. Graduation in civil engineering would be preferable but not mandatory. Top salary and good future prospects for the right man. Replies treated confidential. File No. 6837-V.

ESTIMATING ENGINEER required for Toronto district, heavy construction firm. Civil engineer preferred, age 45 to 65, interested in full time estimating work with background of experience in road building and municipal work. File No. 6840-V.

SENIOR STRUCTURAL DESIGN ENGINEER required by consulting engineering firm in Southern Ontario. Applicants must have 8 - 10 years' experience of which 6 - 7 years should have been on the design of industrial, commercial and institutional buildings. First-class structural steel design experience is essential. Please reply in confidence giving fullest particulars of experience and responsibilities, and salary required. File No. 6843-V.

CONSTRUCTION ENGINEER required for Buildings & Grounds Department of a Maritime University. Qualifications of candidate should be: Graduate civil or mechanical engineer; minimum of two years' experience; background preferably in construction supervision of buildings and underground services. Some design experience would be helpful. File No. 6849-V.

ELECTRICAL

YOUR OPPORTUNITY IS EXCELLENT for a future in a new modern Montreal area plant of a large American manufacturer. Electrical engineer desired with experience in the design of armature, stator and field coils to coordinate engineering and shop practices in their manufacture and in rewinding motors and generators. Initial training period at headquarters in U.S.A. Salary is commensurate with experience and ability. All replies are confidential. File No. 6790-V.

ELECTRICAL DESIGNER with at least 5 years' experience in the consulting field specializing in light industrial and commercial work. Salary commensurate with qualifications. Location of work Toronto. Interviews can be arranged in Montreal. Write Paul C. Ellard & Associates, 669 Bayview Avenue, Toronto 17, Ontario. File No. 6845-V.

MECHANICAL

MECHANICAL ENGINEER desired for design and performance calculation of steam generating equipment in engineering department of firm located in central Ontario, applicants should have two to five years' experience in above field, and University or Technical education. Alternatively applications will be considered of personnel having similar length of experience in estimating steam generating equipment. File No. 6836-V

MECHANICAL ENGINEER. Long established well known manufacturing concern located in the Maritime Provinces requires a graduate mechanical engineer in age range 21 to 28. Applicant should have a special interest in all phases of manufacturing a wide range of products. File No. 6844-V.

MISCELLANEOUS

PRODUCT ENGINEER requested by Montreal manufacturer to take charge of product design, with a view to setting up design department. Experience in design of heating and air conditioning units, household appliances or similar items involving sheet metals preferable. All inquiries confidential. File No. 6803-V.

GRADUATE ENGINEERS, Civil, Mechanical, Electrical required by leading consulting engineering office in Montreal. Civil engineers with experience in structural steel, reinforced concrete and construction engineering. Knowledge of prestressed concrete design preferred. Mechanical engineers for heating, ventilation and refrigeration. Experience in field and consulting engineering office preferred. Electrical engineers with experience in power generating plants, transmission lines and industrial installations. Permanent positions with good starting salaries, wide range of employee benefits and opportunities for advancement. Write, outlining your qualifications and experience to File No. 6813-V.

ALL AROUND ENGINEER for a long established growing plant in the Eastern Townships of Quebec. The job carries the opportunity of taking charge of all mechanical, heating, construction, refrigerator, electrical, automotive, materials handling matters using a trained staff. Emphasis on organizing, planning. Engineer should enjoy contract with men and operations. Permanent position, good salary. File No. 6817-V.

MECHANICAL-ELECTRICAL ENGINEER required by Quebec City consulting firm. Applicant should have a minimum of three years' experience in the design and layout of heating, ventilating, plumbing and electrical systems for large public buildings, and should be fully qualified to take charge of this department. Applicants should send resume of education, experience and salary requirements. File No. 6827-V.

ASSISTANT INSTRUMENT ENGINEER. Required by Pulp and Paper mill Eastern Ontario. Should be graduate chemical, electrical or mechanical engineer with one to three years experience in instrumentation or pulp and paper manufacture. Salary dependent on qualifications and experience. File No. 6835-V.

PHYSICAL METALLURGIST required for materials engineering section of major metallurgical and chemical plant in Western Canada. Work will entail advising on application of metals in process equipment, investigation of service failures and non-destructive testing. If interested write giving particulars of qualifications to: Supervisor, Staff Department, The Consolidated Mining and Smelting Company of Canada Limited, Trail, B.C. File No. 6838-V.

ENGINEER required well versed in agronomy or hydraulics, to sell water pumps and irrigation equipment. Must be prepared to travel abroad with probable headquarters in Belgian Congo and have fluent knowledge of French and English. American manufacture. Interviews arranged, Montreal or New York City. File No. 6841-V.

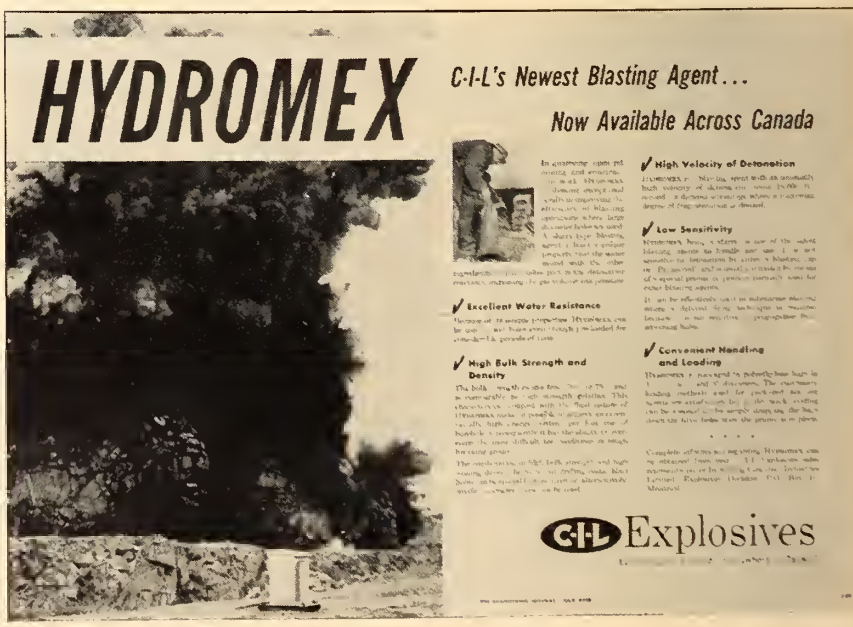
E.I.C. CERTIFICATE OF ADVERTISING MERIT

Canadian Industries Limited, Explosives Division, two page, two colour, advertisement has been selected as "the best" from the viewpoints of ACCURACY—INFORMATION—ATTRACTION, by a jury of fifty readers of *The Engineering Journal*.

The advertisement, which occupies pages 148 & 149 of the issue, is an announcement regarding "Hydromex", the Company's newest blasting agent. The copy outlines uses, qualities and conveniences of the product. This useful information is emphasized by a most dynamic presentation.

The names of the readers of *The Engineering Journal* who are asked to serve on the selection juries are taken from the general mailing list in such a manner that each Province is represented. A new jury serves each month. It is believed that by this means of selection it will be possible for the Institute to assist advertisers in preparing advertisements which give engineers the information they want in the way they want it.

The advertising supervisor for C.I.L., Explosives Division, is Mr. W. L. Hill. The advertising agency is Cockfield, Brown of Montreal, and Mr. B. Fuller is the account executive.



C-I-L'S CERTIFICATE WINNING ADVERTISEMENT

The Canadian Industries Limited, Explosives Division, two page, two colour, advertisement on pages 148 & 149, was judged "the best" in the July issue. The illustration on the left is a dynamic shot of a blast. It provides an excellent background for the word "Hydromex" which is printed in red. On the right hand page, the copy covers uses, properties, strength, density, velocity of detonation, sensitivity and conveniences of the product.

"COLD SURFACE" CRITERION WASTES MONEY!

How J-M engineers determine economic insulation thickness

to give you more for your insulation dollar

OVER-ALL cost of the operation should always be the determining factor in selecting insulation thickness. Yet, millions of dollars have been wasted because of rigid adherence to the cold surface temperature method. When Johns-Manville insulation is applied, J-M engineers carefully determine which thickness will provide the greatest operational savings. And this "economic thickness" is usually more (or less) than the cold surface method indicates.

Here's how it works. The annual cost of the heat loss through the insulation is plotted for various thicknesses. Also plotted is the annual cost of insulation. A third curve is then drawn as the sum of heat loss and insulation cost. The economical thickness is found where this third curve reaches its lowest point.

To arrive at the above figures in a given instance requires the following: 1. Cost of heat production per million Btu; 2. Rate of heat loss through insulation in Btu per unit area per hr; 3. Annual hours of operation; 4. Applied cost of insulation per unit area; 5. Rate of amortization and required return on the insulation investment cost. Items 2 and 4 are available from the insulation manufacturer; others are normally supplied by the plant engineer.

For more complete information, call or write Dept. IA, Canadian Johns-Manville Co. Ltd., Port Credit, Ontario. Ask for reprint of technical article "Select Economic Insulation Thickness."

JOHNS-MANVILLE

JOHNS-MANVILLE JM PRODUCTS

MEET THE AUTHORS

A. R. Morse, JR.E.I.C., assistant research officer, National Research Council of Canada (*Shock Hazards of Electric Currents*).

Mr. Morse served in Royal Canadian Signals 1940-1946. He is a graduate of University of Manitoba, electrical engineering, 1949. A large measure of his work at N.R.C. has been in investigating the cause of explosions of anaesthetic gases and of grain dust clouds in order to devise safety measures to prevent these explosions.

Gaynor P. Williams, research officer, Snow and Ice Section, Division of Building Research, National Research Council (*Frazil Ice—A Review of its Properties with Selected Bibliography*).

Mr. Williams graduated in 1949 with B.A.Sc. from the University of British Columbia and obtained an M.Sc. degree from Utah State Agricultural College in 1951. He worked with PFRA, Department of Agriculture as field engineer on irrigation and drainage problems in British Columbia until February 1952 when he joined the Aluminum Company of Canada as hydrology engineer at Arvida, Quebec. He joined the NRC in February 1955.

C. R. Crocker, M.E.I.C., Senior Research Officer, National Research Council, Ottawa (co-author of *Precast Concrete for Winter Building*).

Mr. Crocker graduated from the University of New Brunswick with degrees in electrical and civil engineering; worked with the New Brunswick Department of Highways and the Federal Department of Mines and Resources. In 1946 he joined the National Research Council and in 1950 went to Division of Building Research. He now heads the building practice, construction section.

A. W. Smith, Junior Research Officer, National Research Council, Ottawa (co-author of *Precast Concrete for Winter Building*).

Mr. Smith graduated from the University of New Zealand (B.E. Hons., 1955) and worked until 1957 as civil engineer for the Housing Division of the Ministry of Works, Wellington, New Zealand. He joined the National Research Council of Canada in 1957 and is working in the construction section of the Division of Building Research.

J. J. Traill, M.E.I.C., consulting hydraulic engineer (*Tests of Hydraulic Turbines—An Appraisal*).

Mr. Traill graduated in civil engineering from the University of Toronto in 1906 with a B.A.Sc. and C.E. Until 1920 he was on the staff of the University of Toronto as professor of mechanical engineering. From 1920 to 1954 he worked with the Hydraulic Department of The Hydro-Electric Power Commission of Ontario. Mr. Traill was special lecturer in fluid mechanics at the University of Toronto from 1954 to 1957.

R. J. Bedard, former editor of Genie Construction (*Business Training for Professional Engineers*).

Mr. Bedard graduated from the University of Montreal and is at present attending the University of Geneva, Switzerland, working on research towards a Ph.D. He is the author of numerous contributions in Canadian and foreign technical journals.

P. R. Stratton, P.ENG., A.M.I.C.E., project superintendent, The Hydro Electric Power Commission of Ontario (co-author of *Silver Falls Generating Station* with C. T. Bath, B.E., P.ENG., A.M.I.E.(Aust.)). (Paper appeared in the October *Engineering Journal.*)

Mr. Stratton received his engineering education at London (England) Polytechnic and worked as articled engineer with the Essex Rivers Board. He later was employed as field engineer for Richard Costain Ltd. and as ganging engineer for the Great Ouse River Board. Since 1952 he has been with Ontario Hydro, serving as design, planning and construction engineer and as general superintendent.

Mr. Stratton is now construction engineer on Atomic Energy of Canada's CANDU project.

We are indebted to the Engineers at Canadair, Montreal, for their co-operation in the preparation of the paper on Materials Handling, appearing in this issue.

THE CHALLENGE OF ENGINEERING

From the Address of Dr. K. F. Tupper, Retiring President, at the Annual General Meeting, Toronto, June 8, 1959.

THE INTEGRITY OF AN ENGINEER is reflected in the soundness of his work, and there is a particular quality or attribute of engineering work about which I hold some views. This is the property of permanence, longevity, durability.

We engineers may—perhaps without knowing it—be responsible to a very large degree for how rich a world we live in and for how long hours most people have to work. That may seem a rather astonishing statement, so please hear more.

The rate at which we accumulate wealth depends on two simple factors—rate of production and life of article or work produced. I use the word wealth in its economic sense to denote the things which man has by his own efforts produced by working on materials which nature provides. Wealth includes buildings, bridges, roads, coal piles above ground, oil paintings, anything which man has devised.

I want to make now a simple analogy to get a point across. At one time I was concerned with the production of radio-isotopes. These are radioactive atoms, most commonly produced by bombarding an element with neutrons in a nuclear reactor. By putting a certain amount of target material in the reactor and operating the reactor steadily at full power, one can create a constant quantity of the desired radio-isotope each unit of time, say each hour. Unfortunately, however, if you want to produce 1,000 times as much as can be produced in an hour, it is not necessarily a good idea simply to let things run 1,000 hours.

The radio-active atoms are themselves disintegrating and this may take place at a fast rate or a slow rate. The usual way of referring to the rate is to speak of the "half life"—a time in which half of any large number of atoms of a given kind will have disintegrated. Suppose we were making an isotope with a half life of 24 hours. At the end of one hour we have a certain amount, and at the end of two hours nearly twice as much. But at the end of 24 hours we have a good deal less than 24 times the first hour's production. In fact, at the end of 24 hours we have lost nearly half of the radioactive atoms we produced in the first hour.

If we want exactly twice as much as exists at the end of the first day, we are really in a fix. In the second day we can produce as much as we did the first day but our first day's production has shrunk to exactly half its size, leaving us with ¾ of what we want. At the end of successive days we have, in fact, the following amounts:—

1/2: 3/4: 7/8: 15/16 —

and if we went on forever we would not quite reach our objective.

In case you want to know how one does get larger amounts, the answer is: use more target atoms, bombard with more neutrons.

Now in the world around us lots of things behave like radio-isotopes—they disappear for one reason or another. I often wonder what actually became of all the pocket knives I had as a boy. Some of them lasted a year, some lasted only a few weeks—even today I think the life expectation of my pocket knife (I still carry one) is only about five years.

I can think of certain roads which I will swear have been torn up and re-built every two or three years —or so it seems.

The house in which I live is about 30 years old. I am glad to say I think that as a whole it will last as long as I need it. As a whole, I said. The roof had to be re-shingled a few years ago. The garage behind the house has not done as well—it is scheduled for a complete re-build this year.

Now the number of pocket knives, garages, miles of road, etc., that we as human beings have at our disposal is determined by just these two factors—rate of production and length of life.

Engineers are today most intimately concerned with both factors. In their role as designers they determine to a very large extent how long many things are likely to last. In their role as producers, they help to determine how many units are produced each unit of time. I say help. Production requires the services of many people, the promoter who conceives the enterprise in the first instance, the financier who brings it into being, and so on to a whole host of people—with particular emphasis on the production workers themselves. In the matter of production the engineer is most certainly a member of a large team. The efforts of all are required in achieving increases in production.

I said earlier the engineer is probably very directly responsible for the amount of wealth we possess and the number of hours we work. These two are about linearly proportional—If we want to produce twice as much we have to work twice as many hours per week. Sometimes I am astonished that this fact is lost sight of. The dynamic prosperity of certain countries today—West Germany for example—is probably due more than anything to the willingness of the people to work long and to work hard.

There is today in North America a philosophy of expendability with which I do not agree—the idea of creating things which are intended not to last very long.

I submit that engineers can make a very real contribution—can easily do so—by seeking to make their work as durable, as long lasting, as circumstances warrant and will permit. They can leave behind them a world containing more wealth for their children and grandchildren to enjoy.

It is perhaps a matter of personal opinion, but I think an engineer lacks integrity if the quality of durability is deliberately skimped in his work.

The second quality is loyalty. Loyalty is a quality highly to be desired in an engineer—and here I have special reference to the employee engineer.

Loyalty between employer and employee is a two-way street. To begin with, loyalty must be deserved, it must be merited. The employer must treat his employees fairly—he must earn their loyalty. The employer must provide some things to be loyal to: standards of quality of product—of service—of honesty in business dealings. I can think of certain organizations—often dominated by one outstanding man—that earn tremendous loyalty in all their employees.

I submit that the engineer must be completely loyal to his employer. This may mean on occasions the implementation of policies with which he does not agree. The procedure to be followed in such cases is quite straightforward. When a course of action is charted with which the engineer is in serious disagreement he is ethically obliged to state his objections to his superiors. In many cases with a further exchange of ideas the engineer may alter his opinion, or, alternatively, the employer may modify the proposed course of action. If this agreement does not result then the engineer, having quite properly registered his objection, should adopt his employer's policy and administer it as though it were his own. It is indeed a form of disloyalty to implement a policy half heartedly or perhaps to give an order and then say "Of course this isn't my idea. I'm against it."

In the rare case where the divergence of viewpoint is diametric and where the matter is one of great importance, an engineer may find himself unable to carry out a course of action about which he has unsuccessfully protested. In this rare case I think he should quietly resign—without flame, smoke, or noise. He and his employer are apparently not compatible and it is better that the engineer should take the initiative in making the inevitable separation. Both self respect and the respect of all around him—including his employer—can thus be retained.

The third quality is what for want of a better term I shall call social usefulness. This means that the socially useful person performs a function of service to the society in which he lives. If our work each day leaves the world a better place in which to live we are performing socially useful work. Much engineering work falls very definitely into this category. The engineer who designs a bridge, manufactures a telephone or builds a municipal water treatment plant performs a pretty obviously socially useful task. Some of our engineering work gets over into areas not nearly so clearly defined as useful. I do not wish to try to identify any of these, partly for fear of giving offense and partly because some element of social usefulness can be discerned in almost any of them (I might think that a certain device—say a juke box—makes the world a less desirable, a less pleasant place in which to live. This, however, is a matter of personal taste and I feel sure my teenage daughter would sharply take issue with me).

I am sure we generally agree that the older professions—in particular Medicine, the Ministry and Teaching—have a social usefulness of a high order. Engineers are also the servants of their fellow men, and the engineers work can make the world a better place to live in. Let us strive to choose our work with this objective.

Finally, I come to a quality called humility—the act of feeling humble. If engineering is to be a profession, the individual engineer must be respected. I do not agree with the idea of trying to gain the respect of our fellow men through the efforts of a paid public relations expert. Respect must be earned and not bought. Consequently I do not subscribe to the doctrine that "Silent Service is Not Enough." I have yet to hear of an engineering job which was done better or quicker or more economically because the engineer tooted a horn to call attention to his work. This is not humility.

Would it not be better for us to concentrate our efforts on the kind and quality of our engineering, praying that we shall be sufficiently successful that our finished job will speak for us; that our own accomplishments will be our advertisements; that our own good engineering work will earn respect for our profession?

I find it a trifle incongruous that some of my engineering friends can find it possible to subscribe simultaneously to the Kipling Ritual and to the slogan "Silent Service is Not Enough." To me these are incompatible one with the other. To the humble engineer I think that "Silent Service" is quite enough.

This is the end of my homily. You may agree with some of my views, you may not agree with all of them. I will consider my message successfully communicated if it makes you think, if it starts some discussions.

MATERIALS HANDLING AT CANADAIR

Prepared in collaboration with Canadair Engineers.

THIS IS necessarily a limited treatment of the subject of materials handling at the manufacturing plants of Canadair Limited, in Montreal. The intention is to present a general outline of the main problems involved in the manufacture of aircraft, with particular reference to materials handling during the planning and assembly stages, and the way these problems are solved.

There is a wide field of operations, classifiable as materials handling, that are not covered here; among them the considerable activity in construction and maintenance involved in the daily work within a plant that has a covered floor area of some 2,600,000 square feet plus a very extensive outside area. Many trucks and other mobile equipment are involved in these operations.

Similarly, the economics of materials handling under the particular conditions of the aircraft manufacturing industry are more suitably dealt with as a separate subject.

What Are the Problems?

Materials handling in a plant that makes domestic appliances or automobiles, for example, is usually a complex, carefully-planned system involving various types of conveyors laid out for rapid and co-ordinated movement of many relatively small components through several stages to the final assembly line. Though periodic model changes affect the system to some extent, the general materials handling layout can often be maintained in its same basic form for considerable periods.

On the other hand, even a fairly small aircraft consists of many thousands of parts ranging from very small (screws, nuts, bolts) to very large (fuselage, wing sections), but the rate of final assembly may be only a few units a month. With many quite lengthy intermediate subassembly operations, great care must be taken in avoiding damage to large or easily-marred components, and the 'conventional' concept of an integrated conveyor system has virtually

Fig. 1 Model table showing layout for CL-44 fuselage assembly shop (upper right), final line (upper left), and preflight area (foreground). The floor is marked in the equivalent of two-foot squares. Note the relative sizes of the CL-44 and the small Sabre (at left).

Fig. 2 Mobile skin handling dolly. Note holes in wooden base for locating wooden positioning rods.

no place in the assembly procedure.

The main factor that precludes any more or less permanent materials handling layout is the vast difference in size of the aircraft that occurs from one contract to the next. For example, Canadair has produced T-33 jet trainers, F-86 Sabres, the CL-28, and the CL-44, the largest aircraft made in Canada. Some idea of the relative size of a Sabre and a CL-44 may be obtained from the illustration of part of an assembly area layout. The CL-28 will be used as an example of some of the procedures adopted.

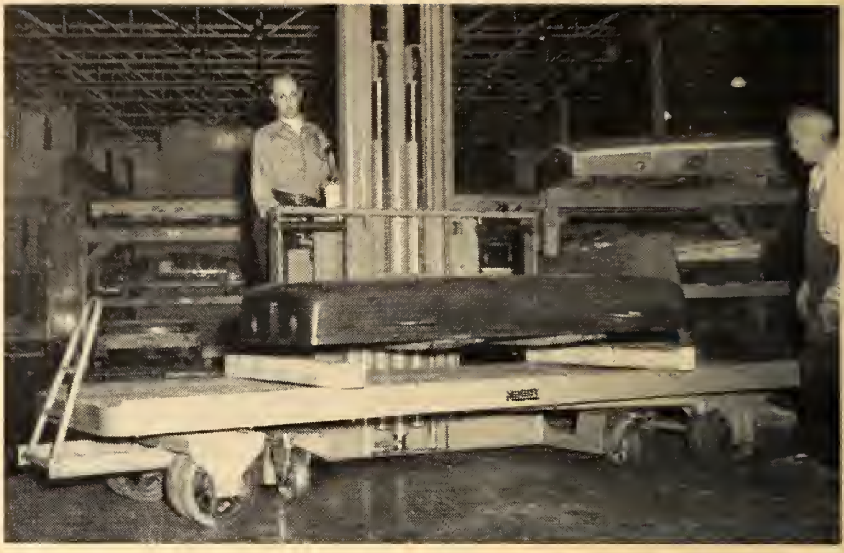

Fig. 3 Four-directional stacker placing a long fabricating tool on a trailer. The trailer has four-wheel steering for manoeuvrability around tight corners.

Planning for a Contract

When a new contract for a particular aircraft is to be undertaken at Canadair, the entire project is planned for the required production rate of that aircraft. Apart from necessary cost estimates, overall planning considers all pertinent factors of space, equipment and materials handling requirements.

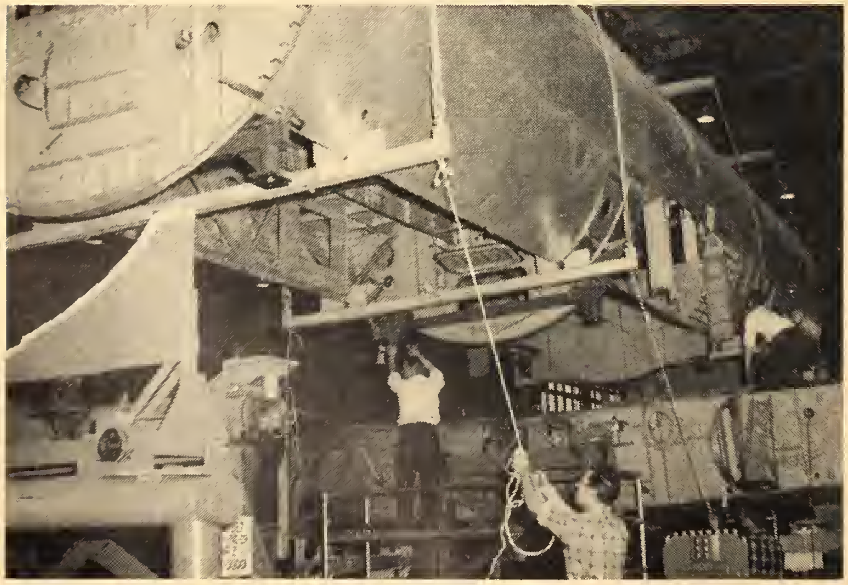
Plant Engineering, in co-operation with Industrial Engineering and Manufacturing Engineering, prepares a block plan of the manufacturing space to make best use of available facilities. At the same time, the flow of materials throughout the plant is planned to reduce backtracking and materials handling to a minimum. This is very important, since handling accounts for a major part of the time taken in aircraft assembly.

Plant Engineering keeps an up-to-date and very accurate record of floor space, known as the Plant Area Manual, which shows areas available or in productive use.

Each assembly department is laid out, in close co-operation with the Material Handling Group, on a three-dimensional master layout table. Using the international scale of ¼-inch to one foot, scale models of benches, equipment, etc. are positioned on the table, which is accurately marked with half-inch squares. A colour code is used for the models; for example, red denotes a component assembly jig, green indicates a machine tool, yellow is for furniture, and white shows racks and benches.

Most of the models are made from coloured plastic by a full-time model maker, with part-time assistance, in a fully-equipped model shop. Actual aircraft models are made from wood in the pattern shop. The models of jigs and fixtures are made with the help of tool drawings from the Manufacturing Engineering Department, and are complete in all essential details. The accuracy of dimensions is important because they are used to determine clearances in width, length, and height; details which are of concern to the materials handling group, as well as the production department.

Fig. 4 CL-28 centre fuselage being lowered into mating position.



General Flow of Materials

As already stated, the general flow of materials from raw stock to final assembly is planned to reduce handling. Raw stock is co-ordinated with the required tooling, and both are shipped from the warehouse to the detail fabrication shops. The existing warehouse buildings are as close as possible to the shops, but are actually separated from them by a main highway. Access between the two areas is by a connecting tunnel.

Detail parts are made in the shops from a variety of metals and plastics. Sheet materials are cut, formed, and drilled and many machined parts are produced. The detail parts are then joined together to make larger subassemblies, after going through various necessary intermediate operations, such as painting, plating, inspection and so on.

Handling of Detail Parts

Movement of raw stock from warehouse to fabricating shops and of detail parts from shop to finishing departments is largely made by means of wheeled dollies, hauled by *mule.*

Closely-finished machined parts are placed directly in special felt-lined compartmented boxes for handling between operations until plating, anodizing, and so on are completed, after which the parts are dipped in a rapid-hardening plastic material which forms a protective coating. The coated parts are then placed in boxes for hauling to the appropriate storage area in the assembly shops.

One of the few automatic conveying operations is found in the anti-oxidation treatment of certain alloy structural parts. The treatment consists of a sequence of dips and washes in a series of concrete tanks which are sunk in the floor. They are forty feet long, four feet wide, and eight feet deep, spaced two feet apart. The area is covered by a stabilized crane of two-ton capacity. When the racks have been loaded, the operator uses a push-button control to raise, traverse and lower the rack into the first tank, and thence in and out of the subsequent baths according to the predetermined time cycle. The paint shop has a standard plot bed and spray booths equipped with conveyors.

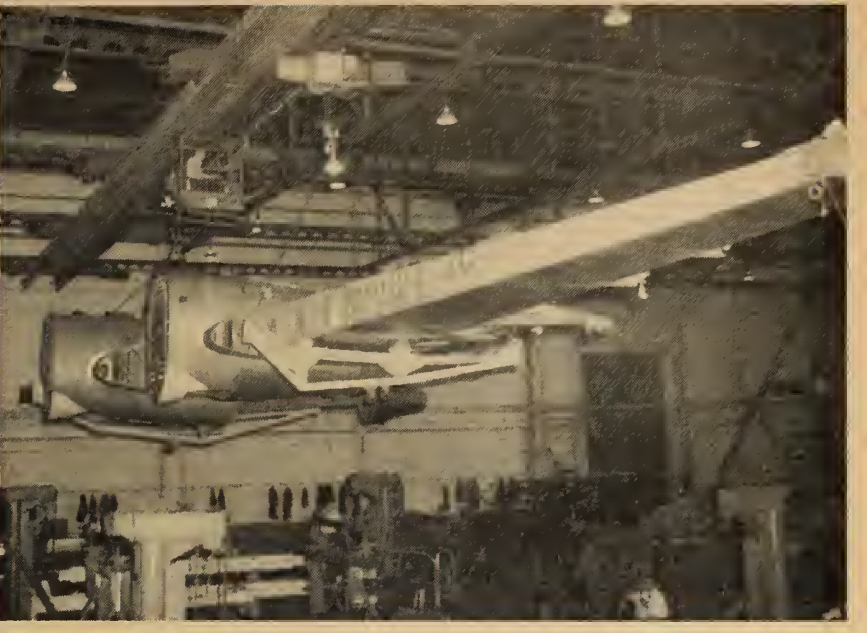


Fig. 5 CL-28 half-wing section being lowered by two-hook 6-ton crane into mating jig.

Handling of 'Problem' Parts

Some of the intermediate parts present particular problems in their handling, especially in the avoidance of damage to highly-finished surfaces or because of the size of the piece.

The skins, or formed metal sheets that make up the outer surfaces of fuselage and wings, may have a very fine (mirror) finish which has to be

Fig. 6 Vertical stabilizer mounted on its special handling fixture.

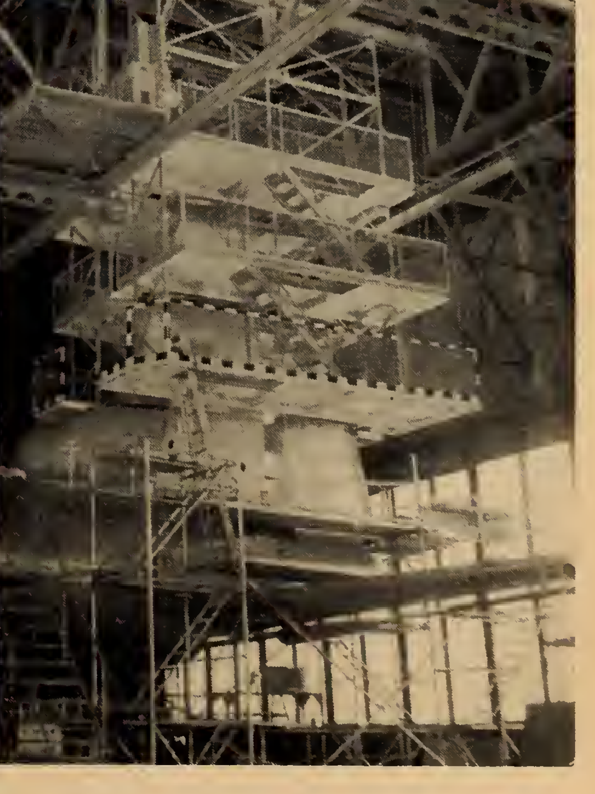

Fig. 7 Elaborate scaffolding used for access by men working on upper surfaces of tail unit.

unblemished when finally assembled into the aircraft. The handling problem is further complicated in cases of very large skins, which may run to some thirty feet long. For many operations the medium-size skins (say, up to 12 ft. long), especially those with a mirror finish, are moved manually and may be laid on a simple rack directly on the floor. (The expense of building special storage tables for these skins is not usually justified.)

Considerable work has been done on the handling of the large wing skins. One method used overhead grabs suspended from a tubular framework. The problem was to get sufficient pressure at the grabs to hold the skin securely without damaging the surface. A simpler variant of this idea was to leave an additional strip of metal beyond the final dimensions of the skin on which the grabs could grip. Damage to this part of the skin did not matter, as it was removed just before final assembly. Another method that has been successfully used it to leave small lugs of excess metal at intervals along the upper edge of the skin. These lugs are drilled to take a suspension pin, and are removed from the skin as late in the assembly operations as possible.

For skins of about eight feet and less, a special mobile skin handling dolly has been developed. These dollies, one of which is illustrated, consist of a rectangular steel base frame fitted with four caster wheels. Removable vertical steel posts are located at each of the four corners of the frame, and within these limits, any desired pattern of spacers may be made, using vertical wooden rods located in a series of holes drilled in a wooden base that runs along and across the main frame. The principle is shown in the illustration. For shallow skin sections, more than one layer may be stored by tying horizontal slats across the dolly uprights at the required height above the base.

This type of dolly is invaluable in the handling of the smaller skins, since it is used as a degreasing rack as well as a storage rack between operations and is also used to move the skins from one operation to the next. The flexibility of the design permits the ready handling of a wide range of skin sizes and shapes.

Another problem part is the wing spar, some 50 feet long in the case of the CL-28 main spar. Because of its length the spar is very flexible and has to be well supported during handling, which is largely done manually.

For moving long parts or tools, another specially-designed dolly is quite extensively used. This dolly has four-wheel steering actuated by the towbar so that it can turn readily around tight corners and in a restricted space.

Handling of Major Assemblies

The handling involved during final assembly obviously varies with the size of the aircraft. As a specific example of the methods used in assembly of a large aircraft, a brief description of the procedure for the CL-28 follows.

The major assemblies which go to make a large aircraft of this type are: (1) Forward fuselage. (2) Centre fuselage. (3) Rear fuselage. (4) Left hand wing. (5) Right hand wing. (6) Horizontal stabilizer. (7) Vertical stabilizer. (8) Rudder, control surfaces. (9) Engines and landing gear.

With the exception of the engines and landing gear, which will not be considered here, the eight main structural assemblies are constructed in special assembly jigs.

When completed structurally, the assemblies are removed from the jig to an installation dolly which secures the units without limiting accessibility, as would the assembly jig. At this stage the various internal fittings are added. After this installation procedure, the assemblies are transferred to the final mating jig, where, as the name implies, they are joined together to make the complete aircraft.

The main items are handled as follows, the dimensions being those for the CL-28.

Forward Fuselage — This unit weighs approximately 3,000 pounds, is 12 ft. in diameter and 20 ft. 2 in. long. After construction in the assembly jig, the unit is moved to its installation dolly by means of a 5-ton overhead crane. From installation dolly to the mating jig, the unit is again moved by the 5-ton crane.

Centre Fuselage — Unit weighs 10,200 pounds, is 12 ft. in diameter and 48 ft. 3 in. long. A specially-designed handling fixture is used to move the fuselage unit from the jig to subsequent operations. Part of the jig is used as a handling fixture, which runs on rails laid on the floor of the shop. The centre fuselage is held in its fixture until it is time for the installation procedure. The handling fixture is then moved out on an extension of the rail lines to a position that can be reached by a twin-hook 6-ton overhead crane, which runs over most of the length of the main shop, where the final assembly areas are located. The 6-ton crane transfers the fuselage unit from its holding fixture to an installation dolly. After installation work is completed, the fuselage unit is removed from the dolly and transferred to the mating jig by means of the twin-hook 6-ton crane with the assistance of the 5-ton overhead crane.

Fig. 8 Four-directional stacker with load preparing to move sideways down aisle. Note position of rotatable front wheel. Stacker can raise loads to a height of 15 feet.

Fig. 9 Hydraulically-operated 'giraffe' hoist is now used to move men working on upper surfaces of aircraft. Two of these units are in use at Canadair plant.

Fig. 10 Fork lift truck with swivelling head attachment about to dump contents of special waste-bin into garbage truck.

Rear Fuselage — Unit weighs over 3-tons, is 12 ft. in diameter and 41 ft. 10 in. long. The handling procedure is similar to that of the centre fuselage. However, the 5-ton overhead crane is used for the transfers from handling fixture to installation dolly and thence to the mating jig.

Half-Section Wing — Each half-section wing (left and right) weighs over 5-tons, is 71 ft. 2 in. long, and has a maximum width of 21 ft. 6 in. The wing sections are assembled in a box structure jig, and all handling from this point through normal operations to the mating jig is done by the twin-hook 6-ton crane.

The jigs, handling fixtures, and installation dollies mentioned above are designed and built to accommodate one specific unit. Though essential to the handling of that unit, the rate of actual handling may be very low. For example, in the case of a contract calling only for two aircraft a month, the handling fixture for centre or rear fuselage need only be moved from its holding position into the main shop twice a month. Certainly a far cry from the automobile assembly line.

The fuselage installation dollies are fitted with wheels, but are not used for actual movement of the unit from one location to another. However, the wheels allow flexibility in positioning the dolly during transfer of the assembly.

The handling fixture for the vertical stabilizer (see illustration) is of relatively simple welded steel frame construction and is mounted on caster wheels. In designing such a fixture, consideration must be given to the protection afforded the very costly assembly while keeping the overall dimensions within limits dictated by convenience of handling, clearances, and so on.

Other Aspects of Materials Handling

There are many examples of savings in time, labour, and cost that have been achieved at Canadair through improved methods of materials handling. Only a few such examples are mentioned below.

The 'Giraffe' — One type of materials handling equipment has been very usefully applied, not to the handling of materials, but to the handling of operating personnel. Two hydraulic '*giraffe*' lifts, of the type shown in an accompanying illustration, are used to move men rapidly and easily from one working area to another on these high surfaces.

Material Storage — Efficient use has been made of storage space with the aid of various types of materials handling vehicles. One particularly useful development is a four-directional stacker which can stack and remove palleted items to a height of 15 feet. The particular advantage of this stacker in handling items for storage is its mobility forward, backward and sideways. As may be seen by the accompanying illustration, the front wheels of the stacker can be swivelled 90 degrees from the forward or reverse travel position, so that the vehicle can be made to travel sideways from a standing start. This enables the stacker to move loads that are longer than the width of the access aisle between storage racks.

The stacker can pick up a load that is, say nine feet long; carry it in the usual forward direction where space permits; turn at the entrance to, say, a seven-foot aisle, and travel sideways up the aisle to the storage point, where the stacker raises the load and advances forward in the usual way to drop the load on to the storage rack. The procedure is reversed for removing long loads from storage.

This ability to increase cubic stor-

SHOCK HAZARDS OF ELECTRIC CURRENTS

A. R. Morse, Jr.E.I.C., *Assistant Research Officer*
Electrical Engineering Section
National Research Council, Ottawa 2, Ont.

Presented at the 73rd Annual General and Professional Meeting of the Engineering Institute of Canada, Toronto, Ont., June, 1959

SOME TIME AGO a query came to NRC regarding the possible change in Canadian death statistics if household circuits were increased to 240 volts to ground instead of the 120 volts to ground now commonly used. The question sufficiently fascinated me that not only did I read many papers on the subject of electric shock, but also I did a little experimenting. From that point, it was a simple step to consider that this subject would be at least of *some* interest to others as well as myself, and that I could save these others the necessity of reading, interpreting and experimenting.

One thing I would like to emphasize, is that I do not intend to discuss the changeover from two prong plugs to three-prong plugs as now being adopted in many parts of Canada. I can only say that having on one occasion fallen victim to the situation of someone "adapting" a three-prong plug to the old two hole outlet, I earnestly endorse a rapid and complete changeover to the three-prong, grounded-chassis 120-volt system.

We are concerning ourselves here primarily with the inter-related factors of the physiological and the electrical. By way of a little background, the many scientific workers investigating electric shock have found that the main factors affecting electric shock are:

A. **Electrical**
Duration of Current
Frequency of Current
Waveshape of Current
Magnitude of Current
Voltage Applied Initially

B. **Physiological**
General Physical Condition of Victim e.g. "Weak Heart"
Body Resistance
Skin Resistance
Contact Resistance
Path of Current-Effect
Phase of Heart Cycle Subject to Shock

Naturally with some factors there is no sharp dividing line between electrical and physiological.

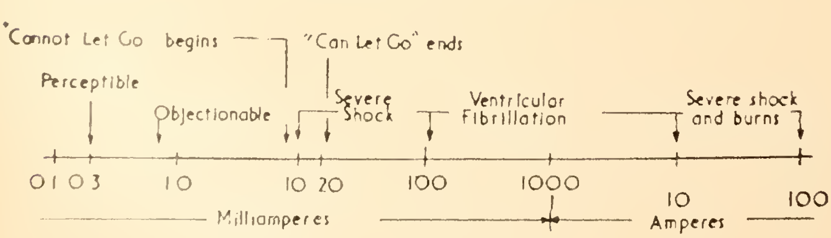
Early investigators were quick to recognize that there were roughly five main effects on the body:

1. Paralytic Injury to the Brain.
2. Injury to the heart as shown by loss of rhythmic heart beat—and hence circulatory failure.
3. Damage to tissue and organs by severe burns.
4. Respiratory failure.
5. Muscular convulsions.

Again there is no complete independence. For example, it was work by Urquhart in 1927 that showed that passage of current through the brain could cause respiratory paralysis and failure of the heart and blood vessels. He demonstrated also—and this is of great importance today—that the usual tests for death were not reliable when a victim has suffered an electric shock of this nature. Hence it is the firmly recommended practice to persist in artificial respiration until success is achieved and the victim revives, or until rigor mortis sets in. Not only is it necessary to be persistent in attempting artificial respiration but also it is important to begin it as soon as possible. This greatly increases the chance of the victim's survival for, owing to the interdependence of the body organs on one another it has been found that the combination of respiratory and circulatory failure rapidly causes brain failure from lack of oxygen, which is of course brought to the brain by the blood after being absorbed in the lungs. Hence one should not lose time or wait for pulmotors. This is the reason for the development of pole-top methods of resuscitation. Naturally, the first duty is to remove, in a safe manner, the victim from the electrical contacts, or to kill the circuit.

Another example of the mutual reactions occurring during electric shock is the case of electric shock

Fig. 1 Effect of 60 cycle current on men.



therapy. Here again the passage of current is through the brain. Side reactions may involve violent muscular convulsions. As a final example, it is obvious that both respiratory and heart failures involve the related muscles.

It was Ferris, King, Spence and Williams who in 1936 concluded from tests on animals with 60 cycle current that the effect of electric shock is related to the magnitude of the current, rather than the voltage, and also is related to the weight of the animal and of the animal's heart. They also discovered that fibrillation of the heart is most likely to occur at one particular point in the heart cycle. In 1939 Wiggers and Wegria also investigated the "vulnerable point" in the heart cycle, and concluded that a shock of duration less than 1/10 second could be fatal. Since 1900 there has been serious work on the reaction of the heart to electric shock. This work today includes the building of practical machines to stop heart fibrillation.

What are the values of 60-cycle currents through the body that give the normally recognized reactions? If we draw a logarithmic scale of current (Fig. 1) from 1/10 milliampere to 100 amperes, we can indicate the various ranges that will be under discussion:

"Perceptibility" depends on the location and size of contact and on the type of current. The value given is for finger contact; tongue contact is probably something less again, and a large area contact is almost an order of magnitude larger.

At the "Objectionable" level, some people find it hard to accept that 1 ma is objectionable, until they have tried it. Beginning with the next level of currents we once again tell the tale as determined by past investigators. This level is commonly known as the "Let-Go" Level. Above about 9 ma, we begin to find victims who cannot let go. And here we call on the work of Charles F. Dalziel and co-workers at the University of California. These workers, after investigating the nature of reported electrical accidents, felt that it was important to have data on the physiological effects of electric currents on humans where the humans grasped a copper wire or pair of pliers in one hand, while making the other contact elsewhere e.g. to the same arm, to the other hand or to the feet. Using the results of tests on over 100 men as a basis, they presented to the electrical profession the following definition of a "Let-Go" Current: —a let-go current is that which 99½% of the healthy adult male population can safely tolerate without loss of ability to voluntarily let go of the conductor which is held in the hand. Naturally any current less than the "Let-Go" Current also can be let go, and also, by definition, almost all adult males can release even more current than the Let-Go Current as defined. Hence there is a good "Margin of Safety." There have been no adverse remarks over the years on the Dalziel choice of what to consider a Let-Go value, and so we assume that this is the established criterion.

To make the definition more rigorous, one should describe in greater detail the electric circuit. A No. 6 copper wire was used as the active electrode. It was grasped by the hand. The other indifferent electrode was a large-area wet contact, usually on the upper part of the same arm, but in some cases on the opposite hand or a foot. These inactive electrode locations had little effect on the let go current. In the course of his experiments, Dalziel tested men who were able to let go currents of as high as 22 milliamperes. The average was about 16 milliamperes while the low was about 9 ma. When plotted on probability paper — percentage who can let go of total persons tested vs current in milliamperes— the experimental points fell quite well along a straight line, thus showing the Distribution to be Normal (Gaussion) See Fig. 2.

Tests with women gave similar results, although women can stand only about 2/3 the current that men can stand. Hence 7 ma forms the "Let-Go" value for women as compared to 9 ma for men.

The test results were also plotted as percent deviation from the mean. (Fig. 3)

Naturally the plot looks very similar to the Distribution plot, but by using percent deviation Dalziel's group discovered they could spare some of their reluctant 134 men from the time-consuming and nerve-racking tests. For now they found that 60-cycle tests on smaller groups of men all yielded deviation curves of the same slope. Therefore, for further different tests, in order to adjust results on small groups to agree with the large group they would run a 60-cycle test first. If the deviation curve agreed with their standard deviation curve, then even though the distribution curve might be different—for example have a different mean value—the new test would be accepted as valid for a large number. It was however subject to adjustment in proportion as the large-number standard 60-cycle test mean differed from the test standard. That is, for example: corrected mean of new test =

$$\frac{\text{mean of Large Standard (15.87 ma)}}{\text{mean of Small Standard}} \times \text{experimental mean of new test.}$$

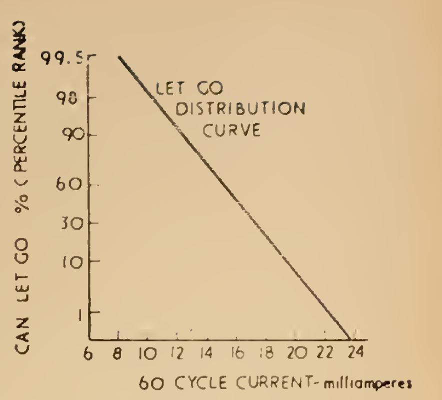


Fig. 2 Percentage of total persons tested who can "let go" vs current in milliamperes.

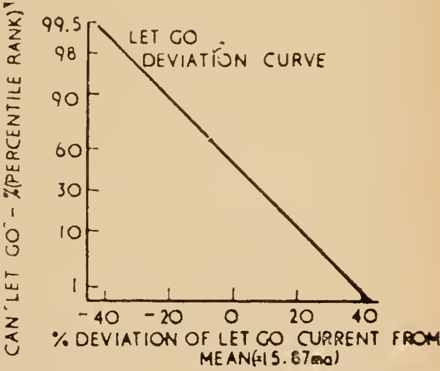

Fig. 3 Test results plotted as percent deviation from the mean.

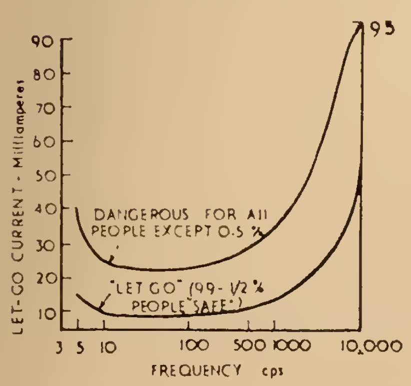
Fig. 4



Work then progressed more rapidly for Dalziel and his confreres. The University of California group have to date published many papers on Let-Go currents, and even Let-Go voltage, under various circumstances. They have confirmed the results of earlier workers that the 60-cycle wave is just about as obnoxious a wave as you can get. See Fig. 4.

Response is rather flat from 10 cps to 1000 cps, increasing about fivefold for dc and for 10,000 cps. The explanation for this evidently lies in the realm of medical physics—in the study of the response of muscle and nerve cells to electric impulse and current. We have a somewhat similar phenomenon with the heart where fibrillation occurs at one particular point of the heart-beat, and is particularly dependent not only on the magnitude of the current but also on the frequency. Incidentally, Dalziel reported that his deviation curves for 10,000 cps tests were appreciably different from his Standard. Physiologically, things didn't feel so bad—you felt that you were being pleasantly cooked to death rather than violently shaken to death, and your ability to let go was slowed down.

With direct current the "Let-Go" is actually based on fear rather than inability to operate one's muscles. For the interruption of direct current produces a violent shock, and sooner or later one feels that one would rather cook than stand that.

This violent shock on interruption of d-c is actually a forerunner to the results obtained when using waveforms of various shapes, for it is found that the peak of the current wave actually governs the physiological effects. When there is a mixture of d-c to a-c, such as occurs with some welding machines (e.g. 6% a-c), a composite Let-Go Curve can be obtained. (Fig.5) We see that a small a-c component reduces the average Let-Go Current appreciably. For example a 6% a-c component allows only 28 ma d-c as compared with 65 ma for pure d-c.

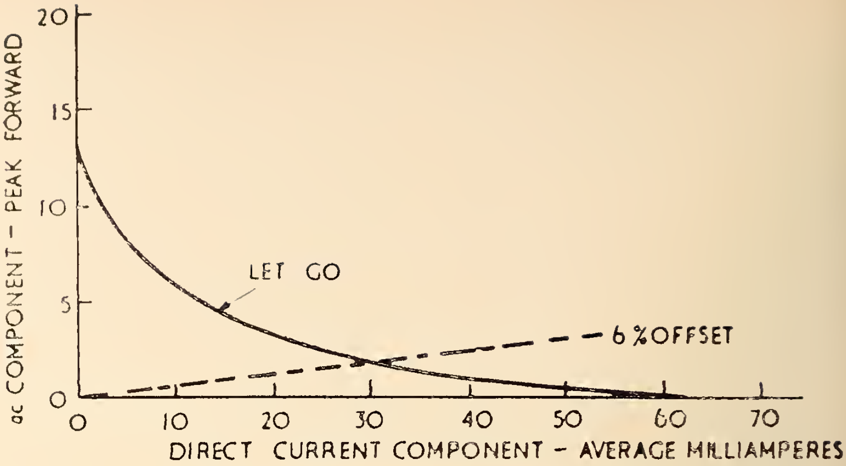


Fig. 5 Composite let-go curve.

The ac crest component shown is that peak of a-c greater than the d-c in the forward direction. See Fig. 6.

We should now correct any lingering impression that the Let-Go value of 9 ma applies to *all* 60 cycle waves. The best way, perhaps, is to state that for a 60 cycle wave, the *crest* value of current tolerable is 13 milliamperes. For waves having a dc component the composite curve must be used.

Before leaving a consideration of Let-Go currents, it would be well to recall that it had been found by Ferris et al that effects were more or less in inverse proportion to the weights of the animal and of the heart. Based on this, and also on their own experimental work, Dalziel and co-workers have stated that children can stand about one-half the current that man can stand; women can stand about 2/3 the current.

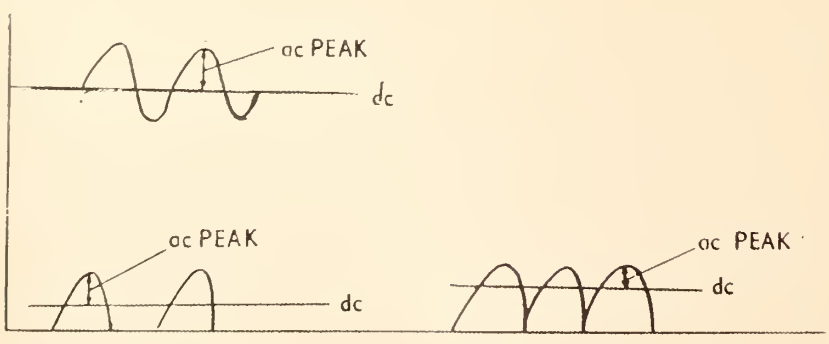
This fact is also useful in determining the *higher* ranges of currents, for tests on animals can be made and the results extended with reasonable accuracy to humans. This has been done, and O. Schneider neatly summarizes the situation. In his preliminary discussion, Schneider distinguishes between (1) the heat effects leading to combustion of tissues and organs and poisoning by combustion products, and (2) the electro-physical effects *proper*, which mainly affect the heart and circulation and presumably the nerves, muscles and brain and hence the respiration.

Now up to 25 ma a-c, the currents cause muscular cramp. It has been stated by several authors that prolonged contact to currents of over 20 ma, and even of over 10 ma where one cannot let go, may lead to a state of exhaustion, loss of consciousness and inability to breathe. The muscular convulsions will cease when the current is removed, but the *inability to breathe may persist*, requiring artificial respiration.

From 25 ma to 80 ma this situation is definitely intensified, and, particularly since it is very doubtful if one can let go, death is very possible.

From 80 ma to 8 amperes, Schneider states that death is instantaneous, due of course to ventricular fibrillation. Naturally, in all the above it is presumed that the current traverses the body, particularly via a hand grasp. While this is not always the case, it is often enough the case to be given major consideration. Also, the heart itself does not require 80 ma to cause fibrillation. Probably less than 1 ma passes through the heart.

Fig. 6 The a-c crest component shown is that peak of a-c greater than the d-c in the forward direction.



Nevertheless, tests on animals have shown that good statistical accuracy is obtained by discussing the total current. Another factor in fibrillation is again duration of contact, but anything over 1/100 second may be fatal. To some extent, the longer the contact the lower the current required for fibrillation. Several authors give from 100 ma to 10 amperes 60 cycle a-c as the fibrillation range.

You probably have noted that I have not tried to define fibrillation of the heart. This might perhaps be more confidently undertaken by someone from the National Research Council Instrument Section, where heart defibrillators have been designed. Suffice to say that the heart loses its rhythm, muscles quiver in an unco-ordinated manner even after the current is stopped, and the heart cannot regain rhythm. Hence the victim is sure to die. Artificial respiration does nothing to restore the heart rhythm.

However, when the current exceeds 10 amperes the heart does not fibrillate but seizes. Cessation of current permits the heart to regain rhythm. This may occur automatically, or of course it can be done by an operation if time permits. No doubt the reader is sufficiently familiar from the newspapers with high voltage accidents of this type. And of course, if a heart is already fibrillating, a large dose of current (of the order of amperes) through the heart for a short time can be used to stop fibrillation.

If the body is subjected to large currents of 10 amperes or more, the fact that fibrillation is not present does not guarantee long survival of the victim. We now enter the range of combustion. The victim is subjected to severe burning of tissues and organs and poisoning by combustion products, plus possible hemorrhage and severe shock. Death is probable, though perhaps not immediate. Resuscitation is often successful, if immediately applied.

The current that the body is subjected to is dependent on the voltage applied and on the total resistance between contact points. An "Ohm's Law" Log-Log "Sensation Chart" (Fig. 7) can be drawn that is very useful for showing the ranges of currents under consideration, and the corresponding voltage and resistance values.

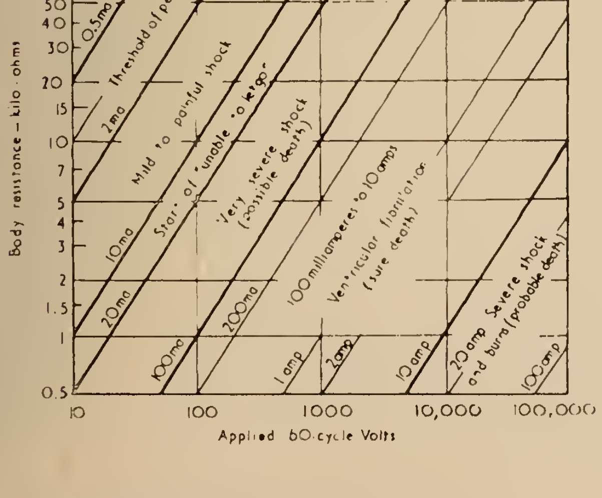
The ranges as they apply to a normal man subjected to 60 cycle sine wave have been shown. At the lower end some overlapping occurs because of the effects of different areas of contact. The smaller the area, the more sensitive the subject is to the currents.

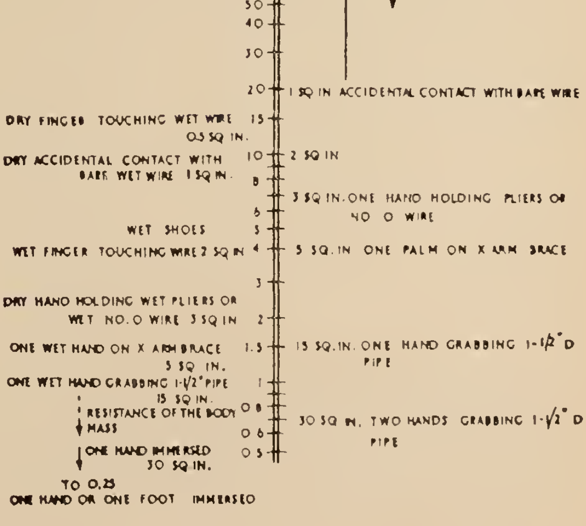
The "total body resistance" between contacts can be divided into three parts. One part is the contact resistance and may be quite low, or it may offer an appreciable impedance. For example, we may consider shoes as an item of contact resistance, as compared to just the interface resistance say between a bare wire and the skin. Another part is the actual resistance of the body itself, discounting the skin. This resistance lies between 500 and 1000 ohms for almost all dangerous body paths, for example from hand to feet. It is very unlikely that it is less than a total of 500 ohms, although from the chest to the back it has been said to be as low as 100 ohms. Also, to some extent it is dependent on the location and area of entry to the current. Kouwenhoven, who has conducted many defibrillating experiments, gives a value of about 100 ohms per cubic centimetre.

The third part of the Total Body Resistance is provided by the skin. It is very fortunate that so very often the skin resistance is high, especially on the back of the hands if exposed to the air. However it is very unfortunate that skin resistance is very sensitive to a variety of conditions and cannot be depended upon. It would be well to discuss this skin resistance a little more fully, for it would be very useful to determine the distribution of frequency of occurrence of total contact-to-contact

Fig. 7 below: 60-cycle electric shock hazard to adult males.

Fig. 8 right: Body contact resistance. →





body resistance under conditions of accidental contact, and the skin is the large controlling factor. From such information one could evaluate the *percent chance* of any particular current flowing in a human being who accidentally exposed himself to some given voltage. For example, we see from the Sensation Chart that for 100 volts an adult must present a resistance of less than 1000 ohms in order to be in danger of fibrillating currents, and for 200 volts the resistance is 2000 ohms. If we knew statistically that the percentage of people presenting 1000 ohms or less is almost identical to the percentage of people presenting 2000 ohms or less, then we might feel, from the point of view of safety against fibrillation, that house circuits for example could be 200 volts to ground instead of the present 110 volts without upsetting Canadian death statistics. Such a situation could occur if, for example, the "frequency of occurrence" curve turned out to be Gaussian along the resistance scale of the Sensation Chart, being practically flat and very low for resistance less than 2500 ohms, and being a maximum at some higher value before falling off again at still higher values.

An article by H. H. Watson in the February, 1959 issue of *Electrical Engineering* reviews a Symposium, held at the AIEE Winter General Meeting in New York in February, 1958, to discuss safety considerations if residential voltages are raised from the present 120-volts-to-ground to 240-volts-to-ground. It is apparent from this article that very serious consideration is being given to raising residential voltage, so the question we have posed is not an academic one. Mr. Watson offers the conclusion that the use of potentials twice as high as the present 120/240 volt level will increase the hazards already present in the existing levels but not in numerical ratio to the increase in voltage. However, I believe his conclusion is not based on the sample situation just given. Rather it is based on tighter safety design measures, limited use of the higher voltage, and probably also on the fact that he is not considering solely shock or death hazards, but also for example, fire hazards.

A start was made at the National Research Council of Canada on measuring the total resistance a body presents to 60 cycle voltages under different conditions of contact, the conditions being designed to duplicate at least to a degree the type of accidental contacts people do make. Unfortunately, this work was interrupted, but results obtained were felt to be of some value, and were given during discussion of a paper by Kouwenhoven et al in New York in 1957. Fig. 8 summarizes the results and covers the same range as the Sensation Chart, for easy comparison. Dry contact conditions are on the right side of the scale, wet contact conditions are on the left side. Values given are, unless otherwise stated, for the resistance of the single contact shown. Total resistance is dependent on the nature of the second contact plus the body resistance which is given as approximately 800 ohms. It was found that resistance during accidental "line contact" (i.e. over say a length of 2 in.) on dry skin is very dependent on the condition of the skin. For instance the back of the hand, while apparently having much thinner skin than the palm, is often very dry and is somewhat hairy and can give very high resistances. Other parts of the body, for example the neck, are not usually as dry. High voltages may cause puncturing of the skin, e.g. through a sweat pore on the back of the hand. Hence at high voltage the resistance may be more likely to change to a final value of below 5000 ohms. Values for wet hands or feet, grabbing or immersed, may go even as low as 250 ohms.

We also determined that the pressure of contact played a very important role in resistance. Presumably this is because of increased effective area of contact and probably also because of a more rapid creation of sweaty contact. For the data shown on the Body Resistance Chart, "reasonable" pressures were used.

The high values shown in the Body Resistance Chart under "dry" conditions should not be interpreted to give anyone a sense of security! This caution is made because it was found that a very small break in the skin could cause a very large change in resistance, for of course it is the skin resistance that accounts for pretty well all body resistance after the first 500 to 1000 ohms.

While we have not achieved our final objective of developing a statistical curve of "frequency of occurrence" against "resistance," an opinion may be offered on the shock hazard of increasing residential voltage. If we consider a reasonable lower limit of total body resistance in most cases of electric shock from residential voltage (120 volts) to be about 1000 ohms, we see from the Sensation Chart that the possibility of Ventricular Fibrillation is very slight. If most accidents occur with resistances above 1000 ohms the victims, while they may suffer severe shock, stand a good chance of survival, particularly as artificial respiration can be effective. Now, if the residential voltage is increased to 240 volts the possibility of Ventricular Fibrillation for the low resistance accident is increased considerably. For 5000-ohm medium resistance accidents (fairly likely—see the Body Resistance Chart) the severity of the shock is doubled by doubling the residential voltage, and as this is a range of "probable death" it is probably safe to say the number of this class of fatalities would be doubled. H. H. Watson further states: "Potentials of 240 volts to ground should be used only for permanently wired fixed appliances." In fact, considering that for children one must halve the shock currents shown on the Sensation Chart, and considering the limited advantages obtained if H. H. Watson's conclusions are adhered to, the present practice of 120/240 residential distribution is probably hazardous enough.

FRAZIL ICE

A Review of its Properties, With a Selected Bibliography

G. P. Williams *Research Officer,*
Snow and Ice Section, Division of Building Research,
National Research Council, Ottawa 2, Ont.

This report reviews the theory of frazil ice formation and the main factors which cause formations. The methods of forecasting frazil ice and the design and remedial considerations are also included. Although the frazil ice problem has been solved at many sites in Canada, this review summarizes investigations which would not generally be available to Canadian engineers.

WHENEVER supercooled water in reservoirs, lakes or rivers comes in contact with hydro-electric plant intakes, water supply intakes, irrigation and water supply canals, there is a danger of serious clogging because of frazil ice. Frazil ice occurring in large rivers is a navigational hazard and can be the cause of serious ice jams. In Canada the work of Barnes[1] is the first major effort to present detailed summaries of available information on frazil ice formation and occurrence. Since then many investigations have been carried out, notably in Russia and other European countries. As no publication is available in English, apparently, which summarizes these more recent developments, this survey of existing information on frazil ice has been prepared, accompanied by a number of selected references.

Theory of Formation

Ice is formed on the calm water of small lakes and stagnant pools when the loss of heat to the atmosphere by radiation, convection and evaporation results in the supercooling of the surface water. In this static type of ice formation described by Devik[2] the crystallization begins partly from solid matter on the beach and from solid material suspended or floating in the water. If the water remains at rest and the cooling continues, a surface sheet of ice is rapidly formed.

With dynamic ice formation as in running water or on the surface of lake water disturbed by wind, surface water exposed to the heat loss will be interchanged with water from lower depths so that a mass of water down to different depths, depending on the degree of turbulence, will be cooled to 0°C without ice formation. If the cooling continues the water near the surface will be supercooled a few hundredths of a degree (Altberg[3]). At a certain stage in this supercooling, frazil ice particles will start to form.

In their early development, frazil ice particles are thin circular discs. Frequently, the particles are of irregular outline but the edges are invariably rounded as shown in the excellent photographs by Schaefer[4]. As growth proceeds, however, flat dendrites grow out from the edge of the flat discs, eventually producing the needle-like fragments commonly recognized as frazil ice. Under favourable cooling conditions these fragments rapidly form and group into the large spongy masses that cause so much trouble on underwater installations. Figure 1 illustrates the different stages in frazil ice formation. Figure 2 shows some micro photographs of frazil ice in different stages of growth.

A similar type of formation occurs in lake water when supercooling coinciding with strong wave-action results in agglomeration (Wilson[5]). Even though the general nature of frazil ice formation has been known for a long time there is still argument and confusion in the literature

Fig. 1 Stages in frazil ice formation.

regarding the phenomenon (Timonoff[6], Lambor[7]).

Supercooling and Nucleation. Investigators seem to agree that supercooled water often exists in streams for long periods — even for days under favourable conditions[8]. There is argument, however, regarding the amount of supercooling, although it is generally assumed that it will rarely exceed .01°C in natural streams and lakes (Schaefer[4]). The theory of supercooling is still a matter of some disagreement. Dorsey[9] indicates that there are two theories to explain the freezing of water and the phenomenon of supercooling. In one, freezing is considered to be initiated by certain aggregates of water molecules called ice molecules. The other theory considers freezing to begin as heterogeneous singularities, i.e., foreign particles in the water which serve as nuclei. Dorsey combines elements of both theories. He distinguishes between an embryo comprised of water molecules only, and a complex embryo with a foreign particle as a centre to which molecules of water adhere.

Altberg[3] believes that crystals do not form in absolutely pure liquid but only upon dust particles suspended in the liquid. He concludes that the ability of a liquid to crystallize depends upon the number of nucleating centres per unit volume. Piotrovich[10] in a more recent study, points out that in water with only a few hundredths of a degree of supercooling, all ordinary inclusions are inactive as crystallizing agents.

Kumai and Itagaki[12] in their cinematographic study of ice crystal formation in water conclude that the rate of growth of discoids (or frazil ice particles) is a function of the rate of cooling of the water and the number of discoids. Their photographs show clearly the development of circular discoids into stellar crystals. Their studies show that with supercooling from 0°C to —0.3°C, discoids and spicules are produced, and from —0.6°C to —0.9°C spicules only are produced.

Much of the work done in recent years on the physics of supercooled water droplets in the atmosphere is of relevant interest to investigators of frazil ice (Schaefer[13]).

Frazil Ice Properties. The frazil ice discoids vary in size. Schaefer[4] observes particles with a range of thickness 25 to 100 microns for particles 1000 to 5000 microns in diameter. Hubbard[14] reports thickness almost identical to those reported by Schaefer. Altberg[3] claims that discoids up to several centimetres in diameter could be grown artificially. Baylis and Gerstein[15] have observed particles that grow rapidly from ⅛-in. diameter up to 4 in. in diameter and 1/32 in. thick.

The buoyancy of frazil ice particles is of particular practical interest. When the stream flow is not extremely turbulent, frazil particles remain submerged and do not appear to collect at the surface. Barnes attempts to explain this phenomenon in terms of viscosity and Stoke's Law[8]. Schaefer[4] suggests that the large ratio of major to minor axis and the small difference in specific gravity between ice and water cause the particles to tumble about within the stream much the same as water-soaked leaves are carried underwater in a turbulent stream.

Schaefer[4] estimates that the volume concentration of frazil ice approaches 10^6 per cubic meter in his observations of frazil ice on the Mohawk river in 1950. Frazil ice particles will adhere to each other and also build up on underwater objects causing many problems. According to Piotrovich[10], when water is supercooled there is a strong increase in the cohesion forces between ice crystals and in the adhesion of ice crystals with stones, wood, metal and other objects in the water. Schaefer suggests that the laminar type of build-up indicates regelation between these ice particles.

Piotrovich also suggests that, as ice does not adhere strongly to certain substances as plastics of purely organic composition, these may be used as coatings to protect against underwater ice accumulations. According to Murphy[16] waterwheels protected by wooden racks are better able to withstand frazil attacks than those protected by iron racks, indicating a difference in the ability to cohere between these two materials and ice.

One point that should be stressed is that ice will not adhere to objects that are slightly above 32°F. This is why the heating of underwater gate racks has often been successful in reducing frazil ice accumulation.

Gale[17] observes that freshly formed frazil ice is "very sticky" and much more difficult to handle than frazil which has passed under surface ice and has not been subject to such strong cooling. This suggests that even slight increases in temperature may reduce considerably the adhesive ability of frazil ice.

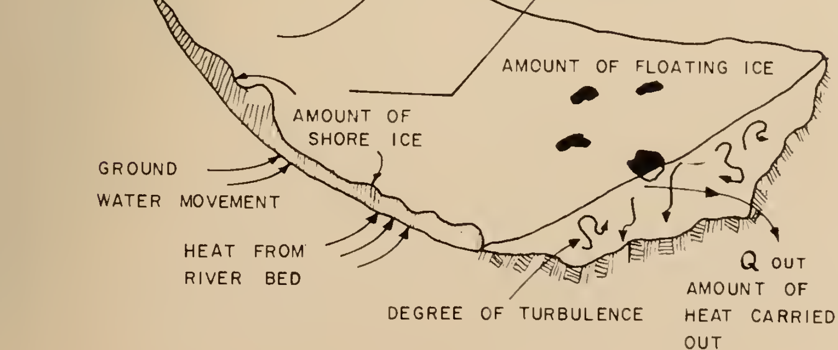
There is no doubt that frazil ice accumulations can reach gigantic proportions in an open river subjected to extreme cooling conditions. Stakle[18] gave an estimate of 476,110 m^3 per km of river for a river in Latvia. Altberg in his studies indicates that the amount of underwater ice produced in a rapidly flowing stream is often 3 to 4 times as great as the amount of surface ice produced under similar cooling conditions. Wilson[19] estimates that the mass of frazil ice floating under surface ice was from 1 to 14 ft thick for the conditions he observed. Hoyt[20] presents two examples in which frazil ice accumulations almost completely filled a stream bed.

Factors Affecting the Rate of Cooling of Moving River Water

Because frazil ice accumulations are often produced by the continued cooling of river water, a brief review of the variables affecting this cooling should be considered. The rate of cooling of a section of river water can be considered as a complex heat exchange problem which, from a practical viewpoint, will not have an exact solution. The heat exchange at the surface will be determined by the radiation, convection and evaporation losses from an open water surface. Net radiation losses will vary with the altitude of the sun, the percentage and type of cloud cover, and the condition of the water surface. Convection losses will vary with the speed and direction of the wind, the degree of air turbulence, and the air temperature. Evaporation losses will depend on the vapour pressure gradient existing between the surface of the water and the air mass, as well as the wind velocity and condition of the surface. In addition, for a given section of the river, the heat carried into and out of the section will vary according to the width, depth and slope of the river. The heat received from ground water and thermal exchange at the river bed might also need consideration.

The factors that might affect the rate of cooling of a section of river water are illustrated in Fig. 3. To calculate any one of these factors with any degree of reliability can be most difficult, especially on a short-term basis. For example, an estimate of the amount of radiation reaching the water surface can be made, if the angle of the sun's rays and the degree of cloudiness and absorptivity of the atmosphere are known. The amount of this radiation absorbed by a water surface is variable. Geiger[21] estimates that approximately 16 to 40 per cent of the total radiation from the sun penetrates to a depth of one metre, depending on the purity of the water. The long-wave radiation is almost entirely absorbed by the first centimetre of water. Whenever the water is disturbed by wind or wave action the reflectivity of the surface is changed as is the amount of radiation absorbed (Powell[22]), making precise estimates most difficult.

Fig. 3 Factors that affect the rate of cooling of a section of river water.



Barnes[1] was a proponent of the theory that radiation from the bottom of the river bed is a factor in the formation of ice on the bottom of the river bed, commonly called anchor ice. This theory is disputed by Altberg[3] on the basis that all long-wave radiation, the type emanating from the bottom of a river, is absorbed by one centimetre of water.

Barnes[1] and Loughland[23] also suggest that large amounts of anchor ice are carried to the surface during daylight hours because the radiation absorbed by the water at considerable depth heats up the water enough to release this ice. While it is true that a small portion of radiation from the sun can penetrate to depths of 20 metres (Atkins and Poole[24]), the larger amounts of heat absorbed at the surface could be carried down to the bottom layers by turbulence and thus heat the bottom surface. Another way in which the buoyancy forces of the ice might overcome the adhesive forces would be when the ice accumulation becomes great enough to float to the surface, without any decrease in the adhesive force.

The main point to be stressed is that all factors affecting the rate of cooling, as shown in Fig. 3, must be considered in an explanation of frazil or anchor ice formations.

Predicting Rate of Cooling from Meteorological Variables

Even though exact determinations of the rate of cooling of moving water would be most difficult there have been attempts to obtain quantitative estimates from meteorological variables.

The St. Lawrence Seaway Studies[25] contain an excellent review of ice formation in rivers. In this report the rate of cooling that can be expected from the difference between mean air temperature and mean water temperature is calculated. From this rate of cooling the order of magnitude of frazil ice production for special site conditions is estimated.

Wemelsfelder[26] in a more recent paper also postulates that the rate of cooling of moving water is principally dependent on the difference between the mean water temperature and mean air temperature. He presents formulae for calculating heat losses from a water surface based on this assumption. He also presents a formula for calculating the rate of heat loss when the surface of the water is partially covered with floating ice. A table is given in this paper which indicates how long it will take river water to cool to freezing temperature, provided the mean air temperature is known or can be predicted.

It must be appreciated that these formulae are necessarily very simplified presentations of a most complex situation. From the theory it is difficult to see how the wind velocity terms can be ignored in any formula. It is apparent from Fig. 3 that there are a large number of variables not included in these formulae which might have important effects on the rate of cooling of river water.

Baylis and Gerstein[15] state that, "frazil ice formed under a wide variety of wind and air temperature conditions". Ruths[27] mentions that, "with air temperatures as low as —25°C or —30°C and no wind, frazil ice will not always appear owing to the presence of a heat insulating layer of moisture saturated air on top of the water which will prevent the cold air from cooling the surface water to the critical temperature".

It also should be stressed that frazil ice is often produced a considerable distance upstream from the sections of the river under study; these geographical factors cannot be ignored in any study. Murphy[16], in 1909 suggested that very large amounts of frazil ice develop in Lake Deschenes, 3 to 4 miles upstream from the rapids near the Hull power plants on the Ottawa river.

These complications do not mean that a practical means of predicting the rate of cooling, and hence of frazil ice formation, cannot be found. They do imply that site conditions must be taken into consideration. Standing[28] gives some practical rules used at a particular plant for forecasting frazil ice as much as 12 hours in advance. On a longer-term basis Wardlaw[29] calculates the mean monthly heat losses from a water surface under winter conditions and obtains reasonable agreement with other calculated values for heat losses from open-water surfaces.

Forecasting Frazil Ice from Water Temperature Measurements

In some plants it is common practice to keep a record of water temperature. Whenever the water temperature is near 32°F and severe wind or temperature conditions are experienced. frazil ice formations may be expected.

Granbois[30] reports a method of precise water temperature measurements with an electric resistance thermometer and recorder. With his apparatus he was successful in measuring the rate of temperature change of river water and relating it to frazil ice formations. His studies indicate that frazil occurs only when the rate of temperature change is greater than 0.01°C/hr between temperatures of 0.1°C and 0°C. At temperature changes less than 0.01°C/hr a natural ice sheet is formed. Granbois in his paper gives a fairly complete description of the resistance thermometer bulb, bridge and recorder which he used.

Anyone contemplating the field measurement of river water temperature near 32°F, however, must be prepared for some problems. Perhaps the main difficulty to be overcome is that as soon as water falls below 0°C, ice begins to form on the temperature indicator.. The only temperature then recorded is the freezing point, even though there may be supercooling present. Granbois overcame this by removing the detector bulb after each successive run and melting the ice from the indicator in preparation for the next run.

Devik[2] measures the amount of supercooling of the surface layer of water with a "moll" thermopile. Special precautions were taken regarding radiation effects, including the taking of measurements just before sunrise. Nybrant[31] points out some of the problems of measuring water temperatures under field conditions. He indicated that sensitive galvanometers are difficult to use and that it is necessary to keep a measuring bridge at constant temperature and to check its calibration frequently. One must also consider the stability of the temperature sensing elements and check their calibration frequently.

Although the work of Granbois indicates that it is possible to measure river water at temperatures around 0°C to the necessary accuracy for frazil ice predictions at a particular site, special precautions and equipment are required which are usually not readily available for field installations.

Design Considerations

Although it is not the purpose of this review to go into detail regarding the design of canals, hydro intakes and racks for ice conditions, some general comments on design are included in order to complete this general review.

In 1919, Wilson[19] stated that hydro plants could be designed to be practically immune from ice troubles. Some of the standard textbooks on hydro-electric design (Creager and Justin[32]) give general consideration to the design of hydro plants to minimize frazil ice conditions.

Loughland[23] gives some general instructions for the design of sluices and canals, including the suggestion that covering the flume will prevent snow from falling into the canal, thus reducing the rate at which the water cools. Carpenter[33] indicates that by covering a flume and providing an additional supply of storage water the frazil ice problem at the Barriere Hydro Plant in British Columbia could be overcome.

In addition to the usual procedure of carefully surveying existing river conditions, ensuring proper approach conditions and locating the racks at a sufficient depth, meteorological factors should not be neglected. For example, care should be taken in determining the prevailing wind direction, for if it prevails towards the intake channel large quantities of ice will be forced into the channel. Even the direction of the wind relative to the flow of the river has a varying effect on frazil ice production. A wind blowing upstream produces more frazil than one blowing downstream because of increased surface agitation (Hendry[34]).

Once a river or canal is frozen over the rate of cooling is greatly reduced by the ice cover and the danger of large frazil ice formations is usually eliminated. For this reason considerable study has been made of the water velocities at which canals or rivers will freeze. The factors affecting the formation of ice covers on rivers or canals are generally the same as those which affect the rate of cooling of a river or canal as shown in Fig. 3.

The St. Lawrence Waterway Project[25] gives some practical information on the relation between water velocities and ice formation. Because velocity and turbulence of water are only two factors which will affect the formation of ice cover it is not possible to give limiting velocities which will apply in every case. In its report the Joint Board of Engineers came to the general conclusion that "smooth ice covers may be expected to form in rivers with velocities up to 1.25 ft/sec in zero weather providing there is no high wind preventing such action".

A committee of the Power Division of the A.S.C.E. investigated ice as it affects power plants and published a special report (Shenehon[35]). In addition to a bibliography on the subject, they give much information of use to design engineers. Some of the effects of ice on stream flow are of special interest to engineers designing canals or modifying river channels under ice conditions ([36, 37, 38, 39, 40, 41]).

Remedial Action

For established power plants and hydraulic works, it is often possible to prevent the formation of frazil ice by electrical heating. Reid[42] gives some details of the heating of rack-bars in hydro-electric plants, including a formula for calculating the power required. He emphasizes that electric heating is of particular value in locations where frazil ice develops quickly and is not of long duration. Ruths[27] gives a table of electrical values, including the power required, used in heating racks at several power houses in Norway. A report by the subcommittee of the Hydraulic Power Committee for the Canadian Electrical Association[43] gives some details of the electrical energy utilized by different companies in Canada for keeping sluice gates free of ice. Various other references are available, indicating that formations of frazil ice have been successfully combatted by electrical heating[44, 45, 46].

Steam heat has also been used for preventing frazil ice formation[43]. Dorion[47] relates some of the difficulties connected with preventing accumulations of frazil ice with steam at a pump intake.

Compressed air jets or air-bubbling systems to prevent ice formation have been applied for many years. Air bubbling systems depend on the fact that warm water below the surface can be brought to the surface by the rising air bubbles and so used to prevent frazil ice at specific locations. Skerrett[48] in 1923 described how jets of compressed air were utilized to prevent ice formation on gates of hydro-electric plants. In 1935 Skerrett[49] gave some details of how ice pressure was prevented by air bubbling systems. Other more recent papers are given by Owen[50], Simmonds[51], and Granbois[52]. Some fairly complete experiments on preventing water from freezing by means of compressed air were done by Kaitera[53] in 1948.

In addition to heat and air bubbling systems other means are being used to combat frazil ice formation. In Switzerland where, because of climatological and hydrographic conditions, frazil ice problems are not generally severe, mechanical devices to clean out intakes are used (Harry[54]). Murphy[16] reported in 1909 that frazil ice can be prevented by creating an artificial barrier across the stream to start surface ice formation.

It has been suggested by Schaefer[4] that the seeding of ponds with dry ice might hasten ice formation. Granbois[30] reports limited success by seeding river water with dry ice; the resulting fragile ice sheet was destroyed as fast as it was formed. Lavrov[55] considers that artificially increasing the number of crystallization nuclei cannot be an effective counter-measure because the intensity of underwater ice formation depends on heat losses from the stream, not on crystal number.

Additional Information The SIPRE bibliography contains many useful references on frazil ice and related problems, including a series of Russian abstracts. A few selected Russian references have been chosen from these abstracts and are listed as a Bibliography.

La Houille Blanche, (Numero 4, juillet, août 1950) contains an excellent review of snow and ice technical terms in French and English. In addition, this volume contains a general review of frazil ice problems and related phenomena.

The Meteorological Abstracts and Bibliography of the A.M.S. for July and August 1956, contain an annotated bibliography on the micrometeorology of snow covers. This would be of value to anyone studying the thermal regime at snow and ice surfaces.

This paper is a contribution of the Division of Building Research of the National Research Council of Canada, and is published with the approval of the Director of the Division.

MATERIALS HANDLING AT CANADAIR

(Continued from page 49)

age space by increased stacking height and narrowed aisle width is a valuable contribution of improved materials handling techniques.

Waste Disposal — The removal of waste materials from work areas is a very costly item in a plant as large as Canadair's. Large annual savings were achieved in this operation as the result of an investigation made by Plant Engineering.

Formerly, wooden waste-boxes were placed at each work area. When filled, the boxes were taken to an open truck (road vehicle) into which two men dumped the waste materials by hand. The procedure was obviously costly in terms of time and manpower.

The new system uses specially-designed steel waste-bins and a high-lift fork truck with a swivelling head to dispose of the waste much more rapidly and economically.

The waste-bins, designed at Canadair, have rectangular corrugated steel bodies, fitted with lifting lugs and a towbar, and with two box-section channels underneath to take the forks of the lift truck. The chassis is mounted on four caster wheels, arranged in a diamond pattern which allows a train of several bins to follow the same course when turning corners.

According to a planned schedule, a *mule* hauls a train of empty bins around the shops, dropping off an empty and picking up a full bin at each scheduled point. When a full train has been picked up, the bins are hauled to a central loading point where a 'Sani-Van' type of enclosed garbage truck is stationed. Here, the *mule* leaves the full bins, which are then picked up by the fork truck, raised, and turned over by means of the swivelling head attachment so that the contents are dumped into the back of the large garbage truck (see cut).

Conclusion

The handling of materials in a large aircraft manufacturing plant may represent more than half the total manufacturing man-hours involved. By careful attention to improvements in materials handling methods, many thousands of dollars are saved annually.

PRECAST CONCRETE FOR WINTER BUILDING

C. R. Crocker, M.E.I.C., *Senior Research Officer*
A. W. Smith, *Junior Research Officer*
National Research Council, Ottawa 2, Ont.

Presented at the 73rd Annual General Meeting of The Engineering Institute of Canada, Toronto, Ont., June, 1959.
Paper received October 27, 1959.

The protection of freshly placed concrete is one of the problems facing Canadian contractors engaged in winter building. One solution is to use precast concrete which, even in winter, can be manufactured under controlled conditions to ensure maximum strength and durability. There is, however, little experience with such units in Canada because production, although it is increasing rapidly, has been limited. In Europe, on the other hand, precast concrete has been widely used for many years. Experience there indicates that precast concrete can be used in Canada as an aid to winter construction. There are however some practical difficulties to be solved before this practice can gain wide acceptance in the industry. The most serious is that of making connections between members. Although a number of solutions have been suggested, the need for additional research is recognized.

ONE OF THE PROBLEMS facing the Canadian construction industry in wintertime concerns the protection which must be given freshly placed concrete to prevent damage from frost action. This requirement for temporary protection increases the cost of the concreting operation. When added to the increased cost of the concrete itself during the winter months it may raise the final cost in place as much as $5 per yard. There is a natural decrease in labour efficiency if protection is not provided, and a great deal of time can be lost in warming up, and sitting out bad storms.

It is common practice in Canada today to place heated ready-mixed concrete inside a temporary enclosure covered with tarpaulins or plastic, but the whole operation can be very much simplified by mixing, placing, and curing the concrete under the same roof and then assembling the precast components on the site. Protection on the site can then be confined to the joints between the precast parts. It then becomes possible to achieve the valuable economies of factory production.

Fig. 1. The all-important framework can be erected in any weather, and is immediately load - bearing. (Northview Height Collegiate Swimming Pool, Toronto).

The use of precast concrete manufactured in a factory can therefore provide a solution to the problem of winter concreting and at the same time introduce a measure of quality control not usually associated with cast-in-place concrete. The speed with which it is possible to enclose a structure when large precast panels are used promises even further cost savings.

As a part of its research study of winter construction, the N.R.C. Division of Building Research decided to investigate the present status of precast concrete in Canada and to assess the practicability of this practice being more widely used than at present. In the course of this study, an extensive search of American and European technical literature was undertaken followed by visits to engineers, architects, contractors, manufacturers, and research laboratories in the United Kingdom, the United States, and Canada.

Brief History

The practice of precasting concrete is nearly as old as the use of reinforced concrete. Development was slow until World War I when, because of shortages of conventional materials, many nations investigated the possibility of precasting concrete on an industrial basis. By 1930, Germany was producing precast concrete frames, girders, columns, sewers, bridges, fence-posts, lamp-posts, formwork, paving block, and building block, and had already recognized the advantages of precast concrete for winter construction.

In the years following the revolution, much attention was given in the U.S.S.R. to the manufacture and use of precast concrete. So convinced were the authorities of the advantages of this system that by 1934 standard precast concrete structural units were required for all commercial and industrial buildings. By that time precast units weighing 15 metric tons were being fabricated. In contrast to this rapid development in other parts

Fig. 2. Precast concrete roof and frame provide the structural portion of a lightweight enclosure (University of Saskatchewan).

of Europe, little early work was done in the United Kingdom or the United States. Precast floor systems had, however, been developed and were quite widely used, and as early as 1906 American railroads were using some structural precast concrete bridge components. The erection of such large components was no problem to the railroads who could use their heavy wrecking cranes.

The construction industry generally had to wait for the development of the heavy-duty motor truck crane and tower crane before full use of precast building components was possible. The steel shortage brought about by the Second World War resulted in a great increase in the use of reinforced concrete. Much of it was cast *in situ* but with experience came the realization that precast concrete offered a low cost, high quality material that could often replace traditional materials. In the United States the use of precast concrete frames for commercial and industrial buildings increased and large precast girders, which had been used in earlier years, were again used in bridge construction. With the development of prestressing techniques and the introduction of heavy lifting equipment, precasting in the United States began to compete seriously with conventional materials.

Today much use is made of large floor and roofing slabs and tilt-up wall panels, precast on the site and put in place by special erection equipment. At the same time factory precasting is also widely used and has made possible the erection of one factory building at the rate of 7500 sq. ft. per day, with framing and roof decking averaging 10,000 sq. ft. per day.

The precast, prestressed concrete industry in the United States maintains a yearly growth in production of 200 to 300%. At present there are some 200 precast prestressed plants in operation, and a further 150 are under construction or being planned. Girders and beams of I, T, WF, and rectangular sections, roof and floor slabs of double T and channel section, joists of I and T section, rigid frames, trusses, columns, poles, pilings, lintels, bleachers and wall panels are being produced in ever-increasing quantity.

Although the general adoption of concrete column-and-beam frameworks in Britain has been slower and is even today less widespread than in the other countries of Europe, precast floors and rigid frames for single-story industrial buildings are now generally accepted as standard forms of construction. Some manufacturers can produce precast concrete frames at the same price as unprotected steel and at half the price of fire-proofed steel. In an effort to conserve steel and provide schools as cheaply and quickly as possible, the British Ministry of Education sponsored the development of a number of proprietary systems. Their success may be illustrated by the fact that one contractor, using a system of precast units prestressed in place, has built between 40 and 50 schools in three years and is now entering the commercial building field.

In the U.S.S.R. today, precast concrete is being used almost exclusively for building construction. In Moscow and Leningrad alone, some 86,000 apartments to be built in this way are planned for 1959, mostly in five-story blocks. The finished buildings have a neat appearance both inside and out, but the precast products are roughly finished and are generally covered by plaster or brick facing. State control and co-ordination of all construction, and the resulting standardization throughout the country, has permitted the complete mechanization of even pretensioning operations, through the development of continuous wire winding machines and rotating casting beds.

Factory Manufacture

Precasting does not automatically imply factory manufacture nor that it cannot be considered beyond the economical hauling distance from an existing factory. On-site manufacture, however, is generally limited to heavier components that are too difficult to transport, or to large jobs where it is economically practicable to erect a temporary factory. A $300,000 job is regarded in Europe as the minimum size for on-site casting, because this will allow recovery of the cost of plant, moulds, and planning during the course of that single job. On-site manufacture in Canada is generally left to the factory manufacturer who can extend his operation in this way. At present, he has the necessary specialized knowledge, and this situation will probably continue until standard specifications for precast concrete are available. There are exceptions to this general rule, but these usually result from very close co-operation with an experienced architect-engineer. At the present time building codes make virtually no distinction between precast concrete and ordinary reinforced concrete cast-in-place, so that they give no indication of the extra care required with precast work.

Factory production, whether in a permanent or a temporary factory, permits rigid control of mixing, placing, and curing, as well as being completely independent of weather. Hence it is possible to produce high strengths running as high as 9,000 to 10,000 psi, even with lightweight concretes. The central feature of a precasting factory is the concrete mixing plant, operating on a weight batching principle, and similar in all respects to that commonly used in modern ready-mix concrete plants. Some are electronically controlled. In all cases there is some form of continuous inspection and of random sampling, frequently by an independent testing laboratory.

From the mixing plant the concrete is transferred to the casting bays, which frequently operate on a long-line principle. Here the forms are assembled, the reinforcement placed and possibly prestressed, and the concrete compacted and cured. For smaller units and where rapid production is desired, steam or warm water curing is used; with prestressed units, this permits stress release after as little as 12 hours. Larger units may be air cured, which permits stress release in three days. With either method the side forms are stripped and re-used on a daily basis. For winter operation of outdoor casting bays either on the site or at factories, forms are heated by the circulation of steam, hot water, or hot oil.

The continual re-use of standard forms makes it possible to use steel forms. Besides reducing form maintenance costs and producing accurate castings, steel forms produce a smooth finished surface ready for painting. The savings involved in factory production of an integral surface finish are very real and can reduce the construction time very considerably. The exposed face of a wall panel, for example, may be tiled, trowelled smooth, brushed, polished, or treated with an acid solution or water spray to expose the aggregate. It is possible to achieve almost any desired texture or colour, and at the same time to produce a finished surface that requires little or no maintenance. The application of special finishes of this type to a cast-in-place panel would be costly, if not impossible, and would require additional winter protection.

The precast units are easily handled in the factory, usually with gantry cranes. Some factories that use a vacuum process to remove surplus water from the compacted concrete also use a vacuum mat pick-up for handling precast components, particularly wall panels. The finished units can be stored under cover if necessary, and standard units can be stockpiled during periods of low demand so that factory production can be maintained at a uniform year-round level. Most units, however, are produced to order and stored until they have reached the required strength, which incidentally means that they have undergone most of their shrinkage. They can be delivered to the construction site in sequence of erection. On well-planned jobs they can be lifted directly from the delivery truck to their final positions. This eliminates on-site storage completely and is a great advantage in wintertime. Erection of precast concrete may depend on solid ground conditions for heavy erection equipment; in this respect it is also more suited to winter than to summer construction.

Fig. 3. The lift slab method is an ideal winter construction method because the concrete slabs can be placed with a single enclosure at ground level (Carleton University Arts Building, Ottawa).

Simplification of Construction Operations

The quality of precast work and the possibility of using prestressing techniques with it are not the only reasons for its increasing acceptance. Simplified construction procedures result in major time and labour savings, which can in turn reduce building costs considerably. The elimination of framework on the construction site is a big factor in reducing costs. Forms must be used, of course, in the precasting plant, but through re-use their number may be greatly reduced. The amount of formwork is also reduced by casting the units in the most advantageous position. A concrete staircase, for example, is best cast upside down in a horizontal form. A vertical wall panel with a double grid or reinforcement is a difficult section to place on the job, but in a precasting plant the concrete can easily be placed in the open face of a simple horizontal form.

In Europe, savings of two to three hours per cubic yard have been recorded for panels of this type. The over-all saving made by using precast concrete for a French apartment building amounted to 50 per cent of the formwork, or from 10 to 15 per cent of the total cost of the building. Construction times are commonly cut in half. One British contractor has found that it pays to redesign cast-in-place buildings as precast structures simply to take advantage of modern methods and equipment. He has achieved such results as being seven months ahead on a 30-month schedule with a job little more than half finished. Such time savings can greatly reduce overhead expenses and interest on capital. They can result in earlier occupancy, and hence in earlier receipt of rents. In the construction of an apartment building in Europe, four months were saved by using precast concrete instead of concrete cast-in-place. The resulting savings, together with the earlier receipt of rents, more than offsets the cost of 30,000 miles of trucking from factory to job-site and of importing and setting up a special crane to handle the precast units. In Canada, because of the long winter season and the desire to close in buildings in the shortest possible time, saving of construction time is of great importance. Precasting avoids cold weather delays. It can eliminate the need for temporary enclosures of any kind and can provide, in itself, an immediate and permanent shell to shelter the work of sub-trades.

Although the labour force required to erect precast concrete is small, it must be highly skilled. In the United States a trained crew of six men erected the frame of a two-story, 17,000-sq. ft. building in four 8-hour working days. In another case, six men erected the frame of 64,000-sq. ft. single-story building in ten working days. Factory processes make best use of less skilled labour and make it possible to build up experienced teams that benefit from year round employment. Experience in the U.S.S.R. has shown that the use of precast concrete leads to an over-all labour saving of as much as 48% for the individual components, compared with monolithic members. In housing, where large precast wall and floor panels are used, labour on the building site has been reduced by as much as 55%, compared with cast-in-place construction.

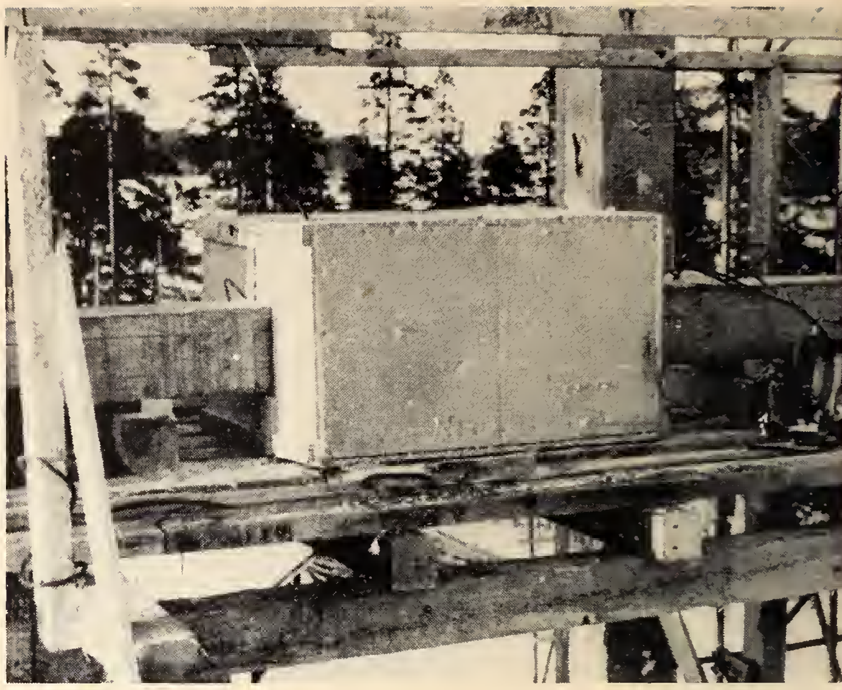

Fig. 4. Joints made with cast-in-place concrete require winter protection. This fibreboard box could be heated with a single electric light bulb.

Connections Between Precast Units

The advantages of using precast concrete are often offset by the difficulty of producing satisfactory connections between precast units. A number of special systems of jointing have, however, been developed. Some are well suited for winter construction, but others require cast-in-place concrete which must then be protected by portable shelters or other means.

There are four main types of joints in common use:

(1) Welded reinforcement joints;
(2) Rigid metal joints;
(3) Prestressed joints;
(4) Cast joints.

The welded joint connects reinforcing bars which have been left exposed during manufacture of the precast units. Only a small space is left between units and this space is later grouted. Rigid metal joints are made by steel connectors consisting of short lengths of structural steel, anchored into the ends of the units to be joined and tied into the main reinforcing by welding. The joint is made by bolting, riveting, or welding the connectors.

Prestressed joints are made by precasting steel reinforcement which is anchored in both units being connected or by using prestressed bolts. This system, which is considered by some experts to be the best one, gives a joint which is able to resist the bending moments as well as the shearing forces which must be carried. Cast joints are made by splicing the ends to be joined with reinforced concrete which is cast-in-place. In such a joint the compressive loads are carried by the concrete filling, while the tensile loads are transferred through the reinforcement which is spliced, or by bond between the reinforced concrete splice and the precast units.

An ideal joint design for precast concrete framing should satisfy three major requirements:

(1) The joint should provide bending moment strength to the maximum possible extent;
(2) It should be economical, with the least possible use of extra steel and labour; and
(3) The joint should allow exact plumbing of a column after it has been erected.

Maximum moment resistance is particularly desirable for large warehouses and industrial buildings, because it is most often very difficult to obtain lateral stability in any other way than by fixing the columns to their foundations. To obtain this maximum rigidity, the reinforcing steel over and under the joint should be made continuous as far as possible. This is most easily achieved by means of welding; it is easier to obtain the desired quality when all of the steel reinforcement is marked according to steel type and yield strength.

To reduce the amount of extra steel required, footplates, for example, should be made as thin as possible and should not be depended on to transfer bending stresses except in the initial stages before final welds are made or filling concrete added. In wintertime, it is a definite advantage to have a rigid metal joint which is capable of taking the construction loads without the assistance of the filling concrete. This concrete can be added at a later more convenient time after the building is closed in. In most instances, the labour involved in making the joint is more significant than the extra material used. Erection time is very expensive and should be kept to an absolute minimum.

For most parts of Canada the rigid metal joint is the most attractive for winter construction projects, but it is also the most expensive. For this reason, one of the other joint systems is generally used and provision made to ensure that no frost damage occurs to the grout around the joints. A good grouted joint is often harder to achieve than generally believed. Frozen members must be heated before the grout is applied. Some engineers believe that porous members can absorb even the water required for hydration of the cement. Temperature, shrinkage, and loading movements are often ignored. Early failures of grouted systems have been attributed to one or other of these conditions. Some designers find it an advantage to use a cast-in-place core for stability. This eliminates any uncertainties about joints between the precast members, and has been shown to fit in particularly well with the general contractor's operation.

Canadian Practice

There are approximately 20 manufacturers in Canada who produce structural precast and prestressed concrete. Over half of them are to be found in or near Montreal or Toronto. Although the greater part of their business is still done in hollow cored and double T floor and roof slabs, a few have now increased their regular production to structural frameworks, sandwich panel walls, and large architectural facing slabs. Some extend their field of operations by site-casting and post-tensioning outside their own area. Precasting is now a $25 million a year business. All the companies report that each year's production is higher than that for the previous year. One company has increased its production six-fold in three years.

A lack of standardization has kept the industry from enjoying the full benefits of factory precasting. Competition is keen, and because of this manufacturers are forced to work very close to design limits. These problems are recognized by the industry but there is some reluctance to establish standard sections on the grounds that such action may restrict the development of this relatively young, rapidly expanding industry.

Canadian designers confirm the advantages of precast concrete for winter construction. In order to make the best use of the precasting method, a designer should be able to co-ordinate architecture and structure. He should have a basic knowledge of the manufacturing processes as well as the construction operations and the equipment used to handle precast components. Better than average supervision of the job must be provided. In short, all the problems facing architect, engineer, manufacturer, and contractor must be considered in the very early design stages. This collaboration encourages new thinking; in many cases the savings resulting from a new method of approach have exceeded those forecast for the precasting method itself.

Conclusion

The use of precasting can limit on-site concreting operations in wintertime to the making of the joints between the precast parts. It can halve construction time and ensure top quality products. Not unnaturally its use is expanding rapidly in Canada. Much of the production of Canadian plants is still restricted to floor and roof panels, but to an increasing extent structural members such as beams, columns, arches, purlins, and load-bearing wall sections are being produced. Full development of this new industry would seem to be restricted by the lack of information in the offices of engineers and architects, and by some hesitation on the part of designers and contractors to full consideration of this new method and the necessary techniques.

As with all building materials, there is still a great deal to learn about precast concrete but this need has been recognized. The American Society of Civil Engineers and the American Concrete Institute have formed a joint committee to study it. One of the first projects to be undertaken by this new "Committee 712" will be an investigation of joint systems for use between structural precast members. From such studies, an increasing fund of knowledge will be accumulated for the use of designers in this country. In the meantime, there is sufficient evidence already available to show that precast concrete has an important place in Canadian wintertime construction, a place long established in northern Europe and Russia.

Acknowledgements

The authors wish to express their thanks to all the engineers, architects, contractors and manufacturers in Canada, the United States, and Great Britain who gave so generously of their time and experience in discussions and whose comments are summarized in this paper.

TESTS OF HYDRAULIC TURBINES

An Appraisal

J. J. Trail, M.E.I.C., *Consulting Hydraulic Engineer*

Toronto 18, Ont.

Presented at the 73rd Annual General and Professional Meeting of the Engineering Institute of Canada, Toronto, Ont., June, 1959

EFFICIENCY and capacity tests of hydraulic turbines have engaged the attention of the writer for nearly fifty years, and recently he carried out tests of the largest turbines in the world at present in service. The range of heads has varied from 16 ft. to 1,130 ft. and of capacity from 200 h.p. to 200,000 h.p. Quantity of water used has been measured by four different methods, but several other methods have been observed or studied. The Gibson Time-pressure method has been chosen for a majority of these tests, but in that regard the writer does not differ from others who have specialized in such tests, each confining his work largely to one method.

It is proposed in this paper to make an appraisal of the value of tests, to describe briefly several of the methods used for measurement of quantity of water flowing and to comment on tests of models of turbines, Test Codes and several other related matters.

Tests of turbines in place as a rule involve some considerable expense and sometimes interfere to greater or lesser degree with the normal operation of the plant in which the turbine is installed. It is reasonable therefore to consider why tests should be made.

The economics of the problem must of course be the determining factor although a long range view should be taken of this. Consider a power plant costing $30 million, comprising two generating units. If the turbine of one unit has an efficiency of 90% over the usual range of operation and the other 88%, the loss of investment represented by the deficiency of 2% in half the plant amounts to about $240,000. Turbine efficiencies over the years have been increased by a much greater amount than 2%.

In the majority of the acceptance tests carried out by the author the efficiency and capacity guaranteed have been realized. There have however, been quite a number of turbines which have failed to attain the maximum efficiency guaranteed, more which have failed to reach the expected efficiency, a lesser number which have failed to have a maximum output equal to that guaranteed and others, intended for continuous use at full output, which have fallen off badly in efficiency as they approached full gate opening. Having in mind the capital value of small increases in turbine efficiency it is certainly in the interests of the purchaser to assure himself by tests that the equipment conforms with the guarantees named in the contract.

There are also secondary benefits from the tests. In multi-unit plants the best overall efficiency of generation requires that the total load on the plant be properly distributed among the units and that the right number of units be in operation to secure this optimum efficiency. The only way to determine the proper number of units and the distribution of load among them is by analyzing the efficiency curves.[2,3] If surplus water is available this does not apply but as a rule, for the major part of the year at any rate, economy of water is an important consideration particularly in the case of developments depending on stored water.

The tests also enable a continuous record of water used to be made a part of operating records.

Considering the value of tests to the industry in general, a review of the experience on this continent over the past hundred years is of interest.

In 1859-60 tests were made of 16 turbines at Fairmount Park Water works in Philadelphia. The weighted average of the maximum efficiencies of these turbines was 72.5%. At the Centennial Exhibition at Philadelphia in 1876, eighteen turbines were tested and showed a weighted average of the maximum efficiency of 75.5%. Turbine manufacturers used the facilities of the testing flume of the Holyoke Water Power Company, at Holyoke, Mass., to test and improve their product, but because the results of these tests were treated as the property of the commissioning manufacturers, a complete record of progress in the industry is not available. However, complete records[1] are given for twelve turbines of various makes and sizes tested in 1896-98. The average of their maximum efficiencies was 83.6%, the highest obtained being 85.4%.

The improvement of 11% over this 40 year period was probably paralleled by a similar improvement in the product of European manufacturers. The North American manufacturer generally produced a series of turbines of similar design and in various sizes, whereas the European manufacturer built turbines fitted to the project in hand. Two turbines installed by European manufacturers at developments in Austria and Switzerland in the late 1890's showed efficiencies of 85 and 86% respectively—figures quite comparable with those recorded in the previous paragraph.[4]

The generation of electrical energy in central stations and its distribution to industries located at some distance from the source of power in the latter part of the 19th century opened the field for the use of larger generating units and gave an advantage to the European turbine manufacturers. In the early years of the present century most of the turbines installed in central stations—notably those at Niagara Falls—were of European manufacture, and tests when made indicated efficiencies of the order of those recorded above. Refinements in design not only in the turbine runners but in gates, scroll cases and draft tubes were responsible for progress in the attainment of higher efficiencies. In one of these plants units were installed in groups of 2 or 3 as power demands increased over a period of about ten years. One of each group was tested by the author a few years later and it is interesting to note that, with one exception, each group showed an improvement in maximum efficiency over the previous group.

During the early years of the century improvements in design and settings of turbines resulted in greatly increased turbine efficiencies, and by 1925 efficiencies in excess of 93% were attained in a number of instances. Laboratories were established by most manufacturers of turbine equipment, improved methods of testing were developed and at least two new methods for the precise measurement of large flows presented. These are The Allen Salt Velocity Method[5] and the Gibson Pressure-Time Method[6,7] The consistently high efficiencies attained by modern turbines are the outcome, in part at least, of the large number of field and laboratory tests that have been made during the last forty years. Dr. Gibson in a recent paper[7] presents the results of 206 field tests by the Gibson Method since 1920, 75% of which showed efficiencies in excess of 90% and 10% in excess of 93%.

Field Tests of Hydraulic Turbines

The quantities to be measured in the test of a turbine are (1) The head acting (2) the power output and (3) the quantity of water passing through the turbine. Brief comment on the first and second of these will be made later. In the four following sections descriptions are given of four different methods commonly used for measurement of the third item.

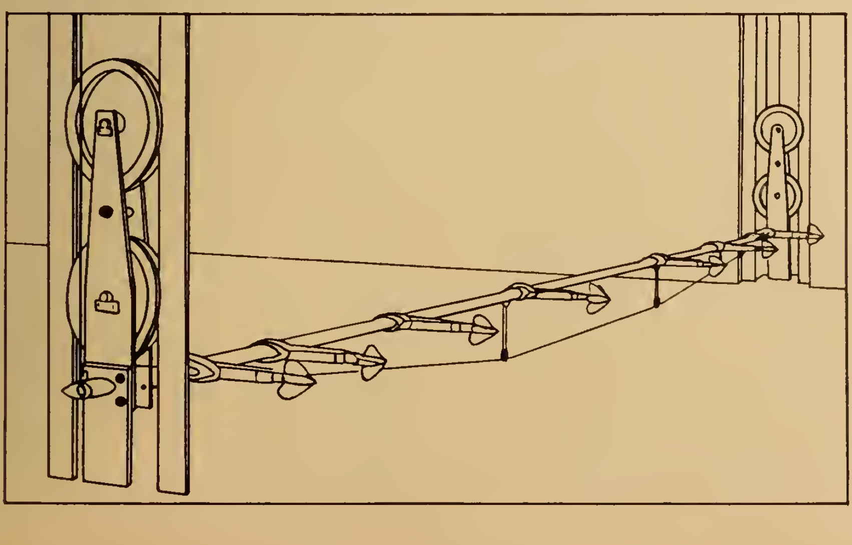
The Current Meter Method

Current meters fall into two classes, namely those with horizontal axis and those with vertical axis. The former usually has four inclined blades supported by radiating spokes (bladed meters) or two or more helical vanes mounted directly on the shaft (propellor meters). The backward thrust of the shaft is taken usually by a jewelled thrust bearing within the meter housing, which also contains electrical contacts to enable a record of revolutions of the meter shaft to be transmitted to a convenient observing or recording post.

The vertical axis meter carries on its shaft four to six hemispherical or cone shaped cups. The shaft is supported on a protected steel pivot and, above the cups, there is a housing for the electrical contact for counting or recording revolutions of the shaft. The vertical axis meter is the type generally used on this continent for measurements of stream flow, for which purpose it has great advantage over the horizontal axis meter.

In stream flow measurements the vertical axis meter is generally supported on a cable or fine wire and provided with a tail-fin which causes the meter to face the direction from which the water in contact with it is flowing. If a moment's thought is given to the use of the vertical axis, or cup type meter, it will be realized that, even if rigidly supported, the full velocity of a horizontally divergent current will be recorded, not the resolved part of this normal to the metering section. If the divergence is in the vertical plane the meter is found to under-register the resolved part of the velocity. This meter, therefore, is not favoured for turbine tests.

Fig. 1—Lightweight meter frame carrying seven meters and movable vertically in stop-log checks.



When meters are used for turbine tests they are of the horizontal axis type and they are rigidly supported with the axis at right angles to the measuring cross-section. If the water flows past the meters at an angle other than normal to the metering cross-section they record approximately the resolved part of the velocity normal to the cross-section. If the angularity of the current does not exceed 8° the recorded velocity will be within 1% of the resolved part of the velocity normal to the metering section.

Current meter manufacturers in Europe for many years have studied and improved their product and one of these claims for certain instruments of this component type is that they record the resolved part of the velocity normal to the metering section for angles of inclination far in excess of the figure given above, in fact, for one type, about 45°. Many other meters record the resolved part of the velocity normal to the metering section at angles well in excess of 8°.

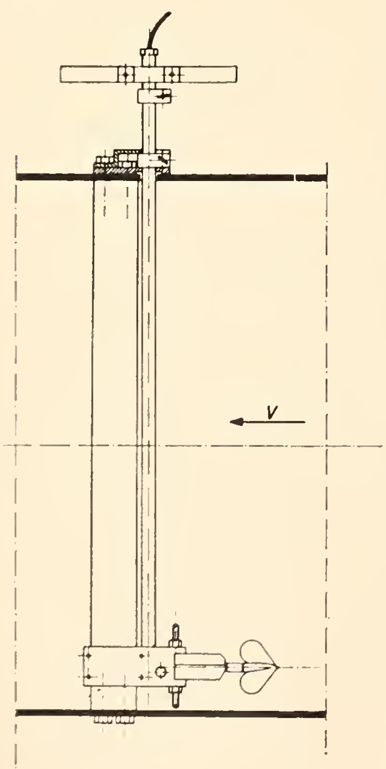
For low head plants it is the usual practice to meter the flow at the intake or in the intake canal where the flow is likely to be less disturbed than at other points along the flow path. It is customary to mount a group of meters on a steel frame moveable vertically, in stop log or gate checks if at the intake, the meters being suitably disposed as to define, as accurately as possible, the variation of velocity across the intake or canal. A light-weight metering frame is shown in Fig. 1. The frame is then lowered until the meters are at a pre-determined distance below the top of the metering section and readings of the various meters transmitted to a chronograph over a measured time interval (also recorded on the chronograph), the time of record being at least one hundred seconds. The meter frame is then lowered to various pre-determined levels in the metering section at each of which the meter readings are recorded. The spacing of the vertical points of measurement is so chosen as to properly define the vertical velocity curve. The position of the meters on the steel frame and the lowest point of measurement should place the meters not more than 8 ins. nor less than 3/4 of the diameter of the meter wheel from the boundary of the metering section.

The number of metering points is defined in various test codes, all differing slightly. The formula considered most generally acceptable, as it conforms closely with a new international code now in preparation, calls for a number of metering points from 10 and 16 times the cube root of the area of the cross section in sq. ft. For example for a metering section 10 ft. by $12\frac{1}{2}$ ft., 50 to 80 metering points are required.

The metering section must be definite in area and susceptible of accurate measurement. An arrangement used by the writer in measurements at a small plant with a curtain wall at the intake extending well below water surface is illustrated in Fig. 2. The meters in this case were mounted on a steel frame moveable in stop log checks and the nose of the meters came within an inch of the timber bulkhead. The arrangement does not comply fully with the test code but was considered satisfactory. In this case the area of the metering section was definite and was measured before the plant came into service. Flow at all points was normal to the section or nearly so. However, European practice would demand a bellmouth upstream from the section to further assure streamlined flow. Even in flow measurements in a canal a bellmouthed structure might be used which would have the added advantage of keeping the area of the section independent of variations in water level.

In European practice by far the larger number of turbine tests are made by current meter even in penstocks from 4 ft. diameter and upward. Various arrangements for supporting the meters are used, two of which are illustrated in Figures 3 and 4. For small penstocks smaller meters are used than for open channels or for large penstocks. The minimum distance of the meter from the wall of the penstock, as for open channels, is usually 3/4 of the diameter of the meter wheel, and the spacing of meters across the diameter is such as to give approximately equal weight to the records of each meter. Measurements are usually made on two diameters. Conductors are led from each meter to a recording chronograph and, if a single meter is used, the reading for each position continues for at least one minute or, if a group of fixed position meters are used over a full diameter, readings continue for at least five minutes.

Fig. 3—Measurement in large penstock with high velocity of flow. Single moveable meter sliding along permanently mounted rod.



The metering section in a penstock is chosen if possible at least 20 penstock diameter downstream and 5 diameters upstream from the nearest bend. Manifestly in many large penstocks it is difficult to conform with these conditions in which cases the flow conditions at the metering section are carefully examined prior to the test.

The Allen Salt Velocity Method

This method, developed by the late Prof. C. M. Allen of Worcester, Mass., might be considered as a positive or volumetric measurement. The method, applicable to closed conduits, is based on the fact that salt in solution increases the electrical conductivity of water. A salt solution is injected at a section in the conduit upstream from two seats of electrodes suitably spaced along the conduit and its passage at the electrodes, together with the elapsed time of its passage, is recorded on a graph. An accurate measurement of the conduit enables the volume between the two sets of electrodes to be computed in cubic feet, V, and, if the time of passage is t seconds, the discharge in cubic feet per second is

$$Q = \frac{V}{t}$$

No empirical coefficients or corrections are used.

Usually, as indicated above, two sets of electrodes are used. In a rectangular conduit these may consist of a series of pairs of iron pipes, the pipes in each pair being a few inches apart and insulated from each other and from the conduit. They are installed parallel with the walls of the conduit and extended from top to bottom. In a circular pipe the bars are so spaced as to give equal weight electrically to equal areas of pipe cross-section. The two banks of electrodes are spaced at such a distance apart that the passage of the salt solution from one to the other at full load is at least nine or ten seconds.

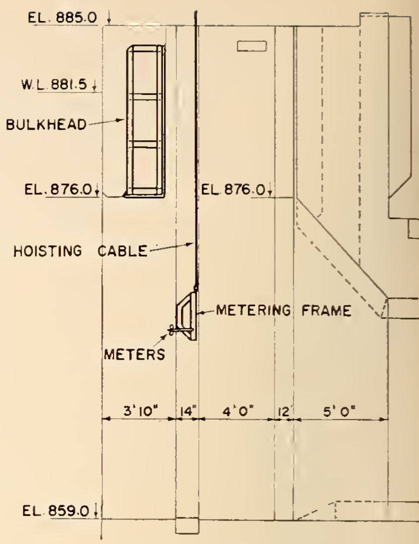


Fig. 2—Bulkhead installed at intake of low head plant to develop a satisfactory metering cross-section.

The salt solution is injected into the conduit under pressure through a system of piping and pop valves controlled by a single quick opening valve.

In some cases only one set of electrodes has been used and the time from injection of the salt solution to its indication at the electrodes is measured. In such cases the volume of conduit from the pop valves to the electrodes is the V of the above equation.

The electrical record of passage is usually made on a direct writing oscillograph with variable speed. A typical chart is shown in Fig. 5. The record shows clearly the passage of the salt solution at each bank of electrodes and, at the top of the chart, a record of time by seconds marked by a chronograph pen actuated by a seconds pendulum or some other precise timing device. The area marking increased amperage as the salt solution passes is marked off and its centre of gravity determined. The time indicated by the location of the c. and g. is taken as the time of passage of the salt solution.

The method has probably a broader field of application for closed conduits than any other method. It has been used successfully in comparatively short converging passages such as are common in low head plants and in circular penstocks of all sizes. Its accuracy has been confirmed by many tests in which other methods of water measurement have also been used. A record of some of these comparisons will be found in Table No. 1.

The method has been used in the laboratory and field in open channels. In such cases the measurement of volume is more difficult because of the free surface.

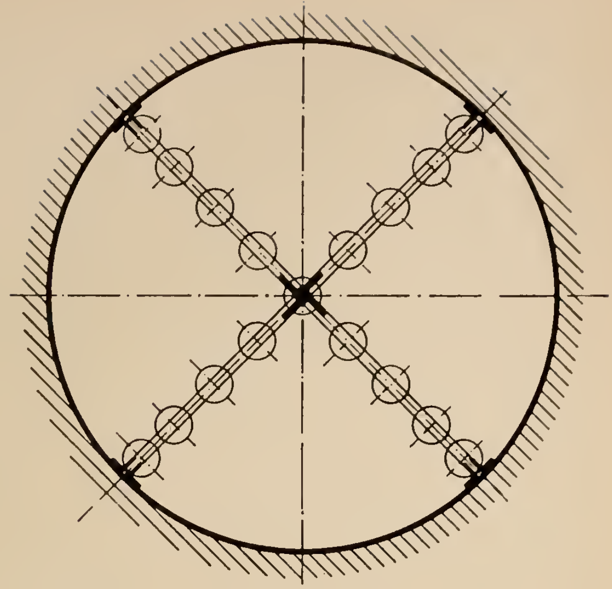

Fig. 4—Measurement in large penstock. Cross-shaped frame supporting thirteen permanently mounted meters.

The Gibson Pressure-Time Method

This method, invented by Dr Norman R. Gibson of Niagara Falls, N.Y., in 1919 is an application of Newton's second law of motion. This second law may be written in the form "The total change of momentum is proportional to the impulse of the applied force".

Consider a mass of water M in a penstock moving with a velocity v feet per second. Its momentum is Mv. If the turbine gates are closed in r seconds so that the velocity is reduced to zero the change in momentum is Mv. Some force P has acted upon this mass to bring it to rest and the impulse acting on the Mass M is Pt. Thus if quantities are measured in dynamical units.

$$Pt = Mv$$

The Mass M can be computed by making a survey of the penstock. If the impulse Pt is measured the only unknown in the equation is v from which the discharge is readily computed.

In practice a differential mercury u-tube is connected to peizometers at two sections of the penstock and one leg of the u-tube, a glass tube, is set up in front of a special camera at the rear of which a photographic film on a revolving cylinder records the movement of the mercury in the u-tube. A high intensity light is set up in front of the u-tube and a seconds pendulum in front of the lens cuts off the light each second, recording time on the film which is usually 11 x 18 in.

The glass tube through which the movement of the mercury column is observed is usually 1/2 in. or 5/8 in. outside diameter of uniform internal diameter and the other leg of the u-tube consists of a honed steel tube of a diameter suited to the test in hand. The glass tube is fixed to the front of the camera and its distance from the lens is such that the movement of the mercury is precisely duplicated on the film.

Instead of a single piezometer usually two or four piezometers are installed at each of the sections in the penstock. These are joined by a ring of piping around the penstock or, alternatively, by separate pipes led to outlets at a point convenient for connection to the Gibson instrument. The mass of water brought to rest, the M in the formula above, is that in the penstock between cross-sections through the two sets of piezometers.

As originally devised a single set of piezometers was used and the u-tube was of the simple instead of the differential type with the leg containing the steel riser open to the atmosphere. The mass of water brought to rest then extended back to the penstock intake and an additional measurement of variation in water level at the intake during closure was necessary. The simple set up is seldom used now. The method herein described is known as the differential method.

In Fig. 6 is shown a reproduction on a reduced scale of a Gibson diagram from a test of a turbine when developing 15956 hp. under a head of 104.6 ft. The closure of turbine gates commenced at point A and was completed at point B_1. The level of the mercury in the glass tube at beginning of closure was at the horizontal line through A and after the harmonic fluctuation of the mercury column have ceased, in about 30 seconds, it was at the horizontal line through B. The vertical lines are those marked on the film by the pendulum as it swings in front of the lens. On this film they are 0.814 in. apart. The position of point B_1 and the recovery line are computed from the information on the diagram but no explanation of this part of the computation will be attempted here. They are described in considerable detail in references 6 and 7.

In that part of the diagram above the recovery line from A to BB_1 abscissae measure time. Ordinates, measuring the movement of the mercury column, are proportional to pressure and the area

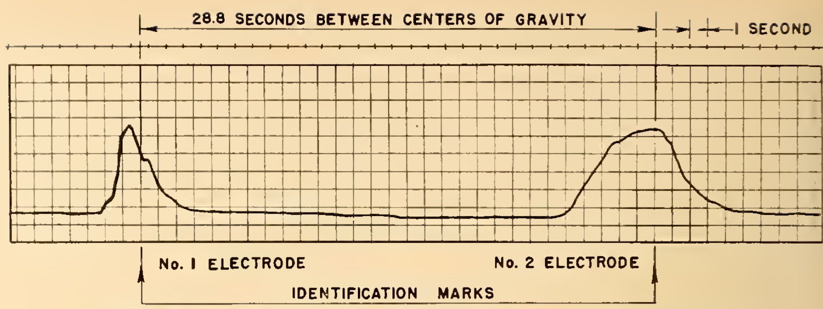
of the diagram therefore is a measure of the impulse or Pt.

The diagram measures the flow cut off as the turbine gates close. There is always leakage past the gates, usually less than one half per cent of the full gate flow. This is measured by a separate turbine gate leakage test and added to the flow recorded by the diagram.

An expert looking at the diagram in Figure 6 will detect at once that closure of the turbine gates was not complete at B B_1 but was at C. The area at C is very slightly greater than at B B_1 but for simplicity in this explanation closure is assumed to have been completed at B.

The method is most readily applicable to measurements of flow in circular penstocks or conduits of any diameter having a sufficient length to give a satisfactory impulse during closure of the turbine gates. Test codes usually demand that the product of length between piezometers and velocity of flow in the penstock shall be at least 200. It is not necessary that the penstock be straight or of uniform diameter. The method has been successfully applied in the short converging concrete conduits common in low head plants.

Many attempts have been made to apply the principle of the method by other devices than the instrument designed by Dr. Gibson, some of them simulating the steam engine indicator. All of these so far built have been inferior in operation to the simple mercury u-tube used by Dr. Gibson.



VOLUME OF TEST SECTIONS BETWEEN ELECTRODES = 5345.37 CU.FT.
AVERAGE TIME OF PASSAGE (ALL SHOTS) = 28.88 SECONDS
DISCHARGE (5345.37) ÷ (28.88) = 185.089 CU.FT./SEC.
=(185.089)(1728)(60) ÷ 231 = 83,074 G.P.M.

Fig. 5—Typical chart from Allen Salt Velocity Measurement.

The Poiran Thermometric Method

This method differs from those described in that it does not measure the quantity of water but instead measures the loss of energy or more properly the mechanical energy converted into heat as the water passes through the turbine. The method is based on the principle of equivalence of mechanical energy and heat. Some attempts to make use of the principle to measure the efficiency of turbines have been made in Germany and Canada, and probably elsewhere, but the technique was somewhat different from that developed by the engineers of Electricité de France.[9]

In tests conducted by The National Research Council (Canada) in cooperation with the Shawinigan Water and Power Company at Grand' Mere[8] the increase in temperature of the water between entrance to and exit from the turbine was measured by a pair of very accurately calibrated thermistors. This increase in temperature when converted to its equivalent in mechanical energy (per lb. of water) represents the part of the net head converted into heat (and lost) and enables a computation to be made of the turbine efficiency. Manifestly identical and very accurate thermistors must be used to measure the very small temperature differences. On the other hand this method measures a small quantity namely the losses which may be only 7 or 8% of the total energy whereas in other methods the useful energy generated possibly 92 or 93% of the total energy. An error of 20% in the losses is equivalent to only about 1% in the end result, the efficiency.

The technique used by the French engineers differs from that used at Grand' Mere in that the change of internal energy of the water at entrance to the turbine is determined for an adiabatic expansion which brings it to precisely the same temperature as the water in the tailrace.

In practice a probe is inserted in the penstock upstream from the turbine casing and through this a small quantity of water flows through an expander, with controllable head loss, and thence through a well insulated pipe to a measuring enclosure, also well insulated against heat loss. In this measuring enclosure a platinum resistence thermistor is placed and an identical thermistor immersed in the tailrace water. The thermistors have been previously calibrated by placing them in the same water bath and determining the setting of a Wheatstone bridge when the two thermistors are at the same temperature. It is claimed temperature differences of 0.001 of a degree can be detected. Investigations have indicated that considerable latitude is permissible in locating the probes and confirmed the uniformity of temperatures at all points in the penstock and tailrace for all ordinary cases.

The pressure in the measuring enclosure is now reduced by controlling the flow coming through the probe until the Wheatstone bridge is balanced and the temperatures in tailrace and the measuring enclosure are, therefore, the same. The pressure in the measuring enclosure is then accurately measured and its temperature observed (to tenths of a degree C.) The flow from the measuring enclosure is then cut off and the pressure there, which is now the pressure in the penstock, is measured. Special equipment enables these pressures to be very accurately determined.

Very briefly the theory on which the determination of the efficiency of the turbine is made is as follows:

The energy supplied to the turbine shaft per unit weight of water call H_u

$$H_u = (H_1 - H_2)(1 - \alpha) + \frac{jc}{g}(T_1 - T_2) - (Z_1 - Z_2)$$

$(H_1 - H_2)$ difference in heights of the water columns corresponding to the pressures in the measuring enclosure $= (P_1/w - P_2/w)$

w is the specific weight of water

α is a coefficient, function of H_1 and T_1, to determine the internal energy of the water (Clapeyron's equation).

T_1 and T_1 Temperatures of the water in tailrace and penstock.

j The mechanical equivalent of heat.

C The specific heat of the water at Temperature T_1 and constant pressure.

g The acceleration by gravity.

$Z_1 - Z_2$ Difference in elevation of points of reference of pressures P_1 and P_2

If H is the net head,

Turbine efficiency $= H_u/H$

This efficiency does not include mechanical losses in bearings nor power withdrawn by accessories (governor, lubricating pumps, etc.)

As the temperature in the measuring enclosure is brought to that of the tailrace by reducing the pressure in the enclosure, $T_1 - T_2$ becomes zero and

$$H_u = H_1 (1 - \alpha) + Z$$

in which Z is the difference in elevation of the measuring points.

Thus the procedure used, instead of requiring a precise measurement of a very small difference of temperature, reduces to a determination of the change of internal energy of the water when the pressure is reduced in the measuring enclosure until the temperature there is that of the tailwater. The coefficient varies with temperature and pressure and can be accurately determined. It generally lies between zero and 0.05.

The French engineers do not consider the method applicable for heads less than 100 meters or 325 ft. Numerous tests have been made on several high head plants and the results compared with tests in which the quantity of water was measured by current meters or weirs. In general the efficiency indicated by the Thermometric method differed from that determined by other methods by amounts varying from zero to one per cent. The results secured in three tests are shown in Fig. 7. Five others are shown in Table I.

Comparison of Four Methods

The neglect to treat various other methods of water measurement in test of hydraulic turbines is not intended to relegate them to a lower grade of acceptability. Volumetric and gravimetric measurements, generally considered to be of the highest order of accuracy, are very seldom applicable. The Weir is limited in its application to comparatively small flows. The Pitot tube has been used successfully in many tests. The travelling screen requires the availability of a straight, very uniform canal and, in other cases, experimental coefficients must be available. It might be argued that the rating curve for a current meter is an experimental coefficient but facilities are readily available for rating meters and experience has shown that the rating of horizontal axis meters remains constant. For the Weir also experimental coefficients are required but a great volume of data collected by many investigators has been crystallized in formulas acceptable for properly installed weirs within certain limits of head and other dimensions.

The first three methods briefly described above have been used most frequently for flow measurements in turbine efficiency tests with a very wide range of flow and the fourth has great promise for plants operating under heads of 300 ft. and upward. It has not received wide acceptance as yet, but it possesses certain merits within its range of application not possessed by the other three methods.

In comparing these various methods one must consider the accuracy of the results, the amount and cost of equipment required, the time required for preliminary preparations for a test, the degree of interference with normal operation of the power plant, the time required for the test proper and the time and expense involved in deriving the final results.

With regard to the accuracy of these various methods one can only reach a conclusion by comparing the measurement of the same quantity by two different methods. Table I submits such comparisons from various sources.

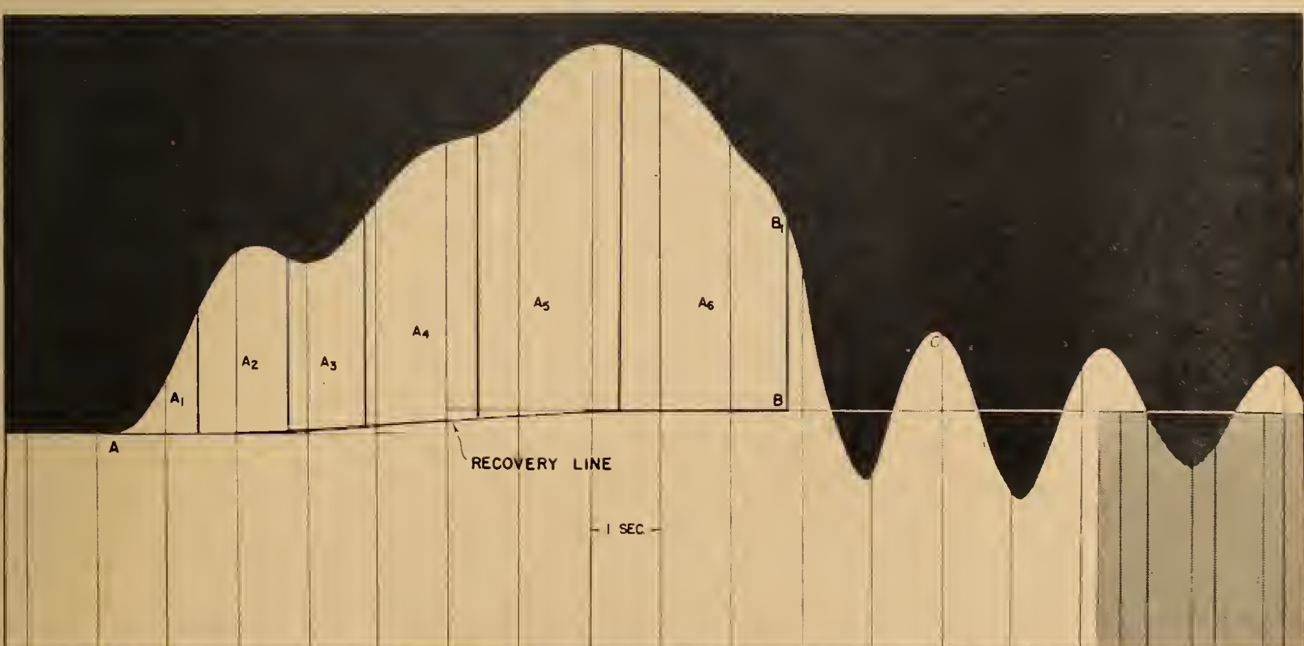
Absolute accuracy of course cannot be claimed in any case. For convenience in this comparison one method in each case has been given a value of 1.000; the figure on the same line under another heading shows the relative quantity as measured by the other method. For example at N.D. de Briancon the weir is marked 1.000 and the Thermometric Method 1.005. This indicates that the Thermometric method gave a discharge half of 1% higher than the weir. It must not be inferred from this that the weir is assumed to be absolutely accurate.

The various methods seldom differ from each other by as much as 1%, in fact agreement is usually much closer than that. All comparisons available have not been shown but of those omitted none was left out because of lack of agreement.

In the final Kinlockleven tests four series of runs are shown, in Series I and II at about 63 cu. ft. per sec. and in Series III and IV at about 75 cu. ft. per sec. The average divergence of current meter and salt velocity in Series I and II is considerably greater than in other cases. This is surprising as in the preliminary tests there at a wider range of flows average divergence was only 0.13 % and maximum in any one run was 1.3%.

The current meter method has been used more widely than any other and in Europe particularly has been developed to a high degree of perfection not only with regard to the instruments and their accessories but also in the standards set for accurate measurement. On this continent the method is thought of as

Fig. 6—Typical Gibson Diagram.



applicable to measurements in open channels or at the intake to a low head plant. In European practice it is used also in penstocks as indicated above even under very high heads.

Reference is made above to the use of movable steel frames to support the meters and bellmouthed structures to improve conditions at the metering section. Manifestly the bellmouth adds to the cost of the test, may be difficult to install and interferes with normal operation of the plant during its installation. The steel frame built to support the meters, sometimes much more elaborate than that illustrated in Fig. 1, also may add to the cost of the test as it is not likely to be applicable, with revision, to tests at other plants.

In current meter measurements in penstocks also special arrangements to support the meters, as illustrated in Fig. 3 and Fig. 4 involve expense additional to the test equipment proper and for their installation interfere with normal operation of the plant although perhaps not for a great length of time.

Criticism has sometimes been levelled at the Gibson method and the Allen Salt Velocity method on the score of special and expensive equipment being required. A comparison of present day costs in two cases may be of interest. A complete Gibson instrument built in 1958 of essentially the same design as Dr. Gibson's original instrument but possessing many minor improvements cost between $9,000 and $10,000.

This included the Gibson instrument, lamp, film drums, glass tubes, steel risers, shipping cases and calibrations. A quotation received about the same time for 12 meters for use in a test of a large plant was $6,084. This included 12 meters, a 14 pen chronograph, clock, meter calibrations and plaster casts of propellors, and shipping cases.

It must be kept in mind that the equipment for both Gibson tests and current meter test will be usable over many years. Two Gibson instruments built forty years ago and used in tests of about 200 turbines are still in use. Minor revisions and replacements have been made from time to time such as new risers and lamps but these have involved expenditures amounting to a small part of their original cost. The same is true of the current meter equipment; some Ott meters purchased by the author 30 years ago are still in service.

The author has no good information regarding the cost of equipment for the Allen Salt velocity method and the Thermometric method but believes it would be less in each case than for the current meters and accessories quoted above.

Table II.

Method	*Weight of Equip. lbs.*	*Installation of Equip. Man Hours*	*Unit out of Service*	*Duration of Measurements*	*Measurements of Discharge*	*Comments on Col. 3*
1	2	3	4	5	6	7
Current Meter	450	20.5			27	Mounting Meters Measurement of pipe
Pitot Tubes	725	28			12	Mounting Pitot tubes Measurement of pipe
Salt Velocity	825	28	About 2 days	9 hrs 15 mins (2 days)	18	Mounting Valves
Salt Titration	1375	23			9	Complete Mounting Sequence

Data are given in Table No. II regarding amount of equipment, preliminary preparation time required for a series of comparative measurements of flow in a 40 in. penstock under a head of about 900 ft.[10]

It should be noted that this was not a test of a turbine but a comparison of measurements of flow by four different methods. The flow was practically constant at about 63 cu. ft. per sec. on the first day and about 75 cu. ft. per sec. on the second. If a turbine test were made covering the full range of capacity of the unit, measurements would probably be at about 25 different rates of flow; the duration of the measurements would be increased somewhat for the current meter and salt velocity measurements and greatly increased for the Pitot tube and salt titration methods. This is because on changing the rate of flow some time must be allowed for flow throughout the system to become stabilized and the duration of a single measurement for the third and fourth methods named.

Special equipment provided in these tests enabled the current meter discharge to be computed for each run in about 15 minutes by means of a hand calculating machine and about five minutes by an electrical calculating machine. Each of the 27 measurements indicated represents two to ten measurements of discharge.

For the Pitot tube a complete set of readings at one rate of flow required about 75 minutes and computation of results about one hour.

For the salt velocity method injections were possible at intervals of one minute and, at one rate of flow, ten separate measurements were possible in ten minutes. Each of the eighteen measurements indicated in Table II represents the result from about 10 salt injections. Evaluation of results appeared to require more time than the corresponding operation for the current meters.

A direct comparison of these results with the Gibson Method is not possible but complete records are available for many tests. One of these in which a single unit rated at 47,000 h.p. under a net head of 133 ft. was tested is selected as a convenient example. Test equipment shipped to the plant weighed 700 lbs. but this did not include electrical instruments for measurement of power output of the unit. Preparatory work required slightly over 1½ days including setting up of Gibson instrument, headwater, tailwater and net head gauges, gate scale and gauges for measurement of rack and penstock losses and preparation of a photographic darkroom. The unit was out of service from 1 p.m. to 5.30 p.m. for measurement of turbine gate leakage, inspection and adjustment of a governor on a Saturday afternoon and was then restored to service until 10 o'clock the next morning. Gibson runs commenced at 10.35 a.m. on Sunday morning, 26 runs were completed at 3.28 p.m. and the unit was restored to normal service at 4 p.m. Thus the unit was out of normal service for ten hours but as these hours were on a Saturday afternoon and Sunday when system load was reduced, and spare capacity was therefore available, the test did not interfere with normal operation of the plant. Preparatory work in this case required somewhat less time than usual, but if more units than one are to be tested in a plant much of the preparatory work would apply to all units.

Corresponding data are not available for the Thermodynamic method but the author would judge from observations of tests that the equipment would be as low in cost, bulk and weight as for a test by current meters, and that preparatory work and interference with normal operation of the generating equipment would be no longer and might even be less than by any of the other methods.

The following comments summarize the conclusions reached by the author regarding these four methods of conducting tests.

1. Under satisfactory conditions for their application all four methods attain the same degree of accuracy.

2. Cost of equipment for a test is considerable in all cases, the current meter method and, possibly, the Thermodynamic method having a slight advantage over the others.

3. Weight and bulk of equipment is appreciable in all cases the current meter method losing its primary advantage if meter frames and supports are taken into account.

4. Time required for preliminary preparations will depend on the individual case under consideration. Table II shows some advantages for the current meter method but in most practical cases it would lose this apparent advantage. For tests at plant intakes and in open canals it might far exceed other methods.

5. The Gibson Method and the Thermodynamic Method probably interfere with normal plant operation to a lesser degree than other methods. This is because with them there may be no interference with normal plant operation during preliminary preparations whereas the current meter and salt velocity methods do so at that time.

6. The time required for a complete test of say 26 runs as in the case of the Gibson test referred to above would be about the same for all methods. If the time required for rating of current meters is taken into account the other three methods would have a distinct advantage.

7. The time and expense for deriving the final results for discharge is probably least with the Salt velocity method. With modern electronic equipment the current meter method might equal it. Without this the Gibson Method and the Current Meter Method would be about equal.

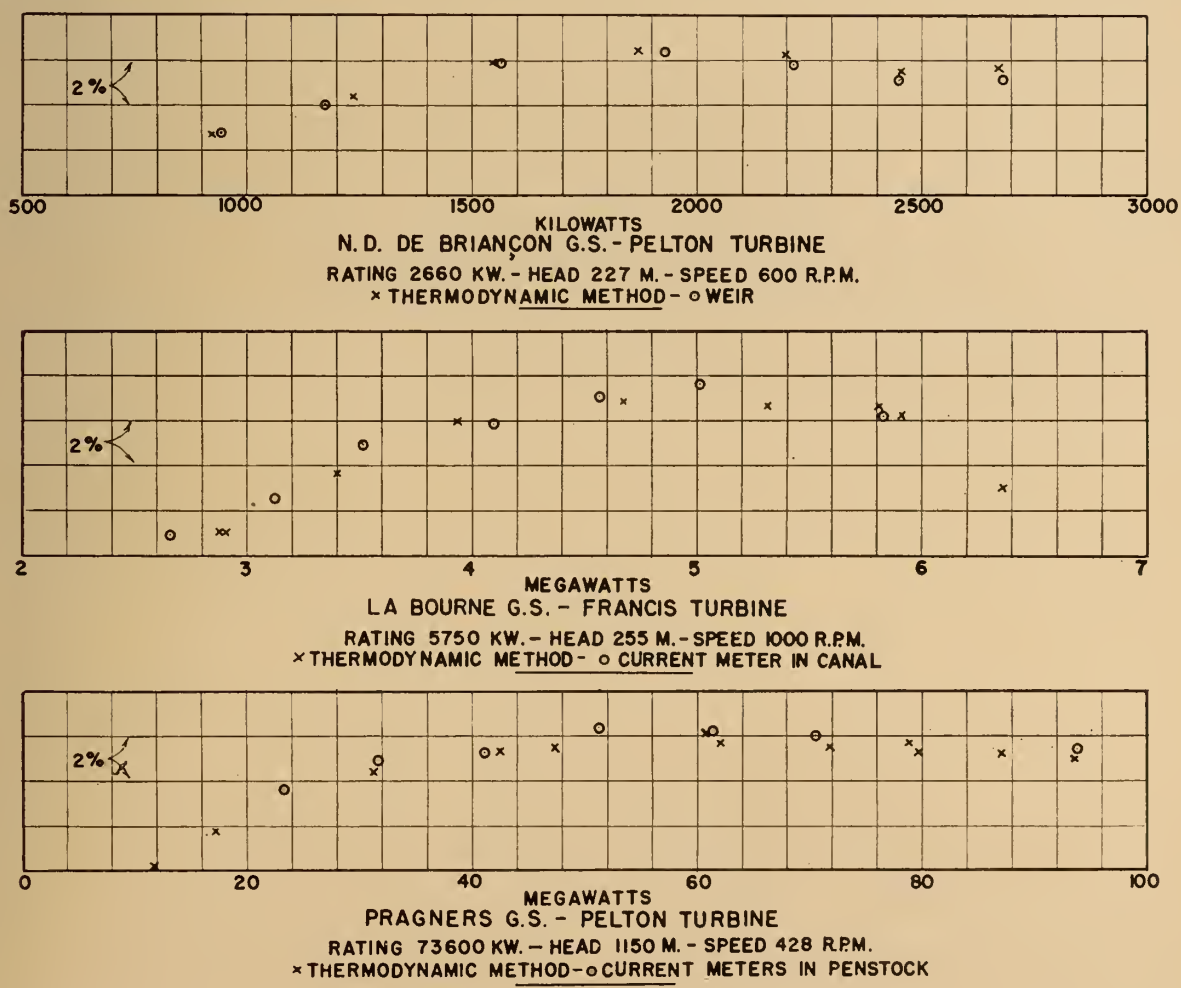
Only brief reference will be made to the two other items in an efficiency test of a turbine namely the head acting on the turbine and the power output. These are measurements that must be made with precision if satisfactory results are to be secured. They are dealt with at some detail in various other articles and test codes. This paper therefore, confines its discussion to the measurement of water passing through the turbine.

The final result sought in a turbine test is a record of capacity and efficiency of the machine along with numerous ancillary results. The flow having been measured, computations to secure this final result are the same no matter what method of water measurement is used. In the author's experience the time required to carry the results to the desired completion generally is as great as to secure the record of flow.

Models of Turbines

Hydraulic turbines have attained their present high efficiency through the immense amount of experiment on turbine runners and settings in laboratories all over the world. Nearly all turbine manufacturers maintain labor-

Fig. 7—Measurements of Turbine Efficiency by Weir and Current Meter compared with measurements by the Thermometric Method.



atories in which tests of small scale models are used to constantly improve their products. A test of a turbine after installation involves considerable expense, may not conform with conditions, names in the contract, as, for example, in the head available at the time of test, and a satisfactory degree of precision in all measurements may be difficult to attain. Tests in the laboratory can be made at more moderate costs, with more complete instrumentation, greater speed, favourable weather conditions and frequently at a range of heads far exceeding the range available in the field. This has led to proposals to substitute laboratory tests of turbine models for field tests of the prototype. It is proposed therefore to discuss laboratory tests and to explore this proposal.

In order to derive the behaviour of the prototype from the results secured from the model it is necessary that between model and prototype it is necessary that there is not only geometric but also dynamic and kinematic similarity. For dynamic and kinematic similarity velocities and forces acting in model and prototype must be similar. In many hydraulic models gravity and inertia are the dominant forces and a relation between model and prototype is readily determined by the Froude number. For hydraulic turbines gravity, inertia and fluid friction are dominant, thus both the Reynolds and Froude numbers apply. In this case as with ship models, there is no simple method of stepping up from model to prototype.

The necessity of having dynamic and kinematic similarity in model and prototype should be stressed. Tests of a turbine model in an open flume, for example, may give misleading results when applied to a prototype with penstock, spiral casing and draft tube, full similarity not being achieved.

Numerous formulas have been suggested for the purpose of stepping up the performance of a turbine model to the prototype. A survey of seventeen of these is presented by Dr. S. P. Hutton,[11] Chief of the Fluid Mechanics Division of The Mechanical Engineering Research Laboratory at East Kilbride, Scotland.

These may be placed in three groups: those in which all losses in the turbine are assumed to behave like friction losses, secondly, those in which the losses are divided into frictional and kinetic components, and thirdly purely empirical formulas. Reference will be made to only a few of these that are in common use although several others are not without merit. Those of Camerer, Staufer and Moody (1935) are in the first of the three groups. Akeret's formula, in common use in France and to a lesser degree in America, is in the second group and the various Moody formulas, with the exception of the one mentioned above, are empirical and therefore in the third group.

Moody in his first formula divided the losses into frictional and kinetic parts but found that for practical purposes it could be used in the simpler form proposed later. A later Moody formula included the effect of head. However, Moody explained at a later date that the exponent of the head term was uncertain and the head term therefore, should be omitted.

The Moody formula of 1942 is the one now in general use and is:

$$\frac{(1 - E)}{(1 - E^1)} = \left(\frac{D^1}{D}\right)^{1/5}$$

where

E is efficiency expressed as a ratio

D is diameter of turbine runner

E^1 and D^1 are corresponding terms for the model

The Ackeret formula somewhat simplified to eliminate new symbols is:

$$\frac{(1 - E)}{(1 - E^1)} = 0.5 + 0.5 \left(\frac{R^1}{R}\right)^{1/5}$$

in which R is the turbine Reynolds number

$$R = \frac{\sqrt{2gH} \cdot D}{\surd}$$

$\surd$ = kinematic viscosity

It seems to be the general consensus that the Moody formula gives an estimate of the efficiency of the prototype that is too high and the Ackeret formula too low at optimum conditions of operation. It is the practice of several turbine builders to use the averages of these two formulas in their estimate of the step up from Model to prototype.[12] From an analysis of the nature of the losses, Dr. Hutton concludes that, at optimum efficiency, about 70% of the losses are frictional and 30% kinetic. Thus the Reynold's number correction should be applied to 70% of the losses and he submits a new formula for Kaplan Turbines which is:

$$\frac{1 - E}{1 - E^1} = 0.3 + 0.7 \left(\frac{R^1}{R}\right)^{1/5}$$

Applying this and the other two formulas to a few specific cases he finds that the new formula agrees with the average of the Moody and Ackeret formulas very well at optimum conditions and for lesser flows than those at optimum conditions but that at larger flows the results are not as satisfactory.

Dr. Hutton in his analysis is dealing with Kaplan turbines and says that it "is asking a lot for one scale formula to be applicable to both Francis and Kaplan Turbines, because the distribution of the losses in the two cases may be quite different." In so far as the Francis Turbine is concerned therefore one must have reservations regarding the accuracy of the results for the prototype derived from tests of a model by any of the step-up formulas. The most widely accepted formulas for this purpose at the present time appear to be the Moody formulas in the form given above, the Ackeret formula or the average of the results from them.

The author is not prepared to accept the test of a model runner, with adjustment of results for dimensions, head etc., as a satisfactory substitute for a field test of the prototype. His reasons are as follows:

(a) The model must have exact geometric similarity to the prototype. This is usually attainable in the Kaplan and fixed blade propellor runner but very difficult with the Francis runner.

(b) Dynamic and kinematic similarity must be attained. This would require a complete installation of model runner, penstock, scrollcase and draft tube something not always readily arranged within the limitations of the laboratory.

(c) There is no step-up formula based on model results that can be relied upon to give exact results at all points for the prototype.

(d) Measurements of water quantities by laboratory methods (Weirs, Venturi meters, etc.) are subject to as great or greater errors as field methods such as the Allen Salt Velocity and Gibson Methods.

(e) Measurement of power output in the laboratory is, he considers, subject to greater errors than measurement of power output in the field where the generator is used as the brake.

(f) The various secondary results from a field test, useful in plant operation, would not be available.

Test Codes

Almost all countries in which the manufacture of hydraulic turbine equipment or its application are of importance have codes governing the conditions under which tests of hydraulic turbine installations must be made. Among these might be mentioned the Swiss, French, Swedish, Italian and American codes. While these are in general agreement as to acceptacle procedure for tests, greater uniformity is desirable. This has become of greater importance as turbine manufacturers from different countries compete for contracts in international trade. Manifestly it is of importance that all should be required to conform to the same conditions.

While their primary purpose is to define acceptable standards for tests they often go far beyond this in suggesting to the test engineer methods of

(Continued on page 80)

BUSINESS TRAINING FOR PROFESSIONAL ENGINEERS[1]

R. J. Bedard, *former editor of "Genie Construction".*

SHOULD engineering schools give their students more training in industrial organization and management, personnel and labor relations, law, and other subjects generally associated with business administration?

The replies to this question are far from unanimous. Some educators and managers argue that the function of an engineering school is to teach engineering. They maintain that industry is the best place to learn about business administration; furthermore, that the pressures on the curricula are such that nothing can be dropped, they say, in order to add more business training in the engineer's curriculum.

To this, many people in education and in management reply that the practice of management is eventually part and parcel of the career of a professional engineer; consequently, they maintain, he should be adequately prepared to shoulder these responsibilities.

There is much evidence that engineers are not happy with the training they have received (or not received) in matters pertaining to industrial management. The survey made by the Corporation of Professional Engineers of Quebec last year has brought this fact into sharp focus. As shown in Table I, less than one half the engineers, and in some cases, less than one quarter, are satisfied with their training in political economy, industrial organization, law, personnel administration, etc.[2]

Should engineering schools give their students more training in business administration? This is no simple question, especially if we keep in mind the pulling and hauling of engineering curricula over the past two decades. The reforms urged recently have suggested that:

1) Engineers should spend a maximum amount of time on the study of the basic principles of physics, chemistry and mathematics;

2) Engineers should be educated as well as trained. In order to give engineering students an education, it has been proposed that they spend at least 20% of their class time on the study of the liberal arts. Needless to say, business subject-matters are not considered to be parts of the "humanistic-social stem" of engineering curricula;

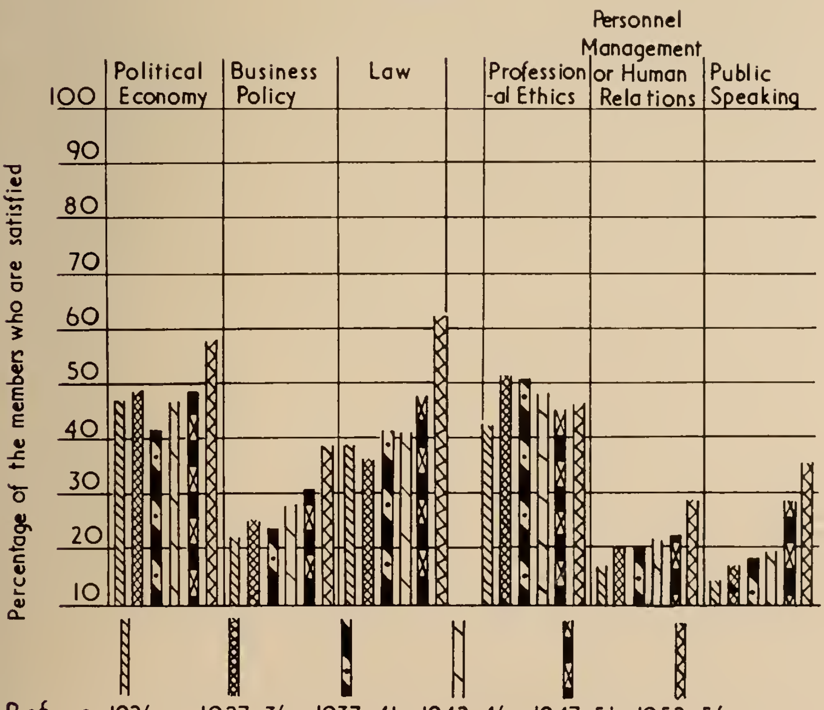
3) Engineers should be "broader," but at the same time the standards of professional competence must be maintained if not raised. Nobody wants "the bridges to collapse, the light to fail, the water to become polluted nor the oysters to become radio-active."

Engineering schools cannot be all things to all men. Choices must be made. To determine what things are the more important, possibly we should try to find out the career patterns of professional engineers.

A survey made by Purdue University among 85 large employers who had a total of 75,565 professional engineers on their payrolls has shown that 41.9% were concerned with research and development, 30.4% were in the actual operation of the business and 27.7% were mostly busy with some human relations aspect of industry.[3]

John B. Rae studied closely the careers of M.I.T. graduates and he found that "nearly half the alumni of M.I.T. have gone into business roles other than that of professional

Table I



engineering."[4] Rae thought his findings were a fair representation of engineers' careers all over the United States.

The fact that a large number of engineers turn managers is in no way exclusive to the U.S.A. In Germany, 36% of the 2,018 graduate executives listed in the directory of directors called "Adressbuch der Direktoren und Aufsichtsräte" hold engineering degrees.[5]

According to the 1957 Survey of the C.P.E.Q., about 65% of the members are employed in executive and supervisory capacities. These figures give a good idea of the career pattern of the professional engineer in Canada, the United States and Germany.

Engineering schools are making every possible effort to give their students the kind of education that will enable them to develop their personal abilities to the limit and at the same time to serve the community as professionals in the best possible way.

The prime concern of the engineering graduate it is expected, will be technology. His curriculum is arranged accordingly. But since a large number of engineers eventually progress into managerial jobs, it is only fair to question what engineering schools are doing for the graduate whose prime function will be management. In other words, are Canadian universities doing an adequate job for the engineer turned manager?

Our engineering schools generally give their students a full course in political economy. To what extent does this course give them a better understanding of industrial operations? It is hard to say. Occasionally, the students are required to pick a full course in accounting or finance or business policy. But this is about all.

Some of our schools of applied science operate an "à la carte" system. Students often take advantage of this to pick law, corporate finance, industrial and labor relations, etc., among their electives.

By any standards the business diet of Canadian engineering graduates is quite weak. When these boys come into industry, management must start teaching them the very elements of the operation of a business. This is often frustrating for the young engineer, and sometimes quite irritating for management. The results of this are well known: a) inadequate growth for the average engineer during the first five years of his professional career; b) frustration and unrest among engineers.

Possibly colleges of technology in Canada could consider giving their pupils a more adequate preparation in this area.

One of our engineering schools is already offering a Business and Engineering course: the School of Applied Science at the University of Toronto. This course is the only one of its kind in the country.

The Business and Engineering option is open to those young men who intend to "get a good technical background for a career in business management." About one fourth of class-time is spent on the study of administrative techniques and problems. Field work plays an important part in the course: the program provides for a minimum of 1,200 hours of practical experience in business or industry as a condition for a Bachelor's degree.

Course IV, as it is known on Varsity campus, is conspicuous by the number of students it attracts each year. On a total registration of 1,985 in 1958-59, one hundred and forty-eight students are taking Engineering and Business Administration.[6]

Indeed we do not suggest for a moment that this is the model on which other Canadian universities should pattern a business training for their students. Although a truly remarkable venture, this is not what we consider to be *the* course.

Over the years, engineering schools have made quite a few successful experiments in the training of their students for eventual managerial responsibilities. It may be worthwhile for our colleges of applied science to draw on this vast pool of experience. Two types of business training are at present offered to engineering students:

A) the horizontal type, that is, business training that attempts to develop broad understanding of administrative problems;

B) the vertical type of training which combines regular engineering instruction with some courses in one particular phase of management or with administrative training for a specific industry. We will now review briefly some of the more effective programs of both types.

The Horizontal Type

1—Massachusetts Institute of Technology a) At M.I.T. the undergraduate course has a duration of four years. The first year is common to all sections. Then the students make a choice of one section among thirty-four.

Sections XVA and XVB (Business and Engineering Administration) offer the students a solid grounding in both engineering and management. The programs of Course XVA and Course XVB are made up of about 50% of technical subject matters (physics, chemistry, maths., drawing, surveying, etc.) and of about 50% of non-technical subject matters ("humanities") and a wide variety of electives related to business administration.

These courses were started in 1914 and ever since have been very popular with Technology students. About 12% of the degrees awarded by M.I.T. since 1920 have been given to people who have picked Business and Engineering Administration courses. During the year 1956-57, a total of 281 students out of a total of 3,656 were registered in these courses.

b) Recent college graduates who have majored in some fields of engineering or natural science can take post-graduate instruction at M.I.T.'s Graduate School of Industrial Management.

The School offers young engineers of outstanding ability a two-year course that entitles them to the Master's degree of Science in Industrial Management.

The purposes of the School are: 1) to assist young men to fit themselves for positions of future business leadership; 2) to study and report on means of increasing the effectiveness of industrial management. "The School is firmly committed to the objective of providing a solid foundation for general management. Students do not concentrate in narrow fields; they don't study skills that can be learned as well or better on the job. Instead, the School concentrates its attention on those areas where learning by practical experience is most difficult."

The foundation subjects studied in the first year fall into four categories: a) those dealing with the environment in which management operates; b) those focusing on the human aspects of administration; c) those devoted to acquiring familiarity with the tools of management (statistics, accounting, etc.); d) those representing preliminary explorations of management functions (production, finance, etc. . . .).

The second-year curriculum includes eight one-semester advanced subjects plus a thesis. Each student picks his own courses; they are generally broadly distributed.

c) The Executive Development Program was inaugurated in 1931 by Prof. Irwin Schell with six students. Since then the E.D.P. has expanded steadily. The Sloan Fellows — as they are known on M.I.T. campus — are young men with ten years or more of successful engineering experience in industry. They are selected on the basis of their promise of growth into major executive responsibilities. Eighteen students are selected among candidates nominated by the top management of a sizeable number of firms, large and small, from all over the United States and from abroad as well.

These young executives spend twelve months at M.I.T. to study in depth the fundamentals that underlie sound management action. Residence in Boston area is compulsory. Since 1953-54, more financial assistance on the part of the Alfred P. Sloan Foundation has enabled M.I.T. to have each year two such groups of eighteen young executives.

During the E.D.P., the Sloan fellows experience a widening of horizons and a deepening of understanding of the environment of industry. When they return to their companies they know more thoroughly how the demands of production, personnel, marketing, financial control, all fit into a total operation.[7] Table III illustrates the makeup of the Program.

Table II
Occupational Pattern of 75,565 Engineers

Degree	(A) New Developments	(B) Operations	(C) Human Relations	Total
B.Sc., B.Eng.	26,541 83.8%	20,058 95.9%	19,489 93.3%	68,086 90.1%
M.Sc., M.Eng.	4,119 13.0%	895 3.9%	1,346 6.4%	6,360 8.4%
D.Sc., D.Eng.	1,016 3.2%	42 0.2%	61 0.29%	1,119 1.5%
	31,696 41.9%	22,993 30.4%	20,896 27.7%	75,565 100%

NEW DEVELOPMENTS: Those who deal primarily with new techniques, ideas or products. This includes research, development, design.

OPERATIONS: Those whose primary function is the operation of existing plants or designs. This would include production, operation, service.

HUMAN RELATIONS: Those who deal principally with the human aspect of technology. This would include production supervision, sales, personnel administration, etc.

2—Carnegie Institute of Technology — A six-million-dollar grant by the Mellon Foundation enabled C.I.T. to create the Graduate School of Industrial Administration in 1949. Since October 1952, the School presents four different programs for the training of engineers in business management.

a) The Master's program. For the students who have had training in engineering or science and who have potential for future industrial leadership. The average age of the students is 28. Nearly all of them have had two or more years of actual experience in industry. The annual intake of students is limited to thirty.

The program is two years in duration. During the first year they study the fundamental principles of marketing, production, personnel, labor relations and finance. The required courses of the second year focus on the formation and integration of policies, integrating the several aspects of management studied during the first two terms, and relating the formation of business policies to the changing world in which modern business exists. Elective courses provide advanced training for each student in the area of management in which he is particularly interested.

b) Carnegie "Tech" offers an engineering course that enables the student to get a B.Appl.Sc. degree in four years; we have just seen that C.I.T. is also offering a two-year program leading to the Master's degree in Industrial Administration.

The College of Engineering and the School of Industrial Administration have started a special program whereby students of outstanding ability may combine the undergraduate degree with the Master's degree in a total of five academic years.

c) In order to train scholars for teaching and research, C.I.T. has inaugurated two doctoral programs related to business management. One is known as the Ph.D. program in Industrial Administration, the other, the Ph.D. program in Industrial Economics. These two doctoral programs do not accept more than ten new students each per year.

d) The Program for Executives is intended for mature business administrators already holding positions of responsibility in industry. The special nine-week programs offered by the School each Spring are intended to provide an opportunity for these executives to study policy formation at the top executive level.

3—Federal Institute of Technology, Zurich — The Federal Institute of Technology started a program of study in administrative techniques and industrial organization (Betriebswissenschaften und Fabrikorganization) in 1936. This course is an adjunct to course IIIA (mechanical engineering) and IIIB (electrical engineering). During the first five terms all the students take the same basic instruction. Then they select a field of study of special interest to them: many students major in engineering administration.

Previous business experience plays a prominent role in these programs. Students must have had at least one year of experience in industry before they are accepted. During their school years they must spend several months in various field work assignments and then write up reports about their observations.

In 1929 Federal "Tech" created a Betriebswissenschaftliches Institut (Institute for Management Research) whose functions are research and the training of administrative engineers. This course is an outstanding example of how business and engineering instruction can be blended together in a highly integrated course. Table IV gives the analysis of the program.

The Vertical Type

1—Stanford's Civil Engineering — Construction Management Program— Every year more civil engineering graduates go to work for contractors and construction firms. Stanford University thought it seemed appropriate to offer courses leading to the Master of Science in Civil Engineering-Construction.

Stanford's graduate construction management program actually began several years ago. Prof. J. Fish, former head of Civil Engineering, was aware that many civil engineers gravitated or were forced into administrative work. It was apparent that these men were badly handicapped because they had no background whatsoever in finance, accounting, personnel, law, and other subjects with which they, as administrators, had to deal. These lessons had to be learned after the men became managers. It was to fill these gaps that prof. Grant developed a graduate program in civil engineering-administration. It combines advanced work in technical subjects with administrative courses offered either by the Engineering School or the Graduate School of Business or the Law School or other departments of the University. A sizeable number of graduate students have now completed this program, while many others have taken some of the courses offered.

The master's program requires 45 or more quarter units which include: 1) a core of mandatory graduate construction and business courses: Construction Administration, Advanced Construction Equipment and Methods, Special Construction Problems, Advanced Engineering Economy, Depreciation of Plant and Equipment. 2) Two required courses in advanced civil engineering: Advanced Foundations Design and Harbor Structures. 3) Elective courses in business and industrial engineering. 4) Elective courses in advanced civil engineering.

Contractors of the San Francisco area have shown much interest in this course. Conversely, the alumni

of the Stanford Civil Engineering-Construction Management Program have proven their worth in the construction industry.

2—Industrial Relations at "Caltech." — California Institute of Technology gives engineering students who so desire a solid background in industrial and labor relations. The Dept. of Industrial Relations was opened at "Caltech." in 1939. Its growth has been phenomenal. The numerous publications of the Department are known throughout the free world.

In the Section of Industrial Relations as in all the other departments of the Institute, research by the staff is a major ingredient of good teaching. Many students take advantage of this high-grade teaching to get acquainted with the personnel and industrial relations problems of a technology-inclined society.

During 1955-56, one hundred and twenty-five students regularly attended classes in labor economics. As a further contribution to the development of professional engineers into managers, the Dept. of Industrial Relations is offering CalTech's alumni seminars and refresher courses dealing with labor relations, personnel selection, and recently, with the management of scientific research.

3—Industrial Engineering at Cornell — Industrial engineering means different things to different people. Quite a few American and foreign universities give instruction in industrial engineering. The Department of Industrial and Engineering Administration of Cornell's School of Mechanical Engineering gives a most interesting and most effective program.

"The Cornell Plan is based upon first developing a sound mechanical engineering program and then integrating with this the necessary business management principles and techniques. A student cannot become a good industrial engineer or administrator unless he is first a good engineer in the true sense of the word. Thus industrial engineering at Cornell is not approached through a general business course with a smattering of engineering or science courses, but rather from a thorough grounding in engineering."[8]

It should be noted here that Cornell is one of the few engineering colleges of the United States to have adopted a five-year course across tho board. The Industrial Engineering course concentrates on fundamental

Table IV

concepts rather than on techniques. Its strength lies in the sequence of the subject matters as well as in their integration with the other engineering subjects.

4—British Engineering Schools offer courses geared to the needs of many different audiences — The Dept. of Management Studies of the Polytechnic, London, and the School of Industrial Administration of the Manchester College of Science and Technology, offer a wide variety of courses to engineering and non-engineering personnel.

The latter, for instance, repeats each year no less than seventeen different programs. Space limitations will not allow us to study in detail every one of these programs. A part-time day course and one evening course have been arranged with the co-operation of the Institution of Mechanical Engineers. The "Administration for Chemist" course has also been opened to give chemical engineers an opportunity to become more familiar with management problems.

Among the many other programs by Manchester College of Science and Technology, let us mention "Administration for Works Managers," "Discussion Groups for Foremen," "Certificate Course in Foremanship."

By so doing, the British colleges of applied science perform a most valuable function in the community. They also serve the engineering profession in a most useful way.

We have found in the first part of this study that more business training is a must for the professional engineer. This, we have seen, is necessary in order to enable him to achieve a full measure of personal development. The management of private and public affairs is part of the responsibility to society of one half the engineers. A knowledge of the fundamental principles of management should in some way be part of the engineer's training.

Some colleges of technology are training men for the management of "men" just as well as they do for the management of "things". In Canada, however, this kind of instruction is next to non-existent. As Robert Doherty said a few years ago, "engineers are literally flung into industrial management and other responsibilities where social and economic elements are dominant, and they have to learn to deal with these new responsibilities while on the job and with no fundamental preparation such as he has had in engineering itself."[9]

Then, what should Canadian engineering colleges do to close the gap?

Over the past two decades this question has been hotly debated by both educators and managers.[10] No final answer has yet been found.

To find out in what direction our engineering colleges should move about management training, more research is needed. Possibly our engineering societies should get together with engineering faculties for a thorough re-examination of the problems involved in management education by engineering schools.

At the undergraduate level, it is doubtful whether engineering schools would serve a useful purpose in dropping fundamental scientific courses in order to include more business subject-matters. In my opinion, a more effective use of the time already alloted to business topics could give undergraduates a better basis upon which to build a career in management.

Canadian engineers should have more opportunities for *graduate work* in business administration. Careful consideration should be given to the necessity of creating four departments of management studies in some of our leading engineering schools, one in the Maritimes, one in French Canada, one in Ontario and one in Western Canada.

What type of training should be offered? This is a question each school should answer for itself. One thing is sure — the instruction given by the schools of commerce generally does not fit the needs of the professional engineer.

Post-university studies

In order to train the managers they need, many firms have become educational organizations as well as business enterprises. Personnel development programs have been arranged both inside and outside business. These programs are intended to enable their participants to take over managerial responsibilities. Many engineers have taken these courses which have proven very profitable to them. These management development programs have a big shortcoming however: "Too little and too late," to quote Colonel Urwick.

Management training is most effective when the young man has been practising his career about five years and has tackled business problems. He is not yet overloaded with business or family responsibilities. He has time left to think and to study.

Engineering schools would perform a most useful service for their alumni if they gave them post-university management courses adapted to their needs and previous training.

Some may challenge these views. This article intends to turn the spotlight on the problems of the engineer turned manager. The hope is that people will start thinking about what can be done to give the professional engineer more opportunities to attain ever higher standards of leadership.

procedure and instrumentation not readily found elsewhere.

There is nearing completion at the present time an International Test Code, the product of Technical Committee 4 of The International Electrotechnical Commission. This, it is hoped, will have general acceptance when completed. At the last meeting of this committee held in Zurich, Switzerland in October 1957 forty-two delegates (three from Canada) were present representing thirteen different countries, a meeting characterized by a most gratifying spirit of co-operation. The products of the labours of earlier plenary sessions and of some eight subcommittees are now in the hands of an editorial committee which will probably report at a meeting to be held in July of this year.

Acknowledgments

The author wishes to acknowledge gratefully the assistance he has had from various sources in the preparation of this paper.

Prof. Leslie J. Hooper reviewed and revised the part of the text dealing with the Allen Salt Velocity Method and supplied other information.

Material available from work with Dr. Normal R. Gibson has been freely drawn upon.

Messrs. M. Remenieras and S. Ferry of Electricite de France and Mr. Pierre Misson of Neyrpic, Grenoble, France supplied data regarding the Thermometric Method.

Data on certain model tests and related matters were made available by Dr. H. S. Van Potter and Mr. R. S. Sproule of the Dominion Engineering Company, Montreal.

Dr. S. P. Hutton of The Mechanical Engineering Research Laboratory, East Kilbride, Scotland supplied material on comparative measurements of water quantities.

Discussions with Prof. Hans Gerber of Zurich, Switzerland and Prof. G. Hutarew of Stuttgart, Germany have been of great value.

Data have also been made available by former associates of the author at the Hydro Electric Power Commission of Ontario, particularly Messrs. A. E. Aeberli, J. B. Bryce and R. A. Walker.

INSTRUMENTATION IN INDUSTRY

The Textile Industry

THE TYPES of plant covered in a survey, by questionnaire, of the textile industry in Canada varied quite considerably. The range ran from the manufacturer of surgical dressings through cotton mills and other fabrics manufacturing, to producers of industrial fabrics such as felts and insulating material.

The types of instrument used also vary with the nature of the industry to some extent, but spinning, weaving, and similar processes are generally high-speed mechanical operations that lend themselves to automatic control of such variables as speed, tension, material feed, etc. Most replies indicated the use of measuring, counting, and recording instruments in this field.

Textile finishing (in some cases), bleaching, and dyeing involve liquid-phase and chemical processes. These require liquid-level controls, temperature and, sometimes, pressure recorders and controls. Spray conditioning machines may incorporate electrical control of spray adjustment, according to operating conditions. Squeeze rolls, for calendering or liquid removal from fabrics, may be controlled automatically or manually for roll pressure via hydraulic or electrical systems.

Power Supply

Most textile plants purchase power from outside suppliers, and a slight majority check supply with their own instruments. Some manufacturers have their own steam plants, some do not, according to the need for process steam in the company's operations.

Who Determines Instrument Requirements?

Nearly all replies stated that instrument requirements are determined by company staff. Specification and recommendation of instruments for purchase is generally the responsibility of the engineering, plant or, in a few cases, maintenance department. These departments are also concerned with the choice of supplier, occasionally in co-operation with the purchasing department.

Servicing of Instruments

The servicing of instruments appears to be about equally divided between the plants' own staff and contract work by instrument suppliers. This is understandable, since investment in instruments in some types of plant is only a small part of the total capital cost of mechanical equipment, and does not warrant the full-time services of an instrument maintenance staff.

Rather more than half the plants replying to the questionnaire use some form of preventive maintenance system for their instruments.

Spare Parts Practice

The general practice in keeping a stock of spare parts for instruments is to build up an inventory based on operating experience.

Instrument Specifications

All plants use mainly standard lines of instruments, but there are also a few cases of the development of special types to the manufacturer's own specifications.

All replies stated that instruments are purchased outright.

Capital Investment

Only a small proportion of replies attempted to give a breakdown of capital investment in instruments and their maintenance costs.

Capital investment varied from less than $5,000 to the $25,000 to $100,000 range. Annual maintenance costs appear to be comparatively low, probably of the order of 5 per cent of instrument investment or considerably less.

Where the use of instruments leads to savings in labour, improvements in quality, etc., the period for recovery of initial investment ranged from as little as one year to as much as nine years.

Gross investment in instruments in the textile industry, and the proportion of capital investment it represents within the industry, is low compared with such operations as the electrical power, petroleum and other processing industries.

IN

BUSINESS AND INSTITUTIONAL BUILDINGS

Canadian Developments

A comparison of curricula, scholarship programs and research projects in the Canadian universities of 1959 suggests most decidedly that training engineers for the atomic, space-conscious epoch ahead presents a challenge.

Many questions are unsettled. Should a grounding in the humanities (called a "Junior Matriculation" by many engineering faculties) precede the highly concentrated technical training which modern technology requires? Or should the engineer become a highly qualified specialist in the first three or four years of university and round out his training with elective courses in contingent humanity subjects? How important to him are business administration and economics? Isn't training in use of the English language essential to him?

For us whose work it is to compile engineering information, communication itself is of first importance. This is quite properly not of equal interest to the professional engineer, but his concern with it is a measure of his breadth of outlook. Almost all Canadian universities include at least one year of English in the engineering degree requirements. Some, such as the University of New Brunswick, require two. Electives in the final year in certain cases allow for the possibility of a second year of English training.

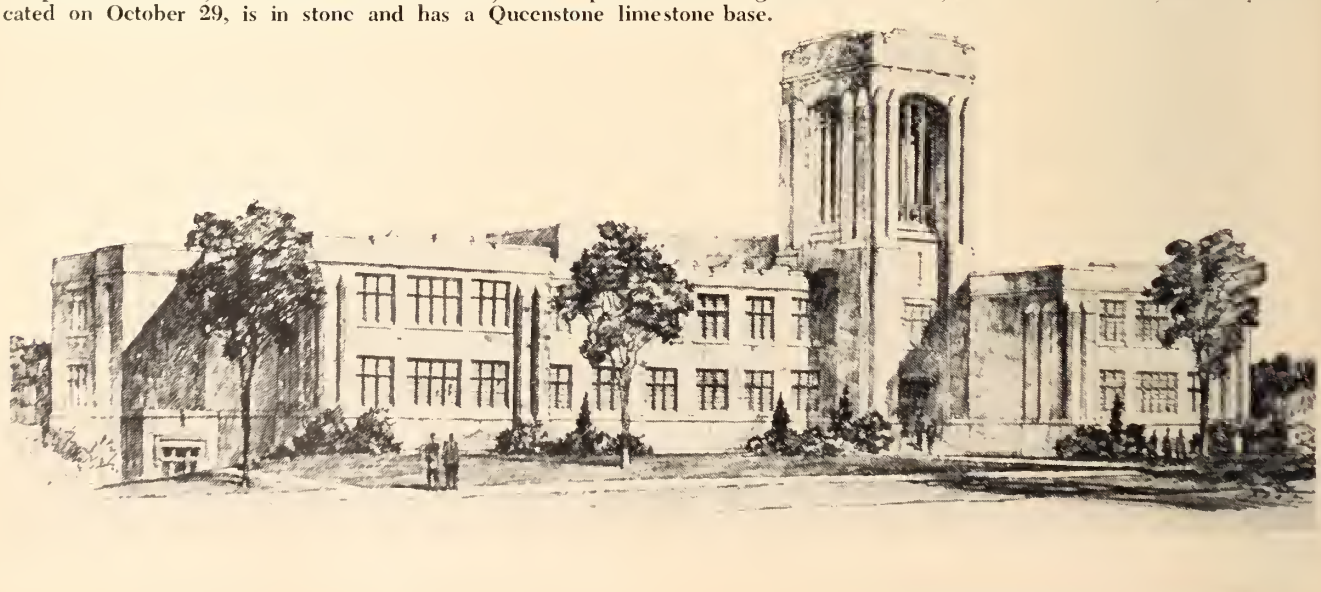
Many of the engineering faculties consider a course in business administration (variously called "industrial management," "business finance," etc.) imperative for the fourth year student, but others do not include such a course even among their electives.

Courses in art and history seem to be making their way into engineering curricula, though they remain in the "elective" bracket in most universities. This whole movement toward liberalizing the engineering program appears the more revolutionary when one considers that humanities programs still have very limited science requirements. Perhaps the engineering faculties will pilot a move by other faculties to give students of the '60s a more truly liberal education.

Enrolment Drop

Registration in first year engineering at the University of Manitoba has fallen off one third from last year. Last year 314 students began the four-year course, while only 217 have enrolled this year. Dean A. E. Macdonald accounted for the drop by various factors—among them stiffer requirements in the faculty (raising the minimum average mark from 50 to 55 per cent) and the fact that thousands of engineers were left jobless when the Arrow was given up. University President H. H. Saunderson blamed the 1957-58 economic slowdown for a slight nationwide drop in engineering registration. He pointed out that the situation is improving—that placing graduates in jobs has been easier this year than in 1958.

The new Engineering Science Building at the University of Western Ontario will provide facilities for courses in chemical, civil, electrical and mechanical engineering. Built at a cost of $1.33 per cu. ft., it contains 110 places for drafting, 125 places in "problem rooms", 300 seats in lecture rooms, and 50 places in reading rooms. The 900,000 cu. ft. structure, officially dedicated on October 29, is in stone and has a Queenstone limestone base.



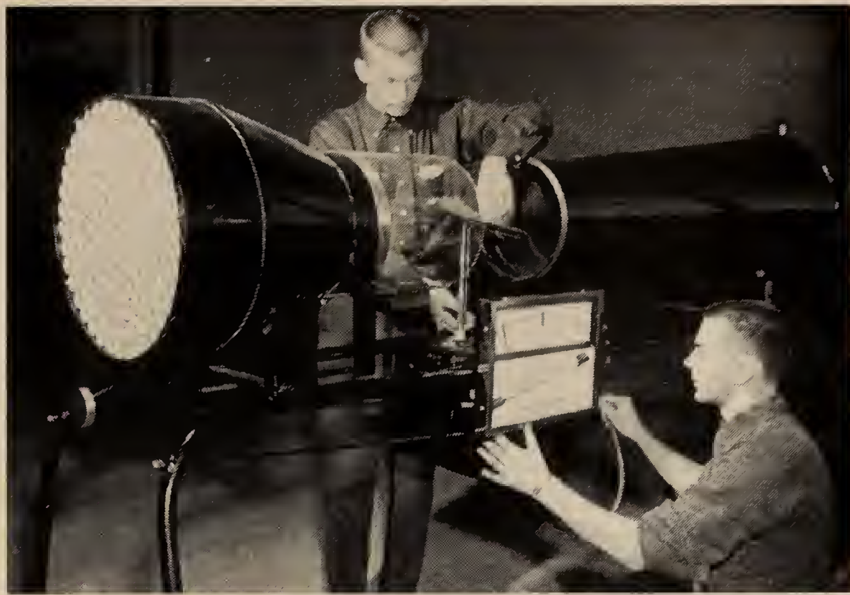
University of Waterloo's Cooperative Course

Two years ago a partnership between industry and education was established when the first 74 students enrolled in the new cooperative engineering course at the University of Waterloo.

This year the total enrolment has come close to the 700 mark and more than 200 companies, representing almost every industry in Canada, are registered with the university to provide off-campus jobs related to engineering.

Classrooms and laboratories are open the year round at Waterloo with half the student body always on campus. Students attend regular classes for three months and then go to assigned jobs in industry to get practical experience for the next three. Although most of the co-operating industries are located in Southern Ontario, students are placed in companies as far away as Regina.

The university's course has been designed in part to attract qualified students who might not otherwise attend university. Because teaching facilities are in operation 12 months of the year, tuition costs are lower than for the traditional course. By working six months of the year, students are able to save from one-half to three-quarters of their tuition and living costs while at Waterloo. Many of the students are former full-time employees of co-operating companies who have been encouraged by their firms to study for an engineering degree.



McMaster curriculum stresses design aspects of engineering and students are required to conduct original research work in their final year. Here engineering students are setting up an experiment using the wind tunnel in McMaster University's new $3½ million engineering building.

Few Show Interest in Toronto Nuclear Course

The $25, 50-lecture course in nuclear engineering being run this term at the University of Toronto has attracted only seven students. The course is intended to outline nuclear energy problems for company executives and technical staff already equipped with an engineering or physics degree. Industrial firms that have not yet contracted to do atomic work apparently feel that they do not want to train executives and technicians at this time.

Shell Merit Fellowship winners from Quebec and Maritime high schools examine a vacuum induction melting and casting unit at Cornell University's School of Chemical and Metallurgical Engineering. The Shell Merit Fellowship six-week seminar at Cornell, sponsored by Shell Oil Co. of Canada Ltd., is designed to help outstanding teachers of high school physics, chemistry and mathematics to keep up with new developments in their fields and with advances in teaching techniques. A similar course for teachers in Western Canada is held at Stanford University.

Saskatchewan Introduces Postgraduate Program

Dr. Arthur Porter, dean of the faculty of engineering at the University of Saskatchewan, finds that a four-year course in engineering is now quite inadequate for training top-grade engineers. A program of honours and post-graduate courses has been instituted at the university this Fall.

The high-speed digital computer is just one of the recent developments which will have a gargantuan effect upon industrial operations. According to Dr. Porter, medical electronics, mechanics, information processing and operational research are the fields in which the engineer must get the most advanced instruction. He also maintains that today's engineering faculties must accommodate a wide range of ability in their students. At Saskatchewan he has introduced honours courses in chemical engineering, engineering physics and geological engineering, with the hope that in another two years still more advanced courses may be added to the curriculum.

The new research work begun at

Saskatchewan has special bearing on the province's engineering demands. Extensive study into materials handling, with special reference to agriculture and the mining and processing of ore bodies, is one of the most important research fields in the university's 1959-60 program.

Essex College Also Introduces Graduate Courses

Essex College, Assumption University of Windsor, Ontario, has announced a series of new postgraduate courses which will lead to an M.A.Sc. degree. The program is planned to accommodate graduate engineers residing within a 50-mile radius. Not more than four, not fewer than two courses must be taken per year according to the new scheme. Each course will be offered in a two-hour period one evening a week during the academic year. The fees for instruction have been set at $100 per course.

Graduate Work in 1958-59 Term

University Research Increasingly Important

Though most research projects carried out in the universities are in the hands of graduate students and professors, there are signs that point to the undergraduate's increasing involvement in the experimental fields.

Civil and electrical engineering vie for first place in amount of research being done in the field. Mechanical follows close on their heels. University staff is commonly involved in government research projects with assistance from graduate students. Undergraduates ultimately gain from such a program because their professors are kept abreast of the most recent developments in their respective fields.

Where Do Bursaries Come From?

In many provinces the provincial government provides bursaries for high-ranking students irrespective of their field of academic pursuit. The federal government also offers bursaries and grants for study and research, but the bulk of these go to graduate students. The greatest single source of scholarship help to Canadian university students comes from industry.

International Nickel Awards Fellowships

Ten post-graduate fellowships have recently been awarded Canadian students in metallurgy, analytical chemistry, geology, physics and mathematics as part of the company's $2,860,000 five-year program to aid higher education in Canada. These fellowships have a maximum tenure of three years and provide an annual stipend of $2,000 with a supporting grant of $500 to the university. Since 1951, thirty-seven such fellowships have been given. Since 1956 an additional 115 four-year scholarships have been established by Inco for outstanding graduates of high schools and preparatory schools. Eighteen of the yearly twenty-five are reserved for students of geology, geophysics, mining, metallurgy, engineering, mathematics and physics.

$1000 in Bursaries From Engineers Wives

The Professional Engineers Wives Association of Ontario presented two first-year engineering students with a $500 bursary each this Fall. Both boys will study at the University of Toronto, one in civil engineering, the other in electrical.

Technical Service Council Places Engineers

Founded to "retain for Canada young engineers with technical and scientific education," the Technical Service Council has been acting since its founding in 1927 as a go-between for Canadian universities and industries. This involves keeping the universities informed of industry's recommendations on engineering and scientific courses and, in turn, helping industries to fill their employment needs.

The council maintains a highly developed office system complete with interviewing facilities, rating techniques and cross-index systems. Current information on employment trends, on changes in supply and demand and on salaries is kept close at hand. Two hundred member companies participate in this non-profit organization.

The Early Post-Graduate Years

The first three years following the undergraduate engineering or science degree are examined in a professional manpower bulletin issued this year by the Department of Labour at Ottawa.* The findings may help in indicating to what degree and how rapidly young professionals are absorbed into employment for which their academic training is intended to prepare and qualify them. Some impression is also given of the graduate's income and geographic mobility at this stage, and it is felt that the analysis may suggest further profitable research in the same field.

Employment

By 1957 almost four-fifths of the respondents to the survey were employed full-time at jobs requiring a technical and scientific background. Such employment was notably higher among engineers than among scientists. In all fields of engineering, well over three-quarters of the graduates had found full-time professional employment, with the single exception of mining engineering where non-technical, non-scientific employment (in most cases supervisory positions are indicated) was high.

The unemployment level, while somewhat higher for scientists than for engineers, was, in the aggregate, very low. Fewer than 1 per cent of the respondents were out of jobs and seeking work.

Approximately 5% of the graduates had acquired non-scientific, non-technical jobs.

The distinction between professional and non-technical and non-scientific employment was made by the respondents themselves. Such a distinction is to a great degree subjective and arbitrary since there are no generally accepted objective criteria. Many positions lie on the borderline (such as technical sales, various supervisory and administrative positions, technical writing and purchasing, to name but a few) because although they may require a certain level of technical competency it is of a rather restricted nature. Such positions can be classified as either technical or non-technical depending on the subjective views of the respondent and the particular characteristics of the job.

In most cases, the positions classified as non-technical and non-scientific by the respondents in this survey included business partnerships or self-employment of a non-professional variety, and in some cases supervisory or administrative work. This was especially true of graduates from engineering and business courses in which about 18% classified their employment as non-professional. A high proportion (14%) of the agriculture graduates also replied that a scientific and technical background was not required in their work; many of these were managing their own farms, a type of work which perhaps does not require technical and scientific training but which nevertheless provides an opportunity for such knowledge to be used quite extensively. Of the mining engineering graduates, 13% were engaged in a non-scientific, non-technical capacity involving, in the main, supervisory work.

Work Experience

Twenty-one per cent of engineers formed two functions in two jobs, compared with only 7% whose functions were the same in both jobs. The same phenomenon is in evidence among the group who held three or more jobs during the three-year period. The percentage values for engineers in order of increasing number of functions are 6, 15, and 18%.

It seems no explanation can be advanced to explain this phenomenon. It may be due to a preference of the employee for a different function at the time he changes jobs or it may reflect the employers' view that experience in one function is prerequisite for the employee to perform a different function satisfactorily. But the report notes evidence that some general hierarchy of functions exists.

Geographic Mobility

It seems that irrespective of the number of jobs held, there is a reluctance or inability to move from the province where the graduate lived or studied.

Nevertheless there was movement. By 1957 11% of the 1954 engineering and science graduates were living in foreign countries, one-half employed and the other half pursuing further

Tables reproduced from Professional Manpower Bulletin No. 5: "EMPLOYMENT OUTLOOK FOR PROFESSIONAL PERSONNEL IN SCIENTIFIC AND TECHNICAL FIELDS 1958-1960", Economics and Research Branch, Department of Labour, Ottawa, February 1959, Price 25 cents, The Queen's Printer, Ottawa, Ont., Canada.

(2) Includes finance, accounting, budgetary control, medical diagnosis, treatment, personnel, industrial relations.

studies. (Of the 122 members of the graduating class who were not Canadian citizens in 1954, by 1957 only 16 were among those who left the country; 65 had acquired Canadian citizenship and 51 were residing in Canada as non-citizens. In all, about 90% of all graduates have remained in Canada after obtaining their bachelor's degree.) In 1954, about 57% of the graduates were residing in Ontario and Quebec, 32% in the Prairie provinces and British Columbia and 9% in the Maritime provinces. Approximately 2% lived in the Canadian territories or foreign countries. In 1957, 60% were living and working in Ontario and Quebec, 24% in the Prairie provinces and British Columbia and 5% in the Maritime provinces. About 11% were residing in the Canadian territories or foreign countries and almost three-quarters of these were in the United States.

The geographical distribution of graduates in 1957 conforms quite closely to the geographical pattern of the net product of manufacturing establishments. In 1954, it rather closely followed the distribution of the total population, which is to be expected as the home address of the students was taken into account rather than their university location.

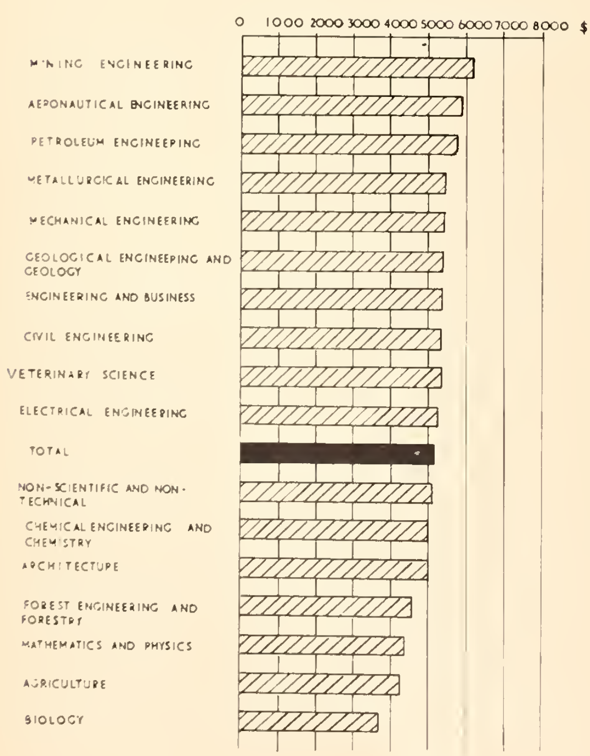
Remuneration

The 1954 graduating class obtained their highest salaries in 1957 from industry (median $5,301), with those employed by governments receiving 12% less than in industry (median $4,676), and those in educational institutions receiving 25% less than in industry (median $3,945).



Median salaries in 1957 of the 1954 engineering and science graduates.

There was little salary variation from one type of industry to another, the highest being for those in public utilities with a median salary of $5,588 and the lowest being for those in transportation with $4,964.

In government service, those employed by municipalities received the highest median salary ($5,050) and those in the employ of provincial governments the lowest ($4,370).

In education, graduates employed by universities received a median salary of $4,312 while those employed by high schools received $3,722.

Among engineers frequent change of job was not a factor influencing salary. The highest proportion of all three groups of engineers, (25% of the group with one, 30% of the group with two, and 30% of the group with three or more jobs), all received between $5,000 and $5,500 per annum. At no other salary level have significant advantages accrued to the engineer who was willing to change jobs more frequently.

The period under consideration (1954-1957) was characterized by a steady increase in the Canadian economy's demand for engineers and scientists, with corresponding shortages. The employment experience of

At the Universities:

Hollister Hall Opened at Cornell

A $2,000,000 building for "instruction and research in civil engineering" was dedicated at Cornell University on October 16. Named for one of America's most prominent engineering educators, L-shaped Hollister Hall contains classrooms and faculty offices in one wing and laboratories and research facilities in the second.

Hollister Hall is the eighth building in Cornell's Engineering Quadrangle. Both a new metallurgical engineering building and a structure for housing two nuclear reactors are proposed for the future. The quadrangle is but one of the accomplishments of Professor Emeritus S. C. Hollister's 22-year term as Dean of the College of Engineering.

Professor Hollister, who resigned last June from the Dean's chair, will have an office in the new building. A former president of the American Society for Engineering Education, he initiated the Cornell five-year program for engineering students, with the double purpose of strengthening technical education for engineers and giving more attention to the humanities.

The new building is the gift of Spencer T. Olin, university trustee.

"Sputnik Fever" charged with Enrolment Decline

The decline in the number of young people now entering engineering schools has been blamed on "Sputnik fever" by Dean Dale R. Corson of Cornell University's College of Engineering. "Sputnik fever" drove many potential engineers in America to study science instead of engineering two years ago, he claims.

In 1958 freshman enrolments were down 11% on the average all over the United States. This year the number of applications was down again.

"There has been a great deal of talk about science in these two years," says Dean Corson. "I think that much of this talk has been misplaced. The satellite and rocket achievements have been engineering achievements, not science achievements, although some of the measurements which have been made with the satellites have scientific interest."

Speaking on engineering curricula, Dean Corson pointed to the dilemma now facing engineering educators: two entirely different curricula are needed. On one hand, the electrical engineer cannot build a super-sensitive receiver for radio waves using the latest developments in solid-state physics unless he understands the physics involved; on the other, the country needs engineers who are going into manufacturing operations, management and numerous other equally important areas which do not require so much scientific training.

The answer, he finds, lies in a "dual-path approach". Beginning in the third year, the engineering student must choose whether he will go in a heavy mathematics-physics direction or take a more normal engineering course.

Harvard and M.I.T. Receive Grants to Study Fusion Power and Space

With a $300,000 grant from the National Science Foundation, Harvard University, Cambridge, Mass., has launched a research project on the behaviour of gases at high temperatures. The study will bear on problems of space travel and atomic power and may even help to explain the workings of the stars.

Massachusetts Institute of Technology (M.I.T.), also at Cambridge, Mass., has received $500,000 from the

Hollister Hall, Cornell University

National Science Foundation for a similar, but separate, study into fusion power, space and space craft.

Nearly a hundred people will be researching in this crucial new field of science, thus establishing Cambridge as one of the world's leading centers for research into power and space. The staffs of the two universities plan a regular interchange of information about their work.

Research at Harvard will be conducted in the High Temperature Gas Dynamics Project under the direction of Dr. Howard W. Emmons and Professor Gordon McKay. The M.I.T. program will be carried on in the Plasma Dynamics Program, headed by Dr. William P. Allis.

"Gas dynamics" and "plasma dynamics" include the study of ionized gases (or plasmas) such as exist in the upper atmosphere of the earth and can be produced in the laboratory. In their most familiar form, they exist in fluorescent light tubes and in the sun where ionized hydrogen atoms fuse giving off enormous amounts of light, heat and other radiations.

In recent years scientists throughout the world have been making concentrated efforts to devise ways by which the fusion reaction (such as takes place in the sun and in hydrogen bombs) can be achieved under controlled conditions. If successful, these studies will give a method of converting unlimited quantities of deuterium (a form of hydrogen in sea water) into power.

The M.I.T. and Harvard researchers do not propose to build elaborate apparatus to produce the fusion reaction. They will concern themselves with fundamental scientific research to learn more about basic principles. Their studies should lead to information about subjects as varied as fusion power, propulsion of space vehicles, entry and re-entry of space vehicles, communication through space, combustion, transformation of energy between mechanical and electrical forces, and astrophysics.

Gulf Oil Donates $1,000 to Colorado School of Mines

The Gulf Oil Corporation has contributed $1,000 to the Colorado School of Mines Foundation, Inc. Dr. John Vanderwilt, president of the that the money will be used as an assistance grant in the petroleum en- mineral engineering college, states gineering department of the School of Mines.

Gulf Oil contributed three-quarters of a million dollars to educational institutions in 1958 and thus far in 1959 has given an additional $170,000 to institutions throughout the U.S.

Doctor of Science in Industrial Health Degree

The Institute of Industrial Health at the University of Cincinnati is offering graduate training for professional personnel in the field of environmental hygiene — industrial hygiene, air pollution, industrial wastes, and industrial toxicology. The professional training is provided for graduates of approved schools of engineering or science.

The three-year course of instruction leading to the degree of Doctor of Science in Industrial Health will comprise two years of intensive academic study and a third devoted to preparation of a thesis.

A limited number of fellowship stipends is available to qualified candidates. Inquiries should be made to the Institute of Industrial Health, College of Medicine, Eden and Bethesda Avenues, Cincinnati 19, Ohio.

On Education:

U.S.S.R. Gives Superior Program Of Secondary School Mathematics

More Russian students take secondary school mathematics than Americans. In general, they spend more time in class studying advanced mathematical disciplines and cover these fields in greater depth than do North American students. So says Bruce Vogeli, a University of Michigan graduate student in a doctoral dissertation just presented to the university. According to authorities, this is one of the most thorough analyses of Soviet source materials for secondary school mathematics ever made in the U.S.

The best American high school programs in mathematics surpass the standard Soviet program. The U.S. is ahead of Russia in modernizing its mathematics courses and has done a better job of developing different types of mathematics programs for its students.

Although Vogeli believes the standard Soviet secondary mathematics program is better than the average American high school program, he asserts that it is inferior to programs in several of the European countries.

Humanistic Education only for Minority

Really humanistic education is suitable only for a minority, Rene Poirier of the Institut de France, Paris, stated recently at the International Council for Philosophy and Humanistic Studies at the University of Michigan.

"The increased independence of pupils toward teachers as well as parents makes it necessary to consider more what interests them and appears profitable to them — in general, studies which will open the door to an advantageous career." Teaching of the mathematical and formal sciences should begin early, according to M. Poirier, and not wait to be tacked on as a postscript to general humanistic training.

Training Atomic Scientists

The shortage of atomic scientists and technicians can not be solved by a crash program designed to turn out pure specialists. The responsibilities of atomic energy workers and the need for ingenuity, initiative, intelligence, and imagination in the field make a broad general education, founded on a solid classical training in physics and chemistry, essential to the specialist.

These are the conclusions of eighty scientists from forty different countries who attended the international seminar on problems of training specialists in the peaceful uses of atomic energy held at the French Center for Nuclear Research at Saclay, 20 miles out of Paris. The seminar was sponsored jointly by the International Atomic Energy Agency and the United Nations Educational, Scientific and Cultural Organization.

Universities face a singular problem in trying to train specialists in the peaceful uses of atomic energy—a field which did not even exist twenty years ago and one in which what is revolutionary today may be obsolete tomorrow. Professors trained classically themselves in formal chemistry and physics find it necessary to get new knowledge rapidly; universities must equip themselves with new laboratory facilities.

The conclusions drawn from the assembled scientists at Saclay were essentially three: universities must work closely with nuclear research centers in training students, if only for financial reasons; the study of nuclear sciences should not be started too early—specialized courses should appear in the secondary school curriculum but only after a solid training in standard physics and chemistry; and international organizations should play a healthy part in solving these educational problems, making two-to-three-year fellowships available for scientists from countries where atomic research is not yet well developed.

Reorganization in the Soviet Union

The twenty-first Communist Party Congress of the U.S.S.R. has defined a seven-year public education program. The following comments on the new program by Yevgeni Afanasenko, Minister of Public Education of the Russian Federation, are quoted from Soviet News Bulletin.

More is demanded today of the Soviet school system. It must overcome a certain gap which heretofore separated it from actual life, and it must train the pupils in a spirit of devotion to socially useful work, to productive labour.

The public education departments, in concert with local organizations and the public, have classified the schools, deciding to which type each one should belong: eight-year, night school (with shifts, or seasonal or correspondence), secondary general educational or secondary general educational polytechnical labour school with production training.

In keeping with the new law compulsory education in the U.S.S.R. is extended by one year to a total of eight years. The basic type of general educational schools will be the eight-year school for all children from the age of seven to fifteen or sixteen. In the eight-year general educational labour school the pupils will learn the fundamentals of science: Russian, mathematics, history, physics, foreign language and geography. Labour training will occupy a conspicuous place in the curriculum, and so will the study of singing, drawing, music, physical culture, and so forth. From the first year the pupils will be taught certain easy work. The boys and girls who are preparing for their future activities will attend practical production courses at the school workshops and plots of land, then in factory and mills, in collective and state farms, and in agricultural machinery repair shops.

The rural districts which heretofore had only elementary four year schools from now on will have eight-year establishments. There will also be boarding schools and hostels. Transportation facilities will be provided for pupils who live far from the school. Steps are being taken so that the children may get their meals at school.

The reorganization provides for the extension of secondary education everywhere; it can be received without stopping work (in shift, night, and seasonal schools), or by stopping work and enrolling at secondary general educational labour polytechnical schools whose pupils will receive production training, and also in technical schools and other specialized secondary educational establishments.

With the help of school teachers and parents the Academy of Pedagogical Sciences and the Ministry of Public Education of the Russian Federation have prepared draft statutes for all types of schools, as well as draft curricula for the new schools and programs for every subject. These documents are being discussed in the schools, in the *Uchitleskaya Gazeta (The Schoolteacher's Gazette)*, and in specialized publications.

Much is being done to expand the number of boarding schools. In line with the decisions adopted at the 21st Party Congress, boarding schools with accommodations for 250,000 pupils will be opened for the next school year in the Russian Federation alone (as against 83,000 boarding-school pupils in 1958-59). Facilities are provided in all the boarding schools so that the pupils will receive an all-round general polytechnical education, esthetical and physical upbringing, and training in socially useful work.

To meet the new requirements of the schools the output of special equipment for them is to be vastly expanded.

The Ministry of Public Education and the Academy of Pedagogical Sciences of the Russian Federation have worked out new curricula for the higher pedagogical educational establishments. Henceforward the students of higher pedagogical schools will have to go through good practical training in factories and collective farms, to get first-hand information on the functioning of schools, and acquire some skills in the field of the arts (singing, music, drawing), so that they may be in a position to combine their duties at school with extra-curricular educational work, and in conducting study circles for the pupils.

The Commonwealth Scholarship Plan

The following is an extract from a speech delivered to the opening session of the Commonwealth Education Conference, which met at Oxford from July 15-29, by Mr. George Drew, Canadian High Commissioner to the United Kingdom and Leader of the Canadian Delegation to the Conference.

Our plans, it seems to me, should be an expression of our belief in freedom. As we seek an answer to this fundamental question, "what do we mean by Education?" I venture to suggest that all universities today should ask themselves three questions.

(1) Is not the most important problem for the world today a moral and a spiritual one? On the material side we are doing very well and we shall do still better and expand it. Our real weakness and the real division between the totalitarian state and the free society lies in the other field.

(2) What are the universities going to do to cure this weakness, whose existence they cannot possibly deny?

(3) Having regard to the fact that our future will be so largely shaped by the thoughts implanted in the universities, ought anyone to be allowed to pass through a university without thinking about this problem?

Certainly there are no easy answers to these questions. But are the answers so difficult as we sometimes seem to think?

If our universities really regarded this as an urgent and serious problem, it could be solved tomorrow. We are dealing with far more complex questions in the mysterious realm of nuclear physics. People who have unlocked the mysteries of the universe by their combined thought and action surely need not be dismayed by this relatively simple task.

Month to Month

ENGINEERS CONFEDERATION COMMISSION

As authorized by the Canadian Council of Professional Engineers and the Engineering Institute of Canada, the Engineers Confederation Commission has been appointed, and held its first plenary meeting in Toronto on October 18, 1959.

Members of the Commission are:

Chairman: John H. Fox, Toronto, Ontario.

Vice-Chairman: George M. Dick, Sherbrooke, Quebec.

Alberta: J. McMillan, J. G. Dale.

British Columbia: W. K. Gwyer, F. A. Forward.

Manitoba: T. E. Storey, N. S. Bubbis.

New Brunswick: T. C. Higginson, James O. Dineen.

Newfoundland: J. B. Angel.

Nova Scotia: J. Hoogstraten, G. F. Bennett.

Ontario: T. Foulkes, D. D. Whitson, C. T. Carson, L. D. Dougan.

Prince Edward Is: W. R. Brennan.

Quebec: E. D. Gray-Donald, J. E. L. Roy, H. Gaudefroy, H. Cimon.

Saskatchewan: J. C. Traynor, J. B. Mantle.

Yukon: E. W. King.

All provinces were represented with all but three of the Commission members present.

Mr. D. O. Turnbull, President of the C.C.P.E., and Mr. J. J. Hanna, President of the E.I.C., were present and addressed the meeting. They stressed the importance and urgency of its task, and each of them expressed the hope that a final report would be forthcoming in time for consideration at the annual meetings of the two bodies in 1961.

To facilitate its work, the Commission was divided into committees or task groups, each charged with the responsibility of preparing detailed recommendations to the Commission, regarding important aspects of the Commission's work.

These committees are:

Committee on Charter—To draft a complete charter using the E.I.C. charter as a basis if possible.
Chairman: J. G. Dale, Alberta.
Vice-Chairman: F. A. Forward, British Columbia.
T. E. Storey, Manitoba.
J. C. Traynor, Saskatchewan.

Committee on By-Laws—To draft all necessary by-laws assuring that these are consistent with the Charter.
Chairman: H. Gaudefroy, Quebec.
Vice-Chairman: C. T. Carson, Ontario.
T. Foulkes, Ontario.
J. E. Leo Roy, Quebec.
L. D. Dougan, Ontario.

Committee on Administration—To spell-out the broad lines of how the new National Body will be administered.
Chairman: T. Foulkes, Ontario.
Vice-Chairman: L. D. Dougan, Ontario.
J. E. Leo Roy, Quebec.
D. D. Whitson, Ontario.
H. Cimon, Quebec.

Committee on Finance—To work out the details of how the new body will be financed, in co-operation with the Committee on Administration.
Chairman: E. D. Gray-Donald, Quebec.
Vice-Chairman: C. T. Carson, Ontario.
T. C. Higginson, New Brunswick.
J. O. Dineen, New Brunswick.
J. S. Bubbis, Manitoba.

Committee on Branches—To determine how the branches will be formed, financed, operated, etc., and their relationship with the National Body and the Provincial Associations.
Chairman: W. K. Gwyer, British Columbia.
N. S. Bubbis, Manitoba.
J. McMillan, Alberta.
E. W. King, Yukon.

Committee on Other Societies—To survey possible co-operation with and participation of other societies (Canadian, U.S., British or Foreign technical societies and professional engineering bodies) as distinct from the two participating groups.
Membership of this Committee will be determined later.

Committee on Services—To outline the various services to be performed by the new National Body.
Chairman: J. B. Mantle, Saskatchewan.
J. McMillan, Alberta.
F. A. Forward, British Columbia.
T. E. Storey, Manitoba.
J. Hoogstraten, Nova Scotia.

Committee on Relationship with the Provincial Associations—To establish the relationship between the new National Body and the Provincial Associations.
Chairman: J. Hoogstraten, Nova Scotia.
G. F. Bennett, Nova Scotia.
J. B. Angel, Newfoundland.
W. R. Brennan, P.E.I.

(Left to right): J. J. Hanna, president, E.I.C.; J. H. Fox, chairman, Engineers Confederation Commission; D. O. Turnbull, president, C.C.P.E.; and G. M. Dick, vice chairman, Engineers Confederation Commission.

Back Row (left to right): F. A. Forward, E. W. King, W. R. Brennan, J. G. Dale, D. O. Turnbull, G. M. Dick, J. H. Fox, J. J. Hanna, L. Nadeau, G. T. Page, J. B. Angel, D. D. Whitson, T. Foulkes, J. E. L. Roy, E. D. Gray-Donald; front row (left to right): J. B. Mantle, J. O. Dineen, T. C. Higginson, L. D. Dougan, J. Hoogstraten, J. C. Traynor, H. Gaudefroy, C. T. Carson, J. McMillan, N. S. Bubbis, and T. E. Storey.

Co-ordinating Committee—To co-ordinate the work of the Committees and to establish the details of implementation of the decisions of the Commission.

Chairman: Chairman of the Commission.
Vice-Chairman: Vice-Chairman of the Commission.
Members: Chairmen or Vice-Chairmen of all committees.

The Chairman and Vice-Chairman are ex-officio members of all committees.

In the interest of convenience and the practicability of holding meetings that would otherwise require extensive time and travel, geographical consideration was an important factor in the selection of committee members.

The Co-ordinating Committee is charged with the special responsibility of ensuring that there is a maximum of liaison and a minimum of overlapping in the work of the individual committees.

Following the plenary meeting of the Commission, each committee had a preliminary meeting to lay plans for the implementation of the program.

The secretariat of the Commission is shared by Mr. Leo M. Nadeau, Executive Secretary of the Canadian Council of Professional Engineers, and Mr. Garnet T. Page, General Secretary of the Engineering Institute of Canada.

As the work of the Commission progresses, further reports will be made. However, it will undoubtedly require several months of committee work before tangible results begin to appear.

A.E.C.L. Reactor School

Atomic Energy of Canada has announced plans to open the Chalk River Reactor School on February 1, 1960. Applicants for this first 12-week course must have their forms in to the Secretary, Chalk River Reactor School by November 15 so that the twelve successful candidates can be notified by December 1.

Candidates for the school must have a university degree in physics, engineering physics, chemistry, metallurgy, or engineering.

The course, taught by senior company executives and members of the staffs of the various A.E.C.L. divisions in Toronto, Ottawa and Chalk River, will give students the basic instruction necessary for a thorough understanding of the design, construction and operation of nuclear reactors.

Set up in response to the wide interest shown in atomic power systems being developed in Canada, the course will be particularly concerned with power reactors moderated with heavy water and fuelled with natural uranium (such as the NPD station under construction at Rolphton and CANDU projected for a site north of Kincardine, Ontario).

NBC-TV Presents Chemistry Course

NBC television is producing a two-semester college-level chemistry course in cooperation with the American Chemical Society and The American Association of Colleges for Teacher Education.

Monday through Friday, from 6:30 to 7 a.m., Professor John F. Baxter, head of the General Chemistry Division at the University of Florida, does a lecture-demonstration on fundamental principles of modern chemistry.

Last year NBC initiated "Continental Classroom" with an eight-month course in Atomic Age Physics which won unprecedented honors. This year some 300 universities have agreed to offer the course for college credit.

Prentice-Hall, Inc., Englewood Cliffs, N.J., has published both the textbook and study guide (entitled *Modern Chemistry*), written by Dr. Baxter and Dr. Luke E. Steiner of Oberlin College to accompany the televised course.

Financial backing for the "Continental Classroom" course is being provided by the Ford Foundation and ten leading industries.

University of Toronto Interviews with Graduates

Interviews for permanent employment of graduates from the Faculty of Applied Science and Engineering at the University of Toronto will be held on January 21, 22 and 23, 1960.

The university requests that information on jobs available be supplied by employers to each department concerned and to the Placement Service office.

Engineering departments at the university include: aeronautical, architecture, chemical, civil, electrical, engineering physics, geological science, geophysics, industrial, mechanical, metallurgical and mining.

Seventy-three Engineers Out of Touch

The Records Department at E.I.C. headquarters has been searching in vain to locate the following seventy-three members. Current addresses, sent to the Engineering Institute of Canada, 2050 Mansfield Street, Montreal, P.Q., will be heartily welcomed.

Members

Andretsch, Richard F., Ohio, U.S.A.
Gregory, Peter G., Ottawa, Ont.
Hussey, C. H., Toronto, Ont.

(Continued on page 118)

Personals

Alexander Watson, M.E.I.C., director of ship construction and supply of the Department of Transport, has been appointed chairman of the Canadian Maritime Commission by Transport Minister Hees.

R. H. Findlay, M.E.I.C. (Royal Technical College '09), consulting mechanical engineer with the Montreal Branch of the Dominion Bridge Company, has retired after 48 years with the company.

H. William Tate, M.E.I.C. (Toronto '10) has retired from the presidency of De Leuw, Cather & Company of Canada Limited, Consulting Professional Engineers, Toronto and Ottawa, and becomes chairman of the board. Leslie W. Pillar, M.E.I.C. succeeds Mr. Tate in the presidency.

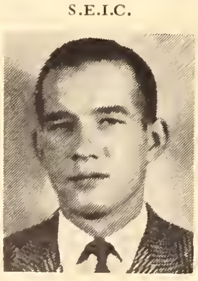
M. Barry Watson, M.E.I.C. (Toronto '10), formerly registrar of the Ontario Association of Professional Engineers and secretary-treasurer of the Dominion (now Canadian) Council of Professional Engineers, has retired from practice to live in Mexico.

R. A. Emerson, M.E.I.C. (Manitoba '30), vice-president of the Canadian Pacific Railway Company, has been made a Commander Brother of the Order of the St. John of Jerusalem by Governor-General George Vanier at Government House, Ottawa.

R. C. McMordie, M.E.I.C. (Toronto '30), has become manager of engineering operations and chairman of the B.C. Power Commission's senior staff executive committee. He is thus the principal engineering officer of the commission, responsible for all engineering and for the production of power.

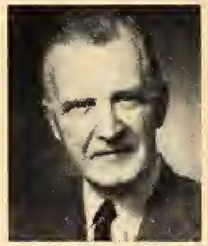
John F. Benjafield, M.E.I.C. (Queen's '33) has been appointed assistant district manager, London District, The Foundation Company of Ontario Limited.

Yvon Jobin
Jr.E.I.C.



Paul R. Ukrainety,
S.E.I.C.

Alexander Watson,
M.E.I.C.



R. H. Findlay,
M.E.I.C.

A. W. Tobber,
M.E.I.C.

Leonard E. Gads,
M.E.I.C.

Andrzej S. Dromlewicz, M.E.I.C., has been made district engineer, Calgary District, The Foundation Company of Canada Limited.

A. W. Tobber, M.E.I.C. (Danzig '34), formerly chief engineer and works manager of Harrington Tool & Die Co. Limited, has been appointed vice-president in charge of engineering and manufacturing.

Leonard E. Gads, M.E.I.C. (Alberta '39), secretary of the faculty of engineering at the University of Alberta since 1946, has been appointed associate dean of the faculty.

A. J. G. Leighton, M.E.I.C. (Saskatchewan '42), has been named director of engineering of the B.C. Power Commission. P. J. Croft, M.E.I.C., is the new director of planning.

V. Douglas Thierman, M.E.I.C. (Saskatchewan '48) has been elected a director of Haddin, Davis & Brown (Alberta) Limited. He is manager for the firm in Edmonton.

H. W. Beekett, M.E.I.C. (Saskatchewan '48) has been appointed construction engineer III for The Consolidated Mining and Smelting Company, Calgary.

D. L. Fuller, M.E.I.C. (Saskatchewan '49) is the new operations manager of Producers Pipelines Ltd., Regina.

C. H. Johnson JR.E.I.C. (Manitoba '49) has been appointed a technical sales representative for petroleum chemicals by Du Pont of Canada Limited. With headquarters in Montreal, he will cover Quebec and the Maritimes.

S. F. Lee, M.E.I.C. (Saskatchewan '50) has become chief engineer of Saskatchewan Government Telephones, Regina.

Yvon Jobin, JR.E.I.C. (Laval '52) is the new superintending engineer in the System Operation, Regional Operation Division of Hydro-Quebec.

Laurie A. Coles, M.E.I.C. (New Brunswick '54), formerly chief engineer for M. F. Schurman Company Limited, has established the firm of Laurie A. Coles and Associates to provide consulting engineering and architectural services in Charlottetown and Summerside, Prince Edward Island.

Marc M. J. Chagnon, JR.E.I.C., (McGill '57) who has been working with the CNR, Montreal has been awarded an Athlone fellowship for two years of post graduate training in the United Kingdom.

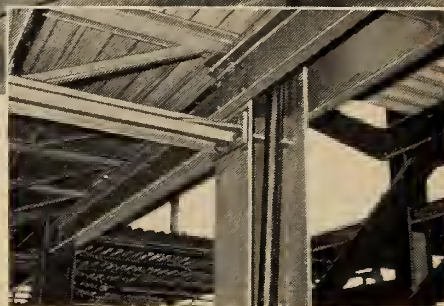
Pierre Fortier, JR.E.I.C. (Ecole Polytechnique '57) has begun work as an analytical engineer with Pratt & Whitney Aircraft Company (Longeuil) after spending two years in England, at the Imperial College of Science and Technology, on an Athlone Fellowship.

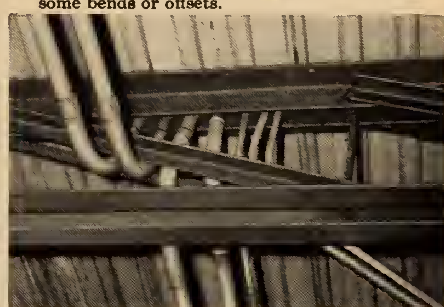
Paul R. Ukrainety, S.E.I.C. (Saskatchewan '57) has returned from a two-year Athlone Fellowship at Bristol, England, working with the Bristol Aeroplane Company Limited, and will begin work towards his M.Sc. at the University of British Columbia on a National Research Council scholarship.

Robert J. Blake, JR.E.I.C. (Toronto '57) has taken a position as plant engineer at the Imperial Tobacco Company's new plant at Guelph, Ont.

Norman Morantz, S.E.I.C. (McGill '59) is studying towards an M.Sc. degree in civil engineering at Lehigh University, Bethlehem, Penn.

Jack W. Hicks, S.E.I.C. (Toronto '59) has taken up the position of construction engineer in Dravo Corporation's contracting division, Pittsburgh, Penn.





NEWS OF THE BRANCHES

BAIE COMEAU

G. W. Scott, M.E.I.C., *Correspondent*

Quebec North Shore Paper Company's Woods Department was host to a number of Baie Comeau members on a 150-mile excursion in the area of the lower Manicouagan River on September 19.

The road-and-water trip included visits to two lumber camps where members saw the latest mechanical equipment for processing and handling pulpwood timber in operation. Of special interest were two entirely original machines for felling, branching and cutting-to-size pulpwood timber without the help of the conventional lumberman and transportation equipment.

Led by Mr. T. B. Fraser, division manager of the Woods Department of the Quebec North Shore Paper Company, the group heard a short talk on the inter-related activities of the company's pulpwood operations and the latest developments by Quebec Hydro on the Manicouagan River.

BELLEVILLE

D. A. Law, JR.E.I.C., *Correspondent*

Eighty thousand fires accounting for a $100 million loss occur in Canada each year, Mr. Gordon Shorter, M.E.I.C., Building Research Division of N.R.C., told members at the October 5th meeting.

Mr. Shorter, speaking on Fire Research, showed the film "The Saint Lawrence Burns" and explained that only through objective thinking in field investigations, materials testing, and statistics study can the situation be improved. This, he pointed out, is what his department at N.R.C. is trying to do.

Past-chairman T. E. Flinn introduced the speaker in the absence of the 1959-60 chairman, W. C. Benger.

CAPE BRETON

Harold M. Aspinall, M.E.I.C., *Correspondent*

On tour throughout the eight provinces and the Yukon, visiting the Institute's 59 branches, President Hanna addressed the membership here on September 18th. Discusing various aspects of industry across Canada, Mr. Hanna indicated that our economic system was being adjusted to meet modern demands and minimize trends toward depressions. He emphasized that E.I.C. organizations could help by conducting talks and discussions on economic problems, employer-employee relations, and similar subjects.

E.I.C. headquarters are most anxious to help branches with their technical programmes, he stated. Decentralization and maximum service are two constant aims.

Director of Technical Services, J. Hance Legere, expressed the regrets of the General Secretary, Dr. Garnet Page, in not being able to attend the meeting. He stated that headquarters would probably be able to supply one or two speakers for branch meetings. He also reminded members that a staff of qualified librarians is available at the Montreal office to help members obtain any information they may need from technical books and periodicals.

The chairman, W. Dodson, presided over the dinner meeting, held in the Isle Royale Hotel, Sydney, where 43 members were gathered. President Hanna was introduced by the immediate past-chairman, J. Vince Palmer.

CORNER BROOK

H. A. Hinton, JR.E.I.C., *Correspondent*

President Hanna and Dr. Page met the members of the branch at a stag dinner on September 16 in the informal atmosphere of a summer cabin. Dr. Page's work as General Secretary won unanimous acclaim.

Following the dinner Mr. Hanna gave a highly thought-provoking talk on the opportunities and responsibilities of engineers as members of the community. Dr. Page outlined the present activities of the Institute and discussed some of its projects ahead.

HALIFAX

W. J. Phillips, M.E.I.C., *Correspondent*

The Association of Professional Engineers of Nova Scotia held a luncheon and reception at the Lord Nelson Hotel on September 22 in honour of President Hanna. Among the special guests were J. Hance Legere, accompanying Mr. Hanna on the visit; W. J. Phillips, Chairman of the Halifax branch; John H. Boyce, branch secretary-treasurer; and Halifax Branch Councillors G. F. Vail and E. D. Wickwire.

More than fifty members attended the branch meeting that evening—a reception and buffet supper at the Halifax Curling Club. During the day President Hanna had had the chance to renew old friendships among the branch members, including two past-presidents, Drs. J. B. Hayes and Ira P. MacNab.

Speaking to the assembled Halifax members, Mr. Hanna pointed out that the increased enrolment in Canadian universities and migration of foreign engineers to this country had given Canada a good number of qualified engineers and relieved the pressing shortages of four years ago. He reported on current affairs of the Institute and announced that *The Engineering Journal* would expand shortly.

KITCHENER

John F. Runge, M.E.I.C., *Correspondent*

Approximately sixty members from Kitchener, Guelph, Galt and the surrounding area attended the annual stag held at Waterloo Fish & Game Club September 16.

Spareribs and pigtails, baseball, and horseshoes added to the evening's entertainment.

LAKEHEAD

G. O. Hanson, JR.E.I.C., *Correspondent*

Guided by Refinery Engineer Tom Ferris, Safety Engineer Bob Faircloth and Sales Engineer Wayne Cheney, 35 members toured the Husky Oil Refinery on McKellar Island, Fort William on September 16. They were shown various processes used in extracting the many products from crude oil.

In the laboratory, Max Eger, plant chemist, explained the various tests and control methods used to provide consistent products, all of which must meet rigid government specifications.

Dean Stevens, refinery superintendent, explained the operation of the refinery: Forty-five to fifty per cent of the crude is refined into light fuel oils and gasoline. The remainder goes into bunker fuel oil, asphalt, roofing tars, and pipe line enamel. Only about two per cent of the crude is lost in the processing.

The tour and talk were followed by a delicious luncheon given by the Husky Oil Company.

LETHBRIDGE

Ronald J. Knight, JR.E.I.C., *Correspondent*

Members of the Montana Section of the A.S.C.E. were guests of the Lethbridge branch August 29 at the annual tour-and-meeting which is held alternately in Alberta and Montana. Members and guests met for lunch in Waterton and then toured the British American Oil Company's gas and sulphur processing plant at Pincher Creek.

The Lions Club hall in Waterton Lakes was the scene of the dinner meeting. R. L. Francis, JR.E.I.C., welcomed the guests and Mr. L. J. Walker, chairman of the Montana section of A.S.C.E., replied on behalf of our Montana friends. Mr. T. W. Pierce, M.E.I.C., Waterton Lakes National Parks Supt., Alberta, Traced developments in the formation of Waterton Glacier International Peace Park and gave special praise to Rotary International for its ground work and continuing support of this "Hands Across the Border" idea. He even suggested that the park would be a fitting place for a meeting such as ours.

LONDON

L. Scott Murray, M.E.I.C., *Correspondent*

THE LONDON BRANCH of the E.I.C. is conducting a Professional Development Course which consists of seven lectures and a field trip on nuclear energy. This course has been worked out with the cooperation of the University of Western Ontario and McMaster University, as well as Canadian Westinghouse and Canadian General Electric. We are expecting an enrolment of about 40 members.

MONTREAL

J. A. Randle, M.E.I.C., *Correspondent*

THE STUDENT GUIDANCE COMMITTEE of the Montreal Branch met on September 22 and elected Julien Dubuc, JR.E.I.C., chairman of the Junior Section, to its chairmanship.

SASKATOON

W. A. Friebel, M.E.I.C., *Correspondent*

DR. NEIL B. HUTCHEON, assistant director of building research with the National Research Council, Ottawa, spoke to Saskatoon members September 8 giving his impressions of India from a recent trip under the Colombo Plan.

His conclusions, after three months of helping building researchers in India, were that India is "a land of sick people, sick animals and sick apparatus."

Both agriculture and industry in India lag 200 years behind the West and a complex economy does not speed their progress. Compared to Canada's 3.8% arable land India has 48% coupled with a 40-inch rainfall. "India's main problem," stated Dr. Hutcheon, "is to change from a hand production economy to the use of energy and machines."

India must make better use of her cheap labor force, selecting the things they can produce best by scientific methods and discarding the rest. Laboratories better equipped than those in Canada are to be found in parts of India but too often the instruments themselves are not in working order.

• NEWS OF THE BRANCHES

(Continued)

WINNIPEG

Peter M. Abel, JR.E.I.C., *Correspondent*

REPRESENTATIVES OF THE MANITOBA HYDRO-ELECTRIC BOARD conducted sixty E.I.C. members through the Selkirk Generating Station, currently under construction, on September 17.

The capacity of the plant will be 132,000 kw.; two steam generators will provide up to 625,000 lbs. of steam per hr. at a pressure of 875 psi and a temperature of 915° F.; the steam will drive two C. A. Parsons turbine generators, each having a capacity of 66,000 kw. Auxiliary services — the coal handling plant, the water treatment plant, the cooling water system, and the 115 KV switching station were also shown the members.

The Manitoba Hydro-Electric Board kindly served refreshments afterward.

New Officers of the Branches

CHALK RIVER

C. E. Lawrence Hunt, JR.E.I.C., chairman.

C. E. Lawrence Hunt, JR.E.I.C.

LAKEHEAD

P. W. Pinn, M.E.I.C., secretary.

NEWFOUNDLAND

A. E. O'Reilly, M.E.I.C., secretary.

NIPISSING & UPPER OTTAWA

J. M. Rosborough, M.E.I.C., chairman.

R. S. MacLennan, M.E.I.C., vice-chairman.

W. A. Adams, S.E.I.C., secretary-treasurer.

ST. MAURICE VALLEY

W. A. Pangborn, JR.E.I.C., chairman.

W. A. Pangborn, JR.E.I.C.

SARNIA

A. W. Wirth, M.E.I.C., chairman.

VANCOUVER ISLAND

R. W. Lockie, JR.E.I.C., secretary-treasurer.

NEWS OF THE

Associations and Corporation

Registration of Canadian Engineers Reaches 74.1%

A survey conducted in late 1958 by the Department of Labour and recently made public shows that 74.1% of all qualified engineers in Canada are registered. Of 13,534 questionnaires sent out, 10,044 came back with answers. They reveal these figures:

These totals include graduates from accredited engineering courses and non-university graduates who are members of provincial engineering bodies.

Figures include only those who were members of the association in the province in which they were residing. An additional 181 engineers (or 2.4%) reported membership in a provincial association other than the association of the province in which they were residing.

Province	*Total No. of Reporting Engineers(1)*	*No. Reporting Membership in Provincial Association(2)*	*Per Cent*
Newfoundland	42	23	54.8
Prince Edward Is.	10	4	40.0
Nova Scotia	182	111	61.0
New Brunswick	133	75	56.4
Quebec	1,994	1,347	67.6
Ontario	3,589	2,794	77.8
Manitoba	229	166	72.5
Saskatchewan	184	117	63.6
Alberta	596	414	69.5
British Columbia	743	485	65.3
Yukon & Northwest Territories	19	3	15.8
	7,721	5,539	71.7

Quebec Engineers Against Unionism

The proposed revision of the Code of Ethics has recently submitted to the Corporation of Professional Engineers of Quebec as approved by an overwhelming majority. One of the major changes deals with membership of professional engineers in trade unions. It reads:

"The engineer shall not be a member of a Trade Union nor participate as such in any form of Trade Union activities, since he would then uphold a philosophy and certain methods of negotiation, incompatible with true professionalism such as the use of strikes and the like."

The revision will not be effective until approved by the Lieutenant-Governor-in-Council.

Quebec Corporation Campaigning Against Illegal Use of Title "Engineer"

The Corporation of Professional Engineers of Quebec is intensifying its campaign against individuals and firms who are illegally using the title "Engineer". Jean-Paul Dagenais, Jr.E.I.C., of Montreal, has been appointed professional conduct officer by the corporation to investigate all such cases involving infractions of the Professional Engineers' Act.

W. J. Riley, M.E.I.C., president of the corporation, says the eight-man governing council is moving promptly to halt this abuse. He emphasizes that industrialists, contractors and the public at large should realize the dangerous implications arising out of the illegal use of the title.

States Mr. Riley: "Whenever one requires the services of an engineer, one expects to deal with a duly qualified professional whose training at the university and later experience qualify him to undertake and carry out successfully the complicated engineering projects of our day and age."

Opportunities Today Are Better, Says Ontario's Director

Canada's systematic expansion has resulted in better opportunities for engineering graduates than ever before, according to Col. T. M. Medland, executive director of the 18,500-member Association of Professional Engineers of Ontario.

In commenting upon recent reports of falling enrolment in engineering courses at Canadian universities, Col. Medland noted there were 1,299 freshman engineering students registered in Ontario universities and colleges this year. He compared this figure with last year's enrolment of 1,283.

Col. Medland also noted that the number of students taking mathematics and physics in Ontario's twelve universities and colleges which offer engineering is on the increase.

National Society of Professional Engineers (USA)

Engineering employee sentiment toward unions is being tested often these days. A union request for a new election at the Pennsylvania Power and Light Company on charges that the company had unduly influenced the election last December was recently turned down by the National Labor Relations Board. The next major test will probably be among the engineers of Western Electric across the United States. The company, whose election date is coming up, has circulated an 18-page booklet entitled "Why Western Electric Opposes the CWEPE-N Union—A Look at the Record" to its engineers.

Starting salary data from ten leading American engineering colleges (MIT, Columbia, University of Pennsylvania, Lehigh, Case, Purdue, University of Michigan, Northwestern, UCLA, and Georgia Tech) shows a four per cent gain over 1958 and a ten per cent increase over 1957, according to the monthly bulletin published by the Society of Professional Engineers (USA).

News of Other Societies

Testing Laboratories and Chemical Consultants

A crusade for more extensive use of testing and analysis was launched at the annual meeting of the Association of Canadian Testing Laboratories and Chemical Consultants held recently in Toronto.

"In view of recent occurrences where buildings and bridges have collapsed," said E. S. Darby, associate president, "it is evident that testing of construction materials is imperative to prevent such tragedies." He referred to four instances in particular—the recent breakdown of a bridge on Highway 401; the bridge over Burrard Inlet, Vancouver; the steel structure for an industrial building in Toronto; and the collapse of a curling rink in an Ontario city.

The campaign will take the form of a public education project to make manufacturers more aware of the importance of pre-construction testing.

The Association also awarded its first scholarship in the amount of $50 to the Haileybury School of Mines, in memory of a former president of the association, the late J. White.

Canadian Copper and Brass Development

The Canadian Copper and Brass Development Association, a non-trading, non-profit organization, was formed in 1958 under the sponsorship of the copper and brass industry of Canada. Its purpose is "to promote, stimulate and develop the use of copper, its alloys and compounds in all the phases of modern living."

Composed of twenty-five member companies, the association provides technical assistance with manufacturing and processing problems; acts as a liaison with governmental departments on municipal, provincial and federal levels and with other non-trading organizations including the Canadian Standards Association and the National Research Council; supplies technical assistance and information to educational institutions; and endeavors to keep the public informed of existing practices and new developments in the copper-brass field.

European Federation of Chemical Engineering

The European Federation of Chemical Engineering, of which E.I.C. is a member, has recently published a leaflet on its aims, functions and membership.

The federation is defined as "a loose association on a non-profit making basis of technical and scientific societies . . . which are concerned with the fields of chemical technology, chemical engineering and process engineering."

With offices in Frankfurt, London and Paris, the federation aims to "promote European collaboration in the field of chemical engineering, which includes chemical plant engineering, chemical process engineering, and structural materials and unit operations."

It endeavors to keep informed of fundamental data, laboratory techniques, measurement and control techniques, works techniques, and structural materials techniques.

European Congresses about every three years, working parties to deal with individual problems, and constant promotion of the exchange of views among member societies allow the federation to gain and disseminate information vital to the profession of chemical engineering.

American Society of Mechanical Engineers

An estimated 4500 engineers will descend on Atlantic City, New Jersey, late in November for the annual meeting of The American Society of Mechanical Engineers. Under discussion will be the latest developments in hundreds of fields, ranging from rocket ships to textiles. Air pollution, hi-fi radar, plastic pipe and solar air-conditioning will be dealt with in technical papers and discussion. Other sessions will deal with rocket ships for manned space travel, new types of ships that fly above the water, and new and better artificial hands for amputees.

Lieutenant General James M. Gavin, formerly director of U.S. Army Research and Development, will speak on "The Challenge of the 60's".

Recent Meetings

Canadian Construction Association

The second Labour Relations Seminar in Canada for construction executives was held at Banff on October 10 and 11. The seminar, sponsored by the Alberta Builders' Exchange Council, included discussion of 1) the law in union-management relations; 2) management rights and union security; 3) economic determinants in collective bargaining; and 4) the conduct of bargaining.

Plans are in progress for seminars at Quebec City, Dalhousie University, Halifax and Queen's University.

Society for Experimental Stress Analysis

The annual meeting, held on October 21, 22, and 23 in Detroit, Michigan, dealt with Biomechanics. Among the technical papers presented were: The Human Body as a Receiver of Mechanical Energy; Theory of the Transmission of Vibratory Energy through Body Tissue; The Response of the Human Body To Low Frequency Vibrations; Experimental Investigations on Brain Concussion; Structural Response of the Human Body to Acceleration; and The Mechanism of Concussion—An Application of Experimental Mechanics in Neurological Science.

National Conference On Industrial Hydraulics

The 15th Annual National Conference on Industrial Hydraulics, sponsored by the Illinois Institute of Technology, took place on October 22 and 23 in Chicago. Papers were presented on components and accessories, machine tools, pneumatics, pumps, materials forming machinery, mobile equipment, servomechanism and systems, space hydraulics, aircraft systems, automotive subjects, and hydraulic fluids.

Society for Nondestructive Testing, Inc.

The society held its first meeting of the year on October 15 in Montreal. "Qualification and Certification of Nondestructive Testing Personnel" was discussed by a panel of four. Future meetings are being planned to discuss the fields of ultrasonics inspection, eddy current, and isotope radiography.

Coming Meetings

Illinois Institute of Technology: "New Ideas 1960", February 5-6, 1960, at the institute, Chicago, for industrial executives. Subjects: forecasting by product line, improving quality, engineering economics applications, production line balancing and theory, uses of operations research in sales, organization for total quality control, material handling methods, and trends in product design.

Institution of Electrical Engineers, Electronics and Communications Section, London: Third International Conference on Medical Electronics, second half of July, 1960, in London. Object: to disseminate information to medical practitioners and electrical engineers who are not experts in medical electronics and to provide specialist sessions for those engaged in medical electronic work.

International Association for Bridge and Structural Engineering: Sixth Congress, June 27 to July 1, 1960, in Stockholm. Themes to be discussed: basis of structural design, metal structures, steel skeleton, reinforced and prestressed concrete, prefabricated structures, and important progress in bridge and constructional engineering.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

RADIOTECHNIQUE ET TELEVISION

Another in the series of "Aide-mémoire" issued by Dunod, these two small volumes contain a wealth of condensed information, including the radio amateurs Code Q, low frequency, capacitance, electronic tube characteristics, construction of radio stations, etc. (H. Aberdam. Paris, Dunod, 1959. 2 vols., 580 fr. ea.)

LA COULEUR DANS LES ACTIVITES HUMAINES, 2IEME ED.

All those concerned with the use of colour will welcome the appearance of this second, revised edition. There are two chapters on the relations between lighting and colour, and a discussion of the physical aspects of colour, and its effect on humans. The second half of the book is concerned with the use of colour in different locations, offices, homes, schools, hospitals, etc. (M. Déribéré. Paris, Dunod, 1959. 351p., 3800 fr.)

ANALYSE DE VARIANCE ET PLANS D'EXPERIENCE

An explanation of the principal results obtained from the analysis of variables, and their applications. It is one volume of a series on probabilities, statistics and operations research. (Daniel Dugué and Maurice Girault. Paris, Dunod, 1959. 68p., 800 fr.)

L'ENTREPRISE ET LA STATISTIQUE TOME 1

One of a series dealing with the economics of plants and other commercial enterprises, this volume is concerned particularly with statistical methods and documentation. After an introductory section the author discusses the history of statistical methods, statistical analysis, and different types of calculating and other machines.

Following chapters consider methods of presentation of results, and their interpretation; the organization of national statistical information especially in France, and the various types of information available—production, prices, employment and wages, banking and commerce, national revenue, etc. A bibliography is included. (R. Dumas. Paris, Dunod, 1959. 402p., 3400 fr.)

NOTIONS SUR LES CIRCUITS D'IMPULSION

Translated from the English, the purpose of this book is to present a basic introduction to impulse circuits. It covers electronic tube circuits, multivibrators, trigger circuits, amplifiers, and applications. (F. J. M. Farley. Paris, Dunod, 1959. 162p., 960 fr.)

INSTRUMENTS ELECTRONIQUES DE MESURE

In this translation from the 1954 English edition, the author surveys the whole field of electronic measurement, the devices used, and the classes of instrument using these devices, with some typical examples. Sections on radiation measurement are found in parts 2 and 3, and there are also sections on cathode-ray instruments, photoelectric measuring instruments and rectifier instruments. Bibliographies are included. (E. H. W. Banner. Paris, Dunod, 1959. 480p., 5400 fr.)

VUES SUR L'AUTOMATISME

A French translation of a report first published by the British Department of Scientific and Industrial Research. The six chapters include a general introduction to the history of automation and the possibilities of automatic production; technical evolution; automatic machining; automatic processing, especially of fluids; automatic data processing; problems of organization; the effect of automation on management and labour.

There is a brief discussion of the future of automation, and a useful bibliography for further reading. (Paris, Dunod, 1959. 140p., 1300 fr.)

EVACUATION ET RECUPERATION DE LA CHALEUR DES REACTEURS NUCLEAIRES

Volume 3 in an introductory series on nuclear engineering, designed to give the reader the scientific basis of atomic reactors.

The topics covered in this volume are: reactor cooling; the use of steam and gas turbines; thermic cycles of some reactors. The two previous volumes were concerned with the physics, control and protection of nuclear reactors. (Richard Alami and Paul Agerson. Paris, Dunod, 1958. 246p., 2900 fr.)

LA FATIGUE DES METAUX, 4IEME ED.

Results of recent research into the fatigue of metals, conducted both in France and abroad, are incorporated into this edition. Some of the topics covered include: the character of fatigue breaks; theory of the mechanism of metal fatigue; fatigue tests; limits of endurance of metals and alloys; the effect of different factors on fatigue, temperature, corrosion, etc.; strength of joints. Long bibliographies are included in each chapter. (R. Cazaud. Paris, Dunod, 1959. 574p., 6900 fr.)

INITIATION AUX PROCESSUS ALEATOIRES

This volume is concerned primarily with the calculation of probabilities, stochastic processes, and Poisson's process. It is another in the series on probabilities, statistics and operational reserch. (Maurice Girault. Paris, Dunod, 1959. 106p., 980 fr.)

PRESENTATION DES STATISTIQUES

With the increased use of statistical analysis, the problem of presentation of statistical information has increased. This volume discusses the methods available, and tries to point out the pitfalls. The first part covers statistical observation, structure and reproduction of charts, and statistical series. Part two considers graphical presentation, describing the various types and their reproduction, and empirical series. Examples are given in all cases. (P. Pepé. Paris, Dunod, 1959. 242p., 3500 fr.)

LES PRINCIPES DE LA THEORIE ELECTROMAGNETIQUE ET DE LA RELATIVITE

A discussion of the basic principles of electromagnetic theory and relativity, in which the topics covered include electrostatics; electromagnetism; Maxwell's theory; Lorentz' theory; principles of relativity before and after Einstein; dynamics; Newton's Law; mathematical analysis. (M.-A. Tonnelat. Paris, Masson, 1959. 394p., 5000 fr.)

FRICTION ET LUBRIFICATION

The first five chapters discuss the various types of friction and their causes, the part played by oxides and surface films, and methods of measuring local temperature caused by friction. The sixth chapter covers friction in nonmetals, while the remainder of the book deals with the behaviour of lubricated surfaces.

The book is based on research carried out at Cambridge University, and is translated from the English. (F. P. Bowden and D. Tabor. Paris, Dunod, 1959. 170p., 1150 fr.)

(Continued on page 101)

• LIBRARY NOTES

(Continued from page 99)

LA COMMANDE ELECTROMAGNETIQUE ET ELECTRONIQUE DES MACHINES-OUTILS, 2IEME ED.

The problems raised by the electro-magnetic and electronic control of machine tools are covered in this manual. The first part discusses general theory, the types of motors used, and speed regulation. Part two is concerned with electro-magnetic control and covers choice of motor and electric apparatus. Electronic control is considered in the last section, which covers electron tubes, thyratrons, servomechanisms, etc. Control plans for both methods are discussed. (A. Fouillé and others. Paris, Dunod, 1959. 332p., 3900 fr.)

RECHERCHE OPERATIONELLE: CAS PRATIQUES ET METHODES

Translated and adapted from the 1956 U.S. edition, this volume is essentially a case book, showing the use of operations research. Discussed are applications in: the U.S. Air Force; British coal mines; delays in toll-collecting; iron ore loading and discharging; stock control; the Monte-Carlo method in a military problem. Most of the articles listed in the fourteen page bibliography appeared in U.S. publications. (J. F. McCloskey and J. M. Coppinger. Paris, Dunod, 1959. 248p., 2600 fr.)

PRATIQUE DE LA MESURE ET DU CONTROL DANS L'INDUSTRIE, TOME 2

The first volume in this series covered pressures, levels, and flows. This volume is concerned with the measurement of temperature, humidity, density and weight. The author reviews the principles of each type of measurement, gives examples of calculations for each important formula, and describes the workings of the different types of instruments available. There is a useful bibliography.

A third volume will cover calorimetric measurement, conductivity, gas analysis, and miscellaneous measurements. (J. Burton. Paris, Dunod, 1959. 392p., 4600 fr.)

BETON-KALENDAR 1959

This German concrete manual, now in its 48th year, contains all its usual features. New material added includes additional German standards related to concrete and concrete construction; arenas; elastic slabs; revised chapters on staircases, and stretcher walls. Much of the material is given in tabular form in this mine of information. (Ed. by Georg Ehlers. Berlin, Ernst, 1959. 2 vols., 20DM.)

SYMPOSIUM ON APPLICATION OF SOIL TESTING IN HIGHWAY DESIGN AND CONSTRUCTION

The papers presented at this 1958 Symposium covered: highway soil engineering; core drilling machines; soil exploration and mapping in Illinois; value of soil test data in road planning; methods of compacting granular soils; Ohio's typical moisture-density curves; compaction characteristics. Of particular interest is a paper on the investigation of banded sediments along St. Lawrence North Shore. (Philadelphia, American Society for Testing Materials, 1959. 127p. $4.00. s.t.p. no.239.)

THE LOGIC OF SCIENTIFIC DISCOVERY

The first English translation of the 1934 German edition, this text has been brought up to date by means of footnotes and 150 pages of appendices. It presents the author's picture of science as an attempt to find a coherent theory of the world, composed of bold conjectures and disciplined by penetrating criticism. The author contends that the growth of science depends on this intellectual daring and rational criticism. Also to be published this year is a complement to this volume, Postscript: After Twenty Years. (K. R. Popper. Toronto, University Press, 1959. 480 p., $7.50.)

VOICE ACROSS THE SEA

Many E.I.C. members will remember the joint meeting held with the I.E.E. and the A.I.E.E. to commemorate the opening of the first Transatlantic telephone cable in 1956.

This is the non-technical story of the laying of submarine cables from the first attempt in 1858, to 1956, and shows convincingly the great progress which has been made in the past century. Many well-known names were associated with the early attempts; Cyrus Field, Lord Kelvin, Samuel Morse, Thomas Edison and Oliver Heaviside, and although the engineers connected with modern cable-laying seem to be largely anonymous, their achievements are equally important. (A. C. Clarke. Toronto, Musson, 1958. 208 p., $3.75.)

MAN-MADE SUN: THE STORY OF ZETA

A relatively non-technical account of recent efforts to harness atomic energy, culminating in the construction of ZETA, zero-energy, thermonuclear assembly, in which temperatures of a million degrees were reached, and maintained for a relatively long time. The book explains the generation of power by electricity, the structure of the atom and its nuclei, thermonuclear reactions, the construction of ZETA, and future sources of power. (J. D. Jukes. Toronto, Nelson, Foster and Scott, 1959. 136p., $3.25.)

METAL INDUSTRY HANDBOOK AND DIRECTORY, 1959

The first three hundred pages of this Handbook include data on the general properties of metals and alloys, British Standards, Ministry of Supply, aircraft and Admiralty specifications. General data and tables are included in Section 2, and information on electroplating and allied processes in Section 3. The Directory Section includes information on British technical and trade associations, a classified directory, and an alphabetical list of firms. (London, Iliffe, Toronto, British Book, 1959. 564p., $4.50.)

HANDBOOK OF THE AIRCRAFT INDUSTRY

The first section of this handbook contains information on the British aviation industry, aeronautical engineering as a career, and the training facilities available in Britain, as well as a who's who of prominent men in the British aircraft industry. Part 2 provides an historical survey, and Part 3 a review of the main aspects of aeronautical engineering. Further sections deal with research and development, guided missiles and civil aviation. Also included are a pictorial guide to modern aircraft, condensed technical data, a glossary of aeronautical terms, and a list of abbreviations. (Ed. by J. L. Nayler and T. F. Saunders. London, Newnes, 1958. 341p., 35/-)

ANALYSIS OF STRAIGHT LINE DATA

Intended primarily for engineers and physical scientists interested in doing their own analysis, rather than relying on a statistician, this volume covers in detail the analysis of experimental data which can be described in terms of linear relationships. Emphasis is placed on the choice of the best method of analysis to use, and the influence of the assumed statistical model on the success of the analysis. Each subject is introduced with data from an actual experiment, and the topics covered include: classical model, x known without error, variance of y constant; samples from bivariate normal populations; several lines, analysis of variance; orthogonal polynomials; the use of transformations; cumulative data, the fading line. There is a useful bibliography. F. S. Acton. New York, Wiley, 1959. 267p., $9.00.)

GLIDING: A HANDBOOK ON SOARING FLIGHT

The author of this volume is Chief Flying Instructor at a British Gliding Centre, and in the first section he explains everything a beginner needs to know before flying solo. The second section contains further instruction, including chapters on safe flying in high winds, aerotows, stalling, spinning and turning. The final section is for the experienced, and is concerned with cross-country flying, cloud flying, soaring, instrument flying, longer flights, and qualifications for international awards. (Derek Piggott. Toronto, Macmillan, 1958. 261p., $5.00.)

THE CANAL BUILDERS

A most interesting account for the general reader of the history of canals and canal builders from the dawn of civilization to the St. Lawrence Seaway. The first canals in Egypt or Mesopotamia were built for irrigation, and later came the canals for navigation and city water supplies. The author describes the Arabian achievements in the Dark Ages, the advances made in Italy during the Renaissance, Brindley, Telford and the English canals, the U.S. canals of the nineteenth century, Suez, Panama and the St. Lawrence. There are several interesting illustrations, and a list of books for further reading. (Robert Payne. Galt, Brett-Macmillan, 1959. 277p., $5.00.)

ROCKET ENCYCLOPEDIA ILLUSTRATED

This encyclopedia, the first in English on the subject, includes information on all aspects of rocketry: rocket power and applications; propellants; engines; assemblies; components; missiles; test and ground equipment; historical events; biographies, etc. Each term is concisely defined, and an explanation in a more readable style appended. There are many illustrations, some of which are here published for the first time, and these are keyed to the text by the use of bold-faced type. Cross references are indicated by italics. A valuable compilation for both the engineer and the layman. (Ed. by J. W. Herrick and Eric Burgess. Los Angeles, Acro, 1959. 607p., $12.50.)

*THE DESIGN OF SHELLS

The fundamental aspects of the design and analysis of shell structures is presented. Although the book deals at length with the theory of the subject, it is practical in its approach to the problems involved, and deals with the design of actual structures, the completion of which are shown in photographs. Aspects treated are the membrane theory, the differential equation of shells, symmetrical problems, the end and North shell, shells with prestressed boundary beams, anisotropic shells, plate approximations, the balanced shear method, and end frames and arch beams. (A. Chronowicz. Toronto, British Book Service, 1959. 202p., $9.50.)

*ENGINEERING STATISTICS

Statistics is presented as a science for making decisions. Following an introduction to the basic fundamentals of probability and distribution theory, a coverage is provided for both the theoretical aspects and practical applications of the normal distribution; the Chi-Square, t, F, Binomial nad Poisson distributions; significance tests, tests about one and two parameters; estimation; fitting of straight lines; analysis of variance; quality control and sampling inspection. Liberal use is made of Operating Characteristics Curves to assist in grasping more difficult statistical concepts, and selected examples are used to solve a wide variety of typical enigneering problems. (A. H. Bowker and G. J. Lieberman. New York, Prentice-Hall, 1959. 585p., $11.00.)

*SYMPOSIUM ON PAPER AND PAPER PRODUCTS

Seven papers intended to acquaint the paper technologist with some of the new developments in paper technology and the methodology which has been evolved. Synthetic fiber papers, internal bonding of paper, and Clupak paper are among the topics discussed. (Philadelphia, American Society for Testing Materials, 1959. 73p., S.t.p. no.241, $2.75.)

*SYMPOSIUM ON STABILITY OF DISTILLATE FUEL OILS

Eight papers dealing with the resistance of fuel oil to breakdown or decomposition. The papers discuss stability problems, past and present, and measures to relieve them. (Philadelphia, American Society for Testing Materials, 1959. 56p., $2.75, S.t.p. no.244.)

*THE EFFECT OF RADIATION ON MATERIALS VOL. III

Papers providing new data on dosimetry techniques; radiation facilities and techniques; and radiation effects on reactor materials and various other materials. (Philadelphia, American Society for Testing Materials, 1959. 169p., $4.25. S.t.p. no.233.)

*REPORT ON PROPERTIES OF CAST IRON AT ELEVATED TEMPERATURES

Report on properties of six commercial low-alloy gray irons, and of one unalloyed ferritic nodular iron, evaluated at 800°F and at 1000°F by means of tensile tests, creep-rupture tests, thermal-shock tests, growth tests and metallographic examinations. Tests showed that the alloys are promising for applications involving thermal shock at temperatures up to 800°F, but not at 1000°F. Development of alloys suitable for use to 1000°F appeared possible. (Philadelphia, American Society for Testing Materials, 1959. 90p., $4.25. S.t.p. no.248.)

*THE STRUCTURE OF METALS

Modern concepts of the electron theory of metals are described. This is followed by a discussion of the experimental techniques which have been developed to test the theory, and to establish such factors as width of the valence band, shape of the "density of states" curves, shape of the Fermi surface, and the numbers and signs of charge carriers in electrical conduction. The dislocation theory of plastic deformation is then presented, and the experimental techniques associated with it described. The papers in this book constitute lectures given at the Institution Metallurgists refresher course in 1959. (Toronto, British Book Service, 1959. 118p., $6.00.)

*OPERATIONS RESEARCH

This text begins with a brief survey of the elements of probability theory, including the concepts of probability of an event, randon variable, probability distribution, and conditional probability distribution. Sampling is then discussed, and an introduction is given to the Monte Carlo method of simulated sampling. Succeeding chapters present various problem areas in operations research, specifically, inventory, replacement, waiting lines, competitive strategies, allocation, sequencing, and dynamic programming. (M. Sasieni and others. New York, Wiley, 1959. 316p., $10.25.)

*SURVEYING, 4TH ED.

In addition to the basic principles of surveying, sufficient information is provided to develop a sound working knowledge of special surveying topics such

(Continued on page 107)

• LIBRARY NOTES

(Continued from page 104)

as photogrammetry and the use of accurate design topographic maps for determining earthwork quantities. In this edition not only have changes been made to bring the book up-to-date, but major changes in the presentation have been made as well. This is particularly true in the case of modern surveying equipment and practices, which are introduced early in the book. (H. Bouchard and F. H. Moffitt. Scranton, International Textbook Co., 1959. 664p., $10.50.)

°SAMPLING INSPECTION TABLES, SINGLE AND DOUBLE SAMPLING, 2ND. ED.

The previous edition presented a working set of sampling inspection tables for control of quality and economy of inspection within a manufacturing plant. In addition to these tables, the present edition contains a collection of "Probability-of-acceptance" curves called Operating Characteristic curves. These curves may be used to determine how particular sampling plans chosen from the tables will operate for all possible levels of presented quality. The use of the sampling tables is discussed, and a new chapter is included which discusses the practical significance of the Operating Characteristic curves. (H. F. Dodge and H. G. Romig. New York, Wiley, 1959. 224p., $8.00.)

°INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING, PUBLICATIONS 1958

Papers dealing with such topics as analyzing deformations of plane trusses, general instability of low framed buildings, bending of a sectorial plate, stability of pony-truss bridges, stability of rib-reinforced cylindrical shells under lateral pressure, cyclic loading of portal frames, analysis of thin elastic shallow segmented shells, and a model continuous beam bridge with steel deck. Papers are written in English, French and German with summaries of each paper in all three languages. (Switzerland, Verlag Leeman, 1958. 296p., 40 Sw fr.)

°SERVOMECHANISMS AND REGULATING SYSTEM DESIGN. VOL. 1, 2ND. ED.

The nature of the feedback control system problem is described and an analytical approach to servomechanism and regulator design is presented. Emphasis is placed on the complex plane, the attenuation-frequency, and root-locus methods of control system analysis of both simple and more complex systems. In conjunction with the multiple-loop systems, techniques are described for complicated control problems with simplified analysis methods. The use of these methods permits the designer to arrive at a workable design fairly readily. The present edition reflects recent advances within the field. (H. Chestnut and R. W. Mayer. New York, Wiley, 1959. 680p., $11.75.)

°HIGH TEMPERATURE MATERIALS

A summary of the state of knowledge as well as of recent developments in the field of materials for use at temperatures above 1500°F. The characteristics of nickel- and cobalt-base alloys and cermets are summarized and the factors that control their performance are indicated. This is followed by a discussion of refractory metals, and of dispertion hardening as a means of obtaining high strength. The concluding portion of the book deals with gas-metal interactions and considers vacuum melting and its effects on properties, the effect of testing environment on properties, and oxidation resistance. The papers in this book constitute the proceedings of a conference held in Cleveland, Ohio in 1957. (Ed. by R. F. Hehemann and G. M. Ault. New York, Wiley, 1959. 544p., $17.50.)

°GROUND WATER HYDROLOGY

An account of ground water hydrology that presents the fundamentals of the subject as well as recent methods being used in the field. The basic quantitative aspects relating to use, occurrence, movement, water wells, and ground water levels are followed by discussions of ground water quality, conservation of ground water, methods of investigating ground water by surface and subsurface procedures, artificial recharge, and sea water intrusion. A review is also given of the various types of laboratory model and numerical analysis studies. (D. K. Todd. New York, Wiley, 1959. 336p., $10.75.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Aircraft

Pressure distribution and force measurements on a VTOL tilting wing-propeller model; part 1: description and tabulated results, by J. A. Dunsby and others.

Some data on elevator damping and stiffness derivatives on a delta wing aircraft model at supersonic speeds by K. J. Ruckeman. Ottawa, N.R.C., National Aeronautical Establishment, 1959. (LR-252, LR-250).

Beams and girders

Normal mode analysis of beams of non-uniform cross-section with tabulated results for some linearly tapered clamped-pinned beams, by R. S. Julius and S. Ranta. Ottawa, N.R.C., National Aeronautical Establishment, 1957. (LR-210).

Bibliographies

Bibliography of periodical literature on Canadian geography, 1930-1955; part 3. Quebec and Ontario. Ottawa, Geographical Branch, 1959. (Bibliographical Series No. 22) 50c.

City planning: a basic bibliography with special reference to civil en-

gineering and land surveying, by G. C. Bestor and H. R. Jones. Sacramento, Calif. Council of Civil Engineers and Land Surveyors, 1957.

Pumped storage for hydro-electric power; a selected list of references in English. Knoxville, Tennessee Valley Authority, Technical Library, 1959.

Canada. Mining

Coal mines in Canada. Ottawa, Dept. of Mines and Technical Surveys, Mineral Resources Div., 1959. (Operators list 4). 25c.

Chloride Salt

Ice melting properties of chloride salt mixtures. Wash., N.R.C., Highway Research Bd., 1959. (Bulletin 220). 50c.

Concrete reinforcement

Reinforced concrete design handbook of the American Concrete Institute, 2d ed. Detroit, American Concrete Institute, 1955.

Helium

The story of the early days of the extraction of helium gas from natural gas in Canada, 1915-1920, by J. Satterly. Ottawa, Mines Branch, 1959. (Information Circular no. 105.) 25c.

Industrial resources

Man and raw materials, by E. W. Pehrson. Phila., ASTM, 1958. (Edgar Marburg Lecture, 1958.)

Muskeg

Muskeg access: the slipe-haul method, by J. Cuthbertson and N. W. Radforth.

Proceedings of the fifth muskeg research conference, 4 March 1959. Ottawa, N.R.C., Associate Committee on Soil and Snow Mechanics, 1959. (Technical memoranda nos. 58 and 61.)

Permafrost

Proceedings of the permafrost research conference at the Bldg. Res. Centre, Ottawa, March 27, 1958. Ottawa, N.R.C., Associate Committee on Soil and Snow Mechanics, 1959. (Technical memorandum no. 60.)

Science. History.

From Euclid to Eddington; a study of conceptions of the external world, by Sir E. Whittaker. New York, Dover, 1958. $1.35.

On mathematics and mathematicians, by R. E. Moritz. New York, Dover, 1958. $1.95.

Philosophy and the physicists, by L. S. Stebbing. New York, Dover, 1958. $1.65.

The philosophy of space and time, by H. Reichenbach. New York, Dover, 1957. $2.00.

Slabs

The freezing and melting times of slabs and cylinders, by D. C. Baxter. Ottawa, N.R.C., 1959. (Mechanical engineering report MK-1).

Soil mechanics

Proceedings of the twelfth Canadian soil mechanics conference, Dec. 8 and 9, 1958. Ottawa, N.R.C., Associate Committee on Soil and Snow Mechanics, 1959. (Technical memorandum no. 59.)

Technical writing

Writing and publishing technical book; how to prepare manuscripts of business, industrial, engineering and professional books—and how to arrange for their publication. New York, Dodge, 1959. Free.

Turbines

Untersuchungen über den Ventilationsverlust von Turbinenrädern, by P. Suter and W. Traupel. Zurich, Verlag Leeman, 1959. Sw. Fr. 6.

Wave mechanics

A drift monitoring system and a rapid calibrating technique for the capacitive wave profile recorder, by R. J. Harron. Ottawa, N.R.C., 1959. (Mechanical engineering report MI-818A.)

New Journal

The Institution of Mechanical Engineers announces publication of a new quarterly, the Journal of Mechanical Engineering Science. Its object is to permit effective reporting of contributions of a specialized and scientific nature, prepared by authors engaged in fundamental research in the field of mechanical engineering. The subscription will be £3 a year. A copy of the first issue is on file in the E.I.C. Library, for members to examine.

Dexion (Canada) Limited announces the opening of a new Montreal office and warehouse at 5085 Cote de Liesse Road.

International Rectifier of Canada, Ltd. has opened an Ottawa office at 1581 Bank Street.

Conference Schedule

Institute of Radio Engineers, Aeronautical and Navigational Engineers, East Coast Conference, Baltimore, Md., October 24-26.
Institute of Radio Engineers, Electronic Devices Meeting, Washington, D.C., October 27-29.
American Institute of Chemical Engineers, Sheraton Palace, San Francisco, December 6-9.

The Canadian Chromalox Company Limited has introduced their new electric cabinet convector heaters. Constructed of heavy-gauge metal, these units are designed to permit easy air access through the bottom louvers.

Graver Water Conditioning Company (**A Division of Products Tank Line of Canada, Ltd.**) has developed a spur-gear drive for heavy-duty applications of the Rota-Rake clarifier and thickener. The Rota-Rake is a horizontal flow water and liquid-treatment unit for gravity sedimentation and sludge thickening.

Conference Schedule

American Oil Chemists' Society, Fall Meeting, New York, October 17-19.

The 1959 Gilbreth Medal Award of the Society for Advancement of Management was presented to Gerald B. Bailey of Woods, Gordon & Co., Toronto, at the society's 14th Annual Management Engineering Conference in New York.

Sarnia Scaffolds Limited, with head offices at Berryman Avenue, St. Catharines, Ontario, and branch offices across Canada, will continue the scaffold business established by Sarnia Bridge Company Limited and Sarnia Scaffolds (Western) Limited, distributing the same products and specializing in the sale and rental of equipment to the construction industry.

Canadian National Railways reports the foundations for steel work have been completed and the Dominion Bridge Company is ready to erect steel on their new 17-storey headquarters office building at the corner of Mansfield and Lagauchetiere Streets in Montreal.

The Canadian Choromalox Company Limited announce their new catalogue **CC-59** showing the latest developments in the home, commercial and industrial electric space heating applications. Copies available free, on request.

Design Engineering's directory of suppliers for 1960 will soon be available to assist the design engineer in his choice of materials and where to buy them.

Bepco Canada Limited's Bepco Journal treats of electro-mechanical brakes in the September issue. For the Bepco Journal or literature on Bepco products write to the head office at 4018 St. Catherine St. West, Montreal.

Standard Wire and Cable Limited, Toronto, have just issued a one-page price list which enables the purchasing man to shop for a whole range of products at a glance.

Armco Drainage and Metals Products of Canada Ltd. report the successful use of a large flat-bottom corrugated metal underpass structure to carry small farm lanes and service roads under limited access highways.

Industrial Research Magazine (summer issue) describes applications of new devices being developed by Underwater Manipulators for keeping waterways ice-free in winter, aerating ponds and lakes, controlling waves, communicating through water, and mining the ocean-bottom.

Canadian Applied Research Limited announce the introduction of the ANADAC (Automatic Navigation Display and Computer) series of dead reckoning navigation instruments. These are designed and manufactured by CARL who also produce ice detectors designed for airframe and engine intake installations.

The Master Builders Company Ltd., Toronto, have available a free Bulletin MBR-P8 containing twelve case histories of tunnel concreting.

Warnock Hersey Company Limited have published the first issue of their house magazine W. H. News, which deals with hidden problems of seaway construction.

Creosote Information Bulletin, Vol. 2 No. 5, published by the coal tar products division of Dominion Tar and Chemical Company, Limited gives a through description of leaching (insect burrowing) in untreated wood used for marine piling.

Canadian Dexion News, Vol. 3 No 3, describes with pictures many uses for Dexion slotted angles and grid. They can be quickly assembled and are rust-proof and lightweight. For catalogue and price list write Dexion (Canada) Limited, 114 Clayson Road, Toronto 15.

Gypsum, Lime & Alabastine Limited's summer bulletin Vol. 27, No. 2 entitled

"The Clearing House" describes and illustrates ornamental plaster work in churches and other buildings.

American Air Filter Company of Canada Ltd. has released a new product bulletin describing the characteristics and operation of the Amerclone dry, centrifugal dust collector. This Bulletin 291A is available upon request from the company at 400 Stinson Blvd., Montreal 9.

James Howden & Company of Canada Ltd., 1510 Birchmount Road, Scarborough, Ont., has a 16-page brochure available illustrating how fuel costs can be reduced with the Package Ljungstrom Air preheater.

Gigantic Pipes o' Pan? No, but . . .

DAVIESHIP can build any size or shape of engineering structure you may require!

It would take a gargantuan Pan to lift that 25-ton steel Half Arch Pipe! It is 6′ in diameter and 130′ long from base to tip of cone. Yet this fantastic pipe is only one of 48 which DAVIESHIP is building for the Cargill Grain Company's new Baie Comeau grain terminal — and only one portion of the order now being filled for them at DAVIESHIP. Other portions include a grain warehouse, headhouse, storage bins, hoppers, casings and shipping galleries. As you can see, no steel fabrication is too large or too intricate for the DAVIESHIP Engineering Division to handle! Give us a call if we can serve you in any way.

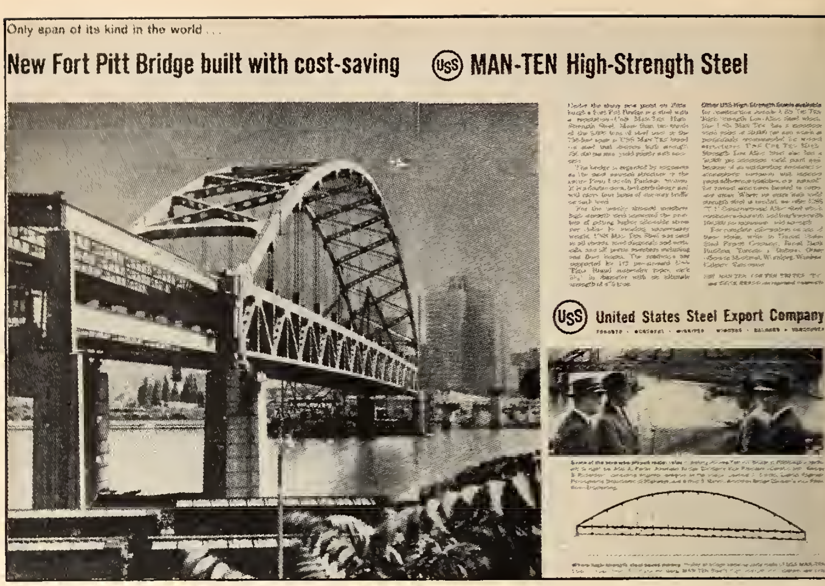
E. I. C. CERTIFICATE OF ADVERTISING MERIT

In the August 1959 issue, the advertisement of the United States Steel Export Company was judged the "best" by the fifty readers who were asked to scrutinize the advertisements. The advertisement occupies pages 10 and 11.

The advertisement, printed in blue and black, features the "ONLY SPAN OF ITS KIND IN THE WORLD . . . NEW FORT PITT BRIDGE BUILT WITH COST-SAVING USS MAN-TEN HIGH-STRENGTH STEEL."

A new jury of readers serves each month. The members are asked to select what they consider to be the "best" advertisement, in the issue under consideration, from the viewpoints of ACCURACY — INFORMATION and ATTRACTION.

The E.I.C. Certificate of Advertising Merit won by this advertiser will be presented to Mr. W. Jones, Manager of the Advertising & Market Development and a duplicate will be presented to Batten Barton, Durstine & Osborn Inc., the advertising agency which prepared and placed the advertisement.



UNITED STATES STEEL EXPORT COMPANY WINNING ADVERTISEMENT

Reproduced above is the United States Steel Export Company's advertisement which was judged the "best" in the August issue by a fifty reader jury. Judging was based on ACCURACY–INFORMATION and ATTRACTION. The copy of the advertisement is concise and outlines the materials used for the construction of the bridge. It concludes by giving the addresses to be used to obtain complete information on the steels used in the bridge.

LEONARDO DA VINCI *possessed what was possibly the most imaginative and versatile mind of all time. He was, among other things, an artist, an engineer, and an inventor. Reproduced here are original sketches by Da Vinci for a foot-propelled paddle boat, showing details of gear mechanism, paddles, cam, and fly wheel.*

IMAGINATION

In their offices and drafting rooms and in their huge, all-enclosed yards, Canadian Vickers put imagination and creative skills to work. Here, ships are built on a year-round basis . . . passenger ships, destroyer escort vessels, tankers, tugs, ferries, dredges, scows . . . all built by Canadian Vickers to play an important role in our economy.

In their shops, Canadian Vickers also design and manufacture machines and equipment for every imaginable industrial need . . . thereby fulfilling their pledge: "If Industry Needs It . . . Canadian Vickers Builds It . . . Better."

A MESSAGE FROM THE PRESIDENT

For many months the Council has been considering ways and means of expanding the technical content of *The Engineering Journal.* At the same time, consideration was given to the wider dissemination of the information the publication contains.

After a thorough study and surveys extending from February through August, the Finance Committee and the Publications Committee recommended, and the Council decided that the distribution of *The Engineering Journal* is to be enlarged to reach over 32,000 Canadian engineers. This will enable the publication to render an improved and enlarged technical service to the maximum number of engineers. Members and non-member engineers alike will receive the Journal at no charge, as a result of this expanded E.I.C. service to Canadian engineers. Commencing January, 1960, E.I.C. members will not be required to pay the annual subscription for the "Journal".

During the Fall of 1959, I visited about half of the branches, and told them about the Institute's new policy for the circulation of *The Engineering Journal* beginning with the January 1960 issue. However, since some branches will not have received this information directly from me prior to the end of the year, I am having this message printed in the December issue so that every member may know of this new policy, and the reasons for it.

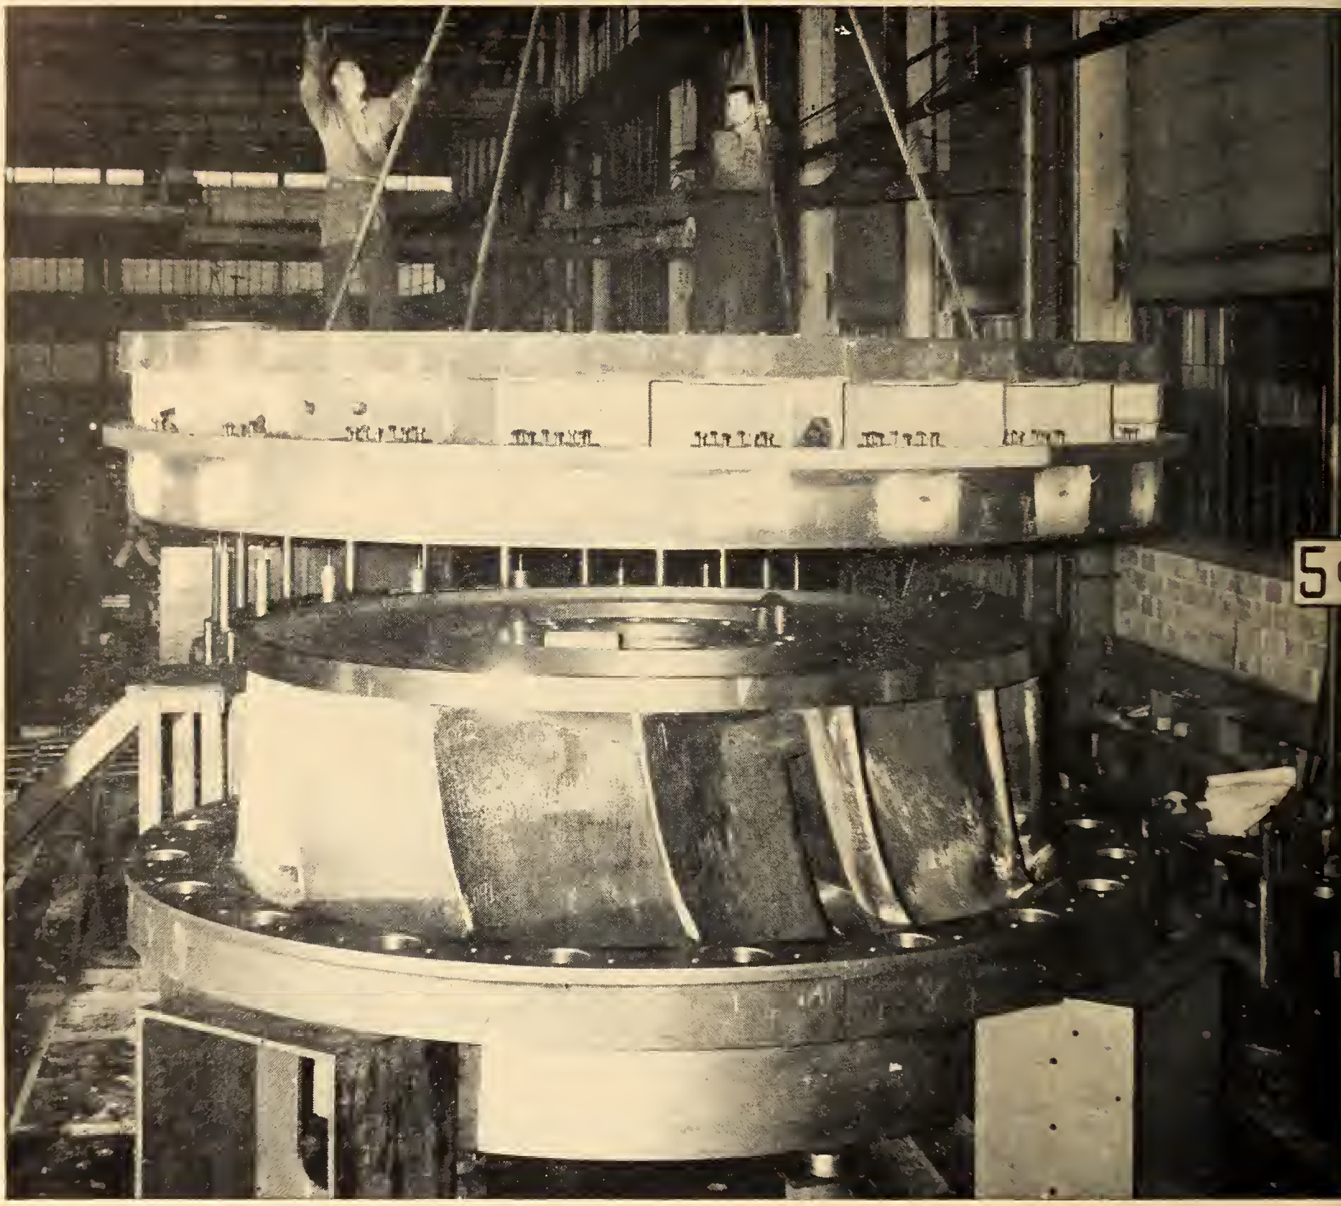
Naturally, to be successful in this enlarged area of service to the profession, *The Engineering Journal* must continue to receive the support, helpful suggestions and, most important of all, technical papers of high quality from the membership.

Most E.I.C. members will probably read this message during the Christmas season. May I, therefore, conclude by extending to you and your loved ones my most sincere best wishes for a wonderful Christmas and a pleasant and successful New Year.

Yours truly,

J. J. HANNA, M.E.I.C.
President
THE ENGINEERING INSTITUTE
OF CANADA

SHIP TO HYDRO QUEBEC AT BERSIMIS NO.2



Bersimis No. 2 will add another 900,000 h.p. to Quebec Hydro's capacity for meeting the ever increasing demand for power in the Province. The site, 22 miles downstream from Labrieville on the Bersimis River, provides a gross head of 386 feet. The tunnel for the water supply measures 38 feet in diameter and 2,692 feet in length; the water will flow at a velocity of 21 feet per second when all units are operating at rated load.

Five Dominion Francis Turbines of 180,000 h.p. each, running at 163.6 rpm, drive vertical generators of 120,000 KVA. They will produce 2,500 million KWH annually—more power than the total capacity available in Chile.

The photograph above was taken during test assembly at Dominion to check runner clearances between the head cover and lower ring.

Write for Bulletin 201—"Hydraulic Turbines".

BRANCH OFFICES, TORONTO, VANCOUVER

MEET THE AUTHORS

G. D. Campbell, M.E.I.C., Director of Technical Services, Canadian Good Roads Association (*Highway Research Activities in Canada*).

Dr. Campbell graduated in 1951 from the University of Manitoba with a B.Sc. in civil engineering, and received his M.Sc. from Purdue University in 1952. After two years on the staff of the Federal Department of Public Works, Ottawa, he returned to Purdue University where he earned a Ph.D. degree in 1956. For the next year Dr. Campbell was engineer-observer for the Canadian Good Roads Association at the AASHO Road Test at Ottawa, Illinois. In the fall of 1957 he was appointed to his present position.

W. J. Pardy, M.E.I.C., assistant superintendent, Power Cable Engineering, Northern Electric Company Limited (*Edmonton Installs Canada's First Oil-Filled Pipe Cable System*).

Mr. Pardy graduated in 1944 from Queen's University with a degree in electrical engineering. He joined the Wire and Cable Division of the Northern Electric Company Limited as a development engineer in 1946. Mr. Purdy is a member of the Corporation of Professional Engineers of the Province of Quebec.

C. Z. Monaghan, M.E.I.C., superintendent, Electric Light and Power Distribution System, City of Edmonton (*Edmonton Installs Canada's First Oil-Filled Pipe Cable*).

Mr. Monaghan graduated from the University of Alberta in 1939 with a B.Sc. in electrical engineering. He began his civic employment as a draftsman in 1940 and became superintendent in 1950. He has served two years on the executive of the Edmonton Branch of the Engineering Institute of Canada, acted as meetings committee chairman for the Alberta Association of Professional Engineers and been chairman of the Underground Committee of the Western Zone, Canadian Electrical Association.

In 1959, he was appointed to a C.S.A. Committee on High Voltage Power Cable.

E. L. Brown, M.E.I.C., field engineer, The Shawinigan Engineering Company Limited, Montreal (*Geological Features and Foundation Treatment at the Beechwood Development*).

Mr. Brown graduated from the University of New Brunswick in 1944 with a B.Sc. degree. He was employed by the New Brunswick Electric Power Commission on the Beechwood project and has since been with The Shawinigan Engineering Company Limited on their Beaumont Development. He is a member of the Association of Professional Engineers of New Brunswick.

I. D. MacKenzie, M.E.I.C., geologist, The Shawinigan Engineering Company Limited, Montreal (*Geological Features and Foundation Treatment at the Beechwood Development*).

Mr. MacKenzie joined the Shawinigan Engineering Company in 1940 and has since worked on hydro developments and other structures in Quebec, New Brunswick, Newfoundland and Labrador as well as Manitoba. He is a member of the Corporation of Professional Engineers of Quebec, the American Concrete Institute, and the Geological Society of America.

W. M. Newby, M.E.I.C., consulting engineer, Niagara Falls, Ont. (*The Economics of By-Product Power Generation*).

Mr. Newby graduated in mechanical engineering from Queen's University in 1940. He was employed for one year after graduation with the Canadian General Electric Company Limited and joined H. G. Acres and Company Limited in 1941. He became chief project engineer, Thermal Division in 1957, a position he held until July 1959 when he began a private consulting practice.

W. P. London, M.E.I.C., chief engineer, Thermal Division, H. G. Acres and Company Limited (*The Economics of By-Product Power Generation*).

After his graduation from University of New Brunswick in 1934, Mr. London spent two years with the New Brunswick Electric Power Commission and five years with the Bathurst Power and Paper Company Limited. He joined H. G. Acres and Company Limited in 1941 and became chief engineer, Thermal Division in 1957.

I. W. McCaig, M.E.I.C., hydraulic engineer, H. G. Acres and Company Limited, Niagara Falls, Ontario (*Photography and Electronics as Tools in Hydraulic Experimental Work*).

Mr. McCaig graduated from Glasgow University in 1943 and served during the war on research at the Marine Aircraft Experimental Establishment. He joined Babtie, Shaw and Morton, consulting engineers, Glasgow, in 1946. In 1952 he came to Canada and joined H. G. Acres and Company in 1953 where he is now in charge of the Hydraulic Section.

K. W. Gent, instrumentation engineer, H. G. Acres and Company Limited, consulting engineers, Niagara Falls, Ontario (*Photography and Electronics as Tools in Hydraulic Experimental Work*).

Mr. Gent is a graduate of the Institute of Civil Engineers, London, England, 1934. He has held various positions with navigation and land drainage authorities, including the City of Westminster and the River Nene Catchment Board. In 1947 he joined James Williamson and Partners, Glasgow and in 1948 came to Canada to work for H. G. Acres and Company Limited, where he is now in charge of hydraulic model studies in the laboratory and experimental hydraulic and stress measurements in the field.

J. N. Mustard, assistant engineer-in-charge, concrete control department, The Hydro Electric Power Commission of Ontario (*The Use of Fly Ash in Concrete by Ontario Hydro*).

Mr. Mustard graduated from the University of Toronto with a B.A.Sc. in civil engineering in 1941. He was overseas with the Royal Canadian Engineers from 1941 to 1946 and has worked since with the Ontario Hydro.

At time of going to press no information was available on Mr. C. MacInnis, Jr.E.I.C., co-author of the above paper.

F. S. Howes, professor of electrical engineering and director of university extension at McGill University (*Something Can Be Done About Noise*).

Dr. Howes received his B.Sc. with honours in electrical engineering from McGill in 1924 and his M.Sc. in 1926. The Ph.D. degree was granted by the University of London in 1929. He returned to McGill University as a lecturer in electrical engineering in 1929 and was appointed director of University Extension in 1949.

Dr. Howes is a fellow of the Institute of Radio Engineers and a member of the Corporation of Professional Engineers of Quebec.

HIGHWAY RESEARCH ACTIVITIES IN CANADA

Gordon D. Campbell, M.E.I.C. *Director of Technical Services*
Canadian Good Roads Association, Ottawa, Ont.

Presented to the Seventy-Second Annual General Meeting of The Engineering Institute of Canada, Quebec City, May 23, 1958
Revised and resubmitted for publication November 1959

In recent years the Canadian Good Roads Association has developed as the clearing house for Canada of technical information related to roads and streets. CGRA has organized to stimulate research, publish and distribute information on technical developments and to bring together specialists from all parts of Canada to discuss and resolve common problems in their special branches of highway technology.

As the co-ordinating agency for road research in Canada, CGRA has compiled and published a complete list of all road research projects currently under way or recently completed in Canada. This list contains a description of each project, where it is being done, by whom it is being done, the starting and completion dates, and where the results are available. The survey is intended to co-ordinate research work, to aid practising engineers in incorporating new findings into current practice, to expose areas requiring urgent attention and to stimulate new research work.

The results of this first survey indicate that approximately $1,000,000 was spent in 1958 for road and street research and development in Canada. Thus, for every $1,000 spent on roads and streets in Canada in that year approximately one dollar was spent on basic or applied research. The initial report lists 159 individual road research projects, each dealing with a specific technical problem, under way in Canada today. This data, though encouraging, indicates that Canada lags well behind the United States highway industry and other private industries in its rate of investment in road research. Research must be stepped up to solve Canada's own unique problems and to keep pace with road development in this country.

Introduction

TWENTIETH CENTURY man is very conscious of research. The reason, of course, is that he knows its value. Each year the new products of research and development increase the comfort of modern living, raise the standard of living and increase the hours of leisure. Today we wear nylon shirts, shave with electric razors, buy our food in plastic containers, fly across the country in a few hours and drive to work or pleasure in comfortable, even luxurious automobiles. Such developments did not just happen. Industries methodically set aside as much as two per cent or more of their total income for research and development.[2, 7] These large expenditures are a proven investment which pay off in improved products and lower costs.

Road research and development have lagged well behind the need. This is evident from the deplorable traffic accident statistics, the congested arterial streets and the high percentage of failed pavements on both the rural roads and city streets of Canada. All of these deficiencies could be substantially reduced or overcome completely through adequate planning, better design techniques, improved materials and the better use of existing materials. We should learn the lesson of industry and devote more time, effort and money to road research. This too will pay off in lower road construction costs, lower vehicle operating costs and improved road service.

Road research also lags behind development in other fields of engineering and civil engineering. There is a reason for this. It was explained in 1927 by the world-famous civil engineer Dr. Karl Terzaghi. In speaking to the Boston Society of Civil Engineers about one of the earliest road research projects he said:

"The attempt of the United States Bureau of Public Roads to establish a basis for the design of concrete roads by means of a condition survey undoubtedly represents one of the prominent landmarks in the field of civil engineering. To lead the enterprise to final success requires methods of procedure which are fundamentally new as the methods recently developed in the hydraulic laboratories of Europe for solving the problems of river improvement and of hydro-electric power development. As far as their essentials are concerned their methods resemble those which have been successfully used in medicine much more closely than those which are customary in engineering. Putting these methods into practice, therefore, requires a thorough mental readjustment on the part of engineers engaged in the enterprise.

"The reason for the striking contrast between the high state of perfection of the semi-empirical methods of medicine and the rudimentary state of the same methods applied to foundation engineering is essentially psychological. The rapid development of modern engineering was due to obtaining accurate solutions of various problems by means of applied mechanics. As a consequence, theoretical treatment of engineering problems looked to be so promising and so attractive that almost all the productive brain power available was focused on applied mechanics; those problems which could not be approached from a theoretical standpoint were simply neglected. The result was that some branches of engineering were developed to the very limit of perfection, while others remained in a deplorably backward state. In medicine and in physiology there are no problems simple enough to be treated by means of applied mechanics; semi-empirical methods are the only ones which are apt to give results. Hence, from the very beginning, the men engaged in these fields had to choose between remaining on the general level of ignorance or developing methods for gradually approaching the truth by systematically reducing the importance of possible error. The remarkable success achieved in medicine and physiology is the best guarantee we have for ultimate success of semi-empirical methods in foundation engineering."[5]

In referring to foundation engineering, Dr. Terzaghi included pavement design. He could just as well have included traffic engineering, concrete and bituminous mix design, highway system planning and most of the other phases of road engineering. The ultimate success of the semi-empirical techniques referred to by Terzaghi was proven by the very experiment he referred to as a landmark in civil engineering. The now famous Westergaard formulas for concrete pavement design, which are still in use today, resulted from the concrete road condition surveys of the Bureau of Public Roads in the late 1920's. This technique of "systematically reducing the importance of possible error" is the basis of all road research today. It is a logical and rational basis of working and has produced results which form the basis of the present knowledge of the art.

Once the need for research in the United States was realized and the techniques for conducting it were established, there was a constantly increasing effort devoted to advancing road and street engineering science. Under the direction of Thomas H. Macdonald, the U.S. Bureau of Public Roads provided the leadership in road research both by undertaking numerous large projects on their own and by encouraging universities and highway departments to do likewise. The Bureau also provided financial and technical assistance for research undertaken by the State highway departments.

By the 1940's road research in the United States was a well-organized, highly-developed, co-ordinated effort. At the same time road research in Canada was just beginning. Perhaps the real beginning in this country dates from the work of Dr. Norman W. McLeod for the Department of Transport in developing a method of flexible pavement design for airports and highways at the end of World War II.[3] Since that time interest has increased substantially and road research projects have been undertaken in all provinces of Canada.

Up to the present we have had little knowledge of the extent of the total road research effort in Canada. Unfortunately, the results of much of the work which has been done were lost to the profession and industry as they were not published nor given proper distribution. Equally unfortunate has been the duplication of effort by researchers working independently on the same problems. That is why the Canadian Good Roads Association is working to do away with this waste of valuable time, effort and money. The problem has been attacked in three ways. Specialized technical sessions have been provided at the CGRA annual conventions where Canadian highway engineers can present papers for discussion and publication. Secondly, technical committees have been established to discuss current problems and exchange data. Lastly, a road research correlation service has been undertaken. Through the correlation service a survey of road and street research activities in Canada has been made and a book published detailing all current or recently completed projects together with information as to where results may be found. Subsequently, the results of this survey to date, the organization for research in Canada and the areas where research is apparently needed will be discussed.

Value of Road Research

The value of road research has been referred to. Before elaborating on this subject and citing more concrete examples, we should first define the meaning of research. Dr. McLeod has defined it as follows: "Highway research is . . . (the) search for *new knowledge* that is to be applied to the solution of given highway problems (and thus) does not include such routine activities as the testing of materials, traffic surveys, etc."[2]

Beyond this fundamental concept it is important to distinguish between "basic research" and "applied research". Although it is frequently difficult to delimit these areas of investigation, the following definitions may be useful in defining the concepts:

Basic Research—Through scientific study or critical investigation to discover fundamental facts pertaining to the laws governing the operation of a process in order to formulate, test and establish theories contributing to an understanding of that process.

Applied Research—Through study and investigation to effect immediate solutions to current problems or to bring about apparent improvements over existing conditions in the operation of a process or performance of a material. This would include the investigation or trial, or both, of new innovations in planning, design, construction, maintenance or administration techniques currently in use by a road department.

Both types of research are important but by far the greatest portion of road research can be classified as applied. CGRA's survey and correlation service includes both types and could well be termed research and development. Highway engineers are not only interested in hypotheses for the prediction of the migration of moisture in soils but also in improved methods for the compaction of bituminous mixtures in paving operations, for example.

The experience of others outside Canada proves that highway research pays off. In 1936 the State Department of Indiana, together with Purdue University, established a Joint Highway Research Project at the university. The staff of this project are professors and research engineers who teach postgraduate courses in highway engineering and conduct or supervise research work. This work is financed by an annual grant from the State Highway Commission which at present amounts to about $150,000 per year. In a progress report in 1950 Professor K. B. Woods, Director of the project, made the following statement:

"Summarizing the monetary benefits of highway research, it is apparent that any one of several completed studies is already paying dividends equal to the entire yearly cost of the annual highway research program. It is likewise apparent that the surface has only been scratched, and there is every reason to believe that the dividends will be much greater in the years to come than in the past."[7]

In support of this statement Professor Woods cites several specific examples including one finding which alone is estimated to be saving the Indiana State Highway Department between $100,000 and $200,000 a year.

Dr. W. H. Glanville, Director of Road Research, United Kingdom Department of Scientific and Industrial Research, indicated in 1954 that the work of his organization had probably resulted in savings that run into millions of pounds per annum.[1] Dr. Glanville also noted that" . . . a Select Committee of the House of Commons, charged with the task of reducing waste, recommended . . . (in 1953), as a measure of economy, the expenditure on research should be increased by 50%.

Many senior highway officials in Canada have long contended that it is foolish and wasteful to do road research in this country. They contend that the results of the large research programs in the United States are available to us without cost and it would thus be foolish for departments to waste the time of valuable engineers on such work. This theory has some merit but it is certainly far from being correct. It is true that we must utilize the work of the U.S. researchers to avoid unnecessary waste, but we must also do research work of our own. The reasons for this are obvious.

The results of applied research in a particular area are not always directly applicable in other regions. For example, after extensive laboratory and field investigations a state highway department may establish a new specification and test to eliminate the use of a poor performing material. The test would probably be empirical and would satisfactorily discriminate between good and bad materials for the sources of supply in that region. If a Canadian province blindly adopted that specification there is a possibility that it could exclude materials available in that province which have given excellent service. The reason, of course, is that the test was developed without studying these particular sources of supply. Before adopting the research results of a particular agency, we must thoroughly investigate them to determine if they are applicable in our own area.

A second reason why Canadians must do road research is that we have special problems of our own that urgently require solution. Our climate is more severe than that in either the United States or the United Kingdom. Our soils and locally available building materials may also be different. In these cases, to be practical and economical our design practices may have to be different. It is natural that we must investigate these unique problems and develop our own criteria. In other cases our most critical problems may be much less urgent in the United States and hence not receiving attention in that country. We must then do the work and supply the results to our neighbours.

A third reason for doing research in Canada is that such programs greatly aid in the development of our engineers and technicians. The research-conscious practising engineer is more likely to profit from the lessons of experience than the engineer who does not seek to learn the reasons behind observed phenomena. The university professor engaged in research is usually better informed and hence a better teacher. Road research in the universities will also increase the supply of graduate engineers for our highway departments and improve their quality.

In Canada we have the qualified engineers in our highway departments and universities to do this needed research. It is also apparent that these men know the problems requiring investigation. One has only to read the Proceedings of the Canadian Good Roads Association for the past two or three years to see this. These men need only the time, budget and encouragement to get on with the job.

CGRA'S Role in Research

Two of the basic aims of the Canadian Good Roads Association, as stated in its constitution, are:

1) To encourage the development and improvement of methods of planning, design, construction, maintenance, operation and administration of roads and streets in Canada;

2) To advocate the development of technical skills in all branches of the highway sciences through . . . dissemination of information.

The principal function of CGRA today is to serve as the co-ordinator of road and street research in Canada and as the clearing house for technical information in this field. The Engineering Institute of Canada and other national organizations should continue to publish and distribute articles on highway developments. They might even expand their efforts in this direction. However, the annual expenditures on roads and streets in Canada now exceed the one billion dollar mark. This is one of the largest industries in our country. It is therefore necessary to have one central agency devoted solely to this industry to collect and distribute all information on new developments and provide a forum for discussion and resolution of common problems. CGRA is a non-political, non-profit organization which provides the common meeting ground where technologists of both government and industry can contribute equally to the development of the highway sciences. In this regard, CGRA serves Canada as the Highway Research Board does the United States, or the Road Research Laboratory does the United Kingdom.

A brief look at the 1960 Organization Chart of the Canadian Good Roads Association will illustrate how these functions and objectives are discharged. The 25-member Board of Directors this year is under the chairmanship of our president, Hon. Fred M. Cass, Minister of Highways of Ontario. Members of the Board represent all segments of the Association's membership, which includes governments, industry and universities. The Operating Committee also has 25 members who are responsible to the Board of Directors for the implementation of its policies. The present chairman of this group is Mr. Norman H. Bell, President of The White Motor Company of Canada Limited. The Association has nine permanent staff members, including two engineers, working under our Managing Director Mr. C. W. Gilchrist.

The Joint Committee on Uniform Traffic Control Devices for Canada was convened by CGRA in May 1956 to produce a manual containing recommended standard signs, signals and pavement markings for all roads and streets in Canada. It is jointly sponsored by CGRA and the Canadian Section, Institute of Traffic Engineers, and includes representatives from each province, the major municipalities, the Government of Canada and interested national associations such as The Engineering Institute of Canada.

The new Manual, which has been published by and is available through CGRA, was introduced in September 1959 at the annual CGRA convention in Vancouver. Not only has this manual been adopted across Canada, but already the change-over to the new standards is taking place in all provinces.

The AASHO Road Test Observer Committee was authorized by CGRA's Operating Committee in 1955 to observe and report upon all phases of the $22 million road test being conducted at Ottawa, Illinois, by the American Association of State Highway Officials. This CGRA committee is responsible for the dissemination in Canada of all road test information. CGRA also has an engineer resident on the project and working with its staff on the research. This is an outstanding example of co-ordinating research to obtain the maximum benefits from the work of others. Our Observer Committee will endeavour to interpret for Canada and Canadian conditions the results of this project when it is completed in 1960.

The Technical Advisory Committee Information guides all technical activities of the Association. It is composed of 34 members who are the officers of each of the individual technical committees, plus six members-at-large and a chairman and vice-chairman appointed by the Operating Committee. Its present chairman is Dr. Norman W. McLeod, Asphalt Technologist, Imperial Oil Limited, while the vice-chairman is G. B. Williams, Chief Engineer, Development Enginering Branch, Department of Public Works, Ottawa.

The specialized technical committees — Bridges and Structures; Construction and Maintenance; Economics, Finance and Administration; Municipal Roads and Streets; Planning and Design; Safety Education; Soils and Materials; Special Committee on Pavement Design and Evaluation; Traffic and Operations—are each individually responsible for preparing and conducting a session at the annual convention of CGRA. These committees also undertake co-operative studies of current problems and prepare reports for publication. The committees are also free to call upon the Association staff for assistance or to recommend staff undertakings. As a result of committee work, the secretariat of the Association is working with the Dominion Bureau of Statistics to establish a continuing road price index for Canada; it is compiling a bilingual dictionary or glossary of standard road and street terminology; and has completed two annual surveys of highway department engineers' salaries. All the projects under way or completed by the committees are too numerous to describe in this report. However, mention must be made of two of the more important projects currently under way. One is an intensive co-operative study of pavement performance by ten provincial and two federal government departments, which has been in progress for about one year and is designed to develop methods for designing new pavements and evaluating the carrying capacity of existing pavements. The second project is an undertaking of the Committee on Planning and Design in which between fifty and one hundred engineers from every province will participate. Its purpose is to develop a manual of geometric design standards for roads and streets. Having just officially started, it is anticipated that this manual will not be completed until 1962.

CGRA has over 700 sustaining members. This year's convention, which was held in Vancouver in September, attracted over 1,200 delegates, including several hundred highway engineers, administrators and economists. More than 70 authorities presented technical papers or participated in panel discussions in the nine technical and three general sessions. The three-day convention was preceded by two days of committee meetings. Such a conference provides the best possible opportunity for the exchange of technical information and for the presentation and discussion of papers on Canadian road research.

Road Research Survey

The purposes of the CGRA road research survey and correlation service are four in number. They are:

1) To acquaint practising highway engineers with new findings so that research results can be incorporated into current practice with the least possible delay;

2) To acquaint research workers with other activities parallel or allied to their own investigations, thus avoiding unnecessary and costly duplication of effort;

3) To expose those areas of ignorance which urgently require study and investigation;

4) To stimulate and enlist support for the research efforts of the roads departments, universities and industry.

In the initial survey over 100 agencies in Canada were contacted, comprising all major universities, consulting engineering firms and industries as well as the appropriate departments of all levels of government. With the questionnaire a tentative subject classification was provided and each agency was requested to supply a brief report for each separate project in their research program. The information which was requested for all current projects, as well as those completed within the last five years, included: subject classification, title of project, brief description of scope of work, estimated expenditure in 1958, location of the work, names of the investigating staff, starting and completion dates, and where interim of final reports of results are published or are available. Supplementing the questionnaire replies with staff investigation, a complete descriptive listing of all Canadian road research projects, classified by subject, has been published.[4]

Considerably more than half of the agencies contacted reported research programs. The publication, although known to be incomplete, contains data on 159 individual projects. The returns from the questionnaires also indicate that approximately $1 million was spent in 1958 in Canada on road and street research and development.

These estimates mean that for every $1,000 invested in roads and streets in Canada in 1958, one dollar was spent on research and development. This means that in Canada we are spending on road research about one-tenth of one per cent of our total appropriation for highway construction and maintenance. It was reported that in the United States in 1951 about one-fifth of one per cent of road expenditures was allotted to research.[2] This has undoubtedly increased over the last seven years. Thus, the rate of expenditure for road research in the United States is more than double the rate in Canada. Compared to industry, where as much as two per cent of the total income is invested in research and development, our road and street research effort is pitifully small.

Although the road research effort in Canada is obviously inadequate, the scope and volume of the work as compared with but a few years ago is most encouraging. The projects reported to date cover many phases of the highway science such as soils and materials; traffic engineering; economics, finance and administration; planning; design and bridges. However, it is important to note that highway engineering overlaps other branches of science and engineering. Thus, our survey includes research work being done by such agencies as the federal Department of Transport, the Prairie Farm Rehabilitation Administration, and the Ontario Department of Transport. The only work of these agencies which has been included in our compilation is that which has direct application to highway technology. Deducting from our compilation the contribution to road research by such outside groups as those just noted, it becomes apparent that the amount of research either done directly by the highway departments or sponsored by them in the universities is extremely small for the size of the organization, the volume of work done and the opportunity for doing research conveniently and cheaply.

Organization for Research

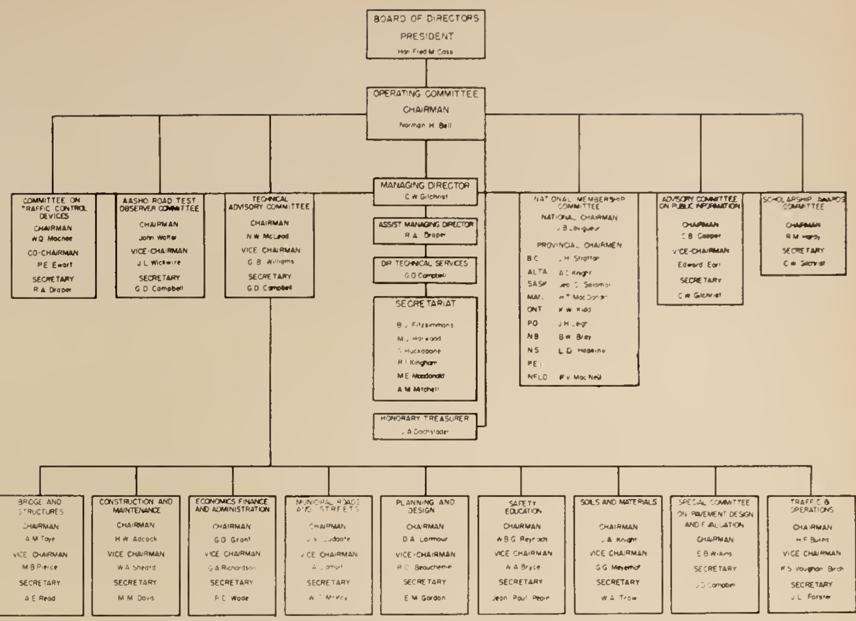
A pattern for the organization of highway research in Canada was presented to the 1955 convention of the Canadian Good Roads Association by Dr. Norman W. McLeod.[2] In this paper Dr. McLeod envisaged an expansion of research in the highway departments and universities, a greater contribution from industry, and a leading role for the Highways Division of the federal Department of Public Works. He saw for this federal government department an opportunity to stimulate and assist research in the smaller provinces, to co-ordinate work nationally and internationally, to develop good relations and a co-operative spirit in research with the provincial departments and among them, and to act as a central storehouse for data obtained from highway engineering research and investigation in every part of Canada. He also urged the development of joint highway research projects similar to those operating in the United States, where the provincial departments finance road research in their provincial universities. Finally, he recommended support for the Canadian Good Roads Association and its technical committees as a means of co-ordinating research; presenting, publishing and distributing technical papers; and discussing common problems.

With one exception these recommendations are gradually becoming a reality. Interest in road and street research in the highway departments has increased. The Ontario Department of Highways has joined with Queen's University and the University of Toronto in creating a fine, active Joint Highway Research Project. A similar undertaking has been established at the University of Alberta with the support of the provincial Department of Highways. The work of CGRA has increased tremendously in the past three or four years, while other agencies are also increasing their road research work. The federal Highways Division has shown considerable interest in road research and has supported the work of CGRA, but to date it has not undertaken any significant research program nor has it assumed a major role in such activities. Although the federal government does contribute to road research through the work of the Department of Transport in developing airport pavement design and construction techniques, through the National Research Council in its basic research on soil mechanics and frost action in building construction, and the Dominion Bureau of Statistics in assembling the facts for transport analyses, it is indeed unfortunate that our national government has not undertaken a more substantial road research program through the Highways Division of the Department of Public Works.

The pattern for road and street research in Canada as it is evolving today is undoubtedly the most effective way of getting the job done. Centralize the discussion, provide a central clearing house for the exchange of data and results, but keep the actual work and the workers dispersed over the entire country. The cheapest and most effective way to get results is to make every engineer a researcher and every construction project an experiment and every highway system a laboratory.

Needed Research

Road and street engineering is no longer an exercise in surveying. Today it is necessary to establish the traffic potential of a route and evaluate its economic justification and relative priority. Geometric design standards must be established for the facility in accordance with the predicted usage during its life. Soil surveys must be made and aggregates sources located and evaluated before the structural design of the road can be determined. The plans and specifications have to be adapted to the materials available. Traffic control devices must be planned and designed, while roadside development can no longer be ignored or neglected. The need for such elaborate planning and complex design has been with us less than 30 years. Many of the factors contributing to the problem are of much more recent origin. It is little wonder that the science of highway engineering is in such dire need of fundamental research and development.



Canadian Good Roads Association — Organization Chart, 1960

Today, satisfactory design techniques for determining the thickness requirements of either flexible or rigid pavements under varying soil and climatic conditions, road usage and axle loadings have not been developed. The currently used tests and specifications for selecting satisfactory aggregates for concrete and bituminous mixtures are far from perfect. In the field of soil mechanics, knowledge of shear strength evaluation is, to say the least, imperfect and the methods of embankment and slope stability analysis are still crude. The mechanics of frost action in soils are not fully understood and the design criteria for preventing frost damage to pavements and structures leave much to be desired. Traffic engineering as a science is still in its infancy. Research is badly needed to develop traffic volume warrants for various road design features. Traffic survey techniques must be simplified and improved to increase their effectiveness and the reliability of results.

These are but a few of the problems of the highway engineer where research and investigation are urgently required. The annual bill for patching inadequately designed or constructed pavements and the economic waste of unnecessary congestion and traffic accidents are strong evidence that such research cannot fail to save the people of Canada large sums of money annually.

Our research survey shows that Canadian agencies are making efforts to solve those problems cited. However, the survey also shows that one of the most important aspects of road and street development has received very little attention. The social and economic effects of highway improvements should receive as much study as the problems of developing improved construction materials or traffic control devices. It is imperative to scientifically assess the over-all purpose and objective in building roads and streets and determine if our plans will ultimately achieve these goals. In the past, many of the major road improvements have become a liability to the community and to the province because, through inadequate planning, they bred accidents, congestion and roadside slums. Rural highway development has been emphasized to

EDMONTON INSTALLS CANADA'S FIRST OIL-FILLED PIPE CABLE SYSTEM

C. Z. Monaghan, M.E.I.C., *Superintendent*
Electric Light and Power Distribution System, Edmonton, Alta.

W. J. Pardy, M.E.I.C., *Assistant Superintendent*
Power Cable Engineering, Northern Electric Co. Ltd., Lachine, Que.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

In 1957, the City of Edmonton placed in operation the first extra high voltage Oil-Filled Pipe Cable System in Canada. The system was expanded with a second installation in 1958.

This paper describes the system, the design of cable and accessories, the installation and the acceptance testing. Service experience to date is discussed and reference is made to operating conditions and maintenance procedures.

Introduction

In 1957, the City of Edmonton placed in operation the first extra high voltage underground Oil-Filled Pipe Cable in Canada. In 1958, a second installation of Oil-Filled Pipe Cable was completed and further expansion of the 72 kv. underground system will take place as load growth requires it.

Edmonton's Power Utility consists of two departments which are fully owned and operated by the City. The City Power Plant generates all power requirements for the City. The Electric Light and Power Department purchases power at the Power Plant bus and carries out all transmission and distribution of this power from the Power Plant to the customer.

In 1956, increasing load led to plans for expansion — a new power generating station to double or triple the system capacity and a revised distribution system to take care of expanding future requirements.

Until 1956, the highest voltage used for transmission in the City was 13,800 volts. The duct lines, cable system and aerial system had been designed to accommodate the total capacity available in the existing Power Plant. With the advent of an expanded Power Plant, it was necessary to study the most economical means of distributing this power throughout a city which was rapidly expanding. Economic studies indicated the voltage level should be 72,000 volts. The location of the Power Plant in the centre of the city dictated that the 72 kv. system, radiating from the new Power Plant, should be underground cable. (Fig. 1)

The Electric Light and Power Department engineers studied the various types of underground cable systems, including oil-filled cable in ducts, directly buried armoured oil-filled cable, directly buried gas compression pipe cable and oil-filled pipe cable. A decision was made to install the oil-filled pipe cable system, because it combined rugged construction with the lowest installed cost.

The first circuit, placed in operation in 1957, ran between the Power Plant and the Namao Substation, a distance of 22,000 ft., with a 1,500 ft. tie-line between the Power Plant and the Calgary Power System. The second circuit, completed in 1958, ran between the Power Plant and the Strathcona Bulk Station, a distance of 17,695 ft.

The Oil-filled Pipe Cable System

The system consists of three single conductor solid type paper-insulated cables drawn into a corrosion protected steel pipe which is filled with insulating oil automatically maintained at high pressure by a pumping plant. (Fig. 2)

All joints are made in manholes and the joint casings welded to the steel pipe to form a continuous pressure-tight system. The cables are brought out to the terminals through either a spreader head or a trifurcating arrangement. The oil in the potheads is subjected to the same high pressure as the oil in the pipe. The complete system is generally provided with cathodic protection.

The System Requirements

The City of Edmonton's specifications were specific without being restrictive. The major requirements were as noted below:

1. The cable to be either Oil or Gas-Filled and in accordance with the requirements of the applicable AEIC or CSA specification. Conductors to be either copper or aluminum. Protective covering over the cable sheath to be provided for prevention of electrolytic corrosion, and cathodic protection to be used.

2. The potheads to meet the requirements of "Standard for Potheads" AIEE No. 48 January, 1948.

3. Service Conditions
Circuit Voltage: 72 kv. — 3 phase — 60 cps
System Neutral: Grounded
Basic Impulse Level: 350 kv. for cable; 450 kv. for potheads
Ampacity: 482 amperes continu-

ously with one two-hour peak of 642 amperes during a 24-hour period
Symmetrical Short Circuit: RMS current 25,000 amperes max. — 10 cps clearing time
Soil Resistivity: 80 thermal ohms per watt per centimeter cube
Soil Ambient: Winter — 20F; Summer — 68F

4. The installation to be acceptance tested with d-c voltage after completion of the installation.

5. The manufacturer to design, manufacture, test, supply, deliver, install, place in successful operation and guarantee the cable, potheads and associated accessories.

The System Components

The Cables. The cables were manufactured and tested in accordance with the Association of Edison Illuminating Companies Specifications for Impregnated Paper-Insulated Cable, High-Pressure Pipe-Type. Fig. 3. shows the details of the cable. The conductors were 650,000 circular mil stranded copper. The ampacity, based on the installation conditions, is 650 amperes at a load factor of 77.15%. In one section where the cable run was situated on a steep slope with a maximum grade of 35%, each insulated conductor was armoured with No. 6 AWG 57-SH aluminum alloy armour wires which were clamped at the splice at the top of the slope to prevent movement of the cables and the splice due to ratcheting of the cables under load cycles. Because of the increased losses due to the armour wires, it was necessary to increase the conductor size to 850,000 circular mils in this section.

The conductor shielding consisted of three metallized paper tapes. The insulation was a 0.295-in. wall of density graded paper using three densities of paper tape. The insulation shielding consisted of a combination of metallized paper, aluminum-mylar and bronze tapes.

A D-shaped brass skid wire 0.1 by 0.2 in. was applied in an open spiral around the completed conductor to support the cable during pulling-in operations.

The Pipe. The pipe used was electric-resistance welded steel pipe, Grade A, per American Petroleum Institute (API) Standard 5-L, 15th Edition, March, 1956. The outside diameter of the pipe was 5-9/16 in. and the wall thickness, 0.258 in.

The interior of the pipe was cleaned and treated with a preservative compound compatible with the insulating oil used in the system.

The outside of the pipe was corrosion protected as follows:

1. Shotblasted and primed with coal tar;
2. 3/32-in. coal tar enamel;
3. Two wraps of fiberglass tape (0.018 - 0.020 in. thick);
4. 1/16 in. plasticized coal tar enamel;
5. One wrap of 15-lb coal tar impregnated asbestos pipeline felt;
6. One wrap of 80-lb kraft paper.

The corrosion protection on each length of pipe was tested at 15,000 volts at the time of manufacture.

The Manholes. Reinforced concrete traffic manholes were constructed for all straight-through joints and for two terminal joints. Manhole inside dimensions were 14 x 5 x 6 ft. A wall thickness of 8 in., a ceiling thickness of 12 in. and a floor thickness of 6 in. of 3,000 p.s.i. reinforced concrete was used throughout.

The Splices. The straight-through splices (Fig. 4) were 50¾ in. overall.

The conductors were joined together with a copper sleeve using four compression indents. After compression, the indents were filled with solder and the connector rounded off

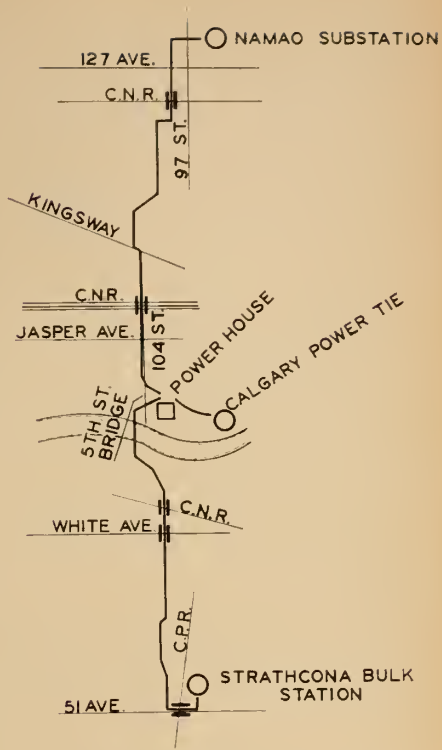

Fig. 1. Location of Namao and Strathcona Circuits and Calgary Power Tie

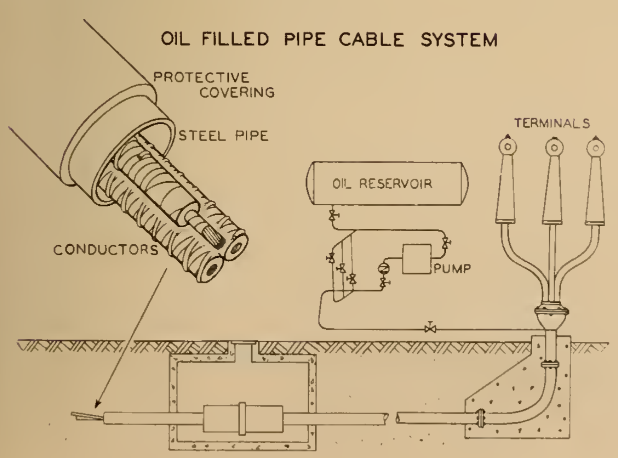
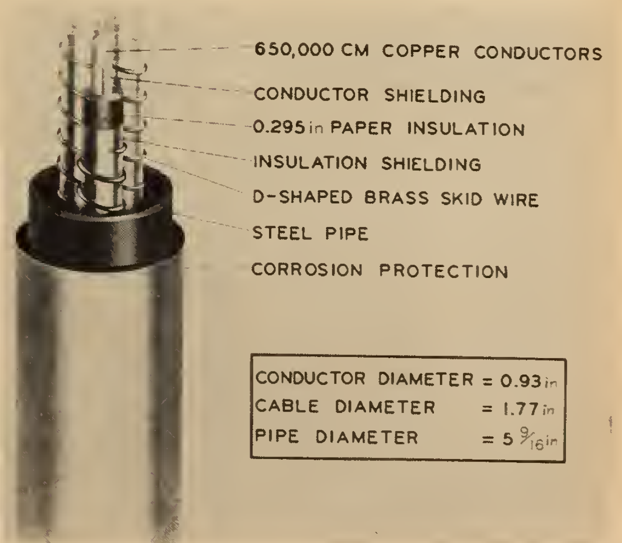
Fig. 2 below—Oil Filled Pipe Cable System

Fig. 3 right—Oil Filled Pipe Cable





with rounding dies. The factory insulation was stepped in ⅛-in. steps and oil impregnated crepe paper insulation applied by hand to the required dimensions. To apply the shielding, three perforated grounding strips were spaced 120° around the joint. Copper braid shield tapes were applied half-lap over the grounding strips and held in place by the pointed perforations. When the shielding was completely applied, the perforations were pressed down.

When the three phases were spliced, two aluminum spiders were placed near the centre of the joint and the assembly bound together with cotton webbing.

The skid wires were soldered to the shielding tapes and after providing slack, were secured to the pipe reducer.

The steel sleeves were slid into position and welded at the centre and at the reducers. The spiders rest on the sleeve and centre the joints in the sleeve.

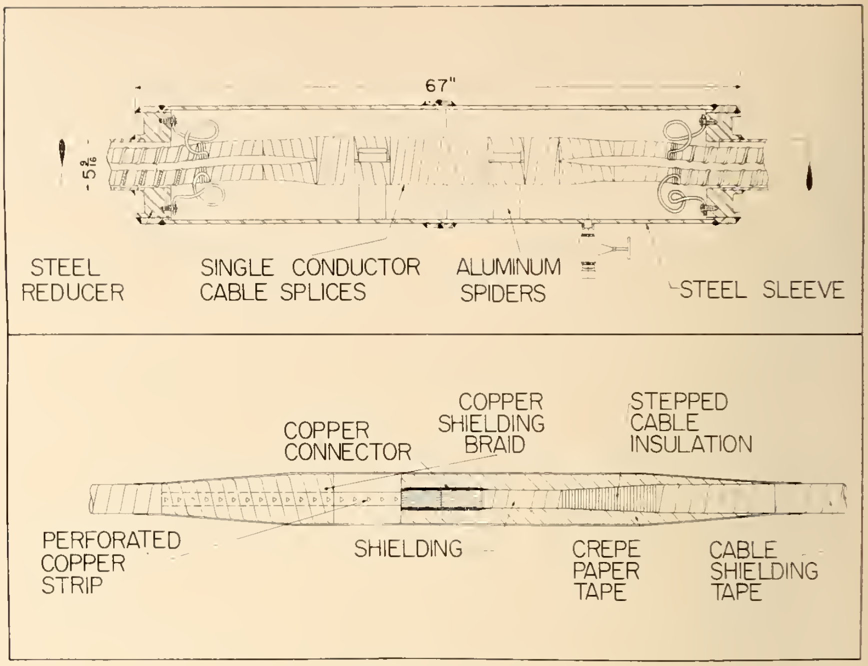


Fig. 4. Oil-Filled Pipe Cable Splice and Splice Assembly

The Terminals. Depending on the pulling conditions and location of the terminals in relation to the pipe line, two methods of terminating the line were employed.

One method used (Fig. 5) was the spreader head. The line pipe was brought above ground in a 7-ft. radius bend and anchored in a poured concrete block which formed part of the tower footings. A spreader head was welded to the pipe. Three copper riser pipes joined the spreader head to the potheads.

The second method (Fig. 6) made use of a manhole at the termination of the line. A trifurcating joint was made in the terminal manhole similar to a straight-through joint, except that one end consisted of a manifold assembly where three copper riser pipes from the potheads were connected to the splice sleeve.

The Potheads. The potheads used were single conductor, 92,000 volt, 200-p.s.i. oil pressure potheads. The terminal stalk was compressed on the conductor in the same manner as the splice connector. Where the insulated conductor passed through the semi-stop plate, a semi-stop feature was incorporated using a gasket which was compressed against the insulated conductor. To compensate for pressure variation in the pipe and in the pothead, eight Alemite pressure fittings were located in the semi-stop plate between the ground plate and the pothead body flange, four for outgoing and four for incoming pressure.

The stress relief cone was built up from a paper roll made from high quality paper, dried and impregnated in the same manner as the cable. The stress cone was shaped manually by rotating and pulling out the paper roll to predetermined dimensions.

After the application of the shielding tapes, a 16-in. stress control tube was located above the stress cone. The porcelain assembly was finally placed and bolted through the semi-stop plate to the ground plate.

The Pressure Control Centre. The pressure control centre is in a pump house approximately 100 ft. from the switchyard terminal structure.

The pump house, designed and constructed by the City, can be heated to a minimum of 60°F under the worst weather conditions to ensure satisfactory operation of equipment.

The control centre is an automatic dual pumping system designed to maintain the pipe oil pressure between 180 and 220 p.s.i. with provision for operation at reduced pressure during installation and maintenance periods.

It consists of the following units.

Oil Storage Tank

Oil is maintained under a positive pressure of dry nitrogen gas in a 4000-gallon (U.S.) storage tank. This storage provides the oil necessary to compensate for volume changes in the main pipe line.

Oil Pumps

Sealed gear oil pumps rated at 5.5 US gpm maintain oil pressure in the pipe by drawing oil from the storage tank and pumping it into the pipe system.

Automatic Pressure Relief Control Devices

These devices provide a fully automatic means for removing the oil from the pipe line. They prevent excessive line pressure by means of automatic mechanical and electromagnetic relief valves by passing oil from the pipe into the storage tank. The valves are mounted in parallel with the oil pumps and are set to open and close at predetermined oil pressures.

Recording Gauges

Recording gauges provide a complete and continuous record of oil pressure in the system. The recorders are mounted in the instrument panel and cover a seven-day period.

Alarm System

Comprehensive alarm circuits are designed to protect the system. The alarm system with a fourteen-lamp annunciator gives visual indication of faulty operating conditions and can be connected to a remote location.

The capacity of the storage tank

and pumps was designed to provide for the installation of an additional circuit. Connection of the control centre to the line was made by the same corrosion protected pipe used for the cable line. The connection was made in the terminating manholes at the switch-yard by means of a valve provided in the splice casings.

The Oil. The oil used to fill the pipe after installing the cable was a high grade, low viscosity type similar to the cable impregnant. Under the most severe condition of suddenly applying the full load of 642 amperes to the cable, which had been idle in mid-winter for a sufficient period to reach the minimum earth temperature of 20°F, the maximum transient pressure rise would be 255 p.s.i. at the Namao Substation end of that circuit. The pipe, potheads and other components were designed to withstand this pressure rise.

Cathodic Protection. The cathodic protection of the carrier pipe consisted of a rectifier as a source of current and a low impedance cell installed on each end of the cable circuit. The cell was located in the ground return at each end of the cable circuit, maintaining a negative potential on the pipe, and at the same time, enabling the cable circuit to be adequately grounded through its low impedance.

Installation

The system was installed by the manufacturer who sub-contracted the installation work. The manufacturer had, at all times, an installation engineer on site to provide technical direction to the contractor and to ensure that the installation was in accordance with specifications and requirements. The City of Edmonton also had an engineer on site to coordinate the installation with various associated aspects such as the survey of right-of-way and grades, parking restrictions, traffic control, repairing of trenches and inspection for adherence to specifications.

Although the system is rugged, particular care was taken in the handling of raw materials. Corrosion protected pipe was blocked and padded to prevent movement and abrasion of the covering during rail shipment. The pipe was handled at all times with wide canvas slings or from the ends, and supported on skids or sandbags during installation.

Particular skills required in the installation were welding and splicing. All welders were required to qualify as prescribed in API Specification No. 1104 "Standard for Field Welding of Pipe Lines". All splicers were required to qualify by completing a splice in a splicing school to the manufacturer's requirements prior to the installation of cable.

Pipe. The pipe was installed with a minimum coverage of 4 feet. It was placed on a 3-in. bed of sand and backfilled so that a minimum of 3 in. of sand surrounded the pipe in all directions. In areas where the excavated material was unsuitable for backfill, being in the nature of cinders, ashes and such, the backfill used was screened sand for at least 1 ft. in all directions from the pipe. The trench was graded to allow the pipe to lay of its own accord without field bending wherever obstructions or services were encountered.

Pipe sections were welded together using chill rings to prevent the formation of weld icicles on the inside of the pipe. All welds were tested by radiographic inspection against the API Specification Standard No. 1104. The film of each weld was examined before the pipe weld was approved.

After welding, all joints were corrosion protected. A fibre mould was strapped around the weld section and filled with pipe enamel. The mould was left as part of the joint protection.

Prior to laying the pipe in the trench in its final location, the pipe coating and all joints were tested at 15,000 volts to ensure that the coating was undamaged. The pipe was laid in the trench starting at one manhole and working to the next manhole. The backfill was then thoroughly tamped in place.

Pipe Testing and Treating. When each manhole section of pipe was completed, the reducers were welded to the pipe in the manhole. A *mouse* was blown through the section to ensure cleanliness. Test caps were fitted to the pipe and a 24-hour pressure test made at 100 psi using high purity nitrogen (99.99% N_2 and 0.01% O_2, dew point -60C). Each section was evacuated to an absolute

Fig. 5. Spreader Head Termination

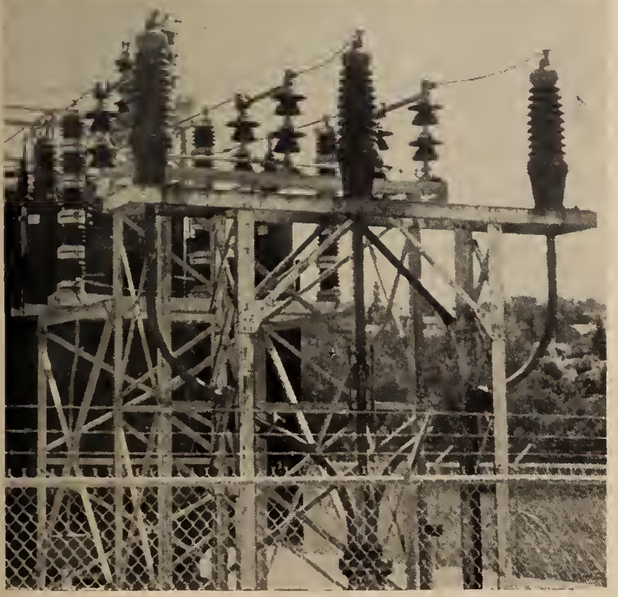

Fig. 6. Trifurcating Termination

pressure of 100 microns of Hg or less and to a maximum pressure rise of 50 microns of Hg in one hour. The vacuum was then broken by admitting high purity nitrogen until a positive pressure of 10 p.s.i. was obtained. The pipe ends were sealed in such a way that this pressure was maintained until cable was pulled.

Casing Pipe. In four sections, the cable pipe passed under railway lines and was enclosed in casing pipe to meet the requirements of the Board of Transport Commissioners for Canada. In another section, where a subway crossing is planned for the future, the pipe was set at a depth of 25 ft. and the line below the proposed crossing cased as an added precaution. The cased sections for the single-line railway and subway crossings were 100 ft. For the main-line C.N.R. crossing and the C.N.R. freight yard cased sections were 534 and 1188 ft. respectively.

The casing pipe was installed by boring, tunnelling and trenching. The cable pipe was pulled into the casing pipe and supported 1¼ to 2 in. from the casing pipe by pipe supporting insulators. The insulators were either prefabricated and strapped to the cable pipe or moulded around it at 10 to 12-ft. intervals. To ensure good thermal conductivity, the space between the pipes was completely filled with sand introduced in the form of a sand slurry.

Submarine Crossing. Where the Strathcona Bulk Station circuit crossed the North Saskatchewan River, a distance of 800 ft., special pipe installation techniques were required. The cable pipe was laid out on shore and welded into two 400-ft. lengths. Each length was coated with two layers of concrete, each a minimum of ½-in. in thickness, with a reinforcing mesh of 18-gauge steel wire between the layers. The concrete protection added extra weight to anchor the cable firmly in the river bottom and protected the corrosion protection from mechanical damage during installation. A trench was dredged in the river bed to a minimum depth of 3½ ft. and the concrete encased pipe was pulled into the trench. The two 400-ft. lengths were welded together during the pulling operation. The maximum pulling tension was approximately 20,000 lb.

Cable Installation. Prior to pulling cable, the splicing sleeves were slipped over the reducers. A manhole blower was used at all times to remove any nitrogen present in the manhole. A 1¼-in. threading cable was blown through the pipe with a special *mouse* designed to lubricate the inside of the pipe. This cable was used to pull a ¾-in. steel winch cable into the pipe for pulling the insulated conductors.

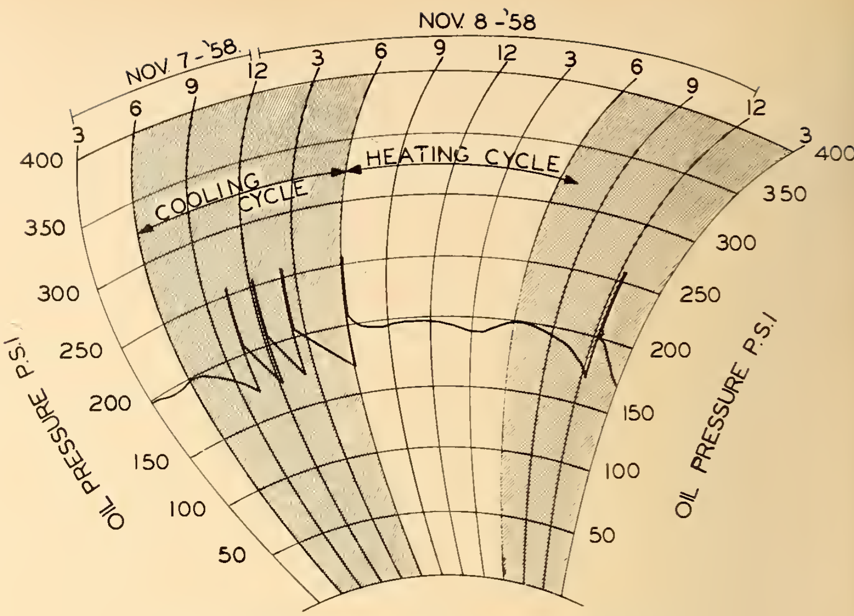

Fig. 7. Typical Section of a Pressure Record Chart

For each pull, three reels of cable were set up in tandem in line with the pipe run. A temporary tent of polyethylene was erected over the cable reels and the feed-in tube to protect the insulated conductors from moisture in the event of a sudden change of weather. Three cables were pulled into the pipe at one time. A continuous flow of dry nitrogen through the pipe was maintained. The cable was cut allowing sufficient cable at the reducer for the joint to be made. The cable extending beyond the reducer was enclosed in a metal night cap bolted to the reducer.

After pulling, each section of pipe was evacuated to a pressure of 1000 microns of Hg or less. The vacuum was broken with dry nitrogen gas and a pressure of 5 p.s.i. applied. The cable was left in this manner until splicing operations were carried out.

Pulling lengths on the Namao circuit were from 853 to 2475 ft. with an average pull of 1870 ft. The maximum pulling tension was 8270 lb.

On the Strathcona circuit, lengths ran from 2137 to 3203 ft. with an average pull of 2532 ft. Maximum pulling tension was 8000 lb. This occurred on a 2410-ft. pull incorporating five pipe bends.

It is of interest that the average pulling tensions on the second installation were 20 to 30% below calculated values. This reduction is believed due to the thorough lubrication of the pipe at the time of blowing the *mouse*, confirmed by the reduced wear of the skid wires observed.

At the terminals where a spreader head was used, the cable was fed into the 90° pipe bend at the termination. Sufficient cable was left at the give-up end to thread through the copper riser pipes. During this phase the cables were carefully supported. As each phase was completed, it was sealed with a pothead night cap.

Where a trifurcating termination was used, the copper riser pipes were installed from the trifurcating manhole to the pothead body flange and the required lengths of cable were pulled through the riser pipes. Night caps were installed at the reducer in the manhole and at the pothead.

Cable Jointing and Potheading. Cable splices and potheads were made under strictly controlled conditions and in accordance with reference drawings. Because it is of prime importance that moisture be excluded from the cable, splicers were provided with special gloves if their hands were moist or perspiring, portable air-conditioners were used to control the humidity in the manholes during splicing, and a tent was used to enclose the terminal structure during potheading.

The average time required for a splicer and his helper to complete a splice was 8 hours. To weld the joint sleeves into place took an average of 5 hours. Welding was done slowly to prevent overheating of the splice.

Two splicers and one helper required approximately 8 hours to complete two potheads. One splicer and helper required approximately 6 hours to complete one pothead.

Line Evacuating and Filling. When all joints and terminations were completed and the piping from the Pressure Control Centre connected to the line, the complete system was evacuated in approximately 30 hours to a pressure of 250 to 500 microns of Hg. This ensured that the line was dry and ready for oil filling. The vacuum pump was left on the line at the high end and oil was pumped into the system through a continuous degasifier at the pumping plant. Oil samples taken periodically from the output of the degasifier gave average breakdown values of 42 kv., assuring complete freedom from moisture and air. Average oil input was 150 gal. per hour and each line required approximately 75 hours to fill. At the completion of filling, approximately 10 gal. of oil was bled from each terminal top. The Pressure Control Centre was cut in to maintain 200 p.s.i. oil pressure and the degasifier disconnected from the line.

Acceptance Testing. The completed circuits were d-c voltage tested before energizing the lines. In the Namao circuit, 127.5 kv. d-c was applied for 4 hours. In the Strathcona circuit, a test set of higher output was used and the test voltage was 170 kv. d-c for 15 minutes. These tests are considered to be equivalent.

Cathodic Protection. After allowing the backfill to settle around the pipe line for approximately a month, a potential survey was made to determine the condition of the pipe coating and the requirements for cathodic protection. Tests showed that the average protective current requirements were in the order of 0.025 ma. per sq. ft. to provide a maximum negative pipe-to-soil potential of from 1 to 1.5 volts. Graphite anodes surrounded by coke breeze were installed as the ground beds at the Namao and Strathcona substations and at the switchyard. Three rectifiers were used, one at each substation and one at the pump house. A low impedance cell, consisting of a magnesium anode immersed in a salt solution, was installed in parallel with each rectifier to bypass the rectifiers in case of fault current on the pipe.

Operating Experience and Practices

Since the first circuit was energized in 1957, no difficulties have been experienced in its operation.

Supervision of the pipe line operation and routine maintenance are simple procedures. Once a week, a visit is made to the pumping station and the recording charts are changed.

Each week the pumps are rotated in operation so that they operate on alternate weeks, and a check is made of the nitrogen pressure and oil volume in the reservoir tank. At this time a visual inspection of the interconnecting piping is made at both the Pump House and the Substation terminals of the pipe line. Since energizing the cable, the load carried by the system has been as high as 40,000 kva. There has not been sufficient change in temperature to plot temperature rise against loading. Between light loading and heavy loading on the cable the oil transfer from the pipe to the reservoir and vice-versa is about 100 gal.

Along with the weekly check of the oil pumping and pressure system, a check is made of the cathodic protection. This check consists of measurements of the magnitude and direction of the magnesium cell current and rectifier output. The rectifier is adjusted to permit a current flow through the magnesium cell from the pipe of not over 0.2 amperes. Once the rectifier has been set to permit proper current leakage through the magnesium cell, no further adjustment is required unless a breakdown in the corrosion protection on the pipe changes the relative magnitudes of currents through the rectifier and the magnesium cell.

Fig. 10 shows a typical section of a pressure record chart taken from the week of November 3rd, 1958.

Nov. 7: 7 p.m. to 10 p.m.
as load drops, the line cools and the oil pressure drops to 170 p.s.i.

Nov. 7: 10 p.m. to Nov. 8: 6 a.m.
the control centre pumps oil into the line and brings pressure from 170 p.s.i. to 250 p.s.i. four times.

Nov. 8: 6 a.m. to 7 p.m.
as the load builds up, line pressure tends to increase due to temperature rise and oil is fed into the storage tank through the control centre bypass valves to maintain approximately 200 p.s.i. line pressure.

Nov. 8: 7 p.m. to 12 p.m.
as load drops, the line cools and the cycle repeats.

In the design of the system, a decision regarding the mechanical protection had to be made. For economic reasons, the decision was in favor of a heavy-wall steel pipe type cable instead of a standard concrete-encased duct line, or buried cable with mechanical protection consisting of concrete block slabs laid end-to-end above the cable for the full length of the cable route. The wisdom of deciding upon the steel pipe encasement was demonstrated recently. A power-take-off-driven boring machine engaged in drilling holes for steel poles, drilled a hole above the pipe and continued downward until it came in contact with the pipe. The wrapping which provides corrosion protection was considerably damaged and the steel pipe was scored. A hole was excavated around the pipe for examination and repair. The scoring did not extend deep enough into the steel to necessitate patching the pipe. Tape was wrapped around the pipe to repair the damaged corrosion protection and the hole was refilled. Those connected with the boring machine operations believe that, if this had been a buried cable installation, the powerful machine would have gone through the layer of concrete slabs and into the cable. On several other occasions, Utilities crossing the pipe with trenches, damaged the layer of corrosion protection with trenching equipment. In each case, it was only necessary to repair the corrosion protection by the application of tapes.

Conclusion

An Oil-Filled Pipe Cable system was chosen by the City of Edmonton as an economical and efficient means of reliably transmitting large blocks of power at 72,000 volts. The success of these first installations in Canada corroborates the wide experience with this type of cable in the United States and elsewhere, and indicates that it will find increasing use in Canada. A new installation in the City of Regina will provide an important power link which will be energized about September of this year.

GEOLOGICAL FEATURES AND FOUNDATION TREATMENT AT THE BEECHWOOD DEVELOPMENT

Mr. I. D. MacKenzie, M.E.I.C., *Geologist*

Mr. E. L. Brown, M.E.I.C., *Field Engineer*

The Shawinigan Engineering Company Limited, Montreal, Que.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

The Beechwood Development of The New Brunswick Electric Power Commission is located on a north-south reach of the St. John River slightly over one hundred miles north of the City of Fredericton. The international boundary parallels the river in this section and lies some eight miles to the west. The Development was undertaken to supply power which is fed into the provincial transmission line network. Two units consisting of Kaplan type turbines rated at 45,000 h.p. at a net head of 57 ft., together with associated generators and other electrical equipment, have been installed. Provision has been made for a third unit. The structures consist of gravity type concrete sluice and regulating sections, a fishway, an intake and powerhouse, a gravity type western abutment with a compacted earth embankment at the eastern end. The maximum height of structures above rock is 80 ft. and the overall length is about 1,750 ft.

St. John River Basin Physiography

NEAR THE HEADWATERS of the St. John River and its tributaries in Maine and Quebec, there are frequent bogs and swamps with lakes and ponds dotting the flatter areas. Much of this territory is relatively unexplored. In the Grand Falls area, the upland surface is dissected by steep sided valleys. Below Grand Falls, the slopes of the valleys and ridges become flatter and the drainage system is well developed with few lakes and bogs. Relief is variable through this region, in general being up to 1,000 ft. in the upper reaches near Grand Falls and in the order of 500 to 600 ft. in the Beechwood-Woodstock areas. From Woodstock to Fredericton there is a less well developed drainage pattern with numerous bogs and lakes. Local variations in relief may exceed 1,000 ft. Below Fredericton, the central plain of New Brunswick is an area of low relief extending down river to Hampstead. From here to the mouth of the river at St. John, the topography is rugged with a series of north-easterly-trending valleys and ridges. Relief may exceed 500 ft. in relatively short distances in this section.

The relief in this basin is controlled to a major extent by the bedrock type. Where the weaker sedimentary rocks occur, the relief is low, whereas in the areas where there are more resistant igneous and older metamorphic rocks, the relief varies to a greater extent.

At Beechwood, it is rolling country with occasional high hills that are indicative of igneous rocks that have intruded the sediments.

A major portion of the watershed is tree covered. In New Brunswick, the cultivated land tends to follow the valley of the river and its main tributaries. The soil is rich and this region is famous for its potatoes, amongst other crops.

Overburden

The major part of the overburden in the basin is of glacial origin, and the composition of the mantle of till usually indicates the type of underlying bedrock or the bedrock lying a short distance to the north-west. Silty till is found in areas where the bedrock is shale or argillite and a sandy till or sandy bouldery till where the bedrock is sandstone or granite.

On the hillsides, the till is generally only a few feet thick and on the steeper slopes, is practically non-existent. As one descends from the ridges, berms of thicker till are found on either or both sides of the majority of the valleys. Further down near or in the valley bottoms of the major streams, deltaic or outwash deposits of poorly stratified sands and gravels frequently occur. Silt deposits were formed in portions of the main valleys as a result of glacial damming, and marine clays have been identified in the southern portion of the basin.

Bedrock

The major portion of the bedrock of the basin is of sedimentary origin, probably of Silurian age; it consists of shales, calcareous shales, limestones and some sandstones. Much of the area has been subjected to intensive folding and the consequent development of cleavage in the shales has been such that, in some sections including the Beechwood area, evidence of bedding has been well nigh destroyed. Some of these shales grade into a poor quality slate or argillite. Two trough-like zones of later Devonian rocks have been reported in the upper and upper central portions of the watershed. Intrusion of more resistant igneous rock associated with these sediments has given rise to the rugged hills that are found on the Aroostook River in Maine and along the Green River.

Below Woodstock, Devonian intrusives are also reported and, here again, the topography is more rugged. Downstream from here, starting a few miles above Fredericton, weaker carboniferous shales and sandstones characterized by a reddish colour underlie this area of low relief. A band of more resistant rocks is found paralleling the coast above St. John. At least a part of these rocks is believed to be of Precambrian age.

While many minerals have been identified in the St. John basin, bituminous coal and limestone have so far had the largest production. More intensive prospecting however may uncover commercially important deposits of other minerals.

Beechwood Site

The St. John River is about 700 ft. wide as it makes its southerly course through the Beechwood site. From a water level at 180, the west bank rises steeply for some 125 ft. On the east bank, there is an abrupt rise of over 60 ft. to a terrace that continues more or less level for some 650 ft. where the main east wall of the valley begins. This wall rises steeply for some 50 ft. and then continues with a gentler rise to above elevation 500.

Surface Geology

Two distinct types of overburden, both of glacial origin, are found at Beechwood. At the higher elevations on the main slopes of the valley, bedrock is overlain by a thin deposit of silty till. At the lower elevation, the overburden was laid down as the ice retreated at the end of the last period of glaciation.

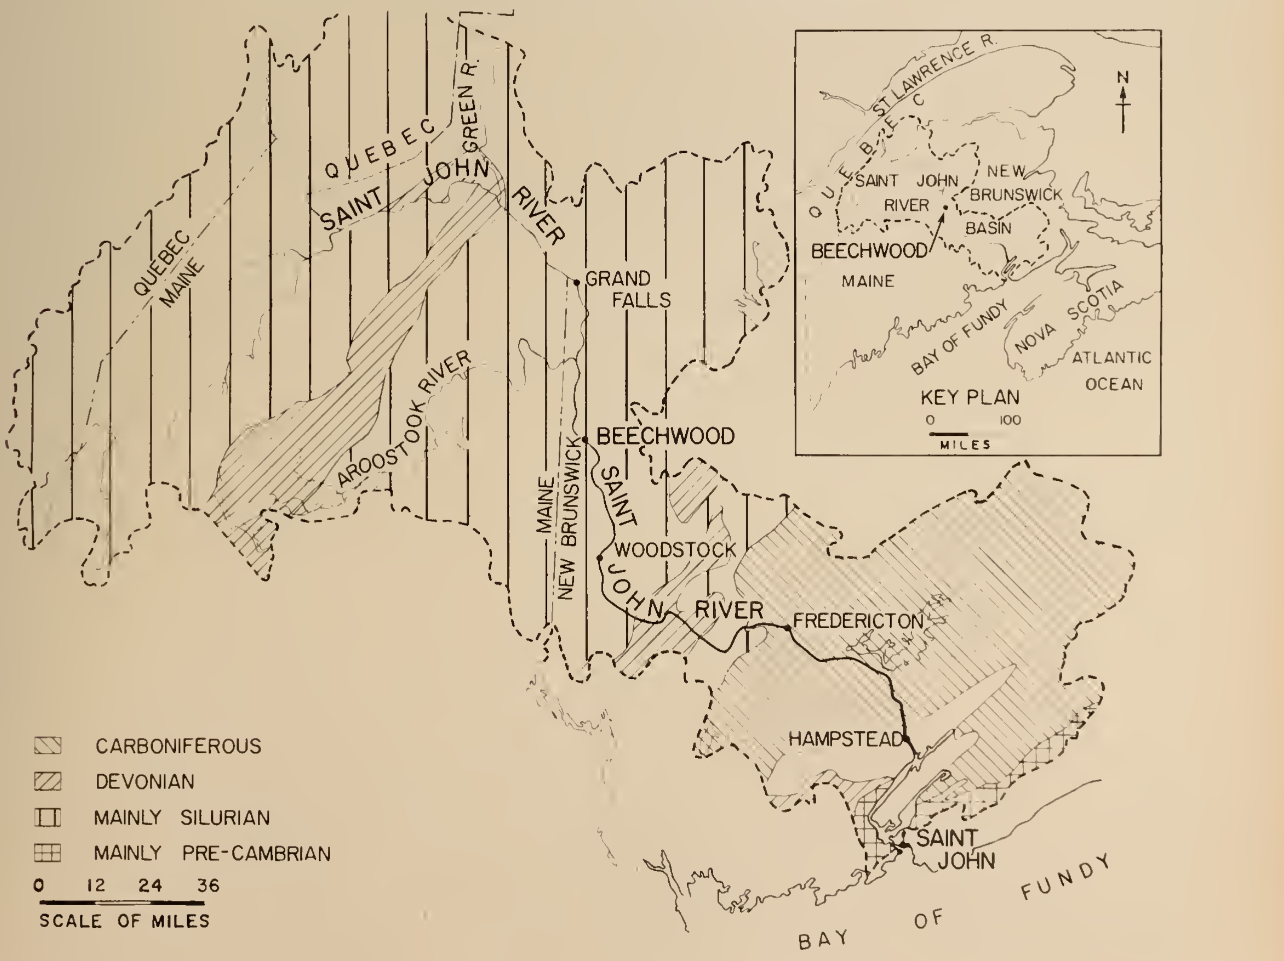
During the main period of glaciation, the whole of the land was covered by untold feet of ice. The ice ceased to advance and began to melt away. The highest part of the land became ice-free first. As the ice continued to melt the tops of the hills and ridges were exposed, while ice still remained in the valleys. A drainage pattern was set up between the valley walls and the ice, and under the ice itself. These streams flowing from the ice were charged with detritus which they deposited as Kame terraces along the valley walls. As further melting took place, the ice retreated gradually upstream and the Beechwood area was free of ice. The river flowing down the valley from this retreating ice dropped outwash deposits of sands and gravels on the valley floor. These outwash deposits were modified as the river channel changed due to varying flow, and more terraces were formed. After the final retreat of the ice from the watershed, the river proceeded to cut down through these deposits giving rise to the present overburden topography at Beechwood.

While not numerous, outcrop at Beechwood shows the bedrock to be an incipient slate or argillite. Cleavage, steeply dipping and frequently at right angles to the river, is well developed. Where identifiable, bedding is frequently contorted. This rock is brownish to dull grey on the weathered surfaces, and dark grey to jet black on the fresh cleavage faces. Although it is a dense rock it is not too resistant to frost action.

Site Investigation

Based on investigation in the late 1920's, the river profile and other considerations, the Beechwood area

Fig. 1 St. John River Basin — Generalized Geology



appeared to be one of the most favourable sites for power development on the St. John River. Starting in 1948, the New Brunswick authorities began subsurface investigation at Beechwood. At this time, 27 diamond drill holes were put down to establish the bedrock profile across the valley. These holes were drilled near the "K" line which eventually became the baseline for the structures. The holes were drilled 20 ft. into bedrock and an examination of the cores indicated that the rock had ample strength to support the proposed structures but that there were planes of seepage in the bedrock.

In 1950, holes 28 to 55 were drilled. This time holes were drilled both upstream and downstream of the "K" line to ascertain whether or not more favourable bedrock elevations could be obtained by moving several hundred feet in either direction.

In 1952, holes 56 to 67 were drilled and more detailed data were obtained.

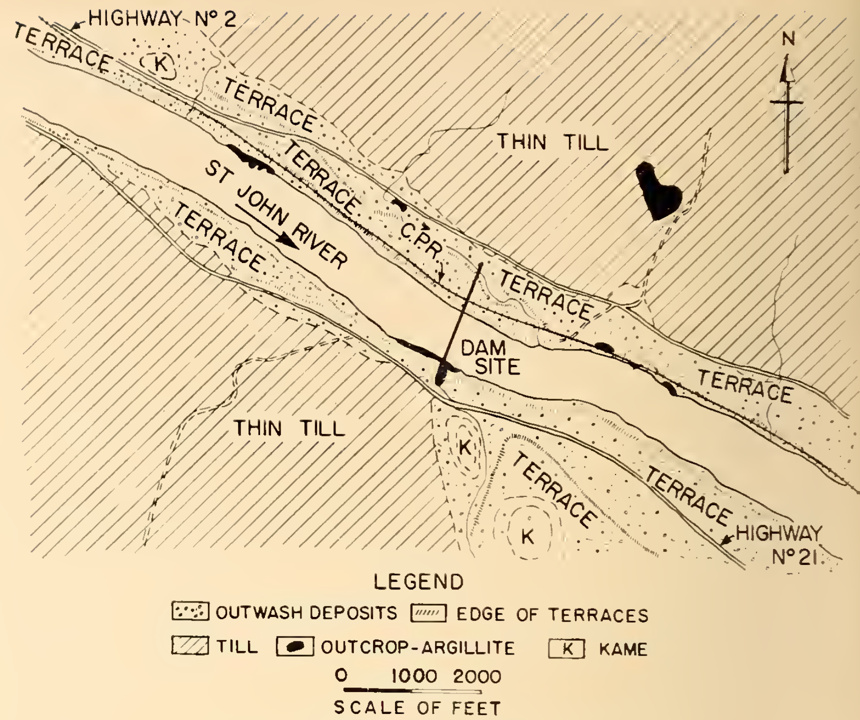


Fig. 2 Beechwood — Surface Geology

With the completion of this drilling, it was apparent that the "K" line represented the most favourable location for the proposed structures. The bouldery alluvium in the river bed varied in depth between 0 to 30 ft. and water testing of the holes put down in the east bank terrace showed this deposit of sandy gravel to be pervious down to bedrock. No evidence of solution along joints had been found in the argillite. Water testing in these shallow holes showed little loss of water except in the upper 10 ft. of the bedrock.

The staff of the Commission assembled detailed records covering the investigation and cores were logged by Dr. W. J. Wright and by Dr. G. S. MacKenzie. Overburden samples were subjected to laboratory tests by Associated Designers and Inspectors at Fredericton. This testing disclosed that, while the sands and gravels were well graded, they contained a sufficient percentage of unsound shaley particles to make their use as concrete aggregate questionable.

This then was the data available when the decision was taken to proceed with the development at Beechwood early in 1954. As the previous drilling had in general only penetrated 20 to 30 ft. into bedrock, it was decided to undertake a program of deeper drilling to prove up foundation conditions to depth. The new holes were drilled to depths of 100 ft. into bedrock with some holes to 150 ft.

Drilling from a barge in the St. John River in the summer and fall of 1954 was a hazardous occupation. During this period extremely heavy rain storms were all too frequent, and the river was in flood stage nearly every month. The water elevation would jump several feet in a matter of hours. Major fluctuations tended to occur on Saturday nights when no one was working and twice a diamond drill ended up on the bottom of the river when the barge broke its moorings and capsized. This drilling program of holes 68 to 94 was finally completed from the ice during the winter of 1954-55.

This drilling disclosed artesian zones in both the overburden and the bedrock. In the overburden, the artesian condition showed up in the drill holes put down along the east side of the tailrace. The indicated flow was small and the head was slightly above river level. In the bedrock, the artesian flows were found largely in the eastern half of the river channel. The maximum static head measured was some 25 ft. above river level. Along the "K" line, the maximum flow was recorded at hole 75 just west of the intake. This hole flowed at a rate of 144 gallons per hour, the measurement being made 4 ft. above river level. At hole 69, near the downstream east side of the tailrace excavations, similar measurements gave a flow of 330 gal. per hour. The artesian flows were encountered in bedrock at varied elevations and correlation of these water bearing zones from hole to hole proved impossible. This was probably due to the cleavage and joint planes being nearly vertical.

By March 1955, drill holes 1 to 94 had been completed in this investigation at Beechwood. Of a total of 7,232 ft. of hole put down, 2,912 ft. were through overburden and 4,320

ft. were cored in bedrock. It was apparent that a very extensive grouting program would be required to prevent passage of water through the bedrock when the head was raised. If the seepage paths were not sealed off there would be a loss of water and possible development of uplift pressures under the structures. Also, there would be an extremely slow deterioration of the foundations due to the gradual removal of the minor zones of more soluble minerals that formed occasional incomplete fillings in the fracture and joint planes. The drilling indicated that there were more of these potential seepage paths extending from about the centre of the river to the east bank. It was also realized that blasting would cause the rock to open up and shatter along the closely spaced cleavage planes, and that care would be required during excavation to prevent excessive overbreak and damage to the foundation rock.

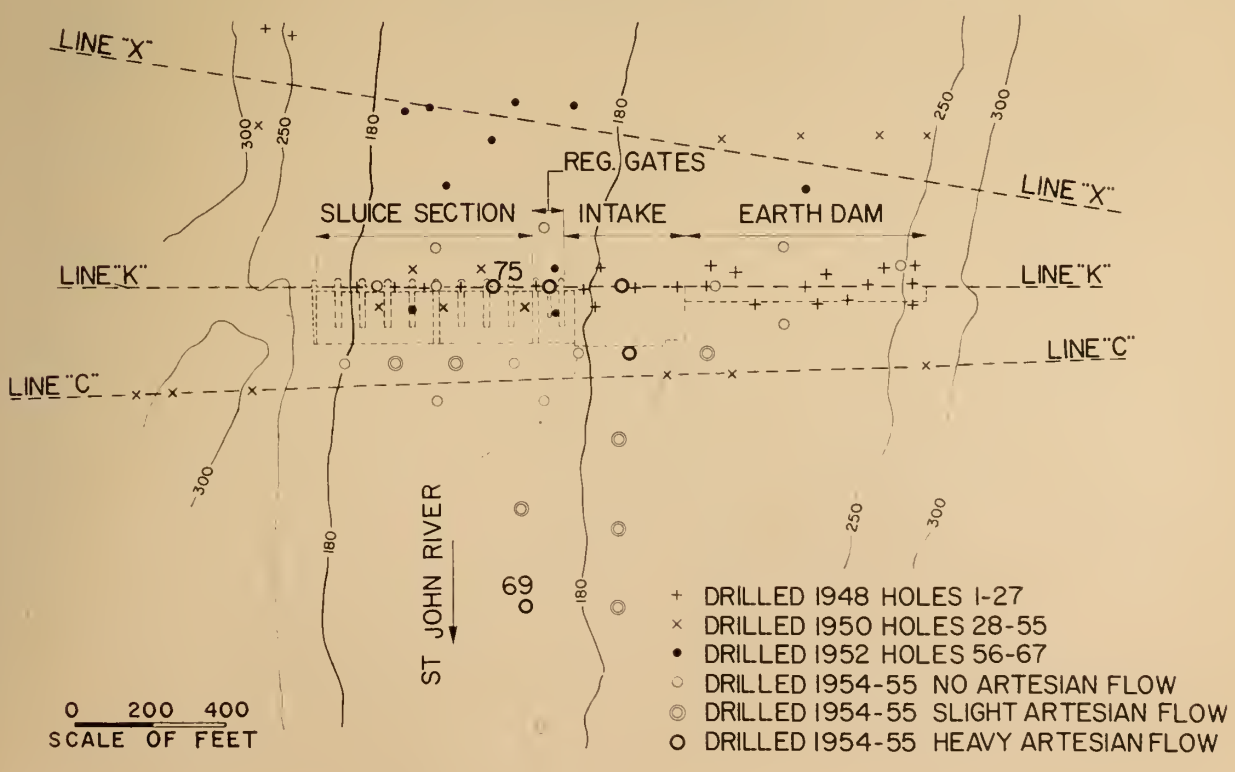
Construction Period

During the first year of construction when the westerly half of the river was dewatered, excavation, drilling, testing and grouting showed that foundation conditions were much as had been expected. As usual, the bedrock surface was found to depart slightly from the profile assumed from the drill hole intersections.

When the overburden was removed, the exposed bedrock surface was found to be massive and to be composed of tough, dense argillite. Considering the glacial and post-glacial history of the valley, it could be expected that any softer zones would have been eroded away. Minor irregularities in the surface were frequent due to differential erosion along slightly less resistant zones. As the work proceeded toward the east bank, more open joints or seams were found to depth in the bedrock. These zones proved amenable to grouting.

During the second season, excavation of the intake-powerhouse area got under way during the winter time. Excavation of overburden and rock soon disclosed a fault that

Fig. 3 Exploratory Drill Holes



crossed the baseline at pier 12 some 35 ft. west of the west end of the intake. This fault ran in an upstream-downstream direction and dipped 45° to the east.

This fault zone was narrow, generally a foot or less in width and consisted of angular fragments of brecciated argillite, unbrecciated calcite in stringers and pods up to 4 in. wide and minor fault gouge. The zone was sufficiently open to allow relatively free circulation of water and minor disintegration would result if the flow of water was to go unchecked. The unbrecciated condition of the calcite and the undisturbed till overlying the zone indicated that this fault was dormant. While five holes had been drilled in this area, none had intersected this fault zone.

The west wall of the draft tube excavation cuts this zone above grade. This left a wedge of rock lying on top of the fault zone unsupported on the east side. It was decided to remove this wedge of rock to the upstream limit of the draft tube excavation and replace it with concrete. Upstream from here to the baseline, the zone was drilled and grouted to refusal to a vertical depth of 175 ft.

The rock in the intake-powerhouse area shattered badly during excavation and opened up along the highly developed cleavage planes. The major direction of cleavage was across the river and dipped steeply downstream. The final boundary between draft tube and intake excavation coincided with this cleavage.

Other cleavages were also well developed and the excavated rock surface tended to break down into small plates standing nearly vertically. An intensive program of grouting was required to consolidate the upper 20 ft. of the rock in this area.

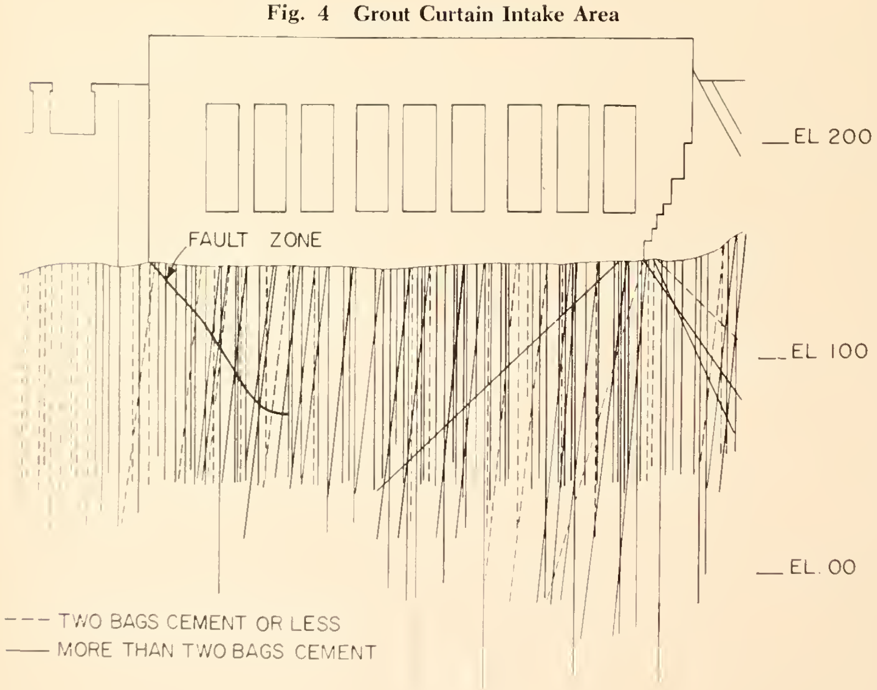
When overburden was removed from the east embankment area, the rock surface was found to be extremely irregular. In order to facilitate the placing of the rolled earth core, the surface of the bedrock was cleaned and gunited. Fill concrete was placed where required, to obtain a relatively smooth surface.

Construction Materials

Due to the shaley nature of the bedrock, it could not be used for concrete aggregates. Coarse aggregate was obtained from an outwash terrace deposit some three miles upstream from the site. The pit run gravel was crushed, the sand was removed, the gravel was washed and passed through a heavy media separation unit. Some 18% of the light weight particles were rejected in this process and the resultant gravel made a first class concrete aggregate. The fine aggregate was a natural sand brought in by rail from St. John Harbour.

As previously mentioned, the glacial till overlying bedrock is a very thin deposit in the Beechwood area. How thin these deposits were was soon learned when borrow pits were opened up for the core material for the east embankment. While the grading of the material was excellent, the thinness of the deposit, the irregular nature of the bedrock surface and the high moisture content made earth-fill construction difficult during wet weather. The terrace deposits provided excellent sand and gravel for the shell of this structure.

Fig. 4 Grout Curtain Intake Area



Grouting

Study of the drilling records, the cores, and the water testing and artesian data obtained during the exploratory work, indicated that, while many of the openings in the bedrock were very thin, they were relatively free of sand, clay and gouge. It was apparent that curtain grouting to seal off the water passages to depth and blanket grouting to seal and consolidate the near surface zone of the bedrock could be effectively carried out using only a cement-water grout without resorting to the use of clay or chemicals. It would be necessary to use a very dilute grout to ensure penetration and sealing of the thin seams and openings.

At the beginning of the grouting operations, a comparison was made between water test data and grout acceptance when the grout used consisted of one part of cement and six parts of water. This indicated that the grout would penetrate and seal the fine seams in the bedrock. Subsequently, this grout mix was used for the initial injection into any hole or section of a hole. Where this grout mix would not build up in and seal the larger openings encountered in the bedrock, the mix was gradually thickened, ratios of one cement to one water sometimes being reached before the pressure began to build up in the drill hole. The ratio of water to cement was then increased and the section of the hole was grouted to refusal with the one cement to six water mix.

Schedule

The grouting program was planned so that the time interval between completion of excavation and the placing of concrete in a section was the minimum necessary to effect the sealing and the consolidation of the bedrock foundations. In some sections, where the primary pattern of curtain grout holes had shown uniform and relatively tight foundation conditions, intermediate holes were drilled and grouted after the concrete was placed in order to expedite the overall progress of the work.

Blanket holes were drilled and grouted prior to concreting except in the intake area where a 3-ft. thick concrete slab was placed and in the east embankment area where the rock surfaces were gunited and a similar slab was placed over part of the area. In both of these sections, the blanket grouting was approximately 90% complete prior to this surface treatment.

In the western section of the river which was dewatered first, 7,080 ft. of curtain and blanket holes were drilled and 260 bags of cement were injected between August 10th and November 16th, 1955. In the central and eastern sections, 100,880 ft. of hole were drilled and 10,395 bags of cement injected between January 30th and August 31st, 1956.

Personnel

The owner provided on-site supervision of this program, assembled all drilling, testing and grouting data, and recorded this information on plans.

The owner's staff normally consisted of one general supervisor in charge of both shifts who also supervised the blanket drilling and grouting. On each shift there was a grouting supervisor, one inspector for each grout pump, and one inspector for each three diamond drills on curtain grouting.

During 1956, the personnel on site for drilling, testing and grouting consisted of one engineer, one clerk, shift foremen for drilling and for grouting, drillers, pump operators, helpers and labourers. In the water testing crews, two men were normally required to set the inserts at the required elevations in the holes and one man operated the pump.

For grouting, the crew consisted of a mixer operator, a pump operator, a labourer for handling cement and two men to adjust the inserts in the hole and operate the control valves at the header.

Equipment

Skid-mounted gasoline-powered diamond drills were used to drill the curtain holes. Pipe "A" frames on these machines speeded up rod pulling. Wherever the rock profile permitted, timber rails were set up to facilitate movement of the drills from hole to hole.

Hole size was AXT—1⅞ in. in diameter. Coring bits were used only when core was required for examination and study.

Four diamond drills, on a two shift basis, were in use at one time during 1956.

The 2-in. diameter blanket holes were drilled almost entirely by wagon drills. These machines were equipped for wet drilling so that the cuttings would be flushed to the surface and not become lodged in the crevices and seams in the rock. Jackhammers equipped for wet drilling were used in the few locations where intermediate holes less than 10 ft. deep were required. Ten wagon drills were in use at one time during 1956.

Small diamond-drill type gasoline-powered pumps were used for water testing and washing of holes. Single expanding type inserts were used for testing holes below any given elevation and double-type inserts for the sectional testing of holes. The latter type was made up to test 5-ft. lengths of hole. The capacity of these pumps was about 750 gal. per hour.

Water meters were used to measure the amount of water injected into a hole. Rubber hose 1 in. in diameter was used for delivery lines.

During 1955, when the western section was grouted, the grout mixing was done at a central location and pumped to the holes. This equipment consisted of a horizontal paddle-type mixer, a double-tank paddle-type agitator and a duplex-slush pump: the flow from mixer to agitator to pump was by gravity. During the second year, a grouting unit consisted of a similar double-tank agitator where the grout was mixed and agitated, and the slush pump, both mounted on a moveable double-deck platform. The grout flowed by gravity from the agitator to the pump. With this moveable set-up, the distance from the pump to the hole being injected was kept under 100 ft.

All this equipment was air powered. The pumps used were the long stroke type and were equipped on the grout end with rubber pistons, rubber-faced valves and removable hardened valve seats and cylinder liners. Dismantling of the grout end for cleaning could be carried out easily and quickly. These pumps were rated at 120 gal. of grout per minute. During 1956, as many as four pumps and three agitators were in use at one time.

Meters were used to measure the amount of water batched and the cement was measured by the bag. A bag was assumed to be 1 cu. ft. for batching purposes. The grout was screened between the agitator and the pump to remove any foreign material.

The hose line from the pump to the hole was 1½ in. in diameter and the return line from the hole to the agitator was one inch hose. An accurate pressure gauge, protected from contact with the grout, was installed on the grout header at the hole. Immediately beyond the header, a stop cock was installed on the return line so that the effective pressure on the hole could be controlled within narrow limits by varying the amount of grout recirculated. With this arrangement, it was possible to maintain high velocities in the pump and hoses thereby preventing blockages due to sedimentation even though a hole was accepting grout at a low rate.

Several types of expanding hole inserts or expansion plugs were used to secure a seal between the wall of the hole and the injection pipe. With rock conditions at Beechwood, the

double pipe assembly with a soft rubber expansion section proved to be the most effective type of insert.

The grout pumps, grout agitators and wagon drills were operated by compressed air. All the air available from the main job supply was used and in addition, during the peak period, portable compressors with a total rating of over 1,100 cu. ft. per minute were required.

The various types of equipment required the following amounts of compressed air:

Wagon Drill	320 cfm
Jackhammer	75 cfm
Grout Mixer	85 cfm
Grout Agitator	85 cfm
Grout Pump	85 cfm

Fig. 5 Fault Zone — West End of Intake

Curtain Grouting Pattern

The grout curtain parallel to the upstream face of the structures consisted of two or more rows of holes. Under the concrete structures, these rows of holes were near the upstream face, in all cases being at least 20 ft. upstream from the rock drains. In the earth embankment, the rows were drilled under the upstream one-third of the core. The distance between the two outside rows varied between 4 and 11 ft. under the different structures. The holes were drilled to depths of 100 to 150 ft.

The position of the holes in the rows was staggered relative to the position of the holes in adjacent rows. The first holes were usually drilled and grouted on 25-ft. centres and additional holes were then drilled and grouted on diminishing centres until the section was grouted up.

When a hole accepted two bags of cement or more distributed throughout the length of the hole or one-half bag or more of cement in any one 10-ft. section of the hole, additional holes were required. These holes were put down on both sides of the hole in question, midway between this hole and the two adjacent holes in the row. This process was repeated as required and, if necessary, additional rows of holes were drilled and grouted until acceptance of grout was less than that specified above.

In the sluice and regulating section all holes were vertical. In the intake and earth fill section, vertical and inclined holes were put down. The inclined holes were sloped to the west at 6° off vertical and upstream to coincide with the upstream line of holes at the maximum depth reached.

At the east end of the intake and powerhouse, drilling and testing indicated that the bedrock was relatively open and artesian conditions existed. A grout curtain beginning at the curtain parallel to the upstream face was extended downstream under the east intake-powerhouse retaining wall for 150 ft. Two rows of vertical holes, 5 ft. apart, were put down to depths of 100 to 150 ft. Between these rows, holes dipping at 60° downstream were drilled and grouted. The holes in rows were spaced twelve feet apart and staggered relative to the holes in adjacent rows.

Fig. 6 Bedrock Cleavage during excavation

Procedure

The drilling of curtain holes usually proceeded to the desired depths with little difficulty. When caving of the walls of the holes or relatively heavy artesian flows were encountered, drilling was stopped, tests were made, and the zones were grouted before drilling continued.

Records were kept during drilling to show artesian zones, changes in colour or volume of return water and the driller's comments on the nature of the rock. Any other information which could be of value for the proper grouting of the hole or for the layout of additional holes was recorded.

The use of grease on the drill rods was prohibited because of the danger of blocking the finer seams.

Due to the volume of water used during drilling, diamond drill holes are relatively free of sludge and normally do not require cleaning prior to grouting. In those holes where the insert could not be lowered to the required depth, a small diameter hose was run down into the hole and the obstruction was flushed out using alternate applications of compressed air and water.

Water testing of the drill holes located the open seams in the bedrock. As the grouting progressed, water testing also gave a measure of the effectiveness of the work already carried out.

In the western section where each hole was drilled to its total depth prior to testing and grouting, the first water test was normally made at a depth of 30 ft. When the leakage in a hole below this depth was less than 60 gal. per hour, the hole was then grouted. When the leakage was greater than this amount, the hole was water-tested throughout its full depth in 5-ft. intervals. A sectionalizing insert assembly was used to locate all the open seams.

In the central and eastern sections, the sectionalizing insert was used for practically all the testing.

Where seams provided interconnection between two or more holes, inserts were placed in the holes and water was pumped down one hole and then the other to flush out the seams. This pumping was continued until the effluent was clear. Dye was added where necessary to prove interconnection between holes.

Both the step method and stage method of grouting were used. In the step method, the hole was drilled to its total depth, tested and then grouted in steps from the bottom to the top. The insert was set ten feet from the bottom of the hole and this section of the hole was grouted to refusal. The procedure was repeated in 10-ft. steps. At the top of the hole, a short length of pipe was cemented into the hole and the final injection was made through a plug valve on this pipe. The valve was closed and the grout was allowed to set up under pressure.

Fig. 7 Near Vertical Rock Face on Completion of Excavation

If the hole accepted more than the two bags of cement, it was washed out 8 to 12 hours later and regrouted.

Where interconnection existed between holes, the holes were grouted up to the level of interconnection and then inserts were placed in the holes above this elevation. Grout was pumped down one hole and allowed to flow out the pipe in the other hole. By restricting this discharge, it was frequently possible to grout up the seams. Where this was not the case, the inserts were raised to the surface and grouting was carried out at reduced pressure; the grout was allowed to set up and the holes were washed out and regrouted. This procedure was repeated to refusal in each of the interconnected holes.

Pressures used were 15 p.s.i. at the surface plus 1 p.s.i. per foot of depth to the point of injection.

The stage method was adopted in the intake and earth embankment areas due to difficulties in sealing the inserts in the holes. The more highly developed near-vertical cleavage in this area was the cause of this difficulty.

With this method, the hole was drilled to 15 ft. and then grouted. Due to surface leakage only low pressures were used in this stage. After 8 to 12 hours, the hole was washed and later deepened 10 ft. This 25 ft. of hole was water tested.

If the leakage was less than 10 gal. per hour the hole was deepened another 10 ft. If the leakage exceeded 10 gal. per hour, the hole was grouted from the surface at a pressure of 50 p.s.i. This procedure was repeated to depths of 85 to 100 ft. dependent on the condition encountered, after which the hole was drilled to its full depth and then grouted in 10 to 20-ft. steps from

Fig. 8 Drilling for Blanket in Intake

the bottom to the surface. Pressures on this final grouting were 1 p.s.i. per foot of depth reducing to 50 p.s.i. at the surface.

Blanket Grouting Pattern

In the western section which was grouted during the first year, the primary blanket holes were laid out on 20-ft. centres throughout the base area of the structures. These holes were drilled vertically 15 to 20 ft. deep and were grouted in one stage. Holes midway between the primary holes were put down in all sections where appreciable quantities of grout were accepted or where the rock surface was seamy or broken.

In the regulating section, the primary pattern consisted of vertical 15 to 20-ft. holes on a 15 by 20-ft. pattern. Here again additional holes were put down between the primary holes, as required to consolidate and seal the surfaces.

Due to the open or shattered nature of the rock surface under the core of the earth embankment, in the intake-powerhouse area and in the tailrace channel extending 100 ft. downstream from the powerhouse, a much closer pattern of blanket grout holes was required.

Due to the nearly vertical cleavage, holes in alternate rows were inclined at 60° to the south and at 60° to the north. This primary pattern was on 10-ft. centres. Additional rows of holes with the holes in alternate rows inclined at 60° to the west and at 60° to the east were drilled midway between the primary holes. These holes were drilled and grouted to an average depth of nearly 20 ft. in two 10-ft. stages.

The rock wall between the powerhouse and intake excavation was drilled and grouted using horizontal holes. Here the pattern was variable.

Procedure

The blanket holes were not water tested. The holes in the western or sluice section and the regulating section were flushed out using air and water alternatively to remove all cuttings and sludge. They were then grouted to refusal from the surface and the grout allowed to set up under pressure.

In the intake-powerhouse area and under the earth embankment, the holes were drilled to a 10-ft. depth, flushed out and then grouted from the surface. Grouting was discontinued on the primary holes when further pumping would not increase the radius of grout leakage at the surface. Frequently, a grout mix consisting of one part of cement to six parts of water was injected for five minutes, followed by a grout consisting of equal parts of cement and water for a 10 minute injection period.

The partially hardened grout was flushed from the holes after 8 hours. Subsequently, the holes were deepened for the second stage, flushed out and grouted from the surface. The maximum pressure used during this second stage was limited to 50 p.s.i. Where the volume of grout acceptance warranted it, the hole was again flushed free of grout and regrouted.

During the first stage of grouting of the holes in the primary pattern, grout often came to the surface within a radius of 3 to 4 ft. from the hole. During grouting of the lower stage, this radius increased to 6 or 7 ft. Grout was observed coming to the surface as much as 12 ft. away. When the intermediate holes were grouted, relatively little grout came to the surface and usually within a couple of feet from the hole. In any sections where grout acceptance or travel indicated incomplete filling of the openings in the bedrock, additional holes were put down and grouted.

Results of the Grouting Program

During the drilling of some of the secondary holes into the fault zone lying in the westerly section of the intake, grout was recovered in the cores. This grout had penetrated and stabilized the loose material in the zone to such an extent that it could be cored for the first time. Examination of these cores and subsequent testing and grouting indicated that this grout had effectively sealed the zone.

In the sluice section, a sump collects the drainage from the contraction joints in the structures, from the rock drainage system under the structures and from the observation wells drilled into rock every 5 ft. along the inspection tunnel. In October 1958, over a year after the head was raised, the inflow into the sump was less than two gallons per minute. This is a very small inflow when one considers that these rock drains alone are draining an area in excess of 60,000 sq. ft.

It would seem therefore that the program of blanket and curtain grouting at the Beechwood Development has been effective.

HIGHWAY RESEARCH ACTIVITIES IN CANADA

(Continued from page 47)

improve interregional communication, while city planning and development has been neglected. Urbanization of the population has thus been promoted while the problems it causes have been forgotten. The highway can destroy the heart of a city which, in turn, can move out to destroy that highway. Such a development serves no useful purpose. It dislocates business and industry, disrupts the population and destroys the benefits of urban living. To avoid such consequences, planning techniques must be improved by research into the economic impact and social consequences of road and street improvements.

Conclusions

A logical pattern for road and street research in Canada has been established. The results of the first research survey of the Canadian Good Roads Association are most encouraging. They show that tremendous progress has been made in such work in the past few years, but also indicate that a much greater effort is needed.

The monetary benefits of road research are known. The need for doing such research in Canada, by Canadian engineers, is evident. Our highway departments, universities and industries have competent personnel to undertake such research. They require only the time, money and encouragement to get on with the job. It is only logical to provide the needed support for this work. The dividends will be great.

THE ECONOMICS OF BY-PRODUCT POWER GENERATION

W. P. London, M.E.I.C., *Chief Engineer, Thermal Division*
H. G. Acres and Company Limited, Niagara Falls, Ont.

W. M. Newby, M.E.I.C., *Consulting Engineer,*
Niagara Falls, Ont.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

Any process for the conversion of heat into electrical energy involves the absorption of heat at a high temperature and the rejection of a large part of this heat at a lower temperature. Where the heat rejected can be used in some other process the over-all economy of the power generating cycle is very much improved. Power produced in such a manner is often referred to as by-product power.

Several processes have been used for the production of by-product power. The most common of these employs steam turbines of the back pressure or extraction type. This type of equipment has wide application and is considered here in some detail. An attempt is made to show what factors affect the over-all economy of such a cycle and what circumstances are likely to favour this type of installation. The effects of initial steam conditions, fuel costs, equipment costs, and load characteristics, both electrical and steam, are considered. These factors are illustrated by a typical example.

The application of by-product power generation to various industries is discussed, and descriptions of plants for the pulp and paper and chemical industries are given.

Although less widely applicable than steam turbines, gas turbines can also be used in a by-product power cycle. This is briefly discussed. Other refinements and alternative cycles are mentioned.

Indications are that Canada will, in future, become more and more dependent on thermal power production. While it is unlikely that any very large part of the country's needs will ever be met by the types of installation described, it is nevertheless important that due consideration be given any possibilities that do exist for the more economic use of our fuel supplies.

THE PRODUCTION of electric power by thermal means involves the conversion of heat into mechnical energy, a conversion subject to the basic limitations of the laws of thermodynamics. The process by which the conversion is effected involves the intake of heat at a high temperature and the discharge of heat at a lower temperature. Only part of the heat taken in can, even theoretically, be transformed into mechnical work. This part, given by the Carnot cycle efficiency, is equal to the ratio of the temperature drop to the absolute inlet temperature.

The Carnot cycle efficiency is, of course, an unattainable ideal and actual processes for the generation of power can achieve only a fraction of this efficiency. Losses are of many kinds, some due to the fact that the actual cycle falls short of the ideal cycle, others due to the mechanical losses and imperfections of the equipment used in the application of the cycle. Typical efficiencies realized in plants of different types are given in Table I.

The term "efficiency" as applied to the theoretical performance of thermal cycles is perhaps somewhat misleading since it implies that the heat rejected by the cycle constitutes a loss and it seems to suggest that this loss could, in a perfect cycle, be completely eliminated. A cycle which rejects no heat is, of course, theoretically impossible. However, cycles in which the heat rejected is not wasted but serves a useful purpose are quite common. It is with this type of cycle that this paper is concerned.

The uses for heat energy are numerous. They include all heating, cooking, evaporation and distillation processes, and occur in such industries as the manufacture of pulp and paper, the refining of petroleum, the distilling of alchohol, and the refining of sugar. Each such manufacturing process offers some opportunity for generating power without wasting heat.

The term "by-product power" has been used quite commonly in referring to power produced by this type of cycle and seems appropriate since power is not the main product but a by-product of the generation of heat for other purposes.

A number of cycle arrangements are possible, each of which may prove economical under certain circumstances. The factors which determine the economy of the process are numerous and not always easy to evaluate. It is essential therefore that a detailed study be made of the circumstances surrounding any particular application before a decision is made. However, there are some general principles involved and certain trends that can be distinguished. A discussion of these may be helpful in indicating in a general way what circumstances favour the generation of by-product power and when a detailed investigation should be undertaken.

Steam Turbines

The most common cycle used for the generation of by-product power involves the use of the steam turbine. In most processes that require heat, steam at moderate pressure and temperature is used as the heat-conveying medium; by generating steam at a higher pressure and passing it through a turbine before delivering it to the process a certain amount of by-product power can be produced.

In studying the economy of such a cycle the steam conditions at turbine inlet and exhaust assume a critical importance. Conditions at the exhaust are usually fixed by the temperature requirements of the particular process and cannot be varied to improve power production. However, inlet steam conditions can and should be selected to give optimum economy.

The simplest cycle for the generation of by-product power is shown in Fig. 1 and involves the use of a back-pressure turbine. This is suitable for the simpler applications where process steam is used at only one pressure and where either a reasonably close correspondence between steam and power requirements exists or there is supplementary power available at reasonable cost. In more complicated circumstances the turbine may be provided with controlled extraction openings to supply steam at other than exhaust pressure, or with a low pressure section and condenser to permit generation of some power independently of process steam requirements. Frequently also uncontrolled extraction openings for feedwater heating can be justified on the basis of the additional output obtained thereby.

For simplicity the discussion to follow will be based on the simple cycle shown in Fig. 1. However, the conclusions are valid in a general way for the more complicated cycles.

The power obtainable from a cycle such as that shown in Fig. 1 depends not only on the initial and exhaust steam conditions but also on the turbine efficiency. This in turn is largely a function of the steam flow through the unit, higher efficiencies being attainable in large units than in small units. The useful output is reduced not only by the losses within the machine but also by the increase in auxiliary power requirements over those for a simple process steam plant. The most important item of auxiliary power is that required to pump the feedwater to the higher pressure. In addition there is some increase in the power absorbed by the boiler auxiliaries as well as a small amount for other purposes.

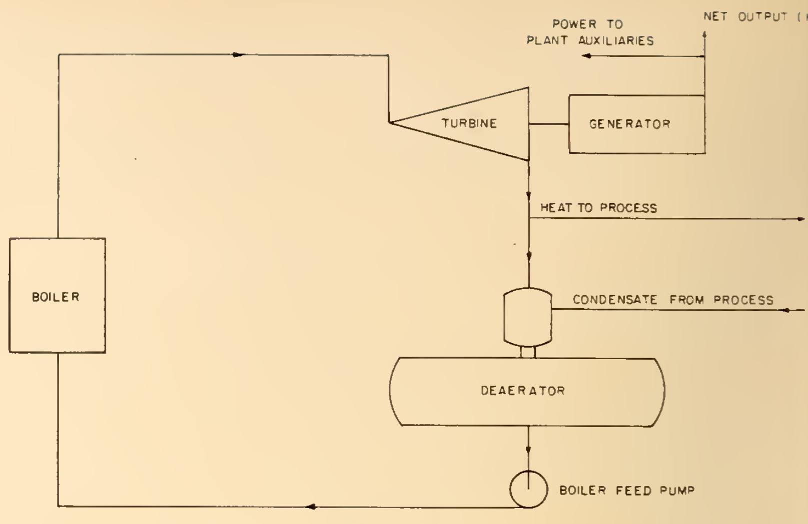

Fig. 1 Typical Back-Pressure Turbine Cycle.

Fig. 2 shows the approximate outputs available for various inlet and exhaust conditions. Although outputs are given in kwh. per million B.t.u. delivered to the process, turbine efficiencies are based on a constant demand of 150 million B.t.u. per hour and the figures are strictly correct only for a plant of this size. Because of the better turbine efficiency larger plants would produce somewhat greater outputs.

To estimate the total cost of by-product power it is necessary to consider each item of cost separately and to estimate, for each, both the cost of producing process steam only and the cost of producing steam and power. The difference then is the cost which must be charged to power generation.

The main items making up the cost of energy are:

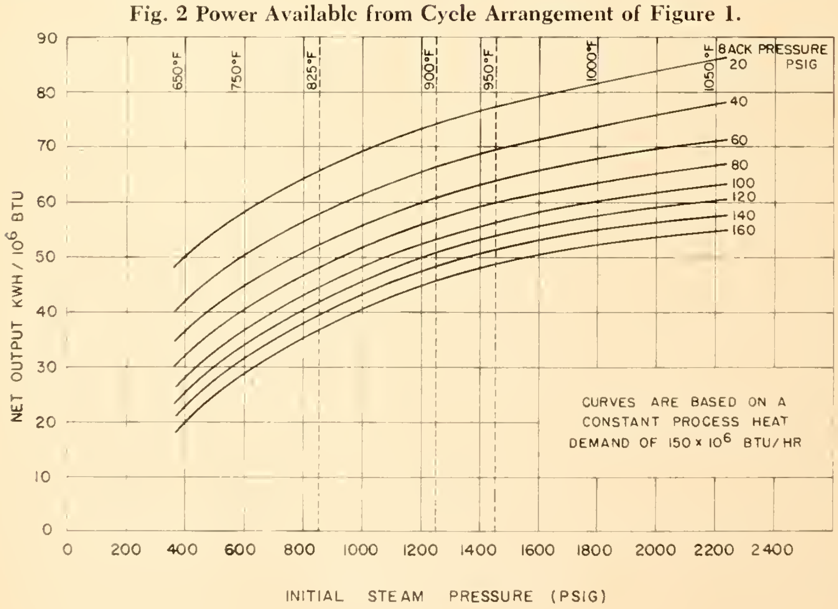
(1) Fuel
(2) Operation
(3) Maintenance
(4) Fixed charges.

Since the fuel charged to the generation of power is only that corresponding to the heat actually converted into power, fuel costs for by-product power are much lower than for power generated by other thermal cycles. The only losses to be considered are the mechanical and electrical losses in the turbine-generator and auxiliary equipment, the boiler losses and the heat equivalent of the additional auxiliary power. The total of these will usually lie between 20 and 25%, corresponding to efficiencies of 75 to 80% and heat rates of 4250 to 4550 B.t.u. per kwh. These may be compared with the efficiencies and heat rates for conventional cycles given in Table I.

Actual fuel costs vary widely throughout Canada from perhaps 15 cents per million B.t.u. for natural gas in some parts of Western Canada to more than 50 cents per million B.t.u. for coal in some areas of the Maritimes and Northern Ontario. The total range of fuel costs for by-product energy is therefore from about .6 mills to about 2.3 mills per kwh.

Operating costs must be estimated for the particular installation. Often it is feasible to operate a combined steam and by-product power plant with no more staff than would be required for a steam plant only. However, in the more usual case at least one additional man per shift will be required.

Fig. 2 Power Available from Cycle Arrangement of Figure 1.



Maintenance costs are variable ınd difficult to estimate. Usually it s satisfactory to assume that the ınnual cost will average 1½ to 2% of the capital cost chargeable to power generation.

Of the various items of cost listed hat of fixed charges, which is of ourse related to capital cost, is by ar the most significant. The capital ost chargeable to power generation onsists of the cost of the turbine-generator with its building, founda-ion, and auxiliaries, the increment n boiler cost due to the increase n pressure, the much smaller in-rement in boiler cost due to the ncreased output, and increments in he costs of feed pumps, piping and ther auxiliaries due to the increases n both pressure and capacity.

To illustrate the general trend, estimates of capital cost have been made for installations operating under the conditions assumed for Fig. 2. Here also a heat output to the pro-cess of 150 million B.t.u. per hour has been assumed. These estimates are shown in Fig. 3. Fig. 4 shows, for one value of back pressure only, the breakdown of these costs into the three major components.

In plotting the curves of Fig. 3 and 4 it has been assumed that the useful gross turbine capacity is that corresponding to the rated output of the boiler. This is an ideal condition that is seldom realized. In most cases there will be fluctuations in steam demand and these will operate to reduce appreciably the firm electrical output of the plant. Actual capital cost per kw. can therefore be expected to be generally higher than those shown.

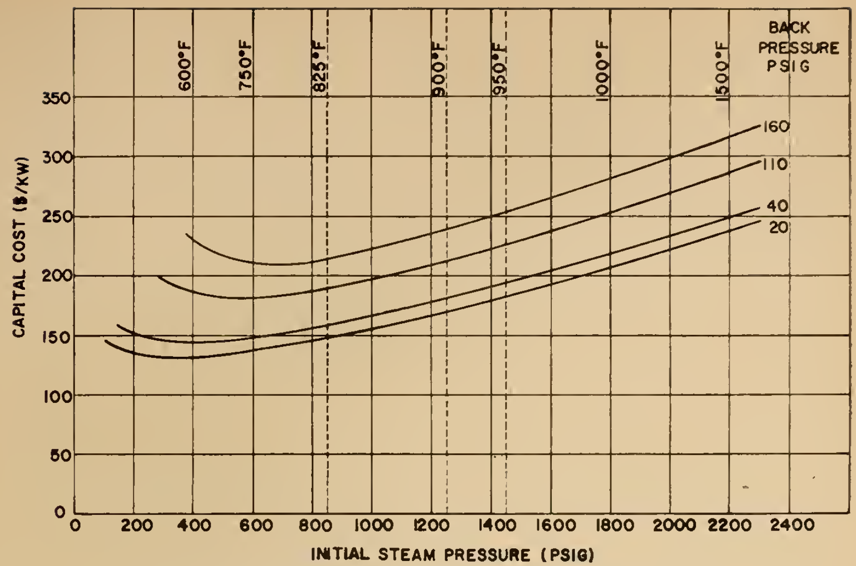


Fig. 3 Capital Cost of Equipment for Cycle of Figure 1.

It will be noted that, even under the favourable conditions assumed the capital costs for by-product power installations are not particularly low. They range from a minimum of about $130 per kw. to a maximum of over $330 per kw. For condensing turbine plants in the same range of sizes equivalent costs would be perhaps $200 to $250.

Two points in connection with Fig. 3 worth noting:

(1) The cost per kilowatt becomes lower as the back pressure decreases. This is a somewhat obvious result and is due primarily to the fact that low back pressures produce greater outputs for the same steam flow;

(2) For each back pressure there is an initial pressure which results in minimum capital cost per kilowatt. This optimum initial pressure increases with increasing back pressure, ranging from about 300 p.s.i. for a back pressure of 20 p.s.i. to about 700 p.s.i. for a back pressure of 160 p.s.i.

The second point deserves further comment. Since the fixed charges on capital investment represent the largest single item of cost, and since the total of the other items does not vary greatly with initial pressure, it is to be expected that the total cost of energy will show the same variation with initial pressure as does capital cost. This might at first glance seem to indicate that moderate initial pressures are invariably more economical than very high pressures. This is not necessarily true. In any actual installation the point of best over-all economy is the point of minimum total costs rather than the point of minimum cost per kwh. This occurs at the point where it becomes cheaper to turn to some other source of power rather than to increase the output of steam power by raising the initial pressure. At this point the incremental rate for by-product energy will equal the incremental cost of energy from another source In many cases where power costs are high this point will correspond to an initial steam pressure much higher than the point of minimum cost shown on the curve.

It should be noted further that the data in Fig. 3 are for relatively small plants and that for larger installations the optimum pressures will be somewhat higher.

While the data of Figs. 2 and 3 are felt to be reasonably accurate for the conditions assumed and while

they show what are believed to be real trends in the performance and cost of back-pressure turbine installations they do not provide answers applicable to any actual set of conditions. A proper evaluation of by-product power generation in any given case is a very complex and tedious undertaking. Some of the complications that must be taken into account are the following:

(1) There are usually fluctuations in steam and power demand. The effect of variations in steam demand has already been mentioned. Variations in power demand have a similar effect. Furthermore there may or may not be coincidence of steam and power demands. In some cases it may be necessary to provide full electrical output at times of minimum or even zero steam demand, and in these cases consideration must be given to supplementary sources of power. In some instances purchased power may be economical. In others a low pressure section of the turbine together with a condenser may be justified, despite the large increase in capital cost and in fuel consumption. There are even occasions when it is more economical to waste exhaust steam to the atmosphere during these periods than to incur the additional costs to provide increased output in other ways;

(2) The need for spare boiler or turbine capacity must be considered. If either or both of these is provided it will of course add substantially to the cost. The question is primarily one regarding the consequences to the industry served of interruptions in either steam or power supply and no useful generalizations can be made. It might be mentioned however that, in the authors' experience, the present trend seems to be in the direction of eliminating spare capacity and accepting the risk of service interruptions rather than to make the very considerable capital investment required to ensure continuous service;

(3) The possibility of interconnection with a utility may have to be considered. In some cases this may result in more complete utilization of the available output. In others, where several plants separted by appreciable distances are involved, it may be possible to use the utility's transmission system to transfer output from one plant to another, thereby reducing the need for spare capacity or minimizing the effects of equipment outages.

It may be of interest to outline the results of a specific study. In the case selected consideration was being given to the rebuilding of a plant for the supply of process steam, and it was felt necessary to consider generation of by-product power at the same time.

Table II presents only the results of the study for back-pressure turbines, although the use of extraction machines was also investigated. It will be noted from this table that the installation cost for this particular by-product power plant is considerably higher than indicated by the corresponding points on Fig. 3. This difference may be attributed to the following conditions:

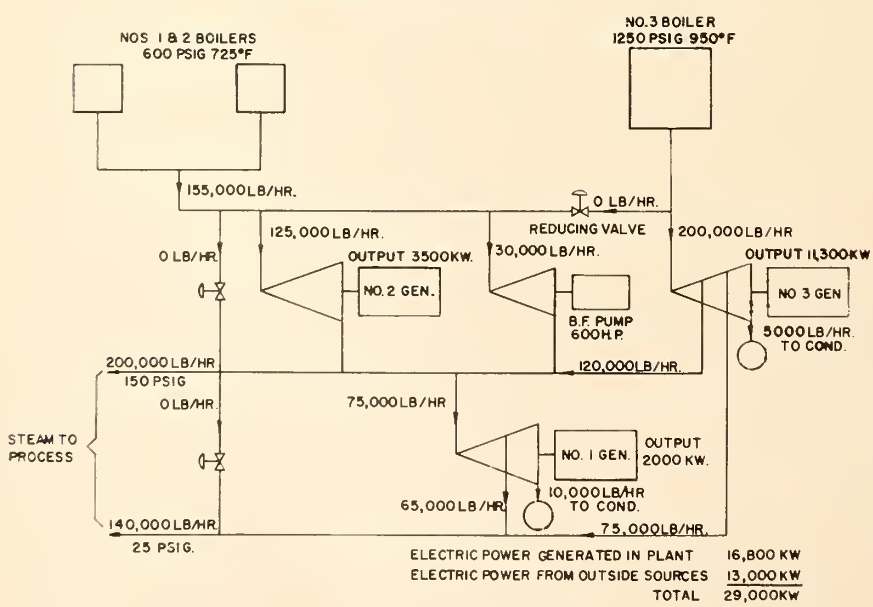
(1) The study was based on the use of turbine-generators of standard ratings;

(2) It was necessary to provide excess capacity in the boiler and auxiliaries. The steam demand showed considerable hourly and daily variation in addition to a seasonal variation due to building heating, the demand for 40 p.s.i.g. steam ranging from 116,000 to 185,000 lb. per hour. Moreover there was a demand for 125 p.s.i.g. steam which varied from 47,000 to 64,000 lb. per hour. The power requirements for this process were large and nearly constant but the nature of the contract for outside power did not permit interchange of energy between the plant and the utility and only small fluctuations in demand for this outside power were permitted under the terms of the contract. By-product power could, therefore, only be generated from the minimum steam flow of 116,000 lb. per hour, but some additional firm power was obtained from the steam required to heat the condensate returning from the 125 p.s.i.g. system.

Examples of Steam Turbine Installations

The pulp and paper industry, which in terms of total value of product is Canada's largest, provides perhaps the most frequent examples of back pressure and extraction steam turbine installations. Here the power demand is generally constant while the steam demand is subject to considerable variations. By-product power is never sufficient to meet the

Fig. 5 Typical Power Plant Cycle — Paper Mill.



total needs and usually supplements power from other sources. Often paper mills are located where fuel costs are high and new sources of power expensive. The incentive to investigate by-product power as a means of meeting increased demand is therefore considerable.

A typical paper mill steam plant designed for by-product power generation is shown diagramatically in Fig. 5. This diagram illustrates clearly the development that has taken place as power demands have increased and it has become necessary to find additional sources of power. It will be noted that for the most recent installation an initial pressure of 1250 p.s.i. has been selected. This high presure may be attributed to the relatively high cost of alternative sources of power.

In the authors' experience all of the by-product power installations supplying paper mills are owned by the paper companies themselves. Investigations have occasionally been made of the feasibility of supplying both steam and power from a plant owned by a public utility but no actual cases of this are known. Presumably the fact that the paper mill is invariably able to absorb all of the power obtainable is a determining factor.

Nevertheless there undoubtedly would be advantages in supplying process steam and power from a plant whose operation could be closely integrated with that of a utility. For one thing a more complete utilization of the available energy could be effected. Secondly the problem of spare capacity could be more efficiently dealt with since a pooling of reserves between the industry and the utility would be possible. Finally an alternative source of power would automatically be available to the industry to take care of periods when the production of by-product power was at a minimum because of reduced steam flow.

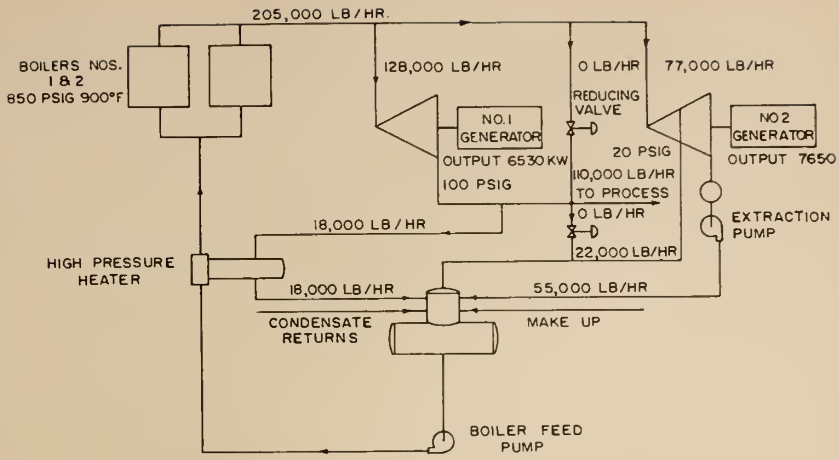


Fig. 6 Typical Power Plant Cycle — Chemical Process Plant.

Undoubtedly the most attractive type of installation for such a combined plant would consist of automatic extraction turbines having a condensing section of sufficient capacity to permit full output under all normal conditions.

A diagram for an isolated chemical plant that is self-sufficient insofar as steam and power requirements are concerned is given in Fig. 6. In this case one turbine-generator is equipped with a low pressure section and condenser to permit generation of sufficient power to supply the plant's needs with minimum process steam demand. Normally there is sufficient by-product power to take care of all requirements and the condensing unit is either shut down or operates with cooling steam only passing through the low pressure section to the condenser.

Oil refineries offer interesting possibilities for the generation of by-product power. The steam demand, for large refineries at least, is usually more than sufficient to permit generation of all of the power needed. The result has been that in some cases in the United States the supply of both steam and power has been entrusted to a public utility. Examples which have been described in the literature are the Linden plant of the Public Service Electric and Gas Company[1], and the Avon (California) steam plant of the Pacific Gas and Electric Company[2]. In both cases large quantities of process steam are delivered to the refineries from extraction turbines and fuel is obtained from the refineries in exchange.

Although no similar plants are known in Canada it would seem that, with Canada's growing oil industry, plants of this type may require consideration in future.

Gas Turbines

While the steam turbine is more widely used for by-product power generation than other prime movers, it is by no means the only type of equipment suitable. The gas turbine in particular offers interesting possibilities, despite its serious limitations. The limitations have to do chiefly with the restricted range of fuels that are suitable and the high excess air which must be used to keep the turbine inlet temperature within the limits of available materials. Of these the first is by far the more important since it rules out completely the use of solid fuels. The second serves chiefly to limit the output available.

Because of the high excess air quantities, the use of the gas turbine for generating by-product power presents a somewhat different problem from that of the steam turbine. It is possible, of course, simply to exhaust the gases from the turbine to a waste heat boiler which uses the heat to produce process steam. However, flue gas losses in this case are abnormally high and the whole process falls far short of the efficiency that can be realized in a steam turbine plant. Steam in this case becomes a by-product of power generation. To avoid the high losses it is neces-

sary to burn additional fuel in the exhaust gases in order to reduce the excess air to a more normal value. The arrangement of equipment in this case is shown diagrammatically in Fig. 7. This results in a large increase in the steam produced for any given electrical output and reduces the power obtainable for any given process steam demand. It does, however, preserve the efficiency of the boiler installation and electrical energy remains a by-product of steam production.

It is apparent that for maximum electrical output from a given amount of heat to the process, the gas turbine should be designed for maximum specific output, i.e. for minimum air flow per kwh. output. This requirement is not usually compatible with that of maximum over-all efficiency and may have a deciding influence on the selection of the particular unit to be used. From the data available it would appear that for a turbine inlet temperature of 1350°F the minimum air flow is about 60 lb. per kwh. and results from the selection of a pressure ratio of about 6:1. Assuming a normal fuel oil and an excess air of 10% at the boiler outlet this results in a power output of about 17 kwh. per million B.t.u. to the process. This figure can be compared with those of Fig. 2 for steam turbines.

The capital cost of gas turbines in sizes that might be applicable to by-product power installations range from \$100 to \$160 per kw. and complete plants might cost \$140 to \$200.

The fuel consumption per kwh. is about the same for the gas turbine operating under these conditions as for the back-pressure steam turbine, the most important losses being the mechanical and electrical losses in the unit itself and the loss in the flue gas leaving the boiler.

Among the advantages of the gas turbine over the steam turbine is the fact that full output can be obtained with no steam demand, with no special equipment and with no additional losses in normal operation. However, its limitations with respect to fuels and the relative uncertainty about its reliability have prevented its being used to the same extent.

It is possible where conditions warrant it to combine the gas turbine with the back-pressure steam turbine so as to obtain a total by-product power output slightly greater than the sum of the two separate outputs.

A further step in the application of the gas turbine involves the use of the boiler furnaces as the combustion chamber for the gas turbine. The furnace then operates under pressure and absorbs heat from the products of combustion reducing the temperature to the point where the gas can be delivered to the turbine. This cycle, which has been described in a number of papers,[3, 4] has been proposed for the generation of power only. It would be equally applicable to the generation of steam and by-product power and should result in an electrical output of about 20 kwh. per million B.t.u. to the process. It too could be combined with back-pressure steam turbines to obtain greater output. At the moment both the probable cost and the reliability of such an installation are uncertain.

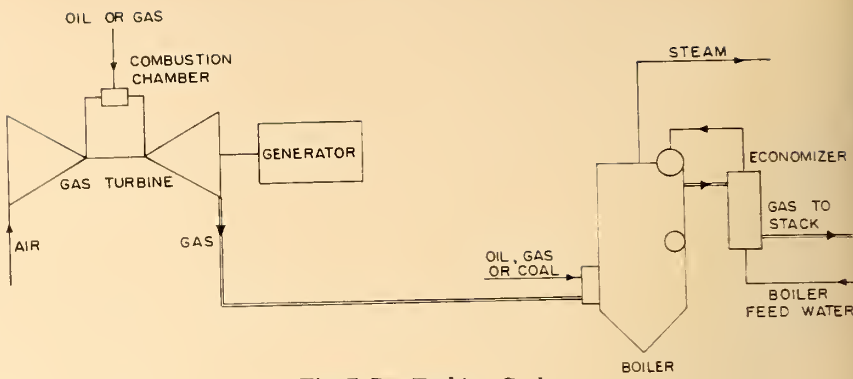

Fig. 7 Gas Turbine Cycle.

Miscellaneous Cycles

A further possibility is the binary cycle which uses mercury in a high temperature cycle and produces steam from the mercury condenser. The steam can then be used either in the generation of additional power or for process work. From the information available[5] it appears that a mercury turbine supplied with vapour at 140 p.s.i.g., 958° F and exhausting to a condenser at 1.23 p.s.i.a., 471° F would produce steam at a pressure of 415 p.s.i. and would deliver about 67 kwh. per million B.t.u. to process. Steam at this pressure could be used in some cases to generate additional power before being delivered to process.

The disadvantages of the mercury cycle seem to be associated with the very high cost of the mercury and to the metallurgical difficulties. At present there seems to be no great interest in its further development.

There are many other devices that could be applied to the generation of by-product power. An interesting, though possibly unimportant, example is the thermoelectric generator. In its most modern form this device is based on the same principle as the thermocouple commonly used for temperature measurement but has been greatly improved in efficiency and practical usefulness by the application of semiconductors. It has been used in remote areas of the U.S.S.R. to permit radio receivers to be operated from the electric power generated by kerosene lamps. Efficiencies of about 10% have been reported[6] corresponding to a power production of about 32 kwh. per million B.t.u. discharged by the lamp.

Summary

This brief outline of the methods available for by-product power generation has, it is hoped, served to call attention to the numerous possible applications of this process. While it is clear that power produced in this way is not necessarily cheap, it is equally clear that in many cases it may be very much lower in cost than alternative sources. Steam turbines are most generally applicable although gas turbines and other types of equipment have their place.

While the field of application is wide, it is evident that no great part of our power needs are likely to be met in this way, at least in the foreseeable future. It is essential, however, in view of the constantly increasing demand for fuel and power, that where such opportunities exist for the more efficient use of our resources they should be given adequate consideration.

PHOTOGRAPHY AND ELECTRONICS AS TOOLS IN HYDRAULIC EXPERIMENTAL WORK

K. W. Gent, *Instrumentation Engineer*

I. W. McCaig, M.E.I.C., *Hydraulic Engineer*
H. G. Acres and Company Limited, Consulting Engineers
Niagara Falls, Ontario.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

The authors review recent developments in the sciences of photography and electronics, and show by means of examples how these developments can be used to advantage in hydraulic experimental work.

Introduction

FOR MANY YEARS models have been used to supplement or replace analytical methods in the design of hydraulic structures and as the magnitude, scope, and complexity of the problems encountered in the design of hydraulic works increased, engineers concerned with these problems became more aware of the advantages to be derived from experimental studies.

In many problems, the fundamental equations governing hydraulic performance are uncertain and a solution by analytical means is either impossible or extremely difficult unless drastic simplifying assumptions are made. In these cases a properly constructed and operated model can usually provide the answers in a very graphic form and at a cost which is often much less than the economics which it permits in the prototype.

The modern hydraulic model has long passed the stage of a natural scale model from which are made simple U-tube and point gauge measurements. In its contemporary form it is a complex machine yielding a whole range of results pertaining to the problem in hand. It may even be termed a hydraulic analog computer.

Although the performance of hydraulic structures can confidently be predicted from models, the predictions are nevertheless subject to certain scale inaccuracies, and to provide data on model-prototype performance relationships the model results should, if possible, be checked against prototype performance. In the past these prototype measurements have been largely restricted to observations of pressures by manometers, velocities by pitot tubes, and discharges by current meter readings. Now, due to improved experimental techniques, both static and dynamic measurements of pressures and deformations can be easily and accurately made in parts of large hydraulic structures where access difficulties had formerly made such measurements impossible.

The recent advances in hydraulic experimental techniques which now permit the solution of many intractable problems, have been facilitated largely by improved instrumentation. This improvement has been effected to a large extent by the use of instruments developed to a very high degree of accuracy in other fields of science. The two specialized fields from which the authors have drawn for the instrumentation of recent experimental work are those of photography and electronics.

Recent advances in photography are not so much new techniques as refinements in existing processes and materials. Electronics, on the other hand, is a comparatively new science which is advancing at a spectacular rate and providing an almost bewildering array of measuring instruments. The following examples show

Fig. 1 Unsatisfactory Intake Transition

how advances in both these sciences were used to obtain information required for the hydraulic design of some major projects in Canada and Pakistan.

Photographic Techniques

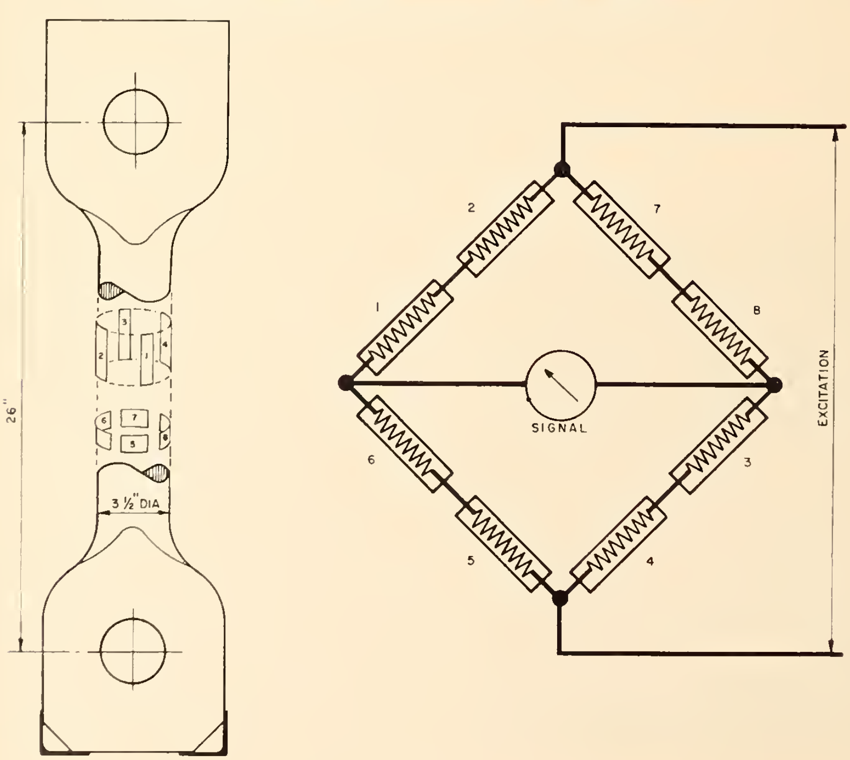
(a) Flow Mapping — The photographic methods used to record the flow in a hydraulic model of the Bersimis No. 1 intake provided an example of how improvements in an established technique could be made to yield additional hydraulic information. The intake of the 1,200,000-h.p. Bersimis No. 1 hydro-electric development in Northern Quebec, is situated on one side of the relatively shallow valley which forms an arm of the Lac Casse reservoir. The design of this intake required extensive tests in two models, the first to determine the direction and velocity of flow in the valley, and the second to determine the optimum geometry of the intake itself.[1, 2]

The scale of the first model allowed approximately three quarters of a mile of valley to be reproduced in the laboratory space available. The problem of recording the direction of flow could have been solved by photographing the tracks of floating lighted candles in a very subdued ambient light. The velocities at different points could have been measured in subsequent runs by opening the camera shutter for short measured periods. This technique has been used in many laboratories. However, as the area to be examined round the Bersimis intake was very considerable and records had to be made at several discharges, and at a number of different reservoir elevations, the above method would have resulted in a multitude of photographs and model runs.

Fig. 2 Transition Given by Shape of Free Jet

Clearly, the number of photographs and model runs could be reduced if the trails of light were punctuated at intervals so that the distance a float moved in a known interval was visible as well as its direction of movement. Further laboratory time could be saved if the lighting on the floats was provided by an external source rather than by candles. It was reasoned that if full advantage was taken of the fine grain high resolution properties of present-day film the runs could be done in normal room lighting. With modern film sufficient contrast could be obtained between the floats and the surrounding model by painting the model a dull black and providing the float tops with highly reflective surfaces.

Fig. 3 Strain Gauge Dynamometer and Bridge Circuit



The average time for the majority of the floats to run the course in the model was in the order of two minutes. The camera aperture was, therefore, adjusted so that topography of the model only just started to register in that time. With this camera aperture, the trails of the float tops were found to be clearly visible. Paper-coated aluminum foil pasted on top of the floats gave the most satisfactory trail. The distance which the floats travelled every 10 seconds was made visible on the photograph by firing flash bulbs at this time interval. The momentary increase in light intensity showed the float's position in the form of a series of bright spots on the continuous trails.

As the camera remained unmoved throughout the entire series of experiments, a preliminary set of pictures of a 12-in. grid (100 ft. in the prototype) was taken at each of the reservoir elevations to be tested, and then transferred to the final prints by double printing. This process eliminated parallax error when analyzing the prints. On one photograph there was a 100-ft. grid of the valley, and the trail of each of the 10 numbered floats. The distance and direction each float travelled between the firing of flash bulbs is clearly visible and can be measured from the photograph. The consecutive time intervals between flashes was indicated by the sweep second hand of the time clock whose images could be seen at the top of the photograph.

After the preliminary tests demonstrated the practicability of this method of recording, it became evident that an improvement would result if an electronic flash were used in the place of flash bulbs. A unit was therefore constructed using a Xenon tube with capacitors and chargers which allowed it to be fired at intervals somewhat less than one-half second if so required. Apart from a saving in cost, the extremely short duration of the electronic flash (1/2000 seconds) enabled numbers printed on the float tops to be clearly defined regardless of how fast the float was travelling.

(b) High-Speed Cine Recording—The use of a cine camera to slow down the motion of high-speed phenomena and make them visible to the naked eye, is well known. It can also be used very effectively to

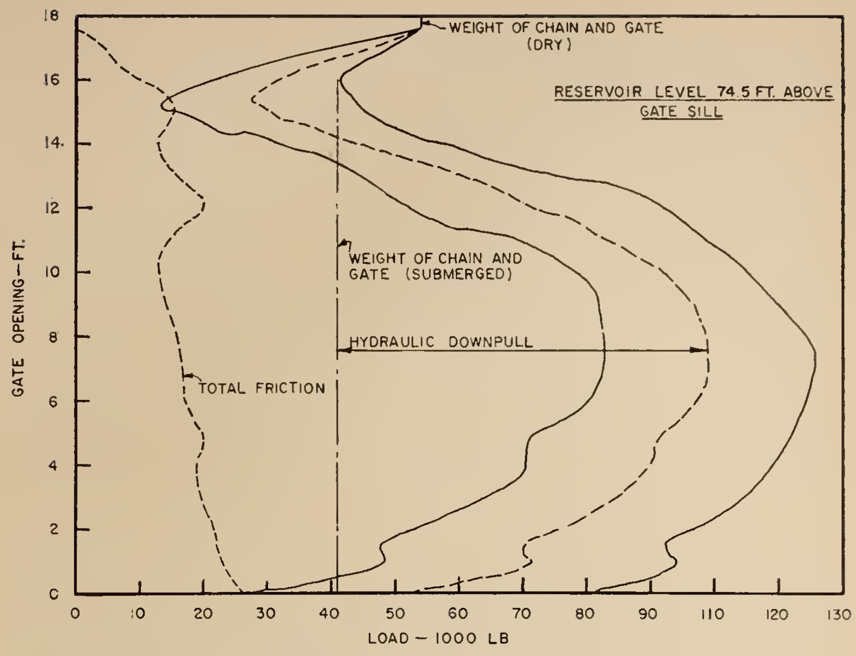


Fig. 4 Forces Required to Operate Low-Level Outlet Gates

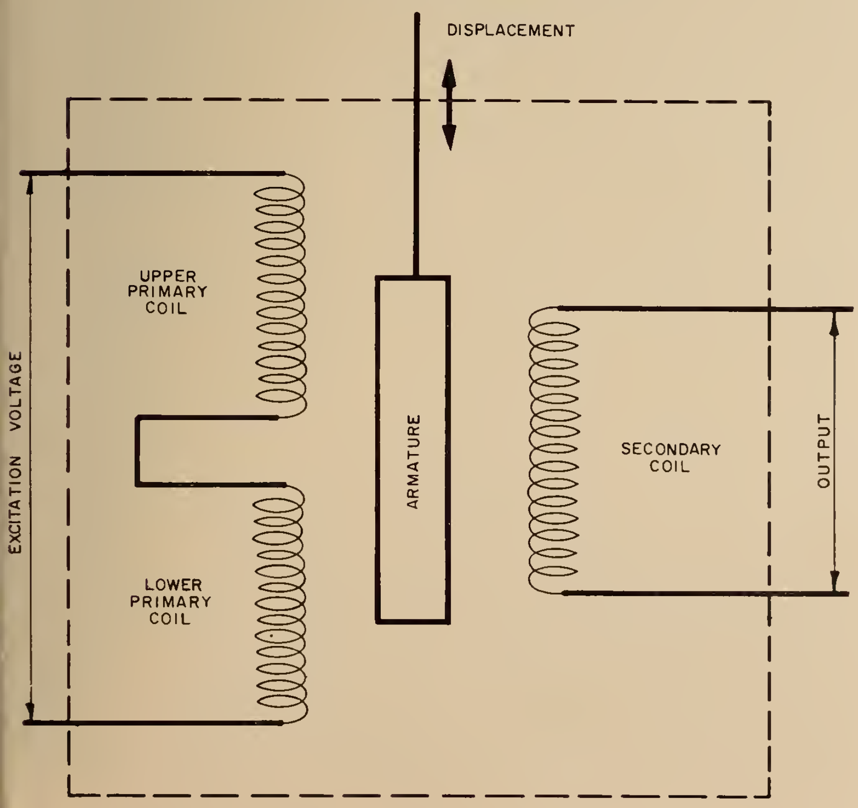
change the time scale of hydraulic experiments. The advantage of this technique was taken in the laboratory at Niagara Falls to investigate possible failure mechanisms of a hydraulic structure. The study was made as part of the design of masonry protection to a rock-fill cofferdam which would be used for dewatering the dam construction area of the Warsak hydro-electric development in Pakistan. The magnitude of floods in the Kabul River on which this development is situated made it uneconomical to divert the entire river discharge during the flood season. The construction schedule was therefore arranged so that work on the base pours of the dam would be made only during low flow period. When the flood exceeded 30,000 cfs the cofferdams would be overtopped and work on the base section of the dam suspended.

Model tests of the typical cofferdam cross section showed that when, at the design flood discharge of 200,000 cfs an artificially lowered tailwater level was raised to a value representative of prototype conditions, the blocks representing masonry protection were suddenly washed away. Because this failure happened without any apparent warning, it was difficult to be certain what was actually taking place. The high-speed motion picture film showed that at the instant of incipient failure, the blocks were lifted off their bedding by an upward flow. As soon as one of these blocks lifted slightly above the adjacent ones, the stream flow carried it out still farther and increased the uplift on the remaining blocks, which then rose up like a blanket and were carried away by the flowing water.

Die injections revealed that the supply of water causing uplift came from downstream through weep holes

Fig. 5 Linear Variable Differential Transducer



left in the masonry protection. Piezometer measurements showed that at the design river discharge of 200,000 cfs, the static pressure from the tailwater was sufficient when combined with dynamic pressure reductions on the curved face of the cofferdam, to overcome the submerged weight of the 4 feet of masonry protection originally proposed. From these same piezometer measurements it was possible to calculate the thickness of masonry needed for a safe design.

(c) Graphic Recording—A camera can also be used as a graphic recorder and thereby greatly simplify some hydraulic measurements. During hydraulic model tests on the low-level outlets of the Lake St. Anne Reservoir, this technique was used to facilitate the experiment required to arrive at the most economic intake transition upstream from the outlet gates.

Although the model of the Lake St. Anne Reservoir outlet was constructed primarily to determine its discharge capacity and the extent of erosion downstream, one side of the model was constructed entirely of Plexiglas to allow visual observation of flow in the conduit.

Tests soon showed that a preliminary design of the intake transition using a single radius was not satisfactory. The water tended to leave this transition tangentially as shown on Fig. 1. Vibration and cavitation damage could be expected from such flow in the prototype.

To find experimentally the natural path of the water and therefore the shortest transition which would give no negative pressures over its surface, a knife edge was inserted in the model on the plane of the dam face. The issuing jet was then photographed through the transparent side of the model and an enlargement, shown in Fig. 2, made to a convenient scale. The shape derived from this photograph corresponded very closely to an ellipse[3] having the equation $x^2 + 10.4y^2 = D^2$, where D is the height of the conduit and x and y are rectangular co-ordinates. This shape was used in the final design.

The reduction in length of transition obtained from this experiment allowed a considerable saving to be made in the volume of concrete in the dam.

Electronic Techniques

(a) Strain and Load Measurements—In 1856 Professor W. Thomson (Lord Kelvin) in a paper before the Royal Society of London,[4] describing his findings on the electro-dynamic

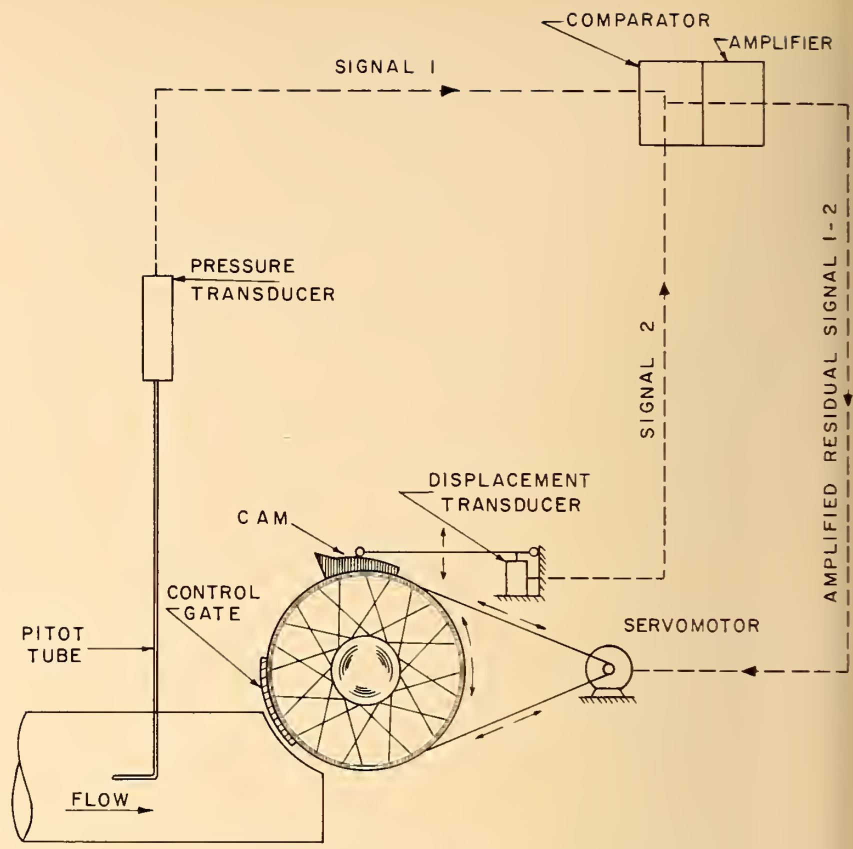


Fig. 6 Diagram of Control Gate Mechanism

properties of metals, reported that the electrical resistance of certain wires changed when they were subject to tension. More than 70 years elapsed before any attempt was made to use this phenomenon to indicate strains, and even then the early electrical strain gauges which used tensioned wires fastened to the objects under test, were expensive, highly specialized instruments which could not be used outside the laboratory.

However, in 1938, both Simmons at the California Institute of Technology and Ruge at Massachusetts Institute of Technology developed almost simultaneously a technique whereby the wires were cemented or bonded to thin paper. These bonded strain gauges could easily be manufactured in quantities, and quickly became popular with research engineers. The bonded gauge,[5] which closely resembles a postage stamp, can easily be cemented on to the surface of the object whose strain is to be measured. Most engineers have now used these gauges for measurements of strain in steel structures and are aware that when such gauges are attached to structural members, they can be calibrated to indicate the magnitude of loads acting on the structure.

The application of this technique was found very convenient when, after the Lake St. Anne Reservoir was constructed, a test was made to find the force required to operate the outlet gates. The 12-ft. wide by 18 ft. high outlet gates in this dam are operated by a chain attached to the centre of each gate. The prototype forces were measured by inserting in this chain a special link in the form of a simple cylinder with thickened ends, and by attaching strain gauges to the link. Four gauges were placed on the link to sense its elongation and four more were placed circumferentially to sense the contraction. By connecting pairs of the gauges in series the resulting four pairs were connected to form the four arms of the Wheatstone bridge circuit shown on Fig. 3. It will be noted that adjacent arms are alternately tension and compression pairs. The effect of loading the link was to unbalance the bridge with all four arms contributing to the effect. A change of temperature, however, does not disturb the balance as the change of resistance is the same in all the gauges and therefore the same in all four arms of the bridge. The possibility of a slight eccentricity of loading in the link led to the use of four tension gauges.

and to provide temperature compensation a further four gauges were necessary. As the latter have to be placed in an adjacent arm of the bridge circuit, they must either be inactive, that is, placed on an unstressed area subject to the same temperature, or active in the opposite sense, as in this case where they sense the contraction. A further significant reason for the multiplicity of gauges was the correspondingly greater signal obtained. The four leads were led to an amplifier which also supplied the excitation voltage and this, in turn, was connected to an oscillograph.

Prior to tests at the site, the link was calibrated in a mechanical testing machine by applying known loads.

The total indicated loads comprise three factors:

(a)—Submerged weight of the gate

(b) — Hydraulic downpull

(c) — The friction of the guides, rollers, and seals.

During raising the total load was the sum of all three, but during lowering the load is the sum of (a) and (b) less (c). Fig. 4 shows that the hydraulic downpull can be obtained by deducting the submerged weight of the gate from the mean operating load.

As the value of hydraulic downpull is affected by the geometry of the bottom of the gate, opportunity was taken at the site to observe the effect of a temporary modification to it. The gate was hauled up on the deck, the modification made, and the test repeated. The entire program, including additional runs to find the starting friction was completed in one day.

(b) Pressure and Movement Transducers — The foregoing description shows the use of strain gauges as a means of measuring forces. If, however, the gauges are fixed to a relatively thin walled vessel subject to fluid pressures, we have another form of transducer and a means of observing and recording pressures. Again, if gauges are applied near the supporting end of an elastic cantilever and the unsupported end is caused to follow a displacement, we have the basis of a displacement transducer. Frequently, the cantilever system is used to measure the displacement of a bellows or diaphragm and thus provide a more sensitive pressure transducer.

However, displacements and indirectly, pressures, can also be measured electrically by an entirely different principle which has definite advantages in certain circumstances where a greater electrical output is required. This unit is known as the linear variable differential transformer commonly abbreviated to LVDT or differential transformer.[6]

An LVDT, Fig. 5, consists essentially of two primary coils, a secondary coil, and an armature of magnetic material. The primary coils are energized from a suitable source of alternating current and connected in series so that their flux is opposing. If the two primary coils are identical and the armature is located so that it receives an equal amount of flux from each, the output of the secondary coil is theoretically zero.

Motion of the armature towards the upper primary coil results in a linearly increasing output of the secondary coil. Similarly, movement towards the lower primary coil again results in an increasing output, but with the opposite phase. Depending on the dimensions of the transformer, it can be made to measure movements ranging between a foot or more and less than a tenth of an inch in each case with an accuracy of one-tenth of one per cent.

(c) Electronically Controlled Dynamic Models — An example of the comprehensive use of electronic techniques in hydraulic model experiments is provided by a recent hydraulic study to establish the minimum stable diameter for the surge tank of the 855,000-h.p. Bersimis No. 2 hydro-electric development currently being constructed in Northern Quebec. To accomplish the purpose of the test, the model had not only to reproduce the inertia and flow resistance of the prototype supply tunnel and the action of the orifice surge tank, but also had to regulate the model discharge so that it varied with the surge height in a manner corresponding to the prototype turbines supplying a constant load under transient hydraulic conditions.

When designing this model it was known that the problem had already been approached in two different ways. The first[7] was to distort the supply tunnel and surge tank scales so that the period of surge oscillations was increased to an extent that the flow could be controlled manually by an operator watching a pressure indicator. The second[8] used a spring-balanced disc in a throated discharge tube. For the Bersimis No. 2 development both these methods were open to objections which could be overcome by electronic control of the outlet valve. The accuracy of response of an electronic controller could be made to suit the very rigid requirements of this model study and could easily be designed to incorporate the non-linear functions required to represent the droop in turbine efficiency curves near full load.

The control gate system of the Bersimis No. 2 surge tank model is shown diagrammatically in Fig. 11. The head at the outlet gate actuated the diaphragm of a pressure transducer operating on the differential transformer principle already referred to. The output of this pressure transducer is, therefore, an electrical signal in which the voltage varies directly with the pressure. This signal was fed into one side of the comparator.

To represent in the model a particular station power output, any instantaneous value of head had to have associated with it a corresponding outflow and therefore a singular position of the control gate. When, due to surges the head changed, the position of the control gate had also to change so that at all times it metered a flow corresponding to that for constant station power output, and the instantaneous value of the head.

Attached to, and rotating on the same axis as the control gate was a cam followed by a displacement transducer also operating on the differential transformer principle. The voltage of the signal from this transducer varied with the lift imparted by the cam and was therefore a function of the gate position. The cam was shaped so that when the signals from the pressure and movement transducers were fed into opposing sides of the comparator, it gave a null output when the discharge and head were correctly related for a particular power output. If during a test there was a change in model head, the balance just referred to was disturbed and the comparator emitted a voltage, the magnitude of the voltage depending on the magnitude of the error, and the direction depending on the sign of the error. As indicated in the diagram, this voltage was fed to a heavy duty amplifier the output of which was led to a reversible low inertia servomotor. The control gate was therefore driven towards its correct position by the error signal from the comparator, the gate position function being fed back. The control thus constituted a closed loop system constantly seeking the balance or null point.

THE USE OF FLY ASH IN CONCRETE BY ONTARIO HYDRO

J. N. Mustard, *Assistant Engineer-in-Charge*
Concrete Control Department

C. MacInnis, Jr.E.I.C., *Research Engineer*
Structural Research Department
The Hydro Electric Power Commission of Ontario

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

This paper is a resume of Ontario Hydro's experiences with the use of fly ash as a partial cement replacement in grouting mixtures and concrete. Field trials have shown that fly ash, because of its pozzolanic properties, can be used to replace substantial percentages of the cement in normal concrete mixes and grouts without adversely affecting, and usually enhancing, the long-time strength attained. Fly ash was also found to (a) reduce the temperature rise in the concrete, thereby lessening the danger of thermal cracking in massive sections; (b) enhance the workability of concrete and grout; (c) provide a somewhat increased setting time, thereby producing concretes and grouts that remain workable for a longer period, and (d) in most instances provide economies. The use of fly ash in both high- and low-pressure grouting mixtures at Niagara and to replace from 20 to 30 per cent of the cement in appropriate mass and structural concrete applications at the Ontario Hydro's St. Lawrence, Caribou, Whitedog and Otter Rapids projects are described. An account is also included of the method developed for batching the ash as a slurry.

FLY ASH is the finely divided residue resulting from the combustion of pulverized coal, as used in many modern steam-generating stations. It is usually collected before reaching the stack by means of electrostatic or mechanical separators or both, and is composed mainly of silica, alumina and iron oxide. It is one of a number of powdered materials having pozzolanic properties, i.e., cementing ability when combined with lime, in the presence of moisture. From early time it has been known that certain finely divided siliceous materials of volcanic origin exhibit cementing properties when mixed with lime. Such substances were used in Italy about two thousand years ago and many of the early structures in which they were used are still standing. This volcanic ash was called "pozzuolana" after the Italian town of Pozzuoli, adjacent to the ash deposits. The term pozzolan has come to mean any activated siliceous or siliceous and aluminous material, natural or artificial, processed or unprocessed, which though not cementitious itself combines readily with lime in the presence of water to form a cementitious compound. The use of pozzolans (both natural and artificial) as replacements for part of the portland cement in mass concrete has come into prominence in recent years. Pumicite, for example, a naturally occurring pozzolan, was used by the U.S. Bureau of Reclamation in the mass concretes for the Friant and Altus Dams, a pulverized calcined siliceous shale was used in the concrete for the Davis Dam. Fly ash also has been used in the mass concretes of many dams including the Hungry Horse, Canyon Ferry and Palisades dams of the U.S. Bureau of Reclamation.

In addition to such use in mass concrete, fly ash has found widespread use in the concrete block industry, ready-mix concrete, structural concrete, masonry cement and cement grouts. Although cost reduction is usually the main motive, technical advantages are also very often achieved. Among the confirmed advantages in the use of fly ash in concrete under proper control are higher strengths, reduced permeability, reduced temperature rise (mass concrete), enhanced workability, reduced mixer and mould wear (masonry units), increased green strength (masonry units) and enhanced sulphate resistance. On the other hand concrete containing fly ash should be carefully controlled to minimize disadvantages such as reduced early strength and increased setting time. The former may necessitate a longer curing period before the concrete is loaded. The increased setting time could cause increased form pressures and therefore call for a lower rate of placing or strengthened forms. On the other hand, an increased setting time can be advantageous in certain circumstances.

Not all ash that is trapped in precipitator systems is necessarily of satisfactory quality, although the ash from the larger furnaces using pulverized coal are most likely to be satisfactory. Ash meeting the requirements of ASTM Specification C350-57T can be considered suitable, since the specification covers composition, fineness, strength performance and other desirable characteristics.

Ontario Hydro's interest in the use of fly ash was initially stimulated several years ago when the lack of low or moderate-heat cement for mass concrete made it desirable to blend a pozzolan with normal cement to prevent excessively high temperatures. Also, when its first fuel-electric generating stations were being built it was known that they would soon be producing a useful by-product which, if suitable markets were encouraged, could lead to a reduction in the cost of power generated from solid fuel. Accordingly, a substantial body of data on the behaviour of fly ash concrete was accumulated by the Commission's laboratories over the past few years with a view to promoting the utilization of this by-product.

These studies clearly pointed to applications of technical advantage and the Commission, therefore, did not wait until it was collecting ash from its own plants before making successful use of fly ash as a component of cement grouts and concrete at several of its major hydraulic developments such as the Niagara, St. Lawrence, Whitedog and Caribou Power Projects.

Before dealing with the specific applications of fly ash at these Commission projects it is proposed to review briefly the extent to which fly ash affects some of those properties of concrete, which were of importance in Commission applications of fly ash.

Properties of Fly Ash Concrete

As mentioned earlier, the main reason why fly ash has found use as a partial cement replacement is, of course, its pozzolanic property, i.e., its ability, in the presence of water, to react with the free lime liberated during the hydration of Portland cement to form an additional cementing material. Because of this, some fly ashes may be used to replace up to 50% or more of the cement in thoroughly cured normal concrete mixes without adversely affecting the long time strength attained and in moderate percentage replacements effecting a considerable increase in ultimate strength. Strength development at early ages is slower however, and for this reason it is seldom feasible to take advantage of the maximum cement replacement that would be feasible on the basis of equal long-term strengths. This is demonstrated in fig. 1 which shows age/strength relationships for two different fly ashes at various percentages of replacement. It is readily noted that the strength behaviour of fly ashes from two sources are significantly different. This difference is considered to be due primarily to fineness, the finer ashes producing the more rapid strength development.

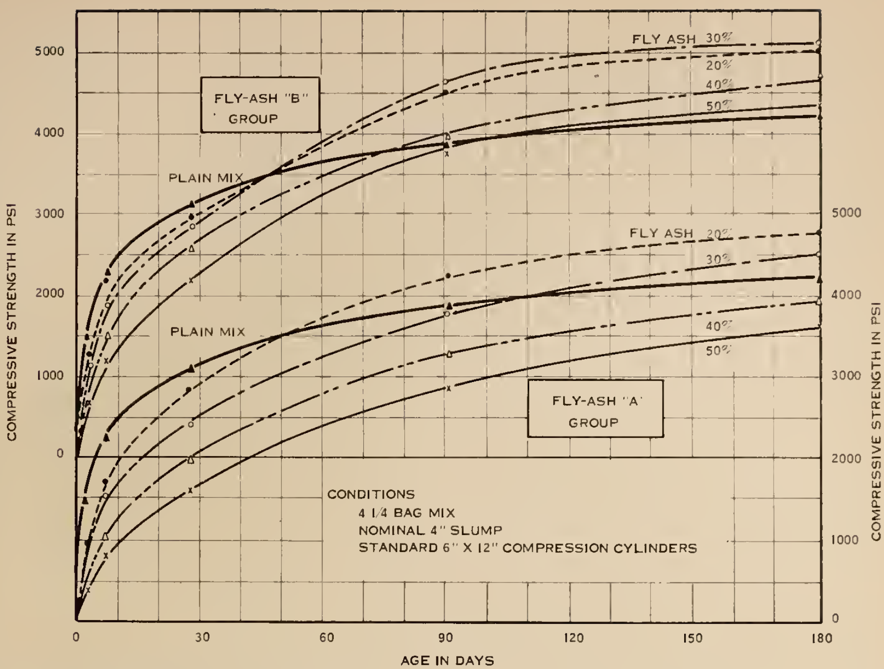

Fig. 1 Age-strength relationship of concretes with various percentages of cement replaced by fly-ash.

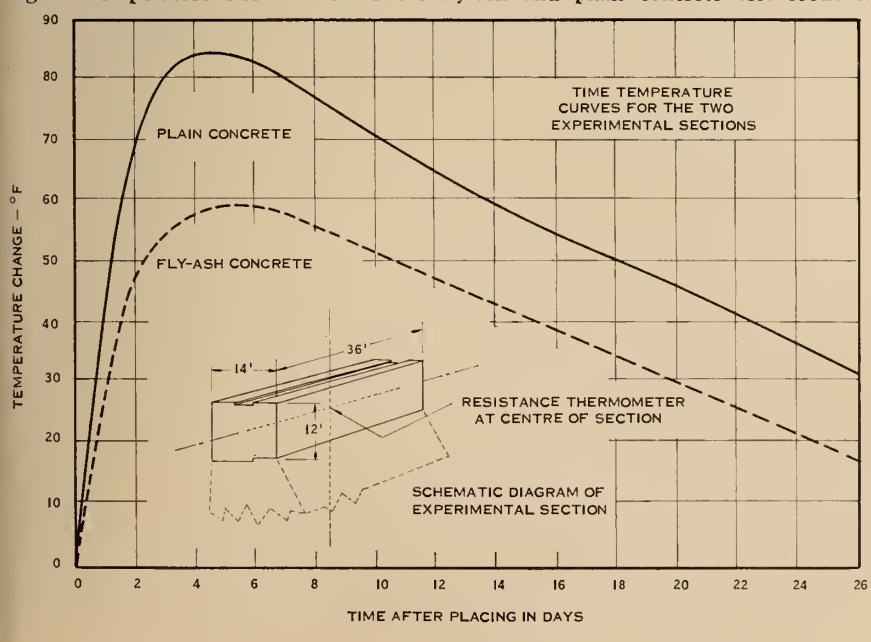
The effect of ash fineness on strength development is further illustrated by the following data on the compressive strengths of nominal 5½-bag concretes using ashes of different finenesses (obtained by blending a fine and coarse ash).

Fly Ash Fineness * (sq cm/gm)	Compressive 28-Days	Strength 91-Days
2305	2570	3550
3620	2750	4080
5445	2940	4140
7625	3300	4510

It may be seen that both the 28-day and 91-day strengths increase as the fineness increases.

A desirable property of fly ash concrete connected with its slower strength development is its lower temperature rise. In massive structures it is desirable that the rise in temperature due to heat evolution not be excessive so that the stresses resulting on cooling of the mass are less likely to produce cracks. There are extensive data to show that temperature rise in massive concrete structures is much less when fly ash is used to replace part of the cement. Figure 2 shows time-temperature curves for two experimental blocks of concrete (12 x 14 x 36 ft) placed in the Commission's Otto Holden Dam, one being made of 6-bag plain concrete and the other having 20% of its cement replaced by fly ash. It can be noted that the peak temperature was reduced by about 25F or approximately 30% in the fly ash mix.

Fig. 2 Temperature rise curves for the fly-ash and plain concrete test sections.



* Fineness is usually expressed in terms of the total surface area of the particles (sq cm/gm) determined with the Blaine air permeability apparatus.

Fig. 3 shows the strength development curves for these concretes and it can be seen that from the age of 15 days the fly ash concrete exhibited considerably higher strength.

Another property of fly ash concrete connected with its slower strength development is a somewhat increased setting time. This too can be advantageous in mass concreting operations where a large area of concrete is exposed and it is desirable to "keep it alive" until the succeeding layer is placed on top. Temperature, of course, also has a great effect on rate of setting of concrete. The extent to which fly ash affects the setting time at two different temperatures is demonstrated in Fig. 4. In this illustration the setting behaviour of the concretes was followed with the Proctor needle, measuring the resistance to penetration offered by the concretes at various ages. A penetration force of 500 is considered to be the limit beyond which concretes are no longer workable. In practical terms then, it appears that a 25% cement replacement by fly ash will produce concrete that "stays alive" approximately two hours longer at 70F and approximately four hours longer when the concrete temperature is 50F.

The properties of fly ash concrete discussed in the foregoing paragraphs, i.e., strength development, temperature rise and setting characteristics along with the enhanced workability that fly ash imparts to concrete were the main considerations in the Commission's applications of this material.

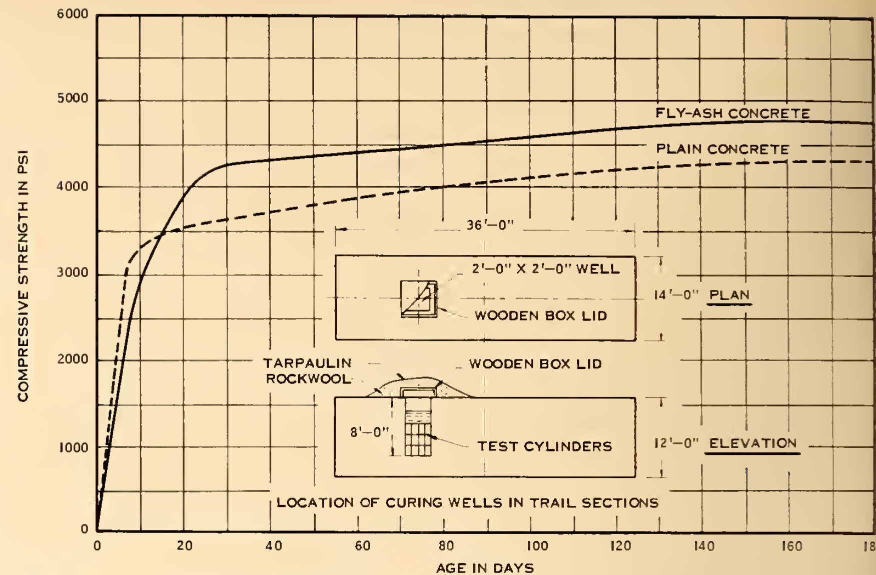


Fig. 3 Age-strength relationships of test cylinders of plain and fly-ash concrete used in experimental sections of Otto Holden Dam.

Commission Applications of Fly Ash

Nine years ago, fly ash was used on a trial basis in one block of the Otto Holden dam for direct comparison with a block of regular concrete. Strength and temperature rise characteristics of this concrete were discussed in the previous section. Repeated examinations of the Otto Holden dam since that time have shown no deterioration of any kind in the fly ash concrete even at the water line where weathering conditions are the most severe. This was convincing evidence of the durability of fly ash concrete without which it might never have been used in such an important a structure as the St. Lawrence Powerhouse. It speaks well for the foresight of those who instigated the tests at Otto Holden, many years before fly ash became available from steam generating stations within the Province.

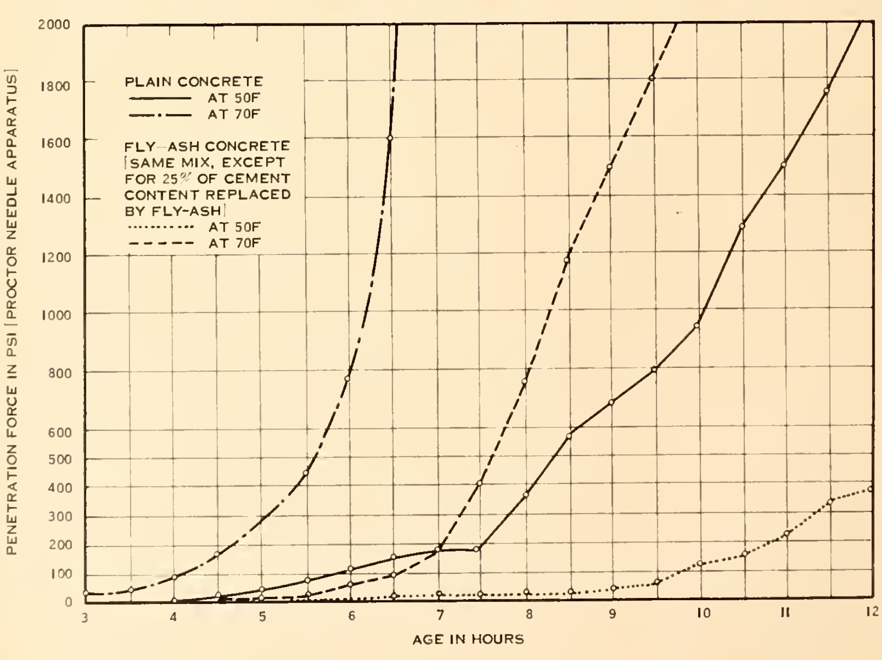
Niagara (Sir Adam Beck No. 2) Project

The first place fly ash was used extensively by the Commission was at Niagara Falls for grouting the small spaces between the rock and the concrete lining above the arch of the two 5-mile tunnels. It was also used in the high pressure grouting of the rock surrounding the tunnels. There were three reasons for deciding to use fly ash in grouting. First, by retarding the set and reducing sand settlement it facilitated the pumping of grout through the long lines of pipes from the surface; second it has cementing characteristics previously described, and third it increases the "flowability" of the grout because of its fine spherical particles. There were two grout mixes used, — low pressure sanded grout 1:1:3 cement:ash:sand, with a water-cement ratio of 0.80, and high pressure grout 3:1 cement to ash with a water ratio of 0.55. Both of these mixes pumped exceedingly well even though they travelled some 1500 ft. and were repumped before they arrived at the required location.

St. Lawrence (Robert H. Saunders) Project

Another application for fly ash concrete came on the St. Lawrence Development, where during the design stages it was found necessary to span the 80-ft. ice sluices with beams

Fig. 4 Rate of setting of plain and of fly-ash concretes at two temperatures.



about 28 ft. deep to carry the 300-ton gantry crane. Fly ash was considered the solution for the thermal shrinkage problems which were inevitable in such massive structural members.

Twenty-five per cent of the cement was replaced with fly ash in these beams and this resulted in a corresponding decrease in temperature rise and thermal shrinkage, which minimized the danger of cracking in the beams.

The concrete of the powerhouse was composed of crushed rock, manufactured sand and portland cement, and it was found that the fine spherical particles of the fly ash seemed to give the concrete additional "lubrication" or response to the vibrator. It also appeared to stay "alive" longer than ordinary concrete of the same temperature. For these reasons it was used in the heavily reinforced and difficult pours around the scroll case and also in the scroll case roof where it minimized shrinkage to such an extent that although they were placed in eight segments, none of the scroll case roofs leaked under full head.

Fly ash particles being lighter and frequently finer than cement, tend to create a dust nuisance when bagged fly ash must be batched manually into the mixer. Normally, of course, this does not constitute a problem in batching plants equipped with a separate storage silo and batching hopper for the bulk fly ash. At the St. Lawrence project where no facilities were provided for storage and batching of bulk fly ash, the material had to be shipped and stored in bags. To alleviate a dust problem, the fly ash was mixed with water in a building entirely separate from the mixing plant. (See Fig. 5). A standard grout pump then delivered the slurry to the batching floor of the mixing plant, where by simply turning a valve, the batcher at the control board could add any specified quantity to the mixing water by watching the dial on the water tank scale. The proportions of ash to water were standardized at one to one by weight which gave a very pumpable slurry. To arrive at the mix proportions, the inspector at the plant had only to deduct the amount of water in the fly ash slurry from the total mixing water, which was calculated easily because of the simple ratio maintained in the slurry mixture. When the slurry was not being drawn off at the concrete batching floor, it was automatically recirculated to the grout pump by means of a two-way valve, thus maintaining the ash in

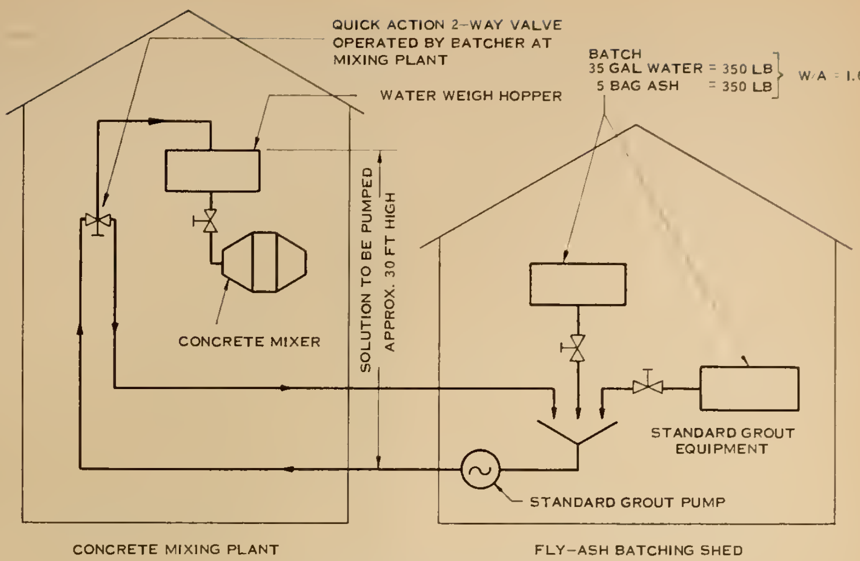


Fig. 5 Fly-ash handling equipment.

suspension. As there was no setting action of the ash in water, the mixture could be recirculated almost indefinitely. Even though the mixing plant inspector was in a separate building from the batching of the fly ash, any error in the fly ash slurry proportions could be quickly detected by checking its specific gravity with an hydrometer.

Thus there were two completely independent operations, the men in the fly ash shed being concerned only with maintaining an ample supply of uniform slurry, and those in the concrete plant having only to turn a valve and draw the ash off when it was required. (See Fig. 7). This had many advantages:— it kept all of the dust out of the mixing plant; it did not interfere with the simultaneous production of regular and fly ash concrete for different parts of the job; and the premixing of part of the cementing agent in water had certain basic advantages from the standpoint of control and thoroughness of mixing.

Whitedog and Caribou Projects

Each of these stations had three generating units, the scroll case roofs of which were about 50 x 50 ft. with a 20-ft. diameter central opening for the turbine. Normally these roofs are placed in four segments diagonally opposite segments being placed simultaneously with a two-week cooling period before placement of the other two segments. This procedure would have involved a total loss of about three months of valuable time for the two projects, to say nothing of the cost of bulkheads, waterstops and drains. Therefore it was decided to place the whole roof of each unit as a monolith, utilizing fly ash to minimize the thermal shrinkage and to assist in keeping the large area "alive" during the placing. In these pours fly ash was used to replace 25% of the cement. A water-reducing retarding admixture was also used in this concrete to lower the water requirement and to ensure proper control of the amount of retardation.

In spite of extra ingredients in the mix, concrete of remarkable uniformity was produced, and cold joints were avoided. The slurry method of handling the fly ash was used at both of these projects, and since it was not convenient to add the slurry to the water hopper at the Caribou plant, a separate measuring tank with an agitator was successfully installed on the batching floor of the mixing plant.

Otter Rapids Project

During May of this year concreting started for the Otter Rapids Generating Station on the Abitibi River south of James Bay. It will be the first hydraulic structure which the Hydro has placed in relatively shallow lifts, and since this practice increases the danger of thermal cracking, fly ash is being used as a partial cement replacement to keep the temperature rise to a minimum. The ash is being obtained from the mechanical and electrical precipitators at the Hydro's R. L. Hearn Generating Station in Toronto and is shipped to Otter Rapids in bulk cars at a considerable saving over the cost of cement. At the job, the ash is stored in a silo and added to the mixers as a slurry which is produced as previously described for the St. Lawrence Power Project where the method was first introduced. At

Sulphate Resistance of Concrete
LT-1—Ordinary Concrete
LT-2—Ordinary Concrete
LT-3—Ordinary Concrete
LT-4—Fly Ash Concrete

Otter Rapids the fly ash will comprise 30% of the cementing material in the mass concrete.

Conclusions

Because of the successful use of fly ash as a cement replacement in the past at the Otto Holden, Niagara, St. Lawrence, Whitedog and Caribou Generating Stations and the present use of our own fly ash from the Hearn Steam Generating Station in the concrete at Otter Rapids, it can be concluded that there are many structures in which fly ash can be used with assurance to facilitate the placing of concrete while at the same time enhancing its thermal characteristics and providing significant economy.

DISCUSSION

Author's reply

As yet, the only coal-burning generating station in Hydro's system that has facilities for dry storage and loading of fly ash is the Richard L. Hearn G.S. in Toronto. These facilities were completed only in the late spring of 1959. Acordingly, few data are available to date on the uniformity of fly ash after it has been drawn from a large number of precipitator hoppers (both electrostatic and mechanical types) and blended in large storage silos. However, periodic sampling from various hoppers over the past several years has indicated that while rather large variations may occur during periods when the furnaces are being started up or shut down, much greater uniformity and a higher level of quality exists when the plant is operating at or near full load. The best estimate that can be made to date of average properties of the ash produced at the Hearn station, Table A, shows it to be fully acceptable according to ASTM specification C350-57T, *Fly Ash for Use as an Admixture in Portland Cement Concrete*. At the station in question, fly ash is separated from the discharge gases in two stages. For each of the eight generating units, cyclone-type mechanical separators first trap the coarser fraction of the tiny particles while two banks of electrostatic precipitators in series entrap the extremely fine particles which have escaped from the mechanical collectors. Because of a flexible handling system, fly ash from each of a multitude of collector hoppers can be selected and discharged in the desired sequence for blending in a large storage silo to achieve a uniform commercial product. Alternatively, sub-standard fly ash which may be produced occasionally, as during start-up periods, can be delivered into a second silo for non-commercial disposal. Accordingly, future users of fly ash from this station may be assured of receiving a product meeting an accepted standard of quality.

PROPERTIES OF FLY-ASH FROM R. L. HEARN GENERATING STATION

Analysis	R. L. Hearn G.S.	ASTM C350-57T Specification
SiO_2	42.0%	
Al_2O_3	20.6%	70.0% Min.
Fe_2O_3	23.8%	
MgO	1.4%	3.0% Max.
SO_3	0.8%	3.0% Max.
CaO	2.8%	—
H_2O	0.4%	3.0% Max.
Loss on Ignition	8.3%	12.0% Max.

Fineness (Blaine Method)
Mechanical Collector Ash —3350 sq. cm/gram = 2800 Min.
Electrostatic Precipitator Ash—7570 sq. cm/gram

Sulphate Resistance of Fly Ash Concrete

Experience in Ontario with sulphate-bearing groundwater is naturally far more limited than is the case in the Prairie Provinces where sulphates occur frequently. So far, as Ontario Hydro is concerned, sulphates in serious concentrations have been encountered only in two locations.

In one instance in South-western Ontario, sulphate concentrations of 1000 to 150 ppm of SO_3 were detected in a water-bearing gravelly layer immediately overlying the bedrock at 80 to 90 ft. below the surface. Soluble sulphates in clay immediately above the gravel layer were 1300 to 6000 ppm. Subsequent construction in this area did not require the installation of concrete in this ground although concrete piles had been contemplated at one stage in the investigation.

At another location in the south-central part of the Province, drainage from a large storage area for bituminous coal was found to have pH values ranging from 8.0 to as low as 2.5 and widely-varying sulphate contents averaging from 100 to 6000 ppm. Minor concrete structures in the drainage path were found to have suffered damage which was limited mainly to surface attack to depths of 1½ in. after service periods as great as 40 years. In 1950, a limited exposure program was initiated in which specimens of ordinary and fly ash concrete made from normal portland cement were immersed in the sulphate bearing groundwater as it was collected in a drainage channel. The results to date, as illustrated by Figure 1 have indicated appreciably superior resistance of fly ash concrete. The condition described appears to be a rather unusual one for this area since examination of several other coal storage locations has failed to disclose such severe conditions. Also, the area most severely affected is restricted to a radius of a few hundred feet owing to the effects of dilution and reactions with soil components. However, in other countries, water draining from coal mines and coal bunkers is known to have damaged concrete, particularly when coal has a high pyrite content.

The Effect of Fly Ash Concrete on Form Pressures

It is true that the fly ash has a retarding effect on the stiffening of fresh concrete; the amount of retardation varying with the percentage of cement replaced by fly ash and the temperature of the concrete. During hot weather the "slowing of the set" is usually beneficial, particularly in massive concrete; and during cold weather, when the materials have to be heated to prevent freezing, its effect can be offset by raising the placing temperature a few degrees. Although the exact relation of "rate of stiffening" to form pressures has not been established, using the ACI Committee 622 from pressure's formula, it can be calculated that raising the placing temperature ten degrees (from 55 to 65) will offset the effect of a replacement of 30 per cent of the cement with fly ash. At lower temperatures the retarding effect is more pronounced requiring a greater increase in the placing temperature or a strengthening of the forms.

PHOTOGRAPHY AND ELECTRONICS . . .

(Continued from page 73)

In addition to the above general description, it can be seen from the photograph that the model discharge issued from a penstock which was tapered in plan and controlled by a form of taintor gate constructed by supporting a curved plate between a pair of light wire spoke wheels. To ensure rigidity and as a precaution against vibration, both the bearings for the wheels and the penstock chute were mounted in a heavy steel framework. The cam is mounted at the top of one of the wheels and the LVDT is actuated by a cam follower. The impact tube in the penstock feeds the total head into the diaphragm of the pressure transducer shown on the bottom left-hand corner of the photograph. As mentioned above, both the transducers were of the linear variable transformer type. The primary windings of both were excited from the same 100-volt supply.

Modifications to the size of the model surge tank were quickly made by placing displacer blocks inside a master tank built larger than the maximum size to be tested. The rise and fall of the water surface in the tank was visible through a transparent panel in the side of the tank. The period of the surge was approximately 14 seconds. Modifications to the station output could be simulated by changing the cam attached to the control gate.

During tests, the control gate was first locked for some minutes at its equilibrium position, then, by means of a mechanical clutch in the drive between it and the servomotor, the system was brought under "governor control". If the resulting oscillations progressively increased the size of tank was below the critical and the tank unstable. If they did not increase, the "governor" was declutched and the control gate moved away from its equilibrium position. Bringing on governor control from this position simulated a station load change and the model accurately reproduced the resultant surges whose damping characteristics could then be studied.

To facilitate observation of surges and to give a permanent record, the output of a second pressure transducer was applied to an oscillograph. Testing with this apparatus proceeded very rapidly. Four tank sizes could be tested at two different station outputs in one morning and the model, in spite of its complexity, more than paid for itself since the results showed that stable operation would be achieved with a prototype surge tank smaller than that which would have had to be adopted if the design had been based on classical analytical studies.

Conclusions

Experience in the operation of a hydraulic laboratory and in conducting prototype tests has shown the authors that the full benefits of experimental work in hydraulics cannot be obtained without the aid of techniques developed in other fields of science and engineering.

The examples described show how modern techniques and instrumentation may be applied to extend the scope of some hydraulic experiments and give increased information about the hydraulic phenomena involved.

Acknowledgments

The data concerned with the two Bersimis developments and the Lake St. Anne Reservoir was made available by the Quebec Hydro-Electric Commission and that concerned with the Warsak development, by the Canadian Department of Trade and Commerce. The detail design of these developments was performed by H. G. Acres & Company Limited, Consulting Engineers, of Niagara Falls, and the model tests were conducted in their laboratory. The authors are indebted to the above for their permission to give this paper. They are also indebted to their colleagues for help and care in performing the experimental work described, to Canadian Vickers Limited for supplying and calibrating the link used to measure hydraulic downpull at Lake St. Anne Reservoir, and to G. Kelk and Company Limited for assistance in the design and construction of the electronic components for the surge tank model's control gate.

SOMETHING CAN BE DONE ABOUT NOISE

F. S. Howes, *Professor of Electrical Engineering*
McGill University, Montreal, Que.

Noise is unwanted sound—The sound of my radio or T.V. receiver is wanted by me but not by my neighbour. It may be music to my ears; it is noise to his. The roar of a motor at midnight may be a most welcome sound to the ears of the owner who has been trying for some time to get it started with a rapidly expiring battery; it is very definitely noise to all of us who are wakened out of a sound sleep by the disturbance as it enters our bedrooms. Noise is unwanted sound.

SOUND IS A DISTURBANCE initiated by mechanical vibration and propagated out from the source at a velocity determined by the nature of the medium. The medium may be a gas, a liquid or a solid — any medium characterized by elasticity and mass. However, most of the sounds that constitute a problem to us are propagated through air — they are air-borne sounds. It is important to remember that the source of all sounds is vibration — sometimes periodic and at a definite frequency; sometimes explosive or in the form of a shock, rising rapidly to a peak value and then dying away. Examples of both types of source are found in the production of human speech sounds; in the instruments of an orchestra or in an industrial plant. The amount of energy involved in the sound depends upon the amplitude of the vibrations and the area of the moving part. The greater the amplitude, the farther the air in contact with the moving part is pushed from its equilibrium position; i.e., the greater the compression and hence the greater the sound pressure. The greater the area in motion, the greater the volume of air compressed and the greater amount of mechanical energy converted to acoustical energy to be radiated away as a sound wave.

If a part of a machine is in simple harmonic motion at a high speed, the sound produced may be a relatively pure musical note. I say relatively pure because there are always some harmonics present and it is in fact the presence of the harmonics which enables us to distinguish between different musical instruments playing, say, middle C. In stringed instruments, the string which is the source of the sound may be struck as in the piano, plucked as in the guitar or bowed as in the violin or 'cello. The frequency of the note depends on the length of the string, its mass, elasticity, the tension on it. The volume of sound produced depends on the amplitude of vibration of the string and on the area set into motion by the vibration of the string. Clearly the string itself could not move much air, but the string is attached to a sounding board — the body of the violin or 'cello or guitar which by responding to the vibrating string modifies the tone but also greatly enhances the volume. Examination of other instruments used in an orchestra or band as e.g. the wind instruments or the percussion instruments bring out the same points — something is set in vibration and a sound is produced which has a fundamental or lowest frequency usually controlled by the player; a quality which is peculiar to the instrument and may depend on the manner of initiating the vibration as e.g. compare the tone of the single reed clarinet with that of the double reed oboe, and a volume depending partly on the player but also on the area of the vibrating part.

To sum up—

1) Noise is unwanted sound
2) It is generated by some vibrating body
3) The acoustical energy involved depends on the amplitude and area of the vibrating part.

The Effects of Noise on People

Most people are startled and annoyed by a sudden loud sound. On the other hand if a noise is sustained hour after hour, day after day, our reaction depends very much on whether the noise intefers with what we want to do. We may be annoyed or frustrated and both of these reactions may make us tired or tense; if this condition is continued over a period of time it may have definite physical effects. But our reactions to noise depend markedly also upon the nature of the noise and its intensity; whether it is high pitched or low; steady or intermittent; whether it makes speech communication or the use of the telephone difficult. Some noises can in time result in temporary or permanent, partial or total loss of hearing. To understand these effects better, we must know something about the hearing mechanism in man — the ear itself.

The hearing sense and the anatomical structure which enable us to hear have of course evolved with man over the millions of years. Acute hearing still has a very marked survival value. How much more must this have been true when man lived a more rugged life with his physical existence threatened by enemies on every side. Those with poor or impaired hearing did not survive; those with acute hearing passed on this characteristic to their offspring. The result is a hearing mechanism that is not only incredibly sensitive but amazingly versatile.

A functional schematic of the anatomical structure of the ear is shown in Fig. 1.[1, 2] The main features are the outer, middle and inner ear; the link motion mechanically connecting the relatively large eardrum to the small oval window at the entrance to the cochlea; the cochlea itself, filled with liquid. The three tiny bones (ossicles) which provide the linkage between the eardrum and oval window, make possible the energy transfer from the outer to the inner ear

The ear receives and responds to air-borne, acoustic vibratory energy over a frequency range of about nine octaves and a dynamic range of more than one million to one. Its output is nerve impulses in the auditory nerve. These impulses convey auditory information to the brain. We are not here concerned with how acoustic energy stimulates these nerve impulses or with the way in which the inner ear performs a partial acoustic analysis of sounds with respect to their pressure, frequency or time of arrival. All these are problems of the physiology of hearing. For the purposes of noise control it is enough to know that the outer ear conducts acoustic energy to the middle ear and that the middle ear serves as an impedance-matching device to deliver the energy efficiently to the inner ear. We also know that the inner ear may be harmed by certain diseases and also by excessive noise.[3]

Although the ear is an exceedingly sensitive device, it is not equally sensitive at all frequencies nor do all ears respond over the same frequency range. An average young ear which we shall refer to as having "normal" hearing, can detect sounds from about 20 cycles per second to 16,000 cycles per second or higher and its dynamic range extends from a sound pressure of 0.0002 dynes per sq. cm. at the threshold of hearing at 1000 cps. to at least 200 dynes per sq. cm. at the threshold of feeling. This very small pressure at the threshold of hearing produces a displacement of the ear drum that is of the order of 10^{-9} cm. This distance is less than one tenth of the diameter of a hydrogen molecule![4] The threshold of hearing and the threshold of feeling for a normal ear are shown in Fig. 2.

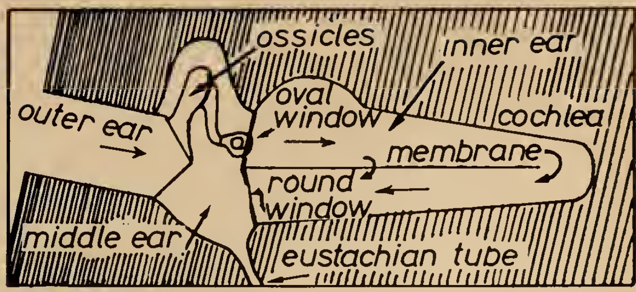

Fig. 1 Functional schematic diagram of the ear.

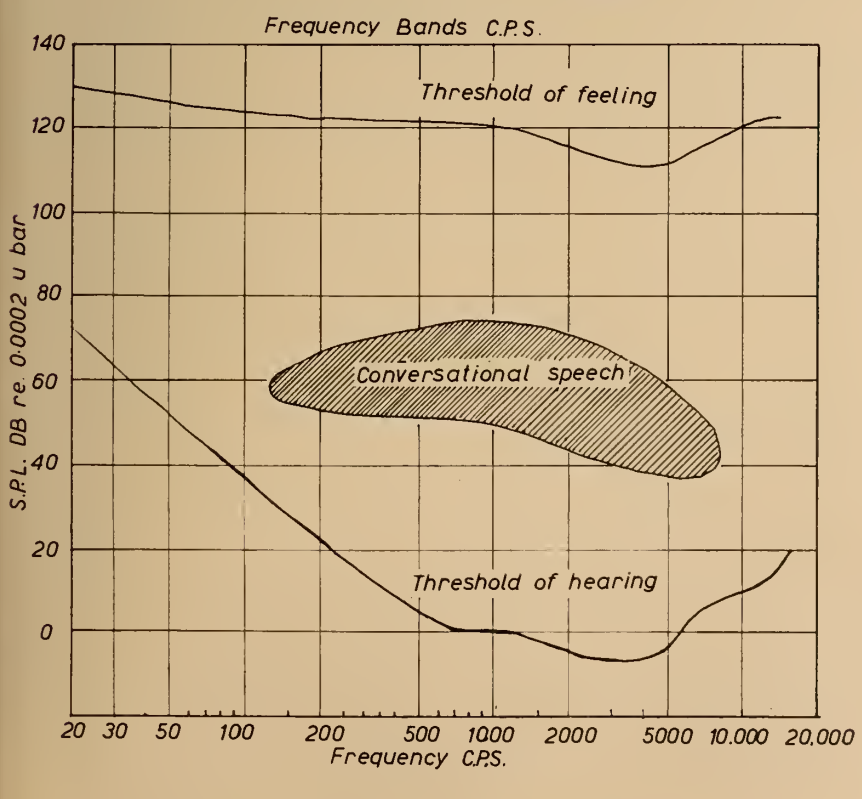
It will be noted that in Fig. 2 the "decibel" system is used to express the sound pressure level. Using this system, the sound pressure level in decibels or db is defined as $20 \log_{10}(P_1/P_o)$ db where P_1 is the sound pressure one wishes to express in db and P_o is the reference pressure. The reference pressure usually is 0.0002 dynes per sq. cm. which is the threshold of hearing at 1000 cps. If we take P_1 as equal to 200 dynes per sq. cm., then the corresponding sound pressure level is $20 \log_{10}(200/0.0002)$ db $=$ 120 db. This is the sound pressure level at the threshold of feeling at 1000 cps. re 0.0002 dynes per sq. cm. The reference pressure must always be stated. The decibel system is also used to express power levels in acoustics. Again, by definition, the power level in db is $10 \log_{10}(W_1/W_o)$ where W_1 is the power whose level one wishes to express in db and W_o is the reference power. W_o is taken at 10^{-13} watts. As an example, the average power level of the male voice speaking normally is 84 db re 10^{-13} watts. Thus $10 \log_{10}(W_1/10^{-13}) = 84$ or $W_1 = 25 \times 10^{-6}$ watts.

Fig. 2 Frequency dynamic range of the ear.



From the above, it is seen that due to the extreme sensitivity of the ear the amount of power involved in speech communication is exceedingly small. One man speaking at normal voice radiates 25 microwatts of acoustic energy. Thus, it would take one million men all talking at once to radiate the acoustical equivalent of the electric energy required to light a 25 watt lamp! Of course it would not work out quite this way because long before a million men could be assembled for the trial, the "cocktail party effect" would set in and everybody would be shouting! But perhaps the point has been made that ears are sensitive and even sounds which are very loud do not involve as much energy as one might suppose.

Fig. 2 represents the characteristic of the "normal" ear, but the normal ear is a young ear. There is a progressive reduction of hearing acuity with age in both men and women although the deterioration in men is somewhat greater at a given age. This loss of hearing acuity due to age is a permanent loss, but age is not the only cause of such loss. Damage to vital parts of the hearing apparatus will of course affect its normal functioning. However, our concern here is with the effects of noise and it has been established that sustained exposure to high intensity sound particularly at the middle and high frequency end of the spectrum can occasion such loss of hearing and that this loss may be permanent.

Noise being unwanted sound is, almost by definition, an annoyance, but the most specific occasion for annoyance due to noise is experienced when the noise prevents one from communicating with someone else either directly or by telephone. The phenomenon responsible for this speech interference is called masking. Speech sounds contain a great many frequency components extending upward to at least 10,000 cycles per second. Most of the energy in speech sounds is at the lower frequencies — up to 3000 cycles per second at least are essential for the intelligibility of speech. And there is very little acoustic power in these high frequency sounds. Thus if noise is present, the intensity of the wanted sound must be increased if it is to be heard above the unwanted sound. This effective raising of the threshold of hearing for the wanted sound by the unwanted sound is called the masking of the wanted sound. When we say that we cannot hear what the other person says due to the noise, we usually mean that while we hear his voice (low frequencies) we cannot understand what he says — because those higher frequency components which are essential for intelligibility have been masked by the noise. So we raise our voice; i.e., put more energy into the high frequency sounds to override the masking noise. The other person also raises his voice and we succeed in communicating. To have to shout to a colleague across the desk or to go to some other location to telephone or to spell out D for Donald, T for Tom and P for Peter, takes time and is annoying, but does enable us to convey meaning in spite of the masking effect of the noise.

Table I

Speech Interference Levels (S.I.L.)—Average Male Voice

Distance Feet	*Voice Level*			
	Normal	*Raised*	*Very Loud*	*Shouting*
0.5	71 db	77 db	83 db	89 db
1	65	71	77	83
2	59	65	71	77
3	55	61	67	73
4	53	59	65	71
5	51	57	63	69
6	49	55	61	67
12	43	49	55	61

Summary

1) The human hearing apparatus in its normal condition is extremely sensitive and responds over a wide range of frequency and sound pressure.
2) Its sensitivity decreases with age and may be seriously impaired by sustained exposure to high level noise.
3) For speech to be intelligible, frequency components up to at least 3000 cps. must be clearly heard. The phenomenon of masking results in noise causing interference with speech communication.

The Role of the Engineer

So far I have been considering the phenomena and effects of noise. A good deal of this is of course familiar to you. What you would like to know now is what you as an engineer can do about the problem.

Noise is just another engineering problem and the approach to this one is the usual approach — get at the facts. When people — any people, complain about noise, they should be taken seriously. Their reaction is qualitative and subjective, but it corresponds in some measure to the quantitative and objective situation. What are the facts? What sound pressure levels at what frequencies are actually present in the area where the people concerned are working? Until these facts are known, nothing can be done. When we know them, we can compare them with established criteria regarding hearing damage risk and speech interference.

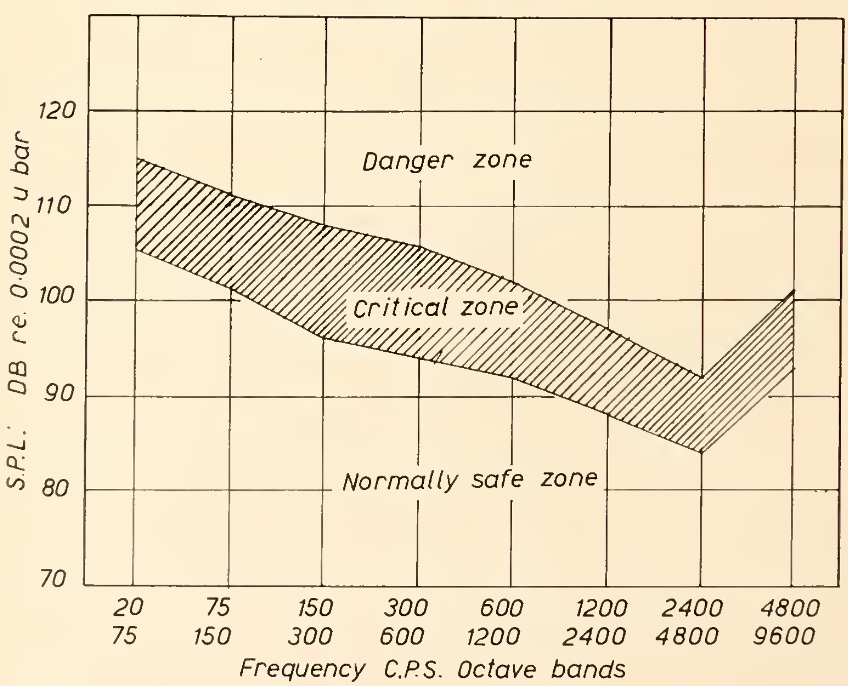
In Fig. 3, "Tentative Hearing Risk Criteria"[5] are shown in the form of a graph. Ears vary a great deal in sensitivity and sound pressure levels which may damage some ears in a short time of exposure may leave other ears unaffected. The safe thing to do is to keep the levels below the critical zone. If measurements indicate for example the sound pressure level in the 300 to 600 cps. band is 100 db, then to avoid hearing damage to those working in that area, the level must be reduced to 94 db or lower.

In Table I are shown Speech Interference Levels in decibels (re 0.0002 dynes/cm²) which barely permit reliable word intelligibility at the distances and voice levels indicated.[4] It is assumed that there are no reflecting surfaces to aid the direct speech.

It will be noted that the voice levels are 6 db apart and that each doubling of distance requires a reduction of 6 db in the permissible S.I.L.

The S.I.L. is defined as the arithmetic average of the Sound Pressure Levels (SPL re 0.0002 dynes/cm²) in the 600-1200, 1200-2400 and 2400-4800 cps bands. Thus for example, if the S.I.L. is 49 db, two people may converse in a normal voice at 6 ft. If they are 12 ft apart, they will be

Fig. 3 Tentative hearing risk criteria.



able to converse equally well if they raise their voices 6 db. However, if they are to converse at normal voice level when 12 ft apart, the S.I.L. must be reduced to 43 db.

Beranek[6] has given noise criteria for offices based upon extensive experience as a consultant on office noise problems. In the table and curves which follow (Fig. 4) NC means Noise Criterion and the NC number refers to the speech interference level. Thus NC-40 means an S.I.L. of 40 db.

These noise criteria are based on today's acceptable speech interference levels. No doubt they will be altered as our knowledge of these matters is extended. Similarly with the hearing damage risk criteria. Hardy's[5] paper referred to was published seven years ago. Glorig,[7] writing five years later, suggests the following:

"If the sound energy of the noise is distributed more or less evenly throughout the eight octave bands and if a person is to be exposed to this noise regularly for many hours a day, five days a week, for many years, then, if the noise level in either of the 300-600 cps band or the 600-1200 cps band is 85 db, the initiation of noise exposure controls and tests of hearing is advisable. The more the octave band level exceeds 85 db, the more urgent is the need for hearing conservation."

However, in spite of the fact that these criteria are likely to change, it is clear that enough data is available to make a start. Using these data as criteria and comparing them with the measured data in the area under study, the amount of noise reduction required may be readily seen.

To solve problems in any branch of engineering, one must know a certain amount of basic theory. The basic theory of acoustics is not especially difficult, but it must be mastered if one is to handle noise problems intelligently and with a minimum of expenditure. In the bibliography at the end of this paper, reference is made to some suitable textual material.

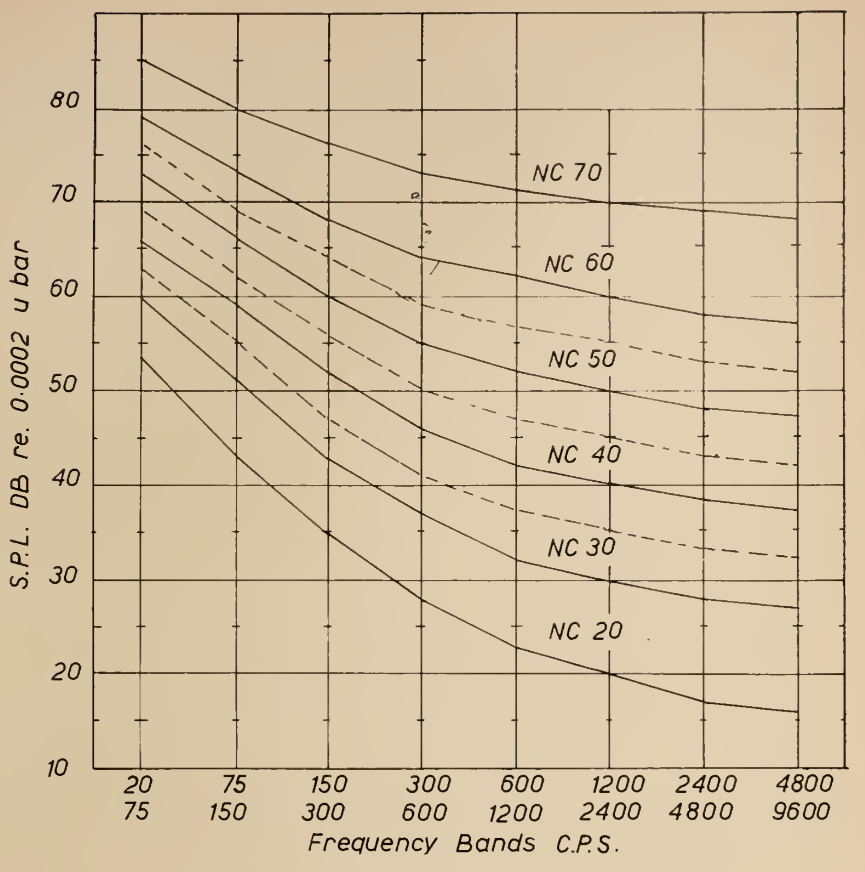


Fig. 4 N. C. curves.

Summary

1) As with any other engineering problem, the engineer must in this case obtain quantitative, objective data about the noise levels in the space he is concerned with;
2) Criteria are available concerning damage risk and speech interference levels which enable the engineer to decide what noise reduction is required in a given area to achieve acceptable conditions;
3) The intelligent application of acoustic theory can lead to a satisfactory solution of many of our noise problems.

Measurements

To obtain quantitative data on the noise at a given location, one must make measurements and the essential equipment for this purpose is a Sound Level Meter and an Octave Band Analyser.

With the Sound Level Meter one determines the over-all sound pressure level at all working locations where it is difficult for two persons with normal hearing to converse at arm's distance.[8]

The Sound Level Meter measures only over-all sound levels. For a more complete description of the sound, measurements involving frequency are also necessary. This is the function of the Octave-Band Analyser. Neither hearing damage risk nor speech interference levels can be determined by a single-number, over-all level. One must also know how the sound energy is distributed over the frequency spectrum.

The Sound Level Meter consists of a microphone, an amplifier, an attenuator and an output meter, all housed in a small portable box. The device is powered by batteries or may be adapted for use with the 110V, 60 cps supply. This instrument which has characteristics specified by the American Standard Association gives the Sound Pressure Level in db re 0.0002 dynes/cm^2. The Octave Band Analyser is used in conjunction with the Sound Level Meter and taken together one obtains the sound pressure level in each of eight octave bands extending from 37.5 cps to 9600 cps.

The Sound Level Meter costs about $350 and the Octave Band Analyser costs about $550. A vibration pickup may be added for $100 making a grand total of $1000 for all of the essential equipment.

Acoustical measurements are something of a science and something of an art still. The available instrumentation is adequate but must be used with understanding and the results interpreted with care. One cannot in a paper such as this go into the details of what to do and what not.

Instrument manufacturers supply very good manuals with their meters and much will be found in the literature to guide the novice. In a good many situations high accuracy in measurement is not essential in a preliminary survey and a preliminary survey may be sufficient to indicate the magnitude of the problem on hand. By the time management has been persuaded to take the matter seriously, the engineer who has been assigned to "clean up the problem" can have acquired considerable experience in making the necessary measurements.

Summary

1) The essential equipment for making noise measurements is a Sound Level Meter and an Octave Band Analyser.
2) This equipment will cost about $900 plus customs duty.
3) With this equipment and a clear grasp of basic acoustic theory, most noise problems can be dealt with fairly adequately.

Treatment

The first problem is always to get at the facts about the actual noise levels that exist and their frequency distribution.

The second problem, assuming that these levels indicate that some reduction is in order, is to isolate the source of the noise — find out what is vibrating. The ideal solution to every noise problem is, having discovered the source, to eliminate the noise at the source. If the source is your neighbour's radio or T.V. or 2-year-old child, the solution may call for more knowledge of psychology than of acoustics. If the source is a machine, some part of which is vibrating, partial redesign of the machine or the stiffening of some structural member may kill the vibration or move it to a part of the frequency spectrum where it is less bothersome. The first step is to locate the source. If the noise cannot be eliminated at the source, it may be possible to modify its environment.

At this point some knowledge of room acoustics is a good thing. A noise source radiates sound in all directions and these sound waves travel out at about 1130 ft. per second toward the boundaries of the room. Some of the sound energy is absorbed at the room surfaces and the remainder is reflected. Depending on the size of the enclosure, there may be many reflections in a second and before very long a diffuse sound field is built up in the room. This diffuse sound field is called the reverberant field. It is always much weaker than the direct sound near the source. The operator of the machine which produces the noise is in the direct sound field; the other people in the room are in the reverberant sound field. The more absorbing material there is on the room surfaces, the weaker will be the reverberant field and hence the less will the other people in the room be affected by the noise. But increasing the room absorption will not help the operator of the machine — his machine makes the noise. Thus to eliminate the noise at the source is to help everyone; to treat the room only is to help the many but not the machine operator. The first effort should therefore be to work on the machine.

If the machine cannot be altered to reduce the noise, perhaps it can be moved or enclosed. Sometimes vibration in a machine is transmitted through its foundation to structural members of the building and so appears on all floors. Resilient mounts for the machine may be the answer. The paths by which noise is being transmitted should be examined. A ventilation duct outlet in one room may be delivering air and picking up noise which is then delivered through another duct opening into another room. The walls between the machine room and an office may have sufficient transmission loss to reduce the outside noise to a suitable level, but there may be holes in the wall to let pipes through. The transmission loss through an opening is zero.

There is no single formula which will give the answer in all cases. Such formulae as there are must be used with understanding and judgment and success in handling a noise problem means reduction of the noise to acceptable levels at reasonable cost. But instrumentation is available to make the necessary measurements and useful theory and criteria have been developed over the past 25 years to handle these problems satisfactorily. What is needed now is the will to do something about noise.

Summary

1) First, determine by measurement the noise levels and the frequency distribution on an octave band basis.
2) Isolate the source of the noise, by modification of the machine, moving the machine, building an enclosure around the machine.
3) The operator of the machine is in the direct field and can only be helped if the noise is reduced at the source.
4) Other people in the room are in the reverberant field and can be helped by the use of sound absorbing material in the room.
5 All the paths by which sound is

Table II

Recommended Noise Criteria for Offices

NC Curve of Fig. 4	*Communication Environment*	*Typical Application*
NC-20 to NC-30	Very quiet office. Telephone use satisfactory. Suitable for large conferences.	Executive office and conference room for 50 people.
NC-30 to NC-35	"Quiet" office. Satisfactory for conference at 15' table. Normal voice 10-30 ft. Telephone use satisfactory.	Private or Semi-private office. Reception room. Small conference room for 20 people.
NC-35 to NC-40	Satisfactory for conferences at 6-8 ft. table. Telephone use satisfactory. Normal voice 6-12 ft.	Medium-sized offices and industrial business offices.
NC-40 to NC-50	Satisfactory for conferences at 4 to 5 ft. table. Telephone use slightly difficult; normal voice 3-6 ft., raised voice 6-12 ft.	Large engineering offices, drafting rooms, etc.
NC-50 to NC-55	Unsatisfactory for conferences of more than 2-3 people. Telephone use slightly difficult; normal voice 1-2 ft.; raised voice 3-6 ft.	Secretarial areas (typing), accounting areas (business machines), etc.
Above NC-55	Very noisy. Telephone use difficult. Unsatisfactory for offices.	Not recommended for any type of office.

NOTE: Noise measurements made for the purpose of judging the satisfactoriness of the noise in an office by comparison with these criteria should be performed with the office in normal operation, but with no one talking at the particular desk or conference table where the measurement is being made.

transmitted from source to receiver must be examined and blocked.

6) Remedial measures are always possible once the decision has been taken to clean up the noise situation.

The Future of the Noise Problem

Not so many years ago, refrigerators and automobiles were very noisy. They are not noisy now because the purchasers of these devices preferred to have them quiet and in a highly competitive market, whoever built the quietest machines sold them. The pressure is now on outboard motor manufacturers, on the manufacturers of all kinds of tools operated by compressed air; on the manufacturers of large power transformers. Not long ago a Russian jet airliner was not allowed to land at New York's Idlewild Airfield because its noise levels were too high.

A corresponding French machine, the "Caravelle", was granted permission to land because it had met the noise limit requirements of the air port authorities. And you may have heard that in Paris taxi drivers are no longer permitted to blow their horns with such gay abandon.

The writing is on the wall. Between customer preference and civic ordinance, the makers of noisy machines, devices and appliances must now be concerned with decibels as well as with horse power, efficiency and cost. This concern will become acute when the purchasing agents for industrial firms begin to add to their machine specifications, the maximum noise levels they are prepared to accept!

But the desire for peace and quiet is not the only force at work in this situation. Certainly the major immediate reason for the widespread attention given to noise problems in the United States is the increasing number of claims for compensation awards on the grounds of deafness incurred while working in a noisy environment. Only recently has Workers Compensation legislation in that country been extended to cover this disability. Some day some union negotiator will lay it on the line that certain specified maximum noise levels must be written into the contract. That will be a bad day for the employer but a happy one for everyone else.

The problem of traffic noise has not been mentioned here although there has been incidental reference to efforts to control aircraft noise in and about airports.

Something can be done about noise and the sooner engineers become noise conscious and begin to work on the problem, the better. The reduction of noise to acceptable levels in the nation's industrial plants and offices is going to cost a lot of money. It may cost a good deal in your own plant, but it will cost a good deal less and a more effective job will be done if those who tackle it are supplied with adequate measuring equipment and know what they are about. The cleaning up of the noise problem is also going to save a good deal of money — in the long run. We are told that public relations, like charity, begins at home. Nothing, one would imagine, could do more for workers' morale than a serious, all-out effort to reduce factory and office noise. A good many precious ears will be saved from partial or total destruction; there will be greater efficiency because of easier communication; less strain on everyone. And perhaps machines might even last longer if they didn't shake so much.

I have, of course, given you an over-simplified picture of what is involved in this noise problem. Some of you know this; the others will find it out when they try to do something about it. However, one cannot give a course in acoustics or apply acoustic theory to a multiplicity of noise problems in a short paper. If I have stimulated your interest in the matter, that will do for a start.

Summary

1) Machine manufacturers will build quieter machines if we demand them.
2) Loss of hearing due to long time exposure to high noise levels may be a responsibility of the employer and call for worker compensation.
3) Unions may justifiably demand the elimination of high noise levels as an industrial hazard.
4) Noise is definitely an engineering problem and the sooner engineers accept it as such, the better.
5) A noise reduction campaign will cost money, but in the long run may well save money also.

DISCUSSION

of Technical Papers and Other Articles

SOME CONSIDERATIONS IN STEAM POWER PLANT DESIGN

A. G. Christie, M.E.I.C., *Professor Emeritus*
Mechanical Engineering Department
Johns Hopkins University, Baltimore, U.S.A.
The Engineering Journal, 1959, October, p. 63.

Discussion on the paper, "A Gas Turbine Power Plant for Locomotives" followed Professor Christie's paper in our October issue, and we offer sincere apologies to our readers and to the authors of both papers for any confusion this may have caused.

Author's Reply

This brief paper brought out a surprising amount of constructive discussion. This indicates that Canadian engineers are keenly interested in, and quite aware of, the problems of modern steam plant construction and operation.

Canadian utilities are growing rapidly and in all probability will continue to do so for many years. Some will triple and others quadruple in size during the next fifteen years which is less than half the expected life of the steam units that will be added. Under such conditions small generating units to fit today's situation, become uneconomic with rapidly growing loads particularly in view of interconnections and pool formations. Hence foresight and judgment rather than probability calculations must govern the choice of new plant. Such considerations point to large unit sizes and the more advanced steam conditions.

Hydro electric power must, in the future, take a secondary place in most Canadian power systems to steam and atomic generated power. Then hydro plants with water storage, will be modified to serve on shift operation to carry peak loads and to serve as emergency stand-by, leaving base loads to the steam and atomic energy stations. This will increase the Kilowatt-hour total output of the steam turbine generators during their useful life and thereby justify the large sizes of such units and their high steam operating conditions.

Mr. Holdup presents certain considerations in plant design based upon operating experiences with shift operation of large plants. These are essentially sound and acceptable.

Messrs. Carruthers, Stanley and Mitchell have submitted comments also based upon operating experiences and such should be kept in mind in the design of new plants.

Messrs. Foster, Bernhardt and others discuss the control of power plants. The control room will be a central feature of all new plants. It is going through a developmental period and its functions will be better understood in the future. Its equipment will be simplified and made more reliable and safe. Complete automatic control of the steam plant and the integration of its performance data can be expected although some problems remain to be solved. Some instruments such as the TV sets used on boilers need to be greatly improved.

Mr. Dryer had much to do with the establishment of the present Preferred Standards for steam turbines and other standards. He urges further standards for large units. No agreement has been reached on such standards.

Dr. Robb has reviewed the historical development of steam plants in Canada.

The suggestion to lower flue gas temperatures drew extended comments. Such lowering introduces design and operating problems but the possible gains warrant the solving of these. Obviously condensation, corrosion and dust collection on any cooling equipment in the flue gases must be considered. Preheating of the cold air to the air heater is required in cold weather. It has been the experience that steam preheaters using bled steam have given much trouble in northern plants, from freezing, particularly with shift operation or varying loads. It has been proposed to use cast iron gilled economizers in the flue gases beyond the induced draft fan and to circulate through these an anti-freeze fluid which will lower the flue gas temperature and transfer the recovered heat to tempering coils in the cold air inlet of the air preheater. Corrosion troubles in chimneys due to low flue gas temperatures can be prevented by acid-proofing the lining.

Mr. Holdup comments on fly ash. The quantities of this ash will increase and it is highly desirable that economic uses for such ash should be developed.

Other considerations were presented by discussors with which one is in general agreement. These will aid in the design of still better steam plants in Canada.

SHOCK HAZARDS OF ELECTRIC CURRENTS

A. R. Morse, JR.E.I.C., *Assistant Research Officer*
Electrical Engineering Section, N.R.C., Ottawa 2, Ont.
The Engineering Journal, November, 1959, p. 50

Author's Reply

Mr. Campling felt that I had created an impression that the proposed residential voltage increase was a complete change from 120 volts-to-ground to 240 volts-to-ground. The criticism is well made. In answer, first I would say that I did refer to H. H. Watson's paper twice in my talk, and on the first occasion I stated that "limited use of the higher voltage" was considered. On the second occasion (see concluding paragraph) I enlarged on this by giving in full one of H. H. Watson's conclusions — "Potentials of 240 volts-to-ground should be used only for permanently wired fixed appliances." Second, I would say that I deliberately emphasized the 240 volt-to-ground hazard as being a general hazard, in contrast to the above restricted hazard for the following two reasons:

(a) It is difficult to see how all concerned can be restrained to the "restricted use" formula, once the door is opened. A paper by Anderson, Hutchinson and Pearson ("Higher Secondary Voltages for Residences" Feb. 1959 issue of Trans. AIEE) makes this perfectly clear. The authors say "Although it may be necessary initially to make provision for supply of 120 volts, the maximum economies of higher voltage secondaries cannot be realized until 240 volts is the universally accepted utilization voltage". Furthermore, in this paper and the Discussion arising from it, it was strongly indicated that it was doubtful if there was any economic gain unless (or even if?) the increase was general. The discussion also showed that several of those commenting feel sure that the possibility of increased hazard to life cannot be avoided and that the small economic gain is not worth it.

(b) While it is not possible to give clear-cut comparisons between British (or European) and North American experience, I would agree with Mr. Flinn that Americans are more inclined to do-it-yourself than the British. Hence the ultimate use of 240 volts-to-ground in America may be a greater hazard than in Britain. Education of the public could only partially compensate. Wills Maclachlan[1], in a paper to the AIEE in 1951 gives a British table showing some figures for electric shock in factories. Unfortunately it does not break down the voltages in the 0-250 volts group. But it is to be noted that resuscitation was twice as successful in this group as in the next group (250-650 volts). One can make the reasonable assumption that, in the range 0-125 volts, resuscitation under similar (factory) conditions would be even more successful than in the 125-250 volt range.

Mr. Flinn refers to the comparison, between different voltages, of the percent of successful resuscitations of "apparently dead" electric shock victims. It is fairly well established (see W. Maclachlan[1]) that for voltages between 250 volts and 5000 volts, successful resuscitation is most difficult. At the high voltage end, it is speculated that increased success is because (a) the victim is thrown clear and hence the current is of short duration (b) the current causes heart seizure and not ventricular fibrillation. Additional reasons may be the high voltage may puncture the skin causing a low resistance path thus giving a current surge above the fibrillation level; the workman involved is not alone and hence rescue is begun rapidly; and his rescuers know what to do. At the low voltage end, it is speculated that increased success is because the current has been too weak to cause fibrillation, but has caused "only" severe shock, inability to breathe, and loss of consciousness. In a sense, the low voltage end is more serious than the high voltage end because: electrical contact occurs more frequently and often under low body resistance conditions, contact is more prolonged, rescuers are less capable, children (who require less current to succumb) form a larger percentage of the victims.

The current required for heart defibrillation is a function of the size of the heart. Experiments[2] with dogs have shown that the resistance of the dog's heart is around 50 ohms and that 60 cycle defibrillating currents between 1 and 3 amperes have been required for a pulse duration of about 1/10 second. I believe human hearts are in the same range of size as the hearts of these dogs. Defibrillators and electrocardiographs certainly have an important place in saving victims of shock, but I feel it is absolutely essential to maintain a high standard of training in rescue work and manual artificial respiration. Especially important is the tradition of not losing a second in commencing resuscitation and in NOT moving the victim, say to a location where there is special equipment, in the meanwhile administering no artificial respiration. Mr. W. Maclachlan (in discussion from the floor) doubted that heart defibrillators would become standard equipment for line crews.

Mr. Maclachlan also mentioned that in one large Canadian Utility, artificial respiration was successful in 100% of the cases where voltages were from 0-750 volts. This is indeed an enviable record. He stated that fibrillation may not have been present in these cases, or may have passed off. He suggested that perhaps fibrillation does pass off after a time and if artificial respiration is continued to "success" or to "rigor mortis", one may, contrary to popular belief, therefore be able to resuscitate a victim of fibrillation. Dr. Ballard pointed out that loss of blood (and oxygen) to the brain during the period of fibrillation is considered to be very serious and even fatal if lasting for more than a minute or so. From all that I have read, I have assumed it to be pretty well proven that recovery from fibrillation is extremely doubtful unless the heart is given some form of defibrillating treatment; Mr. Maclachlan's remarks are therefore, to me, very much appreciated, as he is undoubtedly an authority on the subject.

The increasing use of electrical appliances out-of-doors is going to lead to an increase of deaths from electric shock. Two such cases have come to my attention recently. One involved the use of an electric sander on a car fender. A young girl in her bare feet (it had been raining) was electrocuted upon contact with a defective cord. And in today's paper there is a report of a woman being electrocuted when she stepped in a puddle while using her electric lawn mower. I do not like to contemplate the additional effect on this type of death of increasing the voltage to ground. Nor should we forget the utility men who will be exposed, rain or shine, to 240/480 secondary circuits regardless of the voltage in residences, if the proposed increase is accepted. I agree with Mr. Maclachlan who feels there is still need for study of the problem of electric shock and how to overcome it.

SILVER FALLS GENERATING STATION

P. R. Stratton, P.Eng., A.M.E.I.C.E., *Project Superintendent*
C. T. Bath, B.E., P.Eng., A.M.I.E. (Aust.) *Const. Project Engineer*
The Hydro Electric Power Commission of Ontario.
The Engineering Journal, October, 1959, p. 108.

Reply by Authors

The authors wish to thank Mr. Patterson for his complimentary remarks. Mr. Patterson has rightly pointed out that the method of shaft raising employed at Silver Falls has been successfully used in countries other than Sweden and the authors are anxious to dispell any misapprehension that the system was unique. There was full utilization of any published data or, the subject, particularly the paper *Novel Shaft Boring Method* presented by R. S. Henderson and published in the Institution of Civil Engineers Proceedings Vol. 6

April 1957. The authors also wish to record their indebtedness to Mr. Belanger of Atlas Copco of Canada Ltd. who provided them with invaluable data and introduced them to Swedish engineers who had been actively engaged in shaft raising operations for the Swedish State Power Board projects. In answer to Mr. Koring's request for further information on the shaft raising drill cage it should be understood that its design is largely dependent on the amount of use it will be subjected to and the competence of the rock.

There were two such cages used at Silver Falls G.S. which were simpler and cheaper to construct that those used either at the Scottish or Swedish projects where the usage factor was much higher. The first cage, which is depicted in a sketch accompanying the paper was octagonal and had a sectional cone shaped steel roof which acted as a shield while travelling to and scaling the face. Since it was partially destroyed at the completion of the surge shaft raise it was decided to build a new one. This cage was circular in plan, had closer spaced verticular frame members which acted as rubbing strips, a flattened dome shaped roof with heavy screen cloth as a shield and an improved water and air supply system. The roof was a fixture incorporating an access hatch and six telescopic arms which were used to steady the cage and support loose planking. The original method of pinning the cage to the walls of the raise was discarded in favour of pivoted spuds which jammed into the rock crevices of the raise walls.

The normal mine system of communications between the miners and hoist operator was used plus a field telephone for communication with their helper at the bottom of the raise. Mr. Koring can be assured that the hazards of rock tunnelling and shaft raising were foremost in the minds of those responsible for the operations at Silver Falls G.S. The Safety Officer, superintendents, engineers, foreman and the miners collectively established the procedures and type of equipment to be employed. Having instructed each man on his duties we made practice runs until the superintendent was satisfied that the equipment was functioning correctly and operational hazards were reduced to a minimum. For the shafts, each miner was instructed individually neither to jeopardize safety for expediency nor to deviate from the adopted procedures. The safety program at Silver Falls G.S. was developed from data we had accrued from the tunnel driving operations at Aguasabon G.S. and the East Delaware Aqueduct, which was additional to the valuable guidance received from Canadian Industries Ltd. and the Departments of Mines and Labour. In this regard it is a pleasure to record that there were no fatal accidents during either the excavation or concrete lining of the Silver Falls tunnel and shafts.

Mr. Koring asks whether we would advocate using a churn drill or a diamond drill for a pilot hole. Unfortunately our experience is limited to one application of each and neither proved conclusively that one is markedly superior. However, as Mr. Patterson has pointed out, churn drills have been used successfully down to greater depths elsewhere and in the authors' experience the 9 in. diam. hole slightly off line is preferable to a dead plumb 4 in. diam. hole. We would therefore advocate using a churn drill unless time was of the essence. It is possible that a pneumatic drill on the lines of the 'Mole' drill might be an answer to the problem.

Diamond drilling whether for exploratory holes or for a pilot hole is relatively expensive and should be reserved for situations where a percussion drill is unsuitable or a core is required. At Silver Falls the exploratory holes drilled from the surface during the early stages of the job to establish the tunnel alignment were very costly since they had to penetrate up to 400 ft. of overburden.

These were subsequently augmented during the tunnel drive using a pattern of overlapping horizontal and angle holes which provided more detailed information of the rock formation and cover and anticipated water inflow ahead of the face. Including sampling and testing these holes cost $5.00 per lin. ft. and in no way retarded the tunnel drive.

This probing ahead eliminated most of the inherent risk of the tunnel drive being halted or retarded to overcome adverse rock or water conditions in the 'Depression' area.

In the authors' opinion, the money was well spent and must be considered as an insurance policy, to which most commercial undertakings would subscribe.

Mr. Koring asks for more information on the scheduling and economic aspects of the site preparation construction facilities and tunnel operations.

Originally it was hoped to commence tunnelling operations two months before the actual starting date. A setback was caused by an accumulation of delays in obtaining the specialized equipment and the more extensive nature of the preliminary excavation to establish the portal face. Less expensive and possibly more readily obtainable equipment had been considered, but subsequent events proved that the choice was well founded.

Silver Falls G.S. was placed in service on the date originally specified by the Commissions Engineering Division, any slower less costly method of tunnel driving would have prevented this. Almost half the specialized tunnelling equipment has been sold to private contractors at going prices.

The choice of tunnel driving methods and equipment is inevitably contraversial whenever more than one system can be utilized and the authors would not attempt to dogmatize on such an issue.

The construction roads and facilities were designed to meet the job requirements and standards of accommodation established by the Commission. In some respects they might be considered more extensive than some private companies would employ under the same conditions. Certain factors such as standards of employee accommodation and recreational facilties effect management relationships with the men, the unions, the industry and the public, and the costs incurred must be judged accordingly. The Commission employs engineers and technicians whose main function is to reduce expenditures and improve the standards of their construction camps.

The relationship between the unions and management at the site was excellent considering that the basic philosophy of the construction trade unions runs counter to the establishment of incentive pay. There were no work stoppages and there was a mutual respect by both parties for each others aims and ambitions. Both unions and management were on common ground when discussing the safety aspects of the job and this in itself provided the keystone to their good relationship.

Mr. Koring asks why the average powder factor was 5.1 pounds per cubic yard. During the early stages of the tunnel excavation the powder factor was adjusted both ways in an attempt to establish an optimum which would produce the minimum bootleg and best fragmentation for the mucking machine. After several abortive attempts to reduce the powder factor and rearrange the drill hole pattern, a standard pattern of 72 holes and a powder factor of 5 was established by the superintendent and shift bosses which produced an average advance of 15 ft. per 16 ft. round. No doubt a lower powder factor could have been used for a shorter round.

The overbreak varied considerably according to the rock formation and the experience of the miners and supervisors. Initially the overbreak was excessive until the diameter of the drill hole circle was established and the miners controlled the flair on the holes. During this period the average overbreak was about 18%. After the tunnel had advanced 2,000 ft. the overbreak was nil due to the extremely competent granite formation and this continued until we encountered a blocky formation near the halfway mark. This condition reoccurred for most of the remaining 5,000 ft. of tunnel and in consequence of this the overbreak averaged about 10% for the entire tunnel. This was 2% under the overbreak allowance in the engineers specifications.

Roof bolts were installed to support exposed slip planes and overhanging blocks of rock which the shift bosses and superintendent considered as unsafe. Their concentration varied considerably, but in the worst sections were spaced at about 4 ft. centres and used in conjunction with spreader plates and wire mesh.

The main power supply to the tunnel was 2,300 volts and fed through a 2/0 No. 10 wire armoured cable from three single phase 333 kva. 7200/2300 v transformers. Step-down banks of 3-25 kva. single phase 2300/550 v. Askarel filled transformers were located at each fan station which were at 2200 ft. intervals and 1-5 kva. 2300/110 3 phase transformer were located at 1100 ft. intervals which fed into 1/0 cabfire lighting cables, 550 ft. in each direction. The electric mucking machine was powered through a 1500 ft. No. 14 type W Rinj cable which was supplied by 3-37.5 kva. single phase 2300/550 v. Askarel filled transformers. This bank of transformers was moved into successive transformer caves located at 1100 ft. intervals as the tunnel advanced, the mucking machine never being less than 400 ft. nor more than 1500 ft. ahead of the transformers.

A 5 kva. 3 phase 550/110 skid mounted transformer provided temporary lighting in the vicinity of the working face for those sections which could not be serviced by the permanent system until the next station was established.

A continuous grounding bus of 4/0 bare copper conductor had a grid resistance of about 3 Ohms. The installation was designed for a ±5% maximum voltage variation.

Mr. Koring asks for clarification on the extent of the widening at the passing tracks and the facilities provided at the servicing bays. The passing tracks were located at 7 ft. centres providing 6 in. clearance between the widest parts of the track equipment. The slashing for the passing tracks was carried out without effecting the tunnel progress and consisted of widening 1 ft. at the spring line and forming a vertically sided horseshoe cross section. The servicing bay was slashed out a further 6 ft. to accommodate the flaps of the drill jumbo when fully extended. Included with the servicing equipment was a hand operated hoist attached to a radius arm pressure greasing and compressed air cleaning equipment and electric and gas welding sets.

The 15,000 c.f.m. ventilation system was designed to meet the Department of Mines regulations governing the operation of diesel engines underground, which was about 40% more capacity than would be required to meet the 50 c.f.m. per sq. ft. of tunnel face regulation. Under favourable conditions the worst of the smoke and fumes were cleared in 15 minutes and by using compressed air and hosing down the muck pile the fumes were cleared to a safe level within 30 minutes.

In replying to Mr. Patterson's request for information on the conditions encountered, the authors appreciate that this was an obvious omission on their part. Perhaps one reason for it was that, for the most part, the tunnel and shafts were excavated in competent granite or paragneiss which required only occasional roof bolts for minor slips and blocky ground. The worst section occurred at the 2/3 point of the tunnel where mud seams up to 2 in. wide, major slip planes dipping at 45° to the west and highly fractured paragneiss was encountered. Although steel arch ribs and plates were available at the site it was decided that a heavy concentration of 12, 10 and 8 ft. long roof bolts with 6 ft. long steel spreaders and No. 12 wire mesh would meet the condition with the least delay to the tunnel advance. The section was approximately 200 ft. long and caused an accumulative delay of 3 days. The entire area was gunited to prevent any further loosening of the rock, since the mesh prohibited regular scaling of the section. We had no further trouble in this area.

The rock beyond this point was much 'blockier' than we had previously encountered but by this time the supervisors and miners were well experienced in coping with the less favourable conditions and the 45 ft. per day progress was maintained to the end.

The water inflow as might be expected was greatest in the rock depression area and towards the intake. One of the miners drilled into a water pocket in this area which blew out the steel and sent the man sprawling across the upper deck of the jumbo. While it caused a momentary panic amongst the crew, no one was hurt and the jet of water subsided shortly afterwards, allowing the crew to complete the round on schedule. The total water inflow never exceeded the 250 i.g.p.m. capacity of the 3 in. submersible pumps which were used to repump the water into the discharge line from the sludge tanks. The level grade of the tunnel created a drainage problem during the invert clean up and placed a heavy demand on our supply of 3 in. and 1½ in. pumps, but we considered ourselves fortunate in not encountering a greater inflow than we did.

The rock formations in both shafts were very favourable, the intake more so than the surge shaft, where we took the precaution of guniting the walls to prevent loosening up of the exposed rock.

In conclusion the authors are indebted to Messrs. Koring and Patterson for bringing to their notice certain omissions in the paper and trust that the answers which have been given will shed further light on the excavation of the Silver Falls tunnel and shafts.

The Engineering Journal, October, 1959, p. 73.

Author's reply

The author would like to thank those offering discussion for their interest and kind remarks. The replies to Mr. Travers' questions are as follows:

1. The support given the headworks by the powerhouse substructure

is minor and the headworks alone would probably be stable for all conditions excepting ice thrust. However, since the main pours of the powerhouse substructure were scheduled to be completed before raising the head water, the stability calculations were made to include the effect of the substructure.

2. As noted in the paper, care was taken to bring the concrete of the scroll case roof up evenly so as to prevent side thrust on the embedded parts of the turbine and to ensure that no setting had taken place so as to avoid "cold Joints" in the concrete. Admixtures were used to increase the setting time and to reduce the heat of hydration. The concrete was placed from dump trucks on a Bailey bridge above the form and was distributed through hoppers and elephant trunks. Under similar conditions, the same system would probably be used again, especially if the work occurred during winter when cold water and chilled aggregate would be available at no extra expense. Provision for draining possible cracks would probably be made by pouring the finished floor after the plant was in operation.

3. Smaller gates proved economical when included as part of the dewatering system as steel stop logs of this size were available for final closure from other plants. The large number of small gates also gave better river control.

4. An air bubbler system should reduce ice pressure on the headgates and racks during shut-down and reduce the trouble in opening sluice gates during cold weather. It is also hoped that an air bubble system will prove more economical than gate heaters.

5. No difficulties other than those noted occurred with the sand. The amount of air entraining agent was reduced and the trucking system of distribution proved so successful that no further examination of the sand was made.

In reply to Mr. R. E. Grout's question, the changeover to and from condense at Whitedog Falls is carried out remotely. In operation considerable adjustment of the timing relays controlling the inlet air valve has been necessary to prevent the generator from momentarily drawing large amounts of power from the system when going on condense. Also, it has been necessary to momentarily short out the probes which control the air shut-off because air from the turbo vents finds its way into the probe wells at the beginning of the condense cycle prematurely closing the valves.

Complete heating has been provided for all gates to be used until the air bubbler system has been installed and proved reliable. The author feels that even with the installation of the air bubbler system, gain heaters will be required.

In answer to Mr. Crowley's question regarding the economy of the earth wing dam at the Whitedog G.S. as compared with concrete, on a straight cost basis the earth was cheaper. However, if intangibles such as freedom in scheduling and earlier access from the right banks were taken into account, concrete might prove attractive. This would be dependent upon the overall schedule.

Due to the flow available when the Caribou headpond was being filled, and the good co-operation received, it was possible to fill the headpond and still maintain the required flow downstream. Most of the filling had been completed when the outlet to Tetu Lake was lowered. The water was allowed to drain off slowly without any control. This provided the downstream plants with some benefit which would have been difficult to measure and no consideration was given to compensation.

138 kv UNDERSEA CABLE ACROSS GEORGIA STRAIT

T. Ingledow, M.E.I.C., *President, B.C. Engineering Co. Ltd. Vanc. The Engineering Journal, October, 1959, p. 96.*

Mr. H. W. Smith's reply on behalf of Dr. T. Ingledow

I know Dr. Ingledow would like me to thank those who have submitted written discussion and to express his appreciation for the kind things which have been said in support of our work. Mr. Russell Potter's comments are particularly appreciated, as he was a member of the Public Utilties Commission at the time that regulatory body authorized the project as being in the public interest.

I would like to deal with Mr. Dale Farnham's comments, generally in the order in which they were presented.

The use of vibration resistant alloy E rather than a pure lead sheath, and the use of steel wire armour rather than an aluminum alloy are both a product of that conservative approach which, we feel, should accompany a novel installation. While ocean bottom conditions, as determined prior to installation, indicated that the cables would be supported throughout their length, changing currents could result in suspension of short lengths between humps of hard material, and under these circumstances abrasion and vibration might occur. The materials which have been questioned were chosen with this in mind. The more substantial mechanical characteristics of the cable afforded by the materials used have the incidental advantage of providing added protection against the arduous conditions of handling and laying. It is proposed to construct a one and a half mile causeway for car ferry purposes immediately to the north of the cable installation at Tsawwassen Beach, which could materially change bottom conditions in the vicinity. We were not aware of this possibility at the time the cable installation was made, but it is indicative of the sort of thing we have endeavoured to provide for.

With regard to the complete factory test of the cable, this, as Mr. Farnham points out, would have resulted in a large number of flexible joints being purposely provided. Three such joints were actually used—one being made necessary by a total interruption to factory power supply, and two due to equipment failures. Each such joint has an impulse withstand of 600 kv, rather than 675 kv for an unjointed cable. Further, we consider that such joints are regions of possible weakness, both electric and mechanical, since they are dependent on the human element. It was on these accounts that full factory testing was waived.

I believe Mr. Farnham may have quite unintentionally cast a slur on the Captain of the Monarch in his comments. The performances of both the Captain of the Ocean Layer and the Monarch on our installations were considered magnificent.

I agree with Mr. Farnham's comments with respect to complete field tests. We would like to make them too, but have never been able to get the installation out of service for a sufficient period.

With reference to the possibility of conversion to d-c installation at a later date, we regard the cables as suitable for this service, subject to the approval of navigational authorities.

Dealing with Mr. E. Bent's discussion, we have no indication that the reduction in armour losses due to the use of aluminum alloy rather than steel differs appreciably from the calculated reduction. Bonds between cable armour and lead sheath were made only at the cable terminations, the rubber sandwich being capable of withstanding the voltages which might be applied to it. The application of full gas pressure to the cable results in a measure of mechanical bonding between the lead sheath and bronze reinforcement, etc., which impairs flexibility and handling properties of the cable.

THE INTERCONNECTED POWER SYSTEMS OF NOVA SCOTIA AND NEW BRUNSWICK

G. D. Mader, P.Eng., *Chief Engineer*
Nova Scotia Power Commission, Halifax, N.S.
The Engineering Journal, October, 1959, p. 68.

Author's reply

The discussions presented are appreciated. We will attempt to clarify as briefly as possible some of the points raised.

In reply to Mr. McMath, several reference books and papers on probability analysis were utilized for this study, a list of which would be too lengthy for inclusion herein. Selecting one at random, AIEE Paper 57-692 entitled, "Use of Probability Methods in the Economics Justification of Interconnecting Facilities between Power Systems in South Texas", by A. Pat Jones and A. C. Mierow, may be of some help. Outage rates of 1% for steam and 0.5% for hydro units were chosen.

As regards steel vs. wood pole structures for 138 Kv. lines, the New Brunswick Electric Power Commission has experienced several failures on spar arm wood pole structures including pole twisting and shearing at guy wire pole bands. It was felt that steel towers would be somewhat more reliable under heavy loading conditions. Although first costs are about 15% higher, the annual costs are estimated to average about 1% less than for wood pole lines. In the Halifax area, the Nova Scotia Light & Power Co. Ltd. are using multiple circuit steel towers to minimize right-of-way costs where future circuits will be required.

The Nova Scotia Power Commission does have some wood pole 138 Kv. construction in the Maccan and Trenton areas. However, these lines do not have overhead ground wires since the isokeraunic level is considerably lower than that of New Brunswick.

Mr. Stanley's comments on the cost-size relationship are well taken and studies are currently in hand regarding the merits of larger generating units and utilizing the interconnection for firm power contracts in order to take advantage of the economics inherent in the location of such units. The peaking capacity of hydro plant will also be reviewed with an eye to obtaining optimum benefits for this combined hydro and thermal system.

The development or purchase of future sources of generation and the necessary associated transmission will be studied on a continuing as well as a fully co-operative basis with an eye not only to immediate but longer range requirements as well.

Again, we wish to thank the discussers for the interest shown and would certainly welcome any further comment from other interested parties.

TESTS OF HYDRAULIC TURBINES—AN APPRAISAL

J. J. Traill, M.E.I.C., *Consulting Hydraulic Engineer*
Toronto 18, Ontario.
The Engineering Journal, November, 1959, p. 66.

Author's reply

The author wishes to express his thanks to those who have participated in the discussion of this paper. It is very gratifying to have so many from among those eminent in hydraulic tests and investigations contribute their views to the subject under discussion.

Dr. Gibson outlines briefly the ideal conditions for the application of the Gibson Time-Pressure method but he has applied the method successfully in many instances far removed from these ideal conditions. Reference to one of these cases is made by Mr. Madill, viz. the tests at the Kemano G.S. where the net operating head was 2500 feet. The author, along with many others, has made tests by this method in plants with very short supply pipes and at low velocities, conditions far removed from the ideal indicated by Dr. Gibson. In these latter instances it can hardly be claimed that the same degree of accuracy can be expected as for tests where conditions are more favourable.

Mr. Johnson refers to the late Dr. Thoma's comments on errors in the Gibson method saying that it is "practically impossible to estimate the magnitude of the possible error in a dischage measurement by this method." This gives quite a different impression from that gained by reading Dr. Thoma's paper. Dr. Thoma made a theoretical investigation of the possible errors and arrived at the conclusion that these might amount, in the aggregate to about one per cent. In his analysis he dealt with the tests by the simple application of the method. In the differential application, that now generally used, certain of the errors would be reduced. An extended reference to this matter is made in reference No. 7 and further comments here would be a repetition of the information in that paper and the discussion thereon.

The Poiran Thermometric Method was included in this paper because few references to it have been made in publications on the North American Continent and because it is applicable to the measurement of turbine efficiency where other methods are not so conveniently applied. Dr. Gibson has made three inquiries regarding it. In other methods the useful work done by the turbine is measured. In addition to this the turbine has overcome its own bearing friction loss. In the Thermometric method all losses are measured without segregation. There is thus a slight discrepancy in the mechanical losses as dealt with in this and other methods of measurement. Dr. Gibson's second question asks what steps are taken to overcome possible changes in temperature (of the water) such as those caused by exposure of the penstock to the sun. The thermometric probes measure the temperature of the water close to the entrance to the scroll case (or the nozzle in the case of impulse turbines) thus automatically correcting for temperature changes in the penstock.

The limitation of the method to plants operating under heads of 100 meters and upwards is purely arbitrary. In various test codes, for other methods of testing, some limitation is usually named for acceptable conditions. This is so for tests by current meter, salt velocity and the Gibson method. In drafting the International Test Code some such limitation was considered necessary for the Thermometric method. The engineers of Electricite de France drew attention to a somewhat increased "scattering" of individual test points at low gate openings for tests at heads lower

(Continued on page 93)

Business and Institutional Buildings

NOT VERY long ago, business and institutional buildings might have been dismissed as a field of any importance for the application of control instrumentation on a large scale. As many engineers will realize, this is no longer the case.

The types of building considered here include office buildings, hotels, hospital, educational centres (schools, colleges, etc.), civic centres, government administration buildings, and so on. The principal applications for instruments in these buildings are in the fields of heating, ventilating, and communications. Educational establishments, to a varying degree, include laboratory facilities, and these may require instrumentation in connection with special laboratory services or for instructional purposes. These applications are outside the scope of the general field under consideration.

Applications of Instruments

Some general examples will indicate the scope for instruments in modern buildings of the types mentioned above.

Heating is essential for such buildings in Canada, and large boiler installations are commonplace. These installations require the usual combustion, temperature, flow, and other controls which have been discussed in an earlier article in this series (October 1959 issue). In addition, the control of temperature within a large building can be quite complex. For example, public rooms in an hotel, assembly halls or lecture rooms in a college, and public areas in an office building may be controlled by a zoning system to deal with varying rates of heat loss, different periods and degrees of occupancy (e.g., lecture rooms, which are only occupied at intervals), and other variables. On the other hand, local control may also be provided for temperatures in guest rooms, offices, laboratories.

Ventilating, and sometimes humidity control, is another field in which there may be a need for a complex control system. Here again, conditions in different zones of a large building may be controlled from one or more centres. The variables mentioned above may be taken into consideration in the overall control system.

As an example of a modern control installation, a large hotel has incorporated a supervisory data centre to control the operation of the heating and air conditioning systems. A graphic control panel shows a complete schematic layout of the fan systems, with dampers, heating and cooling coils, fan motors, etc. There are many different air-handling systems within the complete scheme, each of which, with its own variables, can be controlled centrally. An automatic data handling system scans and records temperatures at regular intervals, and warns of any departure from predetermined temperature conditions at various key centres. Such variations are also permanently recorded. Temperatures in public rooms are controlled locally by electronic thermostats, of which the setting can be varied from the central control panel. The flows of steam and water are also totalled on counters in the control centre.

Electrical services may include, in addition to lighting, power supply for operating elevators, pumps, compressors, fans, and so on. Quite large investment in standard metering and control equipment may be involved in a large building.

An interesting method of remote control of services uses the regular electrical distribution system as a means of communication, thus eliminating considerable lengths of cable necessary in conventional control systems. Selected frequencies are imposed on the electrical distribution system by an alternator; the output is coded and controlled manually or automatically from a central control point. Relays at any point in the distribution system receive the coded output and accept or reject it according to conditions. The relays can be used, for example, to start or stop ventilating systems.

Communications may be a very important feature in a modern building. In addition to regular telephone service, internal telephones may be installed; systems for transmitting and printing messages, loudspeaker installations, fire alarms, and others are all in regular use and involve various control systems.

Requirements and Purchase of Instruments

There can obviously be no generalization about the person or department responsible for determining instrument requirements or for their purchase, in this field. So much depends on the type of building, who operates or occupies it, who is the owner, and so on. A commercial or financial organization would probably rely on the advice of consultants or contractors for the specification of instruments, whereas an organization normally involved in engineering might well have considerable direct control of the design and construction of the building, including specification and purchase of instruments. In the case of an educational establishment, the advice of the engineering department or faculty might be obtained.

Service and Maintenance

There are probably few instances at present of instrument maintenance being done entirely by a resident technician or engineering staff, though some preventive maintenance is carried out by building operators' own staff. Other service is often purchased as required or supplied by contract. Spare parts are carried in some instances, but by no means to the same extent as is customary for industrial installations.

Nearly all instruments used are standard lines and are purchased outright. However, with the use of advanced techniques, for example in the field of communication, some specialized instruments may be called for, and there is the possibility of renting, rather than buying, expensive installations such as those used in data processing applications.

Instrument Costs

Comprehensive data on the cost of instruments used in buildings, as discussed here, are not available. However, for a large modern office building the capital investment in instruments may be in the $100,000 to $500,000 range.

DISCUSSION *(Continued from page 91)*

than 100 meters. In the author's opinion this scattering was not serious for heads as low as 80 meters but in drafting this section of the code it was agreed to name 100 meters as the minimum for which the method was fully applicable.

A question raised by Mr. Johnson and Mr. Lester regarding certain features of the method is quite pertinent. Mr. Johnson draws attention to the fact that "accurate measurement of temperature per se is not the problem but accurate measurement of the average temperature rise." Mr. Lester refers to the difficulty introduced in measurement if a tailrace is common to several machines and also to heat exchange with the exterior. Careful and extensive investigations were made of the location of temperature probes at the draft tube exit section and it was found that precise location of the probes was not essential as the thorough mixing of the flow as it passed through the turbine resulted in uniform temperature throughout the measuring section. The correct measurement of *average* temperature rise is thus assured. The author is of the opinion that precisely correct placing of the probes is not as important as correct placing of current meters at a measuring section or correct location of injection valves in the salt velocity method.

The temperature probes at entrance are so placed as to measure conditions at entrance to the scroll case, and at the exit in the draft tube of the unit under test. The tailrace common to several units is seldom, if ever, a problem and the distance between entrance and exit probes so short that interchange of heat with the exterior is insignificant.

One of the difficult problems with which a test engineer must often contend in field tests of turbines is the difference between the rated head and the actual head during a test. Mr. Aeberli's analysis of this problem is a valuable contribution with which the author fully agrees. Variation in headwater and tailwater levels can seldom be controlled and the engineer frequently has difficulty in determining accurately the probable performance of the turbine at the rated head from tests made at a test head differing appreciably from the rated head. For Francis turbines of low specific speed corrections are not too difficult but as the specific speed increases, and particularly for propellor and Kaplan turbines the derived results for rated head become more and more suspect. It then becomes necessary to make adjustments according to the indications of model tests if these are available.

Some years ago the author had an opportunity to make a test of a large turbine at speeds varying from ten per cent above to ten per cent below the rated speed. From these results correction for variation of the test head from the rated head were readily made. The specific speed of the unit was 40 and the indications are that the variations follow the three halves rule over a fairly wide range. In another case for a fixed blade propellor runner a Gibson test was made at a head close to the rated head of 52 feet and, later, Power-gate and index tests were made at various heads down to about 36 feet. It was found that the exponent of the variation of the power with head was quite different from 1.5 and also that it varied with the gate opening. Tests of a model in its proper setting would be of great value in such cases.

A discussion of practice regarding the use of step-up formulas suggested by Mr. Aeberli, it is considered, would be too voluminous to permit its inclusion in this discussion. Much valuable information regarding this subject is contained in the three publications referred to by Mr. Johnson in his discussion.

Mr. Johnson's criticism that the fundamental bases of the Allen Salt Velocity Method have never been rigorously established and his comments regarding errors resulting from incorrect measurement of time of passage of the salt solution cannot be contradicted. Notwithstanding comparisons of the results from this method with measurements by other methods indicate that a high degree of accuracy is secured.

No comments are made regarding Mr. Logan Kerr's discussion but the author takes this opportunity to express appreciation for the kindly remarks from one with whom he has had happy associations in various fields for over thirty-five years.

Canadian Developments

Sixty years ago railways were the arteries of economic development. Spanning the country, they brought gold out of the North, grain and fruit from the West and wood products from the East. In 1959, however, transportation needs go far beyond the conveyance of products and resources. Manufactured goods must be delivered—men must be able to travel in every direction for business—and tourists, demanding a route for their travels, have become a recognizable factor in the national economy.

CHANGES in the volume, nature and variety of byway traffic call for a more complex and flexible system. The speed with which science transforms our daily situation also reminds us that routes must be built today not only to fill our present needs but to meet future trends.

Population increase is outstripped by the rise in number of vehicles on the road and, as innumerable separate units go their independent ways without the need of a despatcher, the highway demonstrates its enormous advantage in flexibility. At the same time a significant economic inducement is offered by a transportation system in which roads of all classes can be freely interconnected.

Highway engineering has been revolutionized and associations have been organized to set standards in roadbuilding practices as well as materials. But the funds for road construction are in the hands of the governments. The Canadian Good Roads Association has had a direct influence upon government road construction policy. For example, only 5% of government-contracted road work is done by government employees as a result of the CGRA's well-substantiated contention that the nation's roadbuilding should be carried out through competitive tenders. Wise planning and budgeting is the CGRA's current preoccupation.

The Economics of Roadbuilding

C. W. Gilchrist, managing director of the Canadian Good Roads Association, claims that if Canadian prosperity continues, $15 billion will be spent on roads and streets in the next 10 years. He predicts that motor vehicle travel will increase from 1958's 36.8 billion miles to approximately 77.5 billion miles in 1968. And yet, he says, there is no integrated plan for Canadian highway development.

Highway economics is worth considering. Accidents, lost time, and vehicle maintenance and operation costs are an expenditure exacted by old roads. Mr. Gilchrist, speaking to the Eastern Canada Association of Highway Officials in New Brunswick recently, pointed out that for each mile of road carrying 2,000 vehicles a day, a paved surface would result in a saving in vehicle operation costs alone of $14,600 a year over a gravel surface. The waste in two or three years, then, would equal the cost of a pavement that would last for 25 years! Mr. Gilchrist emphasized the importance of needs studies in every highway department to bring the level of services up to a desirable standard. Ontario has already done this and Manitoba and Saskatchewan have studies in progress.

Timber being transported by rail for processing.

Highway Engineering

The science of highway engineering has become so highly diversified as to include planning, location, design, construction, maintenance, traffic operations and research. Planning involves study of population and traffic growth and logical prediction of how industrial and residential areas will increase. Vacation habits in any given area must be accounted for as well as congestion factors of other kinds. The requirements and standards of each specific highway improvement and its integration in the overall system thus become the planner's first concern.

Location engineers must select the best, most economical route to serve both the travelling public and commercial drivers. They take the standards deduced by the planning engineer and apply them to the geographical situation. Whereas they once had to cover mile upon mile of prospective road site by foot, photogrammetry now sketches the proposed areas for them. Correlation of aerial photographs with topographical maps results in quite a detailed knowledge of the area under study.

The investigation-design engineer is the next link in the road-building chain; with a knowledge of soil mechanics and construction, he is able to take the plan and profile prepared by the planning engineer and proceed with borings and soundings of the terrain. Design of the highway will depend upon the kind of soil he finds and the amount of bedrock, swamp, and quarry that he discovers, as well as design criteria and the functional demands of the roadway to be built.

AASHO Road Test

The American Association of State Highway Officials is conducting a $23 million road test at Ottawa, Illinois to determine the behaviour of both rigid and flexible pavements of known thickness under moving loads of known magnitude and frequency. Canadian highway technologists await results of the test with considerable interest because the findings should effect not only road and street pavement design, but road operations, design techniques, construction procedures and maintenance practices of all highway departments. In fact, the influence may well be felt by truck manufacturers — in any revision of legal road limits and allowable tire pressures which come as a result of the test. Road administrators and legislators may revise methods of taxing road users and allocating road and street costs. CGRA has taken an active interest in the test since 1955 and employs a resident engineer to assist the committee on the project and report back to the CGRA on developments.

Report on Muskeg Research

A study of road design and performance over muskeg has been published by I. C. MacFarlane of the National Research Council and Alex Rutka of the Ontario Department of Highways. Their interest focuses on Northern Ontario where an expanded construction program must take into consideration quite extensive muskeg regions. They have investigated forty-four different muskeg regions in the area from North Bay to Kenora and Rainy River and studied roads over muskeg for surface condition and performance in comparison with adjacent roads over mineral soil. The men found correlations between: vane shear strength and depth, water content of the peat and depth, vane shear strength and water content, specific gravity of the peat and water content, and acidity and carbon content of peat.

Standards and Traffic Safety

Road Schools for Technical Assistance

According to Alex J. Graham, road superintendent and engineer, County of Carleton, Ottawa, technical assistance to municipalities comes from The Department of Highways, materials and machinery suppliers, consulting engineers and interested organizations. About 86% of the road mileage in Ontario is under municipal authority. Large sums are spent each year and in most cases the work is directed by non-technical staffs. Mr. Graham, speaking at the recent CGRA convention in Vancouver, stated that the value of consultants as a source of technical assistance had not yet been realized. He pointed out, however, that the roads schools held by several of the materials and machinery suppliers, by the Provincial Highway Department, and now by the Ontario Good Roads Association, may fill the municipalities' immediate need for technical assistance. The students they draw are mostly non-technical foremen and members of municipal operating staffs. These are the men who are responsible for large expenditures on the majority of Ontario's roads.

New D.H.O. Claims Committee

The Ontario Government has established a "permanent, independent committee, empowered with authority to consider and settle claims between the Ontario Department of Highways and contractors working on Department contracts." Under the new system, if the contractor is not satisfied with the ruling of the chief engineer, he may appeal to the Special Claims Committee. The contractor is also allowed, if he fails to agree with the ruling of the Committee, to litigate the claim in the Ontario courts. Three distinguished engineers have been chosen by the Ontario Government as members of the Special Claims Committee. They are: Gordon Mitchell, formerly director of seaway operations, chairman; F. Stuart Lazier, and William B. Crombie, formerly of Ontario Hydro.

Uniform Road Markings

A new manual of Uniform Traffic Control Devices for Canada has just been published. The CGRA and the Canadian Section of the Institute of Traffic Engineers have collaborated over the last three years to produce this manual which recommends uniform standards for traffic signs, signals and pavement markings. Before long people driving from coast-to-coast will find that roadway signs and signals convey the same message on intercity highways, city streets and township roads. Some new signs will also appear on Canadian roads. Turn prohibition signs, a black arrow on a green background, will be initiated. Trans-Canada signs will be green and white; school signs, blue and white; civil defence signs, blue and gold.

Accident Study in Alberta

Results of raising the speed limit on four-lane highways in Alberta have been compiled for the months of July and August. Whereas the legal limit for daytime driving was 55 m.p.h., it is now 65 m.p.h. On all but two of eight highway stretches the number of accidents was appreciably decreased. These two highways are undivided. According to Gordon E. Taylor, Minister of Highways, the divided four-lane highways greatly reduce the chances for head-on collisions. Head-on collisions have been completely eliminated to date on the four-lane divided highways in Alberta.

Canadian Highway Safety Council

Ira G. Needles, Chairman of the Board, B.F. Goodrich Canada Ltd., has been elected 1959-60 Chairman of the Canadian Highway Safety Council. He succeeds Geo. B. Kenney of Montreal, associate manager of the Phoenix of Hartford Insurance Companies and director of the All Canada Insurance Federation.

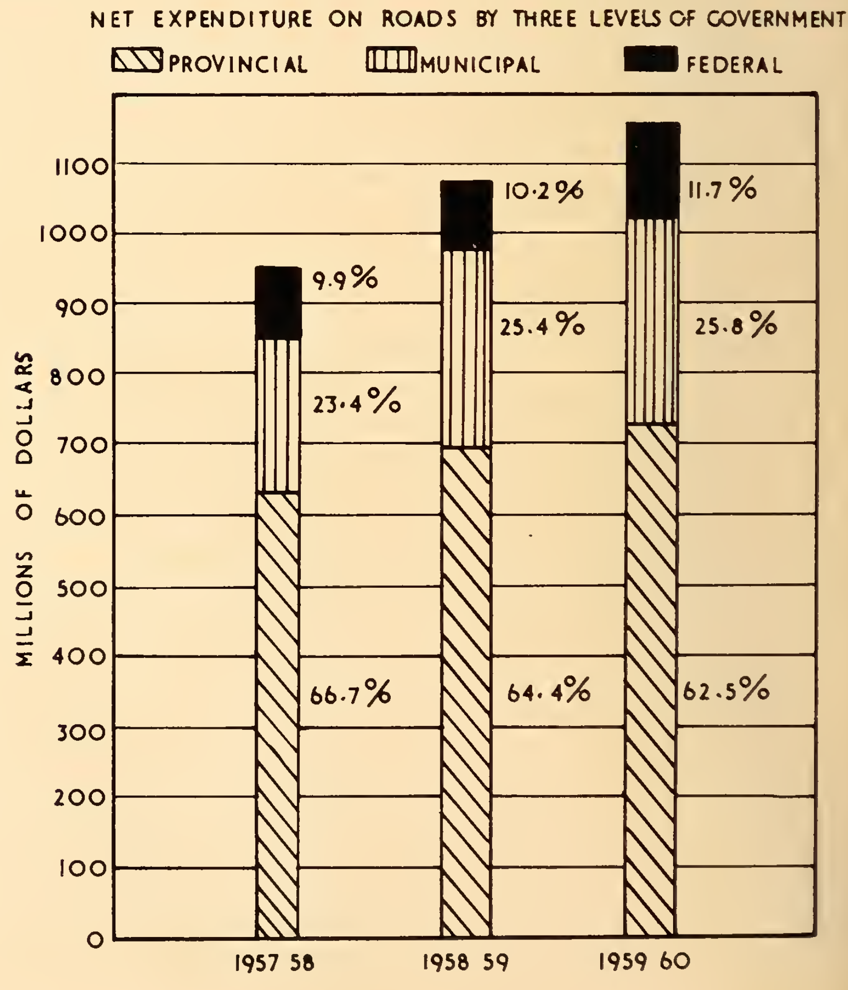
Also elected were Superintendent J. R. W. Bordeleau of RCMP headquarters, Ottawa, as CHSC secretary, and George H. Jackson, vice-president of the Ford Motor Co. of Canada Ltd., as treasurer.

Elections took place at the annual meeting of the Council's general committee in Montreal, Oct. 5. The meeting also elected to change the name of the organization, substituting "Council" for "Conference". It is now the Canadian Highway Safety *Council*.

Provincial Programs and Budgets

Canada spent more for roads in 1959 than ever before. The Canadian Good Roads Association publication "Highway Finance 1959" states that Canadian Governments at three levels will have spent $1,157.2 million on highways by March 31, 1960, the end of this fiscal year. This figure represents an increase of $79.5 million, or 6.9%, over the $1,077.7 spent last year. The increase, however, is at a slightly lower rate than that of the post-war years.

Canadians spent $3 per capita



more on highways this year than last and became some of the highest spenders for roads in the world.

The CGRA booklet shows that the federal government has increased its participation in road-building considerably, while the provincial governments have occupied themselves less with financing roads.

The Roads-to-Resources contributions rose from $6 million to $9 million, but the Trans-Canada Highway support declined by almost $2 million. Greater federal funds are being made available for road projects in the Northwest Territories and the Yukon.

Ontario led in 1959 with a roads expenditure of $268.6 million, an increase of $241.6 million over last year. The next highest spender was Quebec with a budget of $147 million. Last year she spent $177.5 million. British Columbia has also decreased her roads expenditure from last year's $75.8 million to $74.2 million. Manitoba's budget for 1959 shows the greatest increase — from $35.6 million to $65 million.

Cost of Saskatchewan's Ten-Year Program Up

In 1955, when Saskatchewan launched a 10-year program for construction of 12,000 miles of gravelled secondary highways, the costs were estimated at $50 million. Now, due to increases in construction costs, the project is expected to run to $66 million. The provincial government and municipal governments are sharing costs on a 60-40 basis.

Northern Roads

The Department of Northern Affairs and National Resources works in close co-operation with the Department of Public Works and the Department of Mines and Technical Surveys. A committee formed of the three, as well as keeping informed of transportation trends and Northern developments, must constantly predict the consequences of their road projects — what minerals may be reached and what kind of market prospects they may have. The progressive development of these northern roads, in fact, depends to a very great extent upon how much mineral wealth they lead to and how easily they allow the riches to be gotten out to processing centres.

"The development roads," says George M. Carty, chief administrative officer, Department of Northern Affairs and National Resources, "are intended to open new areas to intensive exploration and subsequent investment, and their construction and design reflects this purpose. Since funds are limited, the object is to construct roads initially to meet only essential traffic requirements. However, the basic location and engineering provides for improvements as the traffic warrants."

The oil and gas potential in the north lands which has come to light in the last few years may be the touchstone to extensive northern roadbuilding. Already a road is being constructed from Flat Creek (near Dawson) in the Yukon to serve oil developments on Eagle Plain. This is Canada's most northerly road. Mr. Carty predicts that if oil and gas discoveries proceed as authorities have reason to hope they will, some day before long Canada will need an overland connection with the Arctic Coast. More than half a million acres in the North were added in October, 1959, alone to the eighty-six and a half million already under gas and oil exploration.

Northern Roads for Defence

T. N. Carter, a past-president of the Canadian Construction Association, has said: ". . . within the next decade people will be able to drive from Edmonton to Inuvik on the Arctic Ocean . . . This would have sounded like pure fiction not so long ago but a northern road network is absolutely essential for the development of our country and for the defence of this hemisphere."

Budgets for Northern Roads

Five federal-provincial agreements are now before the federal cabinet for approval and, if passed, could authorize upwards of $20 million in roadbuilding for the year 1960. If these agreements are passed, more than $100 million will be allotted to roads in the North over the next six or seven years. Since the Northern Roads Program concerns the Yukon and the Northwest Territories, appropriations for it are separate from the $20 million set aside for federal-provincial agreements. These two territories alone will probably have a budget of about $10 million.

Saskatchewan Roads Progressing

Rock, rough hilly terrain, muskeg, perma-frost — everything is there to discourage the roads engineers of Saskatchewan's north country. Despite the hardships they have reached Mile 30 on the LaRange-Uranium City road, according to W. A. Sheard, department construction engineer. The road has been cleared to Churchill but for an eight-mile gap. Piers and abutments for the Churchill River bridge have been completed and steel work will be completed by the end of winter.

CGRA Holds "Parliament of Roads"

September 22 to 25 were busy days in Vancouver, as 1,200 delegates poured into the city for the Canadian Good Roads Association's 40th "Parliament on Roads." Hon. J. T. Douglas, Minister of Highways and Transportation, Saskatchewan, described the CGRA as a "hard-working partnership of governments and business in a field that directly serves everyone." He stressed the need for planning and budgeting wisely on all three levels of government to keep up with the nation's highway demands. He also encouraged federal assistance to provinces, noting that Saskatchewan's experience in the construction of the Trans-Canada Highway had proved to him how well federal aid to highways could work to the benefit of both governments and need in no way interfere with provincial jurisdiction (as provided for in the British America Act).

Coast-to-Coast Survey

As a prelude to numerous technical sessions on highway and transportation problems, the CGRA presented a Canada-wide roads roundup and came up with the following information:

British Columbia: working on a 55-mile freeway network to be built in the Vancouver metropolitan area. To cost $465 million. To be completed by 1976.

Alberta: constructing access roads from main highways to 22 towns and making construction of by-passes in, through, and around major cities an important budget item.

Saskatchewan: constructing multi-lane facilities, interchanges and urban road simplification.

Manitoba: establishing a planning section through the Highways Division of the Automotive Safety Foundation to analyze road problems and set roads standards.

Ontario: working towards a completely integrated system of roads. Trans-Canada Highway network in Ontario to be completed by 1960.

(Continued on page 140)

INTERNATIONAL NEWS

A discussion of international highways almost leads one these days to ask: Just where do they end? The reply might well be: At the moon.

Dr. Wernher Von Braun, director of the U.S. Development Operations Division of the Army Ballistic Missile Agency, was recently asked, "When will construction start on the moon—ten, twenty or thirty years?" This was before the Russians' rocket pierced the moon. He replied:

"I could very clearly envision that within another 15 or 20 years, we will have quite some extensive construction work going on on the moon for certain projects. I mean there will be some road building going on."

International Highways

How ever far away such development may be on the surface of the moon, there is much activity across the Earth today to link its continents together. A highway is being pushed across the great Asian desert; another is biting into the tundra and rock of Alaska. There are endeavours to construct a tunnel under the English Channel, and the Inter American Highway is being stretched from Honduras to Costa Rica.

Trans-continental Highway for Asia

United Nations officials have agreed to convert 7,000 miles of ancient caravan routes into a modern continental highway system for Asia. Only by careful study of ancient records will experts be able to re-discover much of the old caravan route and to plot a new course thereupon for the modern Iran-to-Viet Nam highway.

The highway subcommittee of the United Nations Economic Commission for the Far East has approved the project. It divides Asia into three highway regions — Viet Nam, Cambodia, Laos, Thailand, Malaya, and Burma in the first; West Burma, East Pakistan, India, Ceylon, and Nepal, the second; and West Pakistan, Afghanistan and Iran, the third.

Just as these caravan routes were the great trade links of the Ancient World (the "silk road" ran from China through North India to Delhi and on to the Black Sea), authorities have reason to hope that new highway system will revitalize the Asian countries' economies.

To Link Alaska Panhandle with B.C.

Alaska Commissioner of Public Works, Richard Downing, has announced that work will begin on the first 20-mile stretch of the only highway between Petersburg in Alaska's Panhandle and British Columbia's Stewart-Cassiar Route now under construction.

However, B.C.'s first concern has been a corridor road through the Panhandle to the sea as an outlet for future northern industries. Governor William A. Egan of Alaska, has now assured B.C. authorities that he is ready to select land for a corridor and port facilities which, if leased to Canada, would be subject to Canadian laws.

Alaska Highway Paving Shelved

The Alaska Highway will not be paved for at least another two years. The U.S. government has recently shelved a plan to share the $132 million paving costs with Canada.

At the same time Premier W. A. C. Bennett of British Columbia has formally withdrawn his province's offer to the federal government to take over the cost of maintenance on the 600 miles of Alaska Highway in B.C. in return for a tract in the Northwest Territories. According to Defence Minister Pearkes, the federal government is anxious to get rid of maintenance and paving responsibilities on this section of the highway. The wartime project now has less significance from a defence standpoint, but increased civilian traffic to Alaska and the Yukon necessitates a considerable annual expenditure for maintenance.

Inter American Highway

Not to be confused with the Pan American Highway, the Inter American Highway is currently being extended from El Espino in Honduras to Nicaragua's capital, Managua. With the completion of the $6½ million highway, Nicaraguans will have nearly 200 miles of all-weather road. Considered in the context of a climate which thoroughly drenches the land six months of the year, the Inter American Highway is an impressive achievement.

Though ox carts are still much in use in Nicaragua, car and truck traffic is constantly mounting. Nicaragua's rubber crop is but one factor which necessitates highway development and will also make it prosper. The asphalt highway is financed two-thirds by the U.S., one-third by the Republic of Nicaragua.

Tunnel Under the English Channel

Once plans are approved, construction of a twin rail tunnel under the English Channel would take less than seven years. So says the president of The Channel Tunnel Company which was formed several years ago to study the project. Plans have been prepared which would make the building of such a tunnel feasible. Presumably the tunnel would be for a modified railway car which would carry both goods and people. Authorities do not think that automobile traffic would be feasible both because it would be difficult to provide space for breakdowns and because most people would not be able to bear the mental and nervous strain of driving thirty miles through an artificially lit, narrow tunnel.

The Tancarville Bridge

In July of this year a 4,626 ft. suspension bridge was inaugurated at Tancarville on the Seine. Authorized and financed by appropriations from the Special Highway Development Fund and by bonds against the earnings from the bridge tolls, the project, begun in 1937, was held up by the war. Construction got underway again in 1955.

Nineteen thousand metric tons of steel, 117,715 cu. yds. of concrete, and 209,275 cu. yds. of earthwork have gone into making this bridge. Half a century's realization that some large-scale means of conveyance was needed near the Seine's estuary and as many years of small ferries and other insufficient devices have spurred this noteworthy achievement. It is predicted that traffic tolls will soon pay for the bridge. People crossing the estuary of the Seine from the right bank save 60 miles on their way to the West by using the Tancarville Bridge and 43½ miles when going toward the Southwest. The bridge also promises a wholly new economic potential to the rich agricultural regions of Normandy which it unites.

Metropolitan Expressways

Philadelphia's Schuylkill Expressway

Highway engineers have had to cope with some singular problems in order to run an interstate highway between Philadelphia's 30th Street Station and the immediately bordering Schuylkill River. They have met them by constructing an expressway along the lower level of the east side of the station with ramps to the upper plaza overhead. They have extended the plaza to the riverline, laid out a double rotary system around the station, and run a new four-lane boulevard across the river, straight into the heart of the city, to relieve congestion from the station itself.

The highway comprises two 26 ft. wide roadways separated by a 4 ft. raised dividers low enough to be passed over in emergencies. A 25 ft. deep layer of muck and uncompressed silt along the line of the road also had to be calculated. Soils engineers have estimated that settlement will be at a rate of 1 in. in every five years for every additional foot of fill placed on the area. Fill depth varies from 1 to 15 ft. and therefore fill had to be excluded from design considerations. Instead, steel piles were driven through the muck to the underlying mica schist.

Oklahoma City Expressway

A two-mile elevated expressway will cut through Oklahoma City four blocks south of the downtown business district. Six 12 ft. roadways, an 8 ft. divider, and 6 ft. shoulders are its components. The new expressway will link all principal routes in and out of the city and will have only four entrance and exit ramps. The major span is over the main line and yard tracks of the Santa Fe Railway.

Boston's Rapid Transit

Boston's Metropolitan Transit Authority took over an abandoned railroad line on the west side of the city and converted it into a $7 million rapid transit service in mid-1958. Whereas the railroad had carried an average of 2,200 passengers a day, the rapid transit this September was taking more than 25,000 people back and forth from work.

U.S. Cuts Roads Budgets

The U.S. government has released figures on state and interstate apportionments for the fiscal year 1961. The federal allotment falls a good deal short of the amount authorized by law. The $2.7 billion apportionments to states, in fact, is $463,000 less than the obligations made by the states in 1959.

The interstate apportionment for 1961 is $1.8 billion which is $2 million less than the amount authorized by law. Federal aid has been falling off generally since the beginning of the year in all fields of construction.

Auto Design

German automotive engineers are asking themselves if there isn't some replacement for the conventional piston engine in automobiles. Designers are looking for an engine which could do without a gear. The gas turbine would appear to be the most likely prospect, though the high volume of exhaust which it gives off is prohibitive in these days of heavy traffic. In its favour are two factors—its size is one third that of the piston engine and it demands a simpler gear.

International Congress

The 8th International Automobile Technical Congress will be held at The Hague from May 9-13, 1960. The subjects of study include: gasturbines, transmissions, lubrication, combustion, fuels, chassis, gearbox, suspension gears, tires, brakes, body, equipment, aerodynamics, styling and safety. The congress will be carried on in three languages simultaneously, French, English and German.

Highway Engineering

Rubber In Roads

Rubberized bitumen is being used in many parts of the world where heavy-duty surfaces are required. The Queensland district of Australia has more than a thousand miles of such road; New Zealand's Northern Highway is another example; in the Far East an emulsion incorporating latex has been used quite extensively in roads. Both the U.S. and England have been testing rubber as a roads material for a decade.

In an attempt to find an improved form of natural rubber, researchers have come up with natural rubber latex (with and without special additives) and various forms of rubber powder.

Road Roughness Indicators

The Swiss Federal Institute is trying out a new road roughness indicator, the CT-444. The indicator, attached to the back of a truck, is used to determine the surface profile of a pavement, highway, air strip, or street. This equipment is used both to find spots where new surfacing is necessary and to obtain a permanent record so that a re-checking of the same pavement at given intervals can point up areas where preventive maintenance is necessary.

Salt Stabilization

The State of Ohio has completed 681 miles of salt-treated roads in the last five years. Adoption of salt as a stabilizing agent by the Ohio highway department is the outgrowth of experimental work undertaken in 1955 by the state's highway maintenance division to cut down upkeep costs on secondary roads. These farm-to-market roads were the most expensive to maintain of Ohio's 18,000 miles of highway.

Earth Resistivity Interpretation

The Assistant Director of the Testing Laboratory Division, Michigan

State Highway Department, Howard E. Barnes, has written an article on earth resistivity tests for sand and gravel prospecting. The author maintains that engineers have depended too long on a little magic black box. He contends that an accurate interpretation can be made from a set of field data. He discusses the difference between reconnaissance survey and a comprehensive survey, but his focus is on the limitations of resistivity instruments.

American Air Car

An American company began production of a 300 h.p., four-passenger Air Car in November. The car travels on a cushion of low pressure, low velocity air at a height of from six to twelve inches and can travel equally well over land, water, swamps and mud. This Model 2500 will travel at speeds up to 60 m.p.h. Before long both an Air Bus and an Air Truck will be manufactured as well.

Saucer-shaped Skimmer

The British National Research Development Corporation is currently sponsoring work on the SRN 1 Hovercraft. The saucer-shaped craft skims the surface of land and sea supported by a 12-in. cushion of air. The experimental prototype has made the Channel trip from Calais to Dover and is now being tested on land. It holds a considerable potential as a freight and passenger carrier, both as a ferry on the channel and as a carrier over rough terrain.

New French Engineering Company To Advise Petroleum Industries

A new company which will offer consulting engineering services to the petroleum and petrochemical industries has recently been formed in Paris. It is called "Etude et Realization de Projets Industriels (Planning and Undertaking of Industrial Projects).

The new company, headed by an American citizen and professional engineer in the State of New York, Mr. J. G. Devys, will provide market studies and economic evaluations; assistance in technical research; process development, appraisal and design; foreign and domestic contracts in view of common market undertakings; and negotiations for carrying out major industrial projects in Western Europe and underdeveloped countries.

Their address will be: 26 rue de la Pepiniere, Paris 8.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

Noranda Copper and Brass Limited will be the recepient of the E.I.C. Certificate of Advertising Merit for the "best" advertisement in the September issue.

This four-colour advertisement, which appears on page 33, is a dramatic presentation of molten alloy being poured. It is headed "QUALITY THAT FLOWS INTO YOUR PRODUCTS", and the copy covers control of quality and performance. In part, the copy states "every production step is not only rigidly controlled but carefully integrated to assure quality brass mill products that help improve your products, reduce your costs, increase your profits". Emphasis is laid on the fact that Noranda brass mill products are made by Canadians from Canadian ore.

The fifty members who were asked to serve on the jury to select the "best" advertisement in the issue were asked to make their selection from the viewpoints of ACCURACY – INFORMATION and ATTRACTION.

The certificate will be presented to Mr. R. C. DeVilliers, Advertising Manager of the Company and a duplicate will be presented to Hazard Advertising Agency who prepared and placed the advertisement.

NORANDA COPPER AND BRASS LIMITED WINNING ADVERTISEMENT

The advertisement reproduced above was judged to be the "best" from the viewpoints of ACCURACY–INFORMATION and ATTRACTION by the fifty readers who were asked to review the advertisements in the September issue.
The advertisement is printed on good grade coated stock, is extremely attractive and the copy is factual and concise.

Month to Month

Ten Branches Participate in Banff Conference

Below left Mr. and Mrs. Clarence B. Antenbring and Mrs. John B. Striowski stop for a moment in the midst of Banff activity.

Below Professor John Mantle of the University of Saskatchewan, coordinator of the technical sessions at Banff, talks with Dr. John Convey, director of the Department of Mines & Technical Surveys, Ottawa.

Members and their wives from Calgary, Saskatchewan, Central British Columbia, Edmonton, Lethbridge, Vancouver, Vancouver Island, Winnipeg, Kootenay, and Yukon enjoyed three lively days of meetings and good weather at the Western Zone Technical Conference in Banff from October 1 to 3.

Prefaced by the Irrigation Forum on Thursday, October 1, the conference got formally underway with 9 o'clock registration Friday morning followed by the first technical session. The day's program included a general luncheon (with a special luncheon for the Professional Development Seminar), technical sessions, cocktails, a banquet, a soiree review and dance.

On Saturday, October 3, technical sessions filled the morning and were followed by luncheon and golf at the Banff Springs Course.

The ladies were feted on Friday with a tea and bridge parties at Timber Line Hotel and on Saturday they were taken on a grand tour of the surrounding vacationland.

Technical sessions included discussion of irrigation methods, power developments, economics of oil mining, muskeg, construction projects, Northern affairs, land survey, hydro survey, and soils study.

Ottawa Conference Marks 50th Anniversary of Ottawa Branch

The Chateau Laurier bustled with engineers on October 15 and 16 as E.I.C. members from Ottawa and the neighboring branches gathered for the Ottawa Regional Technical Conference. This was the 50th anniversary year for the Ottawa branch and the first year that a regional conference had ever been held in the national capital.

Fourteen papers on subjects as diverse as nuclear research, new power sources, sewage treatment and mining were presented in the course of the two days. The talk given at Thursday's luncheon by Mr. Winnett Boyd of Montreal on nuclear engineering and its bearing on the future development of Canada created considerable interest at the conference and in the press.

Friday's luncheon address was given by Dr. John Convey of the Department of Mines and Technical Surveys. His words on Mining and Metallurgy in the Ottawa Valley formed an appropriate introduction to an afternoon of mining topics.

Mr. R. F. Legget opened the Friday morning session on Ottawa Valley projects with an interesting history of engineering projects of an earlier era in the valley. The conference also featured suitable displays set up by the Atomic Energy Commission and the National Capital Commission.

The conference wound up with a ballroom dinner dance at which members were honoured with an address by the president of the Institute, Mr. J. J. Hanna.

The Engineers' Wives Association planned a full program for the ladies which included a special tour on Thursday afternoon and a coffee party on Friday morning.

McMaster University Inaugurates New Engineering Building

Dr. K. F. Tupper, M.E.I.C., officially opened the new Engineering Building at McMaster University on October 23 with the hope that in it "students will acquire habits of industry—a willingness to work, to concentrate on one thing at a time, to get things done . . . and to read, not as computing machines storing information to give it out upon demand, but critically, using their own judgment."

Following the opening of the Engineering Building, an Engineers Buffet Supper was held. The Autumn Convocation took place that evening.

Honorary Membership to James Alfred Vance

An honorary membership, the highest tribute paid by the Engineering Institute of Canada, was conferred upon James Alfred Vance of Woodstock by President J. J. Hanna at a recent meeting of the London Branch. The council selected five prominent engineers this year to be recipients of honorary memberships, but at the time of the presentation at the 1959 Annual General Meeting Mr. Vance was abroad attending the Tenth Anniversary of NATO as a Canadian delegate.

For many years Mr. Vance was a member of the Woodstock Board of Trade, its president and also a director of the Canadian Chamber of Commerce. Since 1955 Mr. Vance has been an active member of the Ontario Water Resources Commission.

As councillor for the London Branch, vice-president in the Ontario zone, and president of the Institute in 1950, Mr. Vance has served the Institute long and well. In 1953 he was awarded the Sir John Kennedy Medal of the Institute for outstanding merit in the profession.

(Continued on page 135)

Honorary degrees were presented to four members of The Engineering Institute of Canada at the convocation of the University of Western Ontario on October 29. They are (left to right): Henry Gaudefroy, dean of Ecole Polytechnique; Richard Lancaster Hearn, chairman of Ontario Hydro; James Alfred Vance, proprietor-engineer of the James A. Vance Company; and Kenneth Franklin Tupper, president of Ewbank & Partners (Canada) Ltd., Toronto.

James Alfred Vance (right) receives a certificate of honorary membership, the highest honour bestowed by The Engineering Institute of Canada, from President J. J. Hanna.

University Registration

The Institute's tabulation of this year's university engineering enrolment in Canada will be found on the following pages of this issue. This information has been obtained direct from the registrars, and is now an annual Journal service to its readers.

The main highlights of this year's situation, as disclosed by the E.I.C. survey, are the following:

a. The total enrolment in Canadian engineering courses now stands at 14,475 which is down very slightly this year by 77 students.

b. The incoming freshman class is 4150 strong, representing a decrease of 9% as compared with 1958. The drop over the last two years is now 20%.

c. The estimated number of 1960 graduates, making no allowance for wastage during the year, is 2241. This will be a 6½% increase in terms of the 1959 figure, forecast a year ago.

d. New colleges giving recognized engineering courses are still being added to the list. On this occasion we welcome the addition of St. Joseph's University to our survey.

Readers will be able to make further detailed observations by study of the tables. However, if any questions should arise, E. I. C. Headquarters will gladly try to answer them on request.

*Students in Agricultural Engineering who will proceed to their final year in Mechanical or Civil Engineering at the University of Toronto on completion of their studies at Guelph.

**The figures shown for the University of Waterloo are valid only to the end of December, 1959. This is because course intakes are on the "quarter system" and some of these students will be moving on to higher courses in January 1960 and again in April 1960.

74th

E.I.C.

ANNUAL GENERAL

AND

TECHNICAL MEETING

1960

Royal Alexandra Hotel

WINNIPEG - MANITOBA

MAY 25-26-27

Personals

John Bertram Sterling, HON. M.E.I.C.

L. Austin Wright, M.E.I.C.

Lawrence C. Sentance, M.E.I.C.

Nikolajs Strauss, M.E.I.C.

The two new companies, Beaco Limited and Canengco Limited, Montreal, have brought together a number of prominent E.I.C. members to offer independent consulting services in Canada and abroad. **John Bertram Sterling,** Hon. M.E.I.C. (Queen's '11) is to act as director and chairman of the board of Beaco Limited, while **L. Austin Wright,** M.E.I.C., a past general secretary of E.I.C. (Toronto '11) is the director and chairman of the board of Canengco Limited. **Robert F. McCune,** M.E.I.C., has been named director and president of the two companies; **Andrew T. Wilson,** M.E.I.C. (Queen's University, Belfast '46), director and vice-president, Beaco; **Donald C. MacCallum,** M.E.I.C. (McGill '38), director and executive vice-president, Canengco and director, Beaco; **Alexander G. Moore,** M.E.I.C. Nova Scotia '25), director, Beaco; **Thomas A. Monti,** M.E.I.C. (Ecole Polytechnique '41), director, Beaco; and **H. John Racey,** M.E.I.C. (Queen's '28), executive vice-president, Cia. Canadiense Internacional De Ingeneria, a Beaco subsidiary.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Address all information to: *The Engineering Journal,* Editorial, 2050 Mansfield Street, Montreal, Que.

H. William Tate, M.E.I.C. (Toronto '10) is the new chairman of the board of De Leuw, Cather & Company of Canada, Limited, Consulting Professional Engineers, Toronto. **Leslie W. Pillar,** M.E.I.C. (King's '25) has been appointed president.

G. J. Currie, M.E.I.C. (Nova Scotia '31) has been made assistant chief engineer of Nova Scotia Light and Power Company, Limited and subsidiary companies.

Lawrence C. Sentance, M.E.I.C., (Saskatchewan '35) is the new manager of the Canadian Westinghouse Company's atomic energy division.

Robert H. Hobner, M.E.I.C. (Manitoba '35) has been appointed project engineer with the Northern construction division of the Department of Public Works' building construction branch in Ottawa.

Henry W. E. Rosenthal, M.E.I.C. (Darmstadt '37) has been made mechanical engineer in charge of production with L'Hoir Inc. at Levis, Quebec.

S. M. Breuning, M.E.I.C. (Stuttgart '49) has left the University of Alberta for a post at Michigan State University, Lansing, Mich.

Nikolajs Strauss, M.E.I.C. (Latvia '41) has been appointed by the Minister of Public Works, Ottawa, to the post of highways materials engineer with the development engineering branch of the public works department in Banff.

J. A. MacLean, M.E.I.C. is the new manager, central district of Associated Electrical Industries (Canada) Limited. **K. R. Brown,** M.E.I.C. (London Polytech. '44) has been appointed manager of their Pacific district.

(Continued on page 112)

OBITUARIES

Ralph Clinton Purser, M.E.I.C., for many years a member of the administrative staff of the Topographical Survey of Canada, died on September 9, at the age of 73.

Mr. Purser was born at Windsor, Ontario, in 1886. He graduated from the School of Practical Science, University of Toronto, in 1907 and obtained a commission as dominion land surveyor in 1910. He became a commissioned Ontario land surveyor in 1921.

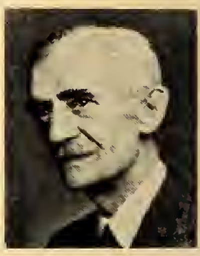
In 1909 Mr. Purser worked in southwestern Alberta as assistant on D.L.S. surveys. The following year he returned to Windsor, Ontario, to work on the staff of J. J. Newman, Dominion and Ontario Land Surveyors, as civil engineer.

From 1911 to 1932 Mr. Purser was chief-of-party and then surveys engineer for the Topographical Surveys Branch of the Department of the Interior, later the Topographical Survey of Canada, in the Canadian West. He was in the administration of this organization from 1924 to 1932.

Instrumental in founding *The Canadian Surveyor,* a magazine published by the Canadian Institute of Surveying and Photogrammetry, Mr. Purser acted as its honorary editor from its inception in 1922 until 1928.

Upon his retirement from the Dominion Government Service in 1932, Mr. Purser took up free-lance writing and acted as Ottawa correspondent for a number of papers. A considerable part of his writing dealt with technical subjects and was published in national trade magazines.

Ralph Clinton Purser, M.E.I.C.



Dr. Edward P. Fetherstonhaugh, M.E.I.C.

Tom Herbert Chapman, M.E.I.C., lost his life in a sailing accident near North Bay, Ontario, June 15.

Born in Toronto, March 20, 1917, Mr. Chapman attended the University of Toronto and received his B.Sc. in mechanical engineering in 1949.

In 1957 Mr. Chapman, working with Milne Laidlaw Associates, consulting engineers to the lumber industry, travelled to Russia and did contract work for the Russian government at Archangel.

Prior to this Mr. Chapman had worked on layout and design conveyor equipment for Linkbelt Limited in 1949-50. From 1950 to 1954 he was an engine salesman for Geo. W. Crothers, Ltd., engineering and selling diesel power units for power sawmills, power shovels and electrical generators.

The Great Northern Woods Co. Ltd.'s projected North Bay plant became his concern in 1954, when he was sent up they by D. W. Milne to develop the first plant in Canada for finger-jointing and edge-glueing white pine.

A squadron leader in the RCAF, Mr. Chapman was awarded the Distinguished Flying Cross for his services.

Edward Phillips Fetherstonhaugh, HON. M.E.I.C., a past president of the Engieering Institute of Canada, died in Winnipeg on October 19th, in his 81st year.

Dr. Fetherstonhaugh was born in Montreal and graduated from McGill University in 1899. After five years of engineering practice in Ottawa and Montreal he returned to McGill, this time as a lecturer in electrical engineering, a position he held until 1907. He then moved to Winnipeg, where in 1909 he was appointed professor of electrical engineering at the University of Manitoba.

During the First World War Dr. Fetherstonhaugh served in France with the Royal Corps of Canadian Engineers and was awarded the Military Cross.

With the return of peace he resumed his teaching at the University of Manitoba, where he became the first dean of the faculty of engineering and architecture in 1921.

Dean Fetherstonhaugh was for a number of years a member of the National Research Council. He had joined the Engineering Institute of Canada as a student in 1899, subsequently becoming a member of the Winnipeg Branch executive, then chairman, then councillor until in 1945 he was elected to the presidency of the Institute. He was the recipient of the Julian C. Smith Medal for that year — the year of his retirement — and in the same year McGill conferred on him an honorary degree of Doctor of Science.

Guy Montague Wynn, M.E.I.C., a member of the Institute since 1915, died in Montreal on October 2, 1959.

Mr. Wynn was born and educated in Niagara Falls, Ontario. After attending Toronto University he joined the Ontario Power Company at Niagara Falls as engineer-in-charge of surveys for construction.

When Mr. Wynn took up a position with T. Pringle & Son, Montreal, 1905, he launched out on a 47-year career with that company. At the time of his retirement in 1951 he was executive head of the firm. Among countless other projects, Mr. Wynn was in charge of the design and construction of the Canadair Ltd. plant, which at the time was considered the largest of its kind in the Commonwealth.

James Alexander Walker, M.E.I.C., died in Vancouver on September 22nd at the age of 72.

As engineer-secretary of the Vancouver Town Planning Commission from 1921 to 1952, Ontario-born Mr. Walker was affectionately known to the people of his adopted city as "Sandy Walker".

He was largely instrumental in drafting Vancouver's zoning by-law, and also created town plans for New Westminster, West Vancouver and North Vancouver city and district. Among the civic structures he helped to develop and build were the new Granville Bridge, Burrard Bridge, and the underground Canadian Pacific Railway tunnel in downtown Vancouver.

Mr. Walker was educated at the University of Toronto and served in the Canadian Army during the First World War. He became a Life Member of the Institute in 1953.

Oliver Tiffany Macklem, M.E.I.C., for thirty years a member of the department of civil engineering at Royal Military College, died on May 1, 1959.

Born in 1883, Mr. Macklem attended R.M.C. and McGill University, where he earned a B.Sc. degree in 1908. He began teaching at R.M.C. in 1909 as an instructor of civil engineering and remained there until his retirement in 1938 but for a period of military service in World War I. In 1920 he was made an associate professor and in 1933 he became a full professor and head of the civil engineering department.

Mr. Macklem came out of retirement for a short time during World War II to teach civil engineering at Queen's University.

William Laird Smith, S.E.I.C., was the victim of an automobile accident on April 19, 1959. He was 23 years old.

William attended Manor Public & High School in Manor, Saskatchewan, and went on to earn his degree in petroleum engineering at the University of Saskatchewan in 1958. In 1959, working as a laboratory instructor in petroleum, he received his diploma in commeıce.

At the time of his death, William was working for British American Oil at Stattler, Alberta.

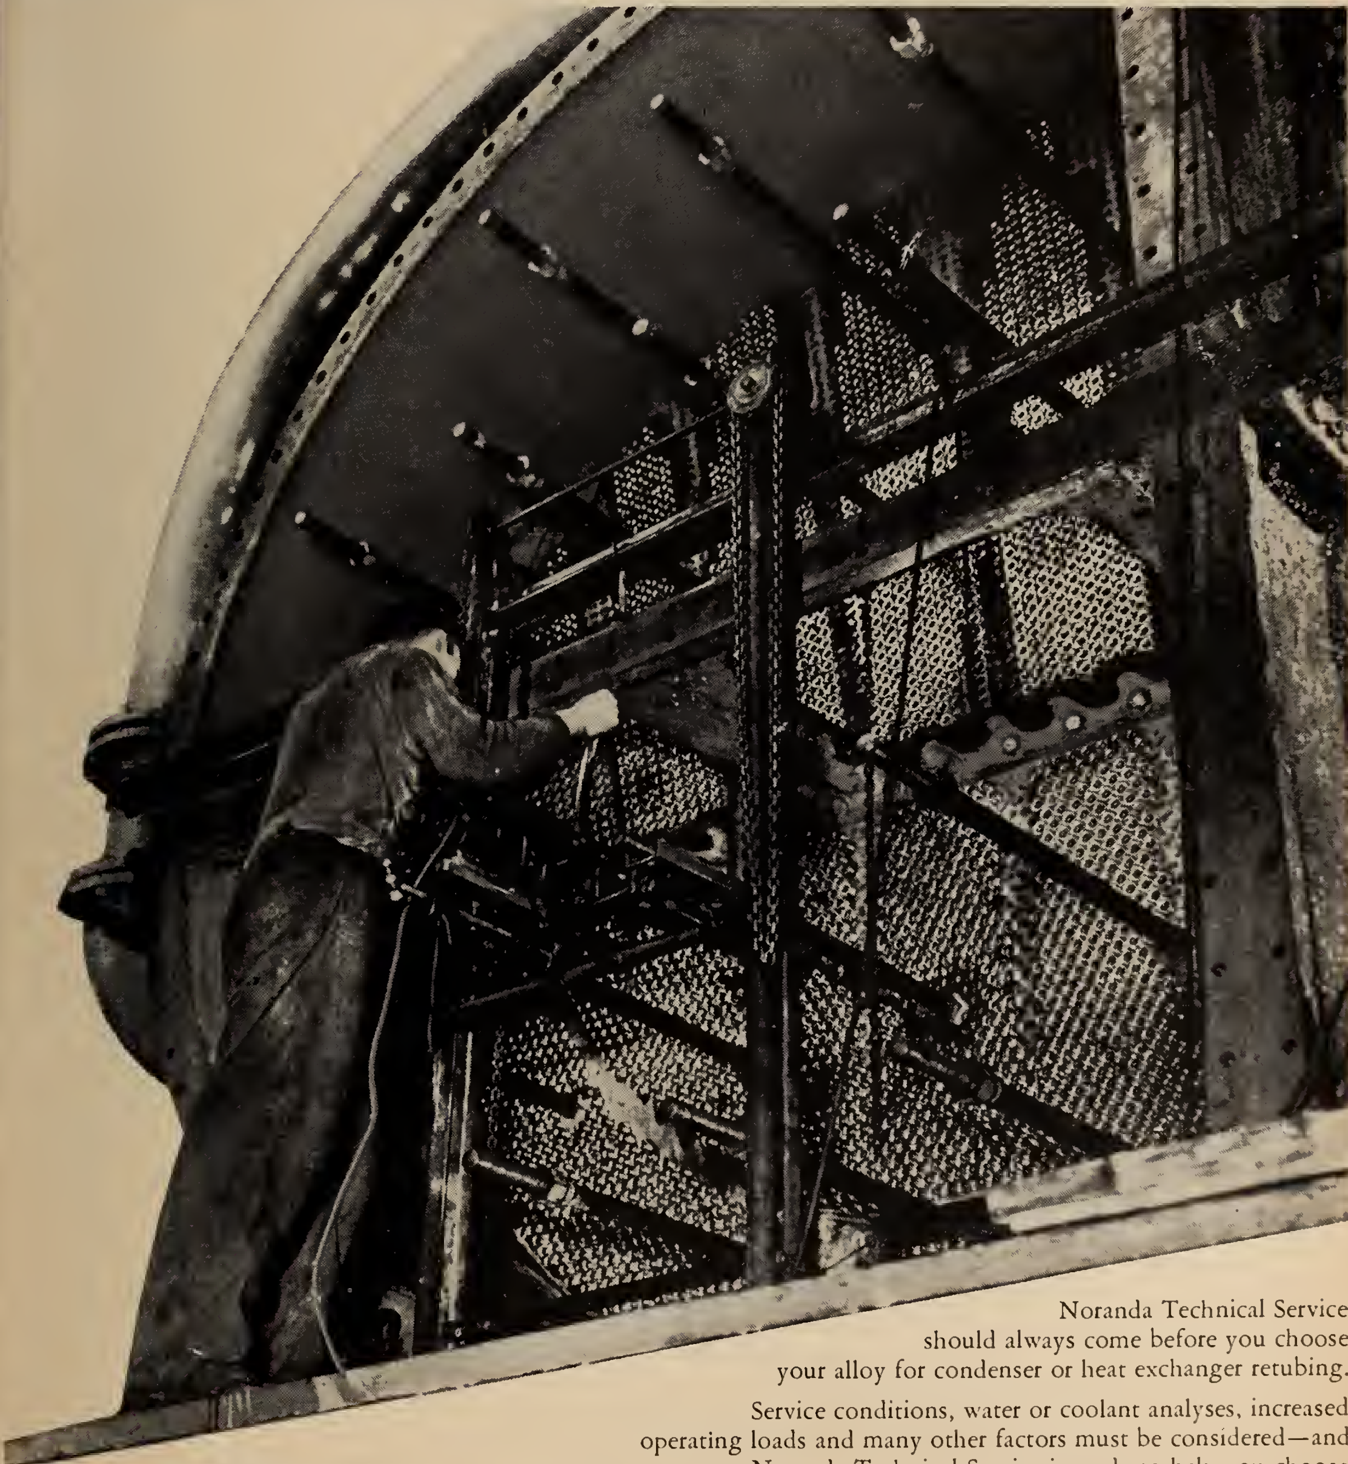
YOU GET THE BEST NORANDA ALLOY FOR RETUBING WHEN YOU USE NORANDA TECHNICAL SERVICE FIRST



Noranda Technical Service
should always come before you choose
your alloy for condenser or heat exchanger retubing.

Service conditions, water or coolant analyses, increased operating loads and many other factors must be considered—and Noranda Technical Service is ready to help you choose the *right* alloy to meet new needs.

Noranda Technical Service helps form the basis for correct alloy selection for retubing. Then you're sure that the alloy you use is the *right* alloy.

Think twice when retubing. Of Noranda Technical Service. And then the alloy. Make no mistake about it

NEWS OF THE BRANCHES

ASSUMPTION UNIVERSITY OF WINDSOR

William Pulleyblank, S.E.I.C., *Correspondent*

President Hanna and J. Hance Legere, director of technical services, spoke to one hundred student engineers on October 23rd. Mr. Hanna stressed the importance of assessing the meaning of engineering as a profession before entering into practice, and suggested to the students that they study the code of ethics in their respective provinces. Mr. Legere spoke briefly on the nature and benefits of membership in E.I.C.

BORDER CITIES

R. L. Kennedy, JR.E.I.C., *Correspondent*

We were honoured to have as guests at our annual dinner dance October 23rd our president, Mr. Hanna, and Mr. J. Hance Legere. A reception preceded a smorgasbord dinner at the Essex Golf and Country Club. In a short speech, Mr. Hanna gave the branch several stimulating suggestions for direction. He also talked on Canada's wealth of resources and warned against squandering them for short-term gain.

CAPE BRETON

H. M. Aspinall, M.E.I.C., *Correspondent*

The wives of members and affiliated members of E.I.C. were guests of Mrs. C. M. Anson at an afternoon tea on October 23rd. Greeting the many guests were Mrs. Anson and Mrs. Clifford Murray, president of the Cape Breton Engineers Wives Association.

On October 30th E.I.C. members held a dance followed by a buffet lunch.

CHALK RIVER

G. R Fanjoy, JR.E.I.C., *Correspondent*

Mr. A. G. Muirhead, general manager of Gillies Bros. and Co. Ltd., sketched the historical development of lumbering in the Ottawa Valley at the September 30th meeting. Lumbering began with the felling of timber to provide agricultural land and to obtain potash and has progressed to the production of sawn, kiln-dried lumber and of pulp. Talking about means of protecting forest stands from fire, Mr. Muirhead pointed out that more timber is destroyed each year by fire than by logging. He suggested that in many cases natural regrowth is preferable to planting.

EDMONTON

I. G. Finlay, M.E.I.C., *Correspondent*

D. B. Menzies, M.E.I.C., Commissioner, City of Edmonton, speaking to branch members on September 28th, outlined several important problems which in his opinion would be solved by amalgamating the City of Edmonton and several fringe municipalities and towns.

On October 28th V. R. Currie and D. Dewar of the Department of Transport spoke on Edmonton's new airport. Mr. Currie explained its construction features, while Mr. Dewar talked about navigational problems.

HAMILTON

C. A. McCurdy, JR.E.I.C., *Correspondent*

A plant tour of the Saint Lawrence Cement Company in Clarkson, Ontario gave members, their sons, and McMaster engineering students a chance to inspect modern dust collecting and materials handling equipment.

On November 26th a progress report on the NRU atomic reactor at Chalk River was presented to members at the Hamilton Armories.

HURONIA

L. Morgante, JR.E.I.C., *Correspondent*

Elected to office at the September meeting were: chairman, S. R. Walkinshaw; vice chairman, A. H. Pangman; directors, F. Alport, E. L. Cavana, R. MacKay, D. M. Harris, W. A. Plant, and C. A. Fry; secretary-treasurer, L. Morgante.

LETHBRIDGE

R. J. Knight, JR.E.I.C., *Correspondent*

The director of planning at Old Man River District Planning Commission, S. J. Clarke, was guest speaker at the October 24th meeting. Outlining the position of a professional planner in today's municipal population explosion, Mr. Clarke explained that the value of city planning is often misunderstood. He pointed out that one has only to view the existing results of poor planning to realize that efficiently coordinated communities do not just happen.

MONTREAL, JUNIOR SECTION

Bernard Michel, JR.E.I.C., *Correspondent*

Twenty-five members participated in the annual golf tournament on September 9th at the St. John Golf Club. A dinner followed.

Registration for the Professional Development Seminar was held on October 8th. Two classes of participants have been formed as a result of high enthusiasm among the junior members.

NIAGARA

E. C. Little, M.E.I.C., *Correspondent*

The annual engineers' dinner and dance were held at Prudhomme's Garden Centre on September 25th for some 225 couples.

On October 28th our president, J. J. Hanna, talked to members about work at headquarters. Technical papers, political legislation affecting engineers, and innumerable subjects such as the Borden Report and how problems which headquarters deals with.

NIPISSING AND UPPER OTTAWA

R. D. Christie, JR.E.I.C.,
Correspondent

Members heard J. F. Chantler, a former chairman of the branch and currently general mills superintendent, Kipawa Mill, Canadian International Paper Co., Temiskaming, Que., talk on Communications and Industrial Supervision in late September.

Speaking on employer-employee relations, Mr. Chantler suggested: "If the subordinate knew he could have understanding without reproach, and disagreement without retaliation, then there would be true communication."

R. S. McLennan of North Bay was appointed vice-chairman and J. Warburton, executive committee member.

ONTARIO AGRICULTURAL COLLEGE

Leeroy L. Gordon, S.E.I.C.,
Correspondent

"Engineering Projects with the United Nations" was the subject of an impromptu talk on November 3rd by H. Kitching, formerly with F.A.O. in Rome and the Colombo Plan in Pakistan. Mr. Kitching outlined the organization of the United Nations and went on to explain F.A.O's place within the U.N. His illustrations of F.A.O. projects were taken from power machinery work, for that has been his own field since 1953. He talked in some detail about assignments he planned in various parts of Africa, South America and Southwest Asia and showed coloured slides of the projects.

SAGUENAY

E. E. Paine, JR.E.I.C., *Correspondent*

P. S. Subramanian and A. Subramanian spoke to a group of members of E.I.C. and the Saguenay Chapter of the Corporation of Professional Engineers of Quebec on October 20th. As senior engineers in the Madras Electricity Authority, the two men spoke on "The Electrification of Madras." They have been concerned with the installation and operation of Colombo Plan hydro-electric plants.

SAINT JOHN

Harley K. Larsen, JR.E.I.C.,
Correspondent

New Brunswick's Attorney-General, Hon. R. G. L. Fairweather, QC, was speaker at a dinner meeting at the Riverside Golf and Country Club on October 26th. He described the duties and responsibilities of his office to the assembled group of engineers and their wives.

ST. MAURICE VALLEY

William B. Scott Jr., JR.E.I.C.,
Correspondent

Fall activities commenced on October 22nd when 40 members with their wives attended a dinner meeting at the Cascade Inn in Shawinigan. Chairman W. A. Pangborn presided and the gathering was addressed by Dr. Gerald Kaine on "The Implications of Recent Advances in Medicine." He covered the development of antibiotics, quinotherapeutic agents, Cortisone ACTH, Insulin and anticoagulants and their use in treating viral diseases, arthritis, diabetes and thrombosis. Recent developments in cancer research were also traced.

SASKATOON

W. A. Friebel, M.E.I.C.,
Correspondent

Cyril N. Hoyler, manager of technical relations at the David Sarnoff Research Centre of R.C.A. Laboratories, Princeton, N.J., spoke to a large gathering on October 19th describing some outstanding advancements in the electronics of solids. He reported that a number of new solid materials have been developed within which electron action can be precisely controlled to achieve a variety of useful effects. Electroluminescent materials, according to Mr. Hoyler, will be the next step in industrial lighting.

We were shocked and grieved to learn that two days after his visit to the Saskatoon branch, on October 21st, Mr. Hoyler was killed in an automobile accident at Moosomin, Sask.

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C., *Correspondent*

A hydro film entitled "From Dream to Reality" describing the Saint Lawrence Seaway in the area of Long Sault Rapids west of Cornwall was shown at the October 16th meeting. This is one of the better films we have seen and goes into such aspects as the many diversions, coffer dams, which eventually resulted in the elimination of the Long Sault Rapids; the building of power dams; flooding of large areas along the river; and moving of several towns.

One of our non-resident members, Mr. G. Cameron of the Hydro Red Rock Falls project, paid us a visit accompanied by several hydro engineers. It is rare that we see non-resident members because of their wide dispersement.

TORONTO

D. R. Abbey, M.E.I.C., *Correspondent*

A Symposium on Engineering Ethics was held on October 29th, with the following participating: Dr. G. R. Lord, head of the department of mechanical engineering, University of Toronto; Dr. G. B. Langford, head, department of geological science, Univ. of Toronto; Mr. J. F. McLaren, James F. MacLaren Associates; and Mr. Joseph Sedgewick, Q.C.

Meetings of the Joint Area Committee (Civil), the Electrical Section, and the Power Section have also been held. Members of the latter heard a paper on the Border Dam Power Plant prepared by Ewbank & Partners (Canada) Ltd. on November 11th.

UNIVERSITY OF NEW BRUNSWICK

Ardean Stairs, S.E.I.C., *Correspondent*

Professor I. M. Beattie, M.E.I.C., head of the civil engineering department at the University addressed student members October 5th on "The Philosophy of Engineering". Chairmen of various committees were elected and the meeting wound up with refreshments. Plans are being made for Engineering Week, January 23-29, 1960.

Senior engineering students went on a tour of the Hartland Bridge and the Beechwood Power Development on September 20th.

VANCOUVER

C. H. White, M.E.I.C., *Correspondent*

The B.C. Electric Small Auditorium was the meeting place for a talk on "Modern Developments in Concrete Technology" October 20th. Raymond J. Schutz, technical director of the Sika Chemical Corporation, Passaic, N.J., was the speaker.

Mr. Schutz stressed the variety of possibilities offered by modern concrete. Unit weights vary from 23 lbs./cu. ft. up to 350 lbs./cu. ft. and compressive strength ranges from 100 lbs./sq. in. up to 10,000 lbs./sq. in. The low-weight and strength concretes, he explained, are lightweight concrete fills, while the high strength concretes are used in pre-stressed work. The high unit-weight concretes are being put into shielding for atomic energy projects.

Franki Pressure-Injected Footings Give Remarkable Saving in Time and Money

Problem

High cost of placing conventional footings in fine running sand and through a water table close to ground surface.

Solution

Because of the ease of installation, Franki Pressure Injected Footings were used, eliminating such expenses as sheeting, pumping and all excavation. Because of their unusual carrying capacity developed by high compaction of this cohesionless soil, only one pressure injected footing was necessary under each column. Cost was halved and only twelve working days were required to place 123 Franki Pressure Injected Footings compared to 5 to 6 weeks which conventional footings would have taken.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

FUNDAMENTALS OF BOILER HOUSE TECHNIQUE

Intended to help bridge the gap between the practical and theoretical consideration of problems concerned with boiler house technique, this text covers types of boilers; water treatment; steam; fuels; flue gas testing; atmospheric pollution; combustion; solid, liquid and gaseous fuels; and boiler house efficiency and testing. (P. D. Dehnel. London, Hutchinson, 1959. 25/-.)

CRUSHING AND GRINDING; A BIBLIOGRAPHY

The first part of this volume contains a series of short reviews of crushing and grinding in connection with ceramics, cement, minerals, chemicals, etc., and of fire and explosion hazards in crushing and grinding operations.

The 2800 annotated references in the bibliography are classified under the general headings of: fundamental aspects; crushing and grinding practice; equipment; coarse reduction; fine reduction; non-mechanical methods; materials; methods of particle size and surface area determination; classification; dust and fire hazards. Each section is further subdivided. There are name and subject indices. (W. H. Bickle, comp. London, H.M.S.O., 1958. 425p., 35/-.)

FEDERATION INTERNATIONALE DE LA PRECONTRAINTE, 3rd CONGRESS, 1958

The increased use of prestressed concrete is reflected in the sixty-two papers presented at this Third Congress, held in Berlin in May 1958.

The speakers came from all over the world, including Eastern Europe, and the papers are written in English, French, German or Spanish. The first session was concerned with developments in design methods. The second discussed progress in prestressing technique as applied on the site, with special reference to grouting, anchorages, reduction of friction, and safety precautions. The last group of papers is concerned with progress in the manufacture of factory-made precast, prestressed, concrete units and in their use and assembly on the site.

A second volume, not yet published, will contain the discussions. (Ed. by R. P. Andrew. London, Cement and Concrete Assoc., 1958. 766p., $40.00, special price to E.I.C. members $30.00.)

THE AUDIO CYCLOPEDIA

Written in the form of 3400 questions and answers, this reference work covers all phases of audio, including hi-fi and stereo. Among the topics covered in the 26 sections are: basic principles of sound; acoustics; constant speed devices; attenuators; sound mixers; vacuum tubes; transistors and diodes; recording of all types; motion picture projection equipment; loudspeakers; test equipment; stereophonic recording.

The information is easily accessible by means of a 54 page index, there are many useful illustrations and diagrams, and the volume should prove invaluable. (H. M. Tremaine. Indianapolis, Sams, 1959. 1269p., $19.95.)

CITIES IN THE MOTOR AGE

This volume is an attempt to summarize and evaluate a conference held in 1958 which discussed the problems of the rapid urbanization of the United States.

It is a penetrating discussion of city planning, the U.S. national highway programme, suburban versus city life, the role of the railroads, and the impact of the automobile on everyday living. (Wilfred Owen. Toronto, Macmillan, 1959. 176p., $4.50.)

*THE EXPLORATION OF SPACE BY RADIO

Surveys the field of astronomical studies, including the radar techniques for the investigation of various aspects of the solar system, as well as the receiving techniques which are used to study the solar and the galactic and extragalactic radio emissions. Specific aspects discussed include the hydrogen line, scintillation of the radio stars, meteors, the aurora borealis, and the Jodrell Bank radio telescope. (R. H. and A. C. B. Lovell. Toronto, Ryerson, 1957. 207p., $7.00.)

CONCRETE: THE VISION OF A NEW ARCHITECTURE

Dealing with the architectural rather than the technical aspects of reinforced concrete, the purpose of this study is to describe the development of a new building material, and to discuss the efforts of architects to find its most appropriate form.

The first part of the volume deals with the history of concrete as a building material between 1800 and 1914, when it came into general use. The second part considers the work of architects of the nineteenth and twentieth centuries.

The third, and largest, section of the book is devoted to the work and theories of Auguste Perret who was regarded as the leading figure in the field during the first half of this century. Many illustrations of his work are included.

The author, an associate professor of architecture at McGill University, worked for some years in the office of one of Perret's pupils. He believes his study will be of interest to the many structural engineers "who have to collaborate with architects, and find their attitude of mind quite incomprehensible." (Peter Collins. Toronto, British Book Service, 1959. 307p., $12.75.)

*JOINTS AND CRACKS IN CONCRETE

Essentially this is a practical guide to the use of joints in the building of sound structures, although some consideration is given to theoretical aspects. It gives a survey of jointing materials and methods of construction, describes correct and economical jointing techniques, and discusses diagnosis and treatment of faults. With the aid of diagrams and photographs most types of concrete structures in which jointing problems are likely to arise are covered, including buildings, water-retaining structures, pavings, bridges, masonry construction, and concrete pipes. (P. L. Critchell. London, Contractors Record, 1958. 232p., 40/-.)

*INTERNATIONAL COMMITTEE ON ELECTROCHEMICAL THERMODYNAMICS AND KINETICS. NINTH MEETING. PROCEEDINGS

A collection of papers discussing thermodynamical data and potential – pH diagrams, electrochemical definitions, experimental methods in electrochemistry, batteries and accumulators, corrosion and protection against corrosion, electrochemical kinetics, and modern electrochemical methods in analytical chemistry. The papers are written in French, German and English. (Toronto, Butterworth, 1959, 489p., $24.00.)

°GENERAL GALVANIZING: A MANUAL OF GOOD PRACTICE

Combines the results of research work with the practical experience of experts in the British galvanizing industry. The manual covers degreasing and paint removal, pickling, preparation of castings, rinsing and pre-fluxing, dipping, fluxes for wet galvanizing, ash formation and treatment, dross formation and recovery, inspection and testing, and finishing treatments. (Montreal, Consolidated Mining and Smelting Co., 1957. 56p., $3.00.)

°MATHEMATICAL PROGRAMMING AND ELECTRICAL NETWORKS

A new approach to mathematical programming based on an analogy with electrical networks. It is shown that any direct-current electrical network made up of current sources, voltage sources, ideal diodes, and ideal transformers is equivalent to a pair of dual linear programs. A simple algorithm is developed for solving diode-source networks which is applicable to network flow problems including the transportation problems. A procedure for algebraically tracing the breakpoint curve of a diode-source-resistor-transformer network is derived, and it is used to obtain optimal solutions to general linear or quadratic programs. (J. B. Dennis. New York, Wiley, 1959. 186p., $4.50.)

°LABOR MANAGEMENT RELATIONS

Employee-employer relations are discussed from a highly practical point of view. Methods are presented for the solution of the problems involved in this relationship, and new techniques are presented for management administration and policy in both union and non-union operations. The importance of proper labor contract language is stressed as are the effect that emotions have in labor relations, the problems of the union shop, and the effect of "right to work" laws and strikes. (C. Wiedemann. New York, Reinhold, 1959: 142p., $3.75.)

°PARIS SYMPOSIUM ON RADIO ASTRONOMY

A collection of papers reporting the latest advances in radio astronomy. The authors discuss moon reflections, radio emission from Jupiter and other planets, radio emission from the quiet and active sun, radio studies in the discrete radio sources (radio stars), radio evidence on the large scale structure of our own and external galaxies, cosmology, and the mechanisms by which solar and cosmic radio waves are generated. These papers constitute the proceedings of a symposium held in 1958 which was jointly sponsored by the International Astronomical Union and the International Scientific Radio Union. (Ed. by R. N. Bracewell. Stanford, Cal., Stanford University Press, 1959. 612p., $15.00.)

°PROGRAMMING BUSINESS COMPUTERS

Intended for the person involved in day-to-day application of electronic computers to business data processing problems, the book begins with such fundamental concepts as the central concept of the file, flow charting, and the general characteristics of electronic computers. Numerous examples are then given to explain the standard techniques of coding. These examples are written in terms of a hypothetical computer called DATAC which is a compilation of the features of many machines. Also included are such advanced techniques as timing estimates, file organization, automatic coding, and random access storage devices. The authors conclude with a summary of the steps involved in establishing a computer application, and an examination of the accounting and auditing problems associated with electronic data processing. (D. D. McCracken and others. New York, Wiley, 1959. 510p., $10.25.)

°AUTOMATION AND COMPUTING

Following an historical background of automation and of analog and digital calculation, the author discusses the logical design of calculating machines and the application of digital and analog techniques to automatic process control, machine tool control, and assembly. The achievements of computing machines in various fields are assessed, including that of sports and translation, and it is shown that automation can play an important part in office procedure and in strategic and economic planning. (A. D. Booth. Galt, Brett-Macmillan, 1959. 158p., $5.00.)

°THE THEORY AND DESIGN OF MAGNETIC AMPLIFIERS

Practical design techniques are combined with theory in this survey of transductors and magnetic amplifiers. Those aspects discussed include transient and steady-state operation of idealized transductors, self-excited and auto-excited transductors, closed loop control systems, transient and frequency response of transductors, high-speed transductors and magnetic amplifiers, balanced magnetic amplifier circuits, low level amplification and multi-stage amplifiers and magnetic modulators. (E. H. Frost-Smith. London, Chapman and Hall, 1958. 487p., $15.00.)

°HEAT TRANSFER ENGINEERING

A unified approach to heat transfer based on two fundamental concepts: the first law of thermodynamics referred to as energy balance, and the various rate equations. The author discusses basic conduction theory; free convection; forced convection, including heat transfer in compact surfaces and to and from liquid metals; radiation between two or more bodies; and unsteady-state conduction in one, two, and three dimensional systems. Various applications are then considered such as the finned or extended surface, the simple boiler and condenser, and the heat exchanger in its various forms. (H. Schenck, Jr. New York, Prentice-Hall, 1959. 310p., $9.25.)

Birmingham College Administrators Visit Montreal

Dr. Venables and Dr. Slater, respectively principal and head of the department of Metallurgy at the Birmingham College of Technology in England, were guests of honour at a luncheon given at the University Club, Montreal, on October 16th, by the Institute. The two men were in Montreal for several days visiting Ecole Polytechnique and McGill University. Dr. Venables also spoke to the Montreal branch of E.I.C. on British Engineering Education.

Present at the luncheon were Dean Mordell and Professor Bruce of McGill, Dean Gaudefroy and Professor Vinet of Ecole Polytechnique, A. Deschamps, G. Boissonnault, G. N. Martin, R. S. Eadie and E. C. Luke of the Institute, representing Dr. Page who was unable to attend.

New Canadian Fairs Council

A committee representing national professional, scientific, engineering and educational organizations has recently announced the formation of a Canadian Science Fairs Council to promote the science fair movement.

Boys and girls attending public and private schools are to show exhibits, demonstrations and collections at these fairs which they have prepared outside school hours. This is an effort to extend students' interest in pure and applied science.

Pending appointment of a full-time science fair co-ordinator, the council will have headquarters in the offices of The Chemical Institute of Canada, 18 Rideau Street, Ottawa.

The new Council is supported by E.I.C., The Chemical Institute of Canada, Canadian Education Association, Canadian Teachers' Federation, Canadian Association of Physicists, and various other professional bodies.

The Engineering Index

The critical needs of engineers and scientists for better access to the rapidly mounting volume of engineering and scientific publications are being studied by a Science Information Service under the leadership of the American Science Foundation.

Engineering Index, Inc., is housed in the Engineering Societies Building, 29 W. Thirty-Ninth Street, New York 18. Since 1885 its job has been to index all technical publications.

Subscribers to the Engineering Index receive abstracts in the form of 3" x 5" library cards daily which give a brief review of all scientific articles which come to the Index's attention. Subscribers who do not wish this complete service can signify their particular area of interest and thus receive all pertinent abstracts, in this same 3" x 5" card form, once a week.

International Association for Bridge and Structural Engineering

E.I.C. recently became a corporate member of the International Association of Bridge and Structural Engineers, as approved by Council in October 1958. The association aims to promote international co-operation among engineers, scientists and manufacturers. With frequent publications, and congresses every four years, it endeavours to disperse knowledge, ideas and results of research work in the sphere of bridge and constructional engineering in general. Headquarters are in Germany and transactions are carried on in English, French and German.

Employment Bulletin No. 59-12

EMPLOYMENT SERVICE

SITUATIONS VACANT

CHEMICAL

CHEMICAL ENGINEERS AND CHEMISTS—with up to 5 years' experience required by leading Chemical manufacturing company to work on the development of new processes and products and the improvement of manufacturing techniques. This is an unusual opportunity to join a top team of Canadian engineers and scientists in a rapidly expanding organization. Salary fully commensurate with experience and qualifications. Applications in writing will be treated confidentially. File No. 6829-V.

CHEMICAL ENGINEER for technical sales. Toronto location. Travel in Ontario. This is an opportunity for an experienced man seeking broad and general sales responsibility in an expanding medium sized chemical company, serving paper, textile, paint and varnish industries. Salary open. File No. 6882-V.

ENGINEERING GRADUATE for general all round duties in chemical process plant in Western Canada. Modern home available. All usual fringe benefits. Permanent position. File No. 6896-V.

MECHANICAL ENGINEER

Required by

SASKATCHEWAN RESEARCH COUNCIL

The position will involve applied research in selected projects concerned with the industrial development of the province. The fields of fluid mechanics, thermodynamics, heat transmission and machine design will be involved, i.e. pilot plant designs, development of pneumatic and hydraulic transport, cold weather lubrication etc. 37½ hour week, 3 weeks vacation, sick leave, pension plan, time allowed for University courses. Salary range $6000-$7500 per annum, dependent upon qualifications. Send full particulars to Engineering Division, Saskatchewan Research Council, Saskatoon, Saskatchewan.

CIVIL

GENERAL SUPERINTENDENT REQUIRED. By General Contractor in Eastern Ontario City. This man must have a proven record of performance on building contracts in excess of one million dollars and be capable of directing the work of several job superintendents with the utmost economy. Applicant must be capable of dealing with Architects and Engineers and settling matters with considerable dispatch. Graduation in civil engineering would be preferable but not mandatory. Top salary and good future prospects for the right man. Replies treated confidential. File No. 6837-V.

THE NEW ZEALAND MINISTRY of Works invites applications for the following vacancies on the Permanent Staff. Positions, qualifications desired and salaries offered are as follows: CIVIL ENGINEER: Corporate membership of the Institution of Civil Engineers, London or equivalent qualification, together with sufficient appropriate experience. Commencing salaries up to £1485 per annum. ASSISTANT CIVIL ENGINEERS: A University Degree in Civil Engineering or Graduate Membership of the Institution of Civil Engineers, London with at least five years of practical experience since commencement of pupilage. Commencing salaries £830 up to £1020 per annum. File No. 6881-V.

ENGINEERING PARTNER. Architect in private practice five years desires civil engineering partner. Location South Central Ontario city. File No. 6883-V.

CIVIL ENGINEER with at least 7 years' structural steel and concrete design experience. Must be able to direct design team in Montreal. Should be bilingual and preferably Canadian University Graduate. State salary expected. File No. 6888-V.

CHIEF ENGINEER, Civil or Municipal. Our client, a very well-established and expanding firm of consulting engineers, requires two chief engineers for Prairie branch operations. Under the general direction of the Branch Manager, responsibilities will involve the direction of all branch engineering work, including the supervision of resident engineers, inspectors, and surveyors, generally engaged in the design and installation of municipal facilities. Requirements include an engineering degree and qualifications for professional registration in any one of the Western Provinces. Applicants should have at least several years of relevant experience, preferably in consulting or municipal work. Preferred age range 35-45. Initial salary $600 to $800 as a minimum, with a very good possibility of becoming a member of the firm within a few years. Write in strict confidence, quoting Reference No. 293, and give full details of training, experience, and personal data to: STEVENSON & KELLOGG LTD., Member Association of Consulting Management Engineers Inc., 810 Royal Bank Building, Vancouver 2, B.C. File No. 6889-V.

The City of Prince Albert, Saskatchewan, (Pop. 22,000), requires an assistant to the City Engineer.

DUTIES: to assist in all phases of Municipal projects and operation of the department, including traffic control facilities. An interest in Community Planning desirable but not essential.

QUALIFICATIONS: Must hold a degree in Engineering preferably Civil from a recognized University.

Position offers varied experience, future security and an opportunity for advancement.

Starting Salary $400.00 to $450.00 per month depending on experience.

Apply in writing stating age, experience and relevant information to the undersigned.

S. E. Parker,
Personnel Officer,
Prince Albert, Saskatchewan.

CIVIL ENGINEER required for appointment to the permanent staff of medium sized firm of engineers and contractors doing heavy construction (Mines, Mills, Grain Elevators, Docks and Bridges) and operating primarily in Northwestern Ontario. Applicants to be Professional Engineers with a minimum of five years' experience in appropriate design and or construction. Experience with heavy piled foundations and cofferdams an asset. Personality and ambition essential. Applicants to give full details and salary expected in first communication. File No. 6892-V.

CIVIL ENGINEER young and energetic, with one or two years' construction experience to eventually manage estimating and expediting for firm of General Contractors, Province of Quebec. File No. 6893-V.

THE ENGINEERING INSTITUTE OF CANADA

This service is operated for the benefit of members of the Engineering Institute of Canada and for organizations employing engineers.

SITUATIONS WANTED

Advertisements are inserted free of charge for members of all classes. Maximum length is 60 words, and repeat insertions must be separately requested in writing for each desired appearance.

SITUATIONS VACANT

Rate: Six dollars per column-half-inch per insertion.

Replies to advertisements should be addressed to the file number, Employment Service, 2050 Mansfield Street. Montreal. Interviews with the Employment Service may be arranged by calling VI 2-5078 at the above address.
