aluminum structures ranged between 50% and 75% of steel and the cost was two to three times. The designer was restricted to the limited number of sizes and shapes available from warehouse stock, unless he was prepared to purchase in mill quantities. The higher price of warehouse material, together with the limitations in sizes, had a considerable influence upon the cost of the structure. Aluminum substations, therefore, could only be justified economically where the initial cost was of secondary importance. Examples of this are coastal regions and locations with an atmosphere heavily contaminated with salt, ammonia or sulphides, where the cost of maintenance of steel stations is excessive.

Welded Aluminum Structures

Aluminum can be arc welded using either one of two conventional methods. Both methods rely upon the use of an inert gas envelope about the arc to prevent oxidation of the molten metal. These are known in the trade as MIG and TIG. The Metallic Inert Gas method uses a consumable aluminum alloy electrode while the Tungsten Inert Gas method employs a non-consumable tungsten electrode. Welders must be specially trained. Cleanliness of the joints is even more important than with steel. A very rigid routine of quality control is necessary to assure high quality welds.

After assessing all the pertinent technical factors, together with fabrication and erection costs, it appeared that a welded construction, similar to the prefabricated steel members previously produced, would be the most economic.

First attempts, at welding substation structures, were far from being competitive, in price, with steel. When using conventional shapes for chord angles and rods for lacing, it was necessary to weld both inside and outside the box member to obtain a good connection. In the welding of tempered alloys, there is a tendency to anneal the metal adjacent to the weld zone, thus preventing the maximum utilization of the physical properties of the alloy. This is due to the precipitation of the alloying elements from the solid solution.[5] The extent of the zone is dependent on the welding speed and other factors which are discussed later in this paper.

The Unique Bulb

It was found in welded test trusses that failure occurred in the chord angle, starting from the edge of the chord angle and progressing inward. The attempts to solve both these problems led to a very interesting and important development.

A bulb was placed at the edge, or toe, of the angle. The legs of the angle were reduced to avoid an increase in the weight. The strength of the chord angle was thus increased without increasing the weight. A notch was placed in this bulb, making possible a combination fillet and butt weld with the lacing. In this arrangement, the weld metal flows down the end and up the side of the lace, producing a strong weld without the need for welding inside.

The most important function of the bulb is the reduction of the heat-affected area. Most experienced welders are familiar with the technique of using a copper back-up plate to rapidly remove the heat from the weld zone to minimize the annealing of the welded metals. The bulb serves a similar purpose so effectively that the chord angle is stronger at the weld than between welds. This means that the slight increase in the moment of inertia of the angle, due to the addition of the weld metal and the small amount of lacing, more than offsets the softening effect on the metal adjacent to the weld zone.

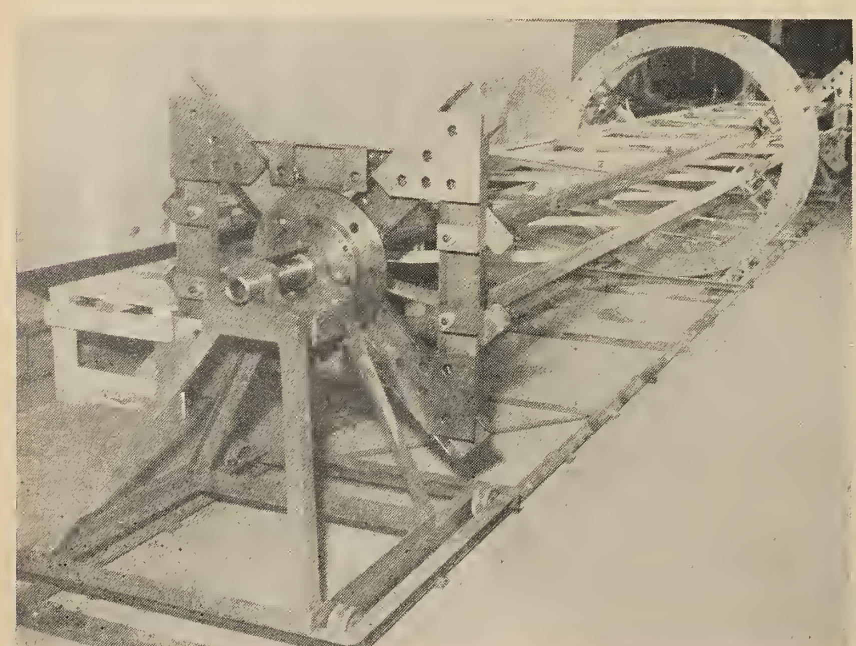
The notch in the bulb performs still another service. By forming a track, when the chord angles are set up for welding, the lacing can be quickly and easily located and held in place until welded.

With welding of substation structures thus becoming economically feasible, coupled with sections designed specifically for welding in order to develop the maximum benefit from the metal, the advantages of shop fabrication accrued.

Production Methods

The next step was to install specialized shop equipment and to develop production fabricating techniques. The extrusions are normally purchased in 30 ft. lengths and must be cut to length for manufacture. Several cutting methods were investigated. A fast, clean cut was desirable; safety and accuracy were important. The solution was in a high speed, carbide-tipped, circular saw. The saw is the type which moves transversely while the work remains stationary. Water is used as a coolant to avoid the necessity for any cleaning of the cut edge prior to welding.

Fig. 2. Partially fabricated column in the special welding fixture



A special welding fixture was designed to accommodate columns up to 36 ft. long. A fixture (Fig 2) consists essentially of 2 large faceplates, fitted with toggle clamps, so that each chord angle can be held securely with 2 clamps at either end. The location of the clamps is adjustable to cover the entire range of column sizes. The face plates are mounted on wheels set on an angle iron track. Their location can be adjusted to suit box members from 4 ft. to the longest.

The fixture is positioned so that the panels of the column are at 45° to the horizontal. Then, the lacing for one panel is laid in place in the tracks formed by the notches in the chord angles. The welder starts welding at one end and proceeds to the other, completing the panel. The face plates, supporting the work, are rotated 90° and locked in position while welding each subsequent panel. The purpose for the 45° angular position for welding is to reduce operator fatigue and to put both chord angles within easy reach of the welder.

To prevent distortion in the longer columns, a third element of the fixture is used. This comprises a ring large enough to surround the largest column. It is fitted with 4 wheels with their faces machined to a 90° vee. These wheels are adjusted to contact the chord angles to prevent their movement. This ring is likewise mounted on wheels and is moved along the track ahead of the welder. With this equipment, it is possible to construct a 30 ft. girder with a maximum deformation due to welding of ⅛ in.

The MIG welding process was selected in preference to the TIG method for several reasons. MIG uses direct current with high current densities, permitting high welding speeds because the current in the consumable electrode is not limited by the melting temperature of the electrode as in the TIG process. A high welding speed means more rapid cooling with less distortion and less annealing in the weld zone. High current densities, together with the efficient heat transfer in the arc, make good penetration possible. The process is ideal for position welding and the automatic feed of the electrode is less fatiguing to the operator and less time consuming than the stick electrode used in the TIG process. The net result of these factors is increased mechanical properties, better corrosion resistance and lower labour costs.

Production welds are carefully inspected for cracks and flaws and samples are tested regularly to assure weld quality. Test specimens are welded under the same conditions as production assemblies. The specimen is cut transversely to the weld and etched to show the weld penetration. Tension tests are also performed to ensure that the weld strength conforms to design requirements.

A 3/64 in. diam. electrode of 56S aluminum alloy is fed into the arc at a rate of 450 in. per min. The arc travel speed is approximately 12 in. per min. Since an Argon gas shield is used to prevent oxidation rather than a flux as with steel, extensive cleaning of the weld is unnecessary. After welding, a light wire brushing is performed, however, to facilitate weld inspection.

Advantages of Welded Aluminum Structures

It is obvious, from the foregoing, that the key to the economic utilization of aluminum in substation structures is its extrudability and weldability. As a result, entire columns and beams can be fabricated in the shop in a fraction of the time required to assemble a bolted structure on the site. Shop fabrication can be performed under more suitable conditions, using specialized equipment and skilled labour more efficiently. Work in the field frequently involves living accommodation for the construction crew. With the reduction in field labour, this expense is likewise reduced.

The light weight of aluminum is reflected in many places. The handling of chord angles in the shop requires only one man; a comparable steel angle would require two men or a crane. Transportation costs and the structure foundation costs are reduced. Smaller crane capacity is possible. Some small stations have been erected by hand. With the reduced weight of the girders, it is frequently possible to attach such items as; switches, 'bus supports, fuses, etc. on the ground and hoist them into place along with the girders. The men can guide and handle the lighter beams more easily during erection.

Since the structural members have not been subjected to the heat of galvanizing pots, they are straight and true. Mating parts are easily aligned. Sharp points are eliminated. The faces of the columns are smooth which simplifies the fitting of components and makes climbing easy.

Aluminum's excellent corrosion resistance gives a better appearance and reduces maintenance and power interruptions for painting. In very aggressive atmospheres, galvanized steel stations may require painting as often as every five years.

With the present price differential of the two metals, the first cost may favour the steel structure. However, with the savings in transportation and erection, the installed cost frequently is in favour of aluminum.

Standard Design

The development of standards was the next logical step in the evolution of this system. Standardization was necessary for many reasons. Since each extruded shape requires its own die and the extrusions must be purchased in 25 ton quantities to obtain the lowest price, it was desirable to keep the number of shapes to a minimum. The present range of columns and girders can be fabricated from a total of 5 shapes, 3 chord angles and 2 tee lacings.

Similarly, the sizes of columns and girders have been standardized. The sizes shown in the table below have been found to satisfy most requirements both structurally and economically.

DEPTH (Inches)	WIDTH (Inches)			
	12	24	30	36
12	x			
24	x	x		
30	x	x	x	
36	x	x	x	x
48	x	x	x	x

The application of these shop-fabricated aluminum members to the standard substation is shown in Fig. 3. This is a 23 kv. 3,000 kva. station with a secondary of 4160 v. It was laid out for 3 secondary feeders ultimately, with 2 connected at present.

The primary structure is essentially a duplicate of the high voltage section of the steel station (Fig. 1) which was previously described. It consists of 12 in. x 36 in. columns, 29 ft. high, with 12 in. x 36 in. girders. It is designed for line pulls of 1000 lb. each. The aluminum weight is 1030 lb., which is 41% of the weight of the similar steel structure.

In the secondary structure, the feeders all leave the station in the same direction so that the weight of aluminum cannot be directly compared with that of the secondary steel structure in Fig. 1. Four 12 in. x 12 in. columns, 20 ft. high, with 12 in. x 24 in. girders and some 12 in. trusses are used in the secondary structure. The aluminum weighs 2600 lb.

If this structure were scaled down to the size of the steel structure (Fig. 1), the weight of aluminum would be 1640 lb. or 40% of the steel design.

By careful co-ordination of the design of the various substation arrangements and voltage classes, standard lengths of columns and girders have evolved. The advantages of standardization have been achieved without losing the flexibility necessary to accommodate special designs.

The reduction in engineering time for standard substations is immense. There is also a considerable saving in designing a special station. Tables of the properties of the various box member sizes assist the designer in quickly selecting the column or girder for his needs. Standard drawings reduce the drafting time to a few hours for standard station arrangements. The draftsman, by using pre-printed detail drawings of columns and girders, has only to add the overall dimensions and locate the holes.

When designing standard aluminum substation structures, careful consideration must be given to; the properties of the aluminum alloy, the deflection of members and the method of splicing and joining sections.

Design Data

The aluminum alloy used in the extruded chord angles and tee lacings is a heat treated alloy with a minimum guaranteed yield strength of 37,000 p.s.i. and a guaranteed ultimate strength of 42,000 p.s.i.[6] The high strength of this alloy allows a working tensile stress of 17,500 p.s.i. to be used in the design of the aluminum structures. This represents a factor of safety of 2.12 based on the minimum guaranteed yield strength. The factor of safety, with respect to yield strength, is larger than ordinarily encountered in specifications for structural steel, because there is a smaller spread between the yield strength and the ultimate strength of aluminum.

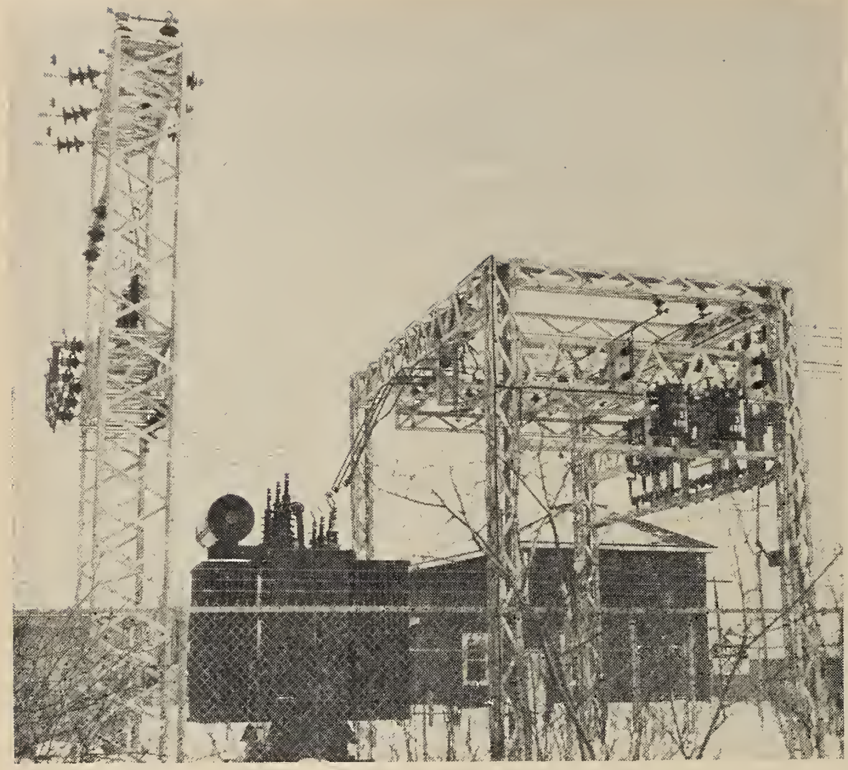


Fig. 3. Prefabricated aluminum structure 23 kv. primary, 4.16 kv. secondary

Deflection is limited to 1/300 of the span by the N.E.M.A. Standard for Power Switching Equipment No. SG6-8.02E, October 1956,[7] but this mainly concerns steel structures supporting air switches. This limitation is intended to prevent binding and difficult switch operation due to misalignment of the operating mechanism. Deflection on upright members can exceed this limit of 1/300 without affecting switch operating mechanisms and, in most cases, a deflection of 1/150 is allowed. Unless higher line tensions are specified, a line pull of 1,000 lb. per conductor is used.

Ice loads, for steel structures, are usually assumed as 100% of the weight of the structure. Because of the difference between the weight of steel and aluminum, the weight of the structure should be multiplied by a factor of 2.8 to calculate an equivalent ice loading.

Splices and connections are made from ⅜ in. thick plate of 65S-T6 aluminum alloy. Bolts, nuts and lock nuts used to assemble the aluminum structure are steel, aluminized to prevent corrosion. Steel bolts were chosen because of their higher shear strength and lower cost as compared with aluminum alloy bolts.

Aluminizing is a relatively new process whereby virtually pure aluminum is applied to steel parts by a hot-dip method. The aluminum is diffused into the steel, forming an interfacial layer which provides a tight metallurgical bond for the outer layer of pure aluminum. Atmospheric exposure tests of aluminized steel have been conducted in the United States over the past 30 yr. The results indicate that aluminized steel has at least three times the life of galvanized steel in industrial and rural atmospheres. Recent tests have also demonstrated the superior corrosion resistance of aluminum-coated steel in marine environments.[8]

The minimum diameter of bolts used in splices, gussets, braces and other structural connections is ⅝ in. The structural members are designed to use as few different lengths of bolts as possible. The nuts are washer faced to bear evenly on the aluminum sections. Split lock washers which might damage the aluminum are not used, but to ensure positive bolting action, concave lock nuts are assembled after the nut has been fully tightened. Aluminum bolts of 24S alloy can also be used but both the bolt and nut should be anodized or lubricated to prevent galling of the threads.

During the month of December, 1959, the James R. Kearney Corporation of Canada, Limited in conjunction with the Aluminium Laboratories Limited, conducted a series of strain tests on various sizes of welded columns to confirm design calculations. Nine different columns were tested and load-deflection readings were made. Final results are not available at the time of writing, but preliminary reports appear to substantiate the design calculations.

Based on the tests, additional design work is proceeding with the objective of reducing the material content still further, particularly in the smaller sizes of welded members.

Conclusion

Standard prefabricated substation structures offer the user many advantages: faster delivery, less field work, less engineering time and lower installed cost. The manufacturing and engineering costs are reduced by the use of standard components and designs.

The use of aluminum adds still more advantages to the standard substation: better corrosion resistance, improved appearance, reduced maintenance, lower erection costs, reduced weight and greater flexibility.

The development of this system has made the installed cost competitive with steel. It appears this trend will continue. Aluminum substations are gaining popularity throughout Canada.

LONG RANGE HYDRO PLANNING FOR MANITOBA

L. A. Bateman, M.E.I.C.,
Systems Planning Engineer,
The Manitoba Hydro-Electric Board, Winnipeg.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

This paper outlines the growth of the Power Industry in Manitoba and the location of the Water Power Resources in and adjacent to Manitoba. It discusses factors which will bear on the development of these resources and the methods used in evaluating system growth. It presents a visionary picture of the full development of the Nelson River and redevelopment of the Winnipeg River and includes an Appendix on economic factors affecting system development with a request for an exchange of views on economic methods of project evaluation.

IT HAS become increasingly important for electrical utilities to plan for their system expansion in an orderly fashion. The complications of system interconnection, of system load growth, and variable costs, make it more important than ever that utilities select a sequence of development which will produce the most reliable power at the lowest possible cost to their consumers. A short review of Manitoba's position is presented for the benefit of those not familiar with the growth of Central Station power in Manitoba.

Growth In Manitoba

Back in 1906, the first Winnipeg River plant at Pinawa was constructed by the Winnipeg Electric Company. Up to that time, power had been supplied by a small number of thermal-generating units, located in the City of Winnipeg proper. The municipal authorities decided to enter the generation field with a municipally owned plant. Consequently the City of Winnipeg, having undertaken to develop the Pointe du Bois site, brought this plant into production in 1911. This was the start of the City of Winnipeg Hydro-Electric System. Subsequently, in 1923, the Winnipeg Electric Company developed Great Falls on the Winnipeg River installing the first high head propeller type units on the continent. In 1931, the Seven Sisters site was developed by a subsidiary of the Winnipeg Electric Company, and the Slave Falls site was developed by the City of Winnipeg Hydro-Electric System. These partial installations gave the area sufficient capacity to meet requirements until the end of the war, and then both utilities were without sufficient capacity to meet all conditions of river flow and corresponding load requirements. Consequently, both Winnipeg Electric Company and City Hydro commenced a programme of extension to the Seven Sisters and Slave Falls sites respectively, and by 1952 and 1949, both of these developments were completed to capacity by these two organizations. In 1931, the Winnipeg Electric Company contracted to generate all the power needs of The Manitoba Power Commission, which supplied at that time all the rural areas of Manitoba including the Western part of the Province.

In 1947, the Manitoba Government retained the services of Dr. T. H. Hogg to bring down a report[1] on the future policy of the Provincial Government regarding generation and transmission of power. In 1948, Dr. Hogg's report was tabled and the main recommendation was to the effect that all new generation should be undertaken by the Provincial Government.

As a result of this recommendation, the Government immediately initiated development of the Pine Falls site on the Winnipeg River which came into operation in 1951 and was tied into and operated by the Winnipeg Electric Company system.

In 1951, The Manitoba Hydro-Electric Board was formed and assumed the ownership of the Pine Falls plant which had been undertaken prior to the formation of the Board by the Department of Mines and Natural Resources, and it proceeded, upon completion of Pine Falls to develop McArthur Falls, which was the last remaining site on the Winnipeg River. The rapid growth of the energy demands in Manitoba and the farm electrification program pointed to additional sources of generation being made available as quickly as possible.

The development of the last Manitoba site on the Winnipeg River then required a move to thermal generation in order to keep generation in pace with the rapidly growing demand. There was also the problem of reorganization of the power industry based on Dr. Hogg's report. Following many months of negotiations and the purchase by the Provincial Government of the electrical assets of the Winnipeg Electric Company, the situation resolved itself into:

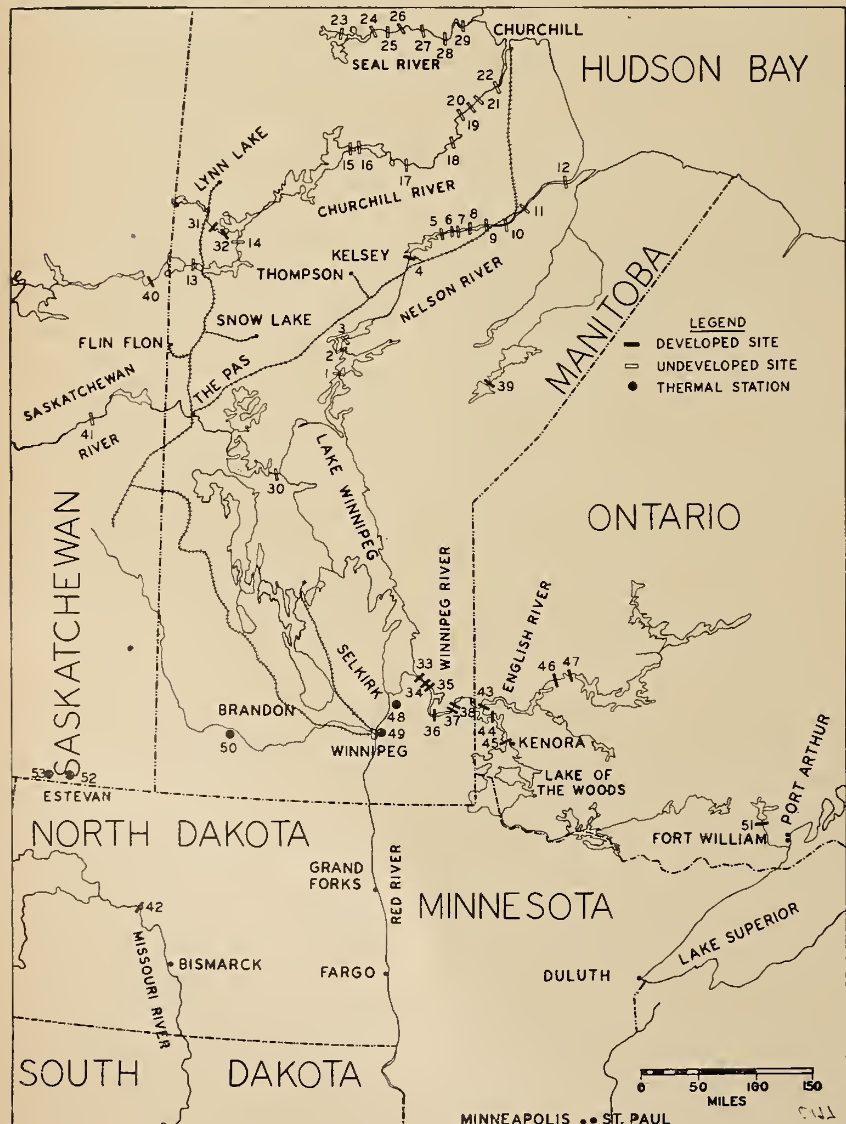
1. The Manitoba Hydro-Electric Board being the principal generation and transmission agency in the Province;
2. The Manitoba Power Commission being charged with the responsibility for distribution in all of the Province except the City of Winnipeg;
3. The City of Winnipeg Hydro-Electric System left with its own distribution within the city, the newly acquired distribution facilities of the Winnipeg Electric Company within the city and the retention of its own two hydro plants on the Winnipeg River, together with the thermal station at Amy St. in the City of Winnipeg proper.

Prior to this re-organization, the City Hydro and the Winnipeg Electric Company were operated as two separate generating systems. However, under the present re-organization both systems operate in parallel and are tied in at the 60 kv. level at both Mill St. and McPhillips St. both within the city boundaries. The accompanying Fig. 1 shows a map of the Province of Manitoba with the location of the major generating stations.

In addition to the outline above The Manitoba Hydro-Electric Board undertook to interconnect with the Northwestern region of the Ontario Hydro-Electric Power Commission in 1957, and have been operating an interconnection with Ontario since that time. In addition, The Manitoba Hydro-Electric Board and The Saskatchewan Power Corporation are constructing a 230 kv. line which will shortly be placed in service at 138 kv. between the Boundary Dam Thermal Generating Station near Estevan of The Saskatchewan Power Corporation and the Brandon Thermal Generating Station of The Manitoba Hydro-Electric Board.

To keep pace with the increasing power demand, The Manitoba Hydro-Electric Board constructed the Brandon Thermal Generating Station installing four 33 mw. units for a total capacity of 132 mw. in 1958. This plant feeds into the 115 kv. transmission system which belongs to The Manitoba Power Commission in its transmission pattern from Winnipeg West to Brandon. In addition, The Manitoba Hydro-Electric Board has constructed a second thermal-electric generating station at Selkirk, some 20 miles north of Winnipeg. The initial installed capacity is two 66 mw units, and these will both be commissioned during 1960. The interconnection with The Saskatchewan Power Corporation, which was briefly mentioned earlier, will operate initially at 138 kv., but a complete provision for future operation of 230 kv. has been built into this line. It is a wood-pole "spar-type construction" line, with a voltage regulating transformer with on load tap changing gear located at the Brandon Thermal Station.

Fig. 1 Map of Manitoba and Surrounding Area showing power developments, and potential developments.



In the northern part of Manitoba, The Manitoba Hydro-Electric Board has the Kelsey Generating Station, at present under construction, to supply a load to the International Nickel Company of Canada. This station is scheduled for commissioning of the first two of five 42,000 hp units in the summer of 1960. The Churchill River Power Company, which is a subsidiary of the Hudson Bay Mining and Smelting Company, owns and operates the Island Falls Generating Station on the Churchill River in Saskatchewan. This plant supplies loads in the Flin Flon area, and the requirements of the Hudson Bay Mining and Smelting Company, located in Manitoba, are met from this generation.

There are two other small electric developments in Northern Manitoba, one at Kanuchuan in the eastern part of the Province, and the second at Laurie River where two plants are developed to supply the Lynn Lake mining operation. Kanuchuan has a present installed capacity of 1900 hp with an ultimate of 5700 hp while the Laurie River site No. 1 has a present installed capacity of 7000 hp, which is its limit, and Laurie River No. 2 also has installed 7,000 hp.

This brief review of the developments in operation or shortly to be placed in operation in Manitoba, will serve as a background for discussion of the more complex problem of the development of the electrical system of Manitoba which follows.

Load Growth

Referring to Fig. 2, Firm Winter Peaks of Southern Manitoba System 1934-35 — 1959-60, it will be observed that from 1940-41 there has been a constant growth of approximately 7% represented by the dots. This trend in 1958-59 was re-established after a two year low from 1956-58, where increases were relatively very small. This return to the trend line was established by the peak of 617.1 mw that was experienced in January 1960.

The 7% load growth when compounded, amounts to a doubling of the electrical system approximately every ten years. The peak load for the Manitoba System in 1948 was 309.6 mw and in 1959 it was 614.1 mw. The energy requirements in 1948 were 1,581,000,000 kwh. and in 1959 they were 3,237,400,000 kwh.

In 1960, with the installation of the

two thermal units at Selkirk, the generation capability of the Southern System will be 850 mw made up as follows:

Winnipeg River	—Hydro-electric	560 mw
Amy Street	—Steam-electric	45 mw
Brandon	—Steam-electric	122 mw
Selkirk	—Steam-electric	123 mw
	Total	850 mw*

*With station service deducted.

When the Northern System capacity, now being installed at Kelsey, is added to this, the figure will exceed 1,010,000 kw. although the Northern and Southern Systems are not interconnected at present.

Assuming that we are going to continue these upward trends in power use, we shall reach a 2,000,000 kw. system by 1970 and a 4,000,000 kw. system by 1980 and perhaps a 16,000,000 kw. system by the year 2000. Now it is to provide for these possible rates of growth that we shall examine the future trends of Manitoba's power generation and major transmission requirements to satisfy loads of this magnitude. We must so maintain our position that we can meet this doubling every ten years should it happen that our expansion continues to assume a 7% or better rate of load growth.

Manitoba is favoured with large base metal resources and potential base metal industries. This is evidenced by the start in Northern Manitoba—at Lynn Lake, Thompson and so on—to bring some of these known resources into production. The map of Manitoba (Fig. 1) shows that most of the hydro-electric resources at our disposal are a considerable distance from the Southern load centres as we know them today. There is every indication that Manitoba may exceed the 7% load growth trend in the future.

System Planning

(a) *Water Power Resources in Manitoba:* The water power resources of Manitoba, both developed and undeveloped, are estimated at approximately 7,500,000 hp at 80% efficiency and 80% load factor. About ¾ of a million hp or about 10% of our total hydraulic resources are located on the Winnipeg River in Southeastern Manitoba, and the remaining 90% or close to 7,000,000 hp of our water power resources are situated in the Northern part of the Province. At the present time, of all the water powers in Northern Manitoba, the site which offers the most encouraging prospect for development for transmission to Southern Manitoba is the Grand Rapids site where the Saskatchewan River enters Lake Winnipeg. At this site upwards of 328 mw can be developed, and the storage capacity behind this site in the Cross and Cedar Lake areas is substantial.

The electrical energy that may be produced at this site is nearly one-half of the total present consumption in Manitoba. This energy production will be made possible by impounding the waters of the Saskatchewan River in a large reservoir with 7,000,000 acre ft. of storage capacity. This 7,000,000 acre ft. of storage capacity is effective on a head of 120 ft. The storage in Lake of the Woods and Lac Seul amounts to 8,500,000 acre ft. and this is effective on a head of 255 ft. for the Winnipeg River system in Manitoba. Both of these storage reservoirs empty into Lake Winnipeg.

The Nelson River which falls through approximately 700 ft. as it travels from Lake Winnipeg to Hudson Bay, offers the richest promise for water power development in Northern Manitoba. Lake Winnipeg, a body of water containing some 18 million acre feet of storage between the elevations of 712 and 715 offers great promise for the development of firm capacity on the Nelson River at all the sites listed in Table I.

In addition to the water resources of the Nelson River there is also the Churchill River with sites available in Manitoba for development. These are detailed in Table II. Mention was made previously of the Island Falls plant on the Churchill River located in Saskatchewan. This plant, No. 40 on Fig. 1, supplies the Hudson Mining and Smelting Company load. This load requires the full output of the Island Falls site, with its accompanying storage on Reindeer Lake, and it is not inconceivable that a tie with the Nelson River site under development at Kelsey or with the Grand Rapids site under development for 1964 will be of substantial importance to the sustained production of mineral wealth from the Flin Flon operation. A cost benefit study on the interconnection with the Island Falls and Kelsey plants is underway.

There is also the Seal River in Northern Manitoba which has some seven sites. These are listed in Table III. The balance of the better known sites in the Province are listed in Tables IV, V and VI. There are innumerable other sites, some on the Burntwood River, in the capability of ten to thirty thousand hp, as well as innumerable other sites in the Eastern part of the Province on the rivers that

*Output Power at generator terminals.

empty into Lake Winnipeg, but most of these have very limited storage and do not appear economic under present known conditions. However, as time passes and more information about our natural resources is gathered, then it is to be expected that certain of these sites will become economically attractive for one reason or other.

(b) *Developed Power Resources Adjacent to Manitoba:* Fig. 1 shows the developed hydraulic sites on the English and Winnipeg Rivers, and the Garrison Dam site on the Missouri River in North Dakota. These with their known installed capacities are listed in Table VIII.

(c) *Power Exports:* Manitoba is at present interconnected at 138 kv with the North West Region of the Hydro Electric Power Commission of Ontario, and a 230 kv tie is under construction between Brandon and Estevan to interconnect the Manitoba System and The Saskatchewan Power Corporation system. This tie will operate initially at 138 kv but full provision is being made for operation at the 230 kv level when conditions warrant.

These interconnections make possible the day to day scheduling of interchange power to the mutual benefit of all parties of the interconnection.

Capacity purchases are also possible on a short term future basis to help the development of the interconnected systems.

The Manitoba Hydro-Electric Board has been aware of the growth of the power facilities to meet increasing loads in the area south of the 49th parallel. The long range program for the Dakotas alone indicates that the 20 yr. power planning program for this area requires an additional 1500 mw by 1980, in addition to that power which is planned. The latest information[2] indicates the following:

State	1958 Installed Capacity in Megawatts	
North Dakota....	507	
South Dakota.....	543	
Total Dakotas....		1050
Minnesota........	1947	1947
Total Dakotas and Minnesota......		2997

This means the Dakotas alone will have an installed capacity of close to 3000 mw in 1980. The growth of the electrical systems in the northern part of the central United States will require the extension of the 230 kv transmission system. This is now at Fargo some 225 miles from Winnipeg and at Garrison Dam some 175 miles from Brandon which is in reach

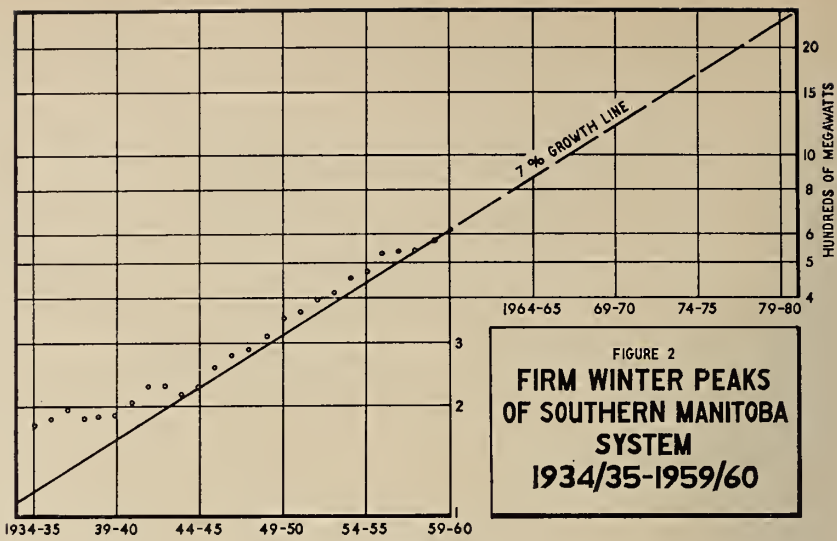

Fig. 2

of The Manitoba Hydro-Electric System. The prospect of development of a large thermal generating station supplied directly from the coal seams adjacent to the Missouri River and the installation of large size units is under study. This thermal generation could be of assistance to Manitoba in the future. In addition, it would provide a ready market for an equichange agreement to be established with the appropriate authorities in the Dakotas for disposal of some of Manitoba's abundant hydro-electric energy and to a considerable degree, justify the high initial costs of transmission from the Nelson River sites in Manitoba.

On the basis of installing capacity at Northern sites, prior to the indicated need of the Southern areas, the power could be made available to the Northern States on a share capacity basis, which, under the terms of the National Energy Board[3] might be classified as plant construction diversity.

Under these conditions energy might be made available at the border at an incremental cost of between .75 mills and 2.25 mills depending upon the amount of energy required and upon the reliability of the interconnection for disposal of this energy. This analysis is based on average flow conditions. Should very low stream flows be experienced in the two watersheds now being considered by The Manitoba Hydro-Electric Board (Lake Winnipeg excluded) then no surplus energy would result. However, the abundance of thermal-energy south of the line might serve as a firming source for the future Nelson River Manitoba Hydro installations. On the other hand when above average stream flows result, large volumes of dump energy could be available at very attractive rates to any thermal producing utility.

(d) *Project Evaluation:* It has been our policy in selecting a new source for development to study various sequences which will provide the most economic power available to the system as a whole, when fully integrated with the existing resources. Consequently in order to properly assess the economics of a project, a study of the system growth and costs for a considerable period of time into the future must be made and these various component costs brought to a "present worth" basis. The date on which this present worth comparison is made is really of little consequence providing all costs are brought to the same common denominator. This common denominator is important and should provide for a means by which the effects of later additions may be eliminated. In order to eliminate the influence of later additions these should be the same for all sequences compared, as far as practicable, or reasonable, beyond the date of cut off.

We believe in evaluating projects that the sinking fund method is the most equitable of all methods of analysis. The development and significance of this sinking fund method, as compared with the straight line depreciation method, is outlined in the attached Appendix.

It is readily appreciated that most hydro developments of large capacity can best be justified if a load building period is overcome either by:

1. The temporary purchase of capacity;

2. The sale of energy or capacity from a new hydro plant through interconnections with other utilities, and this can then be recaptured as the developing utilities load grows to the

point where it can be absorbed within the system.

In Manitoba, the cost of future hydro-electric development, the closest of which (Crand Rapids) is some 250 miles from the Winnipeg load area and the furthest of which is some 600 miles from the Winnipeg load arca, is in the category of marginal economic justification without some prior load building when compared to thermal capacity with present costs.

(e) *Tools:* In Manitoba, to assist in planning the electrical system development, The Manitoba Hydro-Electric Board has installed an A.C. Network Calculator. This unit has the following number of components: 12 generators, 138 impedance units, 24 pi-line units, 60 capacitor units, 72 load units, 18 mutual transformer units and 9 autotransformer units. It also has automatic watt regulators on generators, automatic scale selection on the Master Instruments[4] and a recording table.[5] This calculating board was installed in August 1959, and has been in continuous operation since that time and the planned work load for it will take many more months of time. It is expected then, that this Calculator will be available for use by other than the utilities of Manitoba.

The other components of system development involving the hydraulic work are carried out by utilizing simulation study techniques, and these are best handled by digital computers. This was the case in the determination of some of the hydraulic characteristics for the Grand Rapids site; this work was performed on an IBM 704 Machine. The hydraulic group do simulation studies by hand, when the justification for digital computer use cannot be made.

As any power system develops, so do the number of problems associated with its planned growth, its daily operation, its most efficient use of hydro storage, and thermal capacities, and the minimization of system transmission losses. All of these factors become more complex, and more dependent upon judgment, than upon the ability of man to compute proper results by analytical determination, hence, it is for these reasons that most complex power system developments are aided by mechanical-electrical machines.[6, 7] The combined complexity of both the hydraulic analysis and the electrical analysis of a system point to a greater utilization of the digital computer. These machines assist the Planning people in their task of providing a reliable system to produce energy at minimum cost. There are many systems in the world which have integrated hydro and thermal resources[8] but a careful review of the literature[9] that has been printed to date indicates that there are effectively no two systems with the same basic problems. The development of the rule curves of operation of storage reservoirs is a problem to which there is no easy answer. The answer lies in the installed capacity, the available interconnections and the load and incremental energy cost pattern of the utility which has this storage available for its energy production.

System Development

The next step to meet our expected load growth for 1963 is to be a capacity purchase from the Saskatchewan Power Corporation. This was under negotiation at the time this paper was prepared. Consequently, the first new capacity that Manitoba will bring in above the present capability for the Southern System of 850 mw will be a hydraulic installation at the Grand Rapids site where the Saskatchewan River emptics into Lake Winnipeg. This Grand Rapids plant probably would have an initial installation of two units each rated at 82 mw, 0.95 p.f., 13.8 kv. Propeller turbines appear at this stage to be the economical choice. These, we believe, would be the largest fixed blade propeller type units made to date by any company. Studies are continuing on economic setting, F.S.L. and a number of other factors which must be settled before construction can be undertaken at this site.

The selection of Grand Rapids is the result of a consideration of many alternative sites and many alternative sources of generation. Introduction of the Grand Rapids power into our present system which is predominantly 110 kv. has been settled on the basis of three 230 kv. lines. Essentially, it is desirable to have this 255 miles of transmission line operate at the highest voltage practicable. However, there are operation and design problems associated with system development which have resulted in thc choice of a 230 kv. voltage level to inject this Grand Rapids power into the Southern System. One of the predominant reasons for the 230 kv. voltage level in preference to a higher voltage line has been the line charging requirements. These point to the installation of the largest generator possible at Grand Rapids and the proposed units of 86 m.v.a. will satisfy the line charging requirements provided suitable shunt reactors are installed at the Winnipeg end of these transmission lines.

Present plans call for subsequent units to be installed in 1965 and 1966 bringing the plant to a capacity of 328 mw, with provision for a 5th and 6th unit. The final number of units for this site is dependent upon further studies. The establishment of the 230 kv. connection between Winnipeg and Brandon is planned for completion in the year 1962. The 230 kv. switching station at Steep Rock will permit a 230 kv. tie with the Saskatchewan Power Corporation's Northern System, where they are engaged in developing a hydraulic site at Squaw Rapids on the Saskatchewan River. It will also provide a supply point for the Interlake loads. Following the development of the Crand Rapids site there are several alternatives for future power. These are as follows:

1. An extension of the Selkirk Thermal-Electric Plant;

2. An extension of the Winnipeg River generating capacity;

3. Development of the Nelson River power;

4. Addition of nuclear units.

Selkirk: The site at Selkirk where The Manitoba Hydro-Electric Board will have two 66 mw units installed at this time is capable of being developed to a million kw. The injection of this additional power into the system will probably be made at the 230 kv. level, and connected into the present system at the Rosser Road and St. Vital Terminal Stations where substantial interconnections with several 110 kv. circuits are provided for.

Extension of Winnipeg River Generation: Future development of the Winnipeg River has three major aspects:

(a) Full utilization of energy resources;

(b) Development of peaking capacity;

(c) Development of Spinning Reserve.

While detailed engineering studies have not been completed to date, one attractive scheme for utilization of this river to fill the role outlined above would be the re-development of the upstream plants in Manitoba in such a manner as to reclaim some undeveloped head and to utilize to the maximum the upwards of 10 sq. miles of forebay that are available.

The Winnipeg River plants are designed for a flow of between 23,000 and 36,000 sec. ft., hence by redevelopment and bringing all plants to the same designed load factor, capacity and energy could be realized.

The load factor to which the downstream plants may be developed need only be limited by the hydraulic problems associated with the reaches of the river between these plants.

The Manitoba system which is predominantly composed of fixed blade propeller units must rely on these units operating at relatively low efficiencies to provide spinning reserve, or alternatively rely on thermal units with their associated expense.

The re-development of the Winnipeg River plants for peaking purposes and full utilization of energy resources may well be accompanied by the introduction of Kaplan or other variable pitch blade units to economize on water, particularly in low flow years. Such units would provide efficient energy with a good spinning reserve component. One upstream site on the basis of preliminary investigations would have 225 mw of installed capacity to provide the system with spinning reserve at a reasonable cost. The price would be between $200 and $250 per installed kilowatt on the basis of present day costs.

The programmed installation of additional capacity in the upstream Winnipeg River plants would be followed by a systematic re-development of all downstream plants in such a manner as to have them all conform with this new role.

This peaking capacity associated with the re-development of the Winnipeg River is planned to be delivered into the present system at the 230 kv. level. This would leave the present 110 kv. system to supply local loads, and in addition they would assist the 230 kv. transmission system during peak operation periods. The introduction of the 230 kv. transmission will result in a considerable reduction in transmission losses from Winnipeg River to the Winnipeg load area.

It is quite evident that the full re-development of the Winnipeg River cannot proceed without being co-ordinated with the first and the third alternative sources of new generation or alternatively with nuclear energy development for Manitoba.

Development of Nelson River Power: The fact has been established that the Nelson River represents one of Manitoba's best possible sources of power, with storage capabilities on Lake Winnipeg to permit an installed capacity of upwards of 3,800,000 kw. at 80% efficiency and 80% load factor operation. Some of the major problems associated with development of Nelson River power are of course the site construction difficulties.

We have found in the development of the Kelsey plant that permafrost poses a formidable problem in power development at Nelson River sites. It is not proposed here to enter into a discussion on the construction aspects of development of Nelson River power, except to say that these may have an influence on future development on this river.

Delivery of power from the Nelson River in the magnitudes in which it is available would indicate that the 230 kv. transmission network proposed and economical for the job, which it is being developed to do, would not be the most satisfactory voltage for Nelson River power delivered to Winnipeg.[10] It is proposed that the majority of this transmission would be on the east side of Lake Winnipeg. Using 460 kv. and the difference in distance coming around via Grand Rapids instead of the east side of Lake Winnipeg results in an estimated additional cost of $140 million on a present cost basis. There are many difficulties to overcome in construction in this area which is predominantly muskeg and rock country. The route of these 460 kv. lines may provide part of the tie for the proposed cross Canada transmission line,[11, 12]

Addition of Nuclear Units: The establishment of the Whiteshell Atomic Research Station in Manitoba will provide an opportunity for engineers of The Manitoba Hydro-Electric Board to keep abreast of developments in the nuclear energy field. It may well be that by 1970 this source of energy will be a major contender with Nelson River Power. Manitoba is co-operating in every manner possible toward a sound engineering and economic assessment of this source of energy.

Conclusion

In addition to some of the hydraulic and electrical planning which has been outlined and the presentation of the basis on which projects should be evaluated, the writer has attempted to give a picture of the long range planning that is necessary in order to properly develop and evaluate the growth of the electrical industry in Manitoba. There are many other aspects of this job which have not been mentioned but which will be investigated as time and man power become available.

APPENDIX

Economic Factors Affect System Development

Engineering is closely allied with economics—normally a development program must pass the acid test of economic analysis. When considering new generation for an electrical utility, it is very important to assess the cost of energy production for a number of years ahead. The paper has stated that we believe in project evaluation using the Sinking Fund Method. It is proposed here to discuss the Straight Line Method of depreciation and the Sinking Fund Method and to emphasize the desirability of using the Sinking Fund Method for project evaluation.

Classical accounting usually claims that a system to be "in balance" must have assets in a form represented by physical plant or cash reserves and not be dependent on the earning power of a fund which is subject to changes in interest rate and amount of earning each year.

Many utilities have a practice of using

one method of evaluation for System Planning purposes and an entirely different method of bookkeeping for annual statements.

It is not intended here to propose changes in Annual Statements which are usually made in conformity with the tax laws of the land, but to recognize the importance of proper evaluation of new projects on their acceptance or rejection as economic energy producers.

The Straight Line Method of depreciation in Planning studies results in a distorted picture of the merits of high capital investment, long life, and low operating costs for a hydro site as compared to low capital investment, short life and high operating costs of a thermal development.

It is assumed here that:

1. Hydro sites have a life of 44 years;
2. Thermal - electric developments have a life of 25 years;
3. The cost of money is the same for both projects;
4. The purpose of a depreciation charge is to recover the original investment at the end of the assigned life, (assuming no salvage value).

Straight Line Depreciation: In the Straight Line method, the average annual depreciation charge is the original investment cost divided by the life in years. For example, if the investment cost of a hydro plant amounted to $100 million and the life 44 years, the annual computed depreciation charge of 2.27% would be $2,273,000. If no improvement rate is assigned to this fund in the books, the accumulation will result as shown in the graph Fig. 3, Curve A.

A corresponding thermal plant of equal capacity is assumed to cost $40 million and has an assigned life of 25 yrs. The annual computed depreciation charge of 4% would be $1.6 million. The accumulation will result as shown on (Fig. 3) Curve B.

Payments in either case may be made monthly or annually, in which case the curve could be made to indicate the stepped nature of the payments. This refinement is not shown.

There are variations in the Straight Line Method. The curves of Fig. 3 assume no earning on the Fund, and depreciation charges were computed annually on the original investment. Two alternatives might now be considered.

1. That the depreciation account money earns interest at 5% and would produce an amount of $340 million at the end of the useful life as shown by Curve C of Fig. 4, as compared to the original capital cost of $100 million. This earning could be attributed to the fact that the Depreciation Account might be invested in new plant or in liquid assets for the reserve Account. Curve D of Fig. 4 indicates the growth at 3.5%, while Curve A may be thought of as 0% improvement rate.

2. That the original capital investment is written off each year by the amount of the depreciation charge resulting in a reducing charge against the system each year. This is contrary to normal financing as the book value of assets to secure the bonds on the original investment would be changing each year. It is true that part would be in plant and part in a depreciation account, but we believe in general, accounting practice does not utilize this method and hence, it is not considered further.

Sinking Fund Depreciation Method: In the Sinking Fund Method, a constant amount of money is set aside annually and is assumed to earn interest at a rate equal to the average cost of money over a period of years. This fund may also be invested in part, in new plant which would then be earning interest at the going cost of new money.

For example, if we assume 25% of the Sinking Fund is invested in bonds bearing 4% interest and 72.7% invested in new plant, permitting the reduction of borrowing for that plant which otherwise would have been done at say 5½%, the remainder of the Sinking Fund average 2.3% is left in the Current Account where it may be thought of as idle cash.

Combining the above 3 rates:

$$\begin{aligned} 0.25 &\times 4\% = 1.0 \\ 0.727 &\times 5.5\% = 4 \\ 0.023 &\times 0\% = 0 \\ 1.0 & \qquad = 5\% \end{aligned}$$

Thus the Sinking Fund improves at 5%.

The annual amount must then be set aside to accumulate the Plant "first cost" ($100 million in this case) after a period of 44 yrs. with the average improvement rate of 5% computed as follows:

If:

1 is the annual amount of depreciation,

i is the interest on the annual amount of depreciation at year end.

Sn is the original investment to be recovered at the end of the nth year.

Then $$Sn = \frac{(1+i)^n - 1}{i}$$

$$Sn = \frac{(1+0.05)^{44} - 1}{0.05}$$

$$= 152.0$$

These computations can easily be performed on a log – log slide rule. The interest on the original investment is charged separately as annual payments or bonds, say, to whatever rate the money is raised.

From the above, the constant annual depreciation charge amounts to

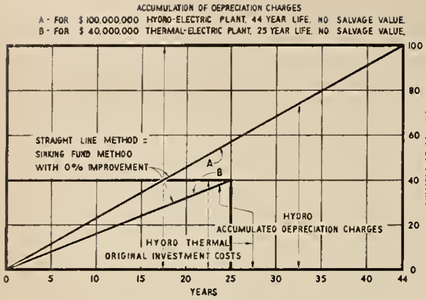

Fig. 3 Accumulation of Depreciation Charges by Straight Line Method.

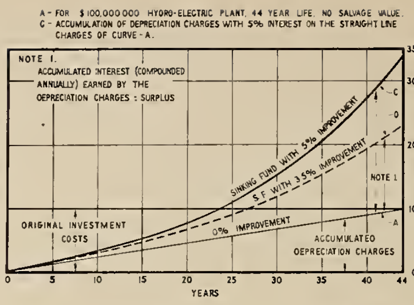

Fig. 4 Accumulation of Depreciation charges by Straight Line Method with various rates of improvement.

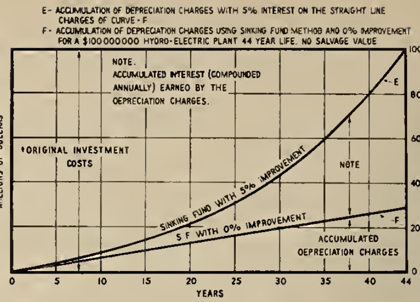

Fig. 5 Accumulation of Depreciation charges by Sinking Fund Method.

$$\frac{100{,}000{,}000}{152.0} = \$657{,}000$$

or say 0.657%.

The accumulation of the constant annual payments with earnings (average improvement rate of 5% from above) is shown in Fig. 5, as Curve E.

The thermal plant of equal capacity considered above would have an annual payment to depreciation account for Sinking Fund of

$$Sn = \frac{1.05^{25} - 1}{0.05} = \frac{3.39 - 1}{0.05} = 47.8$$

$$\text{or} \quad \frac{40{,}000{,}000}{47.8} = \$836{,}000 \text{ annually.}$$

Which is equivalent to an annual charge of 2.09%.

Comparison of the Two Methods: It can be seen that the reduction in annual depreciation charge from Straight Line to Sinking Fund amounts to

(2,273,000 − 657,000) = 1,616,000

for the Hydro Plant and

(1,600,000 − 836,000) = 764,000

for the Thermal Plant. Expressed as percentage of the investment costs, the reduction amounts to

(2.27 − 0.66) = 1.61%

for the Hydro Plant and

(4.0 − 2.09) = 1.91%

for the Thermal Plant.

Since the money set aside each year for Depreciation Reserve will be used by the organization for whatever use is demanded of this money within the tax laws of the country, it follows that a careful look at the Depreciation Reserve Account should be made. The fund need not provide for any more than a repayment of the original Plant costs at the end of the assumed life of the plant; to provide more is charging today's power consumer with tomorrow's plant.

In the hydro plant example, the Straight Line annual payments would amount to

$$100{,}000{,}000 \times \frac{2.273}{0.657} = \$346 \text{ million}$$

at the end of the useful life with 5% interest earnings compounded or $246 million surplus after 44 years. This is illustrated in Fig. 4, Curve C.

In the thermal-electric plant example, the Straight Line annual payments would amount to

$$40{,}000{,}000 \times \frac{4}{2.09} = \$76.5 \text{ million}$$

at the end of the useful life, with 5% interest earnings compounded or $36.5 million surplus after 25 years.

Since a system has capacity additions made every few years to keep it abreast of the load growth, it is easy to lose sight of these excessive Straight Line Depreciation charges. They result in accumulation of reserves beyond the original cost of the plant they are set aside to repay, hence the importance of the method of treating depreciation in project evaluation.

The straight line method overstates the annual charges which are associated with a high capital cost and long life project when compared with a lower capital cost and shorter life project such as a thermal station.

The sinking fund method of treating depreciation for project evaluation takes more adequate account of the virtues of the longer life project and hence serves to provide a more adequate basis of comparison for such alternatives as I have used in the example discussed. Furthermore, it avoids the overstatement of the annual charges by having no inherent surplus.

The sinking fund method of treating depreciation for project evaluation is equitable to all alternatives of new capacity installation and is therefore recommended[13,14,15,16] for project and sequence evaluation in forward planning studies.

This is not to say that for utility accounting purposes where the books of a utility may be required to deal with a whole complex of Plants and Properties that the straight line method of depreciation is necessarily inappropriate. This derives from the fact that in the field of utility accounting the tendency towards overstating the depreciation costs of a particular project such as might be inherent in the straight line method of depreciation, could be partially or perhaps even fully offset by the manner in which depreciation reserves are employed by the utility.

While the author's views on this subject have been stated with some assertiveness, it has been done with the hope that it may elicit a discussion on this. The general question, we believe to be of sufficient importance to warrant the best and most informed views that can be brought to bear upon it for these purposes. An exchange of views and practices on the general question of the treatment of depreciation for project evaluation in System Planning Studies might prove helpful to all who are concerned with power utility economics.

LAKEVIEW & R. L. HEARN GENERATING STATIONS DESIGN

H. A. Smith,
Assistant General Manager, Engineering, The Hydro-Electric Power Commission of Ontario.

W. F. Allen, Jr.,
Mechanical Engineer, Stone & Webster Canada Limited.

This article covers salient design features of two modern thermal power stations of the Hydro-Electric Power Commission of Ontario. Its purpose is to show how the design of the Lakeview Generating Station has evolved from the basic requirements and criteria established for the plant, and how it compares with that of its predecessor, the Richard L. Hearn Generating Station Extension. Design features discussed include turbine inlet steam conditions, turbine exhaust annulus area and condenser size, and steam generator efficiency. The addition of thermal units to a predominantly hydraulic generating system results in two unusual basic criteria for large modern thermal units—an expected low lifetime capacity factor and a requirement for daily start/stop operation. The influence of these criteria is considered with particular reference to centralized control arrangements and to the unusual design provision of a steam bypass system which facilitates rapid starting of the plant.

THE design of a modern thermal power plant for proper integration into a complex electric utility involves an effort of hundreds of thousands of man hours and a vast complex of administrative and technical judgments extending over a period of several years. Such judgments range from those which establish the need for the plant through those which determine the basic criteria of design to thousands of individual decisions, principally of a technical nature, which in the end form the detailed design.

It is the purpose of this paper to present an outline of some of the more important judgments taken in connection with the design of a particular plant—Ontario Hydro's Lakeview Generating Station—to illustrate how the salient design features of that plant have evolved from the basic requirements and criteria established. By way of comparison, the main design features of the R. L. Hearn G. S. Extension, the predecessor to Lakeview G.S., are also given.

Need for Additional Thermal Plant

The need for the Lakeview Generating System was established and approved by June, 1957. At that time two hydraulic plants—Sir Adam Beck Niagara Generating Station No. 2 and St. Lawrence G.S.—representing an installed capacity of 2,310 Mw. were well advanced. An additional four 200 Mw. units at the R. L. Hearn G.S. had been committed for completion by the end of 1960. Nevertheless, the relatively constant annual growth exceeding 6%, coupled with a decision to bring power reserves up to a figure of the order of 12% indicated that an additional 500 Mw. of generation would be desirable in 1961, followed by a further increase of 300 Mw. in 1962.

Since all of the major hydraulic sites in the southern Ontario system were either developed or in progress, two basic alternatives for additional generation were open. The first was to develop hydraulic sites in Northeastern Ontario, particularly on the Abitibi, Mattagami and Missinaibi Rivers. The second was to embark on a new thermal plant in the southern Ontario system suitably close to the main load concentrations. Further expansion of the R. L. Hearn G.S. above the 1200 Mw. rating already committed was considered to be undesirable at that time, from the standpoint of site area and problems of power takeout.

Although the detailed information on the northeastern Ontario sites was relatively limited from the standpoint of surveys and preliminary engineering analyses, the information available pointed to the following characteristics.

1. The most economical long-range development would be as peaking plants to such a degree that their capacity would require firming by energy from thermal plants located elsewhere in the system.
2. The low capacity factor associated with the ultimate rating of such plants was not compatible with system load factor. Thus, progressive increases in peak capacity of several plants would be required over an extended period of time.
3. Because of the large distances from the load centres, and the economic incentive to develop maximum capacity at these sites, the northeastern Ontario generation would require extra-high voltage transmission —expected to be 400 kv. or above— for connection to the main load centres.
4. The capacities of the various hydraulic sites, if initially developed to approximate the system load factor, were small relative to the 800 Mw. required in 1961 and 1962. Thus, simultaneous development of several sites would have been required if the full requirement of 800 Mw. was to have been met from hydraulic sites alone, with the resulting undesirable peaking of engineering work load.

These considerations, in the light of the limited information and advance engineering on those sites led naturally to a basic plan of committing first another thermal plant in the southern system with the intention of integrating with it the development of the northern hydraulic sites on much less of a crash program in order to give more flexibility and a better balanced work load.

It was on this basis that the requirement was established to start a new thermal plant. Subsequent studies on the hydraulic sites have supported this decision.

Determination of Basic Characteristics

Having determined the need for the plant, the next step was to establish some of its basic characteristics.

As far as unit rating was concerned, the principal considerations were capacity required by or acceptable to the system and availability of large-capacity turbine generators. Ontario Hydro had already experienced a trend from 60 Mw. units installed at the J. Clarke Keith Plant at Windsor to 100 Mw. units in operation at the R. L. Hearn plant and on to 200 Mw. units to complete the latter—and this in a period of seven to eight years. The same trend was evident in other utilities as the struggle continued to offset rising costs by increasing unit size. Even at that time there was considerable discussion among utility and manufacturing engineers about 400-450 Mw. units. The choice for Lakeview, inevitably a matter of judging the probable advantages of increased rating against the troubles one may inherit from too large a step, was for 300 Mw. units.

This rating seemed likely to be acceptable from a system security standpoint. It represented a 50% increase from the rating of the larger Hearn units and was likely to offer substantial cost reductions in both unit capital and unit energy costs. Because U.S. utilities already were committed to units of approximately this rating which are now installed, this decision may not be considered very venturesome. However, because of a very important price advantage which prevailed for units of other than American manufacture, it seemed highly unlikely that a U.S. machine would be purchased and at that time no manufacturer outside the U.S. had produced even a 200 Mw. unit.

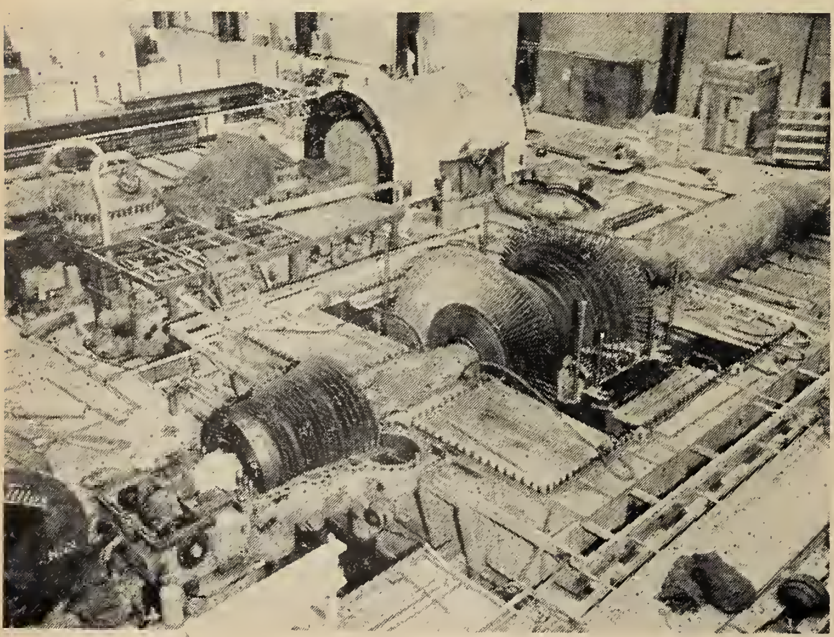
Another important factor in setting the basic requirements for the units was the probable type of operation. From system peak load and energy load studies it was evident that, at least in the initial years, the plant would be operated at relatively low annual capacity factor since energy from the thermal plant was known to be more expensive than energy from existing hydraulic plants. In later years of operation the annual capacity factor at which the units might operate is, at best, a guess. However, the probability that growth in base load thermal power will be derived largely from nuclear plants after 1970 and the continuing technical advance in the efficiency of thermal plant both point toward a relatively low lifetime capacity factor. For this reason it was considered that the new thermal plant should be designed for daily start/stop operation and should not necessarily be designed for the maximum efficiency available at the time. On the other hand, the 300 Mw. rating itself demands relatively high steam conditions and could be expected to give a plant of reasonably high efficiency if it should become necessary to operate close to base load.

Another basic consideration to be settled was the question of maximum plant capacity. This value was chosen largely on the basis of comparing very long-range load projections in the high load density Toronto-Hamilton belt with the probable number of suitable sites which could be acquired. Other considerations included the relationship between plant capacity and system capacity at time of completion, and also the question of what maximum power concentration might be permissible from the standpoint of effective dispersion of stack effluent. The probable full plant capacity selected was 1800 Mw. representing a 50% increase over the Hearn G S. capacity, but with the proviso that, if practicable, the site should be selected and the plant so designed as to allow for expansion to an ultimate capacity of 2400 Mw.

The choice of fuel for the plant was relatively simple. Although major supply facilities for both oil and natural gas were either installed or being installed in the areas containing the main load centres of the system, there was no evidence that either of those fuels would compete economically, at least in the early years of plant operation, with coal imported from the United States as a basic fuel for the plant. This is hardly surprising in view of the anticipated low capacity factor for the plant and the high investment incurred by suppliers for transport and storage facilities for gas and oil. However, it seemed probable that, over the lifetime of the plant, the use of surplus gas at various times of the year might prove advantageous. Therefore it was decided that the plant would be coal fired but that minimum economic provision would be made to accommodate the installation of gas-firing facilities in the future.

The last item in the general specification for the plant was location. Extensive field and office studies were made of alternative sites along the shores of Lake Ontario and Lake Erie. Numerous factors were taken into account in those studies including foundation conditions, costs of dock facilities, effect of shore conditions upon maintenance of clear ship channels and water intakes, water temperature conditions, access for railway and transmission circuits, transmission losses and several others. From these studies, the potential sites were ranked in order of preference and the clear first choice was a site on the western portion of the Long Branch Rifle Ranges in Toronto

Fig. 1 R. L. Hearn Turbine Generator in process of erection.



Township. It offered good foundation conditions, proximity to a high load density area and railway facilities, and reasonably easy access to existing transmission except for a short section across the Queen Elizabeth Highway and a new shopping centre.

On the basis of subsequent load forecasts, it was decided in 1959 to commit two additional units for in-service dates of 1963 and 1964 respectively. The basic specification was not changed with respect to this extension of the original commitment.

In summary, then, the basic characteristics determined for the plant are:

Unit capacity—300 Mw;

Initial plant capacity—two 300 Mw. units, one in 1961, the second in 1962, subsequently extended to include two more units of identical rating, the third in 1963 and the fourth in 1964.

Ultimate plant capacity—1800 Mw. nominal with site to be acquired so as to permit possible later expansion to 2400 Mw.

Type of operation—low lifetime capacity factor with daily start-stop operation.

Fuel—coal with minimum provisions for adding gas firing in the future.

Location—Long Branch Rifle Ranges, Toronto Township.

Arrangements for Engineering Work

With the need and basic characteristics for the plant established, it was necessary to decide upon arrangements for the design work. At that time, Ontario Hydro's organization included only a small group of staff connected with thermal plants at Windsor and Toronto which had been contracted, and this staff group was inadequate to undertake the overall engineering of the new thermal plant. However, since it was evident that in the future much of the load growth would have to be supplied by thermal plant, either conventional or nuclear, Ontario Hydro decided to develop an engineering organization to undertake such work and to assign to it the design of the Lakeview G.S.

Recognizing that proper engineering for such a plant would present sufficient problems even for an experienced design organization let alone one which was just developing, Ontario Hydro retained the services of Stone and Webster to share in the responsibility for the success of the Lakeview Project. Basically the Consultant's terms of reference are:

First, to act in a coaching capacity to ensure the development of an organization within Ontario Hydro competent to handle future thermal plant design and construction;

Second, to provide advice and guidance on engineering and administrative matters in connection with the project;

Third, to provide, from the resources of its own organization any engineering effort which might not have been suitably developed at the proper time by the Ontario Hydro.

Although such an arrangement between a client and a consulting engineering organization may be regarded as rather unusual, experience over the past three years has shown it to be most satisfactory.

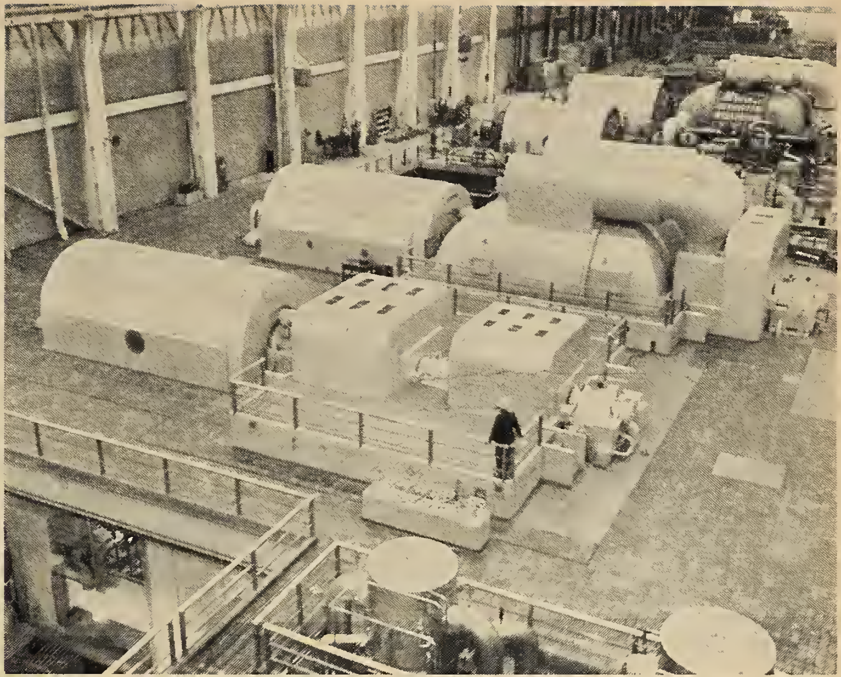


Fig. 2 R. L. Hearn Turbine Generator erected.

Economic Criteria for Engineering

Another class of decision necessary to establish an orderly basis for engineering is what might be called the criteria by which engineering economics are to be assessed. In this case, consistent with Ontario Hydro's policy of attempting to supply power demands with satisfactory service at minimum cost, the over-riding criterion is to obtain the minimum combination of fixed charges on investment, fuelling costs and operating and maintenance costs consistent with high availability. Typical interpretation of this basic criterion is outlined as follows:

1. Both fixed and variable costs as well as expected performance and reliability are to be considered in recommending equipment purchases. The total evaluated cost should normally be used in equipment selection, although lowest first cost should govern when evaluated costs are nearly identical, other characteristics being equal. Special emphasis is to be placed on equipment performance under daily start-stop operation.

2. Special provision for plant expansion should be made only when economic. For such assessments, it may be assumed that the ultimate plant capacity will be reached in 1966.

3. Facilities not directly concerned with economy of power generation are to be held to a practical minimum. No premium is to be paid for special architectural effects.

4. Typical cost data to be used in engineering analyses include:

Fixed charge rate on investment—6.3% per annum. Fuel cost—40 cents per million B.t.u. Lifetime capacity factor—0.30.

The relatively low fixed charge rate of 6.3% arises from the fact that Ontario Hydro is a Commission founded by Ontario municipalities and in effect now operates in partnership with them to supply power to the public at cost. Consequently, it pays no corporation profit tax, and new plant construction is financed by relatively low interest rate bond issues. The fixed charge rate includes interest and depreciation.

Brief Description

The immediate predecessor to Lakeview, the R. L. Hearn Extension consists of four 200 Mw. reheat turbine generator units each served by a 1,350,000 lb. per hr. steam generator. The turbine generators are cross-compound, comprised of, on one line, a high pressure turbine and first intermediate pressure (reheat) turbine driving a 100 Mw. generator at a speed of 3600 rpm, and on the other line, a second intermediate pressure turbine and a double flow, low pressure turbine driving a 100 Mw. generator at a speed of 1800 r.p.m. Fig. 1 shows one of the sets during erection and Fig. 2 shows the set after erection is completed. The turbines exhaust to 90,000 sq. ft. surface condensers. Six extraction points are used for water heating. The steam generators are designed to burn pulverized coal with light oil for ignition and warming. Two steam generators are the natural circulation type and two are the controlled circulation type.

The initial installation at Lakeview consists of two 300 Mw. reheat turbine generator units each served by a 2 million lb. per hr. steam generator. Units 1 and 2 turbine generators are similar to the Hearn units except that a quadruple flow low pressure turbine is used instead of a double flow. The turbines exhaust to 125,000 sq. ft. surface condensers. Seven extraction points are furnished for feed water heating. The natural circulation steam generators are designed to burn pulverized coal with light oil for ignition and warming.

At both plants the unit system of one steam generator and auxiliaries serving one turbine generator without interconnections is employed, with the exception of auxiliary services such as service and instrument air and service water for heat exchangers and bearing cooling.

Steam Conditions

The steam conditions for R. L. Hearn Extension are 1800 p.s.i. 1000°F, 1000°F reheat at the turbine, and for Lakeview, 2350 p.s.i. 1000°F, 1000°F reheat at the turbine. Major factors affecting the selection of steam conditions are: expected plant capacity factor, fuel costs, and fixed charge rate. Although these stations have low expected capacity factors, the low capacity factors are offset by the low fixed charge rate. The result is that the combination is approximately the same as for a large number of investor-owned generating systems operating in North America.

The 2350 p.s.i. pressure is economic for Lakeview (whereas 1800 p.s i. is economic for Hearn) because the percentage increase in initial cost is less, and the gain in heat cycle efficiency is greater for the 300 Mw. plant than for the 200 Mw. plant.

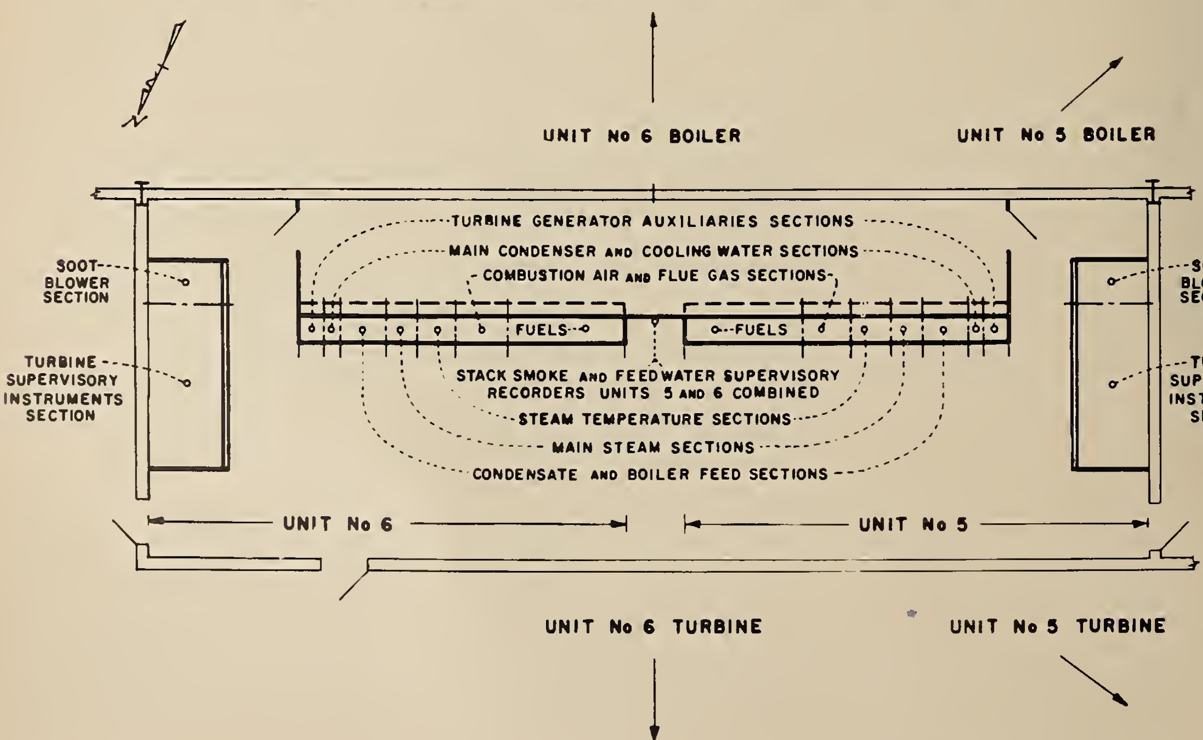
Initial costs for large-size thermal plants are not significantly increased by increases in pressure, because of the reduction in size of portions of major equipment and interconnecting piping. This reduction results from the decrease in specific volume in the steam path and the decreased rate of steam and water flow required for a more efficient higher pressure steam cycle. As a result of the reduction in size, and since pipe wall thickness for a given pressure is in almost direct proportion to pipe diameter, the percentage increase in weight of the piping required is only a fraction of the percentage increase in pressure. Furthermore, temperature rather than pressure dictates the amount and type of expensive alloy materials used. The gain in heat cycle efficiency for a pressure increase from 1800 p.s.i. to 2350 p.s.i. is greater for a 300 Mw. unit than for a 200 Mw. unit, principally because of the relatively smaller shaft and gland leakages for the larger unit.

At Lakeview a further consideration is the limit of pressure at which a natural circulation drum-type steam generator can be expected to perform satisfactorily. This limit is approached at 2,350 p.s.i. at turbine inlet.

The once-through design of steam generator entailed by higher pressures, whether above or below the critical point of 3206 p.s.i.a., involves serious problems in combustion and feed water control, necessitates an extremely high quality of water treatment, and incurs large boiler feed pumping losses. At present the gain in heat cycle efficiency is not sufficient to offset the increases in initial cost associated with the supercritical pressure, particularly when probable loss of availability is considered. Superficial units now operating or under design have been justified mainly as advancements in the art of power generation.

Changes in heat cycle efficiency and initial cost of piping and equip-

Fig. 3 Arrangement of panels in Two Unit Centralized Control Room.



ment due to increases in turbine inlet steam temperature and reheat temperature, can be determined with reasonable accuracy. Fifty degrees F increase in superheat temperature at turbine inlet decreases turbine heat rate by 0.75%, and 50°F in reheat temperature at the turbine decreases turbine heat rate by 0.65%. The present annual fuel saving per unit is $175,000 for superheat temperature and $152,000 for reheat temperature at Hearn, and $252,000 for superheat temperature and $218,000 for reheat temperature at Lakeview.

These are significant amounts of capital. On the basis of somewhat similar savings, a number of units in the 200 Mw. to 300 Mw. range have been designed for 1050°F temperature, and a very small number for higher temperature. However, the selection of 1000°F for Hearn and Lakeview lies largely with the probable loss of availability and replacement cost of superheater and reheater tubing over the life of the plant. These are factors difficult to determine and easy to overlook or minimize. For daily start/stop operation and the attendant difficulty of always accurately controlling furnace exit gas temperatures under rapid start conditions, the expected life of tube materials become even more critical than in the usual case of base load plants. Data now available on some of the 1050°F steam generators in service for several years indicates very short service life for the materials used. Therefore, unless the ratio of annual fuel savings to increase in initial cost is much larger than the normal fixed charge rate, which it is not, it is a prudent course to design for 1000°F.

No implication is intended that steam temperatures have reached a permanent economic maximum. For several years the A.S.M.E. Research Committee on High Temperature Steam Generation have had a testing program for various tube alloy materials at temperatures from 1100°F to 1500°F. Tubes have been tested with 2000 p.s.i. steam at these temperatures for time periods of up to 36 months. The object of the program is to determine the resistance to corrosion and creep, the effects of oxide films on thermal conductivity, the metallurgical stability, and the resistance to thermal shock. From this investigation and others of the sort, metals will be forthcoming with suitable service life. Concurrently the A.S.M.E. Research Committee on the Properties of Steam as part of an international effort is sponsoring research with the aim of ultimately publishing accurate steam properties up to 15,000 p.s.i.a. and 1,500°F.

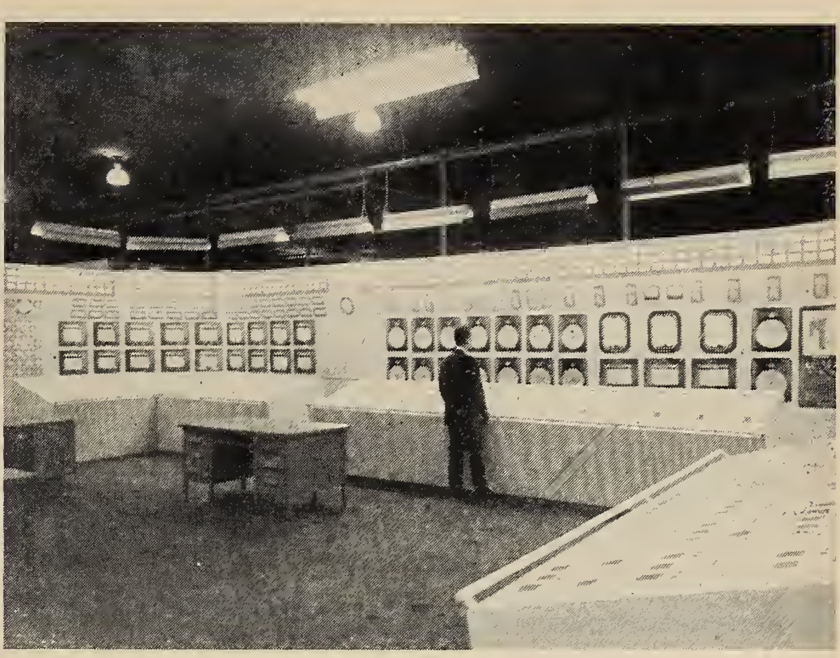


Fig. 4 Mockup of Lakeview Control Room.

As a result of the recent reports on replacement of large amounts of tube surface installed only a few years ago for 1000°F and 1050°F service, tube metal stresses and the maximum temperature limitations on tube alloys were reviewed in detail for the Lakeview steam generator, and limits established somewhat lower and more conservative than indicated by the A.S.M.E. boiler code. The action was taken with the firm expectation that the life of superheater and reheater tubing would be increased considerably.

Turbine Exhaust Annulus Area —Condenser Size

For many years the electric power industry has devoted much attention to the importance of increased pressure and temperature, but until recently it has not devoted the same attention to the gain in kilowatt output and better heat cycle efficiency attainable by increasing the size of the exhaust end of the turbine for locations where cold water is available.

Lake Ontario furnishes an abundant supply of cold circulating water ranging in temperature from 32°F to a maximum, except under extreme conditions, slightly above 60°F. With circulating water available at these temperatures it is usually economic to achieve increased heat cycle efficiencies by the selection of a turbine with a liberal exhaust annulus area, and to proportion condenser size to this area. The condensers may be the single pass type because of the abundant supply of circulating water.

The Hearn 200 Mw. units with double flow exhaust have 37 in. last row turbine blades with a total exhaust annulus area of 183 sq. ft. and a 90,000 sq. ft. single pass divided water box main condenser. The Lakeview 300 Mw. units with quadruple exhaust have 35 in. last row turbine blades with a total exhaust annulus area of 315 sq. ft. and a 125,000 sq. ft. single pass divided water box main condenser. Relative to turbine size these exhaust end sizes are among the largest in operation or under design.

In some cases the manufacturer's experience, or lack of it, with larger blade sizes, will determine the exhaust end size without a complete study; and below the optimum for turbine generator size, fuel cost, capacity factor and range of water temperature. If sufficient design and operating experience has been garnered, the selection of turbine type as influenced by exhaust end size is carried out as an integral part of the overall evaluation, including condenser size and circulating water requirements. For large turbines, exhaust end size variations may result in $1 million or more difference in fuel cost over the life of the plant.

Steam Generator Efficiency— Exit Gas Temperature

Only a portion of the energy supplied to the turbine generator is available energy in the sense that it can be utilized to do work regardless of the degree of perfection achieved in turbine generator design and construction. No similar restriction exists on utilization of energy in the fuel supplied to the steam generator, as substantially all this energy can be released and recovered as heat, provided it is feasible economically to build the requisite apparatus to accomplish the recovery.

It will be increasingly difficult to make great improvements in heat cycle efficiency by increasing turbine inlet steam conditions, even when the present economic limitations on maximum levels of pressure and temperature have been overcome. For example, the gain due to a change in turbine steam conditions from 2350 p.s.i., 1000°F, 1000°F to 4500 p.s.i., 1100°F, 1000°F is less than 5% in heat rate. This fact behooves earnest consideration of reduction in steam generator losses as a means of improving over-all power plant efficiency.

Dry gas and moisture losses constitute the major heat losses from the steam generator; the remaining losses are those due to unburned fuel and radiation. With exit flue gas reduced to the temperature of ambient air, and all water vapour in the flue gas condensed, nearly 100% efficiency of energy conversion can be achieved.

At Hearn, two Lungstrom rotary regenerative air preheaters are furnished of sufficient size to cool exit flue gas to 287°F (uncorrected for leakage) at a maximum steam flow with incoming air at a temperature of 40°F. At Lakeview, the two Ljungstrom air preheaters are furnished of sufficient size to cool exit flue gas to 270°F (uncorrected for leakage) at a maximum steam flow with incoming air at 80°F The corresponding steam generator efficiencies at full load are 88.3% at Hearn and 89.7% at Lakeview. Today's highest steam generator efficiencies are only slightly above 90%.

A further increase in air preheater size will lower exit flue gas temperature and thereby reduce the dry gas loss and improve efficiency. However, operating experience has demonstrated convincingly that the preheater cold end metal temperature must be maintained above the dew point of the flue gas, otherwise corrosion and plugging of the air preheater takes place.

Cold end metal temperature may be considered as the average of inlet air temperature and exit gas temperature, and therefore the higher the inlet air temperature the lower the permissible exit gas temperature. At both plants steam air heaters are provided in the air stream ahead of the air preheater inlet to improve plant efficiency and protect the air preheaters from corrosion and plugging. It may be shown that heating of combustion air above ambient temperature by extraction steam from the turbine is an economically sound method of improving over-all power plant efficiency, and provides a flexible corrosion-protection system for the air preheater.

This improvement is the result of a two-fold gain, (a) an improvement in the thermal cycle due to the generation of additional by-product power, and (b) a decrease in the dry gas loss due to the permissible lower flue gas exit temperature. Approximately 40°F reduction in exit flue gas temperature will raise steam generator efficiency 1%.

At Lakeview, steam air heating will be utilized to raise air preheater inlet temperature to approximately 70°F at full load and 120°F at 10% load for the present fuel. If higher sulphur fuels, such as those available from Nova Scotia, are burned, it will be necessary to heat to 100°F at full load. Although the arrangements are somewhat different, both plants have combustion air intakes within the boiler house, and advantage will be taken of some of the heat dissipated from the boiler casings summer and winter for prewarming combustion air. The inside air intakes also serve as a part of the ventilation systems for both plants.

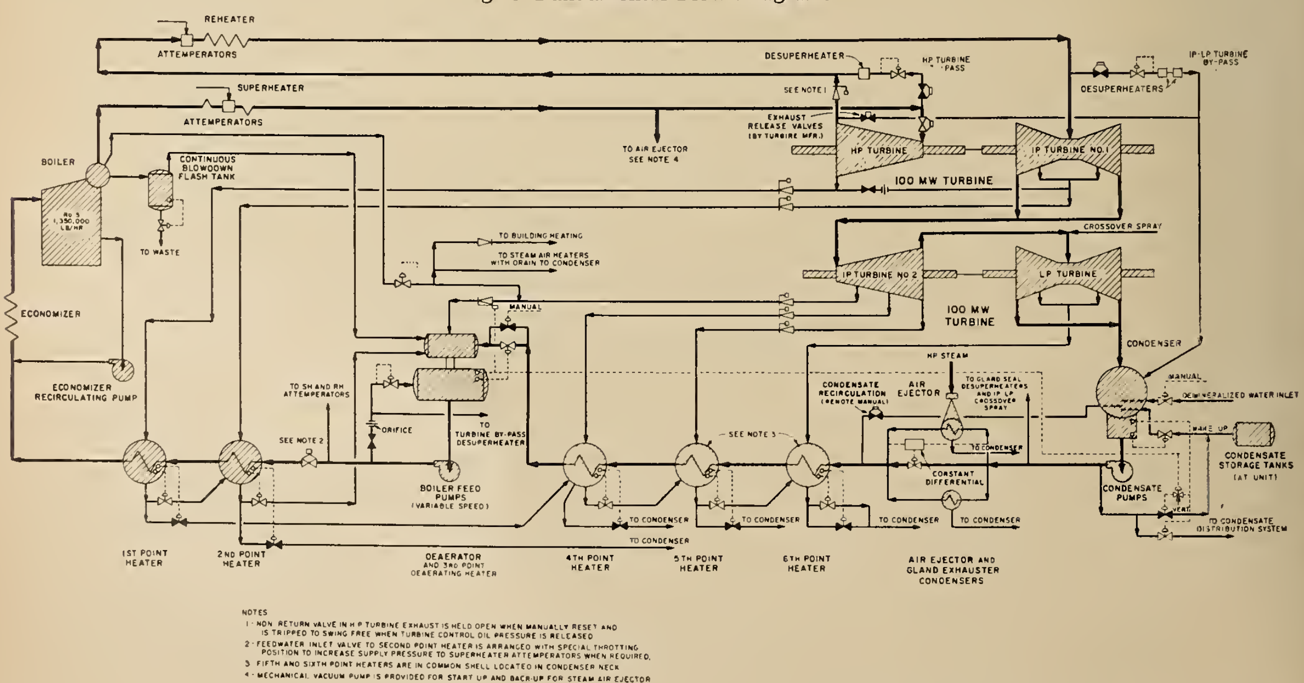
Centralized Control

To fulfil the basic criterion of low operating cost, the necessary operating staff should be kept to a minimum. Centralization of controls is essential, therefore, in order to reduce the number of individual operating duties, particularly in view of the daily stop/start requirements.

At Hearn, the operations of mechanical controls for the four new units are centralized in two control rooms, one for units 5 and 6, and a second for units 7 and 8. Fig. 3 shows the general arrangement of controls for two units. Control of the electrical outputs of the units and associated switching is retained in the original electrical control room, which has been extended to include all the necessary control devices.

At Lakeview, the operations of mechanical and electrical controls for units 1 and 2 are located in a combined mechanical-electrical control room mid-way between the units. Fig.

Fig. 5 Fundamental Flow Diagram.



4 is a mock up of the control arrangement for one unit.

At both plants, all measurements essential for the over-all control and supervision of systems associated with the steam generator-turbine heat cycle are transmitted, either electrically or pneumatically, to the central control room. This arrangement precludes any hazardous fluid in the central control room and allows a much greater concentration of controls and instruments in each panel.

At Hearn, the units can be put into service and operated from the central control room, with the exception of minor local functions which must be performed prior to and during the start-up operations. Among these are the regulating and closing of steam generator vents and drains, turbine drains, and piping drains. Cooling water supplies to pump and fan fluid control drive oil coolers and bearings must be regulated locally. The isolating valves in the steam supply lines to the condenser air ejector and the turbine gland steam system, must also be operated locally.

At Lakeview, additional provisions are incorporated to regulate steam generator vents and drains, turbine and piping drains, and condenser air ejector and turbine gland steam system from the central control room on start-up. This is done by providing either air-diaphragm or electric-motor-operated valves for these services. Cooling water controls for fluid control drives serving major auxiliaries are automatic, normally not requiring operator attention. Lakeview is one of the first, if not the first, large thermal station to be designed for remote start-up to this extent.

For both plants the major control systems, such as combustion control, feed water control, and steam temperature control, are automatic, normally requiring only surveillance and monitoring by the operating staff for abnormal deviations. Under start-up conditions these systems are manually operated from the central control room. Also, for both plants, there are other control systems for major ancillary equipment which are completely automatic, even under start-up conditions. These include minimum flow control for the boiler feed pumps, air ejector and gland condenser, extraction feed water heater drainage level control, and condenser, deaerator and water storage tank level control. Some are brought to the control room in order to apply manual corrections under adverse operating conditions, others are monitored in the control room only for extreme deviations.

Operating cost and capital investment can be reduced by eliminating equipment intended for local operation, such as hand-operated by-passes and shutoff valves. At both plants the conventional hand-operated by-passes have been replaced by electric or diaphragm motor valves on the main boiler feed system, feed water heater drainage system, and deaerator and condenser level control systems. This reduces the amount of operator attention required, particularly during emergency conditions. At Lakeview, initial costs have been reduced on the condensate, heater drainage, and other systems provided with automatic or control-room-operated by-passes, by eliminating many of the shut-off valves normally provided for isolation of control valves. This has been done on the basis that if the primary control fails, bypass control is available, and maintenance can be deferred until an overnight, week-end, or longer shutdown.

This may appear to be a minor item, but consider that approximately $50,000 per unit can be saved for elimination of isolating valves, due to savings in first cost of valves and piping, access platforms, and design cost. On the basis of a turbine generator unit installed each year, this saving can be considered an annual one, and at the current long-term interest rate, would have a present worth in excess of $1 million.

Steam By-Pass System

Perhaps the most unusual, if not unique requirement for large thermal units is the daily start/stop operating condition. To minimize fuel and over-all system power costs it is desirable to reduce the time of the start-up as much as possible, so that only a minimum of thermal generation has to be absorbed by the system, while the capability of hydro-generated power is still in excess of the system demand. The deleterious effects of rapid starting will be least if temperature change in the turbine, and temperature differential between steam supply and the turbine, can be minimized.

At the Hearn Station a high and low pressure turbine steam by-pass system is provided to facilitate the rapid start-up of the turbine generator after an overnight shutdown. The by-pass system will provide hot steam for admission to the high pressure and reheat turbines respectively, and by minimizing development of thermal stresses in the turbine parts, will increase availability and decrease maintenance.

The system consists of a large steam by-pass line from upstream of the high pressure turbine inlet connecting to the cold reheat line, and another large steam line from the hot reheat line to the condenser. Motor operated isolating valves, pressure reducing valves, desuperheating stations and instruments are provided. The fundamental flow diagram for Hearn Station, Fig. 5, shows the major connections for this system. By means of this by-pass, sufficient steam flow (10% to 15% of maximum flow) can be passed from steam generator to condenser to raise superheater and reheater steam temperatures to those required for admission to the turbine.

By suitable unloading procedure, operation of the turbine each day at steam temperatures below the normal 1000°F, at both the high pressure and reheat turbine inlets, can be minimized, thus alleviating repetitive heating and cooling of critical high temperature turbine parts. At the beginning of the shutdown period it is anticipated that the turbine metal temperatures will be almost the same as during normal full load operation, and with the turbine bottled up overnight, it is expected that critical parts will cool only moderately. Temperature recorders are provided to measure the turbine metal temperatures at critical points throughout the unit.

A similar by-pass system has been designed for Lakeview. Installation awaits completion of operating tests on the Hearn System.

Structures

At Hearn, the original completely-enclosed brick station structure was extended to conform to the original station layout as much as possible, and to retain consistent appearance. However, the upper portion of the boiler house and coal and ash handling structures added with the extension have been built with less expensive aluminum siding. At Lakeview aluminum siding is used for the main station structure, although a small amount of brick is used at ground level because of its greater durability and for transformer fire protection. Induced draft fans, hot air ducts, and precipitators are out-of-doors at Lakeview, thereby not only reducing structural costs, but also ventilation requirements.

Investment in large maintenance facilities and shops at Lakeview has been deferred, at least until more units are installed in the station, with the expectation that major repair work can be done at Hearn or elsewhere. Similarly, at Lakeview no substantial investment has been committed for future units, other than the minimum necessary to ensure relatively complete flexibility of design. EIC

Discussion

PROCESSING OF LOW-GRADE IRON ORE USING PETROLEUM AND NATURAL GAS

P. E. Cavanagh,
Vice-President, Premium Iron Ores Limited, Montreal.
The Engineering Journal, August 1959, p. 84

Discussion by William B. Magyar, Jr.E.I.C.

While the article by Mr. Cavanagh was most interesting and timely . . . there are a number of controversial points which require clarification.

For example, the bases for comparison for the processes are questionable and the conclusions drawn by the author are open to considerable discussion and debate. In addition, the article contains a number of technical errors and omissions, especially with regard to the author's interpretations of the Strategic-Udy process.

The recirculated furnace gases are utilized for their heat of combustion and not for prereduction.

No arbitrary figure can be selected as the ideal for maximum prereduction as this factor depends on the characteristics of the ore itself. A free-flowing kiln discharge product (frequently called a sinter) is desired for feeding the electric furnaces. Consequently, the maximum degree of prereduction desired for a particular ore or concentrate must be determined by experimenting.

Mr. Cavanagh's statement that "the maximum degree of prereduction that will prove feasible is about 30% on a rich ore" is true, we agree, for conventional electric furnace smelting, but not for the Strategic-Udy technique.

For example, the following results have been obtained:

A 65% prereduction in the kiln on a normal, direct-shipping, blast furnace type ore containing 56% Fe. No difficulties were encountered in subsequent furnace operations;

Over 70% prereduction has been attained on lean "contaminated" concentrates from a Canadian ore;

Stainless steel grindings — almost 100% metallic — were smelted at SUMAC on a production scale, cast into ingots and returned to the supplier as melting stock. The grindings were cold-charged directly into the electric furnace.

Electric power consumption has been measured accurately on many ore or concentrates at SUMAC via large-scale smelting tests. The smelting of 65% Fe pellets has not yet been demonstrated, but preliminary calculations suggest about 900 kwh. per ton of semi-steel would be required for such material.

No information from Strategic-Materials Corporation was found which indicated a consumption of 1400 kwh. per ton of iron from such material as stated by Mr. Cavanagh.

There is a tendency among metallurgists to compare estimated production costs via these new processes with established blast furnace costs in various steelmaking centres. This type of comparison, unfortunately, does not reflect a true picture.

For a proper evaluation of a new situation one must compare the total costs via the blast furnace route—including coke ovens, sintering, etc. —with total costs via the direct reduction route at the proposed location of the new enterprise.

Consequently, fuel costs will not be the only criterion as suggested by Mr. Cavanagh. Each of the four cost items mentioned in the article become important when local conditions are taken into consideration.

These items were: iron ore required; fuel and power costs; capital charges, depreciation, etc.; and the cost of all other materials, labour, supervision, repairs and maintenance.

It is incorrect to think of direct reduction as an immediate means of replacing currently installed blast furnaces. Most of the blast furnaces are maintained in good condition regardless of their age. They have been paid for many times—on the books.

They are producing pig iron at an enormous rate and they represent gigantic investments.

As a result they will require tremendous tonnages of high grade ores and concentrates for many more years. No efforts will be spared to improve the output of blast furnaces and their ore requirements will be met until the plants become obsolete.

Where the Strategic-Udy plants should be considered are in new-grass root installations and at auxiliaries to consume fine iron-containing materials generated in the blast furnace and ore preparation plants.

Discussion by F.M. Senior

While parts of Mr. P. E. Cavanagh's article, "Processing of Low-grade Iron Ore Using Petroleum and Natural Gas", were well conceived, the discussion of the Strategic-Udy Process in particular is presented in a manner that indicates an incomplete understanding of the metallurgical and thermodynamic factors.

The recent large scale developments of Strategic-Udy have demonstrated a large degree of acceptance by both leading steel producers and some of the world's outstanding iron and ferroalloy metallurgical engineering groups. Both Koppers Co., of Pittsburgh, and Elektrokemisk A/S, of Norway, are joined with Strategic in the development of the process.

It should be borne in mind that Strategic-Udy, (together with Koppers and Elektrokemisk), is currently fabricating equipment for the progressive installation of Strategic at the world's largest electric steel plant, (1,200,000 tons per year with nine 33,000 kva. furnaces), at Matanzas, Puerto Ordaz in Venezuela. Currently Strategic, in a joint venture with The Universal Cyclops Steel Corp. of Bridgeville, is installing a 10,000 kva. furnace and large kiln at SUMAC, the Strategic Plant at

Automation and Control Engineering in Canada

Economic Aspects of Instrumentation

J. Van Damme, M.E.I.C.
Canadian Celanese Limited, Drummondville

IN THE very early stages of any engineering project the question of cost becomes and remains the dominant factor. In industry in particular, the simplest and cheapest design is always the best, and the sole justification for a new piece of equipment is its ability to produce the highest quality goods or services at the lowest price. By keeping this in mind as we approach the intricate and involved technology of modern automatic control systems, the mystery of instrumentation can be by-passed and instruments can be treated just like any other piece of equipment.

The first step is to weigh the cost of the equipment against the benefits to be derived. The evaluation of the benefits is a lengthy business, closely tied to the economics of the process itself. The cost of a control system is made up, not only of the purchase price of the various elements, but also the installation costs and the commitments for the future such as maintenance, operator training, etc.

In its simplest form a control system is a series of components feeding signals from one to another within a closed loop for the purpose of maintaining a given variable at a certain value. All control loops are divided into three main parts, namely a measuring section, a control section and the process or machine elements themselves.

The measuring apparatus is based on some physical or chemical property of the variable in question, such as the movement of a bourdon tube for pressure or the expansion of mercury for temperature. Measurements may be blind, (no reading of any sort), indicating (a pointer moving against a scale), or recording (an inked record on a chart). A variable may be measured in one location and transmitted to another by converting it to an air pressure or electrical signal in what is called a transmitter. The receiver is the device that converts the signal at a remote point into a reading in terms of the original variable (indicating or recording).

The control section is composed of the group of devices which correct the variable to the desired value. These pieces of apparatus are common to all variables and range in complexity according to the accuracy desired and the ease with which the correction can be made. A simple room thermostat in a house is an on-off control working between an upper and lower limit. A simple throttle governor with valve is a proportional control which increases flow under increased load as it takes up a new control point at reduced speed and vice versa. Reset and derivative actions are refinements which come into the picture as a control problem becomes more involved. Complex systems in which several instruments and loops interact with one another are quite common.

A good way to evaluate the benefits that will result from the installation of a control system is to consider the advantages separately under the following headings:

1. Increase in output
2. Improved yield
3. Waste reduction
4. Greater utilization of labour force
5. Improved quality
6. Reduced services
7. Prolonged equipment life
8. Reduced maintenance
9. Reduced down time
10. Replacement of more expensive equipment in new design
11. Achievement of a process or a result otherwise unobtainable.

You will find that only a few of these pay off in any specific application. Some typical examples will serve as illustrations.

A continuous fabric dryer had been used for years at speeds considerably below maximum. All attemps to speed it up failed because of degraded fabric. A moisture controller immediately produced a 20% increase in output with improved quality. Paper machines are benefitting greatly from similar devices. The yield in steel mills has been increased considerably by using instruments to control the dimensions of plate and sheet to tolerances undreamed of 20 years ago.

The most striking examples of all can be found in the reduction of waste. Two air compressors were running continuously to satisfy plant demand. An automatic stop and start on one of them cut the power bill by 10%. Increased production in a certain plant created a water shortage. Before spending $100,000 on extra pumping and clarifying equipment, flow meters were installed in 14 branch lines at a cost of $12,000. By merely confronting each department with a record of its consumption, the total flow went down by 900 gpm. for an annual saving of $15,000 and the proposed extension was postponed indefinitely.

A series of dye jigs transferring fabric back and forth between two rolls had to be reversed by the operators as the fabric ran out. By installing counters on the rolls the jigs were made to reverse automatically. The saving per jig was well over $1000 a year for $200 expenditure.

Instruments can be of great value in new design. For example, $10.000 was saved in a duplicate dilution system for sulphuric acid by replacing vats and tanks with an automatic blending system using flow and conductivity controllers.

Modern oil refineries and chemical processes could not exist without their complex of automatic controls. Many machines or processes found impractical in previous years can now be developed through the use of instruments. The economic advantage is sometimes hard to find because it is several times removed from the controlled variable, but what finally counts is the profit on the final goods.

It requires imagination to take full advantage of an automatic device. One gas station operator using a newly installed automatic shut-off valve on the filling hoses of his gas pumps didn't think much of it. His competitor across the street found business up 25% after installing the same device because he could speed up service by cleaning the windshield while the tank was filling.

The man best situated to evaluate the benefits to be derived from instruments is the process or machine supervisor. If he can team up with an engineer familiar with the instrumentation field, the pair, working together, can produce amazing results.

In estimating the cost of instrument installations, reference may be made to Table I. Figures from this table are accurate enough for preliminary estimates, to be corrected as the design advances. The table will also serve as a basis for individual lists modified to suit local conditions and future developments.

In analysing the cost of a control system, purchase price and installation are not the only factors. Although automatic controls are very reliable they do require some attention from time to time, and thought should be given in the early stages to the means of servicing them. This may be an expensive item. However, an instrument maintenance crew is inevitable in all but the smallest firms since more equipment is being produced every day already fitted with pneumatic controls, and the sooner a firm trains personnel to service them, the sooner it will adapt to modern methods. In large cities the maintenance can be bought from companies specializing in this field.

If a firm decides to build up its own maintenance crew, certain fundamentals should be accepted at the very beginning. Instrumentation is a new field with its own character. It cannot function as an appendage to an electrical or plumbing shop and it has no place in an operational group. Even if there is only one instrument man in the whole organization, he should be a separate entity reporting directly to the senior engineering supervisor and he must be left free to do all types of work on the instruments, whether it be electrical, mechanical, pneumatic, hydraulic or chemical. There is a shortage of skilled instrument repairmen today so the employer must be prepared to pay a premium and train them. The majority of the instrument men must have high technical qualifications (senior matric). Even a slight deviation from these principles will result in costly errors.

The application of automatic controls to established processes will inevitably cause repercussions which can be dealt with more economically if they are foreseen in the original plans. Labour unions have been known to expect workmen to be kept on doing nothing when automation has eliminated their work. The unions may also object to the status of the instrument mechanic whose work classification does not fall into the old AF of L trade categories. Then again, the operators who use the instruments must be trained, since new concepts are involved. The fact that the pen and the index of a proportional controller are seldom together is rarely accepted or appreciated even

TABLE I
Instrument Costs (dollars)

Commercial Controls

Room thermostat, electric on-off	10	Valves, ½ in. radiator	25
Room thermostat, pneumatic master	40	¾ in. radiator	40
Duct thermostat, pneumatic submaster	70	Humidistat	80-100
Dampers with motor	5 to 15 per sq. ft.	Manometers	5-10
		Thermometers	1-2
Industrial Instruments			
Indicators			
Manometers	50-200	voltmeter	300-400
Pressure gauges, air, water	4-50	Potentiometer, galvanometer	150-300
special applications	50-300	Rotameters, air purge	25
Thermometers	8-50	¼ in.	25-75
Flow totalizer, depends on size	100-300	1 in.	50-125
Speed, generator and indicating		3 in.	200-400
Single Case Recorders			
Pressure, 3 to 15 psi air	180	pH	800-1200
other, will depend on element	200-500	Moisture membrane	200
Temperature, pyrometer	200	dew point recorder and special	1000
vapor pressure	250-300	Level	350-450
liquid filled	300-500	Viscosity	500-1000
Flow, manometer	400-700	CO_2	500-1000
orifice plates, nozzles for above	50-200	O_2	1000
special applications up to	2500	Sampling systems for above	300
Conductivity not compensated	800-1000	Smoke recorders	1200
temperature compensation add	200	Self-balancing potentiometers	800-1000
Controllers to Fit in Above Recorders			
On-off	100-250	Proportional and reset and derivative	600-700
Proportional	425-500	Pneumatic-set add	200
Proportional and reset	550-600		
Transmitters — Receivers			
Receiving recorder, pneumatic, 1 variable	180-250	Temperature	250-350
2 variables	300-325	Differential pressure, water	200-250
3 variables	380-410	high pressure and special	300-500
EMF recorder	600-1000	Level	150
Pressure transmitter (depends on element)	200-500	Speed pneumatic	325-420
		electric	200
Remote Controllers for Above			
On-off and special purpose relays, pneumatic	40-150	Proportional and reset	180
Proportional	150	Proportional and reset and derivative	245
Control Valves			
½ in. globe type, water	90-100	4 in. globe type, water	425
1 in. globe type, water	175	5 in. globe type, water	500
2 in. globe type, water	250	6 in. globe type, water	575
3 in. globe type, water	350		

For linear and percentage plugs add 10% to 20%.
Special materials are extra, for example a 6 in. reducing valve for 600 lb. steam costs $2500.

Special			
Static pressure blind controller	100	Six pen recorder add	350
Integrator	100-225	Conductivity electrodes	25-100
Positioner	100-150	pH electrodes	35-150
Accessories			
Polyethylene tubing ¼ in. OD	2½c/ft.	and 4-way	$40 to $50
Copper tubing ¼ in. OD	7c/ft.	Timers	$25 to $75
Tube fittings, each	25c to 75c	3-way air switching valves	$25
Switches, pneumatic, 3-way			

Installation Costs

These vary tremendously with the complexity of the installation and to some extent with wage rates. Basic installation costs of simple temperature and pressure controls is $50 to $100. Flange mounting level transmitters cost $50. Other instruments will range in the same order. Installation costs go up rapidly with specials or unusual conditions. Add extra for
Centralized panels
Extra long runs
Remote power or air supplies
Corrosive conditions
High pressure or temperature
Hazardous atmosphere
Freezing temperature
Engineering services
Start-up services
Delays from process in use

Use a check list to make sure the following extras are not overlooked
Switches
Orifice flanges
Purge systems
Seals
Electrical or air supplies
Gauges
Thermometers
Pilot lights
Alarms
Special wire
Timers
Conductivity and pH cells
Sampling lines
Dessicators

Control valve installations usually require a gate valve upstream and downstream of the control valve with a globe by-pass. Allow the price of the control valve for buying these and installing the valve system.

If the instrument company recommends sending an engineer for installation or start-up, buy the service but base your specifications on results, not equipment.

by senior supervisors.

Measuring instruments are available for most known variables. Besides the common ones, one could mention conductivity, speed, moisture, pH, mass, position, radox potential, acidity, alkilinity, concentrations of substances such as CO_2 and O_2, acetic acid, colour, water hardness and many others. Instrument manufacturers are eager to investigate new fields provided that the expense is justified by sufficient volume of future business.

Most variables can be measured in many different ways, e.g., a flow meter could be a variable area device such as a rotameter, a fixed orifice such as a venturi tube with a differential pressure recorder, an impeller or propeller type totalizer, a volumetric meter such as the gasoline pump at the service station, a hot-wire anemometer for air flow measurement, or a magnetic flow meter.

There are many designs and many manufacturers to choose from. All the major instrument companies are reliable and can be depended on to provide a successful installation; in fact they take such pride in producing results that it is not unusual to find a company refusing to sell an instrument because there is some doubt about it being suitable for the job. The uninitiated engineer can safely rely on the advice of any one of the major instrument companies.

In buying instruments it is wise to obtain proposals from several companies, but the emphasis should be placed on finding the simplest instrument best suited for the job. Dependability, performance, ease of installation and suitability for the application are far more vital than a small difference in purchase price.

Wherever possible, instruments should be chosen from those manufacturers who are well experienced in the field. For instance, one manufacturer specializes in boiler controls, designing them to meet the needs of the boilers. What is standard equipment for him would be special for another firm. This same manufacturer has serious limitations in other fields. A good knowledge of the products and services of each instrument company is essential if the equipment is to be used to the best advantage.

At the close of World War II the instrument field grew very rapidly around the pneumatic controller. These instruments now form the backbone of the automatic control world of the chemical and oil industries. More recently, with the development of the transistor and the magnetic amplifier, a group of instruments has grown up which are generally classed as electronic controllers. The engineer may be faced with the problem of deciding which to use. Generally speaking, the electronic controllers are more expensive than the pneumatic by 10 to 30% and require auxiliary power at the control valves. The electronic controller has the advantage of faster response and many users claim that it will stand up better in tropical climates. Whatever the pros and cons, pneumatic controls are far in front of electronic in both variety and quantity.

Ten years ago, all parts of an instrument were contained in a single case. Today almost any known variable can be transmitted over long distances as an air pressure or an electrical voltage or current, and controls located at the site of the process can be regulated from a remote control room. On small installations the designer is faced with a choice between the integral controller and the remote transmitter type. On the average, the latter costs $100 to $150 more. Where the instrument is bought for a specific application and will never be moved or altered, the single case controller is usually used. Where the possibility exists of altering the requirements of the control system or moving the machine or modernizing the machine or process, or where trials and experimental work are involved, the flexibility of the transmitter type control system makes it well worth the few extra dollars. Most transmitters are built with a range span which can be raised or lowered at will. This gives an accuracy, range and flexibility which can never be achieved in a single case controller. Pneumatic transmitters have a standard output at 3 to 15 p.s.i. making the controllers interchangeable so that servicing becomes a simple matter of replacing a plug-in section. The advantages of the remote transmitter control systems should not be overlooked.

Another alternative facing the designer is whether to make the system indicating or recording. Generally speaking, if a variable is worth controlling, it is also worth recording. There are exceptions, such as comfort cooling controls or storage tank levels. Where an off standard condition costs money, the record is essential. On industrial instruments the recorder costs only $75 more than the indicator and 100 charts can be bought for $2 to $3. Two types of charts are commonly used, the circular 10 in. or 12 in. diameter, and the strip chart 4 in. wide running at 18 in. to 24 in. a day. There is little to choose between them. The circular chart gives a poor time record when the pen is near the hub, but it is stiffer and easier to handle when half a dozen charts are being compared. The man operating the process should change his own charts.

A word should be said about the difference between industrial controls and analytical instruments since they must be treated differently. It is easy and dangerous to confuse the two. The economic advantages of the analytical instruments can only be evaluated by the chemist or physicist associated with the lab requiring them. Maintenance can usually be bought from the supplier and installation usually consists simply of providing a power outlet. Automatic process controls require a completely different approach. An engineering analysis of process lags and capacities and their interaction upon one another is essential. Specification of components will depend on the analysis. Installation techniques can be extremely involved. Familiarity with analytical instruments does not make one an expert in process control or vice versa.

Automatic control systems are not omnipotent. They cannot correct for a change which has not occurred. In other words, they can only bring back a variable to its control point after it has left that point. If, as a result of poor design, this deviation is large, the instrument cannot provide close control. Much expense and redesign can be eliminated by giving thought to process capacities and process lags in the initial stages. For example, a common mistake is to try to get close temperature control from a heat exchanger by placing a control valve at the steam inlet. The exchanger will continue heating long after the steam has been shut off. A bypass and mixing valve should be used and, if necessary, some storage and mixing at the outlet.

Every September the Instrument Society of America holds an instrument show in one of the major American cities. Engineers associated with process development or machine automation are advised to attend.

There is greater progress to-day in the design and development of instruments than in their application and many engineers are unaware of the full value of these tools. Automatic controls developed for a certain industry can benefit many other industries. To keep abreast, the plant and process engineer must scan the field regularly and reanalyze his processes for ways of reducing costs by taking advantage of instrumentation. EIC

Canadian Developments

Small Reactors For Northern Canada

Studies of small United States reactor types that use enriched uranium for fuel have resulted in a report concerning small nuclear power plants in northern Canada. Operating cost of these small reactors was compared with the estimated cost of an oil-fuelled electricity and heating plant proposed for Frobisher Bay on Baffin Island.

The report, prepared for Atomic Energy of Canada Limited, said the annual operating cost of a small nuclear power plant at Frobisher Bay would be 22% greater than the annual cost of operating a conventional oil-burning power plant there. The plants compared would each produce 2,000 kw. of electricity and 17,500 kw. of heat for a population of 1,500.

Another conclusion was that if there were an Arctic centre that required a nuclear plant large enough to produce 4,100 kw. of electricity and 35,900 kw. of heat, then the annual cost of a nuclear plant would be only 2% greater than the conventional, oil-burning plant.

The natural uranium fuelled and heavy water moderated plant such as that built at Douglas Point, Ont., has a low fuel cost but a high capital cost. Because of the capital cost, this type of station will be economic only if it has a relatively large power output, in the region of 150,000 kw. or more. Thus it would be unsuitable for Arctic centres that require small amounts of power and space heating.

Because of this, studies were made of United States reactor types that use enriched uranium for fuel and ordinary water for coolant. Known as pressurized water reactors and boiling water reactors, they have higher fuel costs because they use enriched uranium for fuel, but have lower capital costs because they can be made in smaller sizes.

Unknown River Being Harnessed

Work has begun to harness the troubled waters of the Unknown River in Labrador's hinterland.

In its annual report the British Newfoundland Corporation Limited said construction has started of a 120,000 hp. hydro-electric plant at Twins Falls on the Unknown River, a tributary of the Hamilton.

About $30 million will be spent on the project, and provisions are being made for an increase in output when contracts for available electricity are obtained. Twin Falls is about 240 miles north of Seven Islands, Que.

Initially the power will be transmitted west 110 miles to the new iron mines of the Iron Ore Company of Canada and Wabush Iron Company, Limited. These two companies will participate in the ownership of the Twin Falls project.

The company's primary goal is the harnessing of the 4 million to 6 million hp. potential on the Hamilton River. At Twin Falls, where the estimated potential is 300,000 hp., the company can satisfy smaller power requirements at the same time it is pushing ahead with long-range plans.

Of the Twin Falls potential, development of 120,000 hp. in the first stage will be accomplished by installing two 60,000 hp. units.

The Iron Ore Company and Wabush Iron Company have agreed to take a total of 100,000 hp. of delivered power at Wabush Lake. The balance of the generated power, less line loss, will be available at the Wabush Lake town site. It is expected that the Iron Ore Company will take the first power June 1, 1962.

Frogmen Help Maintain Montreal's Sewer System

One thousand miles of sewer mains accommodate the water needs of Montreal's citizens. This maze also presents the city's Public Works Department with a difficult maintenance problem.

At times the city calls on a firm specializing in underwater work which sends its frogmen deep into the aqueduct and sewer systems.

Problems vary from season to season, and from sewer to sewer. Frazil ice, clogged grilles and jammed gates all can be dealt with effectively once first-hand information has been obtained.

One difficulty was encountered in sewers built in recent years. Deposits of fatty matter and oil forming a gel-like substance had reduced the openings of the main from 12 ft. to 3 ft. In these areas frogmen had to work in thick mud which made their progress extremely difficult.

Boundary Dam Planned as Water Conservation Project

The Boundary Dam on Long Creek at Estevan, Sask., was planned by the Prairie Farm Rehabilitation Administration as a water conservation project.

Subsequently it was built as a reservoir to provide cooling water for the Boundary Dam generating station.

One of the principal activities of the P.F.R.A., a branch of the federal Department of Agriculture, is the construction of water conservation and irrigation projects, of which the South Saskatchewan River Dam is one.

Because the P.F.R.A. carried out the original plan for the Boundary Dam, and because it had the experienced staff the Saskatchewan Power Corporation negotiated with the federal government for the Administration's engineering services for the construction design.

Controlled Explosions Clear Shipping Menace

A sunken freighter lying on her side in 50 feet of water east of Montreal's Jacques Cartier Bridge is being carved to pieces by carefully-controlled underwater explosions.

Following a collision last spring the Federal Express sank 800 feet from shore in the St. Mary's current. Divers are removing this hulk with explosive charges.

Shock waves, which possibly could damage dock installations, are cushioned by a curtain of compressed air bubbles which rise from a perforated pipe placed between the blast and the shore.

A 300-foot steel deflector anchored upstream from the operation enables the divers to place their charges in the swift current.

The four-month project is scheduled to be finished before freeze-up.

University of Waterloo Adds Five Companies to Advisory Council

Five companies have been voted membership in University of Waterloo's Industrial Advisory Council. The Council is composed of representatives of about 30 companies and meets twice a year at the university. It advises on matters of student programing and training relating to the students' industrial assignments which are an integral part of Waterloo's co-operative engineering course. Students in the course alternate attending classes and working in industry every three months. EIC

International News

Contracts Awarded for Cross-Channel Power Link

A power link joining Britain and France has come one step closer with the signing of a £610,000 contract for power cables by the Central Electricity Generating Board.

Awarded the British contracts were Associated Electrical Industries Limited and British Insulated Callender's Cables Limited.

These two cable-making firms will place half the submarine cable link which will connect the national electricity systems of Britain and France. The cables are scheduled to be placed next summer.

Patterns of electric consumption vary greatly between the countries due to difference in climate, clock times, hours of work and habits. These differences in demand upon the two networks result in the availability of some hundreds of megawatts at peak winter loads.

As planned, the connection will transfer 160 Mw. at peak periods, and will transfer power at other times to meet conditions such as surplus or shortage of water at hydro stations.

The ability of the countries to call on one another for extra generating capacity eliminates the need for extra plants and will work to their mutual economic advantage.

The contract calls for the manufacture and placing of two similar 15-mile lengths of single-core submarine cable and two related land cables. The work is to be divided equally between the companies.

The connection between the British 275,000 v. Supergrid and the 225,000 v. French network will be by direct current circuit of 160,000 kw., with a 20% overload for isolated periods of 30 minutes. The direct current transmission will operate at 200,000 v. between poles, with its centre point earthed, and the cables will be insulated for a nominal voltage of 100,000 v. to earth.

Normal full load current will be 800-amp. When completed, this submarine circuit will carry the heaviest d-c. load ever transmitted under water.

The cables themselves, as developed successfully from sea trials, are of the impregnated-paper insulated solid type. The submarine cable conductor cross section is .525 sq. in., and consists of stranded copper wire lapped with an electrostatic screen. The solid type impregnated paper insulation, also lapped externally with an electrostatic screen, is sheathed with lead alloy "E" which is protected against corrosion by vulcanized rubber tapes.

Armouring is provided by a single layer of .232 in. galvanized steel wires with appropriate beddings and servings. The cables weigh about 39 lb. per yd. in air and about 28 lb. per yd. in sea water.

Swedish Firm Lands Large Transformer Order From United States Government

The Swedish Asea Company, competing with American, Canadian and other European firms, has been awarded a $1 million order for 10 transformers from the United States Government, represented by the U.S. Army Corps of Engineers.

Ordered were one 103,000 kva. three-phase transformer for 115 kv. and nine 68,700 kva. single-phase transformers for 230 kva.

The transformers are intended for a large hydro-electric power station at the Oahe Dam on the Missouri River in South Dakota. Shipments of the first units are to start in mid 1961 and delivery is to be finished a year later.

Russian Scientific Papers Available in English

Translations of important Russian books and articles of scientific interest have been made available through the Program for Scientific Translations in Israel.

Material which has been translated into English was selected in accordance with the requirements of the National Science Foundation, Washington, which initiated and supports the program.

The Foundation has entrusted the Program with sole distribution outside the United States of all translations listed. The 1960 catalogue lists 22 broad categories and can be obtained from: Program for Scientific Translations, P.O. Box 7145, Jerusalem, Israel.

Metropolitan Sydney To Have New Concrete Bridge

A Melbourne company which recently completed a 2,074 ft. prestressed concrete bridge has been awarded the tender to build a smaller bridge in metropolitan Sydney.

John Holland (Constructions) Pty., Limited will build a 657 ft. five-span bridge of prestressed and reinforced concrete over the Parramatta River at Silverwater. The company's bid was £460,000. The bridge will have a pair of two-car lanes separated by a median strip, and two pedestrian walks.

El Salvador Gets World Bank Loan For Expansion of Electric Power Facilities

El Salvador, the smallest and most densely-populated of the Central American republics, has been given a loan equivalent to $3,840,000 by the World Bank for expansion of electric power facilities.

The loan will finance imported equipment and services for the construction of the Guajoyo 15,000 kw. hydro-electric power plant and associated transmission facilities.

Receiving the loan was the Comision Ejecutiva Hidroelctrica del Rio Lempa, a semi-autonomous government agency established in 1945 to plan and provide facilities to meet El Salvador's power requirements. It supplies power wholesale to the country's principal distributors of electricity which serve nearly all consumers.

Canada-India Reactor In Operation

The Canada-India Reactor went into operation July 10 at Trombay, India, it has been announced by India's Atomic Energy Commission and Atomic Energy of Canada Limited.

The research and engineering test reactor, a modified version of the NRX reactor at Chalk River, Ont., is the result of five years of close co-operation between engineers, scientists and technicians of the two countries.

The reactor was built through the Colombo Plan as a joint Canada-India project. Canada's share of the cost, which covers the reactor, the start-up and the training of Indian personnel, is about $9 million.

CIR is expected to operate at its full output of 40,000 kw. of heat on a routine basis beginning this autumn. EIC

Month to Month

100 Years Ago

A group of men gathered together on October 10, 1860 for the first meeting of The Association of Provincial Land Surveyors and Institute of Civil Engineers of Canada. The Association, believed the first engineering organization in Canada, had been incorporated under the laws of Upper Canada. Seventeen years later the Canadian Society of Civil Engineers was formed, and by Dominion Act of April 15, 1918, its title was changed to The Engineering Institute of Canada. This change of title indicates the broad general character of the Institute.

Requirements Survey for Professional Personnel

An increased demand for engineers and scientists during the next two years is forecast by the Economics and Research Branch of the Department of Labor. In its 1960 biennial survey of requirement for professional personnel in scientific and technical fields the branch received information in industry, government and education from employers of about 27,200 engineers, 12,500 scientists and about 600 architects.

By 1962 it is estimated 5.5% more engineers will be required. This ranges between a 6.8% increase in demand for metallurgical engineers to 1.4% increase in demand for geological engineers. The average increase in demand for all scientists is 4.6% with the range between 9.3% for mathematicians and 2.6% for agriculture scientists. The anticipated increase in demand for architects is 6.6%.

Institute Represented at Buenos Aires

The Institute had strong representation at the Sixth Congress of the Union Panamericana de Asociaciones de Ingeieros at Buenos Aires, Argentina, September 18-22.

Twenty-one Members from Canada, the United States, Argentina and Uruguay served as delegates or alternate delegates to the Congress. In addition to representing the Institute at the UPADI Congress, Dean H. G. Conn of Queen's University's Engineering Faculty and Dean R. R. McLaughlin of the Faculty of Applied Science and Engineering, University of Toronto, also attended the First Pan American Congress on Engineering Education in Buenos Aires, September 12-17.

Head of the Institute delegation and representing President George McK. Dick, was Dr. James A. Vance of Woodstock, Ont., a Past President. Another Past President, Dr. K. F. Tupper of Toronto, was deputy head of the delegation and President's representative.

Fifteen Institute representatives also formed a Canadian Mission of Consulting Engineers which travelled to other South American countries to promote closer relations between Canadian and Latin American members of the profession.

Following the UPADI Congress the Mission went to Santiago, Chile; Lima, Peru and Bogota, Colombia.

Gordon Churchill, Minister of Trade and Commerce, said Canada's consulting engineers are particularly well equipped to understand Latin American conditions and requirements because in the large-scale development of natural resources in Canada they have solved similar problems.

Objectives of the Mission were to acquaint Canadian consulting engineers with Latin American opportunities; to draw attention of Latin Americans to the availability of Canadian engineering through consulting engineers; to assist those newly interested in export markets to determine for themselves the opportunities in Latin America and the advisability of becoming active there; and to assist those already established to renew existing contacts and to make new ones.

The Department of Trade and Commerce will be represented on the Mission by Chief of the Engineering and Equipment Division, R. A. Frigon, who will act as secretary. Spokesman for the Mission is Charles C. Huston of C. C. Huston and Associates, Toronto.

Besides Dean Conn, Dean McLaughlin, Dr. Vance and Dr. Tupper, the Institute delegates to the UPADI Congress were: Leo Scharry, Honorary Vice-President, E.I.C., Sangamo International Inc., New York City; C. R. Vegh Garzon, Honorary Vice-President, E.I.C., Montevideo, Uruguay; Mr. Frigon, also an Honorary Vice-President, E.I.C.; Professor Carson Morrison, Honorary Vice-President, E.I.C., of Morrison, Hershfield, Millman and Huggins, Toronto; G. R. Adams, Manager, Overseas Operations, Foundation of Canada Engineering Corporation Ltd., Montreal; C. A. Dagenais of Surveyor, Nenniger and Chenevert, Montreal; Frank Athey, Buenos Aires; and W. H. Beaton of Beauchemin, Beaton and Lapointe, Montreal.

Alternate delegates were: N. Fodor of Nicholas Fodor and Associates Limited, Toronto; Paul Pelletier, President of Paul Pelletier Engineering Limited, Montreal; W. N. Papove, General Manager of Pathfinder Engineering Limited, Vancouver; G. G. Hatch, President of W. S. Atkins and Associates Limited, Toronto; Mr. Huston; R. M. P. Hamilton, President of General Engineering Company Limited, Toronto; Harold Wright, President of Wright Engineers Limited, Vancouver; A. T. Hurter, President of Stadler, Hurter and Company, Montreal; and H. B. Tafelmacher, Montevideo.

Among the Institute delegates to the Sixth UPADI Congress in Buenos Aires were, from the left: Dean H. G. Conn, Dean R. R. McLaughlin, Dr. James A. Vance and Dr. K. F. Tupper.

Coal Research Conference

"Institutional Heating with Coal" and "Coal Carbonization" were the themes of the Twelfth Dominion-Provincial Coal Research Conference held in Ottawa this month. During the three days of the conference at Camsell Hall delegates attended three panel discussions and had the opportunity of visiting several Ottawa heating plants.

W. E. Uren, Chairman, Dominion Coal Board, was the chairman of the first symposium which concerned the preparation of coal for coke making. Dr. John Convey, Director, Mines Branch, Department of Mines and Technical Surveys, was the chairman of the two other meetings at which the theme topics of the Conference were discussed.

Mr. Uren was the chairman of the business session which was held on the morning of Oct. 15, the final day of the Conference.

Nominations for Officers, 1961

The report of the 1960 Nominating Committee, as accepted by the Executive Committee of Council at its meeting held on September 9, 1960, in St. Andrews, N.B., is published for the information of all corporate members as required by Sections 19 and 40 of the By-law's.

VICE-PRESIDENTS

One to be elected for two years

Zone A (Western Provinces)	**F. M. Cazalet, Vancouver, B.C.**
Zone B (Province of Ontario)	**Paul E. Buss, Thorold, Ont.**
Zone C (Province of Quebec)	**G. N. Martin, Montreal, Que.**

COUNCILLORS

Two to be elected for three years

Montreal	**T. A. Monti** **R. J. Harvey**

One to be elected for three years

Toronto	**A. M. Toye**
Ottawa	**Hugh C. Brown**

One to be elected for two years

Vancouver	**C. Peter Jones**
Vancouver Island	**L. C. Johnson**
Edmonton	**J. Longworth**
Saskatchewan	**F. W. Catterall**
Winnipeg	**G. Flavell**
Yukon	**G. B. Starr**
Central B.C.	**H. R. Hatfield**
Kootenay	**L. Williams**
Belleville	**T. E. Flinn**
Border Cities	**(C. Maurice Armstrong)** **(J. E. Dykeman)**
Brockville	**R. H. Wallace**
Chalk River	**C. E. L. Hunt**
Kingston	**S. D. Lash**
Lakehead	**D. B. McKillop**
London	**D. M. Jenkins**
Nipissing & Upper Ottawa	**J. F. Chantler**
Port Hope	**H. A. Gadd**
Sudbury	**W. B. Ibbotson**
Baie Comeau	**Emil Bodmer**
Eastern Townships	**A. S. Mitchell**
Lower St. Lawrence	**J. R. Menard**
North Shore Lower St. Lawrence	**R. W. Pryer**
Saguenay	**C. C. Louttit**
St. Maurice Valley	**J. U. Moreau**
Fredericton	**S. B. Cassidy**
Saint John	**J. W. G. Scott**
Amherst	**J. W. Wilson**
Halifax	**W. J. Phillips**
Prince Edward Island	**L. A. Coles**
Corner Brook	**H. B. Carter**
Newfoundland	**V. A. Ainsworth**

President's Column

PRESIDENTIAL visits to important Canadian Engineering and Scientific organizations continued through the summer, culminating in a visit to the Ottawa laboratories of the National Research Council.

During this visit the President was accompanied by: Garnet Page, General Secretary; Hugh Brown, chairman of the Ottawa Branch; Dr. John Ruptash, Dean of Engineering at Carleton University; and Dr. George Glinsky, Head of the School of Engineering at Ottawa University.

The arrangements were in the capable hands of the Chairman of the EIC Committee on Technical Operations, Dr. B. G. Ballard, Vice-President (Scientific) of N.R.C. A great many interesting developments were inspected, including the new Supersonic Wind Tunnel now being erected.

The visit permitted improved liaison between the Institute and our largest scientific research group, the N.R.C.

A considerable amount of EIC attention has been focused recently on the handling of matters relating to membership administration. The ad hoc committee on membership problems, with Mr. Brown as chairman, has met several times. It is hoped that a report on the Committee will be available for study at the next meeting of the Council. Institute membership is a vital subject and is receiving careful consideration.

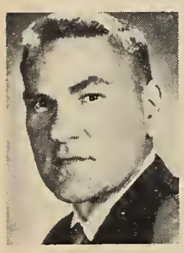
The President and General Secretary, accompanied by their wives, started a tour of the Branches in the Atlantic Provinces and Eastern Quebec early in September, Vice-President and Mrs. T. C. Higginson were with the Presidential group during the Maritime visit. Vice-President and Mrs. Charles Miller were present during the Eastern Quebec portion. This tour included attendance at the Maritime Professional Engineers Meeting at St. Andrew's, N.B.

Many of the Branch Chairmen have answered the President's recent letter to the Branches concerning the necessity for early consideration of next season's activities. It has been encouraging to note the amount of care and interest which has been shown in these replies. They will be given careful study, after which the President will send another letter to Branch Chairmen with suggestions they may consider for their autumn programs. The secret of the success of any organization is largely in careful planning. Any effort which Branch Executives make in this direction will undoubtedly be demonstrated in more effective Branch operations.

• MONTH TO MONTH

(Continued from page 138)

Roger J. Harvey New Councillor



Roger J. Harvey was elected Councillor representing the Montreal Branch at the July 22 meeting of the Executive Committee of Council. He succeeds E. D. Gray-Donald, treasurer of the Institute. Mr. Harvey joined the Bell Telephone Company of Canada as an engineer in Montreal 14 years ago. He now is supervising engineer—Estimates and Design, Outside Plant Division, Egineering Department, Eastern Area. Mr. Harvey first became active in the Montreal Branch of the Institute in 1949-50 when he served as vice-chairman of the Program Committee, then as chairman of the Radio Communications Section. Subsequently he was Program Committee secretary, secretary-treasurer, ex-officio member of the Executive Council and Executive Committee member. In 1956 he became a member of the Admissions Committee.

Argentine Engineering Official Visits Headquarters

EIC headquarters was visited this summer by Senor Dante Ardigo and Senora Ardigo. Senor Ardigo is President of the Centro Argentino de Ingenieros.

By-Law Changes

Eleven amendments to the Institute's by-laws have been approved overwhelmingly by the members. In accordance with Section 80 of the by-laws these amendments, approved for ballot by the Annual General Meeting, were submitted to the membership for a letter ballot. Following are the by-laws considered and the vote totals.

By-law Number	*Yes*	*No*	*Spoiled*
27	5,460	345	8
35	5,645	164	4
29	5,741	66	6
22	5,596	212	5
28	5,661	129	23
11	5,592	211	10
18	5,496	304	13
45	5,749	24	40
48	5,757	31	25
75	5,612	189	12
45a	5,475	321	17

The by-law sections affected deal with re-admission, branch representation, Journal subscriptions, compounding of fees, affiliates, list of members, appointment of secretary, treasurer and committees, papers committee, specifications and honorary vice-presidents; as distributed to the members.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and tranfers were effected at a meeting of council on August 18, 1960.

Member: J. T. Atchison, Winnipeg; C. L. Bailey, Calgary; W. T. Bell, Toronto; R. E. Blaby, Hamilton; J. E. Bryden, Montreal; J. G. Bullivant, St. Catharines; G. E. Buteau, Montreal; D. Critoph, Toronto; J. M. Crow, Montreal; K. M. Dewar, Toronto; A. F. Eshmade, Winnipeg; P. J. Folberth, Niagara Falls; A. Frenkel, Montreal; A. J. Gegan, Niagara Falls; K. Haselsteiner, Vancouver; E. Huni, Vancouver; W. A. Jackson, Toronto; P. S. Jaffray, Windsor; D. R. J. Kay, Galt; A. Kratsios, Montreal; L. E. Lanczi, Montreal; C. A. Macdonald, Ottawa; T. G. H. McKibbin, Winnipeg; W. J. Muir, Montreal; M. T. Neill, Kenogami; T. P. O'Connor, Taylor, B.C.; J. E. G. Palmer, London, England; F. T. Phippard, St. Catharines; J. W. Powlesland, Toronto; J. J. Redmond, Toronto; R. H. Sainani, Montreal; G. Smethurst, Ottawa; P. S. Stefanidis, Montreal; L. Tass, Toronto; J. Thon, Hamilton; O. E. Uusima, Montreal; A. Verdun, Hamilton; A. K. Voss, Valleyfield; R. C. Wyld, Yukon; W. F. Zybala, Montreal.

Junior: A. E. Burwell, Dalhousie; G. E. Courtnage, Sarnia; J. R. Dalrymple, Sault Ste. Marie; C. Grunberg, Montreal; J. A. Higgins, Montreal; J. F. Kojro, Scarborough; L. A. LeBlanc, Shawinigan Falls; I. H. MacLachlan, Montreal; P. Strong, Montreal; G. D. Thomas, Moncton; I. A. Vaughan, Manchester, Eng.

Junior to Member: W. H. Agnew, Ottawa; C. H. Albright, Trail; L. D. Almack, Toronto; F. E. Barrett, Montreal; E. R. Begin, Montreal; A. J. Bennett, Sarnia; L. D. Blachford, Toronto; L. W. Blackman, Winnipeg; J. T. Bone, Montreal; G. S. Bowes, Montreal; A. L. Braund, North Bay; S. E. Bryan, Montreal; A. E. M. Cameron, St. John's, Nfld.; W. L. Hayhurst, Toronto; R. A. Cameron, S. Nelson, N.B.; W. H. Carr, Georgetown, Ont.; M. Carrier, Rimouski; R. R. Carrier, Quebec; F. G. Carrington, Toronto; G. R. Carruthers, Quebec; R. B. Cayford, Montreal; R. O. Chenevert, Three Rivers; R. G. Christie, Westview, B.C.; H. E. Cole, London, Ont.; G. B. Conquergood, Montreal; D. C. Cramm, Hamilton; R. M. Cruikshank, North Bay; D. W. Howard, Toronto; G. N. M. Currie, Montreal; L. J. Delby, Ottawa; D. G. Demianiw, Shawinigan; O. A. Dodson, Sault Ste. Marie; J. D. Dorey, Montreal; W. C. Durant, Peterborough; O. C. Edwards, Vancouver;

G. W. Fleming, Copper Cliff; P. J. Flynn, Montreal; F. H. Foord, Philadelphia, Pa.; D. C. H. Francis, Montreal; W. Fredenburg, Toronto; W. F. Fromm, Rexdale, Ont.; W. Gouldsborough, Peterborough; G. G. Green, Ottawa; P. G. Haley, Calgary; J. G. Hall, Toronto; T. E. Harris, Montreal; R. K. Haun, Arvida; G. O. Hayman, London, Ont.; F. E. Hertha, Vancouver; P. B. Hill, St. Catharines; A. K. Hugessen, Montreal; W. A. Hunka, Toronto; W. C. Hunter, Port Arthur; J. C. Hurtubise, Rimouski; W. A. Inman, Montreal; E. H. Irwin, Beauharnois; W. C. Isaac, Montreal; J. D. Jardine, Kentville, N.S.; C. H. Johnson, Montreal; K. H. Jones, Toronto; W. G. Jones, England; R. L. Kennedy, Windsor; W. W. Kennedy, Montreal; M. Lepine, Montreal; P. J. Limbert, Trail, B.C.; H. R. Lumsden, Toronto; G. A. Mackey, Montreal; W. E. Macklon, Ottawa; G. L. MacLean, Dorval; I. D. Macorquodale, Montreal; J. W. Madill, Courtenay, B.C.; D. R. Matheson, Sydney, N.S.; J. N. Matthews, Toronto; A. McCaw, Windsor; E. D. McCormick, Port Credit; J. H. McCracken, Toronto; A. G. McIntyre, Vancouver; C. S. McKinley, Fredericton; J. W. McLellan, Mexico; W. R. McMillan, Edmonton; J. P. Milette, Quebec; F. I. Morton, Malaya; D. H. Murray, Salvador, C.A.; R. W. Myers, St. John's, Nfld.; G. H. Nagel, Hamilton; J. S. Nelles, Chalk River; J. W. Nelson, Kamloops; H. Newall, Sarnia; C. R. Newton, Toronto; J. D. Nisbet, Sarnia; D. M. Norman, Ottawa; R. Otsuki, Welland; W. G. Peacock, Montreal; A. Perrin, Toronto; A. F. Pigott, Willowdale, Ont.; R. A. Pillman, Niagara Falls; W. G. Plewes, Ottawa; M. Price, Toronto; J. M. C. Profit, Toronto; C. D. Quenneville, Montreal; A. D. Rae, Lloydminster, Alta.; A. D. Reed, Dayton, Ohio; J. A. Reid, Hamilton; J. D. Richards, Montreal; W. J. Ripley, Sudbury; W. E. Rose, Sarnia; R. J. Rushka, Toronto; A. W. Saunders, Toronto; H. G. Saville, Toronto; G. P. Schwarzkopf, Cornwall; G. H. Scruton, Montreal; M. V. Shore, Toronto; C. G. Simms, Toronto; B. W. Sinnamon, Hamilton; F. W. Slingerland, Quebec; J. S. Smeaton, Ottawa; B. A. J. Smith, Quebec; G. A. Smith, Toronto; J. Soucy, Montreal; A. K. Spence, Regina; W. D. Staniforth, North Bay; N. L. Stoddart, Montreal; J. W. Strzelecki, Maple, Ont.; S. N. Teed, Houston, Texas; F. H. Theakston, Guelph, Ont.; G. R. Thim, St. Bruno, Que.; C. G. Thompson, Pensacola, Fla.; E. L. Tong, Toronto; W. I. M. Turner, Montreal; R. W. Vollett, Ottawa; A. R. Walker, Toronto; J. R. A. Walker, Toronto; R. B. Walker, St. Bruno, Que.; G. G. Wellington, Toronto; G. P. Williams, Ottawa; H. R. Young, Washington, R. E. Yule, Montreal.

Student to Member: M. De Atucha, Spain.

Student to Junior: T. R. Horn, Edmonton; F. Williamson, Banff.

STUDENTS ADMITTED

Acadia University: D. J. Perry, V. J. Pike, G. E. Richardson, S. C. K. Wong.

McGill University: R. Peterson, O. Silverman.

University of Toronto: H. F. Ryan, F. Z. Sobolak.

University of Western Ontario: G. T. Suter, J. J. Wideki.

Saint Mary's University: J. C. Y. Fung.
Nova Scotia Technical College: R. A. Barkley.

Queen's University: D. H. Zwicker, B.Sc. (Civ.) 1960.

McMaster University: J. Schroeder.

College Militaire Royal de St. Jean: P. H. Kroeger.

University of Washington: V. B. Kromand.

University of Alberta—graduates: Z. D. Figol, B.Sc.(Civ.) 1960; N. J. Kitz, B.Sc. (Civ.) 1960; J. K. F. Kwong, B.Sc.(Civ.) 1960.

University of Toronto—graduates: A. B. Hall, B.A.Sc.(Civ.) 1960; L. C. Mangoff, B.A.Sc.(Civ.) 1960; R. Partanen, B.A.Sc. (Civ.) 1960.

Student of Corporation of Professional Engineers of Quebec: A. D. Drost.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers became effective August 18, 1960.

ALBERTA

Members: R. J. Finley, I. C. Khosla.

Junior: J. D. Thomson.

Junior to Member: C. J. Farrell, R. H. Vickerman.

SASKATCHEWAN

Members: S. B. Bell, L. B. Brunskill, G. M. Doucet, D. R. Gillard, G. W. Grass, B. A. Holmlund, P. Kents, D. M. Lane, H. Olecko, M. W. Pyke.

Juniors: W. Westgaest.

Junior to Member: H. F. Button, J. W. Chepha, D. J. Ferguson, A. A. Gorkoff, G. F. Hutch, E. H. McIntyre.

Student to Junior: M. T. Dagg, B. J. Pfeffer, D. L. MacLeod.

Students: J. Wolkowaski, R. E. Wood.

NOVA SCOTIA

Members: F. C. Farrell, A. R. Howard, A. R. MacLean, J. Nagy.

Junior to Member: W. R. Lowther.

MANITOBA

Member: W. H. Bender.

Junior to Member: G. S. C. Smith.

Members with No Addresses

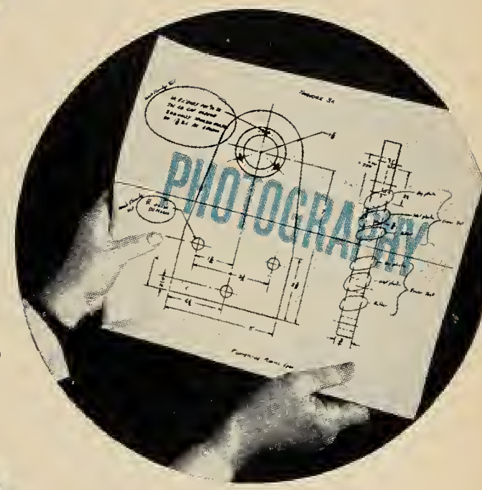
The following members' mail has been returned to headquarters. As a result, their names have been removed from the Institute membership list, but would be readily reinstated if a current address were forthcoming. Information regarding them should be sent to: **Records Department, The Engineering Institute of Canada, 2050 Mansfield Street, Montreal.**

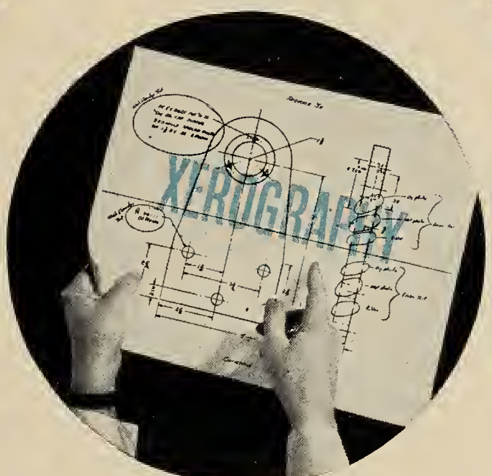
Members
Schuett, George Herbert, Ottawa; Tammik, Kaljo, St. Lambert, Que.

Juniors
Archambault, Pierre A., l'Abord-a-Plouffe, Que.; Bonneville, Jacques Marcel, Quebec; Bressler, Theodore, Ingersoll, Ont.; Collis, James Dean, Pte. Claire, Que.; Cook, Richard Moxley, Toronto; Ferris, Charles Raoul, Edmonton; Fisher, William Henry, Vancouver; Heaney, William Creighton, Montreal; Laberge, J. Peter, Montreal; Lamarche, Paul, Montreal; MacDonald, William Grant, Wiltshire, England; Monaghan, Dennis James, Springfield, N.J., U.S.A.; Overhill, Douglas Tom, Montreal; Paquet, Andre, Quebec; Potter, Gary William, Vancouver; Preston, Keith S., Hamilton; Ross, John St. Clair, Toronto; Roy, Guy Walter, Montreal; Sikal, John Derick, Schefferville, Que. & Toronto; Simard, Jacques P., Montreal; Vosniades, Orpheus, Montreal; Watkins, Raymond Herbert Cyril, Calgary.

Students
Arseneault, Lionel Raymond, Montreal; Bagnall, Ralph Simpson, Charlottetown, P.E.I.; Baron, Roger Jack, Calgary; Blowatt, Kenneth John Richard, Burlington, Ont.; Bowes, Robin Neale, Ottawa; Bowkett, Edmund George Alfred, Winnipeg; Choquette, Roger, Quebec; Christensen, Flemming Henrick, North Surrey, B.C.; Cossette, Marcel, Ottawa; Crooks, Archibald Muir, Jamaica, B.W.I.; Frazer, George Robert, Vancouver; Fulford, Gerald Nelson, Kingston; Hamilton, James Murray, Weyburn, Sask.; Heimark, Harry, Saskatoon; Hersey, Donald Ersel, Fredericton; Hopkins, James Alfred, Halifax; Kappel, John James, Montreal; King, Arthur Emmerson, Halifax; Lecocq, Donald Stanley, Ottawa; Lescuk, John, Toronto; Lum, Peter, Ottawa; Magee, William George, Edmonton; McIntosh, Robert Gordon, Saskatoon; McIntyre, Harold Robert Bruce, Toronto; Myint, Maung Soe, Rangoon, Burma; Olafson, Wayne Allen, New Westminster, B.C.; Pedroso, Hector M., Havana, Cuba; Poulin, Gregoire, Noranda, Que.; Prevost, Marcel Joseph Denis, Sherbrooke, Que.; Provencher, Thomas, Ottawa; Rooney, Francis Joseph, Lancaster, N.B.; Roylance, Campbell Arthur, Winnipeg; Skinner, Antony Simon, Montreal; Strachan, Robert Allan, Vancouver; Swantee, Frank Murray, Pictou Co., N.S.; Topper, Timothy Hamilton, Cooksville, Ont.; Tremblay, Daniel, Timmins, Ont.; Vlahos, George, Montreal; Wells, Lyle Edgar, Ingleside, Ont.; Whitcombe, Richard Milner, London, Ont.

Use any reproduction process . . .

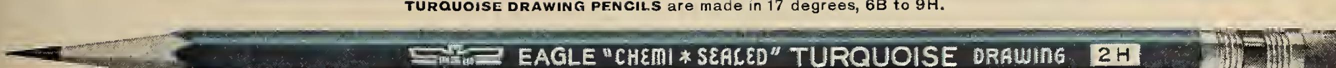




Your drawings reproduce sharper, clearer with Eagle Turquoise

TURQUOISE LEAD HOLDERS hold any TURQUOISE lead (5B to 9H).

TURQUOISE DRAWING PENCILS are made in 17 degrees, 6B to 9H.



TURQUOISE WITH ERASER, in grades 4B to 6H, is increasingly popular as a field tool.

Whatever the process, you'll get sharper, clearer prints if you use an Eagle TURQUOISE. Lines are more opaque and also blacker—because the graphite in TURQUOISE is finer-ground with denser-packed particles.

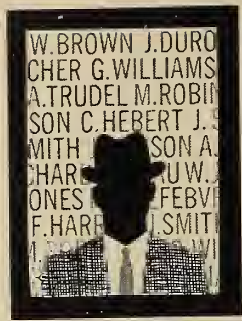
Get smoother, neater drafting, too! TURQUOISE glides effortlessly, evenly over paper, cloth, vellum, "Mylar"® And uniform grading means consistent peak performance.

So, no matter what you draw on, how you reproduce it, use Eagle TURQUOISE for superior results every time!

EAGLE

WANT A FREE SAMPLE? Write for a TURQUOISE pencil or lead, in the degree you'd like to test on your favourite drafting material. Eagle Pencil Company of Canada Ltd., 217 Bay St., Toronto 1.

Personals



Richard M. Dillon, M.E.I.C. (M.I.T. '50) has assumed his duties as Dean of the Faculty of Engineering Science at the University of Western Ontario. Mr. Dillon, who was born in Simcoe, Ont., received his university education at U.W.O. and at the Massachusetts Institute of Technology. During the Second World War he served with the Royal Canadian Regiment and with the General Staff in England, Sicily and Italy. He was awarded the Military Cross for conspicuous service with the R.C.R. in Sicily, and later was wounded in action in Italy. After completing his interrupted education he joined the Design Staff of the Dominion Bridge Company, Limited in Toronto and later became a partner and Director of M. M. Dillon and Company, Limited. For the past eight years he has been head of the Structural Department and has served as Chief Project Engineer. While accepting his new appointment he will continue to serve as a Director and Consultant with M. M. Dillon and Company.

R. M. Dillon, M.E.I.C.

William J. Riddell, M.E.I.C., (Manitoba '24) has been awarded by the Canadian Good Roads Association a special scholarship for post-graduate study in civil engineering. The scholarship is known as an International Road Federation fellowship. Mr. Riddell is an assistant design engineer with the Saskatchewan Department of Highways and Transportation, Regina.

J. Edgar Dion, M.E.I.C. (McGill '24) has recently moved his consulting management engineering offices from the Canada Cement Building to 1980 Sherbrooke Street West, Montreal 25.

Noel Wright, M.E.I.C. (Illinois '28) has been appointed Special Industrial Representative in charge of the New York City office of Southern Canada Power Company Limited.

J. H. Mellor, M.E.I.C., (McGill '30) has been appointed assistant manager-engineering, at Canadian Copper Refiners, Montreal East.

F. Milligan, M.E.I.C.

Frank Milligan, M.E.I.C., (Toronto '48) of Thermal & Hydraulic Equipment, Limited, Toronto, has been appointed sales agent for Ontario by Morris Machine Works, Baldwinsville, N.Y., manufacturers of centrifugal pumps and hydraulic dredges.

L. P. Beaulieu, M.E.I.C. (Ecole Polytechnique '34) has been eleeted vice-president and a director of the Canadian Fairbanks-Morse, Company, Limited. Mr. Beaulieu also will serve as vice-president and general manager of Dynamic Engineering Limited, recently purchased by C. F. M. It will be operated as a C. F. M. subsidiary.

John R. Michie, M.E.I.C., (Toronto '40) has been appointed manager of Frick of Canada, Limited, with head office in Montreal, a subsidiary of Frick Company, Waynesboro, Penn.

Walter H. Ball, M.E.I.C., (Saskatchewan '41) has been appointed Officer-in-Charge of the British Columbia Regional Station, Building Research Division, of the National Research Council.

D. D. Munro, M.E.I.C. (Saskatchewan '45) has been appointed Resident Engineer of the Iroquois Falls Division of Abitibi Power and Paper Company, Limited. Mr. Munro formerly was Resident Engineer, Manitoba Paper Company, Limited, at Pine Falls, Man.

Eric E. Heaton, M.E.I.C., (Queen's, Belfast '47) has formed a new company, Nova Scotia Drilling and Equipment, Limited, Bryant Building, Halifax, N.S. He will serve at president. Mr. Heaton also has established recently a consulting firm in the field of soil mechanics and allied sciences, Eric E. Heaton and Associates, Consulting Soil Engineers, Halifax.

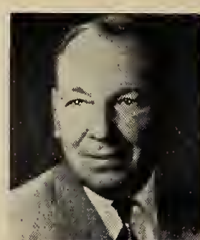
Karl W. Allcock, M.E.I.C., (Sask. '48) has been appointed electrical distribution manager, Saskatchewan Power Corporation, Regina. Mr. Allcock joined the SPC in 1948 and in 1952 was named operating supervisor and assistant to the operating superintendent. In 1957 he was appointed operating superintendent.

G. Valois Bourbonnais, M.E.I.C. (McGill '40) has been appointed chief engineer of Pigott Construction Company's Quebec Division.

Keith Vail, JR.E.I.C., (N.S.T.C. '50) has been appointed resident engineer of construction at Isle Maligne, Que., for the Aluminum Company of Canada. Mr. Vail previously was associated with Pigott Construction Company and the Foundation Company Quebec at Montreal.

W. M. Kelly, M.E.I.C., (Toronto '50) has been appointed vice-president and general superintendent, distribution, for The Consumers' Gas Company.

C. E. Bedford-Jones, M.E.I.C. (Toronto '33) president of F. S. B. Heward and Company, Limited, who recently acquired the interests of Mr. Heward in



C. E. Bedford-Jones, M.E.I.C.

H. E. G. Dupuy M.E.I.C.

the company, has announced that **H. E. G. Dupuy**, M.E.I.C. (McGill '38) has become a partner in the firm and will assume the duties of vice-president and general manager. Mr. Dupuy was eastern branch manager for Babcock-Wilcox and Goldie-McCulloch, Limited. Bedford-Jones also announced the company, while continuing to represent the same manufacturers of steam plant, industrial and marine equipment, has changed its name to Canapower Thermal Specialties, Limited.

(*More Personals on page 147*)

• PERSONALS

(Continued from page 144)

John A. Kerr, M.E.I.C., (Manitoba '52) has taken a position with the Water Resources Division of the Ontario Water Resources Commission.

William A. Porter, JR.E.I.C., (Alberta '56) has joined the editorial staff of Heavy Construction News as Technical Field Editor.

Pierre C. Lefrancois, JR.E.I.C., (Ecole Polytechnique '56) has obtained a master degree from the Graduate School of Industrial Administration, Carnegie Institute of Technology. Formerly with Shawinigan Chemicals, Mr. Lefrancois now is with the commercial development department of Cyanamid of Canada.

J. W. Barnes, JR.E.I.C., (McGill '57) has joined IRC Resistor Division of Renfrew Electric Company of Toronto as chief engineer.

D. E. Stothers, JR.E.I.C., (McGill '58) formerly serving as an officer with the Canadian Army in West Germany, has been selected to attend a Guided Missiles Staff Officers course with the United States Army at Fort Bliss, Texas.

O. J. Hahn, JR.E.I.C. (Alberta '58) has been awarded his master's degree in nuclear engineering at West Virginia University.

Among senior engineering students at nine Canadian universities who have been awarded prizes by the Canadian Construction Association for theses on construction subjects were: **J. O. Bursey,** S.E.I.C.; **J. A. Craig,** S.E.I.C.; **Raymond Goyette,** S.E.I.C. (Ecole Polytechnique '60); **J. Hiley,** S.E.I.C. (Manitoba '60); and **B. A. Lundeen,** S.E.I.C.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

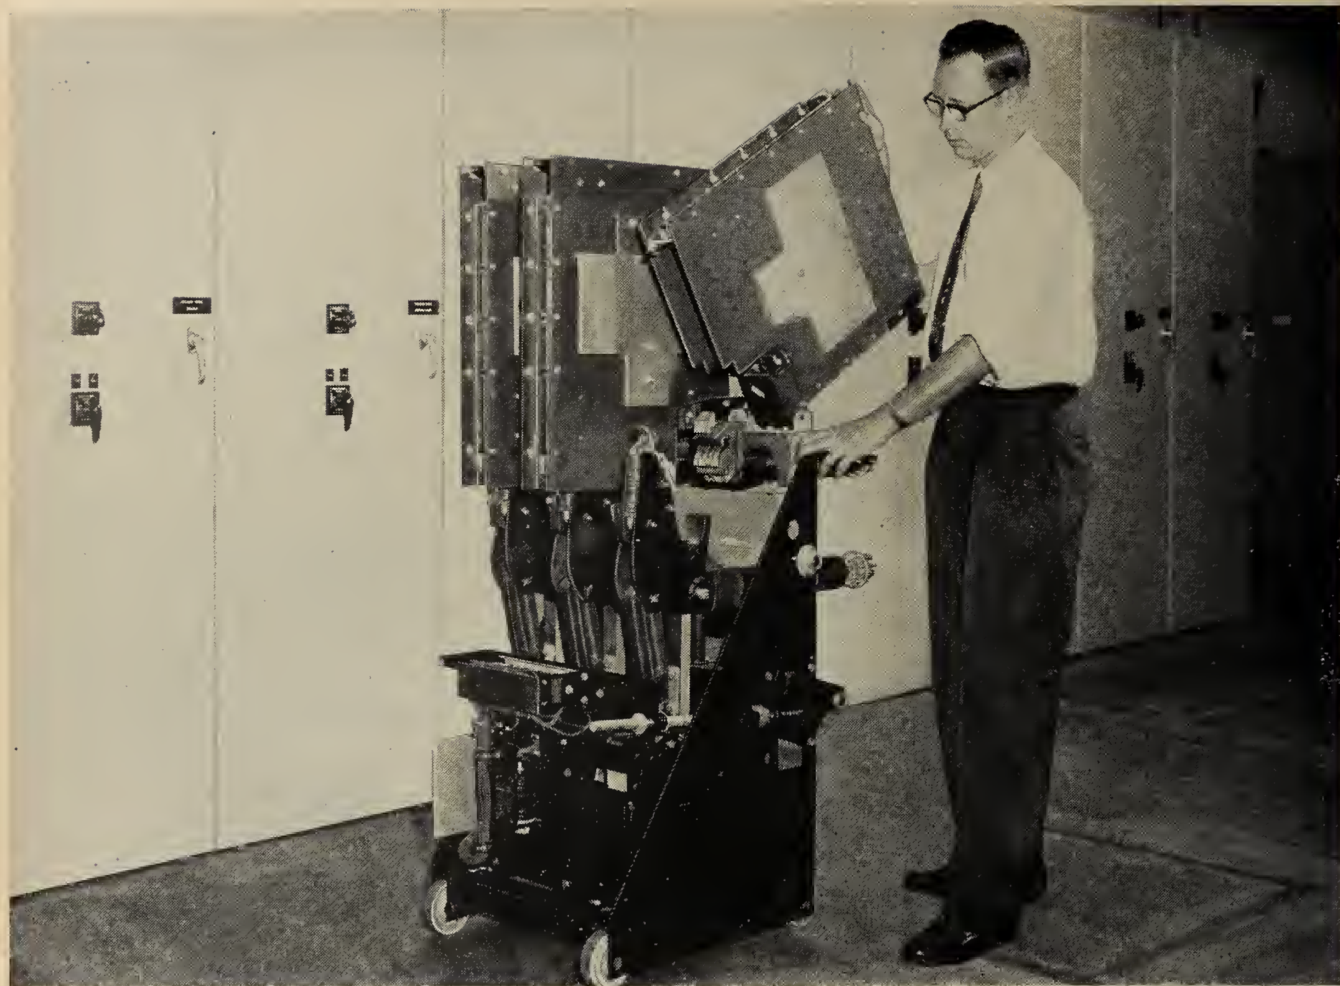
Editorial, 2050 Mansfield Street, Montreal 2, Que.



Group of stainless-clad steel digesters

Other Societies

European Chemical Engineers

G. McK. Dick, president of the Institute, will be a patron of the European Convention of Chemical Engineering to be held in Frankfurt, (Main), June 9-17, 1961. The ACHEMA 1961 also will take place within the framework of the convention.

Included in the program will be: a symposium on "The Physical and Chemical Durability of Structural Materials in the Chemical Industry"; special meeting and lectures 1961 of The Gesellschraft Deutscher Chemiker; and the annual meeting 1961 of the Isotopen-Studiengesellschaft.

American Society of Mechanical Engineers

Henry T. Heald, president of the Ford Foundation, has been selected an Honorary Member of the A.S.M.E. for "effective and faithful service to the engineering profession and to the public."

National Association of Corrosion Engineers

Corrosion resistance to various metals will be discussed in two papers to be presented in Montreal Novemeber 14-16 at the Canadian Region session of the N.A.C.E.

Regional N.A.C.E. meetings in the United States in October and November will be held in Tulsa, Okla., Huntington, W. Va., San Francisco, Milwaukee and Atlanta.

"Stress-Corrosion of Austenitic Chromium-Nickel Stainless Steels," a review of 129 case histories and information on current research activity has been published jointly by the American Society for Testing Materials and N.A.C.E.

The book is available from A.S.T.M. or from N.A.C.E., 1061 M & M Bldg., Houston 2, Tex. Cost is $6 to non-members of either society, $4.80 to members.

Canadian Construction Association

The C.C.A. has published Proceedings of its annual meeting in Calgary last January. Included are: Statement of Policy and Resolutions passed; Code of Practice; the President's address and 15 other major speeches; reports of 14 C.C.A. standing committees; reports of four major C.A.A. sections; and a list of those who attended the convention.

This is available from the Public Relations Department, Construction House, 151 O'Connor St., Ottawa 4.

Oak Ridge Symposium

A five-day symposium during which university staff members were informed of concepts and progress in the controlled thermonuclear field was held at Gatlinburg, Tenn., Aug. 22-26.

The symposium — "An Introduction to Thermonuclear Plasma Physics" — was sponsored jointly by Oak Ridge National Laboratory and the Oak Ridge Institute of Nuclear Studies.

John Fritz Medal Winner

Stephen D. Bechtel, president of Bechtel Corporation, San Francisco is the 1961 recipient of the John Fritz Medal, awarded annually for notable achievement in the engineering profession.

Established in 1902 to perpetuate the memory of John Fritz' achievements in industrial progress, the medal is sponsored by the American Society of Civil Engineers, American Institute of Mining Engineers, the American Society of Mechanical Engineers, American Institute of Electrical Engineers and the American Institute of Chemical Engineers.

Finland's Institute for Technical Research

A number of publications and report series covering wood, metal and electricity, building, and chemistry, have been produced by the State Institute for Technical Research. These are available from the State Institute, Helsinki, Lonnrotink, 37, Finland.

Petroleum Mechanical Annual Conference

The Petroleum Division of the American Society of Mechanical Engineers held its national conference in New Orleans last month. Fifty-seven papers were presented during 26 technical sessions.

International Atomic Energy Agency

Six new publications have been prepared by the International Atomic Energy Agency in Vienna. These deal with research on controlled thermonuclear fusion, disposal of radioactive waste, use of radiation in industry and medicine, and bibliographic information.

The publications, which range in price between $1 and $6, may be ordered from the Publications Sales Unit, International Atomic Energy Agency, Kaerntnerring 11, Vienna 1, Austria. The bibliographies list is free.

American Concrete Institute

The A.C.I. has published a new bibliography, "Fatigue of Concrete", which lists and annotates 114 significant works published since 1898 on the fatigue of plain and reinforced concrete. Copies

(Continued on page 155)

The Associations and Corporation

A report on scholarships and student loans is contained in the June issue of The Alberta Professional Engineer, published by the Association of Professional Engineers of Alberta.

Two Edmonton students attending University of Alberta were awarded $200 bursaries for achieving the highest general standings in the first year of Engineering and of Geology. Arie Reedyk was awarded the Engineering bursary—The H. R. Webb Memorial Scholarship.

Geology student Alice Victoria Payne won the John A. Allan Memorial Scholarship.

The Association's annual report also noted 12 outstanding student loans totalling $2,380. The report was contained in the minutes of the Association's 40th annual meeting, held in Edmonton.

Also contained in the publication were committee reports to the annual meeting, and notes on Algeria's Messaoud oil field.

Obituaries

Alexandre Albert Belanger, M.E.I.C. retired District Engineer of the Board of Transport Commissioners for Canada, passed away on July 22, 1960, at his home in St. Hyacinthe, Quebec. He was 82.

Educated at Ottawa University, Mr. Belanger went to Montreal in 1895 and worked on land surveying and municipal engineering for several consulting firms until 1901. He then joined the engineering staff of the Canadian Pacific Railway, working first in Montreal, then in Calgary. In 1910 he was appointed District Engineer of the Board of Transport and he held that post until his retirement in 1943.

Mr. Belanger joined the Institute in 1899 and was awarded Life Membership in 1944. He was also a member of the Association of Professional Engineers of Ontario.

Morton Farrer Cochrane, M.E.I.C., a retired senior civil servant. He was 77.

Mr. Cochrane joined the old Department of the Interior in 1905, and retired in 1947 from the Department of Mines and Resources.

He was born in Galashiels, Scotland, and was educated at Trinity College, Glen Almond; Heriot Watt College, Edinburg; and the Royal Technical College, Glasgow.

He worked with a Glasgow civil engineering firm from 1900 until he emigrated to Canada five years later.

Mr. Cochrane joined the Interior Department in the topographical surveys branch, transferred to the international boundary branch in 1907 and to the water power braneh in 1917.

M. F. Cochrane, M.E.I.C.

The first St. Lawrence Deep Waterway Treaty of 1932 was prepared by Mr. Cochrane. This treaty was rejected by the United States Congress.

Later he drafted agreements between Canada and the United States and between the Federal and Ontario governments for development of St. Lawrence-Great Lakes navigation and power.

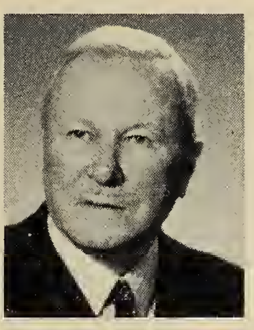
He represented Canada at an international power conference in London in 1925.

Author of a history of water power in Canada, Mr. Cochrane also prepared briefs used in many national and international water conferences and negotiations.

Mr. Cochrane became a member of the Engineering Institute of Canada in 1926, and 20 years later was named a life member. He was an associate member of the Institute of Civil Engineers.

In 1908 he was commissioned a Dominion Land Surveyor.

James Colin Kemp, M.E.I.C., prominent Montreal engineer and executive, died August 20. He was 78.



J. C. Kemp, M.E.I.C.

Mr. Kemp was born in London, England and was educated at Clifton College and University College, Oxford, where he obtained a Bachelor of Arts degree. He received his B.Sc. at McGill in 1908.

After leaving McGill, Mr. Kemp joined the Consolidated Mining and Smelting Company of Canada in British Columbia, later he worked at Drummond Mines, Cobalt, Ont., and R. A. Ross and Company, Montreal consulting engineers.

From 1926 until 1934 he was employed by the National City Company, Limited, after which he transferred to the staff of Dominion Stores, Limited, as manager of the Montreal division.

In 1937 Mr. Kemp became executive director of the Home Improvement Plan. Eight years later he was appointed managing director of George S. Armstrong and Company (Canada) Limited, industrial engineers and management consultants.

Since 1951 Mr. Kemp had been a consulting engineer.

Mr. Kemp was a member of the Engineering Institute of Canada, the Corporation of Professional Engineers of the Province of Quebec, and of the Canadian Institute of Mining and Metallurgy.

J. S. H. Wurtele, M.E.I.C., retired executive of several power companies, died August 6, 1960. He was 79.

Mr. Wurtele was retired vice-president and director of the Southern Canada Power Company, plant manager of the Power Corporation of Canada, Montreal, and president and director of Dominion Electric Protection Company, Toronto, Ont.

He was born in Acton Vale, Que., and received his higher education at Bishop's University, Lennoxville, Que., and at McGill.

His association with power development began in Quebec province and continued in Vancouver and in the state of Washington.

From 1913 until 1917 he was manager of the power department of Algoma Steel Corporation, Sault Ste. Marie, Ont. The following year he joined Southern Canada Power and later became vice-president and plant manager of that firm, and subsequently of the Power Corporation of Canada.

Mr. Wurtele retired in November, 1956.

He became a member of the Engineering Institute of Canada March 20, 1917 and was named a life member of the Institute January 1, 1951.

Mr. Wurtele also was a member of the Corporation of Professional Engineers of Quebec, Ontario, British Columbia and New Brunswick; an associate member of the American Institute of Electrical Engineers; and of the University Club, Montreal, the Lions Club, Acton Vale, and of Delta Upsilon Fraternity.

International Conference on University Reactors

Outstanding authorities on various aspects of reactor construction, operation and education led an international conference on university reactors at Gatlinburg, Tenn., in August.

The conference was intended to benefit universities which have not yet undertaken reactor programs, as well as those institutions now operating reactors. Sponsors were the Oak Ridge National Laboratory, the Oak Ridge Institute of Nuclear Studies, and the Oak Ridge Section of the American Nuclear Society, in co-operation with the United States Atomic Energy Commission.

In addition to about 150 representatives of 40 American colleges and universities there were delegates from Canada, the United Kingdom, Belgium, France, Israel and Japan.

American Society of Civil Engineers

A research conference and three sessions on professional matters supplemented a technical program during the A.S.C.E. annual convention in Boston, October 10-14.

During 39 technical sessions 146 technical papers were presented. There also were panel discussions and joint division sessions.

Coming Events

Power Industry Computer Application Conference, St. Louis, Mo., November 9-11.

Sixth annual conference on magnetism and magnetic materials, New York City, November 14-17.

Symposium on Engineering Applications of Probability and Random Function Theory, Lafayette, Ind., November 15-16.

Second International Reinforced Plastics Conference, London, England, November 30-December 2.

Institute of Radio Engineers, Vehicular Communications, annual meeting, Philadelphia, December 1-2.

Electrical Insulation Conference, Chicago, December 5-8.

1961 SAE International Congress and Exposition of Automotive Engineering, Detroit, Mich., January 9-13, 1961.

Canadian Textile Conference, Montreal, Queen Elizabeth Hotel, February 7-9, 1961.

1st International Congress on the Mechanics of Soil-Vehicle Systems, Turin, Italy, Polytechnic Institute, May, 1961. EIC

News of the Branches

The biennial meeting of the Atlantic Provinces Professional Engineers, held at St. Andrews, N.B., Sept. 7-9, was the largest formal gathering of engineers ever held in the Maritimes. The meeting was sponsored by the Atlantic provinces branches of the Institute and by the Associations of Professional Engineers of Nova Scotia, Prince Edward Island, Newfoundland and New Brunswick.

In addition to area officers who served on the meeting committee, Institute representation included President George McK. Dick and general secretary Garnet T. Page. General chairman of the meeting committee was J. B. Eldridge, chairman of the Saint John Branch. P. J. Delicaet of Bathurst, chairman of the Northern New Brunswick Branch, was one of three joint chairmen. The general secretary of the meeting committee was J. P. Mooney, secretary-treasurer of the Saint John Branch. J. J. Donahue, an Institute Councillor, was a member of the two-man finance committee.

Two professional sessions were held during the meeting. J. E. Hayes, M.E.I.C., Montreal, Chief Engineer for the Canadian Broadcasting Corporation, presented a paper dealing with "The Television and Radio Facilities of the C.B.C."

Canada's rocket program was outlined by Irvine B. Cameron of Ottawa, superintendent of the propulsion wing of the Canadian Armament Research and Development Establishment. Research on rocket propulsion began in 1956, Mr. Cameron said, and static and flight tests have been held since then at Valcartier, Que., and at Fort Churchill, Man.

One aspect of CARDE's studies has been the development of economical rockets for upper atmosphere investigations. A slender, 24 ft. test vehicle, the Black Brant, was fired a year ago from Fort Churchill with several hundred pounds of instruments. It is being used for upper atmosphere studies at 50 miles. A high-altitude missile, the Black Brant II, has been designed with lighter components and a longer-burning engine. Mr. Cameron said Black Brant II, which is to be launched from Fort Churchill, should carry a 100 lb. payload 75 miles into the atmosphere.

"Combined Thermal-Hydro Development" was discussed in a paper prepared jointly by the New Brunswick Power Commission and H. G. Acres and Company, Limited. The other paper, "Corrosion in Action," was presented by R. J. Law of Oakville, Ont., a member of the Development and Research Division of the International Nickel Company of Canada Limited.

Luncheon speakers were E. B. Ross, mayor of St. Andrews, Mr. Dick, and G. B. Williams, Assistant Deputy Minister of the federal Departmnet of Public Works. Lieutenant-Governor J. Leonard O'Brien of New Brunswick addressed the final dinner assembly of the meeting. The Chignecto Canal program was outlined by Brigadier J. M. S. Wardell of Fredericton.

Newfoundland Branch Chairman J. P. Henderson introduces Institute President G. McK. Dick, immediately to his right, at a Presidential dinner at St. John's.

Newfoundland

Anthony Nemee, JR.E.I.C.,
Correspondent

Institute President George McK. Dick and general secretary Garnet T. Page were guests of the Newfoundland Branch at its banquet and dance Sept. 10. Mr. Dick, guest speaker at the banquet, discussed the Institute's objectives.

Suitable leadership and encouragement for Canadian engineers are provided by the Institute, Mr. Dick said. For their part, engineers have many responsibilities in our rapidly-changing world. The Canadian engineer must avoid an attitude of complacency, he said, and must continue to improve if Canada is to meet successfully foreign competition. The Presidential party visited the campus of the $12 million Memorial University which is scheduled for completion early in 1961.

Members of the Branch's new executive are: J. P. Henderson, chairman; A. Butt, vice-chairman; A. E O'Reilly, secretary treasurer; and C Conroy; R. Martin; E. Ball; A. Nemec; M. Tomlinson; D. Sharpe; G. Neary.

Saguenay

Maurice Simard, JR.E.I.C.,
Correspondent

Dr. D. T. Wright, Dean of Engineering at the University of Waterloo, was the guest speaker at a Sept. 15 joint technical meeting of the Institute Branch and of the Saguenay Chapter of the Corporation of Professional Engineers of Quebec.

The curriculum for engineering students at Waterloo consists of alternate periods of study and practical experience in industry. This course of study and related subjects were outlined by Dr. Wright.

The Branch and the Saguenay Chapter of the C.P.E.Q. have chosen a joint executive. Its members are: D. L. Aker, chairman; P. R. Brais, vice-chairman; J. R. Eason, secretary; and councillors A. Pinault, D. H. Hobbs, D. A. Findlay, M. Lavallee, J. J. M. Falardeau and M. Simard. The past chairman is D. W. Stairs.

Autumn Programs

Few of the Branches were active during the summer but several had plans to start their autumn programs. Members and guests of the **BORDER CITIES BRANCH** scheduled a mid-September tour of the H. J. Heinz plant at Leamington, Ont. **CALGARY** began its fall activities with its annual barbecue which followed a Membership Tea held by its Engineers Wives Club. **HAMILTON BRANCH** has scheduled its annual Engineers' Dance for Nov. 5. The Waterloo Fish and Game Club was the site of a stag held by the **KITCHENER BRANCH.** Mr. Dick was guest speaker at a September dinner meeting of **MONCTON BRANCH,** held at the Beaver Curling Club. A dance followed. The **OTTAWA BRANCH,** through the courtesy of Mines Superintendent Edwin R. Tyler, scheduled a field trip to Hilton Mine Sept. 24. The Athabasca Tar Sands were to have been discussed at the Branch's Oct. 6 meeting.

Tour

M. Pierre Danel, M.E.I.C. of France, one of the world's foremost authorities on hydraulics, has scheduled visits to 16 Branches in October and early November. His tour was to have started Oct. 11 in Montreal and is scheduled to end in Chalk River, Ont., Nov. 4. Following is M. Danel's proposed itinerary:

Tuesday, Oct. 11 — Montreal
Wednesday, Oct. 12 — Three River, Que.
Thursday, Oct. 13 — Baie Comeau, Que.
Monday, Oct. 17 — Sydney, N.S.
Tuesday, Oct. 18 — Halifax
Wednesday, Oct. 19 — Moncton, N.B.
Thursday, Oct. 20 — Ottawa
Monday, Oct. 24 — Trail, B.C.
Tuesday, Oct. 25 — Vancouver
Wednesday, Oct. 26 — Victoria
Thursday, Oct. 27 — Edmonton
Monday, Oct. 31 — Saskatoon
Tuesday, Nov. 1 — Winnipeg
Wednesday, Nov. 2 — Toronto
Thursday, Nov. 3 — Kingston, Ont.
Friday, Nov. 4 — Chalk River

M. Danel, president and general director of SOGREAH, is noted for his contributions to many phases of hydraulics and from 1933 until 1945 was in charge of courses at the Ecole des Hydrauliciens de Grenoble and Directeur of the Laboratoire Hydraulique of the University of Grenoble. He is past president of the Association Internationale de Recherches Hydrauliques and is a member of thirteen technical societies and associations in France, Canada and the United States. EIC

• DISCUSSION

(Continued from page 132)

Niagara Falls, Ontario. Both these, and the agreement for a large 30,000 kva. iron smelter at Kingston, Ontario, are commercial sized units.

These actual facts, based on signed contracts, and work now in construction, as well as developments in many other situations, such as the announced plants of Texas steel groups, a Mexican steel group, and others we are not at liberty to disclose, can only demonstrate a wide gamut of acceptance of the advantages of Strategic-Udy.

It would actually appear to us at this time that Strategic-Udy is indeed the very process most likely to supplement the classic blast furnace, and conventional cold charge low shaft electric furnace.

One of the principle developments that the Process has made possible is that of economic smelting of either pig iron or semi-steel, (as well as ferromanganese and ferrochrome), direct from low-grade or contaminated ores, black sand deposits, high copper, high sulphur ores, high titania magnetites, and even fine concentrates, without agglomeration.

In addition, selective reduction has made possible the production of carbon steel and valuable stainless steel from the well-known laterite deposits of the world, as well as low cost production of ferromanganese and ferrochrome from ores that have not been used to date.

The process does not require coke but can use carbon in almost any form. We have had our best successes with use of lignites and high (47%) volatile coals, but any coal, coke breeze, petroleum residue, (even wood chips), can be used.

In the considered opinion of many of the world's specialists in electric furnace techniques, as well as metallurgists of Elkem, Koppers and others who are familiar with electric smelting, the development of the Udy furnace is a basic and fundamental step in the history of pyrometallurgy.

There are three main reasons behind this statement:

Firstly, the Udy smelter is the only furnace that permits the practical utilization of the benefits of preheat and prereduction.

Secondly, it makes possible the practical use of selective reduction and produces a molten product.

Thirdly, it is self-contained and highly economical with respect to energy utilization and it does not require metallurgical coke nor any agglomeration of the charge, since the furnace has no "burden", and fines are normally smelted.

At the same time, of course, the Strategic-Udy Process can easily and economically produce either pig iron or semi-steel direct from high-grade blast furnace type ores.

We think it entirely significant to note that neither the blast furnace, nor the submerged arc low shaft electric furnace, can successfully digest the titaniferrous ores or fines, or nickel-chrome laterites, and this factor is fast becoming of great economic importance.

In addition, the Process produces a molten iron or semi-steel that is ready for foundry use, or, more particularly, for economic refining into quality carbon steel.

There are so many locations in Canada, U.S.A. and other parts of the world where on-site smelting with local raw materials is of vast economic importance that Strategic, Koppers and Elkem, (and others), feel that Strategic-Udy has now emerged as the successful "direct reduction" process.

THE POTENTIAL IN THE FREE PISTON ENGINE PRINCIPLE

A. Braun, *Vice President,*
Free Piston Development Company Ltd., Kingston, Ont.

The Engineering Journal, July, 1960, p. 57.

Author's reply to the discussion by J. D. Fleming.

Most of the many papers referred to by Dr. Fleming are either reporting on, or at least based on reports, of the only free piston gasifier, commercially available to date the GS34 or General Motors version of this unit the GM14. This unit is rated at about 1250 G.H.P. and hundreds of European units have been made and sold and are giving satisfactory service. Since so much has been written on these first units and relatively little written about the possibilities in the basic principle, the above paper was prepared, a fact apparent from its title.

As to the relative values of the air standard and actual gasifier efficiencies the author fails to see Dr. Fleming's point since this question was strongly emphasized by Fig. 6 in which the common trend of the theoretical and actual efficiencies is shown, and where the difference in value between the thermal and actual efficiency accounts for compressor and turbine losses as well as all other losses that cannot be accounted for in an air standard analysis.

Regarding Dr. Fleming's remarks concerning Fig. 3 and the so called "by-pass gas", as mentioned in the paper to avoid confusion references were made to confirm that in the air standard analysis the effect of the "by-pass gas" on efficiency cancels out. The reason for basing the different analyses on the air standard cycle and quoting in Fig. 6 the air standard efficiencies was to stimulate creative work and thus serve the purpose of the paper, the pointing out of the potential instead of repeating figures reported in previous papers.

In this very sense the air standard approach still best serves its old and intended purpose.

The difference between volumetric compression ratio and pressure ratio was defined unmistakenly and the common error referred to by Dr. Fleming was avoided in the paper. The figures quoted in his discussion in this regard are strictly based on GS34 conditions. Engines with overall volumetric compression ratios of 40 to 1 have been tested successfully. Concerning future compression ratios the last paragraph of the paper should be referred to.

The point discussed by Dr. Fleming in regard to multifuel characteristics is practically stated in the first sentence under this sub-heading in the paper and a quite comprehensive picture is given of the existing conditions in the engine. The author agrees that with heavy fuel wear rates increase but in this regard new approaches particularly in view of this new principle, seem possible.

It has been mentioned in the past that the unavailability of suitable auxiliary equipment is a serious drawback in the development of the free piston engine, which is a fact that at times really effects development work. Aside from this short range problem numerous suitable auxiliary devices have been developed which should, once quantities are required, result in lower prices and adequately answer this problem. In one of the author's designs of 80 G.H.P. size this question has been solved quite satisfactorily. Turbines for these small sizes are of the supercharger type and can in quantity be manufactured at very reasonable costs.

The problems quoted under Multiple Gasifier Installations can be greatly influenced by the designer particularly in regards to control, and the free piston principle poses no greater engineering problem than comparable conventional installations.

The author fully agrees with the last paragraph of Dr. Fleming's discussion particularly that free piston engines have their place in the power field. As to the selection of the individual engines available it should again be emphasized that it was not the purpose of the paper to give data and information on what is available but rather to point out the basic potential in the free-piston principle and encourage designers to approach this development with maximum creative freedom, asking for new approaches to explore it.

Much of the development in the Free-Piston field has been restricted to following the lead of others and putting together of old ideas and means found in related fields, and what is worse, making predictions based on this type of analysis. Considerable cautiousness in accepting the free-piston engine can be attributed to this situation. The design engineer should not neglect what has been established but this end cannot be the major part in a healthy creative process.

Dr. Fleming's interest in the paper is very much appreciated and it is felt that had the actual paper been available earlier permitting more careful study of it, it would have eliminated many of the questions raised however this discussion has permitted re-emphasizing the paper's purpose.

MINERAL RESOURCE DEVELOPMENT IN NORTH AND WEST

John Convey

Department of Mines & Technical Surveys, Ottawa

The Engineering Journal, September 1960, p. 66

Author's reply

I am thankful to S. W. Schortinghuis, M.E.I.C., for his comments related to the additional services of government departments other than the Mines Branch whose work is related to the development of Canada's resources.

It is my pleasure to inform Mr. Schortinghuis that the policy of the Mines Branch is to encourage wherever possible the growth of mineral research facilities in Canadian industrial and provincial departments. This sharing of the development problems would free Mines Branch from the many day to day problems which require immediate solution. Such co-operation will enable the Mines Branch to employ its staff and facilities in the solution of the more difficult complex and long-term problems which are directly related to the growth of the Canadian mining, mineral and metallurgical industry. Such research is needed if we expect to hold a competitive position in the modern mineral world market. It is in this way that we may be regarded as showing a greater tendency towards so-called basic research. However, our effort will always be intimately associated with Canadian industry.

In reply to J. S. Roper, I regret that shortage of time prevented me from elaborating on the various Mines Branch divisional functions. However, it is a pleasure for me to expand my remarks in reply to his two questions.

The first as associated with the work of the Branch in the field of industrial minerals. This part of the Canadian mineral scene was once considered lowly in relation to metallics. Industrial minerals covers the wide field of non-metallic minerals, sands, clays, rocks and industrial waters. These commodities have grown immensely in stature during Canada's rapid industrial growth of the past decade. It is true to say that probably no other segment of the mineral industry has had to lean so heavily on the Mines Branch for assistance, first because the problems for investigation in industrial minerals are almost infinite, secondly, because most of the industrial minerals have a low unit value and the industry is therefore

not in the position to support extensive scientific investigations.

The Branch maintains an up-to-date source of information concerning the variety, quality, and availability of industrial mineral resources in Canada. This inventory is maintained through extensive field studies in addition to the research associated with the development of methods of beneficiating products from low-grade deposits that are required to meet the exacting specifications of modern industry. Typical examples of our technical work are:

(1) the development of a brucitic limestone in Quebec;
(2) the rock wool industry;
(3) the production of refractory materials from Canadian kyanite deposits;
(4) the correlation and study of the physical and chemical properties of asbestos in relation to industrial applications;
(5) the development of ceramic electronic components.

These are but a few of the many examples which could be quoted concerning the work of the Branch which covers the development of the Canadian industrial mineral phase of the country's economy.

In addition to the Western Regional Laboratory of the Mines Branch in Edmonton, we also have a group located in Calgary whose work is directly associated with the coal industry of the Alberta foothills. A similar outstation is found in the Maritimes where mining engineers and physicists are actively engaged in the study of ground stress mechanics as found in the Maritime coal mining operations. We also have a physical metallurgical officer attached to the British Columbia Research Council in Vancouver. His work is to give direct assistance to the metallurgical industry of British Columbia.

WATER SUPPLY AND SEWERAGE AT URANIUM CITY

H. P. Klassen, M.E.I.C.
Underwood, McLellan & Associates Limited, Saskatoon
The Engineering Journal, September 1960, p. 61

Author's reply

In answer to questions regarding the system it is quite likely that due to the recession of population below design value that localized areas would experience some freezing. This applies particularly to the Uranium Road section which has a separate trunk sewer draining a small section which has not developed as expected. In a case such as this the corporation would be well advised to consolidate the remaining householders and discontinue service in these isolated areas.

The design of the sewerage system is along conventional lines for Western Canada. The minimum depth is nine feet, with manhole spacing from 300 to 400 feet. Generally the water mains were laid two feet higher than sewer mains to comply with the Public Health Department's requirements.

The material used for building service connections was asbestos-cement building sewer pipe and copper water service pipe. The water pipe was wrapped with an electric thaw wire then securely taped to the sewer pipe. The wire used was a No. 10 copper with weather-proof insulation which was fastened to the main stop and taken right into the building. A transformer is supplied to the householder at a reasonable charge, connected to the thaw wire and plugged into a convenience outlet of the household electric system.

The water supply is of excellent quality chemically as well as bacteriologically requiring no treatment except chlorination to meet the requirement of the Department of Public Health. The domestic consumption was not a critical design factor. The minimum flow requirement in the supply main, to prevent freezing, determined the minimum pumping capacity. This volume of water is more than enough to provide domestic demand.

Fire demand is provided by separate fire pumps driven by electric power and also by a standby gasoline engine in event of power failure. The capacity of the fire pump is 1,200 g.p.m. at a head of 190 feet. As mentioned in the paper the looping arrangement allows feeding of any hydrant from both directions. The hydrants are not the standard in normal use but adapted to on-line installation to eliminate dead areas subject to freezing. Drainage sumps were installed to provide barrel drainage.

The discussion presented by Mr. Sladek is a worthwhile addendum to this paper. It points out that each ensuing project must be designed with a view to all the variable conditions of temperature and soil conditions and that standardization of northern systems cannot be considered with the limited knowledge at hand. The continuous development of new materials especially in insulation materials will improve economy in both installation and operation.

LIQUID PETROLEUM GASES AS FUELS FOR AUTOMOTIVE ENGINES

H. A. Spencer, M.E.I.C.
Research Council of Alberta, Edmonton.
The Engineering Journal, July 1960, p. 62.

Author's reply:

Boyd Candlish, M.E.I.C., makes several interesting technical points about the paper. The first is that major modifications are not required to obtain suitable efficiencies with LPG engines. This point may be correct in that special engine materials are not needed, but conversion of a normal engine still costs in the range of $250-$300, especially since a tank of sufficient strength must be provided.

With regard to efficiencies, I do not agree with Mr. Candlish that propane engines can obtain a thermal efficiency of 40%. Increasing the compression ratio beyond 9 to 1 brings a diminishing return on efficiency, and causes heat timing problems even with propane.

Exhaust gases were mentioned only briefly but two companies in the United States now manufacture propane-diesel equipment for reducing smog on large trucks, the cost of which is considerably less than $200.

My thanks to Prof. W. Alexander, M.E.I.C., for his kind remarks. His question about exhaust gases is well taken. Certainly this is an immediate source of heat and one which could, as he says, be immediately responsive to demand. Certain mechanical problems arise, however in the transmission of heat at 750°F to a gas which must activate rubber diaphragms and valves. Perhaps materials have held back work on this prospect. However it is certainly worth investigation and trial, and I acknowledge the suggestion with thanks.

KELSEY GENERATING STATION DAM AND DYKES

R. A. Pillman, Jr.E.I.C., D. H. MacDonald, M.E.I.C., H. R. Hopper, Jr.E.I.C.
The Engineering Journal, October 1960, p. 87.

Author's reply:

The authors wish to thank Professor A. Baracos, M.E.I.C., R. Peterson, and Messrs. H. B. Dickens and G. H. Johnston for their discussions. Professor Baracos has raised the interesting questions of (1) the desirability of installing pore pressure and settlement measuring devices in the Kelsey dam, and (2) the method of analysis employed to ascertain the rates of thaw and of moisture dissipation as the permafrost beneath the dykes thaws.

Consideration was given to the need to measure pore pressures and settlement in the core of the dam, but in view of the practical difficulties involved in doing this in a dam of the sloping core type, and because of the probable interference with the construction operations and the high cost of such installations it was decided not to do so. Such results would be extremely interesting in view of the type of material used for the core, but they would have had no effect on the design of the Kelsey dam. For this reason reliance had to be placed upon the laboratory test results and an adequate factor of safety provided for all eventualities.

Analyses to determine the rate of thaw beneath the dykes were made by standard methods of heat flow theory. Analyses to establish the rate of moisture dissipation were based upon the results of pore pressure dissipation tests and standard consolidation theory for radial and vertical drainage. These studies indicated that consolidation would keep pace with thawing and that no excess pore pressures would occur. Publication of discussions of these methods is planned later when field data now being obtained are sufficient to allow fair comparison of predicted and actual measurements to be made.

AQUEDUCT AND PUMPING STATION FOR GREATER WINNIPEG

N. S. Bubbis, M.E.I.C.
R. C. Sommerville, Jr.E.I.C.
Greater Winnipeg Water District
The Engineering Journal, August 1960, p. 43

Discussion by K. E. Patrick, M.E.I.C.

May I first congratulate Mr. Nat Bubbis and Mr. Sommerville on a most interesting and informative paper. The description of the various problems that were met in the design and construction of the Second Branch Aqueduct and Low Lift Pumping Station and the solutions to those problems make a valuable contribution to the technical literature.

As one might expect, local conditions were the predominant factor in the design and construction of the Red River tunnel and similarly in the design of the low lift pumping station. This is not unusual in such specialized projects and should create no surprise.

The design of a pipe line, however, even a major one, might be expected to have a more universal application and be less affected by local conditions. But, after Mr. Bubbis' and Mr. Sommerville's paper and with some knowledge of the Greater Vancouver Water District's pipe lines, it struck me forcibly that local conditions may be of paramount concern in their design also. It is about this aspect that I would like to comment.

The Greater Winnipeg Water District in the design and construction of its Second Branch Aqueduct met and coped with the following local conditions. Active sulphate soil, clays subject to large volumetric change with changing moisture content, soil movement, a relatively low static head, a large variation in water temperature through the year and an unusually long pipe line that can tend to produce high surge pressures or water hammer.

By comparison, the Greater Vancouver Water District, I am most happy to say, has none of these problems. In fact the only similarity is that we both must move large quantities of water continuously from where it is to where it is needed.

That doesn't mean that we have no problems. We do. But they are different ones and are met in different ways. Rugged topography, steep side hills, many different types of soil, which while generally chemically inactive, vary from solid igneous rock to glacial tills, to unconsolidated gravels and sands, to silts and clays, high static pressures — up to about 300 p.s.i. and mountain streams capable of very great variations of flow. The rough topography results in pipe lines with numerous bends and curves, both horizontal and vertical, which when coupled with high heads, present anchorage problems best met with pipes having longitudinal strength. Welded steel pipe meets this requirement admirably and thus we have a great liking for it. It is protected inside with a spun lining of coal tar enamel and outside with coal tar enamel protected in turn with asbestos felt wrapping. This has given excellent service in our location, but you can readily see that the Greater Winnipeg Water District first did not have the rough topography nor the high pressures to contend with and second did have a serious soil condition to consider. This difference in local conditions therefore affects the design criteria to such an extent that the type of pipe best suited to one location is different from the type of pipe that is best for another.

Where we have to install a sufficient length of main that is reasonably straight and under light to medium pressure, we also, like the Greater Winnipeg Water District, call for alternative tenders, but in our case the main call is for steel pipe with reinforced concrete pipe the alternative. In the past twenty-five years, steel pipe has underbid concrete pipe whenever such alternative was permitted.

I was most interested in the requirement of the Specifications for the Branch II Aqueduct that the contractor meet a particular roughness coefficient. I believe this is unusual, but it certainly is logical. After all, the whole purpose of spending a large sum of money is to obtain water in quantity at the downstream end. Any reduction from the design flows means that the owner has not obtained what he contracted for. As long as the co-efficient chosen is reasonable, then any values less must be caused by a poor pipe surface or by poor laying. When you note that both the quality of the pipe and the quality of the pipe laying can affect the roughness coefficient, the wisdom of a "turn-key" contract becomes apparent.

Checks on the carrying capacity of new coal tar enamelled pipe of 72 in. and 54 in. diameter indicate a roughness coefficient in Mannings formula of "n" = 0.010 to 0.011 which, I believe, is comparable to a Hazen Williams "C" of 140.

It will be most interesting to hear what coefficient is actually achieved by the Branch II Aqueduct. I'm sure the results will fully justify the consideration, care and hard work that has gone into the design and development of this project.

Discussion by A. E. Barry, M.E.I.C.

The paper by Messrs. Bubbis and Sommerville contains a number of interesting features, and the Greater Winnipeg Water District has over a period of years demonstrated a foresight that is not always present in dealing with problems of this nature. It is desirable to comment on the steps taken so early as 1912 to bring water from Shoal Lake. The project at that time must have been considered a tremendous one, and one which few municipalities to-day would be inclined to face without serious difficulties. The foresight and wisdom of that decision has undoubtedly meant much to the people of the Winnipeg area over these number of years. It is also of interest to note that the measures that were taken in this area nearly 50 years ago are now being attempted in other places in order to safeguard the water supply and growth of the future in those communities.

The development of a water project such as this involves many difficult problems. Not only is there the question of the design of the pipe line itself, but there is the need for protection of the water at its source. In this instance this is a supply which involves two provinces, Ontario and Manitoba. It would be most unwise to spend the money required for such a project without ensuring both an adequate supply and one that will be of good quality to serve the various consumers. Up to the present, there has been little difficulty in protecting the quality of this water. Steps will need to be taken to ensure that as development goes forward in the vicinity of this lake the water quality will not be impaired in any way.

One of the major problems of engineers who are dealing with water supply is forecasting the consumption over a long period in advance. This has been especially so in recent years. The engineers who were responsible for the decisions in the Greater Winnipeg Water District acted wisely, and in looking back over the years since this development occurred one must pay tribute to their foresight and good judgment. If the developments in the future can be predicted with anything like the same degree of accuracy the engineers of today will have much to be proud of.

Reference is made to problems that have arisen in this water supply involving algae growths. These have occurred in surface waters for a number of years. They appear to be increasing in recent years, and steps are being actively taken now to provide measures which will counteract these growths. It is the feeling that in so far as this supply is concerned there are no particularly abnormal conditions to stimulate the growth of algae, but it is obvious that special measures are necessary to keep these growths within reasonable limits.

One of the interesting aspects of this entire project, as well as the additions now being made, is that it is serving an area rather than separate municipalities making provision for their individual supplies. It is most desirable that water problems be regarded on an area basis and boundary lines be forgotten. It is to the advantage of all to have this method of attack followed. This is the program that is now being developed

A GROWING YOUNGSTER

and *idb*

Some youngsters grow so fast that they are always pushing out of their clothes and needing new ones. This was the sort of problem faced by the X-Y Company. Not only was the company's growth phenomenal but new developments in the character and manufacture of the product—foil and transparent paper—had extended its common use into foodstuffs, tobaccos and other perishables and even into the hardware and textile fields. The Canadian consumer was increasingly being offered the cleanliness and convenience of having more and more goods pre-wrapped.

The X-Y Company's growth demanded more machinery and space; the new diversity in wrappers demanded new equipment. The X-Y Company had been doing extremely well, but it had been growing out of its financial clothing. When it first approached Industrial Development Bank for financial assistance, it already owned a plant which was fully paid for. Annual sales were over the million dollar mark, and heading higher.

The growth in market demand was most encouraging but in the endeavour to keep up with it, the company had been unable to set aside funds for adequate expansion. Its assets were substantial but normal commercial financing was not available and the company was not in a position to issue further capital stock successfully. I.D.B. stepped in to provide the needed financing and the productivity of the new machinery quickly fulfilled the highest expectations.

But the youngster hadn't stopped growing, and the same situation arose a couple of years later. Again the company needed new machinery to increase production and again I.D.B. provided the term financing for this purpose. The mushrooming sales chart took another surge upward.

The X-Y Company has benefitted from having alert, courageous management and from having the right goods to sell at the right time and, when opportunity knocked, I.D.B. financing helped the company to open the door.

The I.D.B. was established in 1944 to assist industrial enterprises whose term financial needs cannot be met from normal sources. By extending financial assistance, I.D.B. endeavours to help an enterprise to take advantage of expansion possibilities and progress through its own efforts.

If you are in such a position, write for information and an explanatory booklet to your nearest I.D.B. office, or consult your auditor, lawyer or banker.

INDUSTRIAL DEVELOPMENT BANK

Regional Offices: Vancouver, Edmonton, Calgary, Regina, Winnipeg, Sudbury, London, Toronto, Ottawa, Montreal, Quebec City, Saint John, Halifax.

***I.D.B. can consider proposals for financial assistance in these activities:**
manufacturing, processing, assembling, installing, overhauling, reconditioning, altering, repairing, cleaning, packaging, transporting or warehousing of goods; logging, operating a mine or quarry, drilling construction, engineering, technical surveys or scientific research, generating or distributing electricity or operating a commercial air service, or the transportation of persons, or supplying premises, machinery or equipment under lease to any business mentioned above.

in the Province of Ontario through the Ontario Water Resources Commission. The action taken in the Province of Manitoba in the case of the Greater Winnipeg Water District was an example of forward thinking.

A good deal of study has gone into this work for the extension, and the District has not failed to consult others who may have knowledge and skill to assist in the problem. This method of attack is one to be commended in all such projects.

One can only conclude from a comprehensive paper such as this that the City of Winnipeg and adjacent municipalities have over the years shown leadership in engineering and administration which has resulted in benefit to all concerned. There is little doubt but that the steps now being taken will prove beneficial in the years ahead.

Discussion by L. R. Howson

Mr. Bubbis referred to the method of calling for tenders. As the "turnkey" method was adopted following United States practice, possibly some discussion of the factors influencing the decision to follow that procedure in this case may be of interest.

The scope of work as outlined in the specifications consisted of "designing, manufacturing, supplying, installing, testing and placing into operation a 5 ft. 6 in. diameter pipe line." Sometimes in the United States as will be later referred to, alternate tenders are requested on pipe line materials and their installation separately and the decision is based upon the bids received. In this instance tenders were asked only on the "turnkey" procedure. Alternate specifications were, however, prepared and bids taken on prestressed reinforced concrete and on welded steel pipe with cement mortar lining and coal-tar enamel with double bonded fiberous glass mat and asbestos felt wrapping. This taking of alternate tenders on competitive materials also followed a procedure common in the United States.

Among the advantages believed to result from the "turnkey" type of contract for large pipe line work are the following:

1. It centralizes responsibility which eliminates dispute between pipe manufacturers and the installation contractors relating to such items as delivery, breakage or damage.

2. As Mr. Bubbis pointed out a high "C" Hazen & Williams value was important, a variation of one point below 140 being evaluated at $42,000. While it is believed "C" will exceed 140 as specified, it would be much more difficult to fix the responsibility in case of failure to reach 140 if one contractor made the pipe and another contractor installed it. The "turnkey" procedure is adapted to enforcement of the penalty provision for failure to meet the carrying capacity coefficient.

3. On several comparable jobs in the United States, the contractors have been given the option of a "turnkey" job or bidding separately for either or both items of furnishing materials and for installation. In most cases the overall cost to the purchaser has been bid lower under the "turnkey" alternative.

Among factors contributing to this lower cost of the "turnkey" job are—

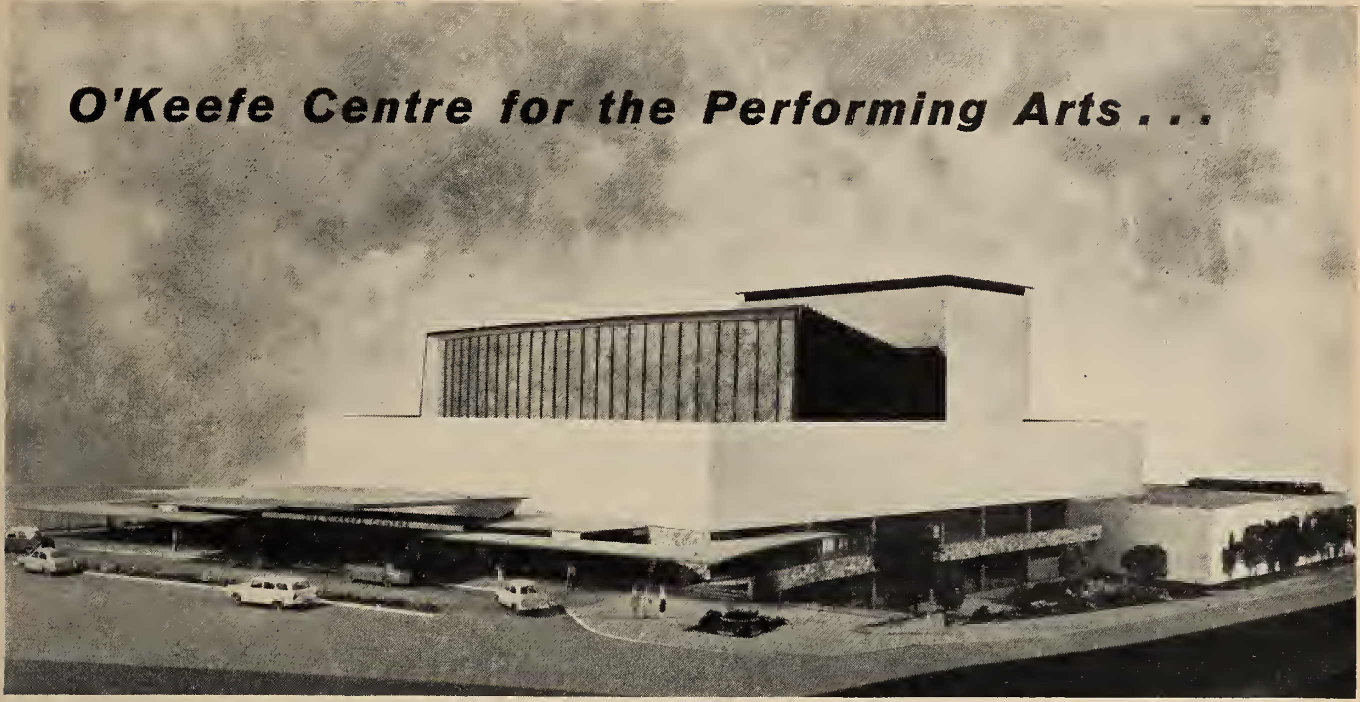
(a) Most of the difficulties experienced in large pipe line work have resulted from the manner of installation. The correction of such deficiencies involves costs to the pipe manufacturer as well as to the installation contractor.

Under the "turnkey" type of contract the manufacturer either installs his own pipe or selects as subcontractor for the installation, some contractor with whom he has had prior satisfactory experience. He therefore can figure the pipe at a lower price than he can offer it to a purchaser who will select the pipe laying contractor competitively and wholly independent of the manufacture. This introduces an element of contingency usually reflected in the price bid.

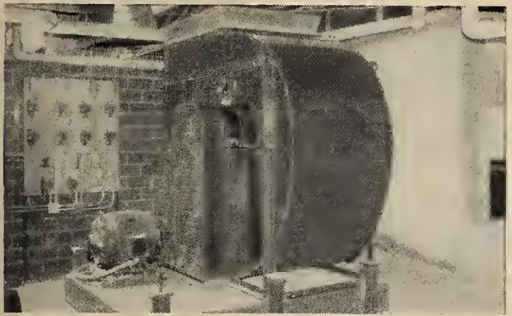
(b) Pipe materials are in constant competition. By bidding through contractors of their own selection, with whose proficiency they are well acquainted, the manufacturer can and frequently does sell the pipe at a lower price than he would bid openly and competitively. In so doing he has not disclosed his normal competitive price.

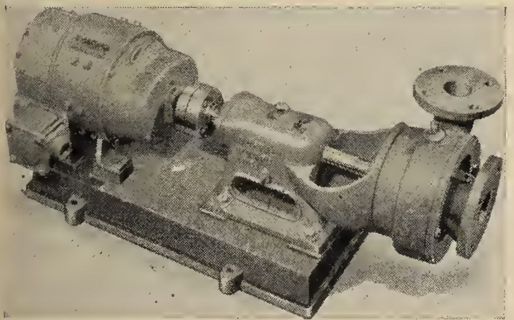
(c) Where a single contractor is responsible for the entire job the making and laying of the pipe can be better co-ordinated with resulting economy.

On each of three pipe line contracts, (of 83 miles, 28 miles and 23 miles) on which the tenders provided for either separate bids on materials and installation or alternate bids on concrete and steel pipe and for a "turnkey proposal", there was substantial advantage in favor of the latter. Our experience has been that, in addition to the financial advantage, the administration of the "turnkey" type of contract is simpler and more satisfactory, both to the owner and to the contractor. EIC



DEPENDS ON TOP QUALITY 'CANADIAN BUFFALO' FAN AND PUMP PERFORMANCE





'Canadian Buffalo' Type "BL" Centrifugal Fans are installed in the 13 low pressure air conditioning systems and in the 17 separate exhaust systems in the O'Keefe Centre. 'Canadian Buffalo' Type "BLH" Centrifugal Fans supply air for the Centre's two high pressure air conditioning systems. 'Canadian Buffalo' Single Suction Pumps (shown) and other types involve a total capacity of 7,500 USGPM in this installation.

Toronto's new O'Keefe Centre is the world's most strikingly modern cultural and entertainment facility. Designed for the ultimate in versatility, its stage will accommodate all types of presentations . . . ranging from grand opera, ballet and symphonies to musicals, jazz and intimate drama.

Since the acoustics are superlative, utmost quiet is required in the functioning of all equipment. This is one of the main reasons 'Canadian Buffalo' Fans exclusively were selected for the O'Keefe Centre. Their ultra-quiet, vibration-free operation is a matter of record.

'Canadian Buffalo' Pumps were also chosen to meet the quality requirements of this exacting installation . . . quiet, efficient, trouble-free operation.

You, too, can enjoy all these advantages of top quality 'Canadian Buffalo' Fans and Pumps. Contact your nearby 'Canadian Buffalo' representative, or write the factory direct.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*REINFORCED CONCRETE RESERVOIRS AND TANKS, 4th ed.

A practical treatment of the design and construction of plain and reinforced concrete reservoirs, tanks, swimming pools, and other water-containing structures above and below ground level, omitting water towers and hollow reinforced concrete dams. The book includes ideas from continental practices, and selected methods of design are treated in detail, the author giving his conclusions as to the simplest solutions for various designing problems. (W. S. Gray. London, Concrete Publications, 1960. 188 p., $2.80.)

*TRANSFORMERS AND GENERATORS FOR POWER SYSTEMS.

A British translation of the original French text. Both transient and steady-state conditions are studied. In addition to chapters dealing with and developing the fundamentals, there are survey chapters giving general treatment to practical aspects of special problems. The volume is divided into two books. Book 1 discusses the transformer, covering electromagnetic theory, windings, insulation, losses, voltage regulation and phase connection, with survey chapters on abnormal conditions, special types of transformers and transformer construction, technical literature, and the particular interests of the specification and the operating engineer. Book 2 deals with the synchronous machine under similar relevant headings. (R. Langlois-Berthelot. New York, Philosophical Library, 1960. 541 p., $12.00.)

*WATER AND AGRICULTURE.

The sixteen pages in this symposium on the agricultural use of water were prepared by experts in the respective fields, and were presented at a 1958 meeting of the AAAS. The papers are arranged in four major groups: water for the future; water sources; water planning and use; and water control. They touch on power, industrial, recreational, and other uses of water only where these impinge on agricultural uses. (ed. by R. D. Hockensmith. Washington, D.C. American Association for the Advancement of Science, 1960. 198 p., $5.00)

*HYPERSONIC FLOW.

Fifteen papers constituting the proceedings of the 11th symposium of the Colston Research Society (Bristol, England, 1959). They cover surveys and details of experimental facilities, techniques for simulating hypersonic flight conditions in the laboratory, investigation of the properties of gases at elevated temperatures, theoretical solutions of particular flow problems, and studies of the configuration, propulsion and kinetic heating of vehicles designed for hypersonic flight. (Ed. by A. R. Collar & J. Tinkler. Toronto, Butterworth, 1960. 432 p., $13.50.)

*ELECTROMAGNETIC ENERGY TRANSMISSION AND RADIATION.

This is the text for one of the eight subjects of the new undergraduate "core curriculum" being evolved by M.I.T. in Electrical Engineering. It treats electromagnetic waves and oscillations by discussing the important linear-system concepts of the time and frequency domains, and the energy-power relations from the theories of lumped circuits and quasi-static fields, extending them to cover "distributed" situations, in which space assumes an importance equal to that of the other independent variables. The objective is to provide a four-way viewpoint-time, frequency, energy (or power), and space. (R. B. Adler. New York, Wiley, 1960. 621 p., $14.50.)

ACRONYMS DICTIONARY.

Everyone plagued by the use of incomprehensible abbreviations and strings of initials will welcome the appearance of this dictionary of "telescope words." It is concerned primarily with abbreviations originating in the United States for U.S. government and military departments and their terminology, but enough of the terms are in common use in Canada to make this volume essential in every library and office. It also includes acronyms for American associations and corporations, as well as for phrases in general, and not so general use. The longest phrase for which an acronym seems to have been found is E.S.P.W.O. for "Exigencies of the Service having been such as to Preclude the issuance of competent Written Orders in advance," while it is to be hoped nobody ever has to use W.W.III (World War 3). (Detroit, Gale, 1960, 211 p., $10.00.)

*ELECTRICAL EFFICIENCY IN INDUSTRIAL PLANTS.

The aim of this book is to assist in the identification and elimination of power loss in industrial plants, from small tool shops to large steel mills. Such elements as preliminary system planning and analysis of systems and circuits, utility rate structures, selection of voltage levels, conducting and interpreting surveys of load, power factor, voltage, lighting, wiring and grounding, selection and purchase of electrical instruments, and optimum inspection and maintenance procedures are discussed. General principles are illustrated with detailed examples from actual practice. (E. S. Lincoln. New York, Dodge, 1959. 235 p., $9.50.)

*HOCHSPANNUNGSTECHNIK, 4TH ED.

The new edition of this German work on H-T technique incorporates all changes and innovations in the field since the third edition (1950). There are new chapters on the increased efficiency of transformers of relatively smaller dimensions and on switching installations and switches which today are meeting the demands of considerably higher power loading. Also considered is the progress in creating high D.C. voltage, in the technique of X-Ray rules, and in R-T equipment for nuclear physics. There is an extensive bibliography arranged according to chapters. (A. Roth. Vienna,

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

Austria, Springer-Verlag, 1959. 756 p., $39.00.)

*THE EXPLORATION OF SPACE

This is a survey of recent developments in the space sciences presented in individually-authored papers, originally presented at a Symposium on Space Physics in 1959. Included are discussions of the nature of the moon, Venus and Mars; solid particles, plasma and magnetic fields in the solar system; astronomy from rockets, satellites and space vehicles; and a survey of the present frontiers of space and the major problems of the future. (ed. by R. Jastrow. Galt, Brett-Macmillan, 1960. 160 p., $5.50.)

*SMALL GAS TURBINES.

This book covers gas turbines ranging from 30 b.h.p. up to about 1,500 b.h.p., emphasizing the medium output engines, and concentrating on their adaption for other than aircraft propulsion purposes. Included are examples of applications for portable and stationary power purposes, for light aircraft and aircraft piston-engine take-off boosters, for guided missiles, and for automobiles, small marine engines, and turbines operated by high-pressure boiler exhaust gases. (A. W. Judge. Toronto, Ryerson, 1960. 328 p., $9.75.)

*DESIGN AND PERFORMANCE OF GAS TURBINE POWER PLANTS.

This volume is designed to provide a basic source of present-day knowledge in the field of aircraft gas turbines. Combustion chamber design includes the basic requirements and processes of the system, experimental techniques, fuel injection, flame stabilization, mixing processes, fuels to be used, and developmental considerations, The mechanics of materials and flutter problems are covered in the following section, and finally the various performance criteria which are used in the design of the engines are considered. *(High Speed Aerolynamics and Jet Propulsion Volume XI)* (Ed. by W. R. Hawthorne, Toronto, Saunders, 1960. 563 p., $17.25.)

*IP STANDARDS FOR PETROLEUM AND ITS PRODUCTS,
Part I. METHODS FOR ANALYSIS AND TESTING. 19TH ED.

Beginning with this 19th edition, the Institute will publish its Standards in four volumes. Volume 1 comprises all the general laboratory methods which form the major portion of the I.P. Standards and includes certain small scale rig tests, specifications for I.P. Standard hydrometers and thermometers, and a table giving equivalence of ASTM and IP methods. (Published by Institute of Petroleum, London, England, 1960. 783 p.

*KINEMATICS OF MACHINES, 2nd. ed.

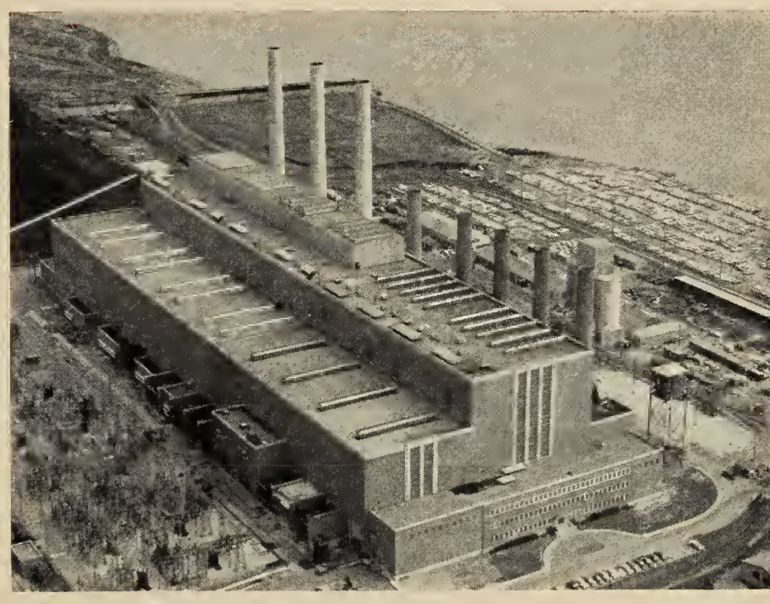
Revisions in this edition include more extensive treatment of Coriolis' acceleration, and new discussions of the four-bar linkage, independent-position and finite difference equations for velocity and acceleration analyses, the theory and application of complex variables for cam design, and Bennett's linkage. There are three entirely new chapters, on dimensional synthesis, mechanical computing mechanisms, and constrained motion and number synthesis. (R. T. Hinkle. Englewood Cliffs, N.J., Prentice-Hall, 1960. 353 p., $7.50.)

*OPERATIONS RESEARCH AND SYSTEMS ENGINEERING.

Lectures by authors from the fields of physics, economics, statistics, psychology, engineering and mathematics for a course for management at Johns Hopkins. Discussed are the philosophical and historical aspects of systems engineering and operations research, and specific methodologies such as statistical quality control, linear programming, the theory of games, information theory, and feedback. Case histories involving war games, a hospital, newspaper operations and a telephone company conclude the volume. (ed. by C. D. Flagle. Toronto, Burns & MacEachern, 1960. 889 p., $18.00.)

*INCOMPRESSIBLE AERODYNAMICS.

The first book of a new series, the Fluid Motion Memoirs, this volume provides a comprehensive review of certain flows of incompressible fluids and is a theoretical and experimental study of the uniform flow of air and other viscous fluids past two-dimensional aerofoils and three-dimensional wings. Related topics



such as flows past joined bodies, shear flows, rotary flows, and boundary-layer control are also dealt with. The information contained here is essential for those in aerodynamics, and is also applicable to areas such as gas turbines, pumps, compressors, ventilating systems, ships' stabilizers, and river erosion. (Ed. by B. Thwaites. Toronto, Oxford Univ. Press, 1960. 636 p., $11.25.)

*DESIGN OF MODERN STEEL STRUCTURES, 2nd. ed.

Joints and connections as rivets, welds, bolts, pins and timber connectors are treated first and then design of members. Both treatments relate the theoretical concepts to the field of design through specifications, which are referred to by official number. Four important structures are presented as major design examples—a building girder and a roof truss designed for both welding and riveting, a low-truss riveted highway bridge, and preliminary design of a multi-story office building with welded joints. Major changes in this edition involve the substitution of ultimate load design for continuous beam design, and emphasis on plastic design considerations. (L. E. Grinter. Galt, Brett-Macmillan, 1960. 491 p., $10.00.)

*AUTOMATIC REFRIGERATION.

This book surveys the aims, principles, and techniques of refrigeration, and the principles of automatic control, studies the design, functions and applications of automatic controls and fluid flow regulating devices, and presents extensive photographs and descriptions of existing automatic refrigeration plants, mainly European. There is an extensive section of operating information, which includes calculation sheets such as those for heat transfer, fluid flow, and plant lay-out operations; conversion tables and tables of meteorological, physical, design and other data; refrigerant tables in both British and metric units; and a bibliography and extensive literature survey. (S. A. Andersen. London, Eng., MacLaren & Sons, 1959. 649 p., 85/-.)

DIRECTORY OF UNIVERSITY RESEARCH BUREAUS AND INSTITUTES.

A guide to U.S. and Canadian bureaus, institutes, experiment stations, laboratories, etc., which are set up on a permanent basis, and carry on continuing programmes of research in specialized fields.

It contains some 1500 listings in over 200 fields, including engineering, chemistry, physics, mining, geology, operations research, computer and data processing facilities, community planning, transportation, etc. For each bureau information given includes sponsoring body, address, year founded, name of director, size of staff, publications, and a description of activities.

This should prove a most useful guide. (Detroit, Gale, 1960. 199 p., $20.00.)

*PROGRESS IN AUTOMATION, Volume 1.

This first volume of a proposed series contains eleven papers from leading British experts in the field of mechanical automation, recording progress in the United Kingdom in devices for industrial control. Following an introduction to the field, with a brief historical note and definition of terms, are six papers covering analogue conversion techniques, process control systems, position control of machine tools, the inductosyn, nucleonic gauges, and nucleonic fluid density measurement. Five papers on applications deal with the Ferranti and E.M.I. systems of machine tool control, control in the manufacture of steel strip, and automatic inspection. (ed. by A. D. Booth. Toronto, Butterworth, 1960. 226 p., $8.50.)

*THERMAL ENGINEERING.

This book is designed to serve as a supplement to thermodynamic texts which give inadequate reference to the equipment used for the generation of power, and refrigeration. It describes principles of construction, operation, and performance of the major components of a thermal power-generating system, emphasizing application of the energy and material balances, and presenting a balanced treatment of fossil and nuclear fuels as sources of energy, the reactions by which energy is released in them, and the manner in which part of this energy is converted into work. The book

includes chapters on power-plant cycles, steam generation and heat transfer, heat exchangers, turbines, pumps, fans, blowers and compressors. (H. L. Solberg. New York, Wiley, 1960. 649 p., $9.50.)

*HIGHWAY AND AIRPORT ENGINEERING.

Three quarters of the book deal with the historical development, planning, construction, and utilization of airports and highways, including a brief discussion of Federal-Aid, toll and bond financing, specifications, contracts, geology and soil mechanics, and safety problems. Design problems discussed include location, types of surface, drainage, grades, curves, and the complications of city streets. A section on aerial surveys is included. The final chapters deal briefly with such other fields of cargo moving as waterways, railroads, pipelines, and conveyors. (A. R. Legault. Englewood Cliffs, New Jersey, Prentice-Hall, 1960. 483 p., $11.65)

*SOILS AND SOIL ENGINEERING.

Fundamentals of soil engineering are covered extensively but briefly, the first ten chapters discussing the formation, distribution, physical properties, and classification of soils, and characteristics such as permeability, consolidation, shear strength and sub-soil stresses. The final seven chapters consider applications, emphasizing those related to foundations, retaining structures, and slope stability, with limited discussion of compacting, soil stabilization, and chemcal grouting. (R. H. Karol. Englewood Cliffs, New Jersey, Prentice-Hall, 1960. 194 p., $11.65.)

*BRITAIN'S SCIENTIFIC AND TECHNOLOGICAL MANPOWER.

This book is the result of study of British official documents dealing with technological manpower and education, made under the aegis of the President's Committee on Scientists and Engineers. This mustering of British manpower and educational statistics and description of postwar development and future demands is simplified by description of the British educational system and relevant social and economic factors. Suitable American statistics have been included where possible to provide an analogy. (G. L. Payne. California, Stanford Univ. Press, 1960. 466 p., $8.50.)

*DER PRAKTISCHE STAHLBAU TRAGERBAU. 2nd. ed.

Although published as the first volume of a revised treatise on steel buildings, this work can be used independently. The author provides a detailed treatment of the design and construction of different kinds of beams, columns, and structural frameworks. There is a separate chapter on construction details and one dealing with connecting methods in steel buildings, such as bolts, rivets, and welding. (A. Gregor. Berlin, Germany, VEB Verlag Technik, 1960. 604 p., DM 44.00.)

*BASICS OF GYROSCOPES.

More in Rider's "pictured-text" series, these two volumes, intended for students and non-specialists, present an explanation of the basic principles of gyroscopes. After a discussion of the construction and physics of gyroscope operation, the author discusses the different types of commercial gyroscopes, and their use as stabilizers, as used in equipment commonly bound to the earth's surface. Changes in design and construction required for uses in space vehicles, missiles, etc., are also considered. (Carl Machover. New York, Rider, 1960. 2 vols. $6.60.)

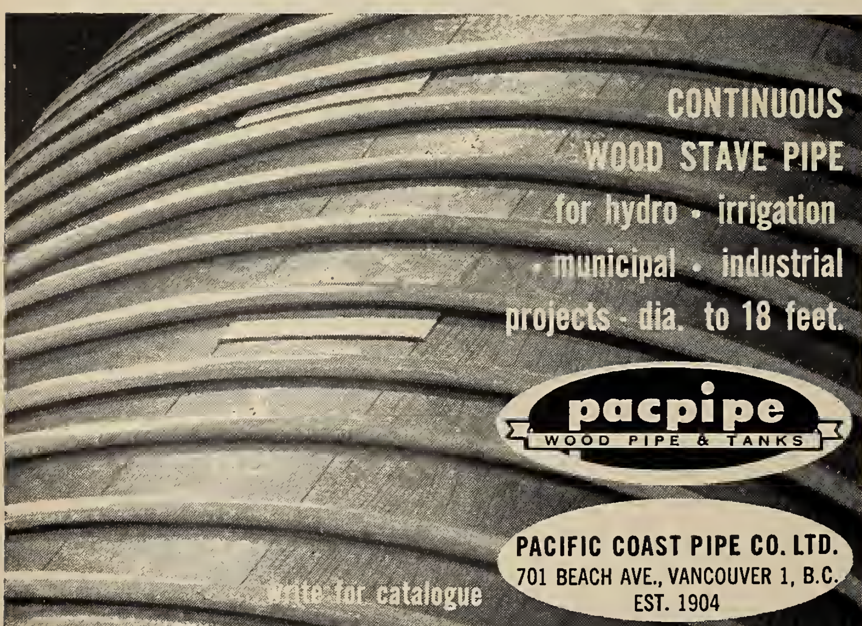
*ORTSFESTE DIESELMOTOREN UND SCHIFFSDIESELMOTOREN, 3d. ed.

The new edition of this extensive German study on stationary and marine Diesel engines retains the detailed treatment of component parts, the descriptions of currently available engines, etc., of the previous editions. There are new chapters on supercharged 4-stroke engines and on the supercharging of 2-stroke engines. Attention also is paid to the increasing importance of heavy oil engines and of the Diesel gas system as well as to the ever-growing request for ready reference formulas. (F. Mayr. Vienna, Austria, Springer-Verlag, 1960. 471 p., $32.55.)

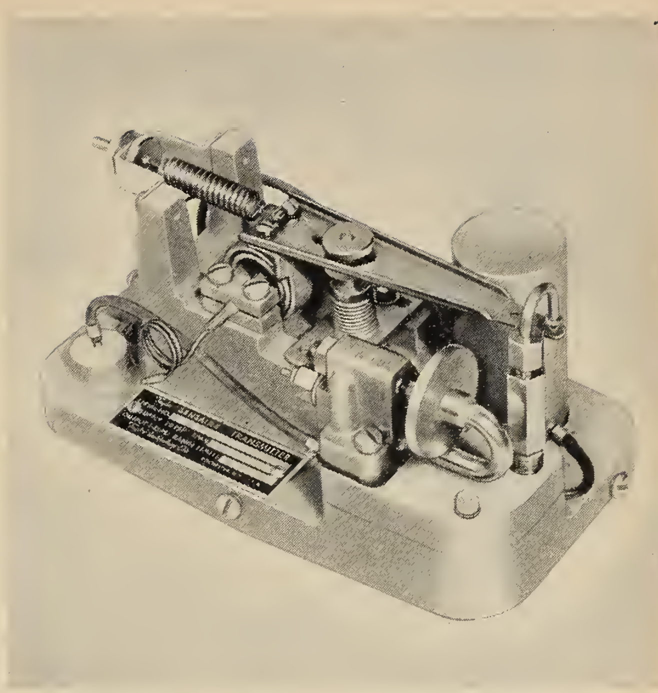
*ELECTRONIC PROCESSES IN SOLIDS.

This monograph is an extension and

(Continued on page 200)



LOW COST AND EASE OF INSTALLATION PERMIT WIDE USAGE.



OPERATIONAL SIMPLICITY IN A RUGGED, COMPACT UNIT.

TAYLOR ANNOUNCES NEW LOW-COST TEMPERATURE TRANSMISSION

New SENSAIRE* Transmitter: rugged, compact, force-balance, with mercury-filled system. Self-compensating for ambient temperatures.

The new Taylor Sensaire temperature transmitter now makes more widely available low cost temperature measurement within limits of minus 30°F. to plus 1200°F., with simplified adjustments and excellent repeatability. Available in range spans of 50°F., 100°F., 200°F., and 400°F.

Individual transmitters are factory calibrated in one of four available range spans. A simple thumb-screw adjustment zero-sets the instrument within wide limits. This adjustment is accomplished with high accuracy, and no further calibration is necessary. Factory calibrated accuracy is well within 1% of rated range, below 550°F; 1½ % above 550°F.

All Sensaire transmitters and components are interchangeable (regardless of range). A measuring system encompassing a new range span or new range limits (other than those obtainable with zero adjustment) may be added in the field.

*Trade-Mark

Taylor Instruments
MEAN ACCURACY FIRST

Unusually Fast Response. Due in part to its extremely small bulb, the Sensaire transmitter has an unusually fast speed of response. However, for processes that require it, the Speed-Act* (derivative response adjustment) unit is available. The Speed-Act feature is of special value where the bulb is placed in a well, or in processes using material with poor thermal transmission rates.

Easy to Install. Mounts in any position. Universal bracket provides for direct mounting on pipe, wall, or wrench head of well or separable bushing. Small and extremely compact, the Sensaire transmitter measures only 7¾" x 4¾" x 4½"; weighs only 7 lbs.

• LIBRARY NOTES

modification of 8 lectures presenting the physical background of electric conduction phenomena in crystals, originally given in 1957 at MIT by visiting Webster Professor (E.E.) P. R. Aigrain. A fair background in calculus and elementary wave mechanics is needed. The fifteen short sections study the motion of electrons without and with an applied field, formulation and solution of the electronic wave equation, conduction theory and phenomena, transport theory, statistical mechanics of electrons in solids, and phonon and nonintrinsic scattering of electrons. (P. R. Aigrain. New York, Wiley, 1960. 67 p., $4.00.)

*SYMPOSIUM ON EFFECT OF WATER-REDUCING ADMIXTURES AND SET-RETARDING ADMIXTURES ON PROPERTIES OF CONCRETE.

Initiated to promote increased understanding of concreting materials and the best manner of combining them to produce the maximum in strength and durability, this symposium consisted of ten papers and a summary, published herein. Topics discussed include effects of admixtures on plastic, hardened, ready-mixed, structural and lean-mass concrete; the uses, specifications for and research objectives in admixtures; admixtures and Portland cement pastes and composition; definition of and functional differences between admixtures; testing and use of water-reduction retarders; and detection of lignosulfonate retarder in cement suspensions and paste. (Philadelphia, American Society for Testing Materials, 1960. 246 p., $7.50.)

*ENGINEERING ECONOMY.

To present engineering economy within the larger context of the analysis of management decisions, this book devotes the first nine chapters to "nearly all the ideas . . . traditionally included in Engineering Economy." These include managerial economics, taxes and replacement policy, and engineering decisions, covering fundamentals, the obtaining of alternatives, sources of information, production and judgment, and evaluating intangibles. The remainder of the book introduces ideas from operations research, management science, and decision theory, including probability and game theory, decisions under risk, under uncertainty, and under pressure, policies of inventory, bidding and purchasing, statistics, diversification, simulated decision making, and the economics of automation. (W. T. Morris. Homewood, Illinois, Richard D. Irwin, Inc., 1960. 506 p., $10.50.)

*THEORY OF THERMAL STRESSES.

The author first develops the fundamentals of thermoelasticity, working from the thermodynamic foundations to various alternate formulations and problem solution methods. Three chapters then discuss the physical basis of heat transfer theory and methods of solution of heat conduction boundary-value problems. Part three of the book then covers practical aspects of thermal stress analysis, mainly from the strength-of-materials viewpoint. The final section describes the manner in which temperature effects can be included in elasticity theory, covering the general nature of the idealizations used in this field, problems utilizing these idealizations, and problems involving plastic flow. (B. A. Boley and J. H. Weiner. New York, Wiley, 1960. 586 p., $15.50.)

*ADVANCES IN COMPUTERS, Volume 1.

This volume is the first in a series intended to survey progress in computer programming at frequent intervals and to present the information to others than specialists in the field. The six papers contained here are on methods of programming for business, scientific, and lingual applications. Automatic translation of languages, machine recognition of spoken words, programming for games, numerical weather predictions, general business applications, and binary

(Continued on page 207)

75th Annual General and Professional Meeting
Vancouver, B.C.
May 31 - June 2, 1961

shell and tube exchangers and related engineered products. Following completion of company training course successful applicants will be assigned to Hamilton and Montreal Branch Sales Offices. Attractive starting salary and wide range of company welfare benefits. Send complete resume and salary requirements to File No. 6923-V.

SALES ENGINEER. The company a well known manufacturer of centrifugal pumps with head office in Toronto requires requires recent graduates for its Montreal and Toronto Sales Offices. After a short training period the successful candidates will be engaged in outside sales work, calling on refineries, chemical plants, major contractors, consulting engineers and pulp and paper industry. Reply, giving full particulars to File No. 7001-V.

ASSISTANT PROFESSOR required for teaching and research in hydraulics and fluid mechanics. Salary $6000 to $8000 depending on qualifications. Please submit full details with application to President, Nova Scotia Technical College, Halifax, Nova Scotia. File No. 7072-V.

CHEMICAL AND MECHANICAL ENGINEERS. For design work for chemical plant in Montreal East. Some experience desirable. Phone or write: Mr. F. S. Runnar, B.A. Shawinigan Limited, P.O. Box 338, Montreal, Quebec. Mission 5-9203. File No. 7111-V.

SALES ENGINEER required by Canadian manufacturer of control equipment for heating, cooling and airconditioning fields. Quality products for oil, gas and electric heating. Location Montreal, bilingual preferred. Please submit full details, age, experience, education and salary. File No. 7124-V.

ELECTRICAL OR MECHANICAL ENGINEER required by Canadian manufacturer of automatic control equipment. To work with small engineering group in design, development and application. Location Toronto area. Please submit full details giving age, experience, education and salary. File No. 7125-V.

SALES ENGINEERS. With B.Sc., Mechanical or Chemical required by fully integrated major oil company, marketing department, for early assignment in Western Canada. If you believe SALES is a true engineering function, then your future professional life can fit this position. Training course given. Excellent remuneration and advancement prospects. Three to five years sales experience desirable but not a requirement. Knowledge of modern industrial equipment a definite asset. Permanent position. Full company benefits. Please give personal history and statistics. File No. 7128-V.

TRANS-CANADA AIR LINES requires an engineer with a University Degree in Mechanical, Electrical, Industrial Engineering or Engineering Physics. Employment will be in the Overhaul Research Services Group of the Winnipeg Maintenance and Overhaul Department. Duties: to carry out technical investigation on aircraft and associated equipment. Requirements: failure investigation, experience in aircraft or Power-plant Overhaul plus experience or keen interest in developing and applying statistical research methods. Industrial Engineering experience an asset. Salary range $5700 to $6700 per annum. Starting rate commensurate with qualifications. Full complement of employee benefits. File No. 7129-V.

• LIBRARY NOTES

(Continued from page 200)

arithmetic useful in designing computing equipment, are the specific topics covered. (F. L. Alt, ed. New York, Academic Press, 1960. 316 p., $10.00.)

***ASTM MANUAL FOR RATING MOTOR FUELS BY MOTOR AND RESEARCH METHODS. FOURTH EDITION.**

This revision brings up to date both the motor and research methods of testing for knock characteristics below 100 octane number and presents a new research method for above 100. Six appendices give technical data on the installation, operation, and maintenance of knock testing equipment. (Philadelphia, American Society for Testing Materials, 1960. 196 p., $7.50.)

***ELECTRICAL SYSTEMS DESIGN, 2nd. ed.**

This second edition includes a wider variety of design details, illustrated and analysed in terms of modern design standards and the National Electrical code. It covers residential wiring, selection and layout of lighting equipment, application of electric heating and air conditioning, and design of signal and communication circuits and layouts as well as preparaton of plans and specifications in the design of total electrical systems for industrial, commercial and institutional buildings. (J. F. McPartland. Toronto, McGraw-Hill, 1960. 208 p., $8.95.)

***WINDSCALE.**

Intended mainly for civil engineers, this book provides a background for all who are interested in nuclear power station engineering and construction by describing the building of the Windscale Works in England. The choice and preparation of a site, and the construction of the pile chimneys and of the effluent pipelines is related. The author then describes the remedial operation for the biological shields of the piles, and the problem of supplying supplementary cooling air to the piles, and finally recounts some of the day-to-day maintenance problems of the reactors. (S. Sinclair. London, Eng., George Newnes, 1960. 136 p., 25/-.)

***STATICS OF SOIL MEDIA.**

This translation of the second edition of Sokolovski's work includes certain revisions and amendments especially provided by the author. The theory of critical equilibrium is discussed in detail in relation to a soil medium, an ideal granular wedge, and an ideal cohesive medium (without internal friction). Applications of the theory are demonstrated in chapters on stability of foundations, slopes, and layered media, and on the pressure of a fill against retaining walls. (V. V. Sokolovski. Toronto, Butterworth, 1960. 237 p., $10.50.)

***ELEMENTARY THEORETICAL FLUID MECHANICS.**

Here the fundamentals of fluid mechanics are developed with a minimum of attention to practical applications in order to provide a basis for the study of applications in many fields of advanced specialization. The author adheres to the basic equations almost exclusively to promote versatility in the fundamentals and avoid formula dependence. The text covers fluid statistics, conservation of matter and of energy, momentum, friction, dimensional analysis and potential flow. Brief treatments of acoustic velocity, cavitation, thermodynamics, and boundary layer theory are presented in appendices. (K. Brenkert. New York, Wiley, 1960. 348 p., $7.50.)

Appointments and Transfers

D. L. George Turvey has been promoted to general sales manager for Armco Drainage and Metal Products of Canada Limited, Guelph, Ont. Replacing Mr. Turvey as Ontario sales manager is **John E. Wilson.**

John W. Ames, chief design engineer—commercial, of Avro Aircraft Limited has been appointed vice-president and general manager of Canadian Applied Research Limited. CARL is a member of the Aeronautical Group of A. V. Roe Canada Limited and is engaged principally in the design, development and manufacture of airborne navigation equipment.

Evan S. Beal has succeeded **Kenneth C. Blackwell** as technical sales representative for petroleum chemicals in Ontario for Du Pont of Canada Limited. Mr. Blackwell has moved to Calgary as technical sales representative for petroleum chemicals there.

Dr. George B. Langford of Toronto was selected Canada's official observer to the Conference of Engineering Societies of Western Europe and the U.S.A. in Brussels. Dr. Langford heads the Department of Geological Sciences at University of Toronto.

Walter Stensch has been appointed chief engineer of the structural deparment of Surveyer, Nenniger and Chenevert, consulting engineers, of Montreal.

Scott W. Hill has been appointed Industrial Products Department representative for Sun Oil Company Limited.

H. J. Lang assumed his duties as president of Canada Iron Foundries, Limited, Montreal, September 1. Formerly he was president of National Steel Car Corporation Limited.

W. R. Clerihue has been appointed Treasurer and Controller of Dominion Structural Steel Limited. Previously Mr. Clerihue had been Controller of Canada Iron Foundries, Limited, and director and Treasurer of Peacock Bros., Limited.

Ronald J. Cooksley, former Ontario Government Industrial Commissioner in Chicago, has been appointed director of industrial development for the Township of Trafalgar.

Duart A. MacLean has been named a Principal and Director of R. C. Thurber and Associates Limited, consulting engineers, Victoria.

Anthony H. Cardwell and **Douglas H. Peacock** have been promoted to top Canadian sales posts by Burroughs Adding Machine of Canada Limited. Mr. Cardwell has been appointed general products sales manager and Mr. Peacock has been named sales manager—computer products.

George E. Temple has been appointed vice-president of Dominion Structural Steel Limited. Mr. Temple formerly was vice-president and general manager of Catalytic Construction of Canada, Limited.

Developments

LOCAL DISTRIBUTION systems in sections of Chambly and Laprairie counties in Quebec which were owned by Shawinigan Water and Power Company, have been purchased by Quebec Hydro. Purpose of the transaction was to prevent duplication of lines and equipment and to effect a consolidation of distribution by Quebec Hydro in the metropolitan area it serves.

INCREASED half-year earning have been reported in an interim report of The Canadian International Nickel Company of Canada, Limited and subsidiaries. For the period ended June 30, 1960, the company showed earnings of $1.50 a share compared with $1.31 a share in the first six months of 1959. Second-quarter earnings of 65c a share compared with first-quarter earnings of 85c and earnings during the second quarter of last year of 73c.

BENEFITS of mechanical demand registers are outlined in a new four-page bulletin distributed by Canadian General Electric Company of Toronto. Bulletin 5146 describes the company's M-30 Demand Register, which when used with either single phase or poly phase GE Watthour Meters, converts them into demand meters.

PARA-FLEX COUPLINGS, manufactured by United Steel Corporation Limited, are designed for high-speed, high-torque and flywheel applications. They feature a pan-shaped rubber flexing element of new design. Designed for speed up to 5,230 r.p.m. the unit may be used with electric motors or internal combustion engines to operate such equipment as hammer mills, compressors, pumps, fans, marine drives, and blowers.

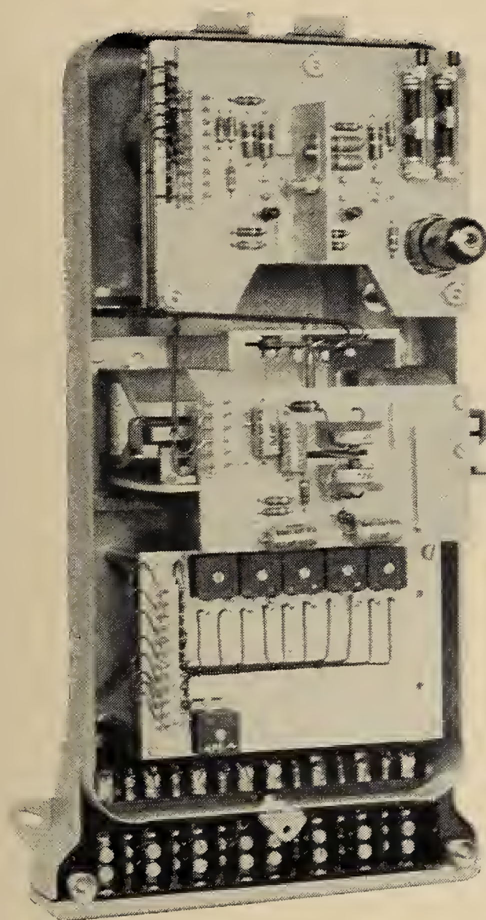
SIX CONE ROOF STORAGE TANKS, each with a capacity of 80,000 bbl., are being built at Fort William, Ont., for Canadian Husky Oil and Refining Limited. The manufacturer is Sparling Tank and Manufacturing Company, a division of Products Tank Line of Canada, Limited. New construction and alterations at Husky's Lakehead refinery will total $1 million this year, about half of which will be spent on storage facilities.

A NEW STRUCTURAL STEEL has been manufactured by the Steel Company of Canada, Limited. Identified under the A.S.T.M. Designation A 36, the new steel is described by the company as having a "cost-to-strength ratio substantially better than for existing carbon structural steel specifications". A 36 specification covers carbon steel shapes, plates and bars of structural quality not over 4 in. in thickness for use in the construction or bridges and buildings and for general structural use.

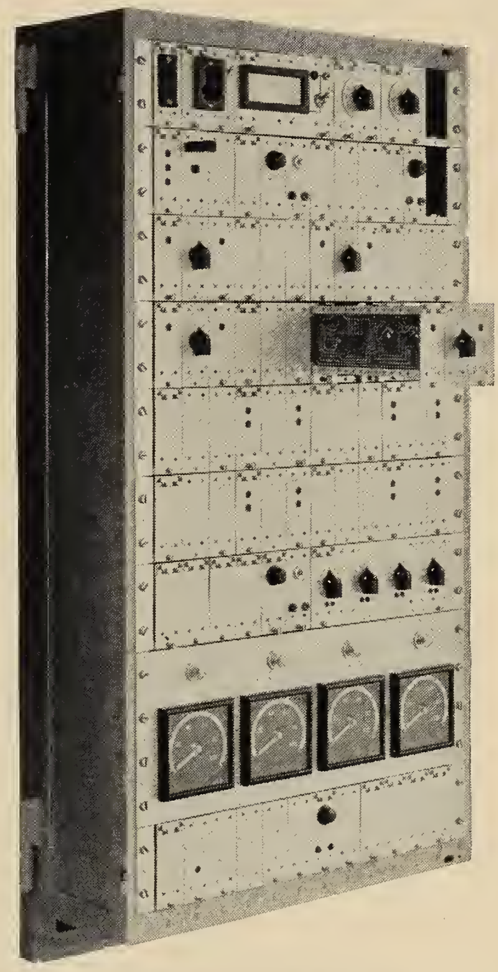
CONSOLIDATED EARNINGS of the Shawinigan Water and Power Company, St. Maurice Power Corporation, and Southern Canada Power Companv, for the first six months of 1960 applicable to Shawinigan common shares were 80c a share. On 7,826,956 shares outstanding June 30 earnings totalled $6,267,553. The half-year earnings last year totalled $5,408,574, or 70 cents on each of 7,638,383 shares outstanding.

CORROSION PROBLEMS affecting outdoor switchgear housing have been attacked by Canadian Allis-Chalmers Limited. The company has introduced an entire housing for ac. switchgear

The World's leading manufacturers of special metering equipment



Transistorized torque balance transmitter



Transistorized channelling equipment

BOUNDARY DAM-132,000 K.W. FOR S.P.C. RELIES ON LANDIS & GYR TELEMETERING

Boundary Dam, the southern cornerstone of S.P.C.'s electrical system relies on Landis & Gyr Telemetering Equipment. Saskatchewan's generation and distribution system is growing at an outstanding pace. Only with extensive use of telemetering is it possible to integrate new generating centres into the existing grid. Landis & Gyr Telemetering Equipment has been chosen by Saskatchewan Power Corporation for its accuracy, speed and outstanding adaptability.

LANDIS & GYR INC.

1010 GROU ST., MONTREAL 9, P.Q. RI. 4-2129

Metering Equipment

You are invited to ask us for tenders on: Electric meters • Active and reactive energy meters • Apparent energy meters • High precision meters • Meters for every rate problem • M.D.—Recorders and printers "Maxigraph", "Printomaxigraph", "Maxiprint" • Totalizing and tie-line metering instrumentation • Prepayment meters • Test sets • Load survey meters • Telemetering • Ripple control • Power factor correction • Reverse power relays • Time switches • Thermal control apparatus • Oil burner relays • Nucleonic instrumentation • Pile simulators for reactors • Flue gas analyzers • Master clock and staff location equipment • Mains supply failure registers • Surge discharge counters.

made of extruded aluminum panels. Aluminum extrusions are snapped together to form a maintenance-free structure for outdoor use. It is called the Aluma-Clad switchgear housing, and requires no paint to protect it against weather.

PRESSURE, VACUUM AND MAGNETIC GUAGES are discussed in two new catalogues available from Peacock Brothers Limited of Montreal. Catalogue PB-065 contains detailed information concerning standard phosphor bronze, steel, stainless steel and K Monel Bourdon tube guages and on Schaffer diaphragm type guages. Catalogue 388 describes magnetic guages produced by Jerguson Gage and Valve Company.

POWER, traced from the first pulse of generation to the moment when appliances are plugged in, was featured in a display at the Canadian National Exhibition. In one of the most comprehensive exhibits ever produced by the Hydro-Electric Power Commission of Ontario, new horizons in the field of electricity were outlined graphically by models, maps and murals along with a full-size home.

OFFICES AND WAREHOUSE will be contained in a new building being erected for Canadian General Electric Company Limited in Lancaster, N.B. The first sod was turned this summer and it is scheduled for occupancy in January. The building will contain 5,000 sq. ft. of office space and 14,600 sq. ft. for warehouse and services.

IRON CLAD CONCRETE FLOORS have shown to ability to outlast by a wide margin floors made of ordinary concrete. A description of a Masterplate floor is contained in a bulletin prepared by the Master Builders Company, Limited, Toronto. The floor has an armoured surface about ⅛ in. thick. This is produced by dusting a dry mixture of Masterplate and cement on the surface of freshly-coated concrete.

A COPPER PRICE CHANGE has been announced by The International Nickel Company of Canada, Limited. The new domestic copper price, effective August 30, is 30 cents Canadian per pound delivered Toronto.

R-27 SILICONE, a Union Carbide product for above-grade masonry water repellents is described in a new brochure from the company's Bakelite Division. The brochure is designed to answer questions regarding performance, meeting of specifications, effectiveness and applications of water repellents made with the product.

320 ACRES HAVE BEEN OPENED by Vancouver's Skeena St. Pumping Station since it was built in 1954. Lowlying sections of the Grandview Highway have been pumped and made available for industrial and residential use.

COMMERCIAL WOOD PRESERVATIVES have been subjected to a 14-year test by the United States Department of Agriculture. In plots in varying climatic conditions around the world, stakes were driven. Some were untreated while others were dip-treated or pressure treated with various preservatives. Untreated stakes that would have lasted about six years at Chalk River, Ont., were destroyed in one year in a more humid climate. Stakes dipped in creosote lasted one to four years longer than untreated stakes, depending upon the climate of the test plot.

A NEW CHEMICAL ENGINEERING BUILDING at University of British Columbia is expected to be ready in September, 1961. Anglin-Norcross (Western) Limited, has been awarded a contract for $608,637 for construction of the three-storey building. It will contain 30,000 sq. ft. of space and will cost $750,000. The structure is the first of six to be built on a 15-acre site at the south end of the campus for the faculty of applied science.

PAINLESS DENTISTRY has contributed a miniature cutting tool to industry. An industrial version of the Borden Airotor used for painless dentistry now is available for precision miniature machining. With a rotating speed of 300,000 r.p.m., and using carbide or diamond point burs, it is possible to machine materials with a hardness factor of 62 Rockewell 'C' 90% faster than with conventional equipment.

TECHNICAL ADVICE to architects, consulting engineers and to the construction industry will be provided at the newly-established Ontario Bureau for Lathing and Plastering. The service is being provided by the Contracting, Lathing and Plastering Association of Ontario, Incorporated in co-operation with the Inter-Provincial Council of Lathers.

BOWATER PAPER CORPORATION LIMITED and its subsidiaries, in an interim financial statement, report a gross profit equivalent to $30,766,000 for the first half of 1960. This compares with a gross profit of $25,385,000 for the six months ended June 30, 1959. An interim dividend of about 14c a share was declared.

TWO HUGE VACUUM TANK CARS have been ordered by Canadian Liquid Air Company. The cars will be nearly twice the length of standard cars and will have an 80% greater capacity. They are 64 ft., 4¼ in. long and have a capacity of 13,700 Imp. gal. The cars are being built by Union Tank Car Company and will be used to transport liquid oxygen and other liquefied atmospheric gases.

GREATER FUEL ECONOMY with high-displacement diesel engines has been attained through co-ordinated research and testing by the White Motor Company and Cummins Engine Company, Incorporated. President Norman H. Bell of the White Company reports the program has resulted in White chassis and Cummins engine modifications that produce 7.3% to 18.5% more miles per gallon than other leading large-displacement engines.

EASTERN AND WESTERN DIVISIONS have been established by Boyles Bros. Drilling Company, Limited. The Eastern Division under the management of Don Mackay will include Boyles Bros. Drilling (Eastern) Limited at Port Arthur, Boyles Bros. (Quebec) Limited at Noranda, Boyles Bros. (Maritime) Limited, at Moncton, N.B., and the newly-formed sales division at Toronto. The Western Division, under the management of Reg McWilliams will include Boyles Bros. Drilling Company, Limited, at Vancouver.

GROWING MARKET DEMAND for marine gas and diesel engines has caused Cooper-Bessemer of Canada, Limited, to reopen its Halifax warehouse. Depressed market conditions caused the company to relocate the warehouse in Gloucester, Mass., but subsequent market expansions have created a permanent need for facilities in Halifax. A company statement said the Halifax facility is anticipated eventually to house gas and diesel engines produced at the company's newly-leased manufacturing facilities at Stratford, Ont.

LARGEST POWER SIZES ever offered by John Deere and Company are included in a new line of tractors and equipment it has developed for earth-moving, logging, landscaping and material handling.

A 51-MILE PIPE LINE extension from Winnipeg south to the international border near Emerson, Man., has been completed by Trans-Canada Pipe Lines Limited. Canadian natural gas now is moving to the United States for purging and testing sections of the Midwestern Gas Transmission lines now under construction from the border to Marshfield, Wis. The American line is scheduled to be finished this autumn.

NATURAL GAS now is being used by Falconbridge Nickel Mines Limited. The 6½ miles of 6 in. pipeline was completed, purged and tested July 14 and use of natural gas began the following month. Initially, Falconbridge will use a maximum of 2 million cu. ft. of gas a day to fire two boilers, each with a capacity of 25,000 lb. of steam an hour, and five sintering machines used in the smelting process.

(More Briefs on page 216)

• MORE BRIEFS

A NEW-TYPE POWER TAKEOFF UNIT that can deliver 70 hp. without requiring changes in other power train components has gone into production at the Automotive Division of Canadian Clark Limited. Designated the P-200 Flywheel Power Takeoff, the new design bolts to the engine flywheel housing, thus is ahead and independent of the clutch and transmission. Primary applications are vehicles such as transit concrete mixers, fire trucks, fuel trucks and farm equipment where large amounts of engine power are required to drive accessories.

OUTSTANDING SALES AND EARNINGS for the fiscal year ended June 30, 1960 have been reported by Beckman Instruments, Incorporated. Sales totalled $54,257,282 compared with $44,872,768 in 1959. Net income per share was $2.24 compared with $1.30.

T. McAVITY AND SONS LIMITED valve manufacturers of Saint John, N.B., has been purchased by Crane Limited. The price was not disclosed. McAvity currently employs about 500 workers in its plants at Saint John and Medicine Hat, Alta. Annual sales exceed $5 million.

SIDEWALK SUPERINTENDENTS in Montreal have been treated to a comprehensive view of a major construction project by means of closed-circuit television. At the construction site of the new CIL House, 90-minute shows were presented each lunch hour. The camera was perched on the 14th floor of the steel framework and four receivers were set up in a public gallery above the sidewalk. The system was to operate for two weeks, with a possibility it may be re-established when the steelwork reaches the final storey — the 34th.

MERGER OF TWO BRITISH FIRMS has been approved by shareholders of the companies. Davy-United Limited and The Power-Gas Corporaton Limited will merge under the title Davy-Ashmore Limited. The Davy-United Group is the largest manufacturing unit in the United Kingdom for the design and production of rolling mills and auxiliary equipment for the steel and non-ferrous industries. The Power-Gas Group, which includes Ashmore, Benson, Pease and Company, Limited, P.G. Engineering Limited and Rose, Downs and Thompson Limited, specializes in the design, manufacture and erection of plants for the iron and steel, chemical, gas, oil, petro-chemical, fatty oil and fish meal industries. The new group controls 11 operating subsidiaries. The Canadian subsidiary is Power-Gas Canada Limited in Montreal.

● MORE BRIEFS

THE ECONOMICS OF GAS TURBINE GENERATION for United States Defence sites and for commercial applications are discussed in a booklet issued recently by Clark Bros. Co., one of the Dresser Industries. A comparative analysis of gas turbine, steam and diesel generating plants is made. Major factors such as installed cost, fuel, operating cost and the time value of money are reviewed through the use of text, charts and graphs.

PREPARING A SPECIFICATION for a Universal Air Data System to be used by all airlines was the assignment given the Air Data System Sub-Committee of the Airlines Electronic Engineering Committee, Aeronautical Radio, Inc. The objective of the specification is to define a central air data system that will provide the required air data parameters for contemporary and future high performance jet transport aircraft. Basis of the system will be a computer which must be adaptable without modification to any of these aircraft and will provide information for cockpit display, flight control use and/or use in other aircraft control systems.

REINFORCED ASPHALTIC CONCRETE HIGHWAY resurfacing has been subjected to a completely controlled experimental field installation. The project was the improvement of a 1½ mile stretch of highway in New York State. Although the existing pcc pavement was generally in passable condition several of its 40 ft. slabs had fairly severe transverse or corner cracks. Because of this and the need to widen the road it was decided to make a test installation of wire fabric reinforced asphaltic concrete resurfacing. The previous condition of the road was recorded carefully on film and by a slab-by-slab crack survey and will be compared with its future condition.

PREVENTION AND CONTROL of Corrosion in industry are outlined in a new manual published for Scientific Surveys Limited, Consultants and Technical publishers, London, England.

DAVIE SHIPBUILDING WINS AD CERTIFICATE

Davie Shipbuilding Ltd. has been awarded an E.I.C. Certificate of Advertising Merit for their two colour, full page, advertisement which appeared on page four of the July 1960 issue. The advertisement is very striking in appearance and the "teaser heading" induces reading of the copy.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

Fifty readers of the "Journal" — representative of all provinces — selected the Davie Shipbuilding Limited advertisement as the best in the July issue from the viewpoints of ACCURACY — INFORMATION — ATTRACTION.

The advertisement appears on page four of the issue. It is headed: "GIANT CAMERA FOR OUTER SPACE? NO, BUT . . ." The copy explains that the structure illustrating the advertisement is a double hopper mill feed bin — "no more than a routine construction job for DAVIESHIP".

The advertisement was prepared and placed by Cockfield, Brown & Co. Ltd., Montreal, Ross M. Mackay, Account Executive. The Company official responsible for advertising is J. G. Fisher of Canada Steamship Lines of which Davie Shipbuilding is a subsidiary.

TWENTY-ONE SENIOR ENGINEERS of H. G. Acres and Company, Limited, Niagara Falls, have pooled their resources and bought back shares of the company held by a United States firm. Through their acction H. G. Acres has reverted to 100% Canadian control. The shares were held by Fluor Corporation of Canada, Limited, wholly-owned subsidiary of the Fluor Corporation of Los Angeles.

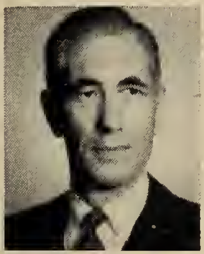
Printed in Toronto

Price $6.00 a year in Canada, British Possessions, United States and Mexico, $7.50 a year in Foreign Countries. Current issues, 75 cents a copy, back issues from $1.00 per copy up. To members, affiliates and other bona fide engineers in Canada—no charge. Authorized as second class mail, Post Office Department, Ottawa.

Meet the Authors

C. G. Kingsmill, M.E.I.C., B.A.Sc. Mechanical (Toronto '24), Director and Assistant to the President, Angus Robertson Limited, Montreal. *(The Warsak Hydro-Electric and Irrigation Project).*

Mr. Kingsmill worked on construction of hydro-electric power developments and newsprint mills prior to joining Beauharnois Construction Co. in 1930. He continued work with Beauharnois Light, Heat & Power Co., and later with the Quebec Hydro-Electric Commission. In 1952 he resigned as chief engineer of the latter's power development division to join his present firm.



C. G. Kingsmill, M.E.I.C.

R. D. Mutch, M.E.I.C., Product Engineer-Cranes, Dominion Bridge Co. Ltd., Lachine. *(Design of Industrial Gears).*

Mr. Mutch was a crane designer with Babcock and Wilcox Ltd. in Scotland for 20 years before coming to Canada in 1948 as chief crane designer with John T. Hepburn of Toronto. He joined his present firm in 1950. Mr. Mutch is a member of the Corporation of Professional Engineers of Quebec.

L. M. Hovey, M.E.I.C., B.Sc. Electrical (McGill '25), Assistant to the General Manager-Planning, The Manitoba Hydro-Electric Board, Winnipeg *(Optimum Adjustment of Governors in Hydro Generating Stations).*

After graduation Mr. Hovey joined Winnipeg Electric Company as draughtsman and junior engineer. In 1929 he became assistant electrical engineer and in 1938 electrical engineer. He has been in his present position since 1953 with the responsibility of general long range system planning. He is a member of the American Institute of Electrical Engineers.

L. M. Hovey, M.E.I.C.

A. B. Howell, M.E.I.C.

A. B. Howell, M.E.I.C., M.Sc. Mechanical (McGill '49), Wing Commander, Staff Officer Aeronautical Engineering, Training Command Headquarters, R.C.A.F., Westwin, Manitoba. *(An Exercise in Operations Research—RCAF Aircraft Maintenance).*

Mr. Howell has, since 1952, been involved with the maintenance of aircraft and R.C.A.F. administration.

W. J. Eden, M.E.I.C.

R. F. Legget, M.E.I.C.

W. J. Eden, M.E.I.C., B.A.Sc. Civil (Toronto '49), Research Officer, Soil Mechanics Section, Division of Building Research, National Research Council, Ottawa; **R. F. Legget**, M.E.I.C., M.Sc., (Liverpool '27), Director, Division of Building Research, N.R.C., Ottawa. (*Soil Problems in Mining on the Precambrian Shield*).

Mr. Eden has been with the N.R.C. Division of Building Research since his graduation in 1949.

Mr. Legget came to Canada in 1929 and was engaged in heavy construction work until he joined the staff of Queen's University. He was later teacher and consultant on soil and foundation problems at the University of Toronto for nine years prior to his appointment in 1947 by the N.R.C. to head the new Division of Building Research. He is a member of the Institution of Civil Engineers, the American Society of Civil Engineers, and a fellow of the Royal Society of Canada and of the Geological Society of America.

B. B. Hope

S. D. Lash, M.E.I.C.

B. B. Hope, B.Sc. (Manchester '57), M.Sc., Research Assistant, Queen's University, Kingston; **S. D. Lash**, M.E.I.C., B.Sc. (Imperial College '28), M.Sc., Ph.D., Head, Department of Civil Engineering, Queen's University, Kingston (*Structural Behaviour of Highway Bridge Decks*).

Mr. Hope is at present reading for his Ph.D. degree in the Civil Engineering Department at Queen's University.

Dr. Lash was an instructor in Civil Engineering at U.B.C. (1935-38). He then joined the N.R.C. National Building Code as Technical Secretary until 1941 when he went on the staff at Queen's. He became head of Queen's Civil Engineering Department in 1955. Dr. Lash has published several papers and was the recipient of the E.I.C. Gzowski Medal in 1942.

THE WARSAK HYDRO-ELECTRIC AND IRRIGATION PROJECT

C. G. Kingsmill, M.E.I.C.,
Director and Assistant to the President,
Angus Robertson Limited, Montreal

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The government of Canada decided in 1955 that their major Colombo Plan Project for the nex few years would be the Warsak multi-purpose development. Previous investigation had established the need for low cost electrical power in the area to aid in the setting up of industries and for deep-well pumping for land improvement, as well as for additional irrigation of the nearby plain. The Warsak development could make a major contribution to these requirements, and in the course of construction a great many Pakistanis could be trained in modern construction methods and later continue to develop their own country. Negotiations were carried out between the Governments of Pakistan and Canada to formulate the contribution that each would make, and the general contract awarded in June 1955.

IN GENERAL it was agreed that Canada would pay the cost of supervisors, technicians, material and equipment that had to be brought into the country, and that Pakistan would pay all rupee costs for labour, for such material as could be produced in Pakistan, for electric power and fuel during construction, and for housing and accommodation. The latter costs were to be paid from counterpart funds from the sale of wheat donated by Canada.

General Description

Warsak is the name of a small village where the Kabul River leaves a deep narrow gorge in the Hindu Kush range to flow across the plain, thence to join the Indus River. It is situated at lat. 34° N, long. 71° E, and the general ground level of the surrounding plain is 1100 ft. above sea level. Climate is subtropical, with temperature ranging from the thirties in the Winter, to as high as 130° F. in the Summer. Rainfall is light, 16 in./yr., and the immediate area is little affected by the monsoon.

The Kabul River has its source in the mountains of Afghanistan, with little storage, and flow ranges from a recorded minimum of 4,180 c.f.s., to a probable maximum of 225,000 c.f.s. Fortunately, the period of low flow corresponds to the best weather for working, and although the work was carried on throughout the year, it was possible to concentrate in the river bottom during the months of September to April. (See Fig. 3).

The permanent work (see Fig. 1.) consists of a gravity type dam 650 ft. long and a maximum height of 270 ft., comprising an overflow section 440 ft. long controlled by nine 40 ft. wide taintor gates between 10 ft. wide piers. A bulkhead extends into the sides of the gorge at each end. Below the dam is a stilling basin designed to dissipate the energy of the water during periods of overflow. A power tunnel in the South bank of the river 39 ft. diam., concrete lined, and 700 ft. long leads the water to a manifold from which six 18 ft. diam. steel lined penstock tunnels take the water to the turbines. The power house is built into the wall of the gorge and the water discharges into a tailrace channel with an outlet just below the stilling basin. Ultimate installation provides for six 55,000 hp. units of which four are now being installed. Auxiliary power is supplied by two 750 kva. house units fed by one 6 ft. diam. penstock tunnel.

An irrigation tunnel 3½ miles long

and 10 ft. diam. inside the concrete lining leads water to a nearby portion of the arid plain to irrigate 100,000 acres of land.

Temporary diversion was achieved by means of a 35 ft. diam. concrete lined tunnel 1,700 ft. long in the North bank which by-passed the cofferdams. The capacity of this tunnel was approximately 30,000 c.f.s. with water at the level of the upstream cofferdam, thereby providing diversion for about 6½ to 7 months per year.

Communications

A broad gauge (66 in.) railroad runs about 1,000 miles from Karachi, the main seaport, to Jamrud Fort, the Pakistan entrance to the famous Khyber Pass. A 15 mile hard top road was built from there to Warsak, over which all equipment and material had to be trucked.

The nearest airport is 19 miles distant at Peshawar, an ancient city with a present population of about half a million. The Pakistan Government Airline flies from Karachi to Peshawar 4 or 5 times a week, via Lahore and Rawalpindi, carrying air freight and mail as well as passengers.

There is a fairly good road from Peshawar to Lahore, but from Lahore to Karachi road travel is difficult, and the passenger train service between Peshawar and Karachi is poor. Telephone, telegraph and air-mail services to Karachi are fair.

Shipments from Montreal, New York or Saint John take from 30 to 35 days, a ship leaving about once a month. Transfer at Karachi to railroad cars, passage through customs, and inland freight to Jamrud averaged about 3 weeks. It will be readily seen that from the time an article was requisitioned at the site, until delivery could be expected, 3 months elapsed provided there was no particular delay by the manufacturer. Air freight had to be used sparingly due to cost, and careful planning kept this expense down to a total of about $40,000. Air-mail takes about 6 days from Canada, and cable service is good.

Local Facilities

Most of the ordinary materials required for construction are in short supply in Pakistan and local purchases were of small volume. Although most foodstuffs are available, a lot of them are of indifferent quality by Canadian standards, and a considerable quantity of food was imported. Approximately half of the diet of Canadian personnel was from local sources.

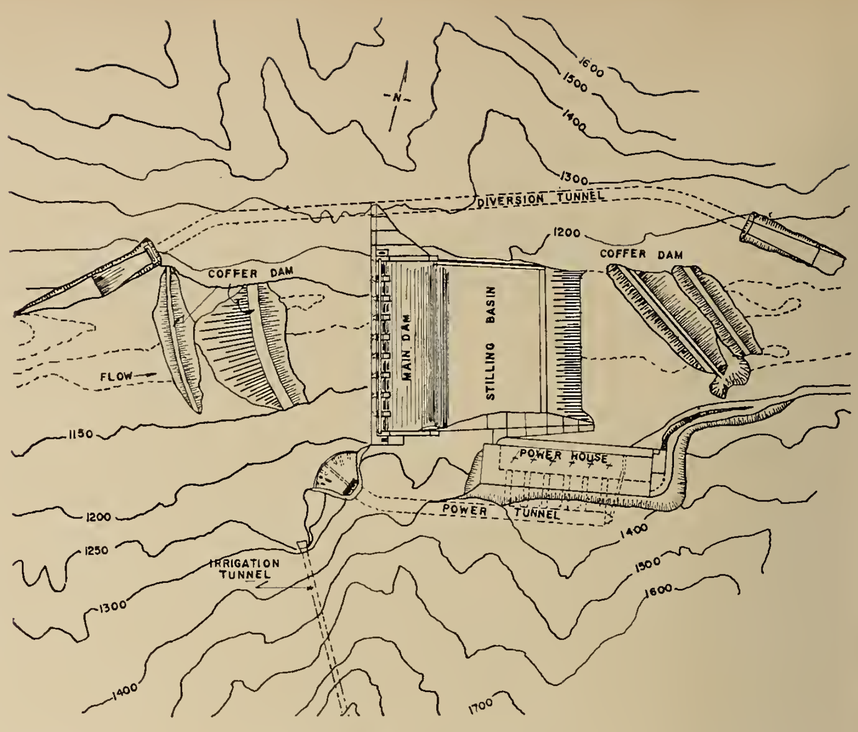

Fig. 1. General Layout of Project

Sand and gravel deposits for concrete aggregate were found within a few miles of the dam, close to the Kabul River. Processing plants were designed to suit conditions, and all aggregates were obtained from crushing, screening and washing. The following quantities were handled:—

Stripping	750,000 cu. yd.
Processing	1,500,000 cu. yd.
Production	1,100,000 cu. yd.

Cement was obtained from a plant at Wah, some 90 miles distant by rail. A consistently good grade of Portland cement was maintained, and during the busy period as much as 19,000 tons per month was delivered, mostly in bulk, in specially built freight cars. It is worth noting that the production from the Maple Leaf Cement Plant at Daud Kehl, an earlier Canadian Colombo Plan Project, made it possible for the Wah Plant to deliver Warsak's requirements without seriously disrupting supplies to other users.

Pakistan agreed to supply 5,000 h.p. of electrical power, and found it necessary to purchase four 1,000 kw. diesel generators which were in operation by July 1956, prior to which a small quantity of local power was made available. Peak requirement was 4,560 kw., major demands being five 200 h.p. compressor motors and two 300 h.p. cableway motors. Power is at 50 cycles, low voltages being 230-400.

Local accommodation had to be constructed, for Pakistanis as well as Canadians. Married quarters were built for Canadians who brought their families, and for the senior Pakistani staff; bachelor quarters and a single men's mess were also built, and Pakistanis were quartered in multiple unit barracks. As timber is in short supply in the country, all buildings are of masonry, bricklaying being a well known trade. Mud bricks or kacha bricks are in wide use and are reasonably satisfactory, but require some maintenance in wet weather. Burnt bricks are also available though much more expensive and were mostly used for the permanent houses. Temporary accommodation was a difficult problem, very little being available, and resulted in the build-up of the Canadian staff being considerably delayed during the first 6 to 8 months. It was obviously undesirable to spend dollars on imported prefabricated houses.

Following considerable study, it was decided to supply air-conditioning for the offices, hospital, and quarters occupied by Canadians. The houses and bachelor quarters had one air-conditioning unit for each occupied bedroom.

Hospital and medical facilities are generally lacking in the East, and it was necessary to establish them based on Canadian standards. A 50 bed hospital was built, and staffed by two

Canadian doctors and nurses, as well as a number of Pakistani doctors, nurses and orderlies. It was fully equipped, and its main purpose was to treat job accidents and sickness amongst the employees and their families. Actually, many patients from other than the Warsak job have been treated, which was greatly appreciated. The training given to the Pakistani staff will be of inestimable benefit.

Preliminary Planning

A good deal of trouble was experienced in making up the construction schedule, with little knowledge of conditions to be encountered. The Canadian Government authorities were anxious to make a quick start once the decision to proceed had been taken; likewise the Pakistani authorities seemed to want to get ahead rapidly, though understandably without full knowledge of what was involved. A preliminary visit to the site revealed sufficient power was not available from the local net-work; construction of accommodation was proceeding slowly; the supply of skilled or semi-skilled men was very limited; and very few foremen could be found. Although it had been hoped the work could be carried out with only about forty Canadians, it was soon realized that more than double that number would be required.

All of these factors made planning difficult, and cost estimating particularly so. Another factor about which little was known was the output of labour, and here some rather vague assumptions had to be made. Knowledge of labour costs or the number of men required to do a certain job on similar work in Canada was of little value. Although the contractor was not expected to make a very close estimate of Pakistani costs, which as previously mentioned covered all labour costs except supervision, it was important to estimate the output and operating efficiency of construction equipment, all of which is closely linked with labour efficiency.

The important requirement of training as many Pakistanis as possible also affected labour cost considerably. It meant that there would always be a rather high percentage of only partially productive apprentices, a condition which persisted throughout the entire job. This had considerable bearing on equipment output, as it resulted in excessive mechanical breakdowns due to continual operation by inexperienced men. The rate of progress eventually attained in the diversion tunnel is an example of the results of the training program. During the last month of this work, the heading advanced 18 ft. per day, in rock that required continual arch support. This was a very creditable performance, and a result of the kind of assistance referred to by H.R.H. The Prince Philip in his address to scientists and engineers in Toronto on June 29, 1959. (*The Engineering Journal*, August 1959, p. 91).

Special Problems Encountered

The general contractor had not previously worked abroad and in fact the writer does not know of any Canadian owned contracting company having undertaken major work outside the Americas. Very few of the men sent to Warsak had ever been to the East, and most of them had not been off the North American continent. The government requirement that all employees from Canada should be Canadians was adhered to, and care was taken when approving men to choose only those who might be expected to make a favourable impression. In addition, in the case of married men, whenever possible, their wives were also interviewed to ascertain whether they were really willing to go, and if they could be expected to fit in well to their new environment.

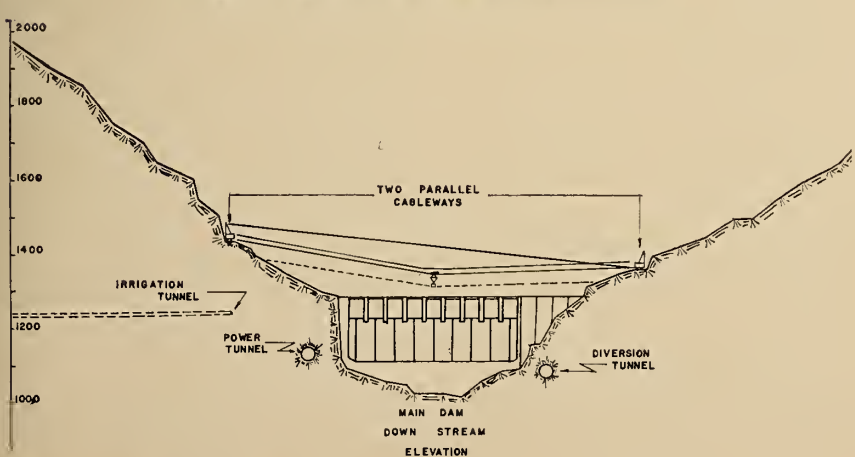
Every effort was made to explain the living and working conditions to be expected. By the nature of his work, a General Contractor has a small proportion of permanent employees available, and it was obviously necessary to recruit a number of men not in the employ of the Company, though many of them had previously worked for the Company at one time or another. The statistics in Table 2 give an indication of the results achieved by the careful

TABLE No. I

Quantities Handled

Common Excavation and Fill	*cubic yards*
Permanent structures	645,000
Diversion tunnel inlet and outlet	37,500
Cofferdams	204,000
Aggregate stripping	755,200
Aggregate processing	1,530,400
Roads	120,000
Construction plant installation	93,500
Silt removal	220,700
Miscellaneous grading	110,000
	3,716,300
Rock Excavation—Open Cut	
Permanent structures	1,199,200
Diversion tunnel inlet and outlet	170,000
Cofferdams	11,100
Roads	271,300
Construction plant installation	109,700
	1,761,300
Rock Excavation in Tunnels	*cubic yards*
Diversion tunnel	86,200
Power tunnel	47,700
Penstock tunnels	25,600
Irrigation tunnel	91,800
	251,300
Concrete	
Tunnel linings	131,000
Main dam	396,920
Stilling basin and wave wall	126,340
Power house	103,050
Power tunnel intake and silt retaining wall	39,590
Roads, bridges and colony buildings	6,700
Cofferdam revetment	18,050
Plant installation and temporary construction	22,230
	843,880
Dry masonry work, misc.	53,600

Fig. 2. Cross Section at upstream face of Dam



checking mentioned above.

It is of interest to note that of the total number of uncompleted contracts, approximately half were during the first year of operations when living conditions left much to be desired, and the contractor was gaining experience in the type of men who could be expected to fit in and work well on a foreign job and in the climatic and other conditions prevailing at Warsak.

An early decision was made to establish living conditions for Canadians reasonably similar to those to which they were accustomed at home; and to take married men and their families, when experience and suitability indicated. The results showed that this decision was justified.

A school was established with Canadian teachers to take pupils up to and including eighth grade, on the general standard of Ontario Public Schools. Special arrangements had to be made by the parents for children above eighth grade.

Full attention was paid to recreation facilities. A building was constructed for movies, dances, etc., and a swimming pool, tennis courts, bowling alleys and billiard tables followed. The Pakistani staff were encouraged to partake in all of these activities, and the benefits were many.

All employees were engaged under contract for a period of 2 yr., plus or minus three months at the discretion of the employer. Basic salary plus foreign allowance was approximately 1/3 higher than an equivalent salary in Eastern Canada, and a further sum of 15% of basic salary was set aside as an incentive bonus, payable only after successful completion of the employment contract. Three weeks annual leave was granted, and termination leave of 1 day for every 15 days of completed contract was allowed for home leave. Transportation both ways was paid for the employee and his family on the basis of first class air fare. It was felt that the above terms were sufficient to attract good men, though at times certain classifications were difficult to find, particularly during the year 1957.

Considerable space has been taken up in explaining employment conditions for the Canadians who worked at Warsak. These were the key men on a project taking over four years to complete, at a total cost of about $36,000,000 Canadian, in addition to about $25,000,000 in Pakistan rupees. Most of the senior men remained the entire period, with two vacation periods between contracts. The writer feels that an examination of the conditions encountered warrants some further space.

The years 1955-56-57 were years of relatively full employment in the construction industry in Canada, and the Canadians who went to Warsak all left good jobs, friends, homes, and associations to travel almost half way round the world to live and work amongst people of a different race, language, and culture, with whom, superficially, they had little in common.

Furthermore, they were subjected to a climate which for 5 months of the year is excessively hot

TABLE No. 2

Statistical Analysis of Canadian Employment Records

	Married	*Single*	*Total*
Maximum number of employees present	—	—	147
Total employees involved	151	59	210
Still remaining January 31, 1960	—	—	96
Total contracts signed (including renewals)	—	—	309
Contracts uncompleted (all causes)	—	—	49
Contracts broken during first year	—	—	23
% Contracts uncompleted (all causes)	—	—	15.9
% Contracts uncompleted after first year	—	—	12.9
Contracts broken on account of ill health	—	—	7
Contracts broken on account of ill health in family	—	—	5
Employees discharged	2	8	10
Includes for insobriety	2	5	7

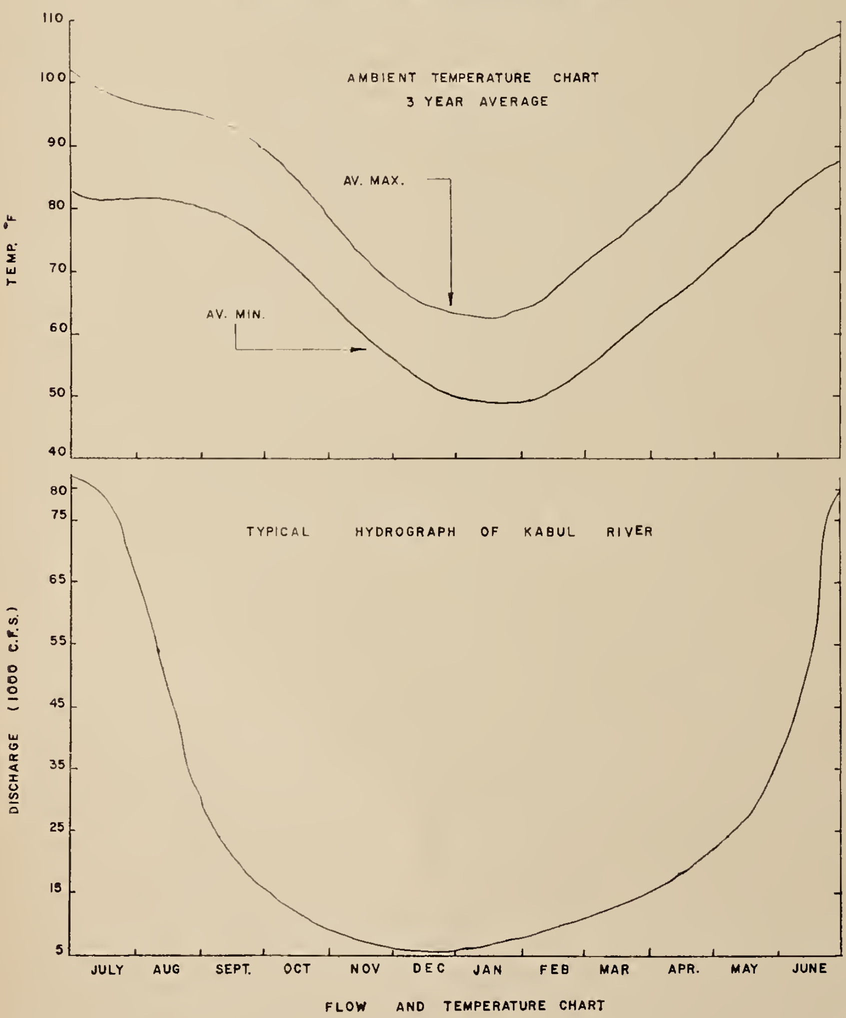
Employees quit	19	8	27
% Employees quit	12.6	13.5	12.9

Fig. 3. River flow and temperature chart



compared to Canada. The tribesmen from whom the great bulk of the labour force was drawn are Pathans, people who have never really known law and order as we know them. They live in what we would describe as almost abject poverty, and their very livelihood depends on the small amount of moisture which falls to yield a crop sufficient for themselves and their few animals. A slight reduction in precipitation results in a poor crop and means near starvation for many.

Patient explanation by the Pakistanis in authority gradually convinced the tribesmen in the vicinity that the completion of Warsak would bring permanent benefit to them, and an opportunity for gainful employment as well as the acquisition of a trade in the meantime. But this took time, and many frustrations were encountered particularly during the first six months or so when the Canadians sometimes wondered if they would ever be able to build up an efficient working force. As will be seen later, such a force was achieved. The method of labour recruitment was working through the Malik, who is the political chief of a village. He it is who receives and dispenses the government grant, and who administers justice of a kind. The labourer pays a small proportion of his wages, either directly or through the company to the Malik. There was seldom any lack of numbers, but especially at first it was difficult to know how many of any particular gang might turn up on the morrow. Gradually the men seemed to achieve a certain sense of responsibility towards their work, they became aware of the opportunities for advancement, and the percentage of absentees declined to less than 8%.

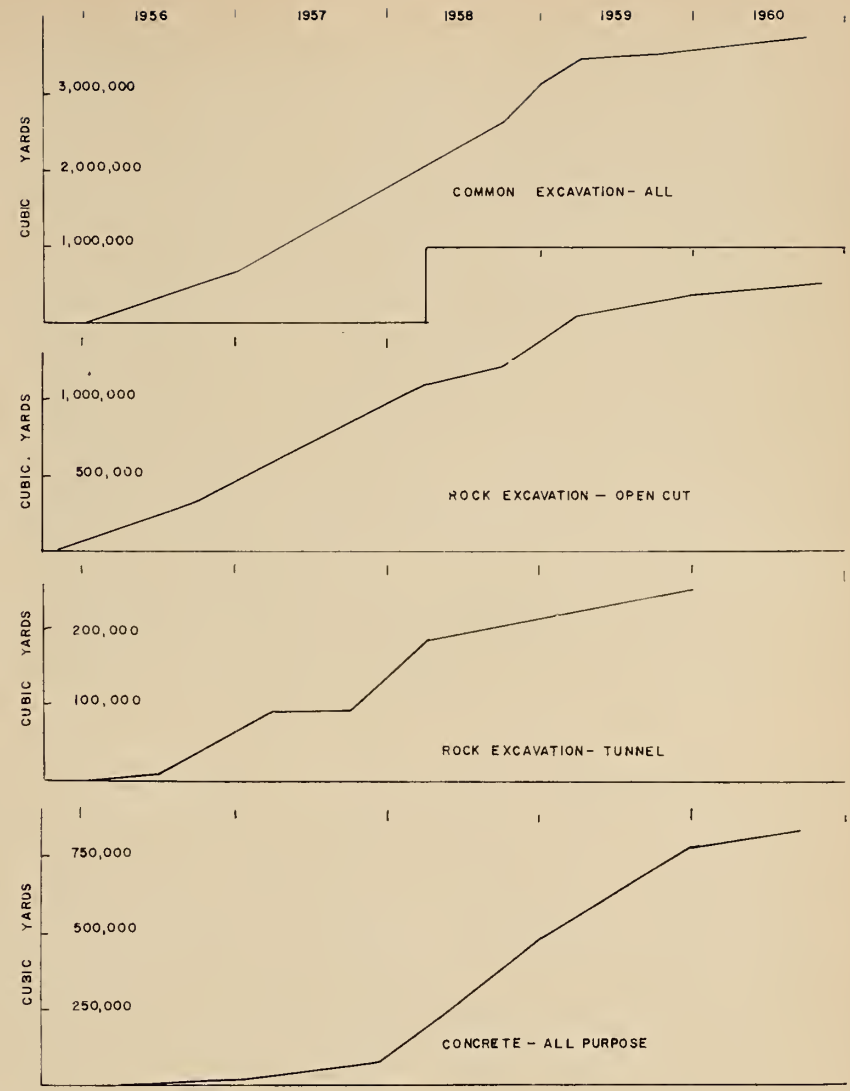


Fig. 4. Progress Schedule

The language barrier continued to be a difficult problem, though many Canadians soon picked up a rough working knowledge of Pashto, the local language. Although the official language of Pakistan is English, which is taught mostly at high school level or beyond, the common language is Urdu, to which Pashto is somewhat similar.

The great majority of Pakistanis are Muslims, one of whose customs is strict adherence to the rules of Ramazan. During this period, which lasts for a month, neither food nor water may be taken between sunrise and sunset, and as a result labour output deteriorated considerably.

Wages paid to Pakistani workmen were based on an 8 hr. day, and varied from about a rupee and a half per day for straight labour to between 6 and 8 rupees for the higher paid daily workers with a few being paid as much as 12 rupees. Transferred directly to dollars, this would mean between 30c and $2.40 per day. Although this looks ridiculously low compared to our standards, it must be remembered that the needs of the Pakistani tribesman are extremely modest, and the cost of the food they eat and the clothes they wear is very low. Anything beyond food and clothing is not a necessity, and few of them have more than bare necessities.

The common diet amongst the tribesmen consists largely of a very coarse bread, and vegetables and fruit when obtainable. They eat little meat, which is relatively expensive. The result is that though they are wiry, strong, and accustomed to a hard life, they have not the physical stamina to do a hard day's work. To improve this situation, the Pakistani authorities instituted a system whereby all workers received a substantial meal on the job, for which they paid 4 annas or about 5 cents. This, combined with their ability to purchase a little better food, gradually improved their physical condition, bringing about an improvement in their output. A bonus system was established in the tunnel work, which greatly improved production.

As mentioned above, most of the workmen were tribesmen, drawn from the immediate vicinity. These men took a certain proprietary interest in the project, to such an extent that it was not easy to bring men from other parts of the country. As no work of this kind had been performed in the vicinity, the skills needed were not available, and most of the crew were trained on the job. Engineers and office workers were brought in without any trouble, provided they could be found and were willing to remain.

It is interesting to note that the traditional method of working a hand shovel is to have either two or three men operate it. One man digs it in, and the other one or two throw the contents by means of pieces of rope attached just above the blade. This, of course, increases the output of shovels, which are in short supply, but certainly does not increase man-hour output.

The job worked six days per week, and most of the equipment was operated three shifts.

Equipment Planning

Certain requirements had to be considered when planning construction equipment.

a) Standardization should be carried as far as practically possible;

b) Purchases should be kept within Canada first, consistent with economy, and within the Commonwealth secondly, again consistent with economy, inasmuch as Warsak is a Colombo Plan Project;

c) As all equipment is to be later turned over to the Government of Pakistan, every effort had to be made to confine purchase to items that would be of best use in the future;

d) Pakistani railroad clearances are somewhat limited.

The great need for standardization can be readily understood. Apart from the reduction of inventory of spare parts, training of repair and maintenance crews is simpler when equipment is from a limited number of manufacturers.

TABLE No. 3
Summary of Equipment and Material Shipped by General Contractor
(Does not include permanent equipment)

	Tons
Major items of construction equipment	2,800
Tunnel arch support (steel)	2,484
Miscellaneous iron and steel	1,578
Reinforcing steel	2,769
Bailey bridge material	1,070
Steel rail	308
Steel sheet piling	464
Steel forms, including tunnel forms	985
Drill steel	177
Lumber and plywood	11,600
Explosives	809
Commissary	653
Personal effects	225
All other items	4,600
TOTAL	30,522

(Total is to January 31, 1960, and balance will be small)

The greater the percentage of Canadian Colombo Plan funds expended in Canada, the less is the drain on the Canadian economy, hence the special requirement to buy in Canada first.

The terms of the inter-governmental agreement provided that all construction equipment be turned over to the Government of Pakistan at the completion of the project. The advantages of such an arrangement to Pakistan are obvious in that the equipment is already on site and assembled, and a number of Pakistanis have been trained in its operation, maintenance, and repair. With this in mind every endeavour was made to restrict equipment to that which would be of future use on any similar project.

It will be seen later that it was not possible to avoid sending a few special items such as cableways, but in general extra large shovels trucks, etc. were not chosen. It is worthy of note that an extension to the original terms of the contract provided for the overhauling of all equipment to put it in good running order before its transfer.

The railroad from Karachi to Jamrud Fort passes over a number of bridges and through tunnels which imposed certain limitations but these were not sufficiently restrictive to cause much trouble.

Repair facilities established at Warsak were considerably more extensive than would be required on a similar job in Canada. (See Appendix). Breakages were heavy, particularly in the early stages of the work, and although a heavy inventory of repair parts was maintained, improvisation was necessary on many occasions. It was not possible to always have available the necessary parts to repair unexpected breakages, nevertheless the equipment was kept operating one way or another. Temporary cannibalization had to be carried out occasionally to avoid too many units of the same type being out of service at the same time. As noted above, it took 3 to 4 months from requisition of parts to delivery at site.

Fig. 5. Excavation for Diversion Tunnel outlet portal

The project is readily divided into 3 main items:

1) Tunnelling through rock;
2) Earth and rock excavation;
3) Concrete placing.

Basic planning for 1) and 2) called for 2 cu. yd. shovels and 15 ton and 22 ton trucks plus standard mine equipment for the smaller diameter tunnel. Later study of the large quantities to be handled in the coffer-dammed area, where operations could only be carried out after unwatering and during the period of low flow, and the probability that operating efficiency would not be above 2/3 of that which would be expected in Canada, indicated the necessity of securing two 4 cu. yd. shovel-draglines in addition to the smaller units.

Placement of concrete in the main dam required considerable study. Conventional methods such as the use of derricks or the construction of a temporary trestle were ruled out by the requirement of placing concrete on the higher levels while the coffer-dams were overtopped, and by the steep banks of the gorge. (See Fig. 2.) The writer suggests that the site almost demanded cableways, and experience has proven that such was the case. Two 11 ton cableways were ordered, to operate on a span of 1,043 ft., with travelling head and tail towers, The sides of the gorge were benched and track laid to cover the entire area of the dam and most of the stilling basin.

A central mixing plant, containing three 2 cu. yd. mixers, supplied most of the concrete required, with an auxiliary plant containing one 2 cu. yd. mixer for additional capacity when needed. Four 6½ cu. yd. transit mixers were used to transport concrete to the power house and other locations not covered by the cableways.

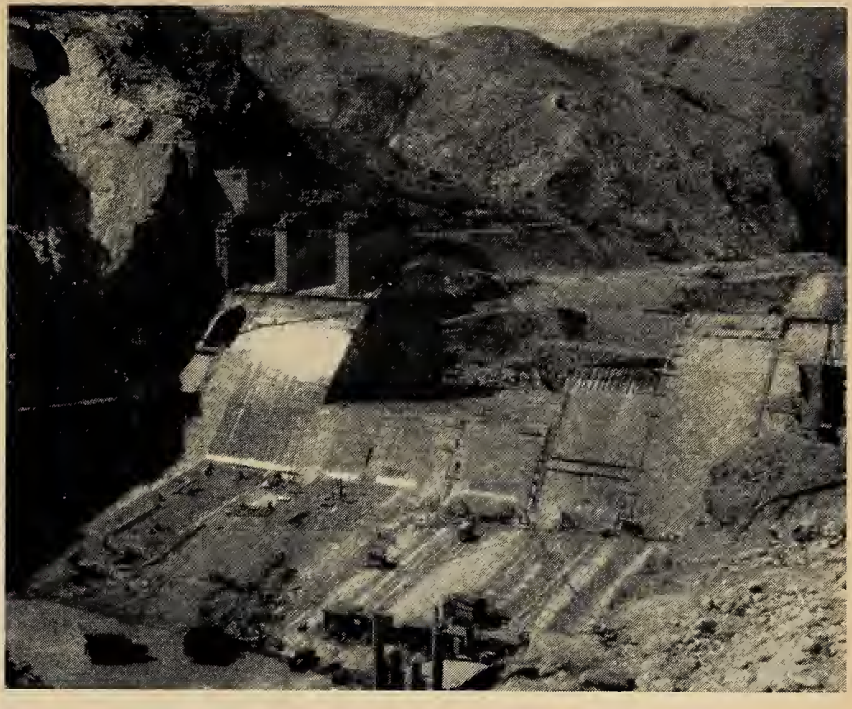

Fig. 6. Main Dam partially completed

Schedule

Preliminary planning called for completion of the project in 1959, which meant that the diversion tunnel, 1700 ft. long with a finished diameter of 35 ft., had to be driven and lined with concrete by September 1956, or about 9 months after the preliminary set-up. Various factors caused revision of this schedule, the chief among them being that insufficient power would be available for the heavy compressor load until midsummer 1956. A more orderly schedule was then set up which allowed time to instal proper repair facilities, organize transportation, build access roads, and establish proper relations with the local Pakistan authorities who were anxious to take as large a part in the work as possible and upon whom depended the supply of men and local materials—their cooperation was essential for the success of the project.

Fig. 4 shows the actual schedule attained, and it will be readily seen that the rate of concrete placement in the dam during the Winter of '58-'59 could only have been achieved on a thoroughly organized job, and is a measure of the success resulting from careful planning, and patient negotiation between the various authorities who found common ground in working for a common aim, resulting in mutual respect and friendship.

The schedule was obviously effected by the capacity of the diversion tunnel, which only permitted working in the river bed when the flow was less than 30,000 c.f.s., or about seven months of the year (Ings[1]). As the Kabul River during flood period carries a great amount of silt, it was imperative that the deep excavation in the centre of the river be filled with concrete to an elevation which would avoid having to excavate large quantities a second time. The concentration of work in the river bottom during the September to April period was therefore very heavy.

Another governing factor in the schedule was the limiting safe velocity in the diversion tunnel, as the concrete lining would have been endangered if the gap in the dam was insufficient to pass the 1959 flood without raising the water above Elevation 1170. This meant that a gap of 150 ft. in the rollway section and three piers had to be left incomplete until the Autumn of 1959.

The remainder of the work, that is the power house, the power and penstock tunnels, and the irrigation tunnel, though of considerable magnitude, was fitted in to the work in the river as required by the overall schedule.

Construction Features

Throughout this paper, an effort is made to describe features which are not ordinarily encountered on work of this nature in Canada, and only such portions of the actual construction work will be covered that are considered unusual.

Access—Reference to Fig. 1. and 2. will show the very limited working area in the immediate vicinity of the principal operations, and the difficulties of access Nearly all the temporary construction buildings had to be located 2½ miles from the site of the work. Access roads to the various working points required far-sighted planning and considerable heavy work to carry them out. As an example, the invert of the diversion tunnel was at Elevation 1092, the excavation for the dam went as low as 1022.5, the central mixing plant was located on a moderately flat area at Elevation 1265, the top of the bulkhead was at Elevation 1290, and the North

Cableway bench was at Elevation 1362. (See Fig. 1 and 2.) These various points were all within a radius of 500 ft., and access to each point had to be worked out. A bridge capable of carrying heavy equipment had to be built across the river immediately below the site, as the nearest crossing was 3½ miles downstream, and was only capable of carrying 24 tons. This bridge, 370 ft. long, consisted of piers of steel sheet pile filled with concrete, and Bailey bridge spans of 120 ft., triple double, good for 70 tons.

The side of the gorge at the location of the dam on the South side was so steep that it was not feasible to maintain access to the upstream area without leaving a hole or tunnel when concreting the South end of the dam. This tunnel was left open as long as possible before being filled with concrete and pressure grouted, after which it was necessary to use the upstream cofferdam for access until the bridge across the dam was completed.

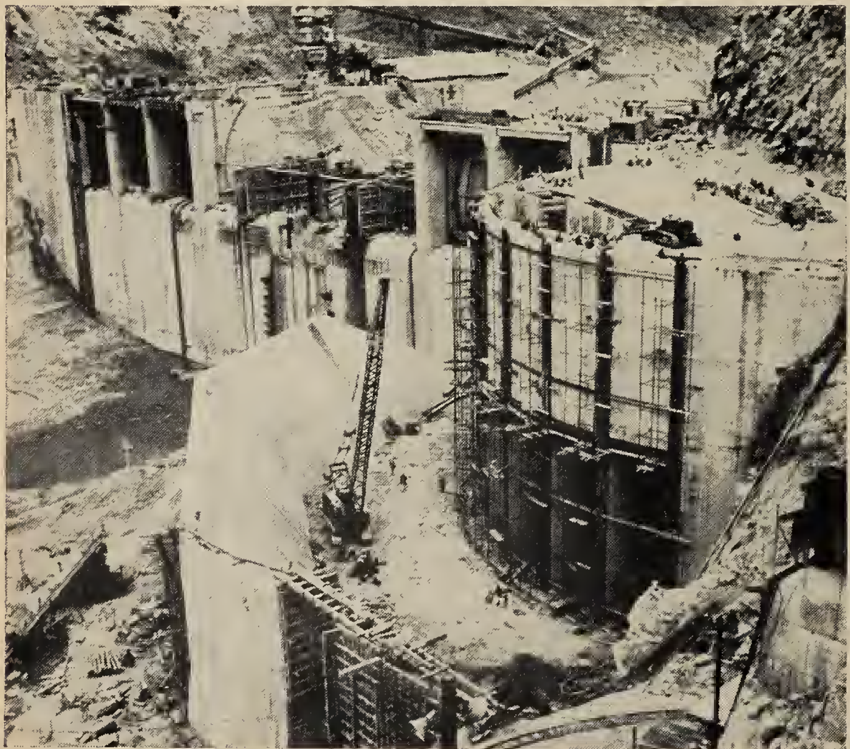
Diversion Tunnel — Driving of the diversion tunnel was carried out from the outlet end by conventional heading and bench method. A movable drilling jumbo on D7 Caterpillar tracks with 20 hydraulic booms was built in Canada for the heading face, excavation was by a 2 cu. yd. shovel with special short boom and dipper stick, disposal was by 15 ton trucks. The entire tunnel had to have steel arch supports and lagging. Concreting of the arch was by pumpcrete into a movable tunnel form 50 ft. in length.

Cofferdams — The upstream and the downstream cofferdam each consisted of two pervious fills with impervious material between them. Thus, there were four fills stretching across the river to close off the flow, which at closure created a total head of approximately 6 ft. Previously, rock from power house excavation had been selected and stock-piled nearby, creating a ready reserve of rock large enough to withstand the velocity of the water. Closure was thus achieved without difficulty. Impervious material had to be trucked some distance from the nearby plain, some of which was likewise stock-piled ahead of time.

In order to ensure that the hydraulic gradient through the upstream cofferdam should be sufficiently steep 16 in. diam. tube-wells were previously driven into the silt immediately below the toe of the slope, and a double row of steel sheet piling was driven through the impervious core of the downstream cofferdam into the underlying overburden. In this way leakage was kept to modest proportions. Actually, the tube-wells were not required.

Reference to the schedule, Fig. 4, shows that the cofferdams had to stand overtopping during the flood of 1958 and 1959. Model testing by the consulting engineer (Ings[1]) indicated the paving of the crest and downstream slope of each cofferdam to prevent erosion. This was done with hand placed rip-rap and cast-in-place concrete of low cement content. The result was entirely successful.

Fig. 7. Power Tunnel Intake, and main dam in background



Excavation — The river bed at the damsite consisted of silt, sand, gravel and boulders deposited by the successive floods of the past centuries. The maximum depth encountered was 90 ft. Reference to Fig. 3 indicates the difficulty of excavating this large volume in the short time available was the chief reason for ordering the two 4 cu. yd. shovel-draglines.

As soon as the area had been unwatered, the large machines went to work as draglines, and the smaller ones proceeded to ramp down to open up the cut for face shovels. The deep excavation under Piers 6 and 7 had to be done by loading into skip boxes handled by cranes at a higher level. The balance of the excavation for the dam and stilling basin did not present any special problems.

Power house excavation into the side of the gorge was preceded by a considerable amount of scaling by hand. The Pakistanis are good at this type of operation but it required many months of work and a debris trench was dug well above the top of the excavation to retain pieces of rock that might roll down later. Further stabilization was necessary in the form of concrete revetment following a rock slide which took place in the first year of operation. The highest point where excavation took place was at Elevation 1,450, and excavation for the floor of the draft tubes was at Elevation 1,080. Here again access roads were a big problem.

Coyote blasting was used with considerable success in the early stages in order to get some of the rock from the higher levels down to where it could be handled by shovels. Of the total amount of power house rock excavation of 523,000 cu. yd. approximately 300,000 cu. yd. were handled by coyote methods.

Power Tunnel & Penstock Excavation — Access to this work had to be through the penstocks, and power house excavation was benched in such a way that access was maintained to penstock invert for shovel and trucks until completed.

First entry was made through penstock No. 1, and all penstocks were excavated full face. The diversion tunnel drilling jumbo was divided in two, each being suitable for a penstock, and mucking performed by Eimco 105 and International TD14 with overhead loader. The power tunnel was then excavated by heading and bench method, using the two modified jumbos side by side to drill the heading, approximately 28 ft. high; excavation was by a Dominion 500 with short boom. The bench was also face drilled by means of modified jumbo.

There was a 42° inclined section near the inlet, part of which was taken out from the inlet end. A pilot tunnel was then driven in the form of a raise from the bottom to meet the upper level, and successive rounds drilled and blasted from the upper level, sending the rock down to where it could be shovel loaded.

The soundest rock (Ings[1]) on the project was encountered on this work, and only at the penstock portals were supporting ribs required. The sound rock continued in the power tunnel until the inclined section was reached, where ribs were necessary. The intersection of the penstocks with the power tunnel incorporated transition sections which produced spans of 60 ft., but sound rock obviated the requirement of arch support.

Irrigation Tunnel — The irrigation tunnel 17,000 ft. long and excavated to an approximate diameter of 12 ft. (actually a modified horseshoe section) was carried out by means of standard mining equipment. A 24 in. gauge railroad was used and mucking was performed by Eimco 21 overhead loaders loading 2 cu. yd. mine cars hauled by battery operated locomotives.

Drilling jumbos travelling on the track were constructed, each with 5 hydraulic booms. Work was carried forward from both the inlet and outlet ends, meeting approximately at the mid-point. Ventilation was achieved by four 5 h.p. fans at each end, supplying air through steel pipe which started at 18 in. diam. and reduced to 15¾ in. diam. Considerable shattered rock was encountered and it was found necessary to support the arch with steel ribs for one third of the distance.

As mentioned previously, the Pakistanis were anxious to take as large a part as possible in the development and early in 1957, it was agreed that the Warsak Dam Project Organization, which is the government agency set up to take part in the project, should do the excavation of this tunnel as a subcontractor with the general contractor assisting where necessary and carrying out general supervision. This worked out well and the two headings met December 28th, 1959.

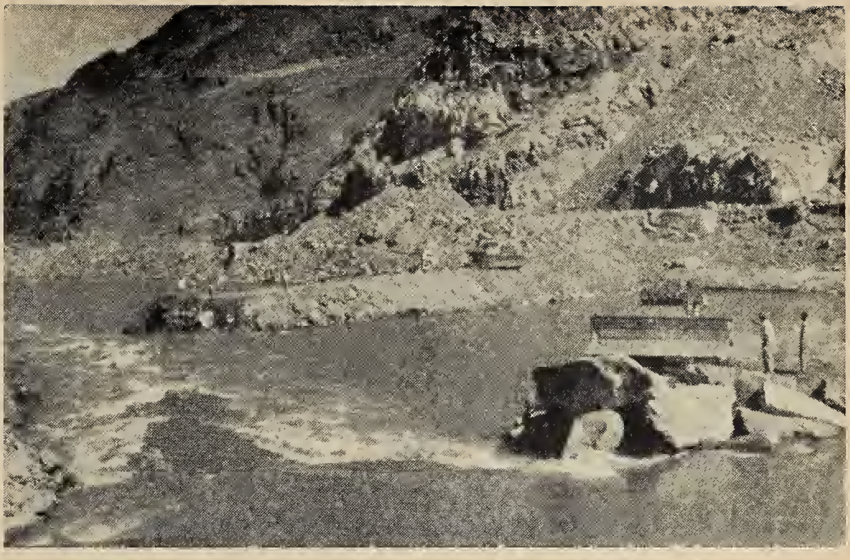


Fig. 8. Placing Selected rock at upstream cofferdam

Concrete for the minimum 15 in. thick lining is being placed by pumpcrete in a 50 ft. tunnel form in each heading, and is expected to be completed in the spring of 1961.

Concrete Placement — The governing factor in the concreting schedule was the necessity of placing sufficient concrete in the dam during the low water period of 1958-59 to achieve a height which would permit concreting to continue on either side of the gap left to pass the flood of 1959. At the same time, the floor of the stilling basin had to be completed in order to avoid having to remove the large volume of silt which would have been deposited in any unfilled excavation.

The above indicated a concrete placement capacity of about 48,000 cu. yd./month in the dam and stilling basin, or roughly the equivalent of the capacity of the main mixing plant, (see Appendix) hence inquiries for cableways were based on this capacity.

A number of manufacturers were contacted, and purchase made of two identical 11-ton Travelift Cableways from British Ropeway Engineering Co. The two units operated on the same tracks, 380 ft. long, laid on benches excavated in the sides of the gorge.

General specifications were:

- 1,043 ft. span
- 22,400 lb. lifting capacity
- 1,200 ft./min. traversing speed
- 200 ft./min. hoisting speed
- 400 ft./min. lowering speed

Concrete was handled in compressed air operated 4 cu. yd. bottom dump buckets, which were loaded at the main mixing plant and brought under the cableway hooks on flat cars travelling on a 36 in. gauge transfer track, hauled by 3½ ton locomotives. Maximum production of the main mixing plant was 49,239 cu. yd. in January 1959, and the maximum placed in the dam and stilling basin using the main and auxiliary mixing plants was 67,224 cu. yd. in the same month. Maximum overall concrete placement rate was 80,172 cu. yd. achieved in February 1959, the mixing plants being supplemented by the transit mixers.

The power house concrete was mostly handled by cranes, and as soon as the substructure had progressed far enough trestle bents were constructed to support Bailey bridge spans capable of carrying the 2 cu. yd. shovels rigged as cranes. Scheduling of this work was not particularly difficult.

Conclusion

The virtual completion of the Warsak project in the Spring of 1960 has brought a considerable measure of satisfaction to all those participating. A little over 4 years ago it was not much more than an ideal, and a number of people with a keen interest in the ideal entertained serious doubt that completion would be realized in so relatively short a time. The organization set up by the inter-governmental agreement called for a degree of understanding and co-operation between the Pakistani and Canadian authorities which, though obviously desirable, appeared to many of us at the outset to be almost impossible of

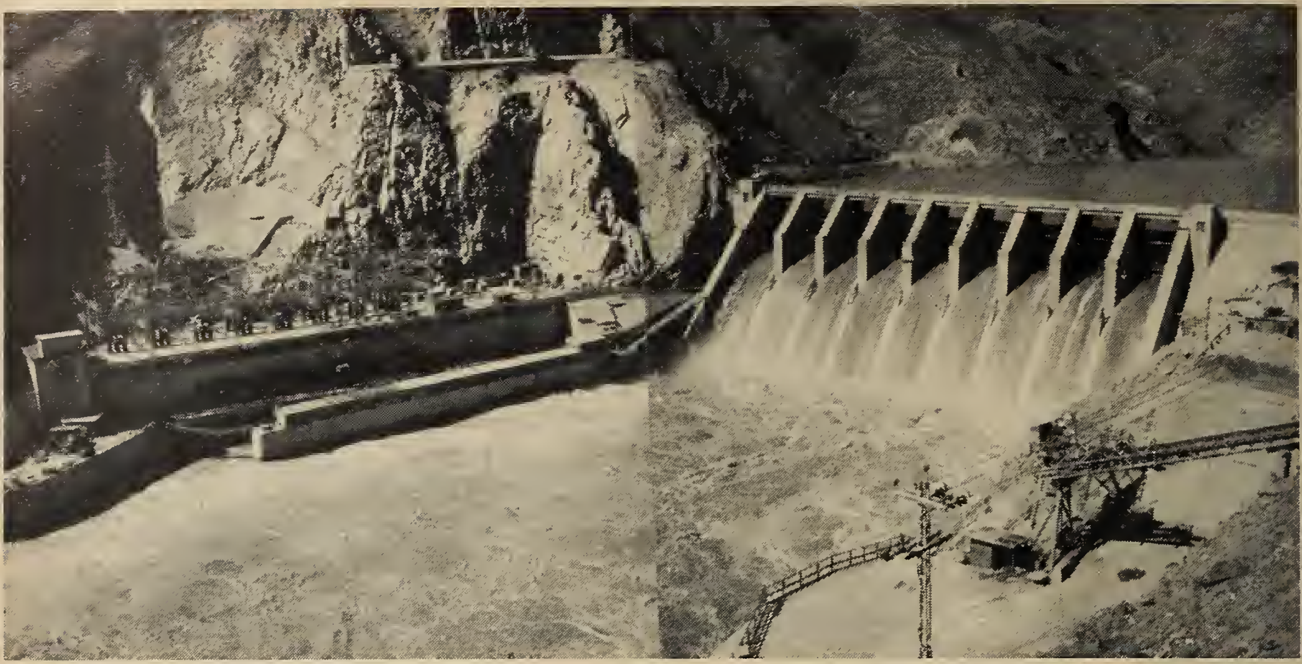

Fig. 9. Main dam and Power House, looking upstream from North bank

attainment. That it was attained in full measure reflects great credit on the people at the site who were determined that Warsak would be remembered as a proof that men of goodwill can work together towards a common ideal even though they started off with little knowledge and understanding of each other.

It would be impractical to attempt to mention all those whose efforts were responsible for the success of the project, and the ensuing list covers only the principals.

In Pakistan: E. L. Miller, Project Manager, H. G. Acres & Co. Ltd.; C. J. Robbins, Manager of Construction, Augus Robertson Limited, to whom I am indebted for assistance in assembling data for this paper; Mohammed Azam Khan, Chief Engineer of Warsak Dam Project Organization; A. R. Qureshi, successor to Azam Khan, following the former's promotion to other duties in 1959; Shah Nawaz, Superintending Engineer, Warsak Dam Project Organization; The Canadian High Commissioner in Karachi and his staff who rendered continuing and valuable assistance.

In Canada: Nik Cavell, Director, Colombo Plan Administration; Orville E. Ault, successor to Nik Cavell, following the former's appointment as High Commissioner to Ceylon; Sheldon Ross, Project Engineer, Foreign Projects Division, Defence Construction (1951) Limited; C. J. K. Smith, Projects Officer, Canadian Commercial Corporation; J. H. Ings, Vice-President, H. G. Acres & Company Limited. (Mr. Ings is writing a companion paper, covering the Engineering aspects of exploration and design of the project.)

Appendix

List of Construction Equipment, Major Items Only.

1 380—¾ cu. yd. combination shovel
6 500—2 cu. yd. combination shovels
2 1601—4 cu. yd. shovel-draglines
8 TD24 tractors
8 TD14 tractors
8 Wheel tractors
2 105 tractor loaders
1 Grader, Model 550
12 15 ton dump trucks
15 22 ton dump trucks
17 Auto-car 14 ton dump trucks
43 Pick-up trucks, ½ to 3½ ton
1 7 ton fuel oil tank truck
20 Cars and station-wagons
1 75 ton low bed trailer and autocar hauling unit
1 50 ton float
1 TM20—20 ton truck crane
1 TM25—25 ton truck crane
1 Central Mixing Plant, comprising 3—2 cu. yd. mixers, complete with hoppers, etc.
1 Auxiliary mixing plant complete, with 1—2 cu. yd. mixer
5 6½ cu. yd. transit mixers
2 200 single pumpcrete
1 200 double pumpcrete
Bulk cement unloading and handling equipment
3 Bulk cement hauling units
2 11 ton Cableways, designed for 1043 ft. span.
Aggregate processing equipment including 10 in. x 24 in. Jaw Crusher, 24 in. x 16 in. Roll Crusher, Vibrating Screens, Washer Classifier-Dehydrator, Feeders and Conveyors.
5 Compressors, 1,000 c.f.m. electrically driven
4 Compressors, 375 c.f.m. electrically driven, and diesel engine auxiliary drives.
5 Compressors, 210 to 315 c.f.m. diesel driven
42 DA35 Drifters, with power feed
20 FM2 Wagon Drills
48 J40 Jackhammers

Machine Shop, repair and maintenance facilities.

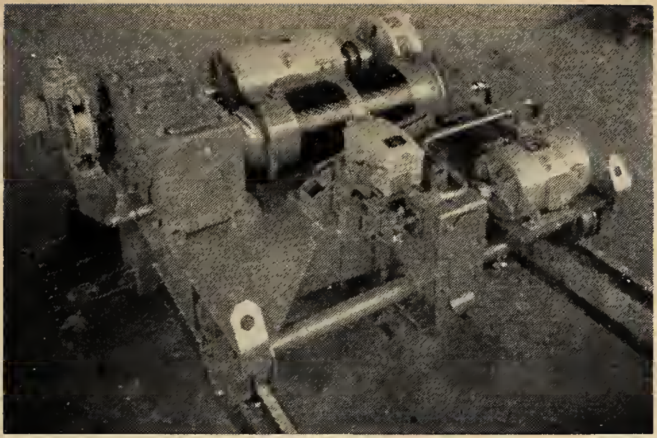
1 Lathe, 8½ x 17 in. swing 8 ft. bed, 4 ft. -6 in. centres
1 Lathe, 7½ x 15 in. swing, 4 ft. centres
1 Screw cutting gap lathe, 28 in. x 48 in. x 20 ft.
1 High speed shaping machine, 20 in.
2 Heavy duty drilling machines
1 Universal milling machine, table 52 x 12 in.
1 Universal iron worker, capacity ⅞ x ⅞ in.
4 Bolt and pipe threading machine, ¼ to 2 in. pipe size
1 100 ton shop press
1 200 ton shop press
1 Pneumatic power hammer, 2,550 ft. lb. blow energy
1 Precision line boring machine, capacity up to 4¾ in. bearings
1 10 ton travelling gantry crane
1 Hydraulic Universal cylindrical grinding machine, 13 in. swing over table, 41 in. between centres.
1 Automatic bar bender, for use up to 1½ in. diam. steel.
Diesel injection special repair and overhaul equipment
9 Welding machines diesel driven
15 Welding machines electric driven

Irrigation Tunnel Equipment

5 4 ton electric locomotives
40 2 cu. yd. side dump cars
12 4 ton flat cars
2 Dynamite cars
2 21 Rocker shovels
Ventilating fans, pipe, etc.

Miscellaneous Equipment

1 25 ton stiffleg derrick, 70 ft. boom
Carpenter shop equipment, complete with necessary wood-working tools.
87 Pumps, various, up to 10 in.
1 9 B3 pile hammer
1 No. 80 pile extractor



DESIGN OF INDUSTRIAL GEARS

R. D. Mutch, M.E.I.C.,

Product Engineer — Cranes, Mechanical Division, Dominion Bridge Co. Ltd., Montreal.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

An investigation into the methods of crane design has been carried out and the results are embodied in this paper with the thought that crane users and possibly others, may find the subject of interest. The reasons for this investigation were manifold. It has been felt for some time that existing general gear design methods are difficult to adapt to crane requirements. For example, the American Gear Manufacturers' Association (A.G.M.A.) specifications, "Strength of Spur Gear Teeth" and "Strength of Helical and Herringbone teeth" apply only to precision cut gearing. The corresponding specifications for "Durability" do not state what surface finish is used as the basis for calculation. Moreover, the use of A.G.M.A. strength formulae imposes an uneconomical amount of work on a design office as these formulae require a layout of tooth profiles to be made for each set of gears to be designed. The Lewis formula, used for many years by crane designers, gives no indication of durability and requires experience to apply it successfully. British Standard Specification 436 is more complete and has wider application to crane gears than A.G.M.A. but has less acceptance in North America and suffers from the defect that its helical gear system is based on constant pitch diameter rather than on the standard normal pitch system used by Dominion Bridge. The B.B.S. addendum modification system is also different to D.B. standard.

NONE of the mentioned design methods relates the face width of gears to the pitch, this being left to the experience of the designer. This has long been felt by the writer to be a serious weakness in existing practice and was one of the main factors prompting the investigation.

In addition to the inadequacies of existing design methods, the increasing use of heat-treated alloys and the ever-expanding range of materials available, made it imperative to establish a logical basis of design that would take into account and make the best use of the enhanced physical properties of these materials.

The investigation, therefore, was planned to establish a method of design which would enable, firstly, the face width of a pinion and gear transmitting a given tooth load at a given speed, to be determined with respect to the materials used, tooth modification and tooth deflection. This calculation requires the setting up of allowable surface stresses and tooth surface form factors, as the face width is a measure of durability. Secondly, the face width calculated from the foregoing is used in a strength formula which gives the minimum pitch necessary to carry the tooth load with adequate regard to the materials used, their fatigue strength, yield point and the properties of the tooth section.

Having established the face width and pitch as above, we have arrived at the optimum relation between these quantities and nothing is gained by varying this relation, with the single possible exception that for helical gears overlap may require a wider face than that calculated on durability and deflection.

Scope

The gears used on overhead travelling cranes fall within fairly narrow limits as regards size, pitch and nature of loading. Speeds are relatively slow and therefore there is no necessity to employ precision cut gearing. Electric motors used as prime movers do not usually run at speeds in excess of 1800 r.p.m. and braking systems are designed to limit lowering speeds to values approximating full load hoisting speeds or less.

All crane gears are subjected to intermittent loading which may vary from a maximum to a value depending on the part of the crane under consideration. For example, the hoisting gear loads can vary from maximum to almost zero, but these gears are subject to heavy shock loads without reversal of direction of loading. The bridge travelling gears, on the other hand, have a much more con stant load pattern with less shock, bu are subject to direction reversals especially where reverse plugging control is used. However, as these factors taken together in each case result in approximately similar dynamic effects it was decided that the gears for all motions of electric overhead travelling cranes would be designed to the same stresses in order to simplify the calculations and obviate the possibility of errors in application.

To conform to the modern concept of classification of cranes by duty, it was also necessary to assess the durability and strength of the gears when used in varying classifications and a series of duty factors for these aspects has been evolved. These correspond to the "daily hours running time" in B.S.S. 436.

Finally, it was felt necessary to conduct a running test to check the validity of the design method and this was carried out.

General: Involute Gears, in order to operate successfully, must satisfy the following conditions:

(a) The teeth acting as small cantilevers must have sufficient strength to resist the applied load (tooth load) in such a manner that the bending stress and deflection is within predetermined limits. This condition fixes the product of tooth size and face. Thus strength requirements can be satisfied with a coarse tooth system and a narrow face or a fine tooth system and a wide face, or any other set of combinations.

However, deflection requirements are not satisfied by a fixed product of tooth size and face width as deflection is independent of pitch. This may be illustrated as follows:

For any cantilever:

$$\delta \sim \frac{wl^3}{I} \sim \frac{wl^3}{bd^3}$$

In a gear tooth:

- l represents tooth depth
- d " " width
- b " " face
- w " " load

It is obvious that l/d is constant for all pitches and thus l^3/d^3 is constant.

Therefore, $\delta \sim w/b$ which is tooth load per unit face. This demonstrates that it is possible to design a gear of Face/D.P. ratio that satisfies strength requirements but not deflection requirements.

(b) The teeth must be capable of withstanding the applied load without exceeding a predetermined surface stress. Excessive surface stress will manifest itself as:

(i) Pitting—caused by surface fatigue which forms a surface crack. Under the action of hydrostatic pressure of the lubricant in the crack, sections of the surface flake away leaving a small pit.

(ii) Scoring—caused by excessive local heat resulting in the tendency of the two mating surfaces to weld together and tear, or score.

(iii) Wear—the result of mild abrasive action. Wear is accelerated if surface stress is high enough to break down the oil film leaving metal to metal contact.

(iv) Ridging—plastic flow of the surface material takes place causing the metal to be pushed up into a ridge across the face of the teeth.

For a given tooth load and material the surface stress is basically proportioned to:

(a) Face width;

(b) Relative radius of curvature of the mating teeth.

It is independent of tooth size.

Since relative radius of curvature is proportional to the respective base circles and the pressure angle, it is proportional to the pinion P.C.D. and the gear ratio, if the pressure angle remains constant.

Addendum modification if employed, will also influence the relative radius of curvature.

Thus it can be said that surface stress is proportional to:

(i) Face width
(ii) Pinion diameter
(iii) Ratio
(iv) Tooth modification
(v) Material

Surface Stress Formula

$$F = \frac{W \cdot Cw}{XcScQ}$$

where F — Face
W — Tooth Load (lb.)
Q — Surface Form Factor
Xc — Speed Factor
Sc — Surface Stress Factor
Cw — Classification Factor

Table I. Equivalent Tooth Load Fd for Static Tooth Load Ft = 1000 lb. k = 1,600 (Precision Gears)

Pitch Line Velocity in Feet per Min.

4 inch	1004	0.995	1043	0.960	1406	0.715	2670	0.375	3720	0.269	4450	0.225
10 inch	1006	0.994	1065	0.940	1627	0.616	3730	0.268	5580	0.179	7200	0.139

The method of deriving the various factors will be briefly described:

Surface Form Factor: The action of two gear teeth in contact is similar to two cylinders rolling together. However, in addition to the rolling, some relative sliding takes place, the amount of sliding increasing as the point of contact moves away from the pitch point (the point of contact at the P.C.D.).

Hertz has suggested an expression giving the maximum surface stress between two cylinders in contact:

$$S = 0.418\sqrt{\frac{Fu \cdot E}{Rr}}$$

where S = max. surface stress
Fu = load per inch of line contact
E = Youngs modulus
Rr = Relative radius of curvature.

Merritt has suggested that an alternative criterion of stress conditions is provided by the expression:

"Surface Stress"

$$= \frac{\text{load/inch of line contact}}{\text{Relative radius of curvature}}$$

$$\text{or} \quad Sc = \frac{Fu}{Rr} \qquad (2)$$

It must be recognized that Sc is not an actual stress but is a mathematical term indicating stress conditions. Substituting for Fu/Rr in equation (1) and assuming $E = 30 \times 10^6$

$$S = 0.418\sqrt{Sc \times 30 \times 10^6} \qquad (3)$$
$$= 2290\sqrt{Sc}$$

As a convenience for calculation an equation may be introduced equating tangential tooth load to Sc for unit D.P. and unit face. Therefore:

$$W = Sx \times \text{Constant} \qquad (4)$$

where W = tangential tooth load
Sc = a predetermined allowable figure.

The constant is sometimes referred to as a "zone factor"—(Z)

$$Z = \frac{W}{Sc} = \frac{Fu \cos\alpha}{Sc} = \frac{Fu \cos\alpha}{Fu/Rr}$$
$$= Rr \cos\alpha$$

where α = pressure angle.

Therefore, $Z = Rr \cos\alpha$ (5)

(See Fig. 1).

Relative Radius of Curvature

$$Rr = \frac{R_1R_2}{R_1 + R_2} \qquad (6)$$

$$R = \frac{d}{2}\sin\alpha + K \operatorname{cosec}\alpha\frac{P_0}{2} \qquad (7)$$

$$R = \frac{D}{2}\sin\alpha - K \operatorname{cosec}\alpha\frac{P_0}{2} \qquad (8)$$

$$P_0 = p\cos\alpha$$

For 1 D.P.

$P_0 = \pi\cos\alpha$
D = T (Number of teeth in gear)
d = t (Number of teeth in pinion)
K = addendum modification (in.)

Substituting in equations (6) and (7)

$$R = \frac{t}{2}\sin\alpha + K \operatorname{cosec}\alpha - \frac{\pi}{2}\cos\alpha \qquad (9)$$

$$R = \frac{T}{2}\sin\alpha - K \operatorname{cosec}\alpha + \frac{\pi}{2}\cos\alpha \qquad (10)$$

An examination of equations (5), (6), (9) and (10) will reveal the fact that Z is dependent only upon teeth in pinion and gear ratio, if D.P. and pressure angle remain constant. A series of Z curves can be produced by plotting number of teeth in pinion against gear ratio. It will be found that for any given pinion diameter and gear ratio, Z is fairly constant regardless of D.P. of teeth. For uncorrected teeth Z would be independent of D.P. and depend upon pinion teeth and ratio only. However, if for any given pinion diameter and ratio the value of Z is calculated for all D.P.'s likely to be used, an average value of Z/P can be determined which will have sufficient accuracy for all practical purposes.

In the surface stress formula

$$Q = (Z/P)$$

is a measure of the ability of the pinion to carry a given tooth load at a given surface stress. Tangential load $W = Sc.Q$ for 1 in. face and for any number of size of teeth under static conditions.

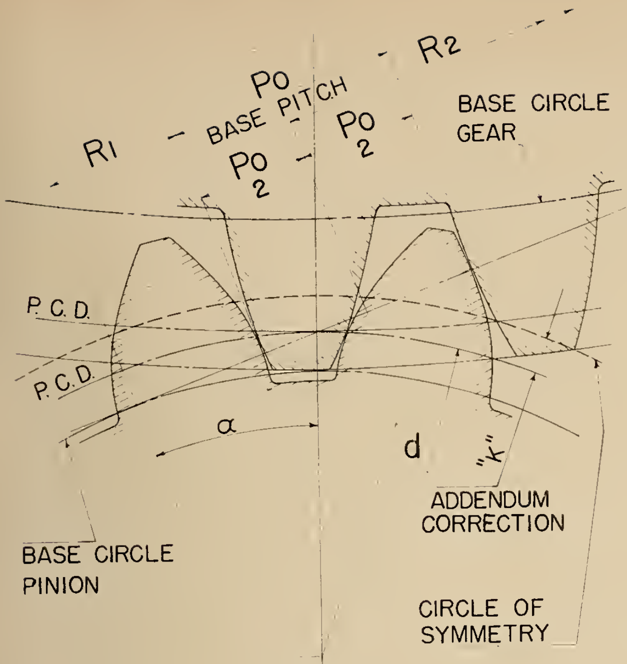

Fig. 1.

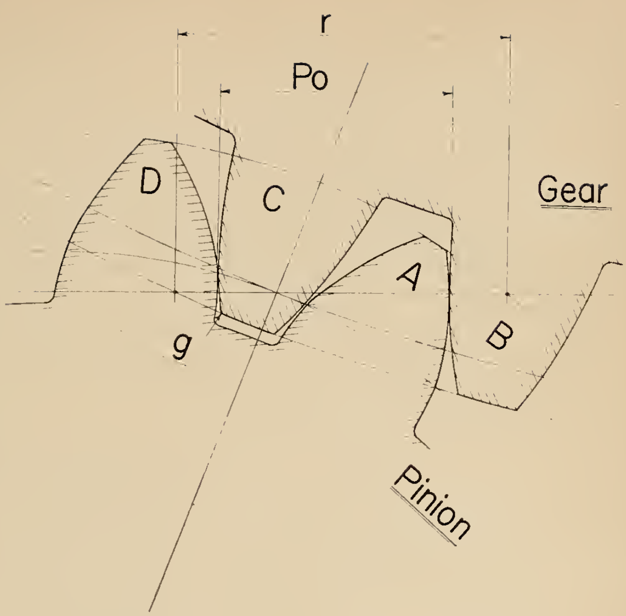

Fig. 2.

Xc-Speed Factor: Various authorities have proposed expressions relating dynamic stresses to the pitch line velocity of the gears. However, most of these seem to be based on the work of Earle Buckingham who has suggested that the maximum instantaneous load on a tooth (dynamic load) is:

$$Fd = Ft + Fi = Ft + \frac{0.05V(kf + Ft)}{0.05V + (kf + Ft)}$$

where

- Fd = total equivalent load applied at the pitch line
- Ft = tangential load required for power transmission
- Fi = the increment load
- k = a factor depending on machining errors
- f = face width
- v = pitch line velocity

the above equation indicates that the dynamic load is proportional to:

1. Pitch line velocity
2. Tooth errors
3. Face width.

To illustrate the effect of these three factors the value of Fd has been computed for various pitch line velocities and face widths. Two values of "k" have been chosen; one to represent Precision Gears having tooth errors of 0.001 in. for 1 D.P. and the other to represent Industrial Gears having tooth errors of 0.003 in. for 1 D.P.

From an examination of Table 1 and Table 2, the effect of tooth error is apparent. The effect of speed can also be readily appreciated. However, the effect of face width merits further attention. From Table 2, it will be observed that a nominal tooth load of 1000 lb. at a pitch line velocity of 1000 f.p.m. is increased to 3350 lb. on a 1 in. face and 10,250 lb. on a 10 in. face. Thus the dynamic effect for a 10 in. face is over 3 times that for a 1 in. face. It is difficult to understand the extreme effect of face width if tooth errors are considered constant. However, it must be noted that face width is indicative of gear inertia and for a given tooth error and speed the dynamic effect would be roughly proportional to the inertia of the gear. Tooth error given is an average value, so the maximum error could conceivably be proportional to face width.

Although the effect of face width on dynamic stresses may appear rather excessive, the indications are that it is an effect that cannot be ignored. The expression

$$Xc = 1 - \frac{\sqrt{V}}{50}$$

although empirical gives results comparable with the Buckingham values in the lower speed range, but not in the higher speed range where Buckingham values indicate more severe dynamic effects, especially in the wider faces. It is felt that this departure is justified because:

1. The effect of dynamic forces usually shows up as a fatigue failure—either surface fatigue or flexural fatigue. In the case of the softer materials tooth wear should reduce errors with a resultant reduction in dynamic effect long before the cycles necessary to cause a fatigue failure are reached. In the case of very hard gears they are either ground precision gears with small tooth errors or when commercially cut are designed with a proportionately lower stress, e.g., Carburized gears, if taken to the limit would be given an allowable stress factor (Sc) of 8000 whereas the recommended value would probably not exceed 5000.

2. The dynamic stresses on gears having tip relief must have an upper limit, as severe stresses with accompanying deflection would cause an increase in the contact ratio. In other words, extreme stresses on one pair of teeth will cause such a deflection that the next tooth will come into action earlier than otherwise. This is particularly true of high speed gears of high tensile material. (Note: Item 2 is an opinion only as no calculations have been made to prove the point.) Table 3 is a comparison of speed factors prepared by various authorities.

However, a 4 in. ϕ is assumed so that pitch line velocity is approximately equal to r.p.m. These B.S.S. values have been taken from the "combined speed and running time" graph using the "12 hour per day" curve at which running time is 1.0 and has no effect. It should be noted here that the B.S.S. factors appear illogical, as the basis of relating speed factors to r.p.m. gives a different value for pinion and gear, surely incorrect when it is considered that one tooth constitutes the action while the other, the reaction. The differences are in direct proportion to the ratio of the pair.

It would appear from an examination of Table 3 that the Lewis speed factors correspond more closely to the recommendations of Buckingham. However, such a comparison cannot be made as some authorities require an additional face factor and others do not. Table 3 shows values for a 1 in. face. Compare this with Table 4 for a 10 in. face.

The suggested factors are more liberal than those of Buckingham for the reasons given. A comparison of Tables 3 and 4 indicates the undesirability of employing large face gears on crane and similar mechanisms.

Surface Stress Factor—Sc: The surface stress factor is related to the actual surface stress by the expression

$$S = 0.418\sqrt{Sc \cdot E}$$

For steel mating with steel this reduces to

$$S_{max.} = 2290\sqrt{Sc}$$

If S be given the value of the surface endurance limit, Sc can be calculated, e.g., assuming a B.H.N. = 200, the surface endurance limit is approximately 70,000 lb. per in.
Therefore,

$$Sc = \left(\frac{70{,}000}{2290}\right)^2 = 940$$

This is a low value which does not take account of :

1. The work hardening of the softer mating surface by the harder ;

2. The easing of the surface stress concentration by the supporting film of lubricant.

Work Hardening—In the proceedings of the Conference on Lubrication and Wear, 1957, there are records of increases of 50 points of B.H. values due to work hardening. On this assumption, the endnrance limit would increase from 70,000lb. per in. to 90,000lb. per in. and Sc would increase from 940 to 1540, a rise of 64 per cent.

Table III. Speed Factors for Industrial Gears — 1-inch Face

Authority	*Formula*	*Pitch Line Velocity—F.P.M.* 1	10	100	500	1000	1500
Buckingham	See Page 3	0.995	0.964	0.735	0.407	0.300	0.254
Lewis	$600/(600 + V)$	0.999	0.985	0.858	0.545	0.375	0.285
A.G.M.A.	$1 - (\sqrt{V/84})$	0.988	0.962	0.881	0.733	0.624	0.535
B.S.S. 436	See Graph *	1.00	0.625	0.410	0.310	0.260	0.240
Merritt	$(1/V)^{0.2}$	1.00	0.630	0.400	0.288	0.250	0.231
Writer	$1 - (\sqrt{V}/50)$	1.00	0.937	0.800	0.552	0.368	0.225

*Speed factors according to B.S.S. are based on R.P.M., not pitch line velocity.

Lubricant Support — Fundamentally the Hertz formula

$$S_{max\cdot} = 0.418\sqrt{\frac{Fu \cdot E}{Rr}},$$

is the measure of load intensity over a small area of Contact A
where $A = F \times \delta$
F = face width
δ = width of area of contact
if, however, the mating surfaces are separated by a film of oil as is the case with mating gears, it is reasonable to suppose that the width δ will increase with a resultant decrease in specific stress.

The Sc values given in B.S.S. 436 are considerably higher than those calculated on the basis of the surface endurance limit of the material, e.g., a steel of B.H.N. 200 is given an allowable Sc value of 2350 as against 940 calculated by the Hertz formula. However, when the effects of Work Hardening and Lubricant support are considered these would seem to be reasonable figures, especially as they are put forward as a result of experience. They will therefore be adopted.

Classification Factor

Since there is apparently no established limit of endurance for surface stress conditions, it would appear that the life of a pair of gears based on surface stress conditions would be proportional to the total number of tooth contacts. Thus a gear running at, say, 500 r.p.m. would have twice the endurance of a gear running at 1000 r.p.m., other things being equal.

However, experience indicates that this rule is not valid; in fact, quite often the very opposite applies, i.e., a faster running gear will sometimes show less surface deterioration than a slow running gear, other things being equal. Darle W. Dudley in his book *Practical Gear Design* reports as follows—"In one recent test by the author a set of precision spur gears was operated for 20 million cycles at a pitch line speed of 6000 f.p.m. Involute measurements showed wear to be less than 0.0001 in. Then the set was run at 1000 f.p.m. with the same torque. After 5 million cycles at this speed, the set was stopped. Wear was measured at 0.0005 in."

B.S.S. 436 apparently takes into account this phenomenon. The following data has been extracted from the graph "Combined Speed and Running Time Factors for Spur and Helical Gears—Wear"—Page 59.

Fig. 3.

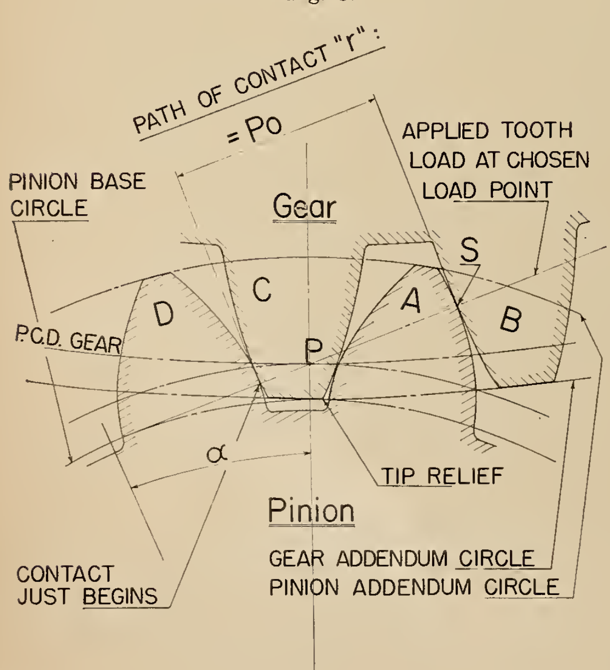

Fig. 4.

	1	*Gear Speed — r.p.m.* 1200	8000
Hours per day	0.5	0.1	0.05
Total cycles*	65,000	15,600,000	52,000,000
Sc given	3.0	1.25	0.875
Speed factor	1.0	0.25	0.14
Actual *Sc*	3.0	5.0	6.25

*The basic life span is 26,000 hours for a gear in continuous use for 12 hours per day. For less hours per day, the life span remains the same but the total number of effective working hours is reduced in proportion, e.g., a gear running for one hour per day would have the life span of the 12 hour per day gear but the effective working hours would be (26,000/12) = 2168 h.

An examination of the above table reveals the fact that a gear making 52 million contacts is permitted an *Sc* value more than twice that of a gear making only 65,000 contacts; apparently due to the higher speed enabling a better lubricant film to be developed.

It must be concluded from these facts that it is extremely difficult if not impossible to predict the life of a gear on the basis of surface fatigue or wear if an adequate lubricant film is maintained and abrasive matter is excluded. The life, although indefinite, will be of considerable duration. High speed turbine gears have been known to run for a year or more and show so little wear that the original machining marks although a few microinches deep were still visible on the tooth surface. During this period many millions of contacts would have taken place. The same absence of wear is sometimes to be noticed on automotive gearing.

Apparently surface deterioration is experienced when the lubricating film breaks down either partially or completely either by excess surface pressure or heat or both. Rough surfaces may also be a cause.

In the absence of more reliable data, it would seem reasonable to base life on the number of starts to which a gear is subjected. During starting, tooth lubrication is poor and metal to metal contact is to be expected, at least, partially. When full speed has been attained, the high speed gears have the benefit of better lubrication, but the low speed gears have the benefit of a smaller number of contacts. It will be assumed that the total effective hours of service will be indicative of the total number of starts so gear life will be based upon the total effective hours of service irrespective of speed. The effect of speed on tooth loading will be allowed for by the application of the speed factor.

A reasonable gear life would seem to be 20 years for wear as deterioration can be observed and replacements made, if necessary. On the basis of 300 working days per year, at 4 hr. per day at maximum load, the total time of maximum load would be 24,000 hr. It is not expected that any general service crane would exceed these hours for any one motion.

Taking the example of a hoisting motion: assuming a hoisting speed of 10 f.p.m. and a lift of 10 ft.:

Time to hoist and lower = 2 min.

Load handled in effective 4 hr. period

$$= \frac{4 \times 60}{2} = 120$$

Over an 8 hr. period, this would constitute a load handled every four minutes.

On the basis of British Standard recommendations for effective full load period, an average bucket crane has an effective four hours per day working period for the closing mechanism.

On this basis, a maximum working period of four hours per day, or 24,000 hr. total working life will be adopted for a Class D crane. Class D will be the basic class and given a classification factor of 1.

A Class A crane will be assumed to have an effective working period of one half hour per day, or 3,000 hr. total life. On the assumption of 5 f.p.m. hoist speed and 20 ft. lift, over an 8 hr. period, a full load could be handled every 32 minutes. This should amply cover all Class A crane applications.

Similar examples could be given for the other crane motions.

Gears will be classified for surface durability as follows:

TABLE V.

Class	Hours Per Day	Total Life—Hours
A	1/2	3,000
B	1	6,000
C	2	12,000
D	4	24,000

The classification factor "*Cw*" is in reality an adjustment of the basic surface stress in order to take advantage of the shorter life required for crane gears of classes lower than D.

Assuming partial metal to metal contact the life of a pair of gears is a function of load and time of running. If the tooth load is excessive, pitting or rapid wear will result in a short time. If it can be established that a pair of gears subjected to a surface stress *Sc* will work successfully for a time *t*, then it can be proved that they will work for a longer time if the stress *Sc* is reduced, or vice versa. Final breakdown may be the result of wear or surface fatigue.

Thus, if t_0 is the life of a pair of gears loaded to a surface stress, S_0, then the life *t* at a surface stress *Sc* is given by the expression

$$t = t_0 \left(\frac{S_0}{Sc}\right)^x$$

where x is a power determined by experiment.

Many authorities give the value of x as 3.

$$S_c = \frac{S_0}{C} \quad \text{and} \quad t_0 = 4$$

where C is the classification factor.

Therefore,

$$\frac{t}{t_0} = \left(\frac{C \cdot S_0}{S_0}\right)^3 = C^3$$

Therefore,

$$C = \sqrt[3]{\frac{t}{t_0}} = \sqrt[3]{\frac{t}{4}}$$

(See Table 6.)

These factors apply to gears encased in a gear box where lubrication is adequate and the ingress of dirt is prevented. *External gears shall be classified one higher than normal to allow for the less favourable conditions.*

It is of interest to compare these classification factors with other authorities.

H. H. Broughton provides an expression for life factors with

$$KW = \sqrt[3]{\frac{27,000}{100 + T}}$$

total life being 26,000 hr.

(See Table 7.)

The B.S.S. 436 expression is

$$Ku = \sqrt[3]{\frac{u}{12}}$$

where u = required hours per day. This assumes a factor of 1.0 for 12 hours per day. On the basis of 4 hours per day for a factor of 1.0 the expression would be modified to

$$Ku = \sqrt[3]{\frac{u}{4}}$$

Table IV. Combined Speed and Face Factor for Industrial Gears — 10-inch Face

Authority	*Formula*	*Pitch Line Velocity — f.p.m.* 1	10	100	500	1000	1500
Buckingham	See Page 3	0.990	0.900	0.474	0.165	0.098	0.073
Lewis	$600/(600 + V)$	0.999	0.985	0.858	0.545	0.375	0.285
A.G.M.A.	$1 - (\sqrt{V/84})$*	0.750	0.730	0.625	0.521	0.337	0.288
B.S.S. 436	See Graph *	1.00	0.625	0.410	0.310	0.260	0.240
Merritt	$(1/V)^{0.2}$	1.00	0.630	0.400	0.288	0.250	0.231
Writer	$1 - (\sqrt{V/50})$	1.00	0.937	0.800	0.552	0.36	0.225

*Included in these values is a face factor based on A.G.M.A. face factor curves.

which would give factors identical to those in Table 6.

The tooth action of a pair of gears is not unlike the action of a roller bearing, the difference being that roller bearings are not subjected to sliding as well as rolling. However, a gear surface fatigue failure usually shows up at or near the pitch line where little sliding takes place. There is also a marked similarity in the type of surface fatigue failure between gear teeth and roller bearings. The S.K.F. Co. gives an equation for the determination of the life of a bearing

$$L = \left(\frac{C}{P}\right)^{3.33}$$

where L = life, C = basic dynamic capacity of the bearing, P = applied load.

It can be readily observed that the formula resembles that given by the writer :

$$t = t_0 \left(\frac{S_0}{S_c}\right)^3$$

t is equivalent to L
t_0 is unity
Sc and S_0 correspond to P and C respectively.

The only difference between the expressions is that the S.K.F. equation provides for a greater number of working hours with a decreasing load and the writer's equation provides for a shorter number of working hours with an increased stress or applied tooth load.

It must be recognized that there is a limit to the lower value of the wear classification factor. As indicated, the classification factor is really an adjustment to the allowable stress to take advantage of the shorter working periods. However, just as an anti-friction bearing has a static capacity above which a bearing may not be loaded because of danger of failure by yielding, so a gear tooth has a limit stress above which the metal of the tooth will yield or the lubricant will "flash" causing welding and scoring of the teeth. This limit is difficult to determine by any means other than destructive tests. The classification factors have been suggested on the assumption that this limit will not be reached, so it is recommended that a pair of Class A gears be designed in accordance with the formula given and tested to determine the validity of the values suggested for the various terms. Having made the determination it can be assumed with reasonable confidence that the other classes of gears will give satisfactory performance ; in all events an early failure will be most unlikely.

Table VI.

Class	*Hours per Day*	*Classification Factor CALCULATED*		*Classification Factor TO BE ADOPTED*
A	0.5	$\sqrt[3]{5/4}$	0.5	0.5
B	1	$\sqrt[3]{1/4}$	0.632	0.6
C	2	$\sqrt[3]{1/2}$	0.795	0.8
D	4	$\sqrt[3]{1/1}$	1.00	1.0

Table VII.

Class	*Hours per Day*	*Total Hours*	*Classification Factor "K" according to Broughton*	1/K
A	0.5	3,250	1,855	.540
B	1	6,500	1,530	.655
C	2	13,000	1.245	.800
D	4	26,000	1.000	1.000

Face Factor

The necessity for a face factor is evident when it is considered that although during assembly a pair of gears may be adjusted for perfect alignment, shaft and other deflections under load will cause alignment error. This error tends to allow only point contact between the teeth at one end of the face so it is necessary that the teeth deflect before full or partial face contact is achieved. Theoretical adjusting factors to allow for this effect can be alarmingly high. However, the calculations for such factors do not take into consideration :

1. Rapid wear at the running-in stage tends to offset the error.
2. Actual tooth yielding or tooth surface yielding may take place in the softer gears.
3. In the calculations of shaft deflection the load is taken at the centre of the gear face but in fact, the deflection of the shaft will cause the centre of pressure to move away from the centre of the face towards the bearing so the shaft deflection is considerably less than calculated.
4. Tooth deflection is a function of the load per unit face and the elasticity of the material, so although hard gears do not receive much relief from wear they have the benefit of the greater deflection which will tend to distribute the load across the tooth face.

Taking the example of a gear box having several pairs of gears, it can be demonstrated that the higher speed gears would require a greater face factor than the lower speed gears. Due to the more favourable speed factor and greater zone factor (zone factor is proportional to pinion size which is usually greater in the low speed trains) the load per inch of face is higher for the low speed reductions so that the deflection has a greater influence on assisting stress distribution across the gear face. Moreover, first motion pinions are often cut into a long slender shaft at one end where angular deflection is considerable. Torsional deflection has also often to be considered. Intermediate shafts have more favourable conditions for although the shaft is stiffened by the pinion and gear the maximum bending stress is calculated for the small section of shaft between gear and pinion. Considering these facts it would seem reasonable to grade the face factors commencing at the first reduction which should have the most unfavourable factor. A.G.M.A. have produced a series of face factors apparently taking these arguments into consideration.

Rather than employ a face factor which is at the best an estimation based on experience, it has been omitted and the speed factor curve given a bias to make some allowance for poor face contact due to shaft deflection.

Spur Gear Strength Formula:

$$\frac{P}{Y} = \frac{Xb \cdot Sb \cdot F}{W \cdot Cs}$$

where
P = Diametral Pitch
Y = Tooth Form Factor
Xb = Speed Factor
Sb = Allowable Bending Stress
F = Required face as determined by surface stress formula
Cs = Classification Factor.

Tooth Form Factor (sometimes referred to as "strength" factor) : The form factor Y is a measure of the strength of the tooth and may be likened to the section modulus "Z" of a shaft or beam. If for a gear of 1 in. face and given profile and chosen load point, the bending stress is computed for a tangential tooth load Wt, then

$$Sb = \frac{Wt}{Y}$$

where Sb = the bending stress
Wt = tangential tooth load
Y = tooth form factor.

For any face and D.P.

$$Sb = \frac{Wt \times P}{f \cdot Y}$$

where f = face width
P = D.P. of tooth

Therefore,

$$Y = \frac{Wt \times P}{f \cdot Sb} \quad \text{or} \quad Sb = \frac{Wt \times P}{f \times Y}$$

The numerical value of Y may be calculated for any gear provided certain basic factors are known :

(i) Tooth pressure angle
(ii) Number of teeth in the gear and pinion
(iii) The chosen load point.

The chosen load point is the highest position on the tooth profile at which the whole tangential load is taken by one tooth. Above this point more than one tooth is in contact, consequently the load is shared. It is at this position of the applied tooth load that the bending stress is greatest. The actual position of the chosen load point depends on the contact ratio which may be defined as the ratio of the length of the path of contact to the base pitch. (See Fig. 2).

Referring to Fig. 2 "r" is the maximum length of the path of contact for the two gears shown. The limits of "r" are the two addendum circles. P_0 is the base pitch and is the distance between two consecutive teeth at the tooth pressure angle. The constant ratio rc which for continuous tooth action should be unity or greater, is the ratio r/P_0. This is a theoretical condition which will give unsatisfactory tooth action if the true involute forms are retained. The teeth would operate satisfactorily under no load conditions but under load the tooth deflection would cause serious interference. If pinion tooth A and gear tooth B deflect under load, the gear tooth C would approach the pinion flank D too early causing gouging at the point. As a consequence, the theoretical involute form must be modified to allow for this deflection. If the gear rotations are reversed, the pinion tooth A would gouge the flank of gear tooth B. In the case of precision gears a controlled tooth modification is applied so that contact is maintained along the full active portion of the tooth profile, the amount of material being removed from the tooth being equal to the calculated deflection under the applied load. Thus full smooth contact is retained under full load. (Under light loads the conditions are not as favourable). Thus the length of tooth contact is retained as "r".

Controlled tooth modification is a costly procedure so in the case of industrial gears, what is known as "tip relief" is applied. This refers to a removal of metal from the tooth profile near the tip of the tooth. The amount removed is usually in excess of the anticipated deflection as pitch errors in machining have also to be allowed for. Consequently, it is impossible to anticipate the tooth action over the portion of the tooth that has been relieved. Therefore, for the purpose of computing "Y" it is assumed that tooth action ceases where tip relief begins. Teeth cut to British Standards are so modified that a contact ratio of unity exists, i.e., $r = P_0$. This of course applies to the condition of unloaded teeth. Under load a more favourable condition is achieved. Tip relief is usually built into the cutting tool so that when the teeth are cut, the teeth are automatically relieved. If, as is usual, the same cutting tool is used for the pinion and gear, an equal amount of tip relief is not achieved. In the case of a very small pinion and a large gear, it will be found that the pinion has almost no tip relief while the gear has almost the full amount worked into the cutting tool.

Pinions and gears for cranes are usually of such proportion that the gear receives the full amount of relief worked into the cutter and the pinion a much less amount. For the purposes of Y factor calculation, it can be assumed that full tip relief is applied to the gear. These conditions have been assumed and the chosen load point determined accordingly. (See Fig. 3.)

Fig. 3 illustrates the condition where gear tooth C is just about to become loaded. The load moving down the face of pinion A has just reached point S. Thus S is the chosen load point. Having made this determination the Y factor can now be computed. (See Fig. 4.)

Per inch of tooth face maximum bending stress

$$S_1 = \frac{Wn \cdot \cos\theta x}{y^2/6}$$

Maximum compressive stress

$$S_2 = \frac{Wn \sin\theta}{y}$$

Maximum tensile stress

$$= \frac{6Wn\cos\theta x}{y^2} - \frac{Wn \sin\theta}{y}$$

$$= Wn\left(6x\frac{\cos\theta - y}{y^2}\sin\theta\right)$$

but $Wn = Wt \sec\alpha$ when α = tooth pressure angle, therefore maximum tensile stress

$$Sb = \frac{Wt \sec\alpha}{y^2}(6x\cos\theta - y\sin\theta)$$

but $$Sb = \frac{Wt}{Y}$$

therefore

$$\frac{Wt}{Y} = \frac{Wt\sec\alpha}{y^2}(6x\cos\theta - y\sin\theta)$$

therefore $$Y = \frac{y^2\cos\alpha}{6x\cos\theta - y\sin\theta}$$

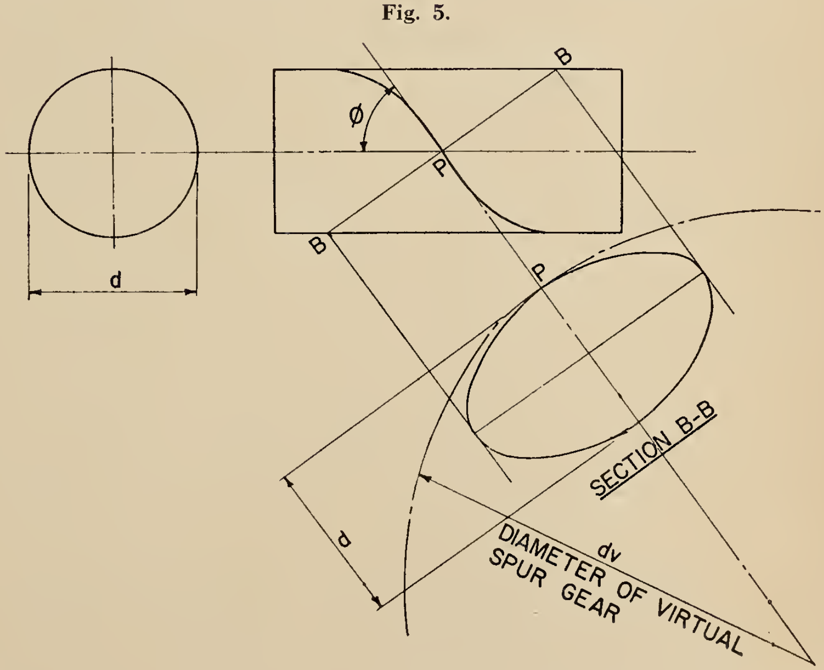
From an accurate layout of the tooth and this formula, Y can be calculated. It will be noted that the maximum tensile stress has been calculated rather than the greater maximum compressive stress, As gear teeth are designed on endurance considerations, it would not be reasonable to compute the compression stress as the more lightly stressed tension side would fail earlier by fatigue than would the heavily stressed compression side.

The Y factor for many combinations of teeth has been computed by the writer but the computations are long and tedious, as a tooth has to be accurately drawn for each combination of pinion and gear teeth. The values of Y that were computed were compared with values submitted by H. E. Merritt and since they corresponded fairly well, it has been decided to use Merritt's figures and graph the results.

For convenience a table of P/Y values for various diametral pitches and mating tooth numbers has been compiled.

Xb = SPEED FACTOR

Fig. 5.



Speed factors for strength will be identical with those for wear.

Sb = ALLOWABLE BENDING STRESS

The allowable bending stress will be based upon the endurance limit of the material but checked against the yield stress so that the factor of safety for yield will not be less than that for fatigue. Adopting as an allowable stress the least of 0.6 L.O.P. and 0.33 U.T.S., a factor of safety of 1.67 on both L.O.P. and fatigue is achieved, on the assumption of no stress concentration. (This is allowed for in the classification factor.) It will be noted, however, that the factor of safety of 1.67 is based upon the endurance limit value 0 – max. This applies to hoist gears for which the forces on the gear teeth do not reverse. When applied to travel gears the factor of safety is reduced to the approximate value (1.67/1.42) = 1.18 or 85% of the limit of endurance. The lower factor of safety is acceptable as it is unlikely that a tooth failure would result in any danger; moreover, the maximum tooth load on the gear is of short duration—during the period of acceleration only. During running, the tooth load is quite often no more than 30% of that corresponding to full load motor torque. Therefore Sb = 0.33 U.T.S. or 0.6 L.O.P. whichever is the least.

Required Face as Determined by Surface Stress Formula—F. This is the mini mum face that will carry the tooth load within the allowable surface stress for any given material.

Classification Factor — Cs

A tentative classification for crane structures has been drawn up with appropriate duty factors based on combinations of "working period", "effective load" and "impact".

However, when considering gear classification, it becomes evident that the factors cannot be applied as for structures. For example, the element "working period" for structures has two values, "short" and "long" according to whether the duty of the crane can be expected to impose stress cycles of less or more than 2×10^6 in the life of the crane. For each stress cycle imposed on the crane structure, many stress cycles will be imposed on the pinion and gear teeth and fatigue in those items is definitely the criterion of allowable stress. All gears, therefore, will be considered as subjected to long working period and the structural element of 1.34 assigned.

Similarly, the element "effective load" must always be taken as "high"—again on the basis of fatigue, as, although the number of occasions when full rated load is handled in unit time may be quite small with respect to the structure, it becomes a significant proportion when considering the gears. The value for this element will be taken as 1.0, as for structures.

Impact, the third element, corresponds to impact on the structural parts as it is of transient and practically instantaneous nature. Two values for impact are therefore used –1.10 for low impact and 1.40 for high impact. Table 8 shows the combinations of these values for each classification and the factors to be used.

Summary of Design Procedure — Spur Gears

1. Determine ratio and probable gear and pinion diameters.
2. Apply surface stress formula to determine face width.

$$F = \frac{W \cdot Cw}{Xc \cdot Sc \cdot Q}$$

F = face (in.)
W = tooth load (lbs.)
Q = surface form factor
Xc = Speed factor
Sc = Surface Stress factor
Cw = Classification factor
Class A — 0.5 Class C — 0.8
Class B — 0.6 Class D — 1.0

3. Apply the strength formula

$$\frac{P}{Y} = \frac{Xb \cdot Sb \cdot F}{W \cdot Cs}$$

Xb = Speed factor = Xc
Sb = Allowable bending stress
F = Face width obtained from surface stress formula
Cs = Classification factor
Class A — 1.5 Class C — 1.9
Class B — 1.9 Class D — 1.9
(P/Y) = strength factor

HELICAL GEARS

General: The method of design of Helical Gears is similar to that employed for spur gears because the normal section of a helical gear tooth is the same as that of a spur gear tooth. For design purposes it is convenient to assume a virtual spur gear having teeth of the same size and shape as the normal section of a helical gear. The load carrying characteristics of such a virtual spur gear bear a definite relationship to the actual helical gear. Therefore by applying the spur gear method of design to the virtual spur, the load carrying characteristics of the actual helical gear can be readily determined.

Virtual Spur Gear: Section *P–P* Fig. 5 (a section through the helical gear normal to the teeth) is an ellipse having a minor diameter d the same as the gear diameter and a major axis = $d \sec \phi$ when ϕ is the tooth helix angle. It can be proved that in the region of the pitch point P the curvature of the ellipse approximates to that of a circle of radius d_v and it may be shown that:

$$d_v = d \sec^2 \phi$$

$$t_v = t \sec^2 \phi$$

where
d = helical gear P.C.D.
t = number of teeth in helical gear
d_v = Virtual gear P.C.D.
t_v = number of teeth in Virtual gear

Helical Gear Form Factor: (See Fig. 6)
(a) Length of line of contact for one axial pitch

total length $= hb + gf = 1$
but $gf = bk$
therefore $1 = hk$
Triangles mhk and ahb are similar

therefore $\frac{mk}{hk} = \frac{ab}{hb}$

but $hb = pa \sec \phi$
$mk = p_{0t} \times r_{ct}$
$hk = 1$
$ab = p_{0t}$

therefore $1 = \frac{p_{0t} \cdot r_{ct} \cdot p_a \sec \phi}{p_{0t}}$

but $r_{ct} = r_{cn} \cos^2 \phi$

therefore $1 = r_{cn} p_a \cos \phi$

Length of line of contact per inch of face
$1_l = r_{cn} \cos \phi$

(*Note:* This is not the full developed length but the error is negligible.)

(b) Load on face of virtual spur gear. Tangential load per inch of face on helical gear W_t
Tangential load on virtual spur $= W_t \sec \phi$
Load on virtual spur at chosen load point $= W_t \sec \phi \cos \theta = W_n$—Fig. 4.

(c) Maximum intensity of load at chosen load point of virtual spur.

Table VIII. Strength Classification Factors

Class	Working Period	Effective Load	Impact	Classification Factor (calculated)	Actual Factor to be used
A	Long 1.34	High 1.0	Low 1.1	1.47	1.5
B	Long 1.34	High 1.0	High 1.4	1.88	1.9
C	Long 1.34	High 1.0	High 1.4	1.88	1.9
D	Long 1.34	High 1.0	High 1.4	1.88	1.9

Referring to Fig. 4.

$$\text{Average intensity of load} = \frac{Wn}{1} = Wc$$

therefore

$$Wc = \frac{Wt \sec\phi \cos\theta}{r_{cn} \cos\phi} = \frac{Wt \sec^2\phi}{r_{cn}} \cos\theta$$

For industrial gears with tip relief it is assumed that ratio of contact r_{cn} = unity. therefore

$Wc = Wt \sec^2\phi \cos\theta$ = maximum intensity, as a constant load over one base pitch is assumed.

Therefore tangential intensity of load on virtual spur $= Wt \sec^2\phi = Wt_v$.

(d) Form Factor

$$Sb_v = \frac{Wt_v}{Y_{vs}} = \frac{Wt \sec^2\phi}{Y_{vs}}$$

but

$$Sb \text{ helical} = \frac{Wt}{Y_{\text{helical}}}$$

Since

$$Sb_v = Sb \text{ helical}$$

$$\frac{Wt \sec^2\phi}{Y_{vs}} = \frac{Wt}{Y_{\text{helical}}}$$

therefore

$$Y \text{ helical} = \frac{WtY_{vs}}{Wt \sec^2\phi} = Y_{vs} \cos^2\phi$$

Note this expression is based upon and is similar to that developed by Merritt. However, Merritt assumes that the transverse D.P. is an integer whereas the above assumes that the normal D.P. is an integer in line with our standards.

Thus in order to determine the Y factor for a helical gear it is necessary to

(i) Determine the number of teeth in the virtual spur gear
$t_{vs} = t \sec^2\phi$

(ii) Find the Y factor for the virtual spur (Y_{vs})

(iii) Apply the formula
$Y = Y_{vs} \cos^2\phi$
to determine the helical gear form factor

where ϕ is the helix angle of the helical gear.

Helical Gear Surface Form Factor—Q as for spur gears $Q = (Z/p)$.

It can be proved that

$Z(\text{helical}) = Z_{vs} \cos^2\phi$

so Q can be calculated in a similar manner to Y (helical), viz:

(i) Determine the number of teeth in the virtual spur gear
$t_{vs} = t \sec^2\phi$

(ii) Find Z_{vs}

(iii) Apply the formula
$Z = Z \cos^2\phi$
to determine the helical gear zone factor

(iv) $Q = (z/p)$

where

z = Helical zone factor
p = Normal diametral pitch.

Helical Gear Speed Factor: The dynamic effects in helical gears, due to tooth error differ little from those for straight spur gears. However, built in to the straight spur speed factor $1 - (\sqrt{V}/50)$ is a face factor to allow for mal-alignment of gears. In the case of helical gears this would appear to be unnecessary.

While the tip relief has no shortening effect on the line of contact in the case of spur tooth, it results in considerable shortening in the case of a helical tooth, the effective length being "l"—Fig. 3b. Allowance is made for this effect in the determination of the load carrying characteristics of the tooth. However, mal-alignment will tend to cause severe unevenness of stress distribution along the line of contact of a straight spur and if tooth deflection is insufficient to compensate, an actual shortening of the line of contact; the effect on helical teeth is less severe as points a and b will tend to move to points a_1 and b_1 respectively keeping l_1 approximately equal to l. Thus although some lack of uniformity of stress distribution may be experienced, there is little likelihood of a shortening of the path of contact.

Therefore it has been decided to omit a face factor and base the speed factor on the well tried expansion.

$$x = \frac{900}{900 + v}$$

Fig. 7 shows the curves for straight spur speed factor and helical speed factor. It will be noted that the curves become more divergent as the speed increases. This is logical as normally it will be found that the higher the speed, the less the load per inch of face and therefore the less the compensating deflection to offset the affect of mal-alignment. Thus it may be reasoned that the higher the speed, the more the necessity for a face factor.

Summary of Design Procedure — Helical Gears

Helical gears will be designed in a manner similar to that employed for straight spur gears.

It can be shown that for helical gears having a small helix angle, Qh and Yh differ little from Q and Y for spur gears. Therefore it is suggested that helical gears having a helix angle *not greater than* 15° be designed as if they were spur gears with the exception that Xh be substituted for X.

1. Determine the ratio and probable gear and pinion diameters.

2. Apply the surface stress formula to determine the minimum face width.

$$F = \frac{W \cdot Cw}{Xh.Sc.Q}$$

where

W = tooth load (lb.)
Cw = classification factor as for spur gears
Xh = speed factor $= 900/(900 + v)$
Sc = surface stress factor—as for spur gears
Q = surface form factor.

3. Apply the strength formula

$$\frac{P}{Y} = \frac{Xh \cdot Sb \cdot F}{W \cdot C_s}$$

where

P = normal diametral pitch
Y = strength form factor (Helical)
Xh = speed factor $= 900/(900 + v)$
Sb = allowable bending stress as for spur gears
F = face width obtained from surface stress formula
Cs = classification factor as for spur gears.

Table 9 is a small section of the table of values of the strength factor P/Y.

It must be understood that the values shown in Table 9 apply only to Dominion Bridge standard gears. Any other gear system which embodies differences in either (a) tooth depth, (b) pressure angle, (c) addendum modification or (d) employs a helix angle greater than 15 , would require that the values ofr Q and P/Y be calculated as proposed in the text.

In order to illustrate the design procedure outlined, a few examples are appended:

Example 1. Drum gear and pinion for a 250-ton hoist motion Class A, spur gears, open, grease lubricated, Gear 45.6 in. p.c.d. material 0.40 carbon steel heat treated to 200-225 B.H.N.
Pinion 13.6 in. p.c.d. material SAE 3140 heat treated to 240-265 B.H.N.
Ratio = 3.35 to 1.
Tangential tooth load 52,000 lb.
Pitch line velocity 65 f.p.m.

Table IX. P/Y Values

Teeth in Pinion	Teeth in Gear: 1 D.P. 40 & over	1¼ D.P. 40 & over	1½ D.P. 40 & over	1¾ D.P. 40 & over	2 D.P. 40 & over	4 D.P. 40 & over	5 D.P. 40 & over
11						8.73	
12						8.48	
13	2.07					8.28	
14	2.00						10.0
15	1.94						9.70
16		2.39					9.54
17		2.35					
18		2.31					
19			2.74				
20			2.70				
21			2.69				
22							
23				3.08			
24				3.05			
25				3.03			
26					3.44		
27					3.42		
28					3.40		

Durability

X (speed factor) = 0.84
Sc = 2300 (softer of pair)
Q = 1.54
C_w = 0.6 (open gears)

Min. face width required

$$F = \frac{T \cdot Cw}{X \cdot Sc \cdot Q} = \frac{52{,}200 \times 0.6}{0.84 \times 2300 \times 1.54} = 10.55 \text{ in.}$$

(make 11 in.)

Strength

Face Width F = 11 in.
S_b = 0.33 × 100,000 = 33,000 p.s.i.
or = 0.60 × 77,000 = 46,500 p.s.i.
C_s = 1.5

$$\frac{P}{Y} = \frac{0.84 \times 33{,}000 \times 11}{52{,}200 \times 1.5} = 3.89$$

From table $\frac{P}{Y}$ for 27 teeth 2 dp is 3.42,
for 24 teeth $1\frac{3}{4}$ dp is 3.05
for 20 teeth $1\frac{1}{2}$ dp is 2.70
for 17 teeth $1\frac{1}{4}$ dp is 2.35
for 14 teeth 1 dp is 2.00

Any of these pinions would therefore satisfy strength requirements.
Example 2.

Intermediate hoist gear and pinion
Class B—helical, enclosed in oil-bath gearcase

Gear 20.45 in. p.c.d. material alloy steel heat treated to 360-390 B.H.N.

Pinion 3.88 in. p.c.d. material as for gear
Ratio = 5.27 to 1

Tangential tooth load = 8530 lb.
Pitch line velocity = 455 f.p.m.

This represents 120 H.P. at 870 r.p.m. at input shaft of gearcase.

Durability

X = 0.664 Q = 0.48
S_c = 4500 C_w = 0.6

Min. face width required

$$= \frac{T \cdot Cw}{X \cdot S_c \cdot Q} = \frac{8530 \times 0.6}{0.664 \times 4500 \times 0.48} = 3.57 \text{ in.}$$

(make 4 in.)

Strength

F = 4 S_b = 53,000 C_s = 1.9

$$\frac{P}{Y} = \frac{X \cdot S_b \cdot F}{T \cdot C_s} = \frac{0.664 \times 53{,}000 \times 4}{8530 \times 1.9} = 8.68$$

From table P/Y for 12 teeth 4 dp is 8.48. This is correct choice as 12 teeth is minimum standard and 12/D.P. = 3 in. for overlap, so the face width of 4 in. is ample. If F had been made $3\frac{3}{4}$ in. P/Y would have become = 8.15 and 12 teeth 4 dp would not satisfy this.
Note: When using Table 9 the tabulated value of P/Y for the pinion selected must never exceed the calculated value.
Example 3.

Consider the effect of changing the classification of the pinion and gear in example 2, assuming that the pitch line velocity remains constant.

Change Classification to A
Durability:

Allowable tooth load

$$= 8530 \times \frac{4}{3.57} \times \frac{0.6}{0.5} = 11{,}500 \text{ lb.}$$

Strength:

Allowable tooth load

$$= \frac{0.664 \times 53{,}000 \times 4}{8.48 \times 1.5} = 11{,}100 \text{ lb.}$$

This illustrates a case in which strength considerations govern the capacity of the pair and shows that for class A, the equivalent input of the gearcase can be raised as regards the intermediate reduction to 156 H.P. at 870 r.p.m.

Change Classification to C
Durability:

Allowable tooth load

$$= 8530 \times \frac{4}{3.57} \times \frac{0.6}{0.8} = 7180 \text{ lb.}$$

Strength:

Allowable tooth load

$$= \frac{0.664 \times 53{,}000 \times 4}{8.48 \times 1.9} = 8730 \text{ lb.}$$

This gives an equivalent input of 101 H.P. at 870 r.p.m.

Test

Unfortunately, space limitations make it impracticable to give a full description of the test carried out as a check on the above design methods. A brief note of the procedure and its results will have to suffice.

A test gear case was built consisting of one reducing gear and one increasing gear, each with a ratio of 7.17 to 1 so that the output shaft ran at the same speed as the input shaft. The input shaft was coupled to a 125 h.p. at 1800 r.p.m. electric motor and the output shaft drove a hydraulic dynamometer which provided wide adjustments of torque.

The gears were designed for 79 h.p. at 1780 r.p.m. class A and were made from heat-treated alloy steel. The teeth were cut after heat-treatment and were given a rather poor finish even for industrial gears. All bearings were rolling type and an extreme pressure lubricating oil was used with splash lubrication.

The duration of the test was as follows:

(a) Run for 30 minutes at 5 hp.
(b) Run for 4 hours 50 mins. at 25 hp.
(c) Run for 5 hours at 50 hp.
(d) Run for 21 hours at 75 hp. Stop and inspect at 4 hr. intervals.
(e) Run for 150 hours at 98 hp. Stop and inspect at 4 hr. intervals.
(f) Run for 3 minutes at 148 hp.
(g) Run for $1\frac{1}{2}$ minutes at 175 hp.

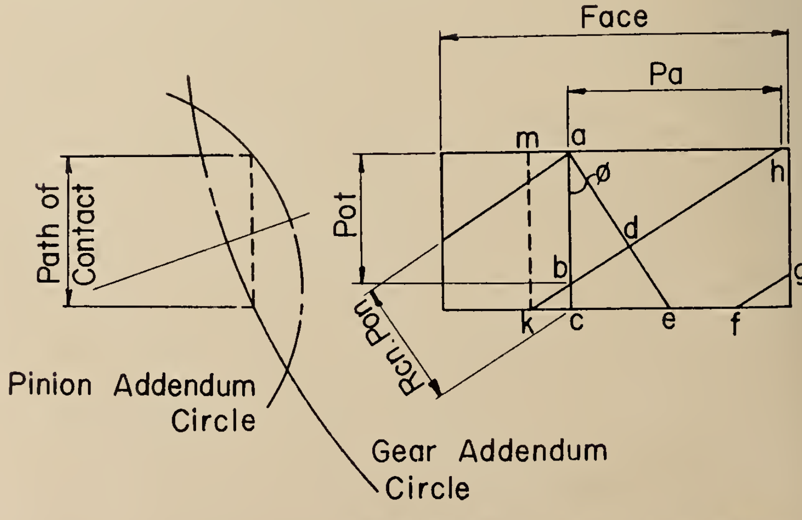
These running periods were calculated to be equivalent to a total of 500 hr. at full rated load and gave approximately 18 × 10^6 load cycles on the pinion teeth.

Results:

After (a) slight scuffing appeared on the output pinion teeth.

After (b) scattered pitting was observed on both gears and a narrow band of pitting showed at the pitch line of the input pinion teeth.

Fig. 6.



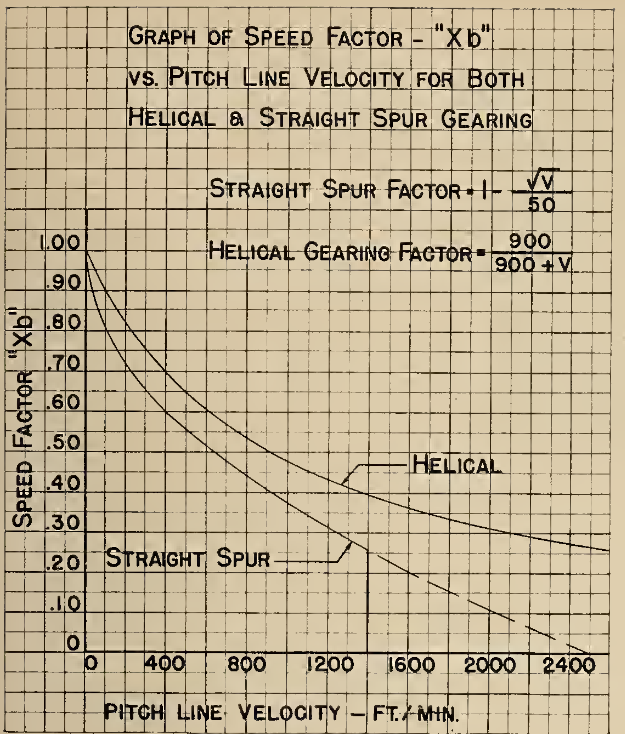


Fig. 7.

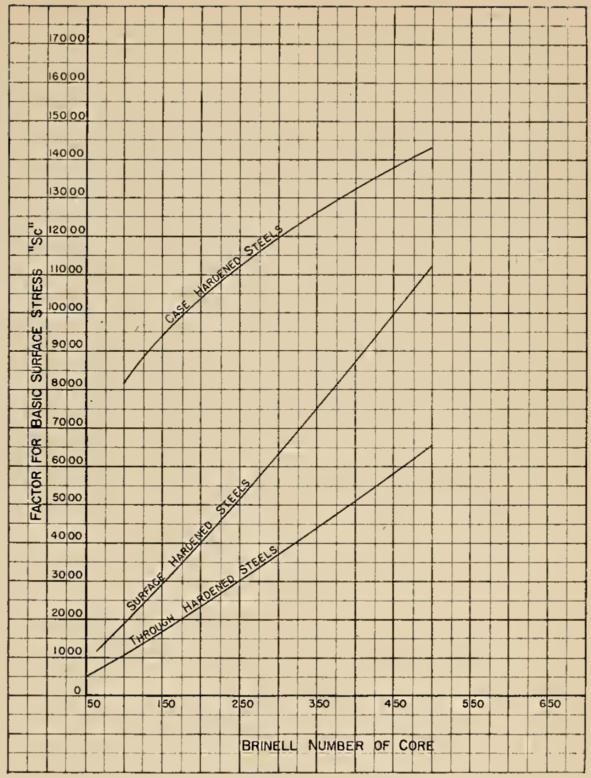

Fig. 8. Approximate Basic Stress Factors.

After (c) pitting had increased on the gears. Heating of the oil became very marked.

During (d) the pinions rapidly acquired a uniform polish and the tool marks disappeared with a small increase in the amount of pitting but with no observable increase in depth. The pitting on the gears spread slowly across the teeth. For the last 17½ hr. of this stage, change in pitting was very slow.

During (e) inaccuracies in the dynamometer were detected and a watt meter was connected in the motor circuit as a check. After this was done, the input was kept steady at 98 hp. whereas for the first 8 hr. of this stage it had varied up to a value of 120 hp.

No radical changes appeared for 118 hours of this stage but subsequently the tip relief area of the pinion teeth showed heavy wear and burring appeared at the tips. Pitting increased and both pinion and gear teeth showed undercutting at the pitch lines.

After (d) and (e) no apparent change was observed but on final dismantling some weeks later, two teeth had broken on the input pinion, the nature of the fractures being typical of fatigue failure.

Although the results of the test may appear unfavourable at first glance, it is felt that the design method has been proved satisfactory for the following reasons :

(a) The finish of the gear teeth was poor. Tooth errors were present much in excess of those to be expected from industrial quality cutting. Therefore a large increment of dynamic loading certainly existed. High local surface stresses would contribute to the early pitting.

(b) The high ambient temperatures experienced during the test (on most days exceeding 90°F.) precluded much natural cooling. Oil temperatures were consistently high and although subsequent analysis of the oil showed no breakdown, lubrication must have been affected.

(c) Dynamometer inaccuracies undoubtedly imposed higher loads than expected, at least for part of the test.

(d) Continuous running periods of 4 hours under full load could never be realized on a class A crane and indeed would only be experienced on a class D or mill crane and then only on the bridge travel motion. The heating aspect then could not normally be experienced on crane drives.

General: The above design method is not expected to supplant existing methods for all applications of gearing but is put forward as a logical basis for design of gears in such applications as cranes where the economics of material and labour costs plus weight saving have to be offset against design costs. It is also realized that the investigation, while fairly exhaustive, has only been carried to a point which would indicate that existing criteria were suitable and, this having been established, these criteria have been accepted as reasonable, without attempting to prove or disprove their derivation. Furthermore, although the introductory remarks on Spur Gears point out that tooth deflection may affect face width, no attempt has been made to set up limits for such deflections. The fact that, in the case of spur gears, a face factor has been embodied in the speed factor (Xc) is considered to cover this, while for helical gears, the requirements of overlap very often require a face width greater than that determined by surface stress considerations.

In conclusion, the writer wishes to acknowledge the very valuable contribution made by Mr. A. C. Briggs now of Dravo Corporation, Pittsburgh, Pa., U.S.A., who made the investigation and report which formed the body of this paper. Mention should also be made of the work of Mr. S. F. Angus, Jr., E.I.C.,
the work of Mr. S. F. Angus, Jr. E.I.C.,
who made the lengthy calculations for Table 9.

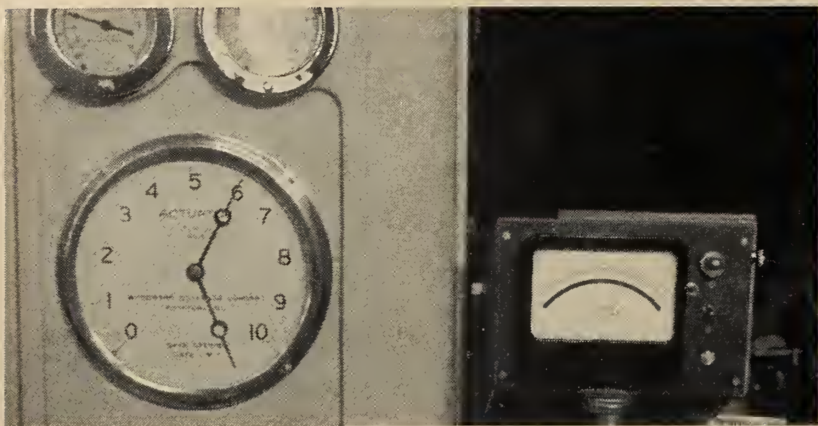
OPTIMUM ADJUSTMENT of GOVERNORS



L. M. Hovey, M.E.I.C.,
Assistant to the General Manager—Planning, The Manitoba Hydro-Electric Board, Winnipeg.

IN HYDRO GENERATING STATIONS

This paper discusses the elementary theory of speed governing, and differential equations are derived in the Appendix together with the main parameters involved in the speed transient of a turbine following a load change and what settings should be recommended for optimum response. As all generating stations are tied together by relatively stiff electrical connections, a method of setting up the governors of each machine will be described which assumes that all machines behave as one equivalent. Methods will be described as to how the primary and secondary compensation can be simply measured in the field and how each is adjusted to a selected value.

THE MANITOBA Hydro-Electric Board supplies the bulk of power to the Province of Manitoba from 4 hydro-electric plants on the Winnipeg River. These stations are tied in with two other plants on the same river which are owned and operated by The City of Winnipeg Hydro-Electric System. The total rated capacity of all these stations is in the order of 585 Mw and, with the exception of one 75 Mw station, consists of conventional vertical machines with prime movers of the fixed blade propeller type. The stations are all of medium head range with short intakes to the turbines.

At the present time there is an interconnection with the Northwestern system of The Hydro Electric Power Commission of Ontario which is also a predominantly hydro system with a number of stations located in the area between the Ontario-Manitoba Boundary and the lake head at Fort William. The generating capacity of this system is somewhat less than the Manitoba System.

The Board has recently brought into operation the Brandon thermal plant of 120 Mw and is at present constructing another thermal station at Selkirk having an initial capacity of 120 Mw.

From the above it can be seen that the integrated system is predominantly hydro and the problem of setting up the governors for optimum performance has occupied our attention over the last few years, particularly since the combined systems are not what could be termed a large system where transient governing problems might be considered of less importance.

The main difficulty with speed governing on an hydraulic turbine is the effect of the water inertia which introduces an unstabilizing effect on the steady state speed unless the governor is provided with a very large temporary speed droop. The water inertia effect tends to increase the turbine output during wicket gate closure and decrease it on gate opening. The effect is therefore just opposite to what the governor tries to do when a speed change occurs. If we try to overcome this effect by decreasing the temporary speed droop then the machine becomes unstable and continues to oscillate about an average speed which, of course, is an impossible operating condition.

As will be shown later, and developed in the Appendix, if the governor is provided with a large temporary speed droop together with a dashpot which will slowly decrease the droop with time, the governor and machine can be made completely stable.

It might be of interest to note that with a steam turbine governor the time lags associated with this type of machine make it possible to operate stably with 0.04 to 0.05 p.u. speed droop and with these small values, it is not necessary to provide a dashpot whereas with an hydraulic turbine, values of temporary droop have to be in the order of 0.20 to 1.0 p.u. to give stable operation.

It can be seen that with such a high temporary droop there will be a relatively large momentary deviation in speed following a load change which will be corrected by the action of the dashpot after a time interval.

The following analysis attempts to show what selection of parameters should be used on such a governor to give the following:

1. Minimum speed deviation after load change;
2. Quick return to normal speed;
3. Adequate stability of governing.

Before proceeding with detailed discussion on hydro governing, reference should be made to the last part of the Appendix which shows mathematically why any governor will hunt or be unstable unless speed droop or some other form of compensation is applied. This latter analysis is more closely applicable to steam turbine governing where the rate of valve movement and trapped steam are the unstabilizing element.

The following analysis of hydro governors is mostly concerned with the transient response characteristics and the adjustments which have to be made to give optimum performance during load swings. It is realized that dead band and friction can materially affect the performance of such a governor for steady state operation. These latter conditions are not too significant for transient performance.

In setting up the differential equation of performance, the following assumptions are made:

1. The steady state speed droop which is about 0.035 p.u. is neglected;

2. The turbine is operating at around the point of maximum efficiency where any change in input torque is closely proportional to the corresponding change in gate position;

3. The change in speed is relatively small say ±0.10 p.u. so that the nonlinear relationships can be linearized

and the gate velocity does not reach its saturation value;

4. The net damping torque at the turbine shaft as a function of load torque and turbine torque is zero. This condition is approximately equivalent to an A.C. generator with a voltage regulator supplying a purely resistive load;

5. The time constant between the pilot valve movement and main servo can be neglected;

6. That for purposes of setting the governors on a multi-machine system the values of water starting time Tw and mechanical starting time Tm can be weighted for the group in such a manner that the group will behave as a single equivalent machine;

7. That the mechanical inertia of all rotating loads is neglected.

It is felt that the above assumptions are somewhat on the conservative side, particularly as regards the damping effect. However, excellent results have been achieved in using the above assumptions, working out the main equations, and setting up the adjustable parameters which result.

Stemming from the above assumptions the main differential equations involved are as follows:[1]

Machine acceleration

$$Tm\frac{dn}{dt} = g + 1.5h - \Delta M \qquad (1)$$

Water acceleration

$$-0.5Tw\frac{dh}{dt} = Tw\frac{dg}{dt} + h \qquad (2)$$

Governor response

$$-\delta Tr\frac{dg}{dt} = Tr\frac{dn}{dt} + n \qquad (3)$$

Where

n = Relative per unit instantaneous speed
h = Per unit instantaneous head
g = Per unit instantaneous gate
ΔM = Per unit step load torque change
Tm = Mechanical starting time, seconds
Tw = Water starting time, seconds
Tr = Dashpot relaxation time constant, seconds
δ = Temporary speed droop

δ and Tr are known as primary and secondary compensation respectively[5]. As we are mainly interested in the speed change following a load change, the variables h and g can be eliminated and the following differential equation of n can be written

$$0.5\delta TrTmTw\frac{d^3n}{dt^3} + (\delta TrTm - TwTr)\frac{d^2n}{dt^2} + (Tr - Tw)\frac{dn}{dt} + n = 0 \qquad (6)$$

See Appendix for derivation of equations (1), (2), (3), and (6).

The equation (6) represents continuous oscillatory or damped functions of n with time t and the Routh-Hurwitz criterion for stability is that

$$0.5\,\delta TrTmTw > 0,$$

$$(\delta TrTm - TwTr) > 0 \quad (Tr - Tw) > 0$$

$$(Tr - Tw)(\delta TrTm - TwTr) > 0.5\,\delta TrTmTw$$

From these conditions it can be seen that if Tr is less than Tw we could have instability.

Typical values of these parameters for a short intake plant could be

$$Tm = 9$$
$$Tw = 1.2$$
$$Tr = 5$$
$$\delta = 0.30$$

As shown in the Appendix and Fig. 2 various degrees of stability can be maintained for various values of the ratios Tw/Tr and $Tw/\delta Tm$, but if any of these values fall outside the boundary of the curve (Fig. 2) instability can result.

Analog computer studies[1] have been made for various values of the above ratios and a plot of the resulting speed transients is shown on Fig. 2. Note that as the boundary curve is approached the speed transient becomes more oscillatory. These were taken for step load changes.

Several authorities[1,12] have indicated that an optimum speed transient results when $Tw/Tr = 0.2$ and $Tw/\delta Tm = 0.5$ or $Tr = 5Tw$ and $\delta = 2Tw/Tm$. However, for setting up the governors on the Winnipeg River generating stations we have selected the ratios

$$Tw/Tr = 0.25 \qquad Tw/\delta Tm = 0.5$$

$$\text{or} \quad Tr = 4Tw \qquad \delta = 2Tw/Tm$$

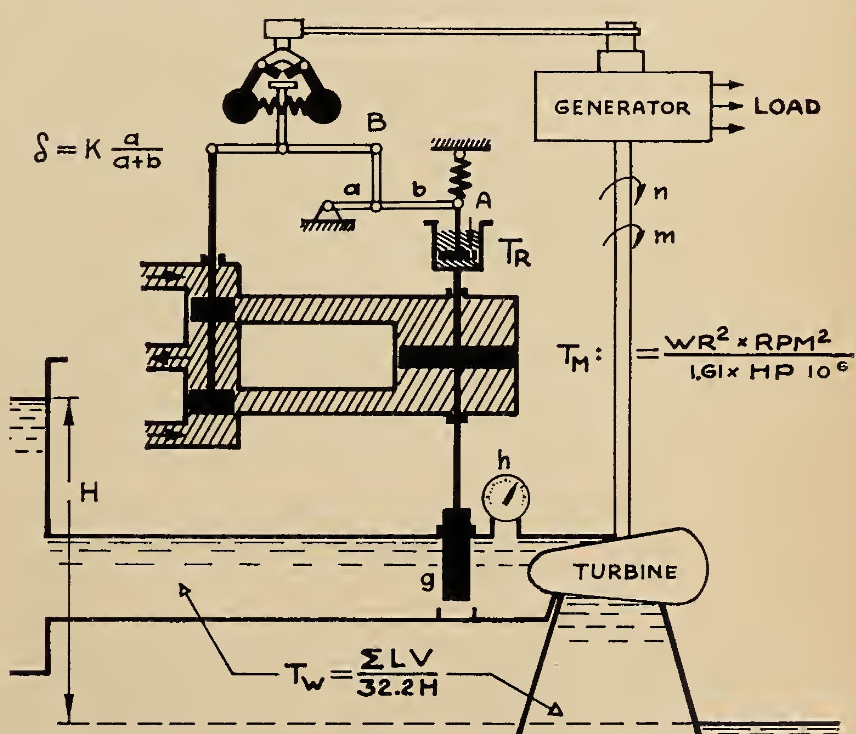
The computed speed transient resulting from inserting the above parameters in equation (6) is shown in Fig. 5.

Fig. 1 shows diagramatically a typical water wheel generating unit and its governor together with the significant parameters which affect governing.

The fixed parameters are Tw and Tm for the particular machine and only δ the temporary droop and Tr the dashpot relaxation time constant are each adjustable. The temporary droop is adjusted by changing the lever ratio $a/(a + b)$. The dashpot relaxation time constant is adjustable by means of the needle valve opening shown in the sketch as a small hole in the dashpot piston.

Fig. 6 shows the internal construction of a familiar actuator type governor used on this continent. The temporary droop is adjusted by selecting certain hole combinations on the top and bottom floating levers, and close adjustments are finally made by altering the throw of the eccentric which drives the large dashpot piston. These adjustments can only be made when the machine is shut down or on hand control.

Fig. 1. Sketch showing hydraulic turbine and generator with typical governor.



The needle valve opening can be altered with the machine on the line and Fig. 3 shows the general arrangement on this type of dashpot.

As there are no calibration marks on this type of actuator indicating the values of temporary droop and dashpot time the following procedures were developed for measuring these quantities.

To measure the temporary droop the machine is off the line and running on governor control at speed no-load. An accurate tachometer is set up beside the governor pedestal. With the dashpot needle valve open about one-eighth of a turn, control is taken away from the governor head by using the gate limit (red pointer) to depress the speed by 0.10 p.u. or down to 54 cycles. When the speed is steady at this point the needle valve is closed tight and a reading of the gate dial opposite the black pointer is recorded. The gate limit now is suddenly removed, which puts the machine back on governor control, and as there is a 0.10 speed error below rated speed the gates suddenly open and momentarily stop at some position up scale on the gate dial. This point is recorded. Due to water inertia the actual speed of the machine does not change perceptibly during this gate transient so we have a measure of temporary droop in accordance with the following relationship:

$$\delta = \frac{0.10}{c - d}$$

where

c = Reading on gate dial where motion momentarily stops.

d = Initial reading on gate dial to hold speed 0.10 p.u. below normal.

For example, if c equals 0.2 gate and d equals 0.4 gate we have

$$\delta = \frac{0.10}{0.4 - 0.2} = 0.50 \text{ p.u.}$$

By making successive tests, each time altering the lever ratio, we arrive at the selected value of temporary droop. Note that with needle valve closed, temporary droop is theoretically permanent.

In making this measurement care should be exercised to be certain that the small dashpot piston does not bypass as this will give a false reading. This difficulty may be overcome by taking a smaller speed interval.

As the speed no load point on a propeller wheel is about 0.3 p.u. gate the temporary droop selected from the governor equation is modified for purposes of measurement in the following manner:

Let δ = Droop from equations

Let f = p.u. speed no load gate position

Measured Droop = $\delta/(1 - f)$

For example, if δ = 0.33 and f = 0.33

Measured droop should be

$$0.33/(1 - 0.33) = 0.50 \text{ p.u.}$$

To measure the dashpot relaxation time constant Tr for a given needle valve opening refer to Fig. 3. The former shows the setup diagramatically, together with the exponential characteristic, and the latter shows the actual arrangement used for carrying out this measurement. The actual measurement of Tr is carried out with the machine shutdown or on hand control by manually depressing the small dashpot piston until the pointer is a little above the 1.00 figure. It is now released and as the pointer passes the 1.00 figure a stop watch is started and as the pointer comes opposite the figure 0.37 the stop watch is stopped and the time interval read. This is Tr in seconds for the particular needle valve setting. This measurement is repeated for the opposite direction and a relationship is found for Tr as a function of various needle valve openings. As a rule, it is found that the needle valve opening is very critical for a given Tr. Needle valve opening is recorded in fractions of turns.

Outline of Basis for Setting Winnipeg River Governors

As stated earlier in this paper weighted averages of Tm and Tw for all machines are used for purposes of arriving at a common temporary droop and dashpot time for each machine. Table I gives the ratings of all groups of similar machines with the individual Tm and Tw for each group.

From Table I Weighted average

$$Tm = \frac{4{,}617{,}000}{783{,}000} = 6.00 \text{ seconds}$$

From Table I Weighted average

$$Tw = \frac{778{,}000}{783{,}000} = 0.99 \text{ seconds}$$

The above figures are rounded off to

$$Tm = 6 \text{ seconds}$$

$$Tw = 1 \text{ second}$$

From the appendix it will be noted that the selected optimum settings of temporary droop and dashpot time are

$$\delta = 2Tw/Tm \qquad Tr = 4Tw$$

which gives

$$\delta = 2 \times 1/6 = 0.333 \text{ p.u.}$$

$$Tr = 4 \times 1 = 4 \text{ seconds}$$

Since most of the machines have a speed no load point under average head condition of about 0.333, the corrected temporary droop for measurement purposes is

$$\delta = \frac{0.333}{1 - 0.333} = 0.50 \text{ p.u.}$$

For measurement purposes all machines have therefore been set at the following values using measurement methods as outlined above.

$$\delta = 0.50 \text{ p.u.} \qquad Tr = 4 \text{ seconds}$$

Operating results with these settings have been very successful up to now although instability was experienced at Seven Sisters which turned out to be due to worn dashpot pistons. This problem was temporarily overcome by using a heavier oil in the dashpots until such time as they could be repaired.

No attempt is made to reduce the dashpot time constant below 4 seconds for on load conditions. However, this value is sometimes increased manually while a machine is being synchronized, but is put back to normal after the circuit breaker is closed. The normal frequency fringe for the system just under ±0.1 of a cycle.

Conclusions

1. Methods are now available which make it possible to predetermine governor settings. While it is realized that certain assumptions are made in order to simplify the mathematical approach it is felt that the application of the method as outlined has resulted in improved transient response on the combined system.

2. Adequate measuring techniques have been developed so that the computed values of dashpot relaxation time Tr and the temporary droop δ can be applied to a governor without having to guess or calculate the position of these adjusting devices.

Acknowledgement

I would like to acknowledge with thanks the co-operation of the Operating Divisions of The Manitoba Hydro-Electric Board and City of Winnipeg Hydro-Electric System who made equipment available for tests and arranged for the installation of the necessary measuring equipment.

Appendix

Derivation of Mechanical Starting Time Tm of Machine: This parameter may be defined as the time in seconds required to accelerate the machine from zero reference speed to rated speed with rated torque applied.

The differential equation of motion of the revolving mass is

$$I\frac{d^2\theta}{dt^2} = Mg \qquad \text{(a)}$$

where

I = WR^2 = Moment of inertia of rotating elements lb. ft².

M = Rated torque of machine in lb. ft. corresponding to rated HP. at rated speed r.p.m.

g = Acceleration due to gravity 32.2 ft.sec².

$d^2\theta/dt^2$ = Angular acceleration in radians per sec. per sec.

Integrating equation (a) once we have

$$I(d\theta/dt) = Mgt + k$$

when $t = 0$, $d\theta/dt = 0$

$$\therefore \qquad k = 0$$

Substituting WR^2 for I and 32.2 for g, we have

$$\frac{WR^2}{32.2}\frac{d\theta}{dt} = Mt \qquad \text{(b)}$$

By definition $t = Tm$, when $d\theta/dt$ = rated speed, and M = rated torque. Under these conditions

$$\frac{d\theta}{dt} = \frac{2\pi \cdot \text{RPM}}{60} \text{ radians per second}$$

and $2\pi\text{RPM} \cdot M = \text{HP} \times 33{,}000$

$$\therefore \qquad M = \frac{\text{HP} \times 33{,}000}{2\pi\text{RPM}}$$

Substituting these relations in equation (b), we have

$$\frac{WR^2}{32.2} \times \frac{2\pi\text{RPM}}{60} = \frac{\text{HP}33{,}000}{2\pi\text{RPM}} \times Tm$$

$$\therefore \quad Tm = \frac{WR^2 \times 4\pi^2 \times \text{RPM}^2}{32.2 \times 60 \times \text{HP} \times 33{,}000}$$

$$Tm = \frac{WR^2 \times (\text{RPM})^2 \times 10^{-6}}{1.61 \times \text{HP}}$$

If we call n = per unit rated speed
m = per unit rated input torque

we can rewrite the acceleration equation using Tm as follows:

$$Tm\frac{dn}{dt} = m$$

here dn/dt is expressed in per unit speed change per second.

If we integrate this equation once

$$Tmn = m \cdot t + c$$
$$c = 0 \text{ when } n = 0$$

and substituting $n = 1$ and $m = 1$

$$\therefore Tm = t \text{ as per definition.}$$

The application of these normalized or per unit quantities simplifies the analysis considerably. Note that if we substitute Kw for HP. and divide by 2 we obtain the familiar inertia constant H used in electrical stability studies.

$$\frac{WR^2 \times (\text{RPM})^2 \times 10^{-6}}{1.61 \times 1.34 \times Kw} \times \frac{1}{2}$$
$$= H = \frac{0.231 \times WR^2 \times \text{RPM}^2 \times 10^{-6}}{Kw}$$

Differential equations of governing: As noted previously the three inter-related equations are as follows:

Machine acceleration

$$Tm\frac{dn}{dt} = g + 1.5h - \Delta M \qquad (1)$$

Water acceleration

$$-0.5Tw\frac{dh}{dt} = Tw\frac{dg}{dt} + h \qquad (2)$$

Governor Response

$$-\delta Tr\frac{dg}{dt} = Tr\frac{dn}{dt} + n \qquad (3)$$

Derivation of Machine Acceleration Eq. (1): From equation (1) we have the machine acceleration

$Tm(dn/dt)$ = Net change in per unit torque.

The net change in per unit input torque for small changes is made up of three variables, namely:

g = per unit instantaneous gate

$1.5h$ = per unit instantaneous torque due to per unit instantaneous head

ΔM = per unit torque change due to a step load change

The per unit torque due to the head is assumed equal to the per unit power input which is a function of:

$$1-(1+h)(1+h)^{1/2} \quad \text{or} \quad 1-(1+h)^{3/2}$$

which, for small changes, is approximately equal to $1.5h$.

If load torque is assumed positive, then this component of torque has a negative sign indicating deceleration. Therefore, the full machine acceleration equation in per unit form is

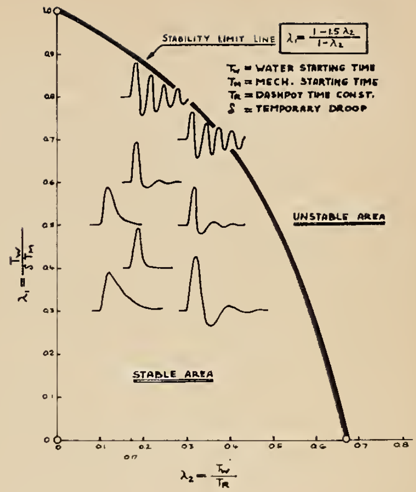

Fig. 2. Curve showing stability criteria for a hydro governor.

$$Tm(dn/dt) = g + 1.5h - \Delta M$$

which is equation No. 1.

NOTE: for load off the sign of ΔM is negative and accelerating torque is

$$g + 1.5h + \Delta M$$

Derivation of Water Acceleration Eq. (2)[2]: The velocity of water in a turbine and intake can be represented by the following relationship:

$$u = K \cdot H^{1/2} \cdot G \qquad \text{(c)}$$

where

H = head
G = Gate position
u = velocity
K a constant

For small variations from a steady state condition, differentiating (c) gives

$$\frac{\Delta u}{u_0} = \frac{1}{2}\frac{\Delta h}{H_0} + \frac{\Delta G}{G} \qquad \text{(d)}$$

where

u_0 = nominal rated velocity
H_0 nominal rated head

Since force equals mass times acceleration, we have the water acceleration due to a change in head expressed by the following equation:

$$\rho LA\frac{d(\Delta u)}{dt} = -A\rho g\Delta h \qquad \text{(e)}$$

where

ρ = mass density of water lb. cu.ft.

A = area of water passages sq.ft.

g = acceleration due to gravity 32.2 ft./sec²

L = total length of water passage in feet

ρLA = mass of water in turbine passages in lb.

$A\rho g\Delta h$ = change in force at turbine runner

Note that there is a negative acceleration for an increase in head. In per unit form equation (e) becomes

$$\frac{Lu_0}{gH_0}\frac{d}{dt}\frac{(\Delta u)}{(u_0)} = -\frac{\Delta h}{H_0}$$

The co-efficient of per unit acceleration may be expressed as a nominal starting time Tw where

$$Tw = LU_0/gH_0 \text{ in seconds.}$$

This constant is usually determined by integrating the various LU_0 sections of the turbine intake + scroll case + draft tube and is usually expressed as $Tw = (\Sigma Lv/gH)$ where L, v, H are rated conditions and $g = 32.2$.

If we let

$$v = \frac{\Delta u}{U_0} \qquad h = \frac{\Delta h}{H_0} \qquad g = \frac{\Delta G}{G}$$

we have
$$Tw\frac{dv}{dt} = -h \qquad \text{(f)}$$

and from equation (d)

$$v = \frac{h}{2} + g \qquad \text{(g)}$$

differentiating equation (g) we have

$$\frac{dv}{dt} = \frac{1}{2}\frac{dh}{dt} + \frac{dg}{dt}$$

and multiplying by Tw

$$Tw\frac{dv}{dt} = \frac{Tw}{2}\frac{dh}{dt} + Tw\frac{dg}{dt} \qquad \text{(h)}$$

Substituting equation (f) in (h)

$$-h = \frac{Tw}{2}\frac{dh}{dt} + Tw\frac{dg}{dt}$$

and rearranging, we have the equation

$$-\frac{Tw}{2}\frac{dh}{dt} = Tw\frac{dg}{dt} + h$$

which is equation No. 2 for water acceleration.

Derivation of Governor Response Eq. (3): Referring to Fig. 1 the dashpot characteristic is such that if a sudden opening G of the gate occurs, point A moves up a distance equal to the gate movement and then settles back at an exponential rate which is a function of the spring constant and the needle valve opening. If we let y equal the distance up of point A at time t, the differential equation of motion of point A is $dy/dt = -K \cdot y$

Where K is a constant. If we put $K = 1/Tr$ the solution of this equation is

$$y = G \cdot e^{-(1/Tr)t}$$

e = Base of natural logarithms

Note that dy/dt equals velocity of dashpot piston at any time t. Tr is known as the relaxation time constant or secondary compensation which is a function only of needle valve opening for a fixed spring.

When $t = Tr$,
we have $Y = Ge^{-1} = 0.368G$

In the governor response equation, we assume a negligible time constant relating pilot valve position to main servo valve. This relationship is very nearly achieved in modern actuator governors for small displacements of the mechanism.

To derive the governor response characteristic, refer to Fig. 1 and assume that the speed is below normal, or a negative per unit instantaneous relative speed $-n$. The gate is opening as a result of the pilot valve being lifted and we have a differential equation of motion involving the velocity of point B as a function of flyball displacement in response to relative speed, and also in relation to the gate velocity as modified by the dashpot piston velocity.

Taking velocities in the gate opening direction as positive, we have the velocity of point B in relation to gate opening velocity equal to

$$\delta(dg/dt) + (n/Tr)$$

Where $\delta(dg/dt)$ equals velocity upward of point B due to gate movement and n/Tr equals velocity downward (this is actually negative as n is negative) due to the dashpot relaxation time Tr, which velocity at any instant is n/Tr (Point B has same time constant Tr as Point A).

Since the gate is opening, the rate of change of relative speed dn/dt is positive and under this influence, point B moves downward at a rate equal to dn/dt and since this is in the negative direction, is $-(dn/dt)$. As point B is common, we have the two velocities equal to one another.

$$\delta\frac{dg}{dt} + \frac{n}{Tr} = -\frac{dn}{dt}$$

or re-arranging

$$-\delta Tr\frac{dg}{dt} = Tr\frac{dn}{dt} + n$$

which is the equation No. 3 for governor response.

Derivation of Differential Equation of Speed vs Time:

Let $p = d/dt$

Original equations now become

$$Tmpn = g + 1.5h - \Delta M \qquad (1)$$

$$-0.5Twph = Twpg + h \qquad (2)$$

$$-\delta Trpg = Trpn + n \qquad (3)$$

From (3)

$$g = -\frac{(Trp + 1)n}{\delta Trp} \qquad (4)$$

From (2)

$$h = \frac{Tw(Trp + 1)n}{\delta Tr(0.5Twp + 1)} \qquad (5)$$

Substitute (4) and (5) into (1), we obtain

$$Tmpn = -\frac{(Trp + 1)n}{\delta Trp} + \frac{1.5Tw(Trp + 1)n}{\delta Tr(0.5Twp + 1)} - \Delta M$$

Above equation is now all in terms of n and t and cross multiplying. Final equation is, substituting $(d/dt) = p$

$$0.5\delta TrTmTw\frac{d^3n}{dT^3} + (\delta TrTm - TwTr)\frac{d^2n}{dt^2} + (Tr - Tw)\frac{dn}{dt} + n = 0 \qquad (6)$$

This third order equation represents a damped or undamped oscillation of n depending on the value of the co-efficients. The Routh-Hurwitz criterion for stability or damped oscillation is as follows:

That

$\delta TrTm - TwTr > 0$ or $Tm - Tw > 0$

$Tr - Tw > 0$

$(Tr - Tw)(\delta TrTm - TwTr) > 0.5\delta TrTmTw$

The latter unequality is the deciding criterion and multiplying out, we have

$$(\delta TrTm + Tw^2) - (TwTr + 1.5\delta TmTw) > 0 \qquad (7)$$

Let $\dfrac{Tw}{\delta Tm} = \lambda_1$ and $\dfrac{Tw}{Tr} = \lambda_2$

Divide (7) by $TwTr$

$$\therefore \left(\frac{1}{\lambda_1} + \lambda_2\right) - \left(1 + \frac{1.5\lambda_2}{\lambda_1}\right) > 0$$

Multiply by λ_1

Now $(1 + \lambda_1\lambda_2) - (\lambda_1 + 1.5\lambda_2) > 0$

The limit of stability is reached for any condition where

$$1 + \lambda_1\lambda_2 = \lambda_1 + 1.5\lambda_2$$

or

$$\lambda_1 = \frac{1 - 1.5\lambda_2}{1 - \lambda_2}$$

We can therefore plot a curve of λ_1 vs λ_2 where all values of these quantities between the curve and the X and Y axis represent varying degrees of stability and all values outside the curve represent unstable conditions.

The following is a table of corresponding values of λ_1 and λ_2 from which a curve may be plotted:

Table II

$\lambda_2 = (Tw/Tr)$	$\lambda_1 = (Tw/\delta Tm)$
0.00	1.0000
.05	.9736
.10	.9444
.15	.9118
.20	.8750
.25	.8333

.50	.5000
.55	.3889
.60	.2500
.65	.0714
.67	0.0000

Fig. 2 shows a plot of λ_1 and λ_2 together with a series of approximate speed transients for various combinations within the stable area. These were determined from an analog computer study[1].

To solve equation (6) for a given step load change ΔM.

First determine λ_1 and λ_2 for the estimated optimum transient from Fig. 2, and from these values calculate δ and Tr.

Substitute these values in the coefficients of equation (6). The equation now takes the general form

$$\frac{Dd^3n}{dt^3} + \frac{Ed^2n}{dt^3} + F\frac{dn}{dt} + n = 0 \qquad (8)$$

There are three roots of the auxiliary equation, of the general form

$$\alpha, \qquad \beta + j\gamma, \qquad \beta - j\gamma,$$

The general solution of (8) is

$$n = Xe^{\alpha t} + Ye^{(\beta + j\gamma)t} + Ze^{(\beta - j\gamma)t} \qquad (9)$$

Where X, Y, Z are arbitrary constants which can be determined from initial operating conditions and

$$j = \sqrt{-1}$$

Equation (9) can be rewritten as follows:

Where A, B, C are arbitrary constants

$$n = Ae^{\alpha t} + e^{\beta t}(B \sin \cdot \gamma t + C \cos \gamma t) \qquad (10)$$

For the first initial condition we have, when $t = 0$, $n = 0$. Substituting in equation (10) above $0 = A + C$.

For the remaining initial conditions, refer back to equations (1), (2), (3). For $t = 0$ equation (1) becomes for a load off condition.

$$Tm\frac{dn}{dt} = 0 + 0 + \Delta M$$

$$\therefore \quad \frac{dn}{dt} = \frac{\Delta M}{Tm} \qquad (11)$$

Differentiate equation (1) as follows:

$$Tm\frac{d^2n}{dt^2} = \frac{dg}{dt} + 1.5\frac{dh}{dt} \qquad (12)$$

From equation (2) at $t = 0$, we have

$$-0.5Tw\frac{dh}{dt} = Tw\frac{ag}{dt}$$

$$\therefore \quad \frac{dh}{dt} = -2\frac{dg}{dt} \qquad (13)$$

From equation (3) at $t = 0$, we have

$$-\delta Tr\frac{dg}{dt} = Tr\frac{dn}{dt}$$

$$\therefore \quad \frac{dg}{dt} = -\frac{1}{\delta}\frac{dn}{dt} \qquad (14)$$

Now dn/dt at $t = 0$ equals $\Delta M/Tm$

Substitute this relation in (14) and we have

$$\frac{dg}{dt} = -\frac{\Delta M}{\delta Tm} \qquad (15)$$

Substitute (15) into (13) we have

$$\frac{dh}{dt} = +\frac{2\Delta M}{\delta Tm} \qquad (16)$$

Substitute (15) and (16) into (12) we have

$$Tm\frac{d^2n}{dt^2} = -\frac{\Delta M}{\delta Tm} + \frac{3\Delta M}{\delta Tm}$$

$$Tm\frac{d^2n}{dt^2} = +\frac{2\Delta M}{\delta Tm}$$

$$\therefore \text{ At } t = 0 \quad \frac{d^2n}{dt^2} = \frac{2\Delta M}{\delta Tm^2} \qquad (17)$$

Summing up initial conditions at $t = 0$, we have

$$n = 0$$

$$\frac{dn}{dt} = \frac{\Delta M}{Tm}$$

$$\frac{d^2n}{dt^2} = \frac{2\Delta M}{\delta Tm^2}$$

Referring back to equation (9) we have differentiating same

$$\frac{dn}{dt} = \alpha Ae^{\alpha t} + e^{\beta t}(B\gamma \cos \gamma t - C\gamma \sin \gamma t) + \beta e^{\beta t}(B \sin \gamma t + C \cos \gamma t)$$

$$\text{at } t = 0, \qquad \frac{dn}{dt} = \frac{\Delta M}{Tm}$$

$$\therefore \quad \frac{\Delta M}{Tm} = \alpha A + \gamma B + \beta C \qquad (18)$$

$$\frac{d^2n}{dt^2} = \alpha^2 Ae^{\alpha t} + e^{\beta t}(-B\gamma^2 \sin \gamma t - C\gamma^2 \cos \gamma t) + \beta e^{\beta t}(B\gamma \cos \gamma t - C\gamma \sin \gamma t) + \beta e^{\beta t}(B\gamma \cos \gamma t - C\gamma \sin \gamma t) + \beta^2 e^{\beta t}(B \sin \gamma t + C \cos \gamma t)$$

$$\text{At } t = 0, \qquad \frac{d^2n}{dt^2} = \frac{2\Delta M}{\delta Tm^2}$$

$$\therefore \quad \frac{2\Delta M}{\delta T^2} = \alpha^2 A - \gamma^2 C + \gamma\beta B + \gamma\beta B + \beta^2 C \qquad (19)$$

Fig. 3. Multiplying lever for measuring dashpot time constant Tr.

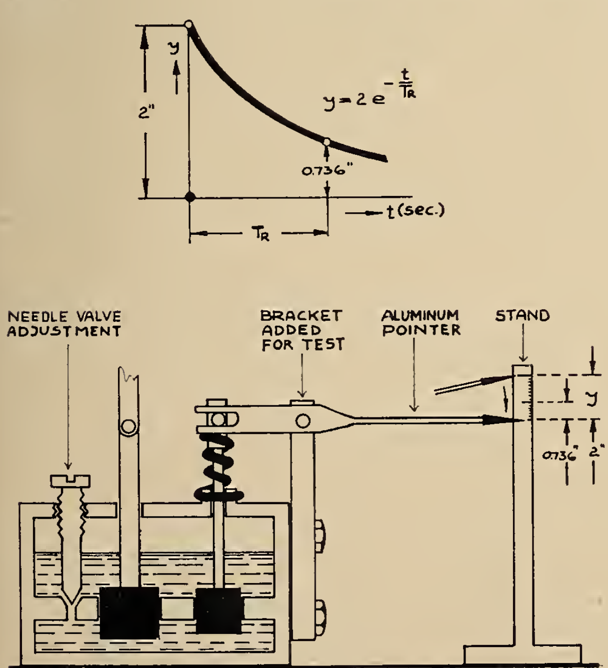

Fig. 4. Typical governor: without speed droop (left), with speed droop (right).

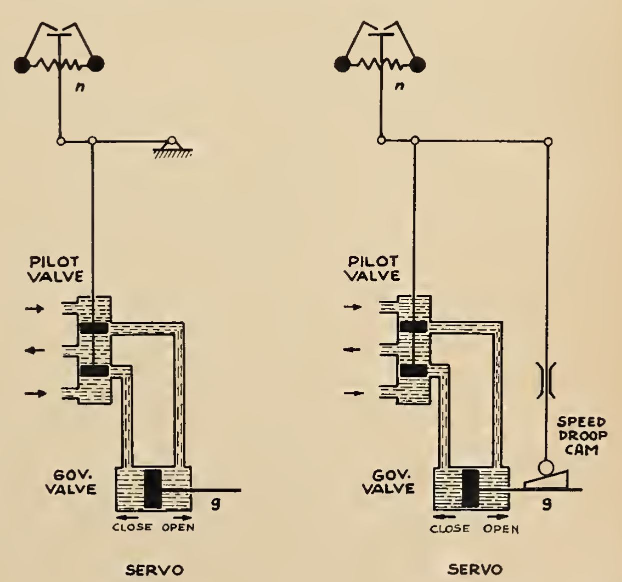

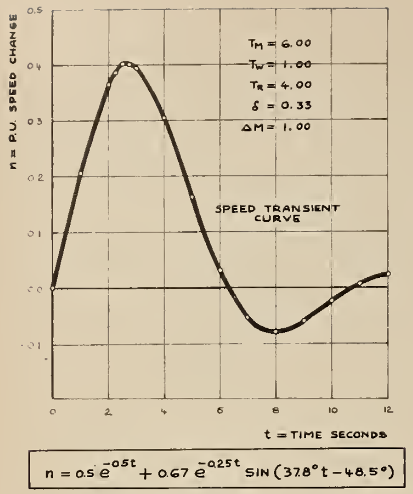

Fig. 5. Typical speed transient characteristic of a hydro governor.

Since at $n = 0$, $t = 0$, we have

$$A = -G$$

$$\frac{\Delta M}{Tm} = (\alpha - \beta)A + \gamma B \qquad (20)$$

$$\frac{2\Delta M}{\delta Tm^2} = (\alpha^2 - \beta^2 + \gamma^2)A + 2\gamma\beta B \qquad (21)$$

From (20) and (21) we can eliminate B and therefore

$$A = \frac{\frac{2\Delta M}{Tm}\left(\frac{1}{\delta Tm} - \beta\right)}{(\alpha - \beta)^2 + \gamma^2}$$

Using this value of A in (19) we can determine B.

Example:

For Winnipeg River we have say $Tm = 6$, $Tw = 1$, $= 0.333$ $Tr = 4$. Substituting these values in original equation gives

$$4\frac{d^3n}{dt^3} + 4\frac{d^2n}{dt^2} + 3\frac{dn}{dt} + n = 0 \qquad (22)$$

Aux. equation is

$$P^3 + P^2 + 0.75P + 0.25 = 0$$

Try first root say -0.5

$$P + 0.5 \overline{\big)\, P^3 + P^2 + 0.75P + 0.25} \; (P^2 + 0.5P + 0.5)$$
$$\underline{P^3 + 0.5P^2}$$
$$0.5P^2 + 0.75P$$
$$\underline{0.5P^2 + 0.25P}$$
$$0.5P + 0.25$$
$$\underline{0.5P + 0.25}$$
$$0$$

Solution of Quadratic

$$p = \frac{-0.5}{2} \pm \frac{\sqrt{0.5^2 - 4 \times 0.5}}{2}$$
$$= -0.25 \pm j0.66$$

Three roots are therefore

$$-0.5 \quad -0.25 + j0.66 \quad -0.25 - j0.66$$
$$\therefore \alpha = -0.5 \quad \beta = -0.25 \quad \gamma = 0.66$$

Solution of equation

$$n = Ae^{-0.5t} + e^{-0.25t}(B \sin 0.66t + C \cos 0.66t)$$

For step function change load off

$\Delta M = -(-1)$, $Tm = 6$, $\delta = 0.333$

$$A = \frac{\frac{2}{6}\left(\frac{1}{0.333 \times 6} + 0.25\right)}{(-0.5 + 0.25)^2 + 0.66^2}$$

$$A = 0.5$$
$$1/6 = (-.5 + .25)\,.5 + .66B \text{ See Eq. 20}$$
$$B = 0.443$$
$$\therefore A = 0.5$$
$$B = 0.443$$
$$C = -0.5$$

$$n = 0.5\,[e^{-0.5t} + 1.33e^{-0.25t}\sin(37.8^0 t - 48.5^0)]$$

This characteristic is plotted on Fig. 5.

Governor Equations in Terms of $\tau = t/Tw$: If we measure t in terms of Tw so that $\tau = t/Tw$ the original equations now become

$$\frac{Tm}{Tw}\frac{dn}{d\tau} = g + 1.5h - \Delta M$$

$$-0.5\frac{dh}{d\tau} = \frac{dg}{d\tau} + h$$

$$-\frac{\delta Tr}{Tw}\frac{dg}{d\tau} = \frac{Tr}{Tw}\frac{dn}{d\tau} + n$$

and the main differential equation of n, using the terms λ_1 and λ_2 now becomes

$$\frac{0.5}{\lambda_1\lambda_2}\frac{d^3n}{d\tau^3} + \left(\frac{1 - \lambda_1}{\lambda_1\lambda_2}\right)\frac{d^2n}{d\tau^2} + \frac{(1 - \lambda_2)}{\lambda_2}\frac{dn}{d\tau} + n = 0 \qquad (23)$$

The initial conditions are now for $\tau = 0$ and for load off

$$n = 0$$
$$\frac{dn}{d\tau} = \frac{Tw}{Tm}\Delta M$$
$$\frac{d^2n}{d\tau^2} = 2\lambda_1\frac{Tw}{Tm}\Delta M$$

It will be noted that for the selected $\lambda_1 = 0.5$ and $\lambda_2 = 0.25$ for Winnipeg River plants, equation (23) has exactly the same co-efficients as equation (22), namely:

$$4\frac{d^3n}{d\tau^3} + 4\frac{d^2n}{d\tau^2} + 3\frac{dn}{d\tau} + n = 0$$

and therefore the roots are the same.

The solution can now be obtained in terms of $Tw/Tm \cdot \Delta M$ and we have for the arbitrary constants

$$A = -C$$
$$\frac{Tw}{Tm}\cdot\Delta M = -0.25A + 0.66B$$
$$\frac{Tw}{Tm}\cdot\Delta M = 0.624A - 0.33B$$

from which $A = \dfrac{3Tw}{Tm}\cdot\Delta M$

$$B = \frac{2.65Tw}{Tm}\cdot\Delta M$$
$$C = -\frac{3Tw}{Tm}\cdot\Delta M$$

The solution of the equation in terms of Tw, Tm, ΔM and the selected λ_1 and λ_2 is

$$n = \frac{3Tw}{Tm}\Delta M\,[e^{-0.25t} + 1.33e^{-0.5t}\sin(37.8^0 t - 48.5^0)]$$

The expression in brackets has a peak value of 0.8, see Fig. 5, therefore, n has a peak value of $2.4(Tw/Tm)\cdot\Delta M$ This latter expression shows that for given values of λ_1 and λ_2 the maximum speed deviation is proportional to Tw/Tm and to ΔM. This simple relationship is very useful in determining the maximum speed deviation for a given step load change when λ_1 and λ_2 are fixed and allows one to quickly estimate the maximum speed change for a given small load change in relation to Tw and Tm.

This relationship[1] is sometimes expressed

$$\frac{\Delta n}{N_0} = K\cdot\frac{Tw}{Tm}\cdot\frac{\Delta p}{P_0}$$

where $K = 2.4$ for selected λ_1 and λ_2

$$\frac{\Delta n}{N_0} = \frac{\text{Change in speed}}{\text{Rated Speed}}$$

$$\frac{\Delta p}{P_0} = \frac{\text{Change in Power}}{\text{Rated Power of Generation on Line}}$$

For example, using Winnipeg River constants, if $Tw = 1$, $Tm = 6$ and $\Delta p/P_0$ say 0.10 p.u.

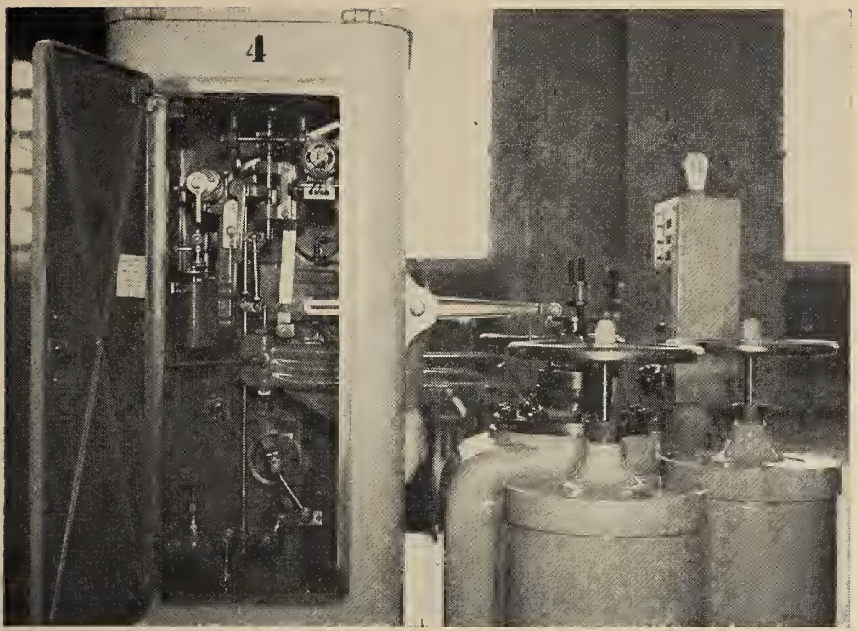

Fig. 6. View of typical actuator governor.

$$\frac{\Delta n}{N_0} = 2.4 \times \frac{1}{6} \times 0.10 = 0.04 \text{ p.u.}$$

speed change or 2.4 cycles for a 10% load change.

Derivation of Simple Governor Equations: Using the same nomenclature and per unit constants as previous and referring to Fig. 4.

Acceleration equation

$$Tm\frac{dn}{dt} = g - \Delta M \qquad (24)$$

When n increases, valve closes and g decreases. However, as n increases g decreases at a time rate depending on a gate closure time say Tg seconds, therefore, the governor equation can be written

$$\frac{dg}{dt} = -\frac{n}{Tg} \qquad (25)$$

Differentiating (24) and substituting (25) we have

$$Tm\frac{d^2n}{dt^2} = -\frac{n}{Tg}$$

This is the familiar simple harmonic motion equation whose general solution is

$$n = A \sin \frac{1}{\sqrt{TmTg}}\, t + B \cos \frac{1}{\sqrt{TmTg}}\, t$$

which shows that the speed is unstable and oscillates up and down at a frequency

$$f\,\frac{1}{2\pi} \cdot \frac{1}{\sqrt{TmTg}}$$

It is obvious that this is an impractical form of governor.

Referring to Fig. 4 it can be observed that the introduction of the cam on the valve rod results in a slower steady state speed as the valve opens.

The equations developed below indicate that this droop produces a stable governor.

Let δ = per unit speed droop of the governor so that for full opening of the valve the steady state speed is permanently down by δ.

The equations now are

Acceleration equation

$$Tm\frac{dn}{dt} = g - \Delta M \qquad (26)$$

Governor equation

$$\frac{dg}{dt} = -\frac{1}{Tg}(n + \delta g) \qquad (27)$$

From (26) $g = Tm\frac{dn}{dt} + \Delta M \qquad (28)$

and $$Tm\frac{d^2n}{dt^2} = \frac{dg}{dt} \qquad (29)$$

Substituting (28) and (29) in (27) we have

$$Tm\frac{d^2n}{dt^2} + \frac{Tm}{Tg}\frac{dn}{dt} + \frac{n}{Tg} = -\frac{\delta \Delta M}{Tg} \qquad (30)$$

The above differential equation (30) represents the well known damped simple harmonic motion, where the damping element is the middle term and is dependent on the speed droop δ. By proportioning the parameters δ, Tm, Tg, various degrees of stability can be achieved as follows:

(1) Highly oscillatory — Low δ, Tm, Tg

(2) Critically damped — $\delta = 2\sqrt{\frac{Tg}{Tm}}$

(3) Over damped — High δ, Tm, Tg

Note that if a signal proportional to acceleration dn/dt can be injected into the governor mechanism in place of speed droop, this will stabilize the machine. This is the principle used in accelerometric governing as used extensively in Europe.

When equation (30) is solved we find that for a load off of 1.0 p.u. the sytem overshoots and then settles down at a steady state speed of $1 + \delta$. The governor mechanism as shown in Fig. 4 is that normally used in steam turbines where Tg can have a relatively low value, and it is therefore possible to operate stably with low values of speed droop in the order of 0.04 to 0.06 per unit. With these low values of droop it is not necessary to provide secondary compensation as is done on a hydro governor.

After a permanent load change for an isolated machine the speed is corrected back to normal by manually adjusting the governor to a different speed droop line.

AN EXERCISE IN OPERATIONS RESEARCH RCAF AIRCRAFT MAINTENANCE

A. B. Howell, M.E.I.C.,
Wing Commander, S.O.A.E.
RCAF Training Command, Westwin, Man.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

Operations Research is a general term that covers many forms of managemen study, but particularly includes mathematical techniques of analysis. The aim of Operations Research has been described by Frank Sawyer of the B.C. Research Council in Western Business and Industry, Aug., 58 as "to maximize the ratio of science to art in the field".

Two major categories of aircraft field maintenance work in the RCAF are the performance of periodic inspections, and the repair of unserviceabilities as they occur in use. The Periodic Inspection which will be classed as a form of unserviceability for the uses of this paper is exactly related to flying hours by definition. The incidence of unserviceabilities caused by component failure or breakdown might also be presumed to be related to flying hours by cause and effect, but a relationship in this has never been fixed for any type of aircraft except in very general terms.

It is the intention in this paper to derive more exact expressions for aircraft group response to use and change, and by relating these expressions to work equations, develop deterministic analyses for the better guidance of maintenance and flying management.

Three assumptions are made (a) Aircraft of the same production identity are subject to a consistent pattern of failure in use, provided their environments, and the techniques of handling applied to them are the same; (b) Handling techniques are subject to a similar pattern of consistency where operators receive the same training, and employ that training to the same ends; (c) The effect of environment upon failure patterns can be isolated and evaluated if the two previous assumptions are correct.

THE DEVELOPMENT OF THE BASIC MATHEMATICAL MODEL

THE FAILURE PATTERN: The overall pattern of failure displayed by an aircraft typical of a group or a fleet of aircraft is a composite of the failure patterns of its various classes or categories of equipment—the engines, the airframe and so on. The failure patterns of individual classes of equipment are separable from each other, but for the broad purpose of this paper the composite pattern will be taken as being as capable of unique identification as the individual pattern may be. Individual patterns may be dealt with as special cases, by extension of the general method.

Symbols and definitions

- N = total number of aircraft on active establishment.
- N_s = number of serviceable aircraft.
- N_u = number of unserviceable aircraft.
- F = flying hours.
- RU = rate at which aircraft become unserviceable (declared).
- RS = rate at which aircraft become serviceable.
- TU = the period of time the average aircraft remains unserviceable during one serviceable plus unserviceable cycle.
- TS = the period of time the average aircraft remains serviceable during one serviceable plus unserviceable cycle.
- TC = the period of time for one serviceable plus unserviceable cycle = $TU + TS$.
- Serv = serviceability = N_s/N
- F/N = flying rate.
- F/N_s = flying intensity.
- SL = Sortie length.

Equilibrium: Only states of equilibrium will be dealt with. At equilibrium the rate at which aircraft become unserviceable is equal to the rate at which they become serviceable, i.e.,

$$RU = RS$$

Rates of becoming Serviceable and Unserviceable, RU and RS: The rate at which aircraft become unserviceable (RU) can be expressed in a number of ways, but whatever form the expression may take it must reflect the following influences:

(a) the effect of periodic inspections (which include modification work);

(b) the attrition effect of flying;

(c) in contrast to (b) above the beneficial effect of increasing sortie length and flying on serviceability;

(d) the attrition effects of ground handling and ground running, which continue whether flying is done or not.

The first agency is simply expressed. Periodic inspections occur exactly in step with flying hours. The expression is:

$$C_1F$$

The second agency is also a function of flying; one can expect the incidence of repair and servicing work to vary first with the type of aircraft, and second with the flying hours. The expression is then of the same form as the expression for inspections, it is:

$$C_2F$$

The third agency is actually a modification of the second. It is a common belief that the ratio of unserviceabilities to flying hours decreases as the intensity of flying (F/N_s) increases. It is certain that Sortie length while perhaps having no effect on the incidence of component breakdown as a function of flying hours, will have an effect on the number of component failures that are involved with each declaration that an aircraft is unserviceable. These two agencies can be expressed conveniently in one factor leading to the tentative expression:

$$C_2F\left[\frac{K - (F/N_s)}{K}\right]\frac{1}{SL}$$

The fourth and last agency is operative only while aircraft are serviceable, its effect will therefore vary directly with the number of serviceable aircraft. The expression is:

$$C_3(N_s)$$

(This may also be taken to include electron "tube" failures which sometime appear more closely tied in with start-up and shut-down than with time-in-use.)

The influences can reasonably be assumed to be independent in their action. The complete expression for RU is then

$$RU = C_1F + C_2F\left[\frac{K - (F/N_s)}{K}\right]\frac{1}{SL} + C_3N_s$$

Division by N_s will simplify

$$\frac{RU}{N_s} = C_1\frac{F}{N_s} + C_2\frac{F}{N_s}\left[\frac{K - (F/N_s)}{K}\right]\frac{1}{SL} + C_3$$

The rate at which aircraft are made serviceable (RS) is the governing rate; and is a measure of the capacity of the Maintenance organization for doing work. The limit of this capacity sets RS and in inevitable sequence the flying rate F/N and RU.

TU and TS

The period of time the average aircraft spends unserviceable (TU) depends upon a number of factors; the nature of the average unserviceability, the organization of manpower, the facilities, the equipment, the quality of supervision, and so on. These factors resolve to a constant, perhaps unique to a given set of circumstances and a certain locale, but still a constant. The variables are manpower MP and RU

$$TU = fcn(MP, RU)$$

TS is a function of aircraft handling and of flying intensity.

$$TS = fcn[(F/N), \text{serv}]$$

Function Relationships at Equilibrium ($RU = RS$): The number of aircraft serviceable (N_s) and therefore available for flying depends on RS, RU, TU and TS. Expressions that link these terms can be derived.

Consider a situation where all aircraft are unserviceable and the function of RS is temporarily suspended

i.e. $N_s = 0 \quad RS = 0$

Consider now that Maintenance work commences at time = 0 and is progressively taken in hand at the rate RS. After a time TU the first aircraft become serviceable, and thereafter aircraft become serviceable at the rate RS. (See Fig. 1.)

Consider also that flying commences with the provision of the first serviceable aircraft. After a time TS (during which aircraft continue to be made serviceable at the rate RS) serviceable aircraft begin to become unserviceable at the rate RU. At this point if $RU = RS$ the fund of aircraft made serviceable (N_s) will remain at this value until the equilibrium state $RU = RS$ is disturbed

$$N_s = RS \cdot TS$$

Similarly $N_u = RU \cdot TU$

At equilibrium $RU = RS$

$$N_s + N_u = RS \cdot TS + RU \cdot TU$$
$$N = RU(TS + TU)$$
$$= RU \cdot TC$$

$$\text{Serviceability} = \frac{N_s}{N} = \frac{RS \cdot TS}{RU \cdot TC} = \frac{TS}{TC}$$

$$TU = \frac{1 - \text{serv}}{\text{serv}} \cdot TS \quad \text{and so on.}$$

WORKLOAD EQUATIONS AND THE OPERATIONS CURVE

The Datum Point

In dealing with manpower, and its output under workload, it is necessary to define some basic and measurable standard of manpower potential, from which calculations can be extended. The point at which this basic measurement of potential will be made will be called the Datum Point, and it is defined as:

That point of reference chosen from field data where the workload and the manpower in use are in balance and where defined standards of efficiency economy and work quality are maintained.

The Field Work Pattern

Fig. 2 shows a typical curve of field operations (Curve 1) in the convenient coordinates of Serviceability and Flying Rate. This field curve pretty exactly reflects demand, and may, but more probably does not maintain equilibrium in its excursions from the Datum Point. The second curve (Curve 2) is developed on the premise of equilibrium at all points, and a linear relationship between output response and Flying Rate; this curve reflects a regular progression in developed potential for sustained equilibrium under varying workload (the arguments for this type of curve will follow in their place) and is shown here for the sake of comparison.

Week by week workload (flying hours) will vary because of weather, change of task, peaks and valleys in operational demand. This variance must be accepted by the working contingent. Technical management must use the manpower potential available to a maximum advantage. This is done by alternating periods of relative strain with periods of relative relaxation coinciding with rising and falling demand. Thus area (B) may be considered as representing a state of relative strain (relative to Datum Point effort), and area (A) is a state of relative relaxation. In passage from area (A) to area (B) or area (B) to area (A) work output (and workload at equilibrium) goes through the Datum Point.

This cyclic phenomenon is particularly marked in operational stations as in Air Division or in Air Defence Command; it is less marked at Training units where the flying task is more constant and predictable, but it is evident to some degree at all RCAF flying units.

Symbols and Definitions

- dp = datum point.
- I = time a/c remains u/s for average inspection.
- S = time a/c remains u/s for average failure.
- a/c = aircraft.
- AE = aero-engine.
- AF = air-frame.
- I_w = the time the average a/c is actually under work during I.
- S_w = the time the average a/c is under work during S.

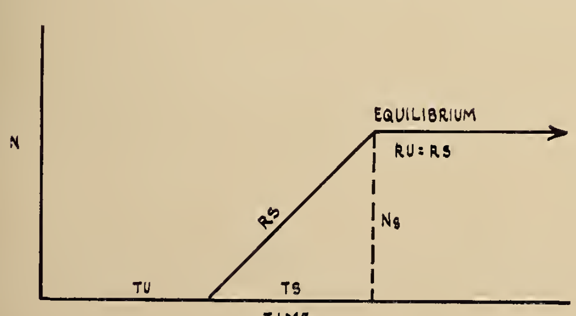

Fig. 1. Function relationship.

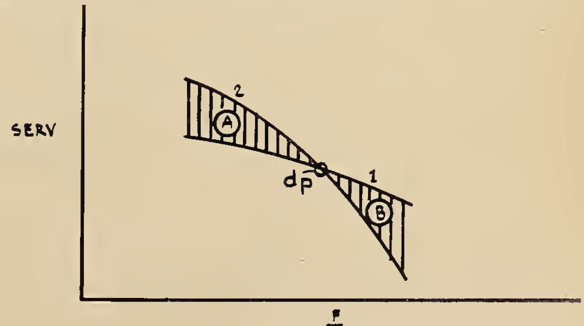

Fig. 2. Theoretical and field work patterns. Curve 1 is the field work curve.

M_i = the number of tradesmen fully employed during the average inspection.
M_s = the number of tradesmen fully employed during the average snag rectification.
γ = $I_w M_i$ — the man days required to perform the average inspection.
β = $S_w M_s$ — the man days required to perform the average rectification of failure.
M_{serv} = the number of tradesmen necessarily allotted full time to Servicing duties.
TMP = total manpower, Maintenance plus Servicing.
MP = manpower general.
MPa = manpower available for repair and inspection work.
MPr = total manpower required for repair and inspection work.
Q = Queue.
K, C = constants.
Subscript i = inspection.
Subscript s = snags.
Subscript w = work.

$$a = C_1 \frac{F}{N}$$

$$b = C_2 \frac{F}{N}\left[\frac{K - (F/N_s)}{K}\right]\frac{1}{SL} + C_3 \text{ serv}$$

$$A + B = (a + b)\frac{1}{\text{serv}}$$

Aircraft Trades and Manpower Calculations

There are seven trades involved in the maintenance and servicing of RCAF aircraft. In calculations to follow only the personnel in the trades of AE and AF are considered. The reason for this is that the other trades Electrical, Instrument, and so forth, can be considered auxiliary, not in importance of course, but in functions and numbers. The trades of AE and AF contain the major proportion of tradesmen; the work of AE and AF is easier to observe and record than of auxiliary trades because they participate from the beginning to the end of any inspection, and they are at least equally if not more involved in repair work. From these circumstances, and by the fact that the numbers of auxiliary tradesmen bear a constant proportionate relationship to the number in the primary trades of AE and AF for any given aircraft and given task, the complication of directly calculating their work can be avoided, as when the number of AE and AF tradesmen are determined for a given circumstance, the total number of tradesmen required can be obtained by the proportionate addition of auxiliaries. Throughout this paper manpower calculations will be of AE and AF only; the all-trades manpower values being neglected for the sake of simplicity.

Manpower Required (MPr): The equation for Manpower Required per aircraft is obtained by multiplying the elements of inspections unserviceability rate, and the breakdown rate in the equation for RU/N by the respective values of mandays required to recover these unserviceabilities, i.e.:

$$a\gamma + b\beta = \frac{MPr}{N}$$

or in terms of F/N_s

$$A\gamma + B\beta = \frac{MPr}{N_s}$$

Manpower Available and Total Manpower: Total manpower (TMP) is considered as being made up of two elements: Manpower available for Maintenance work (MPa) and Manpower necessarily allotted to Servicing tasks (M_{serv})

$$TMP = MPa + M_{serv}$$

or $$\frac{TMP}{N} = \frac{MPa}{N} + \frac{M_{serv}}{N}$$

The personnel represented by M_{serv} are assumed to be limited in their work to purely Servicing tasks; as refuelling, marshalling, the performance of Daily Inspections, starting up and so on, all functions which have no bearing on Serviceability as such, M_{serv} under the restriction of the definition term "necessarily allotted" will vary with the flying load, and the number of serviceable aircraft, and may be adequately described by the equation:

$$M_{serv} = K_1 N_s + K_2 F$$

or $$\frac{M_{serv}}{N} = K_1 \text{ serv} + K_2(F/N)$$

Because M_{serv}/N is a variable term, the manpower available for Maintenance (MPa/N) will be variable within a fixed complement of manpower TMP/N

$$\frac{MPa}{N} = \frac{TMP}{N} - \frac{M_{serv}}{N}$$

Other MP Relationships: Other relationships of time, task, manpower and unserviceabilities rates are needed for analysis, and may be constructed with the elements of I, S, M_i, M_s and the rate equations for RU/N or RU/N_s.

The rate at which manpower changes tasks per day per aircraft is

$$aM_i + bM_s = \frac{MP \text{ change (or turnover)}}{N} \quad \text{(per day)}$$

The total number of unserviceable aircraft at any time is

$$aI + bS = \frac{N_u}{N} = 1 - \text{serv}$$

The total number of unserviceable aircraft upon which manpower is employed at any time is

$$\frac{(Nu)_w}{N} = aI_w + bS_w$$

The queue of unserviceable aircraft awaiting manpower at any time is

$$\frac{Q}{N} = aI + bS - (aI_w + bS_w)$$
$$= 1 - \text{serv} - (aI_w + bS_w)$$

Other relationships will suggest themselves.

The Standard Operations Curve

An Operations Curve is constructed by extension from a given Datum Point and expresses at every point in its length equilibrium between the rates of becoming unserviceable and recovery ($RU = RS$). The extensions might follow any number of paths, and a Standard Operations Curve against which actual extensions may be compared requires definition.

The Standard Operations Curve will be based on the queue of unserviceable aircraft awaiting manpower

$$\frac{Q}{N} = 1 - \text{serv} - (aI_w + bS_w)$$

The circumstances of a fixed complement of men and a fixed task (F is constant) but a variable number of aircraft in use (N is variable) will occasionally require analysis and for these circumstances the change of queue with changing numbers of aircraft is simply expressed: queue will vary exactly with N, i.e.

$$\frac{Q}{N} \alpha \frac{N}{F}$$

or

$$1 - \text{serv} - (aI_w + bS_w) = K\frac{N}{F}$$

where the constant of proportionality is fixed by the circumstances of the Datum Point.

For a fixed complement of men, a fixed number of aircraft but a variable task (F is variable) which is the more common case, and therefore the more potentially fruitful field for analysis, queue cannot be described so directly or exactly. Queue in this case would seem to be more closely related to manpower and manpower potential than any other element. On this line of reasoning queue will be accepted as varying inversely as the difference between MPa/N and MPr/N, and the Operations Curve that develops from this premise will be taken as the Standard Operations Curve for variable F and constant N for a fixed complement of men, i.e.

$$\frac{Q}{N} = \frac{K}{(MPa/N) - (MPr/N)}$$

or

$$1 - \text{serv} - (aI_w + bS_w)$$

$$= \frac{K}{(MPa/N) - (MPr/N)}$$

where the constant of proportionality and values of I_w and S_w are fixed by the circumstances of the Datum Point. As will be demonstrated, I_w and S_w are necessarily constant for a best utilization of MPa. Typical curves are shown in Fig. 3.

ANALYSIS OF THE TRANSIENT STATE

The Transient State ($RU \neq RS$): Up to this point analysis methods have been developed within the restriction of equilibrium ($RU = RS$). In dealing with the transient state ($RU \neq RS$) a new line of development must be followed. The transient state is probably more common than a state of equilibrium, if we include the small and random fluctuations that invariably, and hour by hour, surround a point or state of equilibrium. But unless these fluctuations become extremely large which would be a rare circumstance, they can be ignored. The significant transient state is the sustained one, usually planned and which can occur or develop in a number of ways. One possible exercise in transients is shown in the two diagrams in Fig. 4.

In the diagrams—point (A) represents point of departure and point of return and is in fact, the Datum Point for the exercise. The transition from (A) to (B) marks a major change in workload, accomplished in what might be thought of as zero time. The line BC marks a true transient state, in this case $RS > RU$. In passage from B to C flying potential (serv) is increased until intersection with the Operations Curve at C restores equilibrium. The transition from C to D is again a major change of workload accomplished in hypothetical zero time; point D being a point of choice. The line DA marks a transient state as did line BC but in this case $RU > RS$. In passage from D to A flying potential decreases until finally intersection with the Operations Curve at A again restores equilibrium. The decline in potential from D to A can proceed by a number of paths, as by constant F/N or constant F/N_s or any desired variation of these rates.

Transient State Calculation: In the transient state $RU \neq RS$ and the recovery rate (RS) may be greater or less than the becoming unserviceable rate (RU) depending on the workload and manpower available.

The rate of change of serviceable aircraft in respect to time must be equal to the difference between RU and RS, i.e.

$$\frac{d(N_s)}{dt} = RS - RU$$

or in terms of (N_s/N) = serviceability

$$\frac{d(N_s/N)}{dt} = \frac{d(\text{serv})}{dt} = \frac{RS}{N} - \frac{RU}{N}.$$

There is an expression for RU/N in terms of F/N and serv. RS/N can be expressed in terms of F/N and serv.

The substitution of these expressions for RS/N and RU/N leads to a differential equation in serv and time (assuming F/N constant or expressible in terms of serv), or substituting for

$$F/N = F/N_s \cdot \text{serv}$$

(assuming F/N_s constant or expressible in terms of serv).

Transient state developments for an exercise based on the pattern of the one shown in Fig. 4 are calculated in Appendix A using typical field data.

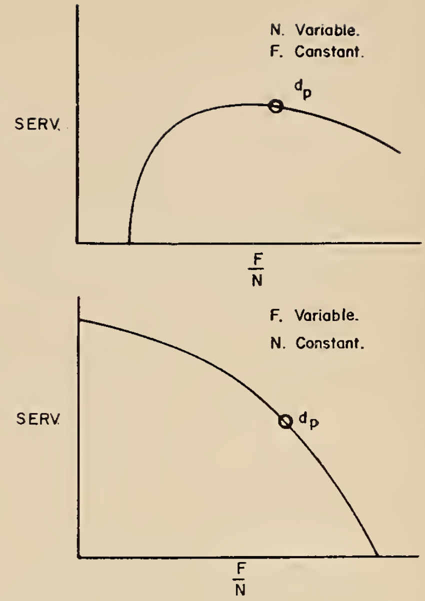

Fig. 3. Typical standard operations curves.

PRACTICAL TESTS OF THE ANALYTIC APPROACH

Collection and Processing of Data

Analytic methods, however useful they may promise in concept, can never be better than the data used in them. So with the development of an analytic method there must be a parallel development of means for collecting data of the desired accuracy, and the simple pro forma directions for data processing.

Samples of the reporting form and the process sheet that have evolved during the course of some 8 months of trial are shown in Appendix C(1) and (2) They cannot be claimed as being the last word, but they achieve three prime requirements:

(a) they provide internal checks for consistency and relative accuracy;

(b) they facilitate a maximum accuracy consistent with the limitations of skill and time that are a part of field personnel and circumstances;

(c) they have been reduced to the barest bones of simplicity, and still provide the essential statistics.

The pro forma for data processing is self-explanatory. A little background however is necessary to evaluate the data reporting form.

There are seven essential elements of aircraft performance data; items B to G of the report form and statistics of loss of effective aircraft through non-availability of components to be replaced—"Awaiting Spares", and "Awaiting Flight Test" shown on the report form.

There are five essential additional elements of data for manpower analysis; these are items H to K of the report, and constants for the M_{serv} equation on the report form. Manpower data for repair and inspection work are based on observation of men employed, and the tasks upon which they are employed, at a defined schedule of times during each working day. The system and the observation schedule can best be described by a diagram. (Fig. 5.) The hatched areas represent MP employed, the vertical dimensions of the hatched areas represent the number of aircraft being worked on.

Manpower data for M_{serv} equations are obtained by continued observation, which is expected by repeated corrections or confirmations of initial estimates to establish accurate values for the constants.

Behind the daily data reporting a secondary system of accuracy checks is employed. The reports themselves provide means of checking relative accuracy; the secondary system is designed to check absolute accuracy and is based on the basic aircraft log books which by routine maintenance procedures are entered for many purposes including the recording of all unserviceabilities. For various reasons these log books do not lend themselves to day by day reference; however they are a good source of history, and should fundamentally be the most accurate if not the most convenient source of unserviceability data. The data supplied by the report forms (recorded independently of log books) are therefore compared for absolute accuracy with data drawn from log books for selected periods in past time.

The log books also provide statistics of total major breakdowns as distinct from total number of declared unserviceabilities. The rates of breakdown and the rates of declaring unserviceable (grounding the aircraft) are found clearly separable except for Harvard aircraft, and the separation can in some degree at least be related with the Sortie Length for the type of aircraft involved.

Field Data Checks

Some data results from Harvard and T33 aircraft are shown in Fig. 7 and 8.

From these and other results it may be deduced that for the basic relationship of RU/N_s against F/N_s

(a) the relationship is essentially linear for the F/N_s values investigated and therefore, for practical purposes the correction factor

$$\left(\frac{K - (F/N_s)}{K}\right)$$

may be neglected for the F/N_s range in use.

(b) The data deviation for collection increments below 500–600 flying hours is in the range of ± 30 per cent, but as the flying hour increments increase, the data deviations diminish so that for flying increments of 1500 flying hours or more innate deviation is not distinguishable from reporting or recording error, which is estimated as ± 5 per cent.

(c) The factor for SL cannot be said to be tested. Sortie Length is relatively constant for any given type of aircraft for Training Command uses. The effect of its variation can be guessed but it could not be confirmed. Therefore for the further uses of this paper the term $1/SL$ will be dropped from the RU equations.

ANALYTIC USES

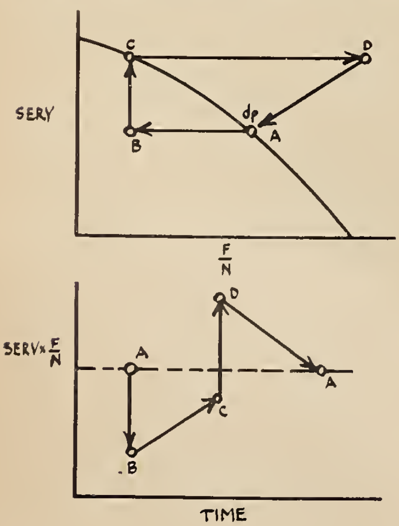
Categories of Investigation

There are two general categories of analysis:

(a) The situation analysis;

(b) extrapolation from the known state to the unknown state through the development of Curves of Performance Indices and Operations Curves.

Fig. 4. A development based on transients.



Performance Indices: The end products of RCAF flying stations activities are many and varied, but the prime one is useful flying hours. Utilization of RCAF aircraft is fixed by definition as so many hours per month per aircraft. This definition sets the basic task goal in terms of F/N. The efficiency with which the task is performed, the economy of resources, the reserve of potential and so on, constitute a fruitful field for analytic investigation and which is best approached through the use of what will be called Performance Indices; a number of useful members of the PI family are:

(a) serviceability

(b) $\text{serv}\,\dfrac{F}{N}$

(c) $\text{serv}\,\dfrac{F}{N}\cdot TS$

(d) $\text{serv}\,\dfrac{F}{N}\left(\dfrac{MPa - MPr}{N}\right)$

(e) $\dfrac{F}{RU}$

(f) $\dfrac{MPr}{F}$

(g) $\dfrac{MPa}{F}$

(h) $\dfrac{MPa - MPr}{N}$

Situation Analysis: A prime use of the situation analysis would be to provide guides to better management of resources in hand, and better utilization of manpower and equipment already in use. The situation analysis is readily directed at the calculation of optimums.

The best way to indicate its use is to give an example.

The daily turn-over of manpower on task has a direct relationship with the number of aircraft held unserviceable under work. The higher the rate of manpower turn-over (and therefore work turn-over) the smaller will be the number of aircraft under task.

The number of aircraft held unserviceable under task is directly related to time on the job, the equation here is

$$\frac{(N_u)_w}{N} = aI_w + bS_w$$

The values of I_w and S_w are fixed by the terms M_i and M_s the average crew sizes for inspection and repair work respectively. The higher these values the lower will be the value of I_w and S_w (γ and β are constant) with a corresponding reduction in $(N_u)_w$.

The values of M_i and M_s fix the rate of manpower turnover per day per aircraft per task for a given flying rate and serviceability

$$MP/N(\text{turnover}) = aM_i + bM_s$$

Then to have a least value of

$$[(N_u)_w]/N$$

M_i and M_s must be at maximum values, but there are two circumstances that make large values of M_i and M_s difficult, the first is the bottleneck effect, by which the number of men that can actually be employed in a task is limited by the accessibility of the task; the second is the organizational difficulty of handling a large crew turnover.

The requirements then are conflicting; both MP/N (turnover) and $[(N_u)_w]/N$ should approach minimum values. An optimum relationship can be derived assuming equal weight for both requirements

$$\frac{(N_u)_w}{N} = aI_w + bS_w \rightarrow \text{a min.}$$

$$\frac{MP\ (\text{turnover})}{N} = aM_i + bM_s \rightarrow \text{a min.}$$

If both equations are to approach a minimum their product must approach a minimum.

$$a^2 I_w M_i + b^2 S_w M_s + ab(S_w M_i + I_w M_s) \rightarrow \text{a min.}$$

but $a^2\gamma + b^2\beta$ and ab are constant in value at a given flying rate and serviceability, therefore

$$S_w M_i + I_w M_s \rightarrow \text{a min.}$$

or

$$S_w M_s \left(\frac{M_i}{M_s} + \frac{I_w}{S_w}\right) = \beta\left(\frac{M_i}{M_s} + \frac{I_w}{S_w}\right) \rightarrow \text{a min.}$$

As β is constant, and as

$$I_w M_i = \gamma \quad \text{and} \quad S_w M_s = \beta,$$

a minimum occurs when

$$\frac{M_i}{M_s} = \frac{I_w}{S_w} = \sqrt{\frac{\gamma}{\beta}}$$

The relationship may be used by comparing actual manpower disposition with it, confirming the disposition as acceptable or establishing the need for adjustment.

PI and Operations Curves

Two examples of uses of PI and Operations Curves will be given.

The first is the calculation of build-up and decay of potential as fixed by defined rates and intensities of flying, and a given Operations Curve. The example will also demonstrate the use of transient equations. The first example is based on Fig. 6.

The exercise is limited to a discussion of potential decay from Point (D) to point (E) given that flying intensity (F/N_s) can be maintained at a constant value from (D) to (E) and that in this passage all unserviceabilities are covered as they occur to the limit of MPa, and inspection work is only undertaken as men can be spared from repair work. The M_i and M_s values remain constant throughout the exercise.

The exercise is based on the following data:

(a) The Datum Point values (at point A) are:

$F/N = 2.0 \qquad \gamma = 40$

$\text{serv} = 0.50 \qquad \beta = 2.0$

$$\left(\frac{MPa}{N}\right)_{dp} = 1.30 \text{ (remains constant)}$$

(b) The RU/N equation is:

$$\frac{RU}{N} = \left(0.01\frac{F}{N}\right) + \left(0.10\frac{F}{N} + 0.10\,\text{serv}\right) = a + b$$

(c) Potential is to be spent by constant $F/N_s = 8.0$, continuing until $F/N = 4.0$ at (E).

(d) The Serviceability at the beginning of the exercise is 0.90.

The questions to be answered are:

(a) How long does it take for the serv to decline from 0.90 at point (D) to 0.50 at point (E)?

(b) How many hours are flown?

The calculations are given in Appendix A and the answers are given in Table I compared for interest with the results if a flying rate of $F/N = 4.0$ had been sustained from (D) to (E) instead of flying intensity of $F/N_s = 8.0$.

Table I
Comparative Answers for the First Example given under PI and Operations Curves

	Time for Potential to Subside from (D) to (E)	Total Flying Hours at (E)
at constant $\frac{F}{N_s} = 8.0$	6.70 days	$33.7N$
at constant $\frac{F}{N} = 4.0$	12.9 days	$51.6N$

In the second example an aircraft establishment of 100 will be reduced to 75 with a reduction in workload but without reduction of a flying task set at 200 hours per day.

The example proceeds in two stages:

(a) an improvement in Serviceability by better manpower disposition between inspections and repair crews based on obtaining a closer approach to the disposition $\frac{M_i}{M_s} = \sqrt{\frac{\gamma}{\beta}}$

(b) an increased flying intensity.

The calculations are extensive and are contained in Appendix D.

The data upon which the calculations are based are as follows:

(a) the original state:

$F/N = 2.0$ (datum point values)

$\text{serv} = 0.60$

$MPa = 3.0 - 0.40(F/N) - 0.20\text{serv}$ (datum point values)

$MPr = 0.44(F/N) + 0.10\text{serv}$ (datum point values)

$I = 7.0$

$S = 0.65 \qquad \gamma = 30$

$I_w = 6.0 \qquad \beta = 1.0$

$S_w = 0.40$

$RU/N = 0.01(F/N) + 0.140(F/N) + 0.10\text{serv}$

(b) in the next step an Operations Curve is generated with improved values of I_w and S_w

$I_w = 3.5 \qquad I = 4.0$

$S_w = 0.40 \qquad S = 0.62$

(The new value of I is based on the change in I_w, S is adjusted to round serv off to 0.70.)

(c) in the last step an Operations Curve is generated on the basis of the data of sub para (b) but the Datum Point is now based on increasing F/N_s from approximately 3.0 to $F/N_s = 5.0$ and the Datum Point moves to $F/N = 2.65$ and serv $= 0.53$.

The original and final states are compared in Table II.

Conclusions

The assumptions of the Thesis appear to be correct, within certain statistical limits and population levels. These limitations rule out discussion of small numbers of aircraft with small accumulations of flying hours. There is still a prospect of useful analysis if large accumulations of flying hours can be gathered for a small population, but the results must be used with caution, as the average aircraft of the small population may not be a true average of the aircraft as a class because a complete stratum of individual variations may not appear.

Data collection for analysis does not require expert attention, once familiarity with the methods and terms is gained.

The analytic method then may be said to have a prospect of day by day use and application. Nothing more can be claimed in advance of test in practice.

Table II
Tabulated Answers to the Second Example given under PI and Operations Curves

	Task	N	Serv	MPr	F/RU	F/N_s
Original	200 Hrs/day	100	0.60	94 mandays/day	5.5	3.3
Final	200 Hrs/day	75	0.53	91 mandays/day	5.8	5.0

Appendix A
Calculations of the Transient State

Step (1). Calculate the difference between the energy available, and manpower required for snag work between D and E. Given—Manpower available per aircraft is

$$\frac{MPa}{N} = 1.30 \text{ mandays/day/aircraft} \qquad \text{at } \frac{F}{N_s} = 8.0$$

$$\left(\frac{MPr}{N}\right)_{\text{snags}} = \left(0.10\frac{F}{N} + 0.10\,\text{serv}\right)\beta$$

$$= \left(0.10\frac{F}{N_s} + 0.10\right)\beta\cdot\text{serv}$$

$$= 1.80\,\text{serv}$$

Then

$$\frac{MPa}{N} - \left(\frac{MPr}{N}\right)_{\text{snags}} = 1.30 - 1.80\,\text{serv}$$

Step (2). Form the Transient Equations.

There are two stages of work applications

Case (a) from serv $= 0.90$ to serv $= 0.72$, i.e. when $1.30 - 1.80\,\text{serv} = 0$ ....(serv $= 0.72$) during which only snags are dealt with

Case (b) from serv $= 0.72$ to serv $= 0.50$ during which more energy is available than is needed for snags and this excess can be applied to inspection work.

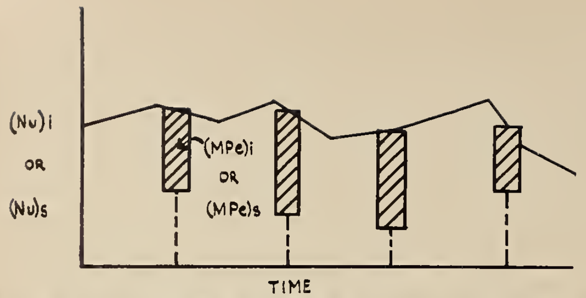

Fig. 5. Manpower observation—method and schedule. The hatched areas represent MP employed, the vertical dimensions of the hatched areas represent the number of aircraft being worked on (Nxi or Nxs of the process sheet Appendix B). Random observations are made within scheduled periods of 30 minutes each.

Case (a)

$$\frac{d(\text{serv})}{dt} = \frac{RS}{N} - \frac{RU}{N}$$

$$= \frac{1.30 - 1.80\,\text{serv}}{\beta} - 0.01\frac{F}{N_s}\cdot\text{serv}$$

$$= \frac{1.30 - 1.96\,\text{serv}}{2}$$

$$dt = \frac{2}{1.96}\,\frac{d(\text{serv})}{(0.66 - \text{serv})} = -1.02\,\frac{d(\text{serv})}{\text{serv} - 0.66}$$

$$t = -1.02\log(\text{serv} - 0.66) + C$$

evaluating C from $t = 0$ at serv $= 0.90$

$$t = 1.02\left[\log\frac{0.24}{\text{serv} - 0.66}\right]$$

Case (b)

$$\frac{d(\text{serv})}{dt} = \frac{1.30 - 1.80\,\text{serv}}{\gamma} - 0.01\frac{F}{N_s}\cdot\text{serv}$$

$$= \frac{0.26 - \text{serv}}{8}$$

$$t = -8\log(\text{serv} - 0.26) + C$$

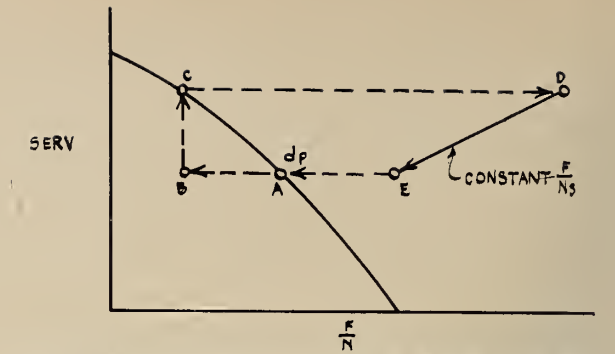

Fig. 6. The transient exercise involving calculation of decay of potential from Point D to Point E described in the text and in Appendix C.

evaluating C from $t = 0$ (for case (b)) at serv $= 0.72$

$$t = 8\log\left[\frac{0.46}{\text{serv} - 0.26}\right]$$

Step (3). Calculate time required

Case (a)	serv = 0.90 to serv = 0.72	$t = 1.42$
Case (b)	serv = 0.72 to serv = 0.50	$t = 5.28$

Total Time = 6.70 days

Step (4). Calculate the Total Flying Hours (TFH)

$$TFH = \left(\frac{F}{N}\right)N\cdot t = \left(\frac{F}{N_s}\right)N\cdot\text{serv}\cdot t$$

$$= 8N\cdot\text{serv}\cdot t = 8N\int\text{serv}\cdot dt$$

Case (a)

$$dt = -1.02\,\frac{d(\text{serv})}{\text{serv} - 0.66}$$

$$TFH = -8.16N\int\frac{\text{serv}\cdot d(\text{serv})}{\text{serv} - 0.66}$$

$$= -8.16N[\text{serv} + 0.66\log(\text{serv} - 0.66)] + C$$

Fig. 7. Three months' data collection (June—July—August 1959) of Total Unserviceabilities from the Log Books of two separate fleets of Harvard aircraft. Each fleet contains 50 a/c.

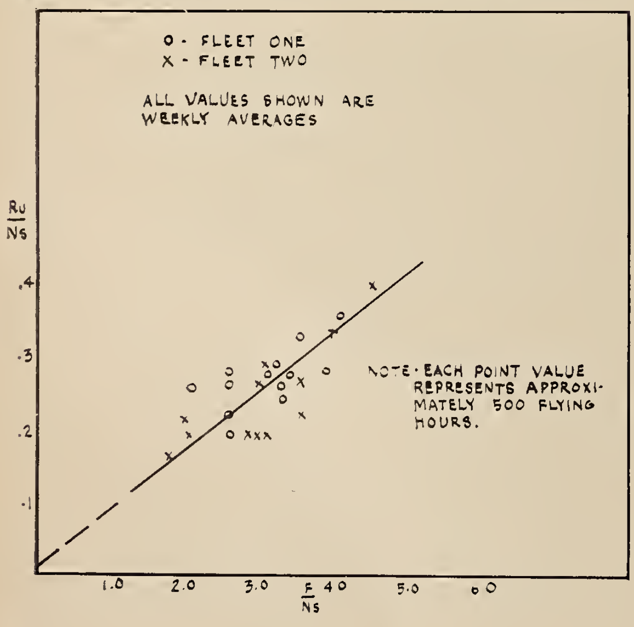

Fig. 8. Data collection from daily records averaged on a semi-monthly basis of incidence of Declared Unserviceabilities for 80 T33 aircraft May to December 1959.

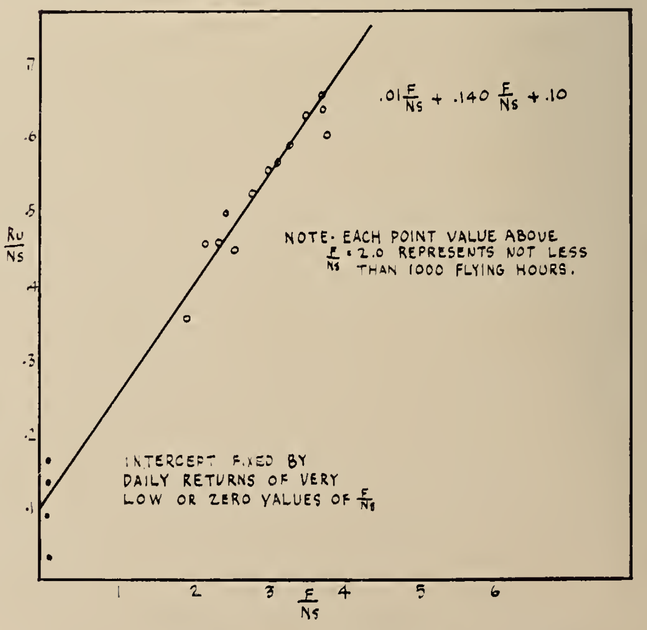

evaluating TFH from serv $= 0.90$ to serv $= 0.72$ gives

$$TFH \text{ for case (a)} = 8.8N$$

Case (b)

$$dt = -\frac{8d(\text{serv})}{\text{serv} - 0.26}$$

$$TFH = -64N[\text{serv} + 0.26 \log(\text{serv} - 0.26)] + C$$

evaluating TFH from serv $= 0.72$ to serv $= 0.50$ gives a

$$TFH = 24.9N \text{ for case (b)}$$

Total TFH serv $= 0.90$ to serv $= 0.50$

$$= (8.8 + 24.9)N = 33.7N$$

Appendix B

Calculations for Problem on Aircraft Establishments

Step (1). Calculate the equation for the original Operations Curve, calculate F/RU, MPr/MPa, and MPr.

The standard Operations Curve equation is

$$1 - \text{serv} - (aI_w + bS_w) = \frac{K}{(MPa/N) - (MPr/N)}$$

$$1 - \text{serv} - \left(0.06\frac{F}{N} + 0.056\frac{F}{N} + 0.04 \text{ serv}\right)$$

$$= \frac{K}{3.0 - 0.40(F/N) - 0.20 \text{ serv} - 0.44(F/N) - 0.10 \text{ serv}}$$

$$1 - 1.04 \text{ serv} - 0.116\frac{F}{N} = \frac{K}{3.0 - 0.84(F/N) - 0.30 \text{ serv}}$$

K is calculated from the dp values $F/N = 2.0$ serv $= 0.60$ and the original Operations Curve equation is

$$2.83 - 1.19\frac{F}{N} - 3.42 \text{ serv} + 0.097\left(\frac{F}{N}\right)^2$$

$$+ 0.91 \text{ serv} \cdot \frac{F}{N} + 0.31 (\text{serv})^2 = 0$$

The equation for $$\frac{MPr}{MPa} = \frac{0.44(F/N) + 0.10 \text{ serv}}{3.0 - 0.40(F/N) - 0.20 \text{ serv}}$$

$$\frac{MPr}{MPa} \text{ at the } dp = 0.452$$

$$\frac{MPr}{N} \text{ at the } dp = 0.94N$$

MPr with $N = 100 = 94$ mandays/day

Now calculate the equation for F/RU

$$\frac{RU}{N} = 0.15\frac{F}{N} + 0.10 \text{ serv}$$

$$1.0 = 0.15\frac{F}{RU} + 0.10\frac{N_s}{RU}$$

$$\frac{F}{RU} = \frac{1 - 0.10(N_s/RU)}{0.15} = 6.6 - 0.66\frac{N_s}{RU}$$

APPENDIX C. (1.)

β	Sw × Ms	
γ	Iw × Mi	
MP_R/N	$a\gamma + b\beta$	

$$= 6.6 - \frac{0.66}{0.15(F/N_s) + 0.10}$$

$$\frac{F}{RU} = 6.6 - \frac{4.4}{(F/N)\cdot(1/\text{serv}) + 0.66}$$

F/RU at dp for the original state is

$$6.6 - \frac{4.4}{4.0} = 5.5$$

Step (2). Calculate the equations for the Operations Curve with an improved value of $I_w (I_w/S_w$ and M_i/M_s more closely approaching $\sqrt{\gamma/\beta})$. This time

$I_w = 3.5$, $I = 4$ $S = 0.62$

$$1 - \text{serv} - \left(0.035\frac{F}{N} + 0.056\frac{F}{N} + 0.04 \text{ serv}\right)$$

$$= \frac{K}{3.0 - 0.84(F/N) - 0.30 \text{ serv}}$$

evaluating K at $F/N = 2.0$ serv $= 0.70$ gives the general equation

$$2.91 - 1.11\frac{F}{N} - 3.42 \text{ serv} + 0.89 \text{ serv} \cdot \frac{F}{N}$$

$$+ 0.076\left(\frac{F}{N}\right)^2 + 0.31(\text{serv})^2 = 0$$

APPENDIX C. (2.)

The equation for MPr/MPa is the same as in Step (1), then

$$\frac{MPr}{MPa} = 0.46 \qquad \left(\frac{MPr}{N}\right)_{dp} = 0.95N$$

$$MPr \text{ at } N = 100 = 95 \text{ mandays/day}$$

The equation for F/RU is the same, then

$$\frac{F}{RU} = 5.4$$

Step (3). Calculate the Operations Curve equation for the final step. This development is based on the same data as for Step (2) except that N is reduced to 75, $F/N_s = 5.0$.

$$F \text{ is still } 200 \qquad \frac{F}{N} = 2.65 \qquad \text{serv} = 0.53$$

$\frac{MPa}{N}$ takes on a new value

$$\frac{MPa}{N} = 4.0 - 0.40\frac{F}{N} - 0.20 \text{ serv} \qquad (N \text{ now } = 75)$$

then

$$1 - 1.04 \text{ serv} - 0.091\frac{F}{N} = \frac{K}{4.0 - 0.84(F/N) - 0.30 \text{ serv}}$$

evaluating K at the dp values of $F/N = 2.65$ serv $= 0.53$

$$3.75 - 1.21\frac{F}{N} - 4.55 \text{ serv} + 0.076\left(\frac{F}{N}\right)^2$$

$$+ 0.91 \text{ serv} \cdot \frac{F}{N} + 0.31(\text{serv})^2 = 0$$

$$\frac{MPr}{MPa} = \frac{0.44(F/N) + 0.10 \text{ serv}}{4.0 - 0.40(F/N) - 0.20 \text{ serv}}$$

$$\left(\frac{MPr}{MPa}\right)_{dp} = 0.432$$

$$\frac{MPr}{N} = 1.21$$

$$MPr \text{ at } N = 75 = 91 \text{ mandays/day}$$

The equation for F/RU is the same as before, then

$$\frac{F}{RU}(\text{at} dp) = 5.81$$

SOIL PROBLEMS IN MINING ON THE PRECAMBRIAN SHIELD

R. F. Legget, M.E.I.C.
Director, Division of Building Research, National Research Council, Ottawa.

W. J. Eden, M.E.I.C.
Research Officer, Soil Mechanics Section, Division of Building Research, National Research Council, Ottawa.

Presented at the E.I.C. Annual General Meeting, Winnipeg, May 1960.

Soils encountered in mining operations on the Precambrian Shield are almost all glacial in origin, ranging all the way from well-drained sand and gravel deposits, such as eskers and some moraines, to the silts and clays deposited in glacial lakes. All too many experiences in Canadian mines have shown that the latter cannot safely be regarded as "just mud" to be moved or built upon as the case may be. The character of typical glacial clays is described, and the reason for their unusual properties—an artificially high natural moisture content—is explained. Against this background examples are given of satisfactory experience in handling such material (as at Steep Rock) and in founding mining structures upon them (as in the Malartic field), with some constructive reference to troubles that have been experienced elsewhere with soils of this type.

WHEN subsurface exploration work is carried out at a mining property, the soil mantle covering the bedrock is generally considered to be mainly a nuisance, delaying the drilling program and increasing its cost. The driller usually lists the soil mantle simply as "overburden" or "soil" without attempting any detailed description. Although soil is regarded by exploration drillers, and even by some mining engineers, as an impediment to their work, it can be the over-riding factor in determining the economic feasibility of a mining property. Two of the most serious failures of mining enterprises on the Shield were due to soil and not to rock problems. The purpose of this paper is to demonstrate that a general knowledge of the properties of soils can be of fundamental importance to any mining development program and that soil conditions at a mining property can be assessed as a part of the exploration program for the orebody at small additional cost.

Soils of the Shield

The present physiography of the Precambrian Shield has been largely determined by the Wisconsin glaciation. The entire Shield was covered by a continental ice sheet which removed almost all previously existing superficial deposits and many of the softer rocks of the Shield. The drainage pattern previously existing was disturbed leaving a new and very young drainage system. The Shield also inherited a sporadic mantle of unsorted glacial till usually granular in character. On higher ground, gravel deposits such as kames, eskers, and terraces are numerous. Deposits such as these have assisted greatly in the construction of transportation routes in otherwise difficult terrain.

Some parts of the Shield have been subjected to inundation by glacial lakes, and by the sea along the Gulf of the St. Lawrence and along the Arctic coast. In such areas, lacustrine and marine deposits occur which are usually more troublesome than the glacial and glacial-fluvial soils. Most of these soils are comparatively recent in origin and have been subjected to very little erosion due to the generally poor drainage conditions. Because of the poor drainage, peat deposits have accumulated on the surface of much of the Shield; these are now widely known as the Canadian phenomenon of "muskeg".

The water-laid fine-grained soils of the Shield can conveniently be grouped into three classes: lacustrine sands and silts, fresh water varved clays and silts, and post-glacial marine clays. The last-named group occurs only in the St. Lawrence lowlands below elevation 700 and along Hudson Bay, James Bay and the Arctic coast below elevation 800 ft.[1] The varved clays and silts have a much wider distribution, being confined to former glacial lake basins. They are characterized by a laminar structure consisting, usually, of alternating layers of silt or silty clay and clay. Lacustrine silts and sands are also widely distributed in the vicinity of the old glacial lakes, being frequently associated with the varved clays.

It is the varved clays that are so frequently encountered in mining operations on the Shield. When disturbed they liquefy very easily and so constitute the "mud" that is so often an impediment to Canadian mining development. Unless carefully examined, the varved structure of these soils may not be recognized but it is usually present even though it does not affect directly the instability of the soils when they are disturbed. Many mining engineers will have seen small slides in this type of soil but its basic instability is most pointedly illustrated by the experiences at the Beattie and the Josephine Mines. These will be summarized but only with constructive intent, so that the failures involved may form a background for a better appreciation of the character of some of the soils met with on the Shield, which it is the purpose of this paper to illustrate.

The Josephine Mine: October 1946

The Josephine Mine[2] was started in 1941 to win iron ore that had been found in a vertically inclined body of haematite under Parks Lake in the Algoma District of Northern Ontario. To control underground water, it was decided to dewater Parks Lake and to provide a permanent surface pumping installation to take care of local drainage. The sediments in the bottom of Parks Lake, consisting of 5 or 6 ft. of organic ooze on the surface underlain by 6 or 7 ft. of fine bluish silt, and the remaining depth, varved clay, were left undisturbed after the dewatering operation. A vertical shaft was then sunk at a site adjacent to the lake to a depth of 1225 ft. Seven levels were established at 265 ft., 415 ft., 515 ft., 715 ft., 815 ft., 1015 ft., and 1190 ft. respectively below the shaft collar. Fig. 1 shows a vertical section of the mine.

Mining started in November 1945, ore being won by the open stope method, working from the lower levels up. It continued until 13 October 1946 by which time 173,000 tons of haematite had been extracted. By the end of June, the 6-36 stope had caved up to 30 ft. above the fifth level. Caving continued during July and August and the stope seemed to increase above the fifth level. On 14 September, men working on the fourth level heard considerable caving in the east end of the mine and examination showed that the 36 stope was caving rapidly. By the end of September the cave had opened the stope to a height of 35 ft. above the fourth level. Movements continued and it was soon impossible to follow the progress of the caving in detail. A simple calculation, based on the known expansion of broken ore relative to ore in place, showed that caving could not continue beyond the third level. Despite this a slight depression in the lake bottom was observed on 9 October.

This depression had the general outline of the 36 stope and was located directly over it. As no increase in water was noted underground, operations were allowed to proceed. A small quantity of muck was pulled from the 36 stope to check for a further depression. Between 9 and 13 October, 220 tons of ore were drawn from the stope. As a result, in the early morning of 13 October, a further subsidence was noted.

At 9.30 a.m., the shift boss found black gelatinous ooze in the east end of the fifth level. It was coming through the broken ore in the workings. Immediately salvage work was started on a round-the-clock basis. From 13 to 15 October salvage work continued and a small flow of the ooze continued. At 2.30 p.m., 15 October, men on the fifth level heard a noise similar to escaping air. The cause of the noise was black ooze pouring down the ore pass. Immediately all men were taken out of the mine.

Very shortly, a decided movement was noted in the lake bed. First the original depression settled with the cracks increasing in size. Later, slabs of mud with grass began to move into a central vortex. The flow continued, gradually increasing in volume and speed. About 5 p.m. an old pump barge 30 ft. x 16 ft. x 6 ft. began moving toward the hole. When about 25 ft. from the vortex, it dammed the flow momentarily and a hole appeared in the lake bed. The mud cascaded over the edge of the hole and disappeared. The barge moved until it reached the hole, tipped, and dived in end first. It wedged momentarily, and as the hole increased in size, disappeared. It could be seen that the walls of the hole were a grey, claycy material. At this point the hole continued to enlarge rapidly. Air was gulped down and later regurgitated explosively throwing muck about 200 ft. in the air. By 5.30 p.m., the hole was 60 ft. in diameter. Gradually, the movements slowed until at 6 p.m. all movement had ceased.

On the following day, a survey showed that the resulting depression covered about 3½ acres, had a mean depth of 14 ft. and 80,000 cu. yd. had disappeared into the mine. The mud had risen in the shaft to within 30 ft. of the fifth level. It was estimated that voids underground were about 85,000 cu. yd. To prevent any further movement, the mine was filled with water. It is believed that most of the material which entered the mine was from the surface layers of organic ooze and fine silt.

The published account of this failure raises a number of questions regarding the cause of the cave-in. Although no comment can be made on the behaviour of the orebody in caving, it is almost certain that the principal lake bottom sediments which filled the mine were typical glacial and post glacial soils of the type that liquefy so quickly following disturbances such as that caused by the caving that extended up to the lake bottom.

Beattie Mine: July 1943

The Beattie Mine was located at Duparquet in Northwestern Quebec, about 22 miles from Rouyn. Mining was started in 1931, the gold-bearing ore being won by a combination of "glory-hole" and underground stoping methods. The "glory-hole" was worked during the summer months and the ore was extracted underground during the winter. The "glory-hole" was gradually enlarged each season; by about 1937 it was 1,000 ft. long with an average 100 ft. width. The west end of the pit was entirely in rock while the eastern end was covered by overburden. The overburden was made up of varved clay overlying water-laid sand. The stripping of the overburden was accomplished with a tower dragline and grew progressively deeper with each season. In 1937 a small landslide occurred at the eastern end of the pit, but it did not seriously interfere with mining operations. Several other small landslides occurred from 1937 to 1942. About the middle of June 1943, a tremendous earth flow, involving several million cubic yards of varved clay, occurred which completely filled the "glory-hole" and all the underground workings. So fluid was the clay that it ran along an underground drift over half a mile towards the neighbouring Donchester Mine which had an underground connection with the Beattie Mine.[3]

While production continued at the Donchester Mine, steps were taken to rehabilitate the Beattie property. Surface stripping operations were continued as weather permitted to remove the clay from the pit. Underground the workings were cleared by sluicing with high pressure water jets and pumping the resulting slurry to the surface. In June 1946, shortly after the surface stripping activities began for the season, another large earth flow occurred, again completely filling the "glory-hole" and the underground workings. Fig. 2 is a panoramic view of the lake which now occupies the crater formed by the two large earth flows. The rock wall of the "glory-hole" appears on the right of the photograph.

Both these unfortunate developments at important mines have one feature in common — the sudden liquefaction of soil which had appeared to be reasonably solid material. This property of soils is well recognized in modern studies of soils and is generally designated as high sensitivity.

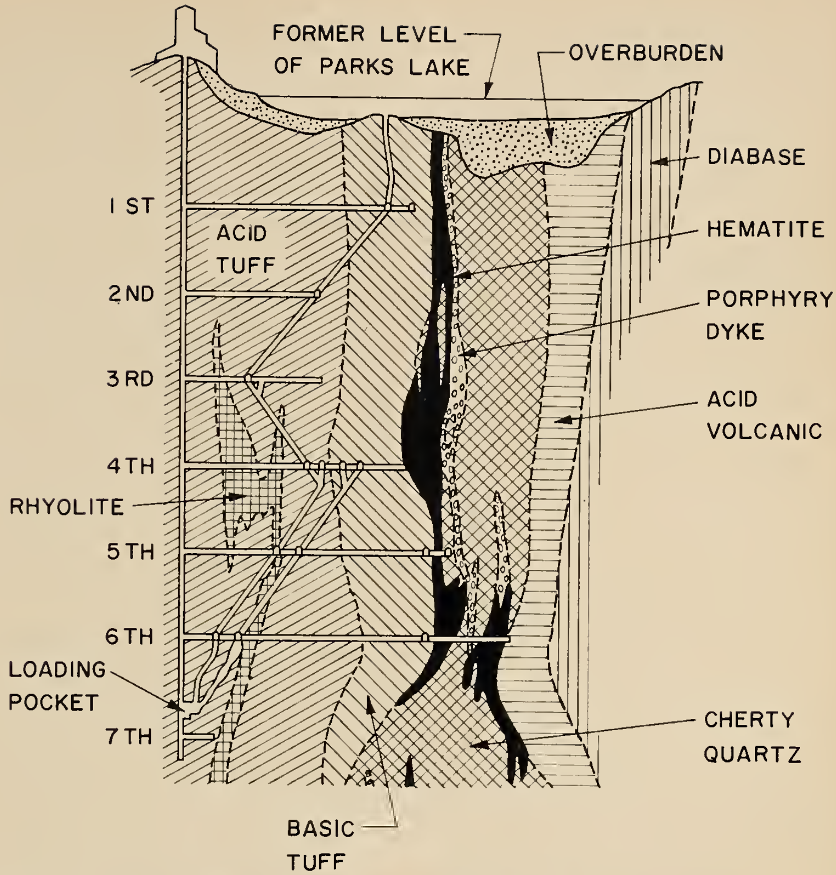

Fig. 1 Shaft section of Josephine Mine (after Gallie, 1947)

Modern Soil Studies

The scientific study of soils, called *soil mechanics,* is now a well recognized part of the practice of civil engineering. Although only about a quarter of a century old as an organized discipline, soil studies have been carried out throughout the whole history of modern civil engineering but only by individuals working alone until about 1925. Today, technical journals and excellent text books bring together in convenient form modern knowledge of the character and behavior of soils as used by the engineer. A selection of recommended texts is listed at the end of this paper.

The accurate determination of soil types is a first step in the proper engineering study of soils. This can be approached by investigating first the distribution of different size soil particles which make up the soil mixture. Fig. 3 is an illustration of the way in which the mechanical analyses of soils can be graphically represented. Cumulative curves have been plotted for a silty glacial till, a uniform sand, a lacustrine silt, and a marine clay. Mechanical analyses of soils are carried out first by sieving, and then by a sedimentation process for particles smaller than No. 200 sieve.

As soil studies have progressed, the significance of mechanical analyses as a means of distinguishing soils has decreased because the properties of importance in the engineering use of soils are not always related directly to mechanical composition. "Indicator tests" have therefore been developed to illustrate the reaction of the soil particles with varying quantities of water because, as can well be imagined, it is the variations in the three-phase air-water-soil mixture that is significant in determining the behaviour of soils. The indicator tests normally conducted are the determination of the natural water content and the "Atterberg limits".

Atterberg limits are given by two tests designed to indicate the plasticity characteristics of cohesive soils. Such soils can exist in three states: liquid, plastic or solid. The liquid limit, as determined by the Atterberg method, is the water content at the change from the plastic to the liquid state as determined by an admittedly arbitrary but simple and satisfactory test procedure. The plastic limit is the corresponding water content defining the change from the plastic to the solid state and is determined by an even simpler test. The difference between the two water contents is defined as the plasticity index. The interrelation of the indicator test results and their use in distinguishing soil types is well shown by the simple but very useful diagram reproduced as Fig. 4.

Procedures for all of these tests have been set out in ASTM Standards;[4] the test can be done at small cost and with a minimum of equipment. Beyond the indicator tests, there are now laboratory tests that determine the mechanical strength of soils either in their natural or in a disturbed state. The most important mechanical property is the shear strength of the soil. This can be determined, with a reasonable degree of accuracy for cohesive soils, by means of unconfined compression tests conducted upon cylindrical soil samples carefully preserved so as to be as close as possible to their original condition and moisture content when tested.

Of special importance for the fine-grained soils encountered on the Shield is the relation between the natural water content of a soil and its Atterberg limits. This relation can be expressed in a number of ways. One of the most common methods is to use the "liquidity index". This is expressed as:

$$LI = \frac{Wn - PL}{LL - PL}$$

where LI = liquidity index
Wn = natural moisture content
LL = liquid limit
PL = plastic limit.

If the liquidity index of the soil is greater than unity, the soil will have a natural water content higher than its liquid limit so that it would be expected to be in the liquid state. Much of the fine-grained soil found on the Shield has a liquidity index considerably greater than one and yet it is to all appearances in a perfectly stable plastic condition. The appearance is deceptive, however, since the soil is inherently unstable, the excess of water being held in what may be called an internal microscopic honeycomb structure, formed by minute soil particles during the course of sedimentation. It follows that, if such soils are disturbed from this natural but inherently unstable condition, the soils will lose their natural character and liquefy in a very short period of time, with results that can be disastrous.

This high liquidity index does not require a laboratory for its detection since it can be readly detected merely by taking a sample of the undisturbed soil and moulding it between the fingers. The excess moisture will soon make itself evident by the dramatic change in consistency between the undisturbed and remoulded clays. This is a simple field test that should therefore be familiar to every mining engineer engaged in work on the Shield. If he encounters soils with a high liquidity index he should immediately take steps to have proper soil studies made so that danger may be avoided and the natural characteristics of the soil used to good advantage.

Buildings at Malartic

As an illustration of what a careful but relatively simple soil study can do, there may be mentioned the design and construction of buildings for the Malartic Goldfields mine at Halet, Quebec. Those who know the clay belt of northern Ontario and Quebec will be familiar with the numerous foundation problems that have developed with buildings constructed directly upon the clay of this area, particularly if loads have been heavy. With such examples as a guide, the consulting engineer to Malartic Goldfields Ltd. (E. H. Bronson) consulted the senior author while he was on the staff of the University of Toronto and so was able to undertake such special soil studies. An investigation was made of the soil conditions at the site of new mine buildings that were planned. Eighteen simple auger borings showed that rock level was generally about 35 ft. below the surface so that it could be used for the support of extra heavy loads. The overlying soil had a high liquidity index but at the same time had a reasonable shear strength if not disturbed. Most of the foundations for the necessary buildings were therefore designed as spread footings using a safe bearing capacity for the soil as determined by shear tests; the heavier loads were carried to rock by means of 235 end-bearing piles. No real problems were encountered during construction and the buildings have continued to serve satisfactorily, in contrast to other buildings not very far away from the site, constructed upon exactly the same type of clay but without the benefit of preliminary soil studies.

Experiences at Steep Rock Lake

As a further example of what can be done by the application of soil studies to mining development, there may be mentioned the experience gained with the development of the great iron mine of Steep Rock Iron Mines Ltd. In 1943 and 1944 Steep Rock Lake, with an area of about 10 square miles was drained by pumping, following completion of a major river diversion project. The bed of the lake consisted of varved clays to depths up to about 150 ft. with liquidity indices up to 1.5. The instability of this vast deposit of soil is well shown in Fig. 5 showing the "stream" of soil which flowed down a relatively flat slope after being shaken out of a dragline bucket in which it had been excavated in the form of a tough, sticky but coherent mass. All the soil surrounding the areas that had to be cleared for open-pit working was characterized by corresponding potential instability.

The mine management supported fully the idea of careful soil studies.[5] These demonstrated that, if undisturbed, the soil could be trimmed to slopes that would be stable and safe. Extensive test boring, soil sampling, and soil testing showed that, despite the wide extent of the soil deposits to be dealt with, there was a reasonable degree of uniformity to soil properties that permitted over-all slope designs to be prepared. Basically the method used was to trim the excavated soil to a slope of 1 in 3, limiting the vertical height of each slope to 20 ft. A horizontal berm, the width depending on the shear strength of the soil, was then excavated, and graded gently away from the slope so that drainage would not reach the erodible face of the slope but would be collected in ditches at the back of each berm and led away under constant control. The most striking example of this general design was the Hogarth Barrier, a natural dam 160 ft. high consisting entirely of the unstable soil already described, trimmed as indicated, stretching across the Middle Arm of the lake. It served to isolate the area of the so-called "A" orebody which was then excavated in open pit to a depth of over 500 ft. below the original lake level, and 200 ft. below the top crest level of the barrier which was, originally, the level of the bottom of the lake.

It must be stressed that the figures given for the slopes used at Steep Rock are of relevance only for soils with the exact characteristics of those encountered in the bed of Steep Rock Lake. These were based on a large number of relatively simple shear tests on undisturbed soil samples. The Steep Rock experience, however, illustrates what can be done, even in a lake-bed filled with unstable soil, by the application of the scientific approach to soil, coupled with a full

Fig. 2 View of crater left by earth flows at Beattie Mine

appreciation on the part of management of the vital importance of even the simplest precautions in maintaining unstable soil in its natural state, and in controlling all ground and surface water in the vicinity.

Soil Studies in Exploration Work

In the exploration stage of mining development, geophysical surveys may be conducted, air photographs obtained and studied, and a test drilling program initiated. All these approaches are also commonly used in soil exploration work. In mining development, therefore, it is possible to combine preliminary soil studies, where soil is present in any significant quantity, with normal mining exploration at little, if any, extra cost and with the expenditure of very little extra time, provided only that soil exploration is recognized as an essential part of the preliminary program.

All the geophysical methods normally used in the search for ore, with the natural exception of the use of the Geiger counter, can be used to indicate depths to bedrock and significant changes in the character of overburden. Seismic methods are particularly applicable to determinations of depths to bedrock so that in areas such as that in the vicinity of the Beattie Mine it would be possible to determine well in advance of mining operations whether there is a rock barrier between any body of open water such as Duparquet Lake and the area to be developed for mining purposes. Aerial photo interpretation is now an established technique with an appreciable literature of its own (some reference to which is made in the accompanying bibliography). In many cases it is possible to distinguish major soil variations from a study of aerial photographs and identify land forms that may reveal soil conditions.

A test drilling program is naturally the most positive way of determining soil conditions. If overburden is present over an orebody, the exploratory holes necessary for ore exploration must be cased down to rock. Durng the sinking of holes to rock level, soil samples that provide definite information on soil properties can readily be obtained, with very little delay, by forcing split-barrel or Shelby soil samplers into the undisturbed soil. These samples can then be subjected to the simple indicator tests already mentioned and can give a good general picture of subsurface soil conditions. These could be supplemented later by more detailed studies if necessary. Observations of water levels in completed drill holes can often give invaluable information about groundwater conditions. It must be emphasized that only by means of actual undisturbed soil samples can subsurface conditions be determined with accuracy, sediment in wash water being never completely reliable and sometimes quite definitely misleading.

In the case of granular soils, a careful record of the necessary force to drive in the samplers can indicate the density and strength of the soil being penetrated. The bearing capacity can be determined, at least in a preliminary way, from the number of blows required to drive a standard split-barrel sampler 1 foot, given the weight of hammer used and its drop. Even in the case of cohesive soils, the driving record will give at least an indication of the variability of the soil formation and a general idea of its strength characteristics. Soil samples, obtained as indicated, must be used for accurate determination of bearing capacity and other necessary strength characteristics for all cohesive (fine-grained) soils.

Some Soil Problems in Mining

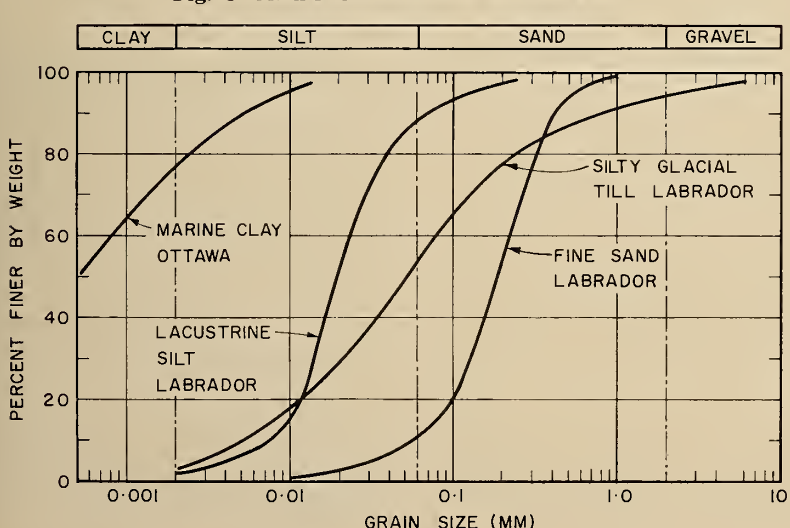
Some of the major soil problems that may be encountered in mining operations on the Precambrian Shield may be briefly noted in conclusion to illustrate how the application of soil mechanics studies may assist in the successful development of a mining property. Table I presents this information in summary form in relation to the main types of soil that may be encountered.

Roads: The first construction work at a mining prospect is usually the building of access to the property, either road or rail. Road construction will almost always be the first requirement, but soil studies are similar for both road and rail construction. In each case it is desirable to achieve an all-weather road requiring a minimum of maintenance. Frost action and soft ground crossings are the main problems in road construction. Aerial photographs can be of great assistance in locating the route to avoid muskeg areas and to take advantage of the best soil conditions. If soft ground deposits cannot be avoided, aerial photographs and the muskeg classification system developed by Radforth[6] can assist in minimizing the problem. The height of fills should be kept to a minimum. If it is necessary to construct fills more than 5 or 6 feet high, an investigation should be conducted by auger borings. The severe winter climate of the Shield, coupled with poor drainage conditions, makes frost action a major road problem. The only positive method of overcoming this problem is by the selection and use of non-frost susceptible materials for road building.

Deep excavations: In sinking shafts or stripping overburden from open pits, deep excavation in soils may be necessary. In granular soils excavation work can proceed only if success is first achieved in controlling groundwater. Slopes will be stable when cut to the angle of repose of the material. For deep shafts, groundwater can be controlled by several methods including dewatering by well points, freezing, grouting, stabilization by electroosmosis, or chemical grouting. The choice of method will depend largely on the exact soil conditions.

For fine-grained soils, in addition to the control of water in any pervious strata encountered, the shear strength of the soil must be consid-

Fig. 3 Grain-size distribution of four soils



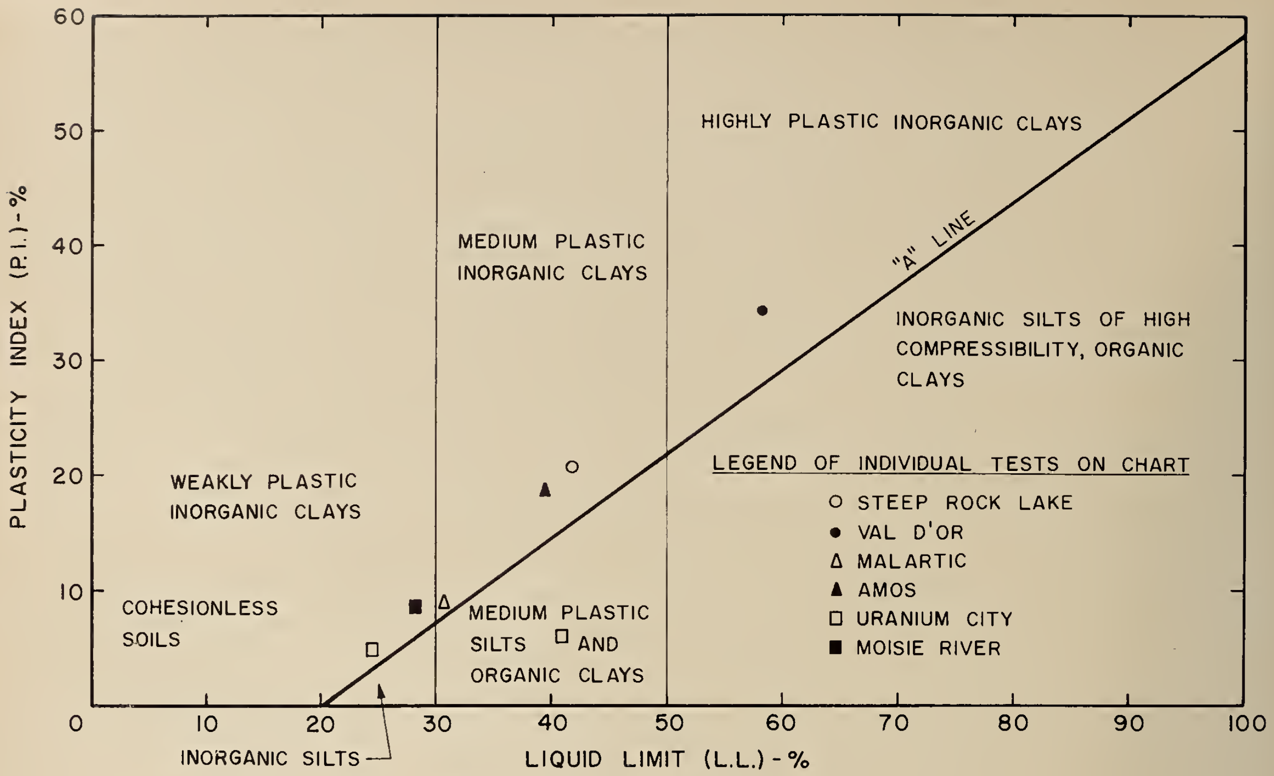


Fig. 4 Casagrande's plasticity chart

ered. It can be shown that a shaft in cohesive soil, even though adequately shored, should not proceed beyond a depth defined by $Dc = Nc \cdot (S_s/\gamma)$, where Dc is the critical depth, Nc is the coefficient depending on the dimensions of the shaft (9 for deep shafts), γ is the density of the clay, and S_s is the undrained shear strength.[7] If an open excavation proceeds beyond this point, the bottom will probably blow in. Special construction methods will then be necessary to complete the shaft to the desired depth. Side slopes and the shear strength of the soil will limit the depth to which open excavations for pits can be carried. In all cases of deep excavation in soils, a test boring and soil testing program conducted by a competent authority can lead to safe design and construction methods. When the soils involved are sensitive, it is imperative that the risk of failure be kept to a minimum. This can be done by the careful application of soil mechanics.

Foundations for buildings and surface installations: As the experience at Malartic Goldfields Mine has shown, it is quite possible to found buildings directly even on sensitive soil. With adequate soil information available, safe designs can be determined from the shear strength and compressibility characteristics of the soil. If the soil conditions are difficult, pile foundations, to transfer loads to bedrock, may be the only satisfactory solution. In keeping with the over-all and always dominant requirement that soil should be disturbed as little as possible from its natural state, piles should only be used when preliminary soil studies have shown them to be absolutely necessary. At Malartic, they were useful in conveying the heaviest loads directly to bedrock so that the necessary disturbance of the varved clay by driving was immaterial. Pile driving in such clays usually tends to liquefy them to a certain extent so that, in extreme cases, it is possible actually to reduce the bearing capacity of a building site (on sensitive clays) rather than to increase it by the driving of piles. The use of piles should never be considered without first obtaining expert advice on the necessary foundation design.

Stockpiles: It is sometimes necessary to build up large stockpiles of ore or other material on a mining property. The loads so placed on the underlying ground can be considerable; there have been many instances of failure of underlying ground. If this merely disturbs the ground under the pile the consequences may be serious enough, but soil failure will always affect a considerable area around a pile so that adjacent structures may be moved or even destroyed. Soil studies are therefore an essential preliminary to the start of any stockpiling on any surface other than solid rock.

Tailing dams: Correspondingly, in ore processing operations, it is sometimes necessary to store the tailings from mill operations. If this cannot

TABLE I

Soil Problems in Relation to Mining

Soil Type and Condition	*Type of Problem*			
	Road Construction	Shaft Sinking	Deep Open Excavations	Building Foundations
Well drained gravels and sands		Adequate shoring	Side slopes = angle of repose	Possibility of settlement under vibratory loads
Saturated gravels and sands	Drainage will control frost action	Adequate shoring and control of seepage water (quicking)	Control of seepage water. Side slopes = angle of repose	Possibility of settlement due to vibratory loads and drawdown of water table
Saturated glacial till	May be frost susceptible in which case drainage will not prevent frost heave	Adequate shoring and control of seepage if any. In extreme depths, a possibility of bottom heave	Control of seepage water. Side slopes = 1½: 1 except for extremely deep excavations or where till is loose	If till is dense, a bearing capacity of 5T/sq ft can be expected. Little possibility of settlement except where till is very loose
Saturated silts and sandy silts	Drainage alone will not control frost action. Adequate non-frost-susceptible base must be used.	Adequate shoring—control of seepage pressure vital to prevent quick conditions	Control of seepage water and pressure vital. Side slopes subject to erosion	Bearing capacity limited. Subject to some settlement under static loads and drawdown of water table
Saturated silty clays and clays, varved clays	Frost susceptible. Safe height of fill limited by shear strength	Adequate shoring—control of seepage water—depth of open shaft limited by shear strength	Control of seepage water. Depth of excavation dependent on side slopes and shear strength. If LI exceeds 1, failure can be disastrous	Bearing capacity limited by shear strength and consolidation characteristics—heavy stockpiles subject to base failure
Muskeg	Route must be carefully selected to take advantage of most woody peats. High fills may require complete removal of peat. Grassy bogs if crossed must be excavated	Must be removed and site drained	Must be removed entirely or positively drained	Buildings should not be founded on peat—must be removed from site

be done in a natural depression, it is common practice to form "earth dams" with the tailings, gradually increasing the height of these dykes as storage increases. Care in the preparation of the site of such an artificial dam will always be necessary; study of the mechanical properties of the tailings, as deposited, will always be advisable since adequate dimensions for the cross-section of the dyke can then be determined and precautions taken against possible slope failures that can have serious consequences.

Conclusions

The object of this paper has been to indicate the nature of some of the soil problems that have been encountered by the Canadian mining industry, with special reference to the Precambrian Shield. Paradoxically, although rock conditions on the Shield are good on the whole, some of the most treacherous of all soils have been formed from these rocks. The drainage on the Shield is generally poor. The fine-grained soils usually have a low strength, high compressibility characteristics, and high sensitivities. Because of their high sensitivity, failure in fine-grained soils can have disastrous consequences.

During the exploration phase of a mining development, with slight additional expense, information can be obtained from which it is possible to anticipate generally the problems that may be encountered with soils. If bad or unusual soil conditions are indicated, expert assistance in design and construction should always be obtained. Continuing attention to all soils encountered in mining operations, however, on the part of all responsible for development work, is the best insurance for avoiding trouble. Recognition of soils as materials that can be tested and used to good advantage if only their properties are known can turn even the most serious potential soil problems into an engineering challenge.

STRUCTURAL BEHAVIOUR OF HIGHWAY BRIDGE DECKS

S. D. Lash, M.E.I.C.
Head, Department of Civil Engineering, Queen's University, Kingston.

B. B. Hope,
Research Assistant, Queen's University, Kingston.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The paper describes a series of static tests carried out on the deck systems of three highway bridges. Two of the bridges were tested in the field and the third was re-constructed and tested in the Structural Engineering Laboratory at Queen's University. The two bridges tested in the field had 6 inch reinforced concrete slabs supported by steel stringers at 3 ft. 3 in. centres. The test results indicate that there is an appreciable amount of composite action present in this type of bridge even though shear connectors were not used. This composite action is due to friction between the slab and stringers and considerably reduces the stress in the stringers. The bridge tested in the laboratory had a laminated timber deck supported by steel stringers. Composite action was negligible. The experimental bending moments and deflections are compared with the theoretical values obtained using a method of harmonic analysis developed by A. W. Hendry and L. G. Jaeger. The agreement between the experimental and theoretical values of bending moment and deflections is good, especially for the laboratory bridge. It is concluded that the lateral distribution of concentrated loads may be estimated with reasonable accuracy by the Hendry and Jaeger method. For bridge decks of the type investigated this distribution is considerably more favourable than that indicated by current specifications. All three bridge decks carried relatively large loads, applied between the stringers, before local failures occurred.

A COMMON TYPE of bridge floor consists of a concrete slab or timber deck supported by a number of longitudinal steel beams (called stringers) which are supported either by the abutments of the bridge or by transverse floor beams. The elements of such a floor, i.e. the deck and the stringers, are usually designed by empirical rules and there is considerable uncertainty about the ultimate strength of the whole assembly. The tests described in this paper were carried out in order to provide further information in this matter.

A bridge floor may be regarded as an elastic plate of rather uncertain properties, supported by a series of elastic beams, which in turn may have elastic supports. The floor is required to carry both distributed and concentrated loads. There is usually some uncertainty about the degree of composite action that may exist between the deck and the beams, i.e. there may or may not be slip between the beams and deck. It will be obvious that any rigorous analysis of such a structure is bound to be complicated and must be based upon assumptions which may not correspond to actual conditions. Consequently it has become common practice in designing bridge floors to follow rules, which, although they lead to safe structures, result in unknown factors of safety.

Design Practice

The deck and stringers are usually designed for concentrated loads caused by vehicles. In designing decks, it is assumed that a wheel load is distributed longitudinally (i.e. in the direction of the stringer) over some effective width of deck. In designing stringers however, no longitudinal distribution is considered, but distribution may be assumed to take place laterally. The general specifications for highway bridges of the Department of Highways, Ontario, 1935 required interior stringers to be designed for a concentrated load of $1.3S/6$, i.e. $S/4.6$ times a wheel load for a concrete deck. S is the average spacing of the stringers in feet. For a laminated timber deck the fraction of a wheel load for which the interior stringers must be designed is $S/4$ provided S has a value of between 2 ft. and 4 ft. The Specification of the American Association of State Highway Officials (AASHO) 1953, gave corresponding figures of $S/5.0$ for a concrete deck and $S/4.25$ for a timber deck 6 in. thick. In the most recent AASHO Specifications (1957) the relative coefficient for a concrete deck is $S/5.5$ and that for a timber deck remains at $S/4.25$.

It should be noted that the expressions given for bending moments in interior stringers are intended to allow for loads from more than one wheel being transmitted to a particular stringer.

The allowable stress in stringers permitted by AASHO specifications is 18,000 p.s.i. for ordinary structural steel (ASTM A7) but a higher stress is permitted when determining the load capacity of an existing bridge. In a previous report Wright[1] has described in some detail the methods commonly used for rating existing bridges and has recommended a procedure based on separate load factors for live and dead load.[2] In North America, the most widely used method is that contained in the AASHO Specifications. These permit the "safe load-carrying capacity" of a bridge to be based on a stress of 0.82 times the assumed yield point of the material. For the ordinary grade of structural steel used (ASTM—A7) this would be 27,000 p.s.i.; for the steel used in older bridges, a stress of 24,600 (based on an assumed yield of 30,000) would commonly be assumed.

Theoretical Action

The following theoretical discussion concerns a concrete deck supported by stringers running longitudinally (i.e. in the direction of traffic). The discussion is valid nevertheless for a laminated timber deck though it must be appreciated that the moment of inertia in the longitudinal direction and the composite action are both zero. A laminated timber deck cannot, by virtue of its method of construction, contribute to the strength of the stringers and its sole function is to distribute the loads laterally to the neighbouring stringers.

Composite Action: Much experimental work has been done in the laboratory on composite action but this has tended to be concerned with beams in which there was little or no slip between steel and concrete. In a composite beam bridge shear connectors are usually provided so as to ensure that there is no slip and no tendency for the slab to lift away from the steel. In ordinary bridge floors with concrete decks where shear connectors are not provided there may still be some significant degree of composite action.

We are primarily concerned with the tensile stress in the lower fibre of the steel beam. If we neglect all composite action and assume that all the load is resisted by the steel beam:

$$f = (M/Z) = aM \quad (1)$$

If we neglect all composite action but assume that part of the moment is resisted by the slab then:

$$f = bM \quad (2)$$

If we assume full composite action:

$$f = cM \quad (3)$$

In a practical situation where there is partial composite action, we have:

$$f = dM \quad (4)$$

and we would expect "d" to have a value between "a" and "c". It will be convenient to express "d" as:

$$d = a + k(c - a)$$

and we will call k the "degree of composite action". For full composite action $k = 1$, for no composite action $k = 0$.

$$\text{in general,} \quad k = \frac{(a - d)}{(a - c)} \quad (5)$$

The values of a and c may be calculated by the usual methods, making some reasonable assumptions about the elastic moduli of the slab and beam. The value of d may be determined experimentally, if strains are known on the bottom and top surface of the steel beam. The theory is as follows:

Assume strains as shown in Fig. 1 are positive then slip $= \epsilon_t + \epsilon_{bc}$. Considering axial forces in the steel and the concrete.

$$T = \left(\frac{\epsilon_b - \epsilon_t}{2}\right) EsAs$$

$$C = \left(\frac{\epsilon_{tc} - \epsilon_{bc}}{2}\right) Ac\frac{Es}{n}$$

$$T = C$$

hence:

$$\epsilon_{tc} - \epsilon_{bc} = (\epsilon_b - \epsilon_t)n\frac{As}{Ac}$$

Assuming that the slab and the beam have the same curvature:

$$\frac{\epsilon_b + \epsilon_t}{d} = \frac{\epsilon_{tc} + \epsilon_{bc}}{t}$$

$$\epsilon_{tc} + \epsilon_{bc} = (\epsilon_b + \epsilon_t)\frac{t}{d}$$

The total moment of resistance, M is given by M = Moment in slab + Moment in beam + $T(t + d)/2$

$$M = \left(\frac{\epsilon_{tc} + \epsilon_{bc}}{2}\right) Ac\left(\frac{t}{6}\right)\frac{Es}{n} + \left(\frac{\epsilon_b + \epsilon_t}{2}\right) ZEs + \left(\frac{\epsilon_b - \epsilon_t}{2}\right) Es\,As\left(\frac{t + d}{2}\right)$$

which reduces to:

$$M = \frac{\epsilon_b + \epsilon_t}{2}\left[\frac{t^2}{6d}Ac\frac{Es}{n} + ZEs\right] + \frac{\epsilon_b - \epsilon_t}{2}\left[EsAs\frac{(t + d)}{2}\right]$$

$$= \epsilon_b\left[\frac{t^2}{12d}Ac\frac{Es}{n} + \frac{ZEs}{2} + EsAs\frac{(t + d)}{4}\right] + \epsilon_t\left[\frac{ZEs}{2} - EsAs\left(\frac{t + d}{4}\right)\right]$$

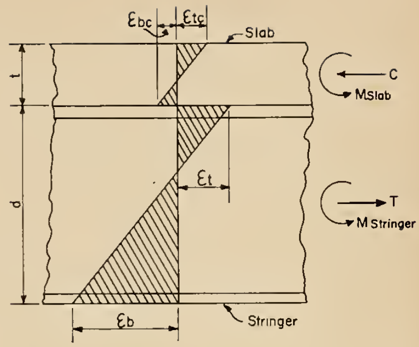

Fig. 1. Strains and Moments in a composite beam

For any particular structure this reduces to:

$$M = A\epsilon_b - B\epsilon_t \quad (6)$$

where A and B are coefficients.

Experimentally we can determine the ratio of ϵ_t to ϵ_b and hence we can express M as

$$M = C\epsilon_b$$

$$\text{or} \quad \epsilon_b = M/C$$

$$f_b = (E/C)M = dM \quad (4)$$

This theory may be modified if ϵ_t is measured at some point other than the upper surface of the top flange.

Load Distribution between Stringers:

i. *Introduction*

Theoretical studies of the load distribution between stringers have been made by many investigators and in some instances these have been supple-

	XIII	13	20	74	Slab failed in shear along beam A.

mented by experimental work using models.

Three main lines of investigation have been pursued.

(*a*) Extensive studies at the University of Illinois by Jensen, Newmark and others[3,4,5], lead to the development of a modified form of moment distribution. This is believed to be the basis of the AASHO specifications referred to previously.

(*b*) Massonet[6] and Guyon[7] have developed theoretical analyses based on the assumption that the slab and the stringers may be regarded as an anisotropic plate. The calculations are complicated but the results can be expressed in a series of simple design charts. These are currently used in Germany, Belgium and some other European countries.

(*c*) Hendry and Jaeger[8] have developed a method of harmonic analysis based on the assumption that the loading on stringers may be represented by a Fourier series. This method also leads to simple design charts and it has been found to be basically a simpler method to use where charts are not available than the two preceding methods.

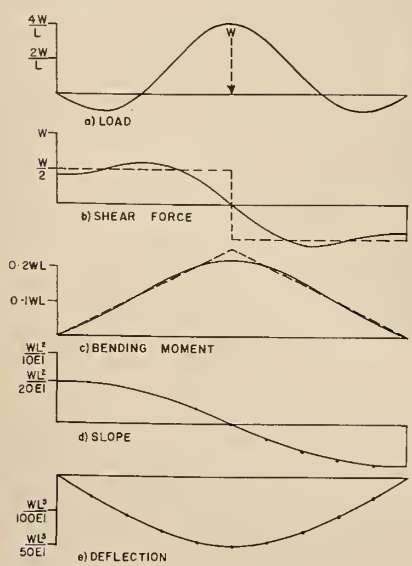
ii. Harmonic Analysis

The analysis of a bridge deck by harmonic analysis has been fully described in a recent book by Hendry and Jaeger[8] and it is therefore not necessary to repeat it here in detail. In principle, the method is as follows:

The loading on a simply supported beam is expressed as a series:

$$W = w_1 \sin \frac{\pi x}{L} + w_2 \sin \frac{2\pi x}{L} + \ldots + w_n \sin \frac{n\pi x}{L}$$

Fig. 3. Harmonic representation of a concentrated load



i.e.

$$W = \sum_{n=1,2,3}^{\infty} w_n \sin \frac{n\pi x}{L} \qquad (7)$$

With such a loading, shearing force (F) bending moment (M) slope (θ) and deflection (y) are given by:

$$F = \frac{L}{\pi} \sum_{n=1,2,3}^{\infty} \frac{w_n}{n} \cos \frac{n\pi x}{L} \qquad (8)$$

$$M = \frac{L^2}{\pi^2} \sum_{n=1,2,3}^{\infty} \frac{w_n}{n^2} \sin \frac{n\pi x}{L} \qquad (9)$$

$$\theta = \frac{L^3}{EI\pi^3} \sum_{n=1,2,3}^{\infty} \frac{w_n}{n^3} \cos \frac{n\pi x}{L} \qquad (10)$$

$$y = \frac{L^4}{EI\pi^4} \sum_{n=1,2,3}^{\infty} \frac{w_n}{n^4} \sin \frac{n\pi x}{L} \qquad (11)$$

The coefficients w_1, w_2 are evaluated by the usual procedure of Fourier analysis as:

$$w_n = \frac{2}{L} \int_0^L W \sin \frac{n\pi x}{L}\, dx \qquad (12)$$

Although several terms may be necessary in the series to give a reasonable approximation to a given loading, the equations for moment, slope and deflection converge very rapidly and a single term may represent deflection very closely.

The distribution of load between stringers is then determined by considering relative displacements of the slab and the stringers and the slab.

The slab will function to some extent as a plate and consequently some part

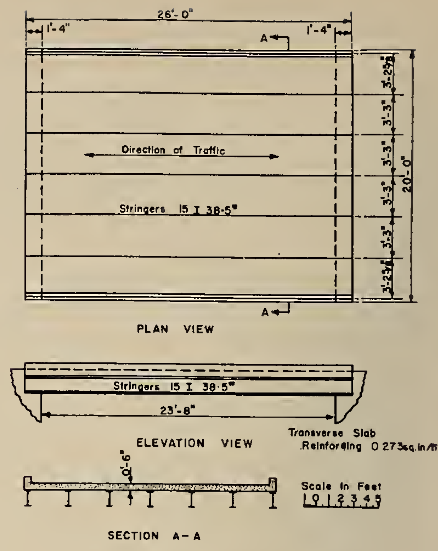


Fig. 4. Bannockburn Bridge

of the load P will be transmitted longitudinally to the end supports. (The amount to be transmitted will be increased if transverse supports are provided at the ends of the slab).

Hendry and Jaeger suggest that this may be estimated by assuming that the total load carried by the stringers is:

$$Ps = \left[\frac{nIs}{nIs + (ht^3/12)}\right] P \qquad (13)$$

where n is the modular ratio.

Alternatively, allowance may be made for the longitudinal moments carried by the slab by considering composite action.

Table II
Tests of the Poplar Hill Bridge

Type of Test	*Cycle*	*Location of Loading Pad (Refer to Figure 9)*	*Load Increments (Kips)*	*Maximum Load (Kips)*	*Field Observations and Remarks*
Flexural	I	1 and 2	20	80	
	II	3 and 4	20	80	
	III	2 and 3	20	140	
	IV	2 and 3	20	160	Continuation of cycle III.
	V	3	40	139.4	Stringer under the load yielded at a load of 139.4 kips.
	VI	6 and 7	20	100	
	VII	8 and 9	20	100	
	VIII	6 and 7	20	100	Results combined with cycle VI.
	IX	7 and 8	20	160	Maximum capacity of the loading system.
	X	8 and 9	20	140	Failure of the edge panel occurred about 12 mins. after application of the load.
	XI	6 and 7	20	140	There appeared to be no reduction in strength of this edge of the bridge as a result of the failure of the other edge in cycle X.
Slab-Punching	V	5	40	155.2	The slab failed in diagonal shear at a load of 155.2 kips. NOTE. The failure experienced in cycle X was a combination of slab-punching and lateral buckling of the edge stringer.

As an example of the method consider a slab resting on three simply supported stringers as shown in Fig. 2. The span of the stringers is L and their moment of inertia is I_s. The slab has a total thickness t and the spacing of the stringers is h.

Representing the deflection of each stringer by a Fourier series and considering the first term only we have if x be measured from mid-span:

$$y_1 = a_1 \cos \frac{\pi x}{L} \qquad (14)$$

$$y_2 = a_2 \cos \frac{\pi x}{L} \qquad (15)$$

y_1 and y_2 are the deflections of stringers (1) and (2) respectively: a_1 and a_2 are their mid-span deflections. The deflections are directly dependent upon loads and in general

$$EsIs \frac{d^4 y_1}{dx^4} = Ky_1 \qquad (16)$$

where K is a constant

From (14) and (16)

$$K = \frac{\pi^4 EsIs}{L^4} \qquad (17)$$

Consider a transverse strip of deck of unit width. It carries a central load Ky_2

Fig. 5. Poplar Hill Bridge and Laboratory Bridge
(Note: The dimensions in brackets refer to the Laboratory Bridge)

and has a net deflection $y_2 - y_1$. Then from moment areas:

$$\frac{Ky_1 h^3}{3EcIc} = y_2 - y_1$$

substituting

$$K = \frac{\pi^4 EsIs}{L^4} \qquad (18)$$

and letting

$$\alpha = \frac{12}{\pi^4}\left(\frac{L}{h}\right)^3 \frac{LEcIc}{EsIs}$$

we get

$$\frac{4y_1}{\alpha} = y_2 - y_1$$

and

$$a_1 = a_2\left(\frac{\alpha}{4 + \alpha}\right)$$

$$y_1 = \frac{\alpha}{4 + 3\alpha} A \cos \frac{\pi x}{L} = \rho_1 A \cos \frac{\pi x}{L} \qquad (19)$$

or

$$y_2 = \frac{4 + \alpha}{4 + 3\alpha} A \cos \frac{Wx}{L} = \rho_2 A \cos \frac{\pi x}{\pi} \qquad (20)$$

where $\quad A = a_2 + 2a_1$

"A" would be the amplitude if one of the stringers carried all the load, hence ρ_1 and ρ_2 indicate the proportions of the first harmonic of the deflection curve carried by each stringer. They are therefore called "distribution coefficients". If the deflection of the loaded girder is given by terms such as $\cos p\pi x/L$ or $\sin p\pi x/L$ distribution coefficients may be found by substituting α/p^4 for α in the formulas for first harmonic coefficients. In this way we can obtain the deflection curve for each stringer no matter what load may be applied. Similarly, we can determine the distribution of load, shear or bending moment. In practice, it is only necessary to distribute a limited number of harmonics because coefficients for the unloaded girders decrease very rapidly, i.e. the loading components represented by the higher harmonics are mostly retained in the loaded girder.

As an example let us assume that a single concentrated load is applied at mid-span of the middle stringer.

The load may be expressed as:

$$W = \frac{2P}{L}\left[\sin\frac{\pi x}{L} - \sin\frac{3\pi x}{L} + \sin\frac{5\pi x}{L} + \ldots\right] \qquad (21)$$

Obviously this equation does not represent a concentrated load at all closely (see Fig. 3) but if integrated, it will describe very accurately the deflection curve of a beam carrying the concentrated load and consequently it may be used to determine distribution coefficients:

if $\qquad \alpha = 1$

then:

$$\rho_1 = \frac{\alpha}{4 + 3\alpha} = 0.143 \qquad (22)$$

$$\rho_2 = \frac{4 + \alpha}{4 + 3\alpha} = 0.714 \qquad (23)$$

Thus, if only the first harmonic be considered, 71.4% of the load is carried by the central beam. Considering the third harmonic, (the second harmonic is zero with the load at midspan) ($p = 3$) and substituting $\alpha^1 = \alpha/p^4$ we get $\rho_1 = 0.003$, from which we find that the load carried by the central beam is (0.714 – 0.003) 100 or 71.1% of W. It is unnecessary to consider further terms in the series. The assumption $\alpha = 1$ in this example corresponds to a relatively flexible slab. If we take $\alpha = 10$, we find, considering the first harmonic only, that 41.2% of the load is carried by the central beam. Considering the third harmonic makes more difference in this case and gives 38.4% on the central beam.

The distribution coefficients depend only upon α which has been defined as

$$\frac{12}{\pi^4}\left(\frac{L}{h}\right)^3 \times \frac{LE_cI_c}{E_sI_s}$$

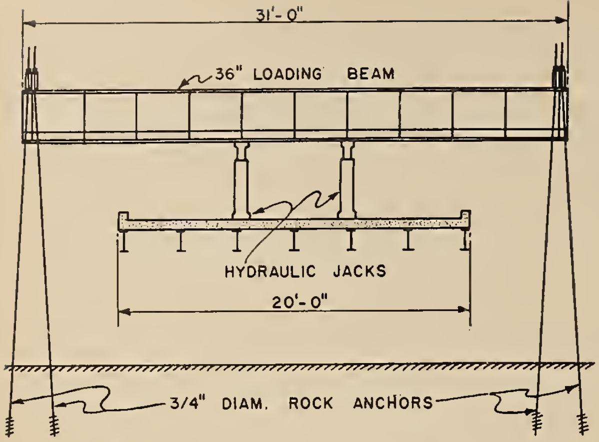

Fig. 6. Arrangement of the loading system (Note: At Poplar Hill and in the Laboratory the tie rods were anchored under the floor beams)

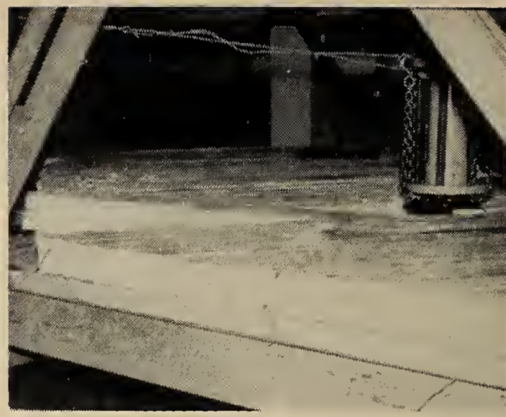

Fig. 7. Photograph of the deck after local failure of the timber laminations

and in this expression the only uncertainty concerns the value of E_cI_c/E_sI_s.

The value of E_c, the modulus of elasticity of the concrete may be uncertain and as with all reinforced concrete members, there is likely to be great doubt as to the appropriate value of I_c. Should concrete in tension (which may be cracked) be included and should any allowance be made for reinforcement?

As far as longitudinal moments are concerned, these questions have been answered by assuming that the moment of inertia of the slab is $ht^3/12$, i.e. considering the full section to be effective and ignoring the reinforcement. These assumptions may be less reasonable for transverse moments.

In the preceding discussion, it was assumed that the stringers have no torsional rigidity and where I-beams are used this is a reasonable assumption. Hendry and Jaeger show how allowance may be made for any assumed degree of torsional stiffness. This has more application to construction using concrete stringers than to I-beam floors.

The method used for a three-stringer bridge may be extended to bridges having four, five or six stringers and Hendry and Jaeger give distribution coefficients for such bridges.

Observing that

$$\alpha = \frac{12}{\pi^4}\left(\frac{L}{h}\right)^3 \frac{E_cI_cL}{E_sI_s}$$

and assuming that the stringer may be replaced by a uniform plate of effective width B_e where $B_e = Nh$, N being the number of stringers, we have

$$\alpha_N = \frac{12}{\pi^4}\left(\frac{L}{B_e}\right)^3 \times N^4 \times \frac{\text{Total transverse } EI}{\text{Total Longitudinal } EI}$$

L/B_e and the ratio of total transverse EI to total longitudinal EI are the same in the uniform plate and in the bridge with N^1 stringers from the relationship

$$\alpha_{N^1} = \alpha_N \left(\frac{N^1}{N}\right)^4$$

For beams that are not simply supported, loads may be expressed as a series of components each component having the property of the equations given above that the deflection form is similar to the load form. Such components are called "basic functions" ($F(x)$) and they must satisfy the equation

$$\frac{d^4F(x)}{dx^4} = KF(x)$$

which is satisfied in general by :

$$F(x) = A \operatorname{Cosh} \theta x + B \operatorname{Sinh} \theta x + C \operatorname{Cos} \theta x + D \operatorname{Sin} \theta x$$

where $\theta^4 = K$ and A, B, C, D are constants.

Of the four constants, three may be considered as determining the shape of the basic function and the remaining one as determining its magnitude. In analysis, D is assumed to be unity. For bending moments, it is convenient to introduce supplementary functions. The supplementary functions are the same as the basic functions except for a change of sign in the cosine terms. Then :

$$-M = \frac{w_1}{\theta_1^2}\Phi_1(x) + \frac{w_2}{\theta_2^2}\Phi_2(x) + \ldots + \frac{w_n}{\theta_n^2}\Phi_n(x)$$

Similarly other supplementary functions are introduced in the series for shear and slope.

Research Problems: Although theoretical solutions, such as those described above, appear to offer a reasonable approach to the problem of analysing the effects of concentrated loads on bridge floors, there must be considerable doubt as to whether such solutions can be

properly applied to actual structures. It is therefore desirable to carry out full scale tests.

The chief points of uncertainty are the following:

(a) What degree of composite action exists in a typical floor without shear connectors;

(b) To what extent are concentrated loads distributed between stringers. Can theoretical solutions be made applicable to existing structures on the basis of reasonable assumptions concerning elastic constants, moments of inertia and composite action.

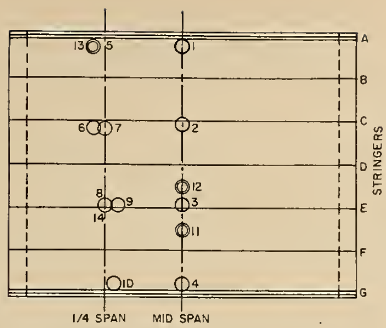

Fig. 8. Locations of loads—Bannockburn Bridge

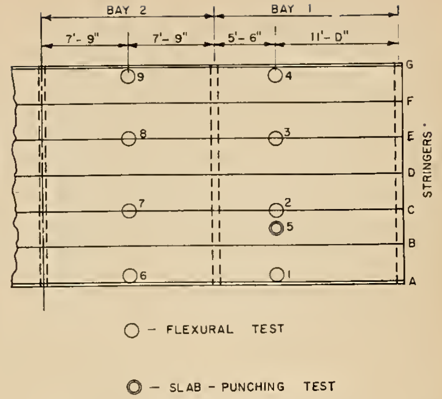

Fig. 9. Location of loads — Poplar Hill Bridge

Full Scale Tests

Description of Bridges tested in the Field: Two bridges were tested — one at Bannockburn, Ontario, and the other at Poplar Hill, Ontario.

The Bannockburn bridge had a single span of 23.4 ft. between abutments and consisted of seven 15 in. I-beam stringers supporting a 16 in. concrete slab.

The Poplar Hill bridge had a single span of 64 ft. It consisted of two trusses which supported floor beams at panel points which in turn supported stringers and a concrete slab. Tests were made of the strength of the floor but the trusses were not loaded. Details of the bridges are shown in Fig. 4 and 5.

The floors of the two bridges were similar in many ways. Both had relatively closely spaced stringers supporting a 6 in. slab. In the Bannockburn bridge, the stringers were supported directly on the abutments of the bridge; at Poplar Hill they were supported by floor beams. The slab at Bannockburn was about 30 yr. old but was in good condition. It appeared to be separated from the stringers by a layer of paper used as a form liner. The slab at Poplar Hill had been replaced six years previously and was in excellent condition. There were no shear connectors in either floor.

The floors were loaded by four 50 ton jacks resting of 15 in. diam. steel plates and arranged so as to simulate loads produced by the rear wheels of trucks. The reaction of the jack was taken by a large beam spanning the bridge transversely. The reaction from this beam was taken by short cross beams at the ends which were anchored by tie rods. At Bannockburn, these tie rods were anchored in the ground; at Poplar Hill they were attached to the floor beams of the bridge. The general arrangement of the testing equipment is shown in Fig. 6 and 7.

Strains were measured on the stringers by electrical resistance gauges. The location of these gauges at Poplar Hill was on the outer face of the lower flange, and the inner face of the upper flange at the mid span and ends of each stringer. At Bannockburn the gauges were located at the mid span and quarter span of the stringers. In addition, at Bannockburn, strains on the concrete slab were measured using a mechanical demountable strain gauge (DEMEC). An attempt was made to measure slip between the stringers and the slab at a number of places on both bridges.

Description of the Bridge tested in the Laboratory: The bridge tested in the laboratory was originally located on a County Road south of Napanee and was called the 'Big Creek Bridge'. This bridge was dismantled and re-erected using high-strength bolts in the Structural Engineering Laboratory

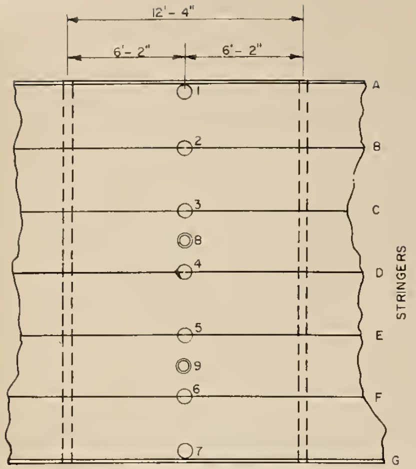

Fig. 10. Location of loads—Laboratory Bridge

at Queen's University in April and May, 1959.

The Laboratory Bridge was of the same type as the Poplar Hill Bridge previously described but had a span of 48 ft. Details of the bridge are shown in Fig. 5.

Two types of timber deck were tested, the first consisting of 2 in. by 6 in. spruce joists laid on edge and spanning the stringers perpendicularly, the second consisting of 2 in. by 6-in. spruce joist laid on edge and spanning the stringers transversly at an angle of 45° to them. The laminations were nailed together sing 5 in. nails at 12 in. centres and were arranged so that at least 3 out of 4 laminations were continuous between any pair of stringers.

The loading arrangement was essentially the same as that used at Poplar Hill although only one hydraulic jack was used throughout the tests

Strains were measured, using electrical resistance gauges, at the outside face of the lower flanges and the inside face of the upper flanges of the stringers at the mid span of each stringer and at the ends of the centre stringer and the edge stringers.

Test Procedures: Most of the field tests consisted of applying loads in pairs (representing two wheels on an axle), the loads being applied above the interior stringers and adjacent to exterior stringers. Separate tests were carried out in which a single load was applied to the slab between a pair of stringers — these are referred to as "slab punching" tests.

The complete program of field tests is summarized in Tables I and II and Fig. 8 and 9.

The laboratory tests consisted of applying a single load above the interior stringers. When an edge stringer was loaded the jack was placed on the deck adjacent to the stringer. 'Punching' tests were also performed by applying a single load to the deck between a pair of stringers. The program of tests for both decks was identical and the tests are summarized in Table III and Fig. 10.

Test Results:

i. Ultimate Strength

The Bannockburn bridge was designed for an H-15 loading, the critical load on the stringers being two axle loads of 24 kips each. The stress produced by this load plus dead load assuming the effective wheel load to be given by S/4.6 was 13.4 ksi. Increasing the live load by 30% for impact gave a stress of 16.6 ksi.

The bridge actually supported a test load consisting of two axle loads of 80 kips each applied at mid-span without any signs of distress. A greater load could not be applied at this location owing to weakness in the anchorages of the reaction beam. On the basis of strain measurements, it would appear that the bridge could have carried a single axle load of 160 kips applied at mid-span. Yielding of a stringer occurred under a single wheel load of 106 kips applied over an interior stringer at quarter span. A wheel load of 74 kips applied to the slab near to an exterior stringer produced a local slab failure.

A specification for rating existing bridges proposed in a previous report by Wright[2] was based on explicit load factors of 1.10 for dead loads and 1.25 for live loads. On this basis but omitting any allowance for impact the permissible axle load would be 56.8 kips. The tests show that the actual load factor on live load would be close to four.

The Poplar Hill bridge was apparently designed to carry a 15 ton traction engine with 10 tons on the rear wheels and 5 tons on the roller. The stress produced by this load plus dead load assuming the effective wheel load to be given by S/4.6 was 16.1 ksi. It would appear that no allowance was made for impact. The stress that would have been produced by an H-15 loading assuming the same distribution of load and making no allowance for impact was 19.6 ksi. With impact at 30%, the stress would have been 24.8 ksi.

The bridge supported a test axle load of 160 kips applied at mid-span of an interior panel without any signs of distress. Yielding of a stringer occurred under a single wheel load of 139 kips applied over the third point of an interior stringer of an end span. A wheel load of 155 kips applied to the slab midway between two interior stringers produced a local slab failure and wheel load of 70 kips applied to the slab near to an exterior stringer produced a local slab failure.

It will be clear from the above figures that both bridges could carry static loads about six times as great as those they were originally designed to carry and that under loads of normal magnitude, the stresses in the stringers were relatively small. It is evident that bridge floors of the slab and stringer type are considerably stronger than conventional calculations indicate. It should be noted also that in each bridge, the weakest part of the structure was the slab near to an exterior stringer.

The reasons for this increase in strength will become evident when the deflection and strain readings are examined in detail.

ii. Loads Transmitted Longitudinally by the Slab

As might be expected, the effect of loading the concrete slab is to deflect it into a saucer shape. This was indicated clearly by the measured

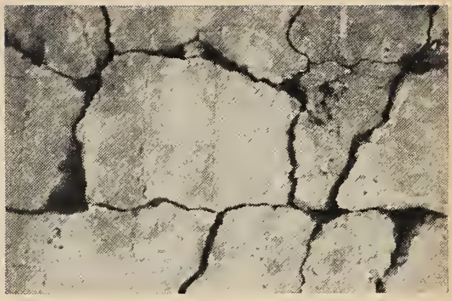

Fig. 11. Photograph of the underside of the deck after local failure of the concrete slab

deflections. It is not possible to arrive at any realistic estimate of the moments in the slab from its deflection or curvature because of uncertainty about the proper value of *I*. The moments of inertia of an uncracked 6 in. slab are 216 in.[4] per ft. of width, neglecting the effect of reinforcement, whereas, if concrete in tension be neglected and reinforcement included, (say ½ in. diam. at 8 in. centres) the moment of inertia is 55 in.[4] There is also uncertainty, though not so much, about the proper value of *E*.

In view of the complexity of plate analysis, it is better to take account of longitudinal moments in the slab by considering the bending of a stringer and slab together; this may be done by considering composite action between the two. If we compare a stringer having composite action with one in which such action is absent (Fig. 1) it will be apparent that the composite action results in an axial compression in the slab. This will reduce the tendency of the slab to crack and hence will increase the proportion of the load tranmitted longitudinally by the slab.

iii. Composite Action

In both bridges, direct measurements were made of slip between the top flange of the steel and the bottom of the concrete slab. These slip gauges showed that slip started to occur as soon as the first load was applied. Evidently there was little if any adhesion between the concrete and the steel. At Bannockburn, it may be assumed that none ever existed because there was paper adhering to the bottom of the slab. At Poplar Hill, there may have been adhesion at some time, but presumably as a consequence of traffic loading this had disappeared by the time of the test. Neither bridge therefore would normally be considered to be of composite construction. In spite of this there is clear evidence that in both bridges there was an appreciable amount of composite action which must have been due to friction between steel and concrete.

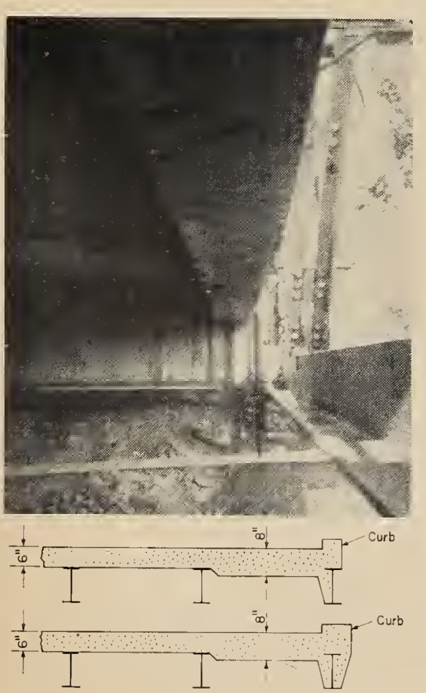
The "degree of composite action" has been determined from the strain measurements made on the steel stringers and the results are given in Tables IV and V.

At Bannockburn, the minimum degree of composite action was about 20% and the average, excluding very lightly loaded stringers, was about 37%. At Poplar Hill, the minimum was about 60% and the average based on 131 observations was 91%. It seems clear that composite action is a factor of major importance in bridge floors of the kind tested. Anything that improves composite action will materially diminish the tensile stresses in the steel produced by static loads. It is important therefore not to paint the top of the beam, to avoid coating it with form oil and not to put any paper of any kind on top of it.

iv. Load Distribution: Stringers stressed below yield

The distribution of loads between stringers may be determined from the experimental results in various ways. Thus we can readily compare deflections, bending moments or maximum strains. It is probably most convenient to compare bending moments and this has been done in Tables VI and VII. These tables show the bending moments calculated from the observed strains and compare them with the theoretical values given by the Hendry and Jaeger theory. In both sets of values, a modular ratio of 10 was assumed, but a different value could have been used without materially affecting the results. For the purpose of computing the parameter a, it was assumed that the slab was uncracked. In preparing these tables comparable results have been averaged wherever possible. This averaging consists of (a) averaging the results of tests which were repeated, and (b) averaging results in stringers symmetrically located with respect to the load. In addition, graphs were drawn showing the relation between load and strain, and these have been corrected when necessary to allow for apparent zero errors. In general it may fairly be said that provided the stringers were not strained to yield, the load-strain graphs were straight lines.

Fig. 12. Edge stringer failure and suggested methods for strengthening the edge panel



The results for the Bannockburn bridge show an excellent agreement for all tests in which the loads were applied at mid-span. The agreement is not close for loads applied at quarter span but the moments calculated from the observed strains are in all cases appreciably smaller than those indicated by theory. It seems probable that the difference was caused by the presence of some restraint at one end of the bridge.

At Poplar Hill, the concrete slab was continuous from one end of the bridge to the other. It therefore seemed reasonable in the first instance to calculate moments in the stringers on the basis of fixed ends at interior supports and then to modify the results by moment distribution. The calculations were lengthy and the agreement with observed moments was not close. On examining the deflection graphs it became clear that there were no points of contraflexure, and much better agreement was obtained by assuming the stringers to have simply supported ends. The reasons for this behaviour are not clear but two explanations are possible:

a. the slab had cracked over the supports;
b. owing to absence of adhesive bond the slab in unloaded spans separated from the beams.

It was not possible to check these ideas in the field. The slab was covered with an asphalt pavement so that cracking of the top surface could not be observed. No actual separation of slab and stringer in unloaded spans was observed but this could easily have occurred without detection.

On examining the results more closely, it will be evident that in a few instances there was a large percentage difference between theory and practice. This was particularly true at Poplar Hill. These large discrepancies occur either in stringers which are remote from the loading points and hence carry small loads only, or on edge stringers. As far as the edge stringers are concerned, it was not possible to apply loads directly above them and so the theoretical results are not strictly applicable.

At Bannockburn, the greatest moment for a 40 kip axle load occurred on an edge stringer. At Poplar Hill, it occurred on the first interior stringer. These maximum moments may be compared on the basis of an empirical distribution factor similar to that given in the AASHO Specifications. If we let the fraction of a wheel load for which stringers should be designed be S/X, then considering the most heavily loaded stringers at Bannockburn, X was 6.3 and at Poplar Hill, X was 6.4. For practical purposes it would seem not unreasonable to assume $X = 6.5$. Admittedly this assumption involves a slight underestimate of the possible maximum moment but this underestimate may be justified if ultimate strength rather than elastic conditions are considered.

v. Load distribution—Stringer stressed to Yield

It proved to be somewhat difficult to apply sufficient load to the Bannockburn bridge to cause yield owing to the inadequacy of the rock anchors. Yield, however, was reached when a single load of 106 kips was applied at the quarter span of Stringer E.

The load required to produce yield at 30 ksi. assuming a degree of composite action (k) of 0.20 was 113 kips which agrees reasonably well with the observed values.

Yield of the stringer caused extensive cracking of the slab on the underside in the vicinity of the load and on the top of the neighbouring beams. Consequently, the slab was no longer so effective in distributing load, and therefore relatively large deflections of the overloaded stringer resulted. The slab and the stringer separated at mid-span by about ¼ in. In spite of this, complete collapse of the bridge did not result and it was possible to increase the load to 110 kips before the anchorage failed. Presumably, the plastic moment capacity of the stringer was sufficient to carry the imposed loads. However, it is imporant to realize that yield of a stringer will cause local failure of the slab, and that this in turn will throw additional load on to the stringer.

At Poplar Hill, yield of a stringer occurred under a single load of 140 kips applied at the one-third point of an interior stringer in the end bay. The calculated load to produce yield, assuming a yield stress of 33 ksi. and a degree of composite action (k) of 0.80 was 132 kips.

The Poplar Hill bridge carried an axle load of 160 kips applied at midspan of an interior bay over interior stringers without *visual* evidence of yield. Under this load however, the bottom fibres of the two stringers under the load points yielded. The calculated axle load to produce yield assuming a yield stress of 33 ksi. and a degree of composite action (k) of 0.80 was 158 kips.

vi. Deflections

The deflection of any stringer depends upon the load it carries and its moment of inertia. The load may be determined in the same way as the bending moment by harmonic analysis and the same distribution coefficients will apply: the moment of inertia will be greatly influenced by composite action. As an approximation, it will be assumed that the moment of inertia is modified by composite action in the same way as the section modulus.

Then: I effective $= I_s + k(I_{cs} - I_s)$

where I_s is the moment of inertia of the slab only, I_{cs} is the moment of inertia of the composite section expressed in steel units using an appropriate modular ratio,

and k is the degree of composite action as previously defined.

Table VIII compares observed deflections at Bannockburn with calculated values assuming a modular ratio of 10 and a degree of composite action (k) equal to 0.3. There is good agreement especially if relative values of stringer deflections are considered. On an absolute basis the agreement may also be considered fairly good, the average ratio of experimental to observed deflection being 0.84.

The results from the Poplar Hill test (Table IX) are less satisfactory. The assumption of a modular ratio of 10 and a degree of composite action of 0.90 leads to an underestimate of deflections of about one third. In order to obtain good agreement a smaller value of stiffness must be assumed. This may be obtained by assuming a larger value of modular ratio or a smaller degree of composite action. It should be noted that the slab at Poplar Hill was about the same as the slab at Bannockburn but the stringers were made smaller, hence the relative effect of an erroneous assumption concerning the slab would be much greater with the Poplar Hill bridge.

The figures given for Poplar Hill refer to an axle load of 80 kips as

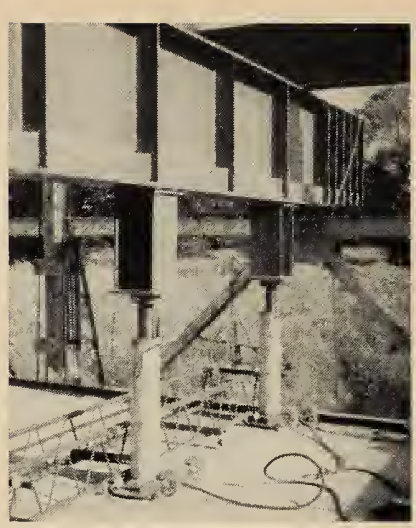


Fig. 13. Photograph of the loading system

compared with 40 kips at Bannockburn. The agreement between observed and calculated deflections is better for smaller loads. As loads are increased the slab cracks in both directions — cracks parallel to the stringers cause a modification of the distribution of load i.e. at higher loads there is less distribution; cracks at right angles to the stringers reduce the effective I of the composite section and hence result in larger deflections.

vii. Effects of Concentrated Loads Applied between Stringers

At each bridge, a number of tests were carried out in which concentrated loads were applied between stringers. These loads were of sufficient magnitude to cause failure of the slab and in some instances the adjoining stringers. (See Fig. 11 and 12).

At Bannockburn, three such tests were made and slab failure resulted at loads of 80, 98 and 74 kips. The smallest figure resulted from applying the load close to an exterior stringer. At Poplar Hill, only one test of this kind was made and failure occurred between two interior stringers at a load of 154 kips. In a later test using two wheel loads, one of which was applied near to an exterior stringer, failure occurred at a total load of 140 kips or a wheel load of 70 kips. A load of 70 kips on the 15 in. diam. loading pad corresponds to a pressure of 396 p.s.i. This is substantially higher than the pressure generally exerted by a truck wheel. Some caution must however be used in drawing conclusions from these results. Different results might have been obtained with different sized loading plates or with small changes in the location of loads.

AASHO Specifications require such slabs as those we are considering to be designed for a moment per foot width of $\pm P_1S/E$ where P_1 is the wheel load, S the effective span of the slab, and E the effective width over which the load is assumed to be distributed.

The allowable wheel load, ignoring impact, according to AASHO Specifications, would have been 9.5 kips at Bannockburn and 12.5 kips at Poplar Hill. The test results indicate no significant difference between the two and there was a minimum over-all load factor of 7.8 at Bannockburn and 5.6 at Poplar Hill.

It should be pointed out that a slab failure near an exterior stringer results in a loss of composite action for that stringer together with a loss of lateral support. The ultimate strength of a bridge deck would be substantially increased if the slab were to be made thicker between the exterior stringer and the first interior stringer. Consideration might also be given to providing concrete encasement for the web of the edge beam. (See Fig. 12).

Results of Tests of the Laboratory Bridge: The laboratory bridge was designed to carry a 15 ton traction engine with 10 tons on the rear wheels and 5 tons on the roller. The original deck was a 6 in. slab of reinforced concrete. Assuming the same load on the timber decks plus the dead load the stress produced in the stringers for an effective wheel load of S/4 would have been 12.5 ksi. The stress produced by an *H*-15 loading assuming the same distribution of load and making no allowance for impact would have been 14.9 ksi. With impact at 30%, the stress would have been 19.3 ksi.

No attempt was made to load the stringers beyond the yield point (assumed to be at 36,000 p.s.i. and each test was stopped before yielding occurred. The average wheel loads required to produce this stress on an interior stringer were:

a) with the deck laminations perpendicular to the stringers, 44.8 kips; and
b) with the deck laminations at an angle of 45° to the stringers, 40.6 kips.

The comparable theoretical wheel loads according to Hendry and Jaeger's theory were:

a) 46.5 kips; and
b) 38.0 kips.

The theoretical values of wheel load to produce a stress of 36,000 p.s.i. in the stringers correspond very closely to the experimentally obtained values.

It has been explained previously that a timber deck can only distribute a load laterally and cannot contribute any strength in the direction of the stringers. It would therefore be expected that the experimental and theoretical results would show close agreement since the only variable affecting the result is the ratio of the elasticity of the timber to that of the stringers. Hendry and Jaeger[8] point out that the result of a poor estimate for the value of the elasticity of the deck has only a small effect on the calculated distribution.

Load Distribution: The theoretical values of the bending moments and deflections have been calculated using the Hendry and Jaeger method. In these calculations the stringers were assumed to be simply supported and the stiffness of the timber laminations was found, by laboratory tests to be 125 x 10^6 lb. in.^{2}/ft. length. These theoretical values are compared with the experimentally obtained values of bending moment and deflections in Tables X and XI.

The results for both decks show an excellent agreement with the calculated values.

Comparing the bending moments on the basis of an empirical distribution factor similar to that given by the AASHO. Specifications we obtain, for the interior stringers, a wheel load fraction of S/5.7. In this instance the value of S is taken as the distance between adjacent stringers measured along the direction of the laminations. For a deck in which the laminations are at an angle of 45° to the stringers the value of S would be $\sqrt{2}$ times the perpendicular distance between the stringers.

Concentrated Load Applied Between Stringers: Two tests were carried out on the second deck with the wheel loads applied between stringers. Failure of the timber deck occurred at wheel loads of 50 kips and 48 kips. One of these failures is shown in Fig. 7.

Table X
Laboratory Bridge
Comparison of Experimental and Theoretical Mid-Span Bending Moments in Stringers

Wheel Load 20 Kips
Load Applied at Mid-Span

Stringer	*Exp. Bending Moment Kips Ft.* M_1	*Theo. Bending Moment Kips Ft.* M_2	M_1/M_2

	Cycle X (Load on Stringer D)		
B	0.0	0.0	—
C	4.3	10.4	0.41
D	41.6	37.1	1.12
E	4.3	10.4	0.41
F	0.0	0.0	—

The allowable wheel load according to the AASHO Specifications would have been 8.0 kips with no impact consideration. The minimum overall load factor (from the test results) would have been 6.0.

Conclusions

The following conclusions are based upon the results of a series of static tests. Caution must be used in applying these conclusions to structures subjected to repeated loads.

1. Bridge floors consisting of concrete slabs resting on I-beam stringers have considerable reserves of strength. They are capable of supporting large wheel loads without risk of either failure or excessive deflection.
2. A realistic estimate of the load distribution between stringers may be obtained by harmonic analysis assuming simply supported ends and the full section of the concrete slab to be effective.
3. The maximum fibre stresses in the stringers and their deflections are substantially reduced by composite action even when there is no adhesive bond between steel and concrete. The actual fibre stress may be estimated with reasonable accuracy on the basis of an assumed degree of composite action.
4. The ultimate resistance of the slab to concentrated loads is much greater than is indicated by conventional calculations. A 6 in. slab with a moderate amount of reinforcement will not fail until a wheel load of about 70 kips has been applied. The slab is weakest near to an exterior stringer. Failure of the slab may result in failure of the exterior stringer.
5. A bridge deck consisting of timber laminations supported by steel stringers can be accurately analysed by using harmonic analysis. In this instance there is no uncertainty as to the amount of composite action since this is zero. The ultimate resistance of the deck to concentrated loads is high for a 6 in. deck supported on closely spaced stringers. With a stringer spacing of less than 4 ft. the deck will not fail until a wheel load of about 40 kips has been applied.

Acknowledgements

The studies reported in this paper were carried out at Queen's University, Kingston, in co-operation with the Ontario Department of Highways as part of the Ontario Joint Highway Research Program.

The field work was planned by Dr. D. T. Wright whilst at Queen's University and carried out under his direction by R. W. Cockfield and B. B. Hope. This report is based in large measure on the two M.Sc. theses submitted by Cockfield and Hope in April, 1959.

The field work was made possible by the assistance of many people. Mr. W. R. Schriever of the Division of Building Research of the National Research Council, gave much helpful advice. The laboratory tests were carried out by T. C. R. Joyce and P. Moran, graduate students in Civil Engineering. The experimental results were analysed by T. C. R. Joyce. Mr. A. M. Toye, Bridge Engineer of the Ontario Department of Highways, took a continuing interest in the project and made many helpful suggestions.

Discussion

BACKWATER COMPUTATIONS FOR THE ST. LAWRENCE POWER PROJECT

Part A—Hydraulic Engineering Aspects of Computations

H. M. McFarlane,
Hydraulic Design Engineer, Ontario Hydro, Toronto

The Engineering Journal, February 1960, page 55.

Author's Reply to Discussion by J. A. Thomas, M.E.I.C.

At Ontario Hydro, backwater computations in river channels containing inconsistencies such as channel enlargements are carried out almost exclusively by means of Leach's Method. In all cases the velocity head at each backwater section or station is included in the solution, and the energy loss in a reach (including bend and expansion losses) is indicated by the slope of the energy gradient. Experience has shown that backwater computations made by means of Leach's Method are reliable, and in the case of the St. Lawrence Power Project the computed slopes were very close to the performance of the headpond reservoir.

The interpolation formulae were intended for use in interpolating only, and as such, gave reasonably satisfactory results. However, it would appear that they might be used at least as a guide if extrapolation were found necessary, although values of Mannings "*n*" beyond the selected range (0.020–0.050) are not normally used in open channel computations.

Fig. 2 in the paper gives the profile computed by the digital computer for the three assumed values of "*n*", and also includes the derived profile interpolated from the other three using the selected value of "*n*". The intention in the paper was to indicate that the interpolated profile based on the selected value of "*n*" indicated slightly higher loss than the profile computed manually using the same selected "*n*" value.

THE EVOLUTION AND APPLICATION OF LARGE SYNCHRONOUS AND INDUCTION MOTORS IN CANADA

G. W. Herzog, M.E.I.C.,
K. Z. Lukaszewicz,
Canadian General Electric Company, Peterborough.

The Engineering Journal, July 1960, page 51.

Discussion by A. J. Girdwood

The authors have presented an excellent summary of the evolution and state of the art of large synchronous and induction machines in general. However, I fail to find too much reference to specific Canadian developments.

Canada has hydraulic power development very comparable in total size to that in the United States. This has resulted in Canadian design engineers accumulating a great deal of experience in large alternating current generators, and making many original contributions to the art. This naturally spills over into the very similar synchronous motor art.

In the field of synchronous motors per se we have also had a very large market in paper mills, and this has made it possible for many original contributions to be made.

More specifically I think of development along the line of stator slot wedges which are designed to improve the flow of air and hence of cooling.

In addition I believe that original methods of constructing stator frames were developed.

In the field of staftless motors, i.e. motors designed so that the rotor mount on the shaft of the driven equipment, (usually air compressors), there have been — I believe — some original mounting methods developed.

Would the authors care to comment on the general subject of original Canadian development work?

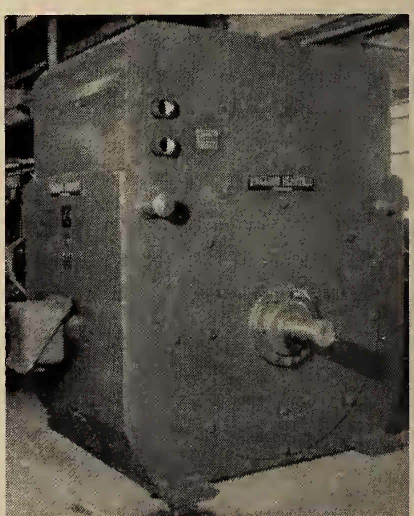
Discussion by John R. M. Szogyen, Jr.E.I.C.

I should like to congratulate Mr. Herzog and Mr. Lukaszewicz for their paper. It is an excellent presentation of Canadian Engineering achievement.

Making electric motors here in St. Catharines we have found, as the authors relate for their own experience, that the introduction of welded construction opened up many possibilities for the application and design of large motors. The freedom of shape which is possible with the welded construction is well illustrated by the authors. I should like to supplement this by my Fig. 1 showing a 1200 hp., 900 r.p.m., totally enclosed water-to-air cooled synchronous motor; this is representative of the predominantly rectangular appearance to which economy and functional design often leads with welded construction.

My Fig. 2 shows five 5000 hp., 275 r.p.m., 6600 volt, synchronous motors of the open type driving pulp grinders in a Canadian pulp mill. The welded construction of these large open motors allows a design that fully utilizes the laminated magnetic stator core to contribute towards the strength of the structure. My Fig. 3 shows the stator of a 4500 hp., 273 r.p.m., 6000 V, synchronous motor of the open type; this motor will drive a reciprocating compressor. It is one of six now being made at St. Catharines for export to Europe.

Fig. 1. 1200 hp., 900 r.p.m. totally enclosed water - air - cooled synchronous motor.



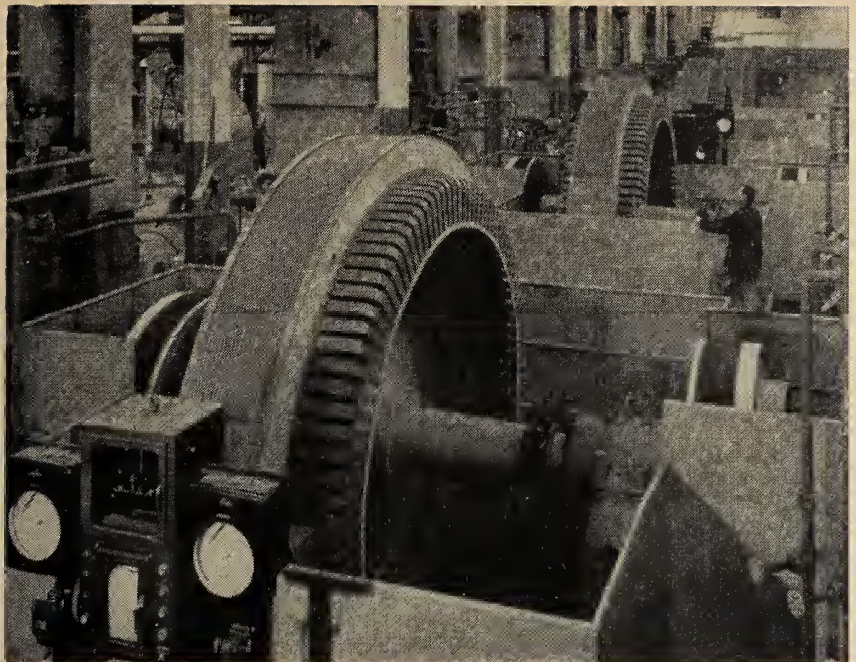


Fig. 2. 5,000 hp., 275 r.p.m., pulp grinder motors installed at Great Lakes Paper.

The authors mention a trend towards applying open-dripproof motors outdoors taking advantage of improved insulation systems. I should like to ask the authors if this trend is not mainly in the southern parts of the United States with climates, and particularly winters, much more temperate than in Canada. It is thought that the Canadian winter with its large quantities of snow necessitates protection of the inner working parts of the motor even though the coil insulation may withstand exposure to moisture. I should like to ask the authors for their opinion on this difference in enclosure requirements governed by climatic differences.

Author's reply

The authors thank those who presented a discussion on the paper. We appreciate your interest.

Replying to Mr. Szogyen's question on the use of enclosures for outdoor operation; certainly sealed insulation systems are not a panacea for outdoor operation in all climates. The choice of enclosure must be governed by service conditions such that snow and dirt do not clog the ventilation passages or adversely affect the motor's operation. Open dripproof motors are replacing totally-enclosed motors to some extent in the pulp and paper industry, rubber industry, and in the steel industry for certain applications.

We appreciate Mr. Girdwood's discussion because of his contribution to the art of designing rotating machines and because of our former association with him. We confirm that the improvements he mentioned were made and also that he contributed to them.

The authors, in writing the paper, had not intended to describe many of the specific details of construction or lay claim to specific developments because it was thought that this information would not be of general interest.

Motors produced in Peterborough are designed in Canada with full knowledge of Canadian requirements and conditions. Development is a continuing process. Many contributions were made to the art over the years both in performance and construction of synchronous and induction machines. Ventilation improvements mentioned in the paper, improved rotor construction, top exhaust frames, the application of epoxy resins to rotor coils, are Canadian developments. Some other developments not mentioned, and which have occurred, include:

Asymmetrical pole spacing to prevent locking;

Part winding starting, now largely abandoned;

Double end rings on amortisseur windings;

Single end ventilation;

Split pole stator windings.

Considerable effort has been devoted recently to the application of the digital computer to the design of rotating machines. Part of this work was reported to the AIEE a year ago in Paper #59-122.

THE ECONOMICS OF AN INDUSTRIAL GAS TURBINE

D. Panar, M.E.I.C.
Assoc. Professor, Mechanical Engineering, University of Alberta, Edmonton
The Engineering Journal, August 1960, p. 59

Discussion by R. E. Chant, M.E.I.C.

The installation described in this paper is not a common application of a gas turbine. The paper therefore describes a problem unfamiliar to the engineer, perhaps too unfamiliar. The

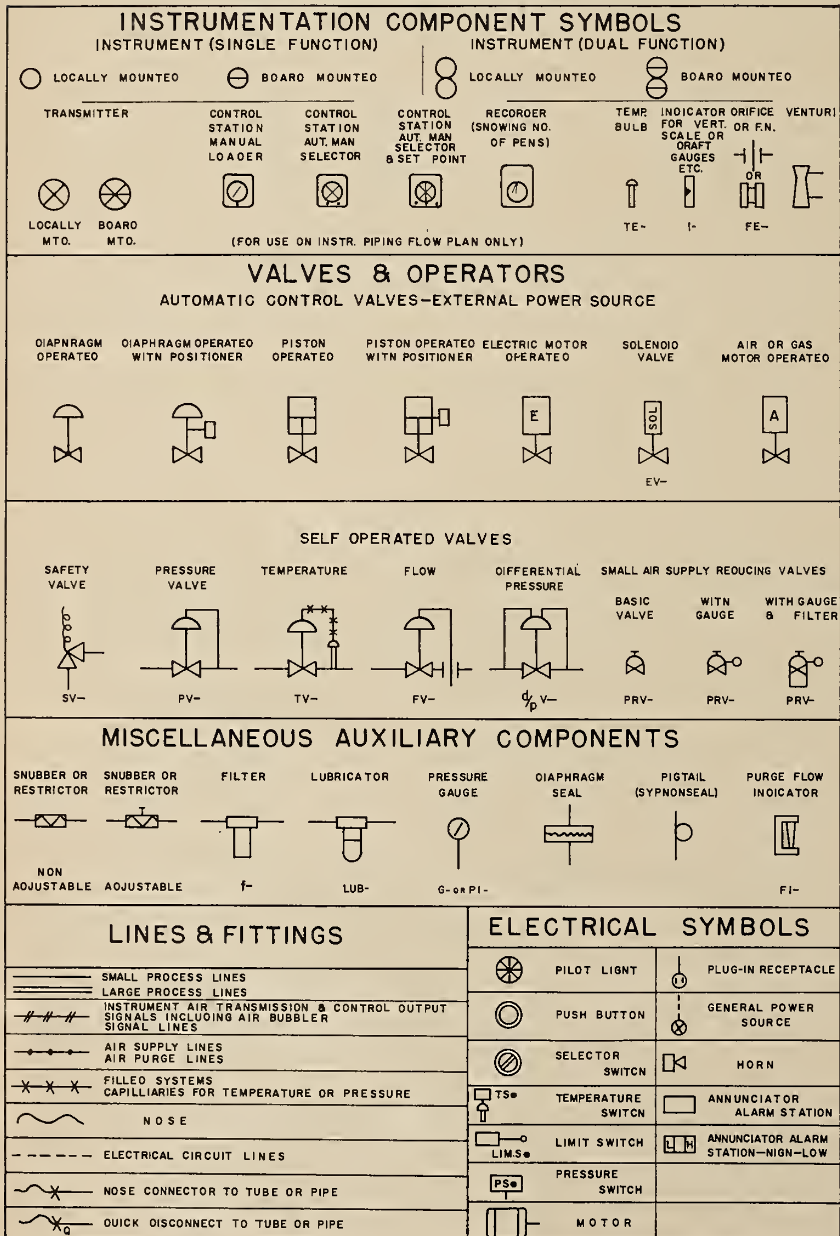
Automation and Control Engineering in Canada

INSTRUMENTATION CODING AND SYMBOLS

J. T. Dykes, JR.E.I.C.

Instrument Engineer, Central Engineering Department,
Dominion Tar and Chemical Company Limited, and Howard Smith Paper Mills Limited, Montreal.

Fig. 1. Instrumentation Symbols.



THE system of coding presented here covers the identification of instrument component functions through the use of a combination of letters and abbreviations; the specific identification of components in control loops by means of a numbering system, and a list of simple pictorial symbols for illustration purposes on flow plans and other drawings. The terminology is based upon standards proposed by the Instrument Society of America (Recommended Practice RPS-1), on an extension of these standards by the Canadian Pulp and Paper Association (Technical Section data sheet S-1) and on methods used within the Dominion Tar and Chemical organization. It is intended that this system will provide a time and space saving method of instrument identification which can be readily interpreted. In particular these coding methods should be used to identify instrument equipment on specification sheets, correspondence, purchasing forms and maintenance records; flow plans, piping and layout drawings; and also as a basis of tagging the actual equipment and interconnecting lines.

Function Identification

The function identification of major instrument components consists of letters or abbreviation used in combination as shown in Table 1. and 1A. The purpose is to identify the component in terms of the process variable and what function the equipment performs. Particular reference is made to primary elements; measuring, controlling, transmitting and alarm devices; and also whether they provide a recording, indicating or integrating function.

The use of the letters or their com-

NOTES:
1. Lower case letters—r, d and t may be used after the first letter to distinguish ratio, difference and time respectively.
2. Used to denote hand operated pilot valves used for remote operation.
3. Applied to valves operated from electrical power measurements and in general to solenoid operated auxiliary valves.
4. Remote operated valves not associated directly with the control of a single process variable.
5. Generally applied to contacts used for alarms or interlocks ("S" may be used as an alternative to "Sw").
6. Q may be used as third letter with I and R where indicating and recording functions also exist.
7. Transducers are further identified by Tx.
8. TW is used to indicate a protective well, while TE indicates a thermal element.
9. Alarm devices refer to actual alarm components, not the switch contacts. Visual or audible signals may be indicated by "L" and "B".

TABLE 1A. FUNCTION IDENTIFICATION FOR SPECIAL PROCESS VARIABLES

Note: This table includes first letter abbreviations to be used for specific applications. Second letter combinations would be in accordance with Table 1. Measurements other than these require full spelling.

Br	Break detections	**Har**	Hardness	**Sm**	Smoothness-surface finish, etc.
Cal	Caliper or thickness	**Lgth**	Length	**SO_2**	Sulphur Dioxide concentration
CO_2	Carbon Dioxide concentration	**O_2**	Oxygen concentration	**Sd**	Draw Speed (speed difference)
Cs	Consistency (% solids)	**Orp**	Oxydation-Reduction Potential	**Th**	Thickness
Fl	Flame detectors	**Pos**	Position, limit, motion	**Tor**	Torque
Free	Freeness (Pulp)	**Prod**	Production, operation	**Vib**	Vibration

binations should be based on the following instructions:

(a) All identifying letters are written in UPPER CASE except for special process variable abbreviations and the optional use of "d", "r" and "t" as per footnotes of Table 1.

(b) It is suggested that for purposes of brevity that the number of identifying terms should not exceed three.

(c) A letter shall have only one definition or significance in its use as a "first' letter in any combination, to define the process variable.

(d) A letter shall have only one definition or significance when used as either the "second" or the "third" letter in a combination, to define the type of device.

(e) It is particularly important in writing the combinations of letters to adhere to the sequence of arrangement shown by Table 1.

(f) No hyphens shall be used between letters or combinations of letters.

Table 1. is a listing of basic function identification letters considered as a general standard. Table 1A is a list of suggested forms to be used in more specialized applications such as consistency, thickness, length and position measurements.

Table 2. is a list of code letters used to describe auxiliary equipment. This is a classification that has not been covered by formal standards. It is presented here to show that a coding problem exists and to provide one solution for coding this group of minor components. This equipment is further identified by either loop numbers as described in the following section or by a consecutive numbering system for such items as filters and reducing valves.

Circuit or Loop identification

Instrument equipment has now been identified in terms of a process variable and in regard to its particular function. The next step in the complete coding of the instrument is to identify it in terms of the particular process application—commonly called the control loop or circuit. The rules and instructions for applying the loop identification are as follows:

1) Each instrument circuit or application should have one number assigned to it which should not be used on any other circuit or application.

2) When used in written work the number should be placed after the letters and separated from them by a hyphen. For example temperature recording controller, circuit No. 1 is written TRC-1.

3) All components in any circuit should have the same number; duplicate components in one circuit are identified thus: PI-1a, PI-1b, PI-1c.

4) For combination instruments that measure more than one variable, or that provide more than one function, each portion of the combination would have its own identification. However, the multifunction component itself is assigned a separate loop number and identified as to function by the letter "K". For example, a combination recorder for flow and pressure would have pens identified PR-1 and PR-5, but the entire recorder would be KR-6.

5) When accessories such as valve positioners, air sets, switches, relays, etc., require identification they should be assigned the same identification number as the other components in their circuit, e.g. solenoid valve EV-20.

The establishment of a loop numbering system in a large plant is not simply a matter of placing all known applications in numerical order. Rather, it is a complex problem which should satisfy the following conditions:

1. Numbers should be kept as short as possible.
2. Loop numbers should, where pos-

TW—Temperature Element Well. (2)
V—Hand Valves — Transfer Switches — Needle Valves — Snubbers, Restrictors, (2) or (3)
VC—Volume Chamber. (2)
WP—Water Purge.

Note:—
(1.) Items to be further identified according to process variable Table 1.
(2.) Items may be further identified according to loop numbers.
(3.) Identical items coded with same number.

sible, follow the sequence of the process.
3. Different processes should have a separate numbering sequence.
4. The system must be flexible in providing for additions to processes and for general plant expansion.
5. Where possible similar processes in separate plants should have the same numerical identification.

It is suggested that the plant be divided into process zones having similar functions. These zones may be further subdivided into particular processes. Geographical zones are generally not recommended. An example of a typical paper mill zoning system is shown in Table 3. This is based on the system used at Howard Smith Paper Mills, Limited, Cornwall, Ontario.

With reference to Table 3 zone O includes miscellaneous equipment and similarly section O of each zone includes equipment common to all sections. If we consider the steam flow transmitter for No. 6 paper machine, the functional identification would be FT—and the loop identification would be 7-621. The complete identification for this equipment would be FT-7-621. In the delegation of numbers, spare numbers are left to provide for additions to the process. In the event that more than 100 control loops are required for a process section, the section number is considered as the first number only. In the case of No. 6 paper machine typical numbers would be 7-699, 7-6100, 7-6101 and so on. This method keeps the numbers small yet retains flexibility.

Symbols

Instrument symbols are used to provide a quick identification of the function and in some cases the location of components. They are used on process flow plans and instrument piping flow plans. In the latter case it is often desirable to draw in a more descriptive way, such items as

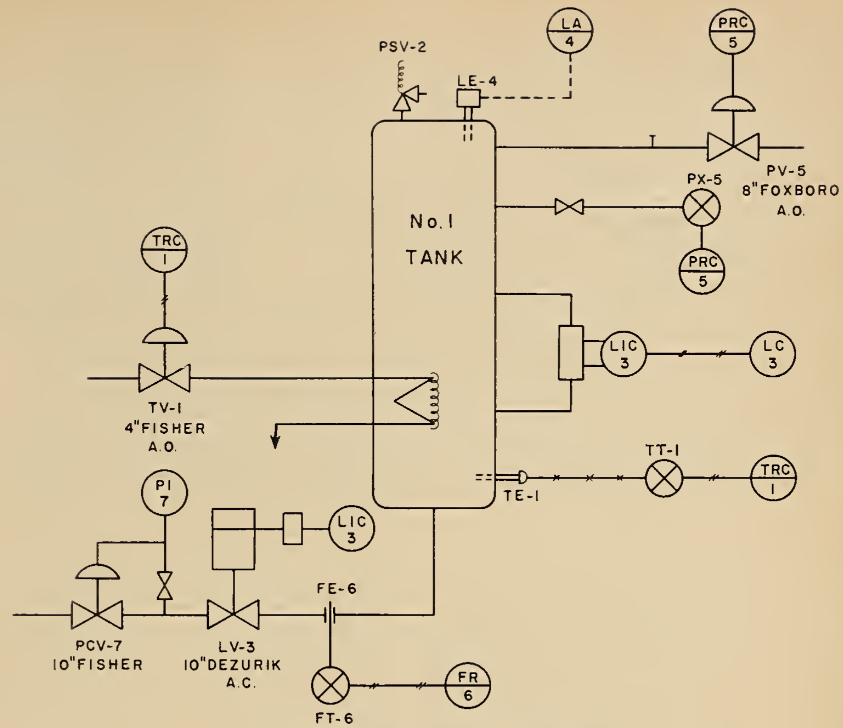

Fig. 2. Typical Process Flow Plan.

recorders, control stations and alarm annunciator stations. In special cases, a brief explanatory notation may be added alongside a symbol to clarify its function or to show pertinent design data. A few such notes are easier to apply and use than a great variety of more complicated symbols.

The symbols shown in Fig. 1 are based on recommended standards by both the ISA and CPPA. These have been extended to include such items as self operated valves, valve positioners, auxiliary equipment and a more detailed identification of control stations and recorders.

Fig. 2 shows an example of how these symbols are used on a process flow diagram. In general only the primary elements, transmitters and final control equipment, together with references to recording or control instruments, are shown on the process flow sheet. On the other hand, the detailed instrument flow diagram must show all instrument components, lines and connections. In this case it is desirable to employ component symbols which are more descriptive, especially in the case of recorders and control stations.

In the establishment of a standard coding system it must be understood that in the interest of simplicity it is not possible to cover every possible variance—nor is it possible to satisfy the opinions of all the experts in regard to terminology. At the same time it is in the general interest of all concerned to standardize at least on the majority of function coding, on the basic principles of loop identification and the graphic symbols for major components and connecting lines. It is hoped that the presentation of this data will assist in the acceptance of a standard method of instrument identification.

75th Annual General and Professional Meeting

May 31-June 2, 1961

Vancouver, British Columbia

Canadian Developments

The massive Place Ville Marie Project in Montreal, featuring a 42-storey Cruciform Building, now is about 18 months from completion. The development, excluding the Cathcart Street Building and the Mansfield Street Building, will have a floor area of more than 3 million square feet. By early autumn about 15 tons of structural steel had been erected and an additional 10 tons was scheduled for erection by early 1961. Approximately 200,000 cubic yards of rock and earth had been excavated and about 50 tons of concrete had been poured.

As the steel work of the Ville Marie Project is etched higher against Montreal's skyline, the value of extensive preplanning becomes increasingly apparent. A. P. V. Bennett, project engineer for the general contractors, The Foundation Company of Canada Limited, says that in the pre-planning of such a large job the temporary services become greatly important. These services include passenger elevator service, plumbing and drainage, heating, light and power, communication, material towers, and the extremely important safety program.

Permanent hoistways are to be used to provide temporary passenger elevator service. These temporary elevators are planned to be in service within four weeks of the completion of the structural steel erection at the various elevator machine room floors. The first instance is the second floor. Initially, elevator stops will be so provided that workers will have a maximum walk of three floors. Longer walks will be required until four elevator banks are in operation, with stops up to the 41st floor. It is planned that in all cases the permanent passenger elevator machinery will be used for temporary service. However, temporary equipment will be provided for the second floor stop.

The temporary plumbing and drainage service includes temporary water lines, sanitary facilities and fire protection. A temporary 4 in. riser will be installed in sections in the core of the Cruciform Building as soon as the metal deck is placed. At the same time a permanent drain stack will be erected to connections which will be made from various services in the building. Fire hose stations will be connected by branch lines from the temporary riser at each floor, and these will remain activated until replaced by the permanent fire protection installation. Where water is not available portable hand-type fire extinguishers will be provided adjacent to the actual work area. On each floor there also will be two 45 gal. drums with a water connection to the riser. This connection will be discharging water continuously into the drums and a suitable overflow pipe will be provided at the top of the drums to connect back into the drain stack.

For sanitary facilities there will be two washrooms at the Plaza level and adjacent to the wet columns and located at every fifth floor there will be additional washrooms in one of the wings. When permanent washrooms are finished in the core of the building the temporary toilets will be transferred and connected in these washrooms. They will remain in service until the permanent washrooms are ready.

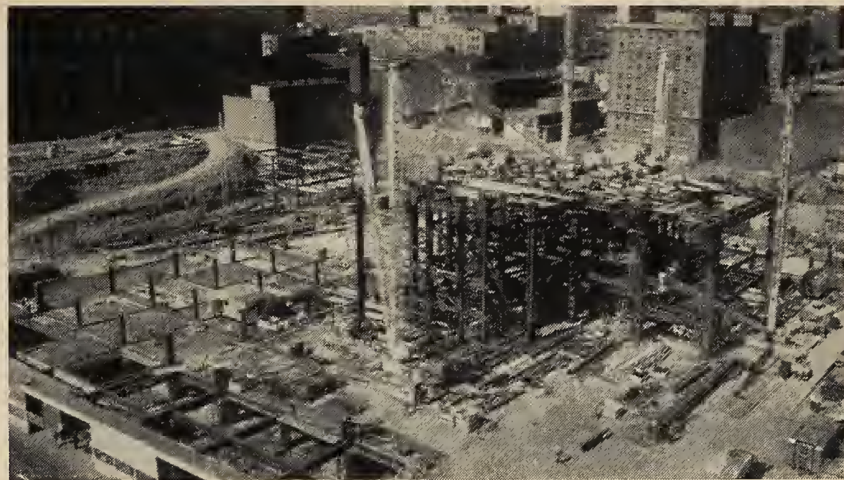
There is no provision for a central steam generating plant on this project. Steam requirements will be provided by the Canadian National Railways from its generating plant. When work permits, a high-pressure steam riser will be erected in stages up to the lower mechanical floor. For the lower 20 floors two permanent secondary water supply risers will be pushed up as soon as possible behind the structural steel. These will be used as temporary steam supply risers. Two permanent re-heat supply risers will be used as temporary condensate return risers. A temporary piping system will be provided at the lower mechanical floor to reduce the high-pressure steam to serve requirements. Four unit heaters will be installed at each floor. The aim in heating the building is to keep to a minimum the temporary requirements and heating, and to put the permanent heating installation into operation as soon as possible. The unit heaters from the lower 20 floors are expected to be re-used in the upper 20 floors during the 1960-61 heating season.

Temporary light and power has been planned in a manner similar to the other services. To be provided for in this instance are general lighting, fire station lighting, special temporary lighting in storage areas, hoisting areas, hoistway

Lower Level Construction

entrances, exits and temporary equipment, passenger elevator service and material tower hoists. A 1,000 kva. temporary sub-station serving the power requirements now is being augmented by a 1,500 kva. unit. Permanent transformer equipment in the sub-station will be put into operation as soon as possible as it is expected that the material hoists will require the full output from the sub-station when they all are working together. Temporary lighting is based on one-quarter watt per square foot.

Three double material towers have been provided for the service of the building during the construction period. Users of the towers will be required to schedule their deliveries sufficiently in advance to avoid congestion at the tower accesses. A closed-circuit telephone service will aid control of hoisting operations. A public address system will provide freedom of communication at all times by personnel in the building.



View Looking North

The safety program is under the direction of Murray Miner who has had field experience and extensive training. Prior to his appointment as Safety Co-Ordinator, Mr. Miner received a course on the Lateiner Method of Accident Control given by the Construction Safety Association of Ontario. Key to the success of the Safety Program is the instruction of all foremen in the application of accident control methods. All foremen, including those of sub-contractors, are given a course of instruction by Mr. Miner, after which they are given a written test. The result of having a foreman with a good knowledge of accident control means that the workers are constantly exposed to a safety-conscious person who can instruct them in safe working habits.

Because of this program the Ville Marie Project has experienced extremely favorable rates of accident frequency and severity. Figures compiled to Sept. 15 showed approximately 1,025,000 man hours had been worked. The accident frequency rate was 45.83 and the severity rate was 963. According to the latest figures available for general contractors, the national average accident frequency rate was 52.9 and the severity rate was 2,583. EIC

International News

Russia's achievements in the field of hydraulic generation and EHV generation are outstanding, concluded a delegation from Canadian electric utilities which visited power installations and industrial centres in European Russia and Siberia in May. Members of the group felt Russian achievements in thermal generation and atomic power generation were not particularly impressive. Short and long-range plans, co-ordinated with the U.S.S.R.'s total national objective, were believed by the group to provide the necessary priority and purpose for such large-scale effort.

Considering their present status and post-war performance it appeared their general objective will be achieved. The delegates also concluded that it would be mutually beneficial to continue technical liason between electric and utility organizations in Canada and Russia and that early consideration should be given to means through which this co-ordination could best be achieved.

The priority in Russia is being placed on the construction of fossil fuel fired thermal stations rather than hydraulic stations. In spite of this priority there was no evidence that hydro plants under construction which were visited were not being pushed to completion at a rapid pace.

Members of the delegation were: H. P. Cadario, Assistant Director of Engineering, Ontario Hydro; J. S. Duncan, Chairman, Ontario Hydro, Toronto; H. M. Ellis, Chief, Electrical Research, International Power and Engr., Consultants, Vancouver; A. E. Grauer, President, British Columbia Electric Company Limited, Vancouver; J. L. Gray, M.E.I.C., President, Atomic Energy of Canada Limited, Ottawa; R. E. Grout, M.E.I.C., Vice President, Shawinigan Engineering Company, Montreal; A. W. Howard, M.E.I.C., General Manager, Calgary Power Limited, Calgary; F. L. Lawton, M.E.I.C., Vice President and Chief Engineer, Power Division, Aluminium Laboratories, Montreal; H. A. Smith, Assistant General Manager, Engineering, Ontario Hydro, Toronto; A. W. Southam, Managing Director, British Newfoundland Corporation Limited, Montreal; and D. M. Stephens, M.E.I.C., Chairman and General Manager, Manitoba Hydro-Electric Board, Winnipeg.

A report of the visit was prepared by Mr. Cadario and Mr. Smith. It was revised to incorporate changes and additions recommended by other members of the delegation. This article was prepared from the report.

Development of the power system has two guides—a 20-year general plan and a more specific seven-year plan due to end in 1965. It was stated repeatedly that increasing emphasis was being given thermal plants because they would provide more capacity in a given time than hydraulic plants. The general approach is to concentrate on large-capacity plants, up to 6,000 Mw. hydraulic and 2,400 Mw. thermal. This would incorporate units up to 500 Mw. hydraulic and 300 Mw. single-shaft and possibly 800 Mw. two-shaft thermal units. Accompanying this is an extensive program for transmission lines. The seven-year plan calls for 6,600 miles of 500 kv. line, 4,000 miles of 300 kv. line, 19,000 miles of 200 kv. lines and 100,000 of lower voltage lines down to 35 kv. The program also incorporates 7,000 new substations.

The following table indicates the development of installed capacity in megawatts in the Soviet Union from 1913 until 1959, and the 1965 target.

Year	*Thermal*	*Hydro*	*Total*
1913	1,082	16	1,098
1925	1,371	26	1,397
1935	6,027	896	6,923
1945	9,872	1,252	11,124
1950	16,396	3,218	19,614
1955	31,250	5,996	37,246
1957	38,356	10,040	48,396
1959	46,520	12,620	59,140
1965	90,400	22,600	113,000

Two aspects of the power planning system in the U.S.S.R. are fundamentally different from the approach generally used in other countries. Firstly, the overall plan for the power system is only a component of a much broader plan for regional and national industrial development. Secondly, it would appear that the broader industrial plan has one primary objective—to attain maximum capacity in the shortest possible time.

Hydro-Electric Stations

Only about 3% of Russia's vast hydroelectric potential has been developed. These resources are scattered, with the largest potential in the northern and eastern parts of Siberia. Large rivers provide for extremely large plant installations such as the 4,500 Mw. Bratsk project on the Angara River. The Bratsk development is now under construction. Other projects are estimated as high as 20,000 Mw. Geological conditions peculiar to European Russia increased problems associated with large plants.

Hydraulic plants on the Volga and other rivers in the area are located mainly on non-rock foundations. Northeastern plants, as Bratsk and Krasnoyarsk, are located on rock. What appear to be satisfactory installations at Kuibyshev and Stalingrad were provided following comprehensive geological investigations, and unusual designs of the powerhouse and spillway for differential settlement. These plants, which have the greatest peak capacity in the world, have experienced considerable settlement without unsatisfactory performance.

Certain plants, including the Kuibyshev and Stalingrad, employ submerged spillways as part of the powerhouse. Russian engineers said this design reduced concrete needs by 10% to 12% and provided increased turbine output due to tailwater suppression, particularly during high-flow periods. Both plants have trash racks on structures separate from the powerhouse. This unusual design was adopted to reduce loss of head at the units due to large amounts of foreign material in the Volga. Methods of removing this at the trash racks apparently were inadequate. Russian engineers indicated this design would not be repeated.

Powerhouse and spillway construction was a mixture of precast and poured concrete. Construction methods, based on maximum mechanization, appeared very efficient. The delegation was told that by 1965 precast concrete will be used for 90% of hydraulic plant construction. Design and manufacture of large hydro turbines and generators are good. They are operating 115 Mw. Kaplan units at Stalingrad and at one Kuibyshev station and are producing 225 Mw. Francis type units for Bratsk. They have designed 500 Mw. units for the Krasnoyarsk station now under construction.

Thermal Power Stations

Post-War operating plants have a maximum capacity of 600,000 kw., with most unit sizes 100 Mw. to 150 Mw. Factory production facilities were geared to produce boilers and turbo-generators of this size with moderate steam conditions.

Factories visited at Kharkov and Leningrad had 200 Mw. and 300 Mw. units in production. The 200 Mw. units were in mass production while the 300 Mw. units were the first in this size. Engineers were making designs for units of 500 Mw., 600 Mw., and 800 Mw. It would appear they intend to expand size and steam conditions rapidly. They intend to standardize certain sizes and mass produce them.

Observed at Leningrad Metal Works were completed 165 mva. turbo-generators with water-cooled stators, although most of their present designs, including the 200 Mw. units, are hydrogen cooled. Production facilities and products, including finished units, appeared good and of high standard.

The use of precast concrete and prestressed concrete at the thermal power stations was most noticeable. Little structural steel was used. To reduce construction time the Russians intend to do more field erection of boilers, including the fabrication of sections in the field.

Nuclear Plants

The nuclear program plays a minor role in the seven-year plan. The general view is that nuclear plants will not compete economically for some time, and that safety and reliability charasteristics are not well known. Neither do they consider they have a good reliable fuel. When such a fuel is developed the program will be accelerated. The present effort is directed primarily toward obtaining experience by building and operating several types of plant. EIC

75th Annual General

and Professional Meeting

Vancouver, B.C.

May 31 - June 2, 1961

Month to Month

Two significant international conferences concerning engineering were held in Montreal early in October. Attending were delegates from Canada, the United States, in addition to guests from France, Mexico, and Russia. The Mexicans were members of a technical educational mission who chose Montreal as the first stop on an extensive tour of Canadian and American university cities. The conferences were the 28th Annual Meeting of the Engineers' Council for Professional Development, Oct. 3-4, and the Fourth Biennial Engineering Education Conference, Oct. 5-6.

The visit of eight Mexican engineers and scientists was sponsored jointly by UNESCO and the Bank of Mexico. Its purpose was the observation of teaching methods and possible applications in industry. The Institute, at the request of the Department of Trade and Commerce, arranged the 10-day Montreal segment, which began Oct. 3. The Mission was headed by Alberto Bremauntz, Representative of the Bank of Mexico, Productivity Office, Industrial Research Department. Others were: Jose Acevedo, Director of the Faculty of Chemistry of the University of Guanajuato; Guillermo F. Davalos, Director of the Faculty of Chemistry of the University of Nuevo Leon; Ruben Ortiz, Director of the Faculty of Chemistry of the Autonomous University of San Luis Potosi; Alfredo Ortega, Director of the Faculty of Chemistry of the University of Yucatan; Antonio Elizondo, Head of the Department of Electrical Engineering at the Institute of Technology and Higher Studies of Monterrey; Jose Raigosa, Secretary of the Faculty of Engineering at the Autonomous University of Guadalajara; and Abel J. Navarro, Advisor on Industrial Research, National University of Mexico. Senora Acevedo accompanied her husband.

A tight working schedule had been arranged for the Mexican group and it entered into the activities enthusiastically. They arrived by air from Mexico City Oct. 3. Dean D. L. Mordell of McGill's Engineering Faculty was host at a luncheon several hours after their arrival. They toured McGill that afternoon and the following day, and attended the E.C.P.D. banquet on the evening of Oct 3. The group entered fully into the activities of the ASME-EIC Engineering Education Conference Oct. 5-6.

Mr. Dick and Senor Bremauntz take notes during University of Sherbrooke tour.

On the Friday of their first week they travelled by train to Sherbrooke. A thorough inspection of the University of Sherbrooke's new engineering and science facilities was arranged through the courtesy and co-operation of Rector Msgr. Irenée Pinard, Gaétan Côte, President of the Advisory Committee of the Science Faculty, Jean-Paul Champagne, Secretary of the Science Faculty and Head of the Electrical Division, and Abbé Sirois, General Secretary of the University.

Following a lunch at which Institute President George McK. Dick was host, the group toured the Sherbrooke plant of Canadian Ingersoll-Rand Co., Limited. They spent Thanksgiving weekend at a Laurentien resort during which they held extensive seminars on the Canadian aspects of their project. On Tuesday they were guests of Dr. H. Gaudefroy, Director of l'Ecole Polytechnique for a tour of the school. The following day the members visited industrial plants in Montreal.

The final item in this segment of their tour was a guided visit to the St. Lawrence Seaway, aided by John Akin, Chief Information Officer of the Seaway Authority. This tour began at the St. Lambert locks, where they saw the *Red Wing*—the largest vessel capable of using the facilities—lock down. Particularly impressive to the visitors was the Beauharnois power station which develops approximately the same amount of power as is generated by all of Mexico's hydro-electric facilities. The tour ended at Ontario Hydro's facilities near Cornwall, after which the group continued by bus to Ottawa where visits to the National Research Council and the University of Ottawa were scheduled. They left Canada by air for Chicago Oct. 15.

E.C.P.D.

The Council, composed of seven American societies and institutes and the E.I.C., is concerned largely with standards of engineering education and with accreditation of engineering schools. The United States bodies which participate are: American Society of Civil Engineers; American Institute of Mining, Metallurgical and Petroleum Engineers; The American Society of Mechanical Engineers; American Institute of Electrical Engineers; The American Society for Engineering Education; American Institute of Chemical Engineers; and the National Council of State Boards of Engineering Examiners.

Reports of internal committees consumed most of the opening day's sessions, which were augmented by luncheon and banquet meetings. Canada's interest in this field does not yet extend to the accreditation of engineering schools, and this was referred to in the banquet address by Col. L. F. Grant of Kingston.

"This is a problem we have not yet faced in Canada," Col. Grant said. "We now have only 11 degree-granting engineering schools, but soon we will have 20. We have talked a lot about it, and have watched E.C.P.D.'s program in the United States with great interest. Their methods will be of great help to us."

Col. Grant is a past president of the E.C.P.D. and a past president of the E.I.C.

He touched briefly on the objectives of E.C.P.D. and said he hopes for continuing firm discussion on a contentious point in engineering education — the proper balance between theory and practice.

Alan Jarvis, editor of *Canadian Art* and a former director of the National Gallery in Ottawa, addressed the luncheon meeting.

Much construction, particularly in the post-war period, has been carried out without taste, Mr. Jarvis said. Of the first million homes built in Canada following the Second World War, only 2% were designed by architects. This was apparent, he said, in a recent report prepared by the Royal Architectural Society. An investigation committee visited 15 Canadian cities and found the same pattern of dullness in the buildings and discontent among the home owners.

"We are sacrificing standards of living for standards of having," Mr. Jarvis said.

The proper balance between theory and practice in engineering education was argued during a panel discussion at the final day of the Meeting.

Dean Dale E. Corson of the College of Engineering at Cornell University suggested engineering students require a large amount of theoretical knowledge. This, he said, would enable them to adjust to changing engineering practices and findings.

Norman A. Hall, Head of the Department of Mechanical Engineering at Yale, insisted that as engineering is a practising profession, there should be proper emphasis on practical courses.

"There is a very real problem involving the effective life of an engineer," Dean Corson said. "Conditions are changing so rapidly that an engineer 10 years out of college may fall behind. Many industries are demanding night refresher courses for their older engineers. Industry's only alternative would be to hire young graduate engineers who are on top of recent developments."

Dean Corson said student engineers must be taught relevant subjects so they can understand problems in depth. The greatest need is flexibility in some courses and in some schools.

"To face present problems we need engineers who are properly phased," Dean Corson said. "Our problems are so complicated we must bring all possible imagination to bear."

Mr. Hall said the ability to design is a basis for engineers and a basis in the E.C.P.D. accreditation program. Cul-

President's Column

NOW THAT the Fall season has arrived the Presidential Visits to Branches have commenced. These opened with the President and Mrs. Dick attending the Maritime Professional Engineers meeting at St. Andrews, New Brunswick. The Presidential party included Vice-Presidents Lawton and Higginson, and General Secretary Page. Past-Presidents of the Institute were represented by Dr. Ira MacNab of Halifax, Dr. John B. Stirling of Montreal and Dr. Clem Anson of Sydney, Nova Scotia.

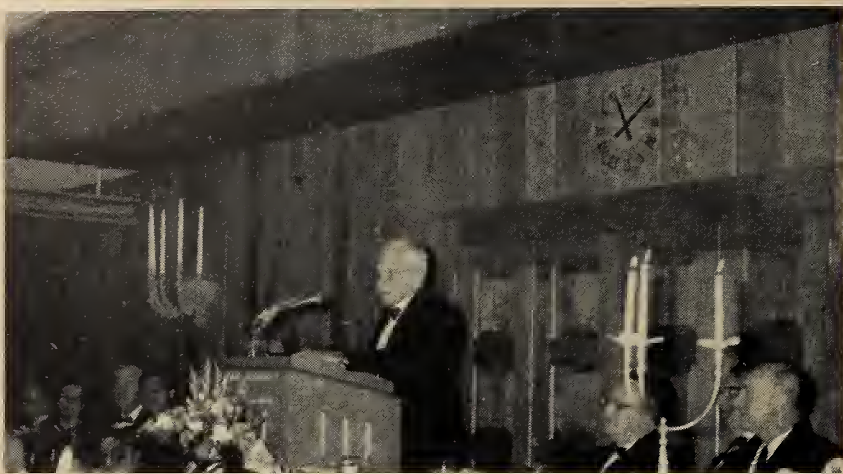
Your President had the honor of addressing the opening luncheon, and chose for his subject, as a token of appreciation of the fairer sex, "The Engineer and His Wife."

A meeting of the Executive Committee of the E.I.C. Council was held during the St. Andrews gathering, with the three Past Presidents in attendance, and several Councillors from Montreal and the Maritimes.

The President and Mrs. Dick proceeded from St. Andrews to visit Branches at St. John's, and Corner Brook, Newfoundland; Halifax and Truro, Nova Scotia; and Moncton and Fredericton, New Brunswick. The tour concluded with visits to Baie Comeau and Rimouski, Quebec. During this tour Vice-Presidents Higginson and Miller and their wives accompanied the Presidential Party through their respective districts, while the General Secretary also was present for the major portion of the program. Enthusiastic receptions were experienced at all points, while the meetings provided excellent opportunities for the President to explain the aims and objectives of the Institute, and to stress the desirability of the Branches developing increasing attention to the provision of technical programs.

The importance of maintaining increasing interest in membership was also pointed out, with mention being made of the new Membership Committee of Council recently formed under the chairmanship of Councillor Stan Cassidy of Fredericton.

The 28th Annual Meeting of E.C.P.D. was held in Montreal, October 3rd and 4th, and was a great success. The 4th Biennial ASME-EIC Conference on Engineering Education which followed on October 5th and 6th at Ecole Polytechnique provided an excellent opportunity for the study of future educational needs for Engineers.



Col. L. F. Grant addresses the E.C.P.D. banquet.

minating experience should provide the emphasis on practice rather than on theory.

Until about 40 or 50 years ago all engineering was basic and practical in approach, Mr. Hall said. In the 1920s and 1930s there was an endeavour to spread engineering curricula to handle new needs, resulting in the birth of such specialties as automotive, air-conditioning and aeronautical engineerng. Eventually ths broke down, he said, because it represented a constraint. This (theoretical) training caused engineers to lack the ability to forsee.

"It also caused the formation of Engineering Science . . . which today is an imperative tool, as drafting once was."

Mr. Hall concurred with Dean Corson that future training must be adaptable and flexible so that future problems can be met, because ". . . . the very nature of progressive engineering produces obsolescence."

Quebec's education system was described at the final luncheon meeting by Dr. Leon Lortie, Head of the Extension Department at the University of Montreal.

Dr. Lortie suggested Canada is losing many of its best brains to the United States not only because of the difference in salaries, "but to greater opportunities, principally in the field of research, academic as well as industrial."

"Very few industrial firms maintain research laboratories," he said. "Canada is greatly handicapped in this respect because few industries that are wholly owned by American companies invest capital or some of their earned revenue in fundamental research, which is always conducted in the huge laboratories of the parent company.

"An exception is the pulp and paper industry which maintains in Montreal the Pulp and Paper Research Institute in co-operation with McGill and the National Research Council where fundamental research on cellulose lignin and other constituents of wood has been going on for close to 35 years.

"It is true that U.S. owned companies based on the use of Canada's natural resources pay taxes, part of which is used for the maintenance and protection of education, but many Canadians feel that our country does not get a fair share of the profits gained from the depletion of these resources and, moreover, loses some of its best talent which is attracted to the laboratories built and operated in part with these profits.

". . . this is one particular aspect of a question with which more than a few Canadians feel uneasy."

The E.C.P.D. meetings were held at the Queen Elizabeth Hotel. Registered were 197 delegates and 30 ladies.

Engineering Education Conference

This biennial conference is sponsored jointly by the American Society of Mechanical Engineers and the E.I.C. and was held in Montreal in co-operation with l'Ecole Polytechnique and McGill University. Registered were 140 delegates and 10 ladies. Theme of the Conference was "The Engineer in 2000 A.D. — How Much Science in his Education?"

The business meetings all held at l'Ecole Polytechnique, were divided into four sessions. The first two, held in the morning and afternoon of Oct. 5, attempted to delineate the role of the engineer in 40 years. The following day's sessions dealt with methods of training the engineer of 2000.

Session I

The conference was opened with remarks by Dean Mordell and a welcome by Dr. Gaudefroy. Four presentations followed. These were made by: Dr. D. M. Myers, Dean of Engineering, University of British Columbia; Dr. P. F. Chenea, Head, Department of Mechanical Engineering, Purdue University; R. S. Sproule, Manager, Hydraulic Division, Dominion Engineering Company, Montreal; and Dr. G. N. Patterson, Director, Institute of Aerophysics, University of Toronto.

Chairman of the first two sessions was Professor Edward McHugh, Dean of Faculty, Clarkson College of Technology, Potsdam, N.Y.

Dean Myers said that engineers, as we know them today, will not exist in the year 2000. The most significant development and influence will be in the field of computers.

What has been done already in this field is not very significant, Dean Myers said, but it has opened the doors to limitless possibilities. Many jobs now being done by engineers are routine and repetitive. Any chore of this nature can be done more efficiently and economically by a computer. He said that as the invention of the steam engine replaced physical effort in many areas, so will the evolution of the computer replace much mental effort.

The biggest needs in the world today are in the field of communications, Dean Myers said. These are communications in the broadest sense of the word — the transmission of intelligence from person to person, from place to place, and from the past to the future. The principles of the modern computing device will have a profound effect on communications. There now are many examples, as control of telephone and cable communication, control of traffic, linear programming in the organization and movement of materials, factory processes and methods.

Because of inconsistent grammar,

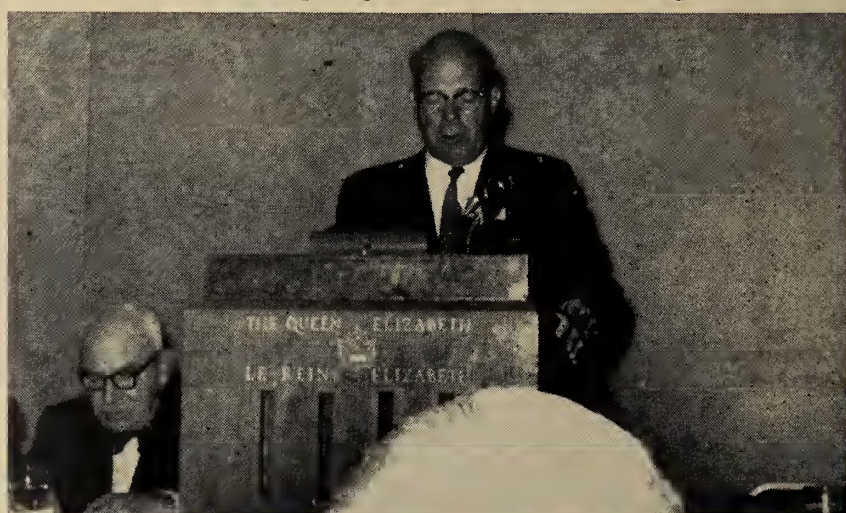
Mr. Everitt reporting to E.C.P.D. luncheon meeting.



PRESIDENT AWARDED HONORARY DEGREE by the UNIVERSITY of SHERBROOKE

President George McK. Dick has been awarded an honorary Doctor of Science degree by the University of Sherbrooke. The degree is in recognition of the important developmental work done by Dr. Dick towards the University and its Faculty of Science. In addition, the President, who is Chief Engineer of Canadian Ingersoll-Rand Company Limited, has made an outstanding contribution through almost five decades to Canadian engineering achievement.

Dr. Dick was born in Scotland and attended public schools there. After a short stay in the Canadian West he moved to Sherbrooke where he worked as an apprentice at Canadian Ingersoll-Rand. During the First World War he designed machinery for the manufacture of munitions.

He attended Bishops University in Lennoxville, Que., after which he entered McGill. He graduated from McGill in 1924 with a degree of Bachelor of Science, Honors in Mechanical Engineering. He was British Association Medallist at graduation and was holder of the Babcock and Wilcox Scholarship. His summer essay took prizes in the Canadian Pulp and Paper Association and the E.I.C.

Included in the early phases of Dr. Dick's diversified career was experience in the pulp and paper field and in the design of stockers and boilers

After re-joining Canadian Ingersoll-Rand Dr. Dick for many years was Chief Hoist Engineer, in which capacity he pioneered the design of many mine hoists used today in Canada. During the Second World War he was Chief Engineer of The Sherbrooke Pneumatic Tool Company, a subsidiary of Canadian Ingersoll-Rand and was responsible for the design of much of the shell manufacturing equipment used by this company.

Later he became Technical Assistant to the Works Manager of the company, a position he held until 1945, when he was appointed Manager of Engineering with duties embracing management of all phases of the company's engineering and technical activities. These duties later were broadened to include complete control of the company's purchasing program, and he became Manager of Engineering and Purchasing. Since his appointment in 1952 as Chief Engineer Dr. Dick has devoted his time principally to the development of new products, materials and processes.

Dr. Dick is a Past Vice-President of the Institute, a member of the American Society of Mechanical Engineers, the Technical Association of the Pulp and Paper Industry of the U.S.A., The Corporation of Professional Engineers of Quebec, The Canadian Institute of Mining and Metallurgy, The Canadian Pulp and Paper Association, and The British Association for the Advancement of Science.

He is a member of the Advisory Committee of the Faculty of Science at the University of Sherbrooke and has lectured there.

When he accepted the honorary degree from the University, Dr. Dick reviewed the achievements of Quebec since his youth, and outlined the technological and scientific advances the world has witnessed in the last 150 years.

"From all this review I can make only one suggestion," Dr. Dick told the convocation, "and it is this: we in Canada, as well as in the other countries of the Western World, must prepare ourselves mentally and technically to carry on this ever-changing program. We must be prepared to meet all challenges to our technical and scientific development on both the academic as well as on the commercial front.

"How can this be done? It can be done by only one method, namely more and better education. There is no short cut, no magic wand which can be waved to give us scientists, technicians and engineers. No country in the world has any simple method; just education in suitable and increasing quantities.

"Curricula must be steadily improved, teaching methods must be raised to maximum efficiency, and education brought within reach of all. The people of our country must be indoctrinated to show interest in the educational processes of our land, while governments must continue to expand their sympathetic assistance to provide funds."

The President sketched the racial and national influences in Canada and suggested these should be accepted as a challenge "to take the best from the magnificent educational legacy of our forefathers and to weave them into a sound and staple pattern in which to project the future educational fabric of our land."

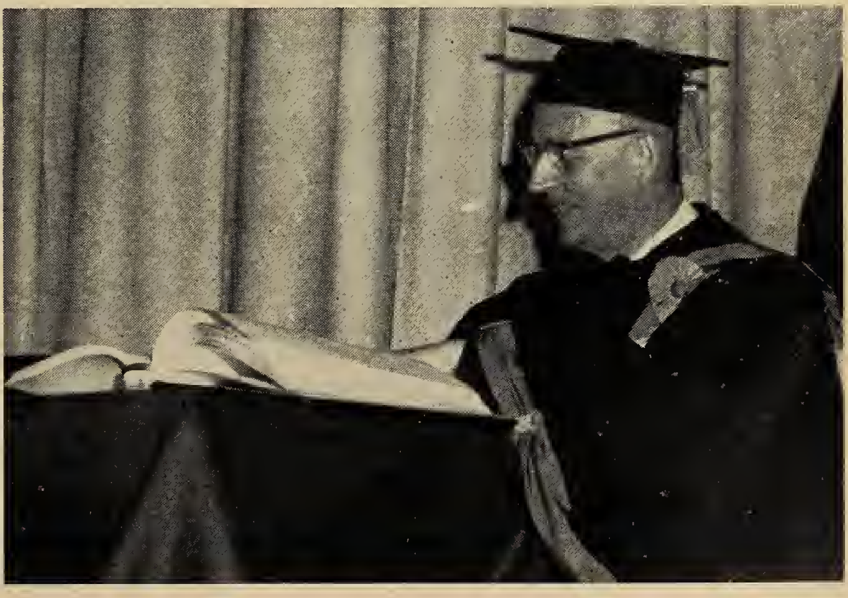
"While I have stressed the scientific and technical aspects of education, let it not be misunderstood that I have, in any way, minimized the wonderful powers of classical studies. A well balanced education discipline must be strived for. Languages, history, logic, philosophy, etc., still have a most important part to play and must be included.

". . . it would seem to be evident that what we need to take care of our technological requirements for the years to come will be more and better engineers and scientists. The men who come out of our universities with Bachelor's Degrees will require a higher standard of broad, as well as specialized knowledge, balanced with a suitable selection of cultural subjects, while those who go on to post-graduate work will also have to be equipped with more scientific knowledge and a greater degree of appreciation of direction, so that their efforts can be trained on the subjects which require attention, and suitable results produced in these fields with the greatest possible speed."

The culmination of the program was a testimonial banquet for Dr. Dick by the Sherbrooke Branches of the Institute and The Corporation of Professional Engineers of Quebec. Among the speakers were Sherbrooke's Mayor Armand Nadeau, C.P.E.Q. President Arthur Piches, Member of Parliament Maurice Allard, Institute Vice-President F. L. Lawton, Dr. J. B. Stirling, Chancellor of Queen's University and a past president of The Institute, and Institute Treasurer E. D. Gray-Donald.

In his banquet address Dr. Dick emphasized that the future of Canada is largely in the hands of engineers and that vision, enthusiasm and the will to work are necessary if this promising future is to be achieved. EIC

Dr. George McKinstry Dick



SESSION I—EDUCATION CONFERENCE

(Continued from page 112)

idiomatic expressions and other internal oddities of individual languages, it is not now possible to have effective translation done by computers. The evolution of a standard form of expression, possibly using different symbols, would allow computers to act as translators and thus would be a basic aid to proper communication.

Engineers must also recognize their social responsibilities, Dean Myers said. Management of world affairs now is in the hands of non-scientific people, and they have let the world down by not taking advantage of scientific advances.

Dr. Chenea felt that in 2000, engineers would still be the planners, doers, and decision-makers they are today — but that they will be doing these things in a different manner. Engineers of the future will not be interested primarily in scientific research, he sad. As today their basis will be design.

"The engineer in 2000 A.D. will live in a greater scientific community," Dr. Chenea said. "The scientific and technical environment will be larger, and he will get much more support from machines such as computers than he does today."

Dr. Chenea referred to science as it pertains directly to the engineers' operations. In addition to the physical, chemical and life sciences which form a background and source material for the engineer, there is a growing science of engineering design.

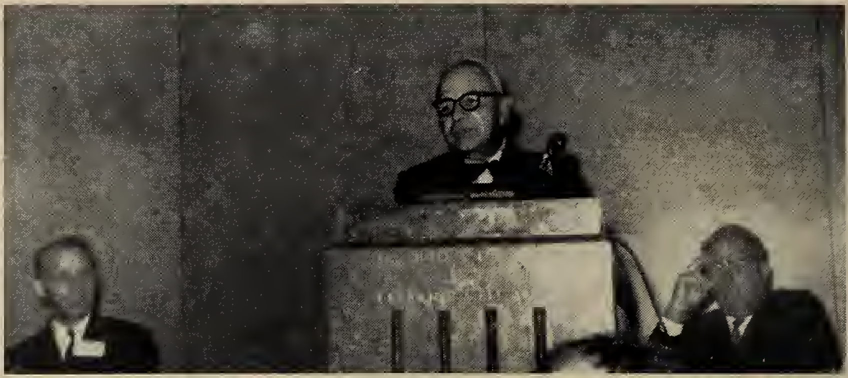
"I refer primarily to the new kinds of mathematics which have to do with hard-headed decision-making and the new kinds of techniques which are available for processing tremendous amounts of data," he said "Both of these will eat drastically into the engineering art and engineering judgement and replace it with rational, and, in some cases, routine procedures."

Computers have the two great advantages of speed and reliability, he said, but in spite of this, and with good reason, many present engineers look down their noses at such sub-human equipment.

"Problems of the future will put much greater emphasis on certainty, and these sub-human machines cannot provide it. Computers can relieve engineers of much of their routitne work and allow them to devote more of their time and attention to creativity . . ."

Dean Chenea said computers may put a great number of engineers out of work. He said General Motors Corporation now is using computers to design gears. Cost per gear design is 42 cents — the lowest charge which a computer can register. In contrast, he said, the best a $10,000-a-year engineer can do is to design two gears a day.

Mr. Sproule questioned the economics of space travel. He said ancient Egypt should provide a firm lesson of what can happen to a civilization if it devotes a disproportonate amount of money and energy on projects of questionable practical value. Egypt never recovered from the expense of building the pyramids,



Dr. Lortie outlines Quebec's education system at E.C.P.D. luncheon.

he said, and we could be endangering our civilization with an overly-energetic program of space conquest.

"Rocketry requires a disproportionate part of valuable engineering talent," Mr. Sproule said. "We should beware of carrying it to excess, and until it should be debated whether rocketry beyond the needs of actual or retaliatory defence is an excess."

Many of the top engineers of 2000 now are living, he said. They are engineering students or recent graduates, and much of their judgement in 40 years will depend on what they have been taught or are being taught.

There will always be a demand for men who can read drawings and catalogues, and who understand nuts, bolts, wheels and levers, he said, but these may not always be considered engineers. Mr. Sproule concluded that in 40 years there will be need for a greater proportion of mechanical engineers with what we now call Ph.D. training.

Dr. Patterson made a plea for a more scientific approach to engineering education. Engineering, development and research are inseparable, he said. Specialties should be expanded and post-graduate work should be considered indispensable.

"It is obvious," Dr. Patterson said, "that the days of the handbook engineer with his empirical outlook are numbered."

"The educational needs of the engineering scientist starting from first principles and not as an extension of the regular engineering course is a subject for urgent consideration," he said. "The place of the engineering research institute in the university and its vital function as the centre of training for the engineering scientist must be more clearly defined, and the needed development and support of such organizations must be given more serious attention."

Walker L. Cisler at the first luncheon meeting of the Education Conference. To his left are Dean Mordell and Mr. Dick.

During the first luncheon meeting, held at McGill, Walker L. Cisler, ASME President and President and Director of Detroit Edison Company, said engineers require a broad approach. They must never forget they are part of the world community and have social obligations to fulfil, he said. The guests were welcomed by Dr. F. Cyril James, Principal and Vice-Chancellor of McGill.

Session II

The afternoon session consisted of a panel of the morning speakers. Discussion was initiated by: Dr. G. M. Shrum, Department of Physics, University of British Columbia; Dr. L. P. Bonneau, Dean, Faculty of Science, Laval University; Dr. B. G. Newman, Professor of

Aerodynamics, McGill; and G. N. Martin, General Manager, Boiler Products Division, Dominion Bridge Company Ltd., Montreal.

Dr. Shrum said our sights are set too low, and that in Canada and the United States we are not lacking engineers — just good engineers. Many engineers just manage to pass their courses and after graduation do their jobs as mere technicians. Engineering education is extremely expensive, he said, and universities should not waste their time and facilities to train technicians.

Dr. Shrum said scientists should not be interested in the sociological side of their work. Sociology and similar professions should be left in the hands of those especially trained for such work.

He also disputed the phrase "sub-human" as a description of computers. "Computers are not sub-human," Dr. Shrum said. "They are super human. They are smarter than 99.9% of the people. It is argued that they are not creative, but extremely little creativity exists now anyway."

Engineers may be trained to make decisions on technical matters, he said, but their training does not necessarily qualify them to be decision-makers in other fields.

Dr. Shrum also said that today a man should not call himself a scientist until he has a Ph.D. degree. There is a need for engineers with Ph.D. degrees, he said, but the need is far greater in science.

Dr. Bonneau said he disagreed with Dr. Shrum that engineers and scientists should not concern themselves with the social aspects of their work. Engineers build tools and machines which create social problems, and they must take the responsibility for these problems. He said the engineer of 2000 must be conscious of his responsibilities, and suggested a balance of science and the humanities in engineering curricula.

Dr. Newman said we can be certain of some engineering in 2000 apart from the fields of computers and space exploration. A great deal of work must be done in the fields of agricultural engineering, nuclear electric power and weather control.

Mr. Martin said engineers, unwisely, are ignoring their social responsibilities. He also said there now is too much specialization in engineering and that this trend must reverse itself. "Fifty-percenters" will find there is no room left for them in the profession, and will be replaced by technicians.

By improving their present training, Mr. Martin said, engineers could become the leaders in industry. If engineers are to lead industries, then they must meet their social responsibilities. At this time, he said, we are not preparing engineers to be leaders.

Answering comments and questions from the floor, Dr. Patterson said while Bachelors of Science in aeronautical engineering sometimes have trouble getting jobs, Ph.D.s have 15 to 20 offers of jobs at top salaries. Top men always are in demand, he said.

Mr. Sproule commented that 50% is not a passing grade in industry. Dr. Chenea defined an engineer as a scientist with a sense of value. Dr. Myers said there always will be consulting engineers as they serve the needs of small, growing industries. In answer to a question from the floor he said he believed the trend towards specialization will reverse itself, although there always will be need for some specialists.

Banquet

The banquet was held at the University of Montreal and was presided over by Dr. Gaudefroy. Guests were welcomed to the university by its Vice Rector, Msgr. Deniger and to the City of Montreal by Mayor Sarto Fournier.

Guest speaker Dr. Karl Stern of the Department of Psychiatry at Montreal's St. Mary's Hospital said that people today view the future with the mixed emotions of strong apprehension and cheery optimism. He said it is unusual for people to look ahead with pessimism.

All previous civilizations were based on rural and agricultural societies — never on technological societies. Through all these, he said, man's attitude was not that of a conqueror of nature. Rather he had a child-like dependence on natural rhythms and recurrences. Great achievements were not in analytical areas, but in intuitive areas. It was the difference between wisdom and science.

The main disadvantage of this rural type of society, Dr. Stern said, was that it held the great danger of stagnation. Our present technological society is both restless and insatiable. In former times leisure moments were creative and contemplative. This has been replaced by empty leisure, and leisure activity has been replaced by leisure passivity.

He said it is unfortunate that the use of wisdom and intuitive intelligence wanes in an age of technology. But these problems inherent in our technological age can be solved, he said, and most probably the solution will come from a synthesis of research and wisdom.

Session III

L. A. Duchastel, Personnel Manager, Shawinigan Water and Power Company, Montreal, was the Chairman of the two final sessions. Presentations were made by: Dr. R. G. Folsom, President, Renesselaer Polytechnic Institute, Troy, N.Y.; Dr. E. W. R. Steacie, President of the National Research Council of Canada; Professor Dana Young, Department of Civil Engineering, Yale; and Dean M. P. O'Brien, Dean Emeritus, The College of Engineering, Berkley, Calif.

Dr. Folsom said that to serve the engineering needs of 2000 there must be greater emphasis on post-graduate work by engineering students. Theses will be design oriented rather than research oriented. Perhaps the degree received will not be a Ph.D., Dr. Folsom said, but it will be the equivalent.

In some schools many courses will be eliminated, he said. These will include surveying, electrical labs, and even drawing. By 1980 the basic engineering course will be five years, he said, and a greater number will go on to further studies. The technical type of institute will vanish.

Dr. Steacie said he could subscribe to neither of the extreme views of engineering education. It will be taught neither as an old craft, nor as a branch of applied physics, he said. Many science students follow post-graduate courses, but too few engineers do the same.

One of the biggest farces today, Dr. Steacie said, is the insistence on professional qualifications. Everyone wants a degree in his own specialty. He said he could see no reason why engineering should be a legally closed profession.

Two groups of engineers now are being lost to the profession, Dr. Steacie said. These are the technicians and the administrators. Many engineers go directly into administration because they feel engineering is a good general educcation. This problem could be resolved if humanities courses provided more science. In projecting engineering wants, we should forget numbers and consider needs, he said. Greater numbers of engineers will be required for some time, but eventually there must be a diminution in the number trained and needed.

"We cannot forever go on increasing the percentage of the population who are engineers," Dr. Steacie said. "One thing that could be done would be to eliminate the university trained engineers who become either administrators or mere technicians."

Professor Young said engineers have every bit as much social responsibility as others, both as persons and as professionals. Engineering education has made tremendous progress in recent years, but this work is not yet finished. The danger now, he said, is that the present impetus will carry too far and that science will overwhelm engineering curricula.

Bigger projects are being tackled by engineers, Professor Young said, and for this reason there is increasing activity in engineering research. The basic knowledge for these bigger projects is not now available elsewhere.

The engineer of 2000 will be exposed to greater numbers of courses in science, research and managerial functions, he said. The core of the engineers curricula will remain the same, although the details will be different.

Dean O'Brien traced the economic development of North America and said this came about under unusually favorable conditions. The energy and initiative of an immigrant population, tremendous natural resources, an uninhabited continent, relative freedom from inhibiting customs and traditions, and, over a long period, the absence of international competition and pressure, formed an environment well suited to the full exploitation of the industrial revolution.

"These circumstances never existed before elsewhere in the world," Dean O'Brien said, "and they can never exist again."

"We are awfully smug about what we have accomplished, but unless we change this attitude — and change it soon — we will be in serious trouble."

In the world of 2000 Dean O'Brien saw more authoritarian governments, particularly in under-developed nations. As population will continue to increase as fast as resources there will be a change in living standards. Under-developed nations will have higher standards while advanced nations probably will experience a decrease.

Private capital will be less important than government expenditure and "engineering will function increasingly under government support or administration," Dean O'Brien said.

World-wide economic competition will become sharper and the battle for engineering products and services will be decided ultimately on the basis of quality and cost.

In the education of engineers for this era he suggested continued emphasis on basic and applied science and on modern analytical techniques, but "exercises in creative design must be increased."

The basic engineering course will be at least one year longer, Dean O'Brien said, and specialists will require even more extensive education.

Institute President George McK. Dick, the luncheon speaker, suggested there are three characteristics which distinguish the "superior" and the "not quite so good" engineers. These are ingenuity, sound judgement, and imagination. If these characteristics are of value, he said, a way must be found to develop them in college.

"Possibly these traits can not be developed by teaching or by other methods," Mr. Dick said. " . . . on the other hand it would seem that if the development of these important characterisics were approached in the way of providing challenge to students while they are yet in reasonably plastic or pliable mental state, then the graduates might be better equipped than they would otherwise be if these important characteristics went unrecognized and uncultivated."

Session IV

This session grouped final comments of five scheduled speakers. A guest speaker was Michael Kostenko, Member of the Academy of Sciences of the U.S.S.R. Professor Kostenko teaches at the Institute Electromechanics at Leningrad.

Professor Kostenko expressed surprise that the development of hydro-electric power on the Hamilton River in Labrador is not being pursued with vigour. In such a scheme a broad outlook is needed. Professor Kostenko said he had been told of the Hamilton's great potential, but that it was not now economically feasible to develop it.

"To us this is a rather narrow outlook. In Russia when we determine potential power we set about to develop it, even though there is no industry in the area. We believe this brings better and quicker results."

Commenting on education problems, Professor Kostenko said that when he talks with a young student engineer he explains the student is being taught what the teachers themselves do not understand.

The other speakers at the final session were: Professor Frank Noakes, Head, Department of Electrical Engineering, University of British Columbia; Professor John F. Lee, Head, Department of Mechanical Engineering, North Carolina State College; Associate Dean R. C. Gildmacher, College of Engineering, New York University; Professor J. H. Keenan, Head, Department of Mechanical Engineering, Massachusetts Institute of Technology; and P. W. Gooch, Chief Engineer, Engineering Division, Canadian Vickers Limited, Montreal.

Professor Noakes forecast a populaton in Canada of 45 million in 40 years. Because of the present lack of decision concerning what should be taught engineering students, he said "the years between 1959 and 1999 will be known as the Age of the Curriculum Diddles." The four-year course will be expanded, he said, and there will be greater emphasis on post-graduate work.

Professor Lee said the pace of future change will be much more rapid than the pace of change in the past. The major factor in engineering education must be doubt—great, profound doubt. While the primary purpose of scientists and philosophers is to know, Professor Lee said, the engineer has another task—that of synthesis. He foresaw a division of engineering, with research engineers seeking knowledge and practising engineers applying knowledge.

Professor Keenan said the greatest future need in engineering will be engineering students. The percentage of engineering students is declining, he said. One reason is the drop in prestige in the public image. This prestige has swung from engineers to scientists.

"This swing was over due and was needed," Professor Keenan said, "but it may be going too far. And it has affected not only the students but the engineers themselves."

Scientists often are given credit for work done by engineers, he said. This must be rectified, and engineers must seek to improve their public image at every opportunity. One manner would be to explain constantly the difference between engineering and science.

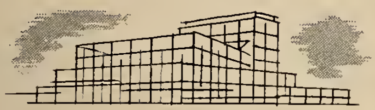
Associate Dean Gildmacher said that because engineering is sensitive to society, there will be many types of engineer in the future. Among the more important will be the engineering scientist.

"We would much prefer, when looking for a heavy project leader, to have an engineering scientist rather than a design man," he said. "I don't feel we can wait for the designer—we need the engineering scientist."

Mr. Gooch said he was impressed with the remarkable agreement among the various speakers. Our future needs, he said, will include designers, project engineers and the entire spectrum.

The most important thing a school can do is to teach a person how to learn, as education certainly doesn't end with a degree. While standardization of parts is essential to industry, Mr. Gooch said, we must appreciate that human beings are non-standard. For the education process to be successful more attention must be given to individual students and requirements.

Lead and Zinc are "behind the scenes" at the O'Keefe Centre



At Toronto's multimillion dollar O'Keefe Centre you will find lead and zinc contributing to the life of the building and the comfort of those who use it. Here are some examples.

O'Keefe Centre for the Performing Arts, Toronto
Architects: E. C. Morgan, Toronto; Page & Steele, Toronto

LEAD FLASHING

Over 4,000 square feet of lead-clad copper flashing were used. Its principal application was for through-wall flashing underneath coping stones as shown below. Both plain and corrugated sheet and strip were laid. Lead-clad copper combines the high strength of copper with the excellent corrosion resistance and non-staining characteristics of lead. Coating, both sides included, averaged 1¼ ounces per square foot.

Lead flashing

LEAD ANTI-CORROSION STRIP

Lead Anti-corrosion Strip

The upper exterior walls of the Auditorium are clad with corrugated bronze sheet panels. Bronze structural members carrying the sheets are secured to the main steel frame. The steel at its junction with the bronze would be subject to corrosion due to the electrolytic action caused by dissimilar metals in the presence of moisture. To prevent this corrosion 2-inch wide strips of 4-pound gauge lead were inserted between the joint faces of the two metals.

GALVANIZED DUCTWORK

Nearly 400 tons of galvanized (zinc coated) sheet were used to make up the extensive heating and ventilating system. Gauge varied from 26 to 16 and zinc coating was standard at 1¼ ounces per square foot (both sides included). The choice of galvanized sheet means long, trouble-free life, ease of fabrication into complex

Galvanized Duct Work

shapes, simplicity of installation and low thermal expansion to help keep duct noise to a minimum. The choice also meant real economy in initial cost at no sacrifice to future service.

Specify LEAD and ZINC — metals you can use with economy and confidence. Contact our Sales Development Division for further information.

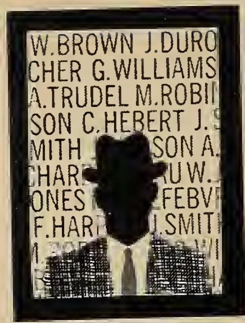
Personals



Hugh Crombie, M.E.I.C. (McGill '18), has been re-elected President of the Canadian Association of Machinery and Equipment Manufacturers. He is Vice-President and Treasurer of Dominion Engineering Works Limited.

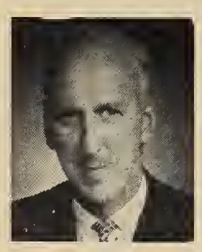
J. B. Nelson, M.E.I.C. has retired from H. G. Acres Company and is now consultant on structural steel design for service buildings, at the approaches to the new Lewiston Queenston International Bridge, for Salter and Flemming, Architects, St. Catharines, Ontario.

J. A. Mersereau, M.E.I.C. has been appointed as maintenance engineer of the highway division of New Brunswick. He has been associated with the maintenance branch since 1945.

Niel Metcalf, M.E.I.C. (Wales '25), has been appointed Assistant General Manager of Burlington Steel Co. Limited, Hamilton. He joined the company as Chief Metallurgist in 1936 and was made assistant to the general manager in 1955.

H. A. Gauvin, M.E.I.C. (McGill '26) has been appointed Deputy Minister of the Quebec Department of Public Works. Since 1956 Mr. Gauvin has been general manager for A. Belanger Ltee., stove manufacturers, Montmagny, Que.

Drummond Giles, M.E.I.C. (McGill '27), and **S. M. Finlayson**, M.E.I.C. (McGill '24), have been elected to the Board of Governors of McGill University.



C. A. Peachey, M.E.I.C.

C. A. Peachey, M.E.I.C. (Toronto '27), has been appointed vice-president and general manager, communications equipment division, for Northern Electric Company Limited.

Ronald C. Marriott, M.E.I.C. (Cambridge University), has been appointed Eastern Area Manager for Ruston & Hornsby Limited. He has had extensive diesel engineering experience in both Great Britain & Canada.

R. C. Marriott, M.E.I.C.

F. F. Fulton, M.E.I.C.

F. F. Fulton, M.E.I.C. (McGill '28), has been promoted from general manager to vice-president and general manager, telephone contract division, for Northern Electric Company Limited.

J. G. Little, M.E.I.C. (Toronto '28), has been promoted to the position of vice-president and general manager, wire and cable division, for Northern Electric Company.

J. G. Little, M.E.I.C.

T. E. Storey, M.E.I.C.

T. E. Storey, M.E.I.C. (Man. '28) has been appointed chief engineer of The Manitoba Hydro-Electric Board. He is now general manager of City of Winnipeg Hydro Electric System.

H. M. Brownrigg, M.E.I.C., (McGill '41) has been appointed vice-president in charge of steel foundry products for Dominion Brake Shoe Company, Montreal.

W. T. Hargreaves, M.E.I.C. (U.N.B. '46), has been named executive assistant to the Public Works Minister of New Brunswick. He has had 26 years of experience in the construction and maintenance field.

W. J. Riley, M.E.I.C. (McGill '48), past president of the Corporation of Professional Engineers of Quebec, was recently elected alderman of the municipality of Rosemere.

Hugh B. Hall, JR.E.I.C. (Toronto '48), has been elected President of American Hospital Supply Corporation (Canada) Ltd., a wholly owned subsidiary of AHSC.

E. I. Lexier, M.E.I.C. (Man. '48), has been appointed to the Board of Directors of Green Blankstein Russell Associates. He is presently Associate in Charge of Engineering.

J. Devlin, M.E.I.C. has retired from the position of Manager Industrial Sales for Texaco Canada Limited. He is now residing in Troon, Ayrshire, Scotland.

E. L. Mercer, M.E.I.C. (Toronto '50), has been made Vice-President of the consulting structural engineering firm of Robert Halsall and Associates Limited, Toronto.

Gerald S. Conger, JR.E.I.C. (N.C.S.C. '52), has been named plant manager of the modern Caldwell Linen Mills Limited, in Iroquois, a subsidiary of Dominion Textile Co., Ltd.

G. J. McGee, JR.E.I.C. (McGill '53), has been named Assistant Sales Manager Structural Products for Dominion Structural Steel Limited. He has occupied senior positions in the design, estimating, cost and sales departments.

Dr. J. D. Scott, M.E.I.C. (Queen's '54), has been appointed assistant professor of Civil Engineering at the University of Waterloo. He was formerly a consulting engineer on soil mechanics in western Canada.

E. A. Thompson, M.E.I.C.

E. A. Thompson, M.E.I.C. (U.B.C. '42), formerly Vice-President and General Manager of Canada Creosoting Company Limited, has been appointed Vice-President and General Manager of Siporex Limited.

● PERSONALS

James T. Cawley, M.E.I.C. (Toronto '43) has been elected Vice-President of District 4 of the Canadian Institute of Mining and Metallurgy. Mr. Cawley is Deputy Minister of Mineral Resources for Saskatchewan and is Chairman of the Saskatchewan Oil and Gas Conservation Board.

Robert W. Blackburn, JR.E.I.C. (U.B.C. '57) has accepted a position as DESIGN ENGINEER, Mechanical Equipment, Civilian Atomic Power Department, Canadian General Electric Co. Ltd., Peterborough, Ont. Mr. Blackburn was formerly with the Engineering Design Branch of Atomic Energy of Canada Ltd., Chalk River.

C. Zeglinski, M.E.I.C., (Manitoba '56) formerly employed by the federal government in Saskatoon, has taken a position as a mechanical engineer with the Winnipeg Public Works Department.

W. J. Brice, JR.E.I.C. (Sask. '55), has accepted a position with Renold Chain Company of England. He will be given a two year training course in England before returning to Canada to take up permanent employment with Renold of Canada. He was formerly a design engineer with the Atomic Energy of Canada Ltd.

James W. Young, M.E.I.C., will receive an Honorary Doctor of Law Degree in recognition of his contribution to science in Alberta by the University of Alberta.

M. C. Schofield, JR.E.I.C. (U.N.B. '58), has been appointed Plant Manager of Canada Wire and Cable Company Limited, Atlantic Division, Lancaster, New Brunswick.

Royal Architectural Institute of Canada

The results of an exhaustive cross-Canada inquiry ". . . to investigate the broad range of problems associated with Canada's residential growth and development," are contained in a report issued recently by the R.A.I.C. The Report of the Committee of Inquiry into the Design of Residential Environment was prepared by its members, Peter Dobush, John C. Parkin and C. E. Pratt.

The object of the project was to study the design of residential environment and to determine how the architectural profession could contribute more effectively to the improvement of the quality of design and the layout of residential areas. To this end the committee investigated: objectives to be sought in the design and layout of the total residential environment; what factors now shape the residential environment, what factors encourage or discourage the achievement of these objectives, and what can be done to modify these factors; ways in which these objectives may be realized more fully, with particular reference to ways in which the architectural profession can contribute more effectively to their realization.

Outlined in the report are the committee's findings and recommendations covering topics which range from the whole cost of housing to the role of governments in this design process. One section deals with conditions which were observed to be present in good housing design.

American Association of Cost Engineers

The A.A.C.E. has named Chaplin Tyler of the E. I. du Pont le Nemours & Co., the recipient of its 1960 Award of Merit. The Award, the highest honor the Association can bestow upon an engineer, was given Mr. Tyler for his "outstanding contributions to cost engineering economics, analysis and its application to the chemical process industry." Mr. Tyler spent several years as an editor of Chemical and Metallurgical Engineering. He is the author of Chemical Engineering Economics and is a contributor to the Encyclopedia of Chemical Technology.

The Institution of Mining and Metallurgy

A. R. O. Williams, a managing director of Consolidated Gold Fields of South Africa, Ltd., and of New Consolidated Gold Fields, Ltd., has been elected president of Britain's Institution of Mining and Metallurgy. Mr. Williams, who will assume office next May, succeeds Professor David Williams.

American Society for Quality Control

The Montreal Section of the A.S.Q.C. held a day-long forum Oct. 22. Approximately 250 delegates from Quebec and Eastern Ontario attended the forum, the theme of which was "Control of Quality Vital to Sound Business Administration". Topics discussed included basic concepts of quality control, control laboratory measurements, design of experiments, gauging problems, quality assurance, quality costs, management aspects of reliability and quality control, sampling problems and tests of significance.

The Society of Naval Architects and Marine Engineers

The 68th Annual Meeting of this Society was held in New York City this month. Six technical sessions which included the presentation of 11 papers, were held following the meeting of Council. Presiding over the meeting was Rear Admiral Albert G. Mumma, USN (Ret.), who was elected Society President for a two-year term in 1958. The Society has approximately 7,600 members in regional sections on the Atlantic, Gulf and Pacific Coasts, the Great Lakes, Canada and Hawaii.

The Society of Mining Engineers

James C. Gray of Pittsburgh has been elected 1961 President of the S.M.E., a constituent organization of the American Institute of Mining, Metallurgical, and Petroleum Engineers. Mr. Gray, Administrative Vice President, Raw Materials, U.S. Steel Corp., will succeed Dr. Arthur B. Cummins of Bound Brook, N.J. Succeeding Mr. Gray will be William E. Stephenson of Poali, Pa., who was selected President-elect for 1961.

Frontiers of Control

The first Joint Automatic Control Conference held in the United States took place this autumn at the Massachusetts Institute of Technology. The latest advances in the field of automation were discussed by some 450 engineers and scientists. The Conference was sponsored by the American Society of Mechanical Engineers with co-operation of the Institute of Radio Engineers, the American Institute of Electrical Engineers, the Instrument Society of America and the American Institute of Chemical Engineers. During the three-day session 57 technical papers were presented. These included papers concerning new techniques in control system theory, testing and programming for digital computers. A conference highlight was the report by a team of outstanding automatic control specialists on technical developments in Russia.

American Society of Civil Engineers

Nine new officers of the A.S.C.E. have been elected by mail ballot of the Society's 46,000 members. The President for 1961 is Glenn W. Holcomb of Corvallis, Ore. Two Vice Presidents elected for two-year terms are Donald H. Mattern of Knoxville, Tenn., and William J. Hedley of St. Louis. Six directors were elected for three-year terms.

Coming Events

Annual meeting, Institute of Radio Engineers, vechicular communications, Philadelphia, Dec. 1-2.

Electrical insulation conference, American Institute of Electrical Engineers, Chicago, Dec. 5-8.

International Congress and Exposition of the Society of Automotive Engineers, Detroit, Jan. 9-13.

Annual meeting, American Astronautical Society, Dallas, Tex., Jan. 16-18. EIC

The Associations and Corporation

The presentation of a $500 cheque to the Vancouver Public Library marked the incorporation of the valuable private library of the Association of Professional Engineers of B.C., into the technology section of the public library. Association President H. P. J. Moorhead made the presentation recently to Peter Grossman, director of the Vancouver Public Library. The cheque is the first annual grant from the professional engineers to the library for expansion and maintenance of the engineering section. EIC

Obituaries

G. W. Coward, M.E.I.C., retired chief engineer for Way and Works on the Argentine Railway, died April 2, 1960.

Humphrey George Berkeley Michell, M.E.I.C., specialist in light and power development, died August 15 in Montreal. He was 65.

Mr. Michell was assistant manager of international operations of the Montreal Engineering Company.

He was born in Miniota, Man., October 1, 1894 and was educated at Dulwich College, England, St. John's College, Winnipeg, and at the University of Manitoba.

From 1920 until 1926 Mr. Michell was distribution engineer for the Winnipeg Hydro Electric System. Later he became superintendent of transmission and distribution for the Mexican Light and Power Company and in 1934 was named chief engineer of the Mexican Tramway Company.

H. G. B. Michell, M.E.I.C.

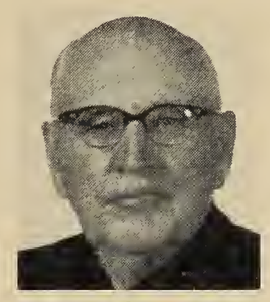
In 1939 he went to Bolivia as manager of the Oruro division of the Bolivian Power Company, and seven years later became general manager of the Bolivian Power Company, Limited, La Paz.

Mr. Michell returned to Canada in 1951 and was appointed to the operating division of the Montreal Engineering Company, Limited. Four years later he became assistant manager of international operations for the company.

He was a director of the Compania de Alumbrado Electric of San Salvador; the Monterey Light and Power Company, Mexico; the Demarara Electric Company, Georgetown, British Guiana; and of the Oriente Electric Company of San Salvador.

Mr. Michell was a member of the Engineering Institute of Canada; a fellow and life member of the American Institute of Electric Engineers, and a member of the Association of Professional Engineers of the Province of Manitoba.

Harold R. Miles, M.E.I.C., retired Division Engineer for Canadian Pacific Railway, Moose Jaw, Sask., has died. He was 81.



H. R. Miles, M.E.I.C.

Mr. Miles joined the C.P.R. in 1901 as Assistant Engineer in North Bay. In 1919, he was appointed Division Engineer in Lethbridge. He was transferred to Moose Jaw in 1933 where he retired in 1941.

Having joined the Institute as an Affiliate Member in 1902, Mr. Miles was given Life Membership in March, 1942.

Dr. David B. Steinman, M.E.I.C., designer of 400 bridges including the Mackinac Straits suspension span, died August 23 in New York City. He was 73.

Although graceful, long-span bridges were his specialty, Dr. Steinman considered the Brooklyn Bridge, built three years before he was born, the most beautiful in the world. From 1948 until 1954 he was in charge of reconstruction of the Brooklyn Bridge. Included in his achievements were: the largest suspension bridge in South America—the Florianopolis span in Brazil, and the Thousand Islands Bridge over the St. Lawrence River.

His earlier bridge projects included the Carquinez Straits cantilever in California, the Henry Hudson hingeless steel arch in New York City and the Mt. Hope wire cable suspension bridge in Rhode Island. At the time of Dr. Steinman's death the firm of Steinman, Boynton, Gronquist and London was working on an "intercontinental" span proposed construction over the Bosporus in Turkey.

Dr. Steinman was born in New York City and was educated at the New York City College and Columbia University. He was an author and poet and left technical books, papers, popular books and poems which were inspired by his devotion to the purpose and beauty of bridges.

Dr. Steinman was granted Life Membership in the Institute in 1960. He was a founder and first president of the National Society of Professional Engineers. During his career, 80 countries honoured him in various ways.

John T. Watson, M.E.I.C., Lethbridge's first city manager has died.

Mr. Watson was born and educated in Scotland. He came to Canada in 1902 and worked for the Canadian Pacific Railway in Calgary as a machinist. In 1916 he moved to Lethbridge and was made chief engineer at the power house. He left his position in the city in 1927 and was employed by the East Kootenay Power Co. until 1928 when he became Lethbridge's first city manager.

Mr. Watson held various offices in the Institute and was granted Life Membership in 1953. He also was given Life Membership in the Association of Professional Engineers of Alberta, the Lethbridge Chamber of Commerce and of the Masonic Lodge.

Archdale M. Wilson, M.E.I.C., chief engineer of the Algoma Central and Hudson Bay Railway in Sault Ste. Marie, died June 29. He was 61.

Mr. Wilson graduated from Queen's University in 1928 and in the same year joined the railway. He was involved in many of the railway's development programs, including total dieselization and major upgrading of roadbeds and bridges. He was instrumental in the mechanization of track maintenance. Mr. Wilson was promoted from assistant engineer to engineer maintenance-of-way in 1944, and nine years later was named chief engineer.

Mr. Wilson was a member of the Association of Professional Engineers of Ontario, the Toronto Railway Club, American Society of Metals and was a member of various educational boards in Sault Ste. Marie.

News of the Branches

Correspondent

Engineers' wives received a tribute from Institute President George McK. Dick during a recent visit. Mr. Dick said the wives can play an extensive and important part in influencing the professional careers of their husbands. The President exhorted the engineers themselves to become more conscious of their own nation regarding professional requirements in Canada in both training and in the acceptance of ideas alien to Canada. He criticized Canadian engineers for their too-ready acceptance, at times, of United States and European influence. Institute General Secretary Garnet T. Page outlined the activities and responsibilities of the Institute and of the importance of the Branch Executive in guiding the technical training of young engineers, and of Branch meetings as a medium of exchange of technical information.

Correspondent

A visit to the Leamington plant of H. J. Heinz Company of Canada Ltd. — one of the largest tomato processing plants in the world — was made Sept. 15 by members, their wives and their guests. The tour coincided with the height of the tomato season and members of the tour were shown the various stages in the processing of ketchup and tomato juice. These ranged from the unloading and preparation of containers and tomatoes to the cooking and canning methods. Of particular interest was the experimental kitchen, where recipes are prepared, and the adjoining laboratory where analyses and tests check nutritional value and quality. M. S. Dixon, company Vice President-Manufacturing, explained a system pioneered at Leamington in which sterilized tomato solids are stored in large, outdoor tanks for year-round processing.

Cape Breton

Lloyd Boutilier, M.E.I.C.,
Correspondent

A group of Cape Breton Branch members travelled to Truro, N.S., Sept. 15 for an informal dinner meeting with Institute President George McK. Dick, T. C. Higginson, Vice President-Maritimes, and their wives. Another representation, from the New Glasgow and Truro areas, headed by J. E. Clarke, also was present. The members found the meeting pleasant and profitable. Following the dinner the ladies were presented with bouquets of roses and the men with Nova Scotia tartan ties. One of the New Glasgow members piped the official party on its way to Moncton.

Chalk River

J. L. Gray, President of Atomic Energy of Canada Limited described a recent tour of Russia's power installations at the opening meeting of the Branch's 1960-61 season. About 250 members and guests attended the meeting during which Mr. Gray showed movies to illustrate his talk. The functional equipment was quite impressive, Mr. Gray said, but little attention had been given finishing detail. Construction of homes was low quality, and everywhere there were crooked windows, poor tiling, rough finishes and generally poor construction methods. Moscow University was found impressive, with its 45,000 rooms — 22,000 of which are in the main building.

A lobster dinner party at the Shore Club, Hubbards, N.S., was held Sept. 13 for Institute President George McK. Dick, Mrs. Dick, T. C. Higginson, Vice President-Maritimes, and Mrs. Higginson. Mr. Dick said engineers should give more recognition to the part played by their wives. In outlining Institute problems, Mr. Dick said a larger membership is required. He referred also to the problem facing engineers generally of maintaining their status in the community. All engineers must increase their technical knowledge, the President said, and must build the prestige of their profession. Members must work for a larger membership, and must generate general interest in the Institute. The dinner was attended by 114 members and guests.

Kodak Industrial X-ray Film speeds the quality control of castings—any dimension!

Dominion Foundries and Steel Ltd., Hamilton, boasts of one of the most versatile and best-equipped non-destructive testing departments in the industry. With Canada's largest cobalt source, Industrial X-ray Film guards the quality of castings from a mere 6 ounces in size to double-flange castings weighing 30,000 pounds each!

The main headache in casting is shrinkage. Dofasco has found that only Industrial X-ray Film can detect the change effectively. Inspection of pilot castings by X-ray saves countless dollars and hours, as well as maintaining the highest quality standards of subsequent casts.

In all facets of operation, Industrial X-ray has become indispensable. Employed in preventative maintenance too, X-ray film checks fatigue and stress of plant equipment before damage can delay production, endanger personnel.

As at Dofasco, Industrial X-ray Film can be the cost and time saving answer to your own inspection problems. Whatever the application, contact your Kodak X-ray dealer or Kodak Technical representative for the profitable facts, or write:

Fifty members visited the Burrard Thermal Power Plant, Oct. 1, as guests of the B.C. Electric Company and International Power and Engineering Consultants Ltd. W. I. O'Hara, Vice President, Civil-Mechanical Design Division of IPEC, gave a pre-tour briefing of the mechanical and electrical installations now under construction. Ultimately the plant will have six gas-fired boilers and turbine-generator units of 157,500 kw. each. Total cost of the plant and auxiliary works will be approximately $95 million. The civil work in the generating plant is mostly complete. The boiler plant and turbine installations for the first unit are scheduled to be finished early next summer. The electrical installation is in a primary stage. Institute General Secretary Garnet T. Page visited Vancouver Sept. 27-28 to assist in organizing the Central Committee for the Annual General Meeting next spring. Dean David M. Meyer of the Faculty of Applied Science of the University of British Columbia is the Chairman of the Central Committee. Other members appointed to date are: W. G. Heslop, Vice Chairman; F. Cazelet, Secretary; Commodore A. C. M. Davy, Western Field Secretary; J. H. Swerdfeger, Branch Chairman; and D. R. Bakewell, Treasurer.

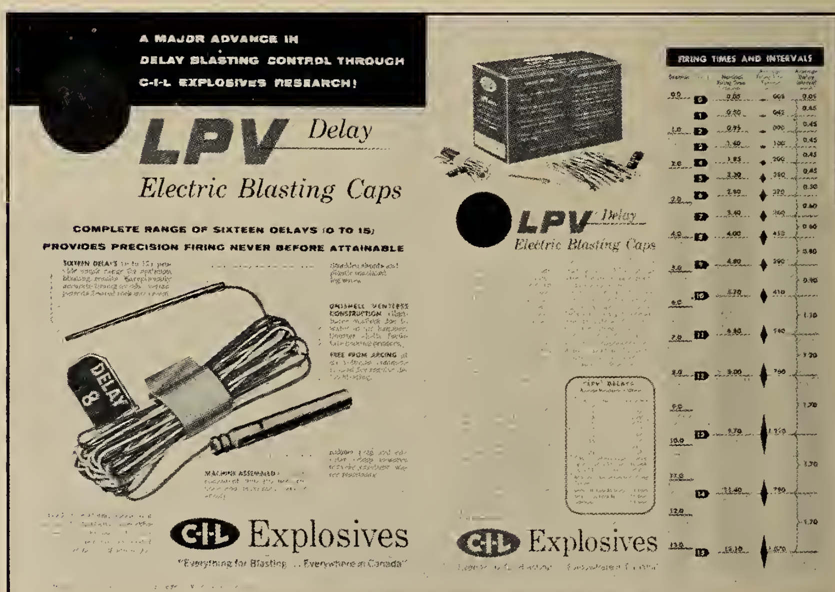
E.I.C. CERTIFICATE OF ADVERTISING MERIT

Canadian Industries Limited, Explosives Division, three colour, two page insert in the August 1960 issue was judged the "best" by a fifty reader jury.

The advertisement appeared as pages 33 and 34 of the issue. It features LPV Delay Electric Blasting Caps. The insert is very striking in appearance. The text describes the range of delays obtainable through the use of these new electric blasting caps. The reverse side presents a tabulation of firing times and intervals.

The advertisement was prepared and placed by Cockfield, Brown & Co. Ltd. of Montreal — B. Fuller, Account Executive — the Advertising Supervisor for C.I.L. Explosives Division is W. L. Hill. This is the second time C.I.L. Explosives Division has been awarded the E.I.C. Certificate of Advertising Merit since the inception of the award in January 1959.



C.I.L.'s CERTIFICATE WINNING ADVERTISEMENT

The above illustration shows the front and reverse side of the C.I.L., Explosives Division, three colour, two page, insert which appeared in the August 1960 issue. This insert was judged the "best" from the viewpoints of ACCURACY—INFORMATION—ATTRACTION by a fifty reader jury.

The insert is printed in three colours — black, blue and red. The copy is concise and factual.

The Advertising Supervisor for C.I.L., Explosives Division, is W. L. Hill. The advertising agency is Cockfield, Brown of Montreal, and B. Fuller is the Account Executive.

● DISCUSSION

(Continued from page 101)

gas turbine has long been promoted as a peak shaving device, and as far as the field of power generation is concerned it is certainly not ideally suited to peaking. With a provincially interconnected power system any thermal generating unit smaller than 20-25,000 kw. is approaching the point where it is too small to be effective, yet the 20-25,000 kw. gas turbine is a mammoth machine compared to the light and compact aircraft power plant. As such, the time lapse between starting and full load is essentially the same as for a steam turbine, once the boiler has been brought up to operating conditions. The application described in this paper retains its versatility, and if it is economically justifiable, then this is presumably the method the utilities would like encouraged. If these smaller units can be procured for a reasonable investment per kw of installed capacity then the combined economics of the power generation should be improved, since the capacity factor of the generating equipment and the load factor of the system will be higher.

Despite the many intangible advantages and indirect economic possibilities the author has kept his analysis simple and direct. In my estimation he has, by a conservative approach, shown that the savings are sufficient to be considered justifiable for a utility or an institution.

Because this is a peaking application and because the cost of fuel is so attractive, the whole criterion in the selection of the type of gas turbine to be used should be one of low initial investment. The given tabulation of operating costs does not indicate this for the fixed element of these costs contains no item for interest on the invested capital. If the interest is taken as 6% the fixed charges then total 8 mills per kwh., which is the largest single cost item. The complexity introduced by the free power turbine is probably justifiable because of the extra operating versatility and the improved efficiency range. However, the cost of the heat exchanger can only be charged against the difference between the cost of high level Btus and low level Btus and under these conditions it would be extremely difficult to justify.

The operating costs show no allowance for maintenance. Maintenance is related to the length of time between reblading and other necessary repairs. The labour costs were worked out directly and in my estimation they are high enough to cover maintenance as well as daily operation. But if reliability is desirable in this, or a multi-unit installation of this type, a full inspection schedule would be a necessity. There are certainly some parts around the combustion can and system that are going to require cleaning, and in all likelihood, replacing.

At this state of the development of the industrial gas turbine, few would accept the life of the blades as 40,000 hr., and therefore assume the casing would not need to come off for twenty years. Not only does this imply that the engine is going to run out its life a full load, but that temperature cycling does not exist or it does not effect the life of the blades. Although natural gas is an ideal fuel, the 40,000 hr. life of the blades is extrapolated from creep test data based on 1000 hr. tests and although extrapolating from 1000 hr. to 40,000 hr. is thought acceptable, metallurgists are not fully acquainted with the effects of thermal cycling on fatigue or creep. Thus I think it would be prudent to inspect the blades every 10,000 hr. replacing the blades whose elongation is beyond a certain predetermined amount. Or to state the maintenance problem another way, "If the turbine inlet temperature is relatively low, it would be safe to use steam turbine maintenance methods at costs (.35 mills kwh.), but if the turbine inlet temperature is approaching aircraft propulsion practice, maintenance schedules keyed to aero-engine maintenance practice should be set up and analyzed".

Again, on the desirable side of the balance, the cost of 28.8¢ per thousand lb. of steam should contain some allowance for the capital investment of the steam generating equipment. This figure could well be $1.00 per 1000 lb. even as an inter-departmental charge and some 50 to 100% greater if it were to represent a selling price.

Professor Panar has indicated that the savings made possible by the peak shaving would yield a return of 8.45% on the capital invested. The analysis is conservative and the saving may well be of the order of 10 or 12%, however, each by-product power or by-product steam cycle must be analyzed on its own merits, and an industrial firm requires a better return on an investment, even before taxes, in order to make an expenditure worthwhile.

Discussion by A. A. Scott, and Paul G. McConnell, M.E.I.C.

Mr. Panar has provided some good and interesting data on the operation of a small gas turbine as a peaking unit. However, it must be realized that the installation described is special in a number of ways. These special features must be realized in considering applying a small gas turbine as a peaking unit in an industrial plant. Specifically, we have noticed the following:

First, regarding the economic analysis:

The system described is rather special because it incorporates not only purchased power and a gas turbine, but also a steam engine generating system. This makes the system described quite unusual and so the results obtained do not necessarily indicate the results that might be obtained from an economic analysis of any other system.

It is questionable whether many industries could justify using money at a 6% interest rate, as quoted in the paper.

Second, is the matter of the standby and emergency. What happens if the unit has to be taken out of seıvice over a peak period? There seems to be two alternatives:

Either the industry goes without power, and the possibility of this is something that should be factored into the economic analysis. Or, power is purchased in the emergency and this in turn brings up two points:

1. If the utility has to provide a service capable of taking the peak in an emergency, it will do so at no charge. This is the Customer element of cost to which Mr. Panar referred;

2. If a new demand is established, the economics of the gas turbine, of course, go out the window, and this is a possibility that should be factored into the economic analysis.

Third, the Paper is, of course, describing one particular system, and therefore does not deal with alternatives that should be considered in any contemplated installation, such as, the use of back-pressure and/or extraction condensing steam turbines depending upon the balance of the kilowatt hour and steam required.

Discussion by E. W. Hill, M.E.I.C.

This paper outlines the essential considerations in applying a gas turbine and in particular, its economic evaluation in conjunction with purchased power, steam turbines and process steam. The method used in evaluation is clear and this installation unquestionably pays its way. However, there are special circumstances about the University of Alberta that make this installation economic, whereas an evaluation in other areas would not prove such an installation economic.

(1) *Fuel Cost*

23¢/BTU x 10^6 is a fuel price that will seldom, if ever, be matched elsewhere in Canada. In other areas, fuel prices (either natural gas or residential oils) are in the range of double to triple the fuel rates in Edmonton. These higher fuel costs put a very different slant on most possible applications for gas turbines.

In Edmonton, the more the gas turbine is operated, the less will be the total cost of power.

In areas with high fuel costs, the reverse situation is the case. In these areas, gas turbines are justified by the lower capital cost/kw. of gas turbines compared with steam units or hydro power. Actual energy charges for the gas turbine will be higher than from other sources of generation, and will tend to effect the capital savings. Consequently the gas turbine is applied and sized to take peak load demands and run with a very low load factor, (at the most 20%).

In effect, on a demand basis, a gas turbine costs about 20/kw/year and other generation about 35/kw/year. Whether this saving can be realized, depends on how *little* fuel is actually consumed for energy.

(2) *Unit Size*

The capital cost of 150/kw for a gas turbine of 1890kw. size is much lower than would normally be expected. Larger units in the 10Mw. to 25 Mw. range can be bought for $90 to $125 per kw. depending on the exact rating given to the gas turbine. However, in the range 3000 kw and below, it has been our experience that diesels are usually much cheaper. It is in the 5 Mw. to 20 Mw. range that gas turbines usually turn out to be the most economic unit.

It is doubtful if gas turbines of such small size would sell at prices in the $150/kw. range today.

In spite of these special circumstances, the author has presented a clear and complete method of evaluating gas turbines, integrated with other sources.

AN RCAF EXERCISE IN OPERATIONS RESEARCH

A. B. Howell, M.E.I.C.

Wing Commander, RCAF, Westin, Manitoba

The Engineering Journal November 1960, p. 72

Discussion by J. P. Jeannoit

This paper presents an analytical study on the complex problem of aircraft maintenance and credit should be given to its author for the interesting relationships and integrating work load and manpower requirement.

Even at its present level of complexity, the analysis has to rely on some approximate expressions and simplified assumption which as the author himself points out requires careful verification prior to application.

One important corner stone of the analysis is the linear relationship found to exist between (Ru/Ns) and (F/Ns). The author does not indicate whether this relationship has been found to vary with aircraft total time and type and frequency of maintenance activity, as it seems often the case. The assumption of a constant (Ru) in time implies that the probability density function of an aircraft becoming unserviceable can be expressed by an exponential function. Such a verification would provide worthwhile support to the analysis.

The equilibrium relationship ($Ru = Rs$), can only be seen to hold true if Rs is not a pure serviceable rate but contains a large hidden idle time buffer (many queueing studies have illustrated this fact). If the true servicing rate was equal to the rate of becoming unserviceable, a queue of unserviceable aircraft would keep building up affecting (Ru) until an equilibrium would be reached for $Ru < Rs$.*

Steady state equations being designed to use average values without apparent consideration to random fluctuations in studied rates, say Rs and Ru, the model does not seem to permit assessment of minimum guaranteed serviceability or operational readiness.** There would be considerable advantage to establishing how much real random fluctuation can effect the validity of the steady state equations. We note that the problem of the random fluctuations is considered insignificant by the author in his discussion of the transient state.

The author's approach in deriving an optimum method of allocating manpower between inspection and repair work can be subjected to discussion. This approach seems to give equal weight to the problem of minimizing the number of unserviceable aircraft and the number of crew turnover. For many an operator this viewpoint is unrealistic.

Finally, the transient state equation appears to provide a good method of assessing the average impact of a changing rate of unserviceability (Ru) such as in the case of a change in the frequency of work and inspection periods. The equation may be valid providing the change in handling does not noticeably disturb the established relationship between the rate of unserviceability and flying intensity $(Ru/Ns) = f(F/Ns)$.

This paper is a forward undertaking in an area where little as yet has been done. Personally, I feel that this area of study can be somewhat classified as a queueing problem. Other attempts, of much smaller scope, have yielded a fair amount of success through the use of queueing theory.

However, a queueing model can present considerable difficulties in as much as the mathematics of queueing theory still have quite a bit of development to undergo.

Probably one of the best exposition of queueing theory and its application can be found in Prof. Morse's book, "Queues, Inventories & Maintenance". A problem of the magnitude presented would ultimately require the use of a digital computer to set up a dynamic model of the maintenance queueing problem and analysis of the type presented in this paper will certainly provide essential knowledge on the effect and interaction of the many variable present in such a model.

Author's reply.

Mr. Jeanniot's kindness in his opening remarks is appreciated. I will answer his observations as they arise in his commentary.

Change of (RU/F) With Time

There is indeed a change in rates of becoming unserviceable for a given flying rate as the aircraft changes its state in the course of time. One would expect, as Mr. Jeanniot observes, a very high (RU/F) ratio for an aircraft newly from the drawing board. This ratio should descend abruptly during shake-down of the type, then continue to descend at an ever-lessening rate to a plateau from which in time through deterioration by aging the value of (RU/F) might be expected to rise again. The data so far collected has not been gathered over a long enough period to show significant change, as all aircraft types involved were well stabilized in use.

Arrival and Servicing Rates Being Equal

In cyclic systems where the cycle includes items in use as well as in queue and in repair and where there is a state of equilibrium, the elements of RU and RS as used in the paper must be equal; if this were not so, the numbers of serviceable and unserviceable aircraft would change in number and equilibrium would be lost.

The *individual* rates of arrival and servicing which we may designate as $\lambda = (1/TS)$ and $\mu = (1/TU)$ are *not* equal but $\lambda N_s = RU = RS = \mu N_n$ at equilibrium.

A current reference on this may be found in the Operational Research Journal for May—June 1960 in an article "Finite Queues and Cyclic Queues" by Ernest Koenisberg.

Fluctuations Within a State of Equilibrium

I am sorry to have given the impression that random fluctuations within a state of equilibrium were considered insignificant in every context. Such fluctuations are *not* important when analysis is applied in increments of 1500 flying hours or more which for a large population of aircraft means a period of a week to 10 days. But when analysis is applied to shorter units of elapsed time (significantly less than 1500 flying hour increments) then the variations *are* important.

The area of analysis for increments of more than 1500 flying hours is essentially deterministic in nature. The area of analysis for small flying increments is probabilistic and density functions for the probabilities involved will have to be determined before a probabilistic solution is possible. I hope that data collection can be refined enough to provide the information required.

The Transient State

Mr. Jeanniot's remarks on the development of transient state equations and the optimum method are well taken.

I wish to thank Mr. Jeannoit for a useful and informed critique.

OPTIMUM ADJUSTMENT OF GOVERNORS IN HYDRO GENERATING STATIONS

L. M. Hovey, M.E.I.C.

The Manitoba Hydro Electric Board, Winnipeg.
The Engineering Journal, November 1960, p. 64.

Discussion by C. L. Avery

The discussion in this paper of convenient methods for field checking certain governor characteristics which affect unit stability and of the mathematical background should be of value to anybody involved with field adjustment of governors. The methods used are quite valid, assuming that the governor has first been found to be mechanically satisfactory from the standpoint of dead band, resolution, dashpot clearance, lost motion, etc.

The optimum values to which the various units on the Manitoba system were set are those determined by analog computer studies and do not include system self-regulating effects. Since the values so determined are based on purely resistance load governors so adjusted should be quite stable on normal system loads.

It would be interesting if Mr. Hovey would elaborate on what improvements in system operation were noted as a result of these adjustments or what tolerance in the adjustments could be allowed before system control is adversely affected.

In the case of the Manitoba system, the water time constants of the dominant plants are approximately the same and setting the individual dashpot time constants as a function of the weighted mean of the system is apparently satisfactory. Where the hydraulic time constants vary greatly between plants on a system it would appear more valid to base the dashpot time constants on the individual plant hydraulic characteristics. It can be seen from basic consideration of the factors affecting any single machine that, while the mechanical inertia tending to stabilize any disturbance is the total inertia of the connected system, the disturbance produced by hydraulic inertia is that pertaining to the unit itself. In other words, while the rotating masses are coupled together the hydraulic masses are not.

The author is to be commended on his very complete discussion of the general problem and this paper is a valuable contribution in a field of great interest to operators of independent power systems.

Discussion by R. Harland

Of the interconnected plants on the Winnipeg River, City Hydro owns and operates those at Pointe du Bois and Slave Falls. As a result, my first concern on reading Mr. Hovey's paper was the way in which common values of T^T and δ would affect the operation of these plants, especially since Slave Falls machines are vertical, propeller type and relatively slow, while Pointe-du Bois uses horizontal, Francis type, medium speed units.

The calculated responses of these plants individually, using Mr. Hovey's suggested values, led to the similar investigation of other plants. These responses are interesting, varying from dead-beat at Point du Bois and practically so at Seven Sisters, to cases of border-line stability at Pine Falls, and a high degree of instability at McArthur.

I therefore have three questions for the author:—

1. If my calculations are correct, and the response of McArthur is unstable, these machines could never be synchronized. Obviously this is not the case in practice. Why?
2. If you integrate the individual response curves of Pointe du Bois and Slave Falls from 0 to 1.28 seconds, you get the per unit drift of each plant from 60 cps. The difference is the number of cycles they tend to pull apart. For a 1 pu step function of load, this exceeds 340 electrical degrees. This must be resisted by the flow of synchronizing power between plants. Has Mr. Hovey done any stability studies under this or similar conditions taking into account governor response?
3. Considering the diversity of shapes of the response curves using Mr. Hovey's suggested values of T^{τ} and δ would it not be preferable to fix his stability criteria 2_1 and 2_2, making at least the shape of the response curves similar, and calculate appropriate values of T^{τ} and δ for each plant from these criteria?

Discussion by I. W. McCaig

It has long been known that the governing stability of a hydro-electric system composed of a number of generating stations is greater than that of some of its individual stations. What has not been known is the optimum method of using the system stability to stabilize governing at stations which have poor regulating characteristics.

Mr. Hovey has shown how, by adjusting the temporary speed droop and dashpot relaxation times of all the turbines of The Manitoba Hydro-Electric Board's systems to a constant value, he has obtained fast response and stable system operation.

An examination of Table 1 and Fig. 2 will show that with the temporary speed droop set at 33% and the dashpot relaxation time set at four seconds on all the governors, McArthur Falls and Pine Falls will, if operating alone, be unstable at full load. Could Mr. Hovey indicate whether there is difficulty in synchronizing units in these stations?

The paper indicates that the governor settings used in The Manitoba Hydro-Electric Board's system are slightly less than the values for optimum damping. In particular, the dashpot relaxation time T^{τ} was made equal to four times the water starting time T_{ω}, rather than the optimum value of five times. Fig. 5 shows that this shorter relaxation time causes slight over-compensation and the speed change falls to a negative value after an initially positive one. Was there some special reason for using a shorter-than-optimum dashpot relaxation time?

Author's reply

The author wishes to thank Messrs. Avery, Harland, and McCaig for their discussions of his paper.

In commenting first on Mr. Avery's discussion, he is quite correct in observing that the optimum settings do not include the system self regulation effect and as a result are conservative as far as stability is concerned.

In connection with comparing the performance of the system before and after making the adjustments, it is unfortunate that we were unable to make tests to indicate any improvement. However, we do know that the present settings do not result in any instability even if the stations become separated. Subsequent tests are, however, contemplated to compare system performance based on using the individual plant characteristics of water starting time and mechanical starting time instead of the weighted

SIMON-CARVES

Build High Efficiency Electro-Precipitator for WORLD'S largest boiler unit at THORPE MARSH POWER STATION for CENTRAL ELECTRICITY GENERATING BOARD

Removing 12 tons of dust an hour

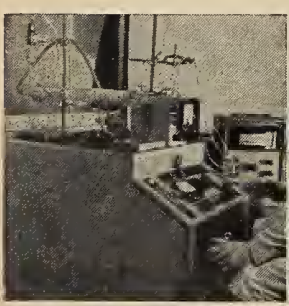
At the new THORPE MARSH power station in Britain, to be built for the Central Electricity Generating Board, SIMON-CARVES have been entrusted with the design and construction of the electro-precipitation plant which will have what is believed to be the heaviest duty yet proposed for precipitators on a single boiler unit anywhere in the world. The unit will have an output of 550 MW and the boiler is expected to produce more than one and a half million cubic feet of flue gas per minute. The plant will remove fine dust, which would otherwise pollute the atmosphere, at a rate of about 12 tons an hour.

SOME APPLICATIONS of ELECTRO-PRECIPITATION

Electro-precipitators will collect industrial mists, dusts etc. found in following industries:—

Chemical
Fertilizer
Metallurgical
Power Generation
Cement Manufacture
Steel
Mining

LABORATORY RESEARCH IN ELECTRO-PRECIPITATION



Investigation on dusts under vacuum

Measurement of dust resistivity

Investigations on discharge through dust layers

Bench scale model precipitator

DESIGNERS, ENGINEERS & CONTRACTORS TO WORLD INDUSTRY

SIMON ENGINEERING GROUP

SIMON-CARVES OF CANADA LTD.

value of these parameters as was described in the paper.

In Mr. Harland's discussion, he points out that certain individual plants, if theoretically isolated on a resistance load, would be unstable, this being particularly the case at McArthur Falls. This reasoning is quite correct. However, it is felt that if McArthur ever did become separated, the increased inertia due to load and the self regulation effect would stabilize the plant. In attempting to answer Mr. Harland's question (1) the explanation as to why McArthur is not unstable at speed no load, is that the water starting time at speed no load, is very much lower due to the lower water velocity. Also, the fact that the self regulating effect of the speed torque curve helps to stabilize the unit. The above two stabilizing influences are somewhat offset by the relative steep torque gate curve at speed no load. Therefore, the explanation for stability at speed no load, would be due to the preponderence of stabilizing effects at this operating point.

In answering question (2), we have never attempted to analyse the stabilizing synchronizing torque which must of necessity flow to hold the system at stable frequency.

Question (3). It is the intention of the author's organization to make some tests based on individual plant settings to determine if there is any improvement or otherwise in system performance as regards frequency regulation. The settings would be carried out in a similar manner as outlined in the question.

With Mr. McCaig's discussion, the author feels that the answers to some of the questions are covered above.

In answer to the last question, the optimum setting was selected to give a slightly oscillatory response for the assumptions as chosen (i.e. resistance load, no self-regulation) on the basis that with the existing self regulating effect the response would be critically damped.

DESIGN OF INDUSTRIAL GEARS

R. D. Mutch, M.E.I.C.
Product Engineer,
Dominion Bridge Company Limited, Montreal

The Engineering Journal, November 1960, page 53.

Discussion by J. B. Mantle, M.E.I.C.

As a teacher of a class in Machine Design involving gear design, I believe that the question as to what constitutes an "industrial gear" and a "precision gear" warrants some discussion. Surely an error in shape of 0.003 in. or of 0.001 in. would not effect impact loading on the teeth if the shape error was all positive or all negative! I feel that in specifying tooth errors reference should be made to surface roughness values. Perhaps Mr. Mutch could give some indication as the RMS surface roughness values that could be expected with "industrial" and with "precision" gears of ID.P. Would it not be practical for design engineers to have a more precise criteria for tooth error than that commonly employed?

A further question is related to the resulting relation between face width and diametral pitch using the design procedure recommended for spur gears. Does this come out as a constant for the usual gear or is it quite variable? I have in mind the commonly used ratio for spur gears of $F = \frac{10.}{P}$

Author's reply

The tooth profile errors are arbitrary values and have been chosen more as an approximation to suit production methods than from theoretical considerations. This was done for the precise reason that Prof. Mantle has mentioned, namely, that few criteria exist, to my knowledge, which would determine to what class a gear should be manufactured.

As tooth profile errors can occur in a random fashion, it seems necessary to take them into account when designing, as there could be no guarantee that the profile error was all positive or all negative across one tooth face or that all the mating teeth would be perfect in profile. In other words, the profile errors could be and often are, variable within the face width of any one tooth. This was demonstrated during investigations into turbine gear failures in warships and the errors were attributed to lack of rigidity in the machines used for cutting the teeth.

The question of surface finish has always been a difficult one and as Prof. Mantle points out, has a definite influence on the performance of gears. Notice is taken of this in the paper where the gear box test is described. For heavy industrial gears I would suggest that a precision gear might be specified as having a surface finish not courser than 32 micro-inches RMS and that a commercial gear would have a finish of 63 micro-inches RMS. These values represent respectively a ground surface and the finest tool-produced surface without grinding as we at Dominion Bridge Company are accustomed to work. Of course, I realise that in other classes of manufacture, these finishes might be regarded as extremely rough and, in high precision work, completely unacceptable. It would seem, therefore, that it would be necessary to establish various degrees of finish for different classes of manufacture, but the above noted finishes could probably be used as a basis for design.

The proportions of face width to diametral pitch can vary quite widely by this design method, depending on the relative values of allowable surface stress and allowable bending stress used for the material under consideration. For example, a 40% carbon steel, flame hardened, would give a relatively narrow face width for wear and a relatively course pitch for strength. However, the factor $\frac{P}{Y}$ generally allows a number of selections to be made for teeth and pitch and the final choice of these values would be guided by the designer's experience. In this respect, the method outlined in the paper may not be quite rigid but it at least determines the minimum face width necessary for the material under consideration.

With helical gears, the minimum ratio of $\frac{\text{Face width}}{\text{D.P.}}$ is determined by considerations of overlap and in such cases the method provides a check on this value and ensures that the face width is adequate for wear. EIC

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

VIBRATIONS MECANIQUES, 2. ed.

Translated, presumably from the fourth English language edition, this volume is intended for both an undergraduate and graduate text, emphasizing the applications of principles and calculations to the practical vibration problems encountered by the practising engineer, It covers systems with one or more degrees of freedom; multicylinder engines; rotating machinery; self-excited vibrations; systems with variable or non-linear characteristics. (J. P. Den Hartog. Paris. Dunod, 1960. 460 p., 65 N. Fr.)

TECHNIQUE METALLOGRAPHIQUE

An introduction to metallography, describing methods of the preparation of metal surfaces for micro- and macrography. The author discusses the various methods of mechanical polishing and of electrolytic polishing; the preparation of test pieces; anodizing; pickling; the uses and methods of macrography. Examples are given of both macrographs and micrographs, taken from work done in an industrial laboratory. A bibliography is included. (A. Roos. Paris, Dunod, 1960. 121 p., 13.50 N. Fr.)

L'USINAGE DES METAUX PAR ELECTRO-EROSION

Much of the early work on the finishing of metals by electro-erosion or spark erosion was done in Eastern Europe. This translation from Polish outlines the research which has been done in Poland, and includes a chapter on recent research which was not in the original edition. The various methods of electro-erosive finishing are discussed in detail, as are the machines used. There is a bibliography, mostly of Polish and Russian articles, covering the years from 1951. (K. Albinski. Paris, Dunod, 1960. 128 p., 17 N. Fr.)

MESURE ET INSTRUMENTS DE MESURE, 4. ed.

Intended both for those who make measuring instruments, and those who use them, this text is concerned with the study of instruments, the choice of a method of measurement, and the use of the results. The first chapter defines the terms used in measuring, and lists the five important points to consider in the use of measuring instruments; extent, sensitivity, precision, acuteness and speed. The five points are discussed at length in the following chapters, while a final chapter covers the interpretation of results. (J. Idrac. Paris, Dunod, 1960. 125 p., 9 N. Fr.)

THERMODYNAMICS AND THE HEAT ENGINE

An introductory study, in which the stress is placed on the importance of the thermodynamic system and its application to the processes of energy conversion. In addition, there is a large proportion of practical description. The topics, which are presented as simply as possible, include in addition to the chapters on thermodynamics, the principles of action of heat engines, engine efficiency, reciprocating gas compressors, air standard cycles, properties of vapours, reciprocating steam engines, steam power plant and cycles, and combustion. (D. H. Marter. Toronto, Longmans, Green, 1960. 812 p., $12.60.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

PHYSIQUE ET TECHNIQUE DES TUBES ELECTRONIQUES

The first volume of this work covered vacuum physics and technology. This second volume is concerned with the study and structure of electron tubes. The first part of the book discusses general principles, starting with a summary of electron physics, and including the behaviour of electrons in metals and their emission, and the behaviour of electrons in electric and magnetic fields. From this the author shows the methods of calculating the elements in the different types of tube — diodes, triodes, high frequency, cathode ray and gas.

The second part is concerned with tube construction: materials used; constituent parts; and the manufacture of cathode tubes and special electron tubes. Throughout the volume, the author is concerned more with the principles involved rather than the ultimate use of the tubes. (R. Champeix. Paris, Dunod, 1960. 427 p., 58 N. Fr.)

COPPER COSTS AND PRICES: 1870-1957

Although this study is concerned with copper, it throws light on the general run of long-run cost increases which may be used in the study of other minerals. This is particularly valuable considering the attention focused in recent years on possible future difficulties in obtaining raw materials.

Some of the topics covered by the study include the effects of unusual events on prices; investment in the mineral industry; price manipulation prior to World War I; an evaluation of competition in the industry; the cost of producing copper; copper resources, and the significance of level price over long periods. This study was sponsored by Resources for the Future. (O. C. Herfindahl. Toronto, Burns and MacEachern, 1959. 260 p., $7.00).

ELECTRICAL TECHNOLOGY

An English undergraduate text, covering the first-year electrical engineering syllabus, and including over 100 worked examples and almost 700 additional problems, with answers. The 21 chapters cover circuits; electromagnetism; electrostatics; d.c. machines; generators and motors; alternating voltage and current; symbolic notation; single-, two- and three-phase circuits; transformers; alternators; thermionics; electric lamps; measurements and accumulators. (Edward Hughes. Toronto, Longmans, Green, 1960. 694 p., $3.25.)

APPLIED MECHANICS

Particularly intended for those writing the applied mechanics examinations of the British Institutions, this volume also includes many worked examples, and

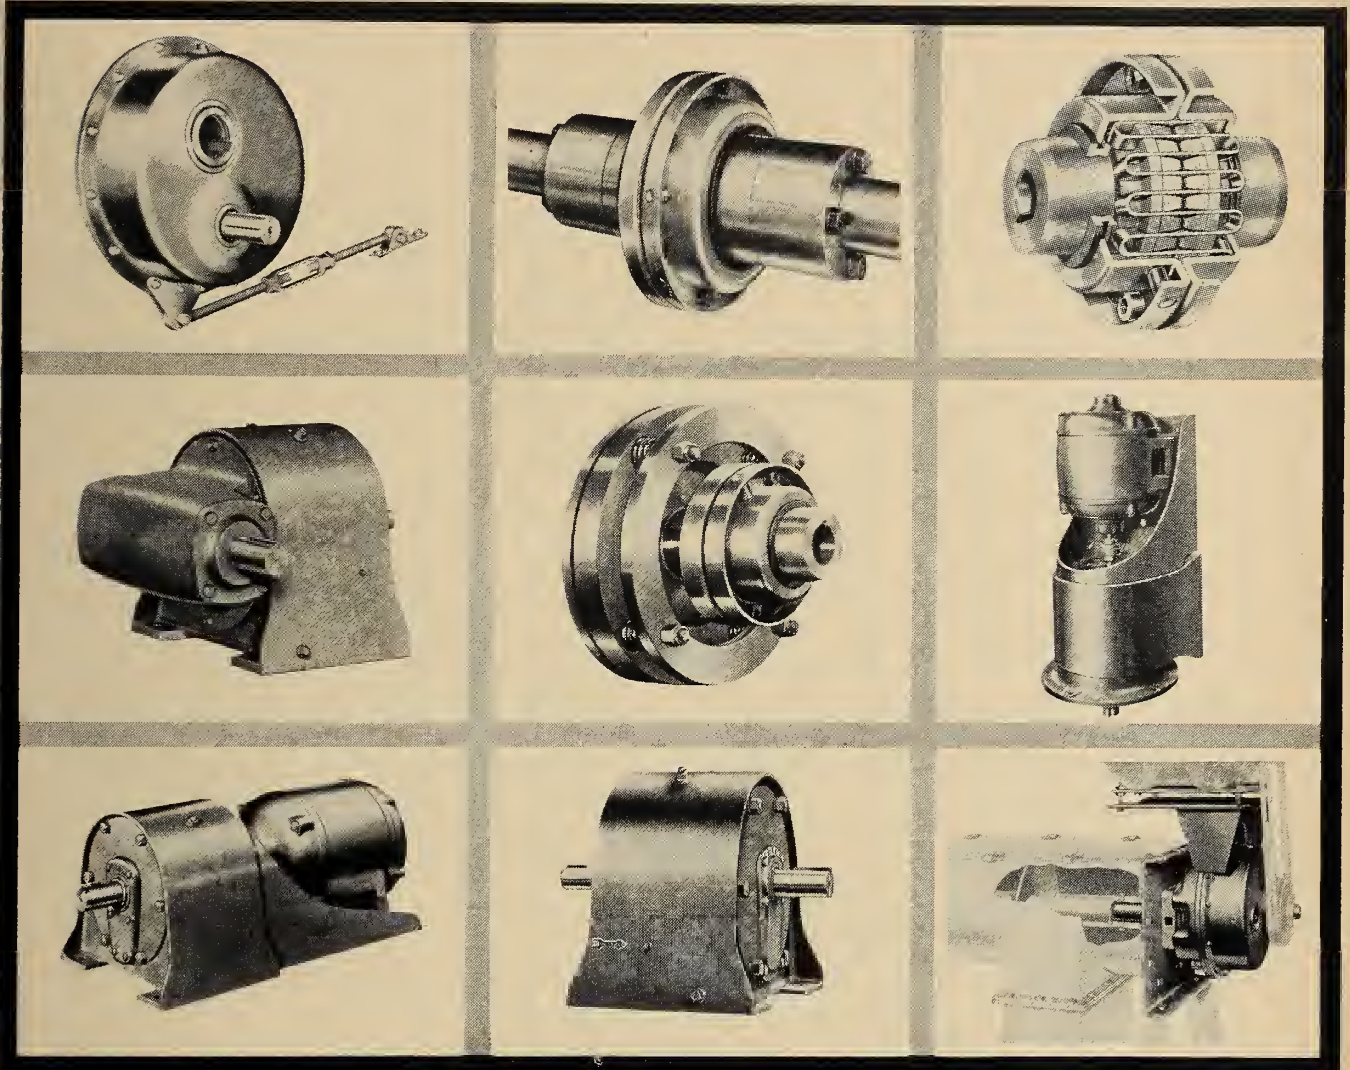
ALLIS-CHALMERS



60F2

All this, with Service too!

Now famous FALK reducers and couplings made in Canada

Let's face it . . . next to the quality of the original product, what you want most in machinery is some assurance of quick parts' service. Now this is guaranteed to you because this distinguished FALK line of speed reducers and couplings is now manufactured in Canada under licence, by Canadian Allis-Chalmers. FALK reducers are available in *any* size, *any* type, *any* output speed, *any* type of motor, *any* mounting, and for *any* service. Parts not readily available from dealers coast to coast can be shipped promptly from Montreal or Milwaukee. FALK has been the choice of discriminating U.S. buyers for over 60 years. Investigate these outstanding reducers through your nearest Allis-Chalmers distributor, or write Canadian Allis-Chalmers. P.O. Box 37, Montreal.

FALK DISTRIBUTORS:

- Gill & Co. Ltd., Saint John, N.B.
- Williams & Wilson Ltd., Quebec City, Montreal, Ottawa, Toronto and Windsor.
- William Kennedy & Sons, Owen Sound, Montreal, Toronto and Haileybury, Ont.
- Vickers-Warnock Ltd., Hamilton.
- M.F. Mills Supply Ltd., Port Arthur, Ontario.
- Bearing Supply & Service Co. Ltd., 472 Notre Dame Ave., Winnipeg, Manitoba.
- Bearing & Transmission Regina Ltd., 1441 Alberta St., Regina, Saskatchewan.
- Bennett & Emmott Ltd., Edmonton and Calgary.
- Galbraith & Sulley Ltd., 1331 West 6th Ave., Vancouver, B.C.

problems and answers. The author covers statics; friction; dynamics; harmonic motion; stress and strain; bending moment; bending of beams; torsion; hydrostatics and hydrodynamics. Although this is an introductory text, the author has indicated, for those who will be continuing their studies, the way in which the subjects develop in later stages. (P. D. Collins. Toronto, Longmans, Green, 1960. 347 p., $3.25.)

HEAT ENGINES

Another first text on heat engines, with less emphasis on the thermodynamic background, and more description and discussion of the various engines. The first chapters cover gases, thermodynamic reversibility and ideal thermal efficiency, entropy, and ideal engine cycles using gases. Following chapters deal with internal combustion engines; steam, and the steam plant; the steam engine; steam turbines; engine trials, combustion; heat transfer and thermometry. Many worked examples are included, as are problems with their answers. (Rayner Joel. Toronto, Longmans, Green, 1959. 531 p., $3.25.)

CONSTRUCTION DU NAVIRE DE COMMERCE

A useful study of the construction of merchant ships intended for those who sail them rather than those who build them.

An introductory section gives general information on different types of vessels, tonnage, definitions of nautical terms, strength of materials and fatigue, and includes a very useful chapter on the provisions of the various international conventions governing safety at sea. The second section is concerned with the actual construction; materials, standards, the different parts of a vessel, hull, paint and fittings, accommodation, piping, ventilation, electrical installations, etc. The third section covers various stages of construction, drawing up plans, laying the keel, launching etc., and inspection of the vessel in service. (E. Chicot. Paris, Editions Maritimes et Coloniales, 1960. 423 p., 32 N. Fr.)

ACCELERATEURS DE PARTICULES ET PROGRES SCIENTIFIQUE

A relatively non-technical account of the principles of operation of particle accelerators and their scientific importance. It discusses the first experiments with accelerators, the invention of the cyclotron, high speed accelerators, and large accelerators. It classifies the accelerators at present in use, and describes them. (N. Felici. Paris, Dunod, 1960. 161 p., 12.50 N. Fr.)

INTRODUCTION A L'ETUDE DE LA RHEOLOGIE

The increasingly high temperatures to which metals are being subjected, the general use of plastics and rubber, and the great precision required of the mechanical engineer, means that the classical strength of materials theories are often not sufficient. Rheology, the study of the flow of matter, is therefore of interest both to industry and science.

The first five chapters of this text are concerned with basic theories and terminology. The second section of the volume considers different materials and their properties: metals and the theory of dislocations; glass; plastics; rubber; paint and varnish; gasoline. Three final chapters discuss the importance and applications of rheology in biology, soil mechanics, and geology.

Each chapter is written by an expert in the field. (Ed. by B. Persoz. Paris, Dunod, 1960. 251 p., 44 N. Fr.)

METHODES MODERNES D'ETUDE DES SYSTEMES ASSERVIS

A review of recent progress in servomechanisms, especially theories which have been developed since 1951.

The first section is concerned with linear systems, particularly poles and zeros and the s plane. The second section discusses the statistical study of servo systems, random input, Wiener's method, etc. The third section considers the extensions of linear methods, systems with several variables, frequency response, and pulse systems. The final section reviews non-linear servo systems, particularly the work on them being done in Russia, and covers the Kochenburger, or describing-function approach, the phase plane, on-off systems, general methods of non-linear mechanics, non-linear stability, and the theories of Poincare and Ljapunov. There is a bibliography, and a useful glossary, in five languages, of the terms used in servomechanisms. (J. C. Gille and others. Paris, Dunod, 1960. 460 p., 64 N. Fr.)

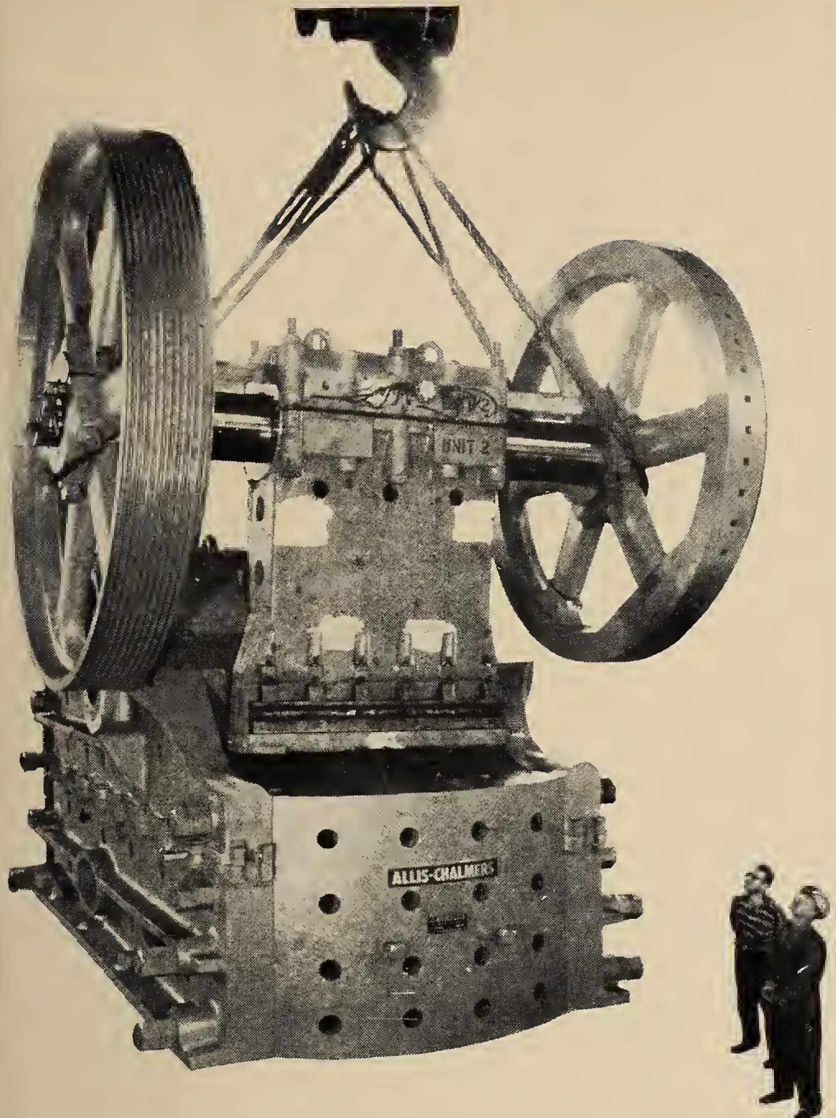
LOGIQUE GENERALE DES SYSTEMS ET DES EFFETS

In addition to discussing quadripoles and servomechanisms, the author attempts to present a picture of the whole field of servomechanism and information theory. He gives his ideas on a "physics of effects", the principle being that a system should be studied according to its logical structure, and not its material constitution. Some of the topics covered include impedance, connected systems, transmission, active systems, non-linear systems, and energy and information. (A. Ducrocq. Paris, Dunod, 1960. 298 p., 48 N. Fr.)

CHEMICAL PERIODICITY

A text book on inorganic chemistry, emphasizing the unity of the subject, by examining closely what is already known, studying the relationships among the elements, and trying to recognize the underlying reasons.

The topics covered include: the periodic law; chemical combinations; the condition of combined atoms; principles of co-ordination chemistry; physical nature of the elements; binary compounds of oxygen, hydrogen, nitrogen, sulphur, fluorine, chlorine, bromine and iodine; inner transition elements; and the period-



Canadian built

Allis-Chalmers Crushers

First choice of Iron Ore Industry

There is no better way to confirm a product's widespread acceptance than naming the users. Canadian Allis-Chalmers is pleased to note that all leading iron producers have installed (or ordered) A-C Jaw or Gyratory crushers. Why? Because they're *priced* right . . . because they're *made* right . . . because they're made *in Canada*.

These mines have installed (or ordered) Allis-Chalmers Crushers, as noted:

- Algoma Ore Properties Limited, Wawa, Ont.
  Three 48″ x 42″ Jaw Crushers
- Dominion Wabana Ore Ltd., Wabana, Newfoundland.
  Two 48″ x 36″ Jaw Crushers
  One 60″ x 48″ Jaw Crusher
- Hilton Mines Limited, Shawville, Que.
  One 4265 SUPERIOR* Gyratory
- Iron Ore Company of Canada Limited, Carol Project.
  One 6089 SUPERIOR* Gyratory
- Lowphos Iron Mines Ltd., Capreol, Ont.
  Two 584 HYDROCONE*
  One 1784 HYDROCONE*
- Marmoraton Mining Co. Ltd., Marmora, Ont.
  One 584 HYDROCONE*
- Nimpkish Iron Mines Ltd., Beaver Cover, B.C.
  One 851 HYDROCONE*
- Quebec Cartier Mining Corporation, Lac Jeannine, Quebec.
  Two 84″ x 66″ Jaw Crushers
  Two 3065 SUPERIOR* Gyratory
- Steep Rock Iron Mines Limited, Atikokan, Ont.
  Two 60″ x 48″ Jaw Crushers

60MM-1

icity of coordination chemistry. Many periodic charts are included, as are references for further reading. (R. T. Sanderson. New York, Reinhold, 1960. 330 p., $11.75.)

MARINE DIESEL ENGINES, 2nd. ed.

Since 1952 when the first edition of this book appeared, there has been a change in marine heavy oil engine practice from atmospheric induction to pressure induction. This change is reflected in the text. The book is intended primarily for marine engineers, and deals with propulsion machinery at present in service.

After two introductory chapters dealing with elementary theory and pressure-charging, there are chapters on the engines manufactured by eight British and European companies, written for the most part by those connected with the companies. The remaining chapters cover various topics and problems the author has discussed with marine engineers, including chemistry of combustion; crankcase explosions; creeping cracks; rating of engines; and engine performance. The author is well-known for his other books on marine diesel engines. (C. C. Pounder. London, Newnes, 1960. 692 p., 70/-.)

ELEMENTARY ENGINEERING MECHANICS

Intended primarily for a two-year technician programme this text requires only a basic knowledge of algebra and plane geometry. It describes the essential elements of statics and dynamics, and their application to engineering problems. The author stresses fundamental concepts, and shows how complicated problems can be solved by correct analysis. (E. G. Key. New York, Wiley, 1960. 457 p., $5.50.)

HEAT TRANSFER

An undergraduate or graduate text, presenting the fundamental concepts, and showing how the mathematically derived results can be used to gain an understanding of heat transfer processes. Conduction, convection and radiation are all discussed, and the topics under which they are covered include steady state heat conduction in one dimension, extended surfaces, viscous fluid motion; boundary layer theory; forced and free convection; combined conduction and convection. Problems and references for further reading are included. (A. J. Chapman. Galt, Brett-MacMillan, 1960. 452 p., $9.00.)

EXHIBITION AND DISPLAY

This well-produced volume studies the three activities which are the object of any exhibit — to explain, to create atmosphere, and to sell. They cover store displays, industrial and government exhibits, and large international trade fairs and expositions. The principles of good display are considered, and attention is paid to circulation, the eye, lighting, special effects and plants. The practice of these principles is discussed in relation to the various types of exhibit. The text is illustrated with more than 350 photographs and line drawings.

Both authors are experienced in the exhibit field. Mr. Gardner's projects include the British Pavilion at the 1958 Brussels Fair, and the 1951 South Bank Exhibition in London. (James Gardner and Caroline Heller. New York, Dodge, 1960. 192 p., $13.75.)

PROBLEMES DE GESTION D'ENTERPRISE, 3 ed.

A discussion of some of the problems faced in the operation of a business, commencing with a consideration of the administrative structure, with examples taken from factories and retail stores with several branches. Succeeding chapters cover the planning of production, budget, financing, the uses of publicity and the uses of operations research in the organization. (M. Bourquin. Paris, Dunod, 1960. 222 p., 27.60 N. Fr.)

*VERS LA MAITRISE DE LA FUSION THERMONUCLEAIRE: PROJET SHERWOOD

A French translation of the first unclassified report on the controlled thermonuclear effort in the United States. Beginning with the basic principles involved in a fusion reaction, it continues with the various methods now being studied to control thermonuclear energy with the hope of eventually producing net power. Methods such as pinch, stellarator, magnetic mirror, and molecular ion ignition are explained. (A. S. Bishop. Paris, Dunod, 1960. 199 p., 39 N Fr.)

*FILES D'ATTENTE STOCKS ET ENTRETIEN

Translated from the U.S. publication, Queues, inventories and maintenance, this is an introductory monograph to the subject of queuing problems and discusses the effect of change of arrival and service distributions on queuing results. Queuing problems are dealt with from the standpoint of the Kolmogorov equations relating the probabilities, and specific applications such as those relating to repair and maintenance of machinery are analyzed and solved. (P. M. Morse. Paris, Dunod, 1960. 205 p., 33 N. Fr.)

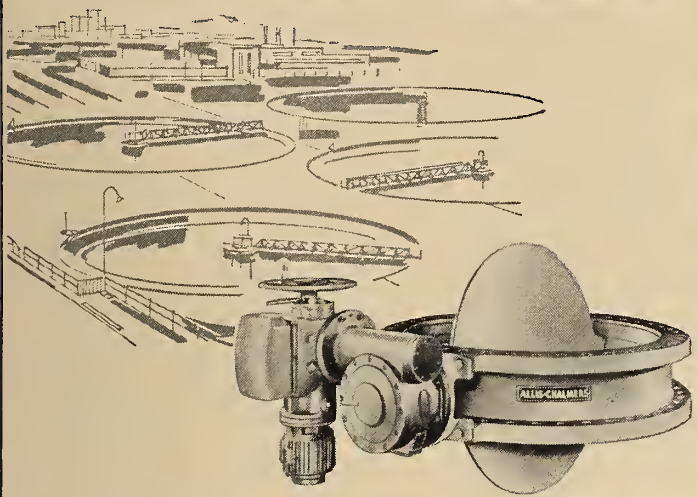
PROGRAMMATION DES CALCULATRICES NUMERIQUES

A translation of one of a series written by Generel Electric authors on various aspects of engineering practice, this volume provides an introduction to the field of computer programming, emphasizing basic principles applicable to all computers. The author discusses the elements of a computer, and their relationships, and gives information on coding, binary and octal number system, and decimal point location methods.

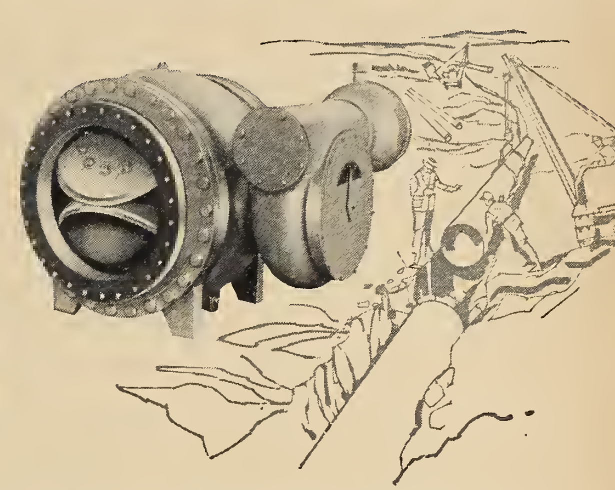
The principles of programming are given with examples and explanations, and application to a representative computer. The original bibliography is included, with a notation when a French translation is available. (D. D. McCracken. Paris, Dunod, 1960. 255 p., 36 N. Fr.)

CANADIAN

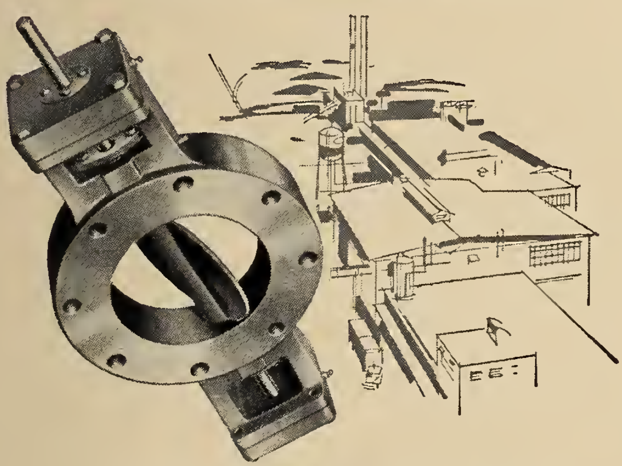
ALLIS-CHALMERS



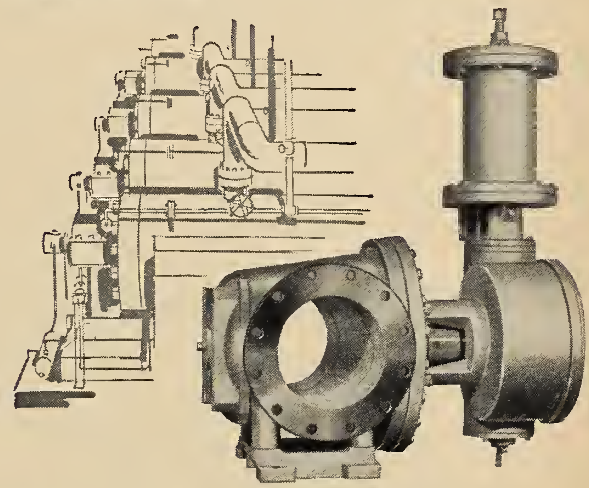
BUTTERFLY VALVES — For liquids or gases — uniform control in all positions, fast positive regulation and closure, minimum pressure drop. Compact and lightweight. Sizes from 1 in.



BALL VALVES — Easy manual shutoff under adverse conditions. Slight wedging action gives unusually drop-tight closure. Sizes: 12 to 48 in.



WAFER VALVES — A new design of butterfly valves with space-saving flexibility, suited to most any type of operation. Sizes from 3 to 36 in., including high-pressure types.



ROTOVALVE — A cone valve suited to virtually any type of operation or location. Offers the least pressure loss, greatest initial shutoff, controlled closing time, positive seating.

Now: for power plants, sewage and water works —

a full line of rotary valves

Serving you even better through a broader line — Allis-Chalmers offers the finest in butterfly, ball and cone valves for industrial applications, power plants, sewage and water works. Also available are complete valving systems in standardized "packages" that provide *remote, telemetered control of valve operation.* These additions further round out Allis-Chalmers line that includes Angle, Needle, Relief valves, sleeve-type values and accumulator systems. *For complete information, contact your nearest A-C Sales Office or write direct to* **Canadian Allis-Chalmers Limited,** P.O. Box 37, Montreal, Que.

Rotovalve is an Allis-Chalmers trademark.

60P4

ELECTRICITY AND MAGNETISM

An intermediate undergraduate text for students having a knowledge of general physics and calculus; and just beginning the study of differential equations. The author has presented his material as clearly and concisely as possible, and where applicable, has related the topics to atomic, nuclear and solid state physics. The topics covered include electric forces and electric fields; capacitance; dielectric theory and behaviour; resistance; thermoelectricity; moving charges and magnetic fields; electromagnetic induction; magnetic properties of matter; galvanometers; etc., transient and alternating currents. The author is professor of physics at McMaster University. (H. E. Duckworth. Toronto, Macmillan, 1960. 424 p., $7.00.)

BASICS OF INDUCTION HEATING

The fundamental principles of induction heating, presented in the familiar Rider "pictured-text" manner. The electrical and thermal aspects are covered, as are mechanical problems, and the various uses of induction heating in manufacturing. The author has worked in the field of induction heating for many years. (C. A. Tudbury. New York, Rider, 1960. 2 vols., each $3.90.)

BASIC CARRIER TELEPHONY

Another in the "pictured-text" series, this volume is concerned with the principles and methods of carrying multiple telephone conversations, etc., over one wire or cable, or radio circuit. It covers telephone carrier definitions and fundamentals, circuitry, modulators, controls, switching, system operations, cable carrier systems, and carrier applications to radio systems. (David Talley. New York, Rider, 1960. 170 p., $4.25.)

WIRE REINFORCEMENT INSTITUTE BUILDING DESIGN HANDBOOK

The first section of this Handbook contains general information and illustrations on the use of steel wire fabric in reinforced concrete construction. The second section, Design, is concerned primarily with the increasing use of heavy welded wire fabric, and as it consists mostly of a series of design tables, should prove a useful working tool. Tables are included for one-way slabs, with spans up to 24 feet, two-way flat slabs, tilt-up wall panels, vertically spanned basement walls, cantilevered retaining walls, and square individual column footings. A.S.T.M. specifications for welded wire fabric are included. (Washington, Wire Reinforcement Institute, 1960. 168 p., $3.00.)

MOBILE MANUAL FOR RADIO AMATEURS, 2nd ed.

Over 80 articles on amateur mobile operation which have appeared in the League's periodical, QST, including articles on the construction of receiving converters, transmitters, antennas, power supplies, and the suppression of noise in vehicles. Also included for the first time are articles on emergency and portable equipment. (West Hartford, Conn., the League, 1960. 282 p., $3.00.)

SOLID PROPELLANT ROCKETS

The Princeton University Press has decided to issue in paperback form sections of its valuable series, High Speed Aerodynamics and Jet Propulsion, in order to make them more easily available to students and research engineers. The books are prepared from the original plates. The first section of this volume covers the combustion of solid propellants. The second section is concerned with the rockets themselves, construction; interior ballistics theory; composition, preparation and properties of propellants; motor design; and development trends. (Clayton Huggett and others. Toronto, Saunders, 1960. 167 p., $2.45.)

ENGLISH DUDEN: A PICTORIAL DICTIONARY, REV. ED.

This is a different type of dictionary. The 25,000 objects it illustrates are divided, by subject, into 368 sections, for each of which there are illustrations, some in colour, and word lists in English. The subjects are in nine main divisions, ranging from atoms through

(Continued on page 184)

HAVE YOU NOTIFIED THE CIRCULATION DEPARTMENT?

YOU CAN HELP THE EMPLOYMENT SERVICE

Hundreds of communications are made yearly between employer and employee through the classified advertisements in The Engineering Journal and Employment Service Bulletin.

In order to give you both better service, we rely on your co-operation.

Employers: Acknowledge all applications received in answer to "The Vacancy" you advertise.

Employees: Acknowledge all applications received in answer to "The Situation Wanted" you advertise.

Courteous, prompt replies cost you little—and they pay often handsome dividends.

UNIVERSITY GRADUATE ELECTRICAL ENGINEER

LOCATION: Sept Iles, Quebec, but required to travel for short periods for field work.

QUALIFICATIONS: At least two years field experience in any branch of electrical power generation, transmission and distribution, preferably with a power utility.

DUTIES: Work involves trouble shooting, records and statistics, system studies, and general assistance in the operation and maintenance of private hydro-electric power systems, plus design of new work and extensions.

Salary commensurate with experience.

Please reply in confidence stating age, education, resume of work experience and references.

IRON ORE COMPANY
OF CANADA
Personnel Department
810 Cote de Liesse Road
Montreal 9, P.Q.

recent graduate in electrical engineering. This position offers a young engineer an excellent opportunity to familiarize himself with industrial applications of both A.C. and D.C. equipment. We also generate part of our own power requirements by means of both hydraulic and steam driven alternators. Good opportunities for advancement. Apply in writing to File No. 7015-V.

ELECTRICAL ENGINEER. Established base metal mining company in Ontario requires the services of a graduate electrical engineer with experience in industrial and power distribution systems. Applicant will be required to design and produce the drawings for the power distribution of a mining plant presently in the engineering stage. Property is in vicinity of medium sized city offering all amenities for family living. File No. 7131-V.

ELECTRICAL MAINTENANCE ENGINEER. Electrical Engineer who has graduated in the last ten years, with three to five years experience, to work in the Electrical Department of a large diversified paper mill in Eastern Ontario. Experience in pulp and paper preferred, with an interest in electronics and controls. Apply in confidence with complete resume and salary requirements to File No. 7148-V.

MISCELLANEOUS

ENGINEERS FOR SALES, project, design, research, development, control and management. Graduates of all types and ages required by clients of The Technical Service Council, a non-profit industry sponsored placement service. Write 2 Homewood Avenue, Toronto 5 for applications. There is no charge for work done on your behalf. File No. 6648-V.

SALES ENGINEER. The company, a well known manufacturer of centrifugal pumps with head office in Toronto, requires recent graduates for its Montreal and Toronto Sales Offices. After a short training period, the successful candidates will be engaged in outside sales work, calling on refineries, chemical plants, major contractors, consulting engineers and the pulp and paper industry. Reply giving full particulars to File No. 7001-V.

ASSISTANT PROFESSOR required for teaching and research in hydraulics and fluid mechanics. Salary $6000 to $8000 depending on qualifications. Please submit full details with application to President, Nova Scotia Technical College, Halifax, Nova Scotia. File No. 7072-V.

SALES ENGINEERS: With B.Sc. Mechanical or Chemical required by fully integrated major oil company, marketing department, for early assignment in Western Canada. If you believe SALES is a true engineering function, then your future professional life can fit this position. Training course given. Excellent remuneration and advancement prospects. Three to five years' sales etxperience desirable but not a requirement. Knowledge of modern industrial equipment a definite asset. Permanent position. Full company benefits. Please give personal history and statistics. File No. 7128-V.

GRADUATE ENGINEER to supervise quarry and lime plant operations in Manitoba. Mining degree desirable but Chemical or mechanical degree with experience in open pit mining or production techniques would qualify. Some construction experience would also be helpful. The successful candidate will be responsible for operating and modernizing two separate quarrying and production plants and would live on location for two to three years. At that time it is hoped he could then accept wider responsibilities and probably reside in Winnipeg. Salary commensurate with qualifications, experience and established ability. Employment benefits include pension, insurance and medical. Please reply by confidential letter stating fully personal experience, academic background and on-the-job experience. File No. 7135V.

CITY OF TORONTO PLANNING BOARD. Applications are invited for the following positions: 2 City Planners Grade II. Salary: $5314 - $6201 per annum. FUNCTIONS: To assist in the preparation of surveys, detailed designs and reports for immediate redevelopment proposals. To analyse and report on road proposals. QUALIFICATIONS: Training and/or experience in planning and physical design. Apply in writing to the Commissioner of Planning, City of Toronto Planning Board, 129 Adelaide Street West, Toronto, Ontario, giving details of experience, qualifications and references. File No. 7142-V.

ENGINEER REQUIRED

Salary Range — $12,000

"The Canadian Association of Broadcasters" requires qualified professional engineer, to locate in Ottawa. Person selected will have, preferably, qualifications recognized by Department of Transport Standards. Send full details in writing to: Post Office Box 627, Station "B", Ottawa.

The City of Prince Albert, Saskatchewan, (pop. 22,000), requires an assistant to the City Engineer.

Duties: to assist in all phases of Municipal projects and operation of the department, with emphosis on the water and sewer systems. Qualifications: Must hold a degree in Engineering preferably Civil from a recognized University.

Position offers varied experience, future security and an opportunity for advancement.

Starting salary $400.00 to $450.00 per month depending on experience.

Apply in writing stating age, experience and relevant information to the undersigned.

S. E. Parker,
Personnel Officer,
Prince Albert, Saskatchewan.

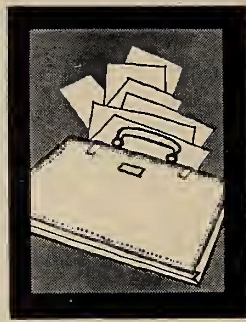
JUNIOR ENGINEERS

required for
Dept. of Lands & Forests
B.C. CIVIL SERVICE

Starting salary $400 to $430, rising to $510 per month. Challenging positions are available in the forest development road program with opportunities for diversified training and advancement within the Department. Applicants must be Canadian citizens or British subjects with graduation in civil or forest engineering. Consideration will also be given to graduates in mechanical or agricultural engineering. For application forms apply IMMEDIATELY to The Chairman, B.C. Civil Service Commission, 544 Michigan Street, Victoria, B.C.

COMPETITION NO. 60:140A.

Business and Industrial Briefs



Appointments and Transfers

Four executive appointments and the addition of three engineers to the staff of its plastics division have been announced by Du Pont of Canada. Three new vice-presidents have been appointed. They are: **Frank S. Capon**, a director since 1957 and treasurer since 1949; **F. G. Raymant**, manager of the textile fibres department; and **H. F. Hoerig**, manager of the research and development department since 1954. Vice-president **R. G. Beck** simultaneously assumes the position of executive vice-president. **A. J. Houston**, an electrical engineer, and **P. A. Turner**, a chemical engineer formerly with the company's petroleum and chemicals section, join the market development section in Montreal. **W. A. Cooksey**, a mechanical engineer, becomes a sales representative in Toronto.

J. C. Cochran has been appointed vice-president and general manager of Murray-Brantford Limited.

The appointment of **C. F. Smith** as Assistant Manager, Advertising and Sales Promotion, Union Carbide Canada Limited, Linde Gases Division, has been announced.

Ross E. Magnus has been appointed Manager of Sales to Equipment Manuacturers for Canadian General Electric's Electronic Tube Section.

Stoody Company of Whittier, Calif. has recently appointed **Max Cadonoff** field representative for Eastern Canada. He will work with the Stoody distributor, Air Reduction Canada Limited in Ontario, Quebec and the Maritime Provinces.

James Kenneth Latta recently joined the Division of Building Research, Construction Section, National Research Council, Ottawa.

A new company FORESTAL, Forestry and Engineering Limited of Vancouver has been formed. The new executive officers are: **Ian C. MacQueen**, President; **J. R. Collins**, **E. S. Reid** and **Cedric W. Walker**, Vice-Presidents.

Thomas Crooks is the new Vice-President, Industrial Sales, of Empire-Hanna Coal Division, The M. A. Hanna Company of Toronto.

James A. Richardson, Vice-President of James Richardson Sons, Limited has been elected a director of The International Nickel Company of Canada Limited.

William M. Hewat has been appointed western district manager for Naugatuck Chemicals, Division of Dominion Rubber Company Limited.

F. H. Van Dyk has been appointed manufacturers' agent for York-Shipley of Canada in London, Ont.

A. D. Ross & Company Limited, subsidiary of The Foundation Company of Canada Limited, has elected **S. J. Spall** a director and appointed him Vice-President and General Manager.

James R. Kleisle has been named a plant equipment sales representative for Corning Glass Works of Canada Ltd., Leaside, Ont.

Developments

Information contained in this section has been culled from press releases. Products and services do not carry the endorsement of the Institute.

TWO GRATE-KILN SYSTEMS successfully operated at the Humboldt Mining Company have confirmed the feasibility of producing higher-quality iron ore pellets from low-grade ore deposits. Located near Ishpeming, Mich., the Humboldt plant is the first installation of the Grate-Kiln system applied to iron ore agglomeration.

THE PERFO METHOD of roof bolting reduces the risk of slippage and eliminates any point of concentrated stress. This method is based on hollow perforated steel pipes cut longitudinally and filled with plastic mortar. The halves are tied together and placed in a drilled hole. A reinforcing bar then is driven into the sleeve, expanding the mortar to fill the hole completely.

THE FIRST CANADIAN installation of Koroseal lining to concrete was completed recently by B. F. Goodrich Canada Limited at the Waterloo, Ont., sewage disposal plant. Applied to two tanks carrying ferric chloride the lining guards against tank seepage. This is an absolute necessity as two walls of the tank also are building walls.

PORTABLE LIGHTING SYSTEMS for many uses can be assembled quickly from industrial lighting components produced by the Joy Manufacturing Company (Canada) Limited. Bulletin B76 illustrates how such lamps, extensions, sockets and other unitized assemblies can be connected to form an economical lighting system which is, in effect, custom tailored to individual requirements.

NITROGEN was used recently to purge a new, 4,750-yard long steel gas main in the United Kingdom. The main has a 24-inch diameter. The object of the operation on the all-welded pipe was to purge the main of air to remove the danger of an explosive air-gas mixture during introduction of gas into the main at a later date.

A NEW NAME has been adopted by the Formed Steel Tube Institute. The Institute, which represents more than 20 leading manufacturers of welded steel tubing, now is called the Welded Steel Tube Institute. A non-profit organization with headquarters in Cleveland, the Institute was established to encourage research and development, foster efficient production, inform member firms of technical advances in the industry, and explore new markets and product applications.

FOUR RUSSIAN TECHNICAL journals, translated into English, will be published during 1961 by the Instrument Society of America, under a grant from the United States National Science Foundation. The 1960 issues to be published are Automation and Remote Control, Measurement Techniques, Instruments and Experimental Techniques, and Industrial Laboratory.

THE SALE in the United States of phosphatic fertilizers produced by the Electric Reduction Company of Canada, Ltd., Toronto will be made through the Agricultural Chemicals Division of Inter-

national Minerals and Chemicals Corporation, Skokie, Ill. Announcement of the agreement was made recently by the presidents of the two companies. ERCO now is building a large phosphatic fertilizer plant at Port Maitland, Ont. Production is scheduled to start early in 1961.

CONCRETE for stadiums and auditoriums is discussed in a publication released by the Master Builders Company, Ltd. Problems encountered and solved in the construction of 16 major stadium and auditorium projects are explained. Included are case histories concerning the Dallas Memorial with its lightweight roof design, the placing of the reinforced concrete dome roof of the Albuquerque Civic Auditorium, and the thin shell concrete roof design at the University of Cincinnati Armory.

SMITH AND LOVELESS COMPANY is the new division formed recently by Products Tank Line of Canada, Ltd. The new division will manufacture in Canada a complete line of factory-built sewage lift stations and sewage treatment plants. The units will be manufactured at the Oakville, Ont., plant of Sparling Tank and Mg. Co.

FINAL BALANCING of automotive engines, a production problem in the Canadian automotive industry, can be accomplished with a special purpose machine designed and built by Standard-Modern Tool Co. Ltd. The machine represents a distinctive Canadian approach to the problem of limited production. It employs two milling heads and a spot welding arrangement and is capable of handling both passenger and truck engines with and without torque converter equipment.

A CORPORATE NAME CHANGE to Rex Chainbelt (Canada) Ltd., by Chain Belt (Canada) Ltd. of Toronto has been announced. The Toronto firm is the Canadian subsidiary of Chain Belt Company, Milwaukee.

THREE NEW PUBLICATIONS have been released by Canadian General Electric Company. GED-4092 describes electric G-E furnaces for stress relieving and annealing large parts or heavy loads with uniform temperature distribution, greater production and lower operating costs. Bulletin GEZ-3025 includes ratings and typical applications for the new G-E industrial mass flowmeter. The third bulletin, RTV-11, describes product and application data on the complete family of room temperature vulcanizing silicone rubber compounds.

A NEW COURSE, "Principles of Semiconductor-Transistor Circuits," is being offered by International Correspondence Schools Canadian, Limited. The course is designed to meet the needs of engineers and technicians who seek training in electronics.

TECHNICAL PUBLICATIONS prepared by certain companies of the Royal Dutch/Shell Group are listed in a catalogue recently distributed. The catalogue lists 142 significant technical publications including chemical engineering, pure and applied mathematics, and pollution.

AN EIGHT-PAGE BROCHURE entitled "GM Diesel Generator Sets for Standby and Continuous Off the Line Power" has been released by General Motors Diesel Limited. The publication contains charts showing technical data regarding generator sets from 13.5 kw. to 260 kw.

INTRODUCTION TO STRUCTURAL MECHANICS, a new textbook, has been written by Paul Anderson, professor of structural engineering, University of Minnesota, and Gene M. Nordby, head of the Department of Civil Engineering, University of Arizona. Chapters on basic theory have been designed to apply to aircraft structures and machine design as well as to traditional structures such as roof trusses, railway bridges, and highway bridges.

A SOLVENTLESS SILICONE RESIN for high temperature insulation now is commercially available, it has been announced by Union Carbide Canada Limited, Bakelite Division. Formerly it was marketed under the experimental designation Y-2090.

• MORE BRIEFS

A PIGEON-HOLE BAR RACK of new design has been manufactured by Service Steel & Engineering Ltd., Hamilton. The rack can be erected quickly from ?solidly-welded frames and brace assemblies. The brace assemblies are built in varying lengths and the pigeon holes are fabricated in a wide range of sizes. It will carry more than 150 tons of 20-foot bars.

WELDED COLUMNS for the 32-storey C-I-L House in Montreal now are being fabricated in the Lachine shops of the Dominion Bridge Company. These columns, the biggest and heaviest ever built in Canada, will be part of the tallest welded rigid frame building in the Commonwealth.

A NEW PIPE-TURNING MECHANISM has extended the life of taconite tailings pipe and speeded turning operations. Because of rapid abrasive wear on tailings pipes, most taconite plants turn pipes periodically so the pipe wears longer and at a more even rate. One advantage of the new mechanism, developed by Lake Shore, Inc., Iron Mountain, Mich., is that pipes may be turned at one-quarter turn increments rather than the usual one-third turn. This gives four pipe-wearing surfaces rather than three.

THE HIGHWAY RESEARCH BOARD of the United States has released four more publications dealing with its findings on road research. Bulletin 249 deals with the surveying and planning of highway projects and needs. No. 250 discusses pavement performance concepts. Asphaltic concrete construction is dealt with on the basis of field and laboratory studies in Bulletin 251. The fourth publication, No. 252, is entitled "Snow and Ice Control with Chemicals and Abrasives."

PLAIN FORGETFULNESS is one of the bugbears eliminated in a new battery-run clock made in England by Robert Pringle and Sons Ltd. Some models run for one year on an ordinary flashlight battery. Other models are designed to run for three to five years without attention with transistors being used in these to store energy for boosting the battery. In effect the batteries give an impulse to the clock movement every two minutes.

A COMPLETE LINE of hydraulic products for the industrial, marine and ordnance fields is presented in a 74-page catalogue distributed by Vickers-Sperry of Canada, Ltd., Division of Vickers Incorporated. Catalogue 50001C introduces new equipment in addition to information on standard Vickers products.

ONE PANEL SYSTEM of house prefabrication has attained a dominant position in housing in Canada's far north. The unusual economics and logistics of far northern building have favored the acceptance of stressed skin plywood systems during the past 13 years. The oldest northern stressed skin units have shown little deterioration after long, hard use. A review of this system is available from the Division of Building Research, National Research Council.

THE WINNIPEG OFFICES of Canadian Industries Limited have been brought under one roof. C-I-L offices formerly in the Somerset Building have been moved to the expanded Midland Street facilities where the company has had offices and a warehouse since 1941.

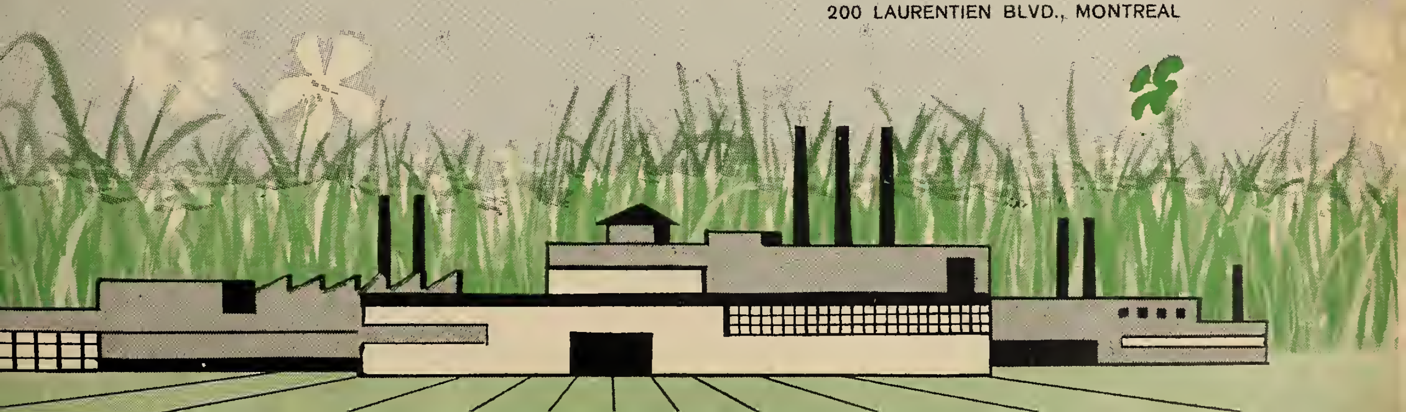
MONTREAL LOCOMOTIVE WORKS, Limited, has concluded an agreement to manufacture and sell in Canada the products of North America's largest exclusive pump manufacturer. The agreement has been made with Goulds Pumps, Inc., of Seneca Falls, N.Y. and the pumps will be marketed in Canada under the trade name "MLW-Goulds."

A CENTRAL HEADQUARTERS for the Ontario business operations of Canadian Industries Limited has been established in a new 14-storey office building in Toronto. Initially, C-I-L will occupy two floors in the building under a long-term lease.

THE FIRST TWO of four axial flow pumps, Canada's largest, have been shipped from the Lachine, Que., plant of Canadian Allis-Chalmers. Destined for use as condenser circulating water pumps at Ontario Hydro's Lakeview generating station, the four units have a 90 in. suction and a 60 in. discharge axial flow with a nominal rating of 100,000 USgpm.

THE CALGARY BRANCH of Dominion Bridge Company, Limited, has completed what its engineers describe as one of the most challenging platework projects ever undertaken by the company—the fabrication and erection of a 1,600 ft. long, 6 in. steel penstock for the latest Spray development extension of Calgary Power Limited near Canmore, Alta.

EXCEPTIONAL FREQUENCY RESPONSE, wide proportional band, low air consumption and temperature stability are characteristics of a new A/D (Advanced Design) Indicating Pneumatic Controller produced by the Bristol Company of Canada Limited. The unit can be used with any of the standard Bristol precision measuring elements for pressure, temperature and flow. EIC



• LIBRARY NOTES

(Continued from page 168)

industry, government, agriculture, transport, finance, science and religion to animals, hunting, the home and music. There is an English index and a German index. The dictionary is primarily of use for translation from German to English, but as the illustrations are the same as in the original German edition, the two volumes used in conjunction would be an excellent aid to translators, or those wishing to learn German.

In this edition, the scientific and technical vocabulary has been brought up to date—nuclear submarines, rockets, satellites, nuclear reactors, etc. — and many American terms included. (Toronto, Clarke, Irwin, 1960. 928 p., $6.50.)

PLASTIC PROGRESS, 1959

The papers presented at the 1959 International Plastics Convention are contained in this volume, together with the discussion on them. They include reports on polypropylene, epoxides, crosslinking of thermoplastics, block and graft copolymers, expanded plastics, and extrusion. There are also reports on recent developments in glass reinforced plastics in Europe, the United Kingdom and the U.S.A. (Ed. by Philip Morgan. Toronto, B.B.S., 1960. 216 p., $13.00.)

LEARNING TO STUDY

Intended primarily for college students who realize they need to cultivate efficient study habits, this text progresses from the broad concepts of learning to more specific areas of skill and knowledge. It first considers the obstacles to effective study, and goes on to discuss concentration, reading, memory examinations, notemaking, vocabulary and report writing. Campus resources for study are suggested, and lists of references for further reading are included. As this is a paperback book, intended for students, it seems unfortunate that it is so expensive. (W. W. Farquhar and others. New York, Ronald, 1960. 243 p., $8.00.)

ENGINEERING MATHEMATICS

Covering the mathematics needed for a degree, this volume is based on Dr. Blakey's University Mathematics, with the more theoretical chapters removed and replaced by chapters on the numerical solution of equations, statistics, relaxation methods, and the Laplace transformation. Other topics covered include limits, differentiation, integration, determinants, conic sections, differential equations, spherical trigonometry, moments of inertia and damped simple harmonic motion. Problems are included, together with their solutions. (J. Blakey and M. Hutton. London, Blackie, 1960. 603 p., 40/-.)

AMPLIFICATEURS MAGNETIQUES

Translated from the 1955 U.S. edition, this volume is another in the series written by General Electric authors. It discusses static magnetic amplifiers, particularly single-phase. The topics covered include the theory of magnetism; characteristics of magnetic materials; magnetic testing; saturable reactor manufacture; properties of metallic rectifiers; peaking transformers; and the applications of magnetic amplifiers. (H. F. Storm. Paris, Dunod, 1960. 560 p., 79 N. Fr.)

THEORIE ET PRATIQUE DES CIRCUITS DE L'ELECTRONIQUE ET DES AMPLIFICATEURS, 4. ed.

The first volume of this new edition discusses the theory of calculus with imaginary components, and its application to the calculation of fundamental circuits for radio and amplifiers, and for electronic circuits in general.

The second volume considers the use of electronic circuits for transmitters and receivers for radio, television, telecommunications, calculating machines, automatic control, etc. Other subjects covered include high frequency amplifiers, changes of frequency, filters, etc. (J. Quinet. Paris, Dunod, 1960. 2 vols., v. 1, 22 N. Fr.; v. 2, 29 N. Fr.)

POUR PROTEGER LES METAUX, 3. ed.

This small manual describes various methods of metal finishing. Some of the topics covered include: surface prepara-

Meet the Authors

Russell E. Potter, M.E.I.C., B.Sc. Civil (Saskatchewan), Consulting Engineer, Victoria, B.C. *(Moran Dam and The Fraser River).*

In 1948 Mr. Potter was appointed executive assistant to the Fraser River Basin Dominion-Provincial Board. He was commissioner on the B.C. Public Utilities Commission and later Project Engineer for the Moran Power Development Company Ltd. In 1957 he started his own consulting practice in Victoria.

Vladimer Bakanowski, M.E.I.C., Principal Computation Engineer, Engineering Department, Du Pont of Canada Limited, Montreal; **Robert N. Boyd,** M.E.I.C., B.A.Sc. Mechanical (Toronto), Supervising Engineer — Design Services, Du Pont of Canada Limited, Montreal. *(Electronic Computation in the Chemical Industry).*

Mr. Bakanowski received his engineering degree from the State College of Machine Construction and Electrical Engineering in Poznan, Poland. After serving as assistant to the general manager of the Lublin Aircraft Plant he came to Canada in 1942 and was engaged as chief designer for Bloctube Controls, Montreal, then joined the R.C.A.F. He left his position as machine designer with Montreal Locomotive Works to join Du Pont in 1950. He is a member of the Canadian Association for Computing and Data Processing.

Mr. Boyd served with the Hydro-Electric Power Commission of Ontario before joining Du Pont in 1941. He was associated with the design of the Kingston plant and was later project engineer then works engineer. He was project engineer and then division engineer on design at the Maitland plant, and works engineer during its 1953 start-up. Mr. Boyd is a member of the Canadian Association for Computing and Data Processing, the American Society for Testing Materials and the Mathematical Association of America.

Jasper H. Ings, M.E.I.C., B.A.Sc. (Toronto '25), Vice President, H. G. Acres & Company Limited, Niagara Falls. *(The Warsak Hydro-Electric Project).*

Mr. Ings' career has covered a variety of engineering work. He has recently been concerned with investigations for power reports, consultations on hydro-electric projects, as well as approval and supervision of overseas projects in Pakistan and India on behalf of the Canadian Government Colombo Plan Administration. He is a member of the Association of Professional Engineers of Ontario, The Institution of Civil Engineers (Great Britain) and a fellow of the American Society of Civil Engineers.

I. R. A. Gregory, JR.E.I.C., B.Eng. Civil (McGill '55), Civil Engineer, Canadian Johns-Manville Co. Ltd., Asbestos, Quebec; **Jasper Mardon,** Chief Papermaking Research Engineer, Oxford Paper Company, Rumford, Maine; **B. I. Howe,** B.Sc. Chemical (Queen's '58), Paper Mill Control Engineer, Quebec North Shore Paper Company, Baie Comeau, Quebec; **G. O'Blenes,** Wiggins-Teape, England; **A. B. Truman,** B.Sc. (Bristol '54), Research Fellow in Paper Technology, University of Manchester, England. *(The Drainage Problem on a Newsprint Machine).*

Mr. Gregory was a research engineer with Anglo-Canadian Pulp and Paper for four years, including one year on loan to Anglo Paper Products research group.

Mr. Mardon has published many technical papers, lectured extensively and been actively associated with a number of significant developments in the paper industry. In 1956 he was one of the recipients of the Weldon Gold Medal (C.P.P.A.), and in 1959 he won the City and Guilds Insignia Award. He is a fellow of the Royal Institute of Chemistry, (England), a member of the Institute of Fuel (England), an associate member of the Institution of Chemical Engineers (England), and a member of various other professional associations.

Mr. Howe joined Anglo-Canadian Pulp and Paper Mills after graduation and spent two years in their control and their research divisions. He was awarded the C. Howard Smith Medal (C.P.P.A.) in 1959. He is a member of the Technical Sections of both the Canadian Pulp & Paper Association and the British Paper & Board Makers Association.

Mr. O'Blenes, along with all the other authors of this paper was formerly with Anglo Paper Products, Ltd., of Quebec City.

Mr. Truman left Wiggins Teape Group Research Organization in 1957 and came to Canada with Anglo Paper Products. He returned to England in 1959 to study for his doctorate and is now a Joseph Dixon Research Fellow. He is also a fellow of the Royal Statistical Society.

George Ford, M.E.I.C., B.Sc. Civil (Alberta '46), M.Sc., Ph.D., Head, Department of Mechanical Engineering, University of Alberta, Edmonton; **James B. Haddow,** B.Sc. Eng. (St. Andrews, Scotland '52) M.Sc., Ph.D., Associate Professor of Mechanical Engineering, University of Alberta, Edmonton. *(Determining Machine Foundation Natural Frequencies by Analysis)*

Dr. Ford joined the University of Alberta in 1942 and was appointed department head in 1959. During the past ten years he has maintained a consulting practice in applied mechanics and structures. He is a Member of Council of the Association of Professional Engineers of Alberta and a member of the American Society for Testing Materials.

Dr. Haddow has been a research fellow at the University of Manchester for the last 2½ years, working on the Mathematical Theory of Plasticity. He worked with Atomic Energy of Canada for three years; he lectured and then became assistant professor at the University of Alberta, and is this month returning to Edmonton as an associate professor.

MORAN DAM AND THE FRASER RIVER

Russell E. Potter, M.E.I.C.,
Consulting Engineer,
Victoria, B.C.

Today the Fraser River is out of the power picture in British Columbia. Yet it lies closer to the load centre of the Province by several hundred miles than either the Peace River or the Columbia. It has more power potential than both the Canadian Columbia and the Peace River combined and could produce power at tidewater at less than one-half the average of those two rivers. It has the site for the world's greatest power plant.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

THIS ONE power plant would turn out power at comparable cost to the lowest in the world; remove the flood menace of the Fraser River;[4] improve navigation to such an extent that the river could be used for an additional 30 miles and probably solve the silting problem of the river. Dredges now remove silt in the lower Fraser at a cost of over $1 million per year.

The reason that the river is not being considered is because of the salmon involved. A short picture of the salmon problem should be shown before going into the power systems possible on the river. The Fraser is a great salmon producing river. It produces all species of salmon like many other British Columbia rivers but its main claim to fame is that it is the largest sockeye producer. Tinned red sockeye brings the highest prices in the industry although it is no higher in food value than the other species, which are all about the same.[1]

To get a true picture of the salmon catch in British Columbia it is necessary to examine four consecutive years. The sockeyes are predominantly a 4 yr. cycle fish. The chum is also a 4 yr. fish, while the pinks have a 2 yr. cycle. The springs may not spawn for 5 or 6 years, or more, but they are a small part of the catch. All species invariably spawn only once. The fish are caught as they return from the sea to their home rivers to spawn. There are a number of important sockeye races and some return each year. The pinks, however, occur in the Fraser only in the odd years, 1951-53-55 cycle. In 1954 only 17½ cases were packed but in the next year the pack was 160,187½ cases. In other rivers the pink run may be in the even years so that the pink salmon catch of the province only varies about two to one on the even and odd years.[2] Even with such great variations occurring the salmon catch in British Columbia has a uniformity that is remarkable. The total salmon catch of a two cycle period of 8 yr. was as follows, all figures being in 48 lb. cases with part cases omitted.[2] (see Table 1.)

The salmon catch of British Columbia, as well as the Fraser River, is made up of five species of salmon and the steelhead. The steelhead is not a true salmon but is caught with them and included in the salmon figures. The pack of the Fraser in the last 4 yr. is as follows, in full cases.[2] (see Table 2.)

On the Fraser River, and probably the other large salmon rivers as well, only the sockeye is likely to be seriously affected by the power schemes. All of the other species of salmon are, for the most part, river spawning fish and the young fry head out to sea soon after hatching, or stay in the river itself for a few months or a year.[1] The sockeye, however, travels to the tributaries of the river on which there are large lakes. Some of these will be close to the sea like Pitt Lake and Harrison Lake, just off the delta and below the power sites; others will be 400 to 600 miles upstream like Stuart Lake and Chilko Lake. The sockeye spawn in the tributaries of these lakes. The young fish find their way to the lake and there spend a year or more before going down to the sea to return in their fourth year to the place where they were spawned. There they spawn and die leaving the life of their cycle in the eggs placed in the gravels of the river. This is, generally, the picture of the sockeye cycle.

The most notable run of sockeye salmon occurs in the South Thompson River. It is called the Adams River run and it occurs in the 1950-54-58 cycle. Here every 4 yr. more sockeye are produced than in all the other parts of the river in the entire 4 years. In the Moran Dam scheme this area was not affected. If the full power of the Fraser was to be developed this area would also be affected as there are plans for dams on the Thompson River as well as on the lower Fraser. While it may be possible for fish to pass one, or even two dams, it is believed that the added delay of several dams would eliminate all runs from a river.[3] The story of the Fraser River salmon is very well shown in the annual reports of the Provincial Department of Fisheries up to 1956 from which all of the above figures were taken. This report is now found in the Report of the Department of Recreation and Conservation.

Preliminary Report

The power story of the river has now been reported by the Fraser River Board in their "Preliminary Report on Flood Control and Hydroelectric Power in the Fraser River Basin"[4] presented to the Federal and Provincial Governments in June of 1958. This report outlines three systems which cover power and flood control on the river. The flood control requirement which is the same for all systems is a minimum of 9.23 million acre feet.

System 1.

Has a usable storage of 16,421,000 acre ft. and 5,089,000 kw. of "nominal prime capability". This last phrase is defined as the maximum load a machine can carry under the most adverse conditions.[4] It is more generally known as firm power and will be so called in the following.

System 2.

Has a usable storage of 26,989,000 acre ft. and 5,341,000 kw. firm. This system includes the Moran Dam, and is the only one of the three that does. The other 2 systems show the Moran head divided into 5 dams.

System 3.

Has a usable storage of 16,586,000 acre ft. and 5,159,000 kw. firm.

Cost

The cost of each of these Systems is placed at about $2 billion. This figure includes transmission and step-up transformer costs amounting to "more than $40. per kw. of installed capacity and more than $60 per kw. of assured energy production."[5]

For System 1. the power cost is given as $1,969,325,000 with an installed capacity of 7,198,000 kw. and firm power as above. This gives a cost of $274. per installed kw. or $387. per kw. firm, including the above transmission costs. In the usual figures of costs per installed horsepower this figure, without transmission, becomes $175. System 3. is much the same. System 2. with Moran Dam shows even better cost figures. The total cost is $1,988,310,000 with installed capacity of 8,001,000 kw. or 10,700,000 hp. Installed figures are therefore $249. per kw. and $185. per hp. less $40. and $30. respectively for the included transmission costs, the net generation costs being $209. per kw. and $155. per hp. installed.

The difference between the three Systems is more or less academic at this stage but they demonstrate that there are enough damsites and storage areas to control the flood of the Fraser in several ways and to develop the entire power of the river without necessarily using any one site to its maximum height, or perhaps leaving it out altogether. In Systems 1. and 3. Moran is developed to only 200 ft. rather than to 720 ft. as in System 2.

System 2. is the spectacular and intriguing plan for the river as it hinges on the mighty Moran Dam. This damsite has been known for many years but it was not until 1954 that a group of men asked the Provincial Government for the right to develop it. This is truly a remarkable power site. The dam proposed, a concrete gravity arch, would raise the river 740 ft. in the Company plan,[6] or 720 ft. in the Report plan.[4] In the conservative words of the Report on page 86 it says: "The generator installation proposed is 3,600 MW, truly an immense project which, if it were built, would dwarf all others on this continent." 3,600 mw. is equivalent to 4.8 million hp.

The Premier was naturally interested but said: "Satisfy the Fisheries people and then come back and see us." This condition had, of course, been expected and did not seem too difficult. The Company at this time believed it had an effective method of guiding the fish electrically.

The problem of taking the adult fish over the dam by mechanical means seems to be the most feasible. Fish ladders miles in length and on steep canyon walls are out of the question, but short ladders leading to large tanks mounted on cars, moving up and down the face of the dam, are quite practical. The number of fish to be handled may be as high as 750,000 in a 24 hr. period, according to an estimate by the Fisheries Department in another study of the river.[7] This is some ten times the maximum number of fish in the river today at this site but indicates what they hope to achieve. Objections have been raised that the fish would be lost in the lake above, but it should be remembered that these same fish will normally travel through larger lakes before they reach their spawning grounds and the 40,000 cusecs through Moran Lake will give much more current to guide them than in the lakes ahead. In any case all of the fish going up will have come down through this lake as fingerlings.

The problem of handling the fingerlings has always been a major one. These 1 yr. old fish which make their migration to the sea with the spring flood have always been considered the most difficult to save. Going through the turbines would kill them

Table I

Year	*Total B.C. Salmon Catch All species*	*Fraser River Salmon Catch All species Canadian Pack*	*Fraser River Sockeye only Canadian Pack*	*% Fraser River Sockeye is of B.C. Salmon All species*
1951	1,957,520	268,233	145,321	7.4
1952	1,305,160	151,147	134,625	10.3
1953	1,826,588	496,936	191,123	10.4
1954	1,747,854	563,807	*497,023	*28.6
1955	1,401,298	294,238	103,678	7.3

*Adams River run 1950-54-58 cycle. The American catch in the 8 year period was a little less than the B.C. catch.

Fig. 1. Aerial view of Moran dam site

or even going over a dam could be fatal.

It has been established that on their migration the young fish keep mostly in the top 15 ft. of water.[8] Few are found below 30 ft. They follow the current and in an ordinary dam this means they would pass into the turbines or over the spillway. At Moran, with a dam over 700 ft. above the tailwater, the turbine inlets would be placed 100 ft. below the lowest drawdown. The regulating gates for passing the flood waters would also be at a similar or greater depth, the dam being designed so that no water passes over a spillway. No small fish would get to such depths and the spring flood that brings them down would put the gates under an even greater depth of water.

The problem then is to create a surface current to the face of the dam and allow enough water to pass through to attract the small fish. This can be done through gates placed in the face of the dam to the maximum drawdown level. The water may then be flumed or even sent over a fall into a deep tailrace pool, it having been determined that the small fish survive such a free fall safely.[9] Both the lift method for the adults, and the flume and fall method for the fingerlings are now being used at various places in the States of Washington and Oregon. I have not seen an actual statement of their losses, if any. The reference quoted is most optimistic.

One Dam

This scheme was worked out over a period of years after it was found that guiding fish by other means was not practical. It appeared that it might be possible to save the salmon if only one dam was built on the river. If this dam were big enough to give complete flood control and an immense amount of power perhaps no other development, at least downstream, would need to be built. The next move was to go to the Fisheries people and try to work with them on the design but this was a false hope. If the rivers are left untouched fishing should get no worse and may get much better. The hope of the Fisheries is to keep all dams off salmon rivers, which means most of the rivers of British Columbia. This will eliminate an estimated two-thirds of the hydro potential of some 22 million kw. firm, only 2.1 million of which has been developed so far. 22 million kw. firm represents an installed capacity of 46 million hp.[10] On the basis of most government reports we can assume that this is a conservative estimate.

So far there has been little or no basic information on the problem of handling salmon past dams. If we must go back to basic research such a program would take 20 to 50 years and probably would come up with the answer that there is no way to solve the problem. It therefore seems that we must face the fact that the choice has to be made for either power or fish on the Fraser River and that we cannot have both.

Ten Dam Scheme

In the Ten Dam Scheme[3] designed to develop the water of the Columbia diverted down the Fraser, the design for fishways amounted to $350 million, with the uncompromising statement that they would not save the fish.[11] In the design of the Moran Dam approximately $50 million was allowed for fish handling devices. A concrete arch was used as the annual runs of salmon could be taken past during construction. However if this were not required a rockfilled dam could be used at a cost reduction of an estimated $100 million. It is quite evident that unless a sure method of passing fish over dams is evolved the attempt should not be made.

The Fraser River Board has examined the power potential of the Fraser and placed it at over 5.34 million kw. of firm power, with an installation of 10.5 million hp. This system also has nearly three times the minimum flood control capacity. The energy is placed at 45 billion kwh. annually. At 6.5 mills, the cost of thermal power, this amount of energy is worth $292.5 million per yr., as a wholesale figure. The retail figure is placed at over $800 million.[12] The value of industry in annual production that would use this amount of power might be placed at many times this figure. At half this mill rate the returns would about meet the requirements of the development.

Moran Dam was estimated at $512 million in 1956 by J. L. Savage of Denver, Colorado, consulting engineer for the Company. This estimate included two transmission lines to the Vancouver area. Its energy output was placed at 20 billion kwh. annually. A 10% gross return would be paid by 2.6 mills at these figures.

An interesting chart was worked out to indicate the loss of salmon if Moran killed off all of the sockeye that go above this point on the river. If the sockeye of the Fraser River were all killed off it would mean that on the Adams River cycle every four years the British Columbia salmon catch would be down 25% to 32% but on the other three years it would be down only 7% to 15%. These are only in the nature of annual variations as can be seen from Table 1.

Sacrifice

It is quite evident that there is no hope of developing the entire power potential of the Fraser without losing sockeye, and the same must be assumed for even the one dam at Moran. For this reason we now feel that the only approach to the power question is to concede that the sockeye pack, or at least a large part of it, on any salmon river will be sacrificed. This premise at least clears the air and places each resource on its own merits.

The figures used have ignored the United States catch of Fraser River sockeye which is a full 50%. The recent alteration to the Treaty calls for the same division of the pink salmon. The alternative to Canada selling out one-half of the Fraser to the United States was to have no Fraser River fish at all. The bulk of the Fraser sockeye return to the river via the Straits of Juan de Fuca and the United States fishermen get at least an even chance at them with the Canadians. As early as 1900 it was realized that an International agreement was required. To conclude the agreement took 37 years. It is highly probable that any power development on the Fraser will be most unpopular across the border and we will find that our own Fraser River has international complications.

A strong plea is made that salmon is an irreplaceable food, but it is easily shown that the beef that could be raised in the Cariboo, if water were made available by raising the Fraser to 1540 ft. elevation, would far sur-pass the amount of salmon lost.[13] Unfortunately there is no alternative supply of water for this land, so we cannot have both the salmon and the beef. Again it is one resource or the other.

The question of where we will use all of this power has been answered by a study made for the Company[6] by the British Columbia Research Council and also by the Fraser River Board. On page 73 of the Report it says: ". . . it is safe to assume that a market will exist in the future for all the power that can be produced economically from the basin." The Fraser River Board evidently made a slight concession to the fish by not including any dams on the Thompson River. However this was theoretical as the four dams on the main stem below Lytton would eliminate the sockeye runs.[14] There would be no reason not to develop the Thompson between Lytton and Kamloops if the lower Fraser were developed. At least another 750,000 kw. firm or 1,000,000 hp. of installed capacity can be generated from the regulated water of the South and North Thompson Systems. The total power available in the Fraser System is therefore at least 11.5 million hp.

The biggest run of Fraser River sockeye in recent times was in 1958 when 606,669½ cases were packed. At $1.00 per lb. this is a value of about $29 million. However, that occurs only once in four years. The lowest year of that cycle was 1956 with 88,132 cases worth $4 million. The four year cycle average was 230,111 cases, worth $11 million. The electric power from the regulated Thompson River alone would have a value at $25 per kw. yr., equivalent to 2.85 mills per kwh., of $18,750,000.

Table II

Year	*Sockeye*	*Spring*	*Steelhead*	*Coho*	*Pink*	*Chum*	*Total*
*1958	606,669	2,709	181	3,203	612	9,468	622,842
1957	121,965	3,126	429	4,836	68,968	5,585	204,909
1956	88,132	2,873	337	12,273	348	9,989	113,954
1955	103,678	6,843	269	15,910	160,187	7,350	294,238

*Adams River cycle.

Just what a large block of low priced power would do for Canada and British Columbia is an interesting study:

a. In the years 1954 to 1958 inclusive we shipped out of Vancouver 3.67 tons of material for every ton we brought in;[15]

b. The world market for light metals, chemicals and manufactured goods requiring power as a substantial part of their cost is growing rapidly;

c. The manufacturing centre for these products will go anywhere in the world where there is low cost power in large quantities;

d. Tremendous quantities of bauxite have recently been found in Australia in the Wiepa District, and in the words of the Australian High Commissioner they ". . . look forward to selling their alumina to the west coast of North America."[16] Our ships could travel both ways loaded with lumber or alumina.

British Columbia could become the primary industrial centre of the Commonwealth and one of the great ones of the world.

At the Eleventh Natural Resources Conference of British Columbia in 1958 the question was asked of the power panel: "At what price per kilowatt hour at tidewater must electricity be available to attract the following industries: aluminum, magnesium, titanium . . .?" The answer was given by Mr. C. C. Marshall of Sir Alexander Gibb and Partners, an engineering company with worldwide experience. ". . . a price of four mills would be attractive, a price of three and one-half mills would be very attracttive . . .". Only the development of the Fraser River will supply immense blocks of power at such low prices at tidewater.

British Columbia needs primary industrial development to take care of the rapidly growing population. Primary industry fosters secondary industry and only power of all our natural resources can be developed and enlarged at will and as it is required.

It is quite possible that the people of British Columbia may prefer to keep their rivers for the sockeye but if they do they should understand exactly what their choice means to themselves and their children.

ELECTRONIC COMPUTATION IN THE CHEMICAL INDUSTRY

R. N. Boyd, M.E.I.C.
Supervising Engineer Design Services, Engineering Department, Du Pont of Canada Limited, Montreal.

V. J. Bakanowski, M.E.I.C.
Principal Computation Engineer, Engineering Department, Du Pont of Canada Limited, Montreal.

Presented at the 74th E.I.C. Annual General Meeting, May 1960.

It is no exaggeration to say that electronic digital and analog computers are revolutionizing the practice of engineering. In the past, much of our engineering was based on "judgment" which some cynics would describe as a euphemism for guesswork based on a highly empirical approach. Our available problem solving methods in many cases were so limited that simplifying assumptions were needed, often in such numbers that the mathematical model obtained bore little resemblance to the physical situation. Hence the need of "judgment" in quotation marks. Electronic computers are changing all this. These new tools do of course, reduce the time and effort needed to perform difficult calculations. Of vastly greater importance, however, they produce better and more economic solutions through the use of more analytical methods, requiring fewer of the simplifying assumptions formerly used. Because of the speed with which solutions can be secured, it is possible when designing equipment, for instance, to prepare several designs and to pick the optimum, rather than to use the first design made, as was often the case in the past.

THE ABILITY to simulate complex chemical and mechanical processes is a treasure-trove, the value of which is even today, not completely known. While the use of "judgment" has been decried, the development of the proper input data for a computer, and the interpretation and analysis of the results obtained will always require sound engineering judgment which can never be replaced by a machine.

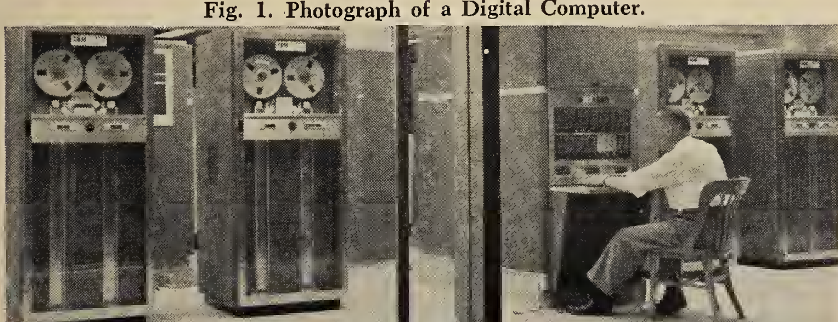
Although the use of electronic computers in the chemical industry is a comparatively recent development, their use in other fields, notably the aircraft industry, has been well established for some twenty years. Indeed, Government specifications for aircraft components frequently require that designs, before acceptance, be proven by computer calculations. Tribute must be paid to the pioneers who developed the equipment and the basic techniques which are now being applied in the chemical industry.

This paper deals with the application of two basically different types of electronic computers, namely, digital and analog. Each has characteristics that recommend it over the other for certain types of computation. There are very few classes of problem which can be handled on either machine with equal facility. In order to explain the areas of application, the paper describes the characteristics of each type of computer, and then presents brief references to typical problems solved by each. Their use is further illustrated by a description in some detail of two specific applications. The paper concludes with some remarks on policy and cost considerations that are of interest to management.

Characteristics of Digital Computers

A typical medium size digital computer is shown in Fig. 1. This is an I.B.M. Type 650, with floating decimal point attachment. One of these has been in use in the authors' company for the last three years. In the photograph can be seen the operating console and the four tape memory units. Not shown in the photo is the high speed unit for printing output data.

Fig. 1. Photograph of a Digital Computer.



Digital computers are basically high speed counting devices and are in themselves only capable of performing 6th grade arithmetic. The highly complex calculations that can be performed on these machines depend on the skill and ingenuity of the programmers who prepare the instructions in language that can be understood by the computers. These machines can easily handle large masses of data and are therefore widely used for accounting data processing. It has often been found that they can be justified for accounting work alone, and any profitable technical applications that are developed amount to a welcome dividend.

The accuracy of a digital computer depends largely on the number of significant figures carried in the machine. The maximum size of problem that can be handled is in large measure independent of the size of the installation. Since solutions are obtained by sequential operations, doubling the problem size on a given machine will double the solution time.

The data supplied to, and the results obtained from, a digital computer must be in the form of discrete numbers. The machine is controlled by a "program" specially developed for the particular problem. If the problem is of a repetitive nature, such as the design of metering orifices, the program can be kept in a library and can be re-used whenever a similar problem is encountered.

Because of the fantastically high operating speeds of modern digital computers, they are particularly effective for the iterative calculations used in trial and error solutions.

Characteristics of Analog Computers

A typical analog computer is shown in Fig. 2. This is an Electronic Associates Pace computer. Visible at the operating console is the "pre-patch" panel, which can be wired away from the machine for the particular problem, and can be inserted into the machine when the problem is ready to be run. The knobs below the panel control calibrated precision potentiometers which are used for setting the coefficients of the problem.

The problem solution can be read on the digital voltmeter to the left of the pre-patch panel, but the results are more often read in continuous form on auxiliary equipment not shown in the photograph. These devices may include a multi-channel strip recorder, X-Y plotter, or cathode ray oscilloscope.

Analog computers use electrical components as the analogs of the physical or mathematical entities being represented. The machines are highly sophisticated—they can, for instance, solve nonlinear higher order differential equations with ease.

These devices are usually limited to problems satisfied by answers having three or four significant figures, and accuracy is entirely dependent on the quality of the components and of the installation.. The maximum size of problem that can be solved is dependent on the size of the installation since the operations are performed simultaneously rather than sequentially as in the case of digital computers. For the same reason, solution time is largely independent of problem size and most solutions are obtained in one minute of machine operation or less.

Input data may be in discrete numerical form but can also be in continuous graphical form. Likewise, results may be discrete or continuous. Very frequently the most useful results are obtained from the multi-channel strip chart recorder.

Before a problem can be run, the pre-patch panel must be wired, an operation that may require a few hours. By this means, the various problem solving components available in the machine are selected and connected together to obtain a representation of the physical problem. These components include summers, integrators, multipliers, function generators, coefficient setting potentiometers, etc.

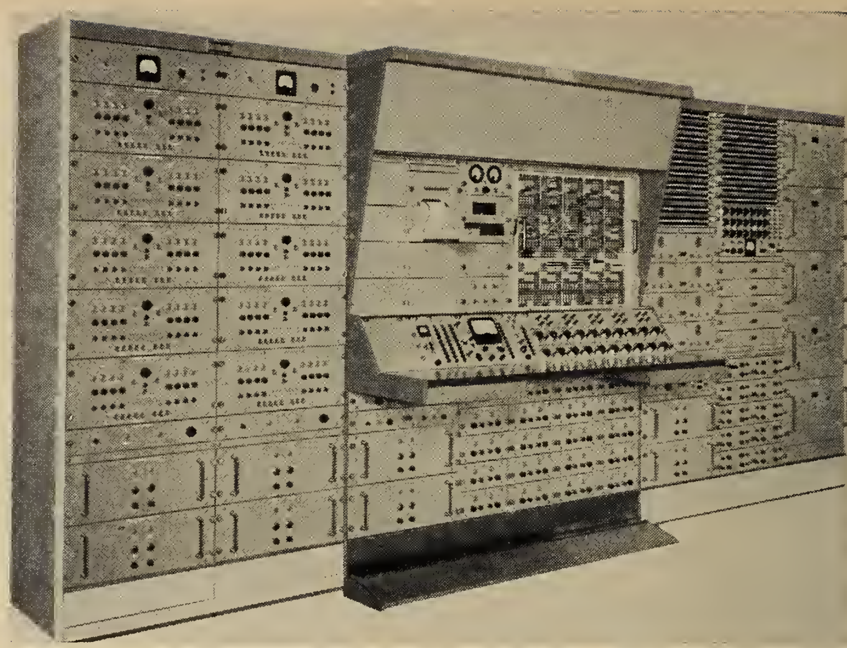


Fig. 2. Photograph of an Analog Computer.

Analog computers are particularly well adapted to the simulation of the performance of chemical or mechanical processes or equipment. When so used, they provide what is essentially a visual working model of the prototype simulated. The designer can, for example, readily examine the effect of varying catalyst concentration on the conversion rate and yield of a given chemical reaction. It is possible to change the time scale of the process to permit, say, the exploration of the mechanism of an explosion at rates slow enough to permit accurate recording. Another very important area of application is the study of the dynamic performance of automatic control equipment. It is possible to evaluate quickly the effectiveness of alternative instrumentation proposals, and to develop for the scheme selected the approximate adjustments required when the control devices are set up in the field.

Uses of Digital Computation

Literally dozens of successful applications have been made in the chemical industry. Probably the most outstanding from the standpoints of labour saving and better answers are the thermal design of heat exchangers, the static design of distillation columns, and the analysis of stresses in complex systems of piping. In the preparation of complicated process flow sheets having many recycle streams, much effort can be saved in determining the heat and material balances by the use of a program to solve the multi variable simultaneous equations that are required.

The calculation of ground level concentrations of atmospheric contaminants at various distances from stacks of various heights requires several days' laborious calculations using manual methods. With the development of a library program for this calculation, answers of high accuracy can now be obtained within a few hours.

Uses of Analog Computation

As mentioned earlier, analog computers are of great value in simulating the dynamic performance of individual pieces of process equipment, and of complete processes. The methods used will depend on the accuracy and completeness of the data available on the prototype. If full data can be secured, including complete reaction kinetics, equilibrium coefficients, etc., and if a sufficiently large computer is used, a detailed analysis can be performed. This will give results having an accuracy of up to four significant figures. Frequently, however, this type of analysis cannot be carried out because of incomplete understanding, because only trends are known, or because a sufficiently large computer cannot be used. Even under these limitations, valuable information on trends can be obtained from a simulation, although the accuracy may be considerably lower.

When a simulation of a distillation unit is performed, for example, alternative automatic control systems can be evaluated and the approximate optimum settings for the gain, reset, and rate functions of each of the automatic control instruments can be established. Such a simulation will also enable the operators to familiarize themselves with the column performance under various upsets in feed composition and flow, pressure, boil-up, reflux, etc. This information will greatly reduce the time needed to "line out" the distillation unit at initial startup and will, through better control, lead to greater throughput and more uniform separation.

Heat Exchanger Stress Analysis Using a Digital Computer

Tubular heat exchangers are widely used in the chemical industry. Many forms are used, a popular style being illustrated in Fig. 3. In this design, the process fluid may pass through the tubes, and if the unit is a heater, the tubes will be surrounded by a heating medium such as steam. Since the tubes are usually rigidly attached to the tube sheets, it is apparent that there will be differential expansion in the longitudinal direction due to the difference between the shell temperature and the tube temperature. This will lead to axial loading of the shell and tubes. The unit illustrated is also subject to other loading resulting from internal pressure in the shell, flexure of tube sheets due to differential hydrostatic pressure loading and to tube forces, and flange moments resulting from the other loads mentioned.

In order to diminish the total stress in the shell, tubes, tube sheets and flanges, tubular heat exchangers are frequently provided with "floating heads" or shell expansion joints. A typical shell expansion joint is illustrated in Fig. 3. Provision for thermal expansion such as this will increase the cost of the unit by 5 to 20% depending on the type of expansion provision made, as compared to the simplest form of heat exchanger, the fixed tube sheet type.

To decide whether the cheaper fixed tube sheet unit can be used in any particular application, it is necessary to carry out a very laborious stress analysis of the entire unit. This calculation usually requires about five

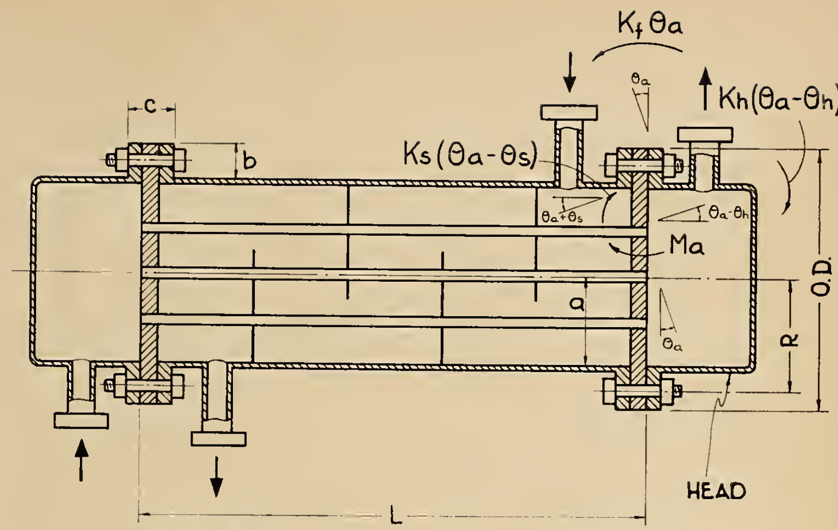

Fig. 4. Cross Section of Fixed Tube Sheet Heat Exchanger.

days if done using manual methods with the aid of a desk calculator. Frequently, provision for expansion is specified arbitrarily, without analytical proof because sufficient know-how and time are not available to carry out the necessary stress analysis.

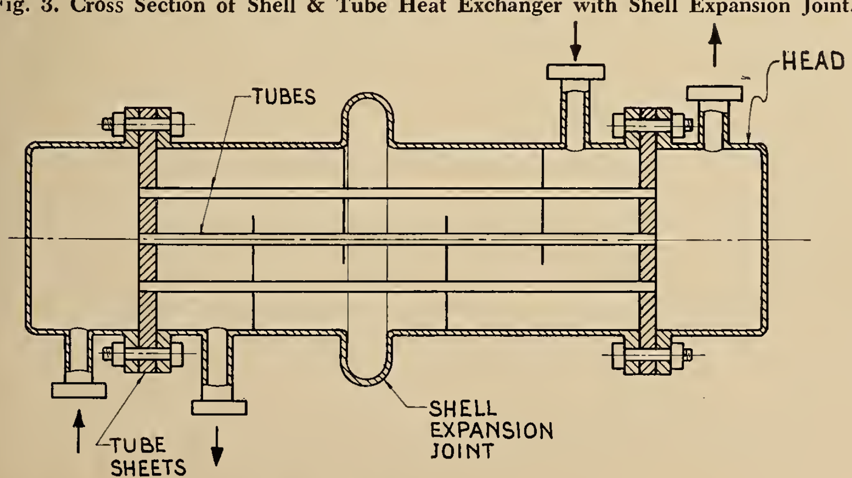
In the authors' company it was felt that the potential savings from the elimination of unnecessary expansion provision in new heat exchangers were great enough to warrant the development of a digital library program to perform the laborious calculations that are required. Such a program has been successfully developed, and is now in use on a routine basis. Running time for the program using an I.B.M. Type 650 computer, is approximately four minutes contrasted with the previously mentioned figure of five days for manual computation.

The mathematical basis for this program is presented in Appendix 1. It was written in Bell interpretive language and contains approximately 800 orders. The program is so arranged that the worst combination of process conditions to which each component is subjected is determined, and is used to calculate the loading and stress in that component. Allowance is made for the stiffening effect on the tubes of baffles, if used. One minor limitation is that the program is restricted to units having the tubes arranged in triangular pitch.

The input data for the program, which are provided by the design engineer, consist of twenty-nine items. These are provided to the computer operator by means of the form shown in Fig. 8. This information is punched on the input cards and these, together with the program deck and the Bell interpretive deck are fed into the computer.

The output data having the form shown in Fig. 11 are printed by the computer's high speed printer. The program is arranged to print each of the desired results in a specific line and column of the printout. The significance of the various numbers is indicated by the notes in the table. All results are printed in Bell floating decimal point notation in which the location of the decimal point is given by the last two numbers. For example, the maximum tensile stress in any tube, under given operating conditions, might be 2274375552, and should be read as 227.4 p.s.i.

Fig. 3. Cross Section of Shell & Tube Heat Exchanger with Shell Expansion Joint.



Because of the ease with which results can be obtained with this program, the design engineer frequently specifies several "cases" for computation. In this way he is able to assess the need of provision for expansion for several alternative designs. He can thus select the least expensive satisfactory design and be confident that thermal overstressing will be prevented.

This program has now been thoroughly tested, and is being used on a routine basis in the authors' company by all engineers who are responsible for the design or selection of tubular heat exchangers.

Simulation of a Continuous Chemical Process Using an Analog Computer

Nitric acid is manufactured in the authors' company and elsewhere by the oxidation of ammonia in the vapour phase under pressure. A simplified flow diagram of the process is shown in Fig. 5. Ammonia is stored in liquid form in two horizontal storage tanks equipped with steam heating coils. Liquid ammonia is forced out of the bottom of the tanks, to the vaporizer, under the influence of its own vapour pressure which is maintained by the heating coils. Flow of liquid ammonia to the vaporizer is regulated by a flow control valve, with cascade control by means of pressure within the vaporizer, where the liquid is vaporized by steam heating coils.

Ammonia vapour then passes through a pressure reducing valve and a temperature controlled regulating valve to the mixer. In the mixer the vapour is mixed with compressed air which is preheated in the shell side of a heat exchanger. The exothermic reaction takes place in the reactor in the presence of a catalyst and the reaction products consisting of oxides of nitrogen, water vapour and nitrogen are then cooled by passing them through the tube side of the heat exchanger previously mentioned. The mixture is then further cooled in the cooler condenser. Condensate is removed in the acid separator and the oxides of nitrogen are passed to the absorber where they are further oxidized and absorbed in water. Nitric acid in finished form is pumped from the bottom of the absorption column to storage.

It was decided to simulate the operation of this unit in order to secure more complete information on the performance of the reactor and the ammonia system under automatic control during various process transient conditions. It was hoped to develop new knowledge of the performance of the plant in order to optimize yield and throughput, to guarantee safe operation, and to establish the best methods of switching from one ammonia storage tank to another. The latter is significant since the ammonia storage tanks were located about 800 ft. from the ammonia vaporizer. This resulted in a pressure oscillation in this long line similar to water hammer under certain operating conditions. The pressure fluctuations were reflected in changes in pressure all the way to the reactor, and resulted in process yield lower than that obtainable under uniform conditions.

It might be asked "why not carry out the necessary investigation on the unit itself, rather than simulate it on an analog computer?" One reason was that it was desired to study several different methods of automatic control, and various other ways of eliminating pressure fluctuations in the reactor. Such experimental work, if carried out on an operating plant, would result in much loss of production and would be very expensive. Furthermore the trial and error process would be very time consuming and could be hazardous.

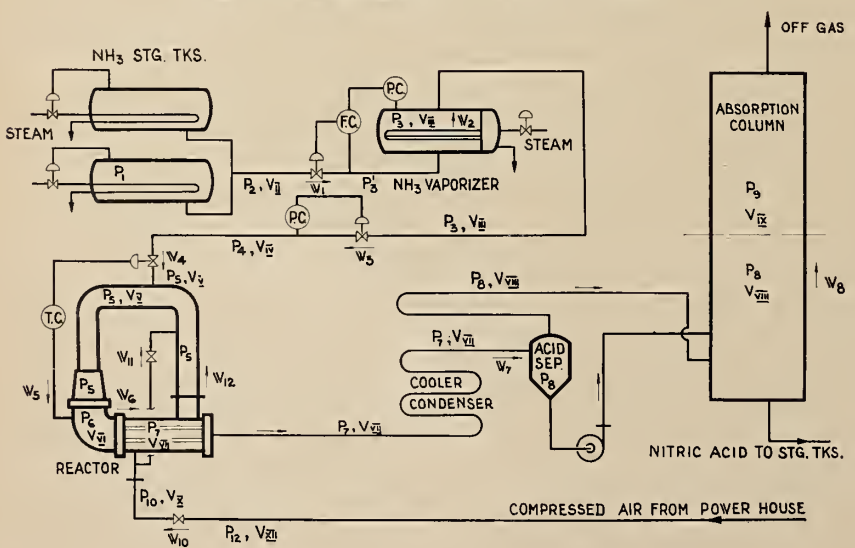
Since the study was concerned with process and instrument dynamics, an analog computer was selected as the most suitable tool for the analysis. The first step was to develop a mathematical model of the complete process, as described in Appendix II. Once this was completed the next step was to prepare a computer wiring diagram to establish the computer elements needed to represent the electrical analogs of the entities described by the mathematical equations. Part of the wiring diagram is shown in Fig. 6 which also shows the scale factors needed to represent the problem within the limitations of the voltage ranges available in the computer. The various symbols of the wiring diagram denote the various machine components used for the problem. Meanings of the symbols are described in the Handbook of Automation, Computation and Control.[1]

The pre-patch panel on the Pace computer was then wired in accordance with the wiring diagram, the coefficients were set on the proper potentiometers, and the arbitrary functions were set on the necessary function generators. This particular problem required a total of 108 operational amplifiers. To operate the simulated plant, external disturbances were introduced at selected points and the response to these disturbances was observed by noting the changes in selected variables on an eight channel strip chart recorder. To assess the effect of a change, say in control valve size, it was merely necessary to change the setting of the potentiometer which represented the control valve capacity, repeat the external disturbance, and observe its effect.

In Fig. 7, for example, the effect on liquid ammonia flow to the vaporizer of an external disturbance of 10 p.s.i./sec. is shown. A disturbance of this magnitude could occur, for instance, when switching from one ammonia feed tank to another. The record shows that if ΔPv, the pressure drop across the liquid ammonia flow control valve is less than 10 p.s.i., the resultant pressure surges in the long ammonia feed line are not damped; with ΔPv over 10 p.s.i., however, the surges are very quickly damped out. Fig. 9 shows the effect on actual reactor temperature of these disturbances. A disturbance introduced at time "*A*" resulted in a swing of about 20 units of temperature about 6 sec. later. Following adjustment of some of the instruments, the same disturbance introduced at times "*B*" and "*C*" led to somewhat smaller temperature swings. Provision of some surge capacity in the ammonia piping system resulted in the charts shown in Fig. 10. The 10 p.s.i./sec. disturbance at time "*D*" resulted in a reactor temperature swing of about 14 units. Further "tuning" of the control instruments resulted in lower swings, that following the disturbance at time "*G*" being about 10 temperature units. Figs. 7, 9, and 10 were traced from the actual strip chart records.

This simulation was highly successful. It revealed information about the dynamics of the process and process equipment which had never previ-

Fig. 5. Flow Diagram of Nitric Acid Plant.



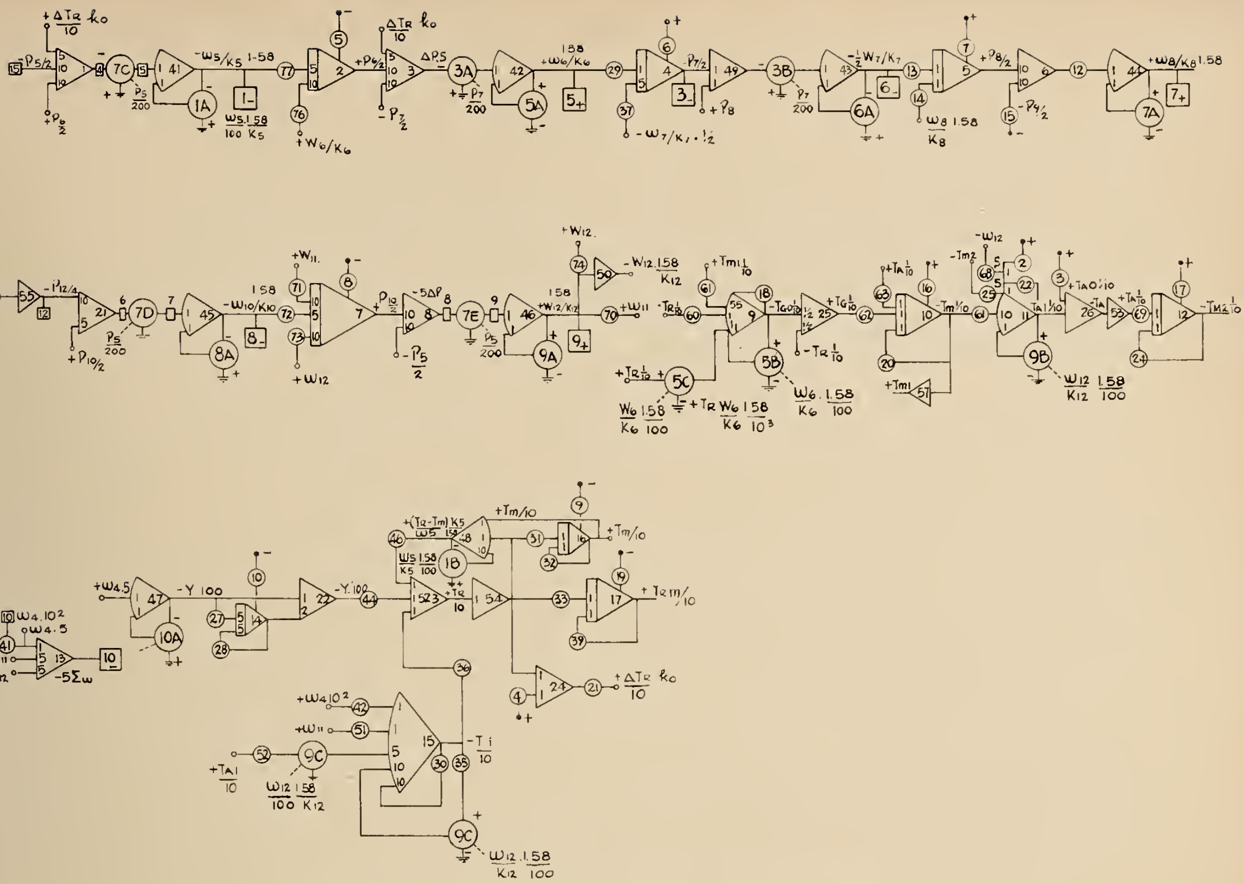


Fig. 6. Part of the Analog Computer Wiring Diagram.

ously been known or appreciated. It enabled the causes of reactor pressure fluctuations to be thoroughly investigated and led to the development of various remedial measures including automatic controls and changes in line capacity. The effectiveness of various safety features was evaluated and the most promising features were thoroughly tested.

Since the system improvements selected as a result of the simulation have now been incorporated into the prototype process unit, there has been ample opportunity to assess the value of the analog simulation. The comparison has shown that the simulation was without question an effective and failthful replica of the plant itself. All components including the automatic control devices, have performed in the manner predicted by the analog computer.

Policy Considerations

In embarking on a technical computation program, management should realize that results will not come quickly. A lengthy period will be required to develop the proper attitude on the part of the organization, to train the staff, to select adequate equipment, and to produce the first paying results.

In attempting to make money from technical computation, experience has shown that one of the biggest obstacles is the recognition of paying problems. Of lesser difficulty is the formulation of the problem, that is, the development of a mathematical model of the physical situation. The translation of the formulation into language that ean be understood by the computer, and the actual running of the problem on the machine, are comparatively easy.

At one time, it was thought that it was sufficient to obtain a computer, to give training in computer operation to the engineers, and to assist the engineers in running a few problems to demonstrate the computer's potential. It was expected that management could then stand aside and let the computer and the engineers grind out the profitable solutions that were sure to follow. This approach, unfortunately, did not work. It led to disappointingly few paying applications. It is now recognized that something more basic is needed in order to stimulate the fundamental analytical approach needed to recognize and solve paying problems. The best way to do this has probably not yet been discovered. Certainly the approach will vary with the type of organization and with its objectives.

In the authors' company, management believe in the future of engineering computation and encourage members of the engineering staff to familiarize themselves with the techniques and equipment. The open-shop approach is used; programming training is being made available to all who desire it and all are encouraged, after training, to make use of computers in the solution of technical problems. Another aspect of our approach is that the responsibility for results has not been delegated to mathematicians who would, perforce, have to learn enough about engineering to enable them to understand the problems presented to them. The responsibility has rather been placed on the shoulders of the engineers whose university training in mathematics is sufficient for the solution of most of the problems encountered. Mathematical consultants have been made available, however, and their services are used for very difficult problems.

In order to stimulate the analytical approach needed to achieve maximum results in this field and to equip the staff with the additional knowledge required, the engineering department of the authors' company is sponsoring a course in advanced mathematics for all of its interested technical staff in the Montreal area. The course provides a review of analytical geometry and calculus, and covers other topics such as ordinary and partial differential equations, matrix

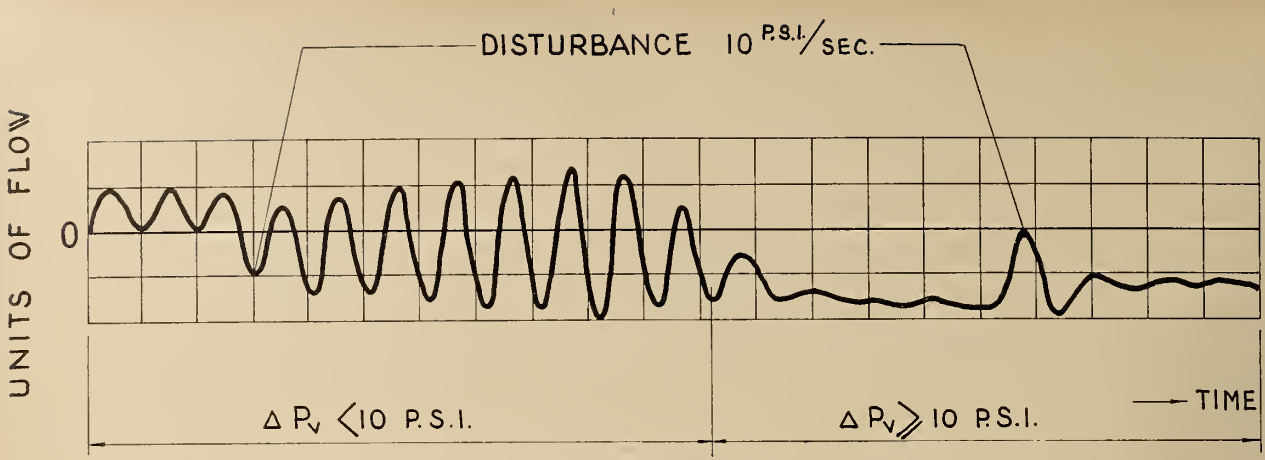

Fig. 7. Record of Effect of External Disturbance on Liquid Ammonia Flow To Vaporizer.

algebra, and theory of probability. The course is by design of a rigorous theoretical nature with as much emphasis on the derivation of theorems as on the solution of problems. It is being given by Dr. Hyman Kaufman, Associate Professor of Mathematics, McGill University.

In some organizations, technical use of computers has lagged because of a policy of allocating machine running cost (perhaps $200. per hr.) to the projects for which the computations were performed. A better policy would be to treat the computer as a necessary tool, and to charge its cost to overhead, in order to remove from the design engineer the burden of having to justify the machine each time it is used.

Cost of Engineering Computation

It is difficult to be specific about the cost of solving various types of problem by computer because every problem is different. The formulation and programming effort required for a problem will depend on its complexity, and will vary from a few man hours to several man months. The cost of a medium size digital or analog computer installation will vary from $100,000 to $500,000 and the rental charge for such facilities will vary from $20 to $200 per hr., depending on a number of factors. The machine running time will vary from a few minutes to several hours or even days depending on the nature of the problem. It is therefore apparent that the cost of solving a problem may vary from a few dollars to several thousand dollars.

At one end of the scale would be the calculation of metering orifices at a cost of about $15 per orifice. Once the data are developed, the cost of designing a fifteen plate distillation column to separate six non ideal components would be about $300 for the first case, and $100 for each succeeding case. Both of these calculations would be done on a digital computer using a library program. At the high end of the scale might be the simulation of a complex chemical reactor on an analog computer. The simulation might include the exploration of yield and controllability at various reaction temperatures and pressures, conversion rates, catalyst concentration, feed impurities, mass flows, etc. Such a study might cost $3,000 to $5,000.

Conclusion

The technical use of digital and analog computers is leading to important advances in the chemical industry. Design engineers are able to develop more efficient and more economic designs of new equipment and processes. Production and technical personnel are able through simulation of new and existing plants to secure with safety a new insight into their processes, thus leading to smoother startups, better operation, and increased yields.

FIG. 8.
REPRODUCTION OF TUBULAR HEAT EXCHANGER STRESS ANALYSIS INPUT DATA SHEET

Equipment No. 511N10

a	inside diameter, in.	27
E_s	modulus of shell material	29×10^6
E_{ts}	modulus of tube sheet material	27×10^6
E_t	modulus of tube material	27×10^6
E_c	modulus of channel material	29×10^6
L	overall length, outside tube sheets, in.	96
N	number of tubes	146
d	diameter of tubes, in. (ignore fins)	1¼
P_t	tube side pressure, lb/sq. in. ga.	150
P_s	shell side pressure, lb./sq. in. ga.	75
p	pitch, in. (triangular)	1½
t	thickness of tube wall, in.	0.011
T_t	maximum temperature of tube, °F.	270
T_s	maximum temperature of shell, °F.	150
T_t–T_s to be given		
ν_t	Poisson's ratio for tube	0.3
ν_{ts}	Poisson's ratio for tube sheet	0.3
ν_s	Poisson's ratio for shell	0.3
α_{ts}	coefficient of thermal expansion for tube sheet in./°F.	6×10^{-6}
α_t	coefficient of thermal expansion for tube, in./°F.	6×10^{-6}
α_c	coefficient of thermal expansion for channel, in./°F.	6×10^{-6}
α_s	coefficient of thermal expansion for shell	6×10^{-6}
t_c	thickness of channel, in.	⅜
t_s	thickness of shell, in.	⅜
h	tube sheet thickness, in.	1¼
l	maximum unsupported span of a tube which is considered as column built-in at tube-sheet and "pinned" at the support plate, in.	23
b	outer diameter of outside flange—outer diameter of shell, in.	4½
c	total thickness of two outside flanges, and tube sheet, in.	3¾

Mathematical Basis for Heat Exchanger Stress Analysis

The basic differential equation and its solutions are as follows:[2,3,4,5,6]

$$x^4\frac{d^4q}{dx^4} + 2x^3\frac{d^3q}{dx^3} - x^2\frac{d^2q}{dx^2} + \frac{dq}{dx} + x^4q = 0 \qquad (1)$$

$$q = A \operatorname{ber} x + B \operatorname{bei} x$$

$$w = \frac{1}{\beta^4 D}\left[{}_fA(\operatorname{ber} x_a - \operatorname{ber} x) + B(\operatorname{bei} x_a - \operatorname{bei} x)\right] \qquad (2)$$

$$M_r = \frac{1}{\beta^2}\left[A\left(\operatorname{bei} x + \frac{1-\nu}{x}\operatorname{ber}' x\right) - B\left(\operatorname{ber} x - \frac{1-\nu}{x}\operatorname{bei}' x\right)\right] \qquad (3)$$

$$\Theta = -\frac{1}{\beta^2 D}(A \operatorname{ber}' x + B \operatorname{bei}' x) \qquad (4)$$

$$x = \beta \times r = \left(\frac{2k}{D}\right)^{1/4} \times r \; ; \quad x_a = \beta \times a \qquad (5)$$

$$k = \frac{N \times t(d-t)E_t}{a^2 \times L} \qquad (6)$$

non uniform effective pressure on the tube sheet is

$$q = (f_t \times p_t - f_s \times p_s) + k(m - \alpha_t \times T_t \times L - 2w) \qquad (7)$$

where p_t = hydrostatic pressure on tube side, p.s.i.

p_s = hydrostatic pressure on shell side, p.s.i.

f = fraction of total tube sheet area on which pressure acts directly.

m = distance the tube sheet edges move in respect to each other under load, in.

$$f_t = 1 - \frac{N}{4}\left(\frac{d-2t}{a}\right)^2$$

$$f_s = 1 - \frac{N}{4}\left(\frac{d}{a}\right)^2$$

When the shell side and tube side of the heat exchanger are subjected to pressure p_s and p_t—the edge rotation of a hinged semi-infinite cylindrical shell and head will accordingly rotate by an angle Θ_s and Θ_h, respectively.

$$\Theta_s = \frac{3^{1/4}(1-\nu_s^2)^{1/4}p_s}{E_s}\left(\frac{a}{t_s}\right)^{3/2} \qquad (8)$$

$$\Theta_h = \frac{3^{1/4}(1-\nu_h^2)^{1/4}p_t}{E_h}\left(\frac{a}{t_h}\right)^{3/2} \qquad (9)$$

The moment applied at the edge of a semi-infinite cylindrical shell, which will rotate the edge through a unit angle, defines the "rotation stiffness" of that edge. The following are the terms defining the "rotation stiffness" for the shell, head and flange of the heat exchanger.

$$K_s = \frac{E_s \times t_s^{5/2}}{2 \times 3^{3/4}(1-\nu_s^2)^{3/4} \times a^{1/2}} \qquad (10)$$

$$K_h = \frac{E_h \times t_h^{5/2}}{2 \times 3^{3/4}(1-\nu_h)^{3/4} \times a^{1/2}} \qquad (11)$$

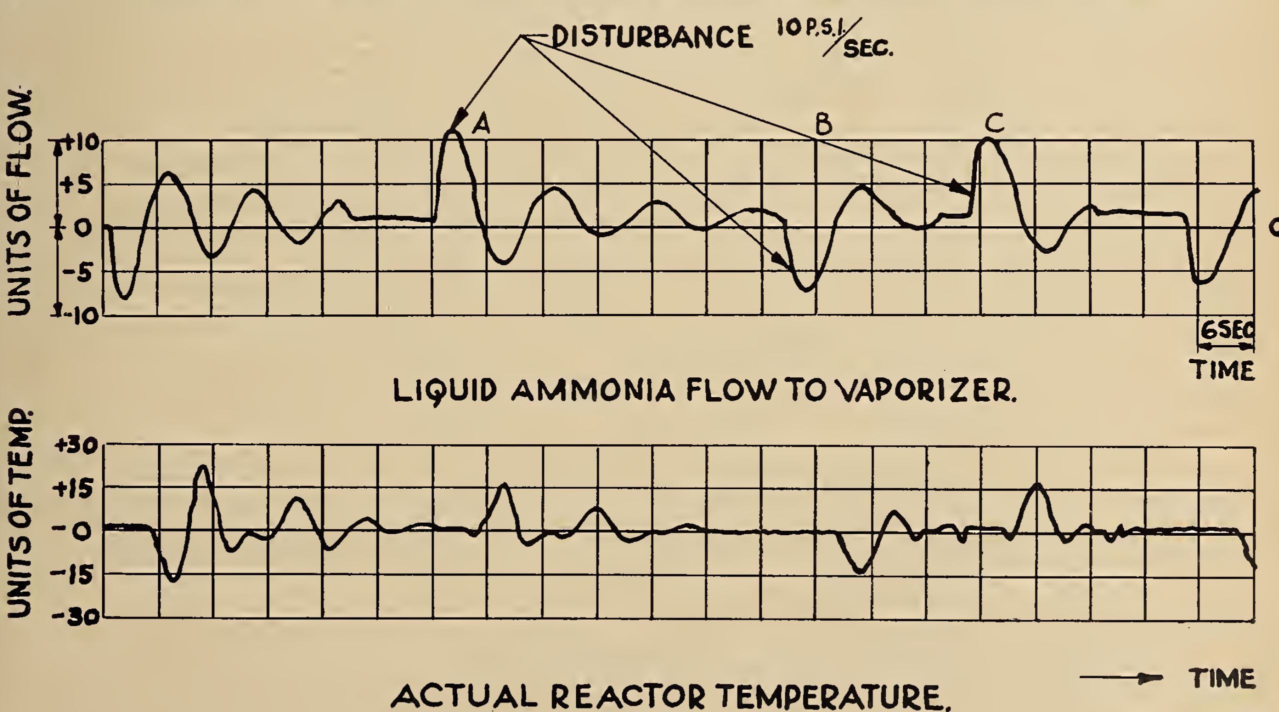
$$K_f = \frac{E_f \times I_f}{R \times a} \qquad I = \frac{b \cdot c^3}{12} \qquad (12)$$

where R = flange bolt circle radius, in.

b = (O.D. − I.D.)/2 of flange, in.

c = combined flange and tube sheet thickness, in.

Fig. 9. Two-Channel Record of Effect of External Disturbance on Reactor Temperature — before Adjustments.



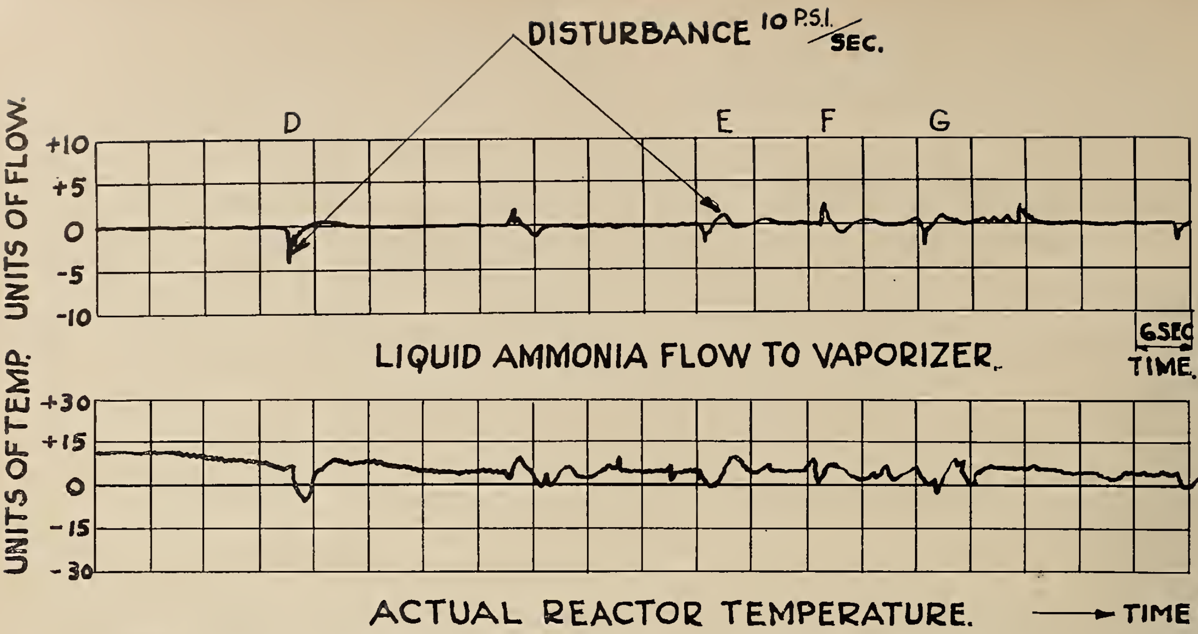


Fig. 10. Two-Channel Record of Effect of External Disturbance on Reactor Temperature—after Instruments were "Tuned Up."

Four edge moments must balance each other at the joint. This condition is reflected by the following equations:

$$M_a + K_s(\Theta_a + \Theta_s) + K_h(\Theta_a - \Theta_h) + K_f\Theta_a = 0 \qquad (13)$$

$$M_a + (K_s + K_h + K_f)\Theta_a = K_h\Theta_h - K_s\Theta_s \qquad (14)$$

Three conditions are needed for determination of the three constants m, A and B (equations 2 and 6); the equations describing these conditions are as follows:

In order to obtain the first equation the edge values of Θ_a and M_a are first obtained from equations 3 and 4 and substituted into equation 14, which yields:

$$A\left[\operatorname{bei} x_a + \left(\frac{1-\nu}{x_a} - \frac{K_s + K_h + K_f}{\beta D}\right)\operatorname{ber}' x_a\right]$$

$$- B\left[\operatorname{ber} x_a - \left(\frac{1-\nu}{x_a} - \frac{K_s + K_h + K_f}{\beta D}\right)\operatorname{bei}' x_a\right]$$

$$= \beta^2(K_h\Theta_h - K_s\Theta_s) \qquad (15)$$

The second equation is:

$$q_a = A \operatorname{ber} x_a + B \operatorname{bei} x_a$$
$$= km + f_t p_t - f_s p_s - k \times \alpha_t \times T_t \times L \qquad (16)$$

The third equation is:

$$\int_0^a 2\pi r q\, dr = \frac{2\pi a^2}{x_a}(A \operatorname{bei}' x_a - B \operatorname{ber}' x_a)$$

$$= \pi a p_t - \frac{2\pi a E_s t_s}{L}(m - \alpha_s \times T_s \times L) \qquad (17)$$

Once the radial moment value is obtained (see equation 3) the maximum bending stress is determined from the following equation:

$$\sigma_{\max} = \frac{6M_a}{h^2\eta_w} \qquad (18)$$

where σ = stress, p.s.i.
η_w = flexural efficiency for triangular pitch.

The load on any tube is given by the following equation:

$$W_t = \frac{\pi a^2}{N}(q - f_t p_t + f_s p_s) \qquad (19)$$

Approximations

$\sin^{-1}x$ is computed in accordance with Hasting's formula:

$$\sin^{-1}x = \frac{\pi}{2} - \sqrt{1-x} \times \psi(x) \qquad (20)$$

$$\psi(x) = a_0 + a_1x + a_2x^2 + a_3x^3 \qquad (21)$$

$a_0 = 1.5707288$ $\quad a_2 = 0.072610$

$a_1 = -0.2121144$ $\quad a_3 = -0.0187293$

* This line shows stress values in the components listed.

E.g. highest tensile stress in tubes is 227.4 p.s.i. and highest compressive stress in tubes is 16944 p.s.i.

[1] Maximum allowable force when tubes are not supported by baffles (332 lbs.).
[2] Maximum allowable force when tubes are supported by baffles (4830 lbs.).
[3] Actual force at tube ends (822 lbs.).

Depending on values of x the approximations are as follows:[2]

For $0 \leq x \leq 10$

$$\text{ber}\, x = 1 - \frac{x^4}{2^2 4^2} + \frac{x^8}{2^2 4^2 6^2 8^2} + \frac{(-1)^{4k-1} \times x^{4k}}{2^2 4^2 \ldots (4k)^2} + \ldots \quad (22)$$

For $x > 10$

$$\text{ber}\, x = \frac{e^{\delta}}{\sqrt{2\pi x}} \times \cos \gamma \quad (23)$$

$$\delta = \frac{x}{\sqrt{2}} + \frac{1}{8\sqrt{2}x} - \frac{25}{384\sqrt{2}x^3} \quad (24)$$

$$\gamma = \frac{x}{\sqrt{2}} - \frac{\pi}{8} - \frac{1}{8\sqrt{2}x} - \frac{1}{16x^2} - \frac{25}{384\sqrt{2}x^3} \quad (25)$$

For $0 \leq x \leq 10$

$$\text{bei}\, x = \frac{x^2}{2^2} - \frac{x^6}{2^2 4^2 6^2} + \frac{x^{10}}{2^2 4^2 6^2 8^2 10^2} + \ldots \frac{(-1)^{k+1} \times X^{4k-2}}{2^2 4^2 (4k-2)^2} \quad (26)$$

For $x > 10$

$$\text{bei}\, x = \frac{e^{\delta}}{\sqrt{2\pi x}} \times \sin \gamma \quad (27)$$

δ and γ are the same as before.

For $0 \leq x \leq 10$

$$\text{ber}'\, x = \frac{4x^3}{2^2 4^2} + \frac{8x^7}{2^2 4^2 6^2 8^2} - \frac{12x^{11}}{2^2 4^2 6^2 8^2 10^2 12^2} \ldots + \frac{(-1)^k \times 4k \times x^{4k-1}}{2^2 4^2 6^2 \ldots (4k)^2} \quad (28)$$

For $x > 10$

$$\text{ber}'\, x = \frac{e^{\eta} \cos \omega}{\sqrt{2\pi x}} \quad (29)$$

$$\eta = \frac{x}{\sqrt{2}} - \frac{3}{8\sqrt{2}x} + \frac{21}{128\sqrt{2}x^3} + \frac{27}{128x^4} \quad (30)$$

$$\omega = \frac{x}{\sqrt{2}} + \frac{\pi}{8} + \frac{3}{8\sqrt{2}x} + \frac{3}{16x^2} + \frac{21}{128\sqrt{2}x^3} \quad (31)$$

For $0 \leq x \leq 10$

$$\text{bei}'\, x = \frac{2x}{2^2} - \frac{6x^5}{2^2 4^2 6^2} + \frac{10x^9}{2^2 4^2 6^2 8^2 10^2} - \ldots \frac{(-1)^{k+1}(4k-2)x^{4k-3}}{2^2 4^2 \ldots (4k-2)^2} \quad (32)$$

For $x > 10$

$$\text{bei}'\, x = \frac{e^{\eta}}{\sqrt{2\pi x}} \cdot \sin \omega \quad (33)$$

η and ω are as before.

Appendix II

Formulation of Mathematical Model of Nitric Acid Plant

The basic equations upon which simulation of the plant performance was established are as follows:

I. From ammonia storage tanks to ammonia vaporizer.

$$\frac{dW_1}{dt} = \frac{A_p}{KM_p}(P_1 - P_2) + \frac{k_1}{KM_p}(L_1 - L_2) - \frac{k_2 W_1^2}{KM_p} \quad (1)$$

$$K = \frac{1}{A_p \rho g}$$

M_p = liquid contained in the pipe—lbs.

$$W_1 = \gamma \cdot K_V \cdot \sqrt{P_2 - P_3'} \quad (2)$$

$$0 < \gamma < 1.0000$$

$$K_V = k_3 \cdot C_V \sqrt{1/G}$$

$$P_3' = P_3 + (h + h_V)\,k_4 \quad (3)$$

II. Ammonia vaporizer.

$$k_5\,A_T \frac{dL}{dt} = W_1 - W_2 \quad (4)$$

$$W_2 = \frac{(T_m - T_L)A_L U_L}{\lambda_L} \quad (5)$$

$$A_L = f_1(L) \quad ; \quad A_T = f_2(L) \quad (6)$$

$$\frac{dT_m}{dt} = (W_s\lambda_s - W_2\lambda_L)\frac{1}{C_{Hm}} \quad (7)$$

$$W_s = \frac{(T_s - T_m)A_L U_s}{\lambda_s} \quad (8)$$

$$T_s = f(P_s) \qquad 84 + 0.8P_s \quad (9)$$

$$\frac{dP_s}{dt} = \frac{(W_{s0} - W_s)K}{V_s} \quad (10)$$

$$T_L = f(P_3) \quad ; \quad 0.4P_3 - 30 \quad (11)$$

$$\frac{dP_3}{dt} = \frac{(W_2 - W_3)\cdot K}{V_{III}} \quad (12)$$

$$W_s = K_V \times \gamma_s \times P_{s0} \times f\left(\sqrt{\frac{P_s}{P_{s0}}\left(1 - \frac{P}{P_{s0}}\right)}\right) \quad (13)$$

$$0 < \gamma_s < 1.0000$$

III. Pressure Control Valve to determine W_3, W_4, W_5 (see Fig. 5).

$$W_3 = \gamma \times K_{V3}\sqrt{P_4(P_3 - P_4)} \quad ; \quad 0 < \gamma < 1.0000 \quad (14)$$

$$\frac{dP_4}{dt} = (W_3 - W_4)\frac{K}{V_{IV}} \quad (15)$$

$$W_4 = \gamma \times K_{V4}\sqrt{P_5(P_4 - P_5)} \quad ; \quad 0 < \gamma < 1.0000 \quad (16)$$

$$W_5 = K_{G5}\sqrt{P_5(P_5 - P_6)} \quad (17)$$

$$\frac{dP_5}{dt} = (W_4 + W_{11} + W_{12} - W_5)\frac{K}{V_v} \qquad (18)$$

IV. Reacted Temperature.

$$T_i = \frac{W_4 \times C_{PA} \times T + W_{11} \times C_{PA} \times T_{A0} + W_{12} \times C_{PA} \times T_{A1}}{W_4 C_p + (W_{11} + W_{12})C_{pA}} \qquad (19)$$

T_i = Temperature at entrance to the air-ammonia mixer, °C.

$$T_R = \left[\frac{7.06 + 2.37y'}{7.52 + 3.94y'}\right] T_i + \frac{y'Q}{7.52 + 3.94y'} - \frac{UA(T_R - T_m)}{C_{HG}} \qquad (20)$$

where Q = 54253 P.C.U./lb. mol. (at 18°C.)

T_m = metal temperature at reactor reaction zone' °C.

G_{HG} = heat capacity of gas contained within reaction zone, P.C.U./°C.

$$C_{HG}\frac{dTm}{dt} = UA(T_R - T_M) \qquad (21)$$

$$y' = y \times (\text{D.T.}) \qquad (22)$$

$$(\text{D.T.}) = \frac{\text{Designed Production Rate} = W}{\text{Actual Production Rate}} \qquad (23)$$

$$y = \frac{W_4}{W_{11} + W_{12} + W_4} \qquad (24)$$

V. Pressure-Volume Systems (see Fig. 5)

$$\frac{dP_6}{dt} = (W_5 - W_6)\frac{K}{V_{VII}} \qquad (25)$$

$$W_6 = K_6\sqrt{P_7(P_6 - P_7)} \qquad (26)$$

$$\frac{dP_7}{dt} = (W_6 - W_7)\frac{K}{V_{VII}} \qquad (27)$$

$$W_7 = K_7\sqrt{P_7(P_7 - P_8)} \qquad (28)$$

$$\frac{dP_8}{dt} = (W_7 - W_8)\frac{K}{V_{VIII}} \qquad (29)$$

$$W_8 = K_8\sqrt{P_9(P_8 - P_9)} \qquad (30)$$

$$\frac{dP_9}{dt} = (W_8 - W_9)\frac{K}{V_{IX}} \qquad (31)$$

$$W_9 = K_9\sqrt{P_{10}(P_9 - P_{10})} \qquad (32)$$

$$\frac{dP_{10}}{dt} = \left[W_{10} - (W_{11} + W_{12})\right]\frac{K}{V_x} \qquad (33)$$

$$W_{10} = K_{10}\sqrt{P_{10}(P_{12} - P_{10})} \qquad (34)$$

$$W_{11} = k_{11} \times W_{12} \qquad (35)$$

$$W_{12} = K_{12}\sqrt{P_5(P_{10} - P_5)} \qquad (36)$$

VI. Heat Exchanger. (See Fig. 14).

$$\frac{dT_{m1}}{dt} = \frac{2UA_1}{C_{H1}}(T_G - T_{m1}) + \frac{2UA_1}{C_{H1}}(T_A - T_{m1}) \qquad (37)$$

where C_{Hj} = metal wall heat capacity, P.C.U./°C.

$$\frac{dT_{m2}}{dt} = \frac{UA_2}{C_{H2}}(T_A - T_{m2}) \qquad (38)$$

$$T_G = \frac{T_R + T_{GC}}{2} \qquad (39)$$

$$T_A = \frac{T_{A1} + T_{A0}}{2} \qquad (40)$$

$$(T_{m1} - T_A)2UA + (T_{m2} - T_A)2UA = W_{12}C_{pA}(T_{A1} - T_{A0}) \qquad (41)$$

$$C_{pG}W_6(T_R - T_{Ge}) = 2UA(T_G - T_{m1}) \qquad (42)$$

THE WARSAK HYDRO-ELECTRIC PROJECT

J. H. Ings, M.E.I.C.,
Vice-President,
H. G. Acres & Company Limited,
Niagara Falls, Canada.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The purpose of this paper is to describe the Warsak Hydro-Electric Project, a joint Canada-Pakistan undertaking of the Columbo Plan. As the project is being constructed some 10,000 miles away in the Asian subcontinent, and under unusual conditions, it is proposed to describe the Colombo Plan operation, the area in Pakistan of the development, and finally the Warsak project itself.

ONE of the greatest developments in international affairs since the end of World War II has been the readiness of the countries of the western world to assist their less fortunate neighbours. The Colombo Plan, under which the nations of south and southeast Asia are striving to improve the health and welfare of their large populations, attempts to combine self-help with assistance from outside.

Emerging from a meeting of the Foreign Ministers of the British Commonwealth of Nations at Colombo in January, 1950, the Colombo Plan's original members were the United Kingdom together with its dependencies in Malaya and Borneo, Australia, Canada, Ceylon, India, New Zealand, and Pakistan. From the start, however, it was intended that additional countries should be invited to participate, and a number have since joined. Each of the underdeveloped members drew up a program of projects extending over an initial trial period of six years, and estimated the external assistance it would need. The assisting countries in turn pledged various amounts of capital and technical aid.

Two particularly valuable features of the Colombo Plan are that the assistance it offers is essentially for long-term benefit, and that it requires the active co-operation of both parties to the project. The Asian countries particularly appreciate participating in the program, rather than just having aid bestowed upon them.

Because of Canada's extensive experience in the design and construction of power development projects, these have figured prominently in the assistance that has been extended by this country. The Warsak Hydro-Electric Project is the largest capital aid program in Pakistan.

West Pakistan

The Islamic republic of Pakistan comprises two political entities, namely, the provinces of West Pakistan and East Pakistan.

West Pakistan, in which the Warsak project is located, is bordered on the southwest by Iran, on the west and north by Afghanistan, on the northeast by the disputed territories of Jammu and Kashmir, on the east and southeast by India, and on the south by the Arabian Sea. The key plan, Fig. 1, shows the location of West Pakistan relative to India and Afghanistan.

West Pakistan presents great variations in landscape and climate, from the snow covered peaks of the upper Himalayas to the grey, sombre desert of the Sind. In elevation, the country varies from the sea-level delta of the Indus to the mountainous peak of K-2 at elevation 28,250 ft. above sea level.

It goes without saying that the institutions, ideas, and beliefs extant in Pakistan are quite different from those in Canada. A genuine effort on the part of the foreign worker to understand and know the people of

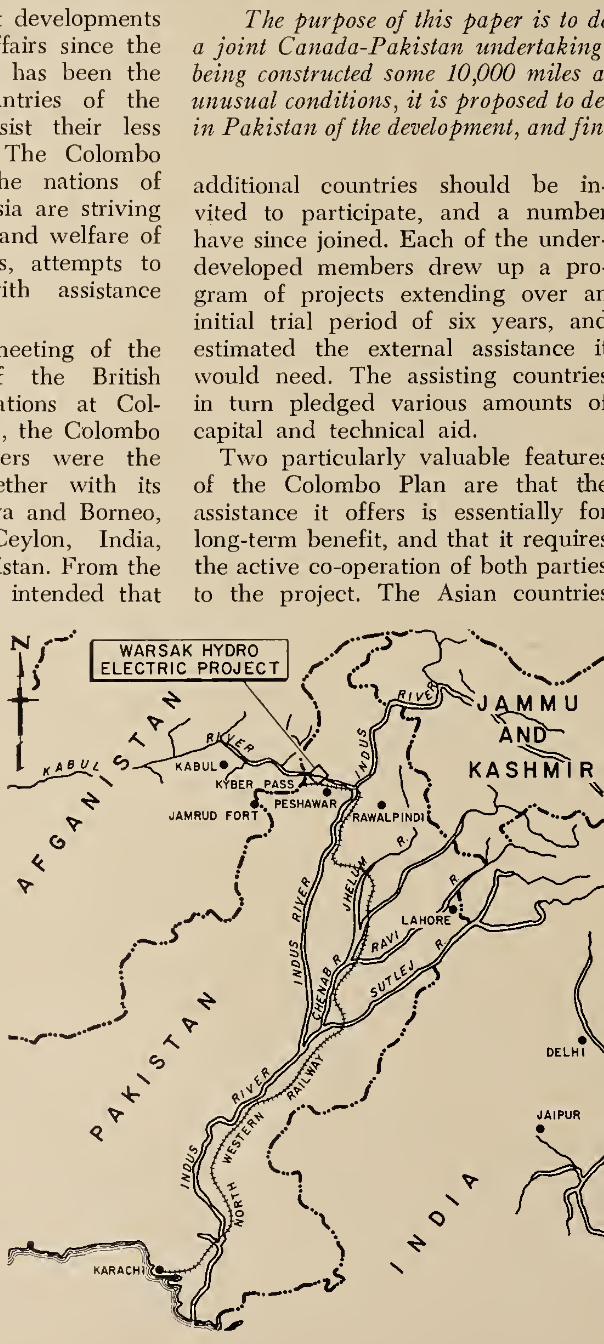

Fig. 1. Location of the Warsak Hydro-Electric Project.

the country is necessary and will go a long way to help him adjust himself to his new environment.

Early Consideration of Project

Consideration of a possible hydro-electric project on the Kabul River was initiated by a note dated August 28, 1948, written by Colonel J. R. Hainsworth, C.B.E., R.E., then the Chief Engineer and Secretary to Government, North-West Frontier Province.

Since then various preliminary reports were prepared until finally in 1952, after the inception of the Colombo Plan, assistance under the Plan was requested from Canada in respect of several hydro-electric proposals, including the Warsak project. As a result, Messrs. J. H. Ings and F. W. Patterson of H. G. Acres & Company Limited visited Pakistan and India in the fall of 1952, inspected the sites, and gathered data.

The Warsak project was among those recommended for inclusion in the program of Colombo Plan assistance. Subsequently formal approval was given and our consulting engineering firm was appointed by the Canadian government to design the structures and supervise construction. Shortly afterwards a general contract for the civil contract was negotiated. An agreement between the Governments of Pakistan and Canada was negotiated, setting out the scope of participation of each of the countries and the responsibilities and services to be undertaken by the consulting engineers and the general contractors.

Location and General Description

The site of the project is on the Kabul River, approximately 19 miles northwest of Peshawar, and 15 miles from Jamrud Fort, the nearest railroad station of the North Western Railway.

The Kabul River rises in north central Afghanistan, and provides drainage for the eastern portion of that country. Through one of its tributaries it also drains the state of Chitral in northern Pakistan. The total drainage area above the Warsak dam site is approximately 26,000 sq. miles.

Kabul, the capital city of Afghanistan, is situated on the river, about 60 miles from the source. From Kabul the river flows eastward, dropping several thousand feet in elevation into the Jalalabad valley and thence to the border between Afghanistan and Pakistan. The river then twists and turns through the hills of the Sofed Koh Range, then flows mainly eastward until it debouches on to the flat land of the Vale of Peshawar at Warsak Head.

The elevation of the low water level of the river at the Afghanistan border is 1267 ft. above mean sea level, and at Warsak the corresponding elevation is 1118 ft. The fall of the river between these two places is therefore 149 ft. over a distance of 26 miles, or an average slope of 5½ ft. per mile. In this reach the river flows in a gorge whose banks rise steeply to several hundred feet above the river level. At intervals the banks are cut by deep ravines or nullahs. The width of the river varies between 200 and 300 ft. at high water level.

The normal headpond level is at elevation 1269 ft., and allows for a 10 ft. pondage drawdown. These elevations are well below the existing maximum high water levels at the boundary, and so river conditions within Afghanistan should not be affected by the development of the power reach located wholly within Pakistan.

The initial development will comprise four generating units of 40,000 kw. each, but the power tunnel, penstocks and powerhouse are being constructed for the future installation of two more similar units. In addition, there will be two small house-units of 750 kva. each which will give service power for running the various auxiliary equipment, lighting, and the operators' colony. The main dam will be a concrete gravity structure some 200 ft. high, completely closing the gorge of the Kabul River.

The project will be provided with a 10 ft. diam. irrigation tunnel 3.5-miles long. This will allow the irrigating of 100,000 acres of the Peshawar plains around Jamrud Fort. This part of the project will provide an opportunity to settle many of the hill tribe families on useful productive lands and will thereby enhance the stability of the whole area.

Geology and Foundations

Since the first investigations were started at Warsak in early 1949, extensive geological investigations have been carried out. In all some 148 holes were drilled, varying in diameter from 1¾ in. to 22 in. Over and above this exploratory drilling some 1800 ft. of exploratory tunnel were driven into the south bank.

General Geology:

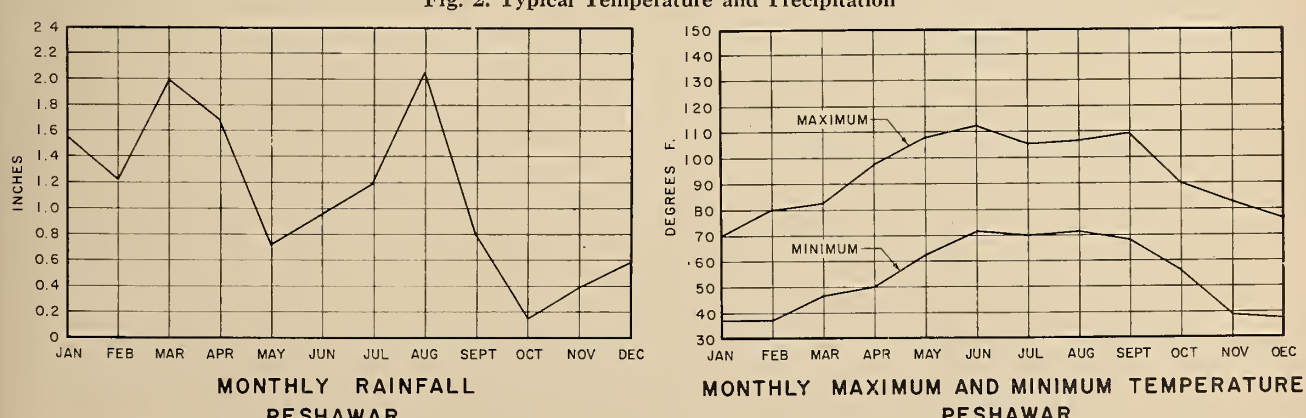
The project is wholly in an area of metamorphic schists and gneisses. The following local succession has been established:

5—Superficial deposits, river gravel and boulder beds, high level terrace deposits and talus.
4—Phyllite group 500 ft. + thick
3—Upper granite gneisses 450 ft. thick
2—Multiple schists 90 ft. thick
1—Lower granite gneisses 600 ft. thick

1—Lower Granite Gneisses—This group is characterized by a persistent upper zone of decomposed gneiss 5 to 15 ft. thick. A faulted and decomposed belt 50 to 100 ft. long outcrops at the diversion tunnel inlet.

2—Multiple Schists—The lower granite gneisses are succeeded by 90 ft. of alternating acid and basic micaceous schists. These schists form an impervious barrier beneath the dam.

Fig. 2. Typical Temperature and Precipitation



3—Upper Granite Gneisses—These are hard, medium grained, whitish gneisses. A conspicuous foliation dips uniformly northeast at 45°, but does not represent a structural weakness in the rock. The principal jointing and some faulting follows this direction. Two other main joint sets are found:

(a)—Joints striking to the northeast and dipping mainly to the northwest at 70° to 80°, but locally to the southeast at 70° to 90°.

(b)—Joints striking northwest and dipping southwest at 40° to 70°.

4—Phyllite Group—This group includes phyllites, phyllitic quartzites and some marbles. These are softer rocks and have been eroded in many places to form nullahs.

Some basic dykes are present which are folded. They do not follow closely the structure of the schists and gneisses. These dykes are of significance because they hold up pockets of water in the overlying granites which facilitates rock slides. The two rock slides behind the powerhouse were probably caused by this condition.

Structure:

The principal structure is a syncline plunging northeast with its axis intersecting the east-west line of the Kabul River downstream from the damsite. The boundaries of the various rock types are cut at right angles by the river. The boundaries, the foliation, the schistosity, and the principal joints all dip downstream at 45° to the east-northeast.

The river line does not correspond to any significant fault movement in the area. A number of small earthquakes are experienced each year and apparently originate outside the area.

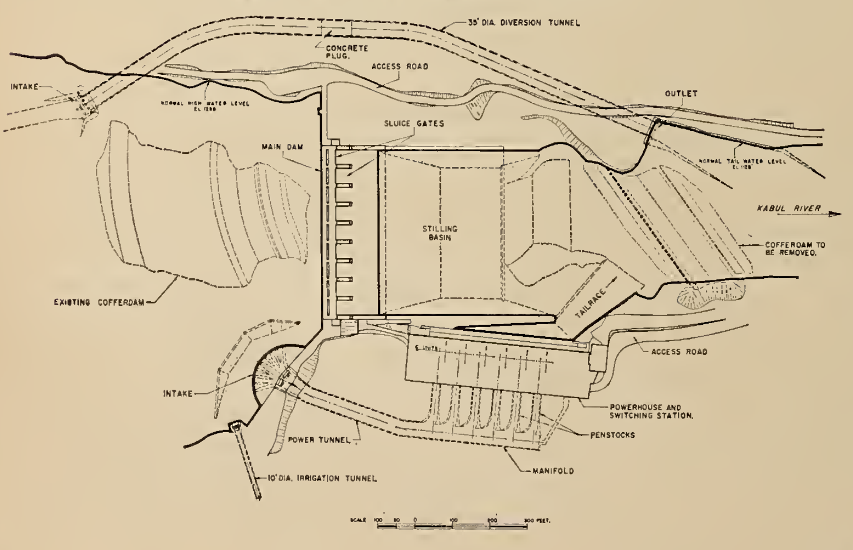
Hydrology

Climate: The Asian subcontinent in general is subject to a monsoon type of climate. During the winter months a high barometric pressure builds up over central China and Siberia, causing air movement from the continent towards areas of low pressure over the Indian Ocean and Indonesian Archipelago. The cold air masses flowing south over India and Pakistan are necessarily dry. Whatever moisture might have been present originally is lost as the air moves over the Himalaya Mountains. Thus, the winter may be expected to be the dry season in which very little or no rainfall occurs south of the Himalayas.

During the summer the barometric pressures over the Asiatic continent drop as the temperature rises and the air flow is reversed. Air masses, originating from the area of the Indian Ocean and having a high moisture content, travel in a northwesterly direction over India and Pakistan, gradually losing their moisture until they strike the Himalayan Mountains where the remaining moisture is shed. The air arriving over Burma and East Pakistan has travelled a longer distance over the oceans than, say, the air arriving over West Pakistan, and has, therefore, a higher moisture content.

As a result the general climate varies from very humid in East Pakistan (80 in. at Dacca) to subhumid in West Pakistan (16 in. at Peshawar). Afghanistan, which contains the greater part of the Kabul River watershed, is shielded from the sea by high mountain ranges which further reduce rainfall, giving a semi-arid climate. The temperatures vary within wide limits, as is typical for a continental climate.

Fig. 3. General Arrangement of Project



While the greater portion of the moisture-laden monsoon winds travel in a northwesterly direction, nevertheless there is a lesser monsoon wind that approaches India from the southwest. This is caused by a deflection of the general monsoon winds by pressure conditions over the Arabian Sea. The result is high precipitation from the Gulf of Kutch down to the Malabar Coast.

Many other local conditions affect the monsoon distribution, with the end result that the Sind area of West Pakistan has practically no rain and the remaining part of the monsoon moisture that reaches the Rawalpindi-Attoc area is deflected north.

The discussion in the preceding paragraphs, while explaining the type of climate over most of West Pakistan, does not cover the Warsak-Peshawar area. Over this zone the wind directions differ from the rest of the monsoon-covered area and, in addition, there are two distinct rainy seasons, one in the early summer and one in the winter. It is quite possible that this variation from the typical monsoon climate of the sub-continent may be caused by Mediterranean pressure variations which do affect neighbouring Iran and Afghanistan.

Temperature changes in the Warsak-Peshawar area show continental changes from highs of 120°F in the summer to lows of 25°F in the winter. Typical precipitation and temperatures are shown on Fig. 2.

Hydrograph of the Kabul River: The Kabul River and its tributaries, the Kunar (sometimes called the Chitral), the Alingar, the Pansjir, the Logar, and the Sarkhab, drain an area of approximately 26,000 sq. miles. This drainage area, located entirely in Afghanistan except for some 5800 sq. miles in Pakistan on the upper Kunar, is surrounded by high mountains on all sides, the narrow gorge extending through the Safed Koh Range from the Jalalabad valley to Warsak being the only low level outlet. The mountain ranges to the north, part of the Hindu Kush, rise to elevations of the order of 20,000 ft. and have permanent snow fields at the higher elevations.

These mountains are tertiary formations as are the Alps in Europe and the Rocky Mountains of North America. Because of the general sparseness of vegetation, soil and loose decaying rock are easily eroded. Consequently, little overburden exists on the rock hills and mountains of the catchment area and alluvial deposits are confined to stretches of flat river valleys where the rivers lose their bed-load carrying capacity. The

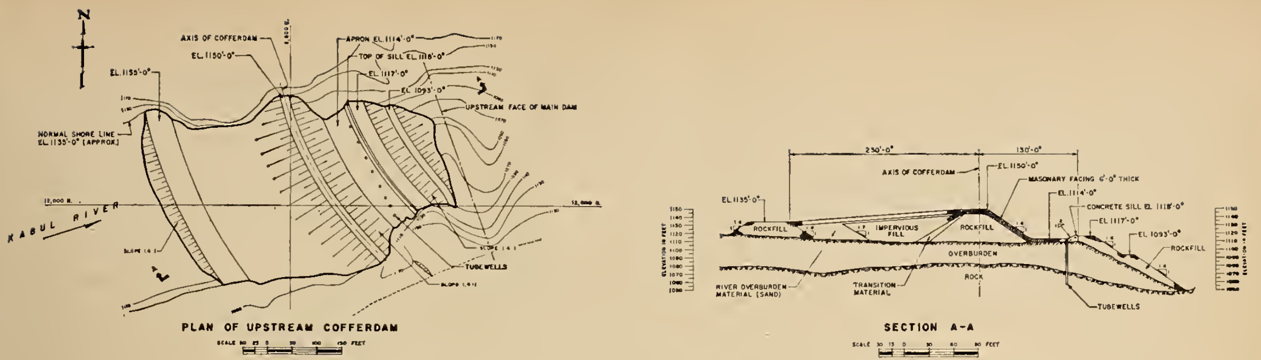


Fig. 4. Upstream Cofferdam — Plan (left) and Section (right)

catchment area will, therefore, probably have little underground storage either in overburden or in rock.

The shape of the hydrograph of the Kabul River shows the following features:

(a)—Between March 1 and April 1 the discharge of the Kabul River increases from a minimum to a maximum which will occur on the average in June or July.

(b)—During August and September there is a sharp decrease in discharge.

(c)—From October to March the flow falls to a low value which is nearly constant each year.

This distribution of the runoff over the year is in general agreement with the climatic conditions as described for Afghanistan and the North West Frontier region. The extent and rate of the spring flood flows is governed by snow melt and temperature conditions in the mountains rather than by monsoon conditions which govern the major rivers of India and East Pakistan.

As the catchment area is generally rock with little vegetation and with no lakes, any precipitation is immediately reflected in the hydrograph. Individual rainstorms appear as sharp peaks. It is not unusual to see rain storms raise the river stage at Warsak by 3 to 5 ft. in a matter of a few hours. The Kabul River flow records are based on gauge readings which have been taken at Warsak Head since 1900.

The bed of the river at Warsak Head is not stable. When the river flow increases, erosion occurs and causes a considerable movement of the bed materials. As the flow decreases, material is deposited in the river bed, especially just downstream from Warsak Head where the river emerges from the gorge and flows through an unstable multichannel section before continuing as a single channel to the Indus.

Since the river bed is unstable, only those water levels recorded during the actual period of discharge measurements may be related directly to the above-mentioned discharge rating curve. Therefore, early investigators adjusted the recorded water levels at Warsak Head to allow for the changes in the river bed and, by means of the discharge rating curve, estimated the river discharge for the period 1900 to 1950. A duration curve of river discharge was prepared on the basis of these estimated discharges.

For the purpose of estimating the magnitude of probable flood discharges, early investigators plotted a probability curve on the basis of the estimated maximum annual discharge during the period 1900 to 1950. This curve was extrapolated to cover the range of flood magnitudes far in excess of those recorded during the 51-yr. period in an attempt to indicate the frequency at which these higher discharges might be expected. From this probability curve the magnitude of floods which might occur *on the average* once in 100 yr., once in 1,000 yr., and once in 5,000 yr., were noted.

While the methods of adjustment of records used by the early investigators are considered reasonable within the range of actual discharge measurement, it is also thought that extrapolation of the derived data to high flood ranges could only be considered a very rough approximation.

Several types of frequency curves were plotted and adjusted and the whole considered with a somewhat sceptical and conservative eye. The safety aspect of flood is of prime importance in any decision or choice of design, and in the design of a dam it includes consideration of the safety of the structure itself, of the life and property endangered by its failure, and consideration of the economic consequences of a failure.

The investigations and studies led to a choice of the following four floods:

(a)—A flood of 28,000 c.f.s. through the diversion tunnel during construction and with no flow over the cofferdams.

(b)—A flood of 200,000 c.f.s. during construction, partly through the diversion tunnel and partly over the cofferdams.

(c)—A flood of 320,000 c.f.s. through the completed dam sluice gates, and without flooding into Afghanistan beyond normal flood levels.

(d)—A super flood or maximum design flood of 540,000 c.f.s. This would involve some flooding in Afghanistan and raising the water levels at the Warsak powerhouse to the draft tube exit deck.

Storage and Flow

The watershed of the Kabul River is completely devoid of lakes that would provide a measure of natural storage or which could be developed to provide cheap artificial storage. Because of the rocky mountainous character of the watershed, the low, flat, wide valleys that exist and which might be developed for storage at reasonable cost, are highly developed agriculturally and could not be converted to other uses without serious adverse economic and political effects.

Also it must be noted that 20,000 out of 26,000 sq. miles of catchment area are in Afghanistan and not Pakistan. This means that any storage that could or would be developed in Afghanistan would be in a foreign country and would be a subject for international treaty and not under Pakistan control.

At Warsak the headpond of the development extends to the Afghan border but lies in a mountain gorge over its entire length. When allowances are made for dead storage, siltation, etc., the gross volume of 62,000 acre-feet is reduced to a useful live storage volume of about 20,000 acre-feet. This volume of pondage will allow for any reasonable daily or weekly load factor for peak discharges up to and exceeding 24,000 c.f.s., but is insufficient for any seasonal storage.

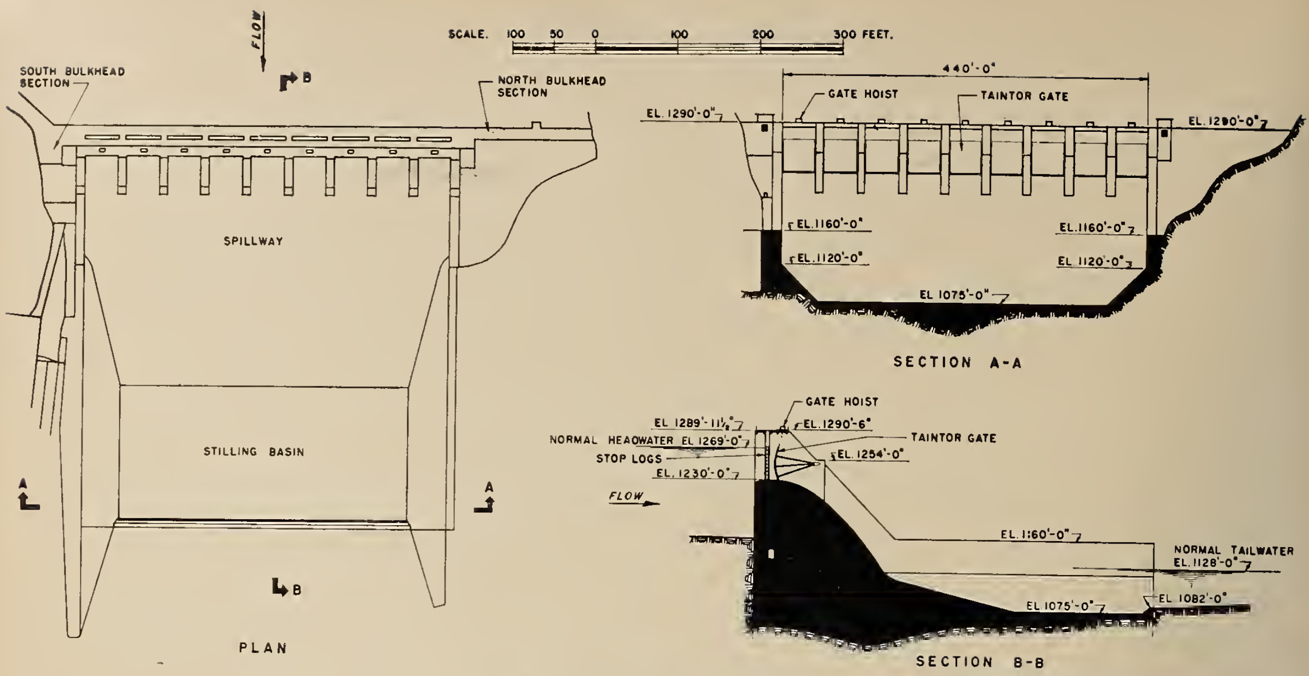

Fig. 5. Main Dam—Elevation and Section

Discounting the development of storage at upstream sites, for the immediate future at least, the following flow conditions pertain:

(a)—The minimum recorded flow in the Kabul River is 4180 c.f.s.

(b)—The minimum recorded 7-day average is 4380 c.f.s.

(c)—The minimum 28-day average is 4800 c.f.s.

(d)—The maximum recorded flow in the Kabul River is approximately 200,000 c.f.s. It is thought, however, that one year when the gauge was lost the flood discharge may have reached a figure of the order of 225,000 c.f.s.

A flow duration curve for the Kabul River, plotted from the records of the past 50 yr. follows:

Flow Equalled or Exceeded	*Percentage of Time*
24,000 c.f.s.	34
16,000 c.f.s.	44
12,000 c.f.s.	50
10,000 c.f.s.	55
8,000 c.f.s.	63
7,350 c.f.s.	70
7,000 c.f.s.	86
6,000 c.f.s.	95.5
4,180 c.f.s.	100

Power

Four hydraulic turbine-generating units are installed and provision has been made for the future installation of two more. Each vertical 55,000 hp. reaction turbine is coupled to a 40,000 kva. vertical water-cooled generator.

The 160,000 installation will be able to maintain power output at 100% daily load factor, in accordance with the following power duration curve:

Power Equalled or Exceeded	*Percentage of Time*
160,000 kw.	15
150,000 kw.	35
140,000 kw.	44
120,000 kw.	52
100,000 kw.	57
80,000 kw.	68
74,000 kw.	85
70,000 kw.	90
63,000 kw.	95
46,000 kw.	100

In an average year this installation could produce, at 100% daily load factor, 1,010,000,000 kwh. A fifth 40,000-kw unit could produce an additional 130,000,000 kwh; a sixth unit an additional 100,000,000 kwh.

Most of the network load will probably be a tubewell pumping load, that could be curtailed without damage to crops. It would seem reasonable to consider 6,000 c.f.s. (available or exceeded 95% of time) as the practical minimum flow. Also, as West Pakistan develops industrially the network load factor probably will change. It is of interest, then, to indicate the firm peak output at various load factors, again on the basis of four units of 40,000 kw. each.

Load Factor Percentage	*Firm Peak Output kw.*
100	60,000
90	67,000
80	75,000
70	86,000
60	100,000
50	120,000
46.5	129,000
41.8	143,000
40	150,000
37.5	160,000

With regard to future expansion of the Project, consideration of the preceding paragraphs on storage, flow and power appears to indicate that:

(a) While development of storage on the watershed could substantially raise the level of minimum firm power, it is not likely to be available in amounts that would influence the installation of units 5 and 6.

(b) The future installation of units 5 and 6 could be carried out at reasonable cost, but would only be justified by the growth of a substantial demand for secondary power.

(c) The future installation of units 5 and 6 might be justified by the future growth of the thermal stations to a level that would allow the availability of summer excess flows to reduce the thermal fuel requirements which are either imported or a depleting natural resource.

Model Studies

The location of the Warsak project in a narrow river valley or gorge created many site problems. Not the least of these was the handling of large volumes of water through a very constricted area under various limiting conditions.

Side Channel Spillway Model: This model (scale 1:100) was constructed during the preliminary examination of the project to test the practicability of a side channel spillway having a discharge capacity of 540,000 c.f.s. The spillway formed a part of a layout utilizing a rock-fill dam. Conditions of approach, of flow in the spillway channel, and of discharge into the river were examined.

As a result of the tests conducted, it was found that there would be a serious erosion problem at the toe of the dam, and that the depth of flow at the channel outfall would be great enough to prevent effective stilling action downstream.

Concrete Overflow Spillway Model: A general model (scale 1:132) was essential in the final design of the Warsak project. This particular model reproduced the concrete dam, the spillway, stilling basin, powerhouse and tailrace, and the river channel for a distance of some 4,000 ft. downstream. Many tests were carried out, many revisions made, and alternatives studied.

The tests on the overall project model indicated the conditions, both upstream and downstream, under which the spillway could pass approximately 540,000 c.f.s. In addition, the same study set the physical characteristics of the stilling basin just downstream from the dam.

The model allowed an accurate determination of the rating curve downstream from the stilling basin and powerhouse so that only the minimum freeboard was required for the tailrace and transformer deck located above the draft tube outlets. Studies of this model also helped to reduce the amount of excavation required downstream from the stilling basin and indicated a layout which would keep the tailrace channel substantially free from harmful wave action and its outfall free from blockage by material carried downstream. At one critical river constriction, the model studies indicated the extent and depth of excavation that would be required when the project was completed and a workshop located in this area could be dismantled. The studies of flow in the river downstream from the dam showed that substantial dumping areas could be made available, and that dumping in these areas would result in a considerable saving in the cost of hauling excavated materials.

Diversion Tunnel Inlets and Outlets: These models were built at scales of 1:48 and 1:72, and were made up to establish the most economical form of excavation at the inlet and outlet areas, and the percentage of recovery of head which might be expected at the outfall. The tests at the inlet were made to establish inlet losses and flow conditions, all of which could affect the upstream cofferdam. These tests resulted in considerable economies being made in excavation and also allowed the calculation of a diversion tunnel rating curve.

Tailrace Model: Tests on the tailrace model (1:40) were made to establish whether there was any hydraulic advantage in skewing the draft tube outlets and also to find the minimum width of tailrace channel which was hydraulically acceptable.

The tests showed that 0.6 ft. of head could be saved by skewing the draft tube outlets and that, by tapering the width of the tailrace, considerable excavation economics could be effected behind the powerhouse. These features were of course incorporated in the final design.

Cofferdam Model: A fairly comprehensive set of tests was carried out on cofferdam models (1:57) to determine the extent of protection which would be required to prevent erosion of the cofferdams upstream and downstream from the main dam area when they were overtopped during the spring floods. A considerable saving in time and costs could be achieved if a design could be produced which would allow such overtopping. The period for construction in the river is limited to about six months a year on the average, and any time saved would be a worthwhile gain if the river construction seasons could be limited to two. The tests carried out showed that, unless the concrete of the main dam could be raised well above the river bed before the spring floods, the downstream face of the upstream cofferdam would have to be protected by 6 ft. of masonry. The tests also showed that, although erosion of the downstream cofferdam would not be severe, it should never-

theless be protected by concreting the top 18 in. of rock fill.

It may be added that the cofferdams under flood conditions were twice overtopped safely and exactly as planned.

General Arrangement

The early investigation and field studies were carried out by Merz Rendel Vatten (Pakistan) Ltd. They submitted reports in 1949 and 1951 and recommended an underground powerhouse and a 235 ft. high rock-fill dam. The rock-fill dam was to have had curved chute spillways at either end and a downstream berm was to accommodate an outdoor switching station.

As an alternative MRV(P) Ltd. suggested a 230 ft. high concrete dam with a surface powerhouse at the toe.

Subsequently H. G. Acres & Company Limited investigated five alternative schemes and estimates of relative costs and construction periods were prepared. These were:

Scheme A—Rock-fill dam and under- ft. diam. diversion tunnels, one side channel spillway. This was essentially the arrangement proposed by MRV (P) Ltd. in 1951.

Scheme B—Rock-fill dam and surface powerhouse, three 50 ft. diam. diversion tunnels, one 35 ft. diam. power tunnel, one side channel spillway.

Scheme C—Concrete gravity type dam and underground powerhouse, one 35 ft. diam. diversion tunnel, overfall spillway controlled by nine sluice gates.

Scheme D—Concrete gravity type dam and surface powerhouse downstream from dam, one 35 ft. diam. diversion tunnel and one 39 ft. diam. power tunnel, overfall spillway controlled by sluice gates.

Scheme E—Concrete gravity type dam, with integral surface powerhouse at the toe. One 35 ft. diam. diversion tunnel. Two chute spillways on either bank of the river.

As a part of the project common to all the schemes, the south bank contained a 3.5 mile long, 9 ft. diam. irrigation tunnel, this tunnel to feed a canal system to irrigate approximately 100,000 acres of arid but fertile plain in the Vale of Peshawar.

Scheme E did not offer any financial advantage, but did appear to have several disadvantages compared with the other schemes. It was therefore not considered any further.

Finally Schemes A, B, C and D were presented, through the Colombo Plan Administration, to the Government of Pakistan, Scheme D being recommended. This scheme is shown on Fig. 3, 5 and 8.

Early in January 1955 the Government of Pakistan approved Scheme D, and the design and construction proceeded on this basis with minor variations. From an engineering viewpoint, Scheme D is fairly straightforward. Flood waters are handled efficiently, diversion is relatively simple and the powerhouse work can proceed independently of conditions in the river bed.

Diversion

In the construction of most hydroelectric schemes one of the contractor's major problems is unwatering the site.

At Warsak any unwatering scheme was hedged about with vexing problems:

(a)—The rock is poor and badly jointed;

(b)—The gorge is narrow;

(c)—The overburden in the river was known to extend to depths of 40 ft.;

(d)—The river is very "flashy";

(e)—The time to do work;

(f)—It was necessary either to overtop the cofferdams or replace them over two or three flood periods.

In order to render construction virtually independent of river flow conditions, three diversion tunnels, each 50 ft. in diam. inside the concrete lining, would have been required. The cost was estimated at $15 million based on 1954 prices. For a project with an earth core rock-fill dam, this procedure would have been necessary to avoid the hazard of overtopping and washing out the partially completed dam. For a concrete dam the situation is entirely different. Under such circumstances the flood waters can safely be passed through the partially constructed dam and the cofferdams either overtopped or replaced. The only diversion capacity required would then be the flow during the working season in the river.

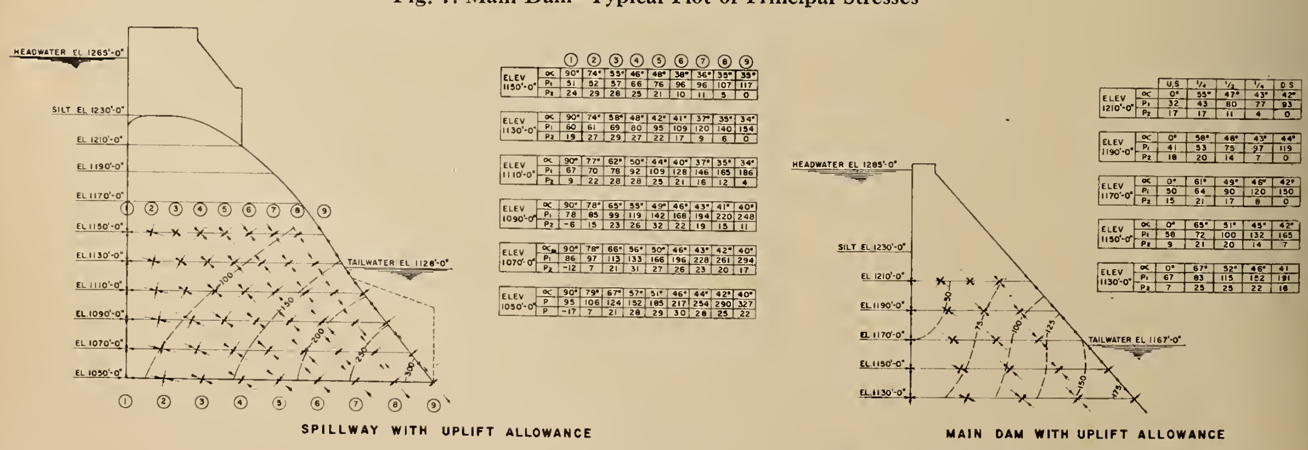
The costs associated with complete unwatering, the hazard of overtopping the unfinished dam, and the extended schedule, were the principal factors which led to the adoption of Scheme D.

Diversion Tunnel: As shown on Fig. 3. the unwatering scheme consists of one diversion tunnel with three earth and rock-fill cofferdams. This diversion tunnel was nominally of 35 ft. diam.

From portal to portal the diversion tunnel is approximately 1700 ft. long. In addition, the open-cut inlet and outlet channels are each several hundred feet long. Except for the transition section at the inlet, the tunnel was driven from the outlet end. The rock throughout was of quite poor quality; it was necessary to use 8 in. steel sets at 4 or 6 ft. spacings over the entire tunnel length.

The concrete tunnel lining was placed with the use of travelling steel forms supplied by Blaw-Knox. First the invert was placed using transit-mix trucks, then the side and arch concrete was placed by pumpcrete methods. A very smooth surface finish was obtained, but it was necessary to grout the crown of the arch to fill the inevitable voids

Fig. 7. Main Dam—Typical Plot of Principal Stresses



that occur at this point.

Before the lining was placed, a grout cut-off curtain was established completely around the tunnel perimeter. This curtain was so located as to be continuous with and form a part of the main dam grout curtain. It is also at the location of the permanent concrete plug that finally blocks the tunnel. Closure of the diversion tunnel is effected by steel head gates operated from a concrete tower above the tunnel intake. Two closure gates are used and their hoists are located on the tower deck at elevation 1257. The gates will be salvaged after use and one of them adapted for use as the permanent head gate of the irrigation tunnel on the south bank of the river.

Cofferdams: There are three main cofferdams. Two of these are in the river bed enclosing the area of the dam and stilling basin. The third is located parallel to the river and permits the uninterrupted construction of the powerhouse.

This powerhouse cofferdam was constructed of earth and rock fill with the top or crest at elevation 1155. This fill rests on overburden which in turn overlies jointed rock. A grout curtain was established in the overburden and to some depth in the rock. That this has been very successful was evidenced by the small amount of seepage into the powerhouse excavation.

As mentioned earlier, the river cofferdams have been designed to be overtopped by the annual floods. Many special problems resulted from this decision which could only be solved by model studies in the hydraulic laboratory. Fig. 4 illustrates the cofferdam resulting from these studies and used at the site.

The first phase of diversion comprised the construction of two rock fills across the river at the location of each cofferdam, thereby diverting a large proportion of the flow through the diversion tunnel and at the same time reducing the velocity in the water contained between the two rock fills. This space was then filled with selected earth materials finally closing off all river flow. The upstream cofferdam was then trimmed to shape and capped with a combination of heavy riprap, masonry and concrete.

The downstream cofferdam to some extent protects the upstream one by backwater effects. It was, therefore, felt that extra precautions should be taken in addition to the masonry and concrete capping. To this end, two lines of sheet piling were driven to prevent erosion at the top and scour at the toe.

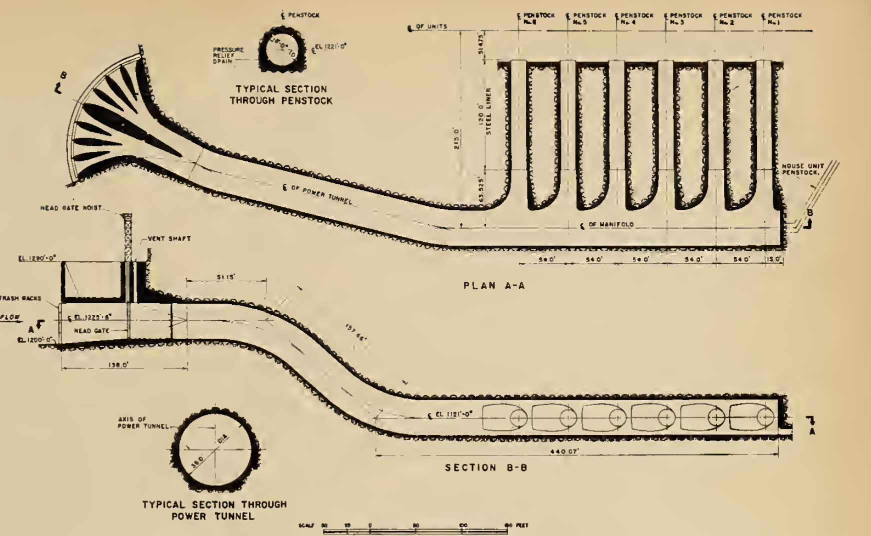


Fig. 8. Intake, Power Tunnel and Penstocks

Once the lowest blocks of the dam had been built to elevation 1130 and the stilling basin was complete, the cofferdams could be abandoned except that the downstream one will be useful until the tailrace plug is excavated. After this the lower cofferdam must be completely removed.

The Main Dam

As a result of the preliminary studies, the dam finally selected for the Warsak project is a straight gravity type concrete dam. The central, or river section, has an overall spillway controlled by nine 40 ft. radial gates.

The deck of the dam is at elevation 1290, or 5 ft. above the forebay level for the maximum design flood of 540,000 c.f.s. The normal regulated headpond level is at elevation 1269. The maximum height of the dam is 250 ft. The general arrangement and typical cross sections through the dam are shown on Fig. 5.

Immediately downstream from the toe of the spillway a stilling basin has been constructed to dissipate the energy contained in the water passed over the dam at flood time. This stilling basin was the subject of extensive model tests in the hydraulic laboratory to determine effectiveness, shape dimensions, elevations, and downstream scour. The model was tested for all flows up to the maximum design flood of 540,000 c.f.s., and operated in a satisfactory manner under conditions of uniform entry flow.

At the main dam flood waters passed over the cofferdams and through a temporary gap in the dam.

Conditions of Loading for Dam Design: (1)—Water Levels—The regulated headwater will be held at elevation 1269 feet with the tailwater at elevation 1128 feet.

In times of maximum flood the headwater level is taken as elevation 1285 ft. and the tailwater at elevation 1167 ft. For the spillway section under these conditions the hydraulic jump reduces the tailwater elevation to 1128 ft. The reservoir empty condition is also considered.

(2)—Uplift—This is included in all stability calculations, and stresses are considered with and without uplift. It is assumed to act over two-thirds of the area of the section and to vary linearly between the full headwater pressure at the heel and the full tailwater pressure at the toe.

This assumption should be conservative, as the dam as designed will have an extensive grout curtain below the inspection gallery. This grout curtain will extend approximately 0.75 times the head below the dam. Immediately downstream from the curtain a system of drain and observation holes will be drilled into the rock.

(3)—Silt—Silt or sediment carried by the flood water will be deposited in the reservoir and is assumed to build up to elevation 1230 ft.

(4)—Earthquake—As the Warsak project is located in an area with a history of fairly heavy earthquake shocks, a conservative assumption is justified in regard to the acceleration factor. In this case, for the inertia of the structure, the ratio of earthquake acceleration to acceleration due to gravity is taken as 0.15. This force is taken to act at 0.4y from the bottom of the section.

The table in Fig. 6. illustrates a typical tabulation of results for one section and one case of loading. Fig. 7. illustrates the plotting of principal stresses, together with contours of equal stress.

Consideration of Results: Stability—

The lowest value of the factor of safety against overturning is 1.41, and this occurs in the spillway section. This is due to a condition which includes all known forces, some of a transitory nature, so that the dam is considered safe against this form of failure.

The lowest value of the factor of safety against sliding also occurs under this same loading condition and is 5.

Stresses due to Differential Deflection—The steep banks of this dam give differences in the depths at each end of a 40 ft. block of the bulkhead section in the order of 35 ft. This results in a difference in the deflections at the ends of the block giving stresses due to the twisting action induced.

These stresses were investigated and the maximum found to be 63 p.s.i. in shear.

Dam Equipment — Discharge through the dam is controlled by a set of nine taintor gates, supplied by Canadian Vickers Limited, of Montreal. The gates consist of a skin plate, curved to a 48 ft. radius, reinforced by horizontal and vertical ribs supported on three main horizontal girders. These girders are, in turn, supported at their outer quarter points by two radial arms. The downstream ends of the radial arms terminate in heavy adjustable trunnions. The trunnion loads are carried back into the piers by a system of anchor bars welded at their upstream ends to the structural framework of the emergency stop-log embedded parts.

Curved roller paths, music note seals, side guide rollers, etc. are provided. Each gate is provided with an individual hoist located on a bridge structure at the level of the dam deck.

In addition to the taintor gates, one complete set of steel emergency stop-logs has been provided. These will allow any taintor gate on the dam to be unwatered for inspection, maintenance or repair. The stop-logs will be handled by mobile equipment operating on the dam deck.

Intake, Tunnel and Penstocks

The power facilities for the Warsak project, consisting of intake, power tunnel, penstocks, powerhouse, and tailrace, are all located on the south bank of the Kabul River. They are adjacent to, but independent of, the main dam structure. Their arrangement and typical sections are shown on Figs. 3, 8, and 9.

Intake and Tunnel: The reinforced concrete intake to the power tunnel is a fan-shaped structure, with its floor at elevation 1200. It is designed to draw water from the reservoir with minimum hydraulic losses. (See Fig. 8.)

The structure consists of nine converging piers supporting trash racks. Six of the piers are gradually eliminated by convergence. The two steel head gates, each 39 ft. high by 17 ft. wide, are operated by individual motors located on top of a steel superstructure. As butterfly valves have been located at each turbine scroll inlet, it was not considered necessary to supply an emergency release button for the head gates in the powerhouse control room.

The steel trash racks, placed in fabricated steel guides, are located at the intake pier noses. They have been designed to allow their upstream surfaces to be completely sheeted. The cost of strengthening the rack bar supports to this extent is but a very small fraction of the costs that would be incurred in constructing a 70 ft. high cofferdam in the intake approach to accomplish the same unwatering.

The main power tunnel in the south river bank is circular in section and 39 ft. diam. inside the concrete lining. There are two vertical and one horizontal bends which align the tunnel parallel to the powerhouse substructure. The lower section is designed as a manifold with 6 penstocks leading to the turbine scroll cases.

Careful studies and model tests were conducted to obtain the best possible shape of the junction between the power tunnel and penstocks.

Penstocks: The water is led from the power tunnel through a concrete transition section to the steel penstocks. These steel penstocks, each 18 ft. diam. by 120 ft. long, are concreted into individual tunnels in rock.

The steel shell thickness varies from ⅝ in. at the inner end to 15/16 in. at the point of connection to the butterfly valve. The design assumed that at the inner end half of the liner the load is transferred to the rock, there then being a straight line variation until the steel shell carries all the load at a point 30 ft. in from the face of the excavated rock cliff.

The plates and cans were assembled in a yard near the colony and welded by Pakistani welders trained on the spot. All the work was carefully inspected using an isotope source. The welded cans were then assembled in the tunnels and four 4 in. diam. drain pipes were erected parallel to the penstock and spaced around the circumference.

Upon completion of the penstock grouting program holes were drilled from the penstocks through the concrete between the shell and drains and on into the drains, the penstock openings then being closed with steel plugs.

The outer ends of the penstocks are controlled and closed by butterfly valves 18 ft. diam. Perhaps the only unusual feature of these rather large valves is that they are operated by vertical spindles. This design was selected to minimize excavation and concrete by placing the valves as close to the turbines as possible and still keep turbulence and hydraulic losses to a minimum.

The Powerhouse

Generating Building: Studies indicated that at this site several millions of dollars could be saved by constructing an external powerhouse on the south bank of the river rather than an underground powerhouse which had been originally contemplated, principally for reasons of security. The external arrangement which was ultimately adopted is shown on Fig. 9.

The powerhouse is of conventional design except for some special features necessitated by location or the cost of shipping materials all the way from Canada. A few of the special features are listed as follows:

(a) The draft tubes are at 60° to the powerhouse centreline instead of the usual 90°. This alignment was adopted due to the limited space available for the tailrace.

(b) The generator floor, located at the top of the generator stator, is 18 ft. below the landing area and access road, and about 15 ft. below the river level at the maximum design flood of 540,000 c.f.s. This floor is about the level of the estimated maximum flood of record, some 225,000 c.f.s.

(c) The superstructure columns are of reinforced concrete up to the top of the crane rail, and the crane rails were precast and lifted into place.

(d) The superstructure above the crane rail is of steel rigid-frame design, with a concrete roof slab.

(e) The concrete roof is of the double slab type with an intermediate waterproof membrane. It is designed to carry the switching station and concentrated truck loads, and in addition to carry a uniform triangular rock load resulting from a theoretical rock slide from a side gully or nullah.

(f) Perhaps the most unusual feature of the powerhouse superstructure is a system of anchored buttresses along the upstream wall. Up to the level of the generator floor at elevation 1149 this south wall is concreted in contact with the rock excavation. Above this level it is free standing. Some apprehension was expressed that a progressive spalling of rock might release large pieces to bear against the upstream side of the south wall. As insurance against this condition, and to place the rock in compression, a series of 5-foot thick buttresses were constructed between the wall and rock. These were spaced at 18 ft. centres, and through each prestressed anchors were located 120 feet into the rock. These anchors were stressed for a 50-ton load with a yield point at 80 tons. In the event, this anchor system was extended to include the west end wall of the powerhouse. The buttresses also served to support a cable and ventilation gallery, and the deck between the rock and powerhouse wall forms a part of the switching station approach area.

The access road from the Vale of Peshawar and the housing colony follows the south shore of the Kabul

River to an area which gives access to the tailrace deck, the powerhouse main door, the control section, and a branch leads to the switching station. The transformers can be moved along the tailrace deck and into the powerhouse for repair.

The general appearance and layout of the powerhouse interior is clearly shown by Fig. 11.

Erection Bays: The eastern 75 ft. of the powerhouse proper is an erection bay or landing area, at elevation 1167. Here equipment and materials are unloaded from trucks and trailers. Subassemblies can be put together prior to being moved into position in the turbo-generator pit. Shaft hatches and transformer detanking hatches have been provided.

There are four floors in the reinforced concrete substructure below the erection bay:

(1) At elevation 1149 the service area comprising machine shop, repair area, battery room and service water filtration.

(2) At elevation 1132, areas for building service equipment, and the oil room.

(3) At elevation 1111, the area for the two house units.

(4) At elevation 1098, a small area for the valves controlling flow to the house units and for unwatering the power tunnel.

Control Building

The control building is located at, and attached to, the east end of the powerhouse.

The lower floor at elevation 1167 contains the main entrance and reception area. The cable terminal room and operators' locker rooms are located in behind with convenient access to the powerhouse. The floor above, at elevation 1182 ft. 5½ in., contains the control room, operators' offices, and a visitors' inspection room, from which the control panels can be seen on the one side, and which looks out over the powerhouse interior on the other side.

The third floor at elevation 1202 ft. 2½ in. has a large isolated room for the control building air-conditioning equipment. In addition there are four general offices for clerical and administrative forces.

The fourth, or top floor, at elevation 1214 ft. 2½ in., is somewhat unusual for a powerhouse. The front part consists of a large visitors' lounge for government officials. This room has been symbolically finished in woods originating in Canada and Pakistan, and has a large picture window overlooking the dam, reservoir, and the Khyber hills. Behind the visitors' lounge there is a small apartment with two bedrooms, living room and kitchen. This apartment is for the convenience and use of senior government officials when visiting or inspecting the project.

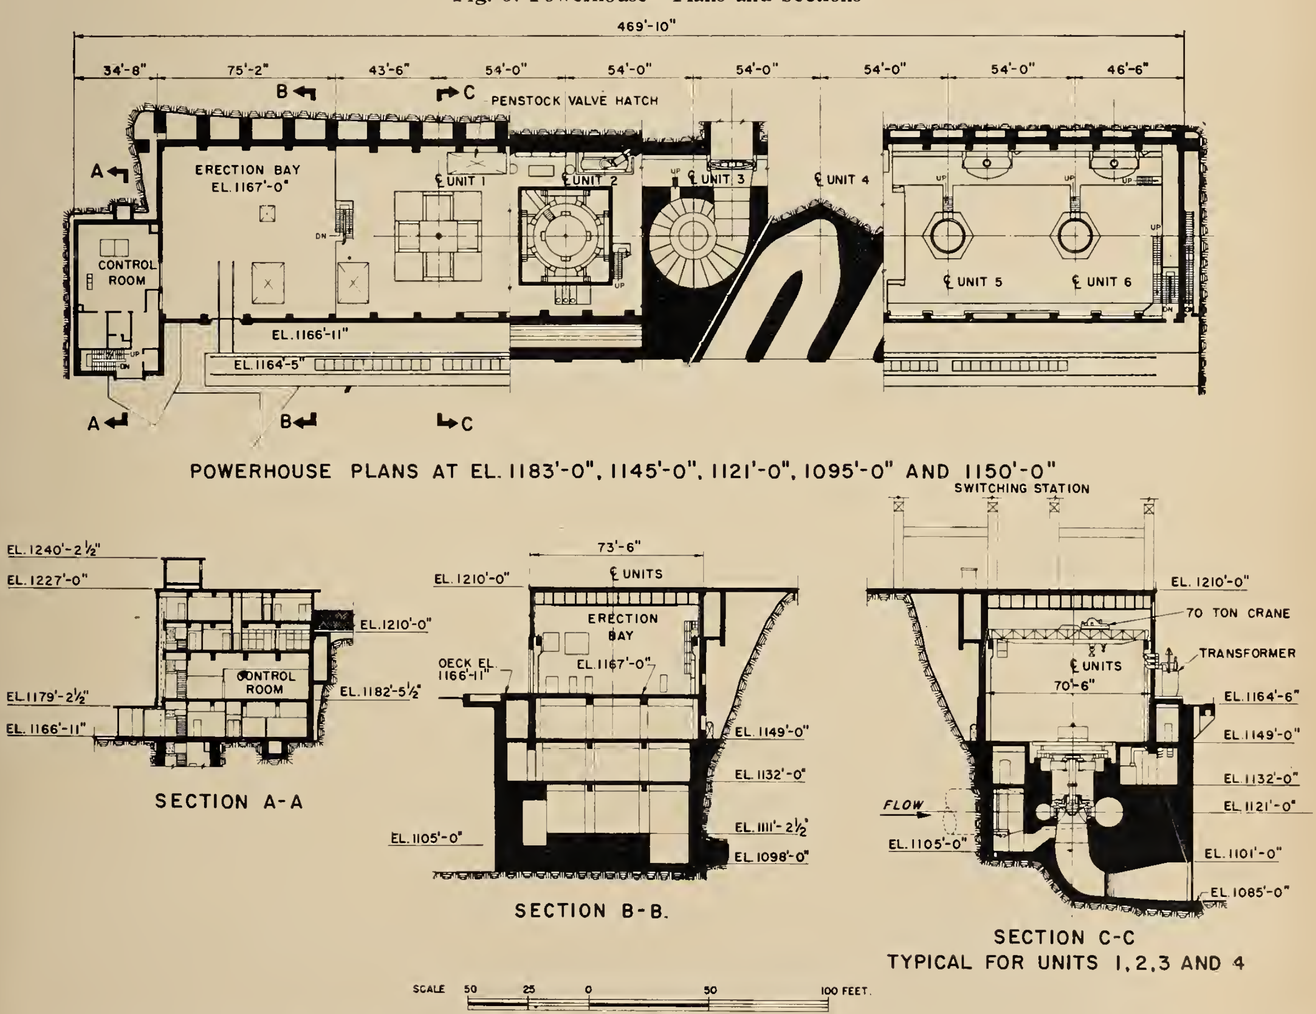
On the roof above the passenger elevator hoist and control gear are housed in a penthouse. All floors are accessible by stairs or elevator, and all are supplied with the usual facilities such as washrooms, lighting, terrazzo floor, air conditioning, etc.

Irrigation Tunnel

The Warsak project can well be described as a multipurpose one in that irrigation is an important, though secondary, feature. Two irrigation systems are contemplated, a major effort to the south and a much smaller layout on the north bank.

South Bank Irrigation Tunnel: At the time that Warsak was approved

Fig. 9. Powerhouse—Plans and Sections



for Colombo Plan participation, only irrigation to the south was contemplated. The diversion of irrigation water, 505 c.f.s. in summer and 350 c.f.s. in winter, was to be accomplished by a 9 ft. diam. lined tunnel about 3½ miles long. The tunnel outlet was to be at as high an elevation as practicable, to command as much as possible of the area between Peshawar, Jamrud Fort and Dera Kohat.

The area to be irrigated belongs to the Mullagori, Afridi and Mohmand hill tubes, and the irrigation end of the project will allow the settlement of these tribes on useful productive small farms. This additional acreage will also make the area of the former North-West Frontier Province almost self-supporting in regard to food.

Studies were made of several tunnel alignments, bearing in mind geology and costs. The layout selected has the intake structure located a few hundred feet to the west of the main power tunnel intake. The tunnel as finally constructed is 10 ft. diam. inside the concrete lining, has only one bend, is 17,100 ft. long, and has its outlet about four miles from the Warsak Colony in a southerly direction.

The intake is provided with coarse racks and is controlled by a steel headgate adapted from one of the closure gates of the temporary diversion tunnel. The air vent normally located just downstream from the headgate has in this instance been enlarged so that a jeep could be lowered into the tunnel for inspection and maintenance purposes.

The outlet end will be equipped with a regulating gate, also adapted from a previously used closure gate. A stilling basin will be constructed so as to allow low-velocity flow into the irrigation canals being excavated by the Pakistan Irrigation Branch forces.

North Bank Irrigation Tunnel: About two years after the job was under way, the appropriate Pakistani authorities decided that some irrigation facilities should be provided on the north bank.

Slots for a small slide gate and for racks were provided by an extension of block 13. A 3 ft. diam. steel pipe was embedded in the dam with the invert at elevation 1250. Beyond this point a 5 ft. diam. tunnel has been excavated for approximately a mile through the hills. This work is being done by the Irrigation Department.

Permanent Equipment

Under the terms of the intergovernmental agreement, the Canadian Government undertook to supply:

(a) "Electrical generating and related equipment (including dam gates and quantities of reinforcing steel) in amounts to be indicated to the Government of Pakistan as funds become available and, in addition, equipment and materials which cannot be made available by the Government of Pakistan."

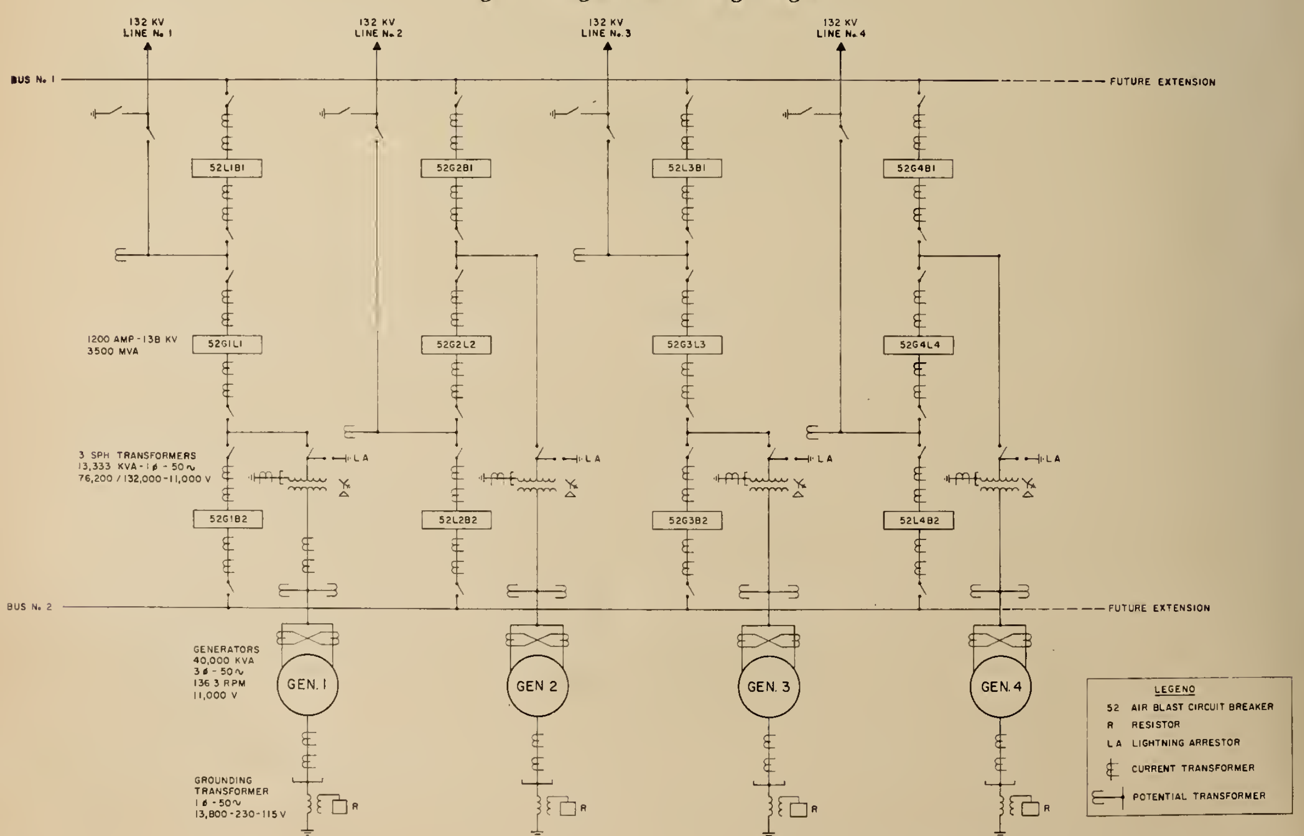
(b) "Construction plant to supplement construction equipment that may be made available by the Government of Pakistan . . ."

In the event, in order not to upset the Pakistan home markets and to speed the project, Canada supplied permanent equipment and materials except cement, and construction equipment and materials except the construction power generating units.

The turbines for this project are rated at 55,000 hp. at a head of 144 ft. and a speed of 136.3 r.p.m. To save time and to take maximum advantage of Pakistani welders trained on site, the scroll cases were preassembled in a special yard and lifted into place in large sections with only a few circumferential welds to be done in place. This procedure also allowed radiographic inspections to be made without interference with other construction operations.

The four vertical generators are type ATI-W-44 poles and are rated at 40,000 kva., 1.0 power factor, 136.3 r.p.m., 11,000 v., 3 phase, 50 cycles. The generator has been designed so that the rotor spider, shaft, and bearing bracket may be removed, leaving the rotor stacking and pole pieces in the pit. This in turn would allow dismantling and removing turbine parts and runner with a mini-

Fig. 10. Single Line Wiring Diagram



mum of disturbance. An extra bonus is achieved in that in this case the powerhouse crane capacity can be greatly decreased, the limiting tonnage to be lifted being governed by a butterfly disc and two quarter sections of body rather than a complete generator rotor. By this means the crane capacity was lowered to 70 tons.

The transformers are rated 13,333 kva., 55°C rise, type ONW, single phase, 50 cycle, 11,000 v. Delta—76,200/132,000 Y v. They are located along the tailraee deck on special pads. Single-phase transformers were specified rather than three-phase because of shipping difficulties arising due to weight and physical size.

The air blast circuit breakers are rated 138,000 v., 1200 amp., 3500 mva, 3 tank, 3 pole, and are located on the roof of the powerhouse together with the associated motor-operated disconnects, and switching station steel structure.

The main control switchboard is a combined benchboard and tunnel type duplex structure for control metering and relaying of both the main generating units, house service units and high voltage breakers. A separate cubicle for indicating alarm and various operating conditions is also located in the control room.

A station service switchboard containing the house unit circuit breaker equipment and station service distribution feeders is located in the erection bay area of the powerhouse.

The facilities provided in the control room allow the station operator to select either automatic or manual control of both the main and house service generating units. The automatic control provides for starting any unit by the operation of one control switch after the penstock valve has been opened. The unit selected will then be brought to synchronous speed and connected to the system. Automatic shutdown will disconnect the unit from the system and close the penstock valve once the turbine wicket gates are closed. Load control of all the units is done by the operator. Manual operation from the control room allows the operator to initiate each step in the startup or shutdown.

Protection of the equipment is designed to allow each main generator and transformer to operate as a unit. The protection of the 138 kv. lines leaving the switching station is a separate entity from this project.

Fig. 10, single line wire diagram, outlines the electrical system.

The nine taintor sluice gates were each 40 ft. high by 40 ft. wide clear opening. The maximum lift of the gate lip is 50 ft. The set of nine gates can discharge approximately 320,000 c.f.s. at normal headpond level. The spillway, however, is designed for a maximum flood of 540,000 c.f.s. with surcharge on the reservoir levels.

The taintor gates will be operated from a console in a control house at the south end of the dam. A timer on the console will operate the gates in a fixed sequence. First the centre gate will rise 1 ft., then the next two, and so on until all gates are up 1 ft. At that time the centre gate will rise a second foot and the whole sequence will be repeated in steps until all gates are fully open. This perhaps elaborate procedure was considered advisable because of the high discharge per foot width of spillway, to operate the stilling basin at maximum efficiency, to minimize downstream erosion, and maintain optimum tailrace conditions.

Most of the rest of the permanent equipment is fairly standard. All items were inspected on behalf of the Canadian Commercial Corporation by the Department of National Defence Inspection services prior to shipment from Canada.

Construction

A Canadian general contractor, Angus Robertson Limited of Montreal, was retained in the summer of 1955, and did an impressive job of quickly assembling several shiploads of construction equipment and preventing delay. He supplied a contractor's complete supervisory staff, plus many categories of skilled workers. It must be remembered at all times that the Warsak project was in an undeveloped tribal area and that all special skills had to be trained. The contractor's problems were covered in a companion paper prepared by Mr. C. G. Kingsmill.

Organization and Acknowledgments

To one accustomed to consulting assignments from private owners or power commissions, the organizational requirements of doing similar work under the Colombo Plan may seem unduly cumbersome. Two factors must, however, be continually kept in mind. In the first place, any Colombo Plan project involves two separate governments and, in the second place, most government operations are necessarily more complex due to their very nature and to the many departments, divisions, or agencies involved.

The complexity unquestionably increases the time and paper work and naturally increases the total cost.

At the site, where the work was actually carried on, there were three groups represented by staff on the job: the consultants, the contractors, and the Pakistanis (Warsak Dam Project Organization). The pace of work was probably faster than would normally prevail in such a tropical climate, but considerably slower than that of similar work in Canada.

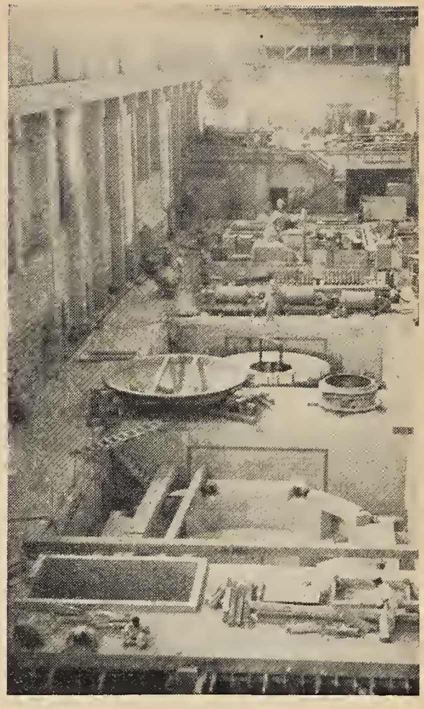


Fig. 11. Interior of the Warsak Station. Erection area at far end.

We had to deal with six Canadian and eight Pakistani government bodies or agencies. Even though at times there may have seemed to be too many cooks, an overall desire prevailed to do a good job with utmost cooperation.

For a project such as Warsak it is impossible to acknowledge the assistance given by all who contributed to its planning, organization, design, supervision, and construction. The author of this paper would like to thank all who contributed to Warsak, whether their names appear below or not.

THE DRAINAGE PROBLEM ON A NEWSPRINT MACHINE

A description is given of the Drainage Tester developed by Anglo Paper Products Limited to investigate the drainage properties of newsprint stock under conditions closely simulating the conditions on an actual paper machine. The value of the drainage resistance coefficient is determined using average rates of flow and average values of suction. Results of other investigators using different types of testing devices are discussed, and some results obtained with an apparatus similar in principle to the Anglo Paper Products tester are compared with the results of this investigation. Finally, the experimentally-determined drainage coefficients are compared with those found on the paper machine itself.

FIG. 1 shows in line form the wet end of a typical Fourdrinier paper machine on which almost all of the drainage occurring in the table role section is due to the suction produced hydrodynamically under the wire where it passes over the supporting table rolls. The theory of this process has been the subject of several papers since 1956. These theoretical treatments have considered the process of draining water as a specialized form of filtration, and equations have been evolved relating the suction produced by a table roll to the drainage resistance of the fibre mat on the wire.

It is possible, therefore, to compare theory and practice in a number of ways, according to the known experimental data:

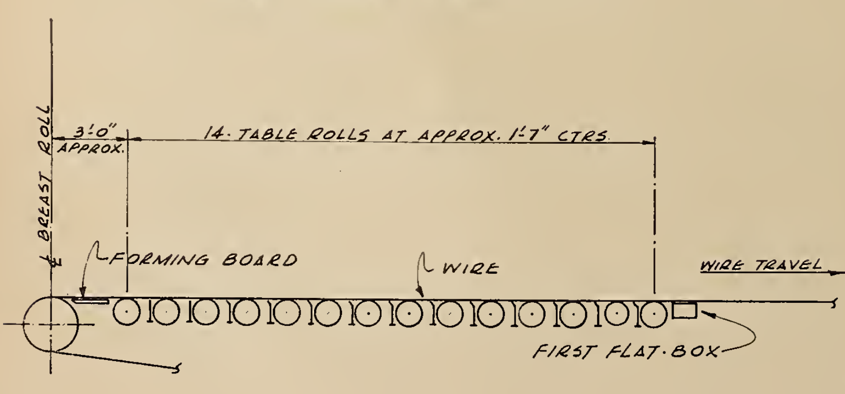
(a) if the exerted suction is directly measured, and discharge quantity from a table roll known, the distribution curve for the suction which theory predicts can be compared directly with that measured;

(b) if the quantity drained at a roll is measured and the theory assumed to be correct, drainage coefficients can be calculated and then compared, after suitable weighting, with those determined from laboratory experiments.

In practice the total drainage of the wire table is measured, and a laboratory determination of drainage resistance can be used if certain assumptions are made so that the total amount drained from all table rolls can be compared with that measured.

The results obtained can then be used to predict performance under different machine conditions; for example, changes of machine speed or stock temperature. In the present treatment only the end results of the major theories advanced are considered.[5]

Fig. 1. Typical Fourdrinier Wet End.



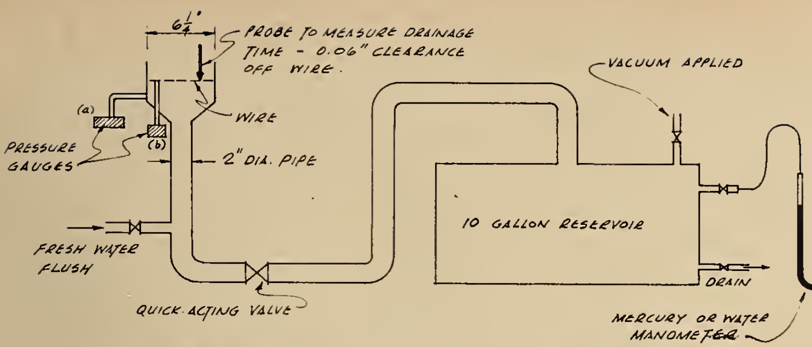


Fig. 2. Diagramatic sketch of A.P.P. drainage tester.

If the drainage resistance of the fibre mat can be accurately determined then the drainage of actual paper machines can be compared with that predicted from theoretical treatments and laboratory measurements, and ultimately, for different stocks, accurate predictions of the drainage capacities of any given paper machine will be possible.

The laboratory determinations so far described in the literature have the following weaknesses of (i) using very dilute solutions, rather than consistencies ordinarily used on the paper machine, and (ii) excessively long drainage times which are not realistic compared to operating conditions.

Because of these weaknesses no correlation between laboratory-determined drainage resistances and paper machine operation is possible. Accordingly, a new type of drainage testing machine was developed by Anglo Paper Products Limited*, which works on the principle of a suddenly-applied vacuum at the underside of a wire on which is a sample of paper stock of the consistency used on the paper machine. Fig. 2 shows a diagrammatic sketch of this drainage tester.[1] (See Appendix 1.)

It is the purpose of this paper to describe measurements made on this Sheet Machine, enabling the drainage resistances to be determined, and the results of the application of these resistances to paper machine data.

Experimental

The operation of the Sheet Machine may best be described by reference to Fig. 2.

The apparatus was designed so that a controlled suction was applied at all times; with the quick-opening valve to the vacuum chamber closed the section of piping between valve and wire is filled with water to the level of the wire. The vacuum chamber is then evacuated to the required vacuum and the pulp mixture is added to the top of the wire and agitated continuously. The agitator is then removed and simultaneously the valve to the vacuum chamber is opened. The probe of the electronic apparatus registers the liquid level throughout the draining process, thus giving a measure of the time during which drainage takes place, as well as the actual drop in level which occurs.

*J. Mardon and B. Wahlstrom.

A typical suction-time recording is shown in Fig. 3 in which the upper plot shows the drainage time (from the change in liquid level to complete drainage) and the lower plot shows the change in pressure. It may be noted that complete drainage is reached at the point where maximum suction is recorded; following this, air is pulled through the wire and the applied vacuum is gradually lost until atmospheric pressure is finally attained once more.

Drainage tests on the Sheet Machine have been photographed using a Fastax camera in order to check the electronic measurements visually[13]. For photographic study of these tests a ruler was placed upright in the stock container so that the actual depth of the stock could be seen on the film. Analysis of the film on a frame-by-frame analyser enabled one to check the time of drainage, although of course, no check could be made on the applied vacuums since the speed at which the film was exposed (1,000 frames per second, usually) was known. In the actual analysis of the films it was found that the presence of the ruler was of little help, and that more accurate readings could be made using the cross-hairs of the analyser with the ruler serving only as a means of obtaining the proper scale. Fig. 7 shows a typical plot of film results.

Analysis of the suction-time recordings may be done as follows (for simplification, newsprint stocks only are considered in this paper)[7]. It should be noted that for purposes of plotting suction versus drainage time the peak suction recorded on the trace should not be used, but rather the *average* suction value which is determined, with reference to Fig. 4, by:

$$S(\text{ave. over time } t/x) = \frac{1/2 \times (t/x) \times S_{\max}}{t/x} = \frac{S_{\max}}{2}$$

$$S(\text{ave. over time ``}t\text{''}) = \frac{1/2 \times S_{\max}(t/x) + 0(t - t/x)}{t} = 1/2 \times S_{\max}(t/x) \times 1/t = \frac{S_{\max}}{2x}$$

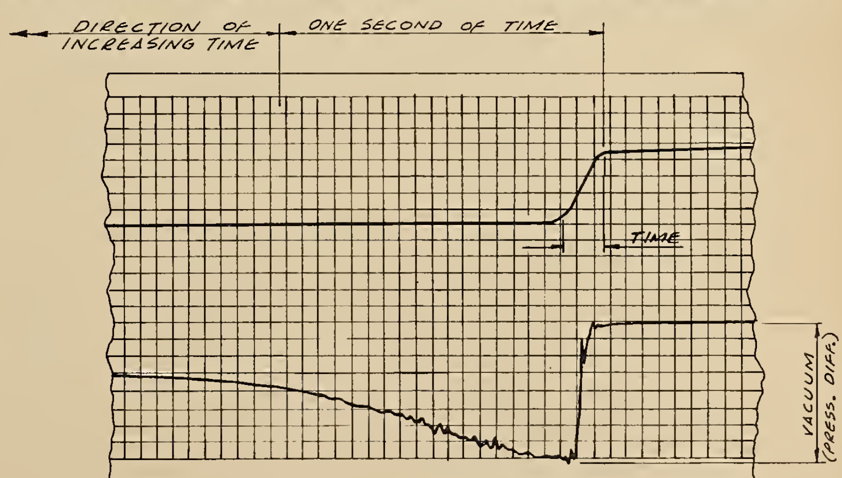
where:

x = any integer greater than one

$S_{\max}$ = peak suction recorded

The above assumes a linear drain-

Fig. 3. A typical drainage recording. (*Note*: **this is a tracing of an actual recording.**)



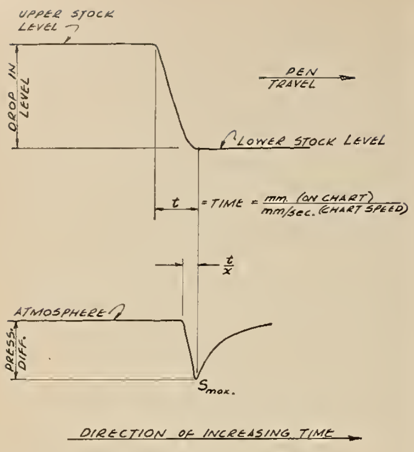


Fig. 4. Analysis of drainage recordings.

age rate curve; this assumption may be safely taken for the present discussion of tests on newsprint stock.

The laboratory determination of drainage resistance of a pulp stock is accomplished by calculating the reciprocal of the resistance, or the drainage coefficient. It has been found that depending upon whether the flow through the wire is laminar or turbulent this coefficient appears in the relationship:

$$W^{\psi} = \frac{K}{\mu} \cdot S,$$

ψ being equal to 1 and 2, respectively, for laminar and turbulent flow.

where:

W = drainage *rate*
K/μ = drainage coefficient
S = Suction

In actual fact the value of "ψ", the power to which "W" is raised, probably lies somewhere between unity and two, since the flow is neither completely laminar nor completely turbulent.

In performing the drainage tests on the A.P.P. Sheet Machine one measures the time during which drainage takes place. If, at the same time, one knows the area of the mat through which the water drains, and the total amount of water drained is collected, it is possible to calculate "W", the average drainage rate through the mat of pulp.

$$\text{e.g.}\ -W = \frac{\text{quantity of water drained}}{\text{mat area} \times \text{drainage time}}$$

$$= \text{drainage rate (average)}$$

TABLE I

Results of Application of Taylor's No-Mixing Theory To A Paper Machine (Machine Speed U = 980 cm./sec.)

Roll No.	*Radius (cm.)*	*K/μ (cm³/dyne-sec.)*	*q (cc./sec.)*	$S_{ave.}$ *(cm. H_2O)*

Thus, having determined from laboratory results the value of "W" and simultaneously obtaining the suction exerted (by means of the electronic measuring devices) one may calculate the value of K/μ, the drain-

Fig. 5. Suction vs Drainage Time-Mixed Stock.

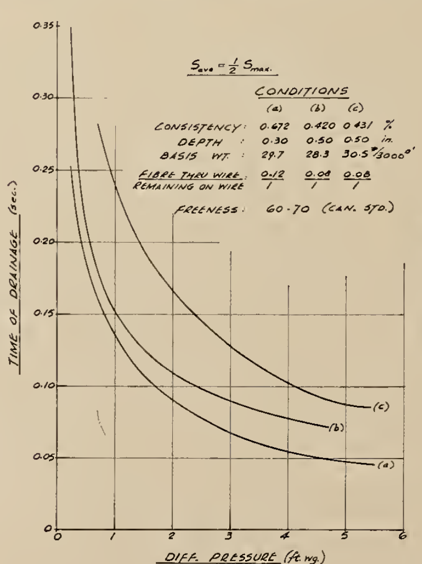

Fig. 6. Suction vs Drainage Time Headbox Stock.

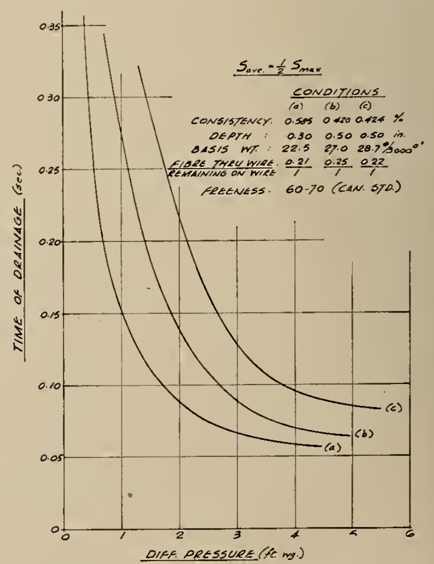

age coefficient.

This has been done using both mixed (in the laboratory) and actual headbox stocks, and an average value of $K/\mu = 12 \times 10^{-5}$ cm³/dyne-sec. will be used to illustrate a comparison with the drainage on an actual paper machine.

Discussion of Results

The results of a number of tests made on the A.P.P. Sheet Machine are plotted in Fig. 5, 6, 7 and 8 [1]. Fig. 5 and 6 represent plots of average suction versus drainage time for mixed and headbox stock respectively, where the average suction has been taken as one-half the peak suction recorded on the tracing.

For the headbox stock (Fig. 6) there appears to be an exponential decrease of time with pressure in every case; that is, a rapid decrease to about 1.5 ft. wg. of suction, then a slow rate of decrease of drainage time to about 3.5 ft. wg. and then very little change in time for further suction increase. The corresponding curves for mixed stock (Fig. 5) are more uniform in slope and do not exhibit such a markedly exponential change in drainage time. The exponential nature of the curves for both cases, however, is borne out by straight-line plots using logarithmic axes.

On each figure the ratio of stock going through the wire to that remaining on top is noted. For headbox stock, Fig. 6, this varies from 0.21/1 to 0.29/1, and for mixed stock, Fig. 5, it is much less, being between 0.08/1 and 0.17/1. Comparable figures obtained for an operational newsprint machine were between 0.41/1 and 0.51/1, which might indicate that the A.P.P. Sheet Machine is directly comparable with the wire part of a paper machine at the suction boxes, rather than at the first few table rolls. However, some discrepancy is definitely due to the upthrust of water through the wire on the upstream side of a table roll on the machine which disturbs the fibre mat already formed and so allows more fibre to drain through with the water.

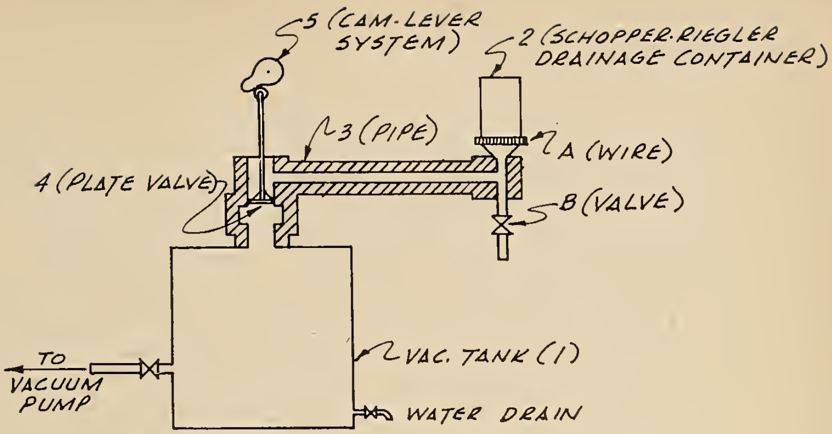

Fig. 8. Apparatus used by Müller Rid & G. Pausch.

Method: Drainage container (2) placed on wire (A) with valve (B) open and drainage occurs by gravity until no water drains off. Valve (B) then closed and valve (4) opened by cam (5), thus putting vacuum on bottom of sheet. By rapid valve opening some air enters tank (1), raising tank pressure, and thus quantity of air through sheet can be measured. By weighing sheet after removal from wire and find bone-dry weight percentage of water is found.

Regarding the time element, drainage times appear to be shorter for mixed stock than for headbox stock. This is due to the number of fines present in the latter which are absent in mixed stock.

Total times of drainage vary within the range of 0.15 to 0.30 seconds.

Comparison with Existing Literature

Part A: Numerous investigators have employed various types of apparatus to study aspects of the drainage problem. Bergstrom and Knell[8] used water only to determine the pressure drop across the wire by placing the wire at right-angles to the flow in a pipe, thus allowing continuous flow which is not possible on the A.P.P. machine, although the latter is superior when using stock.

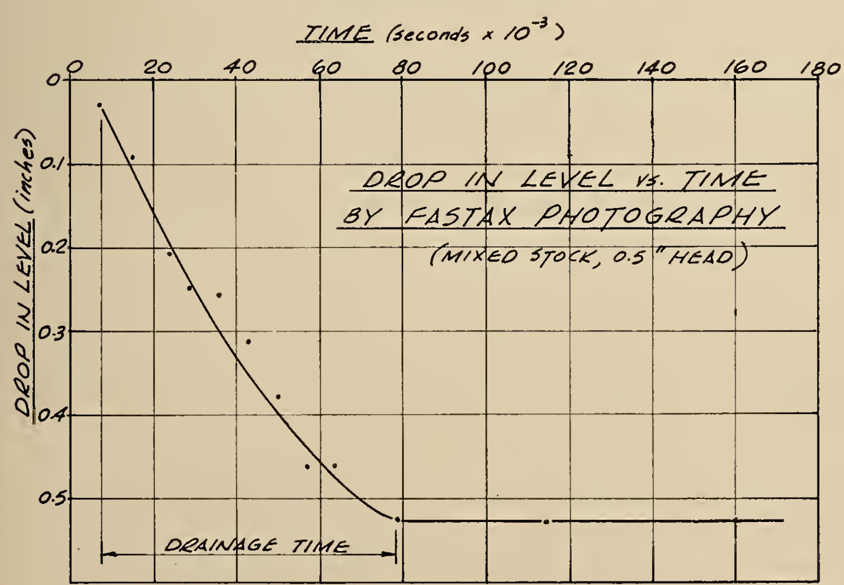
Corte[9] used apparatus similar to a Williams freeness tester to determine the relationship between stock quality, concentration, temperature and drainage time, but his times were very long and he used dilute suspensions draining by gravity alone.

Brecht and Rosenlaw[10] used an apparatus similar to that of Corte, but did not use stock in their measurements. Hanatchek[6] continued along the same lines, also using water.

Ingmansen, Whitney and Han,[11] and Hendry and Maynard[12] studied drainage resistances of pulp, but their apparatus entailed a long, slow period of drainage.

There is one set of results which will be compared with the A.P.P. curves. Muller Rid and G. Pausch[4] using the apparatus shown in Fig. 8 conducted drainage tests on various stocks. Their apparatus was similar in principle, if not in action, to the A.P.P. machine. These results are plotted in Fig. 9 along with the duplicated curves of Fig. 5 and 6, and appear to roughly parallel the bottom portion of the A.P.P. curves.

Fig. 7. Drop in level vs time by Fastax photography.



The total suction times are of the order of 0.20 seconds as compared with 0.30 seconds on the A.P.P machine, while vacuums are much larger than for the latter results.

Actually, these Rid-Pausch curves do not compare well with the A.P.P. results in view of the fact that the former investigators allowed drainage to proceed by gravity before applying any vacuum, and used much freer stocks than the A.P.P. newsprint stock. Although a considerable amount of drainage takes place under vacuum, the vacuum applied is extremely high (about four times that exerted by the A.P.P. machine) and so the two sets of results are not strictly comparable. Like the tests of other investigators mentioned above the method of Rid and Pausch does not approximate closely drainage on an actual paper machine, but is akin to the operation of the flat-box section. However, since the apparatus used resembles the Anglo Paper Products machine the above remarks are included.

Part B: If, for any paper machine, a material balance is available which gives the total drainage on the table roll section, then provided the average drainage coefficients corresponding to those on the wire can be obtained from laboratory measurements, a comparison of the predictions from theory of the total table roll section drainage can be made with this material balance.

Knowing this, certain forecasts can be made regarding changes in machine speed, stock temperature, etc.

This treatment has been applied to a newsprint machine with 14 table

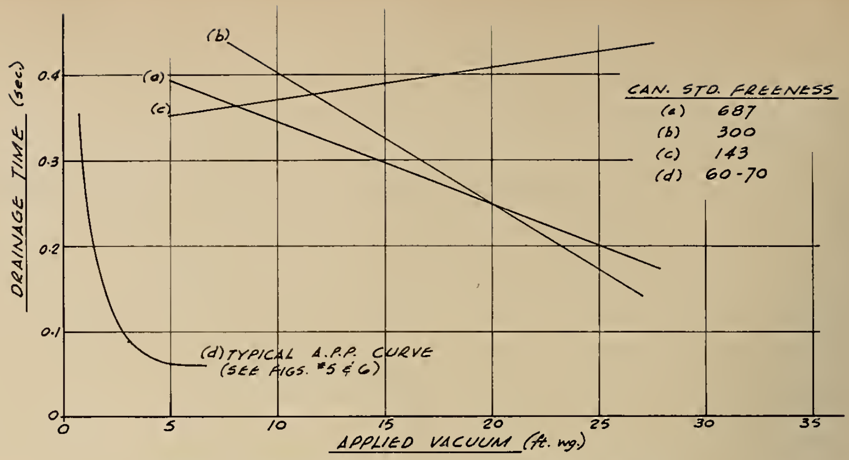


Fig. 9. Comparison of A.P.P. & Rid-Pausch results.

rolls, as listed in Tables I and II (see Fig. 1), and on which approximately 20% of the total drainage was at the breast roll and forming board.

Two theories are used as a basis of comparison for the experimental results with those found on an actual paper machine, both of which were formulated by Sir G. I. Taylor.[2, 3] The first of these assumes no mixing of the stream lines (i.e.—laminar flow) and predicts the quantity of water drained at a table roll to be:*

$$q = 0.295 R \rho^2 U^3 (K/\mu)^2 \qquad (1)$$

where:

q = c.c. per sec. per cm. of width of the wire.

R = table roll radius (cm.)

ρ = specific gravity (unity)

U = wire speed (cm./sec.)

K/μ = drainage coefficient (cm^3/dyne-sec.)

The second theory of G. I. Taylor assumes the opposite case to that of his first theory; i.e. — complete turbulent mixing throughout the depth of the fluid without any surface friction effect, or, turbulent flow with the streamlines no longer existing, and shows the quantity of drained water to be:

$$q = 0.7536 R \rho^2 U^3 (K/\mu)^2 \qquad (2)$$

where R, ρ, U, K/μ and q have the same connotation as before.

In the calculated results which follow the average drainage coefficient K/μ has been taken as 12 x 10^{-5} cm^3/dyne-sec. The simplifying assumption has been made that K/μ varies linearly down the wire table. Although this is known to be incorrect, results have shown[5] that the error involved is not likely to be great. Fig. 10 shows the K/μ distribution used in the present case.

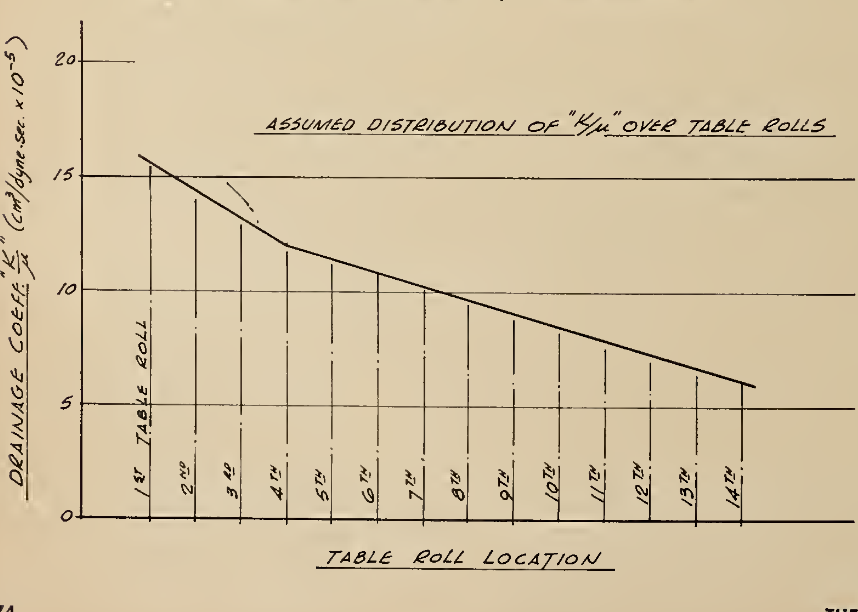
Tables I and II show the values taken for K/μ, the quantity "q" drained from each table roll as calculated by Equations 1 and 2, and the average suction value found for each roll.

For a machine speed of 980 cm./sec. Taylor's No-Mixing Theory yields a total calculated drainage quantity of 709 cc/sec. per cm. of wire width, which may be extrapolated to 405 litres/sec. for whole machine width. This compares well with a total of 376 l./sec. actually found by means of a material balance.

For the same machine conditions as above Taylor's Complete-Mixing Theory gives the results shown in Table II. The total drainage now amounts to 990 l. per sec. over the whole machine width, or about 2½ times the total found from the material balance.

From the above figures it appears

Fig. 10. Assumed distribution of "K/μ" over table rolls.



*Reference 5 gives a full derivation of Equation 1 above and also Equation 2 which follows for Taylor's second theory.

that the No-Mixing Theory gives good agreement with actual machine performance and that the Complete-Mixing Theory gives predicted drainage results that are much in excess of those actually obtained. It is believed from a more exhaustive study than can be reported here that the agreement is fortuitous and that the applicable theoretical treatment must take into account the value of ψ corresponding to that of the drainage process on the paper machine. Cavitation in the draining fluid also affects the results.

Thus, as a first approximation only, for newsprint stocks at speeds in the range of 800-900 cm./sec. the No-Mixing Theory gives predicted drainage values that approximate to those found from material balances if the values of K/μ found by the A.P.P. Sheet Machine are used in the calculations.

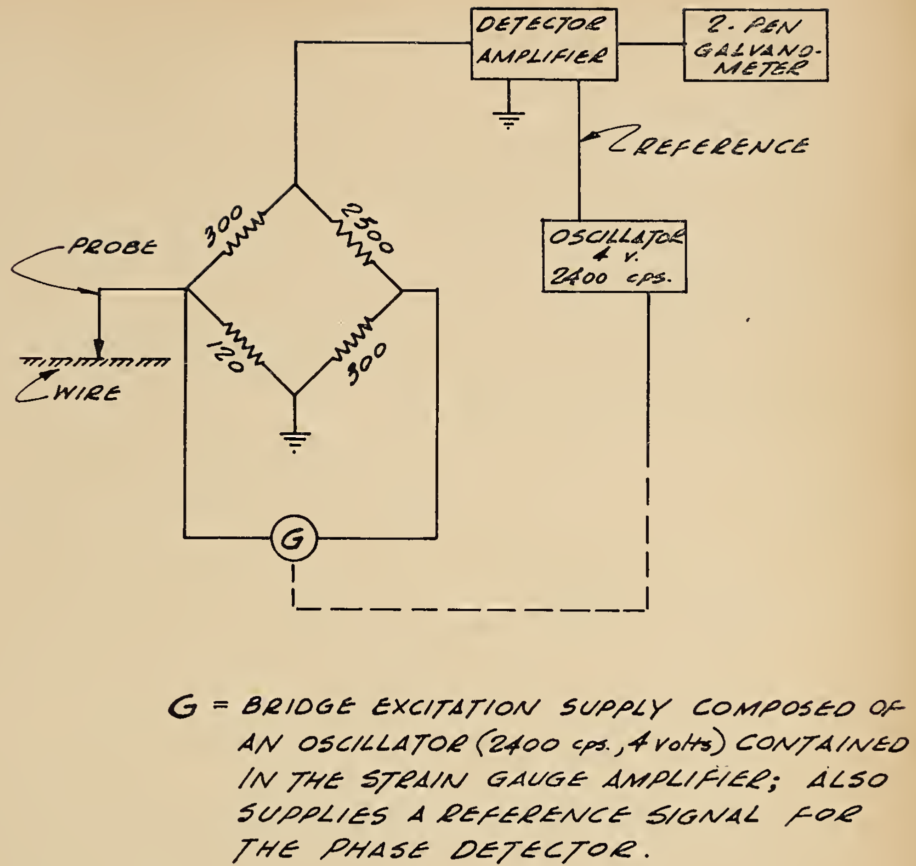


Fig. 11. Circuit diagram of A.P.P. timing device.

Conclusions

Although the foregoing remarks have touched very briefly upon paper machine drainage and laboratory investigation of the drainage problem, certain points stand out in summary.

(1) In order to properly evaluate wire table performance on full-scale paper machines, drainage coefficients must be determined in the laboratory using equipment such as the A.P.P. Drainage Tester which closely simulates actual operating conditions;

(2) Further theoretical and experimental work is needed in this field to enable the exact relationship between theory and practice to be determined.

APPENDIX I

Description of Anglo Paper Products Equipment

The apparatus as shown in Fig. 2 is self explanatory except for the part around the wire. The machine consists essentially of a removable plate and wire suitably centred on the frame. The stock container rests on the wire with an integral round rubber gasket to prevent leakage, and is tightened against the wire by means of four wing-nuts.

Agitation of the stock as required during the time interval between the stock being placed on the wire and the start of the operation is done manually using a large mesh (4 holes per in.) grid.

The pressure gauges used were as follows: (a) a 15 p.s.i. differential Northam gauge, which is a variable reluctance type with two external resistance circuits completing a Wheatstone bridge. This gauge was used in the static position shown in Fig. 2 in determining the pressure differential through the fibrous mat; (b) a 1 p.s.i. differential Statham gauge which is a strain gauge, full-bridge type. This gauge was used in the total head position as shown in Fig. 2 and also in the static position to determine the head loss through the wire of water only.

The centre-line of the static opening was 15/16 in. below the wire while the diaphragm of the Northam gauge was 3½ in. below the wire. The total head tube was placed directly against the underside of the wire.

Fig. 11 shows the circuitry involved in the electric timing device. The probe inserted in the stock had a clearance of 0.06 in. off the wire. Before contact is made by water between the probe and the wire, the electrical path between the probe and the wire, the machine body being grounded, offers infinite resistance; the bridge, therefore, can be balanced.

The resistance of this path varies inversely as the level of stock: the higher the level, the lower the resistance and hence the larger the change on the recorder.

The recording equipment used was the Sanborn 64 Series, Strain Gauge Amplifier with matching Recorder.

DETERMINING MACHINE FOUNDATION NATURAL FREQUENCIES BY ANALYSIS

G. Ford, M.E.I.C.,
Head, Department of Mechanical Engineering, University of Alberta.

J. B. Haddow,
Associate Professor of Mechanical Engineering, University of Alberta.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg.

The analytical procedures outlined in this paper are based on Rayleigh's Principle and may be used to find the natural frequencies for all six degrees of freedom of rigid foundations. Analytical determination of natural frequencies for rotational vibration about various axes is usually not practicable because of the unavailability of the values of mass moments of inertia of machines. For this reason, the application of the method to vertical and horizontal vibration, only, is given here. It is further shown that the values obtained for the vertical natural frequencies of machine foundations agree very closely to those given in the empirical plot of Tschebotarioff.

IT HAS been found[1] that the natural frequencies of most foundation soil systems are less than 30 c.p.s.; consequently there is the possibility of resonance occurring if the rotational speed of a machine mounted on a soil supported foundation is less than 1,800 r.p.m. Most stationary reciprocating machines have rotational speeds less than 1,800 r.p.m., and consideration of the dynamic characteristics of the foundation of such machines is necessary in order that resonance be avoided. Dangerous fatigue stresses and other objectionable factors, such as excessive vibration transmitted to buildings and other adjacent structures, are usually present when the foundation is at or near resonance.

Analytical methods, along with the qualitative consideration of certain factors not amenable to analysis, can provide a basis for at least an approximate determination of the natural frequencies of the various modes of vibration. However, determination of amplitudes of vibration of foundations is highly uncertain by analytical methods.

A rigid foundation is a system with six possible degrees of freedom. If a foundation cannot be considered rigid, then more degrees of freedom are introduced. Each degree of freedom has a natural frequency associated with it, and it is desirable that the rotational speed or twice the rotational speed of the machine should not be within 20% of any one of these natural frequencies. The term "natural frequency" is used with some misgiving, as a soil-foundation system displays non-linear characteristics, and any natural frequency of the system is not a constant but a function of the disturbing force[2]. This indicates that linear theories are not strictly applicable to analysis of the dynamic behaviour of soil systems; however, linear theories can be used if the magnitude of the disturbing force is small compared with the weight of the machine and foundation.

Satisfactory foundations for low speed machines usually have natural frequencies which are higher than the rotational speed of the machine[3]. Foundations for high speed machines, such as gas and steam turbines with rotational speeds greater than 3,000 r.p.m. have natural frequencies below the rotational speed of the machine. The two types of machine, therefore, give rise to rather different foundation design problems.

A Theoretical Analysis of Soil Vibrations

(*a*) *Simple Spring Supported Mass Analogy;* Several procedures have been suggested to determine foundation natural frequencies[3]. Perhaps the most obvious procedure is to consider the foundation as a single degree of freedom spring supported mass, with the soil being assumed a massless spring. The natural frequency is then given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{Kg}{W_v}} \qquad (1.1)$$

where

W_v = weight of foundation and machine

K = spring constant (restoring force per unit displacement)

g = acceleration of gravity

This procedure is an oversimplification and Equation 1.1 gives unsatisfactory results. One refinement consists of making an allowance for the soil which vibrates in phase with the foundation by considering this soil dynamically equivalent to a mass of weight W_s, vibrating with the same amplitude as the foundation.
The natural frequency is then given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k'Ag}{W_s + W_v}} \qquad (1.2)$$

where

k' = coefficient of dynamic subgrade reaction (restoring force per unit area for unit displacement)

A = area of foundation bearing on soil

$k'A$ = stiffness (restoring force per unit displacement)

W_v = weight of foundation and machine.

The determination of f is dependent on the values of k' and W_s.

The value of W_s can only be obtained from the results of experiments. It has been found[1] that W_s is usually the dominant weight in Equation 1.2.

Lorenz[2] assumed k' was constant for a given soil, however, Tschebotarioff and Ward[4] have shown that this is incorrect.

Apart from the indeterminate nature of W_s and k', Equation 1.2 has the disadvantage that it gives the natural frequency for only the vertical degree of freedom, and often other degrees of freedom may have to be considered.

(*b*) *Bearing Pressure;* The average bearing pressure, W_v/A, must be given careful consideration by the designer of foundations for low speed machines.

It has been found[3] that the lower the bearing pressure, the higher is the natural frequency of the foundation on a given soil. This indicates that if the area of a foundation is increased and thus the bearing pressure reduced, the stiffness ($k'A$) will be increased more than the total vibrating weight ($W_s + W_v$). The static modulus of subgrade reaction is increased when the bearing pressure is reduced. It is therefore reasonable to assume that the dynamic modulus will likewise be increased when the bearing pressure is reduced.

(*c*) *Analogous Damped, Spring Supported Mass with Disturbing Force;* When the periodic force is vertical sinusoidal, and acts such that the foundation undergoes only vertical displacement, then the amplitude frequency characteristics of the foundation are similar to those of a damped, single degree of freedom, spring supported mass[3]. Soil vibrators used for experimental work are an example of this[5]. Most machine foundations have more complicated amplitude-frequency relations due to the several degrees of freedom and also the higher harmonics of the periodic disturbing forces. However, some investigators have studied foundations with amplitude-frequency characteristics similar to those of a single degree of freedom, damped, spring supported mass. This suggests that the concept of a spring supported mass with viscous damping is useful for qualitive consideration of the dynamic behaviour of machine foundations. For example, the effect of adding mass to a foundation may be studied qualitatively.

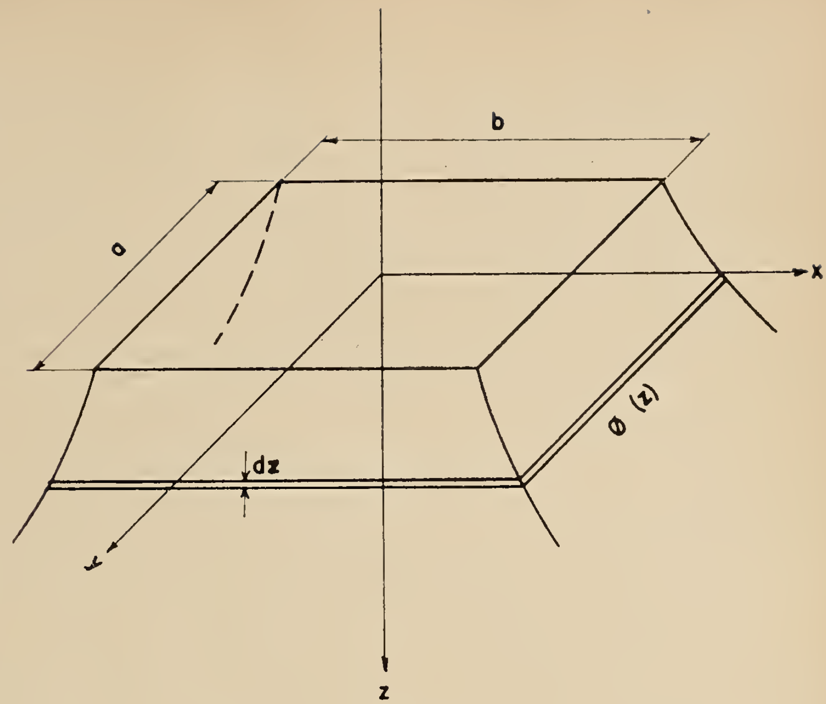

Fig. 1.

(*d*) *A Method for Determining the Natural Frequencies of Machine Foundations*: As has been noted in the foregoing paragraphs there have been some attempts to determine analytically the natural frequencies of machine foundations. On the whole they have not been very successful. A procedure, based on Rayleigh's Principle, outlined in this paper, may be used to find the natural frequencies for all the degrees of freedom of rigid foundations. Analytical determination of natural frequencies for rotational vibration about various axes is usually not practicable because of the unavailability of the values of mass moments of inertia of machines. For this reason the application of the method to vertical and horizontal vibration, only, is given here.

In determining the natural frequency of vertical vibration the assumptions and procedure are as follows:

Assumptions

(1) The system may be considered conservative in order to determine natural frequencies;

(2) Dynamic pressure is transmitted through soil contained in a solid formed by the base of the foundation and the surfaces

$y = f(z)$, $y = -f(z)$, $x = \phi(z)$, and $x = -\phi(z)$

as shown in Fig. 1.;

(3) The dynamic stress at any depth z is uniformly distributed over a section of the solid parallel to the (xy) plane, that is, parallel to the base of the foundation.

The last assumption is inaccurate but is useful for the development of relations which are at best dependent on empirical data.

The notation is as follows:

M = mass of foundation and machine

ρ = density of soil (mass per unit volume)

a = width of foundation

b = length of foundation

A = bearing area of foundation $= ab$

W_{0f} = amplitude of vibration of foundation

f_z = natural frequency for vertical vibration

ω = angular natural frequency

E' = dynamic modulus of elasticity of soil

G = dynamic shear modulus of soil

ν = Poisson's ratio of soil

σ_z = vertical normal stress (dynamic) in z direction

Consider an elemental layer of soil at depth z as shown in Fig. 1.

Let the amplitude of vibration of this layer = W_0.

W_0 decreases as z increases.

Let W_0 be given by :

$$W_0 = W_{0f}e^{-\beta z}$$

β(decay factor) is dimensionally equivalent to L^{-1}

Assume foundation vibrates sinusoidally :

$$W_f = W_{0f}\sin\omega t$$

The maximum kinetic energy of the foundation and machine is given by :

$$T' = \tfrac{1}{2}M\omega^2W_{0f}^2$$

It is now necessary to find T″ the maximum kinetic energy of the vibrating soil.

Let amplitude of dynamic strain at $z = 0$ be ϵ_{z0}.

$$\epsilon_{z0} = \left|\frac{\partial W_0}{\partial Z}\right|_{z=0}$$

$$= \beta W_{0f}$$

Let s be area of layer of elemental thickness at depth z. Amplitude of dynamic strain at z is given by :

$$\epsilon_z = \left|\frac{\partial W_0}{\partial Z}\right|$$

$$= \beta W_{0f}e^{-\beta z}$$

Equating the force acting on contact area ab, to the force acting on elemental layer gives :

$$E'\beta W_{0f}e^{-\beta z}S = \beta W_{0f}abE'$$

$$\therefore\ S = abe^{\beta z}$$

Assume the elemental layer vibrates as follows :

$$W = W_0\sin\omega t$$

The maximum kinetic energy of the elemental layer is given by :

$$dT'' = \tfrac{1}{2}\rho abe^{\beta z}\omega^2W_0^2dz$$

$$= \tfrac{1}{2}\rho abe^{-\beta z}W_{0f}^2\omega^2dz$$

∴ The maximum kinetic energy of the soil is

$$T'' = \tfrac{1}{2}\rho abW_{0f}^2\omega^2\int_0^\infty e^{-\beta z}dz$$

$$= \frac{\rho abW_{0f}^2\omega^2}{2\beta}$$

The maximum kinetic energy of the system is then given by :

$$T = T' + T''$$

$$= \frac{\rho abW_{0f}^2\omega^2}{2\beta} + \frac{M\omega^2W_{0f}^2}{2}$$

$$= \frac{W_{0f}^2\omega^2}{2}\left[\frac{\rho ab}{\beta} + M\right]$$

Consider the strain energy of the system.

The amplitude of

$$\sigma_z = E'\left|\frac{\partial W_0}{\partial Z}\right|$$

The maximum strain energy of the elemental layer is then given by :

$$dV = \frac{|\sigma_z|^2}{2E'}$$

multiplied by the vol. of layer

$$= \tfrac{1}{2}E'\left|\frac{\partial W_0}{\partial z}\right|^2 abe^{\beta z}dz$$

$$= \tfrac{1}{2}E'\beta^2W_{0f}^2e^{-\beta z}abdz$$

Maximum strain energy is then given by :

$$V = \tfrac{1}{2}E'\beta^2W_{0f}^2ab\int_0^\infty e^{-\beta z}dz$$

$$= \tfrac{1}{2}E'\beta W_{0f}^2ab$$

For a conservative system, according to Rayleigh's Principle, the maximum strain energy is equal to the maximum kinetic energy.

i.e. $V = T$

$$\therefore\ \tfrac{1}{2}E'\beta W_{0f}^2ab = \frac{W_{0f}^2\omega^2}{2}\left[\frac{\rho ab}{\beta} + M\right]$$

$$\omega = \sqrt{\frac{E'\beta ab}{(\rho ab/\beta) + M}}$$

$$\therefore\ f_z = \frac{1}{2\pi}\sqrt{\frac{E'\beta ab}{(\rho ab/\beta) + M}}$$

$$G = \frac{E'}{2(1+\nu)}$$

$$\therefore\ f_z = \frac{1}{2\pi}\sqrt{\frac{2G(1+\nu)\beta ab}{(\rho ab/\beta) + M}} \qquad (1.3)$$

$$\text{or}\quad f_z = \frac{1}{2\pi}\sqrt{\frac{2G(1+\surd)\beta g}{(\gamma/\beta) + p}} \qquad (1.4)$$

in which

α = weight density of the soil

p = bearing pressure

g = acceleration of gravity

The natural frequency of the foundation is therefore dependent on the physical properties of the soil, the bearing pressure and the decay factor β.

The decay factor β may be determined from the equation

$$\beta = \frac{B}{m\sqrt{A}(1-\nu^2)}\ \text{ft}^{-1} \qquad (1.5)$$

In which

A is the area of the foundation in square feet

m is a constant given in Table I

ν is Poisson's ratio

Table I

Timoshenko and Goodier[7]

Table of Factors m in Eq. (1.5)

					Ratio a/b			
	Circle	*Square*	*1.5*	*2*	*3*	*5*	*10*	*100*
m	0.96	0.95	0.94	0.92	0.88	0.82	0.71	0.37

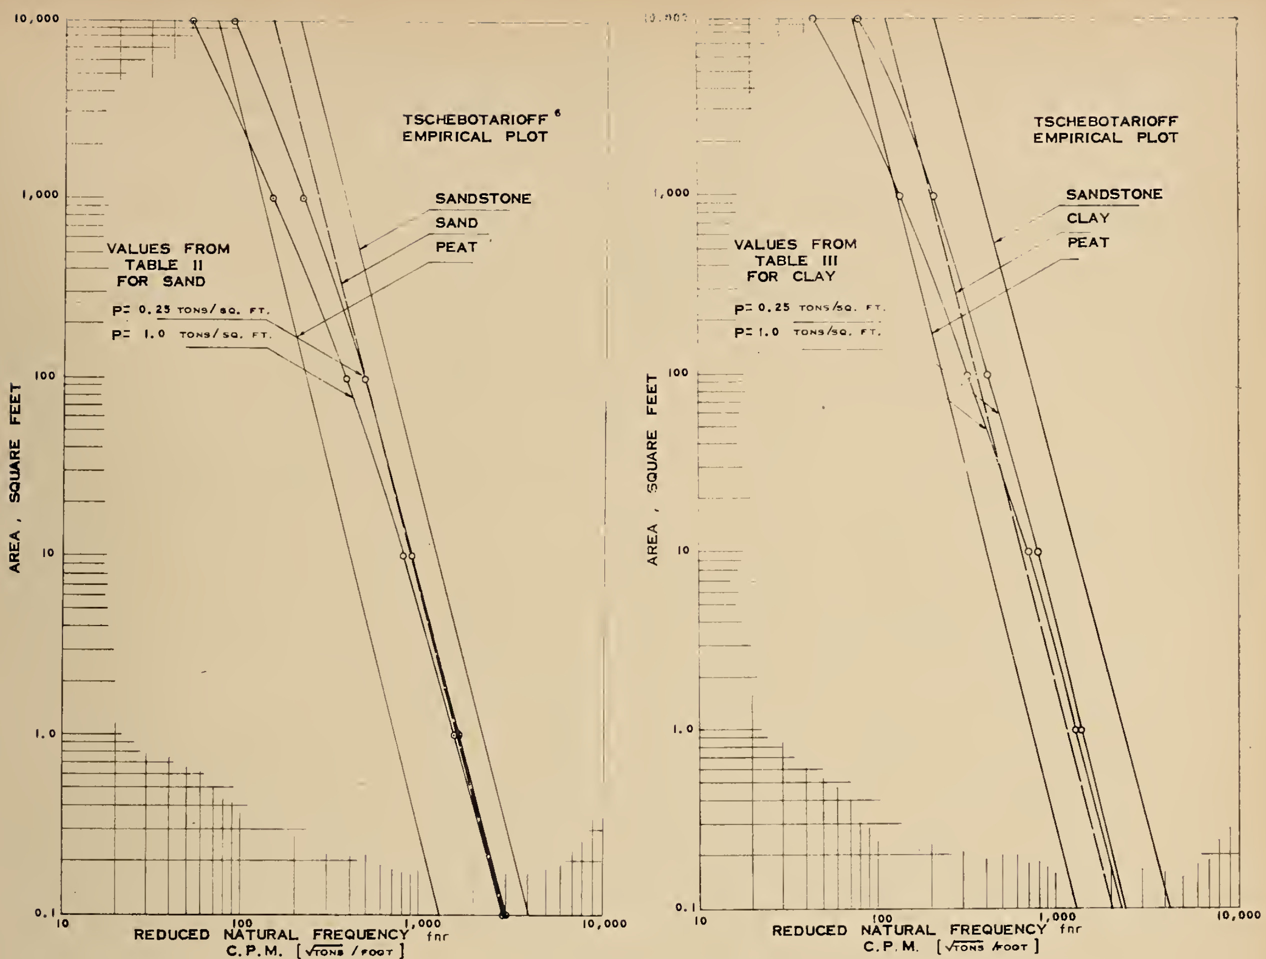

Fig. 2. Comparison of the Values given in Table III with the Empirical Plot by Tschebotarioff.

The derivation of equation (1.5) is given in Appendix 1.

For sand, the decay factor β may be taken as

$$\frac{2.0}{m\sqrt{A}(1-\nu^2)}\text{ft}^{-1} \quad (1.5a)$$

For clay the decay factor β may be taken as

$$\frac{1.5}{m\sqrt{A}(1-\nu^2)} \quad (1.5b)$$

In order to consider the natural frequency for horizontal vibration in the x and y directions of Fig. 1, the same assumptions as before are made along with the assumption that the dynamic shearing stress is uniformly distributed over a section of the solid parallel to the xy plane.

Following a similar procedure the horizontal natural frequency of the foundation may be expressed as:

$$f_x = f_y = \frac{1}{2\pi}\sqrt{\frac{Gab\beta}{(\rho ab/\beta)+M}} \quad (1.6)$$

$$\text{or } f_x = f_y = \frac{1}{2\pi}\sqrt{\frac{G\beta g}{(\gamma/\beta)+p}} \quad (1.7)$$

Newcomb[3] states that the natural frequency for horizontal vibrations is usually very nearly equal to the vertical natural frequency. It is, therefore, evident that if equations 1.4 and 1.7 are compared, β is probably greater for horizontal vibration than for vertical vibration.

Equation 1.4 has been used to determine the natural frequency of machine foundations whose areas range from 1 sq. ft. to 10,000 sq. ft., and bearing pressures from 0.25 tons per sq. ft. to 1 ton per sq. ft. In carrying out the computations it was assumed that the foundations were resting either on sand or on clay. The constants used in the computations were as follows:

Constant	*Sand*	*Clay*
G	2000 p.s.i.	1500 p.s.i.
ν	0.33	0.5
g	32.2 ft/sec²	32.2 ft/sec²
γ	130 lb./ft³	110 lb./ft³
β	equation 1.5*a*	equation 1.5*b*
p	as given	as given

The results of the computations are compiled in tables II and III.

The values given in tables II and III are plotted in Fig. 2 and compared with the empirical plot of Tschebotarioff[6].

Conclusions

1. It is apparent that the behaviour of a machine foundation cannot be considered as analogous to a simple spring mass system with or without viscous damping and linear elasticity.

2. The resonant frequency is independent of the dynamic force.

3. The resonant frequency decreases with an increase in bearing pressure.

4. The method presented in this paper permits the determination of the resonant frequency of a machine foundation by considering the physical properties of the soil, the dimensions of the foundation, and the bearing pressure on the soil. There is a reasonable

agreement between the results so obtained and those given by the empirical plot of Tschebotarioff.

The writers wish to express their thanks to the National Research Council for the Research Associateships awarded to Mr. Haddow during the summers of 1956 and 1957, when the work outlined in this paper was carried out. Thanks are due to Dr. R. M. Hardy who introduced the writers to the topic and to Mr. J. S. Kennedy for reviewing the paper.

Appendix I

Derivation of Equations (1.5), (1.5a) anp (1.5b).

Consider the model shown in Fig. 1 to be loaded with a dynamic load P uniformly distributed over the surface area A.

The dynamic stress at depth z is given by:

$$\sigma_z = \frac{P}{S} = \frac{P}{abe^{\beta z}}$$

The unit strain at depth z is given by:

$$\epsilon_z = \frac{P}{E'abe^{\beta z}}$$

Let W' be the deflection at $z = 0$

$$W' = \int_0^\infty \frac{Pdz}{E'abe^{\beta z}} = \frac{P}{E'\beta A}$$

The vertical deflection of a rigid foundation, resting on an elastic medium, is very nearly equal to the average deflection of a uniformly loaded surface of the same dimensions with the same total load. This deflection is given by Timoshenko and Goodier[7] as

$$W = \frac{mP(1 - \nu^2)}{E\sqrt{A}}$$

where m is a constant dependent on the length to width ratio of the foundation (Table 1).

Put $W = W'$ and $E = BE'$

in which B is a constant to be evaluated for different soils,

then $$\frac{BP}{E'\beta A} = \frac{mP(1 - \nu^2)}{E'\sqrt{A}}$$

$$\therefore \quad \beta = \frac{B}{m\sqrt{A}(1 - \nu^2)}$$

The constant B may be evaluated from vibrator results or field data. The available information would indicate that reasonable values for the constant B may be taken as 2.0 for sands and 1.5 for clay.

Discussion

BACKWATER COMPUTATIONS FOR THE ST. LAWRENCE POWER PROJECT

Part A—Hydraulic Engineering Aspects of Computations

H. M. McFarlane,
Hydraulic Design Engineer, Ontario Hydro, Toronto

The Engineering Journal, February 1960, page 55.

Discussion by T. R. Anand

Mr. H. M. McFarlane's paper describing the theoretical, procedural and technical aspects of a major backwater study with the help of computers is very interesting. Being one of the first extensive uses of computing devices in the hydraulic field in Canada, the study and the experience gained is very valuable indeed.

The writer is in agreement with the formulae used for bend losses, expansion losses and friction losses, but wishes to comment on formulae adopted for interpolation of computations. On page 59 was given:

$$h_{f_2} = \left(\frac{2n_2}{(n_1/h_{f_1}^{1/2}) + (n_3/h_{f_3}^{1/2})}\right)^2 \qquad (1)$$

Where h_{f1} and h_{f3} are computed friction losses for assumed roughnesses n_1 and n_3 respectively, and n_2 is the selected roughness for which friction loss h_{f_2} is required; n_1 and n_3 bracketing n_2.

The basis of this proposed formula is the Manning Formula:

$$Q = \frac{1.486}{n} AR^{2/3} \cdot S^{1/2}$$

or $$Q = \frac{1.486}{n} AR^{2/3} \frac{(hf)^{1/2}}{l^{1/2}} \qquad (2)$$

or $$\frac{n}{hf^{1/2}} = \frac{1.486}{Q \cdot l^{1/2}} \cdot AR^{2/3}$$

Substituting this value of $n/(hf)^{1/2}$ in formula (1) for the values of $n = n_1$ and $n = n_3$.

$$h_{f_2} = \frac{2n_2}{\frac{1.486}{Q \cdot l^{1/2}}\left(A_1R_1^{2/3} + A_2R_2^{2/3}\right)} \qquad (3)$$

or

$$\frac{n_2}{h_{f_2}^{1/2}} = \frac{1.486}{Q \cdot l^{1/2}} \cdot \left(\frac{A_1R_1^{2/3} + A_2R_2^{2/3}}{2}\right)$$

Comparing (2) and (3) it can be seen that formula (3) and hence formula (1) is written for a mean value of conveyance factor $AR^{2/3}$. In other words, the formula given by Mr. McFarlane is strictly true for a value of $AR^{2/3}$ midway between the values for $A_1R_1^{2/3}$ and $A_2R_2^{2/3}$. In actual cases presented by the paper, the chosen value of n for interpolated backwaters is not always the average of values n_1 and n_3 originally chosen. If the divergence between n_1 and n_3 is small and the river section has no abrupt changes, the interpolated values may not differ very much from manually worked out values for n_2. But, if river section has abrupt changes, e.g., islands or sudden enlargements between the bracketing values of conveyance factor, or the value n_2 chosen is significantly different from mean of values n_1 and n_3, corresponding differences would show up in backwater calculations. The author has mentioned a divergence of interpolated values from manual computations. Perhaps it would be advisable to study this divergence in the light of above remarks. The writer is unable to do so for want of actual data.

The use of hydraulic models has been mentioned to verify backwater curves. If the roughness of channels with and without improvements are accurately known and the model constructed to correspond to these roughnesses, such verification may be possible with a fairly large scale model. Otherwise, step-by-step computations usually give results as reliable as any.

Author's reply

I should like to thank Mr. Anand for his discussion of my paper.

Mr. Anand is correct in his conclusion that the interpolation equation referred to above is strictly accurate only if $A_2 R_2{}^{2/3} = \frac{1}{2} (A_1 R_1{}^{2/3} + A_3 R_3{}^{2/3})$ (a)

When carrying out the backwater computation, it was realized, of course, that use of the interpolation equations could introduce small errors in two ways;

1. Without a knowledge of the finally selected channel roughness n^2, it would be most fortuitous if the chosen values of n, and n^2, were such that equation (a) above would be satisfied.

2. The computed profiles to be modified by interpolation include both bend and expansion losses in addition to pure friction losses.

It was felt, however, that the urgency for obtaining backwater slopes in the headpond would not permit delaying computations until the actual channel roughness could be determined, which would have eliminated the necessity for interpolation. In addition, no practical method for separating bend and expansion losses from pure friction losses was evident. Thus it was decided to interpolate the total loss and to make several check computations to determine whether a serious error resulted. As it happened, the results of these checks indicated that errors introduced by the interpolation methods were very small.

The Hydraulic Models for the project were used for many purposes in addition to verifying the backwater curves. One of the more important uses was in redesigning the extensive channel enlargements which were to be made between Chimney Point and Morrisburg. For this purpose a Hydraulic Model is invaluable, since it permits rapid changes to be made in various segments of the enlargement plan until the optimum design is achieved. Since the models were being used to redesign the channel enlargements, they also were used to provide backwater slopes in the areas in which the revised enlargements occurred.

THE PRINCIPLES OF AUTOMATIC CONTROL

Automation and Control Engineering in Canada

The Instrumentation & Control of Central Steam Power Stations

L. G. Holman
Montreal Engineering Company, Limited, Montreal.

DURING the past decade, in common with many of the process industries, the operation of central steam power stations has necessarily been modified by the changing needs of electrical utilities. The new demands of industry were largely the result of increased capital investment due to the larger and more complex prime movers and thermal cycles being installed to meet the post-war growth in electric power requirements. The greater financial risks associated with damage to major plant, and the consequent loss of generating capacity, have led to the establishment of new standards of control and a wider degree of protection than hitherto had been found necessary. The elevated conditions of modern thermal plants and the continued downgrading of residual fossil fuels have created new problems in the operation of steam plant, with risks of costly and frequent maintenance. In addition to the need for safer operation, increasing operating costs also have encouraged the use of instrumentation to obtain optimum cycle performance and to economize in manpower.

Significant progress made in the development of new equipment and techniques, in its application to central station instrumentation, has contributed to the achievement of these objectives. Although the goals of minimum operating expenditure, improved reliability and more efficient use of personnel must remain, there have been changes in emphasis due to the changing needs of industry.

In its broadest sense instrumentation in central steam stations is used to control the operating cycle, to provide records for trend observations and history and to check the plant performance. Progress has been made from local rudimentary control to the remote central control centre with miniaturisation of instruments, perhaps electronic controls and automatic data processing. The "computer" controlled stations are to be commissioned shortly. This continual change has developed a need for a new kind of steam plant operator with new skills and outlook. It has resulted in remarkable improvements in the kilowatts per man ratio.

How effective these changes have been is adequately demonstrated by the delivered cost of power which remained remarkably stable for many years. With this successful record it would seem difficult to justify further efforts. But continued progress is needed to keep pace with ever-mounting costs, and the continued demand for more power, coupled with economic pressure to maintain the low cost of delivered power. Because of rising costs for material, fuel and labour, outdated equipment and methods will not produce at to-day's rates.

Although the capital cost per kilowatt installed decreases as units get larger and pressures and temperatures are elevated, the complexity of the unit increases. This in turn creates operating problems. Minute percentage losses, normally insignificant on small units, take on greater annual dollar values. Therefore, if minimum operating expenditure is the objective, it becomes more important to ensure that the unit is meeting its design conditions and that any deviation in performance is detected and evaluated. To secure improved reliability, sufficient information must be made available to the operator. The tools must be supplied to protect the multi-million dollars invested.

Operational Factors

Experience and thorough studies of central stations have revealed that for most modern thermal generating plants the central control centre generally results in the most efficient use of operating personnel. Unit size has little or no bearing on the number of personnel required to operate the unit. Obviously such factors as fuel firing equipment, and whether the station is on base-load service or two-shift service, are more important in determining the number of operators.

As steam-electric generating units have increased in size and complexity the tendency has been to provide more instrumentation and control. Thus, to-day's station has sophisticated control loops unknown until recently. The instrumentation provided for a given unit should be roughly the same irrespective of the rating — except for minor differences due to such factors as feed heating system and fuel fired — as the same number of functions must be performed. Thus the ratio of dollars per kilowatt has little or no meaning as far as instrumentation is concerned. As a result a most comprehensive scheme can be provided for about $1.5 per kilowatt for a 200 Mw unit whereas the minimum central control requirements for a 20 Mw unit will cost about $4 per kilowatt installed. (See Fig. 1).

A highly skilled operator thoroughly conversant with all the operational aspects of boiler, turbo-generator and associated auxiliary plant is usually in charge of the central control room. The number of his plant assistants varies with the number of units in service and the degree to which remotely-operated equipment has been applied. The amount of remotely-controlled plant which can be economically justified depends largely on the frequency of its operation and the importance of the standby equipment to the continued operation of the station. One approach commonly in use is that only major auxiliaries such as boiler feed pumps together with associated valves should be remotely operated. Secondary auxiliaries remain locally operated as in a conventional steam plant. This is to avoid the questionable expense of motorizing the multiplicity of valves, which are frequently quite small, to isolate or control auxiliaries and also to conserve control room operating surface which usually is at a premium. In the modern minimum-staffed station this method can be employed on the assumption that normal and emergency shut-downs and hot restarts can be safely achieved by the normal shift complement. A cold start-up may be planned so that additional personnel can be on hand to perform the many manual functions involved after prolonged shutdown.

Central Steam Station Instrumentation

The trend to central control schemes with minimum operating personnel established a need for an array of plant information readily accessible to the operator. Provision of the extra data required for remote operation with conventional instrumentation is extravagant both in control panel area and control room space. The result is that a single operator would be unable to supervise the overall unit properly and perform the remote manual functions adequately. It was a natural development that various degrees of miniaturisation of panel-mounted instruments occurred and that various forms of telemetering displaced the traditional methods of remote indication. This has the added advantage that high-pressure instrument-impulse lines are kept away from the control room area with elimination of possible hazards and reduction of instrument-installation costs. The end product of this progress has been that remote console type control centres are being used instead the usual vertical instrument panels. In Canada there are at least two successful examples of this form of control installation where one operator and two helpers are in charge of two complete boiler-turbo-generator units with auxiliaries.

In this type of application, indicators, boiler control instruments, burner controls, generator and auxiliary control switches are placed immediately at the operator's finger tips on what might be termed the working surface of the console. The recorders used for trend purposes are located adjacent to this area. Other recorders for historical and performance records, and annunciators are placed in less prominent areas. These new methods of designing control desks have resulted in startling reductions in the length of desks. A modern console for the control of a complete boiler, turbo-generator and auxiliaries unit can be as short as six feet. It is readily understandable that such a desk can be supervised easily without strain or unnecessary movement providing the arrangements and grouping of the instruments and control stations is a logical presentation of the operating procedure.

As already shown the changes in instrumentation have been largely logical developments of already well proven practices in areas where shortcomings had been revealed in applications for power plant service. With the advent of remote central control rooms, transmission of impulse signals became a problem as units were installed further away from the control centre, so directly connected instruments could no longer be used. In order to avoid long high-pressure impulse lines, transmitters now send pneumatic or electric signals to the receiving instruments and controllers in the control room. This method has the advantage that except for transmitters, which are usually rugged, most plant instrumentation can be located in the improved control room environment unaffected by dirt, heat and vibration.

Generally, instruments now in use are developments of measuring techniques which previously were not sufficiently reliable for powerhouse service. Refinements made possible more ambitious schemes. Probably the most outstanding example is the almost universal practice nowadays of providing oxygen and combustible gas analysers to monitor the combustion process to secure not only efficient operation but maximum safety. While frequently gas sampling still presents problems, under some conditions this type of instrument is often used to initiate a final combustion control impulse. Closed circuit television has also become a useful tool in the remote supervision of furnaces and steam drum water level.

The increasing use of higher steam pressures and temperatures demands greater attention to chemical conditions of steam, feedwater and condensate. The constituents of these media are still largely determined on a routine basis by chemical means in the laboratory. However, there is a greater tendency to employ continuous determination and recording methods to avoid the possibility of overlooking deteriorating conditions of a transient nature between sampling periods. There is also the desire to reduce the tedious and time-consuming laboratory work and to obtain consistently accurate results. Sometimes after satisfactory results with this kind of instrumentation the scope has been widened to regulate the injection of corrective chemicals on a continuous basis to maintain the desired protective residuals.

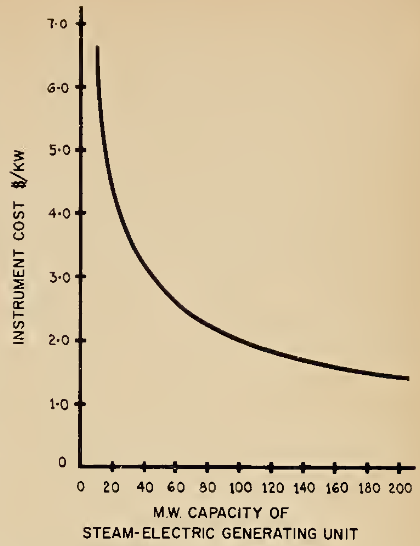

Fig. 1. Approximate instrument cost — Central Controlled Unit.

Generally, instrument trends have been from direct reading to telemetering of one sort or another, from full size to miniature and from local control of major plant to remote panels in the central control room. New instruments coming into use are components eventually for use in control loops previously regulated by hand on the basis of experience and judgement.

Central Steam Station Control

Control systems in steam power stations are expected to respond to all load demands on the unit while maintaining optimum efficiency. They will protect the unit from improper operating conditions in furnaces and from stresses due to undue variations of pressure and temperature. These requirements differ from the duties performed by control systems in process industries where a relatively constant throughput or load is maintained.

The various controls applied to steam-electric generator units have undergone development and variations to meet changing situations and the following is intended to review the more important innovations.

(a) *Master Control:* The established practice of interconnecting all boilers and turbines in a station has given way almost entirely to the unit system consisting of one boiler — one turbo-generator unit with all of its own associated auxiliaries. This simplifies the "Master Control", since the unit is unaffected by thermal changes of the other boilers and turbines. The Master controller settings are made to suit the thermal response of its individual steam generator. The advent of the unit system in central steam stations has resulted in a drive to achieve better response to load changes at the generator. The first major success came with the development of a two-element master control (See Fig. 2a) which uses the influences of steam pressure and steam flow to produce a corrective control signal representing both direction and magnitude of the variations in load. Although there are many units successfully employing two-element master control systems it was recognised that the best response would only be obtained when the changing load on the generator was used as a primary impulse for master control.

A number of unique factors associated with the operation of supercritical pressure "Once Through" steam generators have led to the introduction of the Direct Energy Balance method of control. (See Fig. 2c). As shown in Fig. 2a and 2b, it has been the normal practice in conventional control schemes to regulate the turbine governor to meet the desired generator electrical *output* and to maintain steam pressure by adjusting the *input* of fuel and air to the boiler. Thus in these schemes the boiler firing rate follows the turbine demands. While these well-tried methods have generally proven satisfactory, particularly where boiler units have relatively large thermal storage capacities, advances in boiler design have indicated that supplementary devices, to anticipate load changes, are desirable.

The so-called Direct Energy Balance method of control is one attempt to overcome the shortcomings of conventional systems. As shown in Fig. 2c, this method relies on regulating the *input* of fuel and air to the boiler to give the desired generator electrical *output* with steam pressure maintained by regulation of the turbine governor.

(b) *Combustion Control:* Combustion control might be defined as regulation of fuel and combustion air supplies to the furnace to meet the load demand and to ensure optimum combustion efficiency. This is still substantially true but as the combustion process and furnace equipment has increased in complexity, control systems have necessarily become more intricate. The additional requirements of safety are becoming more prominent, as it has been estimated that the chances of a boiler being damaged by furnace explosion during its lifetime are at least three to one. In the interests of fuel economy, closer tolerances are placed on excess combustion air. This means that operation is closer to the process of incomplete combustion. It is, therefore, mandatory that deviations from the control point are virtually eliminated.

In the quest for more definite control of fuel and air and checks to prevent the formation of explosive combustible mixtures, supplementary actions such as fuel limiting control have been used to over-ride "Master Control" when necessary. Of these, probably the most interesting is the gradual adoption of the oxygen analyser as a fuel combustion control trimming action. Early attempts were somewhat unsuccessful for many reasons. The main reason was the unreliability of the gas sampling system and the high maintenance factor of the analyser and its associated equipment. While these faults are still largely present, ways of avoiding difficulty are now commonplace. The oxygen analyser is a particularly useful tool when firing multiple fuels since the oxygen in flue gas values is very similar for all fuels. Nevertheless an oxygen trimming control system must recognize that different excess air values are required for different loads throughout the load range and with different fuels and the various combinations of fuels in the multi-fuel fired furnace. Provision also must be made for the analyser to be removed from the control loop for servicing. All of these features contribute to very complicated control schemes with probable sacrifices in simplicity and reliability.

Though not strictly a part of combustion control, this article would be incomplete without reference to lighting off and firing sequences and interlocks which of necessity are closely allied in an integrated combustion control scheme. The central station shift operator confronted by a console covered with a multiplicity of control devices and instruments obviously must be given assistance in following the correct sequence of operation, where this is possible without compounding control components at the expense of reliability. The philosophy of permissive control and interlocks is a very controversial subject. In the face of more complex cycles and operating sequences with greater chance of injury to plant and personnel as the result of even minor operating errors, even the most avid opponent of this form of control is apt to welcome the protection offered. The arguments against the various hardware upon which these systems depend are gradually fading as experience is gained and suitable equipment becomes available.

The schemes which can be provided are almost infinitely variable and could form the subject of a complete study. Electric utility operators have a prime interest — to produce electric power continuously. Nuisance shutdowns cannot be tolerated. Consequently sequential circuits and interlock systems always are designed with absolute reliability as a basic requirement. The principle generally adopted during a correct operating sequence must first be traced and carefully studied on a step-by-step basis. Each function is related to its succeeding step and a decision made as to whether progress should be made on a permissive basis, i.e., when one manual function has been completed the monitoring circuit permits progress to the succeeding step; or whether the first and following steps can be sequenced automatically from one initiating manual action. Power Station practice is usually a combination of both methods.

In the power industry the control circuit generally uses the station batteries as the DC power source as this is the most reliable power supply available in the plant. Other users sometimes prefer AC supplies for this service because AC is compatible with other equipment, and components are then also standard "off-the-shelf" items. Flame monitoring devices are becoming more popular on large multiple burner boilers as alarm devices for selected fuels and the future is certain to bring an extension of this practice with practical application of these devices and as newer versions become available.

(c) *Feedwater Control:* The three-element feedwater control using the combined influences of Steam Flow, Feedwater Flow and Steam Drawn Water Level is almost universally used in central steam stations and is probably the most successful control loop in the automatic boiler control system. From the control point of view, problems are relatively few and where they do occur are usually caused by characteristics of particular boilers. With the higher pressures in use today, extremely high pressure drops across the feedwater control valve are apt to give rise to damage to inner valve components and valve bodies. This is so particularly during start-up when the valve is subject to the full pressure drop of the boiler feed pump shut-off head. To reduce the damage during start-up, boiler filling valves specially designed to withstand the excessive pressure drop service are being used in conjunction with boiler filling pumps of smaller capacity.

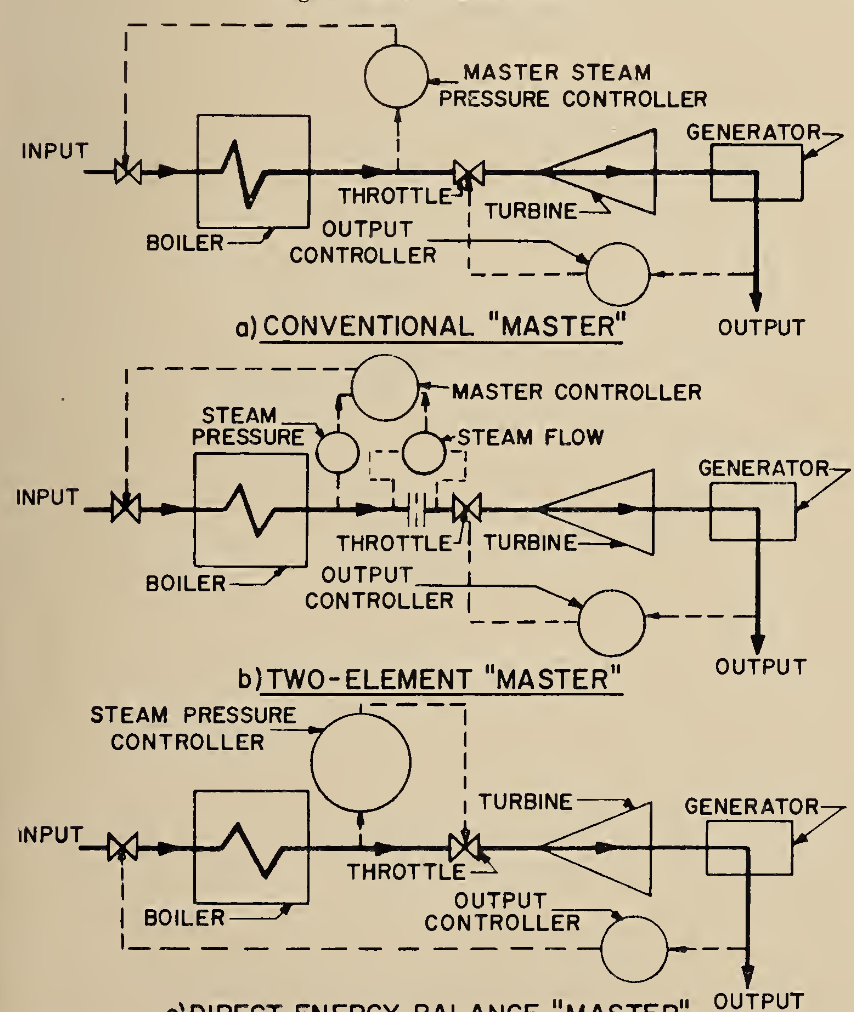
With the large units now being installed, direct connected remote water level gauges can no longer be used due to the great length of impulse lines. Consequently level transmitters are used to transmit to remote points. These transmitters usually incorporate some form of density correction to overcome the problem of incorrect readings associated with higher working pressures.

(d) *Steam Temperature Control:* Every steam temperature control seems to have its individual difficulties but these can be minimized by sufficient care during the design stages. Some of the problems are unquestionably related to the slow response of the initiating element. By necessity, the well in which the bulb is installed is heavily constructed, adequate for the service conditions, which may involve considerable time lags. Although temperature control is always the most difficult loop in any process to apply successfully, the development of multiple element control using some influence such as air flow through the unit as an index of load and heat transfer conditions, has resulted in considerable improvement. Such an influence, by its nature, has the disadvantage that the control loop is affected before the set-point has been achieved. This can be overcome by using some form of indexing system to eliminate the air flow signal until the required steam temperature has been reached.

In order to obtain wide range of control of superheat temperature it is quite common to combine sequentially attemperation or desuperheating with flue gas re-circulation or burner tilt. This is to avoid the excessive quantities of desuperheating spray water, with obvious repercussions in the form of superheater deposits, which would be required to cover a wider load range.

(d) *Miscellaneous Control Systems:* Throughout the powerhouse there are increasing numbers of simple control systems taking over the many functions previously operated manually and continuously. These various pressure, temperature and level controls now are usually installed and operate after commissioning with little care except routine maintenance.

Fig. 2. Forms of Master Control



Automation in Central Stations

Today's modern steam power station has units electronically controlled and provided with data logging equipment. There can be little doubt that many stations will be fully automatic within the foreseeable future and in this context "automatic" does not mean "manless". The central station now is in a transition period and the majority of new installations will take steps part of the way towards the ultimate goal of total automation. There is fairly common agreement throughout utilities that the concept of the automatic station has gone further and faster than expected, and probably too fast for the present state of the art.

From a theoretical viewpoint there is no reason why a system cannot be provided to start up a unit automatically by push button. The main limiting factor is the complexity of the equipment required to perform the operation together with the analyses, programming and computing associated with the automatic operation and monitoring functions required.

In the light of this extremely intricate equipment it would be well to consider how often these start-up and shut-down functions would be used during the life of the unit after the initial commissioning.

There are two basic approaches to the automatic station.

(a) Digital Computing equipment is used to program start-up, shut-down, logging and optimize the control cycles and Analogue computing equipment, which is well proven, controls the cycle in operation, i.e., the existing analogue controls remain in their entirety. This is sometimes referred to as the "Time shared Approach";

(b) A large high-speed digital computer is employed to perform and monitor all the operations required in a power station, including all the functions listed under (a) above. This method besides being probably the most expensive, introduces a more complex digital computing system with the possibility of less reliability.

In both cases the short-comings of hardware available at the present time i.e. solenoid valves, pressure switches, relays, are likely to jeopardise the success of these highly ambitious projects but in the long run there is no doubt that these problems will be overcome successfully.

Canadian Developments

National Research Council Develops Radio Direction Finder

Research in cathode ray direction finding has been carried on in Canada for 40 years. Recently a highly-developed instrument using a twin-channel receiver concept was developed at the National Research Council and now is in production for the Navy.

A report on the history and progress of the development has been prepared by C. W. McLeish of the NRC's Radio and Electrical Engineering Division.

The first research in cathode ray direction finding in Canada was conducted by General A. C. L. McNaughton and Colonel W. A. Steel between 1921 and 1925. In 1925 they were granted a patent on the twin channel direction finder.

Before the Second World War laboratory equipment covering both the low-frequency marine and the high-frequency bands were built at NRC. These were used as navigational aids and for research in locating thunderstorms. During the war, equipment for the armed services was used both as an aid to navigation and for locating transmission sources in air-sea rescue and tactical operations.

Since 1945 many sophisticated radio navigational systems have been developed which supplant direction-finding in that role. It is still required to a limited extent, however, for emergency operations.

The environment in which a system is to work affects firstly the design, and finally the limiting performance. The first design choice in the case of the new instrument being produced for the Navy was between the twin-channel receiver and the simpler single channel (azimuth scanning) receiver.

The latter was rejected on the basis that its output indication sometimes is severely affected by the modulation of the received radio signal. The azimuth indication of the twin channel receiver is independent of the character of the modulation. In the 3-30 megacycle frequency range for which the instrument is designed, sensitivity should be limited not by internal receiver noise but by external atmospheric noise. This is not difficult to accomplish with modern components but there is an additional limit set by co-channel interference.

Since there are literally thousands of signals in the band at one time a very high degree of selectivity is desirable. This is obtained easily in the twin-channel system but is restricted in single-channel systems by the rate of scanning they employ.

Finally, all direction finding systems which operate at frequencies where the radio waves are propagated via the ionosphere depend for accuracy on the roughness and variability of this reflecting medium.

The limit, which is close to one degree (rms error) may be achieved with a very large and expensive receiving antenna which samples the radio field over many wave lengths. A narrow aperture (fractional wavelength) antenna can provide bearings with an accuracy of about three degrees (rms error) on long distance transmissions. The errors are less than half for ground-wave signals. This accuracy is considered sufficient for normal applications, although in this respect the system does not reach the absolute limit set by its environment.

Dosco Opens Lewis M. Fulton Pipe Mill in Montreal

The Dominion Steel and Coal Corporation, Limited, has opened its new continuous weld pipe mill. The $3 million mill shares a 45-acre site beside the Lachine Canal with an electrical steel plant, a rolling mill, a wire products mill for making chain link and other types of fencing, and the industrial fasteners department.

Premier Jean Lesage opened the mill which is named after Lewis M. Fulton who first became connected with Dosco in 1911 and who retired as general manager of the plant Dec. 31, 1958.

The Montreal plant was built in 1911 by the Canadian Tube and Iron Company. Dosco started to acquire the company in 1941 and completed acquisition of controlling interest in 1943. It continued to operate as The Canadian Tube and Steel Products Company until last year when it became known as Dosco's "Montreal Works."

Since Dosco acquired the plant it has made continuous improvements until, now, it is a complete steel mill. For many years steel pipe was produced in an old butt weld pipe mill which performed well for a long period of time. Ever-increasing demands for a better product at a cheaper cost necessitated, ultimately, the scrapping of this old mill.

The new mill will provide continuous welded pipes from ⅜ in. to 4 in. in diameter, in lengths varying from 16 ft. to 42 ft., and at production rates ranging between seven and 22 tons an hour.

Canadin Nuclear Association Formed

Early in 1960 the Ontario government sponsored Canada's first conference on nuclear energy. This was called to meet the need for a clear definition and public awareness of the future promised through the peaceful uses of nuclear energy.

Discussions pointed to the need for an organization to represent all bodies concerned with the nuclear field in Canada. A result was that a small group of representatives from interested industries was appointed to study all aspects of such an organization.

Thus, the Canadian Nuclear Association was formed, and its directors now invite participation from all organizations and individuals who are, or expect to be, engaged in some phase of development or utilization of nuclear energy.

Halifax International Airport Opened

Following official opening ceremonies in the early autumn the Halifax International Airport has settled into a busy routine. The $18 million airport was opened by Hon. George Hees, then Minister of Transport.

There are three miles of runways, the longest of which is 8,800 ft. and can be extended to 10,000 ft. The five-storey terminal building cost $4.5 million. It is 1,260 ft. long and has a total area of 165,000 sq. ft.

Full travel facilities include air line offices, customs, health, immigration services, and business offices. EIC

International News

Solar Energy in France

Eighty percent of all hot water being used by a large French hotel in Perpignan in the Pyrenees is being heated by the sun. This new solar-energy heating system has been developed by the scientists of the National Center for Scientific Research at Mont-Louis, near Perpignan. They believe, according to 'France Actualle', that "if developed on an industrial scale, this could bring about a considerable revolution in energy production". They claim that mass production of heating apparatus based on this principle is already practicable and the cost would be relatively low. An industrial solar furnace at Mont-Louis has been in operation since 1952 turning out refractory products and this recent work in regard to the storing of the sun's energy was put into practice in the Spring.

At this hotel 25 special, two-square-meter mirrors, inclined at 45° angles and facing directly south have been placed on the hotel's roof terraces. They absorb infrared rays from the sun by means of specially treated sheets of metal, and heat more than 1,000 gallons of water. The water is brought to a boil on the roof of the hotel and is then piped to two basement storage tanks where a 60°C. temperature is maintained. Regular circuits then distribute hot water under pressure to all parts of the hotel. An electronic regulating device maintains the thermo-dynamic yield of this installation at a constant level, also automatically switching on an emergency central heating system in the unlikely event of there not being sufficient sun to heat the water to the proper temperature.

Obviously there are still a great many discoveries to be made in this field and the French are already constructing a second solar furnace at Odeillo, about 10 miles from Mont-Louis. It is planned this will go into operation in 1962 and is expected to produce 500 metric tons of refractory products a year at half the cost of manufacturing similar products in steel plants. A $600,000 Institute for Atmospheric Research is being built on the Lannemezan Plateau facing the French side of the Pyrenees and is sponsored by the Board of Scientific Research in France. After being transformed into a "solar-receptor area", the special covering of the 150 acres is to be heated to a high temperature which in turn will cause convective currents in the atmosphere planned to produce artificial rain. This new Institute at Campistrous is to be equipped with radar and an atmospheric goniometer.

Computer Instruction included in U.S. Engineering Courses

The University of Michigan has in the past year, been carrying out a project under which computer techniques were introduced to engineering students. The Ford Foundation last fall granted the University $900,000 for a three-year program in this field.

Forty-nine engineering courses used the computer as a regular part of course instruction and it appeared that even with a relatively small amount of computer background, students were able to solve problems assigned. Prof. Katz, who is in charge of the project, said in a report given at a conference at the University in September, that the best problems for computer instruction are yet to be found. Changes in mathematics instruction would be necessary and the project also found that the faculty must be trained in programming and solving problems themselves before assigning them to their classes. University administrations must accept the responsibility for the support of computer equipment for instruction. In the near future costs for computers for instruction are likely to match the costs of instructional laboratories, a fact which should be made clear to college administrators. An outline of the three-year program is also listed in the report.

Expected Reductions in Nuclear Power Costs

Prospects of reductions in the cost of generating nuclear power have been indicated in a report prepared by the International Atomic Energy Agency presented at their General Conference in Vienna recently. Nuclear power is still in its early phase of development and substantial cost reductions can be expected from technical improvements that are likely to emerge from the continuous research and development that is going on in several fields. Especially significant will be the possible reductions in fuel cycle costs, resulting from lower fabrication and re-processing charges, higher burn-ups and a fall in uranium prices. Development of improved but low cost reactor materials should also result in an overall economy. Savings can be expected from the standardization of reactor components. With better understanding of essential safety requirements and through the use of improved techniques, containment and control of reactors will become simplified and less expensive. Finally, when several nuclear power plants of essentially the same design are built, the engineering development expenses will be spread out and the cost per unit will decrease.

U.K. Vehicle for Road or Rail

A vehicle that may be converted from truck to rail wagon has been developed in the U.K. Made by the Pressed Steel Company, Oxford, England, this 11-ton capacity truck can be driven to the railhead and, at a touch of a button, the rear wheels retract and the rail wheels are lowered. Hitched to a freight train it travels as a rail wagon to its destination where, converted once more to a truck, it completes the journey by road.

Northern Ireland's Oil-Fired Generating Station

Coolkeeragh Power Station, Northern Ireland's first oil-fired generating station, has two 30,000 kw. sets in commission with one 60,000 kw. set to be installed for commissioning by the fall of 1961. The 60Mw. turbine-generator, feed heater, and condenser are being manufactured by Associated Electrical Industries (Manchester) Ltd. The Transformer Division of the A.E.I. has also supplied two 37,500 kva., 11,800/35,-400v., 3-phase OFW cooled generator transformers and are manufacturing a 75,000 kva., 3-phase generator transformer, with a ratio of 11,800/120,-000v. ON/OFB cooled, which will be fitted with an on-load tap-changer.

The station is designed to meet demands of future industrial development. It also will supply Londonderry city when the generating station there is closed by the Londonderry Corporation Electricity Department. EIC

Month to Month

September Executive Committee Meeting

The Institute's Executive Committee of Council, President Dick presiding, met in St. Andrews, N.B., Sept. 9. The following, taken from the minutes of the meeting, reports the highlights.

Membership List

The General Secretary was authorized to distribute bills for 1961 fees early in December. Members are also being sent a card requesting information which will enable Headquarters to classify the membership according to their fields of engineering interest. This information also will enable Headquarters to publish a membership directory early in 1961. Three thousand copies of the membership list will be produced. Copies will be distributed at no cost to universities, Branch Chairmen, Councillors, members of the Committee on Technical Operations, and others who require them. It was agreed in principle that other E.I.C. members desiring copies will be able to purchase them at a small charge.

Committee on Membership

The Executive Committee agreed on the need for a more vigorous membership program. The necessity of a national committee on membership was evident, this committee to work through the Branches and other E.I.C. facilities with the object of promoting a serious drive for new members. Finance Committee Chairman F . L. Lawton observed that the Institute is at present serving only a portion of its entire potential membership: consequently the Institute is not as strong as it should be. There is a vital need for a national membership committee, and a vital need for the strongest possible activity at all levels of the Institute.

It was resolved that a national committee be formed with S. B. Cassidy of Fredericton, N.B., as chairman. This committee is responsible for actively co-ordinating and encouraging the following specific activities of the Branches on which the prime responsibility for direct membership activities shall continue to rest:

a) Formation of active Branch membership committees by all Branches

b) Recruiting of new members of suitable calibre for the Institute

c) Investigation of cases of apparent loss of interest in the Institute affairs and activities by members as indicated by non-payment of fees, by direct complaint, by notice of intention of resigning, or in other ways. The function of the Committee in this field shall be to encourage the Branch Committees to carry such investigations to the point at which the cause of difficulties could be determined, and the matter then referred to the relevant Branch or Institute body for action

d) Investigation of reasons for unwillingness to join the Institute on the part of apparently desirable candidates where such cases come to the attention of Branch or Institute Committee members.

The Committee shall assist actively the Branch Membership Committees in the performance of their functions in establishing suitable terms of reference for operational procedures. The Committee shall provide effective liason between various Branch Committees, and act as a clearing house for information of common interest to Branches relating to membership.

The Committee shall periodically advise Council on matters relating to membership and assist in formulating policy in this connection.

Headquarters Re-Organization

The General Secretary reported that in view of the present enlarged program of Institute services it had become evident that the staff must be organized in a pattern which follows these major activities. The Institute's broad activities provide an adequate technical program, a service to increase and maintain its membership, and the necessary administrative functions that will enable all the programs to be carried out with the maximum efficiency and to render all possible assistance to Branches. Exclusive of the publications and library activities, which come under the direct responsibility of the General Secretary, there now are three major divisions of activities at Headquarters:

I *Membership Services,* under its manager, E. C. Luke

II *Technical Services,* under its manager, J. H. Legere

III *Financial,* records and other supporting administrative services under the Controller and Office Manager, T. R. Montgomery

Engineering Education

On the recommendation of the Chairman of the Committee on Technical Operations and the Chairman of the E.I.C. Committee on Engineering Education, it was resolved that the E.I.C. Committee on Education be constituted as a division of the Committee on Technical Operations; and that Dean Arthur Porter, Chairman of the Committee on Engineering Education, continue as Chairman of the Engineering Education Division of the Committee on Technical Operations.

Commonwealth Co-operation

There are many members of the Commonwealth sister societies now resident in Canada who are not members of the E.I.C. Members of such sister societies resident in Canada do not have a professional home. The E.I.C. now has in the Committee On Technical Operations and in its several divisions the organizational framework for co-operation with members of sister societies.

The councils of the four societies concerned have expressed the hope that institution members in Canada will give this plan their whole-hearted support, in the knowledge that by so doing they can take an active part in technical activities which will contribute significantly to the development of engineering in Canada.

Basis of Agreement

1. Members of other Commonwealth societies resident in Canada are invited to participate in the activities of the Engineering Institute of Canada, both on a national and local basis. Branches of the E.I.C. are encouraged to establish specialist sections and/or specialist engineering discussion groups wherever justified by numbers and interest.
2. All members resident in Canada are invited to submit papers for consideration by the appropriate Engineering Division of the E.I.C. Committee on Technical Operations for presentation at Annual, Regional and local meetings of the E.I.C. They are also encouraged to submit papers of a more local character to the E.I.C. Branch in each area.
3. Members of another Commonwealth society resident in Canada are to be represented on the appropriate Engineering Division of the E.I.C. Committee on Technical Operations, where warranted and justified by the number in that speciality and as agreed by the society concerned, by a representative appointed thereto by the governing body of the sister society. Members so nominated are to become full voting members of the

President's Column

DURING the past few weeks Presidential visits have been made to the St. Maurice Valley Branch and to the Saguenay Branch. Splendid meetings were held at Shawinigin and Arvida, with good attendances at both places. Sherbrooke Branch tendered the President a Testimonial Banquet on October 29th, following the Convocation when the University of Sherbrooke awarded the President the Degree of Doctor of Science (Honoris Causa).

Many messages of congratulations were received by the President, for which he extends his sincere thanks.

A Council Meeting was held in Sherbrooke the same day.

Other Presidential activities included attendance at Queen's University when a Past President of the Engineering Institute, John Bertram Stirling, B.A., B.Sc., LLD, was installed as Chancellor. This is a great honour to a very worthy Past President and the Engineering Institute extends its sincere congratulations to Dr. Stirling on this memorable occasion.

The Engineering Institute of Canada was also represented by your President at the Annual Dinner of the R.C.E.M.E. Corps Association of which our Treasurer, Mr. E. D. Gray-Donald is President. Many members of the Institute are R.C.E.M.E. officers, including Past-President, L. F. Grant, who responded to one of the toasts.

Considerable activity has been shown by the new Committee on Membership. This very important Committee is being very effectively headed by Councillor Stan Cassidy of Fredericton, N.B. Stan is looking to every E.I.C. member to be a member of his Committee, to utilize the entire existing membership to recruit new members. While we are proud of the extent of our membership coverage we must all realize that there are still a great many engineers in Canada who should be members, and we make a special plea to all members of the Institute to constitute themselves as members of this new Membership Committee, and to extol the benefits and advantages of E.I.C. membership, with the object of bringing in new members.

The Committee on Technical Operations under Dr. Guy Ballard, Vice-President (Scientific) of the National Research Council, Ottawa, is furthering the Institute's technical activities in various directions, not the least of which is in branch activities. Our greatest contribution to our members is to make them more aware of the possibilities for their technical improvement, and this Committee is working towards increasing the interest of members and branches in this important phase of our responsibilities.

CHAIRMEN OF COMMITTEES

Standing Committees

Admissions:	P. W. Gooch, Montreal
Finance:	F. L. Lawton, Montreal
Legislation:	W. B. Pennock, Ottawa
Library & House:	T. N. Davidson, Montreal

NIAGARA PENINSULA
Chairman, F. R. Denham, P.O. Box 512, Fonthill, Ont., Tel. RE. 4-4525.
Secretary, Gordon G. Jacox, 8 Springhead Gardens, Welland, Ont.

NIPISSING and UPPER OTTAWA
Chairman, (Change of address) R. S. MacLennan, M.E.I.C., 442 Oak Street East, North Bay, Ont. Bus. Tel. GR 2-5250 — Res. Tel. GR 2-4976.

Secretary-Treasurer: Donald W. Briden, M.E.I.C., 734 Birchwood Rd., North Bay, Ont. Bus. Tel. GR 2-1300 — Res Tel. GR 2-1052.

NORTH EASTERN ONTARIO
Chairman, I. M. Foster, P.O. Box 672, Kapuskasing, Ont.
Secretary, J. W. Blakeman, c/o Spruce Falls Power & Paper Co. Ltd., Kapuskasing, Ont.

NORTHERN NEW BRUNSWICK
Chairman, George A. Bird, M.E.I.C., 51 Gerrard Street, Campbellton, N.B.
Secretary-Treasurer, M. B. Martin, Jr. E.I.C., 10 Andrew Street, Campbellton, N.B.

NORTHERN NOVA SCOTIA
Chairman, J. E. Clarke, 38 Maple Ave., New Glasgow, N.S.
Secretary-Treasurer, R. S. Morrow, 151 Almont St., New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE
Chairman, R. W. Pryer, 192 Cartier Avenue, Seven Islands, Que.
Secretary-Treasurer, L. E. Fischer, c/o Iron Ore Co. of Canada, Dock Terminal, Seven Islands, Que.

OTTAWA
Chairman, H. C. Brown, c/o Canadian Westinghouse Co. Ltd., 1800 Bank St., Ottawa, Ont., Tel. RE. 3-2500.
Secretary, J. N. Prichard, 2234 McQuaig St., Ottawa 1, Ont., Bus. Tel. CE. 6-7531, Loc. 226.

PETERBOROUGH
Chairman, R. M. Allemang, 714 Walkerfield Ave., Peterborough, Ont., Bus. Tel. RI. 2-7711, Ext. 361.
Secretary-Treasurer, Peter Tuck, c/o Canadian General Electric Co., 107 Park St. North, Peterborough, Ont., Tel. RI. 2-7711, Ext. 471.

PORT HOPE
Chairman, J. L. Sylvester, 71 Walton St., Port Hope, Ont.
Secretary-Treasurer, D. A. Runciman, 49 Chapel St., Cobourg, Ont.

PRINCE EDWARD ISLAND
Chairman, R. D. Donnelly, Box 184, Charlottetown, P.E.I.
Secretary-Treasurer, E. S. Chandler, 242 North River Rd., R.R. 2, Charlottetown, P.E.I.

QUEBEC
Chairman, B. I. Burgess, c/o Canadian General Electric Co. Ltd., Industrial Centre 5, Quebec, Que., Tel. MU. 3-3431.
Secretary-Treasurer, Marc Bergeron, c/o Concrete Repairs & Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY
Chairman, D. L. Aker, c/o Aluminum Co. of Canada, Avida, P.Q.
Secretary-Treasurer, J. R. Eason, 533 Normandie St., Arvida, Que.

SAINT JOHN
Chairman, J. B. Eldridge, 569 Sand Cove Rd., Lancaster, N.B.
Secretary-Treasurer, J. P. Mooney, 50 Princess St., Saint John, N.B.

SAINT MAURICE VALLEY
Chairman, J. I. Butcher, 1005-124th Street, Shawinigan, Que.
Secretary, J. E. Dunn, Box 951, Three Rivers, Que.

SARNIA
Chairman, A. W. Wirth, 611 Cathcart Blvd., Sarnia, Ont., Tel. ED. 7-8221, Loc. 608.
Secretary, R. W. Hodgson, 885 Kemsley Drive, Sarnia, Ont., Tel. ED. 7-8221, Loc. 656.

SASKATCHEWAN
Chairman, L. T. Holmes, 3057 Retallack Street, Regina, Sask., Tel. Lakeside 3-7560.
Secretary-Treasurer, R. Bing-Wo, 2043 Cameron Street, Regina, Sask.

SASKATCHEWAN BRANCH SECTIONS

Regina
Chairman, L. T. Holmes, M.E.I.C., 3057 Retallack Street, Regina, Sask.
Sec.-Treas., Reginald Bing-Wo, M.E.I.C., 2043 Cameron St., Regina, Sask.

Moose Jaw
Chairman, J. C. MacKay, M.E.I.C., 1270 Brown Street, N.W., Moose Jaw, Sask.
Sec.-Treas., T. L. Salmon, M.E.I.C., 1057 Henry Street, N.W., Moose Jaw, Sask.

Prince Albert
Chairman, William S. Paine, M.E.I.C., Assistant City Engineer, Department of Highways, City Hall, Prince Albert, Sask.
Sec.-Treas., R. Wayne Kyle, M.E.I.C., Assistant City Engineer, Engineering Department, City Hall, Prince Albert, Sask.

Estevan
Chairman: A. Guthrie, M.E.I.C., Box 1276, Estevan, Sask.
Sec.-Treas., Gerald R. Ursenbach, M.E.I.C., Producers Pipelines Ltd., Estevan, Sask.

Saskatoon
Chairman, R. C. Strayer, M.E.I.C., University of Saskatchewan, College of Engineering, Saskatoon, Sask.
Sec.-Treas., F. W. Catterall, M.E.I.C., Underwood, McLellan & Assoc., Box 539, Saskatoon, Sask.

Yorkton
Chairman, R. G. Brown, M.E.I.C., Box 579, Yorkton, Sask.
Sec-Treas., C. L. Slegel, M.E.I.C., 83 Elizabeth Avenue, Yorkton, Sask.

SAULT STE. MARIE
Chairman, N. A. Paolini, c/o Dominion Bridge Co. Ltd., P.O. Box 520, Sault Ste. Marie, Ont.
Secretary-Treasurer, M. R. Wright, c/o Dominion Bridge Co. Ltd., P.O. Box 520, Sault Ste. Marie, Ont., Tel. AL. 6-5611.

SUDBURY
Chairman, R. P. Crawford, 218 College St., Sudbury, Ont.
Secretary-Treasurer, C. L. MacMillan, 1237 Woodbine Ave., Sudbury, Ont.

TORONTO
Chairman, A. M. Toye, 102 Bideford St., Downsview, Ont., Tel. CH. 4-2571, Loc. 492.
Secretary-Treasurer, C. L. Thompson, c/o Honeywell Controls Ltd., Vanderhoof Ave., Leaside, Toronto, Ont., Tel. HU. 9-2151.

VANCOUVER
Chairman, C. P. Jones, 4130 Capilano Rd., North Vancouver, B.C.
Secretary-Treasurer, R. Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND
Chairman, L. C. Johnson, 3051 Larkdowne Rd., Victoria, B.C.
Secretary-Treasurer, R. W. Lockie, 314 Cadillac Avenue, Victoria, B.C.

WINNIPEG
Chairman, W. L. Wardrop, 456 Notre Dame Ave., Winnipeg, Man.
Secretary-Treasurer, W. N. Isberg, 39 Turner Ave., Winnipeg 12, Man.

YUKON
Chairman, J. H. Reeves, c/o Northwest Hwy. Maintenance Est., Whitehorse, Yukon.
Secretary, J. P. MacGowan, c/o Northwest Hwy. Maintenance Est., Whitehorse, Yukon.

ONTARIO DIVISION
Chairman, H. R. Sills, 542 Gilmour St., Peterborough, Ont.
Secretary, John G. Hall, 92 Heddington Ave., Toronto, Ont.

Notice

IMPORTANT CHANGE IN MEMBERSHIP PROCEDURE.

Council recently approved a change in membership application procedure whereby reports in writing will be required in future from all applicants' references (sponsors). This will be accomplished by the use of a new combination letter and form, which will be distributed BY THE APPLICANT HIMSELF to the three or more persons selected for references. The report portion will then be completed and returned directly to Headquarters by each referee.

An initial supply of these forms will be forwarded to all branches as soon as they are available, and the new system is to be introduced at once. Each applicant for membership will, therefore, be given three (more if needed) blank copies of the new form, IN ADDITION TO the membership application form.

Council is confident that this procedure will do much to improve the admission process, and at the same time guard the level of qualifications for membership.

YOUR CO-OPERATION IS REQUESTED.

1960 Annual General Meeting

Minutes of the Seventy-Fourth Annual General Meeting of The Engineering Institute of Canada, held in the Ball Room of The Royal Alexandra Hotel, Winnipeg, Manitoba, on Wednesday, May 25, 1960, between the hours of 10.00 a.m. and 12.00 noon, presided over by President J. J. Hanna, Calgary, Alberta.

Call to Order and Notice of Meeting

The President called the Seventy-Fourth Annual General Meeting of The Engineering Institute of Canada to order at 10.00 a.m. The General Secretary read the notice of the meeting, which, in accordance with Section 52 of the by-laws, had been mailed to corporate members before the Thirtieth day of April, 1960.

President's Opening Remarks

The President extended a sincere welcome to the many members who were in attendance at the meeting.

Confirmation of Minutes

It was moved by Mr. C. Fisher, seconded by Professor A. C. Davidson, and carried unanimously that the minutes of the 73rd Annual General Meeting of the Institute held in Toronto on June 8, 1959, be taken as read and adopted.

Report of Council, Report of Finance Committee, Report of Official Auditors, and Treasurer's Report for 1959

It was moved by Mr. H. V. Page, seconded by Mr. A. W. Wirth, and carried unanimously that the report of the Council, the report of the Finance Committee, the report of the Official Auditors, and the Treasurer's report for 1959, as printed in the Annual Report for 1959, be adopted.

Official Auditors for 1960

It was moved by the Treasurer, Mr. G. N. Martin, seconded by Mr. J. Benoit, and carried unanimously that the firm of Peat, Marwick, Mitchell and Company, Chartered Accountants, of Montreal, be appointed the official auditors for the Institute for the year 1960.

Report of Committees, Representatives, Branches, and the Ontario Division

It was moved by Mr. Harvey Self, seconded by Mr. E. B. Hubbard, and carried unanimously, that the reports of the Committees, Representatives, Branches, and the Ontario Division, as printed in the Annual Report for 1959, be adopted.

Nominating Committee, 1960

The General Secretary reported that the Nominating Committee for 1960 has been appointed, as listed on page 22 of the Annual Report for 1959. One member is serving on the Committee from each Branch, with Mr. John H. Budden, Montreal, Quebec, as Chairman.

Annual Meeting Council, May 24, 1960

It was noted that there were no items of business referred from the Annual Meeting of Council, except for the report of the Engineers Confederation Commission, which would be received later at this Annual General Meeting.

Proposed Amendments to E.I.C. By-Laws

The President stated that for some years it has been apparent that certain changes to the Institute By-Laws are necessary to have them conform with current practice, as approved by Council. Accordingly Council had appointed a special committee with Mr. J. S. Waddington of Brockville as Chairman, and Messrs. Janitsch and Dolphin of Belleville and Kingston, respectively, members, to prepare appropriate amendments to the By-Laws. These proposals were approved by Council and were mailed to corporate members not less than twenty-one days before this Annual General Meeting, as required by Section 80 of the By-Laws.

The President stated that the proposals were now before the membership for discussion: the members present may propose an amendment or amendments thereto, and all proposals together with such amendment or amendments as approved by the Annual General Meeting shall be printed on a letter ballot to be submitted to the corporate membership of the Institute by the General Secretary not later than two months after the meeting. An affirmative vote of two-thirds of all valid ballots shall be necessary for the amendment or repeal of existing By-Laws, or for the adoption of new By-Laws.

Section 27—Readmission: To agree with Council decision, January 1955, it is proposed that the Section be written as follows:

> "The Council, at its discretion, may re-admit . . . any person . . . provided that one year's arrears have been paid".

It was moved by Professor A. C. Davidson, seconded by Colonel L. F. Grant, and carried unanimously that this Annual General Meeting approves the amendment to Section 27, Re-admission, for submission by letter ballot to the corporate membership.

Section 35—Investments: To provide more flexibility in implementing Council's orders, it is proposed that Section 35 be written as follows:

> "Any two, the treasurer, the chairman of the finance committee, and the general secretary, or one of the above along with a member of the finance committee, shall invest the funds of the Institute as may be ordered by Council."

It was moved by Mr. E. D. Gray-Donald, seconded by Mr. T. Foulkes, and carried unanimously that this Annual General Meeting approves the amendment to Section 35, Investments, for submission by letter ballot to the corporate membership.

Section 29—Branch Representation: To clarify the apparent meaning of the present Section it is proposed that Section 29 be written as follows:

> ". . . 3 councillors from each branch having 400 and less than 601 members, and an additional councillor from each branch for each 200 members over 601 . . ."

It was moved by Mr. R. B. Chandler, seconded by Professor W. G. Heslop, and carried unanimously that this Annual General Meeting approves the amendment to Section 29, Branch Representation, for subsequent submission by letter ballot to the corporate membership.

Section 22—Journal Subscription: To agree with Council's decision, September 1959, it is proposed that Section 22 be written as follows:

> "Honorary Members, Members, Juniors, Students and Affiliates shall receive the Journal of the Institute free. Subscription charges to all others shall be as Council directs from time to time."

It was moved by Professor A. C. Davidson that the change to Section 22—Journal subscription, as proposed be deleted and the following substituted:

> "That the $4.00 per annum Journal subscription for Members and Juniors be retained, and the $2.00 per annum Journal subscription for Students be retained, and that these funds be used as follows:
>
> — of the $4.00 from the Members and Juniors
>
> a) $1.00 per Member or Junior be rebated to the Branch for use in Branch activities.
>
> b) $1.00 per Member or Junior be given to the Committee on Technical Operations to support its work.
>
> c) $1.00 per Member or Junior be used to pay in part the reasonable travelling expenses of Branch Councillors for attendance at Council meetings.
>
> d) $1.00 be put in the Reserve Funds of the Institute to be used at the discretion of Council, without recourse to the membership at large concerning its use.
>
> — Of the $2.00 from the Student members, $0.50 be allotted to each of the items (a), (b), (c) and (d) above, with the added provision that the $0.50 rebate to Branch be used solely for Student activities in the Branch."

Professor Davidson stated that it is obvious from Branch Officers Conference discussion that most Branches require more money to operate effectively. The Charter of the E.I.C. states that one of its objectives is to promote the technical welfare of the Canadian engineer: the Committee on Technical Operations is the most effective medium through which this can be done, hence the proposal that it be given the necessary funds to expand its activities. Professor Davidson stated that it is unreasonable to expect councillors, as members of the governing body of the Institute, to continue to pay their own way to meetings of Council at which the work of the Institute is conducted. If councillors are prevented from attending for financial reasons, then they are also prevented from contributing to the work of the Institute.

Professor Davidson urged the meeting to take note of the fact that the body which is strongest financially will succeed: the Institute should do everything in its power to promote the technical welfare of the Canadian engineer, to publicize his work in Canada and in the world, and to ensure that Canada's engineering achievements are not lost because of diffidence or false economy.

In seconding the motion, Mr. Harvey Self, Toronto, spoke in very firm support of the proposals put forward by Professor Davidson, with particular reference to the situation in Toronto vis-à-vis work with the students, the cost of Branch administration, and the necessity to promote adequate technical activities. He urged that as professional engineers the membership should be aware of its responsibilities, and be prepared to pay higher fees, if necessary, to promote the activities of the Institute.

The Treasurer, Mr. G. N. Martin, said he is in favour of Professor Davidson's objective of obtaining more funds for the Institute's work. However, he strongly recommended that this be done by raising the fees rather than by interfering with a considered separate proposal concerning free distribution of The Engineering Journal, since this proposal has many far-reaching implications.

Mr. J. H. Budden, Montreal, was in sympathy with Professor Davidson's objective, but not with the proposal regarding how this should be achieved. He thought it would tend to make the operations of the Finance Committee inflexible, and suggested that to attain the desired end, branches should instruct their councillors regarding means of raising additional fees, and how they should be expended.

Mr. C. G. Southmayd, Montreal, Chairman of the Student Policy Committee, stated that admirable work is being done by Faculty Advisors on University campuses throughout Canada. He strongly urged however, that the student fee should not revert to $4.00 per annum.

Mr. Matthews, London, and Mr. Pennock, Ottawa, spoke in favour of Professor Davidson's objective, but expressed the opinion that this should be achieved at the appropriate time by raising the fees of the Institute rather than by the method proposed.

President-Elect George McK. Dick endorsed the Treasurer's remarks, and said that if the Institute is in need of more money the best method of obtaining it is by raising the fees at the appropriate time.

The motion which had been moved by Professor A. C. Davidson, seconded by Mr. Harvey Self, was put to vote, and was defeated.

It was moved by Mr. Cassidy, seconded by Mr. Southmayd, and carried that this Annual General Meeting approve the amendment to Section 22, Journal Subscription, for subsequent submission by letter ballot to the corporate membership.

Section 28—Compounding of Fees: To agree with Section 22 as revised, to take account of the age of a member at the time of the compounding of fees, to distinguish between the fees paid by members in different localities, and to remove the stipulation that there shall be no refund of fees that have been compounded, it is proposed that Section 28 be written as follows:

"A Montreal Branch member in good standing may compound all his future annual fees by a single payment in accordance with the following schedule:

Age of Member at time of compounding	$ Amount
25	415
30	395
35	375
40	345
45	310
50	270
55	220
60	160
65	90

"All other branch residents may compound future annual fees by paying 90% of the amounts shown. Branch non-residents or non-residents may compound all future annual fees by paying 80% of the amounts shown. For intermediate years direct interpolation will apply.

"In the advent of discontinuance of membership for any cause there shall be a refund of compounded fees in the amount of 90% of the unused portion, with age 70 taken as the reference year for such calculation. Payment received for compounding of fees shall be kept in a separate fund during the period of membership of the compounder, and only the interest used for the current expenses of the Institute and the rebates to the branches."

It was moved by Mr. J. H. Budden, seconded by Mr. J. H. Fox, and carried that this Annual Meeting approves the amendment to Section 28, Compounding of Fees, for subsequent submission by letter ballot to the corporate membership.

Section 11—Affiliates: To clarify the meaning of the Section as it is presently interpreted, it is proposed that Section 11 be written as follows:

"An Affiliate shall be a person of professional status not an engineer, who collaborates in their projects or in advancing engineering knowledge."

After discussion, it was moved by Professor A. R. Edis, seconded by Dr. B. G. Ballard, and carried, that Section 11, Affiliates, be approved by this Annual General Meeting for subsequent submission by letter ballot to the corporate membership as follows:

"An Affiliate shall be a person of professional status **other than** an engineer, who collaborates with engineers in their projects or in advancing engineering knowledge."

Section 18—List of Members: To agree with present practice, which is not to issue a list each year, but on the other hand, to avoid excessive intervals between the issue of lists, it is proposed that Section 18 be written as follows:

"A list of members with the names arranged alphabetically and geographically, indicating the zones and branches, shall be sent at Council's direction to corporate members at intervals not exceeding 5 years."

After discussion, it was moved by Mr. Cassidy, seconded by Mr. C. V. Antenbring, and carried that Section 18, List of Members, be approved by the Annual General Meeting for subsequent submission by letter ballot to the corporate membership.

"A list of members with the names arranged alphabetically and geographically, indicating the zones and branches, shall be sent at Council's discretion to corporate members."

Section 45—Appointment of General Secretary, Treasurer and Committees: The functions of the Papers Committee are now performed by the Committee on Technical Operations and it is proposed that the words "the Papers Committee as described in Section 48" be deleted from Section 45, and the words "A Committee on Technical Operations of at least 6 members" be inserted in Section 45.

It was moved by Dr. B. G. Ballard, seconded by Professor W. G. Heslop, and carried unanimously that this Annual General Meeting approve the amendment to Section 45, Appointment of General Secretary, Treasurer and Committees, for subsequent submission by letter ballot to the corporate membership.

Section 48—Papers Committee: To agree with Council's decision, February 26, 1955, March 1956 and subsequently, it is proposed that Section 48 be deleted in its entirety and a new Section 48 substituted, as follows:

"The Committee on Technical Operations shall consist of representatives of the several technical divisions of the profession. It shall keep all technical activities of the Institute under constant review. It shall recommend to Council the establishment of such divisions of the Committee on Technical Operations as necessary to carry out reviews of specific fields of technical activity and also such special or standing committees of the Institute as may appear warranted by developing needs in technical areas. It shall recommend to the Publications Committee particular papers for publication. The divisions of the Committee on Technical Operations shall encourage the formation of technical sections dealing with its area of engineering in the branches, assist such technical sections in their work, and co-ordinate all activities of such technical sections in the various branches. It shall report quarterly to Council on the technical activities of the Institute."

It was moved by Mr. S. Barkwell, seconded by Mr. W. B. Pennock, and carried unanimously that this Annual Meeting approves the deletion of Section 48, Papers Committee, and the insertion in its place of the new Section 48 entitled "Committee on Technical Operations," for subsequent sumission by letter ballot to the corporate membership.

Section 75—Specifications: The Institute has not in recent years issued specifications and in view of the activities of the Canadian Standards Association and other bodies it appears unlikely to do so, and it is proposed that Section 75 be deleted.

It was moved by Mr. A. M. Toye, seconded by Mr. J. H. Budden, and carried unanimously that this Annual General Meeting approves the deletion of Section 75, Specifications, for submission by letter ballot to the membership.

45 (a) Honorary Vice-Presidents: Since there is at present no provision for the appointment of Honorary Vice-Presidents, it is proposed to authorize the President to make such appointments under Section 45 (a) as follows:

"The President may appoint a corporate member as an Honorary Vice-President for the purpose of representing the President or the Institute on a specific occasion other than at the deliberations of the Council or Committees of the Institute."

It was moved by Mr. Sillitoe, seconded by Mr. D. B. McKillop, and carried unanimously that this Annual General Meeting approve the inclusion of Section 45 (a), Honorary Vice-Presidents, in the By-Laws of the Institute, for subsequent submission by letter ballot to the corporate membership.

A motion by Mr. Harvey Self proposing an increase in membership fees of the Institute was ruled out of order. Mr. Hutchison, Toronto, gave notice of motion concerning a proposed increase in fees; and the General Secretary advised that if members desire to put forward a proposal to increase the membership fees of the EIC, the correct procedure, in accordance with the By-Laws, is for at least twenty corporate members in good standing to petition the Council for this change in By-Laws prior to October 1st.

Report of the Engineers Confederation Commission

The President stated that at the 73rd Annual General Meeting it was indicated that the Engineers Confederation Commission would be formed to prepare detailed proposals for Confederation based on a joint report of the E.I.C.'s and the C.C.P.E.'s Committees on Confederation, approved one year ago. On May 24, 1960, the Council of the Institute received the progress report from the Chairman of the Commission, Mr. John H. Fox (see page 111, June 1960 issue of The Engineering Journal).

The General Secretary read the progress report, dated May 5, 1960, of the Engineers Confederation Commission.

Mr. John H. Fox, Chairman of the Engineers Confederation Commission, was called on by the President to address the meeting, and report on the work of the Commission. Mr. Fox expressed his thanks to the Institute for this opportunity to address the Annual General Meeting on a subject close to the hearts of those present and himself.

He paid tribute to the tremendous assistance given to himself and the Commission by President J. J. Hanna, President D. Turnbull and President-Elect George McK. Dick, since the Commission was appointed. He also extended his personal thanks to every member of the Commission which he said at its meetings has had almost 100% attendance, and particularly to recognize the work of the Secretariat composed of Leo M. Nadeau of the C.C.P.E. and Garnet T. Page of the EIC.

The report presented to the 74th Annual General Meeting of the Institute was first presented to the Annual Meeting of the Canadian Council of Professional Engineers on May 11, 1960, at the same time that copies were mailed to members of the Council of The Engineering Institute of Canada. The report is published in full in the June 1960 issue of the Journal, and every effort was made therefore to ensure that the report was in the hands of both groups at about the same time.

The Commission has approached its task within the eight basic clauses and has tried to adopt a broad attitude throughout its work. The Commission is aware of the tremendous privilege which it has of participating in this work for the professional engineers of Canada, and realizes that if Confederation is achieved Canada will find itself in the position of giving world leadership in the formation of a national engineering group. Any recommendations which the Commission may make will not be restrictive but permissive, and they will not be terminal as to any date. In other words, the Commission does not envisage planning on something which will become effective on a specific date.

Mr. Fox gave a brief background of the course of negotiations from 1955, when proposals were totally unacceptable to both parties, to 1959 when the Joint Report was accepted by the EIC and the C.C.P.E., and the Engineers Confederation Commission was formed. Mr. Fox assured the Annual General Meeting that the report presented today represents some real progress in the work of the Commission. Mr. Fox then elaborated on the highlights of the report.

Mr. Fox noted that J. Graham Dale, Alberta, recently elected President of the C.C.P.E. has been replaced on the Commission by J. F. McDougall, Edmonton. Mr. Leo Roy has replaced Mr. George McK. Dick, as Vice-Chairman of the Engineers Confederation Commission, and Dean Jacques Lemieux of Sherbrooke has replaced Mr. Roy as one of the EIC representatives in the Province of Quebec. The Councils of both societies have reappointed the Chairman, Vice-Chairman, and members of the Commission for a second year, consistent with the provision of the Joint Report.

Mr. Fox stated that the final report of the Commission will be a factual presentation, and will not attempt to indicate whether or not the plans should be carried out. This problem will be referred to the membership for decision. The Commission is, however, hopeful that the answer will be obvious.

Mr. Fox stated that to-date there has been a minimum of publicity, for which he accepts responsibility with the full endorsation of the Commission. He stated that the time is now past when it is necessary to withhold publicity and that information will be available more frequently. (Applause.)

It was moved by Mr. R. B. Chandler, seconded by Mr. P. W. Gooch, and carried, that the 74th Annual General Meeting of the Engineering Institute of Canada accepts the progress report of the Engineers Confederation Commission, and records its sincere appreciation to Mr. John H. Fox, its Chairman, and the various sub-committee chairmen, for the outstanding work done todate on the preparation of a Charter that will provide an acceptable basis on which to include Confederation for Canadian engineers.

President Hanna thanked Mr. Fox for presenting his report in person to the meeting.

Honours, Medals and Prizes

The President announced that at its meeting held on April 30, 1960, the Council of the Institute unanimously voted that the following honours and medals be awarded for 1960:

Honorary Memberships
"Chosen from those who have become eminent in engineering or kindred sciences, and elected by unanimous vote of Council."
Bristow Guy Ballard,
William Percy Dobson,
John Norison Finlayson,
Richard Lankaster Hearn,
Otto Holden,

Julian C. Smith Medals (1959)
"For achievement in the development of Canada."
Clarence Decatur Howe,
Hugh Andrew Young,

Gzowski Medal
No Award.

Leonard Medal
"For papers on mining subjects."
Victor Dolmage, M.E.I.C
J. W. Stewart, M.C.I.M.

For their paper:
"Demolition of Ripple Rock"

Plummer Medal
"For papers on chemical and metallurgical subjects"
John Templeton Hugill, M.E.I.C.
For his paper:
"A large Capacity Oxygen Plant for Copper Refining"

Duggan Medal and Prize
"For the best paper dealing with the use of metals for structural and mechanical purposes"
Alan Garnett Davenport, Jr. E.I.C.
For his paper:
"The Wind-Induced Vibration of Guyed and Self-Supporting Cylindrical Columns"

Ross Medal
No Award.

Robert W. Angus Medal
"For the best paper on a mechanical engineering subject"
John James Traill, M.E.I.C.
For his paper:
"Tests of Hydraulic Turbines — An Appraisal"

Sir George Nelson Award
No eligible papers received.

Canadian Lumbermen's Association
No eligible papers received.

Junior Prizes
H. N. Ruttan
John Galbraith
Ernest Marceau
Phelps Johnson
Martin Murphy
— No recommendations

Report on Election of New Officers
The President stated that a new President, three Vice-Presidents, and the appropriate number of Councillors were elected at the December 1959 meeting of Council in accordance with the By-Laws, as follows:

(1) Extract from Minutes of February 20, 1960, meeting of Council:
"President 1960-61
60/31 On the recommendation of W. K. Gwyer, Chairman, and the majority of the 1959 Nominating Committee, the name of George McKinstry Dick, Sherbrooke, Quebec, has been nominated as the next E.I.C. President. It was:

RESOLVED unanimously that GEORGE McKINSTRY DICK, Sherbrooke, Quebec, be elected President of The Engineering Institute of Canada, for the year 1960-61, to take office at the conclusion of the 1960 Annual Meeting." ..

(2) Extract from Minutes of December 18, 1959, meeting of Council:
"Report of Nominating Committee
59/1109 It was noted that only one nomination has been received for each vacancy on the Council of the Institute for the year 1960 and that these nominations were accepted by Council on September 12, 1959, and October 17, 1959, and were published in the October, 1959, issue of The Engineering Journal for scrutiny by the membership.
59/1110 It was moved by Mr. Martin, seconded by Mr. Davis, and carried unanimously that, in accordance with Section 42 of the By-Laws, the following officers be declared elected by acclamation and asked to take office at the Annual General Meeting of the Institute to be held at the Royal Alexandra Hotel, Winnipeg, on May 25, 1960:

Vice-Presidents
One to be elected for two years
Zone "B" (Province of Ontario)
Edgar A. Cross, Toronto, Ont.
Zone "C" (Province of Quebec)
Charles Miller, Baie Comeau, Que.
Zone "D" (Atlantic Provinces)
T. C. Higginson, Saint John, N.B.
Two to be elected for three years
Montreal .... Paul G. A. Brault
R. A. Phillips

One to be elected for three years
Ottawa .... John S. Watt
Toronto .... A. C. Davidson

One to be elected for two years
Vancouver .... W. G. Heslop
Edmonton .... S. R. Sinclair
Lethbridge ...... R. D. Livingstone
Calgary .... W. G. Sharp
Saskatchewan ...... J. L. Thompson
Winnipeg .... N. S. Bubbis
Sault Ste. Marie .... W. M. Hogg
North Eastern Ont. .. (No nominee)
Huronia .... Frederic Alport
Sarnia .... J. E. Harris
Kitchener .... L. J. R. Sanders

(3) Extract from the Minutes of the April 30, 1960, meeting of Council:

"Councillors
60/157 **Baie Comeau Branch:** To complete the remainder of Mr. Charles Miller's term of office as councillor for the Baie Comeau Branch on his election to the Vice-Presidency, the Branch has nominated Mr. G. J. Lane, M.E.I.C. It was:

RESOLVED unanimously that G. J. Lane be elected councillor representing the Baie Comeau Branch to take office at the 1960 Annual Meeting and to complete the remainder of Mr. Miller's term of office, until May 1961.

60/158 **Saint John Branch:** To complete the remainder of Mr. T. C. Higginson's term of office as councillor for the Saint John Branch on his election to the Vice-Presidency, the Branch has nominated Mr. J. J. Donahue, M.E.I.C. It was:

RESOLVED unanimously that J. J. Donahue be elected councillor representing the Saint John Branch to take office at the 1960 Annual Meeting and to complete the remainder of Mr. Higginson's term of office, until May 1961."

President-Elect George McK. Dick was introduced to the meeting. (Applause.)

Other Business
The President read a telegram from the President of the Royal Architectural Institute of Canada which extended good wishes to the Institute on its 74th Annual Meeting.

It was moved by Dean H. G. Conn, seconded by Past-President V. A. McKillop, and carried with acclamation that the 74th Annual General Meeting of the Engineering Institute of Canada congratulates Past-President J. B. Stirling, one of the Institute's most respected senior members, on his appointment as Chancellor of Queen's University. The meeting recognized this appointment as an honour, not only to Dr. Stirling, but to the engineering profession and the Institute.

It was moved by Past-President V. A. McKillop, seconded by Past-President James A. Vance, and carried unanimously that a message of encouragement and sympathy be sent to Mrs. L. F. Grant, wife of Past-President L. F. Grant, in her illness. Colonel L. F. Grant stated that he wished to express to his friends and associates his deep appreciation of the expression of sympathy accorded.

Vote of Thanks
It was moved by Past-President James A. Vance, seconded by Past-President L. F. Grant, and carried with acclamation that a hearty vote of thanks be accorded to the retiring President, Vice-Presidents and members of Council in appreciation of the work they have done for the Institute during the past year.

Motion of Adjournment
It was moved by Mr. J. H. Budden, seconded by J. B. Angel, and carried that the 74th Annual General Meeting of The Engineering Institute of Canada be adjourned.

The meeting adjourned at 12.00 noon.

J. J. Hanna,
President.

Garnet T. Page,
General Secretary.

The Engineering Institute of Canada,
2050 Mansfield Street,
Montreal 2, Quebec.

COMMONWEALTH CO-OPERATION

(Continued from page 88)

Division or Committee.

4. Where a Branch of the E.I.C. has appropriate specialist Engineering Sections, members of sister societies resident in the area are invited to participate in local activities on the same basis as the E.I.C. members in those Sections, and are to be represented in each case, where warranted and justified by numbers in that speciality and as agreed by the societies concerned, by a member appointed to the appropriate Section executive, the appointment to be made by the sister society. Members so appointed are to become full voting members of the Section Executive.

5. Where a Branch of the E.I.C. has appropriate Engineering discussion groups, members of sister societies resident in the area are invited to participate in the activities of the Groups of their interest on the same basis as E.I.C. members.

6. Where a Branch of the E.I.C. has neither an appropriate specialist Engineering Section nor an appropriate specialist Engineering discussion group, members of sister societies resident in that area are invited to participate in Branch activities on the same basis as E.I.C. members.

7. Such members of other societies resident in Canada and wishing to participate in the activities of an E.I.C. Branch will be billed by the E.I.C. Headquarters in the amount of $3.00 per annum to cover the cost of meeting facilities, mailing notices, etc. They shall be eligible to receive the Engineering Journal at the same rate as E.I.C. members, and the Transactions of the E.I.C. at a cost of $1.00 per annum. Where reciprocity is accorded by the other Commonwealth society, members of the E.I.C. resident in that country will be billed by that society for out-of-pocket service costs plus additional charge at member rates for the publications of the society.

8. It is the hope of the Council of the E.I.C. that members taking advantage of these arrangements will ultimately become members of the E.I.C.

Branch Chairman,
Branch Secretaries,
The Engineering Institute of Canada.

Gentlemen:

Enclosed is a copy of a letter and attachment which we are sending to all members of the three Institutions named, in Canada. Enclosed also is a copy of the Memorandum setting forth the basis for E.I.C. co-operation with these members, as approved by the Councils of the four societies concerned.

From the above you will note that E.I.C. Headquarters is now writing to each Institution member in Canada, and is sending the "Journal" to each of them. They are also being sent a statement requesting the sum of $3.00 per year, if they desire to take advantage of this agreement. We will also write to them regarding their participation in the overall technical activities of the Institute, so that items 1, 2 and 3 may be carried out.

A great deal of responsibility for the success of this plan rests with each Branch of the Institute. Item 1 states that Branches of the E.I.C. are to be encouraged to establish specialist engineering discussion groups wherever justified by numbers and interest. The importance of this aspect of the plan cannot be over emphasized; and the Committee on Technical Operations and the Headquarters' staff will be glad to advise and assist any Branch which may desire assistance in this area of activity.

The responsibility for the effective implementation of items 4, 5 and 6 rests completely with the Branches, and the co-operation of all Branch Executives will be appreciated. To clear up any possible misunderstanding, the intent of giving the one Institution representative a vote in the executive of the Branch Technical Section is to permit participation and representaton of the group of the Institution members which he represents in the work of the Technical Section. It is not intended that these voting privileges be extended at the level of the Branch Executive itself.

The administrative action required by item 7 is being taken by E.I.C. Headquarters. We are sending each Branch Secretary the following information:

(a) A list of all members of the three Institutions in each Branch area.

(b) The names of those who remit the $3.00 annual fee.

(c) The sum of $2.00 for each of (b) above, to be used by the Branch in serving these members. The remaining $1.00 is to cover Headquarters administrative costs.

Item 8 is self-explanatory. It is hoped that the local and national activities of the E.I.C. will encourage the Institution members ultimately to become full members of the E.I.C.

Council hopes that each Branch will give this scheme its whole-hearted support, for the improvement of the Institute's technical activities and services to the profession of engineering in Canada.

Yours very truly,
Garnet T. Page, M.E.I.C.,
General Secretary.

Another Victory for General McNaughton

General the Hon. A. G. L. McNaughton, Hon. M.E.I.C. has a history of achievement for the Canadian people. Recently, a tribute was paid to him in an Ottawa datelined editorial which appeared in the Winnipeg Free Press. The editorial entitled "Victory for General McNaughton", called him "the real hero of the Columbia negotiations".

Following are excerpts from the editorial:

"It is a notable event when a public man, single-handedly, scores the greatest triumph in his career. This is especially so when the fruits of the triumph go not at all to himself—save in credit—but entirely to his country.

"General the Hon. A. G. L. McNaughton, age 73, chairman of the Canadian Section of the International Joint Commission . . . has had one of the most unusual careers in Canadian military and public life. He fought in many real battles in World War I. He prepared for but never fought in any of the battles of World War II. He engaged in and was overwhelmingly defeated in a short political engagement in 1944-45.

"But of all the varied contests and strivings of a long life spent mostly at what might be termed the command posts of military or public affairs the battle of Columbia River marks the greatest achievement in General McNaughton's career.

"The writer followed the Columbia River negotiations very closely, from 1950 until the change in government in 1957. These were the crucial years. And it may be said, without peril of contradiction, that General McNaughton in this matter, took on a lost cause and confronted his opposite numbers on the U.S. section of the International Joint Commission. He had no cards in his hand. The St. Laurent government was but lukewarm in supporting him. In reality he fought alone."

The editorial outlined the practical problems involved in the negotiations and the United States philosophy concerning power development particularly in the Western United States. The Pacific states were clamouring for the 2,600,000 h.p. available from the Columbia River. They faced a power shortage and the United States of course was eager to pay for the storage facilities in Canada, and powerful interests in Canada were favorable to this U.S. ambition.

"General McNaughton announced a completely revolutionary policy when he insisted that Canada should build and operate any storage dams in Canada and must receive, free of charge, 50% of all downstream benefits. One half the power obtained in the U.S. in this way must be returned to Canada.

"If General McNaughton had exploded hydrogen bombs at Washington, D.C. and in the Pacific states, the shock would scarcely have been greater."

Through extremely strenuous and imaginative negotiations during which the United States had four chairmen of their section of the Commission, General McNaughton achieved 90% of his objective.

"General McNaughton, although his own government was plainly shocked . . . put his engineers to work and was able to announce that, failing a satisfactory settlement with the U.S., Canada would divert the flood water of the Columbia out of this river and ino the Thompson River. Thence it would flow through the Fraser to the sea—all in Canada. This would mean that Canada would get all the power from the flood water and the U.S. none."

With no real support from either the Federal or the British Columbia governments General McNaughton made his point and saw negotiations concluded in what was a signal victory for Canada.

"Single-handed, with no help except from a few senior officials and his own devoted staff, General McNaughton made it possible for the Canadian government to establish the principal that Canada is entitled to receive one half of the downstream benefits of water storage in this country. For unexplained reasons, he was allowed to play no part in the final negotiations."

"General McNaughton is entitled to be acclaimed, without qualification, as a man who refused to admit defeat, refused to be turned aside by the discouragement and by lack of support, and who, in the end, achieved the seemingly impossible."

October Council Meeting

Council of the Institute met in Sherbrooke, Que., on Friday evening, Oct. 28, and Saturday, Oct. 29. President Dick presided. The following is a summary report of the meeting.

Annual and Regional Meetings

The General Secretary reported on his visit to the Vancouver Branch Sept. 27-28 to initiate arrangements and local planning for the 1961 Annual General Meeting. A series of extremely useful meetings was held, and local planning is well advanced. Chairman and Vice-Chairman of the 1961 AGM, respectively, are Dean D. M. Myers and Professor W. G. Heslop.

Other appointments include: F. M. Cazalet, Secretary; C. Peter Jones, Program Chairman; John Davis, Hotel Arrangements Chairman; A. D. Cronk, Public Relations Chairman; and H. R. Wright, Banquet and Dance Chairman.

Future Annual General Meetings

Council approved the following schedule of future Annual General Meetings:

1961 Vancouver May 31-June 2 Hotel Vancouver
1962 Montreal June 13-June 15 Queen Elizabeth
1963 Quebec May 22-May 24 Chateau Frontenac
1964 Banff May 27-May 29 Banff Springs
1965 Toronto May 26-May 28 Royal York
1966 Winnipeg May 25-May 27 Royal Alexandra
1967 Montreal May 31-June 2 Queen Elizabeth
1968 Halifax — —

Committee on Membership

On the recommendations of S. B. Cassidy, Chairman of the Committee on Membership the following were appointed members of the Committee:

R. Bing Wo, Regina
Colonel W. A. Capelle, Ottawa
Gaetan Cote, Sherbrooke
Professor J. W. Dolphin, Kingston
C. Fisher, Winnipeg
Yvon Hardy, Montreal
C. Peter Jones, Vancouver
R. J. Kane, Montreal
Miss Elsie MacGill, Toronto
Professor G. F. Vail, Halifax

Ex. Officio:

Hugh C. Brown
The President
The Vice-President

Mr. Cassidy said the Committee will hold its first meeting concurrently with that of the Executive Committee in Toronto, Nov. 19, and that Branch Chairmen, Secretaries, and Chairmen of Branch Membership Committees located near Toronto were invited to attend.

He urged every member of the Institute to be prepared to participate in the work of the Committee on Membership. The President said he anticipates the Committee will embark on an intensive campaign and that all Councillors and Branch Officers can expect to be asked to work closely with the Committee.

Dr. B. G. Ballard, Chairman of the Committee on Technical Operations, said the CTO is aware of its responsibility to assist the Committee on Membership particularly in respect to younger members. Dr. Ballard suggested that forums be held at the Branch level at which prominent engineers discuss what is expected of engineers with university students. It was agreed that this suggestion be referred to the Committee on Membership.

Technical Operations

Council discussed the part the CTO should play in assisting with the technical programs of regional technical conferences. It was resolved that Council entrust responsibility for co-ordination of regional technical conferences and approval of requests for holding such meetings to the Committee on Technical Operations.

It was further resolved that the resolution adopted above be referred to the By-Laws Committee for examination, tying in with Section 54 of the By-Laws, and subsequent presentation with other by-law changes at the appropriate time.

Sub-Committee on Water Pollution

A. L. Van Luven of Montreal is chairman of this Sub-Committee established by the Committee on Technical Operations. The Sub-Committee is to study all phases of the use, conservation and pollution of water resources in Canada.

It will become familiar with work now being done by many organizations in this field, and solicit and analyze views of all Canadian organizations concerned with water pollution. Later, if justified, it will suggest a program for action by governments and industry. Reaction of all interested organizations to this suggested program will be ascertained.

It will make a final or interim report to the E.I.C. on these matters with recommendations preferably no later than the 1961 Annual General Meeting. With approval of Council this report will be sent to the Prime Minister and to provincial premiers. This will provide an objective, scientific and unbiased analysis of the use, conservation and pollution of water resources in Canada which can be used by the federal and provincial governments as a comparison with their own work.

Branch Operations

President Dick, Past-President J. J. Hanna, Vice-Presidents Lawton and E. A. Cross spoke in firm support of a proposal by the General Secretary that a Committee on Branch Operations be established. The consensus was that the three vital and related activities of the Institute are: the rendering of maximum assistance to Branches, the work of the Committee on Technical Operations, and the work of the Committee on Membership.

The objective of such a committee would be primarily to provide encouragement and assistance to Branches when required. Included among the methods by which this could be accomplished are the Branch Officers' Conference, forums at annual general meetings, and the appointment of a CTO representative at each Branch to help integrate and promote the technical program of the Branch.

It was resolved that a Committee on Branch Operations be established, with the object of studying and recommending regarding Branch operations, and providing a focus of activity for rendering maximum assistance to Branches.

Royal Commission on Publications

The Institute has been invited to prepare a submission to this Commission. The Commission is to inquire into the position and prospects of Canadian magazines with special consideration being given to competition from similar publications which are edited largely or entirely outside Canada, or are largely or entirely foreign in content.

The General Secretary was authorized to prepare a submission to this Commission, subject to approval of the submission by the President, the Chairman of the Finance Committee, and the Chairman of the Publications Committee.

Royal Commission on Government Administration

A Royal Commission was established recently to make a thorough study of the operations of the Federal Government. The President reported that he had instructed the General Secretary to recommend concerning a special committee to prepare a brief for presentation by the President to this Commission.

Council ratified the President's action and agreed that a special committee should be appointed.

Senate Special Committee on Manpower and Employment

The E.I.C. has been invited to prepare a submission to this Special Committee.

Council resolved that a committee be appointed to prepare a presentation to be submitted to the Committee by the President.

Tariff Board Submission

In June, 1946, the Federal Government removed the tariff on several classifications of engineers' plans. The Institute protested this action, and in January, 1951, the Tariff Board held a hearing to consider the method of valuing plans for customs purposes and to hear arguments for or against the 1946 action. The Institute asked for the restoration of a tariff in certain cases, and a change in the basis of evaluation. Two tariff items now are to be studied again by the Tariff Board.

The General Secretary made certain proposals which might be considered a basis for discussion of an Institute brief to the Tariff Board.

After discussion it was resolved that the General Secretary's statement of proposals and background be communicated to all members of Council. Councillors are to discuss this at the Branch level, and to submit comments and suggestions to a Special Committee which Council authorized the President to appoint to prepare a brief for submission by the President to the Tariff Board.

Confederation

During the summer, several committees of the Engineers Confederation Commission were extremely active and the General Secretary has devoted a major portion of his time to the work of these committees.

Dr. J. Hoogstraten recently resigned as E.I.C. representative for Nova Scotia to the Engineers Confederation Commission, because he moved to Manitoba. Council ratified the nomination by E.I.C. Councillors in Nova Scotia of G. F. Vail as Dr. Hoogstraten's successor.

E.I.C. ELECTIONS AND TRANSFERS

A number of applications were presented for consideration and on the recommendation of the Admission Committee, the following elections and transfers were effected at a meeting of council on October 29, 1960.

Member: H. B. Baardman, Montreal; M. E. Belgrave, British Guiana; J. C. Campbell, Sydney, N.S.; D. R. Cole, Edmonton; J. D. Coughlan, Montreal; J. J. Danic, Sarnia; L. D. Dougan, Sarnia; G. I. H. Drewett, Edmonton; R. H. Edwards, Longueuil; C. K. Fong, Hong Kong; D. F. Griffiths, Trail; J. V. Johnson, Yukon; P. B. Lawrence, Toronto; T. C. Morgan, Ottawa; R. F. Norman, Toronto; F. B. Odasz, Calgary; J. D. Palmer, Kingston; R. S. Phillips, Peterborough; W. M. Prentice, Toronto; R. M. Richardson, Calgary; P. E. Riverin, Montreal; P. A. Schaerer, Ottawa; S. Shivdasani, Montreal; C. G. Smallridge, Montreal; W. J. Swarbrick, Vancouver; H. H. Warsch, Ottawa; A. H. Yarberry, Montreal.

Junior: C. N. Armstrong, Kitimat; A. Cowley, England; I. W. Geba, Montreal; B. J. Maunder, Port Coquitlam; J. L. McDougall, Velder Crossing; R. M. Savoie, Drummondville; R. E. Walker, Prince Rupert.

Junior to Member: A. Ainley, Toronto; E. R. Acton, Brockville; A. Alexander, St. Catharines; D. G. S. Anderson, Waterloo, Ont.; J. Anderson, Toronto; D. B. Ashenden, Brockville; S. M. Bancroft, Ottawa; D. J. Bazett, Toronto; G. Bird, Toronto; J. R. Bisaillon, Quebec; D. D. Brouse, Toronto; W. A. Brown, Scarborough; J. G. Celmins, Toronto; W. O. Chisholm, Toronto; W. B. Chong, Toronto; E. K. Christian, Toronto; R. H. Clendining, Toronto; W. H. Correll, Toronto; J. F. M. Craig, Nobel; R. M. Currie, Oakville; K. I. Fletcher, Sault Ste. Marie; L. J. Foord, Peterborough; R. W. Goldie, Montreal; A. G. Hamilton, Port Credit; C. Hebert, Oshawa; J. C. Huot, Quebec; S. R. Johnson, Toronto; J. L. Kendry, Asbestos; F. B. Kraft, Preston; W. A. H. McCorquodale, Syracuse, N.Y.; I. B. Miller, Toronto; H. R. M. Murray, Yale, B.C.; R. J. Noonan, Winnipeg; R. O. Olsen, Buckingham; W. P. O'Malley, Montreal; J. A. Pihlainen, Ottawa; G. W. Piper, London, Ont.; D. G. Pyper, Toronto; D. A. Ridler, Toronto; J. T. Rogers, Peterborough; P. A. Ross-Ross, Chalk River; J. W. Saunders, Montreal; H. N. Shoji, Toronto; G. A. Sicotte, Montreal; D. S. Simons, Winnipeg; W. B. Sproule, Sault Ste. Marie; H. M. Steckley, Toronto; J. J. Stefaniszyn, Montreal; J. M. Sterling, Toronto; L. W. Stock, Toronto; W. D. Tanner, St. Catharines; E. Turcot, Montreal; T. G. Tustin, Montreal; J. L. Vachon, Ottawa; E. C. Walton, Toronto; A. A. Williams, Montreal; B. A. Wilson, California; A. Woinowsky-Krieger, Quebec; P. Yachimec, Toronto; K. H. Yeo, Hamilton.

Student to Junior: J. L. Coughlan, Montreal; L. E. Wells, Perth.

STUDENTS ADMITTED

McGill University: I. A. Cermak, A. H. Cohen, A. Giannetti, R. G. Haack, C. W. L. Horn, V. K. Jyoti, I. Lamoureux, P. Linke, A. P. M. Lyell, J. G. Masstrom, S. M. Newman, B. Ornstein, P. A. Osho, G. M. Peck, G. F. Reynard, J. K. Siebrasse, T. H. F. Tan, T. Tarasofsky, N. Theodore, J. C. Vanagas, T. D. Wyglinski, G. A. Yane.

University of Toronto: F. J. Boyer, A. Buttemer, G. D. Caldwell, W. R. Campbell, J. Citron, G. T. Coffey, D. Currey, D. H. Dignan, G. J. Fournier, C. A. Fuller, K. C. Galbraith, J. A. Gibson, S. M. Glogowski, D. Hilson, M. J. Huggins, G. V. M. Jacquemain, P. J. Jaunzems, O. M. Kaustinen, F. J. Keenan, D. J. Lamb, M. S. C. Law, D. McHardy, R. E. Pearson, L. J. Regimbal, P. J. Rolfe, I. R. Russell, H. B. Snell, R. H. Temple, W. S. Wolfe, G. J. Woolgar.

Nova Scotia Technical College: D. T. Campbell, C. B. Day, G. M. Dlugosch, P. J. Driscoll, J. V. Gavin, F. A. Gervais, R. A. Gould, E. B. Hatfield, W. R. Hicks, J. R. Kane, C. R. King, J. B. Lavigne, D. P. MacAulay, D. J. Major, E. R. Trask.

Loyola College: B. W. A. Abela, S. J. Abela, F. K. Aitken, F. H. Allen, R. Allen, R. L. Bayly, R. J. Bernard, J. E. P. Bilodeau, D. J. F. Bryden, J. W. Bush, P. R. Byers, J. E. Cain, G. K. Carrall, B. Castongway, T. S. Coughlin, C. R. Cooper, R. A. Deegan, P. De Grace, J. P. G. Desrosiers, F. Diamente, A. B. Edwards, V. M. Espaillat, M. J. Feeney, D. E. Fisher, D. H. Forbes, J. R. Fortin, M. Frappier, P. F. Gaboury, J. A. Galle, P. R. Grant, J. R. Greene, G. L. Harold, R. A. Harrison, J. J. G. Hemens, K. L. W. Hui, D. W. S. Kay, A. E. Kennedy, R. J. Kind, J. S. K. Kwan, G. Laberge, E. A. D. F. Lamoureux, D. C. L. Louie, J. E. J. G. Lapierre, E. C. S. Lau, S. Y. S. Lau, B. W. Lawson, J. Leclerc, M. B. Ledwidge, S. Legedza, A. J. Lemay, W. W. Leus, M. Levasseur, L. J. Liebich, L. Mahoney, F. J. McCaughey, M. McAughey, K. J. McGuire, L. T. McKinnon, T. Molloy, G. P. Morrison, A. J. O'Doherty, J. H. O'Donnell, A. J. O'Grady, F. J. O'Hara, W. R. Oulton, R. Paci, P. Peduhha, K. J. E. Peter, M. Przystal, J. Resther, O. Roy, A. G. Russo, L. G. Sablauskas, J. Scheigetz, D. P. Scipio del Campo, L. Sheehan, A. P. Smeaton, E. Smilgis, R. B. L. Stoddart, M. F. Sullivan, R. A. P. Sweeney, J. M. Thibault, G. J. Tokar, P. Y. Tong, J. Trifilette, J. W. T. Tsang, F. Turco, R. Valiquette, A. J. Viney, R. A. Walsh, R. J. Wiseman, P. Wong, S. S. A. Wong, D. Zee.

Sir George Williams University: V. Bartfay, N. J. Bertalanits, J. Bourdeau, R. D. Bourke, A. C. F. Chau, D. C. Chong, B. Cytrynbaum, P. T. Dalamangas, A. R. Degruchy, J. G. Descoteaux, P. N. Foster, S. L. Garelick, E. S. Hewitt, W. Huculak, S. T. Le Bedis, E. Y. M. Lee, J. N. Malhotra, J. M. N. Martin, F. Masters, P. Ratki, I. D. Robertson, M. Talerman, J. G. Thistle.

Dalhousie University: J. F. Adams, B. W. Aikman, B. Balbirsingh, G. O. Bishop, A. R. Blenkhorn, L. G. Currie, A. B. Ferguson, A. A. Ferguson, C. A. Hamer, D. S. Hopkins, R. L. Howe, A. Leung, E. A. MacAulay, D. R. MacDonald, G. W. MacDonald, I. F. Macdonald, S. W. March, J. L. McLean, A. G. Roop, G. L. Trider.

Carleton University: R. F. Alexander, R. M. Bayley, J. A. Dolan, J. M. Hamilton, G. E. Kirby, K. A. H. Lythall, F. D. McAllum, M. H. Quast, R. W. Smith, L. Thelwell, W. E. Wilson.

University of Western Ontario: J. G. Gammage, G. J. Kopp, J. A. Lyons, E. A. Marriage, R. J. Morris, J. R. Nancekivell, J. S. Scherer, M. W. Stewart.

McMaster University: J. J. Brokloff, I. A. Hollis.

University of Alberta: D. E. Laukner.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers became effective October 29, 1960.

ALBERTA

Member: M. J. Baron.
Junior to Member: A. W. Peterson, S. A. Rokosh.

SASKATCHEWAN

Members: P. Graystone, B. V. Loginoff.
Student: E. H. J. Rotelick.

NOVA SCOTIA

Members: M. R. Evans, C. F. Pearce, L. M. Shaer.
Junior to Member: I. C. MacInnes.

MANITOBA

Member: A. F. Klymchuk.

University Registration

A general increase has been noted in this year's university engineering enrolment as tabulated (on the following pages) by the Institute from information obtained directly from registrars. This tabulation now is an annual Journal service to its readers.

Several highlights of this year's situation, as revealed by the E.I.C.'s survey, are:

Total enrolment in Canadian engineering courses now stands at 14,940, an increase of 465 from last year;

The engineering freshmen number 4,461 in the autumn of 1960, compared with 4,122 last year;

The estimated number of 1961 graduates, making no allowance for wastage during the year, is 2,651. This is an increase of 410 over the previous year.

Civil, electrical, and mechanical engineering remain the most popular. The following is a list of the 1961 graduates, with the previous year's estimates in brackets. Civil 779 (644), Electrical 644 (513), Mechanical 508 (438).

New colleges giving recognized engineering courses are still being added to the list. On this occasion we welcome Loyola, Montreal, and Laurentian, Sudbury.

Readers will be able to make further detailed observations by study of the tables. However, if any question should arise, E.I.C. Headquarters will gladly try to answer them.

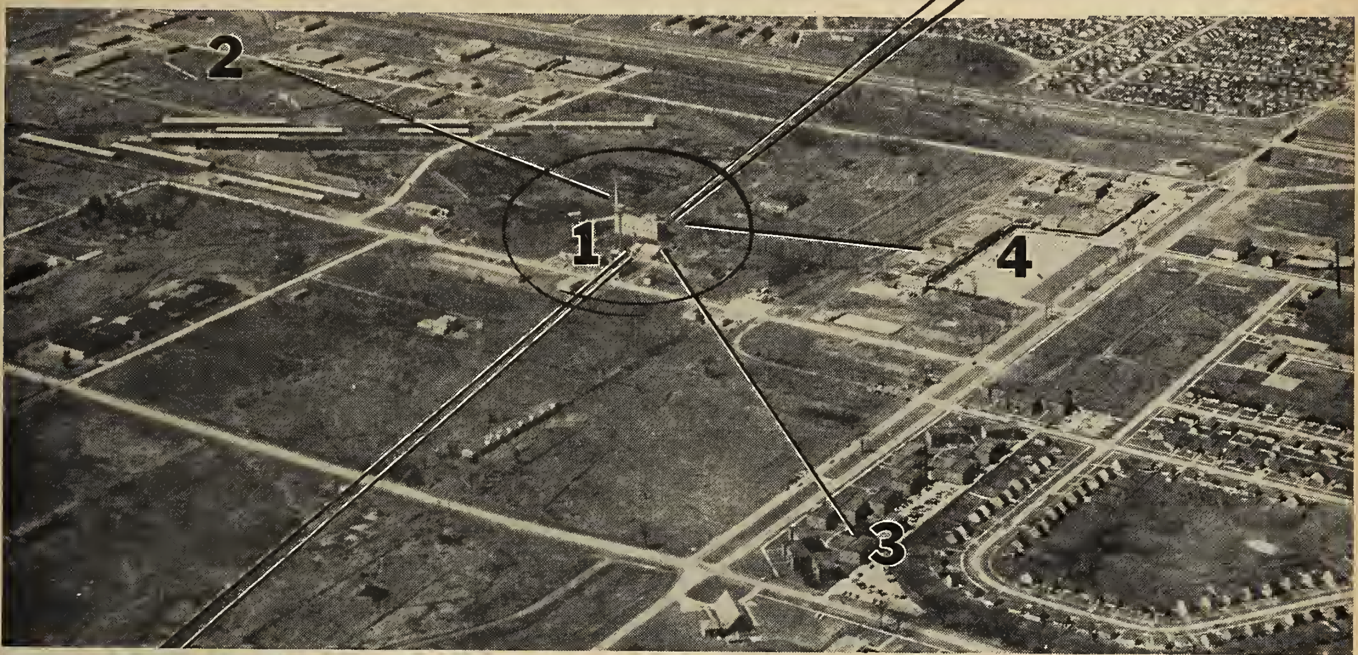
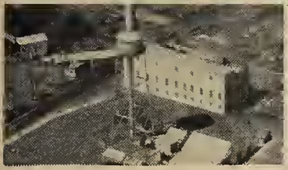
How to pull Industry and Commerce to a Planned Townsite and/or Industrial Park

LOW COST Central Heating

For factories • Shopping Plazas • Apartment Blocks • Schools • Churches





1 Located centrally in the Ajax Development this "furnace" is capable of supplying plentiful heat—or steam—to buildings within 2-mile radius with total coverage of over 16 square miles

2 "Main Street" is a happy street for factories at Ajax because there is no need for outlay in individual boiler-rooms. Over 20 factories are saving by using the central heat facilities.

3 "$12,000 added to net profits" (savings equal to 6% on an investment of $200,000) that's what central-heat means to the owners of the Ajax Apartment Development pictured here.

4 No capital cost of boiler-room—no labour cost—no boiler room maintenance or repair for shops in this 45 unit Plaza—at Ajax—using the central heat service. Pipes are underground immediately available.

*AJAX, ONTARIO... *has central heating plant which wipes out capital boiler room cost and all labour costs completely for scores of users—manufacturing and commercial plants, stores, apartment blocks, etc.*

The prime target in manufacturing must be to keep productivity high—and overhead low—if we, as Canadians, are to compete successfully. As Canada swings to an industrial economy more planned townsites like Ajax, Ontario, are developing with factories, commercial projects, plazas, homes, churches, schools, carefully, skilfully integrated by Canadian Architects and Engineers.

Into these ideal communities are being incorporated ultra-modern amenities and money-saving services. Central Heating is a notable example offering convenience, avoidance of capital and labour costs in individual heating plants, air-pollution control—and MONEY-SAVING resulting in lowered unit cost of all articles manufactured. Capable of burning any fuel these central heating plants can utilize whichever fuel is most economical.

Coal is—and will continue to be for decades to come—the most economical fuel in most communities. That's why it is the fuel used in the Ajax, Ontario Central Heating plant and most other central heating plants in this country. We suggest you investigate the Central Heating Plant Plan—for similar projects in your area.

**Ajax, Ontario is a planned community developed by Duffins Creek Estates Limited—a company jointly owned by Perini Limited and Principal Investments Limited.*

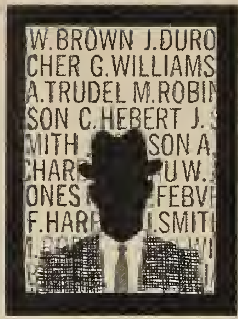
"Here's what central heating means to Commerce and Industry in Ajax" says Gordon Gilchrist . . . Chief Engineer at Ajax Heating Plant.

"Our plant at Ajax is adaptable to burning any fuel—oil, gas or coal—whichever will allow us to deliver heat or process steam cheapest to our customers. In this area nothing can equal coal for low cost so coal's the fuel we buy. With our modern stokers and ash-handling equipment one fuel is the same as any other as far as manpower is concerned."

For further information or additional case histories showing how other plants have saved money burning coal the modern way, write to Bituminous Coal Institute of Canada at 159 Bay Street, Toronto 1.

Where costs count—Coal is the fuel BCi **BITUMINOUS COAL INSTITUTE** OF CANADA

Personals



Dr. John Bertram Stirling, HON. M.E.I.C. (Queen's, B.A. '09 B. Eng. '11, LL.D., '51), installed Oct. 20 as the eighth Chancellor of Queen's University, said at the Convocation that engineers in growing numbers are replacing lawyers and accountants as managers in industry and business.

Dr. Stirling, president of E. G. M. Cape and Co. Limited, said engineers recently were elected Chancellors of four universities: They were: Dr. R. E. Powell, McGill University; Rt. Hon. C. D. Howe, Hon. M.E.I.C., Dalhousie University; Dr. C. J. Mackenzie, Hon. M.E.I.C., Carleton University and himself.

J. B. Stirling, HON. M.E.I.C.

Men with engineering training take a practical view of affairs, Dr. Stirling said in explanation of the trend.

The Chancellor, who obtained his bachelor of arts degree before taking engineering, said he felt the social sciences should be integrated to some extent with practical training in engineering.

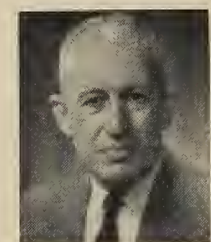
"To an engineer, the type of training given by an arts degree is very much of an advantage. It provides an education. Any strictly engineering course is inclined to be somewhat narrow.

"I don't think I would have gone nearly as far in my profession as I have," Dr. Stirling said, "if I had not taken an arts training as well as engineering. I have observed that in other successful executives as well."

G. H. Thompson, M.E.I.C., (McGill '13), has been named president of Calgary Power Ltd. He joined the company in 1925 and was appointed vice-president in 1941. He is also a director of the company.

Charles L. Brooks, M.E.I.C., (McGill '22), assistant general manager, Montreal area, the Bell Telephone Company of Canada, has retired.

H. W. Casperd, M.E.I.C. (London '28), has been appointed vice-president of Foundation of Canada Engineering Corporation Limited and will be in charge of Fenco's Toronto Office.



H. W. Casperd, M.E.I.C.

A. B. Hunt, M.E.I.C.

A. B. Hunt, M.E.I.C. (Toronto '28), has been promoted to vice-president, research and development, for Northern Electric Company.

Peter Corobow, M.E.I.C., has been appointed vice-president and general manager of the Chevalier Gaz Propane Limited.

H. R. Whitley, JR.E.I.C. will attend the University of Minnesota for a further year of graduate work in hydraulics. He has divided his time in England, between studies and work experience, under the Athlone Fellowship.

D. C. Bryden, M.E.I.C., (Alberta '28), has been appointed general manager of the City of Winnipeg Hydro-Electric System. He joined the company thirty years ago and before his promotion was assistant general manager.

D. C. Bryden, M.E.I.C.

J. Russo, M.E.I.C.

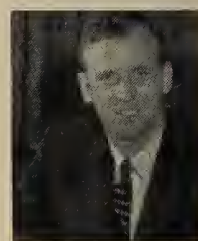
John Russo, M.E.I.C., (Belgrade '34), has been appointed general manager of BETA Construction Limited-General Contracors, Montreal.

Sam Roth, M.E.I.C., (McGill '48), has been appointed manager of the new Research and Development Department of Canadian Aviation Electronics Limited.

J. K. Ayles, M.E.I.C., (London '50), has been appointed division engineer with the Department of Highways and Transportation for the Swift Current area.

Harold B. S. Brownlow, M.E.I.C., has been chosen a member of The Select Group of about six North Americans by the Royal Society of Arts in London. Mr. Brownlow is projects manager and engineer for the construction by Golden Eagle Refining Company of Canada, Limited of a new oil refinery at Holyrood, Newfoundland.

H. B. S. Brownlow, M.E.I.C.



L. C. Webster, JR.E.I.C.

Lorne C. Webster, JR.E.I.C., (McGill '50), has been appointed assistant general manager for the Canadian Import Company.

Obituaries

James Earl Bennett, M.E.I.C. (Saskatchewan, '26), prominent design engineer for the Dominion Department of Agriculture, Prairie Farm Rehabilitation Administration, Regina, died July 2. Mr. Bennett became a member of the Institute in 1930 and was also a member of the Corporation of Professional Engineers of Saskatchewan.

Emmett Patrick Murphy, M.E.I.C., former deputy minister of Public Works of Canada in 1942, died June 17 in Ottawa. Mr. Murphy was a construction engineer and joined the Institute as a student member in 1909; he became a life member in 1950.

Albert Lawrence Killaly, HON. M.E.I.C., died September 9. He was 84. Mr. Killaly, a native of Prescott, Ont., was prominent in the canal engineering field. He became a student of the Institute in 1900 and was made an Honorary Member in 1953. On the formation of the Peterborough Branch in 1919 he was a member of the first executive. He was chairman of the Branch in 1925.

Other Societies

Lecture Tour

Dr. Evert Arne Bjerhammar of the Swedish Royal Institute of Technology is engaged in a two-month tour of United States engineering colleges. The tour is sponsored by the Engineers Joint Council and the American Society of Civil Engineers under a grant from the National Science Foundation, and is co-ordinated by the Surveying and Mapping Division of the ASCE.

Dr. Bjerhammar, Professor of Geodesy at the Royal Institute in Stockholm, is well-known in international surveying circles. His specialties include optical and electronic distance measuring devices, paralyx triangulation automatic mapping, and applications of the calculus of matrices to the method of least squares.

Canadian Soil Mechanics Conference

Field consolidation studies of marine sediments beneath earth embankments, river bank stability in glacial lacustrine deposits, and geotechnical properties of tills were among the topics discussed during the two-day Soil Mechanics Conference in Niagara Falls, Ont., in October. This was the 14th in a series of Soil Mechanics Conferences sponsored by the Associate Committee on Soil and Snow Mechanics of the National Research Council.

R. F. Legget, M.E.I.C., Ottawa, Chairman of the Associate Committee on Soil and Snow Mechanics, outlined the recent formation of the Geotechnical Division of the E.I.C.

More than 150 delegates heard three papers presented by geologists and seven by soil engineers. In addition, more than 30 formal discussions by invitation were presented as well as informal discussions from the floor.

NEC—AIEE

By co-ordination between the National Electronics Conference and the American Institute of Electrical Engineers, the national conference of the AIEE was held in Chicago in October, coinciding with the dates of NEC. Several jointly-sponsored technical sessions were presented.

During the NEC an award of $500 was given David K. Cheng and Mark T. Ma, both of Syracuse University, for their paper, "A Mathematical Approach for Linear Array Analysis." This annual award is given for an original paper presented during previous NEC adjudged the best on the bases of scholarship, originality, significance and clarity.

The American Society of Mechanical Engineers

Approximately 6,000 persons attended the Winter Annual Meeting of the ASME which was held in New York City Nov. 27-Dec. 2. Some 300 speakers addressed as many as 12 simultaneous sessions. Developments in aircraft, rockets, solar energy, power production, machine design and many industrial operations were among the topics covered. During the same week, the 1960 Exposition of Power and Mechanical Engineering, sponsored by ASME, was held at the New York Coliseum.

The Chemical Institute of Canada

A symposium on explosives technology was one of the features of the Canadian Chemical Engineering Conference sponsored by the Chemical Engineering Division of the Canadian Chemical Institute of Canada in Quebec City. Twenty-nine technical papers were presented. One session of papers on chemical engineering and computers featured a discussion on computers and control.

Coming Events

International Congress and Exposition of the Society of Automotive Engineers, Detroit, Jan. 9-13.

Annual Meeting of the Highway Research Board, Washington, D.C., Jan. 9-13.

Annual Meeting, American Astronautical Society, Dallas, Tex., Jan. 16-18.

Conference for Land and Construction Surveyors, Pennsylvania State University, Jan. 16-18.

Annual Meeting, American Physical Society, New York City, Jan. 31-Feb. 4.

Winter Convention on Military Electronics, Institute of Radio Engineers, San Francisco, Feb. 1-3.

Reinforced Plastics Division Conference, Chicago, Feb. 7-9.

Winter Meeting, International Institute of Sugar-Beet Researches, Brussels, Belgium, Feb. 21-22.

Conference of Protective Coatings Division, Chemical Institute of Canada, Toronto, Feb. 23.

Conference of Protective Coatings Division, Chemical Institute of Canada, Montreal, Feb. 24.

Annual Meeting, American Institute of Mining, Metallurgical and Petroleum Engineers Inc., St. Louis, Feb. 26-March 2. EIC

The Associations and Corporation

Ontario

The Association of Professional Engineers of Ontario has announced the winners of its $250 scholarship awards at University of Toronto, and Queen's University. The awards are presented annually by the Association to the student who, taking honors in engineering, obtains the highest standing in his work in the academic year.

This year's winners: U of T, last year, Yiu Chung Li, Toronto; 2nd year, G. M. Bragg, Islington; 3rd year, J. G. Heller, Toronto. Queen's: 1st year, Edward Langstaff, Rainy River; 2nd year, S. E. Frost, Port Hope; 3rd year, D. R. Morton, Kingston.

The entrance scholarship, awarded alternately to U of T and Queen's, was presented to Grant Davidson, Deep River, who is taking engineering physics at U of T.

British Columbia

Gold medallions signifying life membership in the Association of Professional Engineers of B.C. have been presented to R. A. Story and F. C. Underhill, both Vancouver. Presentations were made by H. P. J. Moorehead, Association president.

More than 250 municipal engineers, public works officials, municipal suppliers and their wives attended the 18th annual meeting of the Municipal Engineers' Division in Trail. Technical sessions and a business meeting were held.

News of the Branches

Assumption University

Dean G. Morrison, S.E.I.C.,
Correspondent

Election of officers constituted the main business of Assumption's first meeting of the season. Members are: chairman, William Pulleyblank; Vice Chairman, John Lindsey; Treasurer, Lloyd Kubis; Secretary, Dean Morrison; and course representatives William Lourette (chemical); Alan Pelanzer (Electrical); Kenneth Long (Civil); and Walter Sigmund (Mechanical).

Belleville

A. F. G. Tooth, M.E.I.C.,
Correspondent

Mr. A. E. Cross, regional Institute Vice President, was the guest at a smorgasbord offered by the Belleville Branch Nov. 14. A feature of the meeting was an illustrated talk concerning atomic reactor installation in Bombay, India, given by G. R. Adams, Vice-President and General Manager of Foundation Overseas Limited.

The Branch's first meeting was held Oct. 3, in the Assembly Hall of the Ontario Hydro Building. Chairman H. T. Floyd presided. Speakers were M. J. McInroy, Sales Service Manager, Automatic Electric Company, Toronto, and Donald Ross, City Engineer and Commissioner of Works, Kingston.

Mr. McInroy and Mr. Ross are members of a newly-formed organization known as the Committee for the Advancement of Professional Engineers, and this was the subject of their talks and subsequent discussions. Mr. McInroy dealt with the formation of CAPE, problems facing employee engineers, and the presentation of a brief to the Council of A.P.E.O. Mr. Ross dealt with employer-employee relations and the professional status of engineers, both of which, he said, could be improved through CAPE.

Border Cities

Wallace A. Macdonald, JR.E.I.C.,
Correspondent

Some 200 persons attended the Border Cities Branch annual dinner dance at the Essex Golf and Country Club, Oct. 21. Members and guests met for a reception and a smorgasbord dinner. Chairman James Reid expressed the Branch's delight concerning the attendance and the representation from the E.I.C. student section of Assumption University. Past Chairman Earl Dykeman was presented with a gold E.I.C. pin.

Mr. Pariset (left) chats with Halifax members during the Branch's mid-October meeting. To Mr. Pariset's left are: John Jay, secretary-treasurer; W. T. Windeler, program committee chairman; and G. H. Dunphy.

Brockville

D. B. Ashenden, JR.E.I.C.,
Correspondent

Thirty members are participating in the Branch's fifth lecture course of the Professional Development Committee. Interest in the course is keen, largely due to members of the committee.

The use of computers in Canada was the theme of an Oct. 24 meeting held at the Maitland, Ont., works of Du Pont of Canada. Speakers were R. N. Boyd, M.E.I.C., Supervising Engineer, Montreal Engineering Department, Du Pont of Canada, and N. P. Turner, Controls Systems Engineer, Maitland Works, Du Pont of Canada.

Mr. Boyd said the three great advances of the present age were, energy, automation and computers. He said computers would be responsible for the greatest ultimate benefit in that they would revolutionize engineering. They can dispose of guesswork and lead to better and more economical conclusions. He differentiated between digital computers, capable of sixth grade mathematics, and analog computers which are capable of solving complex differential equations.

One of the principles of using computers is to train engineers to recognize paying problems and stimulate an analytical approach. To encourage and stimulate use of computers, Mr. Boyd's company established a course in advanced mathematics for engineers given by a McGill University professor. Sixty engineers volunteered for the course which consisted of 41 three-hour lectures twice a week.

A major application of computers by Du Pont has been the complete stimulation of a new chemical plant. This enabled operators to practise their functions before the plant had been built.

Mr. Turner demonstrated the use of the analog computer in the Maitland Works. As an example, Mr. Turner took a tank being filled and emptied at various rates with automatic level controls. The various perameters which affected the level in the tank were presented in mathematical form, and connected to the analog computer. Any of the variable quantities, such as the cross section area of the tank, could be changed to show the resultant changes in other variables.

Lively discussion followed the talks. The speakers were introduced by H. Gilchrist, and thanked by Mr. Ashenden.

Calgary

R. L. Turner, S.E.I.C.,
Correspondent

The second weekly meeting of the season was held early in October. After a roast beef lunch, 28 members listened to a talk by Mr. Henninger concerning "Thrift and Saving". Mr. Henninger said we should pay ourselves a salary in the form of savings from our earnings. Following the Branch's first dinner meeting, Bert Howard described his trip to Russia.

Cape Breton

Lloyd Boutilier, M.E.I.C.,
Correspondent

Guest speaker at the Oct. 17 meeting of the Branch was Lt.-Col. Ed. Thorpe, Civil Defence Co-Ordinator for Cape Breton and Commanding Officer, 2nd Battalion, Nova Scotia Highlanders Militia. His subject was national survival.

Lt.-Col. Thorpe discussed preparation for survival from an atomic blast, the danger of fallout and the quantity of radiation which produces various degrees of injury. The Army is the most responsible force in survival training, he said, but other organizations and groups, such as police, firemen, engineers, welfare and rescue personnel must be trained to participate. He stressed the importance of engineers in restoring services following such an attack. Lt.-Col. Thorpe also outlined the structure of the Emergency Measures Organization in Canada.

A film, "Radioactive Fallout", and a question period followed the talk. Lt.-Col. Thorpe was introduced by Branch Vice-Chairman Rod Bradley, and was thanked by Vince Palmer.

Central B.C.

A. F. Joplin, M.E.I.C.,
Correspondent

A joint meeting of the Central B.C. Branches of the Institute and of the Association of Professional Engineers of B.C. was held at the Kamloops Golf Club Oct. 21. Following dinner a business session was held under the direction of Branch Chairman H. A. Price who also reported on the Institute's Annual General Meeting.

Guest speaker E. Davis, Superintendent, Kamloops Branch, British Columbia Telephone Company, described "What Happens When You Lift Your Telephone Receiver." Mr. Davis discussed automatic telephone equipment, illustrating his points with a model of a line finder switch. He explained how each selection chooses the path dialed. Mr. Davis also discussed operator distant dialing now in operation for long-distance calling by operators, and direct distance dialing which rapidly is being placed in service at the Kamloops exchange.

Following the talk was a visit to the

(Continued on page 113)

• NEWS OF THE BRANCHES

(Continued from page 110)

Kamloops exchange which now is being converted from manual to dial equipment. All were impressed with the magnitude of the change-over and the multiplicity of the company's operations, which include transmission of television for the local station. Highlights were direct dialing to New York City and a call to an operator in Honolulu. The change-over is expected to be finished in the spring.

Halifax

H. F. Peters, M.E.I.C.,
Correspondent

Ernest Pariset of Montreal's LaSalle Hydraulic Laboratories discussed developments in hydraulic turbines at the Oct. 18 meeting of Halifax Branch. M. Pariset, who came to Canada from France five years ago, substituted for Pierre Danel, a noted French hydraulics expert who was forced to cancel his visit because of illness.

M. Pariset described in detail the effects of recent research in improving the efficiency of turbines and extending their efficiency over a greater range of specific speeds. Of special interest was the development of the ball turbine in which the generator is mounted underwater and closely connected to the turbine which is of the variable pitch type. The unit can be mounted at any angle such as tidal power plants. M. Pariset also discussed some of the considerations governing tidal power. He illustrated his talk with slides. Two French films were shown following the discussion.

Kingston

R. O. McGee, Superintendent of Patents, Department of National Defence, was guest speaker at an October meeting of Kingston Branch. Mr. McGee discussed the nature of the patentable invention and the relationship of the engineering works to patents. These included a brief discussion of other forms of industrial property protection such as trademarks and copyright, procedures involved in obtaining a patent, the rights of a patentee and the infringement of a patent. There was a reference to the respective rights of employee and employer in inventions.

Kitchener

A. R. LeFeuvre, M.E.I.C.,

Thirty-five members of the Branch took part Oct. 27, in an interesting field trip through the Guelph plant of Federal Wire & Cable Limited. Refreshments were served by the company following the tour.

Lethbridge

P. A. Harding, JR.E.I.C.,
Correspondent

The Can-Pack method of beef processing was explained at the Oct. 29 meeting of Lethbridge Branch by Fraser Gardiner, M.E.I.C., construction engineer with Canada Packers Limited, Toronto. Mr. Gardiner first explained the older, bed system of beef processing in which the employee works much harder and in more tiring positions. The Can-Pack method employes a variable-speed conveyor which carries the work to the employee.

The worker stands on a platform which can be raised or lowered by a foot-controlled compressed air device. The method allows more efficient use of tools such as the hide cutter, bone cutter and tail puller. Mr. Gardiner said average per capita consumption of meat in Canada is 143 pounds, of which 64 pounds are beef. Automation also was well illustrated by a film showing the hydrogenation of oils. In closing, Mr. Gardiner said the packing plant now being completed in Lethbridge will dress approximately 1,000 cattle a week.

Montreal

J. R. Sabourin, M.E.I.C.,
Correspondent

Le Chapître de Montréal est celui qui comprend le plus de membres de tous les groupements régionaux de l'Institut des Ingénieurs du Canada. Ses activités diverses couvrent un vaste champ d'action, et à ce sujet trois projets importants mis de l'avant récemment, seront en voie d'exécution dans un avenir très prochain.

The Special Meetings Section of the Program Committee is organizing a two-day Regional Technical Conference at the Mount Royal Hotel on April 6th and 7th, 1961. The subject is Urban Transportation — a live topic in Montreal and one in which all members are vitally interested.

The Branch is assisting Headquarters in organizing a Joint Hydraulic Conference to be held in Montreal on May 7th to May 10th, 1961 by the E.I.C. in co-operation with the A.S.M.E. Most of the papers will deal with hydraulic machinery, but some 18 papers from Canadians will give a civil slant.

Le Comité d'orientation des étudiants du Chapître de Montréal a offert son appui à l'Institut de Chimie du Canada dans la promotion d'une Exposition des Sciences destinées aux étudiants des cours supérieurs, les 7 et 8 avril prochain. Ceci est en outre des activités régulières de ce comité dont la fonction principale est de conseiller et d'orienter les étudiants destinés aux de génie.

The Evening Education Committee is making arrangements with McGill to give evening courses which will permit one to qualify as a member of the Institution of Mechanical Engineers and as a member of the C.P.E.Q. Courses will begin at the third year engineering level and, if they prove successful for mechanical engineers, the courses will be enlarged to include other branches of engineering.

Une section d'étudiants, la première du genre dans la région de Montréal, est présentement en voie de formation au Collège Loyola. Elle est activement supporté par la section junior de l'Institut et un comité spécial composé de membres a été créé dans le but d'encourager la formation de groupements semblables dans les autres universités.

The Junior Section recently polled

the members enquiring into the desirability of forming a Social Club. Two-thirds of the replies were favourable. Although 1200 engineers have indicated a willingness to join a Social Club, the cost of forming one would be substantial and, as a result, the Junior Section is making a careful investigation of all facets before proceeding further. The Junior Section strongly believes that a Social Club would provide the members of the Montreal Branch with a very worthwhile service and that the prestige of the E.I.C. would be substantially increased.

La Direction a décidé à l'avenir d'émettre sous forme bilingue tous les bulletins de scrutin, factures, et formules d'application jusqu'ici uniquement rédigés dans la langue anglaise. Le Chapître de Montréal entrevoit également dans l'avenir prochain la publication dans les deux langues de tous les pamphlets, bulletins, et brochures destinés à ses membres.

The Branch sponsors at least one technical meeting per week. Of interest to all is a series on labor relations subjects organized by the Management Section. In November there was a talk on conciliation. In December there will be a discussion on the contentious subject of professionalism versus unionism for engineers. In late January or early February a meeting will consider labor unions and automation. Members are urged to read the Program Notices to make certain they are not missing a talk of prime importance.

Newfoundland

Anthony O. Nemec, JR.E.I.C.,
Correspondent

The main topic considered at the Oct. 19 meeting was the proposed Newfoundland Engineering Conference to be held next autumn at the new Memorial University. It is proposed to have a series of technical papers given by engineers from the local branch, and by other engineers working in Newfoundland.

Niagara

E. C. Little, M.E.I.C.,

Forty-two members and guests were present at a dinner meeting Nov. 2 which inaugurated the Branch's activities for the season. The meeting coincided with the date of the official opening of the Sewage Treatment Plant for North Bay, West Ferris and Widdifield. Guest speaker was D. S. Caverly, M.E.I.C., director of plant operations of the Ontario Water Resources Commission. Mr. Caverly was assisted by B.C. Palmer, supervisor of sewage works of the O.W.R.C.

Mr. Caverly outlined the history, organization and activities of the O.W.R.C. He said the North Bay plant is unique in that the methane gas given off in the process of digesting the sewage will be used to heat the incoming sewage, to power the air compressors and to heat the central building.

University of Saskatchewan

Arthur F. Hinderks
Correspondent

The role of the mechanical engineer in the chemical industry was explained to the Oct. 12 meeting by R. N. Boyd, Supervisor of Engineer Design Services, Engineering Department, Du Pont of Canada Limited.

Mr. Boyd discussed the various roles which may be played by newly-graduated mechanical engineers. Industry today is expanding continually, he said, and mechanical engineers are playing an ever-increasing part in this expansion. The highlight of Mr. Boyd's discussion was a film on Du Pont of Canada. The film gave a general picture of the industry, then showed the various phases in which a mechanical engineer can find challenging situations. A lively, informal discussion session and a question period followed.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

Catalytic Construction of Canada Limited is the winner of the E.I.C. Certificate of Advertising Merit for the month of September 1960.

Their 4-color advertisement headed: "VISION Seeing ahead" is one of an historic series and links the vision of Jacques Cartier with the vision of Catalytic Construction of Canada Limited. The whole advertisement is very striking and the illustration is different to that usually found in trade or technical periodicals.

The judging of the advertisements was done by fifty readers of the "Journal" — five from each province — who made their selection from the viewpoints of ACCURACY — INFORMATION — ATTRACTION.

Catalytic Construction of Canada Limited is headed by G. R. Henderson, M.E.I.C., and the advertising agency who prepared and placed the advertisement is Clifton Train & Associates—Clifton Train being the Account Executive.

CATALYTIC CONSTRUCTION OF CANADA LIMITED WINS CERTIFICATE

The four color full page advertisement of Catalytic Construction of Canada Limited which appeared on page 135 of the September issue was judged the "best" in the issue by a fifty reader jury. The Canadian organization is headed by G. R. Henderson, M.E.I.C. and the advertisement was prepared and placed by Clifton Train & Associates — Clifton Train, A/E.

More than 100 members attended a Nov. 2 meeting to hear French hydraulics expert Pierre Danel. Due to an indisposition, the paper was presented by M. Danel's associate, M. Pariset. After its presentation M. Danel discussed several aspects of the work in reply to questions.

Neil McMurtrie, Design Engineer, Transmission Section, Ontario Hydro, addressed the Electrical Section Oct. 11 on the subject "Extra High Voltage Transmission at the Coldwater Project." The Coldwater project is a pilot study of the problems associated with extra high voltage transmission. The subject is becoming increasingly important. Available sites for development of hydraulic generators are becoming more distant from points of power usage.

In a joint meeting with the Chemical Institute of Canada, the Power Section heard a paper on water treatment practices for the power industry. The paper was presented by Eugene Driscoll of the Technical Department of the Permutit Corporation.

On Oct. 27, C. G. Miller, Products Manager, Graver Tank & Manufacturing Co., presented a paper on the theory and application of Geodisic Dome Construction. The speaker traced the development of geodisic theory, its adaptation to the practical needs of construction, and the erection of a 384 ft. diameter dome.

• DISCUSSION

(Continued from page 81)

The task of presenting, in a short paper, the principles of automatic control could be undertaken only by such an outstanding expert as Dr. Porter. Even then one has a feeling that the presentation is too specific for the general reader and too general for the professional.

I would like to devote this brief discussion to:

1) a few remarks about some popular misconceptions in the field of automatic control and
2) a suggestion in what field of automatic control the research is particularly necessary.

It is unfortunate that the concept of "feedback" is not taught much earlier than in Electronics or Automatic Controls. The most natural place would be in the study of Mechanics. It is about time to realize that Newton's Third Law, for instance, is nothing but the action of "negative feedback".

It is fashionable to talk about "information-handling" capabilities of feedback systems. Unfortunately, the word "information" has anthropomorphic connotations which probably account for its popularity, but add little to understanding. The real implication is that feedback in automatic control is used to transmit signals from one part of the system to the other.

It is extremely annoying to hear about the "intelligence" and "reasoning" capacity of digital computers as if they were the only examples of systems exhibiting such characteristics. The truth being of course, that any analog computer has the same properties. Thus an analog integrator has a "memory", an analog differentiator can "predict" future and an analog adder can "decide".

Following the common practice of Operations Research, one has to "optimize" everything these days. It is questionable whether one should talk about the "optimization" of a complex nonlinear system. One cannot "optimize" a system whose analytical characteristics are not known.

The subject of "adaptive" systems is very popular today. One must remember however that such systems are not peculiar to the availability of electronic circuitry and computers. An automatic gearshift of our modern cars is a very good example of such an "adaptive" system to which one could attribute a very "intelligent" behavior indeed!

The field of linear automatic control theory is certainly very well developed. We can not say the same about its *nonlinear counterpart*. As far as the theory of *large systems* is concerned, neither the linear or nonlinear varieties have been yet really touched. I would like therefore to end this discussion with the suggestion, that more effort be exerted towards the understanding of the behavior of systems in these almost virgin fields. Let us "understand" first, and "optimize" later!

Discussion by J. H. Milsum:

Dr. Porter has prepared an important paper. There is always need for thoughtful searching and provocative evaluations of a new science, and for prediction of its future trends. The timing is opportune in view of the current "coalescing of the computer and automatic control branches" as Dr. Porter says; incidentally, a more directly-applicable metaphor might be "a fruitful growth from the cross-fertilization of these two fields"! The paper's value derives from Dr. Porter's attempted synthesis, for the purpose of better control systems, of the ideas behind such subjects as information theory, learning machines, multi-variable searchers and adaptive goal-seeking. The continued references throughout the paper to biological adaptive systems implies that important results should ensue from cross-fertilization between these fields also!

To this discussor, the paper divides into two parts which are approximately characterized by the two principles of automatic control which Dr. Porter enunciates;

Feedback: In this half the basically deterministic type of control system is discussed, including the adaptive or optimizing type and including deterministic systems subjected to stochastic signals. Some comments follow below.

Noise Generation: Self-organizing control systems inevitably must operate on a probabilistic basis. Conditional probability appears to be a basic tool here in the pattern recognition needed for learning ability. One might wonder however whether the ability to store, and learn from, past data might not be considered principles in their own right.

In the broad review conducted in this paper Dr. Porter only briefly mentions some important subjects in which much progress remains to be made;

Sampled-data systems, with their ability to time-divide a controller among many control systems.

Non-linearity of all systems, which becomes particularly important as systems are optimized (both the inherent non-linearities, e.g. friction and saturation, and the designed non-linearities, e.g. bang-bang controllers).

The practising control engineer cannot expect any help from this paper in deciding on conventional controller adjustments in a particular problem; but he will find prediction of the problem he will be confronting in future years.

Adaptive Control

The following comments relate to adaptive control. It is worth reemphasizing that feedback itself introduced the first measure of adaptability to controllable system-disturbances. As closed-loop theory was developed, the 'tolerance' of a system to disturbances came under closer scrutiny, and adaptive or optimizing techniques were considered. Optimization conceptually requires a second 'executive' control loop so that optimal operation is obtained according to some criterion. A common, obvious criterion of optimality is an economic one, and one large-scale example in use today is linear programming applied to manufacturing and distributing processes. Control is of course discrete because the large-scale computer calculations necessary are only carried out periodically. However the principle is the same as in conventional engineering control systems. In the high-performance aircraft field adaptive auto-pilots have become necessary, and a universal auto-pilot which can fly all aircraft without preference is already a possibility.[1]

Model Control

Under 'Prediction and Feedback' the author discusses three techniques which use models of the process in the control system. This discussor feels that the conceptual advantage of the methods of Fig. 3 and 4 are not easily realized mathematically when one designs the system. Thus the dotted-box of Fig. 3 is critical and does not exist in the Reswick method (Fig. 4). In a forthcoming paper[2] Reswick shows that the main application of his method is for the rather special case of a pure time-delay process. It is not clear to the discussor that genuine prediction exists in either of these methods. The author's own sampled-data method (Fig. 5) does involve prediction but the use of the polynomial model is not clearly explained, and Fig. 5 does not help very much.

End-Point Controllers

This last method bears on the subject of end-point controllers as in automatic landing of aircraft, stopping of elevators and completion of batch chemical reactions. The end-point is here the critical performance index, and predictive-model controllers have a fruitful application.[3]

Correlation Work

The Delay Line Synthesiser (DLS) provides an approximation to the impulse response by a discrete set of values in time. However the DLS can accept either continuous or discrete signals.

The author emphasizes that an automatic control must reject random information. However in the suggested use of the DLS the system is interrogated as to its transfer function by purposeful introduction of random signals, which do not interfere with normal operation. One of the new adaptive auto-pilots is incorporating this technique. Again it is interesting that interceptor pilots are known to interrogate their aircraft subconsciously with a high-frequency low amplitude oscillation of controls.

Discussion by G. L. d'Ombrain

Dr. Porter's paper is a most valuable statement of the position of automatic control today and in the future. I would like to confine my remarks to the work which is likely to be pursued, indeed is being pursued currently, in this field in the context of Dr. Porter's remarks.

In the past, considerable attention has been given to attempts to determine the characteristics of processes with a view to being able to control them more adequately. The idea has been that if we could stimulate processes adequately on an analogue computer then we should be able to design control systems with intelligence in order to get an optimized control. While much effort has been put into this, I do not think that the control engineer can with honesty say that he has succeeded to any real extent. The reasons for this are manifold. The obvious one is often quoted that plant managers do not like having plants interfered with, and this of course is true. But even where pilot scale plants have been organized and instrumented to obtain the appropriate knowledge, the interpretation of this knowledge has been exceedingly difficult since most plants are highly non-linear.

Reswick propounded ideas using auto- and cross-correlation which would enable, in theory, the process transfer characteristic to be determined utilizing normal plant operating records. The type of instrumentation required is not normally present on plants. The methods also necessitate linear theory and there obviously has to be an engineering approximation, therefore, in the interpretation of results that are obtained. The self-optimizing, and decision taking forms of control as outlined in Dr. Porter's paper seem to suggest a much more satisfactory approach. Here we may neglect the non-linear behavior of the process, we may to a certain extent ignore the problem of predicting its transfer characteristic, and we may make the computer itself do much of this work for us.

I would ask the author whether it is a correct interpretation of his paper to suggest that the immediate future will see processes being controlled on a number of minor loops as they are today utilizing those variables which have fast times of response, so that the control loops have rapid responses, properties for example such as temperature, pressure, level, flow, to a lesser degree pH, conductivity, etc. Added to this will be some decision taking type controller with inbuilt optimizing features which will be fed with appropriate information from instruments usually of analysis form which are not necessarily fast response in themselves, such as gas chromatographs, and that this information will be acted upon by the controller to deliver information which allows the alteration automatically of the set points of the appropriate minor loops. The reluctant break away from pneumatic to electric controllers which has swept through the instrument manufacturers in the last two or three years should help this approach considerably.

Discussion by V. J. Bakanowski, M.E.I.C.

In studies of dynamics of chemical processes it appears, judging from a cross-section of contents of technical papers published on this subject that the chemical industry is ahead of most of the universities in their work in this field. Of course we, in the chemical industry, would like to see the universities develop a substantial lead in the field since this would provide the best guarantee in future for firm and sure progress of chemical process control methods.

It is therefore very encouraging to read Dr. Porter's paper. It provides assurance that in the not too distant future when our knowledge on chemical processes, techniques for their mathematical formulation and hardware are improved, the universities will show us the way to apply the new analytical methods which Dr. Porter is developing today.

Author's reply:

Professor Glinski's remarks are of a very general nature and are not specifically concerned with the paper. However, he has raised several controversial points which must be challenged. For example, he suggests that the concept of "feedback" should be introduced in the study of Mechanics and he further suggests that Newton's Third Law exemplifies the principle of negative feedback and should be taught accordingly. This appears to me to be a retrograde step. Engineering students already have enough to cope with in understanding and applying the principles of Mechanics without introducing unjustifiable complications. It is well known that negative feedback characterizes many processes — physical, biological and sociological — but, in introducing students to these subjects, it is surely inadvisable to confuse them with a hierarchy of more and more abstruse ideas before they have understood the basic elements.

Professor Glinski objects to the use of the term "information" in feedback control. But it is difficult to understand why, because today communication theory, and the concept of measuring information, is proving a valuable aid in control system engineering. We do handle information in controlling processes and "information" is surely a respectable word. I agree with Professor Glinski that it is highly undesirable to talk about the "intelligence" and "reasoning" capacity of digital computers, but I strongly disagree that such properties may be associated with analogue computers. Further, I am astounded to read that "an analogue differentiator" can "predict" the future—this is, of course, nonsense. The suggestion that it is not possible to optimize a system whose analytical characteristics are not known, is of course true, but it is also impossible to optimize a process whose analytical characteristics are known because the environment cannot be predicted. And I fear that Professor Glinski has misunderstood the main arguments considered in the paper which suggests that at least some improvement of performance can usually be achieved by effective utilization of information appertaining to the process and to its environment.

I am grateful to Dr. Milsum for raising several important items. I agree that with the limited length of the paper several highly important aspects of control system technology were omitted. For example, sampled-data systems are likely to prove more and more significant for the reason mentioned by Dr. Milsum and also because a sampled system may, in many cases, prove optimum from the standpoint of information assimilation. In so far as non-linearity is concerned one might expect that the probabilistic approach to control system optimization may, in the future, by-pass some of the difficulties inherent in the design of non-linear control systems. However, the answer to this question is not likely to be available for several years. I am grateful for Dr. Milsum's comments on adaptive control which indicate that the subject can be "brought down to earth"—the example of the high-performance aircraft auto-pilot is particularly appropriate and I hope the universal system at present under development proves as effective as theory suggests.

Since the paper is intended necessarily to discuss principles rather than techniques it was perhaps excusable that the methods of Fig. 3 and 4 should be introduced to exemplify important principles. I agree with Dr. Milsum that the Reswick and Lang-Ham techniques are to a large extent of academic interest only.

I think some misunderstanding has arisen in connection with the role of random information in adaptive systems. My point is that if the environment is absolutely random and if the process is characterized by a very wide band-width it is not possible to introduce meaningful automatic control because prediction is impossible. I believe the purposeful introduction of random signals as a sort of search mechanism is of the highest importance and I am glad that Dr. Milsum agrees with this view.

I am very impressed with the competent summing-up by Dr. d'Ombrain of the more important principles introduced in the paper. For example, it is interesting to note that Dr. d'Ombrain also suggests that non-linear behaviour of a process may not preclude its optimization by means of probabilistic pattern recognition techniques. On the whole, I agree with the interpretation that the future evolution of automatic control will increasingly involve the decision-taking type of controller utilizing information from elaborate analytical instruments, and subsequently establishing behavioural patterns which in turn will be utilized to modify the minor loop set-points in a manner tending to satisfy process goals.

It is particularly gratifying to note the comments by Mr. Bakanowski. It seems to me that the role of universities in such fields as control technology is to explore more profound concepts and to speculate on advances which may not perhaps come into effect for many years. Industrial research and development laboratories cannot be expected to undertake much speculative research because of the importance of dealing with day-to-day problems and problems which may arise within, say, the next five years. However, the university research worker certainly requires the encouragement of his industrial colleague and thereby really effective collaboration between the two complementary groups of research workers will be strengthened.

WANTED

NOVEMBER 1960 ISSUE

The Engineering Journal

The Engineering Institute has received so many requests for additional copies of the November issue of The Engineering Journal that the available supply has been exhausted.

It would be greatly appreciated if readers who do not keep their copies on permanent file, will return them to the editorial office at:

900 Sherbrooke St. West
Montreal 2, Que.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

REINFORCED CONCRETE CHIMNEYS, 2nd. ed.

Since the publication of the first edition in 1940, Mr. C. P. Taylor, one of the authors has died, and this edition has been revised by Mr. Turner. Recent information has been included in this edition, as is an improved method of analysing annular sections subjected to bending and direct thrust. U.S. specifications for reinforced concrete chimneys are referred to, and wind forces have been reconsidered in the light of recent aerodynamic experiments. A new chapter deals with deflection and sway. Other topics covered are temperature, stresses, and flue openings. An example of the complete design of a chimney is given, and there is a bibliography of 21 items. (C. P. Taylor and Leslie Turner. London, Concrete Publications, 1960. 81 p., $2.80.)

CALCUL DES PROBABILITIES EN VUE DES APPLICATIONS

A basic introduction to the principles of calculation of probabilties, commencing with a review of stochastic mathematics and games theory. The various theorems and laws relating to probabilities are discussed and explained, and numerous worked examples given. This volume is one in a series on probability, statistics and operations research. (Maurice Girault. Paris, Dunod, 1960. 162 p., 14.50 N. Fr.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

***STRUCTURAL ANALYSIS OF "UNISTRUT" SPACE-FRAME ROOFS.**

The two parts of this report cover the recommended method for computation of safe roof loads and the tables of computed factors to be used in safe load computations. The volume of text analyses "Unistrut" space-frame construction empirically, with a history of its development, and its general behavior on various types of supports, and outlines the general theories on which the analysis is based. The proposed method of computation is then applied to five test structures with the results of the tests, and then to a series of untested structures. The tables in Part B present computations of distribution factors, carry-over factors, and fixed-end moments. (P.H. Coy. Ann Arbor, University of Michigan Press, 1959. 2 volumes, $18.00.)

***FUEL CELLS.**

This volume contains the papers and subsequent panel discussion heard at a 1959 Symposium sponsored by the American Chemical Society. The nine papers include a general introduction to fuel cells, and discussion of high-and low-temperature hydrogen-oxygen fuel cells, carbonaceous fuel cells, the electrode processes in fuel gas cells, molten alkali carbonate cells, catalysis of fuel-cell electrode reactions, and electrode kinetics of low-temperature hydrogen-oxygen fuel cells. (Ed. by G. J. Young. New York, Reinhold, 1960. 154p., $5.75.)

***GLASS: ITS INDUSTRIAL APPLICATIONS.**

This book covers the manufacture, the physical and chemical properties, and, particularly, the applications of all types of glass. It is semi-technical and is directed to those involved in the design, specification, testing, fabrication, purchase, or sale of glass products, rather than to glass manufacturers. The information given here reflects recent advances in the field and includes new information on such subjects as glass bead reflectroization and the "float glass" process for making flat glass. (C. J. Phillips. New York, Reinhold, 1960. 252p., $6.95.)

***INFRARED RADIATION.**

This book presents information on the components of infrared radiation units and the laws of physics by which they operate. It then outlines the applications and potentialities of infrared in science, medicine, technology, and industry. A generalized infrared system is developed step by step from the source of the signal through the methods of transmission to the final display. The latest material on infrared artificial sources, research in wavelength transmission, infrared instruments, detectors, and spectroscopy is given. (H. L. Hackforth. Toronto, McGraw-Hill, 1960. 303p., $11.50.)

***CONTROL SYSTEMS ENGINEERING.**

The specialized backgrounds of eleven authorities have been integrated into this single concise volume covering the mathematical aspects of control-systems engineering as applied to the study of complex large-scale automatic control systems. The role of mathematical models is indicated, and there is thorough coverage of modern theory from the trial and error procedures used in the design of linear systems to the application of game theory in the synthesis of complex systems. The background material on feedback theory, matrix methods, statistical theory, systems analyses, time-domain synthesis, sampled-data systems, etc. is directed toward the control engineer who wished to use mathematics in his procedures. (Ed. by W. W. Seifert and C. W. Steeg, Jr. Toronto, McGraw-Hill, 1960. 964p., $17.25.)

***WATER SUPPLY AND SEWERAGE, 4TH. ED.**

Presupposing a knowledge of hydraulics, this revised edition presents principles and present-day practices, introducing the subject with a discussion of sanitary engineering in modern life—the role of the sanitary engineer, the relation of population to consumption and disposal, and other problems. The supply of water is discussed in detail, including sources, collection and distribution, quality, clarification and filtration, and pumping stations. Sewerage is fully treated from the standpoint of sewer design, construction, maintenance, characteristics and flow; sewage disposal, sedimentation and filtration; sludge treatment and disposal; and miscellaneous problems. The final chapter discusses financing and management of the relevant plants and systems. (E. W. Steel. Toronto, McGraw-Hill, 1960. 655p., $12.75.)

MANITOBA HYDRO-ELECTRIC BOARD INSTALLS 1,250,000 LBS. OF B&W STEAM PER HOUR

MORE POWER FOR THE SELKIRK SETTLERS and others . . . 132,000 kilowatts will be available to the residents of Manitoba in 1960.

In the Manitoba Hydro-Electric Board's Selkirk 132,000 kilowatt Generating Station, two B&W Stirling Boilers will combine to deliver 1,250,000 lbs. of superheated steam per hour . . . at 875 p.s.i. and a temperature of 915° F.

Each of these B&W Boilers is designed to burn pulverized lignite . . . each has 12 burners and 4 pulverizers . . . each is equipped with fully water-cooled furnaces, self-draining superheaters and regenerative air heaters . . . and can be converted for gas or oil burning.

For information about steam generation 'phone or write the nearest B&W office. There's a B&W representative qualified to discuss steam for processing or power.

THE DRUM MOVES IN. Here is one of the two B&W steam drums being moved into position for installation. Each B&W Boiler can supply 625,000 lbs. of superheated steam per hour.

STEAM FOR PROCESS - B&W - STEAM FOR POWER

BABCOCK-WILCOX AND GOLDIE-McCULLOCH LIMITED, GALT, ONTARIO MONTREAL • TORONTO • CALGARY • VANCOUVER

*WELDING HANDBOOK, SECTION THREE: MISCELLANEOUS METAL JOINING AND CUTTING PROCESSES, 4TH ED.

Inclusion of chapters on the adhesive bonding of metals and the welding of plastics in this handbook marks the recognition by the AWS of adhesives as structural materials and of plastics as weldable materials. Other topics covered include forge, thermit, induction, ultrasonic, and stud welding, welding by cold working, surfacing, brazing, soldering, arc and oxygen cutting, and metal and ceramic spraying. Section 1 of the Handbook—General; Section 2—Gas, arc & resistance welding processes; sections 4 & 5 to follow. (Ed. A. L. Phillips. New York, American Welding Society, 1959. $9.00, various pagings.)

*THE DYMAXION WORLD OF BUCKMINSTER FULLER.

This book reflects the author's impressions and interpretations of the life and work of Richard Buckmaster Fuller, whose "Dymaxion" idea—getting from any type of structure the maximum net performance per unit of energy input—has created over the past thirty years a steady stream of startling cars, houses, maps, domes and systems of mathematics. Admittedly biased by personal warmth, the author's account is vastly interesting, and nearly 200 pages of superb glossy annotated photographs further illustrate the man and his work. (R. W. Marks. New York, Reinhold, 1960. 232p., $12.00.)

*VACUUM METALLURGY CONFERENCE, 1959: TRANSACTIONS.

The papers of the third annual conference held in June 1959 discuss new developments in vacuum arc melting and casting, vacuum investment casting, vacuum induction melting, vacuum degassing, electron-beam techniques, and applications of the products of vacuum metallurgy. (Ed. by R. F. Bunshah. New York, University Press, 1960. 212p., $7.50).

*DESIGN OF STEEL STRUCTURES.

This book emphasizes the fundamental principles of structural mechanics, the behavior of actual and idealized structures, and such practical requirements as safety, feasibility, and economy, correlating these concepts with current design practice. It is intended as a textbook in both elementary and advanced civil engineering courses. Following a general introduction to structural design principles the book covers elasticity, plasticity and safety, riveted, bolted, pinned and welded connections, tension compression and light-gage members, beams and girders, and the design of steel bridges and of steel buildings. (B. Bresler and T. Y. Lin. New York, Wiley, 1960. 710p., $9.75.)

*DECISIONS UNDER UNCERTAINTY; DRILLING DECISIONS BY OIL AND GAS OPERATORS.

The first objective of this book is to describe problems in drilling for gas and oil — to drill or not to drill — and how business men actually make drilling decisions. The second objective is to explore the possibilities of the application of mathematical theories to such decisions. The methods suggested for this purpose are clear and simple, requiring only a working knowledge of arithmetic and high school algebra. (C. Jackson Grayson, Jr. Boston, Division of Research, Harvard Business School, 1960. 402p., $6.00.)

*1959 REFERENCES ON FATIGUE.

This is a list of references published in 1959 dealing with the fatigue of structures and materials. Brief abstracts are included where available, and the references are arranged so that the sheets may be cut apart for filing as desired. This is the tenth volume in the series, which covers references published 1950 to 1959. (Philadelphia, American Society for Testing Materials, 1959. 88p., $4.00. s.t.p. 9-K.)

*ELEMENTARY INTRODUCTION TO NUCLEAR REACTOR PHYSICS.

This textbook for undergraduates in physics and engineering is an elementary account of that branch of physics involved in the study and design of nuclear reactors. The first three chapters deal with fundamental aspects of nuclear physics directly related to the physics of nuclear reactors. The discussion then develops the concepts of the compound nucleus, neutron cross-sections, and their relationship, and examines the physical aspects of nuclear fission, the interaction of neutrons with matter in bulk, and thermal and fission neutrons. Neutron diffusion theory then is considered, and the non-stationary reactor described and explained. The concluding chapters deal with the detection, measurement, and safeguards against nuclear reactor radiations. (S. E. Liverhant. New York, Wiley, 1960. 447p., $9.75.)

FUNDAMENTALS OF TRANSISTOR PHYSICS.

A broad introduction to the field of transistors, providing an analysis of the action of semi-conductors from the physics viewpoint. Introductory chapters cover the principles of atomic physics and electrical conduction. The author then discusses the practical transistor and its fundamental circuit, and compares it to similar vacuum tube circuit. Related semiconductors such as the double base transistor, the double base diode, and the silicon control rectifier are covered, as are the four-layer diode, the bilateral transistor, solar generator, photo transistor, tunnel diode, etc. (Irving Gottlieb. New York, Rider, 1960. 146p., $3.90.)

PRINCIPLES OF ECONOMICS AND THE CANADIAN ECONOMY.

The aim of this volume is to provide the reader with a description of the principles of economics, and to show their application and operation in the framework of the Canadian economy. The author has divided his subject into eight parts, the first of which provides an introduction and description of the different forms of business organization. Other parts cover: the theory of price and pricing; the business firm and industry; competition and monopoly; the distribution of income, including production, wages, trade unions, in Canada, the U.K. and the U.S., rent, interest and profit; international trade; public finance; money and banking; the national income.

The author provides the historical background for the various Canadian policies and institutions, and compares the Canadian situations with that in the United States. This is a very interesting and useful volume. (R. C. Bellan. Toronto, McGraw-Hill, 1960. 540p., $7.50.)

***METHODS AND TECHNIQUES IN GEOPHYSICS, VOLUME 1.**

A collection of papers dealing with modern physical techniques employed in determining and dealing with physical information about the earth. Contributors from the U.S., Canada, and Britain discuss measurement of temperature gradient in the earth, heat flow over land, geomagnetic elements, gravity at sea, and in palaeomagnetism; earth currents and the detection of earth movements; borehole surveying; properties of rock under high temperature and pressure; and the latitude, longitude, and secular motion of the pole. (Ed. by S. K. Runcorn. New York, Interscience, 1960. 374p., $10.00.)

***TECHNICAL COMMUNICATION.**

Written with the engineering student in mind, this book will also be useful to the practicing engineer and those in some other professions. The first three chapters discuss the qualities of good writing, the organization of material, and the use of exposition. The business letter is covered in detail. There is an extended treatment of reports and information on technical articles, magazine writing, oral communication and the use and preparation of tables and figures. The final section of the book is a manual of general composition, containing a review of the general principles of composition and a glossary of usage. (G. C. Harwell. Galt, Brett-Macmillan, 1960. 332p., $3.75.)

***PROGRESS IN NON-DESTRUCTIVE TESTING, VOLUME 2.**

This is the second volume in a series of annual critical reviews on international progress in non-destructive testing. Papers included cover the uses of radiology with high-energy X-rays, electrical methods, radioisotopes, ultra-sonic waves, and paramagnetic resonance in this type of testing. The theory and practical application of these methods of studying and detecting flaws in metal structures are presented, as well as studies of ageing and precipitation in metals using anelastic damping measurements. The mechanical testing of high polymers is also dealt with. (Ed. by E. G. Stanford. Galt, Brett-Macmillan, 1960. 250p., $12.00.)

°HANDBOOK OF GEOPHYSICS, REV. ED.

Sixty experts collaborated in the preparation of this encyclopedic source of geophysical information, which contains many tables, figures, and references to other publications. Included are papers on model atmospheres and atmospheric pressure, density, composition and electricity; atmospheric exploratory devices and acoustic propagation; temperature, wind, precipitation, clouds, visibility, the sun, meteors and the ionosphere; thermal and cosmic radiation; electromagnetic wave propagation and geomagnetism; terrestrial surface parameters and jet aircraft condensation trails. (U.S. Air Force. Galt, Brett-Macmillan, 1960. Various pagings, $15.00.)

°SYMPOSIUM ON FATIGUE OF AIRCRAFT STRUCTURES.

Presents nine of the twelve papers given at the Symposium. Of the remaining three, two will be published later and one has been withdrawn. Topics covered include the handling of fatigue data in a practical design case, probable loading conditions encountered by aircraft, supersonic fatigue test methods, fatigue behavior under high biaxial stresses, helicopter problems, methods for improving fatigue behaviour, methods for predicting rates of fatigue crack propagation and cumulative damage due to variable-amplitude loading. (Philadelphia, American Society for Testing Materials, 1960. 138p., $4.00. s.t.p. 274.)

°SYMPOSIUM ON SPECTROSCOPY.

This volume contains sixteen papers presented at the Symposium dealing with such topics as atomic, X-ray, infrared, molecular, ultraviolet, magnetic resonance, and electron paramagnetic resonance spectroscopy, flame photometry, infrared and spectroscopic analysis, and applications in geochemistry, petroleum technology and other fields. Also included is a non-symposium paper dealing with application of spectrography to the analysis of water formed deposits. (Philadelphia, American Society for Testing Materials, 1960. 245p., $7.00. s.t.p. 269.)

°PAPERS ON SOIL, 1959 MEETINGS.

This volume includes 29 papers presented at four separate sessions of the 62nd annual meeting and the 3rd Pacific Area meeting, ASTM, during 1959. Strain-rate effects, consolidation of clays and soils, repeated loading measurements, and a literature survey 1846-1958 on dynamic resistance of cohesive soils, are considered in 8 papers from the Symposium on Time Rates of Loading. Nine papers from the Symposium of Atterberg Limits discuss manifold aspects of the various Atterberg Limit tests. Three papers presented at the Session on Soils cover laboratory and field tests on granular materials, application of lime for soil stabilization, and the preconsolidation of a sensitive clay. The remaining nine papers were presented at the Symposium of Soils for Engineering purposes, and cover problems related to soil density, moisture content, load and compression testing and a proposed classification system for soils. (Philadelphia, American Society for Testing Materials, 1960. 375p., $9.00. s.t.p. 254.)

INSTITUTION OF STRUCTURAL ENGINEERS JUBILEE SYMPOSIUM ON HIGH STRENGTH BOLTS, 1959. PROCEEDINGS.

This volume includes the nineteen papers presented at a Symposium on the structural use of high strength bolts, together with the discussion on them. The papers are divided into three sections, the first being concerned with history, research and principles of design of these bolts. The second section covers the properties of bolts, and the tools used to place them. The last set of papers discusses the use of bolts in various types of structure, and in different countries. (London, Institution of Structural Engineers, 1960. 203p., £4.)

Correction

On page 168 of the November Engineering Journal the publisher of *Mobile Manual for Radio Amateurs, 2nd Ed.*, was incorrectly stated. The book was published by The American Radio Relay League, West Hartford, Conn.

If you are an E. I. C. member, you are a member of the Membership Committee.

Stan Cassidy

From letters to the editor . . . .

Erich J. M. Knitel, M.E.I.C., of Montreal, asks: "Can Canada in the long run afford to lose qualified engineers?" He answers his own rhetorical question with "certainly not, but she does; and there are only vague tendencies to avoid such a situation."

Mr. Knitel reviews efforts on both sides of the Iron Curtain to provide engineers and technicians and feels statistics prove the free world is being out-stripped in this sphere.

"'One sole technician is worth more than 10 Communists'," he quotes Lenin as having said, and feels this is a reflection "in the intensive but silent efforts of the Soviet Union."

The Federal Government of West Germany appreciates this situation, Mr. Knitel says, and to help rectify it, the Internal Department recommended: unification in the structure of engineering schools and in the access to engineering schools; adequate salaries for lecturers; establishment of scholarships for engineering schools.

"When we consider the situation in Canada," Mr. Knitel writes, "we must say there is quite a similarity to the . . . problem. In other words, Canada does not produce enough engineers to exploit in an adequate way her natural resources and consequently to offer a solution to the crucial unemployment problem."

"From this, it is quite obvious that Canada can not afford to lose any engineer, not only because she reduces her capacity to settle her own technical problems, but also each engineer leaving Canada reduces the national patrimony of Canada but shows this with a lack of patriotic feeling.

"On the other hand, there are several reasons which encourage the migration of engineers from Canada. At least there is nothing done to prevent such an intolerable situation.

"Essentially, the reasons are: more attractive salaries elsewhere; professional recognition; more interesting and diversified working fields; more freedom in the application of engineering knowledge; greater opportunities of professional advancement.

"These are the facts. The writer knows at least 10 cases where this happened. From his own small circle of personal friends, he, for instance, is the last of six immigrant engineers in electronics who did not go to the United States. The other five went.

"What has Canada done to avoid this? Nothing, with the excuse that we are a democratic country. It is said that nobody can be forced to do something he does not like—and there is the crucial point. It is obvious nobody should be forced to remain, but remaining ought to be made so attractive that everybody would like to stay.

"Thus, it lays in our hands and in the competent authorities to wake up, to do something (other than) talk about it, in order that migration of engineers from Canada would be avoided in a natural way."

● LIBRARY NOTES

(Continued from page 132)

*MANUEL DE POSE DES PIPE-LINES.

A guide for engineers and technicians, this book also demonstrates one aspect of modern developments in construction processes and illustrates the application of assembly-line techniques to this field. An introductory chapter assesses the importance of pipelines in the petroleum industry, describes the features of pipeline projects unique amongst hydraulic projects, and gives a general survey of the elements of pipe-line construction. Succeeding chapters treat in turn each step in construction, such as location, survey, excavation, and final covering of the trench; transport, laying, bending and joining of the pipe; and miscellaneous topics such as special features of the construction camp, and the crossing of existing lines and of bodies of water. (L. Lévêque. Paris, Eyrolles, 1960. 181p., NF 24.35.)

*MATERIALS SELECTION FOR PROCESS PLANTS.

This handbook contains data on the mechanical properties, fabrication characteristics, and corrosion-resisting qualities of metals, plastics, rubbers, paints, and cements for use in process equipment. The emphasis is on the prevention of corrosion, and the various types of corrosion and their prevention are first presented. The author then outlines information on the properties and applications of iron, steels, plastics, rubbers, chemical-resistant cements, paints, and alloys of nickel, copper, aluminum, lead, and titanium, gathered from his own experience, from literature sources, and from manufacturers' catalogs. (R. E. Gackenbach. New York, Reinhold, 1960. 318p., $8.50.)

*THE USES OF ELECTRICITY IN THE OIL INDUSTRY.

A reference book for electrical and power engineers in the petroleum industry, and for manufacturers of electrical equipment for use in the industry, which details the practices adoptel by British oil companies. One chapter also describes where these differ from continental and North American practices. Distributed in America by Professional Books Inc. (Ed. by E. A. Reeves. London, Ernest Benn, 1960. 296p., $10.00.)

*DICTIONARY OF NUCLEAR PHYSICS.

5,000 English-German and German-English terms each, used in uranium mining, reactor building, nuclear fission and fusion, isotope research, and in other fields of nuclear physics. Particular consideration has been given to nuclear physical symbols and abbreviations of which more than 600 are included. (Ed. by H. Rau. New York, W. S. Heinman, 1957. 247p., $5.00.)

*VDI-STEAM TABLES, 5TH ED.

In this new edition the temperature range remains the same but the pressure range has been extended to 500 atm. The three sections of the tables are as follows: state of saturation (temperature table); state of saturation (pressure table); values of volume, enthalpy and entropy for water and super-heated steam. The large folded Mollier diagram is in a pocket at the back. The foreword and the explanatory introduction are given in three languages — German, English and French. (Ed. by E. Schmidt. Berlin, Springer-Verlag, 1960. 119p., 15 DM.)

INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING, SIXTH CONGRESS, 1960. PRELIMINARY PUBLICATION.

This preliminary volume, published before the Congress, which was held in June, contains the papers on basic subjects which were to be discussed. Six working sessions were arranged, the first of which dealt with general questions, the basis of structural design, the properties of materials, and the development of methods of calculation. The first of the two sessions on metal structures considered new developments of connections, welding and pre-stressed, high-strength bolts, while the second dealt with the steel skeleton, design and execution, slabs and walls, and safety. Two sessions on reinforced and pre-stressed concrete dealt with developments in bridge building, safety, reinforced structures, connection methods and the redistribution of stresses due to creep. The sixth session was devoted to composite construction and new developments, particularly in the fields of nuclear power, dams and bridges. Altogether 58 papers are included, and five Canadian engineers are among the authors.

A final report will contain the discussion on the papers listed above, as well as additional papers on practical applications and special problems. (Zurich, Leemann, 1960. 928p., 70 Sw. Fr.)

*VIBRATIONS FROM BLASTING ROCK.

The author's purpose is to compile in brief but useful detail the most important factors concerning the nature and effect of vibrations generated by the use of explosives. He discusses explosives and blasting caps, rocks and their rupture by blasting, the elastic-wave pattern of vibrations, and the effects on neighboring structures of explosion energy waves. (L. Don Leet. Toronto, Saunders, 1960. 134p., $5.95.)

*INTRODUCTION TO STRUCTURAL MECHANICS.

For civil engineering students in a first course in structural analysis. The general theory and the applications of that theory to structures such as roof trusses, railway and highway bridges, are treated in separate chapters. General methods rather than techniques of limited application are emphasized. (P. Andersen and Gene M. Nordby. New York, Ronald Press, 1960. 340p., $9.50.)

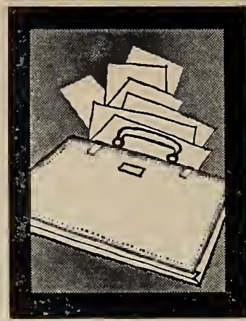
Business and Industrial Briefs



Appointments and Transfers

Canadian Liquid Air Company Ltd. has appointed **James Baillie McClelland** Manager, Technical Development, Ontario Region.

The appointment of **J. Milton Murdock** as Product Manager, Pump Department, has been announced by Montreal Locomotive Works Limited.

W. S. Haggett has been named President of The Bristol Aeroplane Company of Canada Limited and of its subsidiary, Bristol Aero-Industries Limited.

John Inglis Co. Limited, Toronto, has appointed **P. C. Hensman** as Manager, Hydraulic Department.

The promotion of **Allon D. Mack** to Sales Specialist, has been announced by Markel Electric Products, Ltd., Fort Erie, Ont.

Norman K. Anderson has been appointed Vice President, Marketing, by the Canadian Locomotive Company, Limited, Kingston.

The General Sales Division of B.C. Electric and the Industrial Development Department of its affiliated company, Western Development and Power Limited, have been merged. **E. D. Sutcliffe** has been named General Manager of the new division.

Trane Company of Canada, Limited, Toronto, has appointed **Brian E. Judges** as General Sales Manager.

Edmond G. Eberts has been appointed a technical sales representative by Union Carbide Canada Limited in their Chemicals and Plastics Division at Montreal.

Frederick L. McAdam has been appointed chief engineer of Marshall Macklin Limited, Consulting Professional Engineers and town planners, Don Mills, Ont.

John A. Fuller has been appointed Sales Manager of Worthington (Canada) Ltd., Toronto.

J. W. Craig has been appointed Vice President of Canadian Refractories Limited.

Developments

Information contained in this section has been obtained from press releases. Mention of products and services does not imply endorsement by the Institute.

A SERIES of special pipe nozzles has been installed in the side of a blast furnace at Hamilton. The nozzles are physical evidence of a joint experiment by Dominion Foundries and Steel Limited, Imperial Oil Limited and Esso Research and Engineering Company to determine whether heavy fuel oils can be burned in blast furnaces. If the experiments are successful it will mean increased efficiency for steel makers at a time when they are facing mounting costs and competition.

THE EFFECTIVENESS and safety of Perlox insulating fill for all cryogenic applications are outlined in a four-page brochure published by Canadian Johns-Manville. Stressed are the reasons why Perlox, completely inorganic, offers maximum safety in all extremely low temperature installations involving oxygen, nitrogen, argon and other gases used in industrial processing.

WELDING METALLURGY is the subject of a pocket-sized booklet published by the American Welding Society. It is a condensed textbook concerning ferrous and nonferrous welding metallurgy prepared and reviewed by some of the finest metallurgists in the United States. It contains 122 pages, 45 illustrations, 25 tables and 25 diagrams.

DIVIDENDS have been declared on two issues of preferred shares of the Shawinigan Water and Power Company. On the series A four per cent cumulative redeemable preferred shares the dividend is 50 cents, and on the series B 4½ cent cumulative redeemable preferred shares it is 56¼ cents.

A TWO-PEN potentiometric round-chart recorder-controller, accurate to within one-quarter per cent has been announced by Canadian General Electric. Engineers at the company's Meter and Instrument Section, Quebec Plant, say the instrument, an adaptation of the G-E single-pen-round-chart model, can be used in nearly any industrial application where two variables must be recorded on a single chart.

CONSOLIDATED EARNINGS of The Shawinigan Water and Power Company, St. Maurice Power Corporation and Southern Canada Power Company Limited amounted to $1.16 per common share for the first nine months of 1960, after deduction of all charges and provisions for preferred and class A common shares. This compares with $1.05 for the nine months ended Sept. 30, 1959.

A METHOD OF PRINTING in which there is no screen formation has produced high quality work in black and white and in full colour in the United Kingdom. The printing company claim that the prints produced are not only exact in tone values, but are of such fine grain that even examination under a magnifying glass shows no loss of detail. For short runs of 500 to 2,000 the process is cheaper than more conventional methods and the cost is not based on per square inch of illustration — as with blockmaking — so that the large illustration is most economical by comparison.

A FULL-SCALE "mock up" of a new 40-million-volt atom smasher at the University of Michigan is demonstrating how to save space and money in building the proposed machine. Built in the University physics laboratory for less than $1,000, the plywood replica already has brought about a saving of $6,000, according to Professor William C. Parkinson who is in charge of the project. The mock-up has shown where a saving of 20 tons of steel could be made in the 340-ton magnet which will encircle the machine's vacuum chamber.

INCREASED LONG-TERM EMPLOYMENT could result from a "joint development of the growing Canadian market for steam turbine generators. The presidents of John Inglis, Co. Limited and of Canadian Westinghouse Company Limited said their firms are co-operating for the production in Canada of such equipment. The feasibility of the arrangement has been enhanced by a ruling of the Department of National Revenue that electric steam turbo generator sets of 700 hp. and greater are of a class and kind made in Canada.

EXPORT COMPANIES have been formed in North America by the Boulton and Paul Group of Companies, the Head Office of which is in Norwich, England. The Group's activities cover constructional engineering, mechanized equipment for steel construction, joinery, wire and wire products, fencing, and builders' equipment. The new companies are: Boulton and Paul of Canada Limited, registered in Toronto; and Boulton and Paul (Nassau) Limited, registered in Nassau.

CANADIAN FAIRBANKS-MORSE has signed an agreement to sell its seven-storey building in Montreal to a real estate syndicate for an undisclosed cash price. President Robert Morse III said the company simultaneously entered into a lease for head office space in the new Canadian Bank of Commerce Building starting in the summer of 1962.

SCLAIR has been registered as the trade name by the plastics division of Du Pont of Canada for the linear polythene resins to be produced at the company's new plant at Corunna, Ont., near Sarnia. The name will identify the resins as Canadian-made and will readily associate them with the St. Clair River Works in Canada's chemical valley, where they are manufactured.

A 32-PAGE BROCHURE, numbered MC211, gives full details of the Mobrey Magnetic Level Switch and Control Range. Installation instructions and wiring diagrams are included in the booklet.

THE LARGEST CONSTRUCTION job in the history of the United States Air Force is described in photographs and text in "Concrete Performance Report" issued by the Master Builders Company. The report gives details of construction of the Air Force Academy complex at Colorado Springs, Colorado. A total of 800,000 cubic yards of ready-mix concrete was designed, controlled and placed under a wide range of conditions during the construction.

HONEYWELL REGULATOR COMPANY recently announced the formation of a new corporate division whose primary objective will be "the advancement of the state of art" of complex integrated control systems for individual and military applications. The move will centralize the company's broad capabilities in developing, installing and servicing specialized control systems such as those needed for complex industrial processes and missile launching installations.

NEW TECHNICAL LITERATURE, containing preliminary data on single crystals of refractory materials, has been issued by Union Carbide Canada Limited, Linde Gases Division. The literature contains a description of the new single crystals, provides data on their physical properties and purity, and describes the size range—diameter and length—in which they may be obtained.

The story behind a brief to the Royal Commission on Publications

Why Canada needs a Canadian business press

Does Canada need a business, professional and technical press of its own? Does this section of the periodical press of Canada contribute to the development and maintenance of the national economic health? Can Canada afford to weaken its independent, Canadian-owned business press?

The business press of Canada is a vital bulwark against further technological and financial dependence upon the United States.

These are the issues behind the brief presented to Canada's Royal Commission on Publications by Business Newspapers Association of Canada. BNA represents some 144 Canadian-owned business, trade, professional, technical and industrial publications, published in English and French. The advertising revenues of BNA member-publications account for two-thirds of the $30 millions in advertising placed annually in Canadian business media.

Among the members of Business Newspapers Association of Canada are the official publications of such respected bodies as the Canadian Manufacturers Association, the Canadian Chamber of Commerce and the Engineering Institute of Canada.

The purpose of the modern business publication might be described as:

1. *To collect and disseminate the experience of those engaged in a certain industry, profession, or trade.*
2. *To act as interpreter of events and developments.*
3. *To serve as a leader of sound thought and policy.*

Canada's business publications play a vital role in Canadian business, professional and industrial life; they are indeed the principal instruments of adult education and training.

The rapid post-war industrialization and development of a complex business community in Canada has made the business executive more conscious than ever of the need for accurate information and sound interpretation.

Business papers in Canada have established themselves as recognized sources of reliable information and ideas—latest inventions, newest developments and technological advances, new production methods, engineering and operating practices, progressive merchandising and retailing techniques, up-to-date economic thinking and policies—without which the Canadian businessman could be operating as he did years ago.

Canadian business publications gather information and attitudes from all corners of Canada and, as a result, many individual business decisions—to buy, to invest, to build or to renovate—are influenced by ideas gained in reading the mature Canadian business press.

It is the function of a good business publication to lead and guide industry thinking; business papers' importance to Canadian business and industry . . . indeed upon Canada's economic health . . . cannot be overstressed.

Here are a few examples of the contribution made by the Canadian business press to business and public life:

¶ A Canadian metalworking publication recently completed a massive census of Canada's metalworking production equipment, a task never before undertaken either by business or government. It revealed that much of this equipment was obsolete, undoubtedly contributing to plant inefficiency.

¶ A Canadian business magazine founded and annually sponsors the Canadian Furniture Mart, which has become the major marketplace for the exhibition and purchase by retail buyers of furniture made in Canada.

¶ A group of Canadian electrical business magazines were responsible for inaugurating the Plantpower Program—an educational activity designed to increase the safety and efficiency of electrical installations in Canada's industrial buildings. This program has since been adopted as a technical service by almost every major Canadian electrical distribution utility.

¶ Another Canadian electrical magazine was responsible for the inauguration of a safe home-wiring program, which has since been adopted by fire departments all over the country, following a series of daily newspaper articles, written by editors of the magazine. In at least one province, changes in legislation for greater public protection resulted from this magazine's activities at the public and industry levels.

¶ A Canadian plumbing and heating journal exposed the public hazards of unqualified installers of natural gas equipment. A series of articles by the magazine's editors, later reprinted in the daily press, resulted in new legislation and stricter control in the public interest.

℄ A Canadian construction magazine last year published a special section on the problems and prospects of winter construction in Canada—a peculiarly Canadian problem. This special section was later reprinted and distributed widely by the Federal Government as part of its program to promote winter construction.

℄ A Canadian packaging magazine was responsible for the foundation of one of Canada's largest trade and technical associations—the Canadian Packaging Association, along with the major Canadian National Packaging Exposition.

℄ A Canadian business publishing company provides a daily reporting service of construction contract awards. Published in a monthly business magazine, these are widely quoted and used in the industry, the daily press and by the Dominion Bureau of Statistics as an authoritative data source.

℄ A business publication serving Canadian retailers in the fashion field realized that, in general, Canadian retailers did not give due recognition to Canadian fashion design. The publication, through a series of articles, impressed this upon the manufacturers and got them to support the establishment of the Canadian Couturier Association, which since has flourished and has, of course, been responsible for the acceptance of Canadian designs which nowadays are shown internationally.

These may seem dramatic and extraordinary examples of the service Canadian business publications render for Canadians. This list can be duplicated one-hundred-fold. Canadian business publications report in detail to Canadians about Canadian professions, technologies and business and provide a platform for Canadian technicians and professional men to address their colleagues on matters of importance.

The national periodical press of any country plays a significant role in the cultural, political, economic and social life of its people. The Canadian business press provides the specialized information needed by Canadians in business and industry.

In Canada, this task takes on a far greater importance because the Canadian people are exposed to such a continuous flood of U.S. opinion and information and Canadian business to continued competition from abroad.

Canada's geographical position, its standard of living, its industrial and commercial development and the language of the majority of its population, leave its business community particularly vulnerable to influence from the U.S.

Business Newspapers Association of Canada believes that a Canada which did not have its own business press would have a much smaller chance of preserving and developing its national identity in the international business world. Yet Canadian business publications are being exposed to very strong competition from foreign publishers on a scale which would seriously threaten the industry's continued existence.

Canadian business paper publishers feel that it is vital that Canada not only retain but develop and strengthen her national identity. Obviously, U.S. publications are edited for U.S. audiences, reflect U.S. philosophies and sell the U.S. business way of life.

The overflow circulation of foreign publications into this country—in the case of U.S. business publications alone over one million copies a year—must have a tremendous influence on Canadians—particularly on our younger business people. The total effect of these publications on the economic and cultural life of Canada is that they, through their editorial and advertising pages, make Canadians most aware of "the American business way of life;" we are in grave danger of becoming pale shadows of U.S. citizens.

For these reasons, we believe, the preservation of a truly Canadian business press is vital to support and foster our national identity as Canadians.

U.S. business publications do not merely overflow into Canada; they compete aggressively for the advertising which is almost the only source of revenue for the Canadian business press. There is increasing competition from U.S. business publishers who offer to Canadians so-called "Canada editions"—a version of the parent magazine with little or no Canadian editorial content and wholly Canadian advertising—or "split-runs," in which the U.S. publisher sells his Canadian circulation separately to advertisers interested in Canada without Canadian editorial content.

If Canadian business publications were to be weakened by "Canada editions" or split-runs of U.S. business publications, the Canadian manufacturer would be at a serious marketing disadvantage vis-a-vis his U.S. or foreign counterpart, who would purchase advertising in these "Canadian" publications at a fraction of the cost of wholly Canadian media.

Canadian business and industry as a whole thus has a vital stake in the preservation of a truly Canadian business press.

Not only is the Canadian business press a vital medium of technical communication which helps keep Canadian industry efficient; it is an important marketing tool for reaching Canadian business buyers with advertising messages from manufacturers and suppliers.

Without a Canadian business press, the competitive pressures on Canadian business could only increase.

Many Canadian industries are subject to extraordinary foreign competition. The Canadian business publishing industry is not alone in this. But because of its peculiar importance to Canada, the position of the Canadian business press, we believe, deserves the attention of Government and industry.

We submit that Canada's business press is a priceless national economic asset which we dare not leave at the mercy of extraordinary competition from abroad.

BUSINESS NEWSPAPERS ASSOCIATION OF CANADA

An organization of 144 *Canadian* business, professional and technical publications

100 UNIVERSITY AVENUE, TORONTO, ONTARIO

Beaver Bill Says —

Mr. John Miner,
Somewhere-in-the-North
Canada

It was a pleasure to hear from you the other day and learn of your current activities.

I was impressed with your observation that you were enjoying work in your new field of responsibility but rather disheartened with the intellectual isolation, in the engineering sphere, so characteristic of small communities like Somewhere-in-the-North.

You'll be interested, I'm sure, to learn there is no valid reason why you and your nine or ten engineer neighbours cannot attend the Annual Meetings and Regional Conferences of your own EIC, or major meetings of either the Institutions of Civil, Mechanical, and Electrical Engineers in Great Britain, or the Founder Societies in the U.S.A., and do this without moving away from Somewhere-in-the-North or spending more than some ten dollars a year between you. How? It's very simple, John.

Your EIC has reciprocal arrangements with the Institutions and Societies whereby EIC members can secure their publications at member rates. The rest is up to you.

However, I suggest, John, there's a very easy way of actually participating. The Manager of Technical Services, EIC Headquarters, will be glad to help, on behalf of the Committee on Technical Operations and its 10 Engineering Divisions, by sending you a few preprints of our own meetings and of any of the other Societies mentioned, once you stipulate your field of interest. Distribute the extra copies to your engineer colleagues. Encourage one of you—say Cam Mechanical (He is very good at this, I recall)—to study one of these preprint papers. Get together at one of your homes or other convenient meeting place. Get Cam to make a brief presentation of the significant aspects of the paper and a few suggested points for discussion. Everyone of you can discuss it. Have someone, perhaps Al Electrical, record the principal points where clarification would be helpful. Send these comments in to the Manager of Technical Services. He'll pass them along to the author. I'm sure most authors will oblige by answering. The Manager of Technical Services will forward the author's comments to you.

It's easy, John. Try it out. I suggest you and your confreres can have a lot of mental stimulation by forming such a discussion group. It's not only good for mental stimulation but it's professionally broadening. Moreover, one of these days, you'll find there's enough interest Somewhere-in-the-North to warrant founding a Branch of the EIC.

Yours sincerely,

Consulting Services

Beaver Bill Says —

Do you have a good idea for a paper? If it's one you should write, don't hesitate. Do it and send it to the Manager of Technical Services at Headquarters. You'll find it a most rewarding experience to turn in a good paper. It's broadening intellectually and professionally.

Maybe it will be selected for an Annual Meeting or Regional Conference. Maybe it will be published in the Journal or Transactions. It's up to you!

● LIBRARY NOTES

(Continued from page 142)

°SYMPOSIUM ON NEWER METALS.

The three sections of this text correspond to the three sessions of the Symposium. Section 1, "properties of refractory metals", includes papers on high-temperature testing methods and properties of molybdenum, tantalum, columbium, and the platinum group metals. Section 2, "Nuclear and light metals", includes papers on beryllium, zirconium, and yttrium. Section 3, "Processing of newer metals", is concerned with purification and fabrication of columbium, tantalum, molybdenum, chromium and lithium. An additional paper is included in this volume to supplement the information on zircaloy alloys, dealing with the application, to the analysis of zircaloy, of coulometric determination of tin. (Philadelphia, American Society for Testing Materials, 1960. 218p., $7.25. s.t.p. 272.)

°SYMPOSIUM ON DURABILITY AND WEATHERING OF STRUCTURAL SANDWICH CONSTRUCTION.

The seven papers presented at the Symposium deal with: the effect of normal aging on strength of glass-fiber reinforced-plastic honeycomb cores; effect of natural environment on sandwich structure with AMS 3722 paper honeycomb-cores; effect of environmental exposure on adhesive-bonded structures; experience with sandwich construction in aircraft applications; temperature rise in structures due to solar heating; effect of climatic variations on polystyrene foam-core sandwich panels in roofs and walls; and experiences with structural sandwich in building construction. (Philadelphia, American Society for Testing Materials, 1960. 71p., $3.00. s.t.p. 270.)

°NOISE REDUCTION.

This volume was developed from lectures given by various authorities at four special summer programs from 1953-1960 conducted by MIT on the subject of noise reduction in industry. The introduction takes the form of a literature survey and bibliography on the historical background. Intended to be readable by graduate engineers in nearly any technical field, the material is organized in four sections — sound waves and their measurement; fundamentals underlying noise control; criteria for noise and vibration control; practical noise control. (Ed. by L. L. Beranek. Toronto, McGraw-Hill, 1960. 752p., $16.75.)

°CALCUL RAPIDE DES POUTRES CONTINUES PAR LA METHODE DE M. CAQUOT.

"Caquot's method" for the rapid calculation of continuous prestressed-concrete beams has been adopted by the French government as a standard method, as being the best, simplest, and most rigorous amongst the many attempts at simplification of these complex calculations. In this book introductory pages explain the need for a method or rapid calculation and describe the Caquot method. In the following first and second major sections, the authors extend the method to apply for all systems and types of loads, first in theoretical and then in practical applications. Section three contains formulae for various load and beam systems. (Marcel and André Reimbert. Paris, Eyrolles, 1960. 260p., NF. 35.45.)

°STAHLBETON TABELLEN.

Tables for the calculation of reinforced concrete structural elements of rectangular or T-shaped cross-section. The basic formulas are given and the method used in deriving the tabular values. These tables replace the previously published tables by Max Ritter. (K. Hofacker. Zurich, Verlag Leemann, 1959. 64p., 15 Sw.Fr.)
