The ultra-high vacuum chambers achieve pressures equivalent to altitudes in excess of 400 miles above earth. Bearing friction, lubricants and the behaviour of metals and plastics under extreme conditions are but a few of the factors which can be tested. Tests of a year's duration are now being planned for the components of an American reconnaissance satellite.

The test chambers range in size from a 14-in.-diameter by 36-in.-high bell jar type system reaching pressures as low as 2×10^{-10} mm of mercury to a large 3½-ft.-diameter stainless steel tank which has attained 4×10^{-10} mm of mercury.

Production Developments in the USSR

Extracted from The 1959 Sir Alfred Herbert Paper by Dr. D. F. Galloway, Director, Production Engineering Research Association of Great Britain.

Whereas in 1913 Russia's industrial production amounted to 2½% of world output, it now represents nearly 20% and exceeds the combined output of France, Britain, and West Germany. The same is true of her generation of electrical power. Russian industry has been gradually moving eastward in order to exploit the large mineral deposits of the Urals, Siberia and the Kuznetsk Basin. Factories in many cases have been built to accomodate the industry of an area; canning machinery, for instance, is manufactured in the Crimea where Russia's highly developed canning industry is centralized.

Although Russian factories are generally clean, natural and artificial lighting in working areas is poor and little use is made of colour for decorative purposes. There is a strong drive towards automation in Russia, but mechanical handling in factories is still sparse. Machines have been purchased from Czechoslovakia, Germany and elsewhere, but there is a movement on now to incorporate Russian machine tools into Russian industrial processes as far as possible.

Discoveries in research laboratories—both in the individual factories and in research centres—are intensively applied to production methods. The First State Ball-Bearing Plant in Moscow is a fair sample of Russia's industrial progress, where research has been incorporated into routine. The plant produces 70,000,000 bearings annually ranging in size from ½ in. to 5 ft. outside diameter and with weights of approximately 1 oz. to several tons. The plant includes a separate automatic factory built in 1952 which produces 2,000,000 bearings annually with a labour force of 12 production workers and 18 maintenance engineers. The automatic line is made up of 150 machine tools, several heat treatment furnaces, special assembly presses, inspection equipment and a unit for greasing, wrapping and packaging the bearings.

Structural Problems of Nuclear Reactors in Great Britain

A report submitted by Dr. A. H. Chilver, Cambridge University.

One of the most interesting fields of structural development in Great Britain during the past few years has been that of nuclear reactor design.

Nuclear power stations under construction are of the gas cooled, graphite moderated, natural uranium type. The structural requirements introduced new problems of irradiation of materials within the reactor. In addition, many new problems of large thin-walled pressure vessels, the creep of materials at elevated temperatures, thermal stresses, and biological shielding are encountered.

The core of a reactor is contained in a thin steel spherical shell, usually about 50 ft. in diameter and 3 in. thick. Gas pressure within the shell is approximately 200 lb./in.^{2} The carbon dioxide gas is circulated through large ducts connecting the sphere to heat exchanges. The main structural problems of the sphere are the duct connections, its support, and the welding of spherical segments during construction.

A considerable amount of research is being undertaken at universities and other research institutions, as well as in the industry itself. Design methods are being developed to deal with problems of stresses in spherical and cylindrical shells due to discontinuities, the buckling of shells and the creep of materials.

Computer methods are also being developed to deal with highly redundant elastic and also plastic structural systems.

West German Reactor Plans

An experimental reactor of the boiling water type will be the source of 15,000 kw. of electricity at Kahl, on the Main River, by the end of 1960, according to the *Bulletin* of the International Atomic Energy Agency. The plant is being built by Essen and Frankfurt-am-Main manufacturers and is based on an American design. To be operated by an Essen utility, the plant will provide technical and cost data for future nuclear power development and will help in the training of nuclear engineers.

Construction of a gas cooled, graphite moderated, high temperature reactor to produce 15,000 kw. is scheduled to begin soon near Juelich. Designed by a Mannheim firm for a Duesseldorf industrial group, the plant will be a joint industry-government undertaking. Government aid is also going into three other nuclear plants, each of approximately 100,000 kw. Five research reactors are now in operation in the German Federal Republic, and three more are under construction. It appears that design studies are also underway for the construction of several nuclear-powered merchant ships.

Atomic Energy's Irradiation Work at Harwell, U.K.

Britain's Atomic Energy Authority Wantage Radiation Laboratories have expanded to a new unit at Harwell, where important research work in irradiation treatment including bulk sterilization of medical supplies is going on. Situated close to two of Britain's high-powered research reactors, Dido and Pluto, the building contains a deep stainless-steel-lined pool filled with water. Fuel elements are brought to the pool from the reactors when a predetermined amount of uranium fuel from them has burned out to allow the initial activity to die down before re-processing. The elements are still so radioactive that the shielded flask in which they are transported is equipped with a cooling device and a "wet cropper" machine is used to transfer the element from the flask to the pool. It "tops and tails" the fuel element and removes the nose and stalk which contain no active material. The active portion is placed in a cadmium sheath which stops all the neutrons emitted by the fuel but does not inhibit the gamma-radiation.

The pool is being used in a wide range of work for both medicine and industry. One example of the latter is radiation treatment of polyethylene to raise its softening point. Also, companies which are to produce lubricants for the Central Electricty Generating Board nuclear power plants are having sample greases irradiated.

California Institute Computer Centre

A Burroughs 220 electronic computer system has been installed at California Institute of Technology as the central unit of their remodelled computer centre. Satellite orbit calculations, simulation of brain functions and calculations of the rate of expansion of the universe are but a few of the uses to which the new computer will be put. It is capable of 300,000 additions or subtractions per minute, and includes a data processor unit, a 55,000 digit magnetic core memory, paper tape input-output units and two magnetic tape auxiliary storage units. Expansion can be made to include an additional 55,000 digits of main memory and eight magnetic tape auxiliary storage units.

Two analog computers are also being installed in the Caltech facilities which have been developed by their own Analysis Laboratory. The basic data derived from these computers will be processed and evaluated by the 220.

L. A. Dubridge, Caltech president, has said, "This new discipline promises to have a profound impact not only on science and technology but on our ability to train and educate creative thinkers in all fields of endeavor."

Australian Travelling Gantry Crane

A 110-ton travelling gantry crane is being operated at the Keepit Dam construction site by the Water Conservation and Irrigation Commission on the Namoi River in New South Wales. The electrically operated crane is required to transfer the 53 ft. x 38 ft. bulkhead gate from its storage postion to any of the six spillway openings in order to protect the radial gates in the event of an emergency and to allow service on these gates. Auxiliary hoists, traversing at right angles to the axis of the dam, are also being used to handle fixed wheel gates and hoists, radial gate hoists, trash racks, cover slabs and other miscellaneous equipment normally located on or below the crest of the dam.

The main hoist lifts a 110 ton load at a rate of 3 ft. per minute, while the auxiliary hoist lifts 5 tons at 25 ft. per minute and loads ranging from 13 to 25 tons at 15 ft. per minute, depending on the position of the load in relation to the axis of the dam. The traversing of the erane and bulkhead gate along 750 ft. of straight track on the crest of the dam is at a maximum speed of 30 ft. per minute. A trailing cable laid on the crest of the dam brings power to the crane.

• CANADIAN DEVELOPMENTS

(*Continued from page 91*)

effected on April 18. Previously the two governments had agreed to give sympathetic consideration to representations concerning implementation of the specific trade agreement. However, the scope for such representations has been enlarged to include any other matters affecting commercial relations between the two countries. Canada could thus, should the need arise, take up with the government of the USSR any special problems concerning the sale in world markets of Soviet products in which Canada has a substantial export interest. Soviet foreign trade organizations will purchase Canadian goods up to a total value of $25 million Canadian provided the total annual value of Canadian purchases from the USSR is not less than $12½ million.

Three Northern Stations for Ontario Hydro

Ontario Hydro is planning a six-year, $182,000,000 construction program in the James Bay watershed involving three new generating stations and North Ameriea's first 460,000 volt transmission line. The station construction will be on the Mattagami River, west of Kapuskasing and Moosonee. The southernmost plant, at Upper Long Rapids, will be completed in 1963 with an initial capacity of 114,000 kw. By winter of 1965 a second station at Upper Long Rapids will be generating 110,000 kw., while the third, of 132,000 kw., at Lower Long Rapids, will be ready for operation in 1966.

Gas Turbines for Quebec

Hydro Quebec has ordered six 6,000 kw. gas turbine generator units from Canadian General Electric. They are to be located at the Commission's substation at Les Boules on the Gaspe peninsula, serving as a standby plant, a peak plant (to add to the supply available from the underwater cables), and a synchronous condenser plant to promote ideal operating conditions.

University of Waterloo to Build $2 Million Engineering Building

Work will begin this Fall on a 133,000 sq. ft. engineering building at the University of Waterloo, according to a recent announcement by Dr. J. G. Hagey, president of the university. The estimated cost is $2 million.

The civil, electrical and mechanical engineering departments will be housed in the new building which is to be composed of three sections—a three-storey classroom and laboratory wing, a one-storey, high-ceiling heavy laboratory wing and a two-storey office wing.

The design of the building will be harmonious with the adjacent chemistry and chemical engineering building and the physics and mathematics building. The three buildings will form a quadrangle to make up an engineering and science cell on the 210 acre campus of the new university.

The engineering and science cell is the first phase in the development of a 65 acre area of teaching buildings. Campus development plans call for three cells—one of general science buildings, one of the arts buildings and the third of joint-use buildings such as the library, administration building, student union and convocation hall.

Award to Seaway and Power Project

The American Society of Civil Engineers' 1960 Outstanding Civil Engineering Achievement Award was presented to the St. Lawrence Seaway and Power Project in a ceremony at the Power Project, May 19. Representatives from the Power Authority of the State of New York, the Hydro-Electric Power Commision of Ontario, the St. Lawrence Seaway Authority and the Saint Lawrence Seaway Development Corporation were present for the occasion.

Whiteshell Nuclear Research Establishment

Eleven thousand acres of land 60 miles east-north-east of Winnipeg have been selected by Atomic Energy of Canada Ltd. for Canada's second nuclear research centre. Although the centre will start as a small unit, it is expected to expand as nuclear research develops, perhaps even to the dimensions of the Chalk River plant. The new development is to be known as the Whiteshell Nuclear Research Establishment as it will be located close to the Whiteshell Forest Reserve. Some work will be done on the site this summer. However, the major construction work will not start until 1961.

It is likely that AECL will install an organic cooled, natural uranium fuelled, heavy water moderated reactor at this site as its next major research project. Close liaison has been set up between AECL and the Manitoba Development Authority. Plans for a residential area are under study.

Month to Month

Supply and Demand Situation for 1959 Graduates

The annual *Bulletin on the Supply and Demand Situation in Regard to University Graduates for 1959*, issued by the National Employment Service of the Unemployment Insurance Commission, shows that the prospects for well-trained university graduates remain good. The demand for engineering graduates is great and yet enrolment fell off temporarily in the Fall of 1959 presumably due to adverse developments in the aircraft industry in Canada.

Employment vacancies for engineering graduates in 1959 numbered 1,597, with the majority of jobs in civil engineering. Mechanical, electrical and chemical were next in that order. Although the rate of increase in total employment was below the 1957 peak, it was still high. Construction and business service industries, colleges and universities, and government agencies were the exceptions, their rates of increase remaining about the same.

A survey conducted in late 1959 by the Federal Department of Labour revealed that 80.3% of all hirings of engineering, scientific and architectural personnel during the years 1956-57 were of either new graduates or experienced Canadian personnel. Only 13.5% of those employed were immigrants already in Canada; only 6.2% were obtained from outside the country.

Recruiting Practices and Procedures

The American Society for Engineering Education has recently published a brochure entitled "Recruiting Practices and Procedures, 1959". Its stated purpose is to "aid in the development and maintenance of high ethical standards in the procedures of college recruiting and in the relations between the employing organizations, college authorities, and college students who are engaged therein."

Recruiting of college students should be carried out to serve best the following objectives:

1. To promote a wise and responsible choice of career by the student for his own greatest satisfaction, minimum wasteful turnover and most fruitful long term investment of his talents for himself, his employer and society.
2. To strengthen in him a high standard of integrity and a concept of similar standards in the employing organizations of the country.
3. To develop in the student an attitude of personal responsibility for his own career and advancement in it, based on performance.
4. To minimize interference with the educational processes of the college and to encourage completion of the individual's plans for further education.

Practices and Procedures: Responsibilities of the Employer:

1. The employer should contact the Placement Office well in advance regarding interview dates, broad categories of work expected to be available, college degrees and other pertinent requirements.
2. The employer should supply adequate literature to give the student a fair picture of the employing organization.
3. When both the parent organization and subsidiary or affiliated organization conduct interviews in the same college, the respective interviewers should explain their missions and connections, both to the Placement Office and to the students.
4. Not more than two and preferably only one interviewer representing an employer should appear for each interview schedule. Arrangements for more should be made with the Placement Office.
5. The Placement Office should be advised in advance of any plans for campus visits by the representatives of an employer, including alumni of the college.
6. An employer who desires to contact an individual student at the time of his interview visit should communicate with him well in advance and notify the Placement Office.
7. The interviewer should clearly explain to the Placement Office and students any special requirements such as the passing of tests, physical examinations, signing of parent agreements, or if his job is affected by any union contract.
8. The interviewer should be punctual and make every effort to avoid last minute cancellations.
9. The interviewer should be careful to follow the time schedule agreed upon with the Placement Bureau.
10. As soon as possible the interviewer should communicate with the Placement Bureau and student regarding the outcome of an interview.
11. The employer should give the student reasonable time to consider his offer, and in no case should the student be pressured into making a decision regarding employment.
12. If the employer invites the student to visit his premises for the purpose of further discussion of employment, the visit should be arranged to conflict as little as possible with class schedules.
13. The employer should not offer the student any special gifts or inducements.
14. Employers should not raise offers already made except when such action can be clearly justified as sound industrial relations practice, such as when an increase in hiring rate is required on an overall basis to reflect salary adjustments.
15. The employer should keep the Placement Bureau informed concerning his interest in particular students and his negotiations with them.
16. When a student has declined a job offer, the employer should accept the decision as final.
17. The employer should engage each student who has accepted his offer except when failure to do so is the direct result of contingencies explained in the interview or unavoidable economic factors not foreseen when the offer was made.

Responsibilities of the College:

1. As part of its general obligation for the development of the student, the college should accept responsibility for stimulation of his thinking about his career objectives and for assistance in overcoming handicaps which may hinder his progress toward objectives appropriate for him. Competent counseling services should be provided for this purpose.

2. The Placement Office should inform employers concerning the number of students available for interview in the several curricula, and the dates of graduation.

3. The Placement Office should announce to students early in the school year which employers will interview students and when.

4. The Placement Office should make employment literature available to students and faculty.

5. When an employer is looking for graduates in several fields (e.g. engineering, psychology, physics) the Placement Office should issue announcements to all qualified students concerned.

6. The Placement Office should not restrict the number of interviews per student, except as necessary to discourage indiscriminate "shopping."

7. The college should provide adequate space and facilities for quiet and private interviews.

8. The Placement Office should provide interviewers with available records of those students in whom they are interested.

9. The Placement Office should arrange for interviewers to meet faculty members who know students personally and can provide information about their work and qualifications.

10. The Placement officer and faculty members should counsel students but should not unduly influence them in the selection of jobs.

11. The Placement Office should make certain that students are acquainted with this statement of "Principles and Practices of College Recruiting."

Responsibilities of the Student:

1. In seeking company interviews, the student should recognize his responsibility to analyze his interests and abilities and consider carefully his career objective and appropriate ways of meeting it. He should read available literature and consult other sources for information about the employer and organize his thoughts in order that he may intelligently ask and answer questions.

2. The student should contact the Placement Office well in advance regarding desired interviews or cancellations.

3. The student should use care in filling out such forms as may be requested in preparation for interviews.

4. In his interviews, the student should recognize that he is representing his college, as well as himself, and should be punctual and thoroughly businesslike in his conduct.

5. The student should promptly acknowledge an invitation to visit an employer's premises. He should accept an invitation only when he is sincerely interested in exploring employment with that employer.

6. When a student is invited to visit an employer's premises at the employer's expense, he should include on his expense report only those costs which pertain to the trip. If he visits several employers on the same trip, costs should be prorated among them.

7. As soon as the student determines that he will not accept an offer, he should immediately notify the employer.

8. The student should not continue to present himself for interviews after he has accepted an employment offer.

9. Acceptance of an employment offer by the student should be made in good faith and with the sincere intention of honoring his employment commitment.

10. The student should keep the Placement Office advised concerning his employment negotiations in accordance with the policy of his Placement Office.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on February 20, 1960.

Member: T. N. Arnold, Ottawa; P. J. Carson, Montreal; A. S. Coghill, Kingston; E. A. Dahl, Montreal; E. R. Dixon, Dundas; F. Engelhart, Montreal; D. A. Fraser, Copper Cliff; S. F. Franks, Ghana, Africa; S. K. Garg, Cornwall; F. S. Hummel, Toronto; P. T. Mitches, London; D. J. Moon, Toronto; E. R. Needles, New York; R. Patel, Ottawa; E. E. Paul, New York; J. G. Pierce, Peterborough; R. P. Preston, Montreal; U. R. Sainani (Mrs.), Montreal; J. A. G. Sneddon, Hamilton; S. Snell, England; E. K. Timby, New Jersey; H. M. Treleaven, Lockerby; P. W. Voisey, Montreal; R. Weir, Toronto; C. E. Welsh, Toronto; D. G. Wilson, Montreal.
Junior: G. N. Gillund, Chalk River; W. C. Gobel, Cornwall; L. B. Malone, Temiskaming.

Junior to Member: G. M. Boissonneault, Montreal; I. M. Campbell, Prince Rupert; G. Charlap, Sudbury; W. J. Cosgrove, Montreal; T. G. Cundill, Colborne; J. D. Denovan, Montreal; G. L. Genest, Ottawa; R. W. Lockie, Victoria; G. D. Mackay, Montreal; A. D. McDonald, Rexdale; W. Pegusch, Vancouver; F. A. Pike, Vancouver; G. L. Roy, Montreal; I. Waterlow, Trail; J. M. White, Ottawa.

STUDENTS ADMITTED

University of Manitoba: R. A. Anderson, W. H. Antonyshyn, J. S. Archer, A. J. Arenson, R. I. D. Barton, L. T. Baydack, F. O. Best, A. G. Bolton, G. M. Cederwall, K. M. Drennan, E. W. Dutchak, N. W. Emslie, S. Freitag, K. J. Gowriluk, R. E. Greenlay, H. M. Holroyde, C. W. Jack, M. Jacobs, W. W. Jonasson, W. H. Kauk, R. J. Keltie, S. J. Kopec, V. Lysack, J. P. Masserey, J. McBride, R. R. McKibbin, R. B. Robertson, E. G. Robins, D. Sader, C. T. Smith, D. W. Snaith, B. F. Thompson, H. E. Wackman, J. S. Websdale, R. B. Williams, L. S. Willison, P. B. Winslow, E. A. Zaleski.

University of Toronto: N. E. Anderson, R. F. G. Baker, P. M. Bishop, J. S. Brooks, N. C. Chaggares, W. R. Collard, J. Ezyk, W. A. Gibson, H. D. L. Gordon, R. A. Guerriere, A. L. Hidi, S. R. Hiseler, I. Holubuc, J. T. Jacobs, B. M. Johnson, T. W. Kolator, J. W. A. Maxwell, W. D. Medweth, J. R. Millar, J. H. Moylan, E. T. Perchyshyn, E. J. Rosseter, D. P. Rutenberg, A. W. Spary, J. M. Toohey, J. T. Unsworth, E. P. Wasylwic, T. A. Woods.

Carlton University: J. R. Barclay, J. N. Beshara, J. R. Bethell, D. A. Brown, E. P. Edelson, D. R. Enns, W. K. Glennie, D. A. Long, J. H. McCalla, A. J. McCann, G. A. McInnes, D. R. Moore, D. G. Munro, J. M. Roll, G. H. Saunders, R. A. Spittall, K. Stoodley, W. E. Stratton, L. Tannis, A. R. Thompson, R. H. Verner, W. G. G. Welsh, J. A. Wrinch.

McMaster University: T. Arciszewski, J. G. Brown, M. B. Carver, P. F. Crath, G. Crouch, D. E. Filman, R. J. Hick, R. J. Kulperger, H. Muzyka, D. B. Rehberg, W. V. B. Reist, G. E. Riley, I. B. Webster, W. Wlisko.

University of Alberta: L. A. Anderson, J. Audia, D. L. Baycroft, N. R. Burroughs, C. C. Fortems, R. S. French, R. A. Heise, J. V. Krupa, J. H. Moore, N. A. Patterson, V. J. Prystawa, P. L. Strohschein, W. Y. Svrcek.

University of British Columbia: L. A. Bergman, D. G. MacDonald, R. A. MacDonald, A. A. Offenberger, E. H. Plato, C. Ramjit, G. D. Rogers, C. Turner, W. A. Walrond.

McGill University: E. A. Adegeye, S. O. Alu, R. E. Amy, M. C. Brown, R. M. Cleary, H. G. Harris, G. J. Hazan, T. H. Moffet, R. F. Neill.

Royal Military College: R. B. Blake, M. G. Corbett, E. E. Goski, J. J. D. Lawson, M. A. S. MacNamara, H. J. Riva, W. N. G. Robinson, B. L. M. Smith, J. F. L. Tremblay.

Saint Mary's University: C. E. Blackie, D. A. Grantham, R. K. Kilvert, J. W. Macdonald, W. G. Spruin, E. J. Thimot.

Nova Scotia Technical College: J. P. Chisholm, R. L. Lathangue, B. P. MacDonald, J. L. MacDonell, G. C. Power, T. R. F. Prescott.

Memorial University: H. Bowering, W. W. Johnston, W. P. Doyle.

Mount Allison University: A. J. McGraw, J. R. Trenholm.

Ontario Agricultural College: P. D. Bright, H. T. Seymour.

St. Joseph's University: J. R. Arsenault, J. S. Terris.

Sir Geo. Williams University: D. C. Hutchinson.

Queen's University: J. A. Choma.

University of Western Ontario: R. J. Janssens.

University of Saskatchewan: M. B. McCurdy.

Acadia University: W. L. DeWolfe.

University of New Brunswick: P. R. Stewart.

Student of C.P.E. Quebec: G. Lapointe.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective.

ALBERTA

Members: W. H. Crowe, C. B. Dibblee, R. W. Gowswell, G. T. Narfason, P. Kolozs, G. R. McAthey, G. L. Williams, S. G. Cowan.
Junior to Member: J. A. Kerr, N. Malychuk.

SASKATCHEWAN

Members: A. P. Belyk, D. R. Brodie, D. S. Cathcart, J. L. D. Cooper, D. H. Filson, R. H. D. Grace, R. D. MacLean, R. V. Milne, W. J. Pearson, A. B. Webb, H. J. Wolbeer.
Junior: H. F. Button.
Junior to Member: G. F. Cox, V. J. Gross, D. M. J. Kent, N. L. King, T. W. McDonald, J. P. F. Mooney, R. H. Russell, E. M. Toth.
Student to Junior: R. A. Baumgartner, R. E. Beveridge, K. Birch, J. W. Rittinger, R. G. Sanders, A. T. Torgrimson.
Students: D. C. Ayotte, J. L. Barber, G. Bender, C. J. W. Biss, M. J. Blackwell, R. E. Bodnar, W. R. Brooks, A. M. Bryski, E. F. Cairns, G. Campbell, D. J. Cartwright, N. Chorney, R. B. Clunie, W. E. Culham, M. T. Dagg, R. E. Dart, R. H. David, D. P. Dean, A. G. DeJager, G. R. Demetrick, N. L. Derksen, A. E. Douglas, J. O. Edler, J. M. Ewart, T. W. M. Field, L. E. Fish, D. P. Foley, R. T. L. Froc, W. J. Gogol, W. A. Gold, T. P. Griffin, R. M. Halko, L. J. Hamblin, T. I. Hellquist, G. K. Hendriksen, M. J. Herasymuik P. B. Hertz, J. P. Hutch, W. G. Irvine, V. J. Isaak, M. W.

A.E.L. design engineers build a new bomb

FOR THE FIGHT AGAINST CANCER

"But can you design and build such a unit?" The speaker was an eminent specialist in cancer therapy at the Montreal General Hospital. The need was urgent. Existing X-Ray equipment for radiation treatment of cancer was expensive to maintain and cumbersome to manipulate. Research had indicated that the radioactive isotope Cesium 137 had excellent potential in cancer therapy and could, if properly harnessed, form a replacement for the 250 KV X-Ray machine and provide up to fifteen or twenty years of trouble-free life.

A. E. L. took up this vital challenge with enthusiasm. Working as a team with the Hospital specialists, A. E. L. engineers laid the foundations of a new design concept. A machine to treat every part of the human anatomy. To accomplish this two interchangeable fully adjustable collimators were produced. One, a continuously variable circular field 'Flexi-collimator' for head and neck treatment and, the other, a square field collimator for trunk and other work. In other words two diverse fields covered by one machine—a feat never before achieved in high intensity radiation therapy with only two collimators.

The Cesium Radiation Teletherapy Unit is now installed in the Montreal General Hospital and medical science has another weapon in the war against cancer.

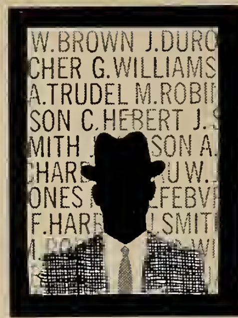
Another instance of how A.E.L.'s skills in research, design, engineering and manufacture are helping to solve problems in a wide range of industries. Your enquiries are invited.

AVIATION ELECTRIC
LIMITED

200 Laurentien Blvd., Montreal, P.Q.

Branch Plant: Aviation Electric Pacific Limited, Vancouver Airport, Vancouver, B. C.

Personals



Richard L. Hearn, Hon. M.E.I.C., (Toronto '13), Director, Atomic Energy of Canada Ltd., has been elected an honorary member of Britain's Institution of Electrical Engineers. The award is for "notable contributions in the development of electricity generation and its supply for the benefit and use of mankind, particularly in Canada, and for the part he has played in international co-operation in this field".

R. L. Hearn, Hon. M.E.I.C.

J. E. Neilson, M.E.I.C. (Queen's '28) was recently elected president and chief executive officer of Foster Wheeler Ltd., St. Catharines, Ont.

H. R. Montgomery, M.E.I.C. (McGill '29), of the Pentagon Construction Company, Montreal, has been elected a vice-president of the Canadian Construction Association. **G. R. Stunden**, JR.E.I.C. (McGill '50), of the Atlas Construction Company, Montreal, is the new chairman of CCA's Road Builders and Heavy Construction Section. **H. J. Leitch**, M.E.I.C. (McGill '26), of the Dominion Bridge Company, Montreal, is chairman of the trade contractors section and **A. W. Purdy**, M.E.I.C. (Queen's '49), of the Canada Cement Company, Calgary, is chairman of the manufacturers and suppliers section. CCA provincial vice-presidents include **H. W. Hilsden**, M.E.I.C. (Saskatchewan '50), of Hilsden & Company, Regina, for Saskatchewan and **R. H. Ansley**, M.E.I.C. (Manitoba '42), of Commonwealth Construction Company, Vancouver, for B.C.

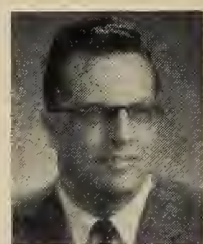
P. D. Dalton, M.E.I.C., (McGill '28), of Dalton Engineering and Construction Company, Toronto, is honorary secretary.

Ralph R. Willis, M.E.I.C. (New Brunswick '31) has been appointed vice-president and general manager of Ross Engineering of Canada Ltd.

G. B. Williams, M.E.I.C. (Manitoba '35), chief engineer of the Department of Public Works development engineering branch, has been selected to fill the new post of Assistant Deputy Minister (Technical), Ottawa. The position has been created to facilitate the Department's handling of technical responsibilities in the engineering and architectural fields.

Harry Jomini, M.E.I.C. (Manitoba '35) has been appointed director of public relations and advertising for the Aluminum Company of Canada in British Columbia.

A. D. Burford, JR.E.I.C. (Manitoba '54) has been appointed to direct the sale of electric and electronic products for Ward Leonard of Canada, Ltd., Toronto.



A. D. Burford, JR.E.I.C.

George P. Hobbs, M.E.I.C. (McGill '40) is the new head of Bowaters Engineering and Development Inc. at Calhoun, Tenn. Mr. Hobbs thus becomes head of the central engineering and research activities of the Bowater Organization in North America.

Walter G. Ward, M.E.I.C. (McGill '42), vice-president and general manager of the apparatus department of the Canadian General Electric Company, has been named president of the Montreal Armature Works Ltd., a company recently purchased by CGE.

L. P. Dancose, M.E.I.C. (Ecole Polytechnique '42), chairman of the Lower St. Lawrence Branch, has been appointed superintendent of buildings, vehicles and supply at the Quebec Telephone Company.

W. D. Stothert, M.E.I.C. (Alberta '45) has been appointed manager of engineering, maintenance, utilities, purchasing, stores, and traffic at the Columbia Cellulose Company Ltd.'s Watson Island dissolving grade pulp mill, Prince Rupert, British Columbia.

Ralph E. Crysler, M.E.I.C. (Toronto '49), **Clark B. Davis**, JR.E.I.C. (Toronto '50), and **Eric G. Jorgensen**, M.E.I.C. (Queen's '49), formerly of the firm of H. A. Babcock & Company Ltd., have opened a new firm of consulting engineers under the name of Crysler, Davis & Jorgensen, Ltd. in Willowdale, Ont.

R. C. McMordie, M.E.I.C. (Toronto '30) is chairman of the recently organized Senior Staff Executive Committee of the B.C. Power Commission which replaces the post of General Manager in the Commission. Mr. McMordie has also been made Manager of Engineering and Operations and Chief Management Officer for the Commission. **A. J. G. Leighton**, M.E.I.C. (Saskatchewan '42) has been appointed Director of Engineering. **P. J. Croft**, M.E.I.C. is the new Director of Planning

C. Albright, M.E.I.C. (Manitoba '50) has been named Maintenance Superintendent for the Phosphate Plant at the Consolidated Mining and Smelting Company of Canada Ltd., Trail, B.C. **W. A. Cairns**, M.E.I.C. (Alberta '36) is the Superintendent of Cominco's new Chlor-Alkali Department.

Jean-R. Cote, M.E.I.C., consulting engineer at Rouyn, Quebec, has been named local representative for Mr. Auguste Martineau, architect, Ottawa.

W. A. Ketchen, M.E.I.C. (McGill '28) was recently appointed vice-president, technical services, of Fraser Companies, Ltd. in Edmundston, N.B.

W. A. Ketchen, M.E.I.C.

L. H. Lafontaine JR.E.I.C. (Reusselaer Polytechnic Institute '53) has been appointed to direct the sales of heat exchangers for the recently established boiler products division of the Dominion Bridge Company Ltd. in Montreal. **Neil Richards**, Jr. E.I.C. (Manitoba '56) has been named sales representative for Alberta, operating from the company's Calgary branch.

Wide open spaces...

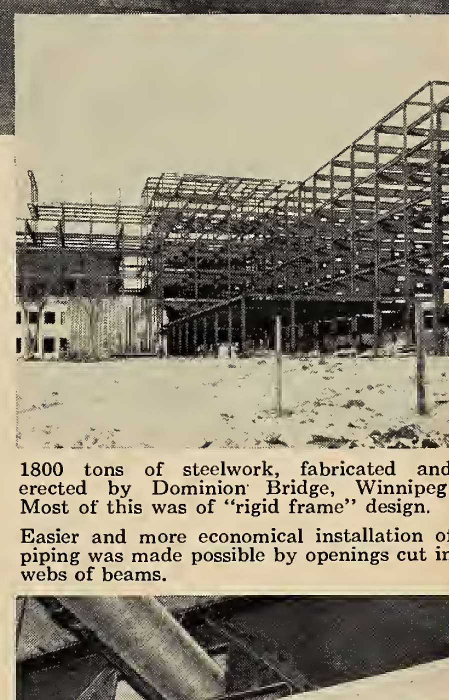
You get space, speed, flexibility and economy with steel construction—all were achieved in the Great West Life Assurance Company's new head office building in Winnipeg.

The use of long span steel beam construction gave large column free areas and allowed maximum flexibility of interior partitioning. Future changes in office and space requirements can be easily accommodated.

In addition, openings in the beam webs provided for passage of electrical, plumbing and heating facilities beneath the floor—without adding to the building's over-all height. Every inch saved in height meant significant dollar savings.

All the steelwork was erected during three months of bitter winter weather. This enabled the sub-trades to move in on time to complete their work.

Architects: Marani & Morris of Toronto and Moody Moore and Partners of Winnipeg. Consulting engineers on structural design: Wallace, Carruthers & Associates of Toronto. Contractor: G. A. Baert Construction Co. Ltd.



1800 tons of steelwork, fabricated and erected by Dominion Bridge, Winnipeg. Most of this was of "rigid frame" design.

Easier and more economical installation of piping was made possible by openings cut in webs of beams.

DOMINION BRIDGE

FOURTEEN PLANTS—COAST-TO-COAST

J. R. McGovern, JR.E.I.C. (McGill '51) has been elected vice-president and general manager of Sola Electric (Canada) Ltd. Re-elected to the company's board of directors, Mr. McGovern will also be in charge of operations of the company's Toronto plant.

Fritz Rumscheidt, JR.E.I.C. (McGill '56), a postgraduate student at the Pulp and Paper Research Institute of Canada, has been awarded the Spruce Falls Power and Paper Company Ltd. Fellowship for the academic year 1959-60 at McGill and PPRIC.

J. S. Kendrick, M.E.I.C. (British Columbia '38), formerly with the Aluminum Company of Canada, has been appointed a Vice-President of Sandwell International Ltd., Consulting Engineers, in Vancouver.

Terence J. Farrell, M.E.I.C. (Manchester University) has been appointed manager of plate and mechanical sales for Canadian Vickers Ltd., with headquarters in Montreal.

Paul E. Paquin, M.E.I.C. (McGill '40) has been promoted to the position of Manager, Electric Welding Division, of the Canadian Liquid Air Company Ltd. He was formerly Manager of Electric Welding Sales.

D. F. Rankine, M.E.I.C. (Manitoba '47) has been named vice-president and manager of Montreal Armature Works Ltd. The company is owned by the Canadian General Electric Company Ltd.

Donald H. McLeod, JR.E.I.C. (Saskatchewan '50) has been named associate-in-charge of the Brandon, Manitoba office of Ward and Macdonald Associates, architects. He will be responsible for the supervision of the firm's projects in Western Manitoba.

R. H. Hall, M.E.I.C., (Saskatchewan '41) has been appointed assistant to the vice-president, research and development of Shawinigan Chemicals Ltd. and has been elected to the board of directors of B.A.-Shawinigan.

N. M. McCallum, M.E.I.C. (British Columbia '23), formerly manager of General Construction Company (Alberta) Ltd., Lethbridge, has joined Willis & Cunliffe Engineering Ltd., Victoria, as a director of the company and chief engineer.

Walter Murray, M.E.I.C. (Edinburgh '26), formerly engineer of Pointe Claire, Quebec, is the new town engineer of Trenton, Ontario.

We offer our apologies to Dr. R. R. Jackson, M.E.I.C. (Alberta '44), formerly associated with the Radio and Electrical Engineering Division of N.R.C., who is at present a Fellow Engineer in the New Products Department of the Westinghouse Electric Corporation, Cheswick, Pa. The Mussens Canada Ltd. appointment attributed to him in the February issue was incorrect.

Roy C. P. Preston, M.E.I.C. (Toronto '50) has been appointed sales manager in the road building materials division of The Pedlar People Ltd. He will be located at the Oshawa head office of the company.

Alec Coghill, M.E.I.C. (Queen's '51) has joined The Aluminum Company of Canada, Ltd., Kitimat Works. Works as metallurgist in the Technical Division.

C. J. MacHutchin
JR.E.I.C.

G. J. MacHutchin, JR.E.I.C. (McGill '52) has been elected president of the Duron Company, Ltd., specialists in epoxy flooring, Montreal and Toronto.

H. B. Tafelmacher, M.E.I.C. (Zurich '46) was recently elected Managing Director of Aluminio del Uruguay, S.A., a producer of aluminum sheets and sections in Montevideo, Uruguay.

Jules J. C. Picot, JR.E.I.C. (N.S.T.C. '55), formerly with the Bathurst Power and Paper Company Ltd., Bathurst, N.B., is now a member of the faculty of the Chemical Engineering Department at the University of New Brunswick.

LEONARDO DA VINCI, *in addition to being an artist, engineer, and inventor, was also a superb craftsman. Reproduced here are original sketches by Da Vinci of boring machines—one for boring cylinders, the other featuring a unique self-centering device.*

CRAFTSMANSHIP

Illustrated below is a giant vacuum column used in oil refinery operations. This is a typical example of the fine craftsmanship and many sided skills demonstrated by Canadian Vickers in the manufacture of all types of petro-chemical equipment.

In their plants, Canadian Vickers also design and manufacture machines, both large and small, and equipment for every imaginable industrial need . . . thereby fulfilling their pledge: "If Industry Needs It . . . Canadian Vickers Builds It . . . Better."

Industrial Boilers • Chemical Process Equipment • Hydraulic Machinery • Ships
Special Machinery • Marine Equipment • Pulp and Paper Plant • Mining Machinery

50-ton vacuum column with overall length of 74 ft., built by Canadian Vickers for a Canadian oil refinery.

Obituaries

George E. Baldry, Affil. E.I.C., died in St. Norbert, Manitoba on October 17, 1959. He was 75.

Born in Osgoode Station, Ontario, Mr. Baldry went to Winnipeg in 1906.

He was president of the Baldry Engineering and Construction Company at the time of his death.

George E. Baldry
Affil. E.I.C.

Stanley H. Cunha, M.E.I.C., senior employee of the Quebec Hydro-Electric Commission died, on March 21, 1960. Mr. Cunha was a Life Member of the Institute.

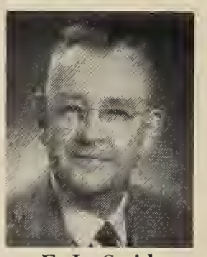
A native of Kingston, Jamaica, Mr. Cunha came to Canada in his early years and graduated from McGill University in 1905.

Mr. Cunha worked many years for the Quebec Hydro-Electric Commission and, even after reaching the statutory retirement age, remained at Hydro-Quebec on a temporary basis to render his valuable services.

A contributor to engineering papers and magazines, Mr. Cunha helped to write several articles on engineering problems encountered in hydro-electric developments.

He was also a Life Member of the American Institute of Electrical Engineers.

A. Love
M.E.I.C.



E. L. Smith
M.E.I.C.

Alexander Love, M.E.I.C., consulting civil engineer, died in Hamilton, Ontario, April 7, 1960. He was a Life Member of the Institute.

A native of Scotland, Mr. Love emigrated to Canada in 1912 and resided in Hamilton from that time until his death. During the First World War he served with the 19th Canadian Infantry Battalion and later with the Canadian Engineers.

As secretary of the Hamilton Branch of the Institute from 1933 to 1936, and as chairman in 1940, Mr. Love enjoyed an active participation in Institute affairs. He was honoured with Life Membership in January, 1955.

Alfred LaBissonniere, Affil. E.I.C., died in Montreal on January 3, 1960. He was 60 years old.

Mr. LaBissonniere was educated at the College of Berthier and Lemmington High School in Ontario. He began his career on the Great Lakes boats, working for the Federal Government, in 1920. Six years later he joined the International Paper Company in Three Rivers, Quebec, and from 1926 to 1936 he studied to receive his first class certificate. In 1936 he became a boiler inspector for the Provincial Government, and from 1939 to 1945 he worked with the Royal Inspection Company.

Alfred LaBissonniere
Affil. E.I.C.

In 1945 Mr. LaBissonniere returned to the Provincial Government as assistant chief inspector and was appointed chief inspector in 1949.

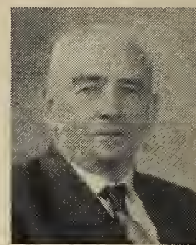
An Affiliate Member of the Institute, Mr. LaBissonniere was also a member of the National Board and of the American Society of Mechanical Engineers.

Eugene Lloyd Smith, M.E.I.C., 59, died in Edmonton on March 21, 1960. Mr. Smith had been assistant superintendent and chief chemical engineer at the Edmonton power plant for the last seven years, where he was in charge of water treatment.

Born in Wentworth, Nova Scotia, Mr. Smith received his education from the University of Alberta, graduating with a degree in chemical engineering in 1930. He joined the city power plant staff in 1935.

Mr. Smith, a director of the Western Canada Water and Sewage Conference, was considered Western Canada's outstanding authority on water treatment. He was a past president of the Edmonton Branch of the Institute and a member of the Dominion Council of Professional Engineers.

Under Mr. Smith's supervision, the Edmonton water treatment plant tripled its capacity during the past five years. Mr. Smith was also in charge of re-equipping the pumping station at the plant.



J. E. Underwood
M.E.I.C.

Joseph Edwin Underwood, M.E.I.C., a Life Member of the Institute, died in Saskatoon April 7, 1960, at the age of 77.

Until his retirement, Mr. Underwood was senior member of the engineering firm of Underwood, McLellan & Associates, Saskatoon. During his more than 45 years of business in that city he was associated with numerous major municipal engineering and surveying projects in northern Saskatchewan, and he was Mayor of Saskatoon in 1932, the year the Broadway bridge was built across the South Saskatchewan River.

A resident of Saskatoon since 1911, Mr. Underwood was born in Wroxeter, Ontario. He graduated from the University of Toronto with a degree in civil engineering in 1909. His first professional work was on surveys for the Federal Government in Western Canada. He later became resident engineer with McArthur and Murphy, Saskatoon. In 1911, associated with Murphy and Underwood, Mr. Underwood supervised the building of hydro electric plants and water systems at Wilkie and Scott, Saskatchewan. One of his larger undertakings was the complete modernization of the Flin Flon townsite in Saskatchewan.

From 1911 until his retirement in 1957, Mr. Underwood was associated successively with Murphy and Underwood, J. E. Underwood and Associates, Underwood and McLellan and Underwood, and McLellan and Associates. In 1952 Mr. Underwood and Mr. McLellan sold their interests in the firm but were retained in the firm as advisors.

A Member of the Association of Professional Engineers of Saskatchewan, the Canadian Institute of Surveying, the Saskatchewan Land Surveyor's Association, the Community Planning Association of Canada, and the town planning board of Saskatoon, Mr. Underwood also served on the execuitve of the Saskatoon Board of Trade.

Other Societies

Instrument Society of America - 1960 I. M. A. Symposium

A three-day symposium on Instrumental Methods of Analysis, arranged by the Montreal organization of the I.S.A., will be held at the Queen Elizabeth Hotel, Montreal, June 1-3. A technical program of more than 50 papers has been arranged and will feature recent developments in the field by a number of eminent international authorities.

Wednesday morning's sessions will be devoted to general topics, with the keynote opening address by Dr. O. Rademaker of Eindoven University, Holland.

The regular sessions, beginning on Wednesday afternoon, have been arranged in two simultaneous groups. While one's particular interests will guide the choice of group, they have been roughly separated so that those interested basically in processing may follow one program, while those interested basically in laboratory developments may follow the other.

Wednesday afternoon's sessions on "Medical Instrumentation" will be chaired by Dr. John F. Davis. The sessions on "Nuclear Instrumentation" will be chaired by Dr. W. H. Stevens. There will be a second session on "Medical Instrumentation" on Wednesday evening, featuring a panel discussion on Medical Analyzers.

On Thursday morning, Dr. P. H. Stirling will chair a group of papers on "Process Gas Chromotography," while W. Forsyth chairs a series on "Spectographic Analysis." In the afternoon Nathaniel Brenner will chair three papers and a panel discussion on "Gas Chromotography," and those interested in tours will be given an opportunity to observe some outstanding instrument installations in the vicinity of Montreal.

Friday morning's program consists of a series of papers on "Electrochemical Methods," chaired by T. S. Kehoe, and a series of papers on "Sample Handling," chaired by L. Maley. The speaker at the noon luncheon will be Dr. Leo Marion of N.R.C. The afternoon sessions are "Electrochemical Methods," chaired by P. W. Dufresne and "Physical and Chemical Methods," chaired by J. P. Strange.

A varied and interesting ladies' program has been arranged, and a number of mixed social functions have been scheduled.

This is the first time that a major I.S.A. technical conference on instrumentation has been held in Canada, and all engineers interested in the subject are urged to attend, whether or not they are members of the co-operating societies responsible for the meeting.

Advance registration is being carried out, and advance proceedings will be available at the hotel. Further inquiries regarding rates, hotel reservations, or details of program are available from:

Mr. N. B. Ward,
4060 MacKenzie Street,
Montreal 26, Que.
PHONE REgent 1-5257

1961 Congress on Large Dams

The 7th Congress of the International Commission on Large Dams will be held in Rome, June 26 through July 2, 1961. Questions for discussion include: the selection, processing and specifications of aggregates for concrete in large dams; underground work in connection with large dams; modern techniques of concrete dams for wide valleys and ancillary works; and sealing of earth and rockfill dams with bitumen and other materials. Following the Congress there will be tours of important dams in Italy. Participants will be in Europe in time to attend the 5th International Congress of Soil Mechanics and Foundation Engineering in Paris, July 17 to 22, 1961.

Anyone interested in the Rome Congress, or in contributing a paper, may obtain further information from: Mr. J. K. Sexton, vice-chairman, Canadian National Committee, ICOLD, c/o Canadian Electrical Association, 35 York Street, Westmount, Quebec.

American Society for Quality Control, Montreal Section

The Montreal Section of A.S.Q.C. held its elections on March 22 and voted into office for the 1960-61 term: chairman, Franklin Clow; vice-chairman, W. Wingfield; secretary, S. Thomas; immediate past chairman, D. W. Guthrie.

World Power Conference

The Madrid Sectional Meeting of the World Power Conference is to be held June 5 to June 9, 1960. Papers will be delivered on these subjects: Methods of Investigation of Energy Sources and Requirements; Efficiency of Production and Utilization of Energy; Technical Developments in Transportation; Establishment of Nuclear Reactors on an Industrial Scale; Functional Inter-Relation between Conventional and Nuclear Production of Energy.

The Associations and Corporation

The Annual Meeting of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. will be held at the Trail Civic Centre, Trail, B.C. on September 15, 16 and 17. Convention chairman is J. F. Millican, Superintendent of Transportation for the Consolidated Mining and Smelting Company in Trail.

A special feature of the program this year will be a special two-hour session on the opening day in which the delegates will be divided into two groups to permit study of specific problems peculiar to professional municipal engineers in one group, and works superintendents and suppliers in the other.

Courses and Fellowships

The Isaac Wolfson Research Fellowship in Metallurgy is offered by St. Edmund Hall, Oxford, England, to applicants between the ages of 24 and 35 from the Commonwealth countries or Israel. Commencing October 1, 1960, the appointment is for three years' research in a field approved by the Isaac Wolfson Professor. It includes a stipend of approximately $2800, free accommodation or a housing allowance, and the whole or part of travelling expenses.

Applications should be sent to The Principal, St. Edmund Hall, Oxford, immediately. Candidates are asked to submit a detailed statement of career to date and of the research proposed, together with two references.

The **Ontario Traffic Conference** will present a series of traffic training courses from May 30 to June 10, 1960, in co-operation with Huron College and the University of Western Ontario, London. The tuition fee of $125 includes meals and accommodation as well as texts and manuals. The purpose of these courses is to provide a knowledge of the basic principles of traffic operation particularly related to Canadian municipalities.

The **Special Summer Program at the Massachusetts Institute of Technology** will include a course in Fundamentals of Adhesion from June 27 to July 1, 1960. The program will be presented by the M.I.T. Plastics Research Laboratory under the direction of Professor Albert G. H. Dietz, and the tuition will be $200. No academic credit is offered.

The **Management Development Center of the California Institute of Technology**, Pasadena, California, is sponsoring seven full-time conferences, four during the period June 19 to 24, and three from September 11 to 16. The conferences will be held on the Pasadena campus, and the fee per conference is $150 with a room charge of $20 per week. Topics for discussion include: supervision of engineers; supervision of technical sales personnel; wage and salary administration; older workers and retired employees; administering an executive development program; and managing office personnel and operations.

The **Fourth International Course on Hydraulic Engineering** will be given at Delft beginning in October 1960. Organized by the Netherlands Universities Foundation for International Co-operation, the eight-month course is for graduate engineers who are interested in one or a combination of its three branches of study; tidal and coastal engineering (including harbours); reclamation; rivers and navigation works (including ground-water recovery). Tuition is 2000 Dutch guilders, and the closing date for application is July 31, 1960. Further information can be obtained from NUFFIC, 27 Molenstraat, The Hague, Netherlands.

A new college, **The College of Advanced Science** has been established at Canaan, New Hampshire for the study of graduate physics and supporting subjects including mathematics and physical chemistry. At present, the college is accepting special students at any college level to study tutorially under Dr. Royal M. Frye, former chairman of the graduate school of physics, Boston University. However, when the full eight-quarter curriculum goes into operation, application will only be open to students with bachelors degrees.

The **British Council** is offering a course on Methods of Concrete Usage at University College, London, September 18 to 30, 1960. The purpose of the course is to supply overseas engineers with an up-to-date survey of methods of using concrete in England. Two days will be devoted to a visit at the Cement and Concrete Association's Research Station. Accommodation will be in London hotels and the fee, approximately $132.

The **Department of Engineering at the University of California** (Los Angeles) is offering three short courses in industrial photoelasticity and strain gauge techniques, August 15-19, August 22-26, and August 29 to September 2. For further information: Mr. Harold M. Kaysen, Engineering Extension, Department of Engineering, University of California, Los Angeles 24, Calif.

New Association of Urban Development Engineers

Convinced that the role of the consulting engineer in land development is here to stay, thirty Toronto engineers involved in land development activities formed an association in November 1959 known as the Association of Urban Development Engineers of Toronto. Membership is open to registered professional engineers who are principals of their firms.

A panel discussion among members of the township engineering staffs of Scarborough, North York, Etobicoke and New Toronto and Col. A. L. S. Nash of the Provincial Department of Planning and Development took place in Toronto on March 31 at the regular monthly meeting of the new association. Control on subdivision activities was the subject of the evening, and future meetings are planned for an exchange of information among others connected with subdivision development such as contractors engaged in sewer, water main and road construction and builders who take over lots and construct houses.

The following elected officers form the executive for 1960: president, R. V. Anderson; first vice-president, P. A. Monaghan; second vice-president, W. A. McArthur; treasurer, J. W. Setchell; secretary, R. E. Winter.

Coming Events . . .

May 23-26, 1960—Design Engineering Conference, New York Coliseum.

June 1—Industrial Education Institute Seminar. Theme: Locating and Developing Creative Engineers. Montreal (June 3—Toronto).

June 1-3—Annual ISA Instrumental Methods of Analysis Symposium, Montreal.

June 5-7—ASME Semi-Annual Meeting and Aviation Program, Dallas, Texas.

June 5-9 — World Power Conference, Madrid Sectional Meeting. Theme: Methods for Solving Power Shortage Problems.

June 13-15 — 43rd Canadian Chemical Conference and Exhibition of The Chemical Institute of Canada, Ottawa.

June 13-17 — Research Conference on Shear Strength of Cohesive Soils, University of Colorado.

June 25 to July 8—International Machine Tool Exhibition 1960, London.

June 27 to July 7—1st International Congress for Automatic Control (sponsored by AACC with ISA, ASME, AIEE, IRE and AIChE), Moscow.

June 26 to July 1—Annual Meeting of American Society for Testing Materials, Atlantic City.

July 21-27—Third International Conference on Medical Electronics and Associated Scientific Exhibition, London.

June 20-24—American Society for Engineering Education Annual Meeting, Purdue University, Lafayette, Indiana.

June 27-29—Canadian Electrical Association Annual Convention, Murray Bay, Quebec.

May 25-27—National Specialists Meeting on Guidance of Aerospace Vehicles (Institute of the Aeronautical Sciences) Boston.

Removal of Members of The Institute with No Addresses

The following members' mail has been returned to headquarters. As a result, their names have been removed from the Institute membership list, but would be readily reinstated if a current address were forthcoming. Information regarding them should be sent to: Records Department, The Engineering Institute of Canada, 2050 Mansfield Street, Montreal.

BUILD IN STRENGTH, DURABILITY AT LOWER COST with 3M Adhesives, Coatings and Sealers

ROLL-ON SEALER. You just roll on 3M Brand Sealer EC-1202, apply the next metal section, then, fasten mechanically through the sealer. It's fabric-reinforced, neither shrinks nor stretches. With minimum labour and equipment, you get a durable, uniform seal that shuts out weather, dust and moisture.

COLD SANDWICH BONDING. 3M Brand adhesive EC-1357 makes it possible for you to bond sandwich panels with a nip roller or cold press. You need no clamps or heated presses to complete tough core-to-skin bonds that resist moisture and high and low temperatures. This one adhesive bonds a variety of sandwich materials quickly and economically.

RESISTS PLASTICIZERS. Sure bonding of nitrile rubber and vinyl plastics to metal is possible with 3M Brand Adhesive EC-847. This fast-drying, high-strength adhesive has exceptional resistance to many types of aggressive plasticizers, oils and fuels. Because of excellent adhesion to steel, aluminum, wood and leather, it serves countless uses.

DAMPS VIBRATION. One pass with a spray gun is all it takes to damp vibration of these movable wall partitions with 3M Brand Coating EC-1034. Heavy-bodied EC-1034 provides an easy answer wherever sound, air or machinery movement makes metal hum or rattle. What's more, it's moisture-proof, abrasion-resistant . . . protects metal and insulation.

SEE WHAT 3M ADHESIVES CAN DO FOR YOU! These are but four examples of ways 3M Adhesive Research is helping industry improve products and cut production time and cost. Look to 3M for the broadest range of adhesives, coatings and sealers experience.

News of the Branches

Dr. C. S. Landon, M.E.I.C., Commissioner of the Greater Winnipeg Sanitary District and the Greater Winnipeg Water District, has recently retired as secretary-treasurer of the Winnipeg Branch of the Institute after ten years of service.

Dr. C. S. Landon, M.E.I.C.

A native of Wellington, Prince Edward County, Ontario, Dr. Landon graduated with a Bachelor of Civil Engineering degree from the University of Manitoba in 1911 and obtained his Master of Civil Engineering from the same institution in 1914. His association with the Greater Winnipeg Water District began in 1916, when he accepted a position as special engineering assistant to the chief engineer. After serving with the 12th Battalion Canadian Railway Troop of the Canadian Expeditionary Force in the First World War, Dr. Landon became engaged in location and construction work in the provincial government highways branch of the Department of Public Works until 1931. From 1932-37 he served as representative for Manitoba in the Department of Labour, Ottawa and, from 1938-50, as regional construction officer for the Unemployment Insurance Commission.

His professional associations have been numerous, as member of the Dominion Council of Professional Engineers in 1940, 1942, and 1947; as member of the board of directors of the Canadian Good Roads Association, registrar and member of Council of the Association of Professional Engineers of the Province of Manitoba since 1934, and as secretary of the Winnipeg Branch for a decade.

Dr. Landon was a member of the University Council of the University of Manitoba, representing the graduates of engineering, for one term. He was also the first president of the University of Manitoba Students Union. He is a past honorary president and past president of the Engineering Alumni Association and a past vice-president of the University of Manitoba Alumni Association.

University of British Columbia

Bud Meckling, S.E.I.C.,
Correspondent

The new members of the branch were welcomed into office on April 1. They are: chairman, Don Nicholson; vice-chairman, Ed Schroeder; secretary-treasurer, Earl Stanley; public relations officer, Ron Barker; and field trip chairman, Victor Maydell.

Baie Comeau

G. W. Scott, M.E.I.C.,
Correspondent

As a preface to an analysis of the many factors affecting the safety of aircraft during flight, take-off and landing, Mr. G. T. McLean, test pilot for Canadair Limited, Montreal, made a general observation that all air accidents are due to human errors of one kind or another.

Mr. McLean, speaking at the March 24 meeting, made a detailed assessment of the take-off and landing characteristics of modern jet airliners compared to conventional airplanes. The operating limits imposed by length of runway and atmospheric conditions, and the relatively tight margin of safety under which the jet airliner operates, were among topics discussed.

Two short films were shown following Mr. McLean's talk, one on Canadair's new and original design of jet trainer, the CL-41; the other on the F-104, the supersonic interceptor built by Canadair to re-equip the fighter component of the RCAF.

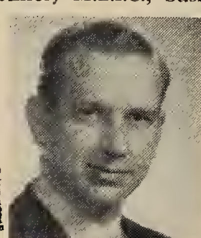
Border Cities

Report submitted by
V. Corin, JR.E.I.C.

On March 16, a joint dinner meeting of the Association of Professional Engineers of Ontario and the Institute was held in the Windsor area. Seventy-five persons attended.

Mr. Dwight Simmons, A.P.E.O. president, discussed the proposed formation

New Chairmen: (left to right) A. H. Austin, M.E.I.C., Kitchener; J. M. Reid, M.E.I.C., Border Cities; G. M. Woods, M.E.I.C., Brockville; N. A. Paolini, M.E.I.C., Sault Ste. Marie; L. T. Holmes, M.E.I.C., Saskatchewan; L. S. Piper, M.E.I.C., Kootenay.



of area groups similar to those of E.I.C. He also discussed the importance of updating and amending the Professional Engineers Act.

Calgary

Herbert Bailey, M.E.I.C.,
Correspondent

President Hanna and Mr. Garnet T. Page, E.I.C. general secretary, brought greetings from Institute Headquarters to the Presidential Dinner and Dance, March 18. Mr. Hanna urged all engineers to take a part in civic and community affairs. Mr. Page stated that the Calgary Branch had contributed significantly to E.I.C. and, in this regard, mentioned the Banff Regional Meeting in October and the recent A.S.M.E and C.C.A. conventions in Calgary.

Head table guests included: Mr. and Mrs. Allan Short, Mr. and Mrs. Bert Howard, Mr. Stewart Bartwell (Winnipeg), Mr. and Mrs. J. J. Hanna, Mr. Garnet Page, Commodore Cecil Davey, Mr. and Mrs. D. C. Jones, Mr. Tom Stanley, and Mr. and Mrs. J. S. Neil.

Chalk River

Report submitted by
C. E. L. Hunt, JR.E.I.C.

Mr. J. L. Galloway, of the Central Analysis Office of the Meteorological Service of Canada, gave a talk entitled "From Surface to Satellite or The Air Above Us" at the March 18 meeting. Beginning with a review of the history of meteorology, Mr. Galloway discussed some of the present theories on observed phenomena and recent information which has made these theories unsatisfactory. He explained the nature of the jet stream and outlined the high-altitude research being done at present in Canada and the U.S.

Fredericton

John M. Burrows, JR.E.I.C.,
Correspondent

"Transportation Demand from a Civil Engineer's Point of View" was the title of a talk by Professor Albert M. Stevens, of the University of New Brunswick's civil engineering department, on March 21. This was the regular joint dinner meeting of E.I.C. and the Association of Professional Engineers of New Brunswick.

Current practice in forecasting transportation demands favours the use of a method which relates the demand to land use. Because of the probable useful relationship between land use and engineering design loads for public works, it was urged that more extensive land use planning be carried out and that the engineering profession develop better correlations between land use engineering requirements. The coming census year is an appropriate time to initiate such a plan, the speaker suggested.

Kitchener

Report submitted by
W. L. Bulmer, M.E.I.C.

The Branch played host to the Grand Valley Engineers Association at a joint dinner meeting in the Iroquois Hotel, Galt, on March 25. Some 80 members and friends enjoyed an address by Mr. John S. Foster, manager of the Douglas Point Project in Bruce County which is being constructed for the nuclear power plant division of Atomic Energy of Canada Ltd.

Mr. Foster outlined the problems involved in selecting the location; compared the estimated cost of power with that of existing coal-fired generating stations; and described the operation of the equipment there. The 200 Mw. station is scheduled to begin construction this Fall using a peak employment of 500-600 persons. Completion is set for 1964 when an estimated 130 employees will be required for its operation.

Kootenay

I. Waterlow, M.E.I.C.,
Correspondent

President Hanna and Mr. E. C. Luke from Headquarters made a visit to the Branch on March 7. The executive meeting in the afternoon was followed by a dinner for the membership.

Laval University

Achille Leblanc, S.E.I.C.,
Correspondent

A banquet was given March 31 by the E.I.C. on the occasion of the graduation at Laval University. Mr. John Finn, assistant superintendent of transmission equipment methods, Northern Electric Company, Montreal, spoke on the topic "The Engineer in Industry".

Previous March meetings included a film from the Shawinigan Water & Power Company on the Beaumont Construction, March 2; a talk on "What For Scientific and Technical Progress?" by Dr. A. Wittenberg, professor of mathematics; and an address by Mr. Piette on laws for engineers.

Montreal

JUNIOR SECTION

Georges M. Desjardins, S.E.I.C.,
Correspondent

At the Annual Meeting held on January 25, 1960, at Institute Headquarters, the following executive was elected: chairman, Robert Walker; vice-chairman, Bernard Lamarre; secretary-treasurer, John Walton; officer-ex officio, Jacques Dubuc.

Nippissing and Upper Ottawa

W. A. Adams, S.E.I.C.,
Correspondent

Three members of the branch were the speakers at the March 16 meeting. Mr. W. M. B. Workman spoke on "Semi-Automatic Ground Environment", discussing particularly the Bomarc defence installations in the North Bay Area. Mr. G. M. Goodreid spoke on "Electrical Heating of Homes" and Mr. A. M. Bruce discussed the relative advantages of tyrex eord and nylon cord tires under the humorous title "Your life is Hanging by a Thread". The dinner meeting was held at the Manor Hotel, North Bay, Ontario.

Ottawa

H. P. Ristow, JR.E.I.C.,
Correspondent

Canada can not afford not to investigate the waters throughout the northern two-thirds of the country, stated Mr. D. A. H. Charles, officer-in-charge on the CGS Baffin, working with Canadian Hydrographic Surveys, Ottawa. He pointed out that the increased importance of air travel in the North requires that a sea route be kept open to bring fuel and supplies to airport bases, and that this can only be done with increased information for safe navigation.

The speaker followed his talk with a showing of colour slides taken on last year's voyage of the CGS Baffin.

Peterborough

D. B. A. Chase, JR.E.I.C.,
Correspondent

Rapid transit is reversing the trend towards the use of automobiles instead of public transportation in large cities, W. H. Patterson, chief engineer on subway construction for the Toronto Transit Commission, told a meeting of the Peterborough Branch on March 22, at the Kawartha Golf and Country Club. Clean stations and frequent service are winning people back to public transportation, he stated.

When Toronto's Yonge Street subway went into operation in 1954, it was hoped to carry 20,000 people per hour initially and 40,000 ultimately. The maximum is already being reached in peak traffic hours.

Mr. Patterson said that the success of the Yonge Street subway led to the approval of a ten-year program of subway construction including the east-west subway. The first stage is scheduled for completion in 1963 and the whole project is expected to be finished by 1969.

Mr. Patterson was introduced by P. F. Peele, Councillor for Peterborough, and thanked by Past President Howard Powell. The speaker was presented with a Peterborough-made wrist watch as a token of appreciation.

Saguenay — Lake St. John

Maurice Lavallee, JR.E.I.C.,
Correspondent

Approximately 50 members and friends met at the Saguenay Inn in Arvida, February 23, to hear Mr. G. W. Fletcher speak on "Atomic Reactor Operating Problems at Chalk River". Mr. Fletcher is head of the reactor technology branch at Chalk River which deals with reactor problems and safeguards.

All equipment built to contain the heavy water moderator is specially designed and constructed under extremely rigid specifications. Detection systems for leaks and failures have been installed to protect the purity of the heavy water. Its purity, stated Mr. Fletcher, must be 99.75% minimum to maintain the chain reaction in reactors.

Saskatoon

W. A. Friebel, M.E.I.C.,
Correspondent

President J. J. Hanna, visiting the Saskatchewan Branch on February 25, pointed out that engineers are likely to have to answer some embarassing questions in the future about what happened to Canada's natural resources. Concern for Canada's resources being put back into Canadian growth should be that of the engineer as well as the economist and politician, he stated.

An honorary membership was awarded Mr. R. A. Spencer, former dean of engineering at the University of Saskatchewan and now a consulting engineer in Saskatoon. Mr. Spencer has been associated with the Institute since 1907.

Vancouver Island

W. Tivy, M.E.I.C.,
Correspondent

Skin diving on construction work at the Dew Line in the Arctic was the subject of a talk by Lt. Cmdr. B. F. Ackerman of the Operational Clearance Diving Unit, Royal Canadian Navy, on the Pacific Coast. He explained that although skin diving is common for removal of ice bergs from harbours with dynamite and for changing screws on small naval vessels, it is still not used widely for making ship repairs. A film was shown of the application of standard diving to salvaging of the ship Normandy in New York Harbour.

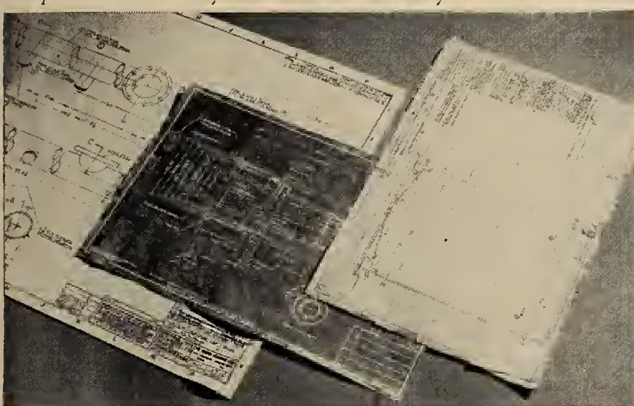
(*Continued on page 154*)

PUT RECORDAK PRECISION MICROFILMING TO WORK FOR YOU . . .

Save time everytime you refer to drawings, everytime you make prints

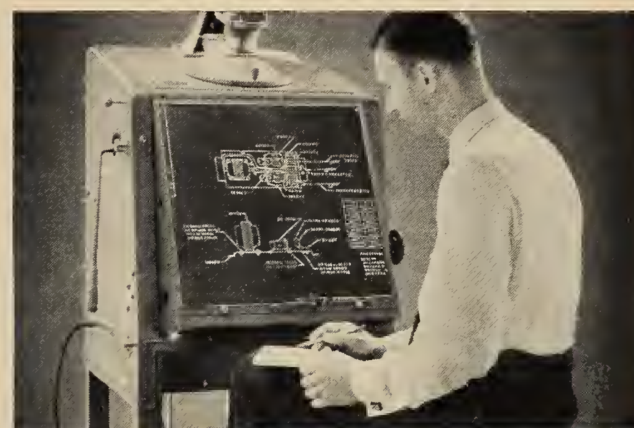
It's easy to take the *wait* out of drafting—do away with waiting for drawings, prints, revision notices.

Recordak Precision Microfilming automates your bulky engineering drawing files—transforms them into trim decks of cards which can be filed at the fingertips and referred to or copied immediately. Here's how this *unique* Recordak System can work for you:



1. All of your drawings and prints—all sizes, ages, colors—are reproduced with needle-sharp line detail and remarkably uniform backgrounds on low-cost 35mm Recordak microfilm. New Recordak microfilming techniques and quality control methods are responsible for outstanding results which more than meet the most rigid government specifications for resolution quality, reduction ratios, indexing data.

2. Mounting these superb 35mm Recordak microfilms in plain or punched Filmsort aperture cards gives you *an active drawing file* that can be kept right at hand in 5% of space needed for original drawings and prints. Duplicate cards can be made directly from original cards for draftsmen, branches, subcontractors, government agencies! Fifty cards mailed first class for just 20¢!



3. Easy to see what a difference Recordak Precision Microfilming makes. Smallest detail is sharp and clear when cards are projected in Recordak Film Reader. Use of these cards in drafting room cuts need for reference blueprints at least 75%.

4. Another saving in printmaking costs. Whenever paper copies are needed, reduced-size prints can be made directly from your Recordak microfilm cards, or duplicate cards, by photographic, xerographic or electrostatic methods. Here again, Recordak Precision Microfilming pays off in improved print quality.

Free booklet—"must reading" for every engineer and draftsman—gives further details on this new system, available through Recordak.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*THEORY OF MACHINES THROUGH WORKED EXAMPLES, 3RD ED.

Worked out solutions are presented for about half of the 340 graded questions dealing with such aspects of machine design as kinematics (analysis of motion in linkages, gears, and cams), friction clutches, belts and brakes, inertia forces, and vibrations. A group of miscellaneous problems are grouped together in a chapter entitled "General Dynamic Problems." Brief reviews of principles, formulae, and methods of solution precede each chapter. (G. H. Ryder. London, Cleaver-Hume, 1959. 280 p., 21/–.)

*AMERICAN POWER CONFERENCE, PROCEEDINGS, 1959.

.These papers give practical information of broad overall interest to those concerned with the generation, transmission or utilization of power. The book is divided into sections dealing with topics of general interest; nuclear energy; electrical, mechanical, and water technology. The papers in each of these areas cover technical, economic, and industrial aspects. They are written by people connected with universities and societies, industries and government, laboratories and utilities. (Chicago, Illinois Institute of Technology, Technology Center. 776 p., $8.00.)

*AIRCRAFT ELECTRICAL ENGINEERING.

A survey of the varied techniques used in aircraft electrical engineering. Special attention is given to the presentation of environmental characteristics and the problems of high altitude brush wear, as well as to the cooling of electrical machinery in high speed aircraft. The aspects covered include vibration problems, direct current and alternating current machinery, switchgear, aircraft batteries and their behaviour on constant potential charge, electrical power systems, electrical installation engineering, and system operation and installation. (G. G. Wakefield. Toronto, Ryerson, 1959. 349p., $9.00.)

MODERN FISHING GEAR OF THE WORLD.

Edited versions of over one hundred papers presented at the first International Fishing Gear Congress, held in Hamburg in 1957. The papers, by experts from many countries, cover the following topics: materials used for fishing twines, and their characteristics, with particular emphasis on synthetics; net making and preservation; net design and efficiency; use of measuring instruments and underwater observations; fishing gear and its operation, different types of trawl, seines, etc.; the location and detection of fish; the attraction of fish; electric fishing. (Ed. by Hilmar Kristjonsson, F.A.O. London, Fishing News, 1959. 607p., £5.5.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 A.M. to 5 P.M.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

ANTI-CORROSION MANUAL, 1959.

In this second edition, a new section has been added on corrosion in industry, covering food manufacture, nuclear power, and petroleum refining. The whole volume has been revised, and several new sections added, including ones on cathodic protection, pipe coatings and tapes, and dehumidification. Chapters have been added on asbestos, clad steel, glass, degreasing, derusting and descaling, aluminum paints, zinc-rich paints, etc. Also included are details of relevant British Standard Specifications, and of British patents issued during the previous year. (London, Corrosion Prevention and Control, 1959. 326p., £3.)

INSTITUT INTERNATIONAL DU FROID, 1958.

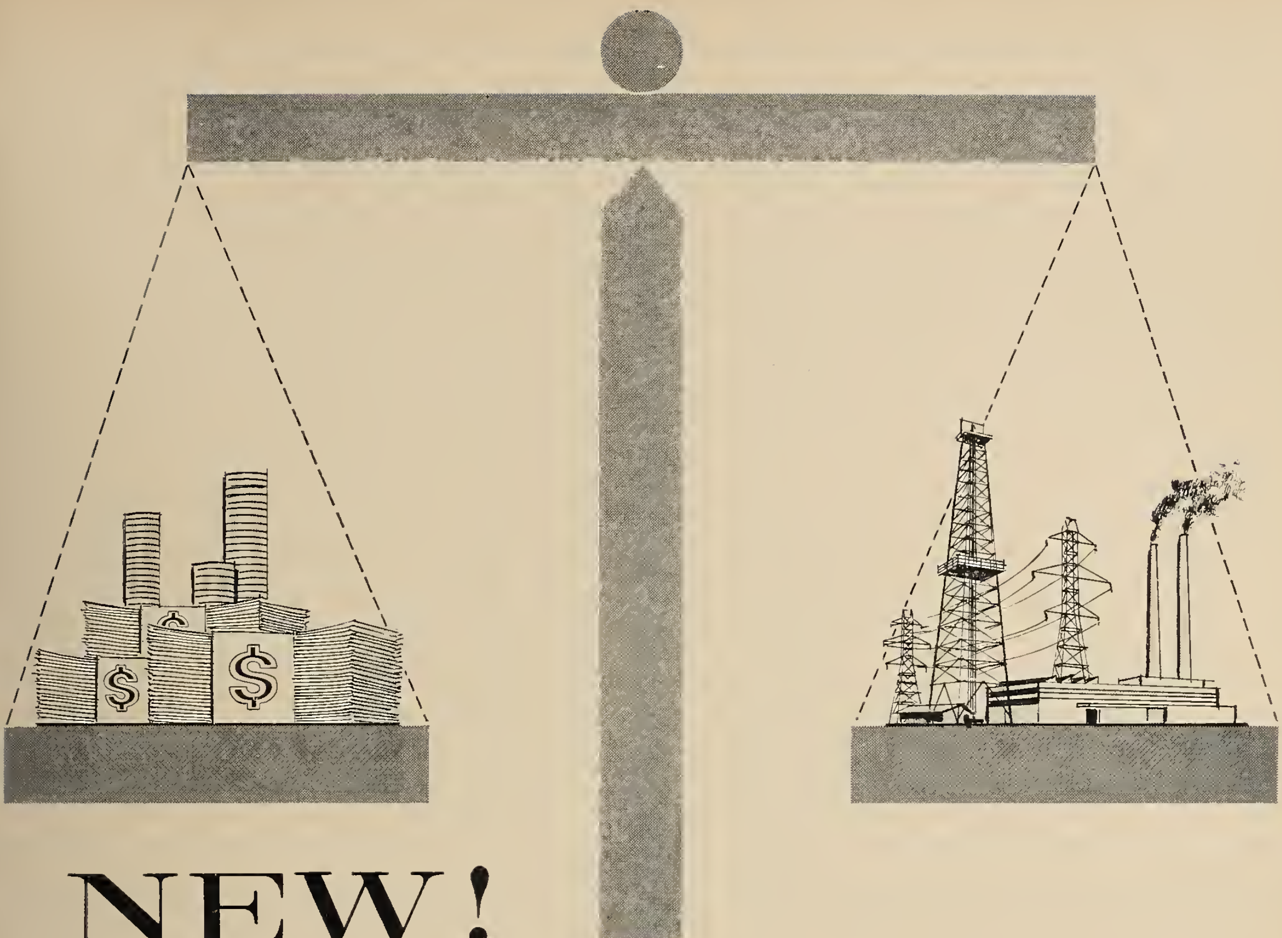
Over four hundred delegates from twenty-two countries attended the 1958 Moscow Conference of the International Institute of Refrigeration. The papers cover five topics: the quick-freezing of foodstuffs; automatic control in refrigerating machines and installations; heat exchangers; electrodynamic compressors; use of antibiotics in connection with refrigeration; the construction, equipment and operation of cold storage warehouses.

The papers are given in either French or English, with a summary in the other language. (Paris, Dunod, 1959. 747p., 6,000 fr.)

CALCUL DES PRIX DE REVIENT ET DES PRIX PREVISIONNELS DANS L'ENTREPRISE DE BATIMENT ET DE TRAVAUX PUBLICS, 2. ED.

This second revised edition is intended for those engaged in estimating construction costs, and tendering on civil engineering works. The author, who has had considerable experience in this field, analyzes the studies which have already been made on the subject, and presents a detailed review of the methods he has used himself.

Some of the topics covered are: organization of a construction company; construction costs; cost of machinery, amortization; price studies. There is a useful bibliography listing books in both French and English. (R. Tofani. Paris, Editions du Moniteur et des Travaux Publics, 1959. 406p., 2,300 fr.)



*MICROWAVE DATA TABLES.

The 26 tables included evaluate basic relationships of frequency, guide and free-space wavelength, standing-wave ration, voltage and power reflection coefficient, and the decibel. It is intended for wave guide engineers and for those concerned with high-frequency transmission lines of the coaxial and similar types. Guide wave-length tables are given for 9 sizes of rectangular waveguide and 2 sizes of circular waveguide. V.s.w.r. and frequency are given to 3 decimal places, and decibels to 2 decimal places; the dependent variable is usually given to four-figure accuracy. (A. E. Booth. Toronto, British Book Service, 1959. 61p., $6.50.)

ANALYSIS OF PIPE STRUCTURES FOR FLEXIBILITY.

The use of high-pressure and high-temperature piping systems has greatly increased the importance of analysis of pipe structures for stress and flexibility. This volume is intended for the piping designer, and covers codes and standards, both British and U.S.; stress calculation, using the elastic centre method; translation of the results of calculations; pipe supports; worked examples of complete analysis for single-plane and three-plane piping systems. (John Gascoyne. London, Pitman, 1959. 181p., 45/–.)

ENERGY PRINCIPLES IN APPLIED STATICS.

The two basic approaches to the analysis of statical systems are considered in this volume, which is confined almost solely to plane pin-jointed systems. The topics covered are: the use of the strain-energy and potential-energy methods of calculating the equilibrium of conservative statical systems; the principle of virtual work; the method of complementary energy; properties of systems with linear characteristics. There is a useful bibliography. (T. M. Charlton. London, Blackie, 1959. 112p., 25/–.)

PRINCIPLES AND USE OF SURVEYING INSTRUMENTS, 2ND. ED.

Intended primarily for students, this text deals with the principles and uses of all types of surveying instruments, while a companion volume covers the principles and practices of surveying. In this second edition, descriptions have been included, of self-aligning levels, wedge telemeters and split-image tacheometers, and of electronic methods of measuring distances. (J. Clendinning. London, Blackie, 1959. 205p., 25/–.)

PROBLEMS IN STRENGTH OF MATERIALS.

The problems in this volume are taken from the examination papers of London University, and of the Institution of Mechanical Engineers. There are 108 problems presented with fully worked solutions, in which emphasis has been laid on graphical or semi-graphical methods of solution, and 260 unworked problems for which answers are provided. The problems are divided into seventeen chapters, each covering a different aspect of the strength of materials. (R. S. Paradise and G. A. Church. London, Blackie, 1959. 278p., 25/–.)

THE TECHNICAL WRITER.

Sub-titled "An aid to the presentation and production of technical literature", it is the purpose of this volume to give the technical writer some idea of the processes through which a manuscript passes before it reaches its final printed form, as well as laying down the principles on which good writing is based.

In their first four chapters, the authors cover the different types of technical literature, the writing techniques used, styles and presentation, and types of illustration. Production problems are next considered, including printing processes, setting out the text, typography, and editing. Two final chapters discuss the organization of a technical publications unit, and problems connected with writing a book. There is a useful bibliography. (J. W. Godfrey and G. Parr. Toronto, Ryerson, 1959. 340p., $9.00.)

THEORETICAL ELASTICITY AND PLASTICITY FOR ENGINEERS.

An introductory account of the theory of elasticity and plasticity, intended for both students and research workers. The topics covered include: an analysis of stress and strain, and the invariants involved; the fundamental problems of bending, torsion and shear of a straight beam; two-dimensional analysis; problems in curvilinear coordinates; loads; theory of thin flat plates; the theory of plasticity for perfectly plastic bodies. Problems, with solutions, are included in each chapter. (D. E. R. Godfrey. Toronto, Longmans, Green, 1959. 311p., $8.40.)

*RANDOM VIBRATION.

The recent development of high power rocket and jet engines has introduced new aspects to the problem of mechanical vibration, since these units generate noise and vibrational energy in a stochastic manner over a wide band of frequencies. The twelve papers included are concerned with this problem and assume that the reader is already familiar with the classical problem of mechanical vibration. The first part of the book deals with the new concepts required to extend ordinary vibration theory into the field of random vibration, while the last part gives a broad picture of the current state of the art of designing and testing equipment which must withstand random vibration. (Ed. by S. H. Crandall. New York, Wiley, 1959. Various pagings, $8.50.)

HIGHWAYS OVER BROAD WATERS.

Growing up in the shadow of the Brooklyn Bridge, David B. Steinman was later to build more than four hundred bridges himself, on five continents. This biography traces the story of his interest in bridges, and his connection with them from his childhood to the completion of his greatest bridge at Mackinac. The author describes the work of designing and erecting many of Dr. Steinman's bridges, and also his activities in various fields of engineering—the founding of the School of Engineering of the City College of New York, the fight to obtain recognition for the engineering profession in New York State, the study of aerodynamic oscillations, etc.

Dr. Steinman has been the recipient of many honours and awards, including the Gzowski Medal of The Engineering Institute of Canada, of which he is a Life Member. (William Ratigan. Grand Rapids, Eerdmans, 1959. 359p., $6.00.)

IGY: YEAR OF DISCOVERY.

The author, the Chairman of the IGY steering committee, here gives a popular account of the work of scientists from 67 countries during the IGY, in the fields of study, the earth and the sun. He touches on the research carried out on earthquake waves, glaciology, oceanography, the atmosphere and upper atmosphere, the ionosphere, the sun, cosmic rays and nuclear radiation. He closes with chapters on the growth of natural science and national and international scientific organizations, and on the organization of the IGY itself. (Sydney Chapman. Toronto, Ambassador, 1959. 111p., $6.95.)

DICTIONARY OF AERONAUTICAL ENGINEERING.

An illustrated dictionary, compiled in the United Kingdom, covering all fields of aeronautical engineering, including terms used in connection with guided missiles, artificial satellites, jet propulsion, rockets, V.T.O.L. aircraft, helicopters, etc. The definitions given are concise, there are many cross-references, and explanations of the multitude of initials and abbreviations now in use are included. (J. L. Nayler. New York, Philosophical, 1959. 318p., $10.00.)

*ENCYCLOPEDIC DICTIONARY OF ELECTRONICS AND NUCLEAR ENGINEERING.

An extensive work that defines terms and provides descriptions and diagrams of equipment, components, and systems employed in electronics and nuclear engineering. Additional definitions are provided for terms in such closely related fields as electricity, physics, chemistry, and acoustics, particularly where they have a bearing on electronic and nuclear applications. Extensive cross-referencing is provided so that related entries may be studied and compared. (R. I. Sarbacher. Englewood Cliffs, Prentice-Hall, 1959. 1417p., $35.00.)

*AN INTRODUCTION TO ADVANCED DYNAMICS.

An intermediate text covering the concepts of classical mechanics, which is intended to prepare the reader for the modern ideas of quantum mechanics. The author discusses the fundamentals of Newtonian dynamics, Hamilton's principle and Lagrange's equations, central force motion, dynamics of a rigid body, oscillatory motion, Hamilton's equations and phase space, and the Hamilton-Jacobi equation. Emphasis has been placed on basic principles rather than on an exhaustive treatment. (S. W. McCuskey. Reading, Addison-Wesley, 1959. 263p., $8.75.)

QUANTITATIVE MOLECULAR SPECTROSCOPY AND GAS EMISSIVITIES.

Many of the topics covered in this text are not discussed in detail in standard works on spectroscopy, although much of the background material is found in texts on astrophysics. The book is intended for students concerned with radiation and other problems connected with missiles and other modern propulsion devices. The subjects covered include thermal radiation; Einstein coefficients; spectral lines; absolute intensities of gases; absolute and relative intensities for atomic and molecular spectral lines; infrared vibration-rotation spectra and bands; infrared gas emissivities; emissivity of heated air; determination of flame temperatures; the effect of radiation on burning rate of solid propellants; radiant-heat transfer for propellants in liquid-fuel rocket motors.

Much of the work is based on research performed by the author's group. There are references at the end of each chapter. (S. S. Penner. Reading, Addison-Wesley, 1959. 587p., $15.00.)

*HYPERSTATIC STRUCTURES, VOLUME 1.

The field of hyperstatic structures is treated as a coherent pattern by means of a diagrammatic "family tree" which emphasizes the relationships existing among various theorems. Sections included deal with the energy theorems of structural analysis, general theorems for linear elastic structures, general methods for linear hyperstatic structures, moving loads on structures, frames with rigid joints, arches, stability of struts and frameworks, and matrix methods. (J. A. L. Matheson. Toronto, Butterworth, 1959. 474p., $15.50.)

*LIQUIDS AND LIQUID MIXTURES.

The equilibrium properties, and development of new methods for calculating the thermodynamic properties, of pure liquids, and the equilibrium properties of liquid mixtures, are discussed in the first two sections of this book. The final section is an account of the theories of liquids and mixtures, developing those parts of statistical thermodynamics common to all theories, and then restricting the account to results than can be compared directly with experiment. (J. S. Rowlinson. Toronto, Butterworth, 1959. 360p., $12.50).

A HISTORY OF WESTERN TECHNOLOGY.

Translated from the German, this is a history of technology in the form of extracts from contemporary writings, from the time of the Greeks to the present. The author has tried to show through these writings the influences which have guided technical progress in each era, and how the intellectual forces of each period affected, and were themselves modified by technology. The writings are from the works of many authors, including not only technicians but philosophers, scientists, economists and poets. The book is well illustrated by contemporary pictures and drawings. (Friedrich Klemm. Toronto, Nelson, 1959. 401p., $7.00.)

As an Electrical Engineer . . .

What do you look for in an underground conduit?

1-LOW COEFFICIENT OF FRICTION	Cornwall Fibre Conduit has a coefficient of .25 to .30 —lowest of any duct.
2-LOW WATER ABSORPTION	C.F.C. absorbs less than 3 per cent after 48 hours total immersion.
3-NEUTRAL PH FACTOR	C.F.C. has a ph of 7 to 7.5 . . . will not attack cable sheath.
4-LIGHT WEIGHT	C.F.C. weighs approximately 2 lbs. per ft., in 4″ size. Easy to handle.
5-RESISTANCE TO CORROSION	C.F.C. is not attacked by acids, alkalies or other materials normally found in soil.
6-EASE OF INSTALLATION	C.F.C. goes down fast, in long lengths . . . tapered joints require no additional joining compounds.
7-EASY TO WORK WITH	C.F.C. is readily cut with ordinary coarse-tooth handsaw — easily tapered in the field with Field Tooling Lathe.
8-NO SHEATH ABRASION	C.F.C. with its smooth inner walls effectively prevents cable abrasion.
9-LOW PULLING TENSION	C.F.C. with its lowest-of-all coefficient of friction allows long, strain-free pulls.
10-CSA APPROVAL	Cornwall Fibre Conduit is made in strict accordance with CSA Specification C127-1957, as prepared by the underground systems committee of the Transmission and Distribution Section of the Canadian Electrical Association.

NUCLEAR POWER PLANTS, PART 2.

Volume 9 of the Proceedings of the Second U.N. International Conference on the Peaceful Uses of Atomic Energy, this volume deals mainly with concepts of future power plants, and with conclusions drawn from experimental power reactors.

The papers from Session B-9 cover various types of power reactor; water, boiling water, organic cooled, gas cooled, liquid metal cooled, and homogeneous reactors. Session B-10 was concerned with power reactor experiments in the different types of reactor, and Session B-11 with experiences with the reactors. (Geneva, United Nations, 1958. 538p., $17.50.)

REACTOR PHYSICS AND ECONOMICS.

Volume 13 in the Peaceful Uses of Atomic Energy series contains the papers presented at Sessions B-19, B-15, and B-14b. B-19 heard eighteen papers on reactor physics and shielding. The twenty-three papers heard at Session B-15 discussed fuel cycles in various types of reactor, and the fuels used. Session B-14 was concerned with the economics of nuclear power, and the papers cover such topics as long-run trends in conventional and nuclear power costs; economic operation of nuclear reactors; combined use of nuclear and hydro-power; nuclear and pumped storage power schemes; Canadian economics related to nuclear power. (Geneva, United Nations, 1958. 635p., $18.50.)

*FRACTURE.

The papers presented at an international conference on the cleavage, ductile, fatigue and high-temperature atomic mechanisms of fracture of metals, ceramics and polymers, held at Swampscott, Massachusetts, in April 1959, form twenty-seven chapters of this book. Each chapter includes an abstract of its paper and intensive references, and most also include discussion of the content. A valuable feature of the book is the summary of the current status of experiment and theory and of the needs of future research, which forms the first chapter. (Ed. by B. L. Averbach, and others. New York, Wiley, 1959. 646p., $17.50.)

*ECONOMIC CONTROL OF INTERCONNECTED SYSTEMS.

Deals primarily with the treatment of mathematical methods, computers and controllers to obtain the optimum economic operation of interconnected electric utility systems, describing pioneer methods in operation applicable to all process industries. Included is discussion of important tools for the development of optimalizing computer controllers, such as theoretical and differential analyzer performance prediction methods, development of mathematical models of process, and use of advanced circuit methods. (L. K. Kirchmayer. New York, Wiley, 1959. 207p., $12.50.)

*COMPRESSION AND TRANSFER MOULDING OF PLASTICS.

A Plastics Institute monograph intended for students of mold design, designers, and mold shop executives. The section on compression molding gives historical background and development, discusses types such as cavity, three-plate, and split displacement molds, pretreating, molding with powders, and the effect of materials on mold design. Transfer molding is discussed in the same pattern, while covering also specific transfer problems as feed systems and size, gate areas and position, clamping pressures, and split dies. (J. Butler. Toronto, British Book Service, 1959. 230p., $8.00.)

*THE MAGNETO-IONIC THEORY AND ITS APPLICATIONS TO THE IONOSPHERE.

A detailed account is given of the theory concerned with the propagation of electro-magnetic waves through a partially ionized gas in the presence of a magnetic field. Two approaches are adopted in developing this theory: a macroscopic one in which the properties of the medium are averaged out, and a microscopic one based on the motion of the individual electrons. Graphical representation is then discussed and simple rules demonstrated for computing curves of refractive index and absorption index as functions of electron density. Applications of the theory to the earth's ionosphere is studied, and a wide range of phenomena capable of explanation in terms of the magneto-ionic theory of a homogeneous medium are indicated. (J. A. Ratcliffe. Toronto, Macmillan, 1959. 206p., $6.75.)

PRECIPITATION PROCESSES IN STEELS.

The report of a conference held at the University of Sheffield in 1958, this volume contains the twenty-one papers presented, together with the discussions which took place. The papers covered precipitation in ferritic steels, and in austenitic steels, intergranular fracture in steels, and precipitation during creep. There are many illustrations, and bibliographies are included in most papers. This is Special Report number 64 issued by the Iron and Steel Institute. (London, Iron and Steel Institute, 1959. 322p., £4.4.)

DICTIONARY OF ATOMIC TERMINOLOGY.

A selection of over 1800 terms used in connection with atomic and nuclear physics, reactor engineering, radiation physics and related fields, in four languages, English, German, French and Italian. The English terms are listed in alphabetical order and numbered, with the equivalents in the other languages in parallel columns. There are alphabetical indexes in the three foreign languages keyed to the English. (Lore Lettenmeyer. New York, Philosophical Library, 1959. 298p., $6.00.)

CURVE SURVEYING.

A handbook for road and railroad

(Continued on page 134)

• LIBRARY NOTES

(Continued from page 130)

surveyors interested in the design or re-alignment of circular and transition curves. The theory is given in full, but tables have been included to reduce the work of calculation. The first two chapters cover the setting out of circular curves with chain, tape and theodolite, and the location of compound and reverse curves. The amount of cant required on a transition curve is discussed, and the cubic parabola, the clothoid and the lemniscate are described. A final chapter covers the re-alignment of railroad curves by the Hallade method. (R. B. M. Jenkins. London, Cleaver-Hume, 1960. 184p., 35s.)

NATIONAL DIRECTORY OF THE CANADIAN PULP AND PAPER INDUSTRIES, 1959-1960.

In this edition the statistical information has been brought up to date, and the product index section under "Paper Products (Classified by Kinds)" completely revised. All the usual features of the Directory are included. Detailed information for the pulp and paper mills of Canada is arranged geographically by province; pulp, paper and board mills are classified by kind; there are lists of pulp and paper distributors, Canadian paper merchants, Canadian trade commissioners, organizations connected with the trade, and Ministries of Lands and Forests in Canada. (Ed. by J. N. Stephenson, Gardenvale, National Business, 1959. 530p., $5.00.)

DIGEST OF LITERATURE IN DIELECTRICS.

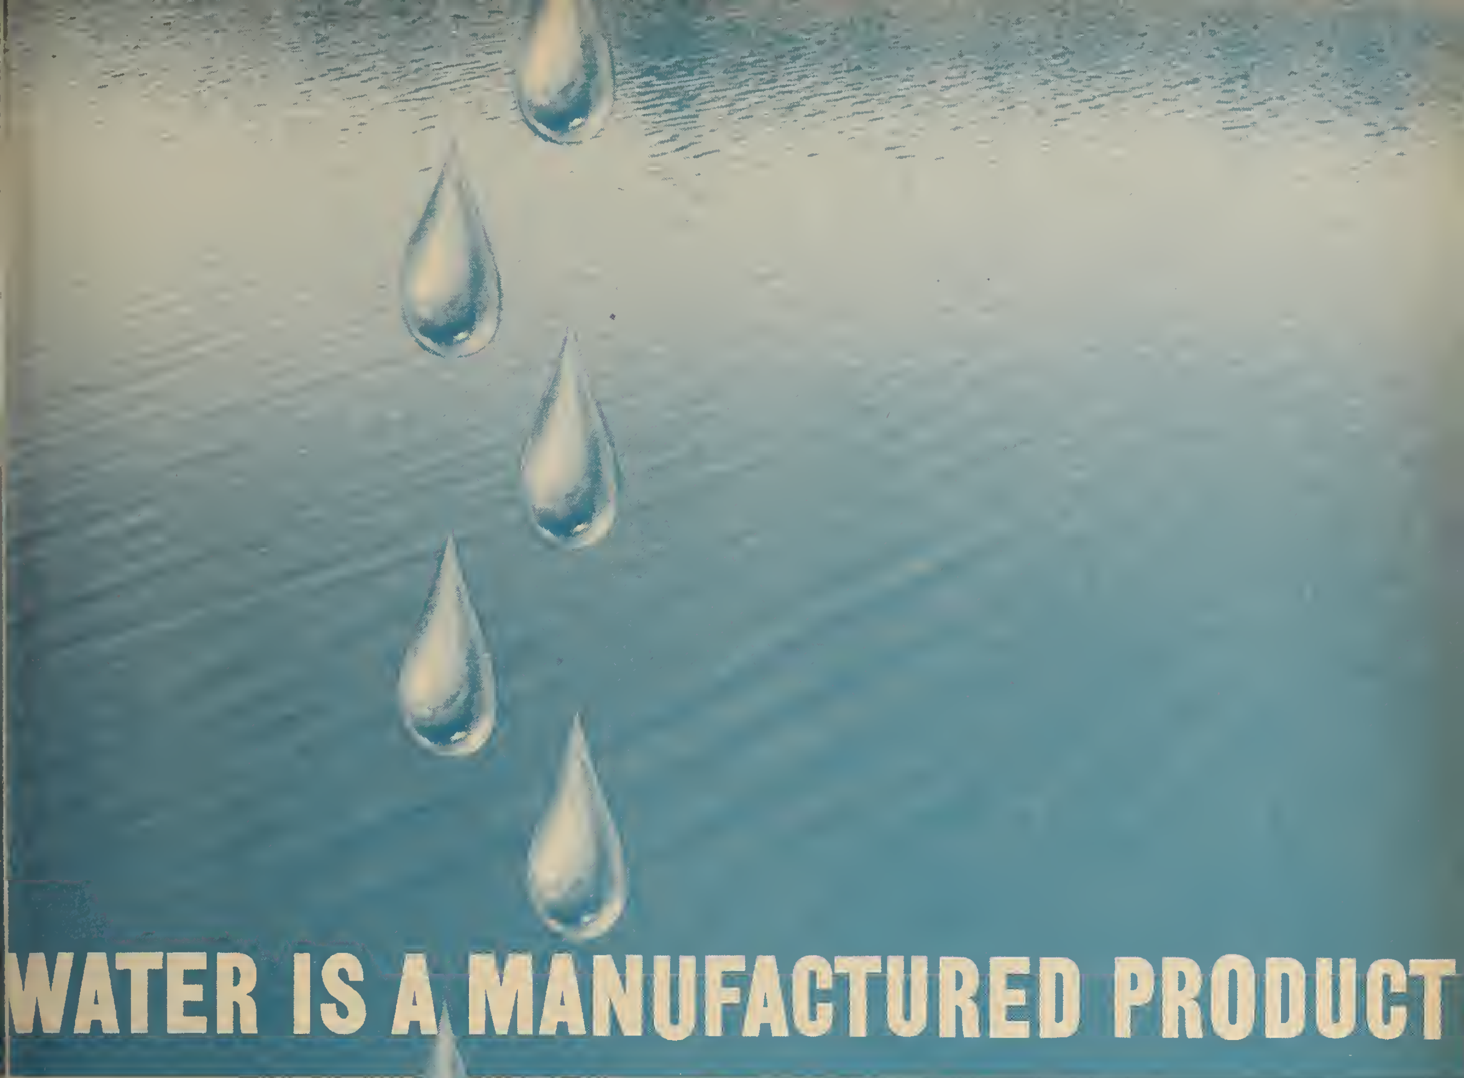
The twenty-second of a series of annual review volumes, this covers material dealing with the fundamental and applied aspects of dielectrics and dielectric phenomena published in the U.S. and other countries during 1958. There are twelve papers covering: instruments and measurements; dielectric constants; molecular and ionic interactions; conduction phenomena in solid dielectrics; breakdown of dielectrics; ferroelectric and piezoelectric materials; ferromagnetic materials; rubber, plastic and ceramic insulation; insulating films and liquids; engineering applications. Each review is accompanied by a bibliography of anything from 41 to 500 references. (Ed. by R. A. Soderman and L. J. Frisco. Washington, National Academy of Sciences-N.R.C., 1959. 293p., $5.00.)

*DATA BOOK FOR CIVIL ENGINEERS, VOLUME I: DESIGN, 3RD. ED.

A concentrated, tabular and illustrated collection of design data for civil engineering structures, with new material in this third edition in the sections on structural steel, concrete, wood, aluminum and masonry; wind pressures on structures; pavements, highways, airports, bridges and waterfront structures; and in drainage and sewage systems. All sections have been revised in accordance with the latest data, codes, standards, and practice. (E. E. Seelye. New York, Wiley, 1960. Various pagings, $24.00.)

*THE PETROLEUM HANDBOOK, 4TH ED.

This new edition of the handbook includes the changes in the industry through expansion of chemical interest and of research carried on in various parts of the world. It is a basic guide to the production, manufacture, storage, transportation, distribution, and application of petroleum products and chemicals. The manufacture of oil products covers distillation, cracking, absorption, reforming, and refining; applications include aviation, automotive, marine, industrial, and locomotive uses, petroleum wax, and bitumen. Petroleum chemicals fabrication and applications deal with solvents, detergents, synthetic resins and fibres, industrial and agricultural chemical derivations. (Comp. by members of the staff of companies of the Royal Dutch Shell Group. London, Shell International Petroleum Co. Ltd., 1959. 678p., No price given.)



*NUCLEAR POWER PLANT.

A review of the basic ideals underlying nuclear power generation for the informed reader. It opens with a concise account of world energy requirements and resources in the present and in the future. It goes on to deal with nuclear and reactor physics and reactions, types of reactor according to different means of classification, reactor engineering based on the unique reactor physics, the control of the heat output of the reactor, instrumentation, and economics of nuclear stations. The appendices contain comprehensive tables of elements, neutron interaction formulae, reactor theory, and a chronology of nuclear power development. (E. Openshaw Taylor. New York, Philosophical Library, 1959. 184p., $7.50.)

*HIGHWAY ENGINEERING, 2ND. ED.

The purpose of this book is to give an integrated picture of the whole field of highway engineering, presenting the material in the order in which it commonly would occur in the development of a highway or highway system. Administration, economics, financing, and planning are dealt with at length, followed by chapters on design, construction and maintenance, which stress fundamental principles. The new edition incorporates the major advances in the field, and shows the effect of the Federal Highway Act of 1956. (L. J. Ritter, Jr. and R. J. Paquette, New York, Ronald, 1960. 751p., $10.00.)

*MARINE CORROSION HANDBOOK.

Here is practical guidance, for non-specialists, on the prevention of corrosion in ocean-going ships, with the view toward application rather than scientific theory. Arranged alphabetically, the book gives rules of thumb for the choice of metals, the use of plastics for metal protection, and information on season cracking, stress corrosion, cathodic protection, anodic cleaning, corrosion fatigue mechanical descaling, and special pertinent qualities of each of the most commonly used metals. The author is Officer-in-Charge of the Dockyard Laboratory at H.M.C. Dockyard, Halifax. (T. H. Rogers. Toronto, McGraw-Hill, 1960. 297p., $12.00.)

*TANTALUM AND NIOBIUM.

This handbook on tantalum and niobium contains all available chemical and metallurgical information and provides text-indexed references to published words from the time of von Bolton (ca 1905). The sixth in a series of such publications dealing with the rarer metals, it gives full coverage to chemical processing, consolidation techniques, reactions with chemicals, gases and liquid metals, physical and mechanical properties, and production and applications of the metals, their alloys and important compounds. All information included has been analyzed by specialists. Comprehensive author and subject indexes are included. (G. L. Miller. Toronto, Butterworth, 1959. 767p., $21.00.)

STANDARDS RECEIVED

Canadian Underwriters Association standards. Canadian Underwriters Association, 410 St. Nicholas St., Montreal, Que.

CUA No. 10: 1959—Standards for the installation, maintenance and use of portable fire extinguishers.

DRIVE TO HIT AT FAULTY VEHICLES

The car with the faulty brakes, lights, signals, steering, exhaust, wipers, horn, tires or mirrors is the target of a road safety campaign across Canada by the Canadian Highway Safety Council. The motto: "**Check Your Car, Check Your Truck, Prevent Accidents**".

• DISCUSSION

(Continued from page 85)

hence the maximum dependable energy output, according to conventional methods. To this dependable energy output he applies an assumed load factor and looks upon the resultant figure as the total power potential of the river system. He then applies a mathematical manipulation to distribute this total power potential over the existing power plants.

Such a procedure invites a few remarks. First of all, the step from maximum dependable energy to capacity potential is somewhat more complicated that the application of an assumed load factor. What is the load demand of the entire system? What is the make-up of the entire system? Are the hydro plants under consideration suitable for being placed in the peak of the load? The answer to such questions will determine the capacity potential, and subsequently we will find the resultant load factor of the hydro plants, rather than the other way around.

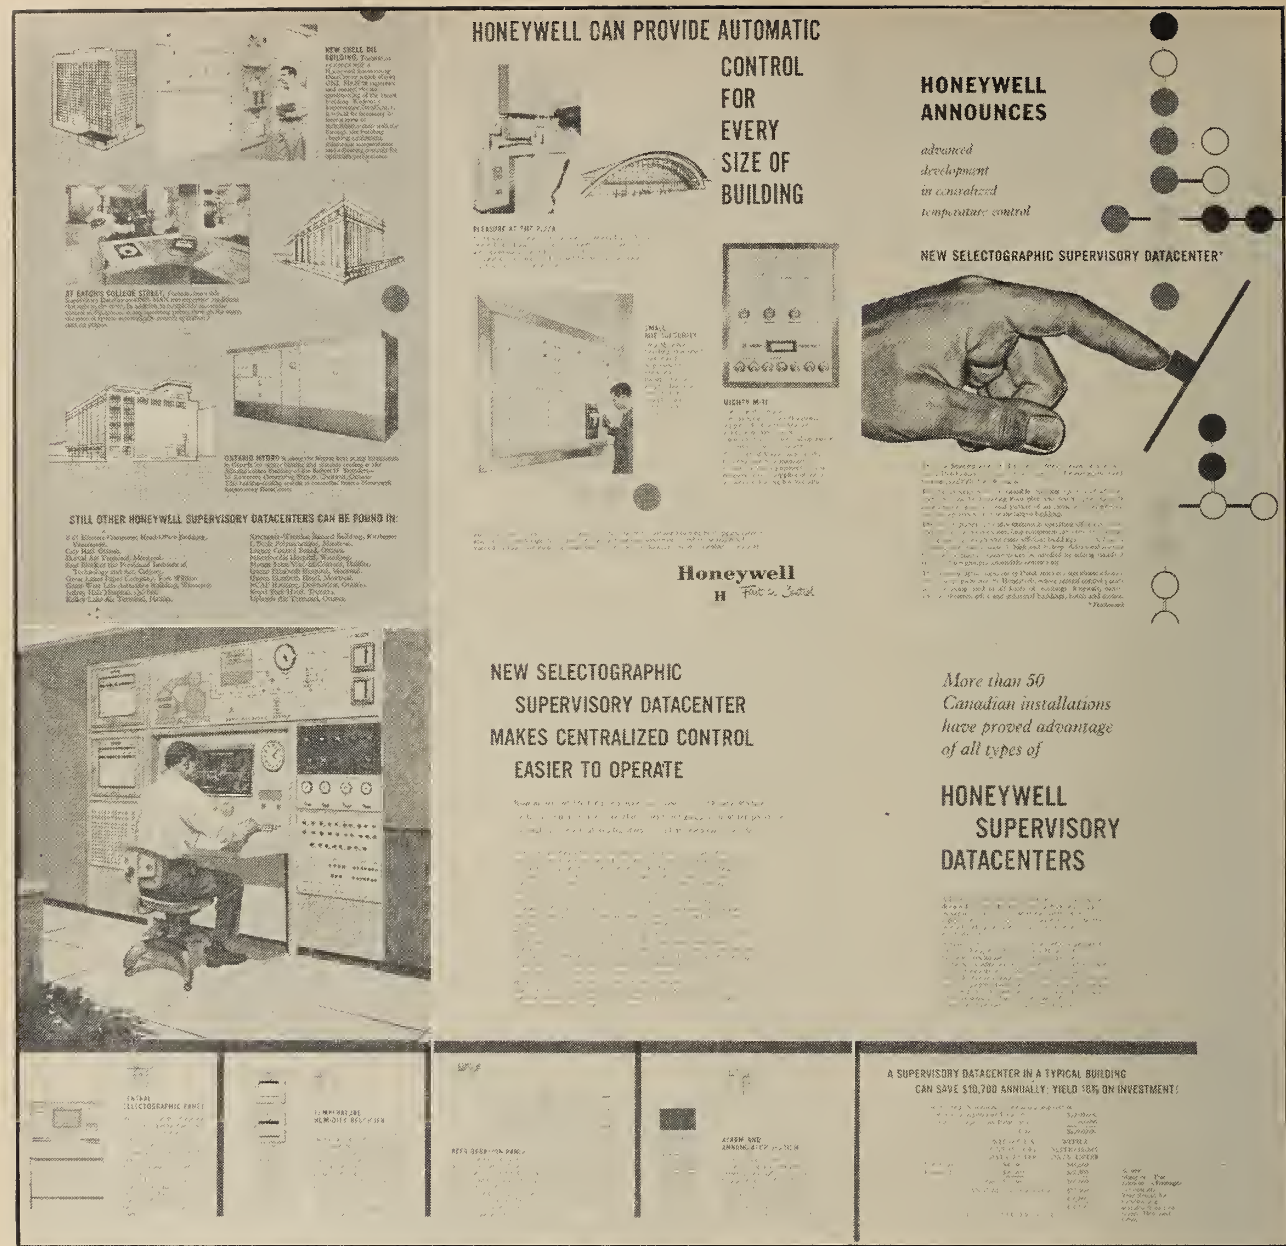
Secondly, even if we take the total power potential of the river system for granted, it would have limited value to distribute this total capacity over the individual plants with a manipulation that fails to take into consideration such governing factors as the incremental cost, pondage capacity, and hydraulic conditions of each individual plant.

Discussion by C. H. Atkinson

The paper presented by Mr. Cavadias gives a logical procedure for determining the energy output from a river system, and it is agreed that the computation of the total system output should give the optimum energy production. However, it is obvious that considerable trial and error guess-work must still remain in computing the regulation table. The reduction of inflow and discharge quantities in this table to energy units certainly simplifies the study, but the assumption of a constant kw.:c.f.s. ratio for each plant, which this involves, could not always be justified. This ratio is directly proportional to the overall plant efficiency and to the head. The former may be expected to remain within close limits under normal operating conditions, but the latter may vary widely, especially if the power plant utilizes the head from a reservoir which is drawn down during the winter. Under these conditions there would seem to be no alternative but to use tentative "Output vs Discharge" curves for the range of head which is envisioned at the reservoir. This in turn would make it necessary to carry out at least part of the regulation study in water-quantity units rather than in energy units, thus complicating the entire study and minimizing the use which could be made of punched-card computing machines.

The question of a variable kw.: c.f.s. ratio and more particularly of a variable head at the respective plants appears to have been purposely avoided by the author in this paper and it would be interesting to hear his comments on the inclusion of this factor in the study of energy potentials of rivers. This would be a step towards a more general case than that discussed in the present paper.

The regulation study is tedious



HONEYWELL CONTROLS LIMITED WINS CERTIFICATE OF ADVERTISING MERIT

Reproduced above, on a greatly reduced scale, is the four color, six page insert of Honeywell Controls Limited which was judged the "best" in the February issue from the viewpoints of ACCURACY-INFORMATION and ATTRACTION. The reproduction shows the front and reverse sides of the insert with the binding margin on the left of the top three pages and on the right of the lower three pages. The insert appeared as pages 109 to 114 of the issue.

E.I.C. CERTIFICATE OF ADVERTISING MERIT — WINNING ADVERTISEMENT

For the third time since the inception of the award of E.I.C. Certificates of Advertising Merit in January 1959, a Honeywell Controls advertisement has received the greatest number of votes by a fifty reader jury. The advertisement referred to appeared in the February 1960 issue. It is a six page, gate-fold, four color insert headed: "HONEYWELL ANNOUNCES advanced development in centralized temperature control NEW SELECTOGRAPHIC SUPERVISORY DATACENTER".

The advertisement has been carefully printed and designed and the copy is concise and factual. The jury which judged the advertisements was composed of "Journal" readers — five in each province. Each month different readers are asked to make their selection from the viewpoints of ACCURACY-INFORMATION and ATTRACTION.

K. K. Warne, Merchandising Manager of the Company, is in charge of the Advertising Department and the Toronto office of Cockfield, Brown & Co. Ltd. prepared and placed the advertisement.

work and if several alternative reservoir sites and capacities are possible the amount of work involved in computing a regulation study for each combination is very large. The author has clearly had considerable experience in this kind of study and it would be interesting to know if he has considered any methods, or manipulations, which may be used to extend the use of punched-card equipment to all phases of the regulation study.

In the last paragraph in section 3, the author mentions that the storages or groups of storages must equal the number of plants in the system before the method of determining the power production of individual plants can be applied. There would be no difficulty however in applying the method to a system where the number of storages is less than the number of plants. In Fig. 2 for example one reservoir feeds controlled flows to two plants, although, in this particular case it may be possible and preferable to group the two plants together if the uncontrolled flow entering the river between them is small compared with the total flow at plant P_2.

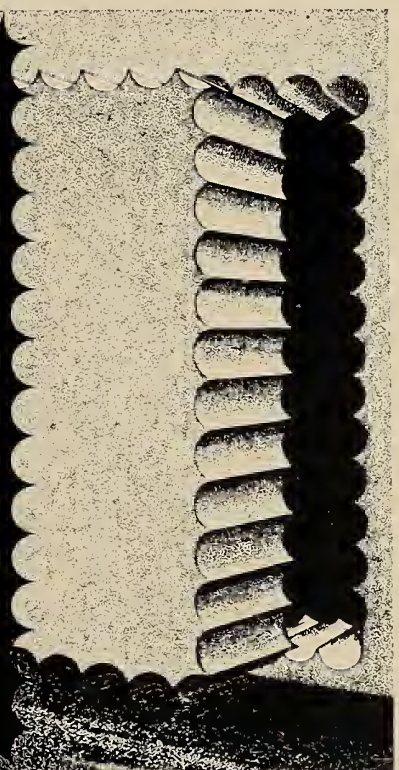
Discussion by G. H. Scruton, Jr.E.I.C.

The method outlined by Mr. Cavadias not only is useful in examining the potential of undeveloped rivers, but also in studying the effect of adding new plants to rivers which already are partly developed and of combining hydro-electric generation with other sources of energy supply. It provides a systematic means of studying the hydro-electric system as an integrated whole, rather than a series of individual plants.

In hydro systems, one of the great difficulties in determining primary and secondary energy estimates from flow-duration curves for individual plants located at some distance from each other on a stream which is regulated by the operation of storages, lies in the fact that the high flows occur at plants close to the storages during the periods of low run-off, while those at plants remote from the storages prevail during flood periods. Under these circumstances the total power approach is of considerable advantage and demonstrates the value of the interconnection of the plants.

For a planned addition to a system, an estimate of the benefit can be obtained by regulating the river for total power output, both with and without the planned addition, and the resulting total power duration curves examined. The difference in area between the two curves represents the increase in system energy production that can be credited to the new asset and the improvement in the curve at the right hand side is the increase in prime production. In one study, in which the method was applied, the increase in prime production equalled the increase in production, and in another, it exceeded the increase in production. In other words, some of the secondary presently generated by the existing plants was converted to prime just by the addition of a new plant. These were important conclusions that were obtained from the use of the total power approach.

In studying installations, the procedure can be followed of dividing the total primary power output by the system prime load factor in the same way that is sometimes followed in studies of individual plants. The difference between the results obtained from the two total curves is



the increase in peak that can be justified by the planned addition which then may be distributed amongst the planned and existing plants using the maximum production principle or, since it is unlikely that changes would be made to existing installations, it can be installed wholly at the proposed new plant or plants following the principle of minimizing the cost.

For interconnecting with other companies and/or with thermal plants, an adaptation of the method shown in the "Hydro-Steam Association" chapter of Doland's book "Hydro-Power Engineering" can be helpful for preliminary studies. The average annual energy contribution of the hydro system to the load is represented by the total power duration curve, and the difference between it and the demand curve is the amount of energy required from other sources. Use of this application to an interconnected system gives an indication of how much of the hydro generation is prime and how much is secondary.

The maximum production principle for selecting installations is an interesting aspect. It appears to give reasonable results for first approximations; however, one must also consider the ponding facilities of the individual plants and the proximity of the power plant to the storages to name just two other conditions. When the plant is near the storages, high flows have prime value and this fact must be considered.

In summary, the paper gives a method of studying a series of hydro plants on one river as a system and permits hydrologists and engineers to express mathematically the firming-up effect of the addition of new plants and other sources of energy to an existing system. It is this total power approach which makes the paper valuable.

Discussion by J. K. Sexton, M.E.I.C.

In his paper Mr. Cavadias derives a set of equations which express in simple form the basic conditions governing the operation of a system of hydro plants and reservoirs for maximum output of primary energy. In so doing he automatically emphasizes the point that while it is possible to compute storage operation in terms of water, or c.f.s., for the simple case of reservoirs supplying a single hydro plant or several hydro plants without significant intervening runoff, it is necessary to base the computations on energy or kwh. per hour for all other cases. Thus in the analysis of a complex hydro system the stream flow at each plant is expressed as the kwh. per hour it is capable of generating through the prime movers at the site, and the volume of live storage at each reservoir is expressed as the kwh. the impounded water can produce at the plants through which it will flow. This is the normal method used by hydro production men to control system operation to maximum advantage.

The computations for such hydro system operation are usually done by trial and error and may in some cases be tedious. Apparently Mr. Cavadias does not depart from this trial and error method in the application of his formulas. He does, however, refer to the use of punched card computing machines and postal card sorting machines in the concluding paragraph of his paper, and it would be interesting if he would enlarge upon this reference. In the writer's experience there are distinct limitations to the use of computers in power supply studies since it frequently happens that there is insufficient repetition of operations to justify the preparatory work involved.

Referring to the details of Mr. Cavadias' paper, it would be interesting to know the reason for the inclusion of columns 12 and 13 in table 1. There is no indication in the paper of the way in which they are used, unless it is that column 13 assists in the trial allocation of load to the plant by indicating the maximum possible.

Mr. Cavadias' method of determining optimum capacities for the various plants of a hydro system is an interesting piece of mathematical deduction, and no doubt that is the way in which it is offered. In actual cases, of course, capacities of individual hydro plants are affected by a number of conditions such as head, pondage, type of construction, distance from markets, characteristics of other plants or the system and interconnections with systems. Moreover, hydro plant capacities usually reflect the changing importance of these various factors as the system evolves. For example, in a number of Canadian systems there is a growing proportion of thermal capacity which requires a review of the capacities in existing hydro plants. In such cases it is usually profitable to add to the hydro capacity far beyond that which was economical before the portion of the energy derived from thermal sources became significant.

Reply to the discussions by the author

In connection with Mr. Sexton's question concerning the use of punched card equipment in Power potential studies, I would like to mention that the equipment used in one particular application was fairly standard and consisted of the following I.B.M. machines:

1) 077 Collator
2) 082 Sorter
3) 407 Printer
4) 602A Calculator
5) 519 Reproducer

In another case a commercial Recording and Statistical Service offered:

1) To punch and check 12,000 cards.
2) To print the corresponding tabulations.
3) To prepare duration tabulations of mean monthly flows for 50 rivers with 20 yr. of records

power on site
from the word GO!

each, for a total fee of $500.00.

The problem of determining the capacities of the plants of a hydro system is admittedly complicated. The relatively simple criterion suggested in the paper is useful in preparing a first estimate of plant capacities, which is a necessary basis for cost estimates. In further stages of the study, the remaining factors mentioned by Mr. Sexton should be taken into account.

Mr. Scruton offers an interesting remark on the usefulness of the proposed method in the case of hydro-steam interconnection. An adequate coverage of this aspect is given in a paper by L. S. Wing and R. H. Griffin, mentioned in Mr. Renger's discussion.

Mr. Atkinson's question concerning the case of variable $\frac{KW}{CFS}$ ratios is interesting. In one system studied by the writer, the $\frac{KW}{CFS}$ ratio used for one plant with variable head, was calculated from the total energy production and the total discharge of the plant during the entire period of record.

This procedure is not applicable when most plants of the system have variable heads. In this case the method described in the paper is not applicable, as Mr. Atkinson points out. This subject merits further investigation.

Considerable work has been done in the last few years on the possibility of extending the use of computing equipment to the main phase of the regulation study. An interesting paper on this question has been presented by J. D. Ellis.*

Mr. Atkinson's last question was caused by a typographical error in the preprint of the paper, which was corrected in the printed version.

In reply to Mr. Kuiper's remarks, I would like to point out that the study of a hydroelectric development is usually carried out in a series of successive approximations, from the first rough estimates to the final design. The methods used at each stage should correspond to the degree of accuracy, both of the data available and of the results required.

The study of load conditions usually precedes the study of plant capacities and therefore the load factor can be considered as known, as was done in the paper.

In connection with the method of distributing the total installation, it should be noted that in order to determine incremental costs, a starting installation figure is necessary and this is supplied by the simple criterion of the paper. This criterion does not apply in the case of peaking operations at one or more plants.

Mr. Thomas's remark concerning the load factor is justified. The load factor used in the paper is applied to the prime power. For studies of this type it is sometimes acceptable to disregard the benefit from the production of secondary energy in determining the total installation.

Mr. Thomas's comment on the determination of the individual installations is obviously due to a misunderstanding of the problem, which is a non-trivial maximization problem with constraints.

Mr. Renger's and Mr. Clinch's remarks on the range of application of the proposed method are justified and constitute a useful complement of the paper. This can also be said generally for most of the comments contained in the discussions of this paper.

*The optimum use of water for Power calculated by Datatron electronic computers; Proceedings 26th Annual meeting. Western Snow Conference, April 1958.

● BRANCH NEWS

(*Continued from page 122*)

Winnipeg

P. M. Abel, JR.E.I.C.,
Correspondent

Dr. D. M. Stephens, chairman and general manager of the Manitoba Hydro-Electric Board spoke on Manitoba's program for power development at the March 17 meeting. After reviewing the history of the hydro-electric development of the Winnipeg River, Dr. Stephens discussed the progress of the Manitoba Hydro-Electric Board which has just completed the Brandon steam plant, is currently constructing the Selkirk steam plant, and is also at work on the Kelsey Hydro plant on the Nelson River.

It was announced that Prof. H. A. McDiarmid of the University of Manitoba's electrical engineering department would succeed Mr. G. C. March as general papers chairman of the branch.

Prizes and medals were awarded to the following university students: E.I.C. Summer Thesis Prizes, Civil III, A. M. Lansdown, "Cement — A Brief Introduction to its Manufacture"; Electrical IV, M. C. Chesley, "Analysis of Sub-transmission and Primary and Secondary Distribution of Electrical Energy and a Study of the City of Winnipeg Hydro-Electric Distribution System". Students papers competition: first, Charles Lamont, Mechanical IV, "Asphalt Paving"; second, Dennis Johnson, Electric IV, "Air Traffic Control"; third, R. Bevis, Mechanical IV, "Petroleum Refining". Presentations were made by Professors Riddell and McMath, chairman of the civil and electrical departments respectively.

Student Section

Don Brown, S.E.I.C.,
Correspondent

Mr. J. J. Hanna, president of E.I.C., addressed a meeting on February 22 and presented a certificate of merit to Miss Wendy Woods who was chosen the outstanding student in third year during the 1958-59 term.

Student branch elections were held on March 24 and the new executive includes: chairman, Brian Grover; vice-chairman, Don Brown; secretary-treasurer, Avron Arenson; membership, Ken Biccum.

Yukon

Lt. J. P. MacGowan, M.E.I.C.,
Correspondent

The Annual Meeting of the Yukon Branch was held at the Whitehorse Inn March 24. The following persons were elected to the new executive: chairman, Lt. Col. J. H. Reeves; secretary, Lt. J. P. MacGowan; treasurer, Mr. G. W. Elkington.

The principal speaker was not able to be present; however, Mr. Grant Starr, the out-going chairman, gave an illustrated talk on the construction of the Banff-Jasper Highway.

Business and Industrial Briefs

Appointments and Transfers

Fred W. Argue, born in Parry Sound and educated in Sault Ste. Marie, has been elected president of Stone & Webster, it was reported recently by the Canadian affiliate, Stone & Webster Canada Limited.

Shawinigan Water and Power announces the election of **H. Greville Smith,** C.B.E., to the board of directors. Mr. Smith is chairman of the board of British Newfoundland Corporation Limited and a director of a number of other companies.

Ronald R. McNaughton, manager of the Metallurgical Division of Cominco at Trail has been elected president of the American Institute of Mining, Metallurgical and Petroleum Engineers (A.I.M.E.).

T. Gordon Willows is the new construction manager of Ontario Hydro's St. Lawrence Power Project at Cornwall. Mr. Willows has been associated with the St. Lawrence project as project engineer, special assistant to the Commission's chief engineer, Dr. Otto Holden and until this appointment, as Field Project Engineer.

Two plant managers in Dupont's chemicals department have switched jobs. **I. D. Vessie,** works manager at the finishes plant at Ajax, became manager, chemicals, at the Maitland Works near Brockville and was succeeded at the Ajax plant by the former manager at Maitland, **W. R. Anderson.**

Ross Engineering of Canada Ltd., announces the retirement of **F. William Hooper,** who has served as Vice President and General Manager of the company since 1935. He is succeeded by **Ralph R. Willis.**

Paul Doyon, B.A., B.Sc., formerly a development engineer at the head office of Canadian Liquid Air Company in Montreal, has been appointed branch development engineer of the Toronto Branch. A native of Sherbrooke, P.Q., he is a graduate of Montreal and Laval Universities and a member of the Canadian Welding Society.

Martin Berlyn has been appointed Manager of Engineering Services by Dominion Engineering. Prior to his present appointment he was Manager of Quality Control Services. Mr. Berlyn has been with Dominion Engineering since 1929.

The appointment is announced of a General Electric (U.S.) engineer to assist Canada in the licensed manufacture of G-E's J79 Turbojet engines for Canada's F-104 Starfighters. **Peter R. Tolley** has been named resident consultant and will be located at the Orenda plant in Toronto.

Business News

LEONARD H. DALE, Managing Director of Dale Electric (Yorkshire) Limited, England, is now touring Canada visiting agents and appointing new agents to handle his company's range of generating plants. The company is one of the largest producers of generating equipment in Great Britain.

WHEN TO APPRAISE is the title of a new brochure put out by Warnock Hersey to describe how valuation services may be profitably applied to many areas of economic activity.

CANADIAN BUILDING DIGEST is the name of a new series of publications now being issued each month by the Division of Building Research, National Research Council. Each issue presents a summary, generally of one topic, for the information of those who deal with the technical and related aspects of building.

SHAWINIGAN'S SPENDING may reach $225 million for the five years 1960-64, the company's president, J. A. Fuller, told shareholders at the annual meeting. Shawinigan expects to begin work on new power producing facilities next year and will have to raise additional funds from investors.

A HIGH SPRAY RATE and exceptional deposit efficiency are features of the new lightweight, compact, Spraywelder Unit now obtainable from Wall-Colmonoy (Canada) Limited. Spray rate is over 12 lb/hr. and the new equipment provides 20% reduction in spray pistol weight.

THE DEPENDABILITY NEEDED in a really lightweight motor-in-head one man vibrator is provided by a new electric Concrete Vibrator announced by Remington Arms of Canada. Known as a Model EV-26, the new tool operates on either AC or DC at the rate of 10,000 vibrations per minute.

COLOUR POSTCARDS are now used by the Walworth Company to illustrate products. Designed primarily for salesmen's use, the cards also have value as direct mail pieces sent to customers with no message other than the printed caption and a signature.

DRAWBACKS IN THE CONVENTIONAL bell and horn signalling method of communication in mines are overcome by the new Westinghouse Minecom System. Minecom is a transistorized radio and telephone system which can be used in a variety of ways. The hoistrope can be used as a transmission medium for either voice or coded audible signalling. It is battery operated from the conveyance and no cables are needed between the transmitter and receiver.

CAUSTIC POTASH is to be produced in Canada by C.I.L. in a new plant to be located on the site of the company's Cornwall works. Caustic potash is used in heavy duty soaps and detergents, liquid fertilizer, oil refining and a number of other industries.

A BUILT-IN BALLAST is a feature of the new Form 400 IB Mercury Street Lighting Luminaire announced by General Electric. The ballast compartment is serviced through the lift-top cover which enables all mounting, connecting and servicing to be done from on top of the luminaire. Installation is simplified and wiring time considerably reduced. The new luminaire is ideal for expressways, downtown business streets or any area where a high level of lighting is desired.

EMERGENCY OXYGEN UNITS that may be kept in readiness indefinitely without production deterioration are available from the Linde Company, a Division of Union Carbide.

INDUSTRIAL AND THERMAL products built by Montreal Locomotive Works will henceforth be marketed under a new name: MLW Industries Division. Announcing the change, William E. Lewis, executive vice president, pointed out that the company now serves not only the railroads but oil refining, chemical processing, power, steel, and pulp and paper, and produces a wide range of general industrial equipment.

WATER AND DAMPNESS are resisted by the closed cell structure of Insulair, a rigid plastic foam material now being produced by Dominion Rubber. The compound insulation and plaster base, eliminating the need for separate base and furring strips and permitting ready bonding to most wall surfaces, reduces material and labour costs.

HYDROSTATIC POWER TRANSMISSION, the newest practical development in transmissions for vehicles, will be shown in New York by Dowty Group Limited, Cheltenham, England, at the British Exhibition, June 10-26 in the New York Coliseum. This first efficient application of hydrostatic power for vehicle use is now incorporated into British road building vehicles, diesel locomotives, cranes and military vehicles, as well as being used in mining equipment, industrial drives and marine applications.

FERRANTI-PACKARD ELECTRIC has been granted exclusive rights to market in Canada the complete line of products of the Capacitor Division of British Insulated Callender's Cables Limited.

A COMPLETE RANGE of AB De-ion moulded case circuit breakers for lighting, distribution and power circuit protection is described in a comprehensive new catalogue prepared by Canadian Westinghouse.

HEATING AND VENTILATING cabinets supplied by the Canadian Blower & Forge Company, Kitchener, Ont., are listed and fully classified in a new bulletin (UH-130).

THE HEAVIEST STEEL COLUMNS ever produced for an office building in the Commonwealth are now being erected at the site of the Cruciform Building in Montreal's Place Ville-Marie. Jointly fabricated and erected for the project by Dominion Bridge and Dominion Structural Steel, the columns weigh over a ton per lineal foot. "A start on the column erection confirms the fact that the initial steel work stage —installation of the steel base plates and grillages for the columns—is nearing completion," explained Quinton L. Carlson, construction manager for Webb & Knapp (Canada) Limited, the owners.

PROMISE OF A MARKET for 500,000 tons of asbestos fibre each year is offered by a research development announced by Johns-Manville. The special grade of fibre required for use in asphalt road paving can be made available in quantities far exceeding present demands, providing a surface that offers high speed and safety to the driver as well as long service and economy for the taxpayer. Total present production of asbestos fibre in the free world is estimated at 1.5 million tons yearly.

CYCLOTRON PERFORMANCES can now be predetermined by means of a magnetic field plotting system of unprecedented speed and accuracy. The new system, developed and placed in operation by Oak Ridge National Laboratory which is operated for the A.E.C. by Union Carbide, makes it possible to evaluate the detailed performance of a cyclotron before it is built. A well-coordinated mechanical and electronic system automatically programmes and positions a sensitive element which provides a voltage signal directly proportional to the strength of the magnetic field. • MORE BRIEFS

(Continued from page 158)

small size of the sensitive element, a wafer of semi-conducting material measuring 1/32" sq. in. area and known as the Hall probe, contributes much to the accuracy of the measurements.

MAN'S FIRST inhabited space station may be packed in a small container as it leaves the earth, blown into shape like a balloon when it leaves orbit, and made rigid by quick-setting plastic foam. Goodyear Aircraft Corporation engineers say that expandable coated fabric structures will make this possible. The fabrics, either of organic or metallic fibres, will be able to withstand high temperatures, extreme cold and the hard vacuum of space. Pre-fabricated sections will be folded into compact packages, boosted into orbit by ferry rockets, expanded by internal pressure and joined to other sections to erect the complete station. Similar expandable shelters may also be the first inhabited dwellings on the moon.

ANTI-SKID characteristics for paper bags and cartons, to reduce damage to goods during warehousing and shipping, can be achieved by Nalcoag 1050, a 50% colloidal suspension of silica in an aqueous solution announced by Alchem Ltd. of Burlington, Ont. This is the first 50% colloidal suspension of silica made available for commercial use. Nalcoag 1050 forms an exceptionally strong bond because of its very small particle size, the particles tend to fill in the minute pores and irregularities of the solid surfaces increase the surface to surface friction, and film strength, and reduce tack and the tendency to accept soil.

A SOLUTION to the difficulties long associated with accurate flow measurement of ethylene gas has been proven in field tests by General Electric using the Company's recently-introduced industrial mass flow-meter. General Electric engineers report it is now possible to measure ethylene flow directly in lb. with accuracy of within 1%.

CAREFUL BLASTING has overcome many difficulties in the formidable task of rebuilding the Trans Canada Highway from the Fraser Canyon in British Columbia. Close control of the muck pile has been achieved, using continuous application of the split second blasting technique with C.I.L. short-period caps. Generally the blasts have been hooked up in series-parallel circuits, care being taken to balance the resistance of the series and so minimize the possibility of misfires.

PACKAGED POWER in mobile and other lightweight generating equipment is offered by Dale Electric (Yorkshire) to provide electricity for specific needs in Canadian industry, communications, the farm or the home.

WITHOUT GRAVITY other than that artificially produced by rotation, great structural strength will not be required in space stations. This is the opinion of Goodyear Aircraft's Frank B. Sandgren, who maintains that the inflated structure for orbital flight will be safe and far lighter than a rigid frame, and will permit storage and transportation in minimum space for minimum weight.

BEST PERFORMANCE and longest service life from industrial storage batteries can be obtained by following the right operating rules. This is what has prompted the Electric Storage Battery's Exide Industrial Division to issue a comprehensive instructional manual, which includes directions for minor repairs.

TWO AUTOCLAVES are being built by the Sparling Tank Company for J. Cook Concrete Block Company of Aldershot. Hot oil heating coils will line the bottom of the autoclaves. The coils will be covered with water and as oil temperature is raised to 550°F the steam from the boiling water will cure the blocks. Substantial savings are expected. Because the hot oil will be under 15 lb. pressure, a stationary engineer will not be required.

"THE DANGEROUS DELUSION" that Canada is fast becoming an industrial nation was criticized by Herbert H. Lank, Du Pont president, at the Company's annual meeting. Urging his listeners to buy Canadian, he pointed out that while the manufacturing industry had grown considerably since 1940 its relative importance in the economy had not changed. In 1940, manufacturing accounted for 26.7% of gross domestic product; in 1958 it was 26.3%.

THE SHELL is the secret of the new long period delay blasting cap introduced by C-I-L. Elimination of the vent hole common to previous slow delays practically eliminates water and air hammer failures and the shorter, rigid shell facilitates priming of explosive cartridges.

Simplicity is the keynote in the new Daystrom-Weston Model 6702 multi-point recorder — simplicity in both design and performance.

Open the door and you see the advantages of the Daystrom-Weston famous *unitized design* — no jungle of wires, no hard-to-get-at areas . . . every component related in the simplest, most serviceable, most efficient way.

Interchangeability is easier than ever — from one number of points to another . . . one range to another . . . one chart speed to another. You need only a change plug and *newly-combined* station indicator and printing wheel — two units instead of three.

The remarkable Daystrom-Weston D-PAK®, solid state Constant Current Source, eliminates batteries, standard cells, standardizing mechanisms . . . and their maintenance!

You also get all the advantages of the full Daystrom-Weston potentiometer line — long-term reliability . . . high resistance to shock and vibration . . . maximum flexibility (recorder-controller "packages", including panels and accessories, can be suited to your specific application).

You get all this, yet a single instrument handling from 2 to 24 points costs 15% less than the average multi-point! And it can readily be converted to a single-point, curve-drawing instrument by means of a pen accessory.

For further information, call or write: Daystrom Ltd., 840 Caledonia Road, Toronto 19, Ontario; 5430 Ferrier Street, Montreal 9, Quebec, a subsidiary of Daystrom Inc.

6017

DAYSTROM-WESTON INDUSTRIAL INSTRUMENTS include a full line of recording and controlling potentiometers with strip and circular charts; mechanical recorders and indicators for pressure, temperature and flow; and non-indicating controllers, both electric and pneumatic.

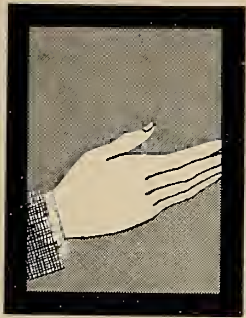
World leader in measurement and control



Meet the Authors

A. G. L. McNaughton, M.E.I.C., B.Sc., (McGill '10), M.Sc., Hon.-LLD., Chairman, Canadian Section, International Joint Commission, Ottawa. *(Pollution in the Boundary Waters of Canada).*

Upon his retirement from the Canadian Army, General McNaughton was appointed Minister of National Defence (Nov. '44-Aug. '45). In 1946 he served as Canadian Representative, U.N. Atomic Energy Commission and was for two years President of the Atomic Energy Control Board of Canada. He was Permanent Delegate of Canada to the U.N. and Canada's representative on the Security Council from January 1948 to January 1950. He is a past president of the National Research Council.

J. R. Menzies, B.A.Sc., (Toronto '26), Chief, Public Health Engineering Division, Department of National Health and Welfare, Ottawa. *(Pollution in the Boundary Waters of Canada).*

For two and a half years after graduation Mr. Menzies was employed on land surveys and townsite work, after which he joined the federal health department. He was appointed to his present position in 1948 and has participated in several studies of pollution problems as chairman or member of advisory boards appointed by the International Joint Commission.

T. V. Berry, M.E.I.C., B.A.Sc., Civil (U.B.C. '23), Commissioner, Greater Vancouver Water, Sewerage and Drainage Districts, Vancouver, B.C. *(Pollution Control in the Lower Mainland Communities in British Columbia).*

Mr. Berry is a member of the American Society of Civil Engineers, the American Water Works Association, the Association of Professional Engineers of B.C., the Water Pollution Control Federation and is a Diplomate of the American Academy of Sanitary Engineers.

P. H. Bouthillier, M.E.I.C., B.Sc., Civil (Alberta '44) S.M. (Harvard '47), Associate Professor of Civil Engineering, University of Alberta, Edmonton. **H. L. Hogge,** M.E.I.C., B.Sc., Chemical (Alberta '50), Provincial Sanitary Engineer, Department of Public Health, Government of Alberta, Edmonton. *(Stream Pollution and its Control in Alberta).*

Professor Bouthillier has been on the staff of the University of Alberta since 1947. He has also worked with the Alberta Department of Health, Division of Sanitary Engineering in connection with pollution studies.

Mr. Hogge has been with the Alberta Department of Public Health since his graduation. He has been involved in stream pollution studies, municipal engineering work and has been Director of the Division of Sanitary Engineering for six years.

N. S. Bubbis, M.E.I.C., B.Sc., Civil (Manitoba '34), General Manager and Chief Engineer, Greater Winnipeg Water and Sanitary District, Winnipeg, Manitoba. *(The Greater Winnipeg Sanitary District and River Pollution Abatement).*

Mr. Bubbis started work with the City of Winnipeg as a pipe plant inspector; he later became Engineer-in-Charge of the drafting and designing branch, and then Engineer of Water Works and Sewerage. He is a past president of the Association of Professional Engineers of the Province of Manitoba, the Canadian Institute of Sewerage and Sanitation, the Western Canada Water and Sewage Conference and the Minnesota Section of the American Water Works Association.

A. E. Berry, M.E.I.C., B.A.Sc. (Toronto '17), M.A.Sc., C.E., Ph.D., General Manager, Ontario Water Resources Commission, Toronto, *(Advances in Sewage and Waste Treatment).*

Dr. Berry was formerly the Director of the Sanitary Engineering Division of the Ontario Department of Health and had charge of water works, sewage works, and all environmental sanitation throughout the province. He is Past President of the American Water Works Association and the Water Pollution Control Federation and a member of other technical and professional organizations.

A. M. Snider, M.E.I.C., B.A.Sc. (Toronto '17), Chairman, Ontario Water Resources Commission and President, Sunshine Waterloo Co. Ltd., Waterloo, Ontario. *(The Ontario Plan for Water Pollution Control).*

Mr. Snider served as Design and Production Engineer of Canadian Ingersoll Rand Co. Ltd., Sherbrooke; later as Chief Engineer and Assistant General Manager, Waterloo Manufacturing Co. Ltd.; and then successively as General Superintendent, General Manager and President of the Sunshine Waterloo Co. Ltd. He was the first Chairman of the Water Resources Committee of South Western Ontario as well as the Chairman of the Ontario Water Resources and Supply Committee.

Leopold Fontaine, B.Sc., Civil (Ecole Polytechnique '30), Assistant Chief Engineer, Quebec Ministry of Health. **Jean Paul Gourdeau,** B.Sc., Civil (Ecole Polytechnique '51), M.Sc. (Harvard), Sanitary Engineer, Quebec Ministry of Health. **R. R. Carrier,** JR.E.I.C., B.Sc., Civil (Ecole Polytechnique '48), Sanitary Engineer, Quebec Ministry of Health, Quebec City. *(Aspects of River Pollution in the Province of Quebec).*

Mr. Fontaine has worked for the Quebec Ministry of Health since his graduation. He is also a professor in Sanitary Engineering at Laval University. Mr. Fontaine is a member of the Corporation of Professional Engineers of Quebec, the American Water Works Association, the Water Pollution Control Federation, and the American Public Health Association.

Mr. Gourdeau is a councillor of the Corporation of Professional Engineers of Quebec and a member of the American Water Works Association and the Water Pollution Control Federation.

Upon graduation, Mr. Carrier worked as a design engineer. He then took post graduate studies at Harvard in Sanitary Engineering and joined the Quebec Ministry of Health in 1952. At present he is also a Professor of Sanitary Engineering at Sherbrooke University. He is a member of the American Water Works Association, and the Water Pollution Control Federation.

A. L. Van Luven, M.E.I.C., B.Sc., Chemical, (Toronto '48), Head, Waste Treatment Division, H. E. McKeen & Company Ltd., Lachine, Quebec. *(A Study of the Use, Conservation and Pollution of Water Resources).*

Mr. Van Luven spent several years prospecting and mining in the Northwest Territories and Quebec. He was also with Canada Packers Ltd. for ten years. He is a member of the Chemical Institute of Canada, The Canadian Institute on Sewage and Sanitation and the American Water Works Association.

T. W. Beak, Consulting Biologist, Collins Bay, Kingston, Ontario. *(The Measurement of Industrial Water Pollution).*

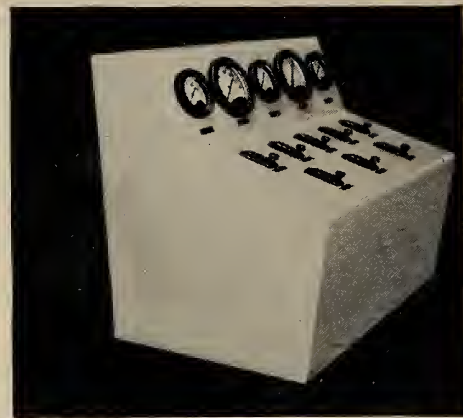
Mr. Beak graduated from London University (England) and held several government posts in the U.K. in the fields of chemistry and biology. He came to Canada in 1955 and set up consulting practice in industrial water pollution problems. He is the Eastern Canadian representative on the Pollution Committee of the American Fisheries Society.

COVER ILLUSTRATION

Water pollution is truly nebulous. Its presence is a matter of degree, and it is no more tractable to preconceived ideas than the fabulous many-headed snake of the mythical marshes. Our June authors tackle this modern Hydra by painstaking analysis of its many constituent problems.

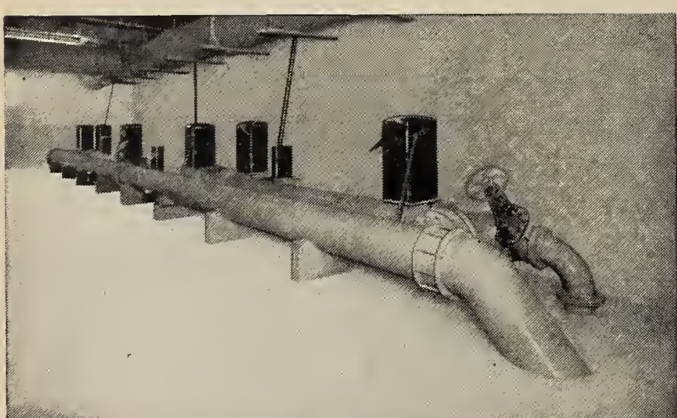
BAILEY at BRANDON

Bailey Control Drives on all remotely controlled Butterfly Valves at the Modern Brandon Water Treatment Plant.



"Flow Control" Desks such as this one are the operating centres for remote butterfly valves.

Bailey Drives are the accurately controlled "Muscles" for positioning and holding Butterfly Valves open in accordance with control requirements. All drives have a positioner inside the enclosure for individual flow characterization.



Below the operating floor, eight Bailey Drives operate Butterfly Valves to control water flow to and from the process.

Message from the President

FOR MANY YEARS the Institute has been Canada's national technical organization of engineers. As such it has endeavoured to present, both to Canada and to the world, a true and complete picture of the engineering activities in this country.

Today this effort is more important than ever before, and your Institute must take an even more prominent part in this most important duty, through its technical meetings, publications, and active participation in national affairs and international engineering activities.

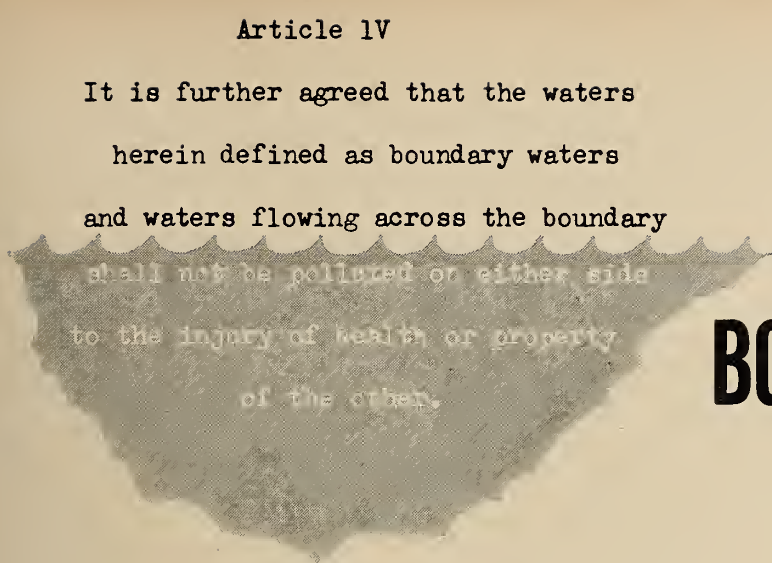
Engineering achievements in Canada represent major advances in technical development, and we must see that these advances are made known both within and beyond our geographic boundaries. The Institute also has an important responsibility of encouraging and directing its members in the presentation of its accomplishments so that maximum benefit is obtained from their effort.

In selecting me for the position of President of the E.I.C. for the ensuing year, I am deeply appreciative of the great honour which has been conferred on me. I am also keenly aware of the deep responsibilities which fall upon me as your President. During my many years of association with the Institute I have enjoyed numerous opportunities for congenial technical and social fellowship, and I feel sure that in my new relationship to the Institute I will find even greater opportunities for the development of this friendly atmosphere.

During the past year as Vice-Chairman of the Engineers Confederation Commission, it was my privilege to have been associated with John Fox and his devoted Commissioners, in the work of implementing Confederation. To this group I extend my sincere thanks and best wishes for a successful continuation of their efforts in this important task.

GEORGE McKINSTRY DICK, M.E.I.C.

President, 1960-61
The Engineering Institute of Canada



POLLUTION IN THE BOUNDARY WATERS OF CANADA

J. R. Menzies
Chairman, Canadian Section, Advisory Boards to the International Joint Commission on Control of Pollution of Boundary Waters.

A. G. L. McNaughton, M.E.I.C.
Chairman, Canadian Section International Joint Commission.

Consideration of pollution and measures for its control in Canadian boundary waters would be incomplete without some reference to conditions in the adjacent boundary waters of the United States. The corollary is also true. The importance of this approach to the problem was recognized many years ago when a "Treaty between the United States and Great Britain relating to Boundary Waters and Questions Arising between the United States and Canada" was signed on January 11, 1909. This Treaty, commonly referred to as The Boundary Waters Treaty, authorized the appointment of an International Joint Commission (Article VII) with three members from each country.

ARTICLE IV of the Treaty states in part that "It is further agreed that the waters herein defined as boundary waters and waters flowing across the boundary shall not be polluted on either side to the injury of health or property on the other".

Under Article IX of the Treaty each country agreed to refer to the International Joint Commission for examination and report with appropriate recommendations any questions "involving the rights, obligations, or interests of either in relation to the other or of the inhabitants of the other". It is under this Article that questions involving the pollution of boundary waters have come before the Commission.

Regarding the use of boundary waters, Article VIII of the Boundary Waters Treaty states, in part, as follows: "The following order of precedence shall be observed among the various uses enumerated hereinafter for these waters, and no use shall be permitted which tends materially to conflict with or restrain any other use which is given preference over it in this order of precedence;

1. Use for domestic and sanitary purposes;
2. Use for navigation, including the services of canals for the purposes of navigation;
3. Use for power and for irrigation purposes".

It will be noted that there is no mention made of use for industrial purposes. It might be assumed that it was intended to fall in the first classification on the basis that industry is usually located in urban communities. It seems likely that if the Boundary Waters Treaty were revised now, industrial water use would be mentioned specifically because of the increasing tendency for large industries to locate outside urban communities.

Investigation of pollution by the International Joint Commission ordinarily is initiated by an appeal to their federal government by those who suffer from the effects of pollution. When the two federal governments agree that the matter should be referred to the Commission, a Reference is drafted by the State Department, for the United States, and the Department of External Affairs, for Canada. The State and Provincial governments which may be involved, are kept fully informed of developments and are afforded opportunities to discuss the problem and the terms of reference. When agreement has been reached regarding the terms of the Reference the Commission is requested to investigate and report upon the matter and to make appropriate recommendations to the two federal governments.

In carrying out its investigations the Commission normally appoints a Board of Technical Advisers to direct the field work and all related duties. The Board members are selected from the staff of federal, state and provincial governments on the basis of their special knowledge or training in the field of pollution control.

Problems involving transboundary pollution have been under reference to the International Joint Commission on several occasions. The first of these was in 1913 and posed the question "To what extent and by what causes and in what localities have the boundary waters between the United States and Canada been polluted so as to be injurious to the public health and unfit for domestic or other uses?" The study which was undertaken extended from the Lake of the Woods through the Great Lakes and connecting waters, the international section of the St. Lawrence River and to the international section of the Saint John River. Most of the analyses were for the purpose of determining the intensity of bacterial pollution and the resulting report noted extensive areas which were, at that time, considered to be seriously polluted, particularly the rivers connecting the Great Lakes and adjacent areas of the lakes affected by pollution brought into them by these rivers.

The Commission reported to the two governments under date of 12 August 1918 that the discharge of sewage in its raw condition into boundary waters had "resulted in a situation along the frontier which is generally chaotic, everywhere perilous and in some cases disgraceful. The Common law having proved inadequate to the task of controlling affairs, it has been supplemented or superseded by legislative enactments, which in their practical working have about as signally failed". (Page 31). The Commission recommended that the necessary jurisdiction and authority in respect to the pollution of boundary waters and waters crossing the boundary be conferred upon it; and for the purpose of giving effect to the jurisdiction and authority so conferred that the Commission be authorized to make such rules, regulations, directions and orders as in its judgment may be deemed necessary; and that power be also given to the Commissioners to appoint such engineers and employees as it may consider advisable. (Page 50).

Further Analysis

When these proposals came to be further analysed and considered by the Governments it became evident that the creation of such an international authority with comprehensive powers and jurisdiction in Boundary Waters would not represent a practicable solution, and hence no action was taken. However, with the worsening of pollution which was evident in the connecting channels of the Great Lakes System, the International Joint Commission received a further reference on 1 April 1946, concerning conditions in the St. Clair River, Lake St. Clair, and the Detroit River. This reference was extended on October 2, 1946, to include the St. Marys River. and on April 2, 1948, to include the Niagara River. The Commission was asked to ascertain whether any of these waters were being polluted on either side of the boundary to the injury of health or property on the other side and if so, to what extent, by what causes and in what localities; and to recommend the most practicable measures for remedying the situation.

Extensive and detailed studies were undertaken in the areas mentioned and in adjacent waters of the Great Lakes. These studies included many types of analyses and observations which were not made under the 1913 Reference. The results were set forth in the Report of the International Joint Commission on the Pollution of Boundary Waters which was transmitted to the Governments of the United States and Canada under date of October 11, 1950.

Objectives

Incorporated in the report just mentioned, was a section entitled "Objectives for Boundary Waters Quality Control". The Commission recommended that these Objectives "- - - be adopted by the two Governments as the criteria to be met in maintaining boundary waters in satisfactory condition, as contemplated in that portion of Article IV of the Boundary Waters Treaty of 1909 wherein it is stated: 'It is further agreed that the waters herein defined as boundary waters and waters flowing across the boundary shall not be polluted on either side to the injury of health and property on the other'."

The Commission further recommended " - - - that it be specifically authorized by the two Governments to establish and maintain continuing supervision over boundary waters pollution through boards of control appointed by the Commission", and to bring to the attention of the competent authorities in the respective countries any pollution found objectionable in the light of the "Objectives".

It is of interest to contrast this recommendation with that which had been made in 1918. Instead of asking for unlimited jurisdiction over pollution, the Commission proposed that governments themselves should adopt specific objectives for boundary waters quality control and that the Commission's duties should extend only to the more modest function of continuing supervision.

In contrast to the fate of the 1918 Reference, the Commission's report of October 1950 was promptly accepted by the Governments. In so doing the merits of the "Objectives for Boundary Waters Quality Control" were recognized at the highest level and subsequent experience has indicated that they were worthy of this endorsement. Several governing bodies, such as the Ontario Water Resources Commission, have adopted the "Objectives" officially or have accepted them as a guide in pollution abatement and control activities.

Shortly after the adoption of the Pollution of Boundary Waters Report, the International Joint Commission appointed Advisory Boards on the Control of Pollution of Boundary Waters in the Great Lakes System and these boards have functioned continuously since then. Their duties have included follow-up studies in the boundary waters and the submission of semi-annual reports to the Commission reviewing all matters of interest in the areas studied under the terms of reference already noted. The Commission has therefore been currently informed of any situations in which the objectives had not been complied with and thus is able to bring these to the attention of the Federal, State, Provincial or Municipal authorities concerned for appropriate action.

Industrial Wastes

A very important phase of control activities has to do with industrial wastes, their effect on boundary waters, and the treatment of objectionable wastes. These activities will be discussed in some detail later.

Another reference to the International Joint Commission was dated June 10, 1955, and was related to the St. Croix River, a considerable portion of which flows along the boundary between the Province of New Brunswick and the State of Maine. Originally it was thought that since it had to do largely with the potential development of the river basin, pollution would not be of great significance. It was quickly realized, however, that pollution was of major concern and would need to be resolved since it was intimately related to many other facets of proposed future development in the basin. Studies were undertaken to evaluate conditions caused by it. Again the Commission has recommended the adoption of "Objectives for Boundary Waters Quality Control" with the addition of an "objective" for dissolved oxygen. This was necessary since restoration of anadromous fish runs was one of the proposals related to future development of the area and dissolved oxygen in the river waters was being seriously depleted by industrial and other wastes in the lower reaches of the river.

The International Joint Commission now has before it a further reference dated May 30, 1959, necessitating a study of pollution in the Rainy River which flows along the international boundary between the State of Minnesota and the Province of Ontario. The Commission has appointed an Advisory Board and detailed studies are being undertaken this year. This is basically a pollution problem although other interests affected by pollution, such as recreation and fish propagation, are intimately involved.

Many other water use problems are under reference to the Commission involving irrigation, power development and control of water levels and flows. Pollution has not been a significant factor in these instances and consequently has had little or no detailed consideration.

To achieve an understanding of pollution in boundary waters it is essential to review developments which were foreseen when the Boundary Waters Treaty was signed.

There is a popular slogan, "Misuse is Abuse". The conditions which have developed or exist might suggest that misuse itself has been an "objective" and, as such, has been eagerly endorsed by many interests. The need for water pollution references to the International Joint Commission emphasizes the fact that in some areas pollution is so severe that it affects citizens and communities on the other side of the international boundary. The complaints may be due to different sources and degrees of pollution. For example, pollutants which cause tastes and odours in public water supplies are significant because so many people are affected by them.

Phenolic compounds, which are frequently present in industrial wastes of various kinds, are incriminated rather often, because objectionable tastes result when they combine with chlorine. Similarly some industrial wastes, such as cyanides, and gross pollution by municipal wastes, are responsible for fish kills, and these receive much publicity because the dead fish frequently become stranded along the shoreline. Of major significance to everyone is pollution from municipal wastes. Prior to the develpment of modern water treatment methods, this form of pollution was of grave importance because many epidemics of water-borne disease were traced to water which was being polluted by human wastes. It still is most important, but too often a false sense of security prevails. Only continuous and conscientious attention to detail by waterworks personnel prevents an upsurge of water-borne disease which would reap a terrible harvest from the fields of careless and thoughtless waste disposal.

New products and processing methods are creating waste treatment problems of increasing complexity. These problems are accentuated by the rapid increase in population, the trend to urban living and increases in the use of water for many purposes, all of which increase pollution and tend to extend it further afield or overload waste treatment facilities, when they exist. The need for finding satisfactory solutions to the resulting problems has been recognized earlier and to a greater degree in the United States than in Canada, largely because of earlier experience with intensive industrial development there and greater density of population. It must be realized that prevention of pollution is better and usually less costly than correction.

Responsibility

The localized nature of pollution problems in Canada cannot and must not be a basis for complacency. While the basic responsibility for control of pollution is that of provincial authorities, a great deal can be done by federal agencies to encourage corrective action. Finally the individual citizen, because he must pay the bill, has a great and leading role to play by accepting financial obligations for the correction of faulty waste disposal methods.

The International Joint Commission's duties are essentially those of a co-ordinating agency which seeks at all times to facilitate the solution of pollution and other problems in international waters which could evolve, if left untended, into matters of international concern. There have been many examples of such situations. One which is associated with the Boundary Waters Reference of April 1, 1946, will serve as an illustration. The City of Detroit, prior to that time, had been experiencing objectionable tastes in its municipal water supply which is taken from the upper reaches of the Detroit River. The municipal authorities suspected that their problems were associated with industrial development in Canada near the City of Sarnia. The studies which were undertaken by the Commission revealed that excessive amounts of pollutants were being discharged by industries in the Sarnia area but it was also demonstrated that taste-producing substances, such as phenols, were entering the boundary waters, above the City of Detroit intake, from industries in Michigan. It was also shown that wastes in the St. Clair River, Lake St. Clair and the Detroit River were crossing the international boundary from each side.

A wide range of remedial actions was initiated following the investigations, and indeed these are still in progress. With very few exceptions the response of industry has been most gratifying and succesful in its accomplishments. In large sections of the boundary waters, compliance with the "Objectives for Boundary Waters Quality Control" has been achieved. A great deal has been accomplished in respect of municipal waste treatment but there are still quite a few municipalities without treatment facilities. Many of these are now planning remedial measures and early completion of this phase is anticipated.

In spite of these improvements much remains which requires corrective action. The need for this extends beyond the connecting waters of the Great Lakes into the Lakes themselves. Data concerning the presence of phenolic materials in Lake Erie indicate that much of the lake fails to meet the "Objectives for Boundary Waters Quality Control". This condition can be corrected in only one way, that is by the treatment or control of the wastes themselves. The condition of Lake Erie is reflected in the Niagara River which, in spite of corrective action by industries in the immediate area, still contains excessive amounts of phenols. This demonstrates beyond question the need for closely co-ordinated control action throughout the boundary waters. Those industries and communities which have responded to appeals for corrective measures can gain little comfort from the knowledge that their leadership is appreciated if, at the same time, it is obvious that others are failing to take similarly effective action.

It is not unusual to hear the plea "Why should we provide treatment facilities when our neighbour shows no indication of doing anything?" The answer is obvious but not too satisfactory—"Someone must be first". Even with the best intentions by all, the race to preserve water quality may well be lost before it starts. It is so difficult to realize the need or the urgency involved. The taxpayer who has no interest in waste treatment is protected in his folly by the best efforts of those who are charged with the duty of protecting his health and property. No doubt the citizen has many ways of spending his money which hold greater appeal to him than waste treatment. If, however, his drinking water supply has a vile taste or he cannot safely swim at his favorite beach, or the fish he had hoped to catch are killed before his eyes, he begins to see the problem in its true perspective. Even then he may have no conception of the degree of urgency or the methods of correction. We must have leadership and guidance but most of all we must realize that "Misuse is Abuse".

Remembering that many of our present problems are of recent occurrence it would be fitting to most sincerely acknowledge the wisdom, foresight and statesmanship, evidenced by the makers of the Boundary Waters Treaty over fifty years ago.

POLLUTION CONTROL IN THE LOWER MAINLAND COMMUNITIES OF BRITISH COLUMBIA

T. V. Berry, M.E.I.C.
Commissioner, Greater Vancouver Water and Sewerage and Drainage Districts.

The nuisances which the nineteenth-century combined sewer removed from the close proximity of residences were transferred to the streams and rivers which flowed nearby. First the smaller and then the larger bodies of water unable to cope with the digestion of the ever increasing waste matters became areas, especially in hot weather, of fermenting liquid and nauseous vapors. Out of these insanitary conditions came the separate systems of sewage transmission and the treatment of dry weather flows in scientifically designed plants intended to make innocuous and easy the final disposal of sewage. And so matters are different today. While sewage disposal is expensive, next to a pure and abundant water supply the public demands efficient disposal without degradation of streams and lakes or ocean fronts. But the problem of water pollution in North America has grown more intense with increase in concentrations of population, greater use of water and the large quantities of wastes attendant on modern industrial processes characterized by high concentrations of chemical and biochemical matters. In many areas the pollution of streams has reduced the available lakes and streams to a point of degradation where their safe use has been jeopardised if not entirely destroyed. This deals with the progressive pollution of streams and adjacent tidal waters in the Lower Mainland communities, past legislation on the problems of pollution and the measures now being undertaken which are expected in the few years ahead to reduce pollution to well within conservative and tolerable limits.

THE LOWER Mainland communities lie astride the Fraser River as it flows from the Municipality of Hope near where the river debouches from its canyons to the tip of Point Grey on the Strait of Georgia and from the International Boundary northerly to the mountains of the Coast Range. This land and water mass has an area of 9,000 sq. miles and is approximately coincident with the administrative area of the Pollution-control Board described in later pages.

The easterly two thirds of the area supports many small communities depending primarily on agriculture and its ancillary industry. The westerly one-third is more heavily populated and in this section are situated the Burrard Peninsula communities, the City of Vancouver, the City of New Westminster and the Municipality of Burnaby. In addition a number of lusty and rapidly growing municipalities adjoin the two trans-continental railroads and the highway systems which serve the Fraser Valley. These cities and municipalities to a great extent depend on the management of the basic industries of the Province and its manufacturers of secondary commodities.

For a better understanding of the problems of water pollution in the area defined above we shall describe briefly the geography, areal development, geology, climatology and domestic water supply of the region.

Geography and Areal Development

The Fraser River flowing through this area is one of the principal rivers tributary to the Pacific Ocean on the North American Continent. The maximum recorded flow of the river is well over 500,000 c.f.s. and the minimum is 30,000 c.f.s.

Upstream from its mouth the Fraser River divides into two main channels — the North Arm and the main channel. The delta land formed between the two arms constitutes the Municipality of Richmond — for many years given over to dairying and small fruit farming. It is now rapidly developing into an urban and industrial community. Vancouver International Airport, a very busy, if not the busiest airport in Canada, occupies a major portion of Sea Island — one of the islands constituting the delta.

The most rapid development of the area under discussion is largely along the westerly end of the Lower Mainland communities. Most of the residential development as well as a major part of commerce and industry is centred in the City of Vancouver but the easterly end of the Burrard Peninsula is rapidly expanding both industrially and residentially — notably in the Municipalities of Burnaby and Coquitlam.

The North Shore communities are predominantly residential but industry is developing along the whole shore of Burrard Inlet east of the First Narrows. Industrial development of the Lower Mainland is now centred on the shores of Burrard Inlet, the North Arm of the Fraser River and on the Fraser River itself to some distance east of New Westminster. Industry consists in the main of lumber and wood products, meat slaughtering and packing, vegetable and fruit packing, petroleum refining, fish processing and canning. Shipping which centres in Vancouver Harbor is an important industry. It transports grain, lumber and timber products, machinery and fish products to all parts of the world. The lands marginal to the Fraser River from the Strait of Georgia to New Westminster and beyond will be developed to a greater extent than now as conditions in the Orient become more stable. The approximate population of the Lower Mainland cities, municipalities and villages at the end of 1959 is estimated at 854,000. This is approximately 54.5% of the population of the Province of British Columbia which is estimated at 1,570,000 at that date.

Topography and Geology

The Lower Mainland area, except the Fraser River delta islands, is largely a varied terrain of rolling hills and mountains. Cut through by the Fraser River as it flows westerly, and indented by Burrard Inlet, the major salt water harbor, the area is characterised by ample grades for discharge of sewage and drainage to the nearest waterways except in the delta lands of the Municipalities of Richmond and Delta.

The characteristic geologic formations in the area are tertiary sediments comprising layers of sandstones, shales and conglomerates in various thicknesses. These lie on the old granitic rocks of the Coast Range batholith of intruded igneous rock. The tertiary sediments are in most cases overlain by glacial and interglacial deposits of thicknesses up to 250 ft. In addition these are in places overlaid by delta deposits of the Capilano, Seymour and Coquitlam Rivers and the Fraser River and its tributaries.

Climate

The climate of the area is a mild one without extremes of temperature. Winds normally are light to medium. Precipitation is relatively high, mostly as rain varying from 37 in. at Vancouver Airport to as high as 150 in. at the mountains north of Burrard Inlet.

Water Supply

In general the major water supply of these communities is from surface water emanating from the creeks and rivers with their sources in the Coast Range mountains to the north. With the prolific rainfall in the area and generous storage in the form of snowfields in the mountains for summer use, the area is well endowed with water potential for large populations.

Twelve cities and municipalities west of the Pitt River and two east of it receive their water from an inter-municipal corporation known as Greater Vancouver Water District. This corporation supplies, *at cost*, these member municipalities and several unorganized areas with water to their boundaries by gravity from three sources of supply namely: Capilano, Seymour and Coquitlam Rivers. The average daily per capita use of water over the entire district is between 130 and 140 imp. gal.

These three rivers have catchment areas totalling 226 sq. miles. About 20% of the land in the watersheds is owned outright by the Water District. The balance is leased to it by the Crown for a period of 999 years for water supply purposes. These watersheds are situated in the mountains to the north and are regions covered with heavy timber growth. No residential or industrial development is permitted within them and the public is excluded by regulation posted at the several places of entry and by patrolling. Hikers, fishermen and mountaineers are excluded also from these rugged catchment areas. Reference will be made later to the sanitary significance of these conditions.

Recreational Facilities in the Lower Mainland

The Lower Mainland has valuable recreational facilities in the form of many miles of good beaches. These beaches probably aggregate 15 to 20 miles in extent. It is estimated that these are visited by 2,000,000 visitors, residents and tourists alike during a normal summer, who enjoy to the full sunbathing, swimming and water skiing.

The mountains to the north, outside the catchment areas reserved for water supply, give opportunities for skiing to thousands of enthusiasts for some five months of the year. The lower reaches of the Capilano and Seymour Rivers, the many lakes in the area and the tributaries of the Fraser River supply excellent salmon and sport fishing.

It is estimated there are over 30,000 power operated boats, commercial fishing and pleasure craft owned and operated in the Lower Mainland waters.[1] The pleasure craft ply the waters adjacent to the Lower Mainland during the summer recreational months and the fishing, tugboat and other commercial craft ply these waters for most of the year.

The mountains to the north of the Fraser afford many excellent climbing areas to mountaineering enthusiasts and golfing is enjoyed practically all the year around on a number of very fine privately owned and public links.

Condition of the Shore and Shore Waters

Virtually all of the municipalities constituting the Lower Mainland have rivers or ocean shores adjacent to them into which sewage can discharge, and it is a matter of good fortune that these communities are not dependent on these bodies of water for their domestic and industrial water supplies.

The danger of these water supply streams becoming polluted therefore, need not occur if intelligent and prudent care is exercised in the management and use of them.

The pressing problem in the Lower Mainland is hence not one of pollution of water supplies but of abatement and prevention of pollution of those streams and bodies of water on which the community depends for recreational, commercial and game fishing, and for the protection of the hygienic and aesthetic aspects of the waters and marginal shores.

At present crude sewage is discharged without treatment into ocean and river waters of the Greater Vancouver area (from Coquitlam to Point Grey) at about 65 known locations. Altogether there are probably over one hundred such outfalls from the Village of Hope to Point Grey, including English Bay and Burrard Inlet. Many of these outfalls discharging crude sewage are adjacent to important beach and recreational areas. In addition there are large contributions of sewage to the waters by ocean-going vessels, the thousands of pleasure and fishing craft and float houses—of which there are many in Burrard Inlet. The towing of millions of feet of logs in large booms into the estuary of the Fraser River from up-coast logging operations adds its quota of flotsam to these waters.

A number of water bodies in the Lower Mainland, evaluated by testing for bacteriological condition and by visual and chemical examination of the waters, are undoubtedly moderately polluted. These are:

Port Moody Bay at the easterly end of Burrard Inlet: The land surrounding the head of the Bay is rapidly being built up both industrially and residentially. The problem of pollution in this area is rapidly growing. A sanitary sewer collecting system and primary treatment facilities is now under construction here to prevent pollution becoming serious.

The North Arm of the Fraser River: Pollution in this body of water

1. Estimate of Registrar of Shipping, Vancouver, B.C.

is recorded by the B.C. Research Council report on "Water Quality in the Fraser-Thompson River System, 1950" as being moderately polluted.[2] Plans of the Greater Vancouver Sewerage and Drainage District call for interception of sewers discharging into this body of water and eventual treatment in the Iona Island plant now under construction. This provision however, does not effectively deal with pollution by sewage in the North Arm originating from Richmond and New Westminster.

Head of False Creek: In due course the several sewers discharging into these waters are to be pumped to sewers leading to the Iona Plant.

English Bay (Kitsilano Beach, Locarno Beach, Spanish Bank, English Bay Beach, First, Second and Third Beaches): These beaches are polluted by water from the head of False Creek and sewage from the Discovery Street Outfall. However, comminution and chlorination of the raw sewage from the latter during the 1959 recreational season kept the beach waters in tolerable and acceptable condition pending the completion of the Iona Sewage Treatment Plant.[3]

Several other localities show mild pollution. These are usually in the vicinity of sewage outfalls, and as these sewers are intercepted and the effluent directed to treatment plants or better points of discharge, it is expected these conditions will be abated.

The Fraser River from Hope to New Westminster shows relatively light coliform counts and very little oxygen depletion. The water is subjected however during the spring and early summer freshets to heavy turbidities which discolour the waters of the estuary of the river and for some distance out into the Strait of Georgia. These discoloured waters during May, June and July intrude into the bathing areas of the south side of English Bay and undoubtedly add to the decadence of these waters evident during these months. (Fraser River flows estimated at New Westminster indicate during a five-year period October 1947 to September 1952, a minimum daily flow of 26,000 c.f.s. and a maximum of 665,000 c.f.s.).

History of Sewerage in the Lower Mainland Communities

The earliest sewers constructed in the area were laid by the City of Vancouver in 1890. Rapid growth in the Burrard Peninsula area (Vancouver, Burnaby, Port Moody, City of New Westminster and University Endowment Lands) during the first decade of the century, stimulated a scientific study and report of the problems of disposal of both sanitary sewage and surface water.[4] Mr. R. S. Lea of Montreal, a member of the Engineering Institute of Canada and well remembered by older Canadian engineers, carried out the study in 1911, 1912 and 1913 and made recommendations to the Burrard Peninsula Joint Sewerage Committee in 1913. The most important recommendations of Mr. Lea were substantially as follows:

1. That the principle of the separate system of sewers be adopted in the areas draining into English Bay, False Creek and Burnaby Lake;
2. That the most suitable points of outfall are:
   (a) Into English Bay on the line of Imperial (now Discovery) street;
   (b) Into Burrard Inlet (Vancouver Harbor) at Clark Drive and other points;
   (c) Into the Fraser River (North Arm);
3. That the interception of floating matter is essential for sewage discharged into English Bay and Burrard Inlet and that there is a possibility of some form of treatment being required in the future for sewage discharged into the Fraser River or its North Arm.

The master plan indicated the sewerage works in considerable detail which, in due course, would need to be provided.

Vancouver and Districts Joint Sewerage and Drainage Board was constituted by Provincial statute in 1913 and charged with the "carrying out of a system of sewage for the area within the Burrard Peninsula in substantial accordance with the Lea Report of 1913". The Province of British Columbia guaranteed its debentures up to $10.5 million. This amount was never completely expended before the Board was reconstituted by statute in 1956.

In 1913 the Attorney General of the Province retained Messrs. C. H. Rust and R. H. Thompson, Consulting Engineers, to report on the proposed enabling legislation constituting the "Sewerage District" and in addition to issue a satement regarding the proposed sewerage scheme "as being feasible and practicable".

These two gentlemen approved of Mr. Lea's "exercising great caution in the matter of polluting any of the waters whether fresh or salt, upon which any of the municipalities bordered and that so far as the scheme is concerned it is safe, feasible and practicable". They continued—"However we believe that he has over-estimated the danger of polluting the various waters referred to and has therefore laid more stress than conditions justify upon the necessity and propriety of constructing the drainage system of that portion of the district discharging into English Bay on what is known as the separate system . . . etc."

In the light of this criticism, Mr. Lea's recommendation as to constructing the English Bay System as a separate system was not adopted and virtually all of the trunks built over the years in the Burrard Peninsula by Vancouver and Districts Joint Sewerage and Drainage Board and the City of Vancouver were combined sewers. While the first capital costs involved were undoubtedly smaller than would have been under the separate system, the Greater Vancouver Sewerage and Drainage District—the successor to Vancouver and Districts Joint Sewerage and Drainage Board since 1956—would not now be faced with treating much larger quantities of highly diluted combined sewage had Mr. Lea's farsighted recommendations been followed.

City of Vancouver Sewerage

While Vancouver and Districts Joint Sewerage and Drainage Board built and operated trunk sewers, intercepting sewers and outfalls servicing drainage areas in excess of 400 acres, the City of Vancouver in general constructed trunks servicing areas of less than 400 acres and all of the lateral sewers within the City. Today the City is about 85% sewered.[5]

Of the other organized communities in the area the following is the approximate provision for sewerage in each as at this date.

In the Municipality of Burnaby sewerage coverage is about 25% complete;

In the City of New Westminster sewerage coverage is about 80% complete;

In the City of North Vancouver sewerage coverage is about 30% complete.

District of North Vancouver, Richmond, Coquitlam, Port Coquitlam, Delta, Surrey, Chilliwack and several of the small communities in the Fraser Valley have each made a start

2. Water Quality in the Fraser-Thompson River System of British Columbia. B.C. Research Council Report—1952.

3. Greater Vancouver Water and Sewer District Report of Commissioner Berry, 1959.

4. Burrard Peninsula Joint Sewerage Scheme—R. S. Lea, 1913.

5. The 400 acre minimum to drainage areas administered by Vancouver and Districts Joint Sewerage and Drainage Board was not fixed by the Statute, but by mutual acceptance between the Board and the City of Vancouver and other member municipalities.

on the construction of central collecting systems. Where no such provision has been made the population depends on septic tanks for its waste disposal. In some areas these work well for a few years. In other areas due to conditions of soil and ground water level these do not work effectively.

The Rawn Report and Master Plan 1953 and the Reconstitution of the Vancouver and Districts Joint Sewerage and Drainage Board[6]

Following the Second World War the metropolitan area of the Lower Mainland experienced the same rapid expansion that had been experienced by urban centres all across North America. This rapid expansion of both industry and population quickly rendered the existing sewerage and drainage facilities inadequate. By 1949 pollution of shore and shore waters in the area, as already pointed out, was becoming evident and the likelihood of continued population growth indicated very forcibly the possibility of greater and eventually intolerable pollution.

6. Sewerage and Drainage of Greater Vancouver Area, British Columbia, Sept. 1953, Gilman Hyde, Rawn and Oliver.

As a consequence the Vancouver and Districts Joint Sewerage and Drainage Board appointed an Engineering Board of Consultants under the Chairmanship of Mr. A. M. Rawn, at that time Chief Engineer and General Manager of County Sanitation Districts of Los Angeles County and later Chairman of the State Pollution Control Board of California. This Board was instructed to "review the system of trunk sewers, interceptors and sewage disposal in and around Burrard Peninsula and to submit a plan and report with recommendations and advice, indicating the steps that should be taken and their probable sequence to provide completely for the collection and disposal of the surface waters and sewage and the type of treatment processes that may be necessary to ensure the protection of bathing beaches and sanitarily acceptable conditions in the Sewerage District and in the surrounding rivers and sea waters.[7] Hope was expressed "that all the municipalities adjacent to the waters both north and south of the Burrard Peninsula from Pitt River to the Strait of Georgia will become interested to the end that sewerage facilities for the whole area may be logically planned in advance of its growing requirements".[8]

The investigations and studies carried out by the Consulting Board were comprehensive and complete. They included the physical, social and economic conditions of the five cities, five municipalities and three unorganized areas in the Lower Mainland and north of the Fraser River to be served with sewerage and drainage. A comprehensive survey of the tidal pattern in the estuary of the Fraser River, the Strait of Georgia, English Bay and Burrard Inlet covering one whole year of tidal and climatic conditions was carried out by experienced teams and the results evaluated by the Pacific Oceanographic Group of the Fisheries Research Board. Assistance was given by the Hydrographic Service of Canada, The Oceanographic Institute of the University of British Columbia and by the National Research Council.

The evaluation of the mass of data accummulated as to the current pattern, density and oxidizing capacity of the receiving waters indicated the appropriateness and feasibility of the points of discharge chosen and the nature of treatment works required.

In its letter of transmittal the Board of Engineers summarised its findings in these terms:

"Full information concerning the investigation is presented in the report. An analysis has been made of all sewerage projects considered feasible and each such project has been evaluated in terms of both general suitability and total cost. Methods of storm water drainage have been studied and costs approximated for providing the minimum degree of service commensurate with protection from flooding due to storm waters.

"The sewerage projects found to be the most economical and satisfactory involved the conveyance of sewage for final disposal to eight locations. Of these, five are tributary to the Fraser River, two to Burrard Inlet and one to the Strait of Georgia. At all but two of these locations conditions are such that sewage can be discharged to the receiving waters without treatment. At these two locations, treatment of sewage will be required. A treatment plant would be constructed on Iona Island to treat the sewage of the western portion of Burrard Peninsula and of Sea Island prior to discharge to Strait of Georgia and a treatment plant would be constructed adjacent to First Narrows to treat the major portion of the sewage produced in the North Shore section before discharge to Burrard Inlet.

"A joint agency similar to the Vancouver and Districts Joint Sewerage and Drainage Board should be formed within the Greater Vancouver area to finance, construct and operate the facilities recommended in this report. The fairest and most equitable distribution of costs will be achieved if each of the political entities within the area assume a proportion of the total annual cost of each project."[9]

The reception of the municipalities when the report was presented in

September 1953 was mixed. Only those municipal members of the then existing Vancouver and Districts Joint Sewerage and Drainage Board accepted the invitation by the Provincial Government to accept membership in a newly constituted corporation others preferring "to go it alone". (New Westminster asked to be excluded although a member of the former Board). It was not until April 1956 that the new corporation under the title of Greater Vancouver Sewerage and Drainage District was constituted by Provincial Statute. Its members were Vancouver, Burnaby, and University Lands. Within the subsequent two years however, three other municipalities saw the advantages of membership and petitioned the Executive Council of the Province to include them in the Corporation. Those added were the Municipality of Coquitlam, the Municipality of West Vancouver and the City of Port Moody. Their inclusion was accomplished by Order-in-Council of the Provincial Executive.

It is fair to state that the reluctance of some of the other municipalities situated in the Lower Mainland to throw in their lot with the new Corporation was not one of dislike of an ad hoc form of corporation to carry out the functions of sewage and drainage disposal, rather it was one of dislike for the proposal as recommended by the Board of Engineers that all members share in a proportion of the total annual cost of each project. The indeterminate costs involved in this formula due to timing, future costs of facilities and other factors, without a doubt deterred them from accepting membership.

As it turned out the legislation constituting the new Sewerage District as finally passed removed what was considered this objectionable provision of the Bill. The annual fixed charges and operating costs of all facilities constructed by the Board are charged only to the member or members who receive benefit from the facility. Where a facility is shared by two or more members the fixed charges and operating costs are shared on a basis of the land and improvement assessments situated within the drainage area served by that facility.

In the four years since re-constitution of the Sewerage District a number of sewers have been built and are in use by the members. The sewage plant on the North Shore—to serve West Vancouver only—has been designed and is under construction. The completion date is programed for spring of 1961. The Iona Island plant has been designed and tenders for it will be called before the mid-year 1960.

The initial construction of the Iona Island primary treatment plant is designed to serve 320,000 population, with an ultimate of 640,000.[10] It is designed for an average dry weather flow of 65 c.f.s.—ultimate 130 c.f.s. The interceptor which transports sewage through a tunnel from the north side of Burrard Peninsula to the north bank of the Fraser River opposite Iona Island, is about three miles long and has a capacity of 400 c.f.s. peak storm flow. The construction for this tunnel was commenced in January 1960 and will be completed in about two years. The total cost of Iona plant including the Highbury intercepting tunnel, crossing of the North Arm of the Fraser River, the effluent channel and dyke across Sturgeon Bank and other appurtenances carries a preliminary estimate of $17 million.

Its completion in 1962 and the later construction of ancillary interceptors, will remove discharges of crude sewage into the south side of English Bay except for an average of one storm overflow of dilute sewage per recreational season from the short outfalls and for an average of three storm overflows per season from the Discovery Street Outfall. The construction of this facility will improve very materially the sanitary conditions of the shores and beaches in this area.

Existing Legislation for Control of Water Pollution in B.C.

There is much legislation on the Federal, Provincial and Municipal statute books to control pollution of rivers, streams and tidal waters of British Columbia. In his review of Pollution Control legislation in British Columbia, Mr. R. Bowering, Director —Division of Public Health Engineering, Department of Health and Welfare, Province of British Columbia, points out that in the Health Act of British Columbia there has been legislation for the control of pollution since the early 1870's and also that the Federal Fisheries Act—with amending Orders-in-Council, has been in existence for many years.[11] He points out however, that all legislation in respect of pollution has over the years been enacted giving various government departments or agencies authority to enforce pollution control measures in order to achieve definite objectives inherent in their own function and responsibility. The Health Act in this regard has as its objective prevention of unsanitary and unsightly nuisances and the protection of the public health. The Fisheries Act has as its objective the prevention of pollution which would result in harmful conditions to the migration, propagation and conservation of valuable commercial and sports fish resources of the lakes, streams and salt waters.

This weakness in legislative control of pollution, however, has to a large extent been rectified, for on 1st of April, 1956 a Pollution-control Board was constituted with wide powers and duties. This Act at the present only applies to the Lower Mainland communities and adjacent waters and its provisions also are not deemed contrary to the Provincial Health Act, the Municipal Act or the Water Act but an "extension of such Acts for the public interest".

Table I indicates the various government authorities having control over pollution in British Columbia.

The hazards of public health that may be caused by pollution and against which the Health Act has for many years waged a continuous battle against increasing odds are:

1. Pollution of domestic water supplies with sewage;

2. Pollution of domestic water supplies by industrial wastes charged with materials dangerous to human beings;

3. Pollution of shellfish growing areas by domestic or industrial wastes;

4. Contamination of bathing beaches by sewage discharges;

5. Contamination of agricultural products by irrigation of crop with contaminated water or by treatment of soil with human excreta—untreated or partly treated.

Despite the overall provisions of the newly constituted Pollution-control Board, the Department of Health still maintains strict control over public water supplies by making it mandatory for municipalities and private developers to submit plans for approval before development is commenced. Such approval is supplemented by inspection and laboratory testing of public water supply systems for sanitary hazards.

All plans and specifications of public sewerage systems must be submitted to the Minister of Health before construction and, where money by-laws are required, submitted to electors for approval. The certificate of approval must be issued by the Minister of Health before submission.

10. Sewerage and Drainage of Greater Vancouver Area, B.C. Gilman Hyde, Rawn and Oliver.

11. Proceedings of 6th B.C. Resources Conference — 1953 "Pollution Control in B.C. Today" by R. Bowering, Director, Div. of Public Health Engineering, Dept. of Health and Welfare.

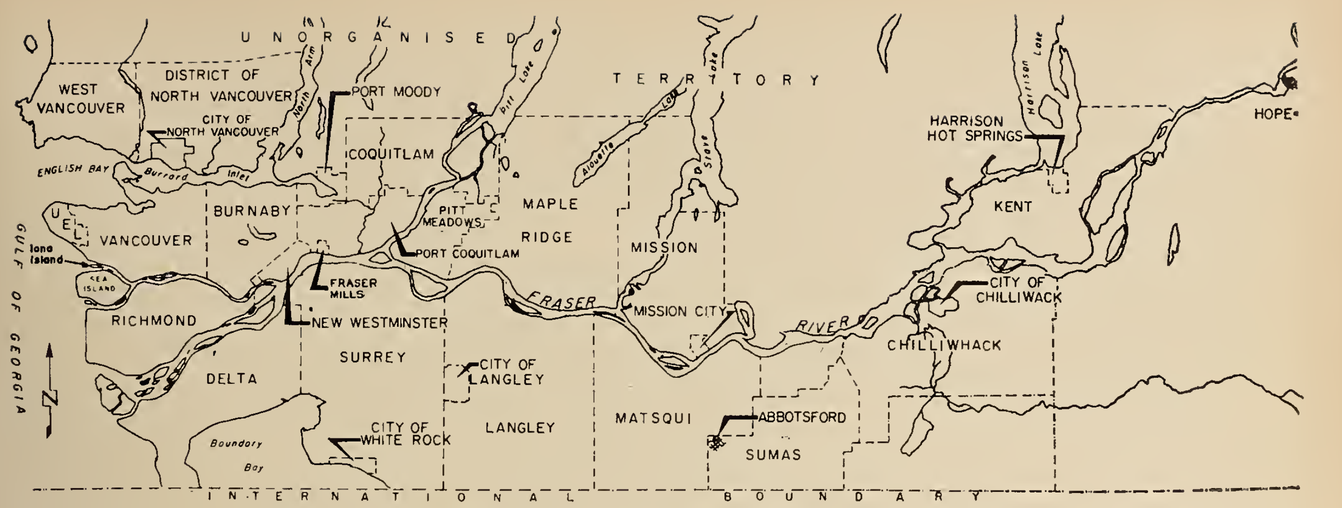

Fig. 2. Lower Mainland Communities of British Columbia, West of Pitt River.

Probably about a half of the population of the Province is served by public sewerage systems. In the Lower Mainland area this percentage is somewhat higher. However, most of the sewage to date is not treated. Table II indicates those municipalities and communities in the Lower Mainland area which are served by some degree of treatment.

As the population growth and concentrations of population have increased, the hazards have likewise increased. Within the next several years a number of communities will be required to build treatment plants. As has been mentioned elsewhere, two treatment plants serving initially over 350,000 are under construction and will be completed within the next two or three years.

In several areas in the Province sewage disposal with resultant pollution has led to abandonment of bathing beaches in order to protect public health. In 1958 the beaches of Vancouver City were "posted" by the Park Board, under whose jurisdiction they fall, on the advice of the local health authorities that the quality of the water offshore had deteriorated below sanitarily tolerable limits. Greater Vancouver Sewerage and Drainage District installed a barminutor and a chlorinator on the Discovery Street Outfall and with a contact time of from 15 to 20 minutes brought the bacterial quality of the littoral waters again to tolerable limits set by the Provincial Authorities for bathing waters.

The other half of the population of the Province not served by public sewerage systems is served by septic tanks or in remote areas by privies. These are controlled by local Boards of Health and by the Provincial Department of Health and Welfare.

The Department of Health is instrumental, where feasible, in encouraging the setting up of watershed areas by local water or health authorities. The constitution of such areas permits very close control of catchment areas by virtue of "Watershed Regulations" promulgated by the Provincial Department of Health and Welfare. Such regulations prohibit access to watersheds except for specific reasons, require medical testing of all persons entering the catchment area and generally require extraordinary standards of sanitation.

The Department maintains laboratories in Vancouver and several smaller units in other parts of the Province where sampling and testing of local water supplies are carried out.

In summary therefore, over the years the Department of Health has been effective in controlling communicable diseases which may be caused by pollution. Since World War II the rapid expansion of population has materially increased the Department's problems but it has carried out an energetic program of health education which has resulted in the gradual acceptance of the organized communities of the urgency for adequate and modern sewage disposal facilities.

Legislation Under the Fisheries Act

The Federal Fisheries Act was enacted to protect both commercial and sport fishing in Canada. In British Columbia the Federal Department of Fisheries is responsible for protection and conservation of marine and anadromous fishes.

The Fish and Game Branch of the recently constituted B.C. Department of Recreation and Conservation (formerly B.C. Game Commission), is responsible for the conservation of the nontidal sport fisheries. The Fisheries Branch of the Department of Recreation and Conservation (formerly the Provincial Fisheries Department), regulates nontidal fisheries and marine shell fisheries.

The Fisheries Act provides that it is unlawful to pollute water with materials that are deleterious to fish.[13] In this regard the Fisheries agencies in British Columbia have special regard for pollution due to:

1. Organic effluents in quantities which in the decomposing processes remove sufficient oxygen from the water below the level at which fish and aquatic life can survive:

2. Industrial wastes containing materials which themselves are lethal to fish or aquatic life on which fish feed;

3. Certain substances cast off from industrial processes such as mining and smelting wastes, sawdust, canning discharges, pulp mill liquors or oil wastes. These can be frequently lethal to fish, or may silt up the streams so as to prevent migration of fish, spawning processes or growth of food.

Water Act

Under the Water Act the Comptroller of Water Rights may restrain a water licensee from polluting the stream or lake under licence to him, where use by the licensee is detrimental to other licensees on the stream or to the public interest. While this provision is not often used it can be invoked when and where pollution conditions have reached an impasse.

Pollution-control Board—2nd March, 1956

From the above remarks relative to pollution control in British Columbia it will be seen that legislation has to a point been quite effective in controlling pollution where it ran

13. The Fisheries Act (Federal)

counter to the public interest in certain cases. Prior to 1956 there was no agency to deal with the overall pollution problem as such.

Officials and commercial agencies for a long time felt that some such agency was badly needed. Pollution of lakes, streams and tidal waters for the most part was still in the preventive stage and if effective measures were promulgated before the problem became a major one in the Province much of the natural-resource potential of the waters of the Province would be prevented from becoming degraded if not completely lost.

Recognizing the need for such an agency the Provincial Legislature enacted in March, 1956 the Pollution-control Act concurrent with the reconstitution of the Vancouver and Districts Joint Sewerage and Drainage Board. This Act set up a Pollution-control Board with wide powers and duties relative to pollution of the waters of the Lower Mainland.[14]

Its preamble reads as follows: "Whereas it is deemed in the public interest to maintain and ensure the purity of all waters of the Province consistent with public health and the public enjoyment thereof, the propagation and protection of wild life, birds, game and other aquatic life and the industrial development of the Province: and whereas it is deemed expedient to require the use of all known available and reasonable methods of industries and others to prevent and control the pollution of the waters of the Province. Now therefore, Her Majesty . . ."

Some of the provisions of the Act are:

1. It defines pollution as "anything done, or any result or condition existing, created, or likely to be created, affecting land or water which, in the opinion of the Board is detrimental to health, sanitation, or the public interest.";

2. *Section 3(1)*. There shall be a board to be known as the "Pollution-control Board" which shall consist of a chairman and such other members as the Lieutenant-governor in Council may from time to time determine;

Section 3(2). The members shall be appointed by the Lieutenant-Governor in Council for such term or terms as the Lieutenant-Governor in Council may determine;

Section 3(3). The Board may determine its own procedure and may elect an acting chairman in the absence of the chairman.

The Board shall have the following powers and duties: (Section 4)

(a) To determine what qualities and properties of water shall constitute a polluted condition;

(b) To prescribe standards regarding the quality and character of the effluent which may be discharged into any waters within the area or areas under the jurisdiction of the Board;

(c) To conduct tests and surveys to determine the extent of pollution of any waters within the area or areas under the jurisdiction of the Board;

(d) To examine all existing or proposed means for the disposal of sewage or other waste materials, or both, and to approve the plans and specifications for such works as are deemed necessary to prevent pollution of the waters of the area or areas;

(e) To notify all persons who discharge effluent into the said waters when the effluent fails to meet the desired standards;

(f) To order any person after six months from date of notification or such longer period as may be determined by the Board to increase the degree of treatment of the effluent or to alter the manner or point of discharge of the effluent being discharged by such person to bring the effluent up to the prescribed standards;

(g) To order any person who fails to comply with an order issued under Clause (f) to cease discharging effluent into any waters in the area as and from a day and time specified in the order.

The Act provides penalties for contravention of the Act or any order of the Board (Section 5). The Act provides also an appeal from any order, determination, or decision of the Board, shall lie to the Lieutenant-Governor in Council, whose decision thereon shall be final and binding. Such appeal must be made within 30 days from the date of any order, determination or decision of the Board.

Section 7 provides—no person shall discharge sewage or other waste materials into the waters of the area or areas under the jurisdiction of the Board without the permission of the Board. Such permission may be in the form of a permit, which may prescribe the degree of treatment of the effluent as well as the location of the point of discharge into the waters of the area and the manner of the discharge as a condition of the permission.

Section 8—provides there may be made available to the Board by the Health Branch of the Department of Health and Welfare such engineers, inspectors, technicians, officers, clerks and employees as are necessary for the administration of this Act.

Section 9 authorizes that members of the Board shall be paid such remuneration as may be fixed by the Lieutenant-Governor in Council, and such actual expenses as may be incurred by them in the discharge of their duties.

Section 10—any moneys required for the administration of this Act or for carrying out the provisions of this Act shall, in the absence of any vote of the Legislative Assembly available therefor, be paid out of the Consolidated Revenue Fund.

Section 11 provides that the Minister of Municipal Affairs shall be charged with the administration of this Act.

Section 12 provides that—notwithstanding the provisions of any other Act, the provisions of this Act shall apply to:

14. Pollution-control Act — Chapter 36 — 1956

TABLE I

Government Authorities Having Control over Pollution in British Columbia.

1.	Federal	Dept. of Fisheries	"Fisheries Act"
		Dept. of Resources and Development	"Migratory Birds Regulation Act"
		National Harbours Board	"National Harbours Bd. by-laws"
		Dept. of Transport	"Navigable Waters Protection Act" "Canada Shipping Act"
		Dept. of Health and Welfare	Advisory to International Joint Commission relative to pollution of boundary streams.
		Dept. of Public Works	"Navigable Waters Protection Act"
		Local Port Authorities—Dept. of Transport	"Navigable Waters Protection Act"
2.	Provincial	Health Branch—Dept. of Health and Welfare	"Health Act" of B.C. Sanitary regulations under Health Act
		Water Rights Branch—Dept. of Lands and Forests	"Water Act"
		Dept. of Municipal Affairs	"Pollution-control Act" 1956
		Dept. of Recreation and Conservation	"Dept. of Recreation and Conservation Act, Ch. 53-1957"
		(a) Provincial Parks Branch	Park regulations
		(b) Fisheries Branch	Federal legislation regarding fish—"Fisheries Act"
		(c) Fish and Game Branch	Federal legislation regarding fish—"Fisheries Act" "Migratory Birds Regulation Act"
3.	Municipal	Local Boards of Health	"Health Act" of B.C. "Sanitary Regulations" under Health Act "Municipal Act—1957" (Sections 531, 634 and 635)

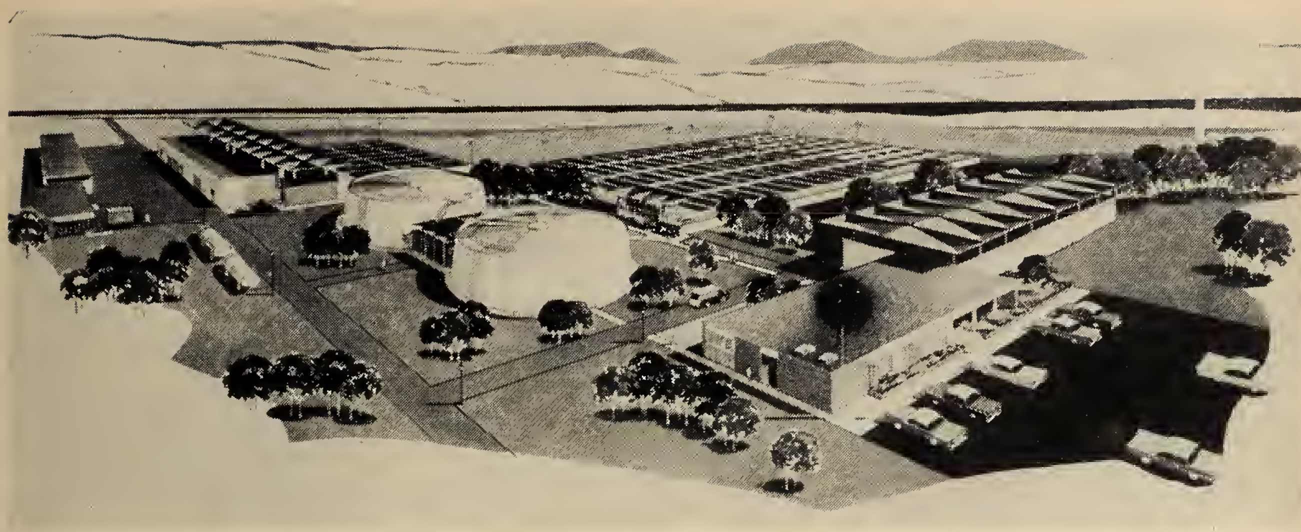

Fig. 3. Iona Island Sewage Treatment Plant.

All the areas of land, contained within the boundaries of a municipality draining by natural or artificial means, into the Fraser River or its tributaries from the Village of Hope to the Strait of Georgia or into Boundary Bay or into the area of the Strait of Georgia contained within a line drawn from the International Boundary-line at longitude 123°-15′ to Halfmoon Bay or into Burrard Inlet.

Any area designated by Order of the Lieutenant-Governor in Council.

Section 13—The provisions of this Act shall not be deemed contrary to the provisions of the Health Act, the Municipal Act or the Water Act but shall be considered an extension of such Acts for the public interest.

Section 14—For the purpose of carrying into effect the provisions of this Act according to its true intent or supplying any deficiency therein the Lieutenant-Governor in Council may make such regulations not inconsistent with the spirit of this Act as are deemed necessary or advisable.

A glance at a map will show that the area covered by this Act is approximately the same area covered by the discussions of this paper. Section 12(b) provides that the Act can readily be extended to other areas of the Province by Order-in-Council. When the Act was passed it was indicated that data and experience gained in administration of the Act in the limited area defined would at a later date make appropriate enlargements relatively simple.

The Board, consisting of seven members, was constituted by Order-in-Council after the Act was promulgated. The Executive Council appointed the Deputy Minister of Municipal Affairs as Chairman and three government officials, namely the Comptroller of Water Rights, the Deputy Minister of Health and Welfare and an official of the Department of Fisheries.[15]

Three members were appointed pursuant to recommendation made by three groups of municipalities. The municipalities north of Burrard Inlet, three in number, recommended one member. The Burrard Inlet municipalities, eight in number, recommended one member. The Fraser-Delta municipalities, three in number, appointed one member. The original seven members still serve.

In the four years since the Board was constituted it has dealt with approximately 40 applications. Applicants for permits are required to file preliminary plans detailing the nature of effluent to be discharged into the receiving waters, the point of discharge, area of land and population to be served, type of treatment proposed and other relevant information. Applicants must display in the local newspapers and in the B.C. Gazette a copy of their application and in addition "post" the application at the point of discharge.

Application for Authority to Build and Operate a Primary Sewage Treatment Plant on Iona Island

Perhaps the most important application dealt with by the Board was that of Greater Vancouver Sewerage and Drainage District for authority to build the primary treatment plant on Iona Island to eventually service all of the University Lands, the City of Vancouver and westerly portion of Burnaby.

This plant, to be constructed on Iona Island (a sand bar of 180 acres in area, in the North Arm of the Fraser River) is planned as a high-rate primary plant with effluent discharge to the tidal waters of the Strait of Georgia through an effluent channel. As reported, the ultimate capacity of the plant is to serve 640,000 population with an initial population of 320,000. The effluent channel will traverse Sturgeon Bank, a tidal flat, for about four miles to deep water. Parallel and north of this channel will be constructed a dyke to deter the highly diluted primary effluent from reaching the southerly side of the island and its westward extension.

Strong disapproval of the application was made by the Municipality of Richmond, in which municipality the plant is to be situated. The Pollution-control Board in due course held a public hearing. It granted the application, making at the same time specific requirements as to the bacteriological conditions of the receiving waters after the plant was placed in operation.[16]

In general these criteria are:

1. The quality and character of the water south of the proposed dyke shall be determined by systematic sampling. The median M.P.N. (most probable number) of coliforms in that water shall not be greater than 35,000 per 100 ml. for any year, nor greater than 10,000 for any five month period from May to September inclusive (the recreational months). Dissolved oxygen shall never be less than 5 p.p.m. If any of these criteria are not met the Greater Vancouver Sewerage and Drainage District shall, without undue delay, take whatever steps are necessary to improve the quality of the water at least suffi-

15. This Department now included in the Department of Recreation and Conservation as "Fisheries Branch".

16. Order No. 23 of Pollution-control Board — April 2nd, 1958

ciently to meet the criteria demanded. Sampling points, methods of sampling, at what stages of tide they are to be taken and other directions were specified.

2. The quality of the water at Iona Beach as determined by systematic sampling shall conform to the following: If the median M.P.N. of coliforms per 100 ml. exceeds 240 in any period between May and September inclusive, the Greater Vancouver Sewerage and Drainage District shall, if requested by the Pollution-control Board, improve by whatever means may be required, the quality of the water at least sufficiently to meet the prescribed criteria.

A comparison of these criteria with those used on the Pacific Coast and other points in North America will indicate they are as stringent as any. The Sewerage District proposes to chlorinate effluent at the Iona plant both before and after sedimentation, during the recreational season if necessary, to attain these criteria.

Appeal by Municipality of Richmond Against Order No. 23

Under Section 6 the Municipality of Richmond appealed the decision of the Pollution-control Board. The Provincial Cabinet heard the appeal, confirmed the decision of the Pollution-control Board but added additional provisos for measures which the applicant must carry out. In its amending order it set the following criteria for condition of water off bathing beaches in the English Bay area, these beaches on the northerly side of English Bay being in an area quite remote from the Iona Plant.[17] These additional provisions are:

1. The Iona plant is to be adequately designed and appropriately landscaped to prevent impairment of the recreational amenities of Iona Island and beach.

2. There must be no public nuisance by offensive odors from plant and works.

3. That conditions, as indicated above by Pollution-control Board Order, apply to beaches at English Bay, Third Beach, Second Beach, English Bay Bathing Beach, Kitsilano Beach, Jericho Beach, Locarno Beach and Spanish Banks.

4. That Greater Vancouver Sewerage and Drainage District indemnify the Corporation of Richmond for impairment of the recreational amenities arising out of breach of the imposed conditions and enter into a written agreement with the Corporation therefor. (This was done in due course by filing a document in a form of guarantee as required by the Order-in-Council).

The above is recited in some detail in order to indicate to what extent the Provincial Government and its instrumentalities are prepared to go in order to effectively control pollution. On the basis that "an ounce of prevention is worth a pound of cure" their intent in this regard is to be highly commended.

Watershed Control

No paper on pollution control in the Lower Mainland communities would be complete without a reference to the matter of watershed management control. Reference has already been made to the encouragement, at the Provincial level, of the setting up by local Boards of Health or Water Authority of closed watershed areas with strict regulations of access and imposition of rigid control where access must be permitted even on a limited basis.

A number of the larger communities in the Lower Mainland area under review and two on Vancouver Island (Victoria and Nanaimo) have acquired by outright ownership or lease the catchment areas of their watersheds, thereby preventing housing, industrial development, logging (in most cases) and uncontrolled hiking, skiing and fishing.

Probably the most comprehensive example of this protection is that of the catchment areas of Greater Vancouver Water District. The Greater Vancouver Water District is a metropolitan district composed of four cities, ten municipalities and two unorganized areas serving a population of about 750,000. Its three catchment areas total 226 sq. miles situated in the rough mountainous country north and east of Burrard Inlet.

By farsighted action taken soon after the Water District's inception in 1926, about 80% of the land is held for waterworks purposes by a 999 year lease of Crown lands. The other 20% is virtually all held in fee simple, the land having been purchased as opportunity offered. The catchment areas are reserved against public access under the watershed regulations. They are declared also to be reserved from being entered on, prospected, mined, located, recorded or acquired

17. Order-in-Council 2167 of the Executive Council of the Province of British Columbia. September 22nd, 1958.

White Rock, City of	6,200	5,500 (3)
*University Endowment Lands (including U.B.C.)	4,600	
Total	853,910	
Population of Province, Dec. 31st, 1959	1,570,000	

* Vancouver, Burnaby (portion) and University Endowment Lands to be serviced by Iona Island plant—first unit 320,000 population, ultimate 640,000. First unit to be completed 1962.

. West Vancouver—Hollyburn Drainage Area—plant under construction First Narrows. First Unit 32,000 population to be completed in 1961. Ultimate 64,000.

(1) Army Camp at Sardis—Primary clarifier—chlorinated effluent discharging into Chilliwack River.

(2) West Lynn—District of North Vancouver, Dorr Oliver Duo clarigester with high rate filter.

(3) White Rock—Activated sludge plant.

(4) Horseshoe Bay—West Vancouver. Large septic tank discharging into Horseshoe Bay.

(5) Ranch Park—Coquitlam. Fairbanks Morse spiragester and chlorination.

(6) Essondale—Mental Hospital. Septic tanks serving individual buildings.

(7) Lulu Island—Richmond. Primary treatment discharging into Middle Arm of Fraser River.

(8) Oakalla Prison Farm. Inhoff tank and secondary treatment discharging into Deer Lake.

under the Mineral Act and the Placer Mining Act. The area is also set up as a reserve against trapping, hunting and fishing.

Other municipalities in the Lower Mainland which have catchment areas protected in a similar way are West Vancouver, City of North Vancouver, the City of Mission and the Elk Creek Water Company's catchment area which serves the City of Chilliwack and environs. Such rigid control gives excellent protection against ravages of forest fire in summer months with consequent loss of forest cover and the accompanying problems of rapid run-off and high turbidity. The protection of the water supply by total exclusion of the public is one of good fortune indeed. With ability to carry out this program by virtually complete ownership of the catchment areas situated so close to the center of population, advantage can be taken of economies inherent in short supply mains, no treatment of the water except chlorination and little risk of contamination by human agency. The catchment areas are covered with dense forest growth. It is quite possible in the interests of a thrifty forest that a program of selective cutting under rigid control of the cutting operations may be undertaken in the future. Much of the timber is mature, some over-mature and decadent.

A program of cutting of mature and over-mature timber would improve the forest and provide a useful income from sale of timber which should be ploughed back into improvement of the forest, the removal of snags and the provision of jeep roads for fire suppression.

Conclusion

The rapid growth of the Province since World War II has brought many problems to the Province, amongst these that of pollution of its waters. At all times a persistent follower of economic development, its presence is inevitable — perhaps in some aspects desirable, but its control within tolerable limits is and will always be difficult.

In the United States it was not until recent years that water resources appeared to be running short. Due to greatly increased population, the almost explosive increase in use of water and the gross pollution of many of its water resources, the country became alarmed and a major program of controlling the deterioration is being carried out at both the State and Federal levels.

In British Columbia we have been fortunate that the experience of other industrial countries in this regard has had its impact on our own thinking before it is too late. Our growth has been phenomenal in recent years and with this growth pollution problems have increased to a point where they are potentially becoming chronic. Due to our other urgent preoccupations the economic depression of the 1930's and the war of the 1940's set back the time when these problems might have received attention.

However the diligence, dedication and persistence of people at government, university and industrial levels has awakened the government and the people to the dangers. Public bodies too have persuaded governments that preventive measures must be undertaken. The reconstitution of the Vancouver and Districts Joint Sewerage and Drainage Board and the creation of the Pollution-control Board after some years of delay, have enabled both Authorities to carry forward their well defined programs of prevention and abatement of pollution in their respective areas.

While some of the trouble spots may not be eliminated overnight — financial and other difficulties will defer them — there is satisfaction in knowing, first of their existence and their scale of pollution, and secondly that there is a well-ordered plan for their elimination. In due course these corrective measures will be carried out. Future generations will be thankful for the diligence of the Authorities in initiating preventive measures during this decade before it is too late to effectively remedy what would develop into a catastrophic condition of environmental waters.

H. L. Hogge, M.E.I.C.
Provincial Sanitary Engineer, Department of Public Health, Government of Alberta

Stream pollution studies are conducted by the Provincial Department of Public Health through the Division of Sanitary Engineering. The data obtained are used to assess the need for waste treatment and also to evaluate the efficiency of control measures. The critical period is winter when ice cover prevents reaeration and the streams are at minimum flow. This has resulted in two significant methods of approach to pollution control, viz. the amount of polluting materials which may be released to a stream is in many cases prorated to river flows and secondly, the method of control by industry includes incineration or ponding. Ponding is a suitable solution because ponded wastes may be released when higher flows and open waters are present. The great reduction between summer and winter in the capacity of a river to absorb oxygen-demanding wastes is shown. One phase is the control of odours; brief mention is made of the effect of a petroleum type odour on fish. Each river is dealt with separately; the probable minimum flows, the critical polluting materials and the existing pollution loads are discussed. The Edmonton area and the North Saskatchewan River are dealt with in detail, as this is the largest center of population and industry in the province. The effect of secondary treatment of the City of Edmonton sewage on the dissolved oxygen content of the river is shown. Similarly the reduction in phenolic and odourous materials in industrial waste is tabulated.

THE ADVERSE effects of pollution, including in extreme cases the stifling of industrial growth, are well known. Many articles and examples could be quoted to justify the maxim that water in large quantity and of good quality is a vital necessity where the growth of populations requires that the growth of industry keep pace to provide full employment and maintain a good standard of living.

It is believed that the situation in Alberta will be of interest because of several factors which are unique to the west central plains area, the most critical of which is the heavy ice cover on the streams for as long as five months of the year.

Prior to 1940 the population and industrial growth in Alberta was such that the streams in the Province were capable of handling the wastes poured into them without any evident ill effect. By 1949, conditions had changed considerably and the Department of Public Health through the Division of Sanitary Engineering began a program of stream sanitation studies. These have continued since that time and the data obtained have made it possible to fully assess the pollution load, set up a logical method of dealing with pollution and forecast for some years the waste treatment that will be necessary. General objectives have been set up for the streams in the province and it has thus been possible to work back to cities and industries and allocate to each an allowable pollution load. As an example, the allowable pollution load for the North Saskatchewan River at various levels of flow was determined and this load distributed among municipalities and industries as pounds per day of B.O.D.. and phenols. Similarly limits were set for other pollutants.

In presenting the data in regard to this province it is intended first to point out those factors which although they may not be unique, are factors which are common to the streams in the Province.

Flows — The major source of water in the rivers on the prairies is the mountain areas to the west. The total preciptation in Alberta averages about 15 in. per yr. but there is a large loss through evaporation and transpiration, so that for streams in the Province which do not rise in the mountains the average runoff can be as low as 20 acre ft. per sq. mile or about one fortieth of the average precipitation. In the area to the south of the Athabasca River there are no large lakes; those lakes which exist are small if one considers the amount of storage they afford in terms of some daily average flows in a stream. These lakes and the streams flowing from them are now in equilibrium and to augment the low flows it would be necessary to create storage.

The mountain areas receive more snowfall than the prairie areas and it is from the mountain snow melt that the major flows occur. The peak flows therefore occur in the summer months from May to September and usually during the period of hot weather in June and July. Conversely the low flows occur during the colder months when there is no snow melt and the water comes from mountain lakes and seepages of ground water.

An interesting river in this regard

is the North Saskatchewan. From Edmonton to Prince Albert (a distance of about 350 miles) the flow is substantially constant; the river neither gains nor loses water in this distance in the winter months. In the Red Deer River the flow decreases during the winter months between the gauging station at Red Deer and the downstream one at Empress.

The maximum flows are not critical for pollution but in some cases the high summer flows are used to dispose of strong wastes which could not be released during the winter months. Table 1 illustrates the variations in the flow in the main rivers for the year 1954-55 which is considered to be an average year.

Since pollution is a matter of degree, one of the key factors in control is a study of river flows, particularly the probable minimum flows. Since the critical months occur in the winter period, the data for plotting were compiled by taking from the Dominion Hydrographic records, the lowest monthly average flows in each of the winters on record. The simplest approach was used and the data were plotted on arithmetic probability paper on which most of the data provided a line of reasonable fit, although some rivers showed well defined breaks at the median values. In order to show most of the rivers on one plot the ordinate "R" was taken as the ratio of the flow for the point of computation, to the average flow for the low winter months on record, in addition; only the lower portion of the plot is shown. The probable low winter flow for any given percentage of time may be found by multiplying the ordinate "R" by the average for that stream shown in Table 2.

For example the lowest average monthly flow which might be expected in the North Saskatchewan once in ten years would be found in the following manner: at 10% of time (once in ten years) the value of "R" is 0.72. The average of the minimum monthly average flows on record is 1,080 c.f.s. (Table 2, Col. 3). The expected low flow would be 780 c.f.s., i.e. 0.72 x 1,080.

In Alberta the probable minimum low flow which is expected to occur not more than once in ten years is used as a basis of computations for determining allowable pollution.

Ice Cover — Ice cover exists on the rivers for a period of several months of the year, during the period of low flows. While there are open points in the upper reaches of the rivers in the foothills, the longer stretches through the prairies are continuously covered with ice. In a normal winter this may reach a thickneess of over 3 ft. It is interesting to note that river ice is often of greater thickness than is the ice on lakes in the same area. The dissolved oxyxgen in the stretches which are not affected by pollution is very close to the saturation value, varying from 10 to about 12 p.p.m. In the freeze up period, which may be due to a cold spell of several days at very low temperatures, a phenomenon occurs as follows: the dissolved oxygen in the river is increased sometimes above the saturation point and the flow is reduced considerably. It is not uncommon to find that for a week or so the flows in the month of November or December will fall to a very low figure in comparison to the flow immediately preceding and following that period. Fig. 1, a hydrograph of the North Saskatchewan River for the period, September to May for the years 1954-55 and 1955-56, illustrates the seasonal variations of the rivers (note the low flows in November 1955).

Ice cover has a serious effect on the capacity of a river to absorb wastes. This is because the ice prevents reaeration and the accompanying resupply of oxygen. Fig 2 illustrates this point. Lines 1, 2, 3 and 4 are based on normal equations used for computing oxygen balance. The population equivalent in terms of Biochemical Oxygen Demand (B.O.D.) was computed on a basis of 0.17 lb. of 5 day 20° C. B.O.D. per capita per day. (Ref. 1 Page 175—Phelps Stream Sanitation.) The values of the constants used in this plot are given in Table 3.

TABLE 3

Values of Constants used in Fig. 2

Curve	*Temperature*	"k_1"	"k_2"	*tc (days)*
1	20°C	0.1	0.5	1.75
2	20°C	0.1	0.4	2.00
3	20°C	0.1	0.3	2.40
4	20°C	0.1	0.2	3.00

k_1 = rate constant for B.O.D. reaction
k_2 = reaeration constant
tc = critical time in days.

Line 5 is plotted on the basis that the ultimate first stage B.O.D. under ice cover in a river is approximately equal to the 5 day 20°C. B.O.D. The reduction in dissolved oxygen in the river approaches 90% of the B.O.D. and appears to be satisfied in about ten days. Fig. 2 is drawn for point source of B.O.D. Multiple sources would give higher allowable total population equivalents except for the

case of ice cover (Line 5) where population equivalents are directly additive.

In addition to the reduced reaeration, the low temperature under the ice lowers the general biological activity of the stream thus permitting contaminants to travel much further.

Turbidity — The turbidity in the rivers is high in the flood season when the snow melts and when rainfall occurs. This turbidity may be of the order of 2,000 p.p.m. or more, and at the peak periods it causes considerable trouble in the intakes for the various cities and industries taking water from streams which have this characteristic. At first hand it can be noted that a sample of water taken from the North Saskatchewan River may have as much as ⅛ in. of sediment in a sample which is taken in a bottle 10 in. tall. It is true however, that this occurs only for a short period of the year, seldom for more than a few weeks. During the winter period turbidity and colour is extremely low giving the water a clear sparkling appearance.

Spring Runoff — It may be interesting to note that spring runoff does not usually cause floods in the rivers. Floods are often evident in rural areas where low roads are flooded, but the flows in the main rivers are not exceedingly high. This may be explained on the basis that the snow melt in the mountain areas which was previously mentioned, does not occur at the same time as the snow melt on the prairies. Storm sewer design in a metropolitan area does not have to be designed for snow melt, since this takes place over several days and the resulting runoff does not approach in intensity the runoff from the conventional thunder storm.

Where the Rivers Flow—One other point which should be considered in connection with the rivers in Alberta is that all of them flow into another province or the Northwest Territories, except one river, the Milk River which flows into the United States. Saskatchewan is the only other province in Canada with this dubious distinction. This has a bearing on the allowable pollution in the rivers. If there were some streams which had ocean outfalls or emptied into very large bodies of water it would be possible to use some of these as open sewers if they were suitably located, and thus enable some industries with wastes which are difficult to treat to save some expense in their operations.

In Alberta an attempt has been made to prorate pollution loads to river flows. It is true that in some areas the laws which regulate stream

Fig. 1. Daily Discharge. For the North Saskatchewan River at Edmonton 1954-55 and 1955-56.

pollution set standards for various types of waste. This has been done because there is some uniformity in the type of waste which has to be dealt with, or the degree of pollution has been such that this was necessary. A more realistic approach, which does not in the least reduce the responsibility of an industry or a city to treat its wastes, is to set some limit to the concentration of the waste which will be permitted in the receiving stream. This last method of stream pollution control is a flexible one. It enables the control authority to set standards for plant effluents which vary with stream usage and dilution.

It has been found sufficient, in all rivers but the North Saskatchewan and the Athabasca, to specify only the general type of treatment that sewage or industrial wastes shall receive. Fig. 3, drawn for conditions of ice cover only, indicates the type of treatment required for municipal waste (sanitary sewage). The curves have been drawn for conditions of ice cover using 6 p.p.m. of dissolved oxygen (leaving 4 p.p.m.). It is assumed also that primary treatment reduces B.O.D. by 33% and secondary treatment by 90%. For any given river flow and for an equivalent population, the type of treatment required may be ascertained. The right hand scale gives the allowable B.O.D. load which varies directly with river flows.

In the case of the North Saskatchewan and in particular the Edmonton area several industries as well as the City contribute wastes to the river. It was necessary to distribute the allowable stream load to each municipality and industry. The allocation to each was made on the basis of need for disposal and the practical limit of treatment. The allowables were stated in pounds per day (phenols, B.O.D.) or in maximum concentrations in a definite volume of waste (odours). On the Athabasca a limit was set for the B.O.D. of the pulp mill effluent, in pounds per day. In each case the allocations were prorated to river flows.

In order to give a comprehensive picture of the existing state of pollution in the Province and of the various control measures being taken, the rivers in the Province will be taken in turn, beginning with the most northerly.

The Peace River

The Peace River is the largest of the rivers in the province, the average flow being 57,000 c.f.s., and the average monthly low flows in the winter being 7,000 c.f.s. At the present time there is no measurable pollution on this river. There are no industries located on the river in Alberta and the Town of Peace River is the largest centre (population 2,293). Although the situation will undoubtedly change in the future this stream is at present too far removed from the centres of population to be of aid in meeting the demands for waste dilution. There is a possibility that a power site will be located on the Peace River in B.C. If this occurs the flows in the river could be conceivably of the order of 36,000 c.f.s. at all times.

The Peace River is a tributary to the McKenzie. It flows close to but does not enter Lake Athabasca except possibly when it is at flood stage. The river is used in season for navigation purposes.

The Athabasca

The Athabasca River rises in the Jasper National Park, some of the flow beginning at the Columbia Ice Fields. The average flow is of the order of 6,600 c.f.s. and the winter flow is as low as 410 c.f.s. (Entrance). Not far from the gates of Jasper National Park is the Hinton town site and a large pulp mill. This mill has been in operation for a period of three years. The river is used as a source of water for the mill and the mill wastes flow into the river. Below this point the river courses for some 300 miles through very sparsely settled country to Smith, and then to the Town of Athabasca which uses the river as a source of raw water for the domestic water supply. Prior to reaching the Town of Athabasca the flow is augmented by the Lesser Slave River which although it is not a large river flows from Lesser Slave Lake and thus has a fairly steady winter flow which is of the order of 801 c.f.s. Below Athabasca the river flows on through the world famous tar sands at McMurray, and then on to Lake Athabasca which is in the north east corner of the Province. These waters then flow northward to the Arctic Ocean via the McKenzie River.

Since the pulp mill has been in operation numerous checks have been made to ascertain the degree of pollution in the river. The data obtained are summarized in Table 4.

There are several points which may be described in general terms. The main effect of the waste is to produce a high B.O.D. in the river, to cause considerable odour and to add to the colour of the water. These effects are more pronounced and prolonged in the winter period. In summer there are some odours arising from the river and at time there is a considerable amount of visible foam.

The condition of the river has been the subject of heated comments by some persons who have seen and used it for recreation in past years, when it was free of any pollution. This is understandable. However, where industry or large populations are centred it follows that the rivers will never be able to retain their original state of cleanliness.

The treatment provided at the mill consists of settling the cooking liquor and that part of the waste which contains the higher amount of B.O.D. and suspended solids. The total use of water at the mill is of the order of 25 m.g.d. The portion of the waste which is settled out is about 8 m.g.d. While these ponds are operating and provide the 72 hr. detention period for which they were designed, the suspended solids are reduced to about 10% of those going into the pond. There is only a slight reduction in the B.O.D. and little if any reduction of the colour and the odour of the effluent.

It is evident that this one pulp mill (450 tons per day) uses all of the available resources of the river. The odour number of the raw water in the Athabasca close to the mill at times reaches 150—this has occurred when the flow in the river was at about 1,200 c.f.s. It is felt that if the predicted 10 yr. low flow or a repetition of the low flows on record were to occur the water supply at Athabasca would be affected. Laboratory tests indicate that the removal of the odour would be difficult. In regard to the B.O.D. load from the mill, it will serve to give some measure of it to point out that it is very close to that of all of the wastes from the city of Edmonton and the surrounding industrial area.

When the mill was constructed it was realized that there would be adverse effects on the stream and a limit of B.O.D. was set so as to permit the mill an allowable load equal to one half of the dissolved oxygen in the stream at low flows.

Up to the present time the mill has not been able to meet these requirements. The problem is somewhat complicated in that the treatment of the waste is very difficult and there are few if any mills where the effluents have been successfully treated. Ponding of the effluent for a period of a few weeks in warmer climates has been successful. The cost of constructing such storage would be enormons at Hinton, and without the assurance of much benefit in the winter period.

TABLE 4

Pollution Data for the Athabasca River (Winter Values)—January 1960

Point of sampling	*B.O.D.*	*D.O.**	*Relative Color (500)***	*Odor No.*
Above Hinton................	0.15	12.0	70	0
Below Hinton (4 miles)........	5.8	10.8	115	150

Athabasca (420 miles).........	1.55	9.4	80	16

*An aerial reconnaissance by helicopter in January indicated that as there were several open points in the river some reaeration could take place.
**Run at a wave length of 500 mμ on a photocolorimeter.

The North Saskatchewan

The largest centre of population and major portion of the industry in the Province is located on the North Saskatchewan River at Edmonton. The population of the City and the suburbs is 320,000. The larger industries are: three oil refineries with a total capacity of about 50,000 bbl. per day, a plant which produces cellulose acetate yarns and various petrochemicals, an asphalt shingle plant and another chemicals plant. There are several other industries which are smaller or do not have liquid wastes of any consequence. These are the cement plants, the steel rolling mill, the plywood industry and a nickel refinery.

The industries mentioned are those which are located outside the City and have separate outfalls. Within the City there are a multitude of smaller industries and there are also three packing plants. These packing plants are one of the major sources of industrial waste both as to the quantity of water which they use and the quality of their effluents.

The impact of stream pollution struck the Edmonton area in 1953 when along with the already increasing B.O.D. load on the river a few more industries contributing to the waste flow were sufficient to exceed the load which the river could handle. One of the most striking effects on the river was the odour and taste present at Prince Albert in Saskatchewan and on into Manitoba. Although there were other contributing factors the main source of the odour was considered to be the primary oxidation unit at one of the chemicals plants. The plant was placed in operation in the fall of 1953 and the odour in the river became apparent at Prince Albert a few weeks after that time. In that year the only possible solution to the problem would have been to close down this plant which was not in itself the only source of wastes. The effect of a plant closure would not have cleared up the problem at Prince Albert for a matter of several weeks.

During the winter of 1953-54 a large amount of work was done to ascertain in this plant and from the other industries in the Edmonton area the source and the strength of the odours in their wastes, and to try to correlate these with the odour numbers in the river. The results of some of these odour tests are given in Table 5.

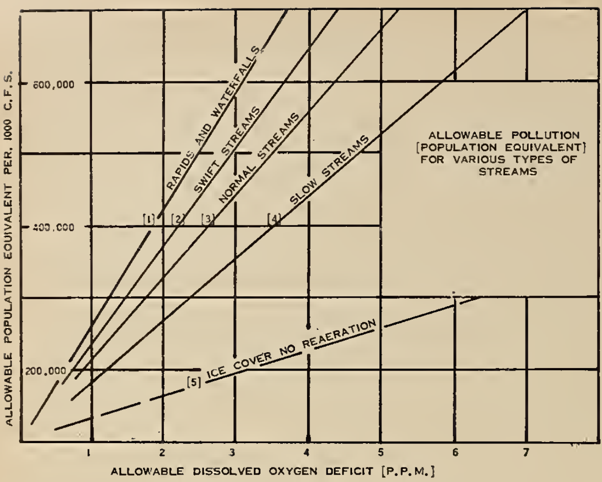

Fig. 2. Allowable Pollution for Various Types of Streams.

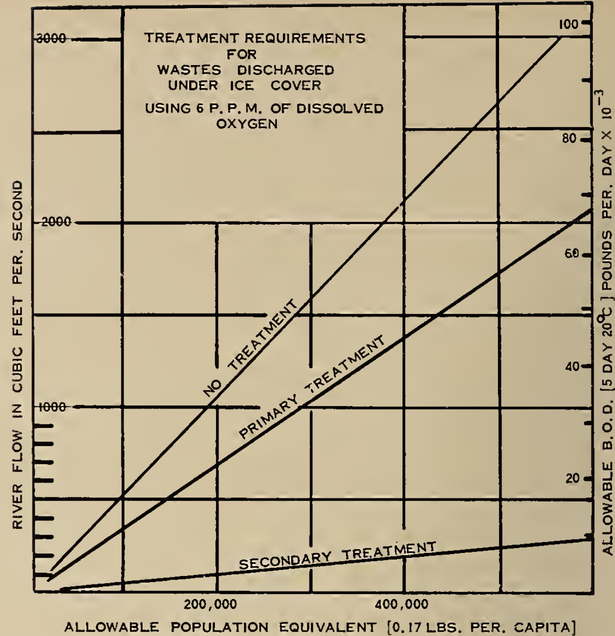

Fig. 3. Treatment Requirements for Waste Discharged Under Ice Cover.

At the same time other factors such as B.O.D., solids, colour etc. were being checked. Previously, some studies had been made as to the B.O.D. and the effect on the oxygen in the river, and an order had been issued to the City of Edmonton to improve sewage treatment facilities. Since this project necessarily involved financing arrangements as well as the time necessary for the drawing of plans and the construction of the plant a target date was set as the fall of 1954, at which time the City was to have the installations in working order.

There was little improvement in the river during the winter of 1953-54. In the spring of 1954 all of the industries in the area as well as the City met with the Provincial authorities to examine the data obtained and to plan the steps necessary to improve the quality of the river.

As a result of these meetings and the full co-operation of industry involved, standards were adopted for the river and permissible amounts of pollution were allotted to the city and industries. On the basis of the allowable loading of B.O.D., the City was allotted 60%, the Industries 20%, and 20% was left for meeting the needs of the future. The effluent quality standards required were comparable to those adopted by the International Joint Commission Report of 1951. In essence it meant that each industry was providing the maximum reasonable treatment for its waste. The word 'reasonable' here is from the outsiders' point of view, and not that of industry, although industry took steps to meet these requirements. For example one oil refinery was permitted an allowable phenol of 3 lb. per day. When one considers the complexity of the operation and the large number of possible sources of phenols in an oil refinery, one might wonder about the relative truth of the word 'reasonable'. In one refinery phenols (carbolic acid) is used in carload lots and yet they were to allow only a few cupfuls to reach the river. This is an example of the critical nature of some industrial wastes; a tolerable limit of 5 p.p.b. of phenols in a river flow of 600 c.f.s. is only 16.3 lb. per day.

In the Edmonton area the industries approached the matter of waste reduction on a physical rather than on a biological treatment basis. That is to say, isolation of the waste as far as possible, burning of those portions which were particularly offensive, and in many cases ponding of the effluents. This has worked out quite well. Ponding of effluents, or that portion of the effluent which causes the most pollution, decreases the pollution in the winter period of low flows. In the spring and summer these ponds may be drained with no ill effect on the receiving stream which at that time is open for reaeration and has a much greater volume of flow. The rate at which these ponds may be emptied is related to river flows in such a way that the permissible concentration of pollutants in the river does not exceed the limits recognized as being safe for a water which is to be used as public water supply.

The City of Edmonton has built a secondary sewage treatment plant, placed in operation in the fall of 1957. The plant is now operating at an efficiency of over 90% removal of B.O.D. One of the problems presented at the city treatment plant was the large amount of packing house wastes which was difficult to treat, in that there was a large amount of fat and considerable suspended solids which constitute enough bulk, that the digestion tanks were taxed to their full capacity in the first year of operation. Since that time the City has required that the packing plants provide primary treatment at the plant, briefly the removal of fats in settling tanks and screening of the effluent by fine screens so that the straw, paunch manure, and hog bristle, is largely removed at the source. In addition to this the City has required that all industrial plants pay an extra amount for the treatment of their wastes, this amount being based on the cost of the treatment at the city plant. The sewage treatment plant is operated as a primary treatment plant in periods of open water. This creates a substantial saving in the cost of power required to operate the blowers of the activated sludge secondary treatment section of the plant.

In spite of the improvements in waste treatment carried out before the winter of 1955-56 the dissolved oxygen in the river that year was reduced to zero at points 100 miles downstream. This caused a pronounced septic odour in the river. It not being possible to speed up the construction of sewage treatment works, the Provincial Government with the co-operation of the City of

Edmonton undertook a project to aerate the North Saskatchewan River using compressed air. A 2,000 c.f.m. blower was set up on the river about 40 miles downstream from Edmonton and distribution pipe placed through the ice, and air injected into the river.

The difficulty of aerating cold water under adverse conditions was realized. It was felt however that the air injected might be trapped under the ice surface and absorbed over a longer stretch of the river. This work was described in detail in a report prepared by Wm. Bailey, of the Division of Sanitary Engineering in 1956.

The data showed an increase in the dissolved oxygen content of about 0.5 p.p.m. at a river flow of 1,060 c.f.s.

The two most basic pollutants on the North Saskatchewan River are those with a high B.O.D. and those with odours or odour-producing substances. The results of controls on phenols and odours are shown in Table 6.

The situation with regard to the dissolved oxygen content in the river and the reduction in the oxygen-demanding materials is shown in Fig. 4. Whereas in 1954 the B.O.D. exceeded the dissolved oxygen, in 1960 the B.O.D. is considerably lower than the dissolved oxygen content; the flow in 1954 and in 1960 was approximately 1,400 c.f.s. at the sampling period. Fig. 5 is an interesting plot showing the decrease in dissolved oxygen as the river flows downstream from Edmonton. These curves are drawn from data based on 24 hr. composite samples, hourly samples being taken. The slope of the curves indicates the rate of the B.O.D. reaction under ice cover. The time of flow from Edmonton to Lloydminster is estimated at 14 days when the flow is 1,000 c.f.s. under ice cover.

In spite of the improvement in the waste treatment in the Edmonton area it is quite evident that at extreme low winter flows present loadings would again cause a serious condition of pollution in the North Saskatchewan River. In spite of more efficient treatment it is apparent that at some time in the future, the best relief for the problem would be to augment the winter flows in the North Saskatchewan River. In general the installation of hydro projects works well for this purpose. Discussions have taken place between the Alberta Government and Calgary Power regarding the possibility of developing hydro-power on the headwaters of the North Saskatchewan. This could increase the average winter flow in the North Saskatchewan to about 3,000 c.f.s. and would approximately triple the average of the low flow months in winter. It will be of some four times the once-in-ten year low flow of about 700 c.f.s., making a tremendous difference in the allowable pollution load on the river.

The Battle River

The Battle River is a very small stream which has a low flow of the order of 0.1 c.f.s. There are no great sources of pollution on this river but the allowable would be quite low. The Battle River is the natural runoff from Pigeon Lake. At various times there have been some suggestions that this lake be used as a source of water supply for the Edmonton area. The limited amount of water would not meet 10% of the water requirement in that area. There is a considerable amount of water for domestic or industrial use but a shortage of water for dilution of the wastes.

The Red Deer River

The Red Deer River flows through the City of Red Deer and then on through Drumheller to Empress and the South Saskatchewan River. The City of Red Deer which has expanded greatly in the last decade is the major source of waste flowing into the river. There are several industries in the City, the main ones being a milk plant and a brewery. Checks on the river have been made and there is a noticeable drop in the dissolved oxygen below the City of Red Deer. Using the minimum 10 yr. flow it was estimated that there was a need for primary treatment of the sewage. The City of Red Deer has been advised of this necessity for treatment and is now proceeding with plans. The City of Drumheller is some distance downstream and checks have been made at that point since the river is used as a source of water supply. The bacterial counts are low enough to be in the range that ordinary treatment of the water will provide a domestic supply which will meet the usual drinking water standard.

The Bow River

The Bow River is a tributary of the South Saskatchewan. It flows through the City of Calgary. Although the quality in the Bow River is good it does not serve as the source of supply for the City. The Elbow River which is smaller in size has for many years served as the source of supply from a reservoir created by the Glenmore Dam.

The Bow River has in the vicinity of Calgary many of the features of a mountain stream. The water is clear, the river bottom is clean and gravelly, and the stream has an abundant supply of rainbow and cut throat trout.

The first work on the Bow River was done in connection with com-

plaints that the fish in the river below Calgary for a stretch of about 50 miles tasted oily, and a very active section of the Alberta Fish and Game Association had for many years been trying to have this matter cleared up. It was found that the oily taste in fish was in proportion to an oily odour in the river. The oil odour persists for a distance of about 40 miles below Calgary. While studies of this taste problem were being made additional data were being obtained as to the general loading on the Bow and an estimate was made as to the required treatment in Calgary. As a result of these studies the City of Calgary has installed a treatment plant to replace one which for many years had been overloaded. It was found that on the basis of the dissolved oxygen content alone the City might have put off treatment of waste. The character of the river and the fact that it was used for fishing and that there were residences along the river downstream from the City required that the visible material in the sewage be taken out. Furthermore, there was considerable material which was stranded on the banks as the stage of the river rose or fell.

Industrial wastes flowing to the City sewers include those from three packing plants, a distillery and a brewery.

There were a few interesting points in connection with the Bow River. In the first few years of study some emphasis was placed on the bacterial counts in the river since it was used as a source of water for the Town of Bassano some 100 miles downstream from Calgary. While at that time the population of the City was about 130,000 and only a portion of the sewage received any treatment, it was a surprising fact that the coliform count in the raw water at Bassano was less than 2,000 per 100 ml. This might be accounted for by the fact that the river was fast and clear and that the biological slime on the rocks acted in the same way as that in a trickling filter.

In regard to the taste in the fish this was verified by placing fish in cages at various points along the river and making taste tests. There is an oily smell to the water in the river and the fish seem to retain this in their flesh. If the fish are removed from the water for a few days this taste will disappear. In 1958 laboratory scale tests were made using refinery effluents and various concentrations of phenols. While there are several factors to be considered the main conclusion was that an odour number in the water of four, the fish would pick up the oily taste in one day.

Pure phenol did not produce taste in the fish, exposed for several days to concentrations close to toxic ones. Details of the test procedure and data obtained are given in a report written by the Division of Sanitary Engineering in co-operation with the Fisheries Division of the Alberta Government (1958).

There is little doubt that the refinery effluents are responsible for the major amount of the oily odour. Odour numbers have been made on refinery effluents and they will at times reach about 2,000. How to remedy the situation is a problem, since there are no previous data on the removal of odours from refinery effluents. The odour of oil is one of the most difficult to remove. The refinery waste is quite low in oils, the effluent running 10 to 15 parts per million, a figure which compares well with any other refinery and with the standards set by many stream sanitation authorities. The refineries, as new sections of the plant are added, are taking great care in the design to see that leaks are readily detectable and that treatment of the waste is well designed. Work is continuing on this project.

The Bow River stays open for a considerably longer period of the year than does the North Saskatchewan and there are usually some open spots, at the rapids and at the two dams below Calgary. The power installations of Calgary Power have increased the winter flows to about 2,000 c.f.s giving the Bow River more winter capacity than the North Saskatchewan. At the present time primary treatment only is provided in Calgary. The status of the river is being checked so that secondary treatment will be installed when necessary.

Among the other effluents which flow into the Bow in the Calgary area is that of a nitrogen plant. This plant effluent could at times have a high carbon dioxide content and a low pH. This problem is taken care of by aeration through falls in the effluent channel. This is sufficient to reduce the carbon dioxide content in the effluent to a point where it will not produce fish kills, of which there had been a few local ones in the past, in the area near the mouth of the waste channel.

The Oldman River

The Oldman River has its head waters in the Crowsnest Pass area and flows easterly through Fort MacLeod, Lethbridge and Taber. One of the main tributaries is the Crowsnest

River, which flows through an area where coal mining has been the main industry for many years. The effect of the coal mining has been that many of the streams at certain times of the year contain fine coal dust. The main method of controlling this is to have the wash water at the tipples ponded.

In the last decade strip mining and the use of heavy machinery has replaced the underground workings to a great extent. A considerable amount of fine coal is left on the sides of the strip mine and on the surrounding area from the handling of the coal. When there are rains, this dust is washed down into the streams. In one case beaver dams have had a very good effect in retaining the coal dust so that it does not reach the main stream. The effect of coal dust on the main streams is that it may be a problem if the stream is used as a source of water with very little in the way of treatment. The coal dust also covers the bottom of the stream so that the natural life on which fish feed is not present. These streams in their natural state abound in rainbow and other trout.

At Pincher Creek there is some pollution from the wastes from the Town but it is relatively small.

At Lethbridge there is a growing pollution load. Part of this load is in connection with the vegetable canning and freezing industry. One fortunate aspect of the situation is that the wastes from the canning industry and also from the sugar refining, occur seasonally and in the period when the river is open. The sugar campaign ends about the end of December at which time there is a good chance that the river is still open. The canning and freezing season ends in September. Data on the pollution loads on the Oldman in the vicinity of Lethbridge are given in Table 8:

The Town of Taber is located not far below Lethbridge and a fairly close watch has been kept on the river so that the raw water at Taber would be in a condition where it could be treated for domestic water supply.

The South Saskatchewan

The Bow River is confluent with the Oldman below Taber and from that point on the river is known as the South Saskatchewan. It flows through Medicine Hat and into the Province of Saskatchewan. At the City of Medicine Hat, the main waste is the domestic sewage from the City. One of the larger industries is a producer of chemical fertilizers. A careful check has been made on the effluent from the fertilizer plant to make certain that the fluoride content in the South Saskatchewan is kept low.

The previous pages have covered the rivers of the Province. There are possibly two other questions which might arise in the mind of the reader. What of those towns which are not located on these rivers and what of the effect of the oil industry on the pollution in the province?

For many of the towns in the province the method of treatment of sewage is by means of long detention sewage ponds. This is by far the best method, on the basis of economics, reliability of the treatment, and from the standpoint of reducing the pollution load on the rivers. Of the 177 cities and towns in the province with sewerage systems there are 114 which use ponds as a means of treating their sewage. Most of these ponds retain all of the sewage flow during the winter period and may be drained during the spring and summer.

The effect of refinery wastes on the rivers has been discussed but what of the oil fields themselves? There is relatively little water pollution from oil field operations. Regulations of the Oil and Gas Conservation Board require that all waste oil be caught in catch basins and it is usually burned (causing some spectacular smoke columns). Similarly salt water is either retained in sumps or collected by pipeline and returned underground. Associated with the gas industry are the sulphur plants and gas processing plants. The volume of waste water from these plants is small. There is however the problem of keeping the odour number of these wastes low so as to preserve the few streams which we have as a source of domestic water supply. Small amounts of hydrocarbons and mercaptans produce odours and tastes in waters which are very difficult to remove.

Gravel washing plants must pond their waste so as to remove most of the silt prior to disposal in a stream.

One could not leave an article of this type without attempting to make some estimate for the future.

The lack of large volume of water in Alberta, for water supply and particularly for waste dilution will become increasingly evident. More effort will have to be made to reduce pollution loads particularly in the winter season.

One method of accomplishing this may be to pond entire waste flows over the winter, even for such large industries as a pulp mill. Another is development of hydro power as a means of increasing the minimum flows in the rivers. Disposal of wastes to deep underground strata may be used in some cases.

It must be pointed out that there are many industries which have no waste disposal problem, so that industrial growth can be maintained in these industries in spite of lack of large water resources.

Abbreviations

B.O.D.—Biochemical Oxygen Demand — given in parts per million by weight.
P.P.M. or p.p.m.—Parts per million by weight.
p.p.b.—Parts per billion by weight.
D.O.—Dissolved Oxygen.
c.f.s.—Cubic feet per second.
°C.—Degrees Centigrade.
T.O.N.—Threshold Odour Number — The dilution required to reduce the odour in a waste sample to a point where it can no longer be detected.
m.g.d.—Million gallons per day.
M.P.N.—Most Probable Number — as used in coliform counts in bacterial tests.

THE GREATER WINNIPEG SANITATION DISTRICT AND RIVER POLLUTION ABATEMENT

N. S. Bubbis, M.E.I.C.
General Manager and Chief Engineer, Greater Winnipeg Water & Sanitary Districts, Winnipeg.

The explosive population growth with its accompanying development of suburbia and the tremendous expansion and almost undreamed-of development of industry which has taken place since the end of World War II, have been the main factors in forcing more Canadians to take an increasing interest in the conservation of our greatest and most important natural resource, Water, by control of pollution. This paper is devoted to the Greater Winnipeg Sanitary District, its organization, the original works constructed, the changes which have taken place including extensions as well as its expanded activities and finally, the plans and indications for future development, all of which may be considered more or less typical of the development of pollution control in this Country during the last quarter of a century.

METROPOLITAN Winnipeg is located at the junction of the Assiniboine River and the Red River of the North and comprises some 16 municipalities with a total area of 264 miles and a population of some 450,000 people. The area's sewerage systems initially and later the sewage disposal treatment facilities developed in the usual orthodox manner.

The City of Winnipeg built its first sewer in 1876 just two years after the City's incorporation. More sewers were added soon after, but by 1882 it was evident that a more comprehensive system was necessary and the City Engineer of Chicago was called in to make a report. On the basis of this report, the City was divided into 21 districts, each drained by a main trunk sewer, emptying either into the Red or the Assiniboine rivers. All of these trunk sewers were of the combined type and the great majority were built by 1914. The other municipalities in Greater Winnipeg dealt with their sewage in a similar manner.

When sewage is discharged into a body of water, certain chemical and biological reactions take place and if the amount of water and the quantity of oxygen dissolved in it is sufficient, the sewage will be oxidized and the water will become purified through the operation of natural phenomena. This method of sewage disposal is known as the 'dilution method'.

Generally speaking, the volume of water flowing in any stream and the amount of oxygen contained in that water is a measure of the capacity of that stream to assimilate and purify the sewage which may be discharged into it. If the quantity of sewage is not too great or too strong, it will be purified and no nuisance will be created. However, if the character of the sewage is very strong or if the quantity is greater than the diluting ability of the water into which it is emptied, then a nuisance results and fish and fauna cannot survive.

Organization of the Sanitary District.

Until the 1930's, with the population remaining fairly static, Greater Winnipeg got along quite well with this system of disposal, but drought years at that time caused abnormally low flows to the river. In one month in 1934 more sewage was discharged into the Red River from the Winnipeg sewer system than was flowing in the river itself. In addition, the population was beginning to increase and industrial development was growing rapidly, with the result that the rivers virtually became open sewers.

This condition and the Federal Government's policy of establishing unemployment relief projects resulted in the passage of the Pollution of Waters Prevention Act in 1935 and in the establishment of the Greater Winnipeg Sanitary District by an Act of the Legislature, also in 1935, to undertake the treatment of Greater Winnipeg's sewage.

It might be mentioned that the organization of the Greater Winnipeg Sanitary District was one of the first cases in North America and the first in Canada where a metropolitan corporation was established to collectively treat the sewage from a number of contiguous municipalities.

When the Act was drawn originally and was presented in the House, it included the nine member municipalities constituting the Greater Winnipeg Water District, which at that time were the only municipalities with sewerage systems discharging into the rivers. However, before final passage of the Act an escape clause was included which permitted any municipality to withdraw from the District within thirty days of the Act's proclamation. In retrospect it became clear that the inclusion of this escape clause was a very serious mistake. Six of the nine municipalities took advantage of it and withdrew from the District. Three of these municipalities rejoined very shortly after, but the other three remained outside the District until 1955. This naturally created some grave problems which will be described later.

Type of Treatment.

Excluding sewage lagoons, the simplest and least expensive method of sewage treatment is known as primary treatment. In this process, the inert grit or inorganic solids are first removed and disposed of, usually by burying. The sewage is then passed through settling basins to remove all organic solids that will settle by gravity alone and the liquid is allowed to pass on to the receiving body of water. The settled sewage solids, called sludge, are then treated in various ways to render them inert and inoffensive before disposal. The primary type of treatment is based on the accepted principle of dilution already mentioned, to purify the liquid part of the sewage.

Where necessary, primary treatment is followed by additional or secondary treatment. The liquid or effluent from the primary process is given further treatment to remove practically all of the remaining solids and in certain cases, the final effluent is given additional treatment by chlorination or otherwise so as to render it completely stable.

Original Works — The District's first consulting engineer, the late Mr. W. S. Lea, M.E.I.C., of Montreal, was charged with the responsibility of designing the system of sewage treatment that would most economically meet the District's requirements. On the average, with the exception of periods of drought, there was sufficient river flow available to meet the minimum requirements for good dilution. Because there were no bathing beaches, no fisheries of any value and no communities drawing their water supplies from the river downstream from the treatment plant, he recommended that only primary treatment was to be provided initially, although some provision was made for the construction of secondary treatment facilities later if required.

One of the first problems that have to be determined in the design of such treatment works is to decide the requirements of present conditions and the provision to be made initially for future growth. It is obvious that some economic balance must be struck to make sure that the works will not have to be enlarged too soon, and at the same time, that not too great an economic burden is placed on the community by providing for works too far in the future. The usual yardstick used is to provide approximately for 30 to 50 years' capacity in those structures that are not easily enlarged or duplicated, such as the interceptors and basic structures, and to provide for 10 to 15 years' capacity for those parts of the works that can be easily enlarged or added to, such as pumps and comminutors at the pumping stations and clarifiers and digesters at the treatment plant. On this basis, the interceptor was designed to take care of a future population of 585,000 with a flow capacity of 160 m.g.d. (U.S.), whereas the plant itself was designed for a capacity of 25 m.g.d. (U.S.) to serve immediately an equivalent of a population of 278,000, and was intended to take care of the community's requirements until approximately 1945 with provision for enlargement to serve an equivalent population of 585,000.

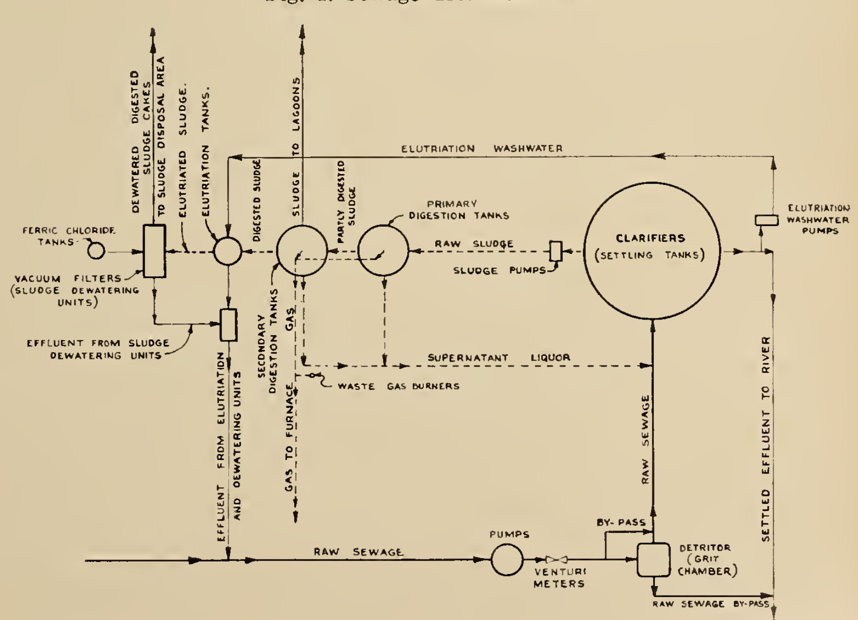
The treatment plant was constructed, in the northern part of the area, well downstream of the then developed area. It was necessary to build intercepting sewers approximately parallel to both rivers to collect the sewage and convey it to the treatment plant. The main interceptor runs along the north side of the Assiniboine and along the west side of the Red. Because of the flat terrain, construction difficulties and economic considerations, it was impracticable to build the interceptor deep enough for all trunk sewers to deliver into it by gravity. It was necessary therefore to construct 16 pumping stations and eight river crossings, two in the Assiniboine and six in the Red.

The original design called for all sewage to be screened and cut up before being discharged into the interceptor. This was accomplished by 24 comminutor stations, 16 of which were combined with the pumping stations. No screening is undertaken at the main plant.

The works originally constructed provided for the following processes of sewage treatment: grit removal, primary settling and separate two-stage digestion followed, by elutriation and vacuum filtration. As the sewage arrived at the plant, some 55 ft. below grade level, it was lifted by low-lift pumps installed in two of three pump wells and passed through a grit removal unit and then to two clarifiers or settling basins. The primary sludge was then pumped to the digesters in which heating coils were installed. Following two-stage digestion, the sludge was elutriated or washed with clarifier effluent to reduce its alkalinity, then vacuum filtered after conditioning with ferric chloride. The dried sludge was ultimately disposed of as a soil builder to market gardeners and others. Provision was made for the installation of additional pumps in the third pump well, the addition of a second grit removal unit, two clarifiers and more digesters. The plant flow diagrams are shown in Fig. 1 and 2.

Subsequent Extensions — As mentioned, it was estimated that the original plant would be adequate until

Fig. 1. Sewage Treatment Plant



1945. However, as a result of World War II and the rapid increase in industrial activity, particularly the packing industry, certain sections of the plant became overloaded by 1942. Due to the War itself and to the restrictions during the rehabilitation period after it, no expansion was undertaken. By 1947 it was obvious that prevailing conditions were not entirely satisfactory. The Provincial Sanitary Control Commission, after discussing the matter with the Sanitary District and the three non-member municipalities who had withdrawn from the District at its creation in 1935, engaged the services of a prominent firm of consulting engineers, Alvord, Burdick & Howson of Chicago, to investigate the situation and make a report.

Two reports were prepared. In one, the consulting engineers reported on operations of the Greater Winnipeg Sanitary District and recommended additions which should be made to the District's facilities in order to provide sufficient capacity. In the second report, they strongly recommended that the sewage from St. James, Fort Garry and Tuxedo outside the District should be treated, and outlined several methods which could be used. One of these was that they rejoin as members.

Following these reports the Provincial Sanitary Control Commission negotiated with the non-member municipalities and the District, with a view to having the recommendations implemented. The non-member municipalities claimed that they were not able to re-enter the District on the financial terms outlined in the consulting engineers' report. Yet on the other hand they did not proceed with the alternative of providing facilities of their own. Under protest, the District agreed to accept the recommendations of the consulting engineers' report concerning the additional facilities which the District should provide, but at the same time demanded that the non-member municipalities should come forth with some plan for taking care of their sewage.

In 1950 the District engaged the firm of Alvord Burdick & Howson to prepare plans and specifications for the extensions required, and when steel became available after the Korean War these works were constructed. Further discussion took place between the three parties, but action did not result until early in 1954, when the Provincial Government stated categorically that it would amend the Sanitary District Act to include the three non-member municipalities and that they would be given until July 1st to work out arrangements with the District for their re-entry; if this could not be done by mutual consent, then the Lieutenant-Governor in Council would specify the terms of their inclusion. Shortly thereafter, mutually satisfactory terms were worked out whereby the three non-member municipalities were permitted to re-enter the District by making back payments equivalent to the amount that they would have paid over the previous 18 years if they had remained in the District. One municipality made this back payment in a single cash payment, while the other two are making annual payments over a 20 yr. period at low rates of interest. On January 1st, 1955, they became full and equal members of the District.

Since 1955, extensions and additions have been made to the original works constructed. The main interceptor has been extended by 1.7 miles and 4.5 miles of secondary interceptors and force mains have been constructed. Seven additional comminutor-pumping stations have been added to the original 24, and six stations have been enlarged. At the treatment plant itself, a 35 m.g.d. pump was installed increasing the pumping capacity by 40%; a second grit settling unit was installed and an additional 145 ft. clarifier was constructed increasing the settling capacity to 42 m.g.d. from 25 m.g.d.; four 85-ft. diam. digesters were constructed tripling the digestion capacity by adding 600,000 cu. ft. to the original 300,000 cu. ft. It was estimated that this would provide sufficient capacity to take care of the population until 1963-1965.

Studies have now been completed which indicate that all of the existing sewers that can be connected to the present treatment plant will have been so connected by 1960. It has also been decided that at least one additional plant will be required; a site has been selected and expropriation is proceeding to secure it.

Special Provisions of District's Act.

The District's Act which was originally passed some 25 years ago had certain farsighted and unique provisions which enabled the District to undertake and extend its functions and activities during the very rapidly changing conditions which have developed over the last few years and might therefore be worth mentioning in this paper. Three of these are: sewer rentals, industrial wastes control and the development of separate sewered systems.

Sewer Rentals — Section 31 of the Act clearly sets out how the District is to obtain its revenues and how they shall be passed along to the sewer users. In October of each year, estimates are prepared of the following year's operating costs and in these costs are included principal and interest payments on the capital debt. The total amount of these estimated costs is then divided pro rata among the member municipalities based on the estimated amount of sewage to be contributed by the municipalities during the following year. In estimating this amount of sewage, the District is permitted to use the water consumption of each of the municipalities for the previous 12 month period of October to September as equivalent to the sewage contribution. These allocations are then levied upon the municipalities and have to be paid quarterly to the District.

Section 31 of the Act then specifies clearly and concisely how the municipalities in turn are to obtain the money for their allocation. This is done by enacting a by-law which imposes a sewer rentals charge on the occupier of any premises using water; this is collected with the water bill. In addition to the amount for the allocation, the municipality can only add an administrative charge for collection. Any surplus collected cannot be used for other purposes but must be kept in a separate reserve fund and used for decreasing future sewer rental charges. The Section further states clearly that none of these charges may be assessed as a levy against land.

This method of financing and collecting the costs of sewage treatment has proved effective, equitable and simple to administer.

Industrial Wastes — Just as is the case with other similar Authorities [2,3,4], one of the major problems with which the District had to deal with was that of industrial wastes. From the start of operations in 1938, considerable difficulty and expense have been caused in the collection system and at the treatment plant by industrial wastes of one kind or another discharged into the sewers.

Prior to the construction of the treatment plant, all industrial wastes which could physically be discharged to the sewers were disposed of in this fashion and then into the rivers. As a matter of fact, it was this condition that turned the rivers into virtual septic sewers during the low water years in the 1930's and resulted in

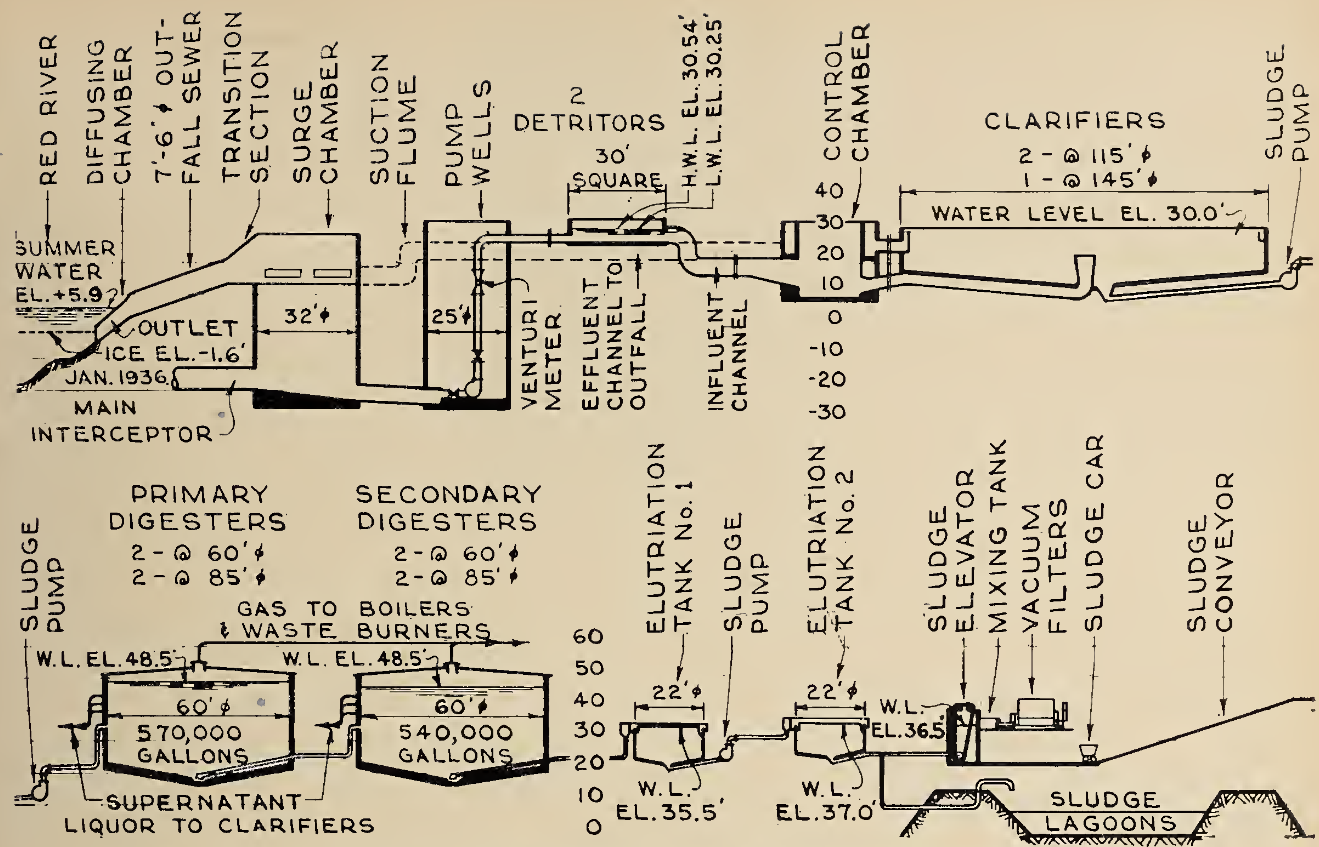


Fig. 2. Section profile through Sewage Treatment Plant showing present installation of 42 m.g.d. (US)

the serious nuisance which then prevailed.

It is not generally realized by the layman that the amount of water used by industries is very large, and that the wastes from many of them contribute a very high equivalent population loading. A few instances may be cited. For every barrel of beer produced in a brewery, about 285 gal. of water are required for processing. For every steer that is processed in a packing plant, 300 to 800 gal. of water are required. For every barrel of oil produced in a refinery, 800 gal. of water are required. Almost all of this water becomes highly polluted in processing and then has to be disposed of, a none too easy task, and the simplest solution is to discharge it to the sewers.

It is therefore quite understandable that these practices which had grown up over the years were difficult to break, especially when the only alternative meant the installation of costly equipment to separate the objectionable wastes and further costs in disposing of it by other means. Winnipeg being the centre of an agricultural area, food processing is one of the major industries and this type of industry produces some very strong wastes. The following examples will give some indication of the magnitude of the waste contributed by industry. Waste from a slaughterhouse-meat packing plant of which Winnipeg has six, will range from a population equivalent of 20,000 to 90,000. The waste that is produced by our beet sugar plant with a capacity of 2000 tons of beets per day, results in wastes approximately equivalent to that from 125,000 to 130,000 people.

Consequently the District was faced from the start of its operations with a real problem in dealing with the wastes discharged to the sewers from various industries. In the original Act, Section 19, the District was given powers to regulate, control and prohibit the discharge of various materials to the sewers, and over the years it has gradually evolved a philosophy on the control of industrial wastes which finally culminated in the passing of By-law No. 80 in August 1957.

Initially, the abattoirs and meat packing plants were the greatest local offenders. The fable of their efficiency to the effect that "they use everything in the pig but the squeal" was unfortunately somewhat exaggerated. The discharge of large quantities of paunch manure, grease, pig's toe nails, etc., resulted in clogging the sewers and plugging the comminutors and pumps. On reaching the treatment plant, the wastes caused further trouble. Frequently, a blanket formed on top of the clarifiers which in cold weather would freeze. In the digesters, a scum blanket in excess of 8 ft. in depth formed, and was most difficult to break up. This required the emptying of the digesters, which is quite a dangerous and unsatisfactory procedure.

An educational program was first tried in order to persuade the various industries to co-operate. With the outbreak of War in 1939, not very much could be accomplished. Following the War, further steps were taken to try and obtain voluntary co-operation and in addition By-Law No. 38 "A by-law to prohibit the discharge into sewers within or entering the Greater Winnipeg Sanitary District of certain detrimental materials and slaughterhouse and packinghouse wastes", was passed in July of 1945.

By 1950, it was apparent that the District's facilities required enlarging and that a more aggressive control program would be required if the treatment facilities were to be capable of proper operation and the additional costs to be paid for on a more equitable basis. While Section 19 of the District's Act provided for the imposition of surcharges for extra strong sewage, these had never been implemented. The District's consultants recommended against the implementation of such charges, feeling that they would discourage the various industries from constructing pre-treatment facilities, but did recommend that screen chambers at the outlets from each of the packing plants be constructed at the District's expense. The screen chambers were constructed later and in addition the following two by-laws were enacted in 1954:

By-Law No. 64—A By-law to prohibit the discharge or drainage of sewage within the District into any river flowing through or adjacent to the District.

By-Law No. 65—A By-law to prohibit, regulate and control the discharge of industrial and factory waste or excessive amounts of any type of sewage or waste water.

Both of these by-laws make provision for licensing. In the case of By-Law No. 64, every person, that is, industry or municipality must obtain a license for any outlet into a river including storm sewers. In the case of By-Law No. 65, it is mandatory for every industry to obtain a license from the District before discharging any industrial waste or large quantity of sewage or waste water into the sewers. It follows the model by-law developed by the Water Pollution Control Federation [7], and sets out the various types of material prohibited and the standards and normal limits of permitted materials such as B.O.D., suspended solids, grease, etc. It also gives the General Manager of the District discretion to permit the discharge of sewage of a greater strength under certain specific conditions. This by-law permits the installation of domestic garbage grinding units in residences but requires that all larger industrial or commercial units be licensed.

While the screen chambers worked reasonably well in preventing large particles, pig's toe nails and a certain amount of paunch manure from being discharged into the sewers, it was still found that the effluent from packing plants was of a very high strength, particularly in B.O.D. and grease. It was then decided to review the matter of surcharges and after a considerable study of the various methods of regulations and formulas used by similar authorities, the District developed a formula of its own for imposing such surcharges. This was incorporated in By-Law No. 80 "A By-Law to provide for surcharges for the discharge of factory and industrial wastes into sewers or rivers within or entering the District." It was passed in August 1957 and became effective on January 1st, 1958. This by-law is a counterpart of By-Law No. 65 and is applied in conjunction with it. Where the District can accept wastes stronger than the set limits and agrees to do so, surcharges are applied in accordance with the formula.

The District's philosophy in making these surcharges was based on the fact that while industry and the community form a natural partnership, this partnership should be an equitable one. The community naturally wanted to see the development of industry since this provided employment for the population and gave an excellent source of tax revenue. Industry on its part naturally wanted to co-operate with the community in order to obtain a market for its products and to have available a labour force. But it should not be subsidized or expect to be subsidized by the community in having its stronger wastes treated on an equivalent basis to that of normal domestic sewage. As long as the District could, it was prepared to permit the discharge into the sewerage system of acceptable industrial wastes of higher than normal strength and to impose surcharges for the additional strength. Knowing the basis of the surcharges, industry could then decide for itself whether it was more economical to provide the necessary pre-treatment to meet the District's standards or only provide minimum pre-treatment and pay the surcharges.

This by-law has now been in effect just over two years, and during this period of time all the packing plants, slaughterhouses, paper mills, breweries, dairies, tanneries and miscellaneous food processing plants such as honey, potato chips, vegetable packing, etc., have been licensed: surcharges have been imposed upon 30 of them.

We can now definitely state that from our experience with this surcharge program it has proved successful, is based on sound principle and is reasonably equitable and not too difficult to administer. We also feel that industry believes us to have been fair and has accepted the plan reasonably well, particularly when one bears in mind the natural reluctance to have to spend money on something that was formerly done at no cost and tended to be considered a non-productive nuisance.

The following are the general effects of the program:

1. There has been a definite reduction in the strength of the sewage going to the sewers as witnessed by the fact that of the industries being surcharged, the B.O.D. has been reduced 30.7%, solids by 57.2% and grease particularly has been reduced by 52.6%. Much of this has resulted from the institution of good housekeeping practice by industry itself. We feel that this has not only benefited the District but industry as well.

2. It has resulted in some decrease in the quantity of sewage contributed by industry. Management watches water consumption much more carefully.

3. The District has collected approximately $100,000 in each of the last two years from these surcharges and thus the parties who are contributing the higher strength are paying a proportionately higher cost for the extra work involved in treatment.

The District intends to continue this program until all industries have been completely investigated. In addition, it will be necessary to continue both the regular and spot sampling of the effluent from the various industries in order to make sure that the best possible job is done with the pre-treatment facilities installed, since it has been observed that only by continual vigilance on the part of both the District and top management of industry, can the best results be achieved.

Separate Sewered Areas — As mentioned, the original sewers constructed in this area were of the combined type. This resulted in the intercepting system being designed to intercept 2.75 times the average dry weather flow. Consequently, during periods of rain, the excess storm water mixed with some of the sewage passed on into the river untreated. While the District has been subject to periodic demands to prevent such spills, it was obvious that the cost to carry out such a program would be tremendous. As a matter of fact, a recent estimate indicated that it would cost at least $200 million merely to convey all of the combined sewage to the treatment plant.

It was however evident that ultimately additional treatment plants would be required and that these would have to provide secondary as well as primary treatment. Consequently, in line with modern practice, it was decided that the future development particularly of the upstream areas along the Red and Assiniboine rivers should be laid out on the basis of separate sewered system. Accordingly, By-Law No. 72 was passed in 1957 which gave the District the authority to designate areas to be served by a separate system of sewers. There was considerable objection to this on the grounds that these designated areas were being discriminated against in that the cost of providing sewers for them would be considerably higher than for the areas served by combined sewers. However, after making a detailed explanation to the municipalities concerned, the District was able to implement this program and all new upstream areas which will eventually be served by the new treatment plant have now been laid out and are being developed on the basis of a separate sewer system.

The District has felt however that those areas which are at present served by combined trunks but have not been fully developed in their upper reaches could be permitted to complete development on a combined sewer basis rather than insisting on separate sewers and providing additional storm trunks at very considerable extra cost. One or two sewer districts immediately adjacent to the plant have also been permitted to be developed on the combined sewer basis. While there are some who feel that we are not being consistent, the District's engineers do feel that it is both economically and practically justified.

Research.

Mark D. Hollis, President of the Water Pollution Control Federation, [1] who is also Assistant Surgeon and Chief Engineer of the U.S. Public Health Service, in a recent review of the progress made during 1959 detailed a number of problems in pollution control and made this observation on waste treatment research: "It is in the field of water pollution abatement research that the lag is greatest among all the elements that go to make up the problem of containing and reducing the contamination of the nation's Water Resource." The lack of research on this problem in Canada is even greater than it is in the United States and much more work on this subject should be done by our universities, by industry and in the treatment plants themselves, particularly in view of the fact that climatologically and for other reasons, Canadian problems are not necessarily the same as they are elsewhere. Furthermore, by doing this kind of research work, we will be able to develop our own sanitary engineers to the point where we will have adequate manpower to deal with these problems that lie before us.

The picture is not entirely black. Recently, the Ontario Water Resources Commission has completed a new research laboratory building in Toronto which should result in a considerable amount of research work being done. Some of the universities are undertaking research programs with grants from the National Research Council. It might therefore be of interest to record one or two experiments that the Sanitary District has been working on over these last few years.

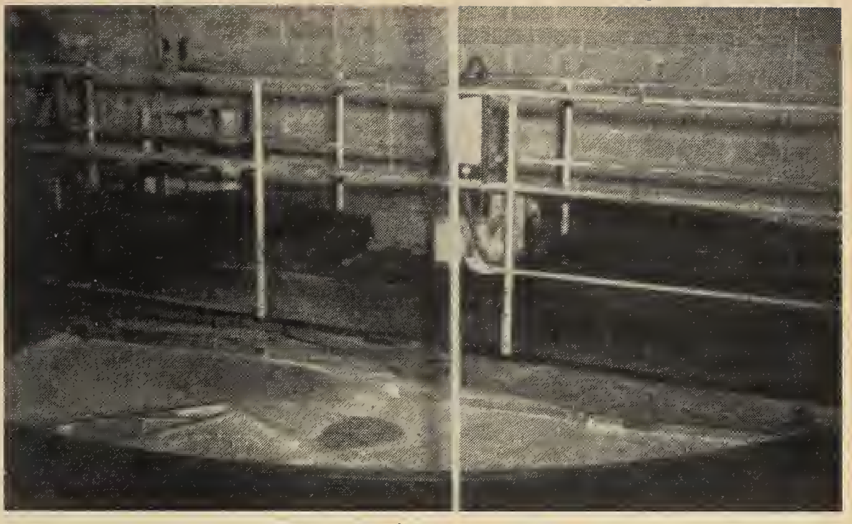

Fig. 3. Pacific Separator Unit

Sludge Handling.

One of the most difficult and costly problems in operating a sewage plant particularly in large communities, is the dewatering and ultimate disposal of the sludge. It is estimated that by 1965 we will have to dispose of some 12 million lb. of dry sludge solids with a volume of more than 15,000 cu. yds. per year. Since it costs the District about $16.60 per ton of solids to dewater its sludge by vacuum filtration we have naturally been on the lookout for more economical methods of sludge dewatering to reduce operating costs.

Various methods have been used for sludge disposal as follows:

1. Sludge has been disposed of by filling gulleys and depressions, and in excavations called lagoons specially dug for this purpose;

2. liquid sludge has been pumped into tanker trucks and spread over fields or pastures;

3. sludge has been dewatered by various means and then either burned, spread on land as a soil builder, or dried and sold as fertilizer.

The first two methods are only applicable to very small communities. Sludge incineration with subsequent disposal of ash is relatively expensive and has generally been used in comparatively large cities. There are a number of plants where sludge has been dried and sold for fertilizer, but in virtually none of these cases has it been an economic success and it has only been used if local conditions make disposal by other means impracticable. The most universal method is to dewater the sludge by various means and then spread it on land as a soil builder.

There are three general methods of dewatering sludge: Spreading on sand beds, placing it in lagoons and by mechanical dewatering equipment. The construction of sand beds is fairly expensive and is economically suitable for small installations where climatic conditions are favorable. Lagooning of sludge has been successful in a number of communities (we will refer to this later in this paper). In the case of mechanical equipment, the sludge is usually dried by means of vacuum filters of the drum type where the sludge is spread on a suitable membrane and a vacuum is applied thus reducing the water content to about 70% to 75%.

In order to dewater sludge by vacuum filtration, it is necessary to apply chemicals so as to obtain a floc. In Winnipeg, ferric chloride is used and is fairly expensive since it has to be shipped in tank cars from Eastern Canada or the United States. Therefore a preliminary step known as 'Elutriation' or washing of the sludge was provided to decrease its alkalinity and thus reduce the amount of chemical needed. However, despite this, the chemical cost has still been extremely high running, to about $8.00 per ton of dry solids for ferric chloride and lime with the new filter.

Consequently, when the extensions to the plant were being planned, our consultants recommended that the sludge be dewatered by lagooning. However, the District's engineers had some reservations about this method because of two factors: first, our relatively impermeable subsoil, and second, our climatic conditions which permit practically no evaporation during the winter months; as a matter of fact, our evaporation roughly balances our precipitation. As a result in 1950 it was decided to construct three and a half acres of test lagoons and to experiment with them for a period of time in order to determine how these would work out under our local conditions.

Experiments were conducted for a period of about three years and while this is a relatively short period of time upon which to make an absolute determination, indications were that under normal conditions of operation, it was practical and economical to lagoon sludge but that it would be advisable as an insurance measure to provide modern vacuum filtration equipment so as to give the plant a degree of flexibility which would enable it to operate under all possible conditions. [5,6]

Four large lagoons occupying some 20 acres were constructed and 65 acres of additional land were purchased adjacent to the plant for future construction of lagoons. These lagoons have now been in regular operation for some four years. Experience has shown that under normal conditions they will work very well and will dewater the sludge much more economically than is the case with elutriation and vacuum filtration. The cost for lagooning, excluding lagoon maintenance, is 96 cents per ton of dry solids as against $16.60 for vacuum filtered sludge..

The method of operation is to fill the lagoon with 10 in. of completely digested sludge, permit it to settle for about 14 days and then decant the surface liquor. This procedure is repeated until the lagoon is filled to the desired level. During the winter the sludge freezes, thus not permitting decanting until the following spring.

However, in order to empty the lagoons economically, it is necessary to use large 12 yd. scrapers and these can only be used effectively at certain times of the year after periods when there has not been any appreciable precipitation. This type of equipment is quite expensive and is almost invariably in use on road building during the summer, so it is not always possible to obtain it just at the time that it is best suited for easy removal of the sludge. For example, the rainfall during the summer of 1959 was very much above normal, and even more important, was spread more or less throughout the entire summer. Consequently, it was not possible to have the lagoons emptied before freeze-up.

A new method of emptying was therefore tried early this winter, after the sludge in the lagoons had frozen and equipment was easily available. The first step was to have a ripper pulled over the deposited sludge by a heavy lugged tractor. The 12 yd. scrapers then moved in and removed the sludge which had been ripped to a depth of 12 in. from the lagoon. Alternately using the ripper and the scrapers, it was possible to empty the lagoons very effectively at a relatively low cost working out to about $1.06 per ton of dry solids moved. The sludge was piled in the regular way and this spring if we find that it will be sufficiently dry to handle easily for spreading, then this will become the regular method of cleaning the lagoons and should prove very effective and economical.

The science of sewage treatment and disposal is in continual flux with new and improved processes being developed continually. Recently, two new processes of handling sludge have been developed. One of these known as the Atomized Suspension Technique (A.S.T.) was developed by the Pulp and Paper Research Institute of Canada. As the name implies, the sludge is atomized into small particles and is introduced into the top of a tall cylinder and oxidized as it falls to the bottom. Following pilot plant studies, a full scale plant installation has been constructed for the town of Beaconsfield, Quebec, close to Montreal.

The second process is known as the Zimmerman process and was developed by Sterling Drug Incorporated in the United States. This process uses the principle of wet oxidation which takes place when the sludge is introduced into a reactor operating under high pressure and temperature. Following pilot plant studies, at the Chicago Metropolitan Sanitary District, that Authority has awarded a contract for the construction of 4 50-ton units. Another contract has also been awarded in Wheeling, West Virginia, for 1 5.6-ton unit.

Both of these processes will be watched very carefully by all sewage treatment authorities to see whether any economies can be effected in sludge disposal by their use.

Secondary Treatment.

All Provincial Agencies responsible for the conservation of water resources and prevention of pollution have become increasingly aware of the urgency of this problem and have been taking steps to deal with the situation. In Manitoba, the Provincial Sanitary Control Commission several years ago, after considerable investigation, tabled an Outline of Policy in the Legislature, which will govern and control the discharge of sewage and wastes into bodies of water in the Province and will therefore determine the degree of sewage treatment required. The following are excerpts from this statement. "The proposed policy recognizes that all bodies of water in Manitoba are an important natural resource of the Province and the need to conserve and utilize the inherent advantage and value of these bodies of water without unreasonable restriction, but with due regard to the needs and requirements of the Public at large, of organized municipalities and of industry and Commerce . . . the proposed policy also takes into account the desirability within practical limits, of protecting these bodies of water so that the normal features of aesthetic qualities, habitat for fish and wild fowl, recreational facilities and drainage works, suffer a minimum impairment", and "the Commission feels that the application of Policy must be based on the premises that any body of water may be necessarily subject to some degree of contamination or pollution" (that is, it is impracticable to always retain the so-called pure condition).

Since the stretch of the Red River immediately downstream from the plant has been zoned as a recovery zone it would indicate that the Dis-

Fig. 4. Effluent end of manure settling tanks and the flow measuring and sampling equipment

Fig. 5. A.P.I. Oil Separator

Fig. 6. Oxidation Pond

trict's initially adopted policy, whereby only primary treatment was provided with the rivers natural dilution properties being used to take care of the primary effluent, will fit in with the Provincial Government's policy. It has nevertheless become increasingly clear that we are approaching the maximum load which can safely be imposed on the river without the danger of creating a nuisance. Furthermore, we must also recognize the fact that standards are tending to become higher and that consideration will therefore have to be given the eventual installation of some degree of secondary treatment at the present plant. The new plant to be constructed will of course include secondary treatment.

For both of these considerations, the District has been carefully watching the extensive use of sewage lagoons which has developed during the last number of years in both the Dakotas of the United States and in the Prairie Provinces. While all of these have apparently worked very satisfactorily, and have done a reasonably thorough job, economically and simply, most of the installations have served relatively small populations. The City of Regina will now probably be using the largest sewage lagoons constructed anywhere.

In order to make them applicable to larger communities, heavier loadings would have to be practicable. So far, there is not sufficient data on the exact loadings, particularly heavier loadings that can be successfully placed in sewage lagoons under controlled conditions in our northern climate. The District therefore last year conducted some initial experiments on the use of lagoons for the treatment of its primary effluent. In these experiments, the lagoons used initially for experimenting on sludge dewatering, already mentioned, were utilized. It is proposed to undertake some further studies this coming year in conjunction with the Provincial Department of Health and Public Welfare. It will be interesting to see what results will come from these experiments particularly under our local conditions.

Conclusion.

Earlier, a statement was quoted from a recent review by Dr. Mark D. Hollis. I would like to refer again to this review in which he states that "while Cities alone in the United States were now spendng at a $400 million per year rate level for new or improved wastes treatment plants . . . this is still below the 'break-even' level considering the growth of sewered population, the War back-log and obsolescence." While in most parts of Canada, we have been blessed with tremendous water resources, it has become increasingly clear that they also are becoming depleted and grossly polluted and we have no reasons to believe that the situation in Canada in regard to conservation and pollution control is any better than in the United States. There are signs however that various forward thinking groups throughout the Country are becoming aware of this problem and that certain action is being taken to try and remedy these conditions. To mention a few of these — the establishment of the Ontario Water Resources Commission, several years ago, and the tremendous amount of work that has already been accomplished by this recently created body; the Quebec Legislature at its recent session appropriated $25 million for pollution control and water conservation; and the Canadian Institute on Sewage and Sanitation at its Annual Meeting last October passed the following resolution on September 29th, 1959.

"1. Water pollution must be recognized as one of the major national problems of the day, affecting the environment, health, and welfare of all citizens of Canada.

2. The Institute, in support of its objective for clean streams pays tribute to the effective work being done by many agencies in this field and urges an intensification of this campaign by all citizens, and all groups interested in health protection, conservation of natural resources, safeguarding of recreational facilities, preservation of fish and wildlife, and the maintenance of a beneficial environment.

3. The Institute is confident that if the pollution abatement program is carried out aggressively our lakes and streams and tidal waters can be restored to and maintained in a condition which will ensure that they can be enjoyed by all citizens and can be utilized for all the many purposes for which our natural resources were intended."

This resolution was circulated among all interested bodies including the three levels of Government.

While this indicates that the trend is in the right direction, we must nevertheless regard this as but a beginning. Much remains to be done and it is to be hoped that we can profit by the experience of the pollution control bodies in the United States and move quickly, since the old saying that "an once of prevention is worth more than a pound of cure" definitely applies to water conservation. The Greater Winnipeg Sanitary District like other similar agencies in Canada, looks forward to playing a continuing role in this national problem.

ADVANCES IN SEWAGE AND WASTE TREATMENT

A. E. Berry, M.E.I.C.
General Manager,
Ontario Water Resources Commission,
Toronto.

Efforts at pollution abatement in water supplies have been increasing in recent years. Construction programs have gathered momentum in Canada as in most countries. Pollution is now recognized as a national and world-wide problem. It is essential that steps be taken to make control measures effective. It is only in this way that water resources can be conserved for the many uses for which they were intended. In these programs, involving high expenditures, critical analyses must be made of methods utilized in waste treatment. This is necessary if the most effective results are to be assured and the most economical solution obtained.

AN APPRECIATION of the objectives in sewage treatment is desirable at the outset. What degree of treatment is necessary, what are the methods in use, and what are the basic principles in these methods? It is desirable to know the nature of sewage and other wastes and the effects these may have on the receiving streams or watercourses. What are the limits to which treatment can go in removing substances found even in minute quantities? How can costs be altered through the design of the treatment works, either the capital costs or operating charges? Should industrial wastes be treated with domestic sewage in the one plant or is it preferable to keep them separate, and what is the result in each instance? These and many other questions come to the fore. What is revealed when an examination is made of the advances that have taken place in this field over the years? More important probably, will be the advances which can be expected in the future, and how the past developments have influenced these. It is obviously not feasible to discuss all details of the progress made in treatment processes. That is a very large field, but it is possible to examine some of the general principles involved in these forward steps.

In sewage treatment, as in most engineering problems, cost must always be given close attention. There are many measures which can be used if cost is not a serious factor. When something like $50 per capita may be involved to build a sewage treatment plant of the secondary type the designer must examine closely all measures which can reduce this cost without detracting from the results he sets out to achieve. The research laboratory and the developer need to direct their efforts at improving existing measures and developing new ones which will aim at economy. In a program of waste disposal many branches of science can contribute. Hence there is need for a co-ordinated approach by many towards both better and simpler methods, and particularly to a reduction in costs.

What Can Treatment Works Accomplish

Sewage and waste purification works can accomplish a great deal. There are also many things they do not overcome in regular treatment. There is a good deal of flexibility in the designs used, depending on what degree of processing is needed. Sewage coming from urban communities is a complex mixture chiefly because it is not merely the domestic wastes from houses and offices, but it contains a high proportion of industrial wastes and substances from many sources. It is common to state that sanitary sewage should contain about 0.20 lb. of suspended solids per capita and 0.17 lb. of B.O.D. (Biochemical Oxygen Demand). This would be in order except that some systems receive much industrial waste while others have little. Some wastes have much organic matter and a high B.O.D. figure. Others have constituents not measured in the normal tests. A variety of chemical wastes may be present, some of which may, even if in only small quantities, travel long distances in a stream. Some are toxic, some produce obnoxious tastes, some carry oil, others may be strongly acid or alkaline, while some carry floating material such as feathers, garbage, or finely divided substances which do not respond readily to the usual treatment processes, and some contain valuable fertilizers for plant growth.

It would be unrealistic to think that the sewage treatment plant should be designed to remove or nullify all of these substances. For one reason, the cost would be very high. The question arises as to whether industrial wastes should be treated with the municipal sewage or be dealt with separately. Some wastes readily respond to the same treatment as sewage, and a joint plant has advantages. In other cases it is preferable to consider treatment of the industrial waste separately where the specific ingredients can be attacked. There is thus no rule that will apply in all cases.

The modern sewage purification plant when designed for full treatment is an effective device. It can remove organic matter as measured by the B.O.D. test from about 300 p.p.m. to 10 p.p.m. or less. A similar reduction can be made for suspended solids. The bacterial content, measured by the coliform test, is reduced in the biological processes, and when chorine is applied to the effluent the reduction in coliform can be almost complete. Thus measured in these terms a sewage treatment plant accomplishes a great deal and converts a heavily laden raw sewage to a clear, odourless water with a low bacterial content. Whether the purification is to go this far will depend on local requirements. In bringing about specific results the plant is designed to fit the local conditions.

Treatment of sewage or industrial waste must be designed to safeguard the watercourse against undue pollution. The final test is not so much the quality of the effluent but the effect on the stream after initial dilution has taken place. The use of that stream will have an important relationship to the degree of purification needed. The volume of water in the stream is a significant factor. The flow of water in the Great Lakes System gives a high dilution for any effluent, and when the water is flowing as in a river there is a continuous mixing and removal. Discharge into a lake may tend to concentrate the effluent at the end of the outfall when the water is quiescent.

Local requirements may place a heavy or a light burden on the treatment processes. The cost will be affected directly. The designer must be prepared to incorporate in the works whatever is needed to satisfy local conditions. He can design for a degree of treatment that will permit the effluent to be discharged satisfactorily in a watercourse with little or no water at times. In the light of these stringent requirements and wide variations it is essential that every true advance be utilized and that there be a co-ordinated effort to seek out the best and most economical means for this purpose.

The stream or lake receiving wastes, either raw or treated, responds to that load and natural purification processes are constantly at work, sometimes more actively than at others. The result may be that organic matter will be reduced readily by the oxygen in the water, the supply of which will be restored from the air and plant growth. Bacteria tend to die out in the water, an unnatural habitat. But other substances may travel long distances in a stream or remain active for a long period in a lake. Chemical substances may travel several hundred miles before their effects are reduced to insignificant amounts. Phenol, as a potent taste substance in water, may likewise travel great distances, and even small amounts as low as one part in a billion may be objectionable in drinking water. Oils and many other substances have disastrous effects on the stream. The great increase in the use of chemical substances such as synthetic detergents, pesticides, weedicides and others, may result in these being carried into the streams and their effects being felt in a variety of ways.

Treatment Processes in Use

The fundamental processes in sewage treatment have been utilized for many years. Important changes have been made in the application of these methods, but the principles have not changed radically. They include physical measures as in screening, sedimentation, flotation, and transportation of materials; biological processes as in sand filtration, trickling filters, activated sludge systems, sludge digestion, lagoons or stabilization ponds, and miscellaneous aerobic methods; chemical treatment as in flocculation and disinfection. These make up the main measures employed in removing the objectionable ingredients from sewage and other liquid wastes. Many modifications of these measures have been instituted and many more can be expected in an effort to assist the basic processes and thereby to shorten the treatment time, increase efficiency, and reduce costs. These advances made over the years are important in meeting the objectives for clean streams and conservation of our national water resources.

The treatment of sewage and industrial wastes readily separates into two parts, one the treatment of the liquid to discharge an innocuous effluent, the other to dispose of the solids or sludge removed in the process.

It may be noted that these advances, now in progress or expected in the future, should not delay the initiation of works any more than the hope for new developments in motor cars, TV, and so many other products should postpone purchases. Public reaction, particularly where there is a desire to delay expenditures, is to wait for new developments. Another extreme view is to assume that advances are not taking place and new measures should not be accepted. Neither of these attitudes favours the cause of sewage treatment. The engineer must choose what may be regarded as a middle course. He must be prepared to design a plant now which will give the desired results. He should incorporate in his design new advances which offer a reasonable chance for success. He cannot risk his professional reputation and gamble with his client's money by specifying something which is not proven. This decision is no easy task, especially when he is confronted with many so-called advances aimed at economy and efficiency. These processes have been numerous in the past, but the mortality rate among them has been high because either they were not proven or other advances made them of less value. Some measures have been quite successful under certain conditions, but not acceptable for others. It thus becomes an important responsibility for the engineer to serve his client effectively by choosing methods and facilities which are modern and economical, but not before these have been tried enough to offer an opportunity for success. The earlier methods, in most respects, were capable of producing a good effluent and obtaining the necessary results, but the means and the cost are considerations which must be examined critically at all times.

What Are The Advances

A review of some of the more significant advances in sewage and waste treatment of the past can aid in assessing what is important now or what the trend may be in the future. It is not feasible to describe in detail these various steps, but certain general principles may be sufficient for the purpose. They can be considered under the broad headings of physical processes, biological treatment, and chemical treatment.

The Physical Processes

Physical processes have been used widely in sewage purification. They remove solids by screening, sedimentation, or flotation. They involve the

Fig. 1 Primary clarifiers at Brantford's new sewage treatment plant. Sludge digesters are in the background.

transportation of the liquids and sludge from place to place and provide other useful work about the plant. They are inter-related to the biological processes, and the two work jointly to attain the same objective. Physical processes are usually cheaper than biological measures. Primary or partial treatment is nearly all due to physical forces.

The opportunity for improvement in physical processes is attested to by the great changes made over a period of years. Mechanization of these methods has greatly changed the operation of sewage works. This process thus keeps pace with similar trends in other fields. While these improvements may not change the quality of the plant effluent to any great degree they accomplish much easier operation and greater convenience.

Some of the improvements which have taken place from earlier days are seen in the mechanical cleaning of screens, thereby permitting smaller openings, the more widespread use of fine screens, grinding of screenings for return to the sewage and consequent ease of handling, mechanical removal of settled grit and the washing of organic material from grit, and the use of mechanically cleaned sedimentation tanks for primary treatment and in conjunction with secondary treatment — all aimed at improved convenience and ease of operation.

Important advances to date in the physical processes have resulted in the widespread application of improved settling efficiencies in mechanically cleaned tanks, and in ways to remove the settled sludge continuously and with little inconvenience. Much has been done to provide better

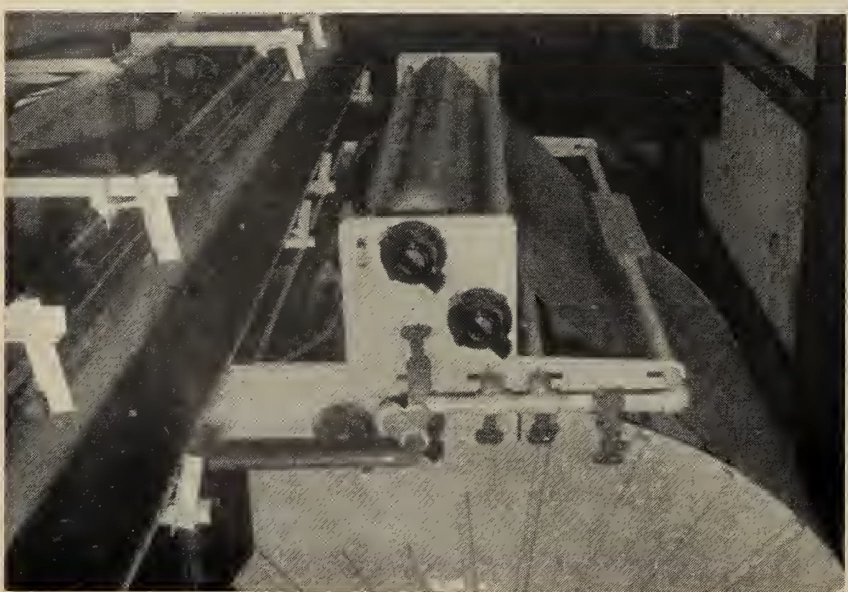
Fig. 2 Air Compressors in the main pumphouse in Stratford's OWRC-built and operated sewage treatment plant which was opened in 1958.

and more correctly spaced overflow weirs, and improved inlet and outlet arrangements for the tanks. Studies have been made on the effects of these on tank performance with the result that the designer has information to permit the best arrangement for these tanks. It can be considered that in sedimentation performance the advances have been directed to improved efficiency in solids removal and convenience of operation. Further efforts in this same general direction can be expected. Most settling tanks are now mechanically equipped, and they provide good results.

Flotation as a physical process acts in reverse to sedimentation, and the solids are floated to the surface entrained in air bubbles. While this is not widely used in sewage treatment it has promising results in certain industrial wastes. The opportunity for removing the solids in this fashion offers efficiency and economy. This is an advance of recent years, and more efforts can be expected.

Grit removal involves careful design of the units as well as effective measures for moving this material from the tanks. Various ways can be used. A further action is the washing of the grit free of organic material. Progress has been made in this with the result that the final product can be deposited almost anywhere without fear of odours or offensive conditions. Much of the advance made in this part of sewage treatment has to do with transportation and washing for convenient and economical disposal.

Fig. 3 A feature of Brantford's new sewage treatment plant is a vacuum filter designed to reduce the moisture content of sludge. The plant was built by and is being operated by the Ontario Water Resources Commission.



The Biological Processes

Sewage purification has always relied on biological processes for secondary or full treatment. They are subject to all the vagaries of bacterial action. So long as this condition prevails the efforts to bring improvements will be directed to assisting these natural agencies, by creating environments in which the processes can proceed rapidly. The steady progress through such methods as sand filtration contact filters, trickling filters, activated sludge, oxidation ponds, and other aerobic methods attest to the efforts made to reach this objective. Rapid oxidation with high purification at minimum cost has been the search over the years. Great improvements have been made, but only general principles can be reviewed at this time.

Automation

Automation has been used in ever increasing ways in sewage treatment. This has offered a wide scope for the engineer and manufacturer. It promises better control of the essential processes and removal of the weakness of the personal element. Automation goes hand in hand with mechanization, and it can be expected that further advances will be made in this direction.

Sludge Disposal

After treatment of the sewage or waste there remains the difficult problem of disposal of the solids or sludge. This has grown to be a major feature of the overall requirements of reducing these residues to something which no longer is dangerous or offensive. Sludge disposal has gone through many changes and the end is not in sight. The efforts of many have been concentrated on this solution.

Sludge being largely organic and subject to decomposition can produce highly offensive odours. The objective is therefore to prevent the escape of odours while at the same time permitting the rapid break-down of organic material at a minimum of cost. The final product must be disposable by piling or put to a useful purpose.

Sludge digestion, so widely used for many years, was a development of the anaerobic process at work in the early septic tanks. Steps were taken to provide the maximum adjustment of the biological environment such as heat and foods. Considerable cost is involved in sludge digestion and in dewatering the resulting solids. The break-down of organics in digestion is relatively slow. Efforts at improvement have concentrated speeding up the process or by-passing this for other measures, and reducing both capital and operating costs.

Sludge disposal is still a real problem, not so much in attaining a satisfactory end product but in improving efficiency and economy. Omission of the digestion process can eliminate the capital costs for these tanks. It is necessary to balance this improvement against the condition of the final product and the annual overall savings.

Dewatering of sludge has been an outstanding difficulty. Open sludge drying beds can result in slow drying, odours and higher labour costs. They are not favoured now. Vacuum filters for dewatering of either digested or raw sludge have gone through many changes. They call for conditioning of the sludge with chemicals, and the control of costs is an important element.

At present a number of other methods for sludge disposal are receiving attention. The dewatering of raw sludge on vacuum filters with sufficient chemicals to prevent odour problems is one approach used in a number of works. Another method employs a rotating filter made of nylon fabric and not requiring chemical conditioning. Still another aims at removal of the water content by sonic or high frequency vibrations. No chemicals are involved.

A recent development in Canada, the atomized suspension technique, embodies different principles. The raw sludge is thickened to about 10% to 12% solids and then sprayed through a nozzle into a chamber heated by electricity or gas. The sludge can be dried or burned at a high enough temperature to avoid odours. One plant is in operation at Beaconsfield, P.Q.

Sludge incineration has been used for many years with satisfactory results. Improvements have been consistent in this method.

The newer or modified methods for sludge disposal must be considered in respect to accomplishment of objectives and assurance of trouble free operation at competitive costs. Any new process requires a period of trial under different conditions to overcome possible defects and to determine costs. It can be expected that the search for the ideal sludge disposal process will continue and that further advances will follow.

Disinfection and Polishing Effluents

Sewage effluents must be discharged sometimes under stringent conditions such as low diluting water, proximity to water intakes or bathing beaches. Further improvements in the effluent may then be necessary. Efforts have been made to polish the liquid by the use of sand filters, and more recently by the use of micro strainers. Improvements are possible in these ways.

Disinfection of effluents is increasing after the practice established in water treatment. In this way the bacterial content can be greatly reduced and other benefits derived. As the trend towards better effluents moves along more use can be expected of disinfecting processes.

Single vs. Multiple Plants

Another advance in sewage treatment has been obtained by using larger plants rather than a number of small ones. This involves no new or different process but rather an opportunity for operating efficiency and lower costs. A small plant can, if properly designed, produce an effluent equal to that of the large unit, but it may not receive the same supervision given at a large plant where trained and capable operators are in charge.

Industrial Processes

Industrial waste treatment processes are numerous. The advances made in these have kept pace with the progress in sewage treatment. Discussion of all these is not feasible. Some of the methods are the same as for sewage, while others depart widely. The changing composition of industrial wastes calls for appropriate measures to meet each new situation.

Summary and Conclusions

Sewage and waste purification has been subjected to many developments, all leading to the objective of high efficiency, well purified effluents, and low cost. Physical processes, biological treatment, and disinfection have all moved steadily forward towards the desired goal. In spite of the improvements there is still much more that can be expected. The need for treatment of sewage and industrial wastes is aggravated by concentration of population in urban centres and by industrial expansion with its great variety of complex wastes. Concentrated research and study of different methods will be needed. The designer of treatment facilities should have access to methods which can be used with confidence to attain the desired results under many different circumstances.

THE ONTARIO PLAN FOR WATER POLLUTION CONTROL

A. M. Snider, M.E.I.C.

Chairman, Ontario Water Resources Commission, Waterloo, Ontario

Conservation, with the best use of national resources, is an obligation resting upon every country. Water must be recognized as a major resource, without which little progress can be made in growth or human betterment. Some parts of the world have abundant water supplies, others are confronted with frustrating shortages. In either case it is imperative that the importance of adequate water supplies be recognized, and that appropriate action be taken to safeguard these waters against abuse. Since the quantity of water in the world remains constant it only changes in quality and in local distribution. The use of these waters to the best advantage for all normal requirements must be the common objective.

THE REPEATED use of water in its journey from rainfall to the sea becomes ever more necessary as populations increase and concentrate in urban centres, and as industry expands. The great deterrent to this maximum use comes from pollution. This can change the water to a damaged, useless resource until the purifying processes of nature restore its quality. Long periods of time and great distances of travel may be required for this restoration. Further pollution may be added along the route with the result that the water continues to be unsuitable for those along the course of travel. In this situation the country's best resource is dissipated and progress fails or is adversely affected.

The Problems of Water Pollution

What are today's problems of water pollution and how can these be kept under control? Are these difficulties greater than in the past, and are remedial measures worthwhile and within the reach of all? Water pollution has always created problems even from the earliest habitation of this country. The situation has deteriorated as communities grew and as industrial wastes became more complex and larger in volume. The time has now come when there is a realization that this national resource must be utilized for the benefit of all. No country can afford the high cost of continuing neglect of pollution control. The means for meeting the situation are feasible and ready to be put into service. The "Ontario Plan" is one approach to this problem. It is now going forward with gratifying success.

Canada, like other countries, has neglected its water resources. The depression years and the war period pushed the normal program into the background. The problem of catching up on this backlog would be great enough, but it has been magnified by the concentration of population in urban centres, which makes it difficult even to hold a balance and not slip farther back. In the same period industry has expanded tremendously in this country. Even more significant are the complex nature of the wastes and the frequent changes in these. To these problems must be added the greatly increased costs for treatment facilities. It is not unexpected that these conditions would create in the minds of the public a desire to defer action on projects which seldom have much public appeal. Against this background must be brought into sharp focus the value of our water resources and the price to be paid if we fail to take aggressive action.

Factors contributing to the pollution problem in the United States are well presented in a statement on hearings on environmental health problems. It can readily be visualized what may follow in Canada as growth continues. The statement contains the following:

"When in the space of fifty years you more than double the population, concentrate two-thirds of it in urban communities, increase the number of automobile vehicles, from about 1,000 to 70 million, and multiply total industrial production by 900%, you are bound to have entirely new environmental problems. Some of the figures of our chemical environment are really astounding. There are more than 500,000 distinct chemical compounds in use in industrial production today, while twenty years ago there were only a few hundred. In addition, they say, upward of 10,000 new compounds are being developed in laboratories each year, and a substantial number of these are put to use. Even more startling figures — unknown billions of tons of wastes are discharged each year into the rivers and streams which provide drinking water for most of the population."

Canada has not yet reached the magnitude of the United States in population and industry, but the problems are not unlike. There is need for prompt action.

Action on Water Resources Eleswhere

It is worthy of note that pollution control is being given a high priority in other countries as well. This is a recognition of the importance of water resources as a key link in that chain of factors responsible for national welfare and growth. Presidential Committees in the United States, composed of eminent men, have given intensive study to their water resources and the programs necessary to protect these for the future. Similarly in Great Britain there is an acute awareness of the priority which must be given to adequate water supplies, both for industry and municipal needs. Without this, there is no freedom in the selection of sites for industry or in the opportunity to expand. Similar emphasis is placed on this problem in most places in the world, so that it may be truly said today there is a greater recognition of the importance of water resources than ever before.

The Ontario Plan

In Ontario, a plan has been developed which gives full recognition to the protection of water resources. It makes it possible to distribute water to wherever it may be needed, and, an important feature, it provides for protection of existing sources of supply against pollution. In this way maximum use can be made of all water resources rather than permitting them to be damaged and rendered useless for much of the time.

The Ontario Plan resulted from the appointment by the Government in 1955 of a committee to study water resources and supply. In the following year legislation was passed to appoint a Commission. The Ontario Water Resources Commission Act came into being in 1957, and it remains in effect today with some amendments. Some unique features are included in this legislation and in the administration of the program. This action was taken when it was clear that water resources must play an important role in the future well-being and progress of the Province.

The Ontario Water Resources Commission

In broad terms the program of the Commission may be divided into two fields: one to exercise supervision over water supplies, sewage works, and industrial wastes in the Province. Water pollution control forms an important part of this. The other is to design, construct, finance, and operate water and sewage works for municipalities and others. Some related activities to these two major fields are included in the program.

Through this new Act the supervision over water and sewage works and control of pollution now comes under the Commission. This function was formerly administered by the Provincial Department of Health, as it still is in most other provinces. This adminstrative change is especially significant insofar as water pollution is concerned. The Act now gives wide powers to deal with stream sanitation. It is not limited to those conditions which may adversely affect public health, but covers any condition which may impair the quality of the receiving watercourse. It is no longer restricted to bacterial contaminants, but extends to all forms of pollution. It includes such substances as silt from gravel washing operations, oil wastes, and chemical deposits, even though these may be of no significance in the transmission of disease. This is a different approach to an age-old pollution problem. The necessity is clear when it is recognized that one of the most difficult pollution problems today comes from industrial wastes, some of which are present only in minute quantities but which substances are continuously changing. Industrial expansion in this Province and growth of urban communities will add further to the need for adequate means of pollution abatement, as has been shown in the United States.

The Construction Program

The Commission, at an early date, adopted water quality objectives for stream sanitation. When this is combined with legislative authority for enforcement, it can form an important part of a desirable overall program. This alone is not adequate. There must be means for aiding the municipalities and for ensuring that the required works can be financed. In the Ontario Plan the Commission is authorized to enter into agreements with municipalities for providing funds and for carrying out the complete program. This does not involve cash grants, but it utilizes the credit of the Province to supply the funds and the technical staff to assist the municipalities in these complex projects. There is thus an effort to bring the maximum assistance to the municipalities in meeting their requirements for pollution control. Industry must also meet its obligation to provide adequate treatment of all wastes and to preserve the purity of the water resources.

Organization of Commission

The Water Resources Commission is composed at present of six members from different parts of the Province. The Commission's activities are organized into the divisions of Administration, Construction, Plant Operations, Sanitary Engineering, Laboratories and Research, and Water Resources. All are co-ordinated to attack best the various problems. A staff of

Fig. 1. Aeration tanks at the new activated sludge plant at Stratford designed to protect the Avon River.

technically trained personnel in these various fields has been recruited. A new and modern laboratory has been opened recently in the Toronto area. Here it is possible to make the various analyses needed for the Commission's program and to conduct research on current problems.

Accomplishments to Date

While the program of the Commission is still much in its infancy the accomplishments to date may be of interest, especially in dealing with water pollution. Some of these may be listed:

1. The unique feature of constructing water and sewage works for municipalities has progressed rapidly. There are now 113 of these projects involving an expenditure of over $48 million of which $34 million is for 53 sewage projects and $14 million for 60 water projects. Forty-eight of these projects are now in operation, and many more will be completed in the next few months. These will mean much towards pollution abatement;

2. It is gratifying to observe that at present nearly all the major municipalities are embarking on sewage treatment programs. At the same time there are programs for treatment of industrial wastes;

3. Stream pollution surveys have been carried out on a wide scale as a means for locating and correcting sources of pollution. Last year nearly 4,000 samples were collected in these surveys;

4. The Commission has just put into service a new and modern laboratory and research building. This will be an important aid in maintaining pollution control. The opportunities for research in this field are fully recognized in the building;

5. The contribution of the laboratory in the Commission's program may be seen in some measure by the fact that last year over 60,000 chemical analyses were made and over 9,000 bacteriological samples were examined;

6. The staff of the Commission has grown from about 25 in 1957 to over 180 at present, and over 70 operators of plants are now serving. Expert technical skills are being developed to give the most effective service in this program.

These accomplishments reveal something of the measures being taken to control water pollution. It is a province-wide campaign aimed at all centres and at all sources of pollution. The program is of great magnitude and involves high expenditures. Some parts of it will take a long time, but the important feature is that the program is in effect and that major advances have already been made.

Status of Pollution

The extent of the problem of pollution abatement in Ontario and its present status can be seen by a review of conditions in certain parts of the Province. In undertaking this assignment to control pollution it was apparent that surveys of sources of pollution and stream conditions must go on continuously. These must deal with domestic sewage, industrial wastes, and all other substances which may impair any of the water resources. Thus the laboratory becomes an important ally for the engineer and the technician engaged in this work. Acceptable standards or objectives must be set up as the goal to be reached.

Planning these surveys calls for a unit upon which to act. This may be done on a watershed basis or on a unit of local government such as the county or municipality. There are advantages to each. The watershed can be used to check all pollution entering a stream and to determine the effects of this on the quality of the water at different points in that watercourse. There is a defect in this method in that the stream may involve several different municipal governments, and when remedial action is being taken there is more difficulty in getting a unified approach. If the county is used as a basis of the survey and report it has administrative advantages. Similarly if the problem concerns only one municipality as in the case of a small lake or short stream, this can be used to advantage to report the findings.

The Ontario Water Resources Commission utilizes both of the above methods in carrying out its surveys, depending on local conditions. It has been found that a county survey brings better opportunities for all municipalities to act together. Even though the County Council may not be directly involved in the remedial measures there is an interest in bringing about good stream sanitation. Since a county is a relatively large area it may contain a good part of the watershed. Several county surveys have been completed to detect all sources of pollution. Once this is done steps are taken to see that all wastes are adequately treated before they reach the stream or other outlet. These surveys bring to light drains and pollution upon which there was little information. They include private outfalls direct to the stream as well as connections to storm drains. This problem is acute in those municipalities where no sanitary sewers have been installed, but where storm drains or open ditches exist. There is little tendency in the built-up sections of these unsewered communities to control connections to the storm drains or plumbing in general. In many places there is so little land that property owners find great difficulty in disposing of wastes except by making connections to storm drains. Conditions at the outlets of these drains invariably are offensive. Consequently, the construction of sanitary sewers should be undertaken as soon as finances will permit.

At the present time there are 976 incorporated municipalities in Ontario. They are composed of 575 townships, 154 villages, 158 towns, 30 cities, as well as 38 counties, 20 municipal Improvement Districts, and Metropolitan Toronto. The installation of sanitary sewers is not often undertaken in a community unless the population approaches one thousand or more. Accordingly, the cities, towns, and villages are the centres in which sewage works are most commonly built. Parts of townships may also be considered as urban centres, and the need for sewage works becomes apparent in these.

At present 246 public sewage works are in operation in Ontario, giving service to about 65% of the total population of the Province. This may be compared to 419 water works systems serving 69% of the total population. It is gratifying that action to provide sewage works in the smaller centres is proceeding at a good rate. This will do much to assist in pollution control throughout the Province.

The advances made in sewage purification plant construction along the major streams of the Province will make an important contribution to pollution removal. The Grand River, with concentrated industry and urban centres, is well along on this clean-up. Sewage treatment plants will give secondary treatment to all sewage, while industrial wastes will meet similar standards. Other streams such as the Credit River, Ottawa River, Thames River, and many smaller ones are making progress to deal with their pollution problems. Municipalities fronting on lakes are actively engaged in similar programs. The objective is a high degree of purification in all places, and sufficient in any event to ensure good quality water in the receiving streams, both as to bacteria and those constituents which tend to abstract oxygen from the stream or to impair its quality.

A number of large centres of population, most of which are located on

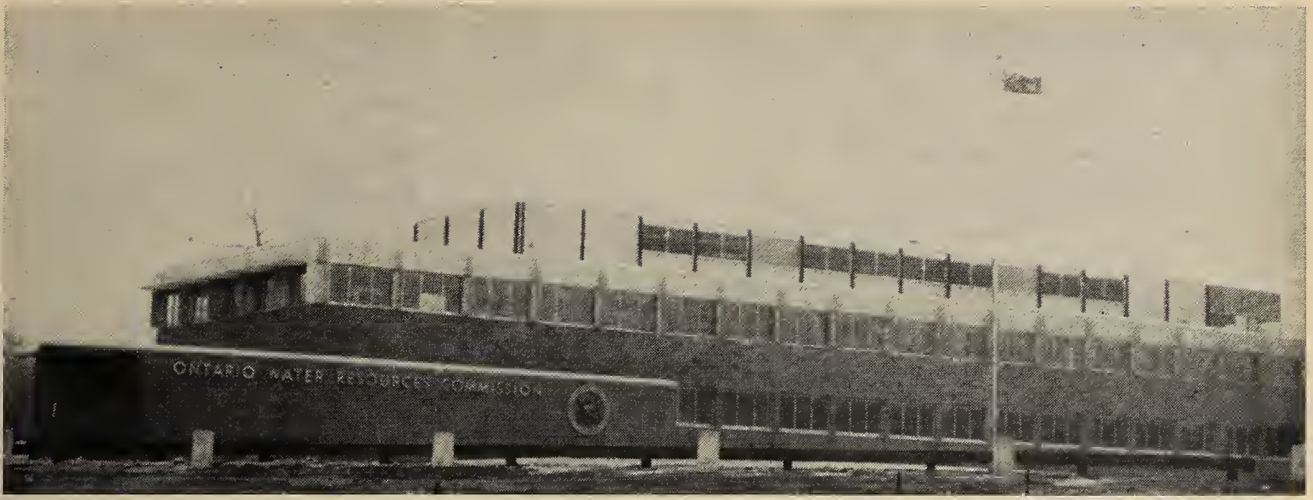

Fig. 2. New modern laboratory and research station.

large bodies of water, had delayed action on sewage treatment and had relied on dilution either alone or to supplement partial purification plants. The adoption of programs of sewage treatment in these places is a highlight of the program of the Commission. These include Port Arthur, Fort William, Sault Ste. Marie, Sarnia, Windsor, Niagara Falls, Hamilton, Toronto, Cornwall, Ottawa and others. The programs are in different stages, but it is possible to look forward with confidence to an early completion of these works.

The selection of design for works and the degree of purification of sewage must be related to local conditions. Where there is high dilution and no direct contact with water supplies or bathing beaches use may be made of the diluting water to aid in the purification of the sewage or industrial wastes. The objectives for water quality prescribed by the Commission recognize this feature. These objectives set the standard to be attained in the stream itself. In general it can be taken that the trend to higher purification of wastes is in effect regardless of the receiving watercourse. Where effluents must go to streams of low flow there is no alternative to a high degree of purification. Fortunately this can be attained in modern treatment works where physical, biological and chemical disinfection can produce an effluent of almost any desired quality.

Boundary Waters

The boundary waters between Canada and the United States are an asset of great importance. The two countries, acting under an early treaty, have entrusted the investigation of these waters to the International Joint Commission. References have been given by the two countries to study the waters and keep them under surveillance. Since most of these involve the Province of Ontario the work has been a joint effort on the part of the International Joint Commission and the Ontario Water Resources Commission. Much has been accomplished, and the program in effect is aimed at safeguarding these great water resources for their many uses in both countries.

The Industrial Waste Program

Industrial wastes are increasing in volume and complexity as the Province grows. Great changes have taken place in the part played by the wastes of industry in water pollution. Ontario has become a major industrial centre, with wastes of all kinds resulting from these operations. Much of the waste is accepted into the public sewers for disposal with the domestic sewage. Part of it goes into streams through private outfalls. The great variety and composition of wastes calls for many kinds of treatment. The fact that the wastes change frequently as new processes are developed adds further complications. Some of the troublesome industrial wastes come from pulp and paper plants, milk plants, packing plants, canning factories, metal plating industries, tanneries, oil refineries, chemical industries and others. Some industries produce wastes which have a highly objectionable effect on a stream, a condition which may travel several hundred miles before the effects are dissipated.

The Ontario plan for pollution control requires that industrial wastes be controlled in the same manner as municipal sewage. Treatment of both must go forward at the same time and to a sufficient degree to offset objectionable conditions in the stream. The facilities of the Commission are available to industry to assist in solving these waste problems. Research is an important tool in dealing with waste disposal and especially is this the case with industrial wastes. The Commission encourages industries of the same kind to organize and to work co-operatively in solving these problems. The new laboratory and research building of the Commission will enable the technical staff to co-operate with industry and attack these problems with a good expectation of success. Efforts in this direction are an integral part of the Ontario Plan.

Operation of Treatment Facilities

The mere construction of sewage and waste treatment plants is not a complete answer to the protection of stream quality. These will be ineffective if they are not operated intelligently. The Commission's program includes supervision over the operation of all these facilities in the Province. The objective is to ensure the results intended when the plant was designed. In those projects which the Commission builds, operations will be directly under its control. Full use will be made of the technical skill of the staff and the laboratory facilities. The responsibility for the results will then rest with the Commission.

Summary and Conclusions

In summary it is well to emphasize that water pollution is a problem of great magnitude. If uncontrolled, it can have disastrous effects on the water resources of the country and the well-being of the citizens. It must be considered as a serious economic factor in our national welfare, and something which calls for the best efforts of all. The Ontario Plan has been devised to attack pollution wherever it may be found, and to provide the best possible facilities for applying remedial measures. The results so far obtained are most encouraging. Efforts are being continued at an accelerated rate to provide clean waters everywhere in the Province.

ASPECTS OF RIVER POLLUTION IN THE PROVINCE OF QUEBEC

Leopold Fontaine,
Assistant Chief Engineer, Quebec Ministry of Health.

J. P. Gourdeau,
Sanitary Engineer, Quebec Ministry of Health.

R. R. Carrier, JR.E.I.C.,
Sanitary Engineer, Quebec Ministry of Health.

Today we are making more demands upon our most valuable servant than ever before. In our homes, water has many functions, old and new. Water turns the wheels of mighty hydro-electric plants that furnish light and power for our industries. And most of the power not created by moving water is created by water in another form, steam. We use water to carry away the wastes from our homes, cities and industries. This use has always been important; today, it is threatening to cut down or prevent our other uses. The beauty of the landscape it creates, the fish and wildlife it supports, the fun of swimming and boating, all these give us pleasure and make it possible for us to return to our everyday lives refreshed and renewed. Water falls upon the earth, runs its life-giving course, and then is drawn back into the air, soon to fall again. This is the water cycle, a "wheel" of water which turns constantly like the turning of the earth itself. But in general we take water for granted. We think of it only in times of flood ar drought, or when the water available is not fit for use.

IT WOULD seem that we should never have to worry about a water shortage since the average rainfall in the Province of Quebec is 38 inches. But, our demands on water are very specific. First we must have a certain quantity of water at a certain place and time. There is plenty of water in the province as a whole, but none in some places. Secondly we must have water for many of our uses, for all water is not exactly alike. None of it in nature is absolutely pure. It contains dissolved gases, minerals and other substances. It may also contain floating or suspended particles. Some of these dissolved and floating substances are very helpful. For example, fish and other water life, cannot live without the oxygen which is dissolved in water. Some "foreign" substances are helpful in some ways and harmful in others. Some actually destroy our water supply by making it unfit for our use.

Strange to say, we ourselves are to blame for most of these harmful substances in water. And the larger and more complex our civilization becomes, the more we pollute our waterway. Cities and industries, mainstays of our modern world, contribute most of this harmful pollution.

Pollution of Water

What is river pollution? It is not easy to give a precise definition of pollution or the word *polluting*. The Oxford English Dictionary defines the word pollution as follows: "The act of polluting or condition of being polluted: uncleanness or impurity caused by contaminations".

To pollute is defined as follows: "To make physically impure, foul or filthy; to dirty, stain, taint or befoul".

Generally, we say that water is polluted when it contains substances that make it unclean or unfit for our use. There are two main forms of pollution in our waterways. The first is silt, the soil that makes our rivers brown and muddy and fills up the reservoir behind our dams. This silt would be a priceless asset, if it were allowed to stay on the land, since most of it is the rich layer of topsoil which grows the best crops and woodlands. But nature's balance has been upset by chopping down too many trees and clearing too many fields. The plants no longer hold the soil in its place, and when a hard rain falls, the water carries the soil with it into the nearest stream. Both the land and the water are harmed, but silt is chiefly a problem for farmers, foresters and soil conservationists. It is basically a land problem.

The second form of pollution consists of our unwanted wastes. These wastes are of two general types: domestic sewage and industrial wastes.

Domestic sewage includes everything that goes down the drain of a city and into its sewer system. This sewage is a cloudy and very dilute aqueous solution containing inorganic and organic matter partly in true solution, partly in colloidal solution and partly in true suspension. Soapy wastes from houses, urine and fæces are present, and there may also be paper, garbage, rags, oil, etc., floating on the surface. The water content of sewage may be as much as 99.9% or more, so that the total dry solid matter (organic and inorganic) is only 0.1% or less. Southgate[1] states that settled domestic sewage contains 250 to 400 p.p.m. of organic carbon and about 80 to 120 p.p.m. of total nitrogen, thus giving a C:N ratio of about three.

Bacteria are also present since sewage, with its varied content of easily decomposable organic matter, is an excellent medium for their development. Most sewage bacteria are relatively harmless, and belong to the class of "saprophytic" bacteria, i.e., bacteria which only feed upon dead organic matter. A few bacteria are very dangerous, since they belong to the class of "pathogenic" bacteria i.e., bacteria which cause disease in man and animals. They are therefore very important from a public health standpoint. Among the more important of the pathogenic bacteria, liable to cause infection, are the following:

1. *Salmonella typhi* causing typhoid fever;
2. *Salmonella paratyphi* causing paratyphoid fever;
3. *Shigella dysenteria* causing bacillary dysentery;
4. Bacteria of the salmonella group, causing gastroenteritis.

Fortunately, pathogenic bacteria have only a short life in water and are less resistant to adverse influences and more easily destroyed than either the normal intestinal or ordinary water bacteria. Hence it is inferred that of organisms of the B. coli group, which can easily be detected and counted, cannot be found, then the pathogens must also be absent. The predominant bacteria, in sewage and river waters, belong to the coliform group, and hence these organisms, though harmless in themselves, are used as test organisms to determine whether a water is safe bacteriologically. A list of the commoner pathogenic organisms found in sewage and polluted streams is given in Table 1.

Next in importance to sewage as a cause of stream pollution, and indeed rivalling sewage in certain districts, is the discharge of industrial waste waters. These wastes include the acids, chemicals, oils, greases, animal and vegetable matter, discharged by the various industries, and they are as varied as the character of the industrial processes from which they originate.

Those which are of sanitary significance in that they place an oxygen demand on disposal plants or on streams from a biological standpoint, are highly concentrated as to solids and oxygen demand since their total solids, suspended solids, and B.O.D. are usually very high. The cost of treatment is usually high, and to offset this at least partially, the reclamation of certain marketable ingredients in the waste is frequently attempted. Special treatments have been devised for reclaiming some of these by-products, with varying financial success; but for some wastes no practical recovery has as yet been worked out. Each industrial waste is a special problem, and general instructions on treatment are of little value. Its particular characteristics must be determined by tests and appropriate methods for handling the waste devised. In general, these wastes are considerably more concentrated than domestic sewage.

Self-purification of Rivers

Sewage and industrial wastes discharged continuously in a river may meet various fates. The river will tend to overcome the pollution load to purify itself, and to recover naturally, in the course of time. Organic matter under suitable conditions is utilized as food by bacteria, and either oxidized or reduced to products such as carbon dioxide, water, methane and others, leaving a relatively stable residue. Dissolved gases and volatile materials such as hydrogen sulphide may escape to the atmosphere. Certain materials may be oxidized chemically within a few minutes after contacting dissolved oxygen in the receiving water.

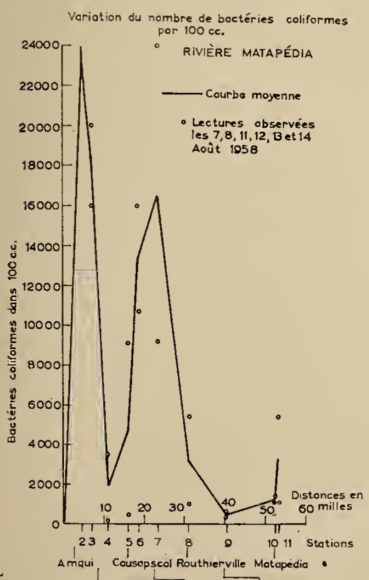
Self-purification of rivers is then one of the most remarkable of nature's workings, leading to the eventual elimination of the organic pollution, and is dependent to a large extent on biochemical reactions brought about by the activities of micro-organisms. Given sufficient dissolved oxygen these utilize the organic matter as food and break down complex compounds to simpler and comparatively harmless end-products. However, massive pollution by organic matter causes the exhaustion of dissolved oxygen. The remaining organic matter is then broken down by a different set of bacteria, the anærobic bacteria, which can utilize combined oxygen in the form of nitrates, sulphates, phosphates, organic compounds, etc. Septic conditions then occur, resulting in the breakdown of organic matter to a different set of end-products, some of which have objectionable odours and may be the cause of complaints. This condition must not be allowed to prevail.

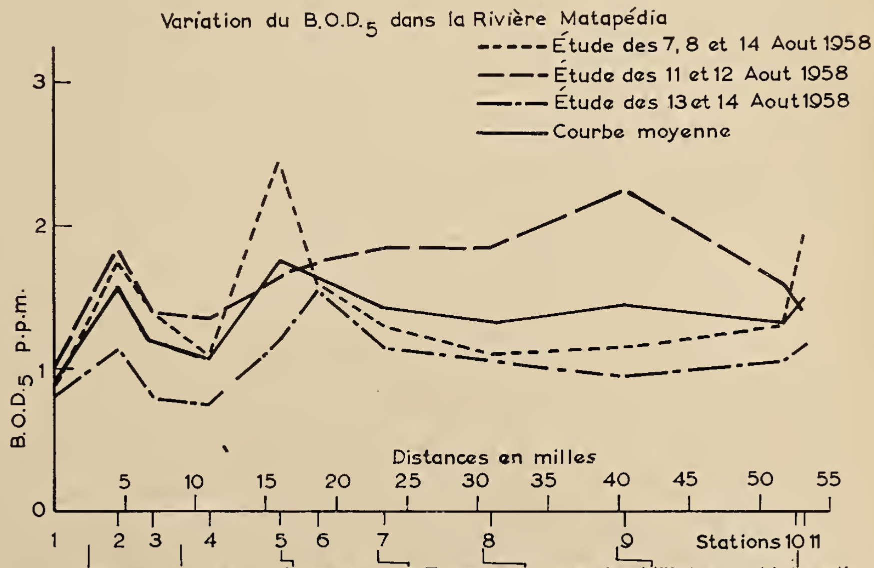
River waters must not be taxed too heavily. It is true that they must continue to receive domestic sewage and industrial wastes. This is generally recognized as an essential and legitimate water use; but there is a limit to the pollution load that a river can handle. Self-purification is a complicated process and each river has its own specific capacity for purifying itself which can only be properly evaluated after an extensive chemical, physical, hydrological and biological survey. The main factors influencing self-purification are:

Dissolved oxygen — Self-purification depends upon the presence of a sufficient quantity of dissolved oxygen. So long as oxygen is not used up too rapidly during the oxidation of organic matter by the activities of bacteria, some improvement in the condition of the stream may be expected. The deoxygenation of river water by the discharge of organic wastes may be a relatively slow process. Studies of the rate of biochemical reaction lead researchers to the conclusion that generally "the rate of biochemical oxidation of organic matter is proportional to the remaining concentration of unoxidized substance, measured in terms of oxidizability".[3]

Kind of organic matter—The rate of self-purification will depend to some extent not only on the amount of organic matter discharged, but also on its character or nature. Oxidation of the more easily decomposed organic matter as domestic sewage begins as soon as it is discharged to the stream, but some substances are more slowly broken down and a few materials such as cellulose are very resistant to oxidation, and may take many months to decompose.

Biological forces—Among the biological agencies playing a vital role in





the self-purification of streams are the bacteria, the algæ, the protozoa, the rotifers, the crustacea and the worms.

Toxic substances—Since self-purification is largely dependent upon the activities of bacteria and other micro-organisms, it is evident that the presence of any toxic substance will tend to reduce the rate of self-purification of a river, by killing the organisms or arresting their development. The extent to which the natural self-purification processes are inhibited will depend upon the nature, degree of toxicity and concentration of the chemical poison.

Physical characteristics of stream—The capacity of a stream to assimilate waste is largely dependent on its physical characteristics. Such physical characteristics as the velocity of the stream current, the slope, the depth and cross-section of the stream, the channel roughness and the character of the stream bed, are all important factors which have a marked effect on the rate of re-aeration, and therefore on the rate of self-purification. Thus, a shallow fast-flowing stream will purify itself in a much shorter time than a deep and sluggish stream.

Dilution—The ratio of the volume of polluting liquid to the volume of the stream water is of great significance, and when organic wastes are discharged to a stream, dilution plays a fairly obvious though important part in diminishing the objectionable character of the pollution. Diluting water may also prove an important means of supplying extra dissolved oxygen, though on the other hand grossly polluted tributaries may turn out to be a liability in this respect.

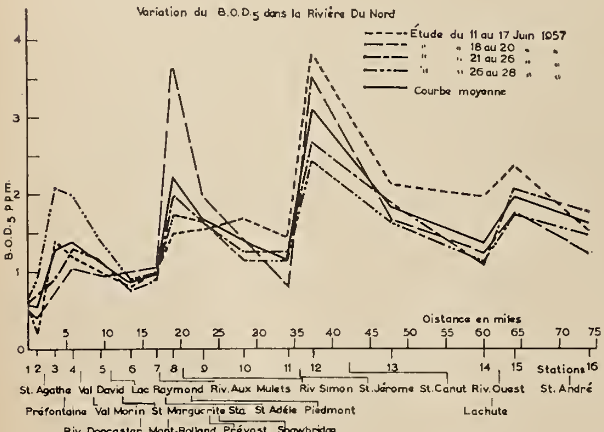
Weather conditions—Sunlight can play an important part in the self-purification of streams by promoting photosynthesis. Wind action may be of value in promoting wave action, thus increasing the rate of absorption of atmospheric oxygen and producing good mixing.

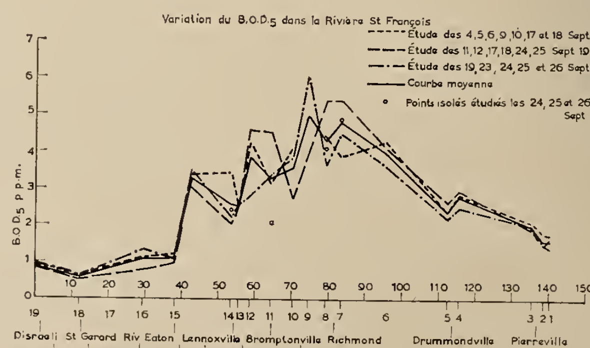
Sedimentation and sludge deposits—Sludge deposits on the bed of a stream are formed as a result of sedimentation and also by the flocculation of colloidal matter. These deposits, owing to their high oxygen demand, can affect self-purification adversely by depleting the river water of dis-

Table 1.[2]

Pathogens in Sewage and Polluted Streams

Organisms	Disease	Remarks
Virus	Poliomyelitis	Exact mode of transmission not yet known. Found in effluents from biological sewage purification plants.
Vibriocholera	Cholera	Transmitted by sewage and polluted waters.
Salmonella typhi	Typhoid Fever	Common in sewage and effluents in time of epidemics.
Salmonella	Food poisoning	
Shigella	Bacillary dysentery	Polluted waters main source of infection.
B. anthracis	Anthrax	Found in sewage. Spores resistant to treatment.
Brucella	Brucellosis—Malta fever in man. Contagious abortion in sheep, goats, cattle.	Normally transmitted by infected milk or by contact. Sewage also suspected.
Mycobacterium tuberculosis	Tuberculosis	Isolated from sewage and polluted streams. Possible mode of transmission. Care with sewage and sludge from sanatoria.
Leptospira icterohaemorrhagiae	Leptospirosis (Weil's disease)	Carried by sewer rats.
Entamoeba histolytica	Dysentery	Spread by contaminated waters and sludge used as fertilizers. Common in warmer countries.
Schistosoma	Bilharzia	Probably killed by efficient sewage purification.
Taenia	Tape worms	Eggs very resistant, present in sewage sludge and sewage effluents. Danger to cattle on sewage—irrigated land or land manured with sludge.
Ascaris Enterobuis	Nematode worms	Danger to man from sewage effluents and dried sludge used as fertilizer.





solved oxygen, and undergoing anærobic digestion. Furthermore, septic action often results in gas evolution, causing sludge to rise to the surface.

Temperature—Temperature plays a vital part in chemical and biochemical reactions, and is an important factor influencing self-purification since, according to the van't Hoff rule, the speed of a chemical or biochemical reaction is doubled by a rise in temperature of 10°C. As far as biochemical and biological processes are concerned, however, the validity of this rule is often limited to a comparatively small range of temperature in the neighbourhood of 20°C. It must also be pointed out that since warm water contains considerably less dissolved oxygen than cold water, a heavy pollution load is much more likely to deoxygenate a stream and promote septic conditions in summer than in winter.

It follows then that too much confidence should not be placed in the self-purifying capacity of a stream. In the Province of Quebec, where the rivers are relatively large, disposal of sewage by dilution is common. But the explosive population growth with growing needs and higher standards now taxes heavily the essentially fixed water resources. Furthermore, highly competitive pressures are brought to bear to commit ever more water to the various competing uses. At the same time, in many areas far too much water is made literally useless by uncontrolled pollution, so that today water pollution control very definitely is a major instrument in water resource conservation.

Pollution Control

To control the discharge of untreated sewage or industrial wastes into a stream, the Minister of Health has certain powers given to him by the "Quebec Public Health Act". These powers may be summarized as follows:

Article 57: Requires that, plans and specifications of public or private drainage works or the installation of any plant for the treatment of sewage, must be submitted to the Minister of Health for his approval. It allows the Minister to require the type of treatment needed, in view of local conditions, for any intended sewage works.

Article 59: States that no municipal by-law, relating to the construction of drainage or sewage treatment works, shall be submitted to the ratepayers, unless their plans and specifications have been previously approved by the Minister of Health.

Article 61: States that the Minister may apply to the "Public Service Board", which after investigation and after consulting the Minister, may order the construction of sewage treatment works for purposes of public health and well-being.

Article 65: States that whenever the Minister finds, after investigation, that the source of water supply of any municipality in this Province, has been rendered impure by reason of the discharge of sewage or other waste matter, or whenever he finds, after investigation, that any stream, lake or pond has been rendered so impure as to give off foul or noxious odours, injurious to the health or comfort of those living in the vicinity, it shall be the duty of the Minister to communicate the result of his investigation to any municipality, corporation or person responsible for such pollution. After having heard the interested parties, the Minister may call upon such municipality, corporation or person to take the necessary steps to do away with such causes of pollution.

Article 67: States that whenever the Minister finds, after investigation, that a sewage treatment work does not produce good results, and that the public health is in danger or that a nuisance exists on account of faulty construction or operation, it shall be his duty to communicate the results of his investigation to the municipality, corporation or person having charge of or owning such plants. Having heard the interested parties, the Minister may order such municipality, corporation or person at fault to alter the plant in such a manner as to give the results required, to the satisfaction of the Minister.

Article 69: States that any municipal corporation ordered by the Minister to do any works or improvements, in virtue of this Act, is authorized for the purpose of obeying such order, to take the necessary amount out of its general funds not otherwise appropriated and, if necessary, to borrow

Table 2

Existing Sewage Treatment Works

Location of Plant	*Owned by*	*Type of treatment*	*Receiving stream*
Asbestos	"Canadian Johns Manville"	Complete	Small brook
Beaconsfield	Municipality	Primary	Lake St. Louis
Belleterre	Municipality	Sedimentation and chlorination	Townsite lake
Bourlamaque	Municipality	Sedimentation	Pond
Caughnawaga	Municipality	Sedimentation and chlorination	St-Lawrence River
Cote St. Luc	Municipality	Sedimentation	Rivière St-Pierre
Drummondville	Municipality	Sedimentation and chlorination	Rivière Noire
Gagnonville	Municipality	Primary	Discharge of Lake Barbel
Hemingford	Municipality	Sedimentation	Odell brook
La Petite Rivière	Municipality	Sedimentation	St-Charles river
Laprairie	Municipality	Sedimentation	St-Lawrence Sea Way
Maria	Hospital	Sedimentation and chlorination	Baie des Chaleurs
Mont-Apica	Department of National Defence	Complete	Upica river
Noranda	Municipality	Complete	Lake Osisko
Parent	Department of National Defence	Primary	Lake Grant
Pierrefonds	Municipality	Sedimentation and chlorination	Des Prairies river
Pincourt	Municipality	Sedimentation and chlorination	Lake St-Louis
Plessisville	Municipality	Primary	Blanche river
Pointe Claire	Municipality	Sedimentation and chlorination	Lake St-Louis
Princeville	Municipality	Primary	Blanche river
St-Adolphe-de-Howard	Department of National Defence	Complete	Lake St-Denis
St-Ambroise-de-la-Jeune-Lorette	Municipality	Sedimentation	St-Charles river
St-Constant	Municipality	Sedimentation and chlorination	St-Pierre River
St-David-de-Falardeau	Municipality	Sedimentation and subsurface drainage bed	Lake Clair
Ste-Foy	Municipality	Sedimentation and chlorination	Small brook
St-Hilarion	Municipality	Sedimentation and subsurface drainage bed	Small brook
St-Hubert Airport	Department of National Defence	Complete	Small brook
St-Jacques l'Achigan	Familial Institute	Primary	Small brook
St-Léonard-de-Portneuf	Municipality	Sedimentation and chlorination	Small brook
Ste-Monique-des-Saules	Municipality	Sedimentation	St-Charles river
Ste-Pudentienne	Municipality	Sedimentation and chlorination	Mawcook brook
St-Sylvestre	Municipality	Sedimentation and subsurface drainage bed	Small brook
St-Sylvestre	Department of National Defence	Complete	Small brook
Ste-Therese	Municipality	Sedimentation and chlorination	Mille-Iles river
Ste-Therese-de-Blanville	Department of National Defence	Complete	Riviere aux Chiens
Schefferville	Quebec Iron Ore	Complete	Pearce Lake
Valcartier	Department of National Defence	Complete	Nelson river

such amount by by-law without being obliged to observe the formalities regarding loans required by the laws governing such municipality.

Existing Sewage Treatment Works

In virtue of these powers granted to the Minister, certain municipalities were asked to provide sewage treatment works in order to treat partially their sewage before discharging it into a stream. The existing sewage treatment plants are shown on Table 2.

Furthermore the municipalities shown on Table 3 will provide during the coming year a certain type of sewage treatment:

Table 3.
Intended Sewage Treatment Works

Location of Plant	*Owned by*	*Type of treatment*	*Receiving stream*
Fabreville*	Municipality	Primary	Mille-Iles river
Henryville	Municipality	Sedimentation	Riviere du Sud
Henryville	Dairy Elmhurst	Complete	Gariepy brook
L'Annonciation*	Hopital des Laurentides	Primary	Riviere Rouge
Notre-Dame-de-Lorette	Municipality	Sedimentation and chlorination	Lorette river
Pierrefonds*	Municipality	Primary	Des Prairies River
Pointe du Moulin*	Municipality	Primary	St-Lawrence river
St-Donat*	Municipality	Sedimentation	Ouareau river
Ste-Dorothée*	Municipality	Primary	Des Prairies river
St-Gabriel-de-Brandon	Municipality	Primary and filtration	Discharge of Lake Maskinongé
St-Placide	Municipality	Primary	Lake Deux-Montagnes

*These plants are now under construction

In the past few years, real progress has been made in stepping up the construction of essential municipal waste treatment for the intended sewage works in the Province of Quebec. A good example of this progress is a revolutionary new method for destroying the bacteria, odour and organic materials in settled, primary raw sewage sludges. This method is called the "Atomized Suspension Technique" and was developed by the Pulp & Paper Research Institute of Canada. In this unit the sludge is atomized with pressure nozzles into an empty tower whose walls are held at a temperature varying from 1400°F at its top to 1000°F at its bottom by four banks of electric heaters controlled individually and automatically. As the water in the atomized spray flashes into superheated steam, the solid particles are completely dried by the time they have fallen half-way down the tower. At this point, air is introduced at low pressure from a compressor so that the solid particles may be combined with the oxygen in the air. The organic material is then burnt to a dry, fine dust or harmless inorganic ash. This unit takes the place of the costly, slower method of sludge digestion followed by the drying beds and then disposal of the dried solids, with its attendant handling costs and nuisance problems.

But the major difficulty was the lack of data on actual stream quality to determine the degree of treatment needed to eliminate undue pollution in a given stream.

Water Pollution Committee

On December 1st, 1955, the Lieutenant-Governor in Council was authorized to form a committee of not more than five persons to study the problem of the pollution of the waters of the public domain of the Province. This committee was asked to inquire into the nature and causes of the present pollution of waters of the public domain, try to find out the remedies therefor, and the measures required to prevent further cases of pollution, and report its findings and suggestions to the Lieutenant-Governor in Council. The members of this committee were named in August 1956.

Following a request from this committee to the Minister of Health for the necessary data on stream quality, the Sanitary Engineering Division of the Department of Health undertook to make a preliminary study on certain rivers presenting complex and difficult problems for an efficient control caused by sewage and industrial wastes. The first rivers chosen were the North river, the St-Francis river and the Matapedia river.

Field Work

For each of these rivers, a sanitary survey of the entire watershed drainage area was made in order to determine the actual and potential sources of pollution. This meant that attention was given to the location of sewage treatment plants, bathing areas, storm drains, sewer outfalls, industrial wastes outfalls, and water intakes. To collect this information, visits were made by a sanitary engineer to the secretary-treasurers of municipalities in the watershed drainage area of the river under consideration. Visits were also made to industrial establishments to determine the pollution load contributed by these industries.

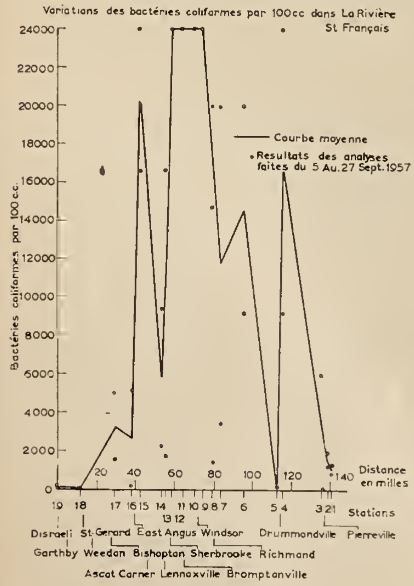
To complete this preliminary study, bacteriological, chemical and physical examinations of the river water were also made by trained personnel equipped with a mobile laboratory. That work included mainly the sampling and analysis of river water.

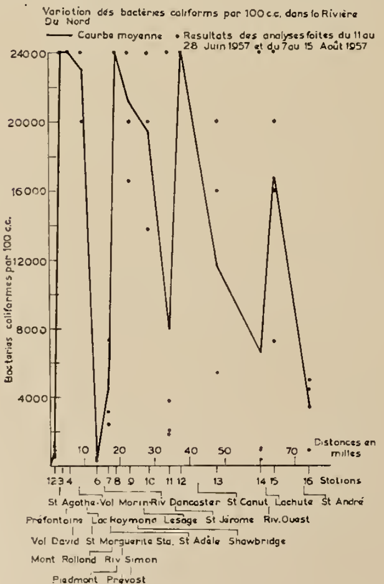
Sampling—Samples were taken upstream and downstream of main sources of pollution to determine their influence on the quality of the river water. Some samples were also taken to determine the self-purification capacity of the river. Finally, some samples were taken on the main tributaries to determine their contribution to the river pollution.

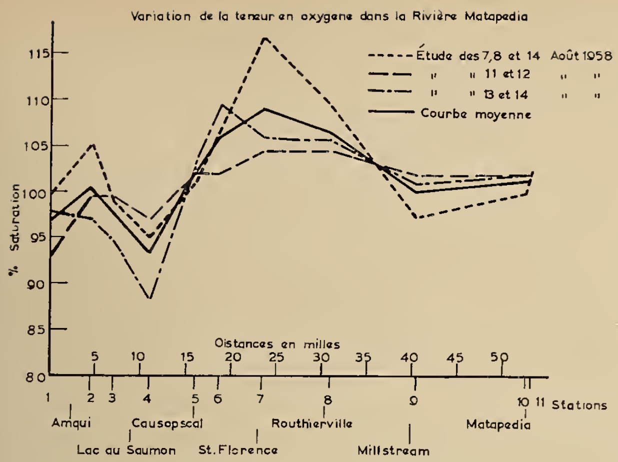
The number of sampling points was the following on each river: 16 on the North river and 3 on its tributaries; 19 on the St-Francis river and 3 on its tributaries; and 11 on the Matapedia river.

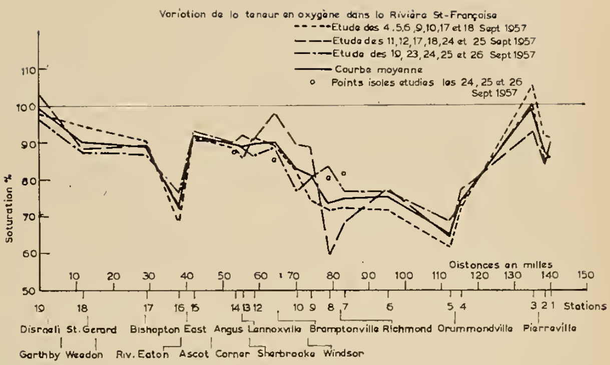
The sampling procedure was in accordance with the sampling directions given in the 10th edition of "Standard Methods for the Examination of Water, Sewage and Industrial Wastes", published jointly by the American Public Health Association, The American Water Works Association and The Federation of Sewage and Industrial Wastes Associations.

Analytical work — All analytical work was made in accordance with









the 10th edition of "Standard Methods . . ."

The field work included the determination of turbidity, pH, temperature, dissolved oxygen and five day biochemical oxygen demand (B.O.D.). Oxygen is needed for the respiration of the organisms that are responsible for the aerobic decomposition of organic matter. Therefore, a determination of the amount and rate of oxygen utilization furnishes one of the best means for estimating indirectly the amount of decomposable matter contained in a water. This determination is called the biochemical oxygen demand, or B.O.D.

The bacteriological examination was made by the Ministry of Health Laboratory in Montreal. That bacteriological examination involved the research of the coliform group of bacteria which is considered a satisfactory indicator of pollution, because these bacteria are found in large numbers in domestic sewage. The result is expressed as the most probable number of organisms per 100 millilitres (MPN per 100 ml.).

The nine graphs represent the variation in five day B.O.D., dissolved oxygen and coliform counts along the three rivers we have studied in the years 1957 and 1958.

Recommended Stream Quality

For drinking purposes — As an aid in determining the treatment of water to make it safe to drink, the United States Public Health Service has classified waters into several groups.[4] The treatment required by this classification is summarized in Table 4.

For water to be generally acceptable, however, other treatment may be required in addition to that necessary for the elimination of disease-producing organisms.

For fisheries — Ellis[5] has given the minimum dissolved oxygen content of water for maintaining fish in healthy condition as 5 p.p.m. at 20°C, or about 57% of saturation, and other authors give figures of the same order of magnitude. Game fish (e.g. salmon and trout) require more dissolved oxygen than do coarse fish.

Other factors may also influence the presence or absence of fish, for example the temperature, the pH, the toxic substances, the geological nature of the strata through which the river flows, the physical character of the stream and of the stream bed, the strength of the current, the relative abundance and nature of the plant life and the fish food present.

For recreational use — Water for recreational use (boating and bathing) should not only be free from colour, odour, or anything visible of an objectionable nature (such as sludge banks, suspended matter, floating material and oil) but also should not contain anything injurious to public health.

In the U.S.A. a number of States have put forward standards for outdoor bathing waters based upon the B. coli count. For example, the Connecticut State Department of Health[6] has proposed a classification of these waters which is given in the following table:

Class	Condition	Average B. coli count per 100 ml.
A	Good	0—50
B	Doubtful	51—500
C	Poor	501—1000
D	Very poor	Over 1,000

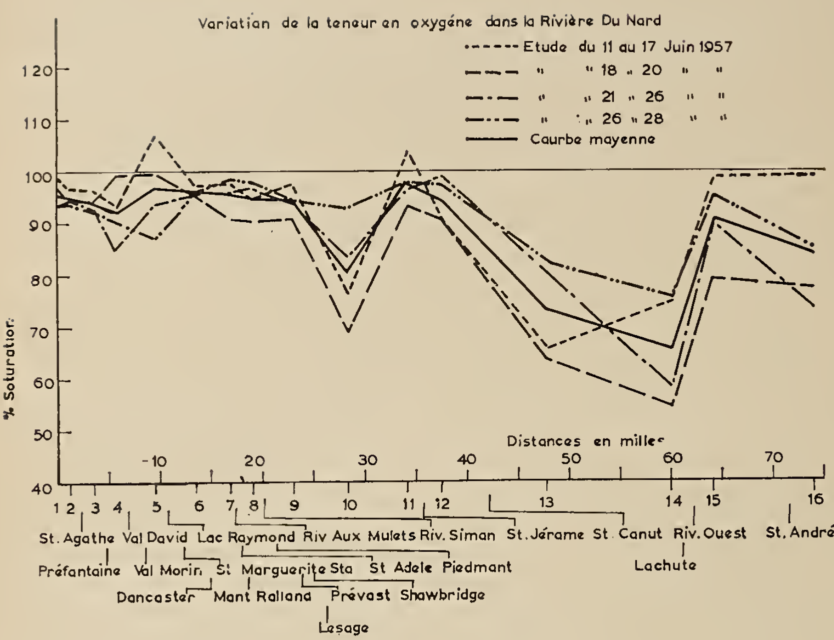
The use of this classification is recommended by the Joint Committee on Bathing Places of the Conference of State Sanitary Engineers and the American Public Health Association.[6]

However, experience allows us to state that bathing is safe in natural waters with a coliform count inferior to 2400 per 100 ml.

For outfalls — A rule of thumb

Table 4

Group No.	Maximum Permissible Average MPN Coliform Bacteria per Month	Treatment Required
1	Not more than 10% of all 10-ml. portions positive; approximately less than 2.2 coliform bacteria per 100 ml.	No treatment required of underground water, but a minimum of chlorination required of surface water.
2	Not more than 50 per 100 ml.	Simple chlorination or equivalent.
3	Not more than 5000 per 100 ml. and this MPN exceeded in not more than 20% of samples.	Rapid sand filtration (including coagulation) or its equivalent plus continuous chlorination.
4	MPN greater than 5000 per 100 ml. in more than 20% of samples and not exceeding 20,000 per 100 ml. in more than 5% of the samples.	Auxiliary treatment such as 30-90 days storage, presettling, prechlorination, or equivalent plus complete filtration and chlorination.
5	MPN greater than 20,000 per 100 ml.	Prolonged storage or equivalent to bring within Groups 1–4.



giving a rough estimate of the required dilution is that untreated, combined sewage may be discharged safely into streams that carry 10 cfs of water per 1,000 persons contributing sewage. However, the required dilution may vary according to the swiftness of streams. For domestic sewage, treated sewage, and industrial wastes, that figure can be apportioned to the relative amount of putrescible matter present. Where the emphasis is on water supply, recreational use of water, and preservation of fish and other useful aquatic life, rather than on the avoidance of nuisance, dilution requirements become very much larger. If available dilution is inadequate, the sewage must be treated before disposal by dilution. These dilutions are permissable on account of the self-purification capacity of streams as already explained in the present article.

However, the de-oxygenation of river water by the discharge of organic wastes may be a relatively slow process. Hence it happens that the point of maximum de-oxygenation usually occurs a considerable distance (often many miles) below the point of discharge, depending on the rate of self-purification. Determinations of B.O.D. and dissolved oxygen at various points in the river are necessary to assess the extent to which self-purification has proceeded.

The Royal Commission on Sewage Disposal[7] considered that the dissolved oxygen content of a river should not fall below about 60% of saturation in the summer if nuisance was to be avoided, but it is generally considered nowadays that this gives a fairly wide margin of safety.

That Commission[8] took the view that a river giving a five day B.O.D. (18.3°C) of 4 p.p.m. would be on the verge of causing nuisance. That figure forms the basis of the following classifications taken from the Royal Commission Reports.

Observed condition of stream	5 day B.O.D. (18.3°C) p.p.m.
Very clean	1
Clean	2
Fairly clean	3
Doubtful	5
Bad	10

Considerations Arising from these Studies

From our results and recommended standards, we could suggest some limitations applicable to the many uses that can be made of the three rivers we have studied. However, on the basis of results from that preliminary survey, it is not desirable to draw at the present time too detailed and far-reaching conclusions.

In spite of the high self-purification capacity we have observed especially in the North and Matapedia rivers, it can generally be said that treatment of industrial and domestic sewage, especially where highly concentrated, will be necessary to allow the use of these rivers for drinking, industrial, fisheries and recreational purposes.

Other rivers under study by the Sanitary Engineering Division are the St. Charles river, the Yamaska river and Lake St. Louis. All studies made up to now were only preliminary. To classify these rivers according to best use in the interest of the public and to determine the sewage treatment needs, a more complete study will have to be made on each of them.

Conclusion

Real progress has been made in the Province of Quebec regarding water pollution control. Under the present legislation, sewage treatment works were built to treat the sewage of certain municipalities, but the Legislative Assembly may have to give larger powers to permit a sewage treatment works construction program tending towards a better quality of receiving waters.

Interest in determining the capacity of natural waters to assimilate wastes will increase in the future as greater emphasis is placed on water pollution abatement. But at present people in the Province of Quebec too often say that paying for sewage treatment means paying for goods they never receive since other towns seem to get all the benefit from their expenditures. They must decide definitely and finally if they will take the road of the conserver and wise user. The choice is theirs. They must choose wisely and soon, for time and our rivers will not wait.

A STUDY OF THE USE, CONSERVATION AND POLLUTION OF WATER RESOURCES

A. L. Van Luven, M.E.I.C.,

Head, Waste Treatment Division,
H. E. McKeen and Company, Ltd., Lachine.

In July, 1959 the author presented a Brief to Honourable E. Davie Fulton, Minister of Justice and Attorney General of Canada, entitled: "Some Aspects of Water Pollution and Some Recommendations for Action on Water Pollution Control by the Government of the Dominion of Canada." This paper is intended to support, and if possible, advance the Brief; firstly, by offering a more detailed review of the concepts involved if action is considered by the Dominion Government and secondly, by encouraging other Canadians to publish their views on this subject. The great amount of work that has been done in the United States in recent years should be very useful to Canada. In this country there is awareness of the problems of water resources and pollution, but coordination and leadership are required. In order to realize the need for anti-pollution work, it is first necessary to understand fully the general principles of conservation and the state of our water resources; therefore this paper deals with these matters at considerable length. The paper concludes with a strong plea for positive action by the Dominion Government and presents a suggested list of research and development projects that could serve as a nucleus for a much needed Dominion program.

THE American anti-pollution work should help Canadians a great deal, especially when we consider the similarity in cultural pursuits, kinds of industry, urban growth patterns, highway building, standard of living, recreation, many points of similarity in topography, climate, geology and hydrography.

In the United States Dr. M. D. Hollis[1] has taken a strong stand for several years. He says that the use and misuse of water, has become a major national issue. Dr. Hollis warns that the current growth of population is taxing water resources that are essentially fixed and that a continuous avalanche of technological changes is outmoding the traditional parameters.

It is claimed that the U.S. population (now 178 million) will be 250 million by 1980; therefore the United States Public Health Service (U.S.P.-H.S.) believes that the continuing avalanche of technological change will be at an ever-increasing tempo, with very significant effects on resources.[2]

In the United States so far the philosophy of treatment has been to do the job in the most economical way—treat the waste a minimum amount and let Nature do the rest, sometimes without proper regard for the time and forces available to her for the extent and increasing complexity of the work required. The U.S.P.H.S. are currently estimating that much of the American yearly water supply must soon be re-used at least six times to meet the demands.

Watson[3] described the wave of State legislation that has resulted from their national pollution problem. He emphasized the importance of inter-State pacts to handle the problem on a river basin basis, and the importance of the over-riding Federal authority. Geuther[4] states that from 1953 to 1956 there were 269 bills (State and Federal combined) dealing with water pollution, with much of this legal activity revolving around the question of proper doctrine.

In summary, as stated by Grayson,[5] the United States have become a nation with "push-button" luxuries and "push-button" shortages. There are shortages of schools, highways, hospitals, housing, water supply facilities and sewage facilities. Action is predicated upon the *understanding* of the people. It seems fully evident that the American resources have some serious limitations, which require action, now, and tremendous expenditures.

Perspective of Canadian Situation 1960

The International Joint Commission for Canada and the United States began in 1909 and has always been concerned with works that might affect the levels of boundary waters and other problems along the borders on a request basis from both Governments.

The work of the Ontario Water Resources Commission is outstanding. This agency is unique in the history of water resource development and anti-pollution because of its very broad and important powers. The O.W.R.C. can force action, finance, construct, acquire, operate and maintain both water and sewage plants. It can control and regulate the collection, production, treatment, storage, transmission, distribution and use of water. It can conduct research programs and prepare statistics for its purposes.

The Greater Winnipeg Sanitary District has instituted a surcharge By-Law that has enabled industry to see where it stands. As a result, it is getting the action required. In New Brunswick, an Act has been passed, recently, which sets up a Commission along lines quite similar to the O.W.R.C. In Quebec, the Provincial Government is making a very careful study of the problem. It is considering a report from the Quebec Water Pollution Committee which seems to be strongly in favour of setting up a Quebec Commission similar to the O.W.R.C. Nearly all of the residential communities adjacent to the waters around the Montreal area are looking to swimming pool construction as a part answer, rather than construct the sewage plants that *must come eventually*. Some communities with both septic tanks and wells are beginning to experience chloride contents in their wells that indicate the need for a careful survey.

At Ottawa, Hon. J. W. Monteith (Minister of National Health and Welfare) on February 2, 1960 announced that his department will expand its research facilities to include a new environmental health centre. In addition, a conference is being planned by the Department of Northern Affairs and National Resources to be held in 1960 under the heading "Resources for Tomorrow". At the present time there is a private bill before the Dominion Government, known as Bill C-34 — "An Act to Amend the Criminal Code". This proposes very high penalties to industry for polluting water.

In Canada today, there are several strong Government organizations actively concerned with this problem. There are varying degrees of awareness of the general pollution picture at all levels of Government. Some Boards of Trade, some technical groups and some service organizations are pressing for action. This is a general picture for the Dominion, but to date many of these efforts, although well-meaning, are not founded on a scientific analysis of the problem or even on sufficient background information, and there is a great need for coordination and leadership.

We need guidance to maintain the quality and quantity of our most important natural resource. Already thousands of square miles have been fished out, shot out, cut over, depleted and polluted, so that both pleasure-seeker and businessman alike are being cheated of their rights.

Some Conservation Concepts

Some people are still shocked by the idea that Canada must conserve her resources; they are still thinking of the wide open spaces of Canada—the granary of the world, etc. These people think that man's chief idea is to *conquer* nature, without realizing that man will remain at the top of creation *only by working with* Nature.

Conservation is the informed, conscientious management of resources; it is development as well as protection; it is use as well as saving. A conservationist is not a hoarder but a person who makes judicious choices; he has three general principles:

He matches the resource and the use so that there is a minimum of waste in either quantity or quality;

He uses recurring resources wherever possible instead of fixed resources;

He protects his sources of supply.

Water is a basic resource which has suffered because of poor understanding and our casual attitude. It has been wasted by unnecessary run-off and excessive use in industry, home and irrigation. Conservation or wise use of resources is primarily a matter of education — educating ourselves to a very important need through the continuous critical correction of past errors. We must come to a full realization of the concept that our natural resources belong to a vast family, of whom many are dead, few are living and countless millions are still unborn.

In our society there will always be exploitation, hence we must have public controls to bring exploitation in line with social objectives. It is hoped that public control would regulate the distribution of water resources (for example, ground water) and thus maximize the return to society, both present and future. In other words, a comprehensive, basic legislative authority should be the cornerstone upon which the maximum conservation and development of water resources will be accomplished for the greatest benefit of all.

Control and supervision must be at least province wide, because all conservation activities must be coordinated. Uniformity of standards can be a very troublesome concept in conservation work, especially in regard to streams, but there must at least be a uniform approach over as wide an area as possible to protect the public interest. Many of the leaders in the anti-pollution and conservation work of the U.S. are convinced that a centralized national agency with strong supporting legislation is absolutely vital to an effective program.[6] We, as a collection of thousands of locally autonomous communities, urgently require a strong over-riding force to choose the desired end use of water which will achieve the greatest public benefit.

Conservation and management of resources require a high degree of skill and many trained people. For example, reservoir management requires a great deal of skill, particularly when the reservoir is used for several purposes such as hydroelectric power and irrigation. It is necessary in this case for the manager to know such facts as the evaporation from the surface, the time and amount of each need, and the expected run-off. In this matter of reservoir evaporation, there may be good possibilities in the use of hexadecanol or octadecanol as a monomolecular surface film to reduce evaporation from a reservoir surface. According to Taylor[7] these chemicals have great promise and have no ill effects on fish or fowl.

Laws are essential in conservation and anti-pollution work and yet neither statutory nor common laws will necessarily prevent water use problems. Before administrative machinery can work properly we must understand the hydrology of any particular water resource, and the public must be informed of the broad social needs of the country. Leopold[8] stresses the concept of water management rather than specific administrative doctrines. He advocates the development and management of resources with an adequate system of continuous appraisal.

Scientific watershed management is becoming increasingly important. Watersheds are affected by forest fires, erosion from overgrazing, over-cutting of timber, etc. According to Taylor[7] only about 20% of rainfall is used productively; some evaporates and the rest is wasted. In our highly developed society, our standards are greatly influenced by our treatment of watersheds which, in turn, control sources of supply, floods, water tables, erosion, land fertility and to a great degree, pollution. Some authorities strongly advocate restriction of access to all watershed head water areas.

Recently certain conservation concepts have changed our thinking. For example, Dibble[9] has discovered that some plants transpire excessively and that it is possible to make far greater use of land in some dry areas by using certain water-thrifty plants.

Upson[10] points out that we should be concerned about discharging sewage to the sea because this practice places fresh water beyond the possibility of recycling in addition to polluting beaches, fisheries, etc.

The reclamation and re-use of water must become a firmly entrenched principle in our society. We simply must realize that some of our modern gadgets are extremely wasteful of both water and sewage plant capacity. For example, our modern living has the joys and the *problems* of automatic dishwashers, automatic laundry machines, and extensively used air conditioning equipment. Garbage grinders increase the water consumption and they also affect sewage treatment.

On the positive side of this story, there is the possibility that the future will see extensive conversion of sea water for domestic purposes in the dryer parts of the world.

Finally, a very important aspect of conservation is popular understanding. According to Grayson[5] public education regarding sewage, water pollution and water resources is essential and money is not the problem; the people do not understand the urgency of these problems.

Our Water Resources

Even though we occasionally suffer deluges and though we know that our earth's water resources are permanent and indestructible, we must also realize that the amount available and its quality at a given place and time are changing. Ignoring the possibility of mining water, the total annual supply is equal to the annual precipitation; this is an almost constant amount. These facts add up to serious shortages in some localities.

Some of these shortages are local and are due to poor distribution or deterioration of quality by industry, municipality or agriculture. Also we can partly correct our water difficulties by making full use of the fact that water is one of our more renewable natural resources; it can be re-used several times in the course of its hydrologic cycle.

Many of our water problems are the direct outcome of efforts to adapt our physical environment to our economic and social needs without reckoning sufficiently on Nature's ways. The most damaging impact of civilized man on his environment is the shattering of the water cycle. In Canada, before the advent of the white man, there was a mutual society of balance among waters, soils, grasses, forests and animal life. Each member of this society contributed its powers of control and protection and was, in turn, controlled and protected. It is useless to spend millions on river control and valley development unless this work is accompanied, for example, by reforestation and good, overall watershed program.

It is becoming more and more evident that our water problems are due to a combination of regional shortages, ineffectual control of pollution and unsolved technical problems. There is a fourth reason that will be dealt with further, namely, the uneconomic pricing of water. Incidentally, we frequently mean insufficient capital investment when we use the words "ineffectual control of pollution."

Water Supply Problems

We have referred to uneconomic pricing as a major cause of our water problems. Undoubtedly there is an obvious need to promote certain social and sanitary uses of water through low pricing, but there also should be much closer adherence to orthodox principles of pricing. There should be extra costs paid by those who deplete or degrade our water resources. Water rate determination is complicated by the necessity of providing fire protection, by politics, and by the very essentiality of water to our existence. However, we certainly must weigh availability against the fact that the installation of meters has been known to reduce water consumption by 50%.

According to Hines,[11] water prices are a hybrid of economic and social forces. The unusual versatility of water as a low cost economic good permits it to satisfy a great variety of private and collective wants but also leads to special problems in pricing and allocating. Some experts have sought to establish water prices according to the value of the end product. This does not seem sound. We have plenty of evidence that water is not priced properly, which of course all ties in with the water resource problem. For example, there are only a few private water companies; water rates do not reflect construction costs and policies differ widely.

The price of water is closely related to our sewage treatment and water pollution problems. The quality of raw water, which greatly influences the price of finished water, is itself largely dependent on how much treatment is given to sewage by the upstream community, when the source of supply is a flowing stream. The net cost of water treatment for a community is also dependent on the condition of its own sewage effluent (being much less if no treatment is given).

Although we shall deal more specifically with water rights and water laws later, it is necessary to point out now that certain guiding legal principles are likely to be forced on us to correct some water supply problems. Water supply facilities are becoming more costly and more complex, hence investment requires more security. This will lead to such measures as:

refusal to grant exclusive control over water;

complete public ownership of all water supply;

ground and surface waters treated as one.

Undoubtedly our future water laws must permit some flexibility but this will certainly require a good system of checks and balances.

Radioactivity is adding to the general supply problem, and there are many unknown factors about pollution with radionuclides. It is known that many radionuclides are isotopes of elements which have biological importance and enter into many biochemical processes. Some radionuclides are accumulated by aquatic life to a very high degree. Some radioisotopes accumulate in bone while others accumulate in soft tissue. Apparently, fish may accumulate radioactive cæsium in their muscles to levels 20 to 50 times the radioactive level of the water, thus making the fish very dangerous for human consumption; fresh water fish concentrate radioisotopes to a much greater degree than do salt water fish, particularly when the fresh waters have a low calcium content. Bottom layers seem to have great absorptive capacity for radioactive materials. The biota in the mud degradate the oranic matter, transferring chemical components from one organism to another. Then soluble salts, together with the organisms, are gradually lost downstream along with their radioactivity. It is argued by some[12] that great care is necessary in monitoring and releasing radioactive wastes to surface waters.

Bernard Baruch once said that water eventually will be more valuable than oil. Perhaps we shall all realize this before long.

Ground Water Problems

Thomas[13] states that when ground water storage is used properly in conjunction with good surface storage, the annual water yield may be increased to about 85% of the average natural supply. The importance of cooperation between industry and municipality is paramount for protection of ground water supplies. Most of us require education in this matter and research must provide much needed data before we can deal adequately with the problems of locating, recharging, conserving and contaminating our ground waters, in addition to the complex legal problems.

The problem of locating ground water is linked closely with evaluation; Kleiser[14] and Miller[15] agree on the general approach to this problem and have outlined some of the methods involved. The basic starting point is a careful study of the general geology of the area. Next, there must be an analysis of all the available well records. Experienced engineers point out that authorities should insist on drillers keeping better records. Adequate information about wells could be invaluable to a water resource program. The required data are:

full results of resistivity surveys where done;

depth and thickness of water-bearing formation;

chemical quality and quantity of water produced originally and periodically;

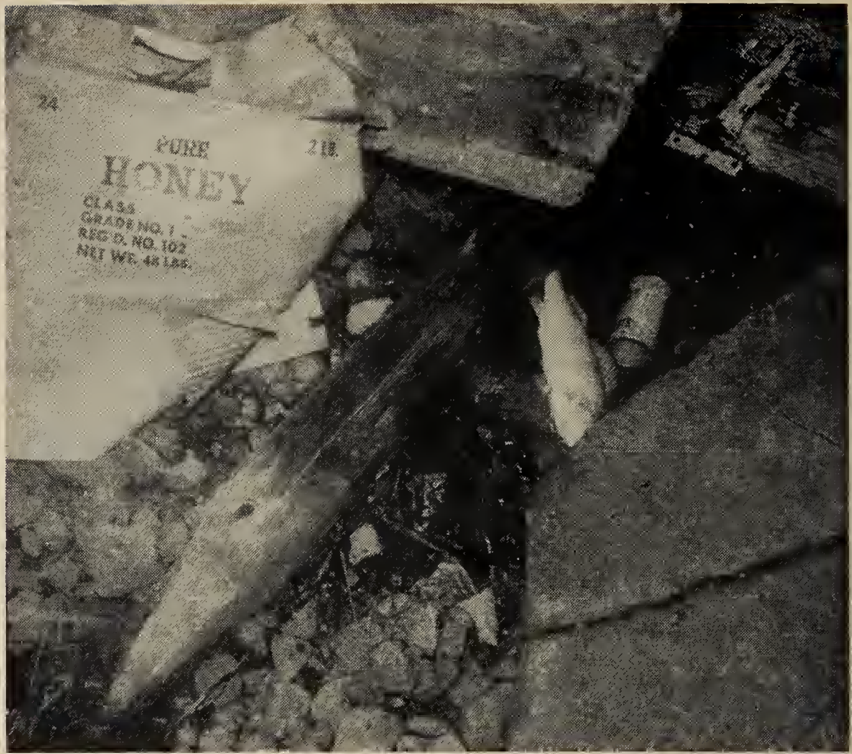
results of all test holes, resistance measurements, seismic surveys, performance tests, etc. for each area in question.

The well drillers might be incorporated into a national fact-finding program.

Various methods have been proposed for recharging ground water storages but all have difficulties. The methods proposed are surface ponding, injection and induced infiltration. Surface ponding is hampered by a gradual loss of permeability. Well injection suffers from chemical precipitation, air-bubble locking, sediment or organic materials. Infiltration, induced by manipulation of ground water levels and by controlling surface-storage reservoirs, is still in its infancy.

A great deal has been written about the California ground water problems; much of this does not apply to our Canadian picture. However, we should mark well the results of California's past disregard for its once extensive ground water resources. Richter and Chun[16] point out that Californian water levels are declining enough to permit alarming sea water intrusion in many areas. They emphasize that much of the trouble is due to human activities, such as sealing natural recharge areas with airports and discharging unnecessary amounts of fresh water into the ocean via sewage disposal systems.

Richter and Chun point out that recharge rates are affected by the natural ground slope, properties of the surface soil (permeability, depth, organic content, etc.) procedures used in the construction, operation and maintenance of a recharging project, the quality of the water involved, and by the geologic and subsurface hydrologic conditions.



Pure honey cartons, rotting fish and old tin cans hardly breed pure water.

Ground water may be mined, and because of this possibility society can, if desired, make a choice between present and future use of a ground water supply. This choice should be made by people who are concerned with the national problem and completely removed from political influence. As an example of the problem it is noted that the underground water level has fallen so much in the Baltimore area that wells must now be drilled 140 ft. deeper than in 1916.

If conservation requirements are to be met, a great deal of water that has been used and perhaps has passed through a sewage treatment plant, *must* be used for recharging ground water resources. Unfortunately there are considerable hazards in this course of action but the hazards must be overcome. These dangers stem from the possible presence of pathogenic organisms (bacteria, viruses, intestinal worms, protozoa) and toxic substances. In addition, such reclaimed water may eventually permit excessive build-up of dissolved salts, and the soil formations may become clogged through the development of bacterial slimes.

Contamination of ground water may also occur on account of poor well-drilling practices. Schmid[17] has suggested that all wells should be supervised and regulated to avoid polluting ground water. He advocates special precautions to keep drillers from violating codes, working alone without sufficient experience, ignoring the Board of Health and using inferior methods.

The legal problems associated with ground water are complex. Thomas[13] has pointed out that the laws governing ground water storage should allow for storage in one area to be used in a distant area if necessary. Gates[18] asks a few pertinent questions on the subject of piping ground water from one area to another, such as: Will the adjacent owner's land be made arid by the lowered water table? If another locality uses the same ground water source how should the rights be allocated?

Before ground water legal problems can be settled there must be agreement on definitions. For example, Gisvold[19] claims that a distinction must be drawn between underground water flowing in a defined channel and underground percolating water. Gisvold would subject underground streams to the same laws as surface water but deal differently with all other underground water. This is contrary to hydrologic principles because all water comes from the same source —rain and snow. As Piper[20] says, ground and surface waters are interrelated and must be dealt with by a single legal principle.

Surface Water Problems

This subject will be dealt with later when we discuss pollution more specifically, but there are one or two special problems that have a strong influence on surface waters. These are the problems relating to reservoirs, (impoundments or storage).

Dams impound water for power production, flood control, navigation, irrigation, and storage. In addition to fulfilment of these purposes, additional benefits accrue such as recreation and removal of sediment from turbulent rivers. However, a serious disadvantage results with conventional, modern dams. Dissolved oxygen is greatly reduced and the river thereby loses the greater part of its waste-assimilating capacity for very considerable distances below these dams. This problem is particularly troublesome for the storage type of reservoirs; these are usually 100 to 125 ft. deep, with the water being retained in them with negligible flow velocity, for one year or so, and discharge intakes very low in the dam so that the outflowing water is always drawn from the hypolimnion stratum. The hypolimnion stratum is cold, dense water, too deep for light penetration, hence no photosynthesis occurs in it and the dissolved oxygen may become negligible after a few months of oxygen usage by the natural organics which settle.

Kittrell[21] offers some possible solutions to this reservoir problem that might be considered by our power development people. For example, he suggests multilevel penstock intakes, high level penstock weirs, changes in tailrace design, use of aeration chambers, pumping from hypolimnion to epilimnion. It is quite conceivable that it might be cheaper to keep these large reservoirs mixed by pumping than to bear the added cost of the sewage treatment plants, which are made necessary by the loss of the natural waste-assimilation capacity.

Another aspect of impoundments is that they are permitting the water to settle so that the top layers are liable to promote better algae growth than before building the dams. This, plus inadequate sewage treatment, is causing taste and odour problems, filter clogging, and growths in pipes and reservoirs.

Industrial Water Problems

Water problems in industry are due to the lack of both quantity and quality, which, of course, is no different from the problem faced by many municipalities that are concerned only with domestic consumption.

However, the industrial water problem merits special mention because localities that do not have plenty of suitable water or a means of obtaining it, are not likely to experience significant expansion through industrial growth. In other words, there will be a shortage of employment in those areas.

Quite apart from the problems involved in the re-use of water, many present day industries are faced with complex production problems because of impurities in their water supply or because of insufficient water of any kind. Such industries include textiles, pulp and paper, electroplating, packinghouses, beverages, dairies, all of which use water directly in their processes. In addition, many industries that use large amounts of steam would welcome water that is less costly to treat.

Eventually, it is hoped, there will be sufficient surveyed and recorded data on our water resources to permit direction of a given industry to an area which has water suitable for the processes in question.

Reclamation and Re-use of Water

Many senior American engineers are proclaiming the need to re-use water several times. Re-use will entail improvements in sewage treatment in order to maintain the quality of water and avoid harmful effects from re-using it. In addition there may be legal problems arising from the use of ground water or other supplies of inferior quality.

Bookman[22] describes the problems, possible uses and need for water reclamation in California. Bookman claims that approximately 28% of the water used in California ends up in the ocean and that this amount will increase because ocean disposal is cheap, offers a high degree of dilution, requires less pretreatment, and is essential for disposal of some saline and toxic waste. However, even though reclamation is expensive and involves problems it will be increasingly essential in the future.

Reclamation problems arise from the increasing use of synthetic detergents which either affect the sewage treatment process or cause the reclaimed water to foam. The possible build-up of toxic waste and mineral salts must be considered and corrected, if necessary. There is a distinct possibility that pathogenic viruses and bacteria could contaminate ground waters. Better monitoring techniques are necessary to protect health and industry before reclamation can be considered on a large scale. Moreover if an industry agrees to use reclaimed water, it would certainly require a good measure of uniformity in the water it receives; this might be difficult if a number of sewage plants contributed to such a scheme.

The use of reclaimed water for agriculture underlines the necessity for very good treatment since Kabler[23] has shown that wet sludge and settled solids may require 12 to 15 months' atmospheric drying to kill pathogenic bacteria. In addition, it will be necessary to guard against such chemicals as boron which is very toxic to plant life, and insecticidal or herbicidal chemicals could kill crops and sterilize the soil.

Whenever reclaimed water is used for ground-water recharge, there must also be ample distance between the points of recharge and re-use, to overcome the aesthetic objections and provide dilution.

We can conclude that wherever we face the necessity of reclaiming and re-using water, we shall certainly be obliged to provide a very high degree of secondary, oxidation type of treatment plus disinfection.

The legal side of the reclamation picture also requires some careful thought. At the present time, some problems could conceivably arise owing to the differences between statutory and common law riparian rights. For example common law riparian users are obliged to return water to the originating stream whereas statutory users do not have this obligation and thus may sell their used water to a reclamation enterprise if desired. It will also be necessary to protect consumers of reclaimed water against improper treatment, negligence, etc.

Some of the waste water reclamation projects in the U.S. are meeting with success, for example, the Amarillo projects described by Scherer[24] and Alexander.[25] Alexander describes the effect of nitrates, chlorides, phosphates, detergents, slime and algae.

Water Rights and Water Laws

The subject of water rights is very important to both Canadians and Americans, and in fact it may be necessary to maintain a considerable amount of similarity in the two sets of water laws owing to the geographic, climatic and hydrologic relationships, even if we choose to ignore the social and industrial similarities.

The current interest in water laws stems from the increasing shortages and demands in addition to the inadequacy of many existing water laws. Smith[26] lists some of the causes for concern, such as the failure of common law to provide adequate protection for established uses and from consumptive uses and diversions; common law also may permit surplus water to be underdeveloped. In addition, there is considerable concern because of the present failure of law to curb the destruction of water resources by pollution and over-use.

The great needs for modern water legislation are to provide protection and economic stability, encourage economic development and insure good distribution of supplies, having in mind the hydrologic and other natural laws. This includes the need to provide protection of quality (temperature, chemical and bacteriological) and recreational facilities. The basic problem will be the constitutionality of the proposed law, but this must be overcome, because even in the eastern part of the continent where the average annual preciptation is nearly twice the amount in the west, the great demands are creating significant problems.

It is easy to see that governments will not be able to overcome all the difficulties by legislation, and in fact statutory controls might easily be guilty of such faults as inflexibility, bias towards some uses, awkwardness (if the permit system is not streamlined), subjection to administrative indescretion, and high cost of operation.

Taylor,[27] discussing the proposed Model Water Use Act, prepared by the Law School of the University of Michigan, explained that the Act attempts to approach uniformity and also to incorporate the best features of various State and Local Laws. This Act aims at comprehensive and paramount control over water resources.

Piper[20] presents some interesting hydrologic background in favour of the proposed Model Water Use Act; he takes the attitude that it is hydrologically incorrect to differentiate between riparians and nonriparians or between ground and surface water. Piper states that society must adopt and then apply properly, selected aspects of the appropriation doctrine, permit system and the improvement-district philosophy, all coupled with wide education about the facts of hydrology.

There seems to be a very pressing need to examine our Canadian Water Laws from coast to coast, extending the work of Gisvold.[19] Such a study might consider and weigh the existing laws against the principles and doctrines that actually do exist in the water field today. It seems that the study would be concerned with such doctrines as Riparian Common Law of Natural Flow,[28] Riparian Common Law of Reasonable Use,[29] Correlative Rights, Comparative Injury, Prescriptive Rights, Prior Appropriation and Police Power (licensing). It seems particularly necessary to study the possibility of substituting the words, "of economic importance" instead of "Navigable Streams", wherever the impossibility of navigation is taken as license to mistreat or mismanage a stream.

Gisvold points out that lawmakers do not want to be unnecessarily restrictive and that laws should be kept simple. However, water is used for a variety of purposes, which creates a multitude of conflicting interests and results in complex water laws. Furthermore, water as property has the characteristic of being able to inflict serious damage on neighbours unless it is properly handled. As examples, dams can break, streams and springs can be denied to downstream users by overuse or wastage upstream, and water can be polluted to a serious and even to a dangerous degree. As Thomas[13] points out, it is as logical to advocate restrictions on water uses as it is to restrict other kinds of property. Our present-day economy demands ordinances and laws that govern building heights, noise levels, location of commerce and industry in zones, etc. Owners submit to these restrictions in return for such provision as police and fire protection. Therefore, it is also logical to regulate water uses that affect pollution and supply and to expect these regulations to change as conditions become more critical.

The Water Resources and Water Rights Acts of Alberta, Saskatchewan and Manitoba seem to be guided by a sound principle. Except for domestic purposes, the use of water is not to be decided by the adjoining landowners but by an administrative body according to the most beneficial use. We must realize though, that any proposed administrative Water-Law machinery, requires for proper performance: full understanding of the hydrological principles and informed public that knows what it wants and the consequences, both now and in the future, having fully considered economic stability, conservation, health, recreation and aesthetic values.

The Pollution Picture

A great deal of the foregoing has dealt with water pollution as it affects our water resources, the water supply problems, re-using of water and our modern concepts of conservation. Now having examined the needs of society and realized the urgency of dealing with pollution, we shall look at the pollution problem in greater detail.

There has been a scarcity of literature about our Canadian problems by comparison with the U.S. and England. However, it is quite evident from the work of the Ontario Water Resources Commission in South Western Ontario that our Canadian situation is very similar to that in the U.S. Piche,[30] Allard,[31] and later the Ontario Department of Health[32] all reported that the Ottawa river is seriously polluted, with several places having coliform counts far in excess of the Ontario objective MPN 2400/100 ml. It was noted that even in seriously polluted parts of the river, the appearance was not unsightly; in fact the river might seem clean until scientific measurements are applied. In the same report, Dr. Allard also showed the pathetically heavy pollution that exists in Lake St. Louis and in the St. Francis river.

Similar work has shown that pollution from domestic and industrial wastes is serious at Winnipeg, Regina, Calgary, Edmonton and Vancouver, and recently the work being done in New Brunswick is proving the contention that Canadians are involved in pollution from Coast to Coast. Stream pollution must be controlled because stream beds are our natural piping systems which we must keep in good working order.

Regarding the International aspect of pollution, we are already working with the United States on the Columbia river system and in the Lake Huron-Lake St. Clair area, St. Lawrence River and elsewhere. In addition we are very mindful of the desires of Chicago to ease their sewage problem by diverting water from the Great Lakes to the Illinois Waterway. Hurwitz and Barnett[33] have shown that Chicago must either divert more water or build more sewage plants.

Recently Dennis[34] reported on a very serious epidemic of infectious Hepatitis that occurred in Delhi, India in 1956 and again in 1958. This epidemic has an important lesson for the Western world. In Delhi, routine water analyses were being obtained which should have provided sufficient warning. It was apparently a clear case of apathetic control, lack of hour to hour alertness, administrative jealousy and competition and failure to take action promptly. These are ever-present dangers to public health.

In the western world, we have many additional pollution problems because our progress in water pollution abatement has been far outdistanced by the speed of industrial and technical progress in other fields. Hollis[35] states that we are no longer able to blame complex organic pollutants entirely on industry. There are small quantities of these complex materials, which break down slowly, if at all, resulting from the use of chemicals in every phase of life—home, business and industry. Sewage should no longer be called "domestic" but rather "municipal".

Problems of Sewage and Sewage Treatment

Suspended solids have been a problem in sewage effluents for a long time because of unsightliness, effect on photosynthesis, effect on benthic organisms and their effect on the self-purification capacity of streams. Unfortunately, there is at present no rational way to prescribe the degree to which suspended solids must be removed from waste water in order to prevent unreasonable impairment of a stream.

Photosynthesis is a biochemical process which catalyses a reaction between carbon dioxide, certain organic nutrients and such chlorophyll-bearing microorganisms as algae. The oxygen liberated as a by-product of photosynthesis is frequently the chief source of dissolved oxygen in streams. Photosynthesis is fully dependent upon the intensity of the sunlight which penetrates the water. Benthic organisms are such as fungi, protozoa, rotifers and nematodes which exist in a thin film on the bottom of streams, helping to keep the stream purified and preserve the natural balance; they are easily smothered by settling solids.

Suspended solids have a considerable effect upon the beauty of water. Future generations will miss a great deal if we fail to consider the aesthetic side of this work, but it is necessary to be practical. There are some streams that never have been sparkling clear even before the country was settled. Further, along practical lines, it is necessary to examine the aquatic biologists' contention that suspended solids are the main reason for fish-kills; fish have sometimes been prolific in heavily silted rivers. Also there can be no doubt of the disasterous effect of toxic substances on fish and other stream life; toxicity is a serious problem both during and after the sewage treatment process and if sewage is discharged untreated. The agricultural use of insecticides and herbicides has resulted in one of our worst pollution problems. These chemicals are sometimes dumped indiscriminately or applied carelessly. Sometimes complex organic chemical wastes and other less complex but strongly toxic wastes can be handled in sewage treatment plants by good mixing with large quantities of domestic type wastes. Generally, however, modern sewage treatment methods do not remove these materials.

Detergents are regarded as a serious problem because of the frothing in sewage plants, in streams, and because 3 to 5 mgl may interfere with flocculation and coagulation in water treatment plants. They increase stream algae problems due to their phosphorous content. In addition, chlorination may produce unpleasant odours in the presence of detergents.[12] We know that commercial alkyl benzene sulphonate, the main surfactant in modern detergents, is not readily broken down by the activated sludge process. However, McKinney and Symons[36] claim that the structure of ABS is open to bacterial attack; they think complete degradation is blocked only by a quarternary carbon in the side chain. Detergents are not toxic to either aerobic or anaerobic bacteria. All detergents are subject to biological breakdown except ABS.

For some time the leading sewage experts have been warning us that sewage must have better treatment to reduce nitrates and phosphates which, in turn, promote algae. There are certain advantages to algae such as promoting reoxygenation by photosynthesis, mineralization and production of a food chain. The disadvantages are algae-toxicity, odours and B.O.D. when the crop dies. At present the disadvantages far outweigh the advantages, hence we have the problem of nutrients in sewage plant effluents. Both nitrogen and phosphate are required for the proper functioning of biological processes. Amino acids, ammonia and proteins are all required by the bacteria. The difficulty arises when the bacteria fail to remove enough of these fertilizer type nutrients. (Incidentally, primary treatment only removes about 25% of the total nitrogen and 55% of the phosphorus. Coagulation and flocculation will increase these percentages.)

Radioactivity has created a new problem a new problem for our society. Many radionuclides are isotopes of elements of biological importance and enter into many biochemical processes. This feature spreads radioactivity but on the other hand some radionuclides are accumulated by aquatic life to very high levels. Setter and Russell[37] list such sources of radioactive contamination as industry, medicine, research, mining, processing of uranium ore, nuclear reactors for power production or research, chemical processing of spent reactor elements for the recovery of reactor fuel and fallout from testing nuclear devices.

Pathogenic bacteria, viruses and parasites in treated effluents constitute serious health hazards. For the same reason as stated when discussing reclamation of water, wet sludge appears to be unsuitable for use in fertilizing vegetables, lawns and shrubbery; the ability of viruses and bacteria to travel far in the water table also demands good sewage treatment. Incidentally, little is known about the travel of viruses except that they can travel much further than bacteria; bacteria are limited to about 250 ft. in sandy formations, but travel much further in coarse formations and still further in the water table, according to Ongerth and Harmon.[38]

Many in the past have felt sure that disinfection with chlorine (0.5 p.p.m. combined residual chlorine for 15 minutes) is sufficient to kill pathogenic bacteria. The work of Kelly and Sanderson[39] shows that some methods of treating sewage do not destroy enteroviruses. They found that, depending on pH and temperature, it may require 9 p.p.m. residual chlorine after 15 minutes contact or 0.5 p.p.m. after 4 hr. to kill some viruses.

Clarke and Chang[40] also conducted some extensive work on methods of reducing viruses in water. They recommend prechlorination (ahead of sewage treatment) with a free chlorine residual of 1.0 p.p.m. and 30 minutes contact time and they stress that pH and temperature can both change the time considerably. It was found that flocculation with chemicals is also quite effective; thus it is quite likely that prechlorination encourages flocculation to occur in the settling tanks.

The question of whether to treat industrial waste separately or jointly with community waste, has presented a problem to many municipalities. Some engineers believe that there should be no joint treatment but, except where there are unusual technical problems, it is generally conceded that joint treatment is better from all points of view. There are exceptions to this rule, as for example, where an industry produces an overwhelming percentage of the waste. Whenever an industrial waste is amenable to treatment by a standard type of municipal sewage process, the question of joint treatment can be answered easily if a satisfactory agreement can be drawn. There have also been too many cases where local administrations have gone overboard to coax an industry into town.

Industrial Waste Problems

The technical aspects of industrial wastes are often complex and their solution may require very expensive procedures. In most cases there is not any economical solution. It is only an occasional enterprise for which the recovery aspect of the waste treatment program can be expected to make the project worthwhile economically.

At the same time it seems sound and fair to both industry and the public that the product bear the full cost of production. In this way the economic dead wood can be recognized and cut out. Waste recovery and waste treatment should definitely be part of the process and part of the cost of production.

In addition to these aspects, business enterprise must be able to budget for future costs and also have some idea of its position relative to competitors. It is necessary for industry to know the economic pros and cons of treating or not treating their wastes. A great number of these industrial questions could be answered easily if municipalities would accept the responsibility of putting a price on their requirements for protection of sewers, sewage plants and resources. This could be done by a surcharge system similar to that inaugurated in Winnipeg with their 1957 By-law No. 80.

Waste Treatment facilities are expensive and with many industrial wastes it is necessary to conduct extensive research and pilot plant work on the spot. There are two or three aspects of this that require thought at Government levels. For example, foreign-controlled plants often do all their research in the head office plant; also small plants often cannot afford this development work without tax concessions.

Standards for Sewage Effluents

There has been a lot of work done on this subject and a great deal of discussion has revolved around the concepts of stream standards and effluent standards. It is now generally conceded that both of these sets of standards should be applied on a somewhat local basis, and usually there should be a combination of these standards. The "local" basis may extend to an entire watershed or be confined to a single stream, but it must emphasize that streams differ widely in their capacity to assimilate wastes.

As examples, iron and manganese can be quite toxic to fish under certain conditions,[12] but the toxicity depends on the temperature, dissolved oxygen content, alkalinity, hardness, content of metallic salts, etc. Mixtures of nickel and zinc, copper and zinc or copper and cadmium are much more toxic than the simple salts. Hence the toxicity of each waste must be determined by bio-assay for any given receiving stream. This is also true for such chemicals as phenols and cyanides, although "Oransco"[12] suggest certain limits which they consider unsafe for these chemicals, again stressing the need for more basic research on phenols and bio-assays for a given stream receiving cyanides.

Weiss[41] has done considerable work along these lines on the toxicity or organic phosphorous insecticides. He has been able to show *in vivo*, the inactivation of fish brain acetylcholinesterase (A. Ch. E.) by these insecticides.

Government Activities

The work of the Ontario Water Resources Commission and of the International Joint Commission has generally been along the lines which are supported by this paper. The Water Resources program[42] in Ontario has been outstanding and this program is unique in the water and sewage field, being comparable to any, and better than most programs of this nature, anywhere.

In the United States, the overriding Federal authority that is provided under Public Laws 410, 845 and 660 has been of vital importance in getting essential work done between States and on a country-wide basis, although the primary responsibility rests with the individual States.

In Canada, overriding Dominion legislation also seems absolutely essential. This country should not be overly concerned with losses of autonomy at the local and provincial levels, because we do not have the same written constitutional set up as in the United States. Surely the desired flexibility can be maintained, and if not, loss of some autonomy is a small price to pay for protected water resources.

The Government must consider, that left to their own devices most municipalities, large and small, fail to develop a sensible water or sewage policy until it is too late to avoid hurting themselves or their neighbours. Often the delays result from lack of financing. Sometimes communities could join forces on these projects if senior Governments made this possible.

Sometimes, when several authorities have water and pollution control powers that overlap in a given watershed there will be differences in the ordinances or in the administration that tend to nullify the efforts of all. Considerations such as these plus a sound research and development program are quite properly the work of the Dominion Government, even if some constitutional problems must be solved first.

Research & Development Program

In explaining the need for more research on water problems, Burney[43] made some statements about the U.S. that are also significant to Canadians. He referred to the tremendous need for a speeded-up program to fight water pollution, and expressed his distaste for the "crash" program that certainly lies ahead. Burney says the U.S. is very close to the time for 100% removal of pollutants from sewage.

We are dedicated to economic growth and we foresee huge population increases yet we still delay the planning and production of essential goods and services until the lack of them creates enormous problems.

Basic knowledge is not keeping pace with the development of the problems and pollution control becomes a series of actions based on expediency rather than a planned program. Facts are needed to justify the huge expenditures that are being, or will be proposed for water resource and sewage programs. Someone should be given the responsibility to present our Government with a well defined, long range research and development plan and an inventory of the problems for consideration at the highest level.

In the U.S. even after 12 years of feverish activity, they now realize that they are embarking on gigantic water projects with alarming gaps in their knowledge of the things they seek to control. The actual limit of error or ignorance is seldom less than 25%, according to Boyce.[44]

In conclusion, the following list of research projects is presented as a possible nucleus for a Dominion Government program, under the leadership of a well organized, effective Water Pollution Control Board. (This includes the formation of a committee, representative of all interests in this field.)

1. Establish engineering parameters which will continuously assess the total pollution and the actual state of our water resources;
2. Probe for new methods of waste treatment geared to remove any and all contaminants;
3. Evaluate the health and economic aspects to crystallize public opinion and establish a basis for a national policy;
4. Develop adequate hydrologic, geologic and geographic data, coordinating these data into a nation-wide scheme. Make an inventory of our total water resources using drillers' reports, etc;
5. Set up a comprehensive watershed research program to learn the effects of logging, farming, recreation, construction and other activities on the quality of water;
6. Collect reliable basic data on water usage by industry and by region from coast to coast, including a detailed survey of selected industries;

7. Investigate the individual and composite effects of the many complex substances that are polluting air and water. This includes a study of agricultural chemicals and how these are handled, surfactants such as alkyl benzene sulfonate, phenols, cyanides, and others. The studies should be concerned with methods of treatment and the establishing of safe limits under continuous exposure.

8. Further evaluate the effect of suspended solids on benthic organisms in conjunction with such American workers as Hoak;[45] then set rational limits;

9. Set up a program for monitoring and releasing radioactive wastes. As suggested by McCallum,[46] measure alpha and beta radiation for both suspended and dissolved solids and then determine better treatment methods. Determine the safe levels for aquatic life by finding: the concentration factors of the critical radioisotopes; organs or tissue which accumulate radioactivity; the most sensitive stages in the lives of marine biology; the method by which organisms assimilate radioactive materials;

10. Evaluate oxidation (stabilization) ponds particularly for various Canadian regions; establish their effects on ground water; establish their effect on pathogenic bacteria and viruses. Where they can be safely used, establish reliable design criteria and especially ascertain the design relationships between B.O.D. loading, volume, depth and desired degree of treatment. Establish any other limitations such as types of wastes;

11. Establish the inactivation of pathogenic organisms that is obtained by all the modern recognized methods of treating sewage and handling sludge. Determine the minimum disinfection required for each method;

12. Study the travel of pathogenic bacteria and viruses in the water table and in various formations;

13. Obtain full data on areas using septic tanks, methods of construction, laying of tile, proximity to wells and the effect with time on these wells;

14. Assist industry in the study of their problems, realizing that many industrial waste problems are highly complex and may require a combination of industrial and sanitary engineering skills;

15. Conduct oceanography studies as related to waste disposal, including a study of salt water intrusion of ground water resources;

16. Estabish the purification capacity and water quality criteria for all rivers and streams of economic importance.

Acknowledgment

The author wishes to express his sincere gratitude to Professor R. R. McLaughlin, Dean, Faculty of Applied Science & Engineering, U. of T. for his critical review and helpful comments on this paper.

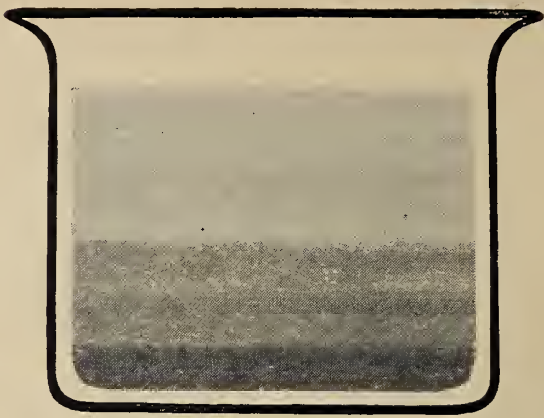
THE MEASUREMENT OF INDUSTRIAL WATER POLLUTION



T. W. Beak

Consulting Biologist, Kingston.

Presented at the E.I.C. 74th Annual General Meeting in Winnipeg, May 1960.

Chemically pure water does not exist in the natural state. The liquid popularly called water is a dilute aqueous solution of many substances. Some of these impurities are essential if the water is to support life or be palatable, some are innocuous but not essential, some are harmful if present in more than certain concentrations. Since so-called pure or unpolluted water contains many other substances, pollution is only measurable as a degree of divergence from some arbitrary standard. Before pollution can be measured it must be defined. Probably the best general definition of water pollution is "some artificial change in a body of natural water which detrimentally affects a beneficial use". As this paper deals with the measurement of industrial water pollution and bacterial pollution is more generally the result of domestic pollution, consideration of this rather specialized aspect of pollution will be omitted. It deals, therefore, with the measurement of pollution other than bacterial pollution in the forms usually resulting from industrial activity. Because potential sources of pollution are manifold and the variety of substances involved very large and ever increasing, many of the procedures used for measuring pollution measure effects rather than the substances responsible. A few of the most common types of measurement of pollution will be discussed and appraised, with special reference to those tests which measure effects.

Biochemical Oxygen Demand

THE B.O.D. test is procedurally simple, but the correct interpretation of the results often requires considerable skill and experience. Briefly, the test consists of enclosing a sample of water in an airtight bottle, incubating it at 20°C for five days and measuring the amount of dissolved oxygen present before and after incubation. The difference is the B.O.D. figure and is most simply expressed as parts per million or milligrams per litre. In practice there are several refinements which have to be used to ensure accurate results but this description is adequate for the present purpose.

The test is intended primarily to measure two things, first, the amount of assimilable organic matter present in the water and secondly, the deoxygenating effect of it on the water. A very wide range of organic materials when present in aqueous solutions are chemically broken down by the action of micro-organisms in the water to carbon dioxide and water. In the process dissolved oxygen is removed from the water by chemical combination with the carbon and hydrogen atoms. If there is no source of replacement oxygen, (as in an airtight bottle) the amount of dissolved oxygen is reduced.

It has been demonstrated experimentally that if an assimilable organic material is present in water with an adequate supply of dissolved oxygen and suitable micro-organisms at 20°C for five days, 68% of the total amount of the organic matter present will be destroyed. If, therefore, the conditions of the experiment are met, the amount of oxygen used up will be a measure of the amount of the assimilative organic material originally present. It is not necessary to know the composition of the organic material, nor does it matter that a complex mixture of organic substances is present. As long as the materials are assimilable by the micro-organisms present, the test will be valid.

It might be thought that the matching of organisms to materials is very complex. In the case of certain substances — particularly synthetic organics — this is true, but micro-organisms are remarkably versatile in their activity and it will usually be found that if an organic material has been present in a body of natural water for a reasonable period (a month or more) there will be micro-organisms in that water capable of breaking it down.

Given normal conditions, therefore, the B.O.D. test gives a measure of the assimilable organic material present and it also gives a measure of the amount of dissolved oxygen this material can be expected to remove from the water. Excluding toxic effects this capacity for removing dissolved oxygen is the most important pollutional effect of organic materials, for the oxygen is essential for the maintenance of fish and other live forms and also for the avoidance of nuisance conditions. Where all or nearly all the dissolved oxygen is removed from water a new group of organisms (anaerobes) take over. These live by breaking sulphate down to sulphide, which results in the stinking condition of badly polluted waters.

The principal shortcomings of the B.O.D. test are first, the effects of toxicity and secondly of non-assimilative organics. If toxic materials are present in the water these will inhibit the activity of micro-organisms in the test and an erroneously low result will be obtained. With experience this can sometimes be detected by judicious dilution or other means but in some cases it invalidates the test under good conditions. In inexperienced hands it can lead to very considerable errors. The organic contaminants in the stream or lake are still in the water and generally a point will be reached where the toxicity is no longer inhibitory and then the full effect of the organic materials will be released.

The synthetic detergents are a common example of unassimilable organics. These materials are not easily attacked by micro-organisms so that they do not register in B.O.D. tests and for the same reasons they are not destroyed in biological treatment processes. This gives rise to the foaming problems which have occurred in many natural waters, as well as in treatment plants, since the introduction of these materials.

Fig. 1a and 1b show the effects of both toxic materials and non-assimilable organics on B.O.D. results.

Fig. 1a shows what happens when conditions are unfavourable for assimilation of organics due to unfavourable pH, presence of toxic materials or other reasons. The readily available food is used more slowly than normally and even when used is only converted to cell substance and absorbed material. After five days less than 50% has been utilised. Fig. 1b shows what happens under favourable conditions. The available material is quickly converted to cell substance and even this is then utilised. Even some of the exotic food is converted. In the five day period about 68% of the original material has been utilised.

Oxygen Sag Curves

The consideration of oxygen sag curves follows directly out of that of B.O.D. In natural waters the breakdown of organics is taking place continuously, using up dissolved oxygen. Under normal conditions the oxygen is replaced by the processes of reaeration — transfer through the surface, turbulence, photosynthesis — and a state of equilibrium exists. If the organic load is steadily increased the rate of use of dissolved oxygen will at some point exceed the reaeration capacity, the equilibrium will be upset and the concentration of dissolved oxygen will drop. If the load is sufficiently heavy all the oxygen may be removed.

The processes of decomposition are continuing, however, and at some point sufficient organic material will have been destroyed to allow the reoxygenation processes to gain ascendancy. The amount of dissolved oxygen then increases until a new state of equilibrium is reached.

This state of affairs can be demonstrated in any river having a severe pollution of organic contaminants, by taking a series of dissolved oxygen measurements downstream, starting above the source of pollution and proceeding down at intervals to a point where complete recovery is found.

Fig. 3 shows the results of one such series of observations, the graphical illustration of which is termed an oxygen sag curve. These results are from the river Thames in England.

The oxygen sag is a valuable measure of pollutional effect on a river. It demonstrates in graphic form one important aspect of the pollution. For a complete picture, however, curves must be prepared for different times and conditions. Water temperatures, river flow, turbulence and fluctuations in pollution load, all affect the oxygen sag curve and these variations should be known. Lowering the temperature has the effect of reducing the severity of the drop in dissolved oxygen but increasing the duration of the effect —a longer stretch of river is affected, but less critically.

Toxicity

Chemicals vary greatly in their toxic effects to life forms. Some, such as cyanide, mercury and zinc are lethal to most living material at concentrations of less than one part per million. Others, such as ammonia, phenol, and some synthetic detergents are lethal in fairly low concentrations — approximately 10-30 p.p.m. Other materials are only toxic if present in comparatively strong solution.

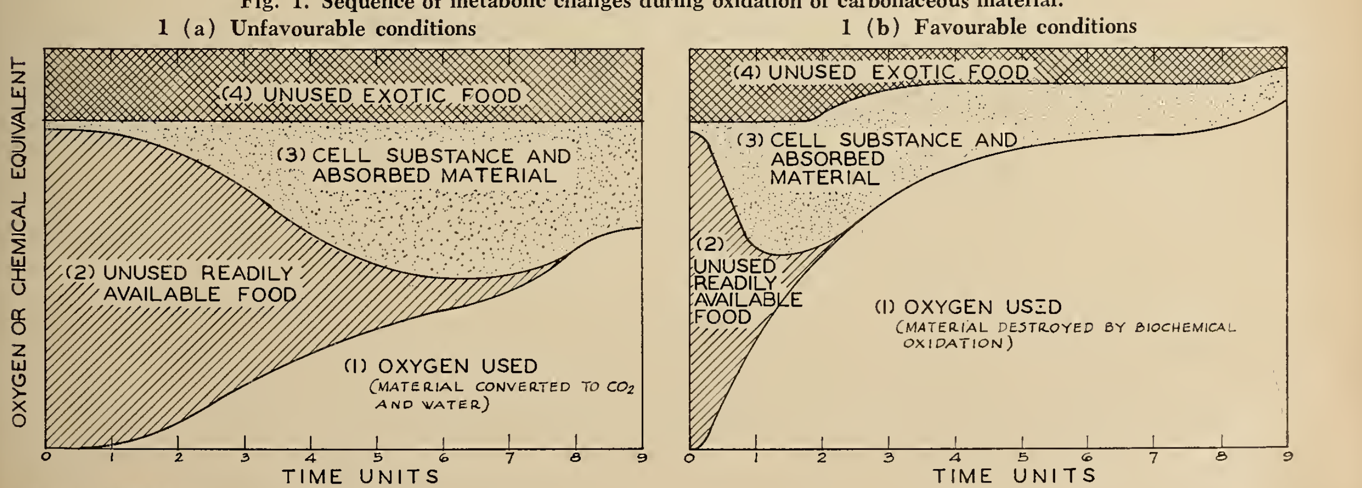
Not only do different substances vary in their degree of toxic effect, but the effect of any one substance varies with the type of organisms on which it is tested, the other properties of the water (pH, presence of other toxic materials), temperature, amount of dissolved oxygen present, and whether there has been a period of acclimatisation. Even individuals within a species vary considerably in their tolerance of most substances.

In some cases it is comparatively easy to analyse water directly for toxic materials, e.g. in the case of most of the heavy metals and some radicals such as cyanide and phenols. Often, however, analysis is difficult and time consuming as with many organic materials and, where complex mixtures are involved, either impossible at present or only possible by considerable expenditure of time and effort by specialists. Even when the content of water is known it is often difficult to assess its effect, because of the many variables; e.g. copper and zinc, if present together, increase each others toxicity, (synergism); ammonia and carbon dioxide reduce the combined toxicity (antagonism). The toxicity of some substances is critically[1] affected by pH; e.g. a decrease in pH from 9 to 8 decreases toxicity of ammonia about eightfold.

For these reasons the most practical course is generally to make a direct measurement of toxicity without isolating the toxic materials. This is generally referred to as a "Toxicity Test" or "Bio-assay".

As with the B.O.D. test, the procedure for a toxicity test is fairly simple, but care and understanding is required for a correct interpretation of the results. In its simplest form a toxicity test or bio-assay consists of exposing one or more of the test animals to known concentrations of the

Fig. 1. Sequence of metabolic changes during oxidation of carbonaceous material.



material being tested and observing the time taken to kill the animal. Unfortunately for simplicity, living material is never uniform and therefore many precautions are necessary if the results are to be intelligible. Among the variations most commonly met in toxicity tests are:

1. Variations due to temperature;
2. Variations due to difference in size or age of test animal;
3. Variations between individual animals of the same species;
4. Variations in chemistry of the dilution water;
5. Variations in oxygen concentration.

Some of these variables can be eliminated by care in the procedure —e.g. animals of the same species and within certain limits of age and size can be used. Even when this is done with great care there will still be considerable variation between individuals. Herbert[2] has shown that the time taken to kill 42 individual rainbow trout, carefully selected for identity of size and age, with 0.14 p.p.m. of cyanide, varied from 29 to 207 minutes. In spite of this, if a suitably large sample is used, the time to kill the majority will show much smaller spread and a reliable mean value can be obtained. It is necessary, however, to use a sufficiently large sample to obtain a reliable mean.

Temperature can be controlled fairly easily and this should always be done in toxicity tests.

Dissolved oxygen can be controlled by passing air or oxygen through the test solutions, but care is necessary to avoid removing volatiles which may significantly affect the results. The best method of maintaining dissolved oxygen is to use continuous flow apparatus. Hitherto this has been difficult and complicated, but a suitable continuous flow apparatus has been developed which should make this method available more easily.

Problems connected with dilution water are best dealt with by using water from the location under test, if this is possible. Differences in pH, hardness, buffer and other chemical characteristics of the water are so important and often so difficult to allow for in the results, that this is the best practical solution to this problem.

The results of a toxicity test may be in one or more of several forms. They may be represented as a concentration which has been found in experiment to kill 50% of the test animals in either 24, 48 or 96 hours. This is called a median tolerance limit, abbreviated to TLm. This is the usual method of expressing results in

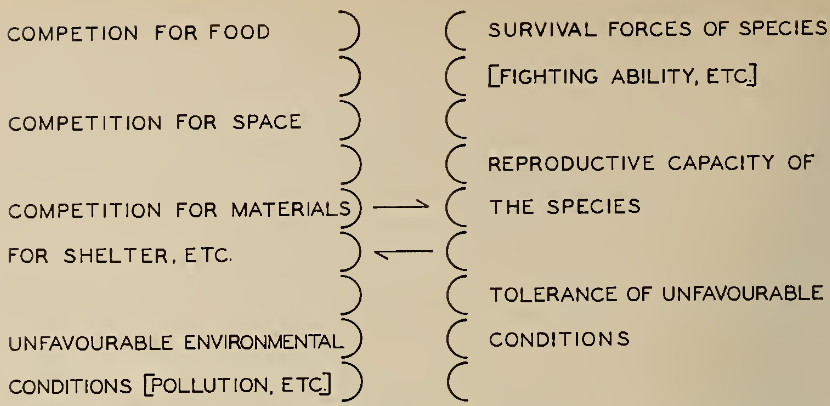


Fig. 2. Diagram illustrating the equilibrium of some of the environmental stresses acting upon each species in a community and the survival potentials which oppose them.

North America. Some European workers, particularly those concerned with fundamental research on toxicity, derive a relationship between concentration of test substance and median survival time at various concentrations. These are but two of several methods which have been used to express the results of toxicity tests.

Whatever method is used, the experimental results show the concentration of test substances which kills fish. In practice one requires to know the concentrations which will not kill fish. The derivation of the latter from the former is a matter of some difficulty and often controversy. The methods used are not suitable for discussion in a general paper of this kind, but it can be stated that it is possible to derive a result which can be used for design[3] data and other practical purposes.

A valuable application of the toxicity test has been developed by Henderson and Tarzwell.[3] They have derived a function called dilution volume, which is the dilution necessary to reduce the whole of a toxic effluent to a concentration which will kill 50% of the test fish.

$$\text{Dilution volume} = \text{Effluent Flow}\ \frac{100 - \text{TLm}}{\text{TLm}}$$

If an effluent is made up of a number of different effluents, the dilution volumes of the components are additive in the total effluent.

Biological Measurement of Pollution

Chemical analysis is and will probably continue to be an important part of the measurement of pollution, but it seldom gives a complete picture, nor is it always the most economical method. Of at least equal importance, although as yet less widely used, is the direct measurement of pollution by biological surveys.

Although this method is of great importance in assessing the effect of pollution on fisheries, it is by no means limited to this application. The effect of pollution on the organisms normally living in the natural waters is a good general measure of pollution. Although there is a quantitative difference between the standards of pollution affecting different uses, they are, with certain exceptions, parallel, and the biological measure of pollution supplies a good general yard stick.

The basis of this method of measuring pollution is that in any body of natural water in the unpolluted state there will be a community of animals and plants which will be typical of that environment. The species represented and the numbers of individuals varies according to the environmental factors, such as, temperature, water movement, season, type of bottom etc., but a state of equilibrium exists at any time. If a change takes place in the environment, such as pollution of the water, the equilibrium will be upset and the qualitative and quantitative composition of the community will change. It is by measuring this change in composition of the community that a measure of pollution is obtained.

Fig. 2 sets out a few of the forces which affect the state of equilibrium of a single species with its environment at any time. If one can imagine a complex system in which there is interaction between the equilibrium of all the species within the community, some idea can be obtained of the mechanics of the system.

If a new stress, such as added pollution, is imposed on a community in equilibrium, it will upset the equilibrium, because different species vary in their tolerance of pollution and their ability to withstand it. The new factor will push the balance against the intolerant species, but because this reduces competition for food it may favour more tolerant species. As a result some species will decrease in numbers, some will increase.

It is important to note that in using this method for measuring pollution we are using the change in

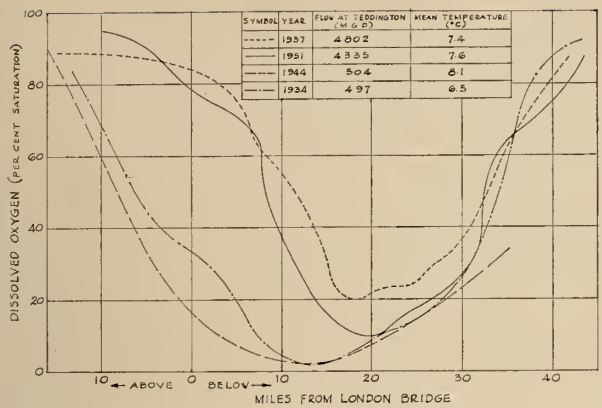

Fig. 3. Oxygen sag curves, for River Thames, England.

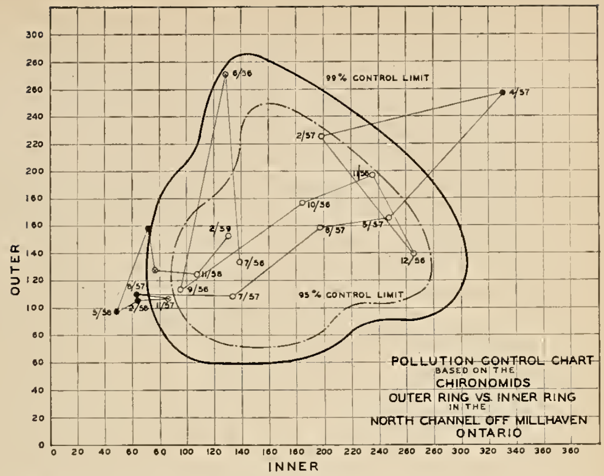

Fig. 4. Chironomid control chart developed from inner and outer rings of samples taken at Millhaven, Ontario, July 1956 to February 1959.

community as the measure of pollution effect. In this way we eliminate the difficulties inherent in trying to establish in absolute terms the composition of a normal community.

This method can be used to monitor changes in pollution, as when a new plant is put into an area and it is desired to check whether the plant has any pollutional effects on the water to which its effluent is discharged. It can also be used to measure the extent, if any, of pollution at existing plant locations.

The first application is illustrated by the work I have done in co-operation with the company's staff at the C.I.L. plant at Millhaven in Ontario.[4] Here a new chemical plant was located on a part of Lake Ontario with high recreational and amenity value. It was essential not only to make provision for proper treatment of all effluents to make them innocuous, but to check that the treatment was effective.

Briefly, the method consisted in making biological surveys and from the data constructing biological control charts which prescribed the limits within which different components of the biological community varied under normal conditions, before the plant commenced operations. By continuing the surveys from time to time after operations commenced it was possible to check whether any changes outside the normal variations had taken place.

Fig. 4 shows one of these control charts. It will be seen that in the period August 1957 to January 1958 the chart showed a definite trend out of control limits. When this was observed investigations were made in the plant and eventually the cause, which was an unknown leak in a storage facility, was discovered. When this was remedied, the chart showed a return within control limits. The single point outside the 99% limits in April 1957 was not a trend, but an isolated observation outside control limits.

This type of application shows how this method can be used to discover an incipient pollution long before it reaches nuisance proportions. The method requires a fair amount of pre-operational survey work, but once the control charts have been set up, a comparatively small expenditure of time and money enables a very close check to be kept.

The second application has probably been more widely used, but the results are not often published. One reason for this is that this work is sometimes carried out where there is a pollution problem and publication of detailed results might incriminate the parties concerned. For this reason a great deal of data remains in the files of companies, control agencies and consultants. It is to be hoped, however, that as cases are cleared up and the data is no longer incriminating, it may be possible to publish the results.

The principle is the same as in the first application except that in this case the changes have already taken place before the survey commences. It is not, therefore, possible to get an exact datum for conditions prior to change. This difficulty is overcome by finding some locations upstream and if possible some downstream which resemble as closely as possible the polluted zone, but are out of the influence of the pollution. These unpolluted zones are used as controls and replace the pre-pollution datum of the first application. The communities of animals and plants in these communities are then compared with those of similar locations in the pollution zone and the differences used to measure the degree of pollution.

The method of illustrating results is still the subject of research. The author has used a method based on an arbitrary scoring system.[5] In this system the organisms found in the normal and polluted parts of the area under study are put into 3 or 4 groups according to their known or estimated tolerance of the type of pollution being investigated. One such grouping is given in reference.[5] The group 1 organisms are those known to be very tolerant of pollution, the group 2 organisms those of moderate tolerance, the group 3 organisms those of slight tolerance and the group 4 organisms those known to be intolerant.

Group 4	Group 3
Intolerant of Pollution	Slightly tolerant
Score 4 points	Score 3 points
Group 2	**Group 1**
Moderately tolerant	Tolerant
Score 2 points	Score 1 point

The organisms found at each location are listed under the group to which they are known or believed to belong. A score is then allotted to each location according to whether organisms of the various groups are present. For example:

- A location with only group 1 organism, a score of 1;
- A location with group 1 and 2 organisms, a score of 3;
- A location with group 1, 2, and 3 organisms, a score of 6;
- A location with group 1, 2, 3, and 4 organisms, a score of 10.

It will be found that, if the organisms have been correctly allotted to groups according to pollution, and if pollution is the only variable factor between the locations, a station which has group 3 organisms will also contain group 2 and 1 organisms and one with group 4 organisms will contain 3, 2 and 1. In practice some allowance is also made for numbers of organisms — e.g. if in the control location there are 10-50 individuals per sq. ft. of a group 4 species, and at another location one individual is found in a few samples, one point and not 4 will be allotted for it, as it appears that the species has only a precarious foothold at this location.

When the results have been set out in this form, each location has a score. This score can then be illustrated graphically as in figure 5. This is a fictitious example, but it is based on results I have obtained in the field.

It is not claimed that this method of illustrating results is quantitative in that a biological score of 5 corresponds with 50% pollution, but from experience I consider that the picture of results as illustrated in this way is in good general agreement with other observations about the pollution; e.g. in pollution where dissolved oxygen is an important factor, the graph of biological score will be in good general agreement with the oxygen sag curve.

One shortcoming of the method is the lack of published data on the tolerance to pollution of any species. An experienced biologist in this field is able to place most of the species he finds in one of the groups with reasonable confidence, but this experience has not generally been put into the literature, so that it is not readily available to other workers. Even an experienced worker often finds difficulty in distinguishing between organisms of Group 2 and 3. In some cases, I have found it better to combine these groups, and then have only 3 groups and allot scores of 1, 2 and 3 with a maximum of 6 if all groups are present. This makes the resultant graphical illustration less sensitive, but eliminates error where I am uncertain of the tolerance of the intermediate species. If sufficient research were done on the pollution tolerance of various species this difficulty could be largely eliminated.

An important application of this method, apart from the assessment of the degree of pollution existing at a particular time, is as a measure of changes taking place in a body of natural water from time to time. It may be that it is desired to know whether the pollution is getting gradually worse as industry and population increases, or to assess whether remedial measures are being effective in reducing pollution. To make such an assessment by chemical surveys is difficult and involves a very extensive program of sampling, because the day to day, week to week and month to month variation in chemical constituents of natural waters is considerable. The biological survey, however, reflects the overall condition and results do not fluctuate with short term changes to anything like the same degree as the chemical content. For this reason surveys carried out annually, biannually or quarterly will show a trend if one is present. In this case the fact that the graphical illustration may not be quantitatively accurate is not too significant, as long as the methods used in deriving it are consistent. A series of curves will be obtained such as in Fig. 6 and these will indicate a definite change in the pollution status of the water. For example, the continuous line (May 1957) shows the score for conditions found on that date. Improvements were made at the plant during the summer of 1957 and 1958 and these improvements were reflected in the curves for May 1958 and May 1959, which show a higher score at several points downstream of the plant.

Conclusions

The methods of measurement of industrial pollution described and discussed in this paper by no means cover the whole field of pollution measurement.

The chemical analysis of water is well described in several text books which deal specifically with the subject. The methods described in this paper are mostly concerned with the measurement of pollution effects. These are not so well described nor their interpretation so widely understood. Their value lies in the fact that they measure directly the effects of pollution in which we are most often interested. They do not require the same degree of interpretation as when the water is analysed for specific chemicals.

No two cases of water pollution require exactly the same combination of methods of measurement. An optimum pollution measurement program must be designed especially for the circumstances. Seldom is it economically possible to make all the measurements which would ideally be required and usually a compromise must be struck. In this case the value of the results will largely depend on how successful the planners of the program are in estimating which methods to include and which to omit. As in many similar situations in engineering, experience is a big factor in the correct assessment of importance and there is really no adequate substitute for such experience.

Discussion

ENGINEERING FOR EXPORT

R. A. Frigon, M.E.I.C.,
Chief, Engineering & Equipment Division, Foreign Trade Service, Department of Trade and Commerce, Ottawa.
The Engineering Journal, March 1960, p. 93.

Discussion by C. C. Parker, M.E.I.C.

May I first speak as President of the Consulting Engineers of Canada: A number of our members recently embarked on our first joint venture abroad, the visit to the British W.I. Federation with a display at the Canadian Trade Fairs in Jamaica and Trinidad last January and February.

In this effort we were assisted by Mr. Frigon, indeed he first suggested it. We made many contacts and intend to follow them up. This is in effect a Canadian version of the European Consortium Mr. Frigon has referred to. I agree heartily with his comment that on-site promotion is necessary for consulting engineers and this kind of approach is less costly to the individual firm. It also has another advantage; I found as representative of a group I was welcomed and listened to by many leaders in public office where if representing my own interests alone, I may not have been so well received.

Our association intends to pursue this effort and appreciates the assistance given by the Canadian Government through the Department of Trade & Commerce and their field representatives. Several of our members are engaged in efforts Mr. Frigon has just mentioned.

My own firm's experience is limited to certain Colombo Plan work and indirectly with the work of the World Bank. I would make one observation only with regard to anticipated public works in the underdeveloped countries. European consultants under pre-war colonial administrations were heavily engaged, in the post 2nd world war period under American financial aid. American consultants were likewise very busy and still are. Undoubtedly, there was rich financial return. Such opportunities cannot be expected in the future, for the rise of nationalist aspirations is giving rise to requests for engineering help advising and teaching native engineers. Thus projects which could most efficiently be done in Canadian Consulting Engineers offices must needs be done on site, with as many native engineers as possible employed on the work. This kind of effort will be frustrating and tedious and undoubtedly not as remunerative financially. But accept it we must, for it is the natural result of the spread of our Christian democratic thoughts and of our recent and continuing technical aid programmes.

PLANNING AND CONSTRUCTION OF THE CHUTE-DES-PASSES HYDROELECTRIC POWER PROJECT

F. T. Matthias,
Director of Engineering and Construction, Aluminum Company of Canada Limited, Montreal.
F. J. Travers, M.E.I.C.,
Senior Project Engineer at Chute-des-Passes for H. G. Acres & Co. Ltd., Niagara Falls.
J. W. L. Duncan,
Electrical Engineer,
Aluminum Company of Canada Limited, Isle Maligne.
The Engineering Journal, January 1960 p. 39

Discussion by T. M. Dick, Jr.E.I.C.

The paper presented in the January Journal on the development at Chute-des-Passes made interesting reading covering as it did the development and construction of the whole project.

However there are one or two points which I would like to have cleared up. In the first place the authors state that, in places the rock surrounding the tunnel was grouted to prevent excessive external ground water pressure from acting when the tunnel is dewatered. Surely grouting the rock will not accomplish this. Consider the accompanying sketch.

The line AB represents the hydrostatic pressure if there is no flow of water through the grouted rock and concrete lining and the pressure on the tunnel is given by FD^1. When the flow of water develops and the grouted rock has the same permeability as the concrete then the pressure line will follow along ACB^1 and the pressure on the tunnel is represented by ED^1. If the grouted rock has a much higher permeability than the concrete the pressure gradient will follow line $ACBD^1$. The pressure in the tunnel is now given by DD^1 which is not much reduced from the full hydrostatic pressure. The reduction is given by FD.

Lastly if the concrete is extremely pervious compared with the grouted rock then the pressure line will approximately follow $ACGB^1$. In this case the pressure on the tunnel is very small and is represented by GD^1.

It seems reasonable to suggest that the pressure gradient lines ACB^1 and

Automation and Control Engineering in Canada

Automatic Handling and Storage

IMPROVEMENT of efficiency in industry need not be confined to manufacturing operations. The handling of materials occupies a considerable amount of time in most industrial undertakings and, though its importance varies greatly, it is rarely negligible economically.

Storage of materials may be considered as an intermediate stage in the handling system, for example, between the receipt of raw materials and their release to manufacturing areas or between completion of manufacturing processes and release for shipment. In very few cases is the solution to the problem of storage as simple as this generalized definition.

An ideal storage and handling system for any particular industrial operation can be devised only by considering all the variable factors involved. These may include, in addition to basic data about the type of material to be handled, such items as the best type of building, various methods of handling, best use of space, and the type of equipment. In addition to all this is the question of how much automation should be applied to the whole operation.

Obviously there is an economic limit to any particular project, though there is practically no limit to the availability of suitable types of building, methods, and equipment to perform complex mechanical handling operations. There must also be a limit to the extent to which automation is introduced to replace manual work, though in certain conditions a high degree of automation can lead to considerable savings through increased efficiency. Examples of this are high-speed sorting or selecting operations, or high-volume withdrawal from storage of orders consisting of many different items.

Automatic Operations

In the field of automated storage and handling, many things can be done. A program of operations may be provided, together with the means of carrying out these operations, so that the required materials may be selected, sorted, taken from one place to another, positioned and otherwise handled, together with necessary recording or accounting data.

Programing involves familiar data processing techniques, and the use of punched cards, tapes, and various memory devices. The program instructions are passed on via electrical, mechanical, optical or other systems to operate deflecting, sorting, selecting and various handling mechanisms, in the correct sequence.

Methods exist and equipment is available to select a whole order of mixed items for delivery from storage to manufacturing plant or delivery area with no manual intervention beyond the initial starting of the whole operation. Again, the limitation to what can be achieved is an economic one.

Receipt to Storage

Without considering complicating factors such as breaking down or assembling palletted or cubed lots of several units, which may be done automatically by mechanical equipment, it is possible for an automatic system to sense codes on individual items, space them out on a conveyor, and divert them to storage from any desired point in the system.

Where different items are received, it may be necessary to accumulate items on conveyor lines in an area between receipt and storage, so that they may be identified and then fed sequentially and in like lots to the storage area. Discharge to storage is controlled electrically to avoid mixing by simultaneous feeding from more than one line. A suitable memory system can note the discharge from a particular line and then, at a set time, cause the load to be deflected or otherwise moved to the correct storage position.

Storage

Material actually in storage may also be subject to automatic control, for inventory and accounting purposes. For example, in a central warehouse that handles many mechanical parts, a system of code numbers may be established (one for each part) and transferred to punched cards. The card may include a record of actual quantity of each item, plus a note of the minimum required inventory of that item, and any necessary details of cost, charges, and so on.

When the card is handled by the appropriate data processing equipment, all necessary data are recorded. If inventory has been reduced to the minimum figure, the processing equipment can automatically prepare an order card which is passed to the appropriate department for consideration.

Ordering replacement stock may also be done by means of a form prepared by a punched paper tape or similar device that contains the specifications of the required material or item. In addition to rapid ordering of replacement parts, such a system is able to make a quick financial accounting of the value of stock at any required time.

Removal from Storage

Many similar techniques may be applied to the handling of materials whether they are being moved to or from storage, but the filling of orders consisting of many mixed items, from storage, can pose several interesting problems.

If items from different locations in the storage area have to be fed rapidly in a certain sequence to, say, a moving container in which an order is being collected, a manual operator may have to work within very close limits to avoid missing one of the containers. On the other hand, automatic handling of the same container can avoid such errors. For example, a labelling system can be used to divert the containers sequentially to the various loading points by means of sensing devices that operate the necessary mechanism. Once deflected, the container can be loaded with the necessary items from that particular area, then the labelling device can be reset to indicate the next deflection point, and the container sent on its way along the main conveyor stream.

There exist completely automatic systems that can pick any desired order without manual assistance. These systems require the installation of special storage racks equipped with release mechanisms that allow an item to be fed, on command, from the rack to a conveyor. Obviously, there are many possible forms of mechanical device and method of operation that can be used to obtain the release of the item from storage.

Whatever the mechanism, signals for automatic operation may be initiated by a program stored on punched cards or tape, or magnetic tape. The program may also designate the destination of the item; for example, to a particular loading terminal in the shipping zone.

The program may operate in two ways to direct items to succeeding areas. One method feeds orders in sequence into the system so that storage racks are selected in rotation and a complete order is assembled in a slug on the main conveyor line. The program can be made to leave adequate space between individual orders so that they can be separated at their terminal.

The other method collates several orders and automatically releases the total number of given items needed for all these orders. The individual items are sent in groups to the packing or shipping area, where they are diverted automatically into zones or containers in which the separate orders are to be collected.

Particular Applications

An example of an automatic warehousing system uses static switching for handling a variety of types of product packed in bags of different sizes. Bags arrive from the manufacting area on a main conveyor from which they can be moved to any one of seven transfer conveyors, at the end of which they are assembled and taken to the appropriate storage area.

Where the main line enters the warehouse, an operator at a control console can select the required destination of each bag as it arrives. The sorting signal is fed into the system, which observes the bags as they move along the main conveyor until they reach the correct point for transfer to the selected transfer conveyor. The system is fully protected against nearly all possible sources of error, such as failure of a pilot device or incorrect calling by the operator, say, for two transfers of the one bag. The system will also allow for the case of a transfer conveyor being full and unable to accept a bag.

The different types and sizes of bag arrive at random, so the system has to synchronize the operator's signal with the actual position of the bag on the conveyor. This is done by means of a shift register, into which a different binary coded signal is placed for each of seven inputs fed into a binary coder from the control panel. The signal remains in a select memory bank until the corresponding bag reaches an actuating device on the conveyor system (for example, a photo-electric cell monitor). The signal then shifts to the memory bank of the first transfer conveyor when the bag reaches the monitor for that conveyor. If the bag is to be transferred only at a later conveyor, its signal is shifted from one conveyor memory bank to the next until the correct conveyor is reached, when the coded information is read out and the necessary transfer mechanism is actuated.

When transfer takes place, the signal for that particular bag is no longer needed and is cancelled out from the shift register. The same sequence applies to other bags in the system.

If a monitor should fail, the coded signal for the bag shifts through or is stored until it can move to a clear bank. If the transfer point monitor fails, the signal for the bag is recoded so that the bag is automatically carried on to a collecting point from which it can be removed manually to its correct area. Bags are also sent to this manual collecting point if a transfer conveyor is too full to accept another bag; if the operator fails to select a destination for a bag; or if two signals are selected for the one bag.

In this particular example, a binary code is used to identify the bags. For nine required readouts the system has four memory channels, all of which are used at the start of the operation. At shift register points along the system fewer channels are needed until, at the last readout, only one channel is required.

Parcel Sorting

Rapid sorting of items such as packages to be sent by parcel post can be achieved using a coding system to indicate destination areas. A two-number code is placed as a magnetic spot on a memory drum which rotates and passes the coded spots beneath a series of read heads. The parcel, or parcels with the same code, are placed in containers which move along a conveyor that passes over a series of belts running across the direction of the main conveyor. Each of these belts corresponds to a particular destination.

When the code spots simultaneously energize two reading heads (connected through an AND static switching circuit) the resultant signal causes the parcel to be dumped on the appropriate destination belt.

The memory drum and main conveyor move at different speeds, and the distance travelled between coding and dumping points is the critical measurement. Coding is done exactly at the right time by memory circuits which remain de-energized until the container holding the particular parcel trips a pulse switch; as soon as this happens, a strobotron writing circuit places the spots on the channels of the memory drum.

Static switching was chosen for the dispatch of outputs to the dumping release mechanisms, rather than relays, because of the continuous high volume of switching required. Unamplified output from the switching reactors is enough to actuate release solenoids in the application mentioned here.

Future Demands

As is the case with most new techniques, the introduction of automatically-controlled handling and storage facilities will be confined initially to particularly intricate or large-scale operations in industries that can afford these techniques.

With advancing technology it is apparent that it is economically feasible and desirable to extend these applications to operations such as mail order houses, postal sorting, high-volume warehousing, and many others for which automatic methods would not have been considered possible even twenty years ago.

Canadian Developments

"It is increasingly clear that we must develop new treatment processes —methods yet unknown and unconceived—which will remove much more of the contaminants from water and wastes than we are able to do by present methods. Because these waste waters are going to become the entire flow of many of our streams as they move along from city to city, science must unravel the mysteries which science itself has created so that our modern urban dwellers—now more than ten million—who must rely on surface water may drink with safety the same water which serves their other needs."[1]

The opening of the St. Lawrence Seaway is one of the new factors in the deteriorating state of Canadian waters and the increasing concern on the part of scientists and legislators. Ontario's urban centres adjacent to the Great Lakes and St. Lawrence Seaway are likely to feel the effects of raw sewage being dumped into the river by lake-going boats. Oil pollution is another problem they present. Ever-increasing metropoli on East and West coasts create a new demand for sewage and industrial waste treatment systems.

The report issued recently by the Montreal Board of Trade concerning water pollution around the Island of Montreal reveals the critical nature of the situation. The Ottawa River and Lake St. Louis are heavily polluted, the former receiving the raw sewage of Ottawa, Hull and Hawkesbury before it enters Quebec. Lake St. Louis, then, is the receptacle for all this sewage as well as the enormous bulk from Montreal lakeshore communities. Two pulp mills along the Ottawa River, in Quebec, also pour their refuse eventually into Lake St. Louis. Although a comprehensive report on the Ottawa River situation was prepared in 1954, a five-man committee was appointed in 1955 to study the extent of water pollution in the Province of Quebec, and legislation was passed in 1955 to assist smaller Quebec communities with construction of sewage and water works, much remains to be done in the Province. The necessity of interprovincial and Federal agreement has been cited as the reason for delay. However, since a sewage treatment plant is planned for Ottawa with a collector sewer to deliver all sewage from below the Chaudière Falls, and since the Ontario Water Resources Commission expects to deal with the Hawkesbury situation shortly, the Montreal water pollution problems lies within the jurisdiction of the Province of Quebec.

The Montreal Board of Trade in its report to the Provincial Government suggests the formation of a commission with wide powers to preserve and control the water resources of the Province: to conduct laboratory research, survey watersheds and lake basins; to construct water supply and sewage treatment plants; to enter into agreements with municipalities or corporations to construct water supply and sewage treatment plants; to raise funds necessary for such construction on the credit of the province; to compel necessary construction and proper maintenance of sewage treatment plants; to prohibit the discharge of harmful material into provincial waters; and to penalize offending parties.

No comprehensive legislation against water pollution exists in Canada. A section of the Criminal Code deals with nuisances; the Shipping Act attempts in part to deal with pollution of navigable waters; the Migratory Birds Convention Act and the Fisheries Act legislate to a degree to protect wild life from the effects of pollution. A number of provinces have anti-water pollution legislation and have formed commissions to study the problems. In Ontario the Commission has especially broad powers of finance, research, construction, and control.

Not long ago Ontario's Prime Minister, Leslie M. Frost, stated that it would take \$2.5 billion over an estimated twenty years to clean up the province's polluted waters. The five-year-old Ontario Water Resources Commission, under the direction of Dr. A. E. Berry, general manager and chief engineer, has made an important start.

During 1959, 19 new joint OWRC-municipal projects were completed and opened, including 12 water works systems and seven sewage works. In the last two years the Commission has undertaken projects to a total value of more than \$21 million. Under construction through OWRC-municipal agreement are another \$20 million worth of sewage disposal and water works projects. The Commission's work is being felt increasingly as new sewage treatment plants at Port Arthur, Brantford, Kitchener, Brampton, Trenton and Huntsville begin to lessen the pollution of receiving waters.

Alberta studies of water pollution were started in the summer of 1950 by the Department of Public Health. At that time municipal sewage was the major source of the pollutants and the

The Atomized Suspension Technique unit, for secondary treatment of sewage, now in operation at Beaconsfield, Que.

1. Gordon E. McCallum, Chief, Division of Water Supply and Pollution Control, U.S. Public Health Service.

Provincial authorities asked Calgary, Edmonton and Lethbridge to expand their sewage treatment facilities in order to give primary treatment to all sewage. In 1953-54 a study was made of a strange odour from the North Saskatchewan River. Extensive study of industrial wastes in the Edmonton area led to control of the situation, however the exact chemical substance responsible for the odour was not determined. The main problem in Alberta is still to maintain sufficient water quality between December and April when the rivers are covered with ice, preventing replenishment of dissolved oxygen supplies and dilution of waste effluents to a safe level.

Since 1955, the treatment facilities provided for new municipal treatment systems in Saskatchewan have been sewage stabilization ponds or lagoons. In the past five years 43 such systems have been constructed, in a few cases replacing conventional systems. Twenty-one conventional systems — activated sludge, standard, high-rate filters, and even an Imhoff tank alone — are in operation.

Canadian sanitary engineers are much concerned in finding new methods of treatment for municipal and industrial wastes. The various provincial commissions have extensive research facilities and various branches of the Professional Institute of Public Service, such as the Department of Fisheries, are making water pollution studies.

In 1953, Dr. William H. Gauvin, Head of the Chemical Engineering Division of the Pulp and Paper Research Institute of Canada in Montreal, while doing research on recovery of chemicals and heat from the spent liquors of sulphite pulpmills, developed the Atomized Suspension Technique for the secondary treatment of sewage. The unit which he developed, the first example of which is now in operation at Beaconsfield, Quebec, is an empty tower whose walls are kept at a temperature of 1000-1400° F. Through an atomizing nozzle at the top of the tower 10-12% sludge is introduced into the heated reactor where a series of physical or chemical transformations take place. When the droplets reach their terminal velocity in the reactor they are repelled from the wall both by the larger thermal gradient next to the wall and by the violence of their own evaporation on the side nearest the wall. This repulsion prevents scaling and corrosion of the reactor wall.

As the suspension moves down the reactor, the droplets become semi-solid particles and enter a drying zone where the internal moisture of the particles diffuses to their surfaces and is evaporated. At the end of the drying zone, physical separation of the solids has been achieved and in the lower half of the reactor the dry solids are suspended in a flow of superheated stream and incondensible gases. Oxidizing air introduced at this stage turns the solids into inert ash. The resulting ash, separated from the gas, can be used as a soil conditioner or passed to the condenser and the plant outfall.

Although the AST unit is in the early stages of application to sewage treatment problems, there is reason to believe that it represents a significant achievement in secondary treatment, demanding less space, time and supervision than conventional processes. However, this is for disposal of retrievable solids in sewage. What is to be done with the effluent from primary treatment is another question.

Opening of Boundary Dam Power Station

The Saskatchewan Power Corporation's new Boundary Dam Power Station near Estevan was officially commissioned on May 14, 1960, by General A. G. L. McNaughton, Chairman of the Canadian Section of the International Joint Commission. The station is situated on Long Creek, an international waterway and tributary of the Souris River, where there are vast supplies of lignite coal. Construction of the power station began in October, 1956, and the dam was completed in the fall of 1957, while the first 66,000 kw. generating unit went into operation in June, 1959, and the second unit in the spring of 1960.

A major part of Saskatchewan's growing power needs will be provided by Boundary Dam and its sister station, the Queen Elizabeth Power Station at Saskatoon. These two large thermal stations will be supplemented by the system's first hydro power when the Squaw Rapids Hydro Station goes into operation toward the end of 1963.

International News

Around the world the crisis of increasing water pollution is impending. Although the necessity of keeping our waters clean has been apparent for over half a century, only in the last decade have legislators begun to face the problems of new industrial wastes and an ever greater volume of domestic sewage. At the same time chemists and engineers have begun to explore for new methods of treating sewage.

Great Britain, France, Germany, the U.S., and Canada are but a few of the countries which recognize that their present water resources are being exhausted faster than scientists can find a way to revitalize used water supplies. They have passed legislation to prohibit as far as possible the further pollution of rivers and lakes by industry; to encourage research in sanitary engineering; to assist financially with construction of new sewage treatment facilities. The greatest need felt at the present time is for new methods of sewage treatment, methods that can meet the new problems posed by chemically complex industrial wastes, by the ever-increasing bulk of municipal wastes and by the new hazard of radioactive particles.

Dr. L. E. Burney, Surgeon General of the U.S. Department of Health's Public Health Service, has stated that an estimated 7,000 totally new chemicals are put to use every year. Conventional sewage treatment methods, designed to deal with essentially organic substances, have little effect on detergents, plastics and thousands of other synthetics which are being poured into our water supplies. He has also pointed out that while we are now still able to get the amounts of pure water that we require, by 1980 the municipal demand will have doubled and the industrial tripled. Gordon E. McCallum, Chief of the Division of Water Supply and Pollution Control of the U.S. Department of Health, Education, and Welfare has cited these figures — Americans now consume approximately 300 billion gallons daily. By 1980 they will need 600 billion gallons. According to our present knowledge of potential water supplies, taking into account all measures available for the reuse of water, the maximum quantity of water available for consumption in 1980 in the U.S. will be 515 billion gallons, or 85 billion gallons less than is called for.

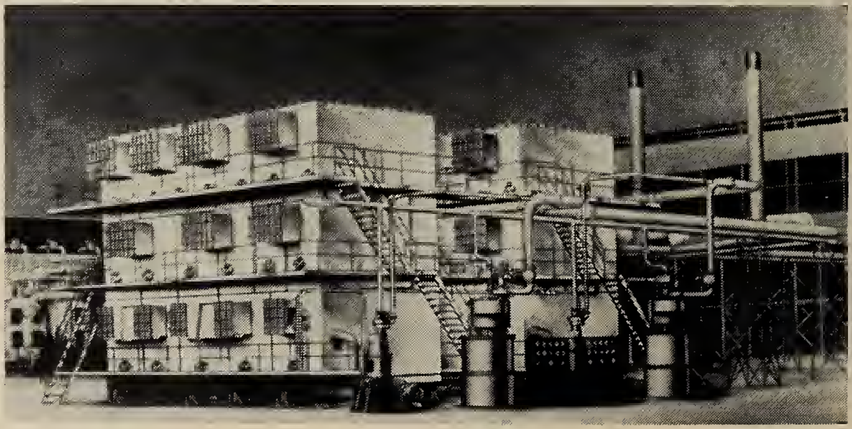
One partial solution to the problem of water shortages appears to be the development of distillation processes for salt water. Sanitary engineers in Glasgow, Scotland have designed a water distillation plant which is operating in various parts of the world, from Aruba in the Netherlands Antilles, to the Channel island of Guernsey. The Aruban plant, the largest distillation works in the world, produces 2,240,000 gallons of pure fresh water from the sea daily. The Guernsey plant is capable of producing half-a-million gallons of drinking water a day. The U.S. has developed a distillation unit, the LTV, or long-tube verticle multiple-effect distillation, which is being used at Harbor Island, North Carolina and Freeport, Texas. Some countries still have sizeable potential water resources as yet untapped, such as Israel where Technion sanitary engineers are investigating the use of the Sea of Galilee waters for drinking purposes.

In July, 1957 the West German government passed laws regulating the use of water. Since then no new water-collecting enterprises have been allowed without government authorization, priority being given to those providing drinking water. Water pollution laws include an enumeration of products which can not be disposed of in water.

Just a year before, in July, the Federal Water Pollution Control Act of 1956 came into being in the U.S. It authorized continued Federal-State-interstate cooperation in programs for controlling water pollution; increased technical assistance to the States, including a broader research program and research fellowships; collection and dissemination of basic data on water quality and treatment; appropriation of $3 million per year for five years for State and interstate grants; Federal grants of $50 million a year for the construction of municipal sewage treatment works; establishment of a Water Pollution Control Advisory Board.

The Robert A. Taft Sanitary Engineering Center has been set up in Cincin-

Sea water distillation plant: The largest installation in the world for converting the sea to fresh water is located at Kuwait in the Persian Gulf. When the new plant is completed, ten and a half million gallons will be distilled a day.



nati, Ohio, as the largest and most modern research facility of its kind in the country. However, extensive research is being carried out in other parts of the country. A study of the beneficial microorganisms in the biological treatment of domestic and industrial wastes has been in progress at the Case Institute of Technology, as a result of two grants from the Public Health Service. Studies of package and subdivision sewage treatment plants have been made recently at the University of Florida Sanitary Engineering Research Laboratory, with the cooperation of the Florida State Board of Health and the U.S. Public Health Service.

A special course in Sanitary Engineering is being offered in Delft, Netherlands, during the academic year 1960-61. The Organization for European Economic Co-operation has endorsed the course for "dealing with a group of technical problems of increasing gravity in densely populated industrial areas" and doing so on an international basis. The belief that water pollution must be dealt with by geographical areas rather than by political units is widespread.

The Chief of the Division of Water Supply and Pollution Control of the U.S. Public Health Service, Gordon E. McCallum, has reported that numerous soluble persistent organics are present in secondary effluents, that is, in water leaving sewage treatment plants, whose effects on human health are undetermined. Viruses of such diseases as infectious hepatitis are known to persist in treated waters, making it clear that ultra-microscopic particles are much more difficult to remove or destroy than bacteria. Soluble chemicals are not appreciably removed from treated water either. Both Mr. McCallum and the Surgeon General, Dr. Burney, have stated that the challenge in combating water pollution is micro-chemical rather than microbiological as it has been traditionally thought.

Some recent developments have been made in treating industrial wastes. A new treatment plant has been installed in a British steelworks which converts the toxic constituents of the effluent into harmless substances by means of bacteriological oxidation. The system involves the isolation of certain bacteria found in well manured soil. These strains are encouraged to multiply and, when properly conditioned, are placed in tanks through which the effluent is pumped. The bacteria absorb the poisonous phenol, using it as a carbon and energy source for reproducing themselves, and thus the process is continuous.

The Swedes have found a method of purifying polluted water by electroshock. Though the process is still in the very early stages of development, experiments have shown that electroshock will kill germs, make solid particles settle at the bottom, and cause certain components of the polluted water to coagulate.

The Great Lakes States and Provinces have similar problems to meet in the water pollution question. They have jointly objected to raw sewage being dumped from lake-going ships using the St. Lawrence Seaway. They coordinately oppose the proposed drilling in Lake Huron. For these reasons they have formed a Canadian-American anti-water pollution committee, and the affected States and Provinces are working with the International Joint Commission on solutions.

An outstanding example of regional cooperation on water pollution problems is the 12-year-old Ohio River Valley Water Sanitation Commission composed of representatives from Illinois, Indiana, Kentucky, New York, Ohio, Virginia, Pennsylvania and West Virginia. It has begun to accomplish its aims with the recent completion of the Alleghany County Sanitary Authority sewage-purification plant which treats the sewage from Pittsburgh's population of 1,400,000 persons at the head of the Ohio River. The Commission plans to build sewage treatment facilities for the 3,600,000 population of municipalities along the Ohio River. It also aims to control industrial waste pollution; to develop information on radio-activity levels on the Ohio River; to try to reduce mine-acid discharges along the river and to bring to a halt the indiscriminate discharge of salt wastes; to curb oil pollution in the river; to inventory aquatic life resources and to develop a monitor system for the appraisal of water-quality conditions.

WINNIPEG COMMITTEE

for the

74th ANNUAL GENERAL AND PROFESSIONAL MEETING

May 25, 26, 27, 1960

J. R. Rettie	Chairman
C. V. Antenbring	Vice Chairman
W. A. Devereaux	Vice Chairman
W. L. Wardrop	Representative & Chairman Branch Management Committee
G. C. March	Secretary
N. S. Bubbis	Publicity
D. C. Bryden	Budget and Finance
R. E. Chant	Technical Papers
F. G. Denson	Hotel Arrangements
W. A. Devereaux	Registration
C. L. Fisher	Reception and Information
G. Flavell	Ladies
J. MacDonald	Plant Visits & Transportation
G. A. Muir	Communications & Projection
R. Noonan	Muriel's Room & Entertainment
T. Weber	Annual Dinner and Dance

Month to Month

(Above) Mr. John Fox of the Engineers Confederation Commission reports to the Annual General Meeting.

(Above right) The Annual General Meeting in session.

EIC *Annual Meeting Winnipeg, 1960*

The new President, G. M. Dick (right) receives the good wishes of his predecessor, J. J. Hanna.

Mr. Hanna congratulates the Right Hon. C. D. Howe, a 1960 Julian C. Smith Medal winner.

Major-General H. A. Young receives his Julian C. Smith Medal from President Hanna. At right, Mr. C. V. Antenbring.

74th ANNUAL GENERAL MEETING

ANY PERFUNCTORY NOTE of appreciation would be a meagre tribute to the arrangements for the 74th Annual General and Professional Meeting. As a thousand members and friends of The Engineering Institute of Canada assembled in the Manitoba capital, the Keystone Province interlocked an impressive number and variety of journeys. Every province from coast to coast was represented, as were our sister societies in the United States and Great Britain. Max Freedman of the British *Manchester Guardian* came from his post in Washington to speak at the Annual Banquet, at which the Mayor of Auckland, New Zealand, was among the head table guests. All found a warm Western welcome, smooth unobtrusive organization, and a program of events that in its conception and execution drew from many quarters the spontaneous comment that this was the most successful Annual Meeting in many a long year.

The efficient transaction of Institute business and the competent handling of professional discussion were the work of many people in the various committees concerned, but all these activities were gaily laced with social events and the whole gift-wrapped in an attractive package that revealed something quite distinctive in the Winnipeg touch.

The Program

Council met on Tuesday, while in other rooms of the Royal Alexandra Hotel the Committee on Technical Operations, the Committee on Education and the Branch Officers' Conference were also in session.

The Annual General Meeting on Wednesday received news of a signal honour to the Institute in the appointment of one of its past presidents, Dr. J. B. Stirling, as Chancellor of Queen's University. The minutes of the Annual General Meeting will appear in an early issue. Technical papers began on Wednesday, accompanied by a novel aid to punctuality — all technical sessions were opened and closed with the skirl of the bagpipes. On Thursday, a lively panel discussion on the relative merits of the yard and the metre was attended by a very large, yet remarkably quiet and attentive audience.

The Committee on Technical Operations convened on Tuesday, and its various divisions began their deliberations the following day. The Students' Conference opened on Wednesday, and the Professional Development Committee met on Thursday. On that day also the Consulting Engineers held their meeting. The Joint A.S.M.E.-E.I.C. International Council met on Friday, and in the afternoon there were field trips to plants in the Winnipeg area.

At the luncheon on Thursday, President J. J. Hanna presented medals, prizes, and certificates of honorary membership. That evening the Consulting Engineers at their Annual Dinner conferred honorary membership of their Association on Dr. C. J. MacKenzie, a past president of the Institute.

At the Annual Banquet on Friday, retiring President Hanna formally introduced the new President, G. M. Dick. The Honourable E. F. Willis, Lieutenant-Governor, bestowed a colourful Manitoba distinction, the Order of the Buffalo Hunt, upon President Hanna and the fraternal delegate from Great Britain, H. Norman Allen, Vice-President of the Institution of Mechanical Engineers. Alderman Crawford, representing Mayor Juba of Winnipeg, gave certificates of Honorary Citizenship to President Dick, retiring President Hanna, past presidents Finlayson and Grant, Mr. Walker L. Cisler, President of the American Society of Mechanical Engineers, Mr. F. A. Marston, President of the American Society of Civil Engineers, Mr. Max Freedman, and Dr. R. L. Hearn. The same honour was conferred on Major-General H. A. Young.

High Fidelity

One insistent theme echoed throughout the meeting: the future of the Canadian engineer is the future of Canada. Nat Bubbis, the publicity chairman, talking to the press on Tuesday afternoon, drew attention to a film showing in the hotel that evening. It was devoted to the Warsak Project in Pakistan, and Nat commended the subject to the newsmen since not only Canadian engineering brains but also Canadian taxpayers' dollars had gone into this Colombo Plan achievement. He went on to say that the technical papers would be of interest not only in the development of engineering, but also in the development of our country. At the opening luncheon next day, the Annual Meeting Committee chairman, Jim Rettie, noted the titles of technical papers read at the Winnipeg meeting of 1911 and commented: "Those boys were really giving Canada a hand." The speaker at the luncheon was the Honourable C. H. Witney, Manitoba's Minister of Mines and Natural Resources, and he depicted today's engineer as a new frontiersman, doing the job that has to be done; the politician had the important duties of ordering it done and dealing with the side effects which are so important to the livelihood and welfare of the people. Each needed the other, and the engineer was often dependent on those less trained and less skilled. On Friday evening, Max Freedman was to make this same point in appealing for a constant line of creative communication between the elected representative and the hard working expert.

"That is your history all through the years", Alderman Crawford told us that same evening, "that you do the things that the rest of us want done." On Thursday, President Dick had told the new Council that we must put Canada out in front with an efficient program of E.I.C. technical operations if we are to keep this country where it belongs. The importance of this goal was highlighted by Max Freedman's claim that it is the glory of the American and Canadian democracies to have proved that there is no conflict between freedom and abundance. And he went on to deplore the attitude of those who assume our civilization to be beyond the meridian of its growth, when in reality "it is but at the cock-crow and the morning star."

The A.S.M.E.-E.I.C. International Council. Standing, L. to R.: G. T. Page (E.I.C.); P. W. Gooch (E.I.C.); G. C. Southmayd (E.I.C.); J. A. Thomas (E.I.C.); H. G. Conn (E.I.C.). Seated, L. to R.: G. M. Dick (E.I.C.); H. I. Muller (A.S.M.E.); L. C. Sentance (E.I.C.), Chairman; J. J. Hanna (E.I.C.); O. R. Schier II (A.S.M.E.).

President Dick and Retiring President Hanna with Mr. W. L. Cisler, President of the American Society of Mechanical Engineers.

At the Awards Luncheon. L. to R.: Dr. W. P. Dobson; Dr. R. L. Hearn; Mr. J. J. Traill. Drs. Dobson and Hearn received Honorary Memberships. Mr. Traill's paper "Test of Hydraulic Turbines—and Appraisal" was awarded the Robert W. Angus Medal.

(Left) The Opening Luncheon. L. to R.: Mr. C. V. Antenbring, joint Vice-Chairman, Annual Meeting Committee; Mrs. S. Barkwell; Hon. C. H. Witney (speaker); Mr. J. R. Rettie, Chairman, Annual Meeting Committee.

(Below) At the Ladies' Dinner. L. to R.: Mrs. E. P. Fetherstonhaugh; Mrs. J. Finlayson; Mrs. W. A. Vance; Mrs. G. M. Dick; Mrs. K. F. Tupper; Mrs. V. A. McKillop; Mrs. D. M. Stephens.

Two 3rd-year Civil Engineering students at the University of Manitoba kept the technical sessions on time. Doug Chivers is the piper, and his standard bearer, Gord Crabtree.

Engineers Confederation Commission

Progress Report to the 1960 Annual Meetings of the Canadian Council of Professional Engineers and The Engineering Institute of Canada

A. GENERAL

1. A short time after its appointment, the Engineers Confederation Commission met in Toronto. The meeting, which had almost full attendance, appointed nine task committees to undertake the major studies required, by the terms of reference assigned the Commission by the Report of the Committees on Confederation, dated March 18, 1959. These committees were appointed on a geographical basis, both to ensure that a broad reflection of opinion from all parts of Canada was obtained, and to keep travel costs to a minimum.

2. The chairmen and terms of reference of these nine committees are:

(a) **Charter—**
Chairman: J. G. Dale.
"To draft a complete charter, using the E.I.C. charter as a basis if possible".

(b) **By-Laws—**
Chairman: H. Gaudefroy.
"To draft all necessary by-laws, assuring that these are consistent with the Charter".

(c) **Administration—**
Chairman: T. Foulkes.
"To spell out the broad lines of how the new national body would be administered".

(d) **Finance—**
Chairman: E. D. Gray-Donald.
"To work out the details of how the new body will be financed, in co-operation with the Committee on Administration".

(e) **Branches—**
Chairman: W. K. Gwyer.
"To determine how the branches would be formed, financed, operated, etc., and their relationship with the national body and the provincial associations".

(f) **Other Societies—**
Chairman: J. Herbert-Smith.
"To survey possible co-operation with, and participation of, other societies, (Canadian, U.S., British, or foreign technical societies and professional engineering bodies) as distinct from the two participating groups".

(g) **Services—**
Chairman: J. B. Mantle.
"To outline the various services to be performed by the new national body".

(h) **Relationship With the Provincial Associations—**
Chairman: J. Hoogstraten.
"To establish the relationship between the new national body and the provincial associations".

(i) **Co-ordinating—**
Chairman: J. H. Fox.
"To co-ordinate the work of the committees and to establish the details of implementation of the decisions of the Commission".

3. The secretariat of the Commission is shared by Leo M. Nadeau, Executive Secretary of the C.C.P.E. and Garnet T. Page, General Secretary of E.I.C.

4. Proper arrangements have been established for the banking, accounting and audit procedures for the operating funds that have been entrusted to the Commission by the C.C.P.E. and the E.I.C. on an equal basis.

B. PROGRESS

1. Following the meeting of the Commission in October, 1959, the task committees proceeded vigorously to develop their assigned work. In March, 1960, so much real progress had been made by the committees that a meeting of the Co-ordinating Committee was held, at which encouraging progress reports were received from all committee chairmen, and further instructions and directions were given to the committees.

2. After the Co-ordinating Committee meeting in March, each committee revised and added to its reports, in preparation for the second meeting of the Commission in Toronto on April 23, 1960, which again had almost 100% attendance. As a result of the work completed at this meeting, the following progress report is submitted:

(a) It is apparent to the Commission that Confederation of the C.C.P.E. and the E.I.C. is possible within the requirements which are set forth in the terms of reference of the joint report.

(b) In more detail:

(i) A final draft of the charter, making use of the present E.I.C. charter, is now complete except for a few minor details. Naturally, the E.I.C. charter has had to be amended substantially to meet the needs of the new national body, and to make specific provisions so that the decisions of the national body are not binding upon the provincial associations if such decisions in any manner concern the application of the provincial engineering acts or other provincial acts. Provision is made for the location of headquarters to be at the discretion of Council. A complete final draft charter should be available at an early date, and no difficulties are anticipated.

(ii) Excellent progress is being made in the preparation of draft by-laws to govern the administration and management of the national body. These draft by-laws are consistent with the provisions of the draft charter. The By-Laws incorporate provisions for the establishment of a national Council, the administration, services, classes of membership, and relationships with other associations and societies that are being planned.

(iii) A plan is being prepared for the administration of the proposed national body, to enable it to render enlarged professional and technical services to the membership. This plan includes methods of organizing the membership so that services may be of maximum value to the largest number of members.

(iv) The amount of the assessment per member is receiving careful attention from the point of view of essential services to be rendered. Every effort is being made to provide these services at the minimum reasonable cost, bearing in mind present overall economic conditions.

(v) Detailed proposals for enlarged branch activity and for branch participation in national activities are being prepared. These proposals allow for the merging of existing association and E.I.C. branches where they exist in the same community, and provide a mechanism for the formation of new branches where requested. Careful consideration is being given to the problem of adequate communications between branches and the national body as well as between branches and the provincial associations. An underlying principle of the Commission's planning with regard to branches is that membership in a branch shall be on a voluntary basis. Provision is being made to allow the formation of student sections of branches in areas where there are universities and where needed.

(vi) Plans have been developed for a programme which will permit the development of national technical divisions and local technical divisions of members of the national body, and for full co-operation with other technical and professional societies, with a view to augmenting the services of the national body to the members by these relationships.

Proposals are also being prepared to allow the development of functional sections at the local, provincial and national levels to permit the grouping of members with common functional interests at any or all levels if and when desirable.

(vii) Generally speaking, the plans for services to be rendered by the national body are a combination, and in many cases an amplification or broadening, of the services now being provided by the C.C.P.E. and the E.I.C. in the interests and for the welfare of the members. Special attention is being given to the provision of a national journal and an overall publication programme.

C. *COMMISSION FINANCES*

The cost of operating the Commission to date has been approximately $10,000.00. It is impossible to estimate the vast expenditure of time, effort, and enthusiasm that has been given freely by each and every member of the Commission, but it is certainly not at all comparable to or represented by this small expenditure of money.

D. *ANTICIPATED TIMING*

It is anticipated that, with the progress made to date and the instructions that have been issued for further work, it will be possible to call two meetings of the Co-ordinating Committee in the Fall of 1960 and a full meeting of the Commission in December. Arising from these meetings, it is hoped that a well developed report, in the final stages of preparation, will be available in January, 1961, for presentation to the C.C.P.E. and the E.I.C.

E. *EXTENSION OF APPOINTMENT OF THE COMMISSION*

It is requested that in order to complete the Commission Programme that the members of the Commission, whose first year of appointment expires in October, 1960, be re-appointed for a second year by the C.C.P.E. and E.I.C. consistent with provision of the joint report.

F. *PUBLICITY*

It is requested that the C.C.P.E. and the E.I.C. re-affirm and continue the existing policy that the only information which these bodies publish regarding the work of the Commission be that which is provided officially by the Commission for that purpose.

It is anticipated that, as the work of the Commission progresses, more complete and detailed information will be made available.

Respectfully submitted,
John H. Fox, Chairman
L. Roy, Vice-Chairman

May 5, 1960.

Officers of the Branches

AMHERST
Chairman, G. C. L. McEnery, 65 Bridge St., Sackville, N.B.
Secretary-Treasurer, G. B. Turnbull, 47½ Havelock St., Amherst, N.S.

BAIE COMEAU
Chairman, E. Bodmer, 197A Champlain St., Baie Comeau, Que.
Secretary, L. Tellier, Manoir Comeau, Baie Comeau, Que.

BELLEVILLE
Chairman, W. C. Benger, 231 Albert St., Belleville, Ont.
Secretary-Treasurer, D. A. Law, 54 Montgomery Blvd., Belleville, Ont., Tel. WO. 2-4511.

BORDER CITIES
Chairman, J. M. Reid, 1511 York St., Windsor, Ont.
Secretary, A. J. Barker, 431 Homedale Blvd., Riverside, Ont., Tel. CL. 6-5555.

BROCKVILLE
Chairman, G. M. Woods, 421 Dibble St., Prescott, Ont.
Secretary-Treasurer, W. E. Currie, 41 Bramshot Ave., Brockville, Ont.

CALGARY
Chairman, J. A. Webb, 78 Maliboo Rd., Calgary, Alta., Tel. AL. 5-6076.
Secretary, A. F. D. Shore, c/o Royalite Oil Co., 615-2nd St. S. W., Calgary, Alta., Tel. AM. 6-7021.

CAPE BRETON
Chairman, W. L. Dodson, 201 Columbia St., Sydney, N.S.
Secretary, L. R. Boutilier, 29 Royal Ave., Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, H. A. Price, 1371 Leir St., Penticton, B.C., Tel. HY. 2-3071.
Secretary-Treasurer, W. J. M. Owen, 634 Eckhardt Ave., Penticton, B.C.

CHALK RIVER
Chairman, C. E. L. Hunt, 31 Thomson Crescent, Deep River, Ont.
Secretary-Treasurer, W. O. Findlay, P.O. Box 661, Deep River, Ont.

CORNER BROOK
Chairman, Kevin St. George, 19 Humber Park, Corner Brook, Nfld.
Secretary, H. A. Hinton, c/o Bowater's Nfld. Pulp & Paper Mill, Corner Brook, Nfld.

CORNWALL
Chairman, L. H. Snelgrove, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.
Secretary-Treasurer, D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Chairman, J. C. Davidson, 350 Victoria Street, Sherbrooke, Que.
Secretary, H. A. MacLean, Moulton Hill Rd., Lennoxville, Que.

EDMONTON
Chairman, J. Longworth, 10818-67th Avenue, Edmonton, Alta.
Secretary-Treasurer, George Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON
Chairman, Wm. L. Barrett, 661 Chestnut St., Fredericton, N.B.
Secretary, E. C. Garland, 806 Hanson St., Fredericton, N.B.

HALIFAX
Chairman, H. A. Marshall, c/o Imperial Oil Ltd., Halifax, N.S.
Secretary-Treasurer, John Jay, P.O. Box 33, Halifax, N.S.

HAMILTON
Chairman, P. J. McNally, c/o S. S. McNally & Sons, 215 Superior St., Hamilton, Ont.
Secretary-Treasurer, David Friesen, Dom. Tar Foundries & Steel Co., Depew St., Hamilton, Ont.

HURONIA
Chairman, S. R. Walkinshaw, 311 Franklin St., Orillia, Ont.
Secretary-Treasurer, Louis Morgante, 36 Borland St. W., Orillia, Ont.

KINGSTON
Chairman, R. J. Kennedy, 2 Grenville Rd., Kingston, Ont.
Secretary-Treasurer, L. C. Miller, 277 Mack St., Kingston, Ont.

KITCHENER
Chairman, A. H. Austin, 51 Waverley Drive, Guelph, Ont.
Secretary-Treasurer, C. G. E. Downing, c/o Ontario Agricultural College, Guelph, Ont.

KOOTENAY
Chairman, L. S. Piper, 104 Kootenay Ave., Trail, B.C., Tel. 1652.
Secretary, I. Waterlow, Supt., Maintenance Refinery, Consolidated Mining & Smelting, Trail, B.C.

LAKEHEAD
Chairman, C. M. Cotton, 426 West Walsh St., Fort William, Ont.
Secretary, P. W. Pinn, 630 Dawson St., Port Arthur, Ont.

LETHBRIDGE
Chairman, R. L. Francis, 1914-14th Ave. S., Lethbridge, Alta.
Secretary-Treasurer, R. F. Smith, Street & Roadways Engineer, City Hall, Lethbridge, Alta.

LONDON
Chairman, George Hayman, c/o John Hayman & Sons, 432 Wellington St., London, Ont., Tel. GE. 2-5343.
Secretary-Treasurer, G. T. Fenwick, c/o Unifin Tube Company, P.O. Box 7, London, Ont., Tel. GL. 1-0230.

LOWER ST. LAWRENCE
Chairman, L. P. Dancose, c/o The Canada Gulf & Terminal Rly. Co., Mont-Joli, Que.
Secretary-Treasurer, Gerard Fournier, c/o Lower St. Lawrence Power Co., 6 St. Jean Street, Rimouski, Que.

MONCTON
Chairman, W. M. Steeves, 169 Reede St., Moncton, N.B.
Secretary-Treasurer, V. C. Blackett, 97 MacBeath Ave., Moncton, N.B.

MONTREAL
Chairman, Jacques Benoit, c/o H. W. Lea, 39 Westminster Ave. S., Montreal West, Que., Tel. HU. 9-6160.
Secretary-Treasurer, G. M. Boissonneault, c/o The Shawinigan Water & Power Co., P.O. Box 6072, Montreal, Que., Tel. UN. 6-5641.

NEWFOUNDLAND
Chairman, R. F. Martin, c/o St. John's Municipal Council, St. John's, Nfld.
Secretary, A. E. O'Reilly, c/o Newfoundland Light & Power Co. Ltd., P.O. Box 976, St. John's Nfld.

NIAGARA PENINSULA
Chairman, F. R. Denham, P.O. Box 512, Fonthill, Ont.
Secretary, Arthur Alexander, c/o English Electric Co. of Canada Ltd., George St., St. Catharines, Ont.

NIPISSING and UPPER OTTAWA

Chairman, J. M. Roseborough, P.O. Box 434, Temiskaming, Que.

Secretary-Treasurer, W. A. Adams, White Oaks Inn, Temiskaming, Que.

NORTH EASTERN ONTARIO

Chairman, I. M. Foster, P.O. Box 672, Kapuskasing, Ont.

Secretary, J. W. Blakeman, c/o Spruce Falls Power & Paper Co. Ltd., Kapuskasing, Ont.

NORTHERN NEW BRUNSWICK

Chairman, P. J. Delicaet, c/o Connolly Construction Ltd., Bathurst, N.B.

Secretary-Treasurer, P. J. Dallien, 921 Carthage Ave., Bathurst, N.B.

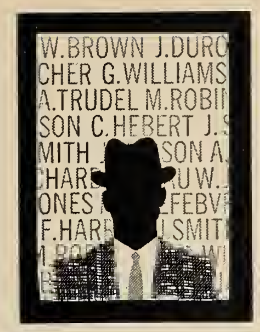
Chairman, J. B. Eldridge, 569 Sand Cove Rd., Lancaster, N.B.

Secretary-Treasurer, J. P. Mooney, 50 Princess St., Saint John, N.B.

(Continued on page 124)

Personals



R. A. Campbell, M.E.I.C. has been appointed director of engineering for Eastbourne Construction Consultants Ltd., Toronto.

H. G. Hilton, M.E.I.C. (Case School of Applied Science '10), Chairman of the Board and Chief Executive Officer of the Steel Company of Canada, retired from active service April 1, after 41 years with the company. Mr. Hilton will continue as Chairman of the Board of Directors of the company.

John L. Cavanagh, M.E.I.C. (N.S.T.C. '11), President of the Malagash Salt Company Limited, and **Geoffrey A. Gaherty,** M.E.I.C. (Dalhousie '09), President of the Montreal Engineering Company Limited, were presented with Honorary Doctor of Engineering degrees at N.S.T.C.'s annual convocation, May 11.

L. W. Pillar, M.E.I.C.

H. W. Tate, M.E.I.C.

H W. Tate, M.E.I.C. (Toronto '10) and L. W. Pillar, M.E.I.C. (Kings College '25) have joined Ewbank & Partners (Canada) Limited, consulting engineers, Toronto, as Principals of the company.

P. W. Voisey, M.E.I.C. has taken a position with the Research Branch at the Central Experimental Farm, Ottawa.

Arthur Piche, M.E.I.C. (Ecole Polytechnique '30) has been elected President of the Corporation of Professional Engineers of Quebec. He is Engineer of Public Works for Quebec City and professor of municipal engineering at Laval University.

Andrew H. Wilson, M.E.I.C. (Glasgow '49) has been appointed Scientific Administrative Officer of the Physics Division of Atomic Energy of Canada Ltd.

G. Y. Sebastyan, M.E.I.C. (Michigan '53) is Research and Evaluation Engineer with the General Engineering Design Section, Airport Development, Construction Branch, Department of Transport, following a recent appointment.

R. F. Swain, M.E.I.C. has retired from the Royal Canadian Navy and is now serving as Superintendent of Ship Construction and Maintenance, Canadian Hydrographic Services, Department of Mines and Technical Resources, Ottawa.

G. Ross Dance, M.E.I.C. (Toronto '34) has been appointed Manager, Nylon Intermediates, at the Maitland Works of Du-Pont of Canada Limited.

Terence J. Farrell, M.E.I.C. (N.S.T.C. '46) has been appointed manager of Plate and Mechanical Sales, of Canadian Vickers, with headquarters in Montreal.

K. R. Meyer, M.E.I.C. (London '37) has rejoined Stadler, Hurter & Company as Project Manager. Prior to this he was Assistant Chief Engineer at the E. B. Eddy Company, Hull, Quebec.

F. C. Ansley, M.E.I.C. (Queen's '37) President and General Manager of Con-Eng Contractors Ltd., has been elected President of the Ontario General Contractors Association.

Marcel Carrier, JR.E.I.C. (Laval '47) has been appointed chief engineer at the Lower St. Lawrence Power Company, **Fernand Roy,** JR.E.I.C. (Laval '50) is the company's new system superintendent, while **Gerard Fournier,** M.E.I.C. (Laval '56) has been appointed distribution engineer.

Robert T. Crawford, M.E.I.C. (Manitoba '48) has been appointed Southern Alberta District Manager of the Canadian Ice Machine Company Ltd., with headquarters in Calgary.

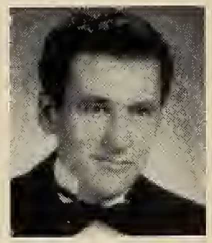
George F. S. Davis, M.E.I.C. (Alberta '49) has accepted the position of Co-ordination Engineer with Rudberg Bros. Inc., Construction Project Managers for the new 34-storey C-I-L House. Mr. Davis was formerly Eastern Division Engineer with the construction subsidiary of the Hudson's Bay Company.

G. R. McMeekin, M.E.I.C. (Alberta '41) has been appointed Special Assistant, Administration of The Consolidated Mining and Smelting Company of Canada Ltd., Trail, B.C.

Jan A. Vandergiessen, M.E.I.C., has been named Alberta Representative of Read Jones Christoffersen, consulting engineers, Vancouver and Edmonton, and will be in charge of the Edmonton office.

Arthur E. Lea, M.E.I.C. (London '46) has recently joined Frederick Parker (Canada) Ltd. as Western District Representative and will reside in Edmonton. He has previously been with the Department of National Defence on development projects for the Canadian Army.

A. E. Lea, M.E.I.C.



R. R. Duquette, M.E.I.C.

R. R. Duquette, M.E.I.C. (Ecole Polytechnique '32) has been elected President of the Association of Consulting Engineers of Canada. He is a member of the consulting engineering firm of McDougall & Friedman, Montreal.

J. E. Miller, JR.E.I.C. (Alberta '52) has been elected to the Board of Directors of Catalytic Construction of Canada Limited. He is General Field Superintendent of all the company's operations.

G. E. Plant, M.E.I.C. (U.B.C. '50) has been named Manager of the Paper Machinery Division of the Dominion Engineering Works Limited.

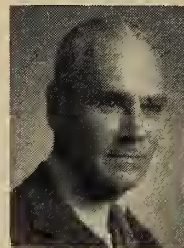
Norman F. Stewart, M.E.I.C. (N.S.T.C. '51) has been appointed City Engineer of Charlottetown, P.E.I. He leaves his post as engineer with the County Construction Company.

J. Douglas Kline, M.E.I.C. (N.S.T.C. '40) was recently elected Chairman of the Canadian Section of the American Water Works Association. He is General Manager of the Halifax Public Service Commission.

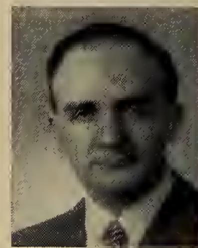
George Lawrence Fox, S.E.I.C. (McGill '59) has taken up the position of Sales Assistant in the Apparatus Division of Canadian Westinghouse Company.

Tony W. Cliteur, JR.E.I.C., formerly employed by the City of Regina, has been appointed Town Engineer for the Town of Kindersley, Saskatchewan.

H. G. Welsford, M.E.I.C. has been appointed Chairman of the Board of Dominion Engineering Works Ltd., Montreal.



H. G. Welsford, M.E.I.C.



W. C. Viner, M.E.I.C.

William C. Viner, M.E.I.C. (McGill '41) is now Chief Engineer at the Donald Inspection Company Ltd., Montreal.

John M. Hubicki, JR.E.I.C. (Toronto '56) is the new County Engineer and Roads Superintendent of the County of Peterborough, Ontario.

Robert T. Bailey, M.E.I.C. (Queen's '48), formerly City Engineer of St. Catharine's, Ontario, is now Works Commissioner of Windsor, Ontario.

Winnett Boyd, M.E.I.C. (Toronto '39) has been appointed President of Arthur D. Little of Canada, Limited, in Toronto. Until this time, he has been President of his own firm, Winnett Boyd Limited, and senior partner in his consulting organization, Winnett Boyd Associates.

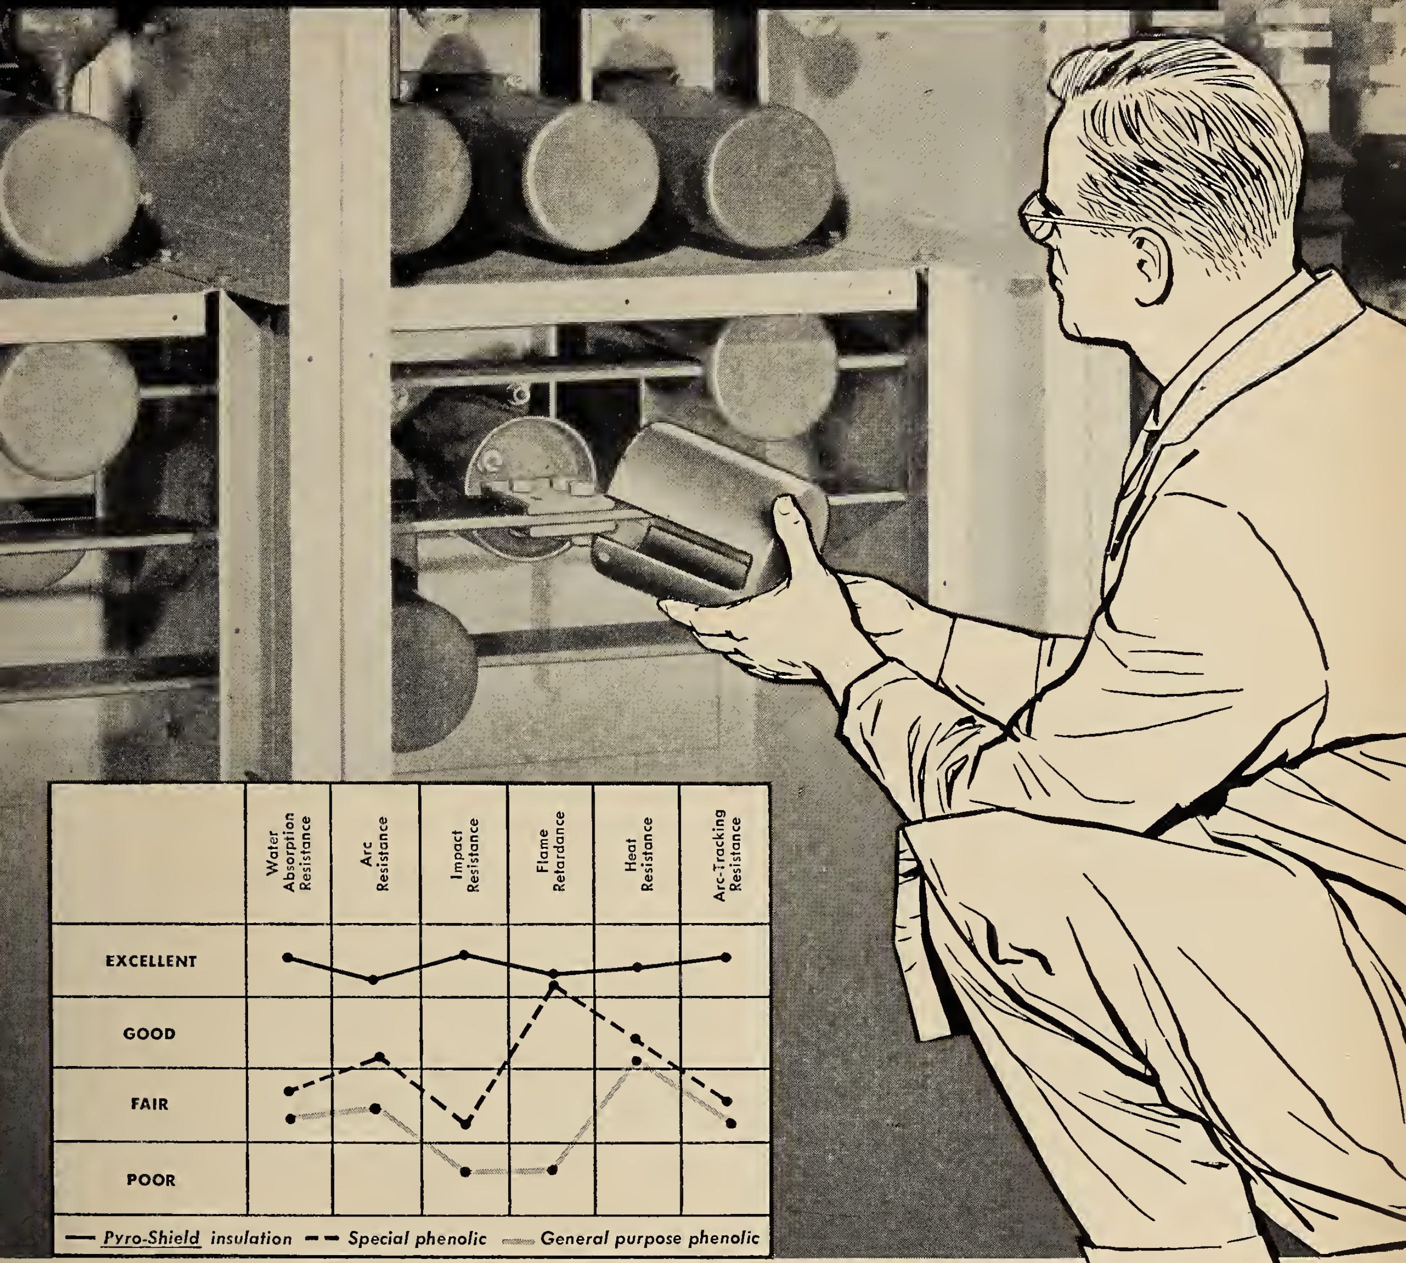
W. Boyd, M.E.I.C.

E. J. M. Knitel, M.E.I.C.

Erich J. M. Knitel, M.E.I.C. (Federal Institute of Technology, Vienna '34) has been appointed Technical Executive Officer in the Montreal Office of the Canadian Overseas Telecommunication Corporation. Mr. Knitel was formerly employed as Staff Engineer with The Shawinigan Water and Power Company.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Allis-Chalmers New 4.16-kv Metal-Clad Switchgear



PROTECTED WITH PYRO-SHIELD INSULATION ALLIS-CHALMERS

New Pyro-Shield Track-Resistant Insulation

Track-resistant *Pyro-Shield* insulation is a polyester glass base material now used in Allis-Chalmers co-ordinated system of switchgear insulation.

One molding connects primary disconnects to bus bars to provide uniform insulation and reduce the number of insulation components.

In addition to being track resistant, *Pyro-Shield* insulation has high impact strength, which eliminates risk of damage from short-circuit stress and assures low moisture absorption.

Other advantages are: high flame retardance; long life — even at high temperatures; resistance to chemical fumes; and bus joint construction that eliminates need for skilled taping techniques.

Get details on this new insulation and other Allis-Chalmers switchgear features, including the low 72-inch silhouette and new *Shelter-Clad* design. Contact your nearby Canadian Allis-Chalmers office, or write Canadian Allis-Chalmers, Switchgear Dept., 55 Burwell Rd., St. Thomas, Ont.

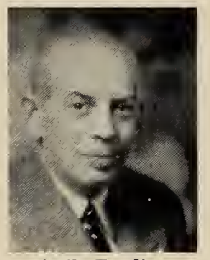
Obituaries

Arthur Balfour Darling, M.E.I.C., President of Darling Brothers Limited, Montreal, died on April 25, 1960.

Born in Montreal in 1902, Mr. Darling graduated from McGill University in 1924 and began his career with the Darling Brothers Company as an engineer. He held various positions with the company and was elected to its presidency in 1956.



A. B. Darling
M.E.I.C.

Mr. Darling was a member of the Corporation of Professional Engineers of Quebec.

He was also a governor of the Montreal General Hospital and a past president and honorary president of the Whitlock Golf Club.

Gilles G. Fortin, S.E.I.C., died suddenly on January 13, 1960, at the age of 22. He had been employed by the Bureau of Patents and Copyrights in Ottawa.

A native of Adamsville, Quebec, Gilles studied at the College Sacre-Coeur in Granby and in May of last year received his degree in mechanical engineering from the University of Sherbrooke. During the summer, for the past two years, he worked for the City of Sherbrooke. He was a member of the Signals Corps at Kingston, Ontario.

Lee Morgan Jones, M.E.I.C., of Islington, Ontario, died on August 21, 1959.

Born in Wales, Mr. Jones came to Canada in 1896 and joined the Canadian Pacific Railway Company in Winnipeg as a draughtsman in 1899. Subsequently he went to work with the Winnipeg Electric Railway Company, directing track-laying and construction of car barns and sub-stations. In 1906 he was appointed Assistant City Engineer of Port Arthur, Ontario, and in 1911 became City Engineer.

Mr. Jones joined the Warren Bituminous Paving Company in 1920. He was elected to the board of directors in 1923 and made Chief Engineer and Secretary of the company. He retired in 1947.

A member of the American Society of Civil Engineers and also the Association of Professional Engineers of Ontario. Mr. Jones was made a Life Member of the Institute in 1947.

He was a member of the Rotary Club for more than twenty-five years and was particularly active on the Crippled Children's Committee of the Toronto club. He was also a member of Deer Park United Church and served as a member of the Board of Managers.

Camille C. S. LeClair, M.E.I.C., formerly of Toronto, died on December 26, 1959, in Devon, England.

After wide experience in senior engineering positions in England and Japan, Mr. LeClair came to Canada and set up a consulting practice and an engineering research organization in Toronto which he incorporated into LeClair Engineering Company in 1954. He later joined Peacock Brothers Limited in Toronto, as Chief Engineer.

In 1944 Mr. LeClair was appointed Staff Officer of the Royal Engineers at First Canadian Army Headquarters. He became first Assistant Director, then Director in the Directorate of Works and Accommodation at headquarters after the war. In 1950 he was appointed command engineer of the Central Command.

Mr. LeClair's original contributions to engineering brought him over one hundred and fifty patents during the course of his career. He was most recently working on the design of Arctic vehicles.

Mr. LeClair was a member of the Institution of Mechanical Engineers, U.K.

Kenneth Hadley Tremain, M.E.I.C., died in Minneapolis, Minnesota, on May 24, 1960, at the age of 55.

A native of Windsor, Nova Scotia, Mr. Tremain received his education from King's College, Windsor; Ashbury College, Ottawa; Royal Military College, Kingston; and McGill University from which he graduated in 1929.

In 1940 Mr. Tremain went overseas, after serving with the 7th Medium Battery of the Royal Canadian Artillery for a year. Upon graduating from the First Canadian Junior Staff College in England, he returned to Canada to assume a staff appointment with the Fourth Canadian (Armoured) Division. In 1945 Mr. Tremain retired from the army with the rank of colonel and was awarded the Order of the British Empire in recognition of his war service.

After the war he joined National Breweries, as a representative of the company in New York. More recently Mr. Tremain acted as Montreal representative of Canadian Zurn Industries.

Lionel Mortimer Stein, S.E.I.C., a graduate in mechanical engineering from McGill University, 1959, died in Boston on April 27, 1960. He was 22 years old.

Frederick Holroyd Paulson, M.E.I.C., of Charles A. Maguire & Associates, Providence, Rhode Island, died in September, 1959.

Charles St. Barbe Kindersley, M.E.I.C., of Calgary, died on February 12, 1960.

Word has reached the Institute of the death of **Digby Wyatt,** M.E.I.C., formerly of J. Brockhouse & Company (Canada), Toronto.

Fred A. Annett, AFFIL. E.I.C., of Flushing, New York, died on October 16, 1959.

Other Societies

1960 Nuclear Congress Papers

The proceedings of the 1960 Nuclear Congress held in New York City in early April are now being distributed. They may be ordered from: The 1960 Nuclear Congress, 29 West 39th Street, New York 18, N.Y.

The Nuclear Congress produced new information in a variety of subject areas related to the application of nuclear energy for mankind's benefit. The Engineering Institute of Canada was one of 28 engineering and scientific organizations supporting the Congress.

Engineering Index

A 1600 page guide to the current technological literature of the world for the year 1959 will come off the presses this month in the form of *The Engineering Index*. The information is indexed under two hundred and forty-nine divisions of engineering. A complete catalogue outlining the coverage of each of these divisions is available upon request.

The Engineering Index, a non-profit organization, hires a staff of qualified editors who review articles concerning the application of engineering methods and concepts in every phase of the economy.

University of Hong Kong Congress

Among the various sessions planned to celebrate the University of Hong Kong's Golden Jubilee from September 11-16, 1961, is a symposium on The Design of High Buildings. It is intended to cover recent theoretical and practical developments, both on the architectural and engineering side, in the planning, design and construction of multi-storey buildings. Those who wish to offer papers are requested to send a synopsis to the General Secretary by December, 1960.

The Institution of Civil Engineers (UK) Award

The Kelvin Gold Medal, 1959 was awarded to Professor Sir Geoffrey Ingram Taylor on February 16, 1960, at the Institution of Civil Engineers, London. Sir Geoffrey's remarkable studies of turbulence, as well as his inestimable scientific contributions during the war years, were cited on this occasion.

ASME Elmer A. Sperry Award

Frederick D. Braddon, inventor of the gyro-compass that guided the atomic submarines Nautilus and Skate under the ice cap of the North Pole, was honoured in Philadelphia on May 4 by four American engineering societies for "an outstanding contribution to the field of transportation".

Canadian Institute of Steel Meeting

More than 200 structural steel and plate fabricators and guests assembled at Montebello, Quebec to elect new officers and exchange technical information on May 13. Among the speakers were Tom Stevenson of the British Iron and Steel Federation, London, England, who discussed Steel Development in the United Kingdom and Europe; G. Hardenberg, Vancouver, co-designer, who spoke on the new Port Mann Orthotropic Bridge; and David Holbrook, President, Algoma Steel Corporation, on Increasing Canada's Steel Production.

AIC Publishes Bibliography

"Evaluation of Strength Tests of Concrete" is the title of bibliography no. 2 published by the American Concrete Institute. This new bibliography lists and annotates selected articles appearing in available technical publications issued from 1924 to 1958 on the subject of compression tests on concrete.

M.I.T. Summer Course

In response to widespread interest in the theory and operation of nonradiative

The Associations and Corporation

At the annual meeting of the Canadian Council of Professional Engineers held in Saint John, New Brunswick, May 11-13, 1960, the following were elected officers for the ensuing year: president, J. G. Dale, M.E.I.C., Edmonton; vice-president, W. L. Wardrop, M.E.I.C., Winnipeg; and member of the executive, D. S. Simmons, M.E.I.C., Toronto.

J. Graham Dale, M.E.I.C., newly elected President of the Canadian Council of Professional Engineers, was born in Cranbrook, B.C. and educated at the University of Alberta, where he graduated in 1934 with a B.Sc. in electrical engineering.

Mr. Dale began his career in engineering with Northwestern Utilities Limited in Edmonton as a serviceman. In 1947 he was made Chief Salesman and Utilization Engineer; in 1952, Manager of Sales and Service; and in 1957, Manager of Customer Service and Utilization.

During World War II Mr. Dale was a member of the reserve forces, serving with No. 1 (R) Armoured Divisional Ordnance Workshop, R.C.O.C. From 1947-49 he was a Captain in the R.C.E.M.E. reserve forces.

He has been a Member of the Institute since 1940; a Member of the Association of Professional Engineers of Alberta since 1941, serving as Registrar, 1943-47, and Councillor, 1948-52, Association's Representative on the Engineering Faculty Council, University of Alberta, 1952-59, Vice-president, 1955, President, 1956, Representative of Alberta on Canadian Council, 1958 to present, and Representative of Alberta on the Engineers Confederation Commission, 1959 to date.

self-contained guidance systems, the Massachusetts Institute of Technology will present a special summer program in Inertial Guidance — Terrestrial and Interplanetary, from July 5-15, 1960. Lecturing will be done by members of the M.I.T. Department of Aeronautics and Astronautics. Tuition is $325, due and payable upon notification of admission. Academic credit is not offered.

Course in Sanitary Engineering, Delft

The Technological University at Delft and the Netherlands Universities Foundation for International Co-operation will offer a course in Sanitary Engineering from October 19, 1960 to September 14, 1961. The World Health Organization and the Organization for European Economic Co-operation will also assist in giving the course. It is aimed at providing civil engineers with special training in sanitary engineering to enable them to take part in the struggle with water pollution in densely populated and highly industrialized areas.

For further particulars, write to NUFFIC, 27 Molenstraat, The Hague, The Netherlands.

Fluid Mechanics and Solid Mechanics Conference

Plans are being made for the Seventh Midwestern Conference on Fluid Mechanics and Solid Mechanics to be held at Michigan State University, East Lansing, Michigan, September 6-8, 1961. Authors who wish to present papers should send in their abstracts by January 1, 1961. For further information, address inquiries to: Professor J. E. Lay, Mechanical Engineering Department, Michigan State University, East Lansing, Mich.

Coming Events:

Dechema — Jahrestagung, Frankfurt (Main)—June 14-16

International Congress of Chemical Engineering, Mexico City—June 19-22

American Society for Testing Materials Annual Meeting, Atlantic City, N.J. —June 26 to July 1

Institute of the Aeronautical Sciences Meeting, Los Angeles, Calif.—June 28 to July 1

Conference on Civil Engineering Education, University of Michigan (Ann Arbor)—July 6-8

Seminar on Low-cost Automation, Pennsylvania State University—July 7-8

Instrument Society of America Instrument-Automation Conference, New York City—September 26-30

Canadian National Material Handling Show and Conference, Montreal—September 26-30

Prestressed Concrete 6th Annual Convention, New York City—September 27-30

Canadian Chemical Engineering Conference, Quebec City—November 6-9

National Die Casting Exposition and Congress, Detroit, Mich.—November 8-11

International Plastics Exhibition and Convention, London—June 21 to July 1, 1961.

THE ART OF FORGING was discussed by Mr. Richard Jamieson, Chief Metallurgist, Trenton Steel Works, Trenton, N.J., at the March 28th Meeting. He described the processes of edging fullering, bending, and blocking impressions, and explained that if dies were available many more castings could be made. Also under discussion were: heat treatment of forgings; specifications in testing; test pieces; and inspection by the periscope or boroscope method.

Six gentlemen associated with the steel industry in Yugoslavia were the special guests at this meeting. Accompanied by interpreters and a U.S. government representative, the men were on tour of steel plants in the U.S. and Canada.

Vancouver, March meeting: Back Row, (left to right) J. H. Swerdferger, vice-chairman; Alan Kay, chairman, structural section; P. N. Bland, councillor; R. H. Carswell, treasurer; Commodore A. C. M. LOCATING A SITE for the Dominion Radio Astrophysical Observatory's radio telescope at White Lake, Penticton, B.C., was the subject of a talk by Dr. J. L. Locke on April 22. The Director of the observatory described the search for a spot free from man-made electrical interference, sheltered by a natural bowl and close to a good sized community.

The main feature of the construction and operation of the telescope was an 84 ft. diameter parabolic antenna, according to Dr. Locke. He described the exploratory nature of the work done there, plotting electro-magnetic emmissions from space sources, analysing them, and collating information.

Eleven members from the Kootenay Branch were present.

The dinner meeting was held in the famous "S.S. Sicamous", the last C.P.R. paddle wheeler on the Okanagan Lake which is now berthed permanently on the shore at Penticton.

"THE STEEL INDUSTRY in Quebec" was discussed at the April 20 meeting by a group of four engineers, Mr. J. A. Retty, Ecole Polytechnique professor, Mr. G. Fauthier, Dominion Steel & Coal Company, Mr. Sibakin, Steel Company of Canada, and Mr. T. Hirst, Sogemines.

Mr. Retty talked about the iron ores of the Province; Mr. Sibakin, about the processes that could be applied in Quebec. On the other hand, Mr. Gauthier dealt with the possible use of our own Canadian coal, while Mr. Hirst made a survey of the future market. The general message was that although Canada would eventually produce coal, it would only be for certain limited uses.

THE HISTORY of radio astronomy was traced by Dr. J. L. Locke, Director of the Radio Telescope Observatory at White Lake, B.C., at a combined meeting of the Kootenay and Central B.C. Branches on April 22.

New Chairmen: (left) R. B. Walker, JR.E.I.C., Montreal, Junior Section; (right) B. I. Burgess, M.E.I.C., Quebec.

Radio astronomy began with the work of Dr. Karl J. Jansky who was engaged in study of static interference of the Bell System of Transoceanic Radio Telephone circuits from 1928-32. He discovered that a noise outside of earth came from a fixed direction out in space. Radar operators during the War also picked up noises that were not from earth. Since 1945 progress has been made in radio astronomy, beginning with small paraboloid collectors and arriving at models such as large-disk fixed collectors in the ground, the 220 ft. collector at Jodrell Bank, England, and the proposed 600 ft. collector being built in Virginia, U.S.A.

A. C. M. Davy, Western Field Secretary, was guest at this combined meeting.

"PLANNING AND THE ENGINEER" was the subject of a talk by Mr. J. W. Wilson, Executive Director, Lower Mainland Regional Planning Board, on April 26th. Opening with a plea to avoid professional arrogance, Mr. Wilson outlined the job of the planner. He stated that planning is essentially more of an art than a science. It is just now coming to first principles, he stated.

Special guests at the meeting were Mr. R. C. A. Stewart, Chairman of the Vancouver Branch of A.I.E.E., and Mr. William Leithead, President of the Architectural Institue of B.C. Thirty-six members and guests were present.

Elected to the 1960-61 executive were: chairman, J. H. Swerdfeger, M.E.I.C.; vice-chairman, C. H. White, M.E.I.C.; secretary, R. Clough, M.E.I.C.; treasurer, R. H. Carswell, Jr.E.I.C.; executive members, S. W. Faliszewski, D. R. Bakewell, and A. W. Greenius. The following will be filling the second year of their term as executive members: G. A. Antenbring, H. Lillie, C. H. Maartman, and A. A. Kay.

Yukon

J. P. MacGowan, M.E.I.C.,
Correspondent

A DINNER MEETING was held in the Inn Ballroom, Whitehorse, on April 21 in honour of E.I.C. President, J. J. Hanna. Approximately 30 E.I.C. members, branch affiliates, and members of the Association of Professional Engineers of the Yukon Territory were in attendance. Following the dinner, J. H. Reeves, chairman of the Yukon Branch, introduced Mr. Hanna.

The president stressed the need for humanitarian thinking in engineering and suggested that E.I.C. meetings should not always feature engineering discussions but should be varied to include topics of general local or national interest.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*THEORY OF MECHANICAL VIBRATION.

This treatment of the theory of linear mechanical vibrations uses analytic principles to demonstrate the unity and coherence of the theory and its connection with other engineering sciences. Four sections cover systems with a single degree of freedom, systems with a multidegree of freedom and the concept of vibration modes, an extension of these results through matrix algebra and generalized coordinates, and the vibration of continuous media. Each part presents first the theory and principles, and a second section contains methods and applications. The principle of superposition, eigen-value problem in matrix, differential and integral equations, and energy methods receive special consideration. (K. N. Tong. New York, Wiley, 1960. 348p., $9.95.)

*NUCLEAR RADIATION ENGINEERING.

The fundamentals of atomic structure, the source of nuclear energy, and the principles of radioactivity are presented for the growing number of administrators who must be technically informed in their dealings with nuclear scientists and engineers. In serving as a primer for those who must speak the language and understand the problems of atomic science, it explains the atomic and nuclear causes of radioactivity, the kinds of radioactivity, the energy release associated with the process of radioactive disintegration. These areas, rather than reactor engineering, are of immediate concern to executives and supervisors of nuclear engineers. A dictionary of atomic and nuclear terms and phrases is included. (F. W. Hutchinson. New York, Ronald, 1960. 155 p., $6.00.)

*PHYSICAL METALLURGY.

Physical metallurgy is treated in terms of atomic processes and interactions, developing a comprehensive physical framework for metals and alloys. Experimental information is compared with the theoretical expectation in order to develop physical concepts that can be applied to real cases. Structure, properties, imperfections, deformation, change of state, and transformations are dealt with in turn, with the underlying theme that the behavior of a metal is determined by its properties and environment, and that these have been determined by its basic structure, chemical composition, and history. (Bruce Chalmers. New York, Wiley, 1959. 468p., $12.50.)

*ANALYSIS OF STATICALLY INDETERMINATE STRUCTURES, 4TH. ED.

Efforts made since 1943 to simplify and render more understandable the methods used in structural analysis are embodied in this fourth edition of a comprehensive text designed to provide a firm grounding in the basic principles and concepts of action of structural members subject to load. Presented are common methods of analysis of statically indeterminate structures in simple form, based on the fundamental principles of applied mechanics. Examples and practical problems illustrate the use of an analytical approach and induce development of problem-solving procedures. (C. D. Williams. Scranton, International Textbook, 1959. 360p., $9.25.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.
Library hours for June, July and August are: Monday to Friday: 2 p.m. to 5 p.m.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

*ELECTRON PHYSICS.

The physics of the free electron is presented in two parts. The first contains a brief survey of methods for the production of electron rays as well as a detailed discussion of the main problems of electron motion; of electron optics, of the flow of electrons in dense space charges, and of the statistical fluctuations in low intensity beams. The second part deals with the fundamental properties of the free electron, namely its charge, mass, wave-length, spin, and magnetic moment. It also includes a description of the study of the free electron by quantitative methods. (O. Klemperer. Toronto, Butterworth, 1959. 248p., $7.00.)

*STRUCTURE AND PROPERTIES OF THIN FILMS

Proceedings of an international conference held at Bolton Landing, New York, in September, 1959, the review papers in this volume contribute to the areas of preparation, growth, and structure of thin films, and their mechanical, electrical, optical, and magnetic properties. A review of processes occurring at the metal surface is also given. Research papers present basic problems in physics and chemistry concentrating on ferromagnetism in very small specimens, the nature of chemisorption, and the effects of small dimensions on various properties. The use of thin films to obtain information about the bulk properties of matter, the investigation of properties of thin films which vary from properties of the same material in bulk form, the growth and characterization of thin films, surface chemistry, and the theory of surfaces are the fields covered. (Ed. by C. A. Neugebauer and others. New York, Wiley, 1959. 561p., $15.00.)

*INDUSTRIAL ELECTRONICS AND CONTROL, 2nd. ed.

A practical survey for the non-specialist, beginning with the theory of solid state conduction and leading to the theory of rectification and amplification via the semiconductor. Current practice in such applications as resistance welding and high frequency heating, and recent developments such as solid-state thyratons, cryotrons, and cold cathode vacuum tubes are covered, and there is new material on semiconductors, magnetic amplifiers, computers, electronic measurements and servomechanisms. (R. G.

A spot safety X-ray inspection of a Super Constellation aircraft tire, using Kodak type 'AA' film.

Kleoffler. New York, Wiley, 1960. 540p., $10.00.)

PRINCIPLES OF FREQUENCY MODULATION.

·An account of the basic principles of frequency modulation, the transmission of frequency-modulated waves, and the difference between frequency modulation, amplitude modulation, and phase modulation. Also covered are interference with f.m., the generation of f.m. waves, and the detection of f.m. waves. One chapter is devoted to the design of f.m. receivers, and another to the application of f.m. in microwave communication systems, radar, telegraphy and facsimile transmission. (B. S. Camies. New York, Rider, 1959. 147p., $3.50.)

HOW TO USE METERS, 2nd. ed.

In this revised edition, new material has been added on transistorized voltmeters, laboratory instruments with greatly increased sensitivities, specialized measurements and advanced meter features. Summary tables have been added for use in comparing meter types. The use of transducers in industrial electronics is also considered.

Information is given on the construction, operation and application of all types of electrical meters. There are many illustrations and diagrams. (J. F. Rider and S. D. Prensky. New York, Rider, 1960. 210p., $3.50.)

PRINCIPLES OF SURVEYING, 2nd. ed.

An introductory text covering the main principles and practices of plane surveying, intended for students. In this edition, the main change is the inclusion of six chapters in Part two on field astronomy, covering its methods and functions; apparent motions of celestial bodies; the celestial sphere; celestial co-ordinates; time; and astronomical observations. The first part of the book covers all aspects of plane surveying.

A companion volume deals with the principles and use of surveying instruments. (J. Clendenning. London, Blackie, 1960. 376 p., 30/-.)

APPLIED HEAT FOR ENGINEERS, 3rd. ed.

In the second edition, chapters were included on compressors and gas turbines, and in this third edition, a chapter has been included on refrigeration, which will be of interest to marine engineers. This volume is intended for an undergraduate text, and covers the basic physical principles of heat, and their application to heat engines. Numerous worked examples are included, as are problems, for which answers are provided. J.-B. O. Sneeden. London, Blackie, 1959. 380p., 25/-.)

FINANCIAL POST SURVEY OF MINES, 1960.

The first section of this survey contains a variety of information on Canadian mining companies and the industry, including an eight-year price range of stock prices, mineral production tables, metal prices, stock commission rates, and milling plants in Canada. Most of the volume is devoted to a geographical listing of all active mining companies, giving a wealth of information on each. Up-to-date maps of important mineral areas are included. (Toronto, Maclean-Hunter, 1959. 372p., $4.00.)

*NUCLEAR PROPULSION AND ENGINEERING FOR ENGINEERS.

The principles of nuclear energy and their application to aircraft propulsion are presented. The author discusses radio-activity associated with energy release; nuclear reactions as a source of energy release; neutrons as triggers of nuclear energy release; energy release characteristics of fission; neutron dynamics in propulsion reactors, steady operation of thermal neutron homogenous reaction and other type of reactors; unsteady reactor operation and control; and nuclear energy extraction and transformation. Since the use of materials and their modes of failure are of considerable importance, the author included a considerable amount of information on high temperature materials, heat transfer, creep, thermal fatigue, corrosion, oxidation, and thermal shock. Although only unclassified data is used, much useful information is included. (D. G. Samaras. Athens. Technical Chamber of Greece, 1955. 701p,. Price not given.)

*THE RADIO AMATEUR'S HANDBOOK, 37th ed.

This annual revision of a handbook written with the needs of the practical amateur in mind, maintains its objective of presenting the soundest and best aspects of current practice rather than the merely new and novel. Major revisions are in the sections on the theory of radiocommunication, construction of equipment, vacuum-tube characteristics, mobile radio equipment, and transistors. Other features are the manufacturers' catalog, instructions, abbreviations and country call-letters for station operation, and extensive vacuum-tube data tables. (West Hartford, American Radio Relay League, 1960, Various pagings, $4.00.)

*ELECTROMAGNETIC FIELDS, ENERGY, AND FORCES.

Emphasizing synthesis as opposed to analysis of fields, this book develops a consistent macroscopic theory of electromagnetism, including that of moving bodies. The process of electromechanical energy conversion is covered, and a power-series technique for analysing quasi-static fields and quasi-stationary systems is introduced. Appendices include material on the four-unit system of units used, and a four-dimensional relativistic fomulation of macroscopic electrodynamics. (R. F. Fano and others. New York, Wiley, 1960. 520p., $12.00.)

*ELECTRONIC CIRCUITS, SIGNALS, AND SYSTEMS.

The matrix, topological and signal-flowgraph methods of circuit and system analysis presented are specifically applied to electronic circuit problems. The analysis and synthesis of pulse, periodic and random signals presented is based on the correlation function and the Fourier integral and series, and transmission of signals through linear, non-linear, and time-varying-linear systems is investigated. The negative feed-back concept in electronic control also is discussed. (S. J. Mason and H. J. Zimmermann. New York, Wiley, 1960. 616p., $12.50.)

*APPLICATION DE LA GEOLOGIE AUX TRAVAUX DE L'INGENIEUR.

Intended for the consulting geologist and for the engineer faced with geologic problems in construction engineering. General geologic methods of terrain and subterranean exploration and documentation, including geophysics, boring and tunnelling are presented. Rocks above and below ground, their properties as natural formations and as building materials, and subterranean hydrology are studied. The final section deals with protective measures against earthquake, landslide, erosion, and heavy snow and wind. (Jean Goguel. Paris, Masson, 1959. 357p., 4300 fr.)

JAHRBUCH DER ELEKTROWARME, 1958/59.

This third year book of the electrical heating industry contains a series of review articles on various aspects of the industry, and problems connected with it, together with abstracts of articles appearing in German and foreign periodicals, and long bibliographies.

Some of the topics covered include: electric furnaces and heating used in various industries such as smelting, metal working, ceramics, wood drying, plastics and rubber; dielectric drying; chemical and technical problems; electric ovens; heat pumps; domestic and agricultural use. The last section of the book is a bibliography of articles from 244 periodicals. (Ed. by Harald Muller. Essen, Vulkan-Verlag, 1959. 628p., 68DM.)

MEHRFELDRAHMEN, bd. 1, 7. aufl.

This seventh edition of the author's well-known work previously entitled "Mehrstielige Rahmen," has been completely revised, and will now be published in three volumes. This first volume deals with formulae for any many-bayed, one and two-storied, immovable

(Continued on page 154)

Creative engineering opens new

GM DIESEL'S ALL-CANADIAN ENGINEERING TEAM SPARKS NEW ADVANCES IN POWER AND TRANSPORTATION ENGINEERING!

Today, with technology advancing at a tremendous pace, the demand for creative engineering is at a new peak. And creative engineering is the specialty of GM Diesel's Project Engineers!

This unique group of Canadian-trained engineers is continually seeking out new applications of Diesel power, new improvements on existing machines, entire new concepts of power and transportation engineering. In recent years, for instance, they have extended their leadership in locomotive engineering design, and now are far ahead in this highly complex and far-reaching field.

It was this leadership that enabled GM Diesel to produce the model GMDH-1 Diesel-hydraulic locomotive—first of its type to be engineered and built in Canada! This versatile engineering group also performed design studies for Diesel-electric generator installations for helping solve the many problems of rugged Canadian operating conditions.

Around the core of this creative group, the whole GM Diesel organization builds its philosophy—a forward-looking approach to the broad problems of Canada's future. In this philosophy—an attitude of mind that creates new basic concepts of power and transportation engineering—the sky's no limit!

How Chilliwack Army Camp handles 424,000 GPD of sewage

Economical primary sewage plant designed with D-O-L equipment

Sewage treatment problems for an army camp are similar to those of many small communities. The aerial photo above shows how they are solved economically and efficiently by a small primary sewage plant installed at the Canadian Army Camp at Chilliwack, British Columbia.

Basic units are a Dorr Type MFC Digester, 30′ dia. x 16′ deep and a Dorr Type A Clarifier, 26′ dia. x 9′ side water depth. The plant is designed to handle 424,000 gallons of sewage per day. Choice of this Dorr-Oliver-Long equipment follows the example set by hundreds of municipal and industrial installations throughout Canada.

D-O-L offers a range of sewage treatment equipment to fit the needs of every type of plant, regardless of size, the kind of treatment desired, or the local conditions involved. For information on specific equipment items or for practical assistance on your particular problem, just drop a line to Dorr-Oliver-Long Limited, Orillia, Ontario.

and elastically movable, continuous frames. It contains 50 formulae for frames with immovable supports and junction points, and 40 for frames with elastically movable continuous beams. (Adolf Kleinlogel and Arthur Haselbach. Berlin, Ernst, 1959. 460p., 68DM.)

DIE ZWEISEITIG GELAGERTE PLATTE: bd. 1. BIEGEMOMENTE UND DURCHBIEGUNGEN.

This first volume deals with bending moments and deflections of bearing plates, and includes a theoretical introduction, over 500 diagrams, and notes on them. A second volume will cover general applications, numerical examples, and tables. (Hugo Olsen and Fritz Reinitzhuber. Berlin, Ernst, 1959. 113p., 24 DM.)

FUNDAMENTALS OF GUIDED MISSILES.

An introductory text, this volume covers the theory, design, operation and maintenance of guided missiles. It commences with a glossary of guided missile terms, and a short history of guided missiles. Succeeding chapters cover aerodynamics, propulsion, instrumentation and control trajectory and guidance systems. There are many illustrations. (U.S. Air Force, Air Training Command. Los Angeles, Aero Publishers, 1960. 575p., $12.50.)

MEN AND MOMENTS IN THE HISTORY OF SCIENCE.

Nine essays reflecting the growing interest of scientists in the history of their fields, written by distinguished Californian scientists to celebrate the 25th anniversary of the History of Science Dinner Club at Berkeley. Some of the subjects covered include Stallo and the critique of classical physics; the history of science and the second law of thermodynamics; Planck's philosophy of science, Marco Polo's description of the world, and the first stellar parallax determination. (Ed. by H. M. Evans. Seattle, Univ. of Washington Press, 1959. 226p., $4.50.)

PRODUCTION TOOLING EQUIPMENT, 2nd. ed.

In this second edition of a text on the design of jigs, tools and gauges, the sections on ceramic tools and workshop and inspection gauges have been revised, and some material on 'throw-away' tool tips added. The first two parts of the book deal with the design of drilling jigs and fixtures, each one being discussed in relation to the component with which it is to be used. The third part deals with cutting tools, and tool layouts for production machines. (S.A.J. Parsons. London, Cleaver-Hume, 1960. 328p., 28/-.)

SANITATION, DRAINAGE AND WATER SUPPLY, 6th. ed.

Now completely revised, this volume shows the applications of developments in sanitary science to sanitary engineering. The subject is treated from the foundations to the completion of a building. It covers site and orientation of buildings; damp prevention; ventilation; water supply and central heating; drainage and sewage. It deals specifically with practices in the United Kingdom. (G. E. Mitchell revised by S. E. Thrower, London, Newnes, 1960. 198p., 30/-.)

A SIMPLE APPROACH TO ELECTRONIC COMPUTERS

An introduction to electronic computers, giving the basic working principles of both digital and analogue machines, and showing the advantages, disadvantages and uses of each. The first part deals with digital computers, and covers number representation, circuits, memory, control, input and output, programming and special purpose machines. The operation of analogue computers is discussed in the second part, together with chapters on basic circuits, and problem solving. (E. H. W. Hersee. London, Blackie, 1959. 104p., 12/6.)

CORRECTION

The book LIANTS ROUTIERES ET ENROBES: MATERIAUX DE PROTECTION . . . mentioned in the April issue of the Library Notes is published by Le Moniteur des Travaux Publics et du Batiment, 32 rue le Peletier, Paris 9e., and not by Dunod as was indicated.

(Continued on page 161)

● DISCUSSION

(Continued from page 101)

$ACBG^1$ will not be obtained in practice as the coefficient of permeability the tunnel lining will always be less than the grouted rock. Therefore immediately after dewatering the pressure on the lining is represented by FD^1 and as the flow of water develops the pressure will drop to DD^1. It would appear that the grouting of the rock cannot be relied upon to diminish the external water pressure by a large amount and it would be preferable to strengthen the tunnel lining. It may be argued that the grouted rock and the tunnel shell will act as a single structural unit in resisting the external pressures. It is my opinion that this action should not be relied upon and in any event the water will still penetrate through the grouted rock to the tunnel shell.

Secondly, it was stated that hydraulic models were used during the design of the intake tunnel. However the authors failed to mention the scale to which the models were constructed.

As Messrs Matthias, Travers and Duncan are no doubt aware the similitude of the forces in the model and the prototype depend upon the Froude number and the similitude of the velocity profiles depends on the Reynolds Number.

To satisfy both criterions simultaneously is usually impossible and the scale selected for the model is a compromise. The writer is curious to know the scale of the models used for the design of the intake. It is not stated either if the models used were two or three dimensional. If two dimensional models were used then the model results give only a rough guide as to the nature of the flow to be expected in the prototype.

It would be appreciated if the authors would be good enough to clear up these points.

Author's reply by F. J. Travers

We have read with a great deal of interest the observations made by Mr. Dick on the question of grouting the rock surrounding the concrete lining of the tunnel at Chute-des-Passes.

We agree with the analysis which Mr. Dick has presented concerning the behaviour of water in rock below the phreatic line with respect to concrete tunnel linings. It was not the intention of the authors to convey the impression that, in theory, grouping will prevent water under high pressure from acting on the tunnel lining when the tunnel is dewatered. However, there are practical effects which are associated with grouting the rock surrounding the lining of the tunnel which modify theoretical considerations.

If the tunnel lining, compared to the rock, is relatively impervious, undoubtedly water pressure will build up behind the lining when the tunnel is dewatered. If the tunnel lining and surrounding rock are porous, any water in the rock will certainly begin to flow toward the emptied tunnel. If the flow of water through the rock can be reduced, and if the tunnel lining provides adequate means of escape for the water, it follows that high water pressures can not be built up behind the lining. Where a water bearing strata of rock is encountered, successful grouting will restrict the flow of water to the back of the concrete lining. Water entrapped between the interface of the concrete lining and the rock can usually find avenues of escape through openings in the concrete, such as small cracks which are inevitably formed in unreinforced concrete, thereby relieving any water pressure which may build up behind the lining.

The hydraulic models mentioned in the paper were three-dimensional. A large topographical model, which incorporated the intake opening at the bottom of the reservoir and included the intake tunnel and intake structure, was made to a scale of 1 inch=5 feet. The main purpose of this model was to observe the action of the water approaching the intake opening and also to provide sufficient data in order to design the shape of the intake opening.

A second model, built to a scale of 1 inch=6 feet, was arranged so that observations could be made in order to predict the behaviour of the rock and water rushing into the intake tunnel immediately after the rock plug was blasted. Through the use of this model, it was possible to design a large sump to catch the broken rock and also to predict the forces which were imposed on the intake structure by the inrushing water after the plug was breached.

EIC Employment Service

THE ENGINEERING INSTITUTE OF CANADA

This service is operated for the benefit of members of the Engineering Institute of Canada and for organizations employing engineers.

SITUATIONS WANTED

Advertisements are inserted free of charge for members of all classes. Maximum length is 60 words, and repeat insertions must be separately requested in writing for each desired appearance.

SITUATIONS VACANT

Rate: Six dollars per column-half-inch per insertion.
Replies to advertisements should be addressed to the file number, Employment Service, 2050 Mansfield Street, Montreal. Interviews with the Employment Service may be arranged by calling VI 2-5078 at the above address.

SITUATIONS WANTED

PROFESSIONAL ENGINEER with successful record as Assistant Production Manager, Chief Engineer, Plant Engineer seeks position medium, small company, consulting firm where wide knowledge of industrial methods, management, plant construction, layout, machinery, plant services can be used to improve and expand the business. Responsibility, challenge desired in place of security benefits. Long term prospects more important than immediate salary. Limited investment possible. Located Atlantic Province. File No. 5734-W.

INDUSTRIAL ENGINEER (Holland) Jr. E.I.C., age 32, married. Interested in permanent position as plant engineer with medium size company. Seven years' experience in plant efficiency, production planning, maintenance and technical sales. Present location Central Canada. Detailed resume available upon request. File No. 5754-W.

MECHANICAL ENGINEER, P.Eng., B.Sc., Jr.E.I.C., age 41, married. 10 years' experience includes quality control, design and maintenance engineering in rubber and chemical industries, in heating, ventilating and automatic control fields. Looking for a more responsible position in a small or medium size progressive industry. Location preference Southern or Central Ontario. Resume and references on request. Located Central Canada. File No. 5797-W.

CIVIL ENGINEER, M.E.I.C., P.Eng., (Ont.). B.A.Sc. University of New Brunswick, 1950. Age 31, married with family. Ten years' experience in construction industry, five in field, including two years as superintendent, and three in office management position. Seeks position with contractor, eventually becoming partner or associate. Located Central Canada, but willing to move anywhere except Montreal or Toronto. File No. 5813-W.

PROFESSIONAL ENGINEER, JrE.I.C., P.Eng. (Ontario) B.A.Sc. Toronto 1954 (Civil). Age 28, married, no children. Experience: 2 years municipal field work and 4 years in pulp & paper industry (plant maintenance, design, layout and construction). Seeks responsible position in industrial or construction fields. Locaton preferred, Southern Ontario. Located Central Canada. File No. 5836-W.

PROFESSIONAL ENGINEER, B.Sc. E.E., 1946, M.E.I.C., age 37, married, family. Presently District Manager Western Canada, sales and service of highly technical products utilized by industrial and utility accounts. Desres change. Seeking challenging position with progressive company in planning, promotion, organization, sales or management. Located Prairie Province. File No. 5866-V.

ENGINEERING EXECUTIVE, M.E.I.C., M.A.S.C.E., M.A.S.M.E., B.S., Ch.E., Illinois Institute of Technology. Seeks relocation General Manager smaller firm requiring all around engineering, business know-how, or as Regional Representative, Project Manager of larger organization, consulting firm. Professionally recognized administrative, organizational leadership skills. Adept at public relations, dealing with problems, people at all levels. 20 years solid well rounded experience. Widower, 3 children. Location U.S.A. File No. 5874-W.

PROFESSIONAL ENGINEER, M.E.I.C., with 20 years' experience in mechanical, structural and electrical fields seeks leading place in design engineering. Location Central Canada. File No. 5875-W.

CIVIL ENGINEER, P.Eng. (Ont.), Jr.E.I.C., B.Sc. Queen's 1949. Married with family, age 35. Experience includes three years' design and five years as field engineer in supervisory capacity on extensive capital expansion programmes with large pulp and paper firm. Desire more responsible position in above or allied industry or in municipal engineering field. Full resume on request. Located Central Canada. File No. 5876-W.

CIVIL ENGINEER, Jr.E.I.C., B.Sc. C.E., P.Eng. Ont., age 30, married. Six years' experience in highway design, construction, and traffic analysis. Two years' experience in hydrometric work. Presently employed in a supervisory position in Central Canada. Desires to Locate in Western Canada. File No. 5877-W.

CIVIL ENGINEER, P.Eng. (Ont.), M.E.I.C., B.Sc. 1948. M.Sc. Age 34 with more than 12 years design and general experience of building, structural, municipal, bridge and highway work. Wishes to associate with a consulting engineer, architect etc. Preferred location Toronto or Southern Ontario. Located Central Canada. File No. 5878-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.A.Sc., Toronto 1950, age 32, married, one child, bilingual. Ten years' general and industrial engineering experience with private electric utility company, including preparation of specifications, approval of drawings, inspection, special studies; 1½ years on assignment in Europe dealing with hydraulic turbines, governors and model studies. Seeking development, project or industrial engineering work. Located Central Canada. File No. 5879-W.

CIVIL ENGINEER, M.E.I.C., wishes to represent manufacturer as a sales engineer or manufacturer's agent in the Maritime Provinces. Now located in Fredericton, N.B., with an office and staff doing general engineering work. File No. 5880-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng., (Ont.), Queen's '52, age 38, single. Four years' maintenance engineering in petro-chemical industry, three years plant engineering in aircraft industry. Past year employed as plant engineer with small manufacturing company. Seeks position with medium or large organization. Prefer Southern Ontario location. Located Central Canada. File No. 5882-W.

CIVIL ENGINEER, Ontario land surveyor, Jr.E.I.C., P.Eng., Ontario, B.Sc. Queen's University, age 28, married, experience in road design, construction, municipal engineering, drainage, land surveying. Seeks challenging position in sales or supervision. Located Central Canada. File No. 5884-W.

ELECTRIC ENGINEER. B.Sc. (N.S.T.C.) M.E.I.C., P. Eng., married. Experience: Nine years' electrical inspection. Eleven years electrical contracting. Interested in design of installation and/or inspection work. Details of experience furnished upon request. Located Atlantic Province. File No. 5885-W.

PROFESSIONAL ENGINEER, Jr.E.I.C., (Mining), 8 years' experience including, surface construction, mine survey, mine planning and layout, and general office work. Looking for a position as industrial engineer in a progressive company. Ready to start at the bottom. Location preferred: Province of Quebec. Located Central Canada. File No. 5886-W.

MECHANICAL ENGINEER, S.E.I.C., McGill 1960, age 24, single. Interested in design, production of instrumentation, hydraulic-pneumatic controls, actuators and general mechanical machinery. Montreal area preferred. Located Central Canada. File No. 5890-W.

GRADUATE MECHANICAL ENGINEER, Jr.E.I.C., seeks a responsible position in

● LIBRARY NOTES

(Continued from page 154)

°VALUE ENGINEERING, 1959.

The basic concepts and philosophies, techniques and applications of value engineering are contained in these papers, originally presented at the Electronics Industries Association Conference on this new engineering specialty, held at the University of Philadelphia in October 1959. Categorizing engineering of the past as "Performance Engineering," or the development of a product to perform a service required by a recognized need, with secondary attention to costs, proponents of value engineering see it as fulfilling the demands of the present era by providing techniques which will vastly reduce costs of present products and evolve better products for known needs as well as by searching out new needs. (New York, Interscience, 1959. 165p., $6.00.)

ASBESTOS; ITS ORIGIN, PRODUCTION AND UTILIZATION, 2nd. ed.

A comprehensive account of asbestos from its source to its end-use, covering types of asbestos, world distribution, mining, milling, commercial application, and substitutes. In this second edition, various minor additions and revisions have been made, and the statistics and lengthy bibliography brought up-to-date, but the most significant change is the addition of three chapters reviewing the Canadian asbestos industry, the location of deposits, and mining and milling practices. There is also a chapter surveying the industry in the United States. The author visited both countries recently. (W. E. Sinclair. London, Mining Publications, 1959. 512p., £3.)

WORLD ALMANAC, 1960.

Now in its 75th year, the Almanac for 1960 covers the main events of 1959, including the opening of the St. Lawrence Seaway, the political changes in the Caribbean, the rise of nationalism in Africa, scientific progress, etc. All the usual Almanac sections are included, information on everything from Amateur athletic champions to Zoological parks. Although the emphasis is generally on United States statistics, no library can afford to be without this useful reference tool. (Ed. by Harry Hansen. New York, World Telegram and Sun, 1960. 896 p., $1.35.)

°THE AERODYNAMICS OF POWERED FLIGHT

Using analysis of rocket thrust as a logical means of introduction to aerodynamics, the author provides a foundation in fluid flow and airfoil theory by developing the concept of lift and drag in incompressible flow, compressibility effects in subsonic flow, shock-wave formation, and super-sonic flight. He introduces the fundamentals of propulsion and propeller analysis, stability, performance and manoeuvering flight, design and testing, and control. The mathematical

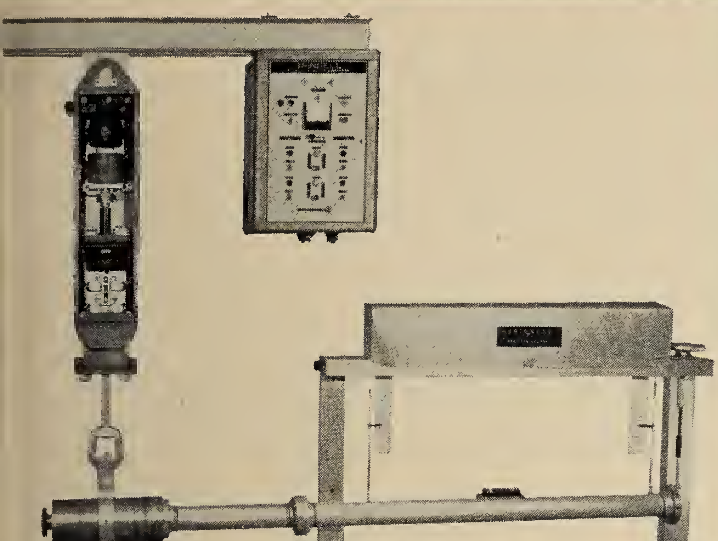
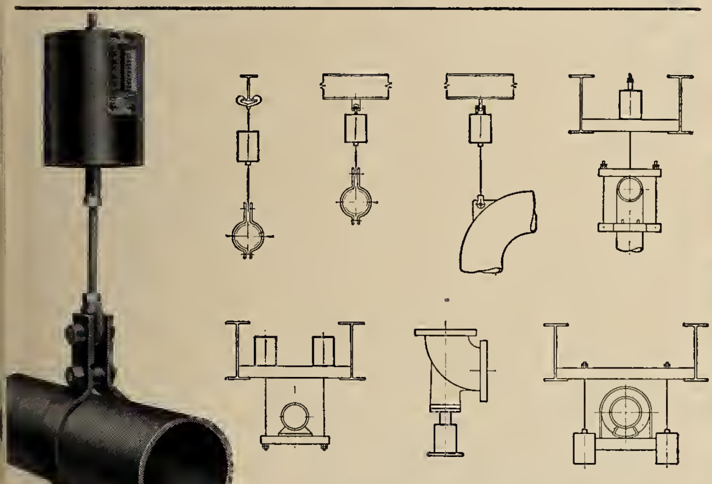
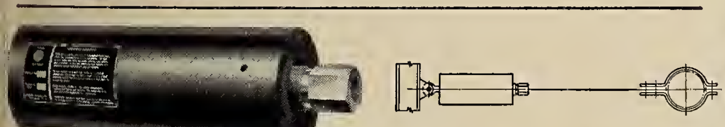
hangers to provide for thermal expansion



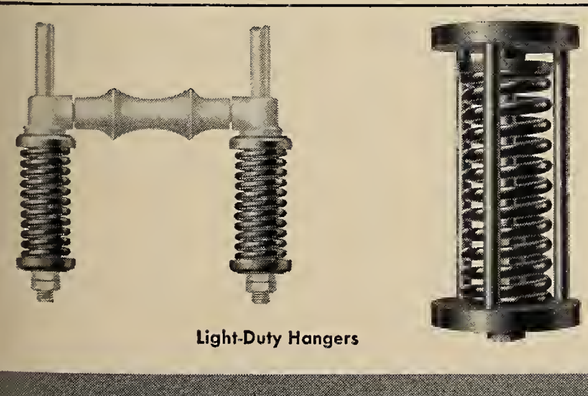
Stress-Trol



Variable Spring Hangers and Applications



Vibration Control and Sway Brace



Light-Duty Hangers

GRINNELL STRESS-TROL* FOR POSITION AND/OR LOAD CONTROL

Keeping the footage of high pressure-high temperature fabricated piping to a minimum has become important because of high piping costs. This can be accomplished by reducing the length of long expansion bends, but providing support for shorter, less flexible lengths of piping presents a new problem. Grinnell Stress-Trol, a motor operated device, solves this problem. It provides:

> **Position Control** — that minimizes stresses in piping and reactions on connected equipment.
>
> **Load Control** — that is constant support with unlimited load and travel capacities.

GRINNELL VARIABLE SPRING HANGERS

When pipe lines are subject to relatively small vertical movement, and do not require a constant support type hanger, Grinnell Variable Spring Hangers are available. The maximum variation in supporting force for standard spring models per ½ inch deflection is 10% of rated capacity. Grinnell offers these hangers in 21 sizes — in short, standard and double spring models, plus a special corrosion-resistant model. There are 7 different methods of attachment.

GRINNELL VIBRATION CONTROL AND SWAY BRACE

When necessary to prevent undesirable movement in lines, Grinnell Vibration Controls and Sway Braces of the energy storing and instant-acting counter force type are recommended. They dampen vibration, oppose pipe sway and absorb shock.

GRINNELL LIGHT-DUTY SPRING HANGERS

Finally, simple and inexpensive adjustable light-duty spring hangers often are all that's required to support piping safely. Grinnell has a complete line of light-duty hangers. They are designed for easy installation and quick, accurate alignment of piping.

The Directors of IPEC — the new corporate name of B.C. & B.B. Power Consultants Limited of Vancouver — are as follows:

Sir Andrew MacTaggart, K.B., Chairman of the Board; A. E. Grauer, LL.D., Deputy Chairman of the Board; T. Ingelow, D.Sc., President and Chief Executive Officer; H. W. Smith, Executive Vice-President; K. H. Kidd, Vice-President; W. I. O'Hara, Vice-President; Sir Thomas Foy, K.B., Director & Consultant; A. B. Robertson, Q.C., Director; R. H. R. McGill, Director.

A. L. Pike has been appointed manager of the Vancouver office of Sheldons Engineering Limited.

G. B. Wood has been appointed Sales Manager of the Steambloc Division of Babcock-Wilcox and Goldie-McCulloch Limited. He will direct the marketing program for the B&W packaged boilers throughout Canada.

Canadian Allis-Chalmers announces three appointments: J. C. Slingsby becomes assistant general manager of St. Thomas Works, G. C. Windeler replaces Mr. Slingsby as manager of the Vancouver office, and he is in turn replaced by E. N. Payne as manager of the Moncton office.

The Steel Company of Canada has appointed Lee T. Craig and Harold M. Griffith to its Board of Directors. Mr. Craig, who has been with the Company since 1920, is vice president of sales. Mr. Griffith, vice president of operations, joined Stelco in 1936.

Arthur K. Howe has joined the technical service department of Sika Chemical Corporation, Passaic, N.J. to assist architects, engineers and contractors with specific technical inquiries on concrete construction and maintenance.

Henry S. Wingate, President of International Nickel since 1954 and a director since 1942, has been elected Chairman of the Board and Chief Officer of the Company.

New Developments

WATER AND SEWAGE works pose a concrete problem because of severe weathering, freezing and thawing, saturation with water and chemical corrosion. Studies of 35 installations are contained in a Master Builders Company publication, documenting the performance of Pozzolith under operating conditions.

RAMP HANDLING for KLM DC7C's and DC8 jets, and freight handling for the airline's Constellation 1049 freighters, will be provided by Bristol's Aviation Services at Montreal, under a contract recently signed.

PERIMETER BLASTING is the name of a new technique introduced to Canada by CIL. Producing remarkably clean-cut rock walls, it is in use in the construction of defense installations and is expected also to assist in mining and the driving of hydro tunnels.

VANCOUVER is to have a second Kodak processing laboratory in Canada. Some 1600 persons are at present employed in the Toronto operations of this company. The new building will have 23,000 sq. ft. of floor space and is expected to be ready to accept film in April, 1961.

GOING CRITICAL at 12.33 AM Saturday, March 26, Oak Ridge National Laboratory's newest reactor, Tower Shielding Reactor II, replaced its predecessor in the work associated with studies of radiation scatter, part of the development of a safe nuclear-powered aircraft engine. Many of these studies require that the reactor be suspended in the air as high as 200 feet. TSR-II is a tank-type heterogeneous reactor, moderated and cooled with demineralized light water, and designed to operate at five thermal megawatts. The core is at the lower end of an aluminum tank, three feet in diameter and eight feet long, which can be suspended from four 324-foot towers.

JET LANDINGS mean fast speeds, long run-outs and, consequently longer taxi runs to and from the hangar. These long distances create more fatigue cycles which generate a high heat build-up and thereby reduce the strength and life of the tire. Goodyear has simulated all these stresses on a new $2 million multi-stage dynamometer system to qualify tires for the aircraft of the future.

NICKEL DEMAND is expected to continue high. Work on its applications is now on a more highly organized and efficient world-wide basis, according to Dr. John F. Thompson, Chairman of the Board of International Nickel. He believes these efforts will lead to absorption of the new nickel supplies and to a progressive decade in the industry.

LOW COST and versatility are features of a new G-E time switch designed for regular duty indoors on advertising signs, floodlighting, heating, air conditioning, refrigeration and motor starting. The 24 hour dial can be used for 12 on-off operations in one day with trippers set as close as one hour apart.

STAINLESS STEEL bonded to plywood forms the exterior walls of an experimental house recently erected at Woodbridge, Ont. It was built by Arctic Units Limited for Thomas Ibronyi, an architect who is writing a thesis for his Master's Degree on building in the Arctic. He wished to show that economical prefabricated buildings can be mass produced for use either in the north or in temperate climes.

• *More Briefs on pages 174, 179*

The excellent shearing action, with traces of boreholes still visible, clearly indicates minimum shock, a firm solid back and safer working conditions. At Lamaque, where this explosive was first tested, scaling and set-up time has been reduced to the extent that 13 ft. stope rounds can now be drilled and blasted compared to 9 ft. formerly.

MARQUETTE UNIVERSITY is to conduct a comprehensive home study course in business administration that Canadian Allis-Chalmers are offering to all their management employees. Subjects treated will include economic theory, the corporation, personnel management, managerial techniques, production and marketing.

GAS TURBINES for natural gas transmission have been ordered by Trans-Canada Pipe Lines. Canadian Westinghouse will make the three 8500 horsepower units which are to act as compressor drivers for the export line to the U.S. The turbines are modified for wide variations of temperature and load.

AS A CHOPPER the symmetrical transistor was thought to have disadvantages such as a need for accurate setting-up beforehand to obtain a low and constant rate of drift with temperature change. Smiths Aviation Division has developed a way for using the transistor, principally for use with thermocouples, with setting up obviated or in some cases reduced to a minimum. Performance can be guaranteed from a standard batch of transistors and the company also visualizes the use of this transistor chopper technique in strain-gauge work.

FIRE AND EXPLOSION because the leg belt slips on the drive pulley is a hazard that has worried grain terminal elevator operators for many years. If the boot becomes choked with grain and causes slipping, friction at the pulley soon produces excessive heat. Measurement Engineering Limited, of Arnprior, Ont., have introduced the Slipmonitor, a simple device installed without modification to leg belt or housing to operate an alarm or shut down the drive motor when belt slipping reaches a preset point, normally 20% of regular speed.

FLEXIBLE CONDUIT produced in a variety of materials was displayed at the Pipes and Pipelines Exhibition in London, England, by Plessey, the manufacturers of "Plessiflex". The "Plessiflex" hose can be used for refrigerant lines and for the conveyance of fluids and gases including corrossive chemicals and hot air for pressure and vacuum installations. It can be produced in stainless steel, mild steel and brass, high purity nickel, high purity aluminum, Monel and Inconel.

OIL HEAT will be more popular if new units increase its efficiency. To this end, Shell offers its new oil burner design royalty-free and will consult with burner manufacturers who are actively pursuing this improvement.

PLYWOOD RESEARCH and promotional efforts are being increased in British Columbia to meet the threatened invasion of traditional markets by new competitors. The plywood manufacturing industry has steadily grown during the past year, but competition is increasing the urgency of new use for the material, and research in the engineered components field is being expanded.

PUMPS AND VALVES have been the concern of Smart Turner of Hamilton, Ont., and of Klipfel Valves of Hamilton, Ohio, for over half a century. These two organizations have now joined forces to extend distribution and services and offer their customers a more diversified line of products.

LONG CRAWLERS are standard on the B-425, Dominion Engineering's new 1¼ cu. yd. capacity pullshovel. The shovel boom is 22 ft. 6 ins. long and the standard dipper sticks have an effective length of 16 ft. 4 ins.

CORRECT PRODUCTION HOURS for a single operation or a series are shown by the Van D. Mark Machine Load Calculator, devised for quick translations of production quantities and rates into shop loads. One setting of the two discs shows the hours needed, and there is no worry about decimal points. Calculator scales are clear and cover a wide range of figures, although only six inches in diameter.

OVER 1,200,000 hp. has now been delivered by General Motors to the C.N.R. The 1000th diesel-electric locomotive was recently delivered to the railway by General Motors Diesel, who during the past ten years have delivered 1740 units, amounting to over 2,500,000 hp., to thirty customers.

NO LONGER than a cigarette filter, a miniaturized synchronous a-c timing motor has been manufactured by The A. W. Haydon Company for application where reliability performance and space are of prime consideration. Designated as the 42100 Series Commercial 60-cycle a-c Timing Motor, this five ounce device provides extremely fast starting and stopping, eliminating prestarting and clutching in many uses. This light weight motor may be employed in the delay relays stop clocks or other custom designed timers, as well as in chart drive and control equipment.

ULTRA-SONIC DETECTION of bubbles is possible through a new device offered by Taylor Instrument Companies of Canada Limited. The apparatus, which can be used in almost any liquid, in open or closed vessels or in pipes, consists of a sensing head assembly connected by a continuous loop cable to an amplifying unit. A pulsed ultra-sonic signal passes through the liquid flowing between transmitter and receiving heads, and the presence of bubbles weakens or interrupts the signal.

NON-COHESIVE MATERIALS such as sands and gravels can be tested for density at construction sites in the field with a new apparatus being produced by Soiltest Inc. The device was originally developed by the U.S. Corps of Engineers at Providence, R.I. to perform what is now known as the Providence Density Test. Oven-dry samples and placed in a cylinder and a spring arrangement applies a 1000 lb. load. Hammering the outside of the cylinder then vibrates the test materials into a more confined volume, and the number of blows required for their maximum compaction is correlated with density. The tester is light enough for one man to carry.

SILICONES enable so many materials of design and production to resist time, heat, cold, moisture, weathering, oxidation, electricity and chemical attack, that Dow Corning has completely rewritten its Engineering Guide for Silicones.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

The Canada Cement Company, Limited advertisement on page 41 of the March issue was judged the "best" in that issue by a fifty reader jury. Judging was made from the viewpoints of ACCURACY—INFORMATION and ATTRACTION. The advertisement is headed: "Safe, sound, smooth: CONCRETE chosen for Quebec's Laurentian Autoroute."

The copy states, concisely, the advantages of concrete for road surfacing emphasizing the all-Canadian aspects of Canada Cement and offers technical literature covering the use of cement. The advertisement is in black and white.

Each month the Engineering Institute of Canada asks fifty different readers to judge the advertisements. Their names are taken from the "Journal" distribution list in such a way that all provinces are represented so that a good cross-section of opinion will be obtained.

The Advertising Manager of Canada Cement Company, Limited is Mr. John V. Tittley and the advertisement was prepared and placed by Cockfield, Brown & Co. Ltd. Montreal.

CANADA CEMENT COMPANY, LIMITED WINS CERTIFICATE OF ADVERTISING MERIT

Reproduced below, on a reduced scale, is the black and white advertisement of Canada Cement Company, Limited, which was judged the "best" in the March issue, from the viewpoints of ACCURACY—INFORMATION and ATTRACTION. The advertisement features the use of concrete for surfacing the new Quebec Laurentian Autoroute.

approach is simple without being too elementary, and problems are given at the end of each chapter. (R. L. Carroll. New York, Wiley, 1960. 275p., $8.50.)

ATOMIC ENERGY IN THE COMMUNIST BLOC.

A carefully compiled account of industrial nuclear developments in the Soviet bloc. The author points out that there are three types of developments: in the U.S.S.R. itself, the spread of nuclear techniques from the military to the industrial field; in the satellite countries of Eastern Europe, the launching of nuclear programmes in economically well-developed countries; in China, the drive for nuclear expansion in a country technologically backward. The author considers Soviet administration of atomic affairs, Soviet nuclear research, nuclear power plans, nuclear resources, co-operation within the Soviet bloc, research programmes in Eastern Europe, the nuclear situation in China. The author has included bibliographical footnotes. (G. A. Modelski. Melbourne, University Press, 1959. 226p., $5.75.)

ENCYCLOPEDIA ON CATHODE-RAY OSCILLOSCOPES AND THEIR USES, 2nd. ed.

Brought up-to-date and greatly expanded, the Encyclopedia commences with several chapters on the theory of operation and the basic construction of cathode-ray tubes. The second section is concerned with oscilloscope circuitry and operation, commercial scope types and maintenance. Applications considered include pulse measurement; transmitter testing; engineering, medical and scientific applications, and oscilloscope photography. There is one chapter of specifications and schematics of commercial oscilloscopes, both U.S. and foreign, and there is an eleven-page bibliography. This is indeed an encyclopedic work. (J. F. Rider and S. D. Uslan. New York, Rider, 1959. about 1350 pages, $21.95.)

THE TECHNICAL INSTITUTE IN AMERICA

The results of a survey made in 1957-1958 to reveal the status and potential of technical institute education in America. The volume is a compilation of facts and opinions on the educational and employment practices relating to the engineering technician as the demand for technological manpower has grown. After a brief historical background, the survey covers the objectives of the technical institute, its curriculum, students, faculty, physical plant, administration, and financial structure, and problems. It also considers the employment opportunities of the engineering technician. (G. R. Henninger. Toronto, McGraw-Hill, 1959. 276p., $6.90.)

ROCKWELL-Nordstrom **VALVES**

DESIGN AND ERECTION OF STRUCTURAL STEEL FOR THE THOMPSON PROJECT

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

W. H. Bender
Project Engineer,
Dominion Bridge Company Limited,
Winnipeg

Preliminary milling operations are scheduled to get underway next month at Inco's mining development at Thompson, Manitoba. This marks the first operational stage, a bare 3½ years after the initial planning of the project. In December, 1956 the International Nickel Company announced that they were going ahead with the construction of a mining development in the Moak Lake, Mystery Lake area, some 450 miles north of Winnipeg. Details and extent of this project were not disclosed at that time, but there were indications that this development would include a reduction and smelting plant. The construction of a refinery, to make this a fully integrated operation, was announced in March, 1959. A townsite with facilities for a population of 8,000 was to be built close to the plant. The town, named after the Chairman of the Board of International Nickel Company of Canada, "Thompson" is located 30 miles north of the half-way point on the C.N. main line between The Pas and Churchill. There was no access to Thompson by road or rail at that time.

DURING THE winter of 1956-57 work got underway on a large construction camp. In the Spring of 1957, a 30 mile long spur was started into Thompson, branching off the railway line at a little place called Sipiwesk. It was a big event for Thompson when on October 13, 1957 the first train rolled into the town's railway station. Thousands of tons of building materials and supplies have been shipped on this line, which still represents the only connection by land to the rest of the world.

To provide power the Manitoba Hydro Electric Board will harness the turbulent waters of the Grand Rapids on the Nelson River, at a site 50 miles from Thompson.

In late 1956, engineering work on the surface buildings started in Inco's Head Office at Copper Cliff. For the purpose of description, the surface buildings can best be divided into four groups, namely:

(1) Auxiliary Buildings consisting of Shops Buildings, Office Building, Warehouse, Change House, Fire Hall and Compressor Building;
(2) Concentrator and Headframe;
(3) Smelter;
(4) Refinery.

Fig. 1. Camp site at Thompson with Office Building in foreground.

All these buildings are steel structures except for the Headframe, which is of reinforced concrete design. Dominion Bridge Company was the structural steel contractor for all surface buildings, with the exception of a Switching Structure and Cottrell Building. The Auxiliary Buildings are of conventional design and are not expected to be of particular interest to this audience.

Prefabricated panels, tar and gravel are used for the roof construction of all buildings. Exterior walls have sheeting—one flat board on the inside and a corrugated sheet on the outside.

Structural Design in General

The three process buildings, Concentrator, Smelter and Refinery were designed according to Inco's own structural specification, which generally follows the AISC except for allowable stresses. The allowable bending stress is 18,000 p.s.i. with a corrosion allowance of 15% added to all external loads. For simplicity of design and detailing, we converted the 15% corrosive allowance into a further reduction and then worked to 78% of all AISC allowable stresses. Beam connections were made for maximum listed loads. The design snow load was 50 p.s.f., wind 30 p.s.f. and wind on the Hoist House on top of the Headframe, 40 p.s.f. The customer specified field riveted connections except for purlins, girts and handrail which were field bolted. Checkered plate and stair treads were also riveted.

The Three Process Buildings

The Concentrator: The Concentrator is a fairly intricate process building and contains mainly the Crushers, the Ball Mills, the Flotation Cells, Sampling Equipment and Sand and Reagent Storage. There are approximately 20 belt conveyors which transport the ore to the various stations for treatment. A 40 ton Overhead Crane serves the Ball Mills for maintenance. In order to maintain handling of the ore at a minimum, the concentrator is built around the lower portion of the Headframe. Adjacent to the Headframe is a one storey Mine Office and Change House. The main frame of the Concentrator was erected with Crawler Cranes. The high portion over the Fine Ore Bins was beyond the reach of a Crawler, and had to be erected with a Stiffleg Derrick which was set up on a Traveller on top of the Mill Aisle. Erection of the Concentrator steel was completed in November-December, 1958.

To erect the Hoist House steel on top of the Headframe, a Stiffleg Derrick and Hoist were set up at the machine floor, 220 ft. above ground and all steel had to be hoisted to this level before it could be placed. There is a 20 ton Maintenance Crane in the Hoist House to serve the friction type hoist for maintenance. From the top of the Headframe, one gets a very impressive view of the entire project.

The Smelter Building: The Smelter is by far the largest and heaviest building of the project. The dimensions are approximately 500 ft. long by 400 ft. wide by 120 ft. high. There are mainly four floors of 20 ft. storey height and the fifth floor in the Roaster section has a 40 ft. tier. Structural design for the Smelter got underway in May, 1957 and was completed about a year later. Design floor and equipment loads are heavy. All working floors are covered with 5/16 in. checkered plate, reinforced by stiffeners to resist concentrated loads. Concrete floors are used in electrical and pump rooms and around the filters. Floor framing was kept uniform in the main process areas so that a high degree of standardization was afforded throughout.

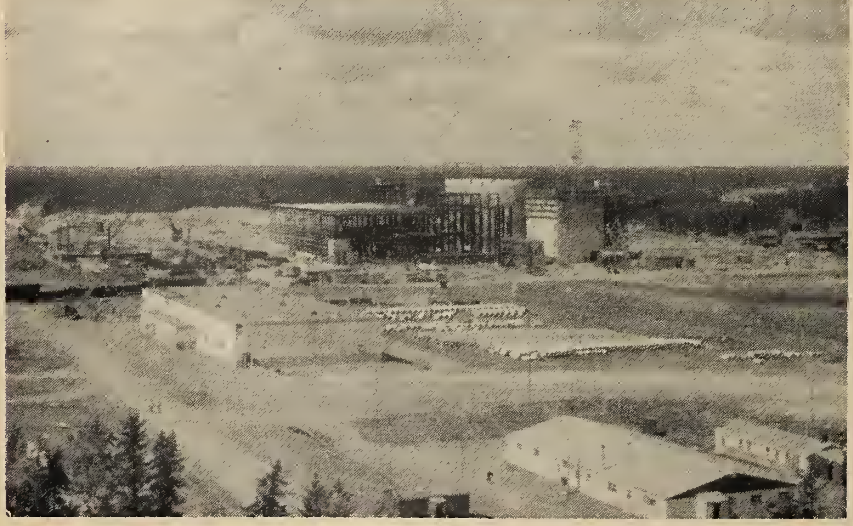
The design of an industrial plant, like the Smelter, must aim to meet the special conditions which arise inevitably from the functions which the building is required to perform. With regard to the structural design, the Smelter Building is by far the most complicated building of the project. The fact that heavy equipment was not purchased until the late design stages, added more difficulty. Many assumptions as to loading and type of framing were made at an early stage of design and as some of the heavier equipment weighs as much as 300 tons, these assumptions had to be reasonably correct or at least on the safe side. In some areas the structural framing is designed and laid out to suit possible future loading conditions arising from changes in process and equipment.

With several engineering groups engaged in the project, co-ordination of their activities became a very important factor. This also entailed advising our Productive Departments of target dates, tonnages, revisions, and cancellations.

During the design of the structure for the Smelter, we were constantly racing against time, trying to keep ahead of the production schedules. Large tonnages of steel had to be released each month for ordering from the mills, and sufficient information made available to our Drawing Offices for the preparation of shop drawings. The latter often became quite difficult as final framing could not be determined in time, pending information on process equipment. In many cases, the main framing was punched for anticipated connections of sub-framing in order to keep field work to a minimum. Although the building is designed for substantial floor loads throughout, there were sufficient significant differences in the column design on account of heavy equipment and contributory areas to warrant 40 different types of columns. All main building columns are spaced on a 22 ft. module and have an excess capacity of 25% at normal stresses. They must be sufficiently robust to withstand the onerous usage to which they are subject throughout their working life. This usage involves not only heavy loadings, but also wear and tear that is severe by comparison to conventional factories and industrial buildings. The hammer type crane columns support the runway for 2 60 Ton Heavy Duty Cranes. Crane runway beams are simply supported and the crane rail is fastened by hook bolts. The direct load on the Crane Columns is over 1,000 kips and sway and wind moments amount to over 1,000 foot kips. The bottom tier up to the crane seat is made of the heaviest 36 in. Wide Flange section as a core and one heavy 21 in. Wide Flange Beam on each flange. The top tier is a plated 21 in. Wide Flange section. The customer favoured the rolled sections on the face of the core over the conventional plate and angle type built up members. The corrosive fumes would have ready access in

Fig. 3. Crawler boom section is used as falsework under cross flue trusses.

Fig. 2. A Stiffleg Derrick on top of the Mill Aisle Roof is erecting the high portion of the Concentrator.



between the contact faces of the various layers of plates and angles. The built up crane column base has a 6 in. slab and is anchored by 4-2½ in. diam. anchor bolts against up lift. Mechanical anchors were used where the rock elevation was too close to the surface to develop the anchor bolts in bond.

Each crane column weighed 20 tons. 2,000 shop rivets had to be driven per column to build up the compound section. All vertical main bracing is made of Wide Flange sections on the weak axis. Corrosion, the desirability of avoiding dirt traps and the ease of maintenance painting were borne in mind when these sections were decided on. There are three lines of balloon flues in the Smelter. The flue side plates are fastened to 8 in. x 8 in. shoe angles, which are not connected to the stringers so that free movement is possible. Also framing into the shoe angle are the side plates of the suspended dust hoppers. The cross flue is carried on 2-80 ft. span bridge type trusses across the crane aisle about 130 ft. above grade. To take the wind forces across the 80 ft. span, lateral trusses in the plane of the flue stringers had to be furnished. Particular attention was paid to the temperature differential between chords of the horizontal trusses. The outer chord is exposed to the atmosphere and if the stringer had been utilized for the inner chord, the temperature differential would have been 500°F. This differential would have resulted in a stress in the diagonals of the horizontal trusses of 40,000 p.s.i. To avoid this, we introduced a separate inner chord along the flue stringers which by virtue of flexible diaphragms, permitted longitudinal movement of stringers without stressing the web members of the horizontal trusses. Stringers are seated on the supporting girders at expansion joints and framed at intermediate girders. These girders are subject to high bending stresses in the YY axis. The flue plates are insulated and covered by a ten gauge casing plate, where exposed to the atmosphere. A high standard of accuracy in detailing and fabrication is essential for this class of plate work, if erection is to proceed smoothly and with maximum speed. Slight errors that could easily be rectified in the shops are magnified at the site and cause disproportionate delays.

The bulk of the Smelter was erected by cranes. In the furnace aisle, lifts were heavy and access was poor. There were approximately 15 plate girders and 24 crane columns to be erected in single lifts at long reaches. The lightest of these members weighed 16 tons. This ruled out the use of cranes. A 15 ton Stiffleg Derrick was set up on a Traveller to erect the entire furnace aisle steel from four positions. To erect the two 60 ton Ladle Cranes three heavy cranes hoisted the girder into place about 70 ft. above ground. Clearances between adjacent framing and lifting at capacity of the crawlers dictated a very accurate synchronized hoisting operation. Furthermore, footings, trenches and other obstructions at floor level restricted us to a small working area. Four converters were also fabricated and erected. The maximum single lift was 68 tons and it was made by two cranes. Erection of the Smelter Building was completed in September, 1959.

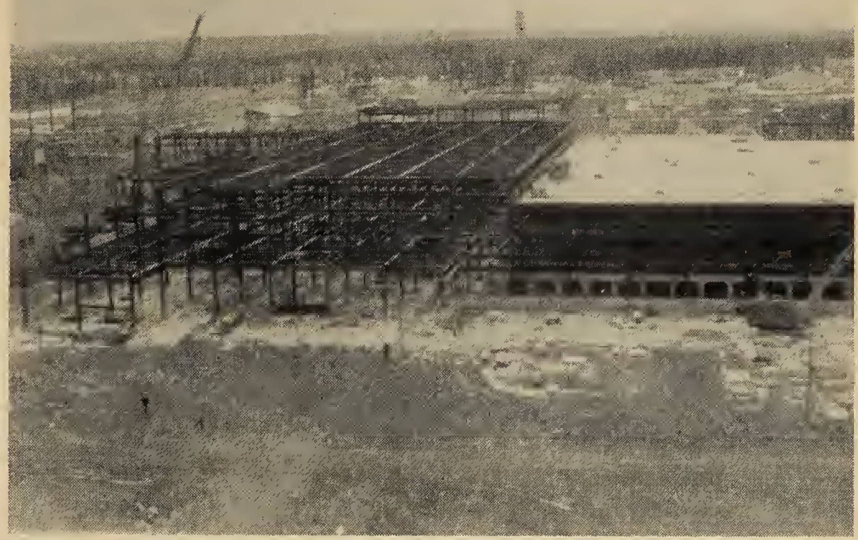


Fig. 4. Erection of Refinery Steel during the fall of 1959.

The Refinery: The second largest building of the project is the Refinery. It is mainly a two storey industrial building, much like a chemical plant. It is 400 ft. wide and approximately 1200 ft. long and houses tanks, containers, vessels and extensive piping. There are numerous runways in the Refinery ranging from 3 ton to 25 ton capacity. Stools and hangers for beam connections are used frequently in this building since there are differences of as much as 4 ft. between girders and stringers in order to clear piping. One noteworthy feature of this building is the fact that there are no windows. Fresh air is supplied by three air conditioning units with large plenum chambers. In one portion, all crane column struts are double plain members to accommodate the duct work for fresh air supply and exhausts. To protect the Refinery structure against severe corrosive fumes, all steel is painted according to Inco's painting specifications. In highly corrosive areas, one shop primer coat was followed by three field coats of anti-corrosive paint. All contact areas with sheeting and roof slabs, as well as areas which are not readily accessible for maintenance painting were coated with a ⅛ in. thick layer of asphalt.

Aspects of Erection

Completion dates for the different stages of the project were set forth by the client. It was a great challenge to meet these dates. Rigid scheduling was required to assure proper flow of material, starting with design and detailing through fabrication and shipping. Extensive planning went into this project so that this large volume of work could be processed through our offices and plants.

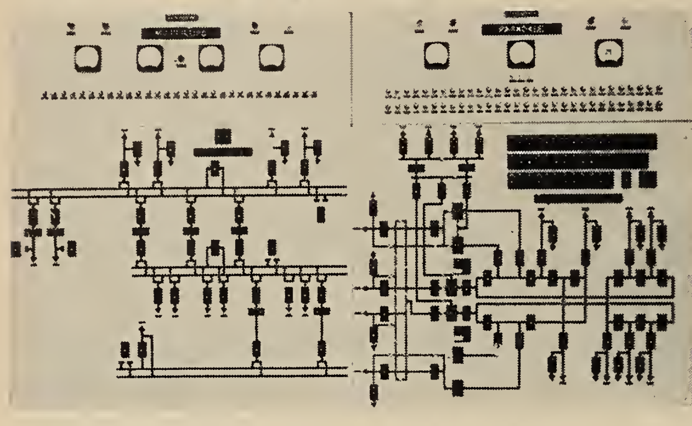
One of the main problems at the site was the providing of man power. It was rather difficult to attract men to stay for an extended period of time in this remote location. When the winter set in, the turn-over increased steadily reaching a peak around Christmas. Sub-zero temperatures as low as 50 below for several days made our operations extremely difficult during the three cold winter months. Despite these difficulties, our crews erected over 1500 tons in January, 1959 and 1700 tons in February, 1959. The record month for erection was April, 1959, when over 3000 tons of steel were erected.

Conclusion and Acknowledgement

Steel work for the Thompson Project is completed. From the start of the design to completion of erection three years have gone by, three very interesting years, crowned by accomplishment.

The author would like to record his appreciation for the guidance, cooperation and encouragement given him by all groups concerned.

MICROWAVE RADIO APPLICATION TO AN ELECTRIC UTILITY LOAD DESPATCH SYSTEM



E. M. Scott, M.E.I.C.,
Assistant Manager, Engineering & Construction Division, The Manitoba Hydro Electric Board, Winnipeg.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

It is almost inevitable that historical facts are bound to work a considerable influence on virtually any considerations that an electric utility gives to the rehabilitation or extension of any of its facilities. Certainly this can be said of the utility's communication system and proved to be the case when, in 1956, the Manitoba Hydro Electric Board turned its attention to a thorough assessment of its then existent communication facilities and to the task that this system, in an extended or modified form, would be required to perform in the years to come.

HISTORICALLY, voice communication had been the primary requirement and this need had been met largely through the medium of privately owned land lines which had been constructed adjacent to, and on common right-of-way with, high tension lines emanating from hydro electric generating stations on the Winnipeg River and terminating at appropriate terminal stations in the Greater Winnipeg area. These were augmented, particularly within Greater Winnipeg, by leased facilities from the Manitoba Telephone System. Also, in the eastern extremity of the system, a single inductively coupled power line carrier link had been established between the Seven Sisters Generating Station and the town of Kenora in Ontario.

By the 1940's traffic density had increased appreciably and a requirement for voice communication with mobile construction and maintenance forces had developed to the extent that a vhf radio system had been added and integrated with the land line facilities.

Working in conjunction one with the other, the land line and vhf radio network had proven adequate up to the mid-fifties. However, by 1956 it was recognized that not only was the existing communications system becoming over-loaded and inadequate but technological advances in such areas as communication, supervisory control, telemetering, and system load and frequency control, when combined with the need for centralized system despatching methods, called for a complete re-appraisal of the communication facilities. Augmenting these considerations too was the recognition of the fact that the electric system was continuing to expand on the national average of 7% per annum compounded and a "look down the road" to a point 20 or 25 years forward was necessary.

In 1956 The Manitoba Hydro Electric Board system consisted of four hydro electric generating stations located on the Winnipeg River, and comprising a total installed capacity of some 420,000 kw., together with the associated transmission lines and three principal terminal stations in the Greater Winnipeg area. In addition, a number of other system developments were either under construction or contemplated which were destined to work a marked change in the total system communications requirements in the space of less than five years. These included plans for interconnections with the City of Winnipeg Hydro Electric System and with the Northwestern Region of the Ontario Hydro Electric Power Commission together with the recognized need for an interconnection with the Saskatchewan Power Corporation in the not too distant future. As to new generating capacity, construction had already been initiated on a four unit 132 mw. thermal electric generating station at Brandon, Manitoba and a decision was imminent which would lead to the advancement of construction of a two unit 132 mw. thermal electric generating station at Selkirk, Manitoba.

Fundamental to these considerations was the realization that while by 1960 the interconnected generating capacity within the Province of Manitoba itself would amount to some 850 mw. at a total of nine generating stations, the characteristic of system load doubling every ten years indicated that any adequate communications system must at least be such that it could be readily capable of comprehending, or being expanded to comprehend, the total system needs at a point approximately 20 years hence. In other words, it was reasonable to presume that by 1980 the generating capacity of The Southern Manitoba System would be in the order of 3,500 mw. and the communications pattern to be adopted must be such as to be capable of catering to such a system.

Up to 1956 centralized system generation and load despatching had not proven requisite but it was recognized that the transition to a centrally despatched system must be effected. Further, the central despatch office which would be created would require an intimate knowledge of pertinent system conditions on a virtually continuous basis. The needs of this despatch office, as had already become the case on much larger systems, would embody not only voice communications but also telemetering of certain system flow quantities, supervisory control of remotely located terminal stations and hydro electric generating stations, automatic system frequency and tie line control, and subsequently, automatic incremental loading of system generation.

In seeking the ideal scheme to be adopted three basic patterns were open to appraisal, namely: land lines, power line carrier and some form of radio medium.

In looking at an assessment of the possibilities it was, of course, first necessary to stipulate the extent and character of the traffic to be accommodated both in the immediate future and in the extended system which might be expected to develop over the years. Fig. 5 comprehends the "immediate future" condition and shows the stations that required communication media and the type and number of functions required to be carried to or from each point.

In the assessment which followed it became evident that no single medium would be ideal for all requirements. Generally speaking the traffic density in the area between Winnipeg and the Winnipeg River was heavy whereas the traffic anticipated between Winnipeg and the western boundary of the Province (like that which might be expected to develop between Winnipeg and potential hydro electric generating sites on the Saskatchewan, Nelson and Churchill Rivers) was not as dense. Further, the distances involved between the central despatch office which was to be located in the new head office building of The Manitoba Hydro Electric Board in Winnipeg, and the Winnipeg River plants, were relatively short whereas the distances involved to existing or potential installations in the westerly and northerly reaches of the Province were very appreciable. Also of importance to the development of the comparative study was the fact that not only did the frequency spectrum available for application of power line carrier impose relatively restricted limitations on the total traffic which could be handled by this medium but also the transmission and terminal station configuration in the Greater Winnipeg area was such that, if a power line carrier system were to be adopted, costs would be increased by the trapping and by-passing which would be necessary, or alternatively, fairly extensive usage of privately owned or leased land lines would be required in the Greater Winnipeg area in order to convey the intelligence the last several miles to the despatch office. Lastly, the critical nature of the communication application was such that its availability must approach 100% and it must, insofar as possible, be completely beyond the influence of storms, atmospheric disturbances, loss of normal a-c. power supplies, and inadvertent action on the part of maintenance personnel. These several influences tended to rule against any serious consideration of the adoption of land lines except where the economics of application of power line carrier or radio proved unjustified.

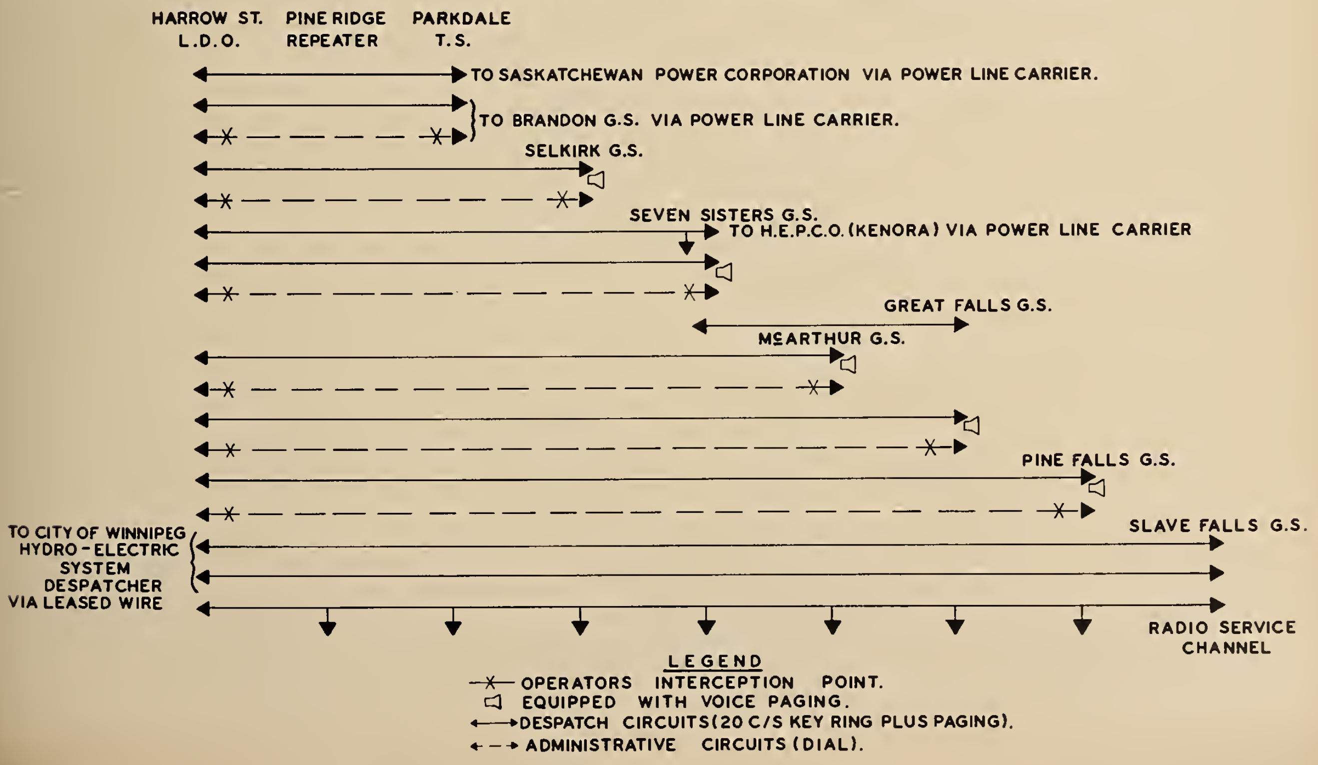
In summary, the development of land lines was ruled out on the basis of both high cost and low reliability. Power line carrier was shown to be the ideal medium for retention and application in those areas where long hauls involving relatively light traffic was required. Microwave radio then proved to be the chosen media for usage where the distances were limited and the intensity of the traffic anticipated to be extreme.

The requirements of both the new thermal electric generating station at Brandon, some 140 miles west of Winnipeg, and the anticipated interconnection with Saskatchewan, involved fairly limited traffic over long distances. As two 115 kv. transmission lines were already in existence between Brandon Generating Station and Parkdale Terminal Station (some 18 miles north of the despatch office) power line carrier was the natural choice. Bringing this information into Harrow Terminal Station, which is located adjacent to the despatch office, directly by power line carrier would have involved extensive by-passing line equipment, i.e. couplers, traps, etc., with additional similar equipment likely to be involved in the future as new planned substations are inserted in the transmission path.

The extension to the despatch office was therefore effected as shown below. On the eastern extremity of the system the requirements of the interconnection with the Northwestern Region of the Ontario Hydro Electric Power Commission System were likewise satisfied by means of power line carrier over the tie line with extension from western terminus of the interconnection at the Seven Sisters Generating Station being accomplished as indicated below.

During the development of the scheme it was also decided jointly by The Manitoba Hydro Electric Board and the City of Winnipeg Hydro Electric System that the latter's hydro electric generating station at Slave Falls should be brought into the radio system to enable voice and telemeter information to be brought into Winnipeg. The City of Winnipeg's generating station at Pointe du Bois on the Winnipeg River was already connected to Slave Falls by telephone pairs and these could likewise be extended to Winnipeg via the radio scheme.

Fig. 1. Microwave radio system — schedule of designated despatch and administrative voice channels.



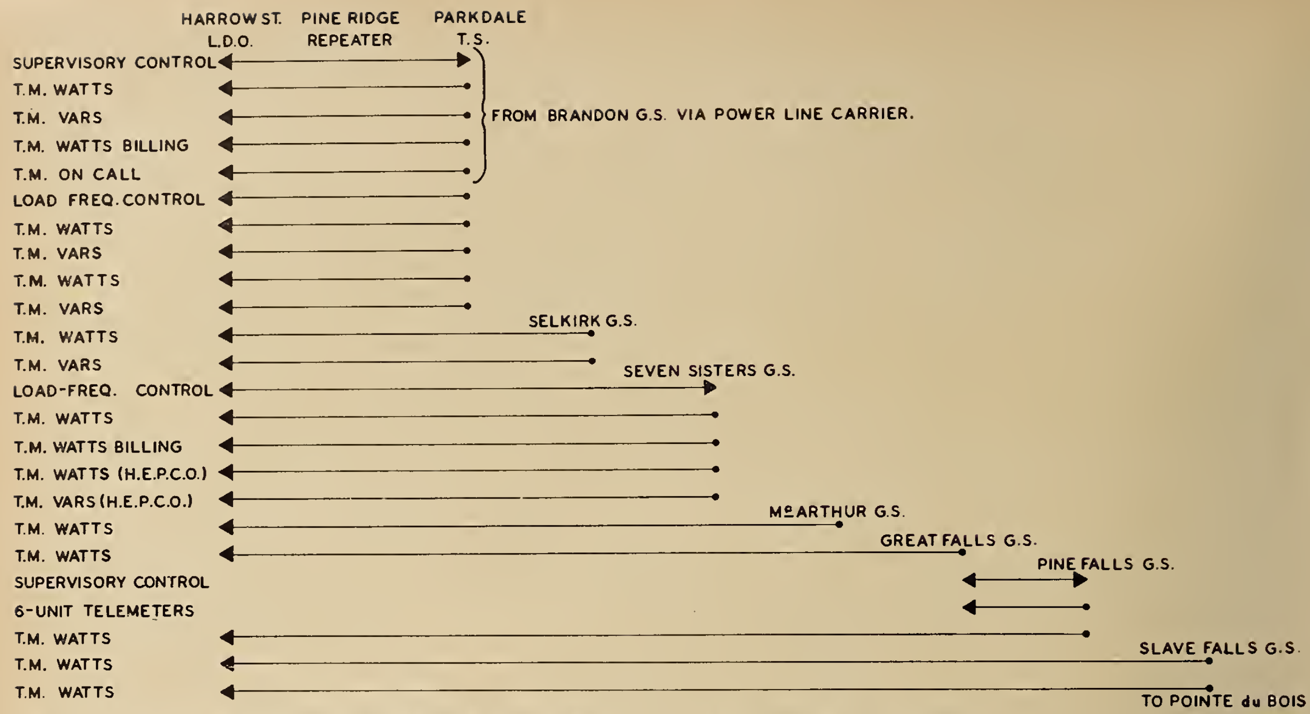


Fig. 2. Schedule of allocated telemetering, supervisory control and load and frequency control narrow band channels.

The results of a detailed field study carried out by the Board were combined with contour information available from Geodetic Survey maps to ascertain the approximate tower heights required for microwave and it was found that by judicious choice of location only one junction repeater point was necessary. Its location on Pine Ridge was such that it could serve the threefold purpose of connecting each of the Parkdale Terminal Station, Selkirk Generating Station and Seven Sisters Generating Station with the Harrow Street despatch office. No one of the three points mentioned could be reached by the despatch office with direct hops while employing realistic antennae heights and adequate line of site clearances. Also the Seven Sisters Generating Station, serving as drop repeater point, proved ideal for relaying to the several other stations on the Winnipeg River.

The decision on policy having been established specifications for a microwave radio system were prepared and the equipment ultimately selected operates in the 2,000 megacycle band. It has a basic capability of 30 voice channels but the specific selection was partially predicated by the fact that with little expense and inconvenience this base band can be expanded to 120 voice channels. In other words the choice of microwave has enabled a broadband path to be established between eight key points and the equipment selected is such as to enable ready expansion on any or all links at very modest cost and without the fear of congested spectrums.

By the use of microwave carrier in the comparatively heavy traffic areas, power line carrier in the lighter long haul areas and leased wire for certain applications in the urban areas, media for the transmission of voice, telemetering and control functions were set up between the load despatch office and all key generating stations and terminal stations on the Board's system. The existing vhf radio and certain of the land lines have not been retired but rather have assumed the new role of providing effective back-up to the new primary modes of communication in addition to the vhf radio's continued important role of coverage to mobile crews engaged in maintenance.

The displacement of the new efficient carriers having been decided upon, it then became necessary to explore their inherent advantages in the most effective and reliable manner to give the despatchers a complete and continuous picture of the system in order that they might exercise intelligent and precise control with a maximum of speed, accuracy and reliability.

Voice Channels

To achieve optimum utilization of the radio baseband together with good signal-to-noise characteristics, single sideband suppressed carrier voice channels in the frequency division multiplex pattern were employed. It was decided that the system should cater for two basic classes of voice traffic namely, despatch and administrative. Further, both of these classifications were established in a radial or spoke-like pattern with the head office building as a hub. It will be realized that this highly desirable radial system with no intermediate stations involving switching equipment is most readily obtainable on a wideband system such as microwave.

One end of each of the despatch circuits terminates at the duplex switchboards of the load despatcher while the other end terminates in the control rooms of the various generating stations and terminal stations. The work of the load despatch office and station personnel is further facilitated by the provision of amplifiers and loudspeakers in the generating station control rooms. The despatcher has merely to depress the appropriate circuit key and commence speaking. He is immediately heard over the loudspeaker in the selected generating station control room. The operator in the generating station control room will thus directly receive instructions with a minimum of time consumption. Should discussion with the system load despatcher be required the station operator has merely to pick up a telephone instrument. In doing so the loudspeaker is cut off and the conversation continues via the telephone sets. Conventional key ringing is available to augment the above process. Also, by simultaneously depressing a number of keys, the despatcher is able to be heard in the several selected control rooms simultaneously thereby saving considerable time and effort. Similarly party line discussions with several station operators can be quickly established.

Of lower priority but nonetheless essential, the administrative circuits provide a rapid and convenient facility over which company business may pass. Each generating station is provided with a private automatic exchange (PAX) to serve the requirements of the power house and the company phones in the townsite. These administrative circuits on the microwave system serve as trunks between the PAX's at the generating stations and the Board's central offices in Winnipeg. Equivalent administrative circuits are provided to terminal station points as required and dial facilities are incorporated so that all the administrative phones throughout the total system assume an equivalent status of being locals to the private branch exchange (PBX) in the Board's head office building. The fact that the administrative channels have been established on a radial pattern equivalent to the despatch circuits results in their ability to perform the alternate function of providing standby in case of despatch channel failure. The despatchers have priority access keys on their switchboards which are at their disposal to cater for this eventuality.

For their convenience the despatchers also have the vhf and company owned land lines terminated on their switchboard. Leased wire lines to important terminal and substations as well as both leased wire lines and vhf radio links to the load despatchers of the City of Winnipeg Hydro Electric System and the Manitoba Power Commission complete The Manitoba Hydro-Electric Board load despatchers complement. Through the medium of power line carrier facilities either installed or being installed in each of the neighbouring provinces, the Winnipeg load despatcher will also be able to speak directly with his opposite number in Ontario at Port Arthur and in Saskatchewan at either Saskatoon or Regina.

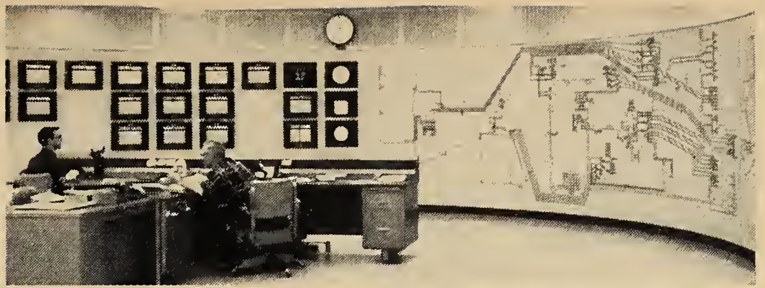

Fig. 3. Harrow Street central load despatch office indicating system mimic diagram, continuous recording equipment, operators' desk and telephone switchboard facilities.

Telemeter and Control Channels

The telemeter and control channel schedule is shown in Fig. 2. Generating station totalized output watt and var quantities together with equivalent quantities from tie lines and certain other selected transmission lines are displayed in the load despatch office together with system key voltages and system frequency on high speed strip chart recorders. The watt and var quantities are converted at the point of origin from currents and potentials by means of one second thermal converters into proportional millivolts. The thermal converter outputs are fed into high speed frequency type telemeters which sine wave modulate (thereby eliminating relays and keys) amplitude-modulated tones on the microwave system and frequency shift equipment on the power line carrier. The reverse or demodulating process takes place at the despatch office channel equipment thereby providing the necessary millivolt input for the recorders.

Fig. 4. M.H.E.B. load despatch office telephone duplex switchboards.

Because of the comparatively quiet medium of microwave carrier with the constant level qualities of frequency modulation, straight forward amplitude-modulated tones were selected for carrying telemeter and control functions. On the inherently noisier or more susceptible-to-noise background of power line carrier, noise immune frequency-shift equipment was selected for these services. The experience to date is such that the record encourages belief that these selections were not incorrect.

Resulting from a program which is current at the present time there will shortly be some ten terminal stations and substations operated by supervisory control from the load despatch office. As this program is extended it is anticipated that each of microwave carrier, power line carrier and leased land line will contribute toward providing the tone channels.

The system tie line load and frequency control installation is also focused on the central load despatch office. As previously indicated watt and var quantities from the tie lines of each of Ontario and Saskatchewan are telemetered to the load despatch office and intelligence is transmitted from the load despatch office to the Seven Sisters Generating Station for the purpose of automatic control of the output of six water wheel turbine alternators at this location. The details of this load and frequency control system are developed in a companion paper but it is perhaps significant to draw attention to the critical, continuous nature of the function which is being served and to the fact that, as in the case of certain of the voice channels referred to previously, the tone channels associated with this system are required to be extended to or work together with associated equipment in Ontario and, in the near future, in Saskatchewan also.

Safety Margins and Standby Equipment

As already stated the assurance of continuity in each of the several services embodied in this communications system is of the utmost importance and has received considerable attention resulting in the specification of suitable safety margins and standby equipment.

Fade margins based on statistical data have been incorporated into all paths of the microwave system so as to ensure propagation reliability during abnormal atmospheric conditions. Duplicate cold standby equipment is provided at all stations of the microwave system so as to be available in the event of failure of the main equipment. Changeover to cold standby is, of course, automatic.

Where a telemeter or control function is considered to be of the utmost priority, the channel has been duplicated as have the power supplies which are involved. In addition, these selected functions are inserted directly into the radio baseband and are not sub-multiplexed on voice channels thereby avoiding an unnecessary link in the chain. Channels in this category include those required for load and frequency control and for supervisory control.

At points such as the Pine Ridge radio repeater a diesel generator has been installed in order to afford an emergency power supply. At this particular point and since it is an unattended station, a control channel has been provided to the load despatch office to enable periodic check runs on the diesel generator unit to be carried out. The fact that the unit has started or has failed to start at any time is annunciated in the load despatch office by means of microwave fault recording equipment. The installation of engine generator supplies will shortly be affected at all other points throughout the microwave system so as to make it completely independent in the case of failure of normal a-c. power supplies.

Conclusion

It must be recognized that the microwave is a complex facility which requires an appropriate standard of preventative maintenance. However, attention was given to on-the-job training of the personnel who have subsequently been required to effect the required maintenance and this same body of personnel was utilized to the greatest possible extent in the installation of the original system.

While the operating experience to date has not been without incident and teething problems still appear (the system was first placed in operation in mid 1959) it is believed that the selection of microwave for application to the heavy traffic density requirements of The Manitoba Hydro Electric Board's Southern Manitoba System has been ideal from the standpoint of economy, reliability, flexibility and overall adequacy.

In equipping itself with a microwave system as the backbone of its communications network The Manitoba Hydro-Electric Board has largely eliminated the problem of detailed forecasting of traffic growth in individual areas. Like its contemporaries in medium size but rapidly expanding power systems, it is believed that the adoption of a "wideband" communication media is required and is wholly justified if not absolutely mandatory in providing the flexibility in communications system planning which is needed. Even in the short space of time which has transpired since the original definition of the total refurbished system, developments have taken place the exact nature of which could not be forseen. However, it has been found that the composite system adopted can be readily and conveniently extended to cater for these new requirements.

From the operator's point of view the system is proving to be approaching the ideal and, assuming confidence in the reliability and performance of the system continues to grow as at present, there should be no cause for undue reluctance or concern when expanded application sees the incorporation of fully automated incremental generation control. Carrier type relay schemes for transmission line protection are already being introduced over links in the power line carrier area of the network and it is anticipated that similar protective relay schemes will before long be employed in the microwave system.

THE EVOLUTION AND APPLICATION OF LARGE SYNCHRONOUS AND INDUCTION MOTORS IN CANADA

G. W. Herzog, M.E.I.C.
K. Z. Lukaszewicz
Industrial A.C. Machine Design Engineers, Canadian General Electric Company, Peterborough

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

Canada's great industrial expansion over the last 60 years and its present high standard of living are interleaved with the extensive utilization of electrical energy. Canada's per capita consumption of electricity, the second highest in the world, which had risen to the value of 5.0 mwh. per capita per annum in 1955, is a tribute to this country's engineering profession. Applications involving large motors are often very interesting and impressive to watch; for example, a 1500 hp. chipper will cut a 30 in. diam., 30 ft. long log in 3/4 in. chips in 30 sec. Large dredges, steel mills, mine hoists and other applications are equally fascinating. The use, characteristics, and construction of synchronous and induction motors has changed from earlier times. This paper presents some of this record as well as describing application considerations, and one manufacturer's modern construction of large synchronous and induction motors.*

FOLLOWING Dr. Nikola Tesla's prodigious inventions of the polyphase AC system and the induction motor in 1888 the manufacture of alternating-current motors in Canada started in the 1890's. Application of both induction and synchronous motors grew as the industrial expansion took place. At first the use of synchronous and squirrel cage induction motors was limited because of the difficulty of developing sufficient starting torque with reasonably low inrush current. Compressors, pumps, motor generator sets were typical low torque applications. For drives such as ball and rod mills where high torques were required during starting the super synchronous motor filled the need for a time. These motors were constructed so that the stator was free to rotate during starting and synchronization, then braked to standstill while the rotor was accelerated to rated speed. The low starting torque was adequate to accelerate the stator. After synchronization high torque, up to the pull-out value, was available to accelerate the load. Super synchronous motors were built in the range of 150 to 600 hp. at speeds of 180 to 300 rpm. However, they were expensive because they required mechanical brakes for the stator, three extra collector rings with brushes for the high voltage stator winding, an additional set of bearings, and presented a problem of supporting the stator winding against centrifugal forces during starting.

Synchronous induction motors and synchronous motors with phase wound amortisseurs used principally to get lower inrushes have not been applied in Canada to any extent because of their high cost and lower efficiency, and because in general Canadian power systems could accommodate higher inrushes than could the European systems for which these motors were primarily designed.

By 1930 the theory of design of synchronous motors was sufficiently far advanced, principally by engineers in the United States, to permit developing of high starting torques with much lower inrush than was possible before. Furthermore, with the growth of power systems, higher inrush values could be tolerated. With these developments the super synchronous motors lost favour. Since then rapid expansion of synchronous motor applications took place, and now about 90% of the large AC motors over say 500 hp., which are built in Canada are synchronous, the remainder being wound rotor and squirrel cage induction.

*Canada Year Book, 1957-58

Characteristics

The fundamental difference between a synchronous and an induction motor is that the synchronous motor's excitation is direct current and is applied to the rotor whereas the induction motor obtains its excitation from the stator. Differences in construction, operating characteristics, and application evolve from this.

Usually, other considerations than the requirement for constant speed determine whether a synchronous or an induction motor is used.

Synchronous motors have the following advantages:

1. Ability to carry load at 1.0 pf.;
2. Ability to supply reactive kva. for pf. correction and for system voltage regulation;
3. High efficiency;
4. In general — have lower inrush current than squirrel cage induction motors;
5. Pull-out torque is proportional to supply voltage, as compared to breakdown torque in induction motors which varies as voltage squared.

Unity pf. motors are selected when reactive kva. is not required and the pull-out torque of 150% is adequate.

0.8 pf. machines, in addition to their advantage of being able to provide pf. correction as shown in Fig. 2, have higher pull-out torque, usually from 200% to 250% or more. They are physically larger than 1.0 pf. machines, therefore they are more expensive and their efficiency is slightly lower.

Efficiency of synchronous motors is higher than of any other type of motor of the same hp. and speed. Efficiencies of 93-95% are common

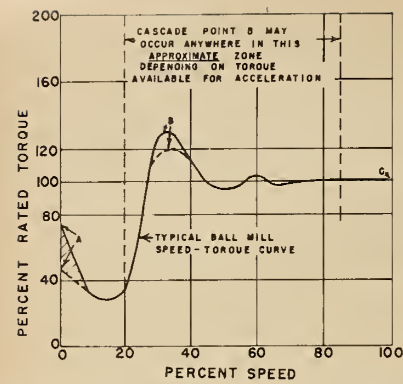

Fig. 1 Typical Ball Mill Speed-Torque Curve

for motors over 1000 hp., and increase with hp. rating.

Lower inrush values for synchronous motors compared to those for squirrel cage induction motors occur because the starting characteristics are more separable from full speed operation.

The advantages of large squirrel cage motors are:

1. Simplicity of starting equipment;
2. Their speed is practically constant, slips of only 1 to 2% at full load are normal;
3. Power factor is quite high and increases with hp. and r.p.m. rating. Values of 85%-90% are common for motors over 500 r.p.m.;
4. They have no collectors to spark, which may make them preferable for some hazardous locations;
5. Their efficiencies are only slightly lower than those of synchronous motors.

Large wound motors have slip, efficiency and power factor practically the same as squirrel cage motors. Their chief advantages are:

1. High torque per amp. during starting. 100% torque throughout acceleration with approximately 100% current, or 200% torque with 200% current is normal;
2. Ability to accelerate very large inertia;
3. Ability to start frequently and stop without overheating;
4. Kinetic energy of the connected inertia can be utilized by the use of a slip regulator to reduce the peak hp. rating and to maintain fairly constant current despite widely fluctuating loads.

However, wound rotor motors are more expensive than the other two types.

Application Considerations

Large motors are individually designed to meet the specifications. The most economical and successful combination of the AC motor and the driven unit is only possible if the characteristics of the motor and the driven load are properly matched. Close cooperation and exchange of applicable technical information between the driven equipment manufacturer, the motor designer, and the user is essential.

For these motors it is as important to match the starting characteristics of the load requirements as it is to have the rated load conditions matched.

An AC motor must be properly specified so that there is no misunderstanding between the one who specifies the rating and the motor design engineer. The use of CEMA, ASA, and AIEE Standards assists in the problem of communication.

The rating must be such that the motor can accelerate its load to rated speed within inrush limitations if any; drive the load within its kva. or hp. rating; carry the peak torque overload; limit current pulsations, where applicable, to agreed values; operate with the expected voltage variations, and be suitable for the expected service conditions of ambient, altitude, air contamination and other special requirements. Some aspects of rating are given below.

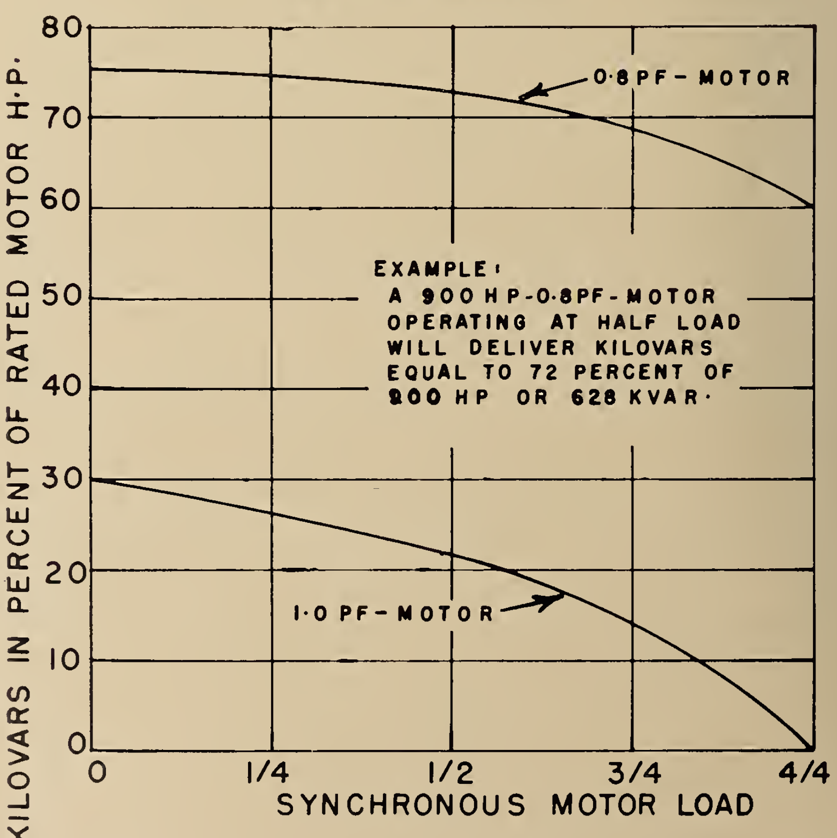
The selection of hp. rating for steady loads requires no comment but for pulsating or fluctuating loads the rating should be established from r.m.s. kva. because power factor may vary considerably for synchronous and induction motors for such conditions. The r.m.s. kva. will always be larger than the corresponding r.m.s. hp.

Whether a motor can successfully accelerate its load to full speed depends upon four things: Inherent torque characteristics of the motor; load torque from zero to synchronous speed; load inertia; voltage value at the motor terminals during starting.

The motor torque must be greater than the load torque at all speeds. The difference between the motor and the load torque is absorbed in accelerating the motor and load inertias. The smaller the difference between these two torques the greater is the accelerating time and the greater is the motor rotor and stator heating. The load torque near synchronous speed must be known to establish the pull-in requirements for a synchronous motor. For all applications then, and particularly for large hp. ratings, knowledge of the load torque is essential to establish the motor design. Where the exact load torque curve with respect to speed is not available an approximate one is better than nothing.

The load inertia must also be known. For a pure inertia load, i.e., a load with a negligible amount of torque during starting, the amount of energy loss in the rotor circuit, which is developed during accelera-

Fig. 2 Typical reactive kva



tion period, is approximately equal to the increase in kinetic energy of the load inertia. Since acceleration times are relatively short, usually less than 20 sec., most of this loss is stored in the rotor circuit. It is therefore essential in squirrel cage induction and in synchronous motors to provide adequate material in the cage and pole face windings to avoid trouble from overheating. It is evident that the amount of load inertia can affect substantially the size, cost and performance of these motors. If in addition to inertia there is a load torque to overcome during starting the amount of heat to be stored is further increased.

For synchronous motors load inertia and load speed-torque curve must also be known before pull-in torque can be determined. This torque is defined as the maximum constant torque under which the motor will pull its connected inertia load into synchronism at rated voltage and frequency when rated field excitation is applied. The speed to which a motor will bring its connected load depends upon the power required. Whether the motor can pull the load into step from this speed depends upon the inertia of the revolving parts. For a given design the maximum slip from which the motor can synchronize varies as one divided by the square root of the motor and load inertia. It is usual to convert load inertia to an equivalent value at the motor r.p.m.

When specifying the locked rotor and pull-in torque requirements adequate margins must be allowed for variation of motor torque due to the expected change in voltage. A motor that cannot accelerate its load is completely useless. However, excessive margins are also undesirable as they may increase the cost of the motor, may increase inrush current and affect other characteristics adversely.

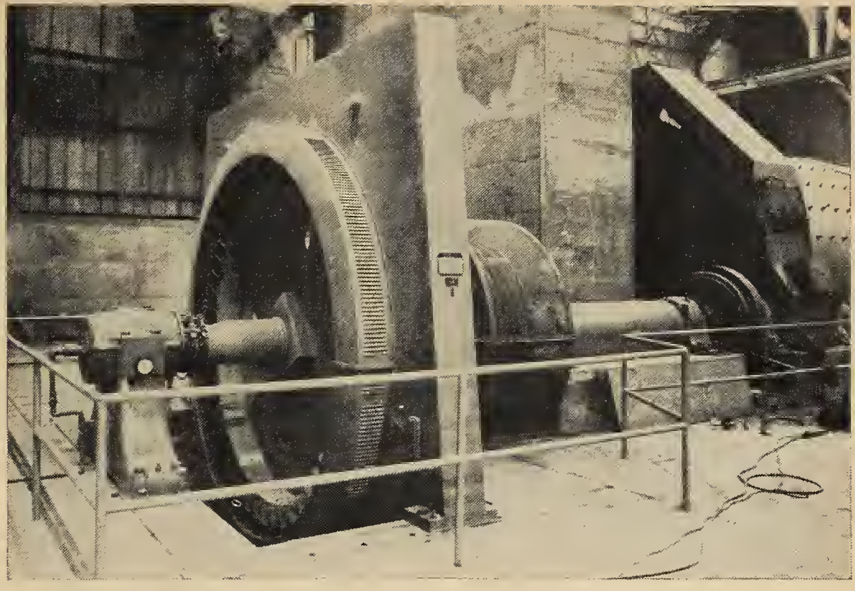


Fig. 3. Synchronous Ball Mill Motors 2500 h.p.—48 Pole—150 r.p.m.—4000 Volts

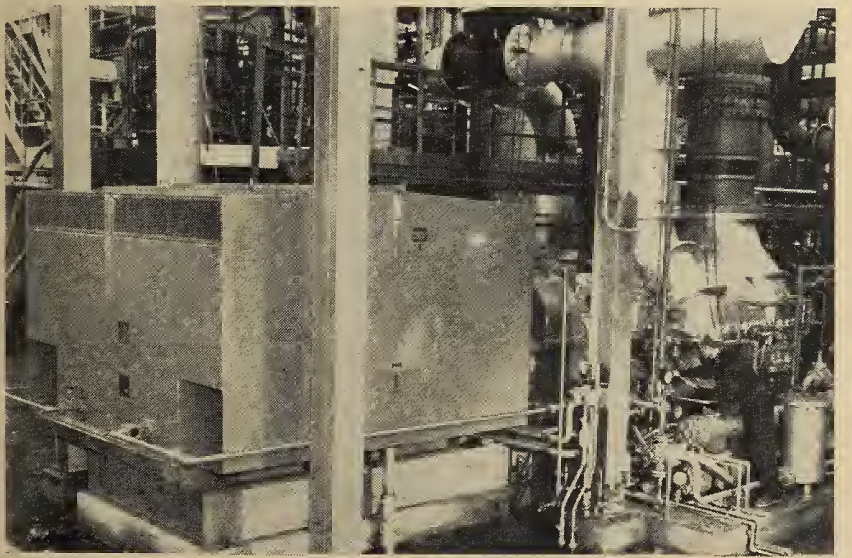
When applying synchronous motors to pulsating loads, such as reciprocating compressors, it is essential to match the motor design with the load to avoid trouble from torsional vibration and to limit the amount of line current pulsation. The responsibility for this is normally taken by the driven equipment manufacturer.

The usual approach to torsional vibration is to consider the effect of excitation from the load torque variations which is the most important. However, there are other sources of excitation such as: unbalanced line voltage which gives an excitation at twice line frequency; unbalanced secondary resistance of wound rotor induction motors which gives an excitation at two times slip frequency; and a pulsating component of accelerating torque during the starting period of synchronous motors which is at twice slip frequency.

Fig. 4. 3600 h.p.—1190 r.p.m.—4000 Volt squirrel cage weather protected induction motor driving a centrifugal compressor



Typical Applications

The requirements for synchronous and induction motors have grown with Canada's industrial expansion both in the quantity of motors and also in their unit sizes. Pulpwood grinder motors 30 years ago had maximum ratings around 2800 hp., now ratings of 5500-6000 hp. are common. Ball mill motors a few years ago were normally rated 600-800 hp., now ratings of 1500 hp. are common and even 2500 hp. motors have been supplied. 7000 hp. MG set motors (with much larger ones considered), 10,000 hp. dredge motors, 6000 hp. reciprocating compressor motors, 10,000 hp. centrifugal blower motors are further examples of the trend to larger ratings. Photographs of some of these installations are included in Fig. 3 to 7.

It may be of interest to list some of the most common applications for large AC motors.

Synchronous motors are used for various types of compressors, fans, blowers, pulp grinders, chippers, jordans, pumps, rolling mills, rubber mills, ball and rod mills, motor-generator sets and less frequently for other applications.

Wound rotor induction motors are used for mine hoists, motor and generator sets usually with a large flywheel, chippers, dredges, ball and rod mills. Wound rotor motors have

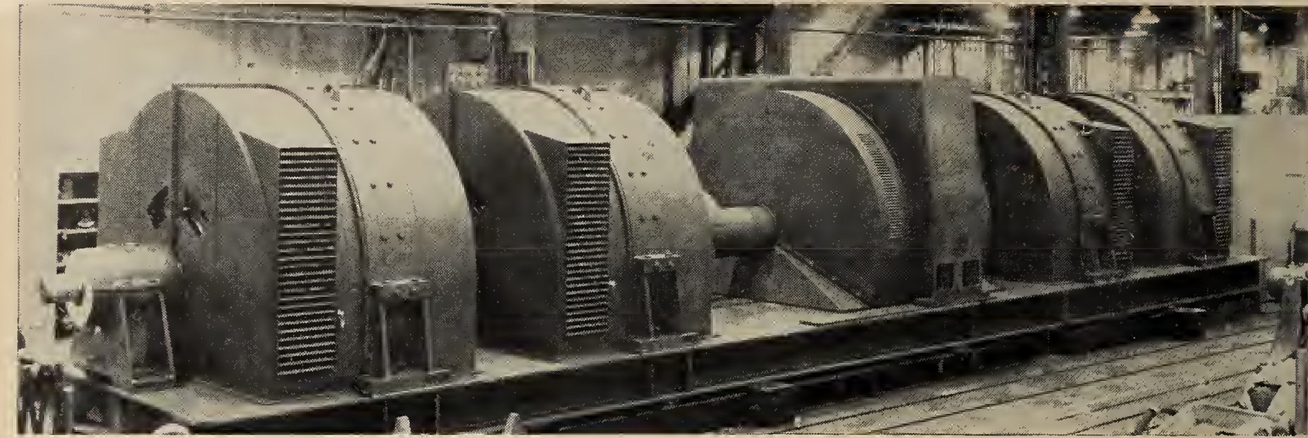


Fig. 5. A 5 unit motor generator set for a steel mill driven by a 7000 h.p.—1.0 P.F.—13,200 Volt—514 r.p.m.

been applied to a large number of mine hoists in Canada. These motors are suitable for manual, semi-automatic or fully automatic operation. Dynamic braking which can be applied reduces the duty of mechanical brakes.

Squirrel cage induction motors are used for vertical and horizontal pumps, high speed centrifugal compressors, fans, jordans, pulverizers, rod and ball mills.

Although it is beyond the scope of this paper to describe in detail many of the applications, a description of a ball mill is included because it exhibits many of the facets of a typical application for synchronous motors.

Ball and rod mills are used for grinding various materials such as ore and cement. A ball mill installation is shown in Fig. 3. During grinding the mills are continuously rotated about a more or less horizontal axis. During rotation the action within the mill consists of continuously lifting portions of the composite materials within the mill until the lifted material falls or tumbles down. The combined actions of impact of falling material especially of the heavy balls and rods (usually of steel) and sliding and tumbling within the mill effectively reduces the particle size. Typical mill speeds are around 20 r.p.m. with the motor speed of 100 to 250 for motors direct connected to a spur gear and 720 to 900 for motors connected to a speed reducer. Typical horsepower ranges are from 200 to 1500, although some larger horsepower ratings have been built; up to 2500 hp.

Fig. 1 shows how the torque required by a typical ball mill varies from breakaway to full speed. The charge is lifted up as a solid mass until at some angle the charge begins to break up or cascade. The maximum torque occurs just before the mill cascades and a good deal of experience has been accumulated to show that the cascade torque is between 100 and 130% of the normal running torque, although certain mill builders feel that the torque may go as high as 140% on occasions. Motor torques normally supplied are 150% locked rotor, 110% pull-in and 150% pull-out for cement mills and 175-110-175 for ore mills. Higher values may be specified to compensate for reduced supply voltage during starting. Pull-in torque requirements are usually based on a load inertia of 3 to 4 times normal at the motor shaft. Normal torques and inertias for other applications are shown in ASA Standards. Occasionally some installations employ standard low torque synchronous motors with a magnetic clutch between the motor and the mill.

Full voltage, full winding starting is the most economical and reliable method of starting large AC motors. This method is now widely used for ball mills. Reactors and saturable reactors placed in series with the stator winding have been used in some cases to reduce the initial shock to the gears.

Approximately once a month it is necessary to position the mill accurately to add fresh balls. This is normally done by running the motor up to speed and pushing the stop button as a certain point on the outer rim passes a mark. Alternatively, specially designed spotting equipment giving a very low speed of rotation can be supplied.

The atmosphere around the mills is usually very dusty. Motors with open construction should have insulation which resists abrasive wear. Other mills are constructed with the motors located in a separate room.

Construction

Construction of synchronous and induction motors has changed from earlier times reflecting changes which have occurred in requirements, service conditions, improvements and refinements in design, and improvements of materials and manufacturing processes. Modern motors are constructed to be mechanically safe, reliable, relatively easy to service and to provide a greater degree of mechanical protection to the windings.

Early machines were built with cast iron stator frames and rotor spiders. Fig. 6 is representative of this construction. Introduction of welded construction about 1924 opened up new possibilities for the application and design of larger motors. The engineer no longer had to choose between designing to fit an oversize casting pattern with the resulting extra cost and weight in the redundant material or having to order an expensive pattern which might have limited future use. In smaller machines, which are made in reasonably large quantities, greater standardization of parts is possible, hence casting construction is still used for bearing brackets, stator frames and some rotor spiders. In large machines, however, modern practice is to use welded construction exclusively with the exception of some smaller standard components such as bearing shells and pedestals.

Great improvements have been made in insulation systems during recent years. The earliest 105C (Class A) insulations used air as the insulator with cotton and other materials as spacers. Later systems, such as varnished cambric, used tape to support the varnish insulating film. Recently film insulations have been developed which support themselves and have superior physical and dielectric strength.

In 130C (Class B) systems for formed coils, asphalt impregnated flake mica tape is used extensively with some of the newer materials such as reconstructed mica are being used for some of the lower voltages.

Sealed insulation systems are now available in both 105C and 130C classes. These systems have the insulation bonded and sealed between layers to resist the penetration of fine dusts and moisture. Overvoltage factory tests are conducted with the coils immersed in water. Supported and vulcanized silicone rubber tapes are employed in the 130C system.

Synchronous machine wire wound rotor coils have been improved in physical strength, reliability, reduced hot spot, and in sealing by the use of the epoxy resin impregnants. 100% solids epoxy resins which have recently become available exhibit temperature and physical characteristics much superior to previously available materials.

Other details of construction have changed considerably and are too numerous to be listed. Improvements in the design of the ventilation are worth mentioning as they resulted in reduction of the hot spot temperature differentials, greater reliability and substantial reduction in size and weight. Rotors of both synchronous and induction motors have been changed to make them more efficient in blowing the ventilating air. Axial flow propeller fans have been employed on some large high speed units. Top exhaust from the stator is used extensively in open machines to minimize recirculation of the hot air.

The freedom of shape, which is possible with the welded construction, permits the design of various types of motor enclosures which may be required, within reasonable cost. Most motors are built with open or open-dripproof construction which are the cheapest and are applicable to indoor conditions where ambient air is sufficiently clean and dry. The ventilating air is taken directly from the room in which the motors are installed and is usually discharged back into the same room. Adequate ventilation of the room must of course be provided to keep the ambient temperature within permissible limits, usually less than 40°C.

Contamination of the ventilating air is a real problem both for the motor designer and the user. The degree of contamination and its effects varies for different industries. In pulp and paper and chemical industries there may be high humidity, acids or alkalis in the atmosphere which can attack the insulation or cause excessive rusting of internal components. In the cement and mining industries there may be a considerable amount of dust which is likely to be quite abrasive and may also be magnetic. In rubber mills carbon black and other compounds may be present in large quantities which may penetrate the winding insulation or clog the ventilating ducts. There are many other contaminants not mentioned here.

The most common solution is to specify totally enclosed pipe or pit ventilated motors. Clean air is brought into the motor enclosure for bracket bearing machines or into the motor pit for pedestal bearing machines. The exhaust can be, as in open machines, into the motor room or out through the ducts. The external ducts may be quite large and usually a separate blower is required. Normal practice is that the motor is not expected to overcome any external duct pressure drop either at the intake or exhaust.

Fig. 7. 8000 h.p.—257 r.p.m.—13,200 Volts wound rotor induction motor

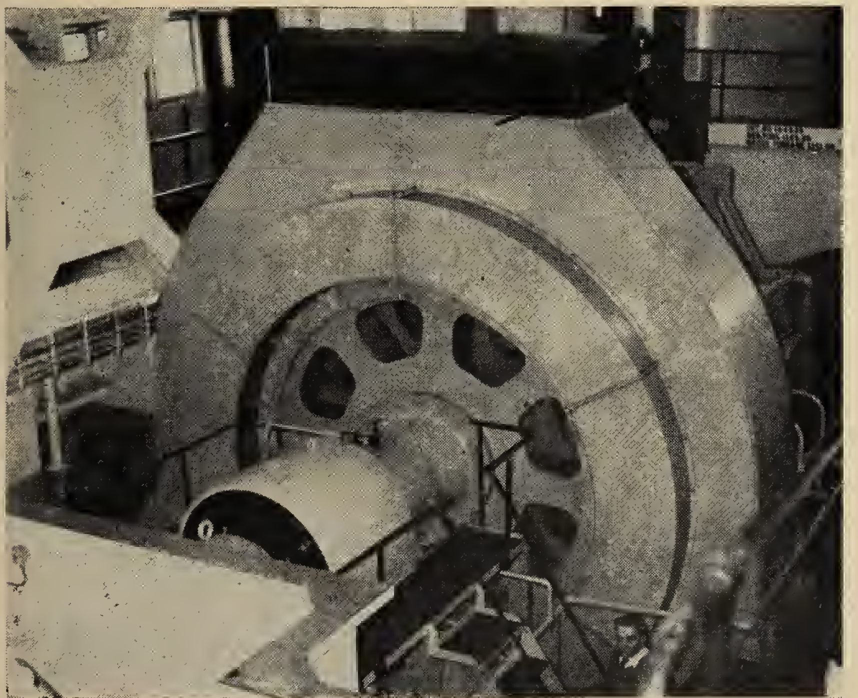

Fig. 6 Synchronous motor built in 1922 to drive a reciprocating compressor

Occasionally totally enclosed water-to-air or totally enclosed fan cooled or air-to-air cooled machines are specified for some applications. The air inside the motor is continuously recirculated which minimizes the need of cleaning the ventilating passages. However, it is necessary to clean the cooler on the water side or on the external air side but this is relatively easy. The air-to-water heat exchanger may be mounted within the motor enclosure, usually above the stator core for easy access, or below the stator core in the motor pit. In the latter case the stator frame is designed to discharge air downwards, through the cooler into the pit and thence back into the rotor. The extra cost of the motors with coolers and cost of cooling water should be compared with the cost of external ducts and blowers, which would be required for pipe or pit ventilated motors.

Locations classified as hazardous by the Canadian Electrical Code because of the presence or the potential presence of flammable gases or vapours or combustible dusts require special construction. Explosion proof and dust-ignition-proof motors are available for some locations in smaller sizes, up to approximately 48″ outside diameter. Their appearance is somewhat similar to totally enclosed fan cooled motors but the construction details are special to meet the requirements defined by the Underwriters' Laboratories. It is impractical to make explosion proof motors in large sizes. Totally enclosed air-to-water cooled motors filled with inert gas, usually nitrogen, under pressure somewhat greater than the atmospheric have been supplied occasionally. The amount of protection against fire or explosion provided depends on the risk involved. Many motors have just the collector rings enclosed and purged with clean air. Forced ventilated motors have also been used. Motor mounted accessories such as relays or space heaters should be designed to minimize the hazard.

Within the last 10 years or so large motors have been built for outdoor operation in weather-protected enclosures. The latest trend is to apply open-dripproof motors outdoors taking advantage of the improved insulation systems. However, when doing so it should be remembered that whilst the insulation may be adequate against moisture, other parts are subject to rusting and dirt can clog the ventilating ducts.

The introduction of sealed insulation systems in the last few years has made it possible to select motors which have a lower degree of enclosure than had been possible in the past. Specific application recommendations are available from the manufacturers.

Design

The electrical, magnetic, thermal and ventilation circuits and the mechanical stresses which exist in A.C. machines are all interrelated so that a change in one usually affects the others. The number and complexity of relationships between the variables makes the design of a rotating machine essentially a "cut and try" process. The dimensions, materials, and type of construction are chosen, then the performance is calculated. The calculated performance is compared to the requirements and if the design objectives are not met the design is altered and the calculations repeated. The rate of convergence depends upon the skill of the designer and upon the severity of the performance requirements.

The availability of digital computing equipment within the authors' company for the last three years has provided a powerful new tool for performing numerical calculations and logical decisions at high speed and low cost. Many more alternatives for a particular rating can now be studied to obtain closer to optimum designs in much less time. Calculation methods can now be used which hitherto were too laborious for routine slide rule operations.

Using the statistical approach and the theory of probability it is now practical and relatively easy to correlate test results from a large number of machines with the new, more precise methods of performance calculation.

With increasing experience, the ability to predict load characteristics has also improved. Whereas in earlier times large factors of safety and margins were used in the motor design to ensure successful operation, present performance predictions, which have been evolved, allow the design of physically smaller and less expensive units with a greater degree of confidence. The development of synchronous and induction motors is a continuing process, and no doubt further improvements are possible despite the fact that over 70 years have passed since their invention.

Conclusions

Knowledge of motor and load characteristics are prerequisites to combining the two for a successful drive. Modern designs and construction features have evolved to produce improved and reliable operation for Canada's particular requirements.

THE POTENTIAL IN THE FREE-PISTON ENGINE PRINCIPLE

A. Braun,
Vice President and Technical Director,
Free Piston Development Company Limited, Kingston.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

A great amount of literature has been published dealing with specific characteristics of free-piston engines. Many of the advantages such as simplicity, good fuel economy, and multi-fuel characteristics have been widely discussed. Furthermore, different possible arrangements have also been written about in a number of publications. Thus on the basis of the above, anybody particularly interested in this field can have a fair understanding of the free-piston engines available and even of some of the engines in the test stage. These early designs, just as with most new developments, represent conservatively designed units to assure the introduction of reliable engines. These first designs can therefore be compared with, for example, early spark ignition (S.I.) and compression ignition (C.I.) engines. Today's free-piston engines, in other words, must be considered as in an early development stage whereas the development stage of modern (S.I.) and (C.I.) engines are advanced designs working near the upper limits of their respective principles. It is the purpose of this paper to point out the not yet utilized potential in the free-piston engine principle and compare it to the potential remaining or further development or advancement possible with the conventional engine principles of today.

THE DIFFERENT Internal Combustion Engines of today are: Spark ignition (S.I.) or gasoline engines; Compression ignition (C.I.) or Diesel engines; Gas turbines (G.T.); Free Piston (F.P.) engines.

In both S.I. and modern C.I. engines the combustion occurs at nearly constant volume. Thus the otto-cycle shown in Fig. 1 can be used to study the influence of compression ratios on efficiency. Both engines are therefore greatly dependent on their compression ratio. The relation between the thermal efficiency and the volumetric compression ratio $r_v = (v_1/v_2)$ is:

$$\eta_{th} = 1 - \frac{1}{r_v^{(k-1)}}$$

where k is the isentropic exponent.

The simple GT can similarly be investigated on the basis of the constant pressure combustion or Brayton cycle shown in Fig. 2. The thermal efficiency for this cycle is usually expressed in this form:

$$\eta_{th} = 1 - \frac{1}{r_p^{(k-1)/k}}$$

where r_p is the pressure ratio of combustion and intake pressure $r_p = (p_2/p_1)$ which in this case (dealing with a steady flow engine) is a more convenient term to establish than the volumetric compression ratio r_v. Since r_v and r_p however are related in the following manner

$$r_v = r_p^{(1/k)} \quad \text{if} \quad r_v = (v_1/v_2)$$

$r_p^{(k-1)/k}$ can be written:

$$r_p^{(k-1)/k} = r_v^{(k-1)}$$

and by substituting. the efficiency term for the Brayton cycle reads also

$$\eta_{th} = 1 - \frac{1}{r_v^{(k-1)}}$$

The combustion process in the F.P. engine is similar to that in the S.I. and C.I. engine and therefore the thermal efficiency can be determined on the basis of the cycle shown in Fig. 3.

The general expression for the thermal efficiency η_{th} is

$$\eta_{th} = 1 - (Q_r/Q_a) \qquad (1)$$

where Q_r = heat rejected
and Q_a = heat added

since the heat in the cycle of Fig. 3 is rejected between state 7 and 1 and is added between state 3 and 4 it follows that:

$$\eta_{th} = 1 - \frac{c_p(T_7 - T_1)}{c_v(T_4 - T_3)} \qquad (2)$$

assuming $c_p(T_6 - T_2) = c_v(T_5 - T_2)$

it follows that

$$T_6 = \frac{c_v}{c_p}T_5 - \frac{c_v}{c_p}T_2 + T_2$$

$$= \frac{T_5}{k} - \frac{T_2}{k} + \frac{T_2 \cdot k}{k}$$

$$= \frac{T_5 + T_2 \cdot (k-1)}{k}$$

since $\frac{P_1}{P_2} = \frac{P_7}{P_6}$

and if the volumetric compression ratio of the compressor is

$$r_{v_c} = (v_1/v_2) = (v_7/v_6)$$

$$\frac{p_1}{p_2} = (v_2/v_1)^k = (v_6/v_7)^k = (1/r_{v_c})^k$$

and

$$T_2 = T_1 \cdot (v_1/v_2)^{(k-1)} = T_1 \cdot r_{v_c}^{(k-1)}$$

and if the overall volumetric compression ratio is:

$$r_{v_T} = (v_1/v_3)$$

$$T_3 = T_1(v_1/v_3)^{(k-1)} = T_1 \cdot r_{v_T}^{(k-1)}$$

and if the pressure ratio is:

$$r_p = (p_4/p_3)$$

$$T_4 = T_3(p_4/p_3) = T_3 \cdot r_p$$

$$= T_1 \cdot r_p \cdot r_{v_T}^{(k-1)}$$

also

$$(v_3/v_2) = (v_3/v_1) \cdot (v_1/v_2)$$

$$= r_{v_c}/r_{v_T} = (v_4/v_5)$$

therefore

$$T_5 = T_4(v_4/v_5)^{(k-1)} = T_1 \cdot r_p \cdot r_{v_c}^{(k-1)}$$

and

$$T_7 = T_6\left(\frac{v_6}{v_7}\right)^{(k-1)}$$

$$= \frac{T_5 + T_2(k-1)}{k} \cdot \left(\frac{1}{r_{v_c}}\right)^{(k-1)}$$

$$= T_1 \frac{r_p + k - 1}{k}$$

By substituting now into (2) it follows that the efficiency for the FP cycle according to Fig. 3 is

$$\eta_{th} = 1 - \frac{1}{r_v^{(k-1)}}$$

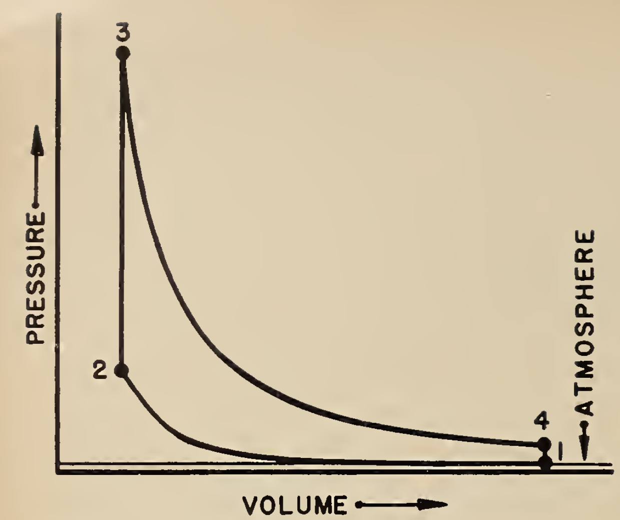

Fig. 1. Otto-Cycle (Constant Volume Combustion)

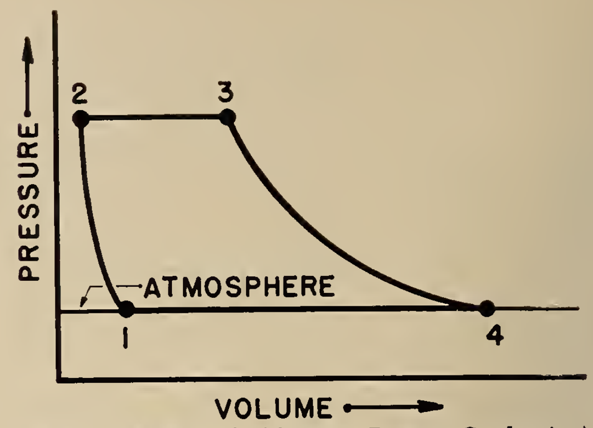

Fig. 2. Brayton-Cycle (Constant Pressure Combustion)

which is exactly the same expression that applies to the other 3 cycles mentioned if r_v represents in the case of the FP cycle the overall or combined volumetric compression ratio of the compressor and engine part.

The expression therefore on the basis of which the thermal efficiencies of the representative cycles of all 4 modern internal combustion engine types can be compared is:

$$\eta_{th} = 1 - \frac{1}{r_v^{k-1}}$$

By finding now the maximum possible compression ratios and their limitations for the above four engine types a valuable indication of their respective actual efficiencies is available.

S.I.—or gasoline engines

Since S.I. engines depend on a fairly homogeneous air to fuel ratio throughout the combustion chamber the air-fuel mixture enters the cylinder during the intake period and a combustible mixture is compressed to a state just below its self-ignition point. There the spark ignites the mixture in one location and from here the flame propagates through the rest of the combustion chamber under controlled combustion conditions. In case the compression ratio is higher than the self-ignition point of the fuel permits, uncontrolled combustion starts ahead of the spark ignition in many different locations of the combustion chamber and so-called knocking occurs, which is a phenomenon harmful to vital parts of the engine and can under no circumstances be tolerated for any length of time and is furthermore an inefficient way to release the fuel energy.

An $r_v = 10$ must be considered very close to the economical and practical limit since otherwise fuel cost would become so high that the gain in efficiency would not balance, and even greater specific output would not warrant the increase.

The Octane number or cost of fuel are therefore the limiting factors for the compression ratio in the S.I. engine.

C.I. or Diesel engines

In the C.I. or Diesel engine only the air is compressed during the compression stroke of the piston and to a state that is substantially above the self-ignition point of the fuel used. Then the fuel is injected into the highly compressed air and around each fuel particle the combustion occurs independently of the overall air to fuel ratio in the combustion chamber as long as each particle finds enough air for its proper reaction. Knocking in the Diesel engine occurs when too much fuel has been accumulated in the combustion chamber before the combustion starts. This happens if the chemical and physical ignition—delay period (which is the time that the fuel requires from the time of entering the combustion chamber until it starts actually burning) is too long. Since the ignition delay period decreases with higher temperatures and pressures i.e. with high compression ratios, it is very desirable in C.I. or Diesel engines to have as high as possible r_v for good combustion behaviour.

With increasing compression ratios, however, the high pressures in the engine require heavy engine structures and at compression ratios above 22 : 1 reach values that result in extremely high bearing pressures in the connecting rod and main bearings besides undesirably high loading of the pistons and liners due to high side thrust.

Therefore mechanical and structural requirements constitute the limitation for the compression ratio in the Diesel or C.I. engine.

Gas Turbines

Gas turbines are steady flow type of engines which means also that the fuel is continuously burnt in the combustion chamber, whereas in the reciprocating type of engines dealt with earlier, the fuel is burnt intermittently.

This means that at the same maximum temperature in the cycle (which as expressed in the efficiency terms is the criterion for good thermal efficiency) the combustion chambers of reciprocating engines have to stand a thermal load only equivalent to the mean cycle temperature whereas in gas turbines the combustion chambers have to stand thermal loads equivalent to the maximum cycle temperature. As shown in Fig. 4 the maximum temperature is substantially higher than the mean temperature and compression ratios in gas turbines are therefore to be kept low.

Metallurgical or material requirements, therefore, limit the use of high compression ratios in gas turbines.

F.P. Engines

The reasons for low compression ratios and the limiting factors for the other 3 engine types in summary were:

S.I. Engines: Air-fuel mixture has to be compressed therefore knock-characteristics of fuel limit r_v. Above $r_v = 10$, fuels get too costly.

C.I. Engines: Load on bearings and pistons put limit to r_v. Above $r_v = 22$ engines get too heavy and life of engines too short. Fuel imposes here no limitation on r_v.

Gas Turbines: Because of continuous combustion, maximum temperatures in combustion chamber and in turbine impose limit on r_v. Above $r_v = 7$ combustion chamber and turbine blade materials do not stand up.

A look at the F.P. engine power plant shows that here the Diesel or C.I. principle is compounded with the gas turbine and in such a way that in the Diesel or C.I. part of the F.P. unit gas is produced to feed the turbine which produces the net power—and no more—of the compound power plant. Because of this characteristic of the F.P. unit itself it is usually called F.P. "gasifier".

Since in the F.P. gasifier the Diesel or C.I. principle is applied to convert the fuel energy into work, it is insensitive to fuel and from a fuel point of view imposes no limit on r_v. Furthermore—as indicated in their name and apparent from Fig. 5—in F.P. engines the two pistons are not connected to any drive mechanism or mechanical power pick-up (except for auxiliary drives) but rather oscillate freely in opposed reciprocating motion inward and outward. Except for losses, all the work done by the Diesel or power parts of the pistons is transmitted to their directly connected compressor parts. Thus bearings are eliminated and side thrust is negligible. In this manner it is possible to fully utilize the Diesel or C.I. principle together with extremely high compression ratios r_v, that would in the conventional type of Diesel or C.I. engine be intolerable.

Similarly the other part of the compound F.P. power plant, the turbine, is employed in such a way that its positive characteristics such as structural simplicity, low weight, superior torque characteristics, and the ability to expand the combustion gases to atmosphere etc. are fully utilized ; the difficulties resulting from high entry temperatures however are eliminated since the temperatures of the gases supplied by the gasifier and entering the turbine are far below those in a conventional gas turbine. The reason for this is that the F.P. turbine part has to provide only the net work of the compound power plant, whereas in the conventional gas turbine the turbine wheel has to provide this net work in addition to the compressor work. The net work in the conventional gas turbine is only 1/3 of the total work to be supplied by the turbine and remaining 2/3 of the work done by the turbine has to be fed back to its own compressor (rotary). Since in the F.P. compound power plant this compressor work is already done in the (intermittently working) gasifier, the enthalpy of the gases and, as said, their temperature for the same net horse power, are substantially lower than in the conventional gas turbine.

Both limitations (regarding the diesel part as well as the turbine part of the F.P. compound power plant) are overcome this way.

Because of the above, present day F.P. engines work with volumetric compression ratios of 40 to 60 : 1. Ratios of 80 : 1 and up are within the scope of relative short range development work and do not represent the limits as in the cases of S.I., C.I. engines and gas turbines.

Quoting the efficiencies corresponding to the r_v values discussed will help to put the potential of the F.P. principle in its proper perspective :

TABLE I

Representative values of r_v of different engine principles and corresponding thermal and actual efficiencies in %*

	GT	*SI*	*CI*	*FP*	
				Present	*Foreseeable Future*
r_v	7 : 1	10 : 1	22 : 1	40 : 1	80 : 1
η_{th}	54.1	60.2	70.9	77.2	82.7
Actual Efficiency	22	28	36	38	41

*Values of actual efficiencies of G.T., S.I. and C.I. engines from p. 235[1].

To evaluate the figures realistically it has to be considered that the thermal efficiencies derived above referred only to the theoretical cycles, and that actual thermal efficiencies besides r_v are influenced by a number of other circumstances such as fluid and mechanical friction losses, heat-transfer rate, combustion efficiency, state of development, etc., so that the percentage increase of thermal efficiency is not the same as the increase of the actual efficiency. The general trend, however, is (with few exceptions) the same as indicated by the thermal efficiency.

It can be seen—even though to different degrees—that the trend is upward and it should be recalled again that G.T., S.I. and C.I. engines work on their upper limits after over half a century of development and research effort, whereas the first F.P. gasifiers were installed only a few years ago.

Moreover, the gain with this new principle is not achieved with a more complicated but rather with a greatly simplified engine that has numerous advantages over the conventional types. Although often quoted[2,3,4,5] a summary will again be of value here.

Multifuel Characteristics

F.P. engines will operate on practically any fuel the injection pump can handle. Bunker "B" and Bunker "C" oil are successfully in use in several installations[2,3,6,7,8] : stove oil or Diesel fuel are the normal fuels in most applications today and ether, gasoline, lubrication oil and mixtures thereof, vegetable oil etc. have been burnt without re-adjusting the fuel injection pump.

The reasons for this will be apparent from a study of Fig. 7.

In regard to the combustion chamber conditions it should be noted that even though the compression end temperature t_3 is substantially above, the combustion end temperature t_4 is below that in S.I. and C.I. engines because of the unusually high air to fuel ratio (based on the air trapped in the combustion section) which results in a lesser degree of chemical attack on pistons and cylinder.

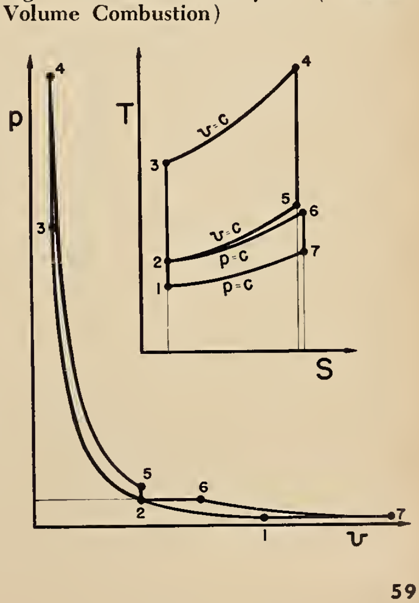
As for the exhaust port deposits, the situation is such that the part of the gas delivered which contains the products of combustion passes the exhaust ports at temperatures between states 5 and 6, which, because of the high back pressure at 6, are much higher than those in the S.I. or C.I. engine (which leave these engines at temperatures equivalent to state 5′) resulting in practically no deposit formation.

In spite of these high temperatures the mean temperature of the gas entering the turbine, as well as the mean temperature of products of combustion plus air passing through combustion cylinder and exhaust ports, is lower than the exhaust temperatures of S.I. and even C.I. engines because of the additional amount of air supplied by the compressor parts of the gasifier which passes through combustion cylinder and exhaust ports at a temperature t_2 and mixes with the products of combustion at temperature t_6 before it enters the turbine at a mean delivery temperature $t_{6'}$ also substantially below the entry temperature of ordinary gas turbines thus resulting in a greatly reduced tendency of chemical attack on vital turbine parts in the F.P. turbine particularly when residual fuel is used.

In order to avoid possible confusion it might be stated here, regarding the difference between Fig. 7 and 3, that the analysis based on Fig. 3 is correct in spite of the fact that in the derivation of η_{th} of the F.P. engine no consideration was given to the mixing of excess scavenging air and products of combustion.

The reason for this is that in the derivation of the η_{th} term it is sufficient to consider only the mass of working substance participating in the actual combustion cycle, when it is assumed

Fig. 3. Free Piston-Cycle (Constant Volume Combustion)



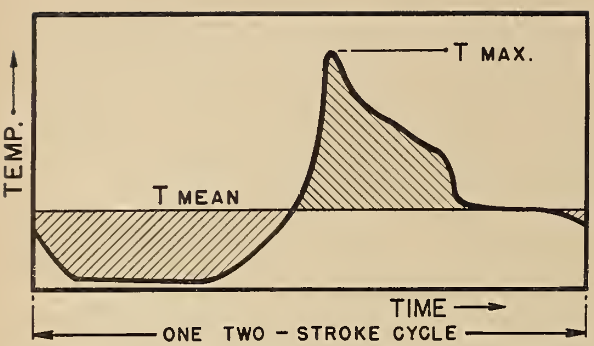


Fig. 4. Gas Temperature in Two-Stroke Diesel Engine Cylinder

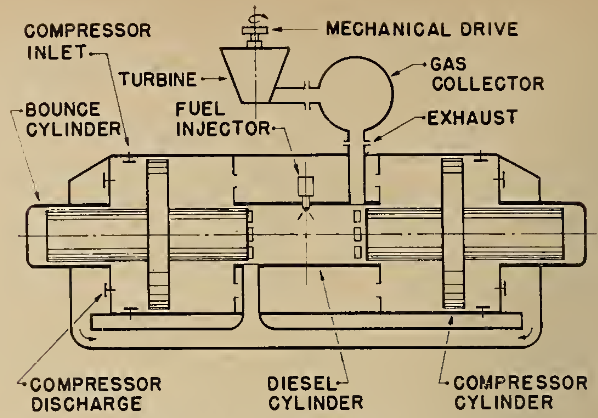

Fig. 5. Diagrammatic Free Piston-Turbo Set

that the additional mass of air supplied by the compressor parts of the gasifier by-passes the combustion section and is then expanded in the turbine back to atmosphere.

Simplicity

As explained above no crankshaft, connecting rods, bearings, camshafts, valve mechanism, flywheel etc. are required, resulting in a structurally very simple engine.

Compactness

Due to their structural simplicity, the high degree of supercharging and the full expansion down to atmospheric pressure F.P. engines are very compact and have a low weight per hp.—including turbine and gearbox where necessary.

Dynamic Balance

With the absence of any drive mechanism and with the opposed reciprocating motion of the two piston assemblies which are essentially the only moving parts in the engine, the gasifier is inherently balanced and since there is no vibration, foundations can be substantially lighter and less costly.

Flexibility of Installation

Since there is no common crankshaft required for a multicylinder installation there is no reason to build multicylinder units. It is, on the contrary advantageous to produce single cylinder units which can be either suitably coupled to power packages or independently installed in sections of the power plant or vehicle, which are of least value otherwise and that can result in optimum weight distribution[9]. The only connection necessary in a multicylinder installation (there have been up to 48 cylinders in one plant)[10] is the delivery piping to the turbine which is either part of the vehicle structure[11] or of relatively small volume, and, as mentioned above, in subject to lower temperatures than those of ordinary S.I. or C.I. engine exhaust pipes.

Flexibility of Operation

In most installations there will be more than one and at least two cylinders or gasifiers installed. Assuming an installation of 4 cylinders or gasifiers on a single turbine it can easily be seen that at 1/4 load for instance 3 of the 4 gasifiers can be shut off and at 1/2 load only 2 will be running, etc. The result is a very flat efficiency or specific fuel consumption (SFC) characteristic over the whole load range. The specific characteristic is of course dependent on the turbine design selected and will vary with individual application.

In contrast to the above it should be noticed that in the conventional S.I. or C.I. engine all cylinders have to be run at the part-load point desired resulting in relative high S.F.C. at part-load.

Reliability

Here again the independence of the individual gasifiers in a multicylinder installation results in an unusually high reliability. Failure of one cylinder in a conventional S.I. or C.I. engine will stop the whole engine, whereas in a F.P. installation the rest of the gasifiers will not be affected by the failure of one gasifier and, moreover, the unit that failed can be repaired while the other units perform their normal duty.

In installations where this point is of particular importance provision can easily be made in the form of an additional fuel supply between gasifier and turbine (afterburning) so that in case of failure of one or two gasifiers, the rest of the gasifiers will still provide full power requirement.

Overload

As mentioned under the previous heading fuel can be introduced between gasifiers and turbine in order to achieve an overloading. The reason for this is that the temperature of the delivery gases is relatively low and that the overall air-to-fuel ratio of these gases is so high that considerable amounts of fuel can be burned after the gases have left the gasifier without getting smokey combustion.

This is, of course, not the most efficient way to burn the fuel but in emergency cases, this characteristic can be of great value. Compared with any of the conventional engines the F.P. power plant has this outstanding advantage which furthermore is not subjected to the short time restriction usually connected with such overload conditions.

Maintenance

The maintenance costs are directly in relation to the smaller number of parts that the F.P. installation has compared with the S.I. or C.I. engine. Also because of the structural simplicity the time required to carry out the work is extremely short and the required skills are less. The lack of bearings etc., side-thrust, and some of the other characteristics mentioned above such as deposits, etc., results in long runs between overhauls. The required time to completely disassemble or reassemble a gasifier is considerably shorter than for any equivalent power plant of conventional design.

Throttle Response

The pistons in the gasifier are essentially the only moving parts and since they operate with their natural frequency between their respective "thermodynamic springs" the response of the gasifiers to the fuel lever position is extremely good ; far better than that of the conventional gas turbine and better than that of S.I. and even C.I. engines.

The response of the whole power plant is to some degree dependent on the gas volume in the piping between gasifier and turbine but this is negligibly small in most installations.

Torque Characteristic

On the usual F.P. gasifier—turbine installation the torque characteristic is essentially that of a hydraulic torque converter (i.e. the stalling torque is approximately 3 to 3.5 times the full speed torque). Thus, for automotive use the F.P. power plant can be considered as having a built-in torque converter at no extra cost. This point together with extremely good throttle response makes it in this respect the most desirable power plant available. The smooth power supply from the turbine has resulted in successful applications to locomotives[12,13] without any intermediate electric equipment.

Economy of Production

Here the simplicity of the engine again results in considerable advantages. By the elimination of many of the intricate and expensive parts of conventional engines far less special machine tools are required thus reducing initial manufacturing plant investment to a fraction, particularly in the cases where a whole line of engines are considered, since one size of gasifier will serve a large range of horse power requirements.

Economy of Operation

Overall specific fuel consumption at the present status of 0.365 lb. fuel/S.H.P. hr. and less[14] has been achieved. This compares very well with the best Diesel engines built and it should again be recalled that this may be done with much cheaper fuel than the comparable Diesel engine would burn.

Conclusion

From this summary it can be seen that F.P. engines, even at their present status, not only compare very well but are in many regards superior to conventional power plants. Specific areas, however, that can still be considerably improved are : power to weight ratio, compactness and fuel consumption. As was mentioned earlier, part of the air supplied by the compressor does not participate in the actual thermodynamic cycle. Since the power produced in the Diesel section of the gasifier has to be used up by the compressor parts in order to achieve the necessary balance within it, the overall air to fuel ratio decreases with increased compressor delivery pressure until it reaches a value that cannot be reduced further (smoke limit of engine)[15]. This critical compressor discharge pressure is about 12 atmospheres or 170 p.s.i.a. which is equivalent to a volumetric compressor compression ratio of $r_{vc} = 6$. Compressor compression ratios of the F.P. engines quoted above are about $r_{vc} = 3.1$. The result of any increase over the present r_{vc} will be better overall efficiency and fuel consumption, still lighter and more compact units

The increase in efficiency is, among other factors, apparent from the earlier study of η_{th}. Reduction in weight and greater compactness result from the higher degree of supercharging and from the increased stiffness of the thermodynamic springs which increase the speed of the pistons.

One further means of increasing efficiency is the raising of the compression ratio in the Diesel section ; another way of getting lighter and more compact units, even after the above mentioned critical compressor discharge pressure has been reached, is supercharging of the compressor sections of the gasifier[16]. It is also worth mentioning that the output of the F.P. power plant increases directly with the speed of the pistons for a given engine design and inversely proportional to the square root of the weight of the pistons.

In conclusion it must be said that the above possibilities cannot be immediately materialized to their full extent and further development and research work is necessary to reach the limits indicated. Since conditions are considerably different from those in conventional engines, new approaches must and can be found, and the rate of progress will greatly depend on the engineering ability and ingenuity of the designer as well as on the effort put into the further development of this interesting and promising type of engine.

LIQUID PETROLEUM GASES AS FUELS FOR AUTOMOTIVE ENGINES

H. A. Spencer, M.E.I.C.
Mechanical Engineer, Research Council of Alberta, Edmonton.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May, 1960.

Supplies of butane and propane are dependent, since they are by-products of refineries and conservation plants, on markets for oil and gas. An analysis of their market has been prepared by R. W. Wright[1] *which shows they are subject to surplus conditions. New markets, particularly seasonal ones, are required to utilize butane and propane locally. Research has been directed to automotive use since farm engines equipped to burn these fuels could take some of the acute summer surplus.*

BUTANE is a hydrocarbon which boils at 32°F. It has an octane rating of 100, making is suitable for engines. Propane boils at —44°F, and has an estimated octane rating of 130. Propane is particularly suitable for high compression engines. Both fuels are difficult to handle since within the range of normal pressures and temperatures they may be either a liquid or a gas. Propane has been the only LPG fuel used extensively in western Canada.

Analysis of Commercial Conversion Equipment

Equipment in use by trucking firms and farmers occasionally gives trouble. When propane is used, it is difficult to set the adjustments correctly because the fuel has such a high octane rating that it will burn quietly even under improper conditions. Although the equipment at present available for conversion to LPG has been refined and when properly set may give adequate service, it is much more sensitive than the conventional gasoline system. A typical system is shown in Fig. 1.

At ordinary temperatures no fuel pump is required since pressure within the tank drives the liquid through the system. Fuel moves through the filter to a pressure reduction valve, to a heat exchanger, where it becomes a gas, through a secondary pressure control valve and to the carburetor. Heat is supplied to the heat exchanger from engine cooling water.

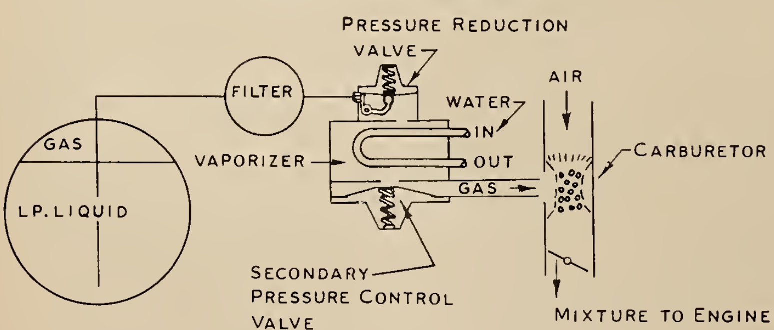
When analyzed, it is obvious that the system will not work for butane below 32°F. Even propane will not work well in cold weather unless some low boiling fuel (ethane, methane) is added. Theoretically, the system should work well for propane at any temperature above freezing but practically this often has not been the case.

Investigations of Automotive Use

Although the Edmonton Transit System is pleased to operate some 30% of its fleet on propane, other fleet operations in Alberta have not been so fortunate. Inconsistency of performance even with factory-equipped units has caused some trucking firms and many farmers to give up their use of propane. In some cases individuals have obtained better performance temporarily on propane by increasing the compression ratio. Where the engine has not been built to take the increased bearing loads this has resulted in failure. Otherwise where compression ratios have not been utilized, the inconvenience of low mileage per gallon, extra pressure tanks, hazards and inadequate service have discouraged many users.

The chief advantages of LPG are long engine life, extra power and cheap fuel. The chief disadvantages are inconsistency in performance and hazards such as leaks which can cause fires. Where propane has been successful, inconsistency has been overcome by careful fleet maintenance and disciplined periodic readjustment, and hazards have been reduced by care, control and education by trade and regulatory organizations.

FIGURE 1. LPG Carburetion



Research

F. V. MacHardy of the University of Alberta did some preliminary work[2] on vapour distribution to cylinders and on carburetor performance. While this portion of the equipment performed satisfactorily, he pointed to the pressure regulators-heat exchanger combination as a "critical component" of the apparatus. The heat exchanger during his tests would refrigerate until it was not performing adequately. Trucking firms which had been interviewed claimed that this portion of the equipment was too sensitive and gave them trouble such as power loss. Burned valves and scored pistons were attributed to the heat exchanger in two possible ways.

The first theory is that overheating of the engine can be caused if the demand for vapour is so great that the heat exchanger cannot supply heat quickly enough and the vapour passing from the heat exchanger through the secondary pressure control valve has such a low pressure that when mixed with the normal amount of air in the carburetor the resulting combination is lean in fuel.

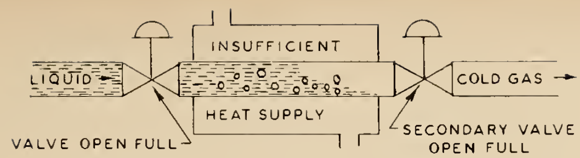
The second theory is that a hot engine will heat the exchanger so that its internal pressure is relatively high, causing the secondary pressure control valve to allow less weight of fuel to pass into the carburetor. The two theories are illustrated in Fig. 2.

The apparatus used in the tests consists of a 60 hp conventional gasoline engine mounted to a hydraulic brake[a], a conversion kit for LPG, 23 gal. and 4 gal. propane tanks. For the first test a separate heating and circulating unit was attached to control the heat in the exchanger. The purpose was to allow the heat exchanger to refrigerate and to check the horsepower as the temperature fell.

Under full load at several engine speeds a characteristic gradual decrease in horsepower was obtained which climaxed in engine stoppage. A series of curves was obtained for propane and butane. (Fig. 3.). Results are shown in Table I.

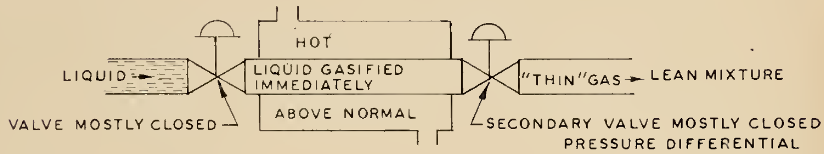
It is evident that under load and

(a) Through the kind co-operation of the Department of Agricultural Engineering, University of Alberta.



FIRST THEORY - INADEQUATE HEAT EXCHANGE

FIGURE 2.



SECOND THEORY - OVERHEATED VAPORIZER

in conditions where the engine cooling fluid which passes through the heat exchanger is either cold or the quantity is insufficient, the function of vapourization is inefficient and sometimes stops altogether. Full load conditions showed a start of this phenomenon for propane at about 30°F and for butane at 75°F.

Under ideal conditions the conventional equipment may prove satisfactory, but when speed and load change, it may not function well or may even cease to function. There is therefore a need for improvements to the available equipment.

Design of Alternate Equipment

(a) *Butane Characteristics:* Since butane is 100 octane fuel, it may best be used in conventional automotive engines. Two methods of achieving this are apparent: (i) to cool the fuel into liquid state and allow it to operate in a normal gasoline carburetor, and (ii) to vapourize the butane under controlled conditions of temperature and pressure, thus to allow accurate mixing of gas with air in the carburetor.

(b) *Propane Characteristics:* Propane has an estimated octane rating of 130 and therefore may be burned in engines whose compression ratios are as high as 16 to 1. High compression thus can make use of a greater percentage of oxygen in the air-propane mixture and can be somewhat more efficient than other types of engine. Application of this principle may be made (i) in converted gasoline engines whose compression ratio has been raised above 8 to 1 and in converted diesel engines with the further addition of an ignition system and (ii) in diesel engines as a fuel additive or in what is often called "dual-fuel" where the diesel ignition supplies the start of combustion and the propane provides variable power through a carburetion system.

Experimental Application

Since the simplest and least expensive technique for butane utilization consists of vapour withdrawal it was decided to run a series of tests with a heated tank, simple pressure control valve and elementary mixer for a gasoline engine. The gasoline equipment was modified simply to selectively bypass the gasoline. A mixer with adjustable venturi was placed on top of the gasoline carburetor, a plastic hose was arranged to carry the gas from the heated tank and a connection made to the engine cooling water. The apparatus is shown schematically in Fig. 4.

The vehicles used were started on gasoline, and when warm, the gasoline was switched off, allowing the engine to use up the fuel in the carburetor

Table I—Cutout Temperatures for Propane

	Time	*Speed*	*Load* lb.	*Horsepower*	*Temperature* °F	*Remarks*
1600	2:20	1600	94	37.5	100	Glycol hot

1:35	2500	90	56.3	82	Hot
1:45	2500	90	56.3	66	Liquid entering

bowl. As the engine began to "fade" butane was switched on and operation continued in a very satisfactory manner. The experimental tank was not insulated but this was considered necessary during cold weather. A test engine mounted on an hydraulic brake was then equipped with this apparatus and results were quite satisfactory. Tables of performance on gasoline and butane are given for this engine (Table III).

In the field of diesel dual-fuel, experiments were carried out with the assistance of the Edmonton Transit System. An older type of bus was made available for testing. Preliminary work involved the adjusting of amounts of propane to diesel by manual control. Tests on hills showed a very great increase in power when propane was allowed into the intake manifold. However, the return to normal load on the level runs caused some difficulty when manual control was used.

The engine governor in the diesel operates a rack and pinion mechanism to change the amount of diesel fuel passing into the engine. When propane was added to the idling or low speed condition, the engine tried to speed up, but the governor, being set by the accelerator pedal for lower speed, sensed the higher speed and cut the diesel injection to the off position. Without diesel ignition the propane could not ignite, and this stalled the engine.

The apparatus shown in fig. 6 was developed. The fuel pump rack was connected to a butterfly valve which controlled the pressure in the plenum chamber of the apparatus and thus controlled the amount of propane drawn in. Diesel and propane were supplied together and controlled together by the engine governor. The power increase was evident and performance was especially good on acceleration.

To discover how much power had been added, the bus was placed on a wheel dynamometer at the Edmonton Transit System. With the rack set to 75% of maximum power the bus produced 55 wheel hp at 30 m.p.h. on straight diesel. It was not possible on this model to operate at full horsepower due to the extensive modifications required.

When converted to dual-fuel with about 75% diesel and 25% propane the horsepower at 30 m.p.h. was increased from 55 to 103 hp.

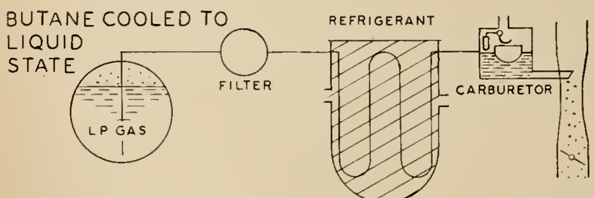
The next tests performed on the bus showed a saving in fuel. Table IV shows a typical pattern taken as an average of several 20-mile runs on dual-fuel.

Future Research

Although the techniques mentioned above are suitable for conversion of gasoline and diesel engines, some modifications and further experiments will make the applications much more useful. For example it would be more satisfactory if all of the high-pressure apparatus used in regulating the amount of LPG were placed inside the fuel tank, so that only low-pressure or pressure lower than atmospheric lines would emerge from the tank. This would eliminate much of the danger due to leaks caused by vibration and would prevent any tampering with sensitive adjustments. This system could be applied both to butane and propane. Also a satisfactory gas producing apparatus of this kind is necessary before much work can be done on the propane-diesel engine.

On the diesel side, many complaints from cities about smog have been voiced. When a diesel accelerates, extra fuel is pumped into the nozzles and is not burned effectively until the engine reaches the proper speed. Propane burns so much more readily that its addition has the possible advantage of overcoming the acceleration smoke. Some experiments in this field have been carried out in Los Angeles. The ideal diesel-propane combination may be a pilot amount of diesel for simplified diesel pumping, utilizing constant quantities of

FIGURE 3.



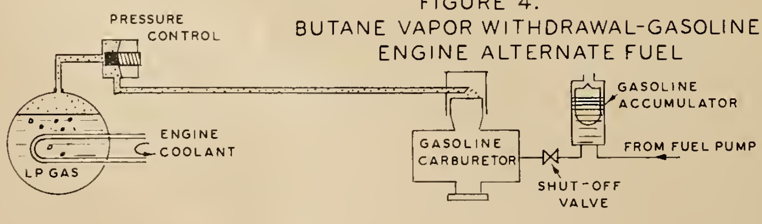


FIGURE 4.
BUTANE VAPOR WITHDRAWAL-GASOLINE ENGINE ALTERNATE FUEL

diesel fuel and obtaining variations in power requirements by throttling the propane. Information needed in this field is the proper ratio of diesel to propane for each power condition.

Conclusions

It has been found that the most straightforward technique for utilization of butane and propane is the heated tank and vapour withdrawal system. The work done on vapour withdrawal provides a simplified system for conversion with conventional piping and no unusual techniques. The diesel-propane dual-fuel engine holds promise of higher than normal efficiencies through a wide range of speeds. Research done thus far will enable operators to experiment with this technique for improved operating characteristics.

APPENDIX I

Calculations for adding heat to liquid fuel under pressure, then expanding to gas form.

Assuming initial conditions to be 35° F and 14.7 p.s.i. in the liquid form for propane:

Heat in liquid = 181.6 BTU/ #

Initially, heat and pressure are required to raise the propane to a state from which by adiabatic expansion it will be ready for carburetion. By reverse calculation, using a Joule-Thompson relation for approximating adiabatic expansion:

$$T = \frac{RT_1^2 \log_e (\gamma_1/\gamma_2)}{(Cp)m(T_{R1} - T_{R2})Tc}$$

where

T = change in temperature
R = gas constant
T_1 = initial temperature absolute
$(Cp)m$ = mean specific heat at constant pressure
γ_1 = activity constant at T_1
γ_2 = activity constant at T_2
T_{R1} = (T_1/T_c) where Tc = critical temperature and
T_{R2} = (T_2/T_c)

By bracketing and graphical extrapolation it is found that if

$$T_2 = 459.6° \text{ A}(32°\text{F})$$

then T_1 is 616.6°A (or 156.7°F) from the above expression.

Utilizing adiabatic expansion, P_1 is determined to be 150 p.s.i. approximately.

From tables,

At 10 atmospheres and 156.7°F
Heat in the liquid = 252.3 BTU/lb.
Latent ht. of vapourization = 143.1 BTU/lb.

Total heat in the vapour = 395.4 BTU/lb.

Final conditions 35°F and 14.7 p.s.i., from tables

Total heat in the vapour = 181.6 BTU/lb

Heat to be added at 10 atm. and 156.7°F is

395.4 − 181.6 = 213.8 BTU/lb.

To calculate volumes:

At 156.7°F volume of the liquid is .113 gal (Imperial)/lb.

At 32.2°F volume is 0.095 gal/lb.

Assuming a heating value of propane at 21560 BTU/lb and a 60 hp. engine at 25% thermal efficiency,

$$\text{Lb. propane/hr.} = \frac{100}{25} \times \frac{60}{21560} \times \frac{3300 \times 60}{778}$$

$$= 28.4 \text{ lb/hr.}$$

$$\text{Maximum volume} = 28.4 \times .113 = 3.2 \text{ gal/hr.}$$

with the above data a heat exchanger may be designed to take a pressure of 10 atmospheres. An immersed pump of the flexible metal diaphragm type is suggested for boosting pressure from that within the supply tank to the pressurized heat exchanger.

LOAD—FREQUENCY CONTROL SYSTEM OF THE MANITOBA HYDRO-ELECTRIC BOARD

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May, 1960.

K. H. Williamson, JR.E.I.C.
Engineer,
Electrical Section,
Engineering and Construction Division,
The Manitoba Hydro-Electric Board,
Winnipeg.

Interconnection between neighbouring power systems is a natural evolutionary process which affords each of the member systems the inherent advantages of economy and reliability of a large generating system without the encumbent and often disproportionate expense of added power developments which can accrue to the individual system in attempting to provide a degree of these advantages for itself. Interconnections offer not only the attractions of greater diversity and reliability through the sharing of generating capacity but also the economy of lowest incremental energy production which can be realized on a larger, more broadly dispersed system and the deferment of capital investment for new machine installations.

IN 1956 The Manitoba Hydro-Electric Board (M.H.E.B.) and the Northwestern Region of The Hydro-Electric Power Commission of Ontario (H.E.P.C.O.) interconnected their respective systems with an 83 mile, 138 kv. single circuit tie-line. Three years later a 170 mile, 230 kv. line, to be operated initially at 138 kv., was projected for completion in 1960 to interconnect the networks of the Saskatchewan Power Corporation (S.P.C.) and The Manitoba Hydro-Electric Board. This three system interconnection embraces a vast area. Three time zones are involved and this fact emphasizes the very real advantage of capacity sharing or availability during the time-displaced load peaks.

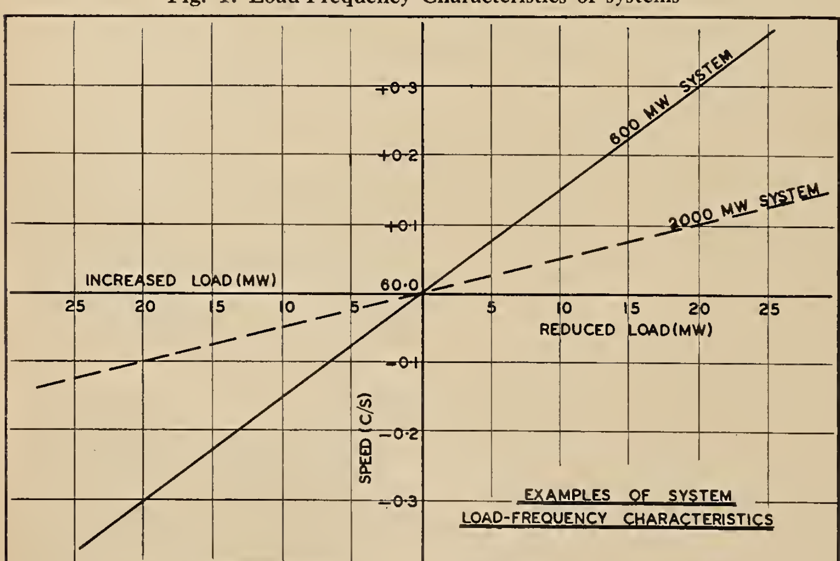
The current-1960 generating capabilities of the S.P.C., M.H.E.B. (including The City of Winnipeg Hydro-Electric System) and the Northwestern Region of the H.E.P.C.O. are approximately 500, 850 and 600 mw. respectively. The first interconnection results now in a combined system capacity of some 1450 mw. and broadly speaking could improve regulation proportionately to the increased capability. By the second interconnection, all three benefit, but especially the S.P.C. which has joined an effective system of nearly three times its own capacity with the corresponding advantages.

By taking liberties in detail to illustrate the principle of the point we are able to represent the load-frequency characteristics of a system by the straight line relationship in Fig. 1[1]. For the example shown, the solid curve could represent the characteristic for S.P.C., H.E.P.C.O., or M.H.E.B., taken as a separate isolated system. As 60 c/s is taken as system frequency, excursions from this value are measures of either excesses or deficiencies in generation. Points on the load-frequency curve of a member system could be obtained by dividing that system into two parts with only a single tie left for interconnection of the two parts. The tie is then loaded to some pre-arranged value, tripped out and the consequent frequency deviation measured. (This method has been employed to determine the correct value of frequency bias for a system.) Fig. 1. then places frequency deviation (usually from 60 c/s) in the ordinate and load deviation, the normally independent variable, in the abscissa.

Fig. 1. also suggests the reduced slope obtained by the double interconnection, i.e. a system of some 2000 mw. Singly, then, the member companies could expect a one-tenth cycle deviation for a 6 or 7 mw. load change. The combined system suggests something like a 20 mw. change would be required before a frequency deviation of one-tenth cycle would occur.

Unfortunately, the simple joining of the member systems by tie-lines does not in itself realize the previously noted advantages. Regulation of tie-line flows is mandatory both for normal operating conditions and during times of unscheduled and unforeseen disturbances in any one of the interconnected systems that may result in tie-line flow fluctuations. Because manual control could never effectively supply the necessary rapid corrective measures, control systems continuously operating upon devia-

Fig. 1. Load-Frequency Characteristics of systems



tions from preset values of tie-line load, system frequency, or both, have been evolved to provide the necessary regulation.

When the H.E.P.C.O.-M.H.E.B. tie-line was completed, load and frequency control equipment was installed for the Manitoba end at the Seven Sisters hydro-electric generating station some 60 miles east of the City of Winnipeg at the western terminus of the interconnecting tie-line. At this time, system dispatching was carried out largely at Seven Sisters so the newly installed load and frequency control equipment found itself conveniently located.

Control Equipment

With the centralizing of system dispatching on the Manitoba System in the new head office building of the M.H.E.B. in Winnipeg, together with the advent of the second tie-line, in this case with the S.P.C., suitable control equipment was required for the new dispatch office. This included the various recording, measuring, scheduling, annunciating and telemetering equipment. The greater part of the generator control equipment originally purchased for the H.E.P.C.O.-M.H.E.B. tie-line functions in the same way but now with operation based upon information from two tie-lines telemetered from the Load Dispatch Office.

The general arrangement is shown schematically in Fig. 2. The S.P.C. and H.E.P.C.O. tie-lines are metered at the Brandon and Seven Sisters Generating Stations of the M.H.E.B. respectively. From these points, the megawatt flow is telemetered to both concerned parties.

At Seven Sisters the quantity is metered and telemetered separately for each participant because of the dissimilarity of the H.E.P.C.O. and M.H.E.B. telemeter systems. Both are, however, of the high speed (0-90% full scale in 1 sec.) frequency type modulating two (main and standby) frequency-shift power-line carriers for the H.E.P.C.O. and two (main and standby) amplitude-modulated tones for microwave radio transmission, for the M.H.E.B.

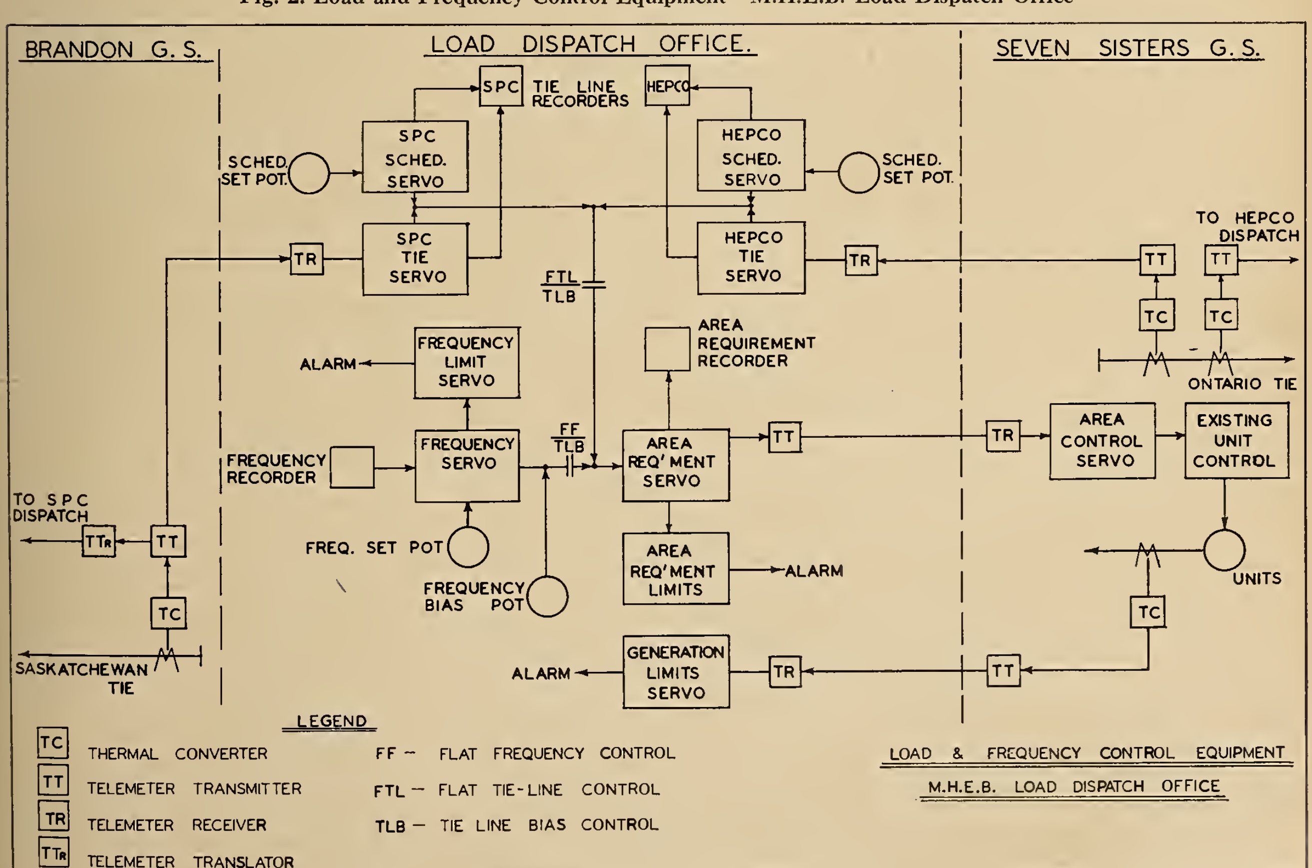
Brandon

At Brandon, a single thermal convertor-telemeter transmitter arrangement is employed to modulate powerline carrier voice-frequency, frequency-shift equipment in both directions. Due to the fact that the S.P.C. telemeter system could be made to operate in the range 7.5-17.5 impulses per sec. and the M.H.E.B. system operates at 15-35 cycles per sec., a simple frequency-halver (telemeter translator) equipped with relay output, was constructed to be driven by the 15-35 cycle unit. This results in both a telemeter cost saving and calibration simplification.

Each of the several M.H.E.B. telemeter receivers convert the variable frequency signals from the transmission channels back into millivolts. These are then tied into the tie-line electronic-bridge servo-mechanisms. A similar signal based upon the position of the schedule set potentiometer positions the schedule servos. The outputs from the tie-line and schedule set retransmitting slidewires are compared. (See Fig. 3). If no signal is produced (the two slides at the same potential), the tie-line flow agrees with the schedule setting and no correction signal is forthcoming. Scheduled flow and tie-line flow are displayed upon two-pen potentiometric electronic recorders for each tie-line.

It will be observed that the schedules can be set individually for each tie-line. This avoids the possible confusion which occurs when net deviation is employed, the operator having to contend with net interchange instead of the actual schedule values. The scheme is readily expandable to cater for new interconnections or for additional ties to existing interconnected systems. The error signals from the two tie-line systems are then algebraically combined before being fed into the area requirement servo, thus automatically

Fig. 2. Load and Frequency Control Equipment—M.H.E.B. Load Dispatch Office



providing the overall error correction.

Frequency Error

In a similar fashion to the above, frequency error is measured by comparing the frequency set point value to that actually appearing on the system. The resultant error signal is combined with that of the tie line resultant flow error before being passed on into the area requirement servo. The frequency error signal may be modified or 'biased' by the setting of the frequency bias potentiometer which is necessary when the tie-line bias mode of operation of the load and frequency control equipment is employed.

The combined error signal then is passed to the area requirement servo which interprets the error signal and decides whether the M.H.E.B. area is deficient in or has excess of generation and passes the correcting signal along (via high speed frequency telemeters) to the control equipment at Seven Sisters which provides the necessary 'raise' or 'lower' signals to the governor synchronizing motors of the generator units under control. Adjustable 'high' and 'low' limit alarms fed from a retransmitting slidewire of the area requirement servo and an area requirement potentiometric recorder are provided. A return telemeter circuit measuring the output of the units under control verifies at any moment that the control action defined at the Area Requirement Servo is in fact being carried out.

Four 27 mw. hydraulic turbine driven generators are under control at Seven Sisters at the present time. All, one or any combination may be placed on control. One unit (any one of the four) is selected as the so called 'master' unit, while the others are allocated their share by load dividing equipment, in proportion to the master unit resulting in an equal distribution at all times.

As the dispatch office equipment has been built up of simple, straightforward components, the later addition of Time-of-Start and Rate-of-Change controls to the schedule servos to permit automatic and smooth loading of the tie-lines will be a relatively simple matter. Likewise, Proportional (Fringe) and Reset (Sustained) equipment can be added readily to modify the Area Requirement output signal. The reset control sets the rate at which the control will correct a permanent or sustained load change. The Proportional control determines the portion of Area Requirement to be corrected immediately by control action, i.e. load changes of short duration.

The three classic methods of control—Flat-Frequency (FF), Flat Tie-Line (FTL), and Tie-Line Bias (TLB) are available. Many excellent papers[1-5] have been written on the principles, techniques, advantages and disadvantages, etc., so they will not be dwelt upon in detail here. It will be observed in Fig. 2 that when, for example, the Flat-Frequency mode is desired, action to the machines under control will be implemented only when deviations from the frequency set point appear, the tie-line servo equipment being switched out. Likewise, when Flat Tie-Line operation is desired, the frequency servo equipment is rendered ineffectual and tie-line flows or rather the deviations therefrom become the controlling quantity. Tie-Line Bias operation makes use of both tie-line flow and frequency information.

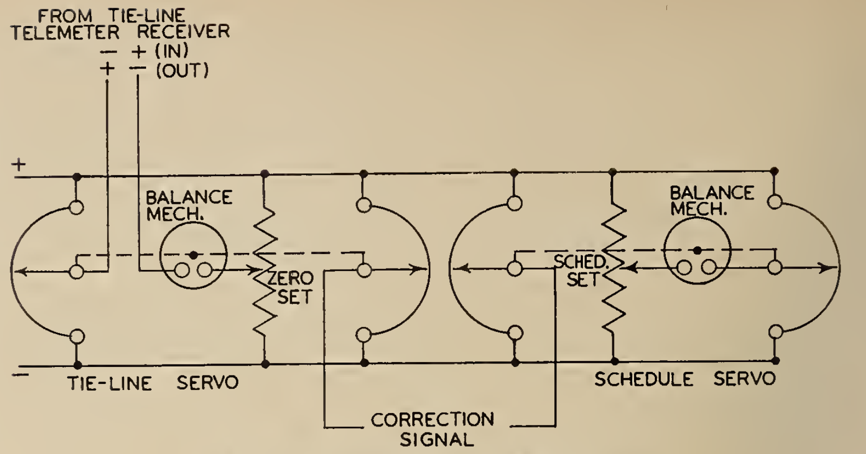


Fig. 3. Tie-Line Flow and Schedule Servos

It will be obvious that if Flat-Frequency operation were to be applied at both ends of a tie-line, schedules could never be maintained. Likewise, Flat Tie-Line at both ends would result in chaotic system frequencies and consequent time errors. One member operating on Flat Tie-Line and the other on Flat Frequency is a workable and often satisfactory mode of operation. Tie-Line Bias operation at both ends has much to offer, at least theoretically, and has found favour in many interconnections.

A system operating on tie-line bias control, at the correct value of bias, would immediately identify whether a load change on the interconnected system had taken place in its own area or not. If not in its own area, it would refrain from any attempt to restore either tie-line or frequency to normal. Any change at this time would only have to be undone later as each area is responsible for satisfying its own load changes and it has been stated that the change occurred in another area. If the load change in the other area had been a sudden increase, the unaffected tie-line bias area, say with a power-frequency characteristic similar to that shown in Fig. 1. would contribute about 7 mw. per .1 cycle deviation (also the correct bias value for this area) which would be its contribution to restoring system conditions. The result is both smooth and direct. If the load increase had been in the area in question operating on tie-line bias, the controls would have immediately called for a raise in output from the units under control.

Flat Tie-Line and Flat-Frequency characteristics are the limiting (maximum bias and zero bias respectively) values of the Tie-Line Bias characteristic. It can therefore be concluded that even an incorrect bias setting offers a more desirable regulating action than a combination of Flat-Frequency-Flat Tie-Line.

The very real advantage in bias operation throughout an interconnection is that no single station or area acts as the master frequency controller and that each area responds and provides for its own load changes. Hence an area operating with controlled machines with different response speeds to those in another area poses no problem under tie-line bias operation. As the Northwestern Region of The H.E.P.C.O. is 100% equipped with hydraulic machines; the M.H.E.B. 67% hydraulic; and the S.P.C. 100% thermal, tie-line bias will receive very close attention.

Discussion

BUSINESS TRAINING FOR PROFESSIONAL ENGINEERS

R. J. Bedard,
Former Editor of "Genie Construction". The Engineering Journal, November, 1959, p. 75.

Further discussion by B. M. M. Carpendale (The author replied in our February issue to earlier discussion.)

I find myself agreeing heartily with most of Mr. Bedard's remarks, but still in disagreement with his proposal.

To begin with, I do not agree that the mode of application of the methods of science is in any way different whether the problem involve men or machines; the snag is that the methods must be used correctly and thoroughly, and this means stating goals clearly, stating the problem clearly, (and correctly), and taking *all* factors into account. This, of course, includes human factors.

The engineers who to our shame (as Mr. Bedard says) have been responsible for much industrial discord made two main mistakes:

1. They looked at the human being as an inefficient machine instead of an entirely different type of productive resource. Man is less effective at doing most of the things a machine can do, but he has capabilities which a machine has not, and these were not employed;

2. They did not take a broad enough view when assessing efficiency, and only took immediately obvious costs into account.

Possibly these shortcomings could have been put right by the engineering schools, but not many of them understood the trouble themselves.

In the second place, I personally am not hostile to the idea of inculcating "leadership" in an engineering school, (if it is possible at all). By "leadership" I assume Mr. Bedard to mean the responsible attitude of the officer (or the "true aristocrat") towards those in his charge, together with an idea of the processes involved and the pitfalls which lie in wait for those who have to try to get things done through people. This is all that could be aimed for; the divine spark which animates a Napoleon cannot be produced to order. However, there are three main difficulties in attempting to generate even a degree of competence in leadership:

1. At present we have submitted to various pressures and so filled our timetables with technical matter that a major change in policy would be needed to give enough time to this "subject" in undergraduate years;

2. It would be an equally great change in policy for us to accept that it was our job to undertake it at any level. Hitherto we have felt that this sort of attitude and knowledge is needed by all leaders in our society, and not just for engineers;

3. What should we teach? In management there is on the one hand a mass of not very exciting or profound knowledge and technique, given in the many text books on the subject. This is what is taught in most schools of management. It is quite suitable for home study, and we do not feel it should take up undergraduate time at a university. On the other hand, for would-be leaders, there are:

i. The attitude of enterprise and responsibility as glorified by Kipling and Miss Ayn Rand (Atlas Shrugged) and

ii. The type of thinking portrayed by writers such as Peter Drucker and Chester Barnard.

As to the attitudes, these are aimed at in certain sorts of schools, by matters neither obvious nor direct, and also ideally in office training. I have never heard of this being attempted by a university, although this is probably not a good reason for not trying. A better reason might be that university training has been traditionally concerned with the brain (or mind?) rather than with attitudes and emotions.

The "thinking" concerned is very much the business of a university but at a graduate level. Although it is not too difficult for undergraduates, it requires too much background knowledge (of a non-university type) to attempt, in an already crowded undergraduate course, to more than suggest some patterns of thought. As a graduate course it seems to be a duplication to compete with management schools.

Is Mr. Bedard really making the point that Universities are producing the leaders of the nation and therefore should give training in leadership? This will involve a great deal more than the knowledge acquired in a school of management.

HIGHWAYS RESEARCH ACTIVITIES IN CANADA

Gordon D. Campbell, M.E.I.C.
Director of Technical Services, Canadian Good Roads Association, Ottawa, Ontario
The Engineering Journal, December 1959, P. 43.

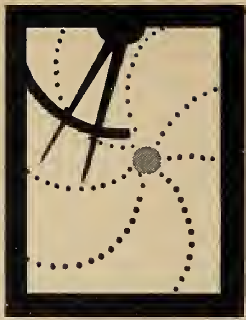
Discussion by G. G. Meyerhof, M.E.I.C.

This interesting paper is very timely because of the great expansion of Canadian highways now in progress. The importance of this subject can be seen from the fact that over 15% of the total expenditure on construction in Canada is in the field of highway engineering, which now exceeds the sum of one billion dollars per year. As the author points out, the outlay of only one-tenth of 1% of this sum for the purpose of research on highway problems in Canada is indeed a very modest investment when the great benefits of this work are considered. In this respect it is of interest to note, however, that the same amount of one-tenth of 1% for research holds also in the other branches of civil engineering activities in Canada.

The author's plea for more highway research in this country should be heartily endorsed. While *basic* research in this field (i.e. long-term research in the fundamental scientific principles) carried out in other countries could indeed be applied in Canada, the results of *applied* re-

(Continued on page 112)

Automation and Control Engineering in Canada



THE VERY diversified fields in which the instrument engineer may expect to operate were indicated quite extensively at the recent symposium on instrumental methods of analysis (Instrument Society of America) held in Montreal.

The program was international in scope and dealt with current practice in Europe and the United Kingdom, though most of the contributors to the technical sessions were from Canada and the United States. Most of the papers were preprinted*, but circulation was limited, and it may be of interest to summarize the main fields in which contributions came from Canadian sources.

The main divisions of the program, in addition to a general session, were: biomedical instrumentation; gas chromatography; spectrographic methods of analysis; electrochemical methods of analysis; physical and chemical methods of analysis; sampling systems; and nuclear instrumentation.

In addition to medicine and nuclear energy, the petroleum and chemical processing industries were prominently represented, but there were also contributions concerning the pulp and paper, metallurgical, textile, and other industries.

General

A wide field was covered by Prof. G. L. d'Ombrain, McGill University, Dr. W. H. Gauvin, Pulp and Paper Research Institute of Canada, and Dr. Leo Marion, National Research Council. More specifically, N. Safran, Provincial Institute of Technology and Art, Calgary, described the industrial laboratory course given at the Institute, and mentioned particularly the training of technicians in instrumental methods of analysis. This is of special local importance, because of the large petroleum and petro-chemical industry, but the subject of training instrument technicians is of very general concern. Dr. F. A. L. Anet, University of Ottawa, described the main principles of nuclear magnetic resonance (NMR) and electron paramagnetic resonance (EPR), which are new forms of spectroscopy in the frequency region corresponding to radio and microwaves. High-resolution NMR is becoming nearly as important as UV and IR spectroscopy.

Biomedical Instrumentation

In the field of medicine, Canadian contributors described several developments. One of these is a transformer-coupled capacitance-resistance bridge for measuring the dielectric properties of human blood at 100 kc./sec. A technique for investigating the human heart in action involves the injection of radio-opaque dyes in conjunction with dynamic radiographic recording techniques. A problem was to synchronize the injection of dye to the heart beat; this was solved after investigation of many methods, such as applications of the electrocardiogram or pressure changes outside or inside an artery, by obtaining a signal periodic with the cardiac rate from a light source and photo conductive cell arrangement that senses the variation in blood flow through the lobe of the ear.

Neurophysiologists are greatly interested in the time pattern of pulses from a living brain cell, which represent individual discharges or depolarizations of the neuronal unit. A new statistical data processing system, consisting of a simple digital computer with associated input and output devices, has been devised to act as a frequency distribution analyzer and as an event correlator, with ability to extract and display instantaneously complex time relationships between the electrical impulses.

Continuous recording of eye movements, and what the eye sees, is carried out by two television cameras: one views the scene, the other follows eye movements by means of a light reflection from the cornea. The two outputs are combined to show, on a cathode ray tube, the scene with a superimposed spot of light that shows where the eye is looking. A matrix of photocells on the monitor tube can note the various points of fixation of the light spot, and the photocell output can be used to operate various circuits. The successive eye fixations can be recorded on punched tape, and subsequently analyzed by computer or used for automatic control of stimuli. Gating and coding circuits are used for the recording. The photocell output fires the first of six 22-millisec. one-shot square-wave multivibrators connected in series, so that the falling phase of each square wave triggers the next multivibrator in the chain. The outputs of the multivator are connected in parallel, and each photocell both triggers the cascade and operates coded-gating circuits, so that the final output signal is in the teletype seven-element code. These signals are recorded on a teletype printer-perforator so that each eye fixation is represented by a symbol.

Gas Chromatography

The field of gas chromatography is of particular importance to the process industries, and is one of the most rapidly-developing techniques. Great interest was shown in the technical session and in a panel discussion of the subject, which is too involved to deal with in detail here.

Spectrographic Analysis

Heavy water is an expensive material, and it is important to detect contamination entering a heavy water system or loss from it. An instrument has been designed to analyze liquids by automatically measuring their infra-red absorption at three or more wavelengths. Specifically, it is used to monitor the isotopic purity of heavy water, but it can be used to

*Proceedings, 1960 Symposium on Instrumental Methods of Analysis, Montreal, 1-3 June 1960 (sponsored by Montreal Section, Instrument Society of America.)

detect changes in deuterium content of ordinary water or to monitor the heavy water content of the air.

In the field of data processing for infra-red spectroscopy, an analogue computer was described which will: plot spectra of any required size; convert %-transmittance signal from spectrometer to absorbance units; integrate absorption bands.

A problem of general concern is the determination and identification of polycyclic aromatic compounds in the atmosphere, since many of these materials are highly carcinogenic. Paper chromatography is used to separate traces of the materials obtained from air samples, and the problem of identification and estimation is solved by using highly-sensitive physical measurement of the different characteristic ultra-violet fluorescence spectra.

The application of gamma-ray scintillation spectrometry to nuclear reactor technology was discussed, with a description of the useful NaI(Tl) spectrometer. Such instruments are based on a combination of a scintillator and photomultiplier with a pulse-height analyzer.

A more general industrial application described was the control of composition of all alloys produced at a major plant in the aluminum industry by means of direct-reading spectrographs. The methods, using both light emission and X-ray emission instruments, are being extended to the production of non-metallic materials such as alumina. Automation and control systems are used to handle large numbers of samples.

Difficulties experienced with scanning mechanism for a densitometer used in chromatographic work led to the development of an economical and reliable recording instrument, using a standard densitometer, a strip chart recorder, light source, and photo cell. The strip chromatogram is attached to the paper chart of a strip recorder with cellulose tape; the chart thus moves the strip which is scanned by a suitably mounted photometer.

Electrochemical Analysis

It was pointed out that electrochemical methods of analysis are not basically new, since they have been used since the days of of Faraday. However, there are many new developments in the field. A good general review of techniques was presented, as were specific applications.

The pulp and paper industry is one of the widest users of continuous pH (and ORP). The extent of such applications was investigated by means of a questionnaire directed to over a hundred paper companies in the United States and Canada, and the results of this survey were presented. Much valuable information was gathered.

The natural gas industry, now very important in Canada, has quite a problem with the control of sulphur in gas to specified limits. An analyzer has been developed which is based on amperometric titration. Sulphur compounds are determined by reactions involving free bromine or iodine liberated by electrolysis of inert salts as long as the reaction proceeds. The generation currents are a measure of the halogen released, and hence the sulphur contents may be found.

Two types of polarographic instruments have been developed for use in metallurgical plants to help control purity of zinc electrolyte. Two voltages are applied alternatively to the electrodes of the instruments; the difference in electrode current at these two voltages is measured, and the instruments calibrated for concentration in terms of current difference.

Also in the field of metallurgy, a simple method has been developed for determining relative saturation of air in alkaline solutions used in processing uranium and gold ores. It is based on the diffusion current produced by oxygen from the dissolved air when a sample of the solution is subjected to a controlled potential applied to a calomel electrode and a platinum cathode.

Nuclear Instrumentation

Several of the papers on nuclear instrumentation were presented by Canadian authors. A nuclear reactor program requires a lot of chemical analyses, and a description was given of several examples of instrumental methods used. These included emission spectrography, X-ray fluorescence spectrography, flame photometry, Polarography, and chromatography.

Canada concentrates on the heavy-water-moderated nuclear reactor fuelled with natural uranium for economical nuclear power production. Solid and gas mass spectrometry are used in investigations of nuclear changes in the fuel which affect various operating conditions. Also of concern is the need for accurate trace analysis, for which nuclear and mechanical instrumentation has been developed to detect alpha, beta, and gamma emitters.

The use of nuclear techniques by the oil industry has led to developments within the industry. One Canadian company has designed a simple liquid scintillation counter to measure radioactive carbon and tritium. The instrument uses sensitive discriminators to eliminate the need for linear amplifiers. Though the subject presented at the session was the technical design and operation of the instrument, it is noted that this was used in a program of tracing water-flood in an oilfield by radio-trace methods.

Physical and Chemical Analysis

Quite a wide field of instrumentation was covered in the session on physical and chemical methods of analysis. Among Canadian applications were the methods of control used in the advanced effluent treatment plant of an oil refinery. This is a biological oxidation plant with chemical flocculation and ozone treatment. Automatic samplers are required to provide samples for laboratory control on a 24-hour schedule, because of wide variations in the waste. Several of the instruments used in this control system were described.

For the pulp and paper industry, a portable electronic brightness meter of the sphere photometer type was described. This has two calibration points which have to be adjusted only daily, and operates on the pull principle, with an a.c. V.T.V.M. as an indicator. Pulp and paper brightness is measured with accuracy of ±0.3%. A calibrated potentiometer serves as a read-out device.

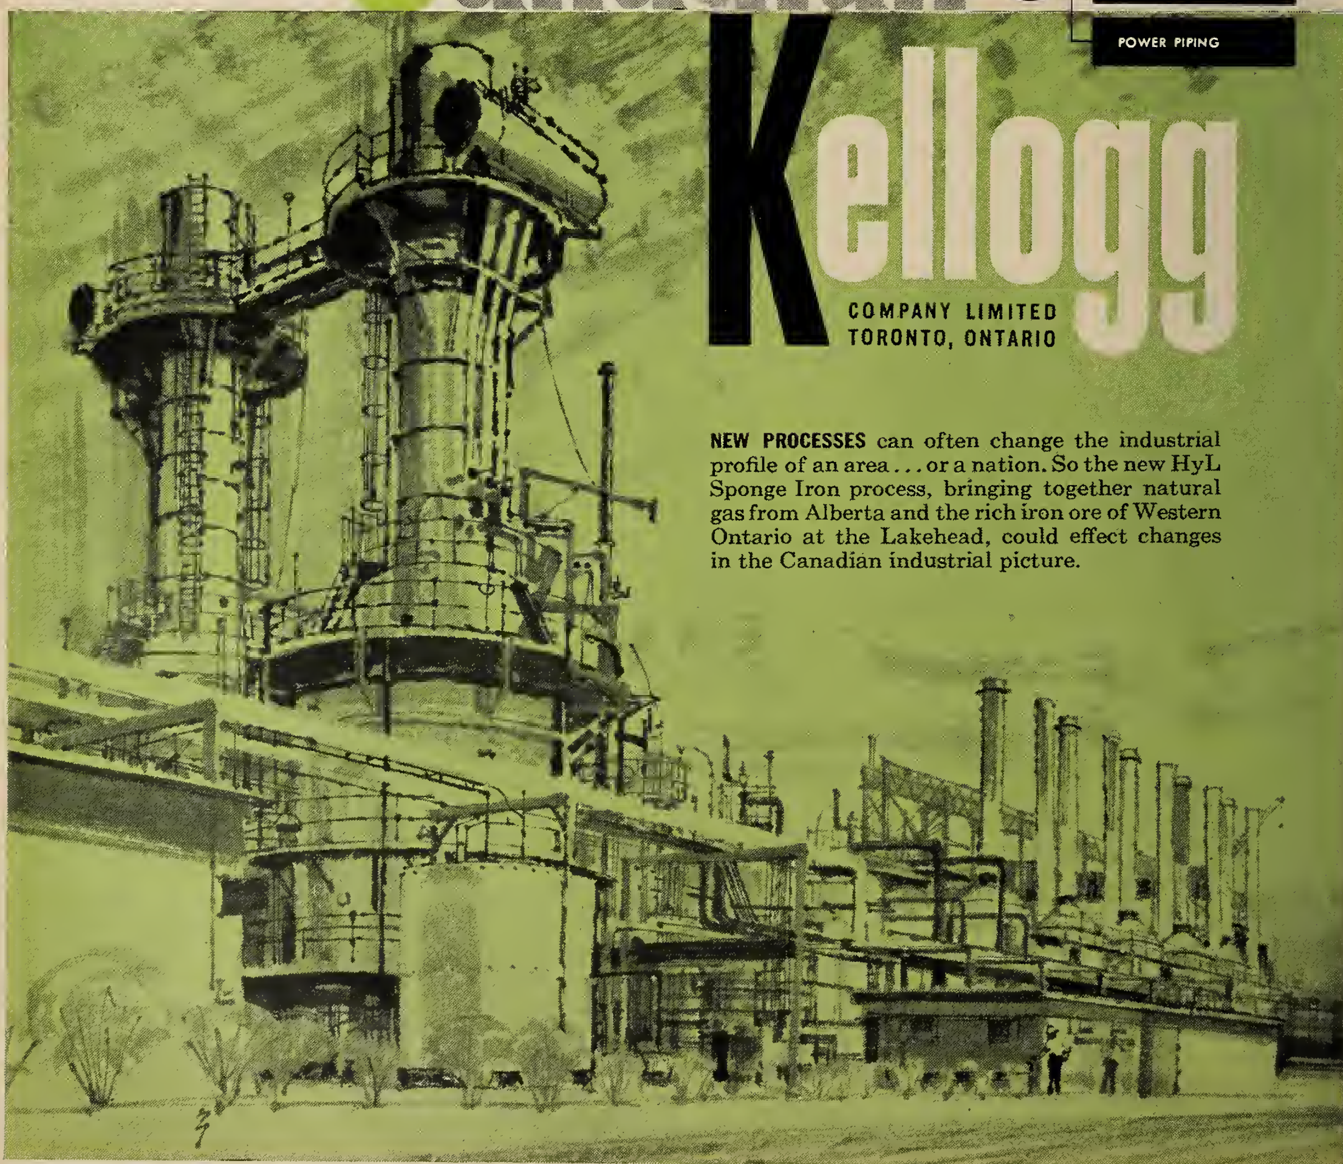
Sampling Systems

The practical value of an analyzer depends on the provision to it of the right sample, in the right form, and many cases of difficulty with process analyzers can be traced to incorrect sampling systems. With complicated processes one may have to invest a higher than usual proportion of capital in a well-designed sampling system if the full benefits of analysis are to be realized. The papers in this session discussed in some detail the various considerations of this nature and some of the snags that are met in field assembly or in specification of sampling systems.

Conclusion

The Canadian contributions to this symposium have been outlined very briefly. The many contributions from the United States and Europe were of equal interest to the instrument engineer.

We are indebted to G. B. Hall of Canadian Industries Limited for the article "Corrosion Problems in Chemical Plant Instrumentation" which appeared in our May issue.



Canadian Developments

Northumberland Strait Crossing Feasibility Study

The problem of spanning Northumberland Strait, nine miles of water subject to considerable tidal variation and severe icing in winter, has been on the minds of engineers since 1891. Recently Major-General H. A. Young, M.E.I.C., Deputy Minister of Public Works, Charlottetown, P.E.I., made public a progress report on feasibility studies for the Northumberland Strait Crossing, including proposed location and alternative designs as well as information on weather and tide conditions.

Construction of such a causeway or bridge would represent a unique accomplishment. The Canso causeway, to take just one example of similar existing structures, is only one eighteenth of the length of the proposed Northumberland crossing. Since March, 1958, the Federal Government has spent almost $600 thousand on this investigation and has called on the Department of Mines and Technical Surveys' Hydrographic Services; the Department of Public Works; and the National Research Council. Should such a project be undertaken, it would involve the Departments of Transport and Fisheries as well as those already mentioned and the Canadian National Railways.

A completely closed causeway would affect the high and low water levels of the Strait and the range of tide in the principal harbours. It would also have substantial effects on short line conditions. Indemnity would have to be paid for land actually flooded and cottages made inaccessible. The total estimate of indemnity is close to $3 million. Remedial works to harbours and channels would call for another $12.5 million. It is believed that a quasi-stationary strip of ice would form to either side of the causeway early in the winter, thus protecting the structure from fast moving ice floes, however the problem of freezing sea spray on the causeway in the early winter months would have to be dealt with.

Borings have been made in the main quarry site and alternate quarry sites on P.E.I.; on two possible lines of crossing to investigate foundation conditions; and on possible lock positions and channel approaches. A test quarry has also been opened in the Bayfield area of N.B. to test for core and armour stone, both of which have been found to exist in sufficient quantity.

The proposed location of such a crossing is a straight line between Jourimain Island and Borden Point, based on minimum fill requirements, availability of fill, good sea bed conditions, and existing road and rail facilities in the vicinity.

The causeway design calls for a crest width of 80 ft. for highway and rail traffic, with a rock-fill constructed to an elevation of minus 20 Canadian Geodetic Datum to form a sill. Causeway slopes would be protected by a layer of armour stone, the 3 to 6 ton blocks placed in layers by cranes to interlock to the greatest extent possible. The design includes one major navigation lock and a secondary lock for small crafts.

A bridge crossing would have the obvious advantage of maintaining present tidal conditions. It would be built to a length of 37,280 ft. and would provide a two-lane highway and single railway. A high level section of 960 ft. would provide a 150 ft. clearance in the central 400 ft. A combined bridge and causeway has also been proposed, with the knowledge that the Strait could be reduced 20 to 25% without increasing high tides very much. In this case, the bridge section would be 6400 ft. Locks would be required to the same degree as for a full causeway.

Quebec Construction Prospects Outlined by CCA President

The 1960 construction program is expected to reach $1,777 million, or nearly one quarter of the Canadian total of $7,317 million, according to Jack M. Soules, president of the Canadian Construction Association. The program breaks down into three roughly equal categories — housing, other buildings, and engineering projects. Housing will be below last year's volume notwithstanding a sizeable carryover of dwelling units being built at the beginning of the year. However, commercial, industrial and institutional construction is expected to increase in volume in 1960, despite completion of seaway projects.

Canadian Space Research

The National Research Council reports that Canada's interest in space research at the present time is purely scientific and that her central preoccupation is with the outer fringes of the earth's atmosphere and neighbouring regions. The International Geophysical Year rocket studies, in which Fort Churchill was involved, established that the density at higher altitudes is much greater than had been thought. This supports the idea that the earth's atmosphere merges with the sun's and never descends to pressures approaching those of interstellar space.

More than 100 rockets were launched from Port Churchill during the Geophysical Year and the latter part of 1959, four of which were instrumented by Canadian scientists. A joint U.S.-Canadian program is continuing there, mainly for the study of cosmic rays, the ionosphere, the aurora, and the physical and chemical properties of the Upper Atomosphere. Canadians are using their own rockets, and a committee under the direction of Dr. D. C. Rose, head of NRC's cosmic rays section, will coordinate the investigations.

Canada is not making space probes of her own, but she will participate in the activities of the Committee on Space Research, of which both the U.S. and the U.S.S.R. are members, and the United Nations Committee on the Peaceful Uses of Outer Space.

Professional Engineer on College of Medicine Faculty

The University of Saskatchewan has appointed a professional engineer to the faculty of the College of Medicine as a result of very productive research in the field of medicine carried out through cooperation between the College of Medicine and the College of Engineering at the university.

Blaine A. Holmlund, lecturer in electrical engineering, will also become lecturer in biomedical engineering in the Department of Medicine. Some of the products of this combined research at the University of Saskatchewan are: a method to record instantaneously the time taken for blood to circulate between the carotid artery in the neck and a variety of points in the brain; the use of the heart-lung machine in "open heart" surgery with an automatic control system which replenishes the reservoir of blood in the machine precisely as needed; and an improved method of determining the tensile strength of delicate sutures used in eye surgery.

International News

New Space Academy

An International Academy of Astronautics, to provide world technical leadership for the peaceful conquering of space and to serve as a clearing house for astronautic information, has recently been established by the International Astronautical Federation and the Daniel and Florence Guggenheim Foundation.

Dr. Theodore von Karman, dean of American astronautical scientists and chairman of the Founding Committee authorized to establish the Academy at last year's London meeting of the Federation, has said that the association will provide "what may be the only intellectual meeting ground" for the scientists and engineers of all nations, East and West.

In his statement announcing the grant for the new association, Harry F. Guggenheim, President of the Daniel and Florence Guggenheim Foundation, said that the Foundation's support of the Academy resulted from its long history of interest in aeronautics. In addition to its Goddard rocket research projects, the Foundation supports research centres in jet propulsion at Princeton University and the California Institute of Technology, an Aviation Safety Centre at Cornell University, an Institute of Flight Structures at Columbia University, a Centre of Aviation Health and Safety at Harvard University, and provides a number of fellowships in the Flight Sciences.

Among the distinguished initial members is Professor John Cobb Cooper of McGill University, General Counsel of the International Air Transport Association; Dr. A. C. B. Lovell, Director, Jodrell Bank Experimental Station, England; Dr. J. A. Van Allen, of the State University of Iowa, discoverer of the Van Allen radiation belts around the earth; Professor J. Ackeret of the Institute of Technology, Zurich, world-famous aerodynamicist; and Professor A. N. Nesmeyanov, President of the U.S.S.R. Academy of Sciences.

It is expected that the Academy will be made an active concern at the Stockholm meeting of the International Astronautical Federation in August and that permanent headquarters will be in Paris.

Highway Construction in the Sahara

French engineers and chemists working on the problem of extensive road construction in the desert have made notable progress. Soil stabilization with sodium lignosulphite and other chemical compounds has been carried out successfully. The moistureless soil of the Sahara treated with limited quantities of water and relative portions of the stabilizing compound becomes solid and water-tight. Some of the local gypsum is also used as a stabilizing agent.

In order to get the necessary water for road construction, wells have been drilled to depths of from 330 to 4,000 feet. Chemicals have been brought in by air, and construction sites have been planned on high output basis, in order to make the operation economically feasible.

Whereas up to 1955 a simple road network of 6,200 miles was sufficient, only 300 miles of which were surfaced, the discovery of natural gas pockets and oil fields in Hassi-Messaoud and Edjele have necessitated a whole new roads system. By the end of 1960, about 1,100 miles of new road will be completed, and construction is now progressing at the rate of 250 miles per year.

U.K. Motor Vehicle Industry Expansion

The current expansion plans of the UK motor vehicles industry provide for the expenditure of approximately $500 million. A number of companies have agreed, after discussions with the Board of Trade, to locate their new plants in "designated" areas as defined in the Local Employment Act, districts of greater than average unemployment.

The British Motor Corporation will raise its annual output from 750,000 to a million vehicles by the end of 1962 and will establish new factories in Scotland and South Wales. They will produce complete heavy commercial vehicles and tractors in Scotland, and car production will be increased by making the fullest use of the company's existing factories, especially in the Midland and Oxford areas. The Ford Motor Company has agreed with the Board of Trade to build a large integrated motor factory on the outskirts of Liverpool, while Vauxhall and Standard-Triumph are also considering expansion and relocation. According to the agreement, companies building in these special areas will be eligible for government assistance.

American Levacar discussed at ASME meeting

Engineers congregating in Dallas in early June for the American Society of Mechanical Engineers sessions were introduced to the new American levacar, a vehicle which may one day glide from one city to another at 500 m.p.h. on a thin film of compressed air. The car is designed to be mounted on flat-topped tracks similar to railroad tracks. Lifted from the track a fraction of an inch by a steady stream of compressed air against levapads which fit around the track, the frictionless car is propelled by an aircraft engine.

Japanese Prefab Plants for Export

The Japanese industrial machinery industry is now exporting pre-fabricated plants and factories for a wide variety of uses, chiefly to the countries of the Far and Middle East. They include units for the processing of pulp and paper, plastics, cement, sugar, textiles and textile synthetics. The export business ranges from supplying, laying out, and erecting abroad to supplying just a single unit of machinery or group of machines, although about 65% of the industrial machinery export is in plant units.

Swedish Research Reactor

The country's third reactor, the R2, is now in operation at Studsvik on the Baltic Coast, south of Stockholm. The reactor, a materials testing unit, is the largest research reactor in operation in Europe. The $6 million reactor is intended for developing fuels, as well as testing materials, for future large power-producing reactors. Later this summer, R2, which is a modified pool type reactor, will be equipped with a new tank, enabling it to be operated at 30,000 kW. The fuel is about 6 kg. of highly enriched uranium.

Month to Month

HONOURS and AWARDS
ANNOUNCED at WINNIPEG, 1960

Honorary Memberships

The highest form of recognition within the gift of the Institute was bestowed on Bristow Guy Ballard, William Percy Dobson, Richard L. Hearn, Otto Holden and John Norison Finlayson.

Dr. Ballard

Dr. Dobson

Dr. Hearn

Mr. Finlayson

The Julian C. Smith MEDAL

"For achievement in the development of Canada"

Hugh Andrew Young

Clarence Decatur Howe

The LEONARD MEDAL

For papers on mining subjects
Awarded to Victor Dolmage and J. W. Stewart for "The Demolition of Ripple Rock". Mr. Stewart is at left. Mr. Dolmage was represented at the Awards Luncheon by Mr. E. E. Mason.

The PLUMMER MEDAL

For metallurgical subjects
Awarded to J. T. Hugill for his paper, "A Large Capacity Oxygen Plant for Metal Refining".

The ROBERT W. ANGUS MEDAL

Awarded to J. J. Traill for his paper "Tests of Hydraulic Turbines — an Appraisal".

The DUGGAN MEDAL and PRIZE

were won by A. G. Davenport, a member of the Institute and now Research Fellow and Research Assistant, the Department of Civil Engineering, University of Bristol, England. He received the award for his paper "The Wind-induced Vibration of Guyed and Self-supporting Cylindrical Columns".

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on April 30, 1960.

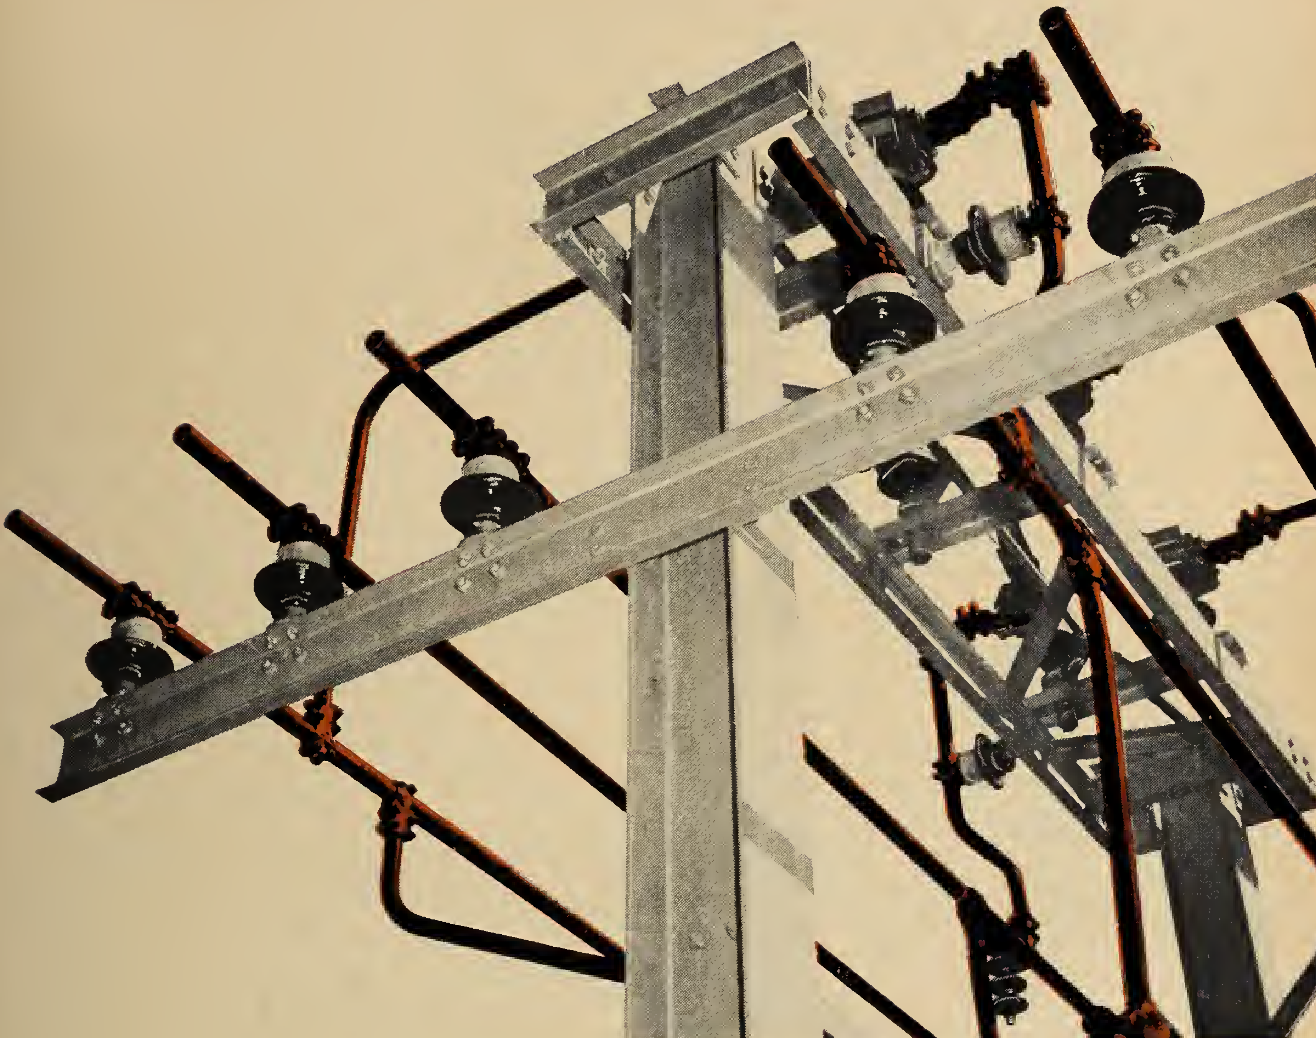
Member: S. I. Ahmed, Montreal; J. M. Bannon, Montreal; A. J. B. Birkmyer, Toronto; J. B. Christensen, Montreal; J. T. Colquhoun, Copper Cliff; K. W. Dollansky, Sherbrooke; B. P. Emo, Toronto; C. L. Erb, Cleveland; S. A. Kazimierowicz, Montreal; G. W. Mitchell, Ottawa, S. Nowski, Toronto; M. M. W. Smith, Vancouver; W. R. Stevenson, Sarnia; B. W. Taylor, Montreal; A. F. Tregenza, Toronto; S. Van Ingen Schenau, Ottawa.

Junior: R. H. Banning, England; A. F. Brodie, Toronto; D. E. Coulter, Toronto; N. Hayward, Niagara Falls; C. R. Keleher, Montreal; T. W-N. Lam, Idaho, USA; S. J. Pellegrini, Peterborough; J. B. Plant, Smith Falls; M. F. Rottman, Toronto.

Affiliate: S. W. Wood, Hamilton.

Junior to Member: D. L. Allen, Atwood, Ill.; C. T. Armstrong, Toronto; J. L. Armstrong, Toronto; J. J. Arnason, Winnipeg; D. T. Austin, Kingston; O. Y. Barde, Montreal; G. F. W. Barrett, Montreal; K. E. Barter, Ottawa; K. O. Bartlett, Fredericton; H. R. Beck, Montreal; G. A. Bernard, Sherbrooke; A. Bernardi, Montreal; G. J. Bialik, Peterborough; A. B. Biggar, Venezuela; J. G. S. Billingsley, Newark, Del.; R. A. Bird, Winnipeg; R. Boisvert, Chicoutimi; L. G. Boivin, Montreal; R. N. Bower, Lethbridge; W. S. Bradbeer, Burlington, Ont.; P. J. Brais, Montreal; S. Bramah, Sudbury; C. G. Brean, Fredericton; J. L. Bremner, Dauphin, Man.; D. W. Briden, North Bay; A. L. Briere, Drummondville; D. N. Brockhurst, Cincinnati; G. Brynildsen, Shawinigan; M. R. Byrne, Hamilton; M. L. Bussiere, Montreal; R. L. Carriere, Montreal; W. L. Cary, Edmonton; W. E. Castellano, Hingham, Mass.; R. R. Cheyne, Br. Guiana; J. A. Choquet, Montreal; P. B. Cleugh, Montreal; D. H. Cohoon, Arvida; G. F. Colford, Montreal; R. C. Cook, Montreal; R. M. Cooper, Montreal; C. P. Corbett, Lucan, Ont.; B. M. Corey, Hamilton; L. J. Cousineau, Montreal; H. J. Cox, Tweed, Ont.; J. P. Dagenais, Montreal; G. R. Decarie, Montreal; A. C. deLery, Montreal; J. Deptuck, Brazil; D. G. C. Donaldson, Ottawa; G. W. Downie, Trail; R. Y. Dubuc, Montreal; I. G. Duncan, Ottawa; A. P. Earle, Montreal; K. R. Ebbern, Winnipeg; G. B. Eccles, Trail; D. R. Ells, Edmonton; W. E. Emmerson, Toronto; T. J. Erskine, Winnipeg; K. J. Fallis, Winnipeg; H. R. Farley, Ottawa; R. P. Fillmore, Fort William; W. M. Flanagan, Toronto; D. M. Foulds, Toronto; S. Gaunt, Montreal; R. J. Gill, Montreal; J. H. Goar, Hamilton; G. Granek, Toronto; T. C. Greenlees, London, Ont.; J. L. Greer, Winnipeg; D. G. Grey, Ottawa; B. J. A. Grondin, Quebec; R. T. Haine, Montreal; E. G. Hale, New Westminster; J. A. Hale, Montreal; R. Halfyard, Mt. Pearl Park, Nfld.; M. A. Hanson, Cornwall; J. L. Harbell, Hamilton; L. E. Hardman, Port Arthur; J. F. Harris, Toronto; J. F. Hewson, Windsor; G. H. Hicks, Vancouver; P. Hobson, Montreal; C. E. Holtby, Montreal; J. W. Howe, Montreal; N. E. Hudak, Toronto; J. P. Huza, Montreal; C. E. Ireland, Winnipeg; D. Johnson, Montreal; R. G. Johnson, Windsor; J. L. Jomini, Grand'Mere; R. E. Jonasson, Peterborough; J. E. Jones, Calgary; L. P. Kenyon, Toronto; M. Kilbertus, Montreal; J. N. Lacroix, Montreal; L. J. Laflamme, Montreal; R. H. Lalande, Noranda; A. E. Lalor, London, Ont.; L. Y. Langlois, Quebec; A. J. J. Laporte, Montreal; L. A. Leeyus, Toronto; P. Lesperance, Montreal; R. J. Lindsay, Montreal; J. D. Logan, Hamilton; J. D. Long, Montreal; B. Y. Lynn, Winnipeg; K. W. Macaw, Winnipeg; A. G. Macdonald, Montreal; N. F. Macfarlane, Montreal; W. R. Macke, Nigeria, Africa; V. G. MacWilliam, Saint John, NB; C. F. Mallory, Montreal; E. V. Malmgren; Winnipeg; G. K. Mantha, Montreal; G. G. Marshall, Winnipeg; H. K. Matthews, Calgary; E. P. McCormack, Montreal; H. O. McCullough, Windsor; C. A. McDonald, Fort Erie; A. McGregor, Winnipeg; J. D. McIlween, Toronto; A. M. McNevan, Montreal; D. A. McRae, Wilmington, Cal.; J. A. McRae, Ottawa; R. L. Mechin, Toronto; S. Meland, Montreal; D. F. Moore, San Francisco; E. A. Moore, Toronto; J. U. Moreau, Three Rivers; J. P. Morgan, Hamilton; B. Moroz, Montreal; W. B. Morrison, Montreal; A. E. Mudge, Fort Erie; T. L. Newell, Montreal; R. K. Nicholson, Montreal; W. H. Nord, Toron-

Preferred for heavy electrical loads...



NORANDA COPPER
TUBULAR BUS CONDUCTORS

Noranda copper tubular bus conductors used for carrying heavy electrical loads feature:

- low electrical impedance to alternating currents
- High current capacity per unit of cross-sectional area
- less skin effect and corona loss than conductors of other configurations
- rigidity and resistance to distortion plus distinct structural advantages
- ease of clamping

For complete information and technical assistance just call the Noranda Sales Office nearest you.

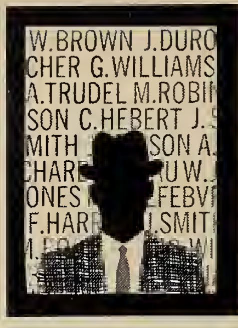
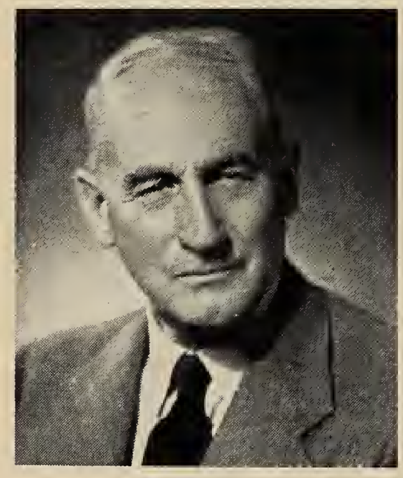
Personals



The election of **Dr. John Bertram Stirling**, Hon. M.E.I.C. (Queen's, B.A. '09, B.Eng. '11, L.L.D. '51) to the Chancellorship of Queen's University is a very great honour to the Institute of which he has been a member for forty-seven years and whose president he was in 1952-53.

Dr. Stirling, in accepting his new office, joins a distinguished group of engineer chancellors, including Dr. C. J. Mackenzie, a past president of the Institute, of Carleton University; R. E. Powell, of McGill University; and the Rt. Hon. C. D. Howe, of Dalhousie University.



J. B. Stirling
Hon. M.E.I.C.

The eighth chancellor of Queen's University and the second engineer to hold this office (Sir Sanford Fleming was in office from 1880 to 1915), Dr. Stirling is President of E.G.M. Cape and Company, Montreal.

He has been a prominent member of the Queen's alumni, serving in the past as President of the Queen's General Alumni Association, Chairman of the Building Committee and Vice-Chairman of the Board of Trustees. In 1951 the honorary degree of Doctor of Laws was conferred upon him by the university.

His professional leadership has been demonstrated widely over the years in the presidencies of the Engineering Institute of Canada, the Canadian Construction Association (1942-43), the Corporation of Professional Engineers of Quebec (1948-49) and the Montreal Board of Trade (1950).

Dr. Stirling has long been admired in the profession and in public life for the quality and diversity of his accomplishments. A strong advocate of individual initiative, he is indeed a fitting person to take up the duties of Chancellor at Queen's University.

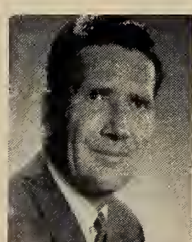
Lawrence MacIsaac, M.E.I.C. (N.S.T.C. '46) has been appointed Industrial Commissioner for the Central Region of the Canadian National Railways at Toronto.

McNeely DuBose, M.E.I.C. (North Carolina State College '12) has been appointed Consultant for Sandwell International Ltd., Power Division. Mr. DuBose is a former executive vice-president of the Aluminum Company of Canada.

J. R. Mills, M.E.I.C., has been elected a director and appointed Vice-President & General Manager of Foundation Maritime Ltd., with headquarters in Halifax.

Yvon Tasse, M.E.I.C. (Ecole Polytechnique '35) has been appointed Parliamentary Secretary to the Minister of Public Works by Prime Minister Diefenbaker.

Y. Tasse
M.E.I.C.

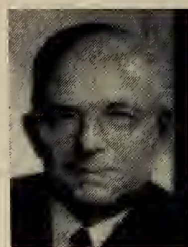


D. C. Jones
M.E.I.C.

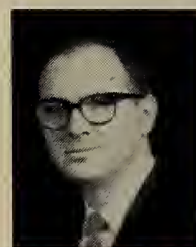
D. Carlton Jones, M.E.I.C. (McGill '34) has been appointed General Manager of the Production Department, Hudson's Bay Oil and Gas Company Limited.

G. R. Adams, M.E.I.C. (Queen's '27) has been appointed Vice-President and General Manager of Foundation Overseas Ltd., a subsidiary of Foundation Company of Canada Ltd.

J. Roy Gordon, AFFILIATE E.I.C., **has been** elected President of the International Nickel Company of Canada Ltd. He is a native of Kingston, Ontario.



J. R. Gordon
AFFILIATE E.I.C.



A. M. Mackay
M.E.I.C.

A. M. Mackay, M.E.I.C. (Toronto '50) has opened a consulting practice at Owen Sound, Ontario, under the name of A. M. Mackay & Associates Limited. The firm will specialize in sewerage, drainage, water, road and structural engineering.

David J. Lewis, M.E.I.C. (Queen's '24) is the new Chief Engineer of the Platework division at the Montreal Branch of the Dominion Bridge Company Ltd.

D. J. Lewis
M.E.I.C.

A. M. Bain
M.E.I.C.

A. Mark Bain, M.E.I.C. (Manitoba '28) has been appointed Assistant to the Director of Engineering at the head office of the Dominion Bridge Company Ltd. in Montreal.

C. N. Simpson, M.E.I.C. (Queen's '40) has been appointed Vice-President and General Manager, Engineering, for H. G. Acres & Company Ltd.

Robert F. McAlpine, M.E.I.C. (N.S.T.C. '28), Vice-President and General Manager of N.S. Tractors & Equipment Ltd., was recently elected 2nd Vice-President of the Canadian Association of Equipment Distributors at its annual meeting in Montreal.

Wide open spaces...

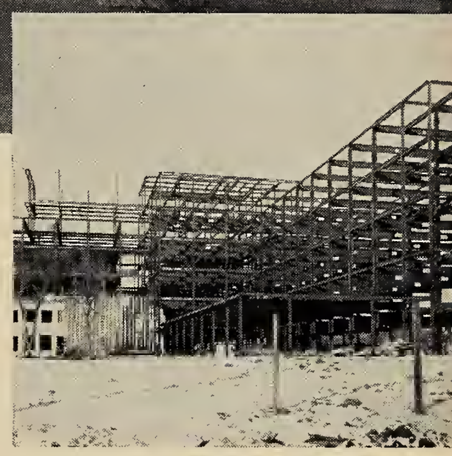
You get space, speed, flexibility and economy with steel construction—all were achieved in the Great West Life Assurance Company's new head office building in Winnipeg.

The use of long span steel beam construction gave large column free areas and allowed maximum flexibility of interior partitioning. Future changes in office and space requirements can be easily accommodated.

In addition, openings in the beam webs provided for passage of electrical, plumbing and heating facilities beneath the floor—without adding to the building's overall height. Every inch saved in height meant significant dollar savings.

All the steelwork was erected during three months of bitter winter weather. This enabled the sub-trades to move in on time to complete their work.

Architects: Marani & Morris of Toronto and Moody Moore and Partners of Winnipeg. Consulting engineers on structural design: Wallace, Carruthers & Associates of Toronto. Contractor: G. A. Baert Construction Co. Ltd.



1800 tons of steelwork, fabricated and erected by Dominion Bridge, Winnipeg. Most of this was of "rigid frame" design.

Easier and more economical installation of piping was made possible by openings cut in webs of beams.

DOMINION BRIDGE

FOURTEEN PLANTS—COAST-TO-COAST

E. L. Hartley, M.E.I.C. (Queen's '33) has been elected President of Dominion Structural Steel Ltd., with headquarters in Montreal. Mr. Hartley will remain Vice-President of Western Bridge and Steel Fabricators Ltd., Vancouver.

E. L. Hartley
M.E.I.C.

A. Raymond
M.E.I.C.

A. Raymond, M.E.I.C. (McGill '34), formerly Vice-President and General Manager of the International Braid Company of Canada Ltd. and President of Safeway Heat Elements of Canada Ltd., has opened a new company, Raymond Associates Inc., manufacturers' representatives, Industrial Supplies and Engineering.

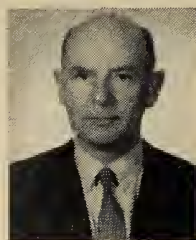
Kent Phillips, M.E.I.C. (Saskatchewan '27) has been elected to a three-year term on the University of Saskatchewan's board of governors. He is General Manager of Evans Construction Company Ltd. and is associated with Kent Phillips and Associates Ltd.

Martin J. J. Dayton, M.E.I.C. (B.C. '49), formerly Senior Assistant Engineer for the Greater Vancouver Water and Sewerage and Drainage Districts, has established a consulting practice in water supply and sewage engineering, in West Vancouver.

D. W. R. McKinley, M.E.I.C. (Toronto '34) has been made Associate Director of the Radio and Electrical Engineering Division of the National Research Council.

W. E. Hickey, M.E.I.C. (N.S.T.C. '38) has been appointed Vice-President and Director of Engineering, The Foundation Company of Canada Ltd., and Executive Vice-President of FENCO.

A. Chmielenski, M.E.I.C. (Warsaw '34) has been appointed a vice-president of Foundation of Canada Engineering Corporation Ltd.



A. Chmielenski
M.E.I.C.

D. W. Hawes
JR.E.I.C.

D. W. Hawes, JR.E.I.C. (McGill '50) has been appointed Chief Engineer of Power Corporation Designers and Consultants Ltd., Montreal.

A. E. Insley
JR.E.I.C.

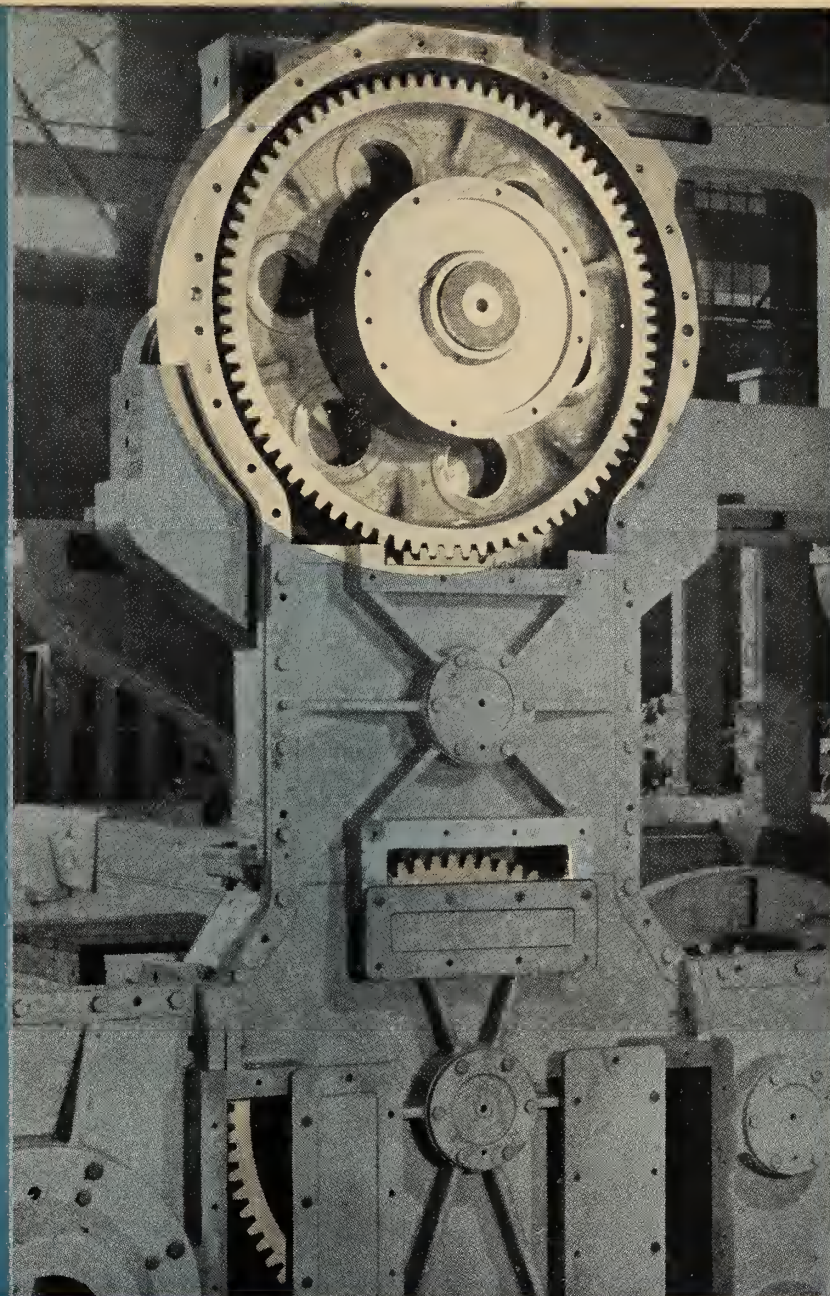
G. W. Spratt
M.E.I.C.

G. W. Spratt, M.E.I.C. (McGill '53), formerly of Macdonald & Macdonald Ltd., has been appointed Chief Engineer of Coast Testing Laboratories Ltd., Vancouver.

D. L. Mackinnon, M.E.I.C. (U.N.B. '39) is the new Assistant to the Vice-President, Administration, The Foundation Company of Canada Ltd., with headquarters in Toronto.

Karl E. Gustafson, M.E.I.C. (McGill '40), chief mining engineer for Pierce Management Corporation, Scranton, Penn., has recently completed inspection and report on two under sea coal mines in Chile, for the World Bank.

GEARS OF DUCTILE (NODULAR) IRON FOR THE WORLD'S WIDEST PAPER MACHINE



Built for Black-Clawson (Canada), Limited, these huge gears, for high speed paper production, were cast to give completely dependable, trouble-free operation. Once again, Canada Iron's technological facilities and large casting equipment were equal to the job.

Rely on Canada Iron's casting experts to help you find the exact casting grade for your needs. Let them show you the advantages of the right metal for the job . . . whether it be Ni-Hard, Ni-Resist, DOMITE* or Ductile (Nodular) cast iron. Consult your nearest Canada Iron office today.

Obituaries

C. Ben Bate, M.E.I.C., died on May 26, 1960.

A graduate in civil engineering from Queen's University, 1915, Mr. Bate went to work on the engineering staff for the construction of additions to the Hawkesbury mill of the Riordon Company Ltd. He later joined Kerry and Chase Ltd. in Pushthrough, Newfoundland, where he worked on power investigation.

In 1958 Mr. Bate retired from Public Service and opened a private practice as a civil engineer at Sillery, Quebec. Just prior to retirement he had been a plant engineer with the Defence Research Board of the Department of National Defence, Quebec.

Mr. Bate was awarded the Order of the British Empire in 1945. He became a Life Member of the Institute in January, 1957.

Richard John **Herbertson**, S.E.I.C., a graduate of the University of Manitoba in mechanical engineering, 1959, was accidently killed on February 5, 1960.

Herbert Christopher Karn, M.E.I.C., former Chairman of the Standards Committee and Assistant to the Chief Engineer of Du Pont Company of Canada Ltd., died April 14, 1960, in his 70th year.

A native of Woodstock, Ontario, Mr. Karn received his degree in electrical engineering from the University of Toronto in 1916. Upon graduation he worked for Canadian Explosives Ltd. for a year in Beloeil, Quebec, then joined the British Munitions Company Ltd., Verdun, Quebec, and subsequently the Hydro Electric Power Commission of Ontario. In 1920 Mr. Karn rejoined Canadian Explosives Ltd. in Montreal and was appointed Supervising Engineer, Power Services, of Du Pont of Canada Ltd. in 1924. He held this position until 1953, when he was made Chairman of the Standards Committee.

Mr. Karn was involved in the construction and rehabilitation of plants in the many different works of Canadian Du Pont between these years. From 1939 to 1945 he worked on numerous projects in Quebec and Ontario for the storage of explosives. In 1946-47 he built the new plant and village at Chalk River. During the last years of his work with Du Pont, in 1953-54, Mr. Karn supervised the writing of engineering standards and segregated engineering records.

H. C. Karn, M.E.I.C.

A resident of Montreal until 1955, Mr. Karn retired to Windsor, Ontario, his birthplace. He was a member of the Corporation of Professional Engineers of Quebec, the Electrical Club of Montreal, and the Corporation of Master Electricians of Quebec; and a Life Member of the Institute.

James Mackintosh, M.E.I.C., for many years a member of the staff of the Hydro-Electric Power Commission of Ontario, has died in Toronto.

Mr. Mackintosh was born at Macduff, Scotland, and attended Gordon's College in Aberdeen and the Royal Technical College in Glasgow. He came to Canada in 1910, working first for the Ottawa Electric Company and then the Department of Railways and Canals as resident engineer on the Trent Canal. From 1917 to 1950 Mr. Mackintosh worked for the Hydro-Electric Power Commission of Ontario, after which he joined H. G. Acres, Consulting Engineers, for two years, working first at Pine Falls, Manitoba and later at Fanshawe Dam, London, Ontario.

A Life Member of the Institute and a member of the Institution of Civil Engineers, London, England, Mr. Mackintosh also belonged to the Scottish Rite of Masons; the Hunter and Anglers' Association; and the Royal Canadian Institute. He was an elder of the United Church for many years.

Arthur Hartley Milne, M.E.I.C., died on May 8, 1960.

A graduate in civil engineering from McGill University, 1917, Mr. Milne was appointed superintendent of buildings with the Protestant Board of School Commissioners of Montreal in 1926. Mr. Milne later worked for the firm deBelle & White, Architects, in Montreal.

Having joined the Institute as a Student Member in 1914, Mr. Milne was given Life Membership in January, 1956.

Vivian Andrew **Newhall**, M.E.I.C., retired city commissioner of Calgary, died recently. He was 71.

Born in Omaha, Nebraska, Mr. Newhall graduated from the University of Toronto, with a degree in civil engineering, in 1911. In that year he was also naturalized and moved to Calgary, where he began work with the federal government irrigation department and hydrometric surveys.

In 1913 he was architect's inspector on the Hudson Bay Company store, and the following year was appointed manager of Western Woodworkers, the construction department of Hudson Bay. He later became design engineer and manager of the Truscon Steel Company's agency in Calgary, and sales manager and a partner in Bell and Morris Ltd. when the agency was transferred to that concern.

B. A. Newhall, M.E.I.C

During World War II Mr. Newhall was chairman of the construction industry group in the payroll section of the National War Finance Committee. From 1944 to 1952 he served as city commissioner of Calgary.

An associate director of the Calgary Exhibition and Stampede Board, Mr. Newhall was also a Life Member of the Institute.

Other Societies

The Institution of Mining and Metallurgy, U.K.

The Annual General Meeting of the Institution of Mining and Metallurgy was held on May 19, 1960, at the Geological Society of London, Burlington House, Picadilly, London. Gold Medals of the Institution for 1959 were presented to Mr. Edward Duffield McDermott and Mr. Julius Kruttschnitt, and honorary memberships in the Institution were bestowed upon Sir Reginald Patrick Linstead, The Rt. Hon. Lord Robins, and George Augustus Whitworth.

Société Royale Belge des Ingénieurs et des Industriels

The 75th Anniversary of the S.R.B.I.I. was celebrated in Brussels from June 21 to 24, 1960. His Majesty the King and the Members of Government were present for the opening at the Palais des Académies. On June 22 a conference on the role of the engineer and the industrialist in the expansion of civilization was held, and on June 23 technical visits were made to Liège, Charleroi and Ghent. The object of the conference was to recall the activity of the Association since its founding in 1885 and to set out its prospects with emphasis on the development of applied sciences, scientific research, the equipment of the Belgian Congo, and the representation of the country abroad in the scientific, technical and industrial fields.

American Society for Testing Materials

The ASTM Division of Materials Sciences, as a part of the ASTM 63rd Annual General Meeting, held a special program from June 26 to July 1, 1960, on Recent Progress in Materials Sciences and the Nature and Origin of Strength of Materials.

The Associations and Corporation

The eighth annual convention of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. will be held in Trail, September 15-17. New features of this year's convention will be a workshop for registered professional engineers employed by municipalities and a panel session by consulting engineers for works superintendents and suppliers.

Included in the convention program are tours of the Consolidated Mining and Smelting Company's Trail and Warfield operations. Over two hundred engineers, suppliers and wives are expected to attend. Sessions will be in the Cominco Centre. J. F. Millican, of Trail, will be the convention chairman.

Maritime Professional Engineers' Convention

One of the major engineering events of the Eastern Seaboard, the semi-annual Maritime Professional Engineers' Convention is being held this year at the Algonquin Hotel, St. Andrew's, New Brunswick, September 8-10. The four Maritime Professional Engineers' Associations and the Engineering Institute of Canada cooperate in its sponsorship.

The technical program will include: I. R. Cameron, Canadian Armament Research and Development Establishment, Quebec, Que., "Manufacture and Testing of Solid Propellent Rocket Engines"; J. E. Hayes, Canadian Broadcasting Corporation, Ottawa; R. J. Law, International Nickel of Canada, "Corrosion in Action"; and G. B. Williams, Assistant Deputy Minister of Public Works, Ottawa.

Institute of the Aeronautical Sciences

The annual national summer meeting of the IAS was held in Los Angeles from June 28 to July 1. General Curtis E. LeMay, vice-chief of staff, USAF, was the guest of honour and principal speaker at the banquet, June 30. Other speakers included: William H. Pickering, Dr. Theodore Von Karman, and Rear Admiral W. F. Raborn, USN.

Conference on Civil Engineering Education

The University of Michigan was host from July 6 to 8 to engineering educators from across the continent gathering for a conference on civil engineering education. Heads of departments of engineering from 138 colleges and universities with accredited curricula in civil engineering gathered to discuss the problem of decreasing enrollments and the need to attract better qualified students into the field.

Canadian Radio Technical Planning Board

The CRTPB was formed in September, 1944, at a meeting convened by the Department of Transport as an organization of users of radio communications and certain allied equipment, manufacturers, engineering and educational societies, and other interested organizations. Its object was and is to formulate sound engineering principles to assist in the development in accordance with the public interest, of the Canadian radio industry. Application for membership, or further information about the board, can be obtained from: The Secretary, Canadian Radio Technical Planning Board, 200 St. Clair Avenue West, Toronto 7.

The Institute of Physics and The Physical Society, U.K.

A new body was incorporated on May 17, 1960, under the name "The Institute of Physics and The Physical Society". The first president of the amalgamated body is Sir John Cockcroft.

Border Cities

A TOUR was made of the recently completed Union Water System, by courtesy of the Ontario Water Resources Commission, on May 11. The plant featured the following automatic operations: chemical feed, compensation for plant and distribution demand variations, backwashing of filter beds, and switching of essential pumps to standby diesel power. The automated control at this plant is believed to be the most advanced on the continent.

THE HARBOUR development at St. John's is the largest single development ever undertaken by the Rivers and Harbours Branch of the Canadian Department of Public Works, according to Mr. Ed Manchul, of the Federal Department of Public Works, speaker at the May 11 meeting. The cost of the project, which is to be completed in 1963, is estimated at $13 million. A large finger wharf will be capable of handling ships of up to 10,000 tons and modern handling facilities and storage sheds will be available. The harbour is to be dredged, and an access road is being built along the North side of the harbour to enable traffic-handling cargo to bypass the downtown shopping areas. At the close of the meeting, Mr. Lowe, of Foundation Engineering Company, consultants for the project, discussed some interesting engineering aspects.

The main social event of the year in the Corner Brook Branch calendar was held on May 6 at the Glynmill Inn. Following cocktails and a lobster dinner, officers for the coming year were elected. They include: Robert Herdman, chairman; Max Promish, vice-chairman; Harold Hinton, secretary; and W. Cunen, treasurer. The outgoing chairman, Kevin George, paid tribute to one of the charter members of the branch, G. P. Hobbs, formerly Mill Manager of Bowater's Newfoundland Pulp and Paper Mills, who will leave Corner Brook shortly to take up the presidency of Bowater's Engineering and Development Incorporated, Calhoun, Tennessee. The evening ended with a dance in the cocktail lounge of the hotel.

Hamilton

C. A. McCurdy, JR.E.I.C.
Correspondent

THE CIVILS Group of the Hamilton Branch concluded their Spring activities with a tour of the Hunting Associates Ltd. plant in Toronto on May 18. Members had an opportunity to see equipment used in interpreting aerial photographs and plotting maps. Numerous illustrations were given of the uses of aerial photography in locating mineral outcroppings and making timber surveys. Aerial photography is also being used to show annual changes in cities. Toronto is completely photographed annually. The same technique is used in making plot plans of industrial installations.

Kitchener

A. R. LeFeuvre, M.E.I.C.

THE ROLE of the University of Industrial Development was discussed by Dr. F. Noakes, Dean of Electrical Engineering at U.B.C., at the May 9 meeting. Dr. Noakes traced the history of research in Canadian universities and most particularly at U.B.C., comparing it with that carried out in American universities. He noted the link between increased industrial activity around large research centres such as Stamford and MIT. Dr. Noakes enumerated the sources of research grants in Canada — NRC, the universities, industry and private funds. He stressed the good that can come from non-specific research on a large scale in a university, and made a plea to industry to take more interest in and supply more funds for university research.

NUCLEAR POWER NEEDS LOOKING AFTER . . .

Horton knows how!

Nuclear power, mighty power source of the future, needs looking after. Nuclear Reactors have to be thoroughly protected to avoid radio-active contamination of people and property. Constructing special steel plate Reactor Containment Vessels requires great skill and vast engineering experience. Horton has the skill and engineering background to erect these special vessels because they have been fabricating and erecting all types of quality steel plate structures throughout Canada for many years. Horton will be pleased to supply you with further information on request.

Correspondent

THE MAY 18 meeting of the Lakehead Branch was addressed by Mr. John T. Hunter of the Ontario Department of Highways. Mr. Hunter spoke of the immense amount of study which preceded the building of highways in the Province. He dealt with the subject of traffic surveys and explained traffic density's priority in highway construction allocations. At the present time the speaker showed that allocations are based on a program extending 20 years into the future.

University of Manitoba

THIRTY engineering students, from Nova Scotia to British Columbia, attended the E.I.C. Winnipeg Annual Meeting, May 24-28. The student delegates welcomed the opportunity to meet students from other school in other parts of the country.

The Winnipeg members are happy to have had the chance to be host to such a large and successful convention and hope that such an opportunity will be forthcoming again in the not-too-distant future.

THE ANNUAL dinner and meeting at the Refectory, Niagara Falls, Ontario, was held on May 19.

Dr. M. Risley, Assistant Director of Education in New York, has made a hobby of humour in all its phases and his talk "He who laughs, lasts" was received with bursts of laughter. An introduction by F. R. Denham and vote of thanks by C. MacDonald were a splendid proof of what is being accomplished by the Professional Development Group.

The executive for 1960-61 includes: F. Ronald Denham, chairman; W. J. O'Reilly, vice-chairman; D. O. D. Ramsdale, past chairman; A. Alexander, treasurer; Harold Jones, Homer S. Lundy, R. McKimmie, W. D. Tanner, J. H. Travers, C. McDonald, W. J. Smith, members of the executive.

Peterborough

D. B. A. Chase, JR.E.I.C.

THE ANNUAL E.I.C. Field Trip was taken to the General Motors plant at Oshawa, on May 16. Approximately 45 members attended and were joined by three members of the Belleville Branch. The trip included a chicken dinner at the Flying Dutchman in Bowmanville. The tour, which was made in a small train, was followed by a lunch and very informative question period.

Following the popular custom of previous years, the winter's activities ended with the Annual EIC Stagg on June 3. This year the "Black Magic" Stag featured an hour-long presentation by Bradshaw the Magician.

The Peterborough Public Library has indicated a willingness to work with a newly formed Library Committee of the Peterborough Branch. The committee will help the library to choose new technical books; will prepare and distribute to members periodically a list of technical books available; and will encourage donations by members both directly and through the branch. Copies of the two biographies recently published by the E.I.C. have been presented to the library as initial contributions.

A CONDUCTED TOUR of the B.C. Forest Products Pulp and Paper Mill at Croften was taken by 28 members and wives on May 14. The tour was very complete, showing the transformation of raw logs into 500 lb. bales of kraft pulp. The capacity of the mill is approximately 600 tons per day.

On May 17 members heard Mr. Abraham Hurlich, head of the Materials Research Group of Convair Astronautics, San Diego, California, discuss materials and fabrication of the Atlas missile.

University of Waterloo

AN ORGANIZATIONAL meeting was held in April and the following officers were elected: John Shaw, president; Per Voldner, vice-president; William Wright, secretary-treasurer.

The film "Blasting A New Niagara", courtesy of Canadian Industries Ltd., was shown to a good attendance of faculty and students on May 13. The film portrayed blasting techniques used in construction of the underground tunnel and surface channel feeding the Sir Adam Beck No. 2 Hydro-Electric Generating Station at Niagara Falls.

A contest for the best technical paper from under-graduate engineering students is being sponsored by the student section. The papers are to be presented next Fall.

THE WINTER activities for 1959-60 closed on April 8 with a smorgasbord and dance at Vasalund. Approximately 180 members, wives and friends enjoyed the fine food and pleasant evening of dancing.

The new executive for 1960-61 includes: A. S. Williams, chairman; D. C. Bryden, vice-chairman; R. M. Fraser, secretary; R. Akister, papers chairman; A. C. Warrender, recorder; G. Flavell, past chairman, D. E. Haig and C. E. Pontifex, members of the executive.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*SYMPOSIUM ON MICROSCOPY.

The papers of this symposium on light and electron microscopy supplement the 1952 "Symposium on Light Microscopy" (ASTM-STP No. 143). Recent advances in microscopy are revised in a brief introduction, which also indicates that refinements and improvements are needed in sample handling and preparation techniques. Nine papers form the body of the symposium, discussing phase and interference microscopes, performance characteristics of objectives, eyepieces and illuminators; and microscopy in the optical, petroleum, ceramic, mineral and textile industries. (American Society for Testing Materials, Philadelphia, 1959. 165 p., $4.75. STP 257.)

TIMBER CONSTRUCTION MANUAL

Four years in preparation, this comprehensive manual covers all phases of timber construction and design, based on the latest CSA specifications. It includes data on both sawn timber and glued-laminated construction, and covers properties, stresses and loads; designs and design charts for beams, joists, columns, connectors, trusses and arches, decking and highway bridges, and information on shop detailing. There is a section on timber technology covering lumber grading and selection, load duration, thermal conductivity, preservative treatments, fire safety, etc. Also included is the complete CSA Specification 086, and C.I.T.C. appearance grade specifications. (Ottawa, Canadian Institute of Timber Construction, 1959. 368p., $6.50.)

> **THE ENGINEERING INSTITUTE LIBRARY**
>
> *The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.*
> *Library hours for June, July and August are: Monday to Friday: 2 p.m. to 5 p.m.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.*

*THE INDUSTRIAL COOLING TOWER

A great deal of wide-spread data has been collected and digested by the authors, who have combined it with their own experience to provide a co-ordinated survey of the whole field of cooling tower technology. Among those aspects treated are heat transfer in cooling towers; the natural draft cooling tower; cooling tower packing arrangements; drizzle precipitation, carryover, and wind effects; cooling water treatment; the structural design of cooling towers; auxiliary equipment, such as pumps and fans; and the construction of cooling towers. Both a theoretical and practical approach are provided. (K. K. McKelvey and M. Brooke. Toronto, Van Nostrand, 1959. 429p., $15.75.)

*FLUIDIZATION AND FLUID-PARTICLE SYSTEMS.

Modern developments in fluid-solids processing such as the moving bed techniques, fluidization, and transport reactors are discussed in this book. Includes material on angle of repose, internal and wall friction, rupture, slide, the application of particle shape factors in calculating fluid pressure drop, and bubble velocity and size of fluidized beds. (F. A. Zenz, and D. F. Othmer. New York, Reinhold, 1960. 513 p., $15.00.)

*ELECTRON TUBE LIFE FACTORS

This book deals with the changes in the properties of electron tubes for periods of time up to 5,000 hours of life under various environmental conditions. The properties measured include transconductance, power output, operation, heater and grid currents, heater cathode leakage, grid emission, interface resistance, and interelectrode insulation. Results of measurements, including percentage of failure, under both test conditions and MIL standard conditions are given, as well as general material on the characteristics, properties, and ratings of tubes, the design and control of the tests, and the analysis, presentation, interpretation and application of the data collected. (Ed. by Craig Walsh and others. Elizabeth, N. J., Engineering Publishers, 1959. 173 p., $9.50.)

*AVAILABLE ENERGY AND THE SECOND LAW ANALYSIS.

Introductory chapters are on the first and second laws of thermo-dynamics and are preparatory for the rest of the book, since both laws are considered in the following analysis of available energy in the mixing of gases, vapours, and liquids; heat-exchangers; turbo-blowers; air compressors; gas dynamics; refrigeration and power plants. The final chapters concern chemical changes, both theory and problems. (E. A. Bruges. Toronto, Butterworth, 1959. 124 p., $5.50.)

*GENIE CHIMIQUE, Volume 1; MECANIQUE DES FLUIDES.

This first volume of a series on the basic aspects of chemical engineering deals with fluid mechanics, and is meant to provide the engineer with tools and methods for solving both routine and more complex industrial problems. The volume is divided into 2 parts: the first, dealing with perfect fluids; and the second, with real (viscous) fluids. The final chapter is a study of the movement of a particle in a fluid, which provides the basis for several process applications: sedimentation, decantation, centrifuging, electrostatic precipitation, etc. (Rene Gilbert. Paris, Eyrolles, 1960. 216 p., 26.25 francs.)

*SECOND PROTECTIVE CONSTRUCTION SYMPOSIUM. PROCEEDINGS: DEEP UNDERGROUND CONSTRUCTION.

This large, two-volume loose-leaf collection of papers stresses primarily the design and construction of deep underground industrial facilities to resist the effects of nuclear weapons. Topics discussed include the need for shelters, weapons effects to be provided against, the interaction of utilities and structural solutions, tunnel design and failure mechanism, and experiences from such fields as submarine design, oil-well drilling, and underground powerhouse design. (Compiled by J. J. O'Sullivan. Santa Monica, Rand Corp., 1959. No price given.)

*MAGNESIUM AND ITS ALLOYS.

The extraction and refining of mag-

PEAK EFFICIENCY FOR HIRAM WALKER

Hiram Walker's new $4 million bottling plant at Walkerville, Ontario, contains the most modern and efficient materials-handling equipment ever developed for a beverage packaging operation. Speed and efficiency prevail — from the seven high-speed lines in the bottling room to the storage conveyors, controlled by an electric-eye system to avoid bottlenecking. As an essential part of this modern equipment, valves bearing the famous "Diamond" trade mark were chosen to service various units within the plant, including steam-heating and sprinkler systems, and sump installations. Whenever and wherever a Jenkins Valve is installed, you can be sure of the utmost in quality, reliability and economical performance. Jenkins Bros., Limited, Lachine, Que.

Jenkins Valves are shown installed at two important centres . . . *left:* on the converter unit, controlling the steam-heating system, and *right:* on the automatic sprinkler system.

nesium, alloy theory and phenomena, and the physical and chemical properties of the metal and its alloy systems are covered in detail. The technology of both casting and wrought alloys is included. (C. S. Roberts. New York, Wiley, 1960. 230 p., $9.00.)

*MECHANICAL PROPERTIES OF INTERMETALLIC COMPOUNDS.

The proceedings of the Electrochemical Society's 1959 Symposium, this book includes papers on the phenomenology of the mechanical behaviour of intermetallics, theoretical and experimental investigations of particular properties, experimental techniques for the preparation and study of intermetallics, and an extensive review of the literature in the field, from about 1908 to date. Included is an index to the compounds discussed. (Ed. by J. H. Westbrook. New York, Wiley, 1960. 435 p., $9.50.)

*MANUAL ON INDUSTRIAL WATER AND INDUSTRIAL WASTE WATER, 2nd ed.

Revision of the introductory section presents a general discussion of the characteristics and potential effects of waste water discharged from the plant, as well as of the characteristics of fresh water for industrial use. The remainder of this volume includes all current ASTM methods for the examination of water. (Philadelphia, American Society for Testing Material, 1960. 653 p., $11.00. s.t.p. 148-D.)

*BITUMINOUS PAVING MATERIALS.

This volume combines the papers presented at two symposiums, one on the methods of test for design of bituminous paving mixtures, and the other on the practical and statistical significance of tests and properties of bituminous binders, and at the technical session on road and paving materials. (Philadelphia, American Society for Testing Materials, 1959. 232 p., $5.50. s.t.p. 252.)

*SYMPOSIUM ON IDENTIFICATION OF WATER-FORMED DEPOSITS.

These five papers present analytical techniques for the identification of deposits in water systems, with discussions of the advantages and disadvantages of each method. (Philadelphia, American Society for Testing Materials, 1960. 74 p., $2.75. s.t.p. 256.)

*SYMPOSIUM ON ELECTRON METALLOGRAPHY.

This volume includes papers on the electron metallography of cast nickel, tin alloys with special attention to their phase morphology, and steels including the structural effects of neutron irradiation. Other papers discuss electron diffraction techniques and electron microphone measurements. (Philadelphia, American Society for Testing Materials, 1960. 128 p., $4.25. s.t.p. 262.)

*SYMPOSIUM ON EDUCATION IN MATERIALS.

Seven prominent engineers and educators present from their varying points of view the impact of engineering materials requirements as related to engineering educators. (Philadelphia, American Society for Testing Materials, 1960. 51 p., $2.00. s.t.p. 263.)

*SYMPOSIUM ON ELECTROLESS NICKEL PLATING.

Six American papers on practical and theoretical aspects of the catalytic deposition of nickel-phosphorous alloys by chemical reduction in aqueous solution. Topics covered include the history of the electroless plating process, the chemical reactions involved and the characteristics of the resulting deposits, process procedures, the advantages and limitations and applications of the process, and methods of testing the solutions used. Included also are an examination of patents in the field, and a bibliography of 136 references. (Philadelphia, American Society for Testing Materials, 1959. 67 p., $2.50. s.t.p. 265.)

NOTE: During the months of **June, July** and **August** Library hours are Monday to Friday, 2 p.m. to 5 p.m. only.

*TEXTILE ENGINEERING PROCESSES

Separate papers by experts in each particular topic provide a systematic examination of British textile engineering from the properties of natural and synthetic fibres, yarns and fabrics, to air properties, humidity and control. Examination of preparatory processes such as opening, drawing, spinning, winding, beaming and sizing follows the raw materials section and precedes discussion of manufacturing techniques such as wearing, knitting, water extraction, drying and conditioning, dyeing and printing. The final chapter describes and explains automatic control of textile plant machinery. (Ed. by A. H. Nissen. Toronto, Butterworth, 1959. 366 p., $9.25.)

*FLUORESCENT LAMPS AND LIGHTING.

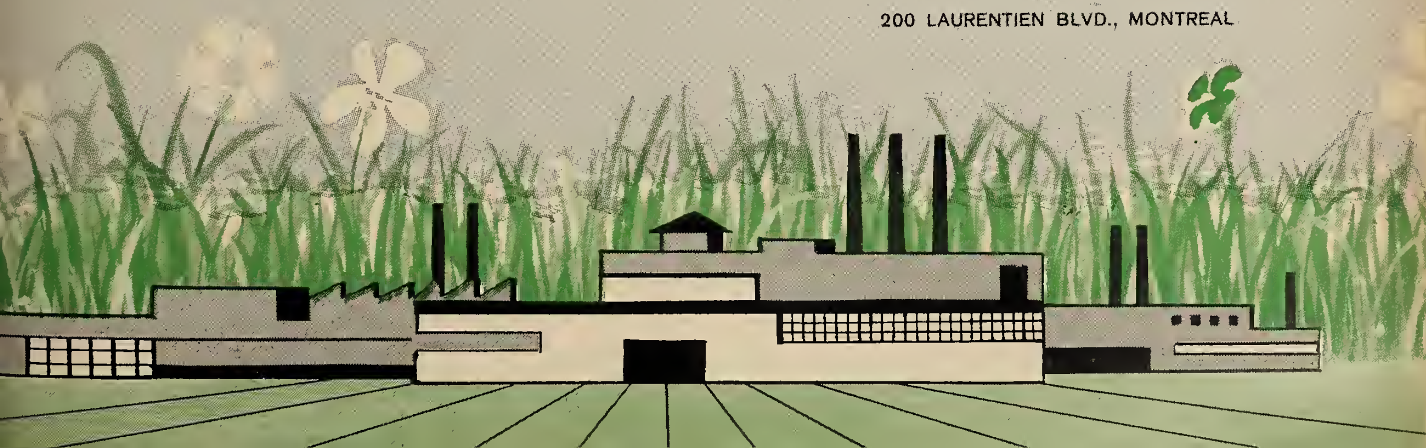
This second edition of C. Zwikker's *Fluorescent Lighting* contains the recent advances in fluorescent lighting techniques and lamp construction. Stabilization of the discharge and ballasts for AC operation are described and developments widening the use of tubular fluorescent lamps, including transistors, new circuits, ballasts, and reflector lamps are discussed. The subject matter of the book ranges from the physics of luminescence to public and private utilization of fluorescent lamps. The appendices discuss lamps with high loading per unit length and the application of transistors in lamp circuits. (Ed. by W. Elenbaas. Galt, Brett-Macmillan, 1959. 346 p., $11.00.)

*CEMENTED CARBIDES.

The historical development of cemented carbides traced in the first chapter is followed by chapters on production and testing methods for carbides and other metallic refractories, with emphasis on sintering. The mechanical and chemical properties of commercially produced carbides and those produced only in experimental quantities, such as oxide and boride materials form the next chapters, and the final chapters deal with applications of cemented carbides in the machine tool, mining, defence and other industries. (Paul Schwarskopf and others. Galt, Brett-Macmillan, 1960. 349 p., $15.00.)

*ENGINEERING ECONOMY, 3RD. ED.

All commonly used economy study methods here are analysed in terms of their background, principles and procedures, together with discussion of the frequent importance of non-monetary factors in economic decisions. This edition is almost completely rewritten. (E. P. de Garmo. Galt, Brett-Macmillan, 1960. 580 p., $8.75.)



*MATRICES.

An introductory college-level development of the theory of matrices. After a review of elementary mathematical concepts, the theory is introduced through linear forms and systems of equations with a complete matrix treatment. The theory of determinents is made to depend on the theory of matrices. Also included are discussions of row and column transformations, equivalence and rank, elementwise and blockwise operations, partitioning, and the MURT technique. (W. Vann Parker and J. C. Eaves. New York, Ronald, 1960. 195 p., $7.50.)

*CHEMICAL ENGINEERING PRACTICE, VOLUME 11: WORKS DESIGN, ETC.

This volume of the series contains papers on the planning and administration of chemical works and factories. The planning stage includes layout and execution of the design, the choice of a site, the design and construction of the building, contracts, and the installation of the works. Administration of employees and materials, quality control, accounting, and cost control are covered in the next chapter. British legislation relevant to chemical factory management and regulation, the industrial hazards of the chemical plant, and British patent regulations are also dealt with. (Ed. by H. W. Cremer and S. B. Watkins. Toronto, Butterworth, 1959. 390 p., $19.50.)

*AIRCRAFT AND MISSILE DESIGN AND MAINTENANCE HANDBOOK.

This work is applicable for piston-driven and jet planes, helicopters and guided missiles. Technical data on electrical and plumbing systems, materials of construction, hardware, color codes, and on processes such as metal spraying, anodizing, plating, and welding are presented here, along with numerous tables and figures illustrating standard methods of equipment installation. The text explains the methods and gives guidance in the handling of materials and tools. (C. A. Overbey. Galt, Brett-Macmillan, 1960. 369 p., $9.75.)

*CATHODIC PROTECTION.

This practical book on the prevention of corrosion by electrolytic means, describes the making of the necessary field surveys and tests, the interpretation of test results, and the design and construction of the appropriate cathodic protection installations. Operational examples of the protection of such underground and submerged structures as pipelines, cables, aviation fuel tank and line systems, lock and dam gates, and ships in storage are given. Also included is an examination of the relationship of cathodic protection to static and power grounding systems. (L. M. Applegate, Toronto, McGraw-Hill, 1960. 229 p., $10.35.)

*ELEVATORS, 3RD. ED.

Comprehensive and practical information on the construction, operation and maintenance of vertical transportation equipment in public and private structures, for maintenance men, mechanics, engineers, and others concerned with elevators, escalators, moving sidewalks, and ramps. Topics covered include a/c, d/c, and electrohydraulic machinery, methods of roping, signals, and safety systems. New material includes conformity with 1955 A.S.A. standards, and electronic and automatic innovations. (F. A. Annett. Toronto, McGraw-Hill, 1960. 388 p., $13.25.)

*HIGHWAY ENGINEERING HANDBOOK.

Written by specialists in each field, the 28 sections in this comprehensive book cover almost every aspect of highway engineering with the primary exception of structures. The first part covers highway administration, finance, planning, economics, route selection, photogrammetry, computers and traffic engineering. Soil testing, exploration, drainage, earthwork, frost, foundations, slopes, etc. are treated in part 2. Part 3 deals with contracts, specifications, soil stabilization, Portland concrete and bituminous materials and mixes. Part 4 includes design and construction of rigid and flexible pavements, highway maintenance and landscaping. (Ed. by K. B. Woods and others. Toronto, McGraw-Hill, 1960. Various pagings, $28.75.)

*SCIENCE AND RESOURCES.

Some of the difficult and critical questions arising from recent advances in science and technology are explored in this collection of paper originally presented at the 1959 Washington "Resources for the Future" Forum. A lead essay in each of the six topical sections discusses advances and state of current knowledge in a specific field, and is followed by two essays discussing the economic, social and political impact of the advances. The six sections deal with human and animal genetics, weather control, geological exploration, chemical technology, nuclear energy and peaceful use of atomic energy, and space exploration. (Ed. by H. Jarrett. Baltimore, Johns Hopkins, 1959. 250 p., $5.00.)

*ADVANCES IN SPACE SCIENCE, VOLUME I.

Embracing nearly all phases of human scientific knowledge, space science has the principle objective of manned space travel and exploration. Bioastronautics—concerning human aspects of space travel—is treated here directly, in articles on manned space cabin systems, the effect of radiation on man in space, and the nutritional aspects of space flight, and indirectly in articles dealing with orbits and interplanetary trajectories, interplanetary communications, and the problems of power supply on board orbital and space vehicles. The latest revision of the Sänger system for the classification of astronautical literature is included as an appendix. The first volume of a projected annual publication. (Ed. by F. I. Ordway, III. New York, Academic, 1959. 412 p., $12.00.)

*SIMPLIFIED DESIGN OF REINFORCED CONCRETE, 2ND. ED.

Prepared in compliance with recommended unit stresses and design procedure and requirements as given in the ACI Building Code Requirements, a major portion of this book consists of illustrative examples of the design of structural reinforced concrete members. This second edition has several new features, including identification of bar sizes by numbers instead of dimensions, an explanation of the practice of using all straight reinforcing bars in the design of beams, current requirements of web reinforcement, and a chapter on the theory and economic advantages of prestressed concrete. New tables have been added, and all new figures are given. (H. Parker. New York, Wiley, 1960. 303 p., $6.50.)

***SCIENTIFIC PAPERS OF SIR GEOFFREY INGRAM TAYLOR, VOLUME II: METEOROLOGY, OCEANOGRAPHY AND TURBULENT FLOW.**

The phenomenon of turbulence and its effect provide the main theme of this, the first of three volumes in this series to be devoted mostly to Taylor's work on the mechanics of fluids, but it also contains a wide range of geophysical investigations. Included are papers on diffusion in the atmosphere, formation of fog, tidal friction, tidal oscillations in gulfs, oscillations of the atmosphere, stability of stratified fluids, and convection from sources. (Ed. by G. K. Batchelor. Toronto, MacMillan, 1960. 515 p., $12.75.)

***PROGRESS IN SEMICONDUCTORS, VOLUME 4.**

This fourth volume in the series contains papers from the Soviet Union, England, Germany, Holland, Japan, and the United States. The scope of the discussions is shown by the titles of the papers: negative effective masses in semiconductors; oxidation phenomena on germanium surfaces; theory of avalanche multiplication in non-polar semiconductors; internal field emission; noise in semiconductors; the electrical effects of dislocations in semiconductors; dielectric properties of solids in relation to imperfections; non-crystalline, amorphous, and liquid electronic semiconductors. (Ed. by A. F. Gibson and others. New York, Wiley, 1960. 291 p., $10.50.)

***MARINE LUBRICATION.**

This book describes the properties, refining, testing and filtration of lubricating oils, the fundamental principles of their use, and the prime movers in which they are used, dealing specifically with the marine power plant and its auxiliary machinery, which have similar lubricating requirements whether used on land or sea. Machinery described includes diesel engines, steam engines, turbines, pumps, compressors, refrigerating, steering and deck machinery, and their fuels. (G. H. Clark. New York, Simmons-Boardman, 1959. 635 p., $16.00.)

***THE INSTRUMENT MANUAL, 3RD. ED.**

Contains descriptions of the purpose, principles, design, and materials of individual instruments used in all areas of measurement and control. The main additions to this third edition are in the fields of nucleonics and viscosity, and in a new section on analogue computers; the earlier chapter on navigational instruments has been omitted. Among the areas of measurement and control by instrumentation discussed are weight, conductivity, hydrogen ion concentration, fluid flow, specific gravity or density of liquids, viscosity, pressure and vacuum, temperature, and moisture content of air and gases. Also described are electrical and electronic measuring instruments, aeronautical, surveying, analytical, meteorological, counting, and timing instruments, as well as microscopes, telemetering systems, and various highly specialized types. (London, United Trade Press, 1960. 742 p., £5.5.0.)

***ENGINEERING THERMODYNAMICS.**

This undergraduate text concentrates on fundamental concepts, the first and second laws, and physical property relationships. It does not attempt to cover all engineering applications of thermodynamics, but illustrates applications of the basic principles presented in the first fourteen chapters in six chapters on fluid flow, fluid machines, gas and vapour power cycles, refrigeration, and binary mixtures. The elements of heat transfer are briefly discussed in the final chapters. Dimensions and units, and a variety of thermodynamic charts and graphs are given in appendices. (J. B. Jones and G. A. Hawkins. New York, Wiley, 1960. 724 p., $8.50.)

SPERRY

SENIOR and INTERMEDIATE NUMERICAL MACHINE TOOL CONTROL SYSTEMS ENGINEERS

Graduates in Electrical Engineering, Engineering Physics or Mechanical Engineering (with electronics training) and three years or more of applicable experience required for original development work.

Challenging work in an expanding Development Engineering department. Experience desirable in one or more of the following fields: Servo systems, digital and analog computer circuit development, hydraulic control systems, general electronic circuitry.

Address replies to:

CHIEF ENGINEER

SPERRY GYROSCOPE

COMPANY OF CANADA, LTD.

P.O. Box 710
MONTREAL 3, QUE.

£A2184 per annum. Professors are eligible for six months' study leave on full salary after three years of service, or twelve months after six years of service. Subject to the consent of the Council of the University, Professors may engage in a limited amount of higher consultative work. With the approval of the University and its bankers, married men may be assisted by loans to purchase a home. First class ship fare to Sydney of appointee and his family will be paid. The University reserves the right to fill the Chair by invitation. Four copies of applications, together with the names of three referees and a copy of a recent photograph, should be lodged with the Agent General for New South Wales, 56-57 Strand, London, W.C.2, and a copy forwarded in an envelope marked "University Appointment" to the Bursar, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, not later than 30th July, 1960. File No. 7071-W.

CHEMIST OR CHEMICAL ENGINEER

Industrial Water Treatment

Large New Jersey chemical company with New York City headquarters has opening offering fine opportunity for experienced water treatment man. Position is in Technical Department, entails correspondence and supervision of field service water, etc. Reply in confidence.

E. F. DREW & CO. INC.,
15 E. 26 Street,
New York 10, N.Y.
Att.: J. S. Beecher.

MISCELLANEOUS

ENGINEERS for sales, project, design, research, development, control and management. Graduates of all types and ages required by clients of The Technical Service Council, a non-profit industry-sponsored placement service. Write 2 Homewood Street, Toronto 5, for application. There is no charge for work done on your behalf. File No. 6648-V.

SALES ENGINEER. Three recent graduates, mechanical, electrical or chemical required by leading manufacturer of air conditioning and ventilating equipment, shell and tube heat exchangers and related engineered products. Following completion of company training course applicants will be assigned to Hamilton and Montreal Branch Sales Offices. Attractive starting salary and wide range of company welfare benefits. Send complete resume and salary requirements. File No. 6923-V.

THE INDUSTRIAL DEVELOPMENT BANK, Montreal, requires a graduate, registered professional engineer having several years diversified employment in secondary industry in Canada. Duties will include studies and reporting on industries. Financial analysis experience valuable but not essential. Must be bilingual. Applicants should be between the ages of 25 and 35. This is a permanent position and provide pension and insurance benefits. Candidates should forward a comprehensive resume. File No. 6999-V.

ENGINEER OR ARCHITECT. A life time career is open to a young engineer or architect in the maintenance department of a large public service organization, located in the Montreal area. Duties include estimating, contract development and supervision in all phases of work required for the operation and upkeep of buildings and grounds. Experience and bilingualism not essential. Starting salary $5,000 per annum. Apply with a complete resume of education, experience, and personal history. File No. 7000-V.

CHIEF ENGINEER. Large Toronto Structural Steel Fabricator and Erector is seeking an experienced Engineer with outstanding capabilities who has held a position of responsibility. This key position offers an excellent opportunity for advancement to a man who has considerable experience in the design of buildings and bridges. Applicants must have professional standing in the Province of Ontario. Salary commensurate with ability. Replies held in confidence. Please write to us giving details of age, education, experience to File No. 7044-V.

CHIEF ENGINEER. Age 35 to 45 for complete responsibility of design office. Structural, electrical and mechanical for work on process and chemical plant projects. Require consulting engineering background with client relationship experience. Excellent opportunity with large organization. File No. 7053-V.

CHEMICAL OR MECHANICAL ENGINEER. With up to three years' experience. Required in the project and design department of a modern expanding chemical company in Southern Ontario. This position offers an excellent opportunity for a young engineer to work with experienced engineers on a variety of engineering problems connected with the chemical industry. Apply File No. 7057-V.

INSTRUCTORS required for Western Ontario Institute of Technology, Windsor, Ontario. Professional engineers with some experience in either a) application of thermodynamics theory), preferably in air conditioning or b) production engineering, preferably in tool design. Stable, congenial employment. Salary range $5,750-$7,800. File No. 7062-V.

MANAGER REQUIRED. For an expanding organization engaged in Transit Mix Concrete, sand and crushed rock. This is an excellent opportunity for the right man, preferably with an engineering background, experience in concrete or construction management. Supply a complete summary including salary required in first letter. File No. 7064-V.

QUALITY CONTROL ENGINEER required. With experience in concrete, aggregates, and related materials, to maintain quality control and customer relations in a multi-plant operation on the prairies. This is an outstanding opportunity with excellent advancement potential. Please furnish a complete resume, including salary requirements. File No. 7065-V.

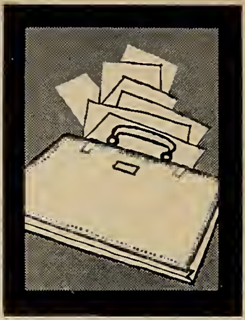
CHEMICAL OR MECHANICAL ENGINEER, young, recent graduate, to conduct field tests on and to service process equipment (centrifuges, vibrating screens, dust collectors, etc.) in the chemical and allied industries. Submit background resume to File No. 7069-V.

ELECTRICAL ENGINEER

The CITY OF REGINA has an opening for a Graduate Electrical Engineer with one or two years' experience, preferably in the Light and Power field. Salary Range: $5,040 to $6,432 per annum, commensurate with qualifications of successful applicant.

Applications and enquiries should be directed to the PERSONNEL DEPARTMENT, CITY HALL, REGINA, SASK.

Business and Industrial Briefs



Appointments and Transfers

J. Warren Millard has been appointed Manager, Eastern District Sales, for Carbide Chemicals Company, a division of Union Carbide of Canada. Mr. Millard assumes responsibility for the Company's chemicals and plastics sales in the Province of Quebec, the Ottawa Valley and the four Atlantic provinces. He will continue to make his headquarters in Montreal.

Four appointments in the Industrial Products Department of Canadian General Electric have been announced. **Joseph K. McLinden** has been given responsibility for Manufacturing instrument and specialty transformers. **Robert D. Maguire** has been appointed Manager, Engineering. **Robert M. Love** becomes Manager, Sales, and **George I. Campbell** is now Manager, Product Planning.

Dominion Engineering announces the appointment of **A. T. Setter** as Sales Manager of the Gear Products Division. Since graduating in Engineering from McGill in 1950, Mr. Setter has worked in various sales capacities throughout Eastern Canada.

Frank N. Buckley has been appointed Vice-President, Sales, of Aero Survey Ltd. Mr. Buckley will direct the sales activities of this company which specializes in aerial photogrammetry, airborne profiles, and airborne geophysical surveys.

New Developments

A PILLOW BLOCK which permits quick replacement of bronze precision liners without removing the bottom half of the housing from its support has been introduced by United Steel Corporation of Toronto. Only the cap half is removed—the shaft is lifted enough for the lower half of the liner to slip out and allow insertion of a new liner. A brass retainer spool recessed between cap and base of housing prevents rotation of the liner with the shaft and eliminates the need for screws. These units are recommended where shock load, high temperature or corrosive conditions prevail.

DOOR-SIZE PANELS in transparent plastic are now offered by Du Pont for use in the construction of greenhouses, car-ports, temporary hangars for small planes, etc. "Mylar" polyester film has a tensile strength equal to one-third that of machined steel. The portable panels measure 6 feet by 3 feet and are rimmed with lightweight aluminum.

STAINLESS STEEL DESIGN will be illustrated in photographs at an International Exhibition arranged for this Fall by the National Industrial Design Council in Ottawa. Atlas Steels, International Nickel and Union Carbide are co-operating to give recognition in this way to the services offered by industrial designers, architects and artists.

A LARGER REACTOR than any at present known may begin to take shape next year. Southern California Edison Company has sent Westinghouse a letter of intent for the design and construction of a 360,000 kw. nuclear power plant. Westinghouse will build the reactor at an estimated cost of $70 million. This type of plant has a 300 ton reactor vessel in which uranium oxide fuel elements are suspended. Water under a pressure of 200 p.s.i. is circulated around these elements, through a heat exchanger, and transfers heat to a secondary system where water is converted to steam to turn the turbine-generator. Westinghouse will supply the steam and electrical equipment for this installation, which will supply enough electricity to meet the residential needs of more than 500,000 people.

SEA WATER distillation is to be employed in Canadian Pacific's new liner "Empress of Canada", built by Vickers-Armstrongs at Walker-on-Tyne. A Weir closed feed system and a Weir sea water evaporating and distilling plant are being installed.

AIRSHIPS may help solve a perplexing space-age problem — transportation of eight-storey-high rocket boosters from factory to launch pad. This is the opinion of Goodyear experts who recently completed a feasibility study. Their analysis indicated that modern non-rigid airships could land practically at the door of the rocket booster factory, pick up a 40 ton booster, and deliver it to the launch site in the United States or overseas. No heavy duty runways would be required — only a comparatively smooth area about 2,300 ft. long.

THE MAGAVERTER, a completely static, solid state, precision analog-to-voltage-to-frequency converter, has just been introduced by Pioneer Magnetics Incorporated of Santa Monica, California. The Magaverter uses only tough, solid state components to produce an output square wave of frequency directly proportional to the input voltage.

GOLD-PLATED frame-grids in the tube permit a very small grid-to-cathode clearance in the Philips 7308/E188CC Special Quality Double Triode, now available from Rogers Electronic Tubes and Components. This results in a mutual conductance of 12.5 mA/V at an anode current of only 15 mA. Both tube sections are separated by a screen, and their cathodes are connected to separate pins. Outstanding microphonic properties make this triode ideal as a cascode amplifier or cathode follower in H.F. and I.F. circuits. Vibrational noise output is 140 mV maximum at vibrations between 50 and 5000 c/s at 0.5 g, and 100 mV maximum at vibrations between 10 and 50 c/s at 2.5 g.

OVER 1000 TONS of aluminum in one all-welded structure is a very unusual feature of construction even on land. The 40,000 ton Oriana now being built for the Orient Line by Vickers-Armstrongs will have this much aluminum in her superstructure. Equipment for the automatic and semi-automatic welding includes self-propelled machines as well as a specially designed welding gantry with four automatic welding heads. Two of the heads are for the welding of aluminum, and the other two are for welding steel sections by the FUSARC/CO_2 process. Quasi-Arc, Ltd., a subsidiary of British Oxygen, supplied the equipment.

• DISCUSSION

(Continued from page 69)

search (i.e. short-term research on the engineering principle involved) in a particular country are not always applicable to other regions, as stated by the author. Thus, in highway planning, design, construction, maintenance and operations there are some typical Canadian problems involved, which can only be studied in this country. This is due to the particular climatic conditions, certain types of construction materials and plant, the general rising economy and rapid rate of expansion in this country and the necessary training of more Canadian highway engineers. The co-ordinating activities of the Canadian Good Roads Association are, therefore, of great importance in ensuring that the special Canadian highway research problems are receiving attention and the results of such work are disseminated with the least possible delay.

Of special importance in the writer's opinion is the author's finding that the amount of research sponsored or carried out by provincial highway departments and the federal highway division in this country is exceptionally small when compared with the magnitude of highway construction undertaken. It appears that most of the Canadian highway research is at present being carried out by our universities or in cooperation with them. In this connection it may be noted that in civil engineering research in Canada generally, about three-quarters of all research is carried out by government departments and only one-quarter (in approximately equal proportions) by the universities and by industry. When it is realized that the planning and design of highways are almost entirely the responsibility of public highway departments, their small contribution to highway research in Canada is rather difficult to understand.

It would therefore seem reasonable to expect, as the author has indicated, that a much greater proportion of highway research should be carried out and financially supported by our public highway departments. The highway problems of general interest to Canada could probably best be solved by setting up under some federal authority, possibly the National Research Council, a National Highway Research Division with its own staff, laboratories and field equipment as has been done in other countries. The problems of special interest to the individual provinces, however, could best be solved by provincial joint highway research projects similar to those operating in Ontario and, to a smaller extent, in

Alberta in cooperation with the local universities in the particular province concerned. In this way, the local problems of highway engineering can be studied in the different areas and the solutions could then be directly applied in the province concerned.

For this cooperation between provincial highway departments and local universities, many more scholarships for graduate studies in highway engineering are urgently required in Canada, and some of these may well be set up by the local industry and the various highway departments for whose benefit the research is partly carried out. In addition, the highway departments should enable their own engineers to obtain special study leave of absence so that they can enrol in postgraduate courses in our universities, possibly under the suggested scholarship scheme. The writer believes that this approach would encourage highway research in Canadian universities considerably and at the same time it would give ample opportunity for such studies to be combined with field investigations without which the results of highway research are likely to be of limited value.

Author's reply:

Dr. Meyerhof has stated that "it appears that most of the Canadian highway research is at present being carried out by our universities or in cooperation with them". In so far as the numbers of individual projects are concerned this statement is very nearly true. However, in terms of the amount of money spent on research this is not the case. A check of our files reveals that approximately 40% of the highway research expenditure is made directly by the provincial highway departments, about 40% by the federal, municipal and other provincial government departments and agencies, slightly less than 20% by the universities and the remainder by industry. It is still apparent that the investment of the highway departments in research is too small but we are encouraged by their rapidly expanding activities in this field during the past few years.

The author heartily endorses Dr. Meyerhof's suggestion for greater cooperation between the highway departments and local universities and for an increase in the number of scholarships available for graduate studies in highway engineering. This, plus a further increase in university research work, cannot but help the highway departments and industry both through the development of solutions to current problems and through the increased supply of trained specialists from the graduate schools.

Somewhat contrary to Dr. Meyerhof's suggestion, the author feels that the best plan for carrying out the majority of both applied and basic research on highways is by having the necessary projects carried out by the universities and by highway departments working in close cooperation. This procedure would ensure the development of both the staffs and facilities of the universities and highway departments and would further ensure that the results of research are quickly recognized and incorporated into current design and construction practice.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

For two successive months this year Canada Cement Company, Limited have presented what, in the opinion of a fifty reader jury, is the "best" advertisement in an issue. Their 4-page, 4-colour insert in the April issue was considered to be the "best" by the jury by a wide margin. The advertisement shows and describes bridges in Ontario, Quebec, New Brunswick, Manitoba & Alberta. The copy emphasizes the versatility of concrete.

The Advertising Manager of the Company is J. V. Tittley and Cockfield, Brown & Co. Ltd., Montreal, are the agents—the Account Executive is J. B. Churchill.

CANADA CEMENT COMPANY, LIMITED WINS CERTIFICATE OF ADVERTISING MERIT

Reproduced here, on a greatly reduced scale, is the 4-page, 4-colour insert of Canada Cement Company, Limited which was judged the "best" in the April issue from the viewpoint of ACCURACY—INFORMATION and ATTRACTION. The insert appeared as pages 169-172 of the issue.

Aviation

There are few industries which, for speed of evolution and progress, can be compared with the aircraft industry. The key to this rapid growth has been research, and it is in this field that 'VSG' variable delivery hydraulic pumps and transmission gears have played an important part not only in this country but overseas.

Test rigs of various kinds both for airframe and jet engine development have incorporated 'VSG' equipment as being most suitable for giving that precise control necessary to simulate the required conditions.

This is just another of the highly varied applications of 'VSG' which has now been serving modern industry for over fifty years.

Meet the Authors

A note on **N. S. Bubbis**, M.E.I.C. (*Aqueduct and Pumping Station for Greater Winnipeg*) appeared in the June 1960 issue of The Engineering Journal.

R. Craig Sommerville, Jr. E.I.C., B.Sc. Civil (Manitoba '49), Design Engineer, Greater Winnipeg Water and Sanitary Districts, St. James, Manitoba. (*Aqueduct and Pumping Station for Greater Winnipeg*).

R. C. Sommerville, M.E.I.C.

Mr. Sommerville spent three years with Canadian National Railways at Hornepayne and Toronto before joining the Greater Winnipeg Water District in 1952. He is now responsible for their Design Department. He took his M.A.Sc. in Public Health Engineering at the University of Toronto in 1954.

Donald P. Wyness, B.Sc. Mechanical (U.B.C. '41) Project Engineer, Sandwell and Company Limited, Vancouver, B.C. (*The Khulna Newsprint Project*).

Mr. Wyness has had wide experience in the lumber and pulp and paper industries as a design engineer, working in various parts of British Columbia. He joined Sandwell and Company of Vancouver in 1951 and was their project engineer in charge of the Khulna newsprint project. He remained in East Pakistan a further year as Resident Engineer at Khulna. This year Mr. Wyness is Project Engineer on Rayonier Inc.'s fine paper mill expansion in Hoquiam, Washington.

David Panar, M.E.I.C., B.Sc. Mechanical (Michigan '41), M.Sc., Associate Professor of Mechanical Engineering, University of Alberta, Edmonton. (*The Economics of an Industrial Gas Turbine*).

D. Panar, M.E.I.C.

At the time Professor Panar took his M.Sc. at the University of Michigan in Industrial Engineering, he was also on their staff as a special instructor. He then entered private consulting practice in air conditioning. He has been on the staff of the University of Alberta since 1946 and continues his consulting work in power plants, heating and ventilating.

E. M. Rensaa, M.E.I.C., B.Sc.Civil (Manitoba '33), M.Sc., Partner, Rensaa and Minsos, Architects and Consulting Engineers, Edmonton, Alberta (*Joints in Precast Concrete Building Frames*).

After working with the C.N.R. and the Federal Department of Public Works in Winnipeg, Mr. Rensaa returned to Norway, his native country, for nine years and started his own designing and consulting practice. Since 1947 he has been a partner in a consulting firm in Edmonton which has pioneered in the development of precast reinforced concrete framework. Mr. Rensaa is a member of the advisory committee on structures and of the reinforced concrete committee of the National Building Code, and has written numerous articles on structural engineering and engineering education.

Walter J. Pearson, M.E.I.C., B.A. Geology (Saskatchewan '50), M.A., Ph.D., Industrial Minerals Geologist, Mines Branch, Provincial Department of Mineral Resources, Regina, Saskatchewan. (*Western Canada Potash and Its Future Prospects*).

Dr. Pearson did geological surveying in several parts of Canada during the field seasons of 1949-55. He joined the Department of Mineral Resources in 1956, and obtained his Ph.D. from Queen's University last year.

Charles D. Stewart, M.E.I.C., B.Sc.Agricultural Engineering (Saskatchewan '49), M.Sc., Ph.D., Professor and Head, Agricultural Engineering Department, University of Saskatchewan, Saskatoon. *(Irrigation Land Development Policies for Saskatchewan).*

C. D. Stewart, M.E.I.C.

Dr. Stewart spent five years in the R.C.A.F. prior to attending university, and was with the Prairie Farm Rehabilitation Administration for a year before doing post graduate studies at U.S.A.C., Logan, Utah. He then rejoined P.F.R.A. for four years as Drainage Engineer, Acting Head of Drainage Division. Dr. Stewart is the Chairman of the South Saskatchewan River Development Commission and of the Saskatchewan Farm Safety Committee. He is a member of numerous other professional societies.

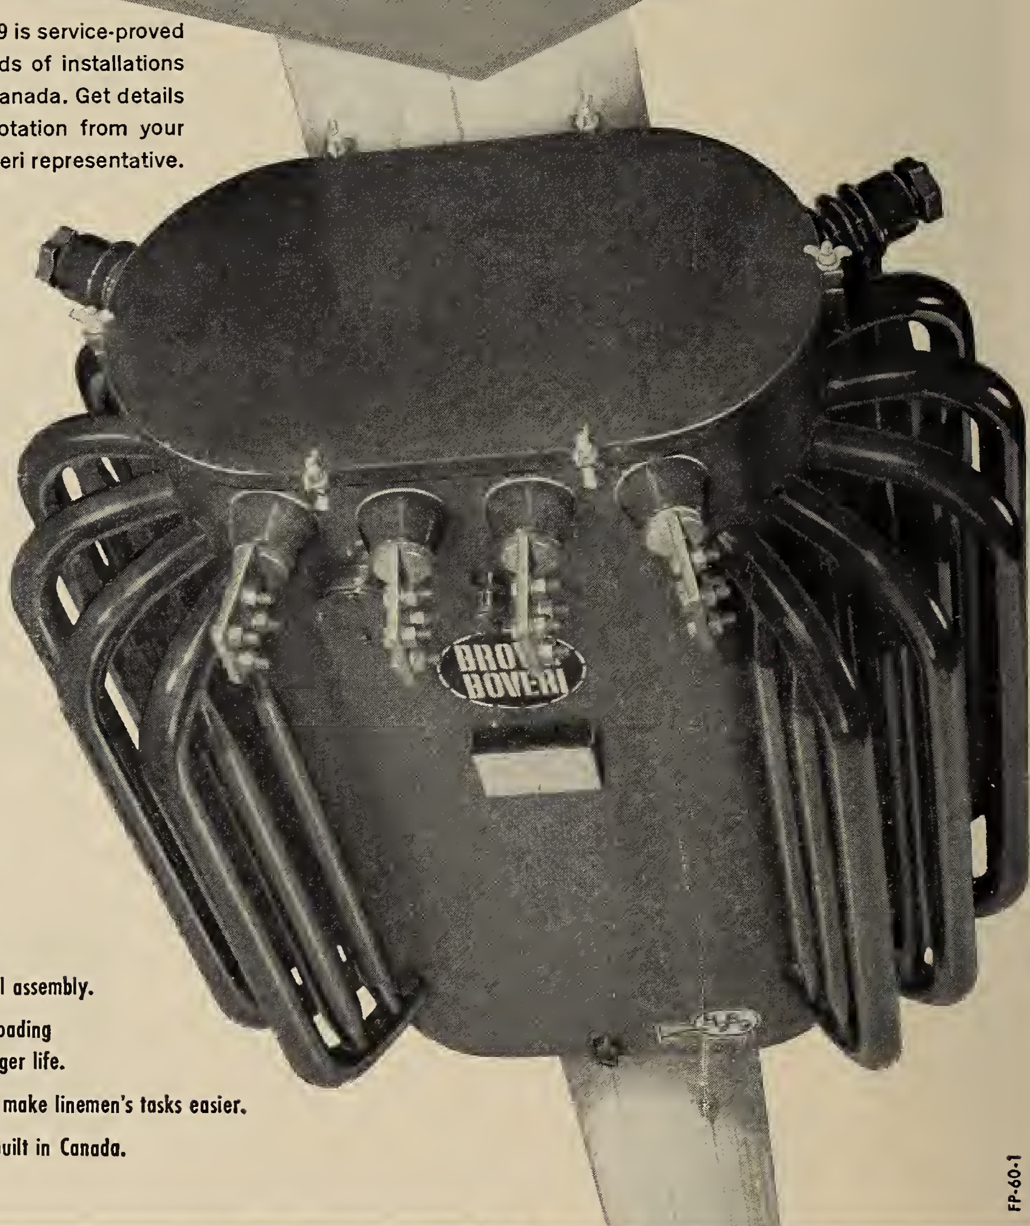
INCREASES Single Pole Output

The BB-99 is service-proved in thousands of installations across Canada. Get details and a quotation from your Brown Boveri representative.



The BB-99 Obround design brings transformer centre of gravity close to pole axis — significantly reduces bending moment. More BB-99 KVA's can be installed per single pole with direct-to-pole, cluster or cross-arm mounting. Brown Boveri BB-99 Distribution Transformers meet latest C.S.A. specifications.

THE BB-99 IS A TRANSFORMER WITH MANY PLUS VALUES:

- Superior electrical design.
- Extremely strong mechanical assembly.
- Excellent impulse and overloading withstand properties for longer life.
- Smaller size, lighter weight make linemen's tasks easier.
- Finest quality throughout, built in Canada.

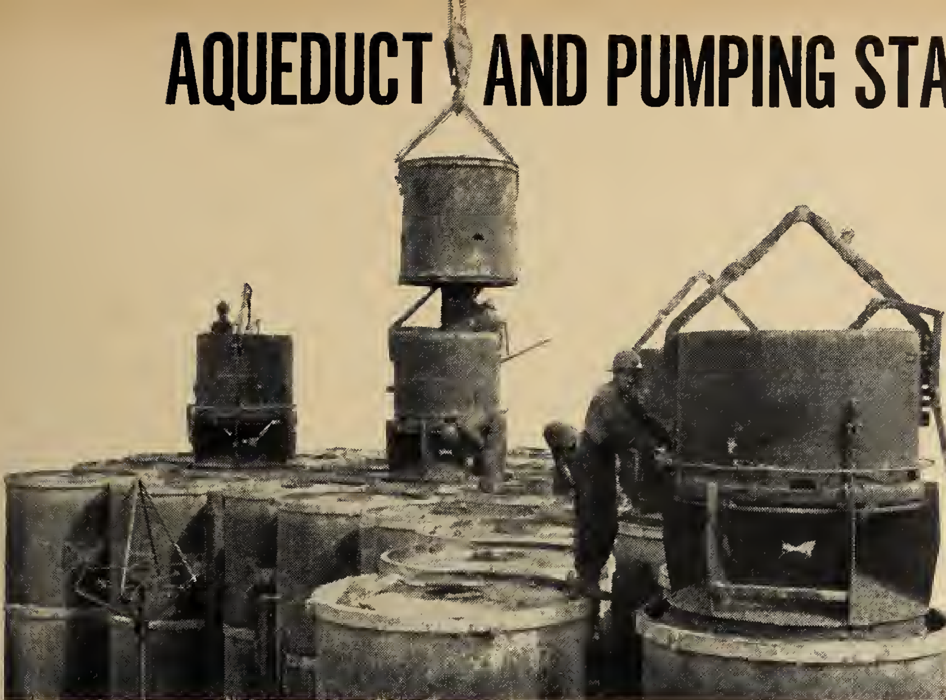
AQUEDUCT AND PUMPING STATION FOR GREATER WINNIPEG



N. S. Bubbis,
M.E.I.C.,
General Manager-Chief Engineer, Greater Winnipeg Water and Sanitary Districts

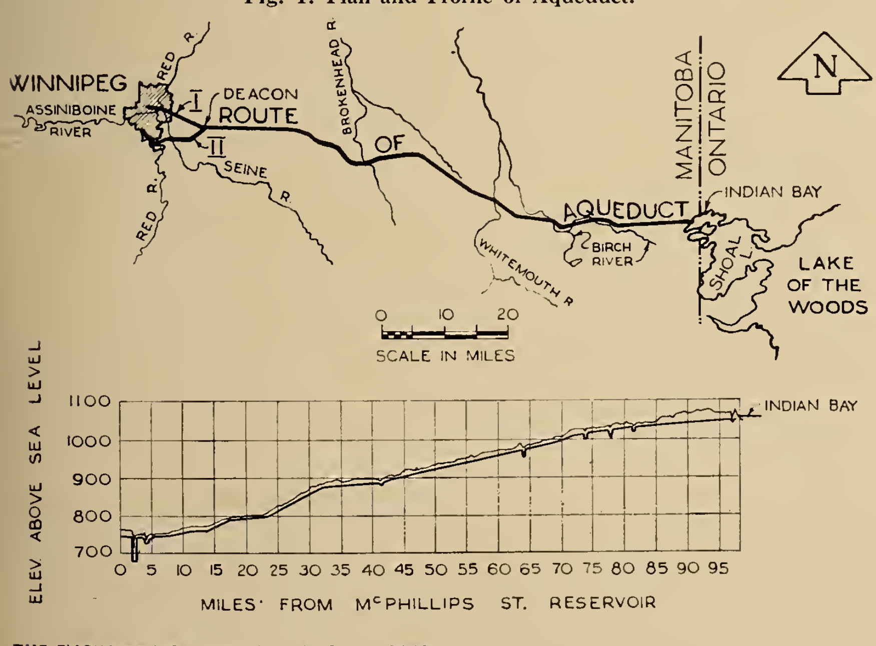
R. C. Sommerville,
JR.E.I.C.,
Design Engineer, Greater Winnipeg Water District

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The Greater Winnipeg Water District was organized in 1913 to bring water from Lake of the Woods to Greater Winnipeg. Between 1915 and 1919 an aqueduct 97 miles in length was built from Indian Bay, on the Manitoba-Ontario boundary, to the City of Winnipeg reservoirs. The most easterly 84 miles, comprising a gravity section of 80 miles and a pressure section of 4 miles, has a capacity of 85 m.g.d. with the continuing pressure section having a capacity of 50 m.g.d. Provision was made for a future addition, which is now under construction, as is also a low lift pumping station at Indian Bay. This paper will describe the design and construction of these projects.

THE CITY of Winnipeg's first water supply system was established in 1888 with water being taken from the Assiniboine River. This source proved unsatisfactory, due to the uncertain quantity, the poor quality despite filtering, and also its doubtful purity. The water was very highly turbid during seasonal run-off and was very hard, requiring the construction of the first lime soda ash softening plant in North America. At the turn of the century this source was changed to wells. While the well water was of excellent quality, it was extremely hard (and not amenable to softening) and it very quickly became apparent that wells could not be relied upon to supply the quantity of water which would be required by the very rapidly growing city.

Fig. 1. Plan and Profile of Aqueduct.



A number of engineering studies were made between 1906 and 1912 with several different water sources being considered. A report made to the Public Utilities Commission in 1912 recommended Shoal Lake as the source and suggested that the adjacent municipalities might join in the project. The Greater Winnipeg Water District was then established with the responsibility of bringing Shoal Lake water into the Greater Winnipeg area. A Board of Consulting Engineers was appointed on April 7th, 1913 to prepare a report upon the best means of supplying the area with water from Shoal Lake, together with an estimate of cost, general plans and specifications of the work. Construction started on October 1st, 1913 and the works were completed in March, 1919.

The consulting engineers recommended the Lake of the Woods source for three main reasons, as follows:

(1) This source could provide an inexhaustible supply of water.

(2) The quality of the water was excellent and came from a virtually uninhabited area.

(3) The average lake level was 290 ft. higher than the reservoirs in Winnipeg.

The importance of the last mentioned factor can be illustrated by stating that between the start of operations in 1919 until the summer of 1951, every gallon of water used in this area was delivered almost 100 miles by gravity and from 1951 until this year, pumping has only been required during peak summer periods.

The gravity flow section is for the most part of plain concrete, of horseshoe cross-section varying in size from 6.35 ft. x 5.35 ft. to 10.75 ft. x 9.0 ft., extends westward from the Intake for about 80 miles and has a capacity of 85 m.g.d. From the west end of this horseshoe shaped section there extends a depressed section of reinforced 8 ft. diam. concrete, 4 miles long, continuing the capacity of 85 m.g.d. to Deacon, the site originally chosen for a future 250 million gallon reservoir. Between Deacon, about 8 miles east of St. Boniface, and the surge tank and booster pumping station located on the east bank of the Red River, there are approximately 49,000 lineal feet of 66 in. concrete pressure pipe, having a capacity of about 50 m.g.d. Fig. 1 shows the plan and profile of the aqueduct.

A 60 in. cast iron pipe crosses the Red River in tunnel and a 48 in. Lock Joint reinforced concrete pipe, approximately 12,000 ft. long, extends through the City of Winnipeg to its reservoirs at the western terminus. This latter pipe, depending on the quantity of water being used east of the Red River and at the James Avenue Pumping Station, has a capacity of 28.5 m.g.d. under gravity conditions or between 38.5 and 42 m.g.d. when the booster pumps are being used.

The original design of the aqueduct was such as to develop its full capacity in several stages as demand required. (See Fig. 2). It was originally estimated that the booster pumping station would have to be built about 1922 when Winnipeg's average daily consumption reached approximately 25 m.g.d. It was also estimated that the second branch aqueduct would be required about 1930 when the demand approached an average daily consumption of 35 m.g.d. However, following the first Great War and the construction of the Panama Canal, Greater Winnipeg's population remained almost constant and did not resume its growth until the Second War, which meant that these additions were not required until very recently

Since 1948 the original plan has been under periodic review. In 1950 a booster pumping station was constructed adjacent to the surge tank to completely develop the first 66 in. pressure line from Deacon to Winnipeg. In 1952 a report, made jointly by engineers of the City of Winnipeg and the District, indicated that a second branch aqueduct would be required by 1963 and suggested a route for this line. Right-of-way privileges were secured by means of an agreement with the City of Winnipeg Hydro Electric System. A further review early in 1957 indicated that the second line would be required by about 1960.

Preliminary Design

The future organization of Greater Winnipeg's water supply has been in a state of uncertainty because it, like other area wide services, has been under review by the Greater Winnipeg Investigating Commission since 1955. The Commission's report was not brought down until January, 1959 and action on it was not taken until the 1960 Session of the Legislature. As a result, an additional burden was placed on the District's design engineers since all of the facilities to be constructed would have to be capable of functioning efficiently whether the organization of water supply remained as at present or whether it was changed to a completely integrated system under a single amalgamated city or some form of metropolitan government.

Nevertheless it was clear early in 1957 that the additional facilities would be required by 1960 and that design and construction would have to proceed almost immediately if the District was to be in a position to deliver the water required into the Greater Winnipeg area at that time. Accordingly, detailed design work was proceeded with, including survey work and soil investigation in the field. Investigation of the proposed crossing of the Red River, including soil and rock borings, had been made during the winter of 1955-56.

A preliminary report of the complete work to be undertaken was presented to the Board of Commissioners on December 13th, 1957. The report included detailed outlines of the various projects which would have to be constructed, a list of items which would require additional investigation, an estimate of the cost and the time table for the calling of tenders and completion of construction. On the suggestion of the General Manager, concurred in by the Commissioners and the Administration Board, a copy of the preliminary report was submitted to Messrs. Alvord, Burdick & Howson, Consulting Engineers of Chicago, for review. The general scheme was approved by the Consultants and a number of very valuable suggestions were made which were incorporated into the final specifications.

The District's Consultants on soil investigation, Messrs. Baracos and Marantz of Winnipeg, were also of considerable assistance in working with the District and with the Chicago Consultants. Borings and soil samples were made under their direction along the entire route of the pipeline to obtain data on which to base pipe loadings and trench dimensions and to detail bedding and backfill procedures.

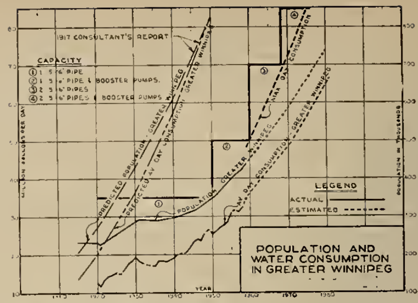


Fig. 2. Population and water consumption in Greater Winnipeg. Curves on left from 1917 Consultant's Report.

General Design of Pipeline

Route: In the original works an arrangement of three 60 in. valves was installed for a proposed reservoir at Deacon, Mile 12.5. These valves permitted a connection to be made fairly readily for the second branch aqueduct at this location, without interrupting the flow. The City of Winnipeg, after consultation with the District, had acquired land for a new reservoir at the south limit of the City of Winnipeg, which location fixed the westerly terminus of the new pipeline. A general investigation was made of several alternate routes between these two points, with detailed planning and cost estimating being made for two alternate routes. (See Fig. 3)

The first route followed the Slave Falls Transmission Line Right-of-Way owned by the City of Winnipeg Hydro Electric System and traversed open prairie for almost its entire length. Very few municipal services existed along this route and no great difficulty was apparent in crossing municipal roads, highways or rail lines. The only extra land purchased was at the crossing of the Seine River in order to permit a better crossing location.

The second route, while more direct and appreciably shorter, passed through the built up areas of St. Boniface, St. Vital and Fort Garry and presented considerable difficulties with location because of existing water, sewer, gas services and pavements. The banks at the crossing of both the Red and the Seine Rivers were more unstable on this route than they were on Route 1. Studies indicated that the use of this route would increase the cost, cause greater inconvenience and disruption and take longer to construct. There was, however, the advantage of a slightly greater hydraulic capacity using this route. After weighing all considerations, Route 1 was selected and this choice was subsequently confirmed by the District's Consulting Engineers.

Design Capacity and Pipe Size: The Red and Assiniboine Rivers divide the Greater Winnipeg area into three sectors, each of which uses about one-third of the total amount of water presently being delivered to this area. From a future population distribution study, based on a forecast made by the Metropolitan Planning Commission, the same ratio will prevail in 1981. From this, it would appear that additional reservoirs and pumping stations will eventually be required on the east side of the Red River and provision was made for this in determining the capacity of Branch II* After a detailed consideration of future water requirements in this area, it was decided that Branch II should essentially duplicate the capacity of Branch I.

The next problem was to determine whether it would be more economical to satisfy the needs of the new South Winnipeg Station by gravity alone or whether booster pumping station facilities should be installed. The size of pipe required to deliver 50 m.g.d. by gravity to the new reservoir is 72 in. diam., using a C value of 140. Various combinations of smaller pipe sizes and continuous or intermittent booster pumping were considered but it proved to be more economical to construct the entire line with 66 in. diam. pipe to deliver 35 m.g.d. by gravity initially, with provision for the future installation of a booster pumping station to increase this capacity to 50 m.g.d.

However, serious consideration was given to constructing the booster pumping station concurrently with the pipeline for use in the event of a break in the existing Branch I. This line has now been in service for more than 40 years and it seems prudent to assume that difficulties with its operations may arise at any time. This has always been of particular concern to the District as the City of St. Boniface, the Town of Transcona and the Municipality of St. Vital perform their own domestic water pumping but have no reservoirs, and are therefore entirely dependent upon Branch I remaining in service for their water supply.

It was found on investigating this problem that if a break occurred in Branch I so that no water was available to the City of Winnipeg by that Branch, the maximum day's demand for that City and the municipalities served by Winnipeg could be satisfied from storage and from Branch II for about three days. By restricting water use to 42 m.g.d., the 1976 estimated average daily demand, water could continue to be supplied for up to 15 days by utilizing storage capacity. St. Boniface, Transcona and St. Vital would, of course, have no water available.

It was felt, therefore that there was no immedate justification for the capital expenditure, together with the maintenance and standby electrical charges which would be incurred by the construction of the booster pumping station on Branch II at this time. However, connections are provided in the pipeline so that the construction may be undertaken readily at any time.

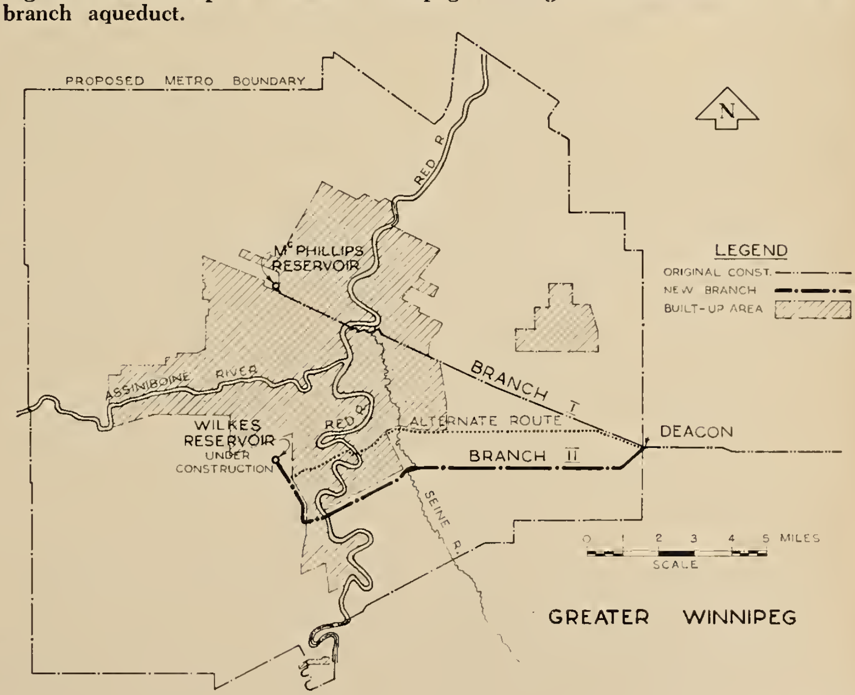
Type of Pipe: Having determined the route location and the pipe size, the next problem was to decide on the type of pipe to be used. The 66 in. section of Branch I was constructed of Lock Joint type reinforced concrete steam cured pipe made from Portland cement and the only serious difficulty that the District has experienced has been with the failure of the crimped copper expansion joints. This difficulty has been overcome with modern concrete pressure pipe which utilizes a steel ring and rubber gasket joint which permits some movement of the pipe.

In the preliminary report on Branch II, the District's Engineers stated that while both steel and reinforced concrete pipe has been used fairly extensively and successfully in long aqueducts, their first choice, based on local experience, was reinforced concrete pipe with rubber ring joints of the Lock Joint type. However, they recommended that bids also be called for steel pipe to ensure that no appreciable saving could be made by the use of this alternative. This recommendation was subsequently concurred in by the District's Consultants who have had extensive experience in pipeline work and they assisted in the preparation and gave final approval to the pipe specifications.

Concrete Pipe: In the detailed design of the pipeline, it was necessary to consider the several types of reinforced concrete pressure pipe. The design head of Branch II had been established at 100 ft and for this particular head, it is common practice to use one of the following types of pressure pipe: reinforced concrete pipe, non cylinder type, not prestressed, A.W.W.A. C-302; or reinforced concrete pipe containing a steel cylinder within the concrete wall yet not prestressed, A.W.W.A. C-300; or concrete pipe containing a steel cylinder in a concrete core, around which is wound prestressing wire, A.W.W.A. C-301. After considering cost, trench dead loads, traffic loads, probable leakage and manufacturing difficulties, it was decided to specify the latter.

The use of prestressed concrete pipe has become fairly common and the usual advantages of prestressed concrete apply. Prestressed concrete

Fig. 3. Outline map of Greater Winnipeg showing alternate routes for second branch aqueduct.



*For simplicity in this paper:
Aqueduct will refer to 85 m.g.d. pipeline East of Deacon.
Branch I will refer to original pipeline West of Deacon.
Branch II will refer to 66 in. pipeline now under construction.

pipe in this size range utilizes a continuous water-tight-steel cylinder, embedded in a concrete core which is wound with high tensile wire so that the concrete is in compression under all design loads. Design formula for this type of pipe have been developed with extensive use of empirical data otbained by pipe manufacturers. Comprehensive limits to the design have been established by the American Water Works Association and deal with normal hydrostatic pressure, water hammer, trench dead loads, live loads and impact.

While the terrain along the route of Branch II is fairly flat, there is some difference in depth of cover over the pipe. It normally ranges from the minimum cover of 5 ft. to about 7 ft. but in some sections, particularly under railway crossings and where the pipe is depressed beneath the Seine River, cover ranges up to about 25 ft. Since the pipe was being laid on a Hydro right-of-way and a patrol road was being constructed closely parallel to the pipeline, the pipe was required to withstand H-20 traffic loading simultaneously with full hydrostatic pressure. A table of minimum acceptable three-edge bearing strengths for various depths of cover was set out in the specifications and the pipe manufacturer was required to design and submit to the District for approval, various classes of pipe to meet these loading conditions.

Similarly, it was important that the steel pipe alternative have sufficient wall thickness to withstand the superimposed loads without "egging" and destroying the bond between the cement mortar lining and the inside of the steel shell.

Sulphate Resistant Cement: The selection of the type of cement to be used for the concrete pipe was another problem which had to be given very careful consideration. It is general practice in the Winnipeg area to use Type V sulphate resisting cement for all subterranean concrete work. It is interesting to note here that disintegration of the concrete in the 96 in. pipe of Branch I discovered in the first year or so after construction, resulted in the commencement of a research program to find more suitable cement which subsequently led to the commercial development of sulphate resisting cements by the Canada Cement Company.

In the construction of Branch I, an underdrain had been installed in the trench during the laying of the 66 in. pipe to provide drainage and to aid construction. On the discovery of the damage to the 96 in. pipe which proved to be due to heavy concentrations of soil sulphates between Miles 13 and 17, these underdrains were extended to lower the ground water table in the immediate vicinity of the pipe in order to minimize the effect of the alkali water. Periodic inspections have indicated that this solution has been quite effective in preventing further disintegration.

Soil samples taken over the route of Branch II for sulphate analyses indicated that concentrations ranged from 25 p.p.m. to 1123 p.p.m. based on 10% aqueous acid extraction. The use of alkali resisting cement is recommended wherever sulphates exceed 350 p.p.m. The difficulty with soil sampling is that the high sulphate concentrations occur in isolated pockets so that random sampling can only give a general indication of the soil sulphate level.

After weighing carefully all considerations, it was decided to specify Type V sulphate resisting cement for the new pipeline, even though this increased the estimated costs by 2%. This was more effective than providing a continuous underdrain over the 12 mile length, and considerably cheaper.

Steel Pipe: It had been decided to call for alternative bids using steel pipe to make sure that no appreciable saving in cost could be made using this material, and careful study was given by both the District's Engineers and the Consultants to make sure that any such alternative would be equivalent in all respects to the concrete pipe specified.

After analyzing wall thicknesses, loading and soil conditions, flow coefficients, construction and installation procedures, particularly under cold weather conditions, it was decided to specify steel pipe (A.W.W.A. C-201) with half inch wall thickness, coated with coal tar enamel and wrapped with double bonded fibrous glass mat and asbestos felt (A.W.W.A. C-203) and cement mortar lined in place (A.W.W.A. C602) as an equivalent alternative to the prestressed steel cylinder pressure pipe.

Trench Design: Because of the influence of external loads on the design of the pipe and the three-edge bearing strengths specified, it was necessary to carefully review the trench width and shape with the District's Soil Consultants and establish trench dimensions. The specifications required that vertical trench walls be maintained in the pipe zone. Trench width was limited to not less than 18 in. nor more than 24 in. greater than the outside diameter of the pipe.

The Red River Valley clays are subject to very considerable volume change with variation of moisture content. The specifications therefore required that the bottom of the trench could not be left exposed for any length of time following excavation and the maximum length of trench ahead of the pipe laying was limited to 300 ft. A 6 in. layer of granular material was specified for the bottom of the trench to provide proper bedding.

Some flexibility in the pipeline was also desirable to take care of differential soil movement, as well as temperature change, since the water temperature varies from 35 to 72° F. The Lock Joint type of joint consists of a round rubber gasket compressed between bell and spigot joint rings with cement grout being poured in both inside and outside joint spaces to protect the steel rings from corrosion. This provides some degree of flexibility but consideration was also given to using a paraplastic material instead of cement grout as a joint filler. The City of Chicago, among others, uses this procedure. However, since the pipe suppliers indicated some reluctance, it was decided to use the conventional cement grout.

Due to the known difficulties in compacting local clays, granular backfill material was specified to a height of one foot above the centre line of the pipe. From this point, excavated material was permitted as backfill but it was required that this material be placed in layers not more than 6 in. thick with each layer being tamped in place for a height of 3 ft. For the balance of the backfill, the Contractor was allowed to compact excavated materials in place, using a light crawler tractor in the trench. This backfill was to be brought to a height of 2 ft. above the original prairie grade to allow for subsidence.

Surge Protection and Overflow: A combination pump well and surge tank was provided on Branch I near the site of the booster pumping station on the east bank of the Red River and this has operated without any difficulties. Considerable study was given to the problem of surge in Branch II. The City reservoir is to be operated as a balancing reservoir so the inlet valve should not be manipulated very often, and by limiting the speed of the valve, no serious surge will occur. Preliminary studies indicated that even when the booster pumping station is constructed and in operation, surge pressures resulting from a power failure or pump stoppage can be held below the design strength of the pipeline and therefore no surge well was provided in the initial construction.

The existing surge tank on Branch I also serves as an overflow during periods of low demand west of the Red River crossing, but an overflow weir at Mile 17 is an additional control point for wasting excess water when the demand is low. This waste water is conveyed to the Seine River through an 11 mile long offtake ditch which causes considerable difficulty and maintenance expense, particularly during the winter, when intermittent spilling fills the ditch with ice.

To obviate this difficulty, a automatic spill valve was installed several years ago in the booster pumping station. This consists of an 18 in. butterfly valve positioned by an air cylinder, actuated by a pressure sensing device. This valve automatically holds the hydraulic grade at the booster station to a predetermined level, corresponding to the crest of the overflow weir at Mile 17 for a given flow rate. A similar device is being installed at the east tunnel shaft on Branch II. The valve and chamber are so arranged as to provide overflow to the Red River when it is below flood stage. When the river is in flood and the valve chamber is inundated, it will be possible to seal off the piping so as to prevent contamination of the potable water supply during these times of high water.

Valves and Meters: Only two main line valves were installed in Branch II. The first was a butterfly valve installed at Deacon to regulate the flow in Branch II. A second, an isolating valve, was installed immediately upstream of the Red River Crossing. Provision was also made at the location of the future booster pumping station for the eventual installation of an automatic valve which will serve both as surge relief and as a device to divert the flow through the new pumping station once the pumps are up to speed.

Automatic vacuum breaking and air release valves are installed at high points on the new pipeline. Each installation consisted of duplex mounting of 6 in. air valves, and 4 in. manual gate valves are also provided for the release of large volumes of air whenever the aqueduct is being charged.

Two long form Venturi meters were installed in the original aqueduct in 1919 at Deacon. Both are constructed of monolithic concrete with bronze throat and piezometer ring. The one located upstream of the branch measures the total flow in the main portion of the aqueduct and the other smaller Venturi measures the flow in Branch I. By installing new registers and electric flow transmitters at Deacon, it will be possible to record and integrate the flow in each branch of the aqueduct, as well as in the main section. Provision has been made for telemetering these readings to a central control station whenever required.

As take-offs will eventually be made at various locations along the line for other municipalities, it was necessary to install a metering device at the entrance to the City of Winnipeg reservoir. Studies were made of the various types of metering devices available, comparing accuracy, head loss, maintenance, construction difficulties and first cost, resulting in the choice of an orifice plate. A stainless steel concentric orifice plate was installed at Station 3+00, together with a low head type of meter and an electric transmitter which will provide an indication and integration of flow to the City of Winnipeg high level pumping station.

Guarantee of C Value: The carrying capacity of any pipeline varies with the frictional resistance (coefficient C) which is dependent upon the smoothness of the pipe interior and the quality of workmanship used in laying the pipe and making the joints. In the case of Branch II this factor is unusually important since the line is a low head pipeline. For example, a decrease in capacity of 100,000 g.p.d. will result from each additional tenth of a foot loss of head.

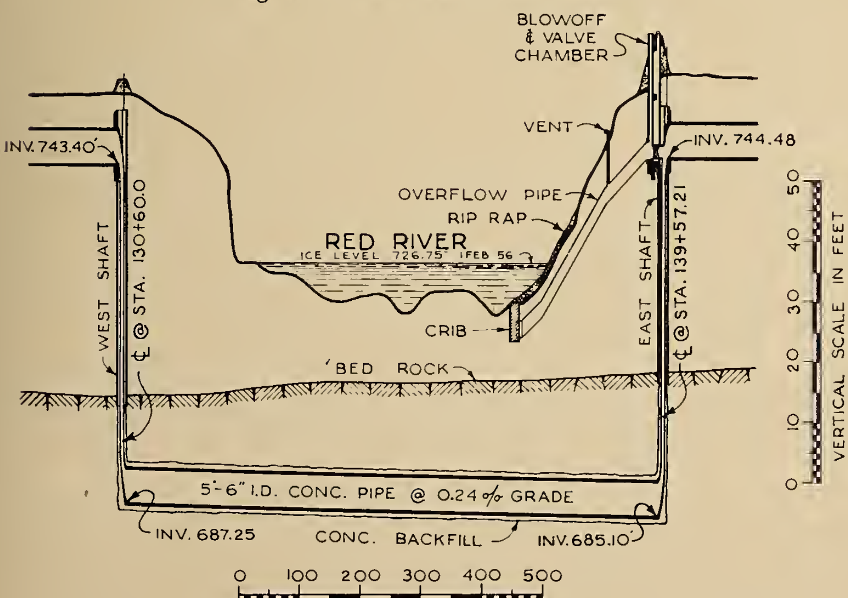
For this reason, a rather unusual procedure was followed in writing the specifications. Bidders were advised that the District had designed this pipeline based on a Hazen & Williams C value of 140 and that they would be expected to construct the pipeline to meet this requirement. On completion, the District would engage a competent independent water flow testing organization to make acceptance tests and any failure to meet the required C value would result in a deduction from the lump sum contract price of $42,000 for each point or major fraction thereof by which the C value falls below 140.

The figure of $42,000 was established by evaluating the loss of capacity resulting from the lower C value on a pro rata basis with the design capacity and the estimated total cost of Branch II. The specifications state that no bonus shall be paid should the C value exceed 140. The report of the independent testing organization would be final and binding on both parties. Corporation cocks are installed at various locations along the pipeline to facilitate the use of Pitometer equipment in making these tests.

It is unfortunate that not many long pipe lines of large diameter are tested immediately following completion to provide more data. We do not know of any other instance where the above mentioned method of guaranteeing the friction factor has been used. It can, of course, only be used equitably if one contractor is responsible for both the supply and installation of the pipe.

Method of Calling for Tenders: It has generally been the District's practice to call separate tenders for material and for installation. In the case of Branch II, however, it was decided, after serious consideration of the problems involved, to call tenders for a completed pipeline job, commonly referred to as a "turnkey" contract. This method had been used fairly extensively, particularly in the United States and has several advantages, including the elimination of divided responsibility between the pipe manufacturer and the installation contractor regarding completion date and progress of the work, as well as the quality and acceptability of the fin-

Fig. 4. Profile of Red River Tunnel.



ished pipeline, thus permitting the guarantee of the C factor.

This procedure was recommended to and agreed upon by the District's Administration Board.

A great deal of interest in the project was exhibited by contractors all across Canada and by several in the United States. More than 75 sets of tender documents were issued and subsequently seven tenders were received. Competition between the steel pipe manufacturers and the concrete pipe manufacturers was particularly keen. Seven bids were received, based on the use of reinforced concrete pipe as specified, varying in total from $3,812,571.87 to $4,533,805.00. Seven bids were also received, based on the use of steel pipe, which were in accordance with the specifications and ranged from $4,093,827.00 to $5,840,000.00. The low tenderer on steel pipe also submitted four alternative tenders, each at variance with the specifications in certain respects. The lowest informal tender was for the amount of $3,704,484.00 and was based on reducing the steel plate thickness, deleting one of the double bonded wrappings specified and substituting a bituminous enamel lining for the cement lining specified. Informal tenders were naturally not considered and a contract was awarded to the low bidder using concrete pipe.

Construction

The contractor moved in a temporary pipe manufacturing plant and set it up on District property in St. Boniface. The winter of 1958-59 was an unusually severe one with very heavy snowfall in mid-November, but the Contractor, with excellent management, was able to pour his footings and erect his plant in time to produce the first pipe on schedule by April 1st, 1959. A total of 4,000 pipes, each 5 ft. 6 in. in internal diameter, 16 ft. long and weighing 11½ tons was produced by October 31st, 1959.

As mentioned, prestressed embedded cylinder concrete pipe (A.W.W.A. C-301) was used. Manufacture consisted of rolling and welding 16 gauge plate into cylinders to which were welded forged steel bell and spigot ends. Each cylinder assembly was hydrostatically tested to 43 p.s.i. (sufficient to stress the steel to 25,000 p.s.i.), then centred in a vertical mould into which 4,500 p.s.i. concrete was poured. After steam curing, this 5 in. thick core was rotated and wrapped with No. 6 gauge steel wire having an ultimate strength of 190,000 p.s.i. The pitch of the wrap was varied according to the class of pipe being produced. In all, six different classes of pipe were designed to cope with the varying cover over the pipeline throughout its length. For instance, Class A pipe was designed to withstand a 5 ft. backfill load, Class B was designed to withstand a 6 ft. backfill load and Class F was an extra heavy pipe designed to withstand up to 25 ft. of over-burden and was used in the crossing beneath the Seine River.

The local soil is extremely active, causing graphitic corrosion of cast iron, as well as affecting Portland cement concrete and steel. Special consideration was therefore given to the protection of the high tensile wire. A mortar coat of 1⅛ in. thickness was asked for instead of the normal ⅞ in. Since it was very difficult to check this thickness once the coating had set, the District assigned an inspector solely to this operation. By using a penetration gauge he was able to check the thickness as the mortar was brushed on. If too thin, additional material was brushed on before the pipe was removed from the machine.

The services of the National Testing Laboratories of Winnipeg were engaged to carry out a rigid inspection of all phases of the pipe manufacture. One pipe from each day's run was hydrostatically tested to 100 p.s.i. and not one of the pipes so tested exhibited any signs of leakage or cracking. In addition, the specifications required that the Contractor demonstrate the adequacy of his design for each of the classes of pipe by carrying out three-edge bearing tests to destruction on one pipe from each class. The short sections of pipe so tested proved the design was more than adequate to meet all conditions and the designs were therefore accepted.

The District had a Canadian materials preference clause in the specifications and it is interesting to note that with the exception of the steel joint rings and rubber gaskets, all other material used in the pipe manufacture was of Canadian origin.

One problem that arose and which gave the District and the Contractor considerable concern was that of small imperfections to the inside of the pipe wall, in the form of pock marking. After exhaustive investigation, it was decided that some degree of pock marking was inevitable in any concrete work where smooth steel forms were used. However, it was found that the prevalence of pock marks was considerably reduced by varying the fineness modulus of the aggregate until the optimum was reached, by adjusting the form vibrators until the maximum amplitude of vibration was reached and by exercising very close control over the time taken by the men to fill each steel mould. It was found that if the moulds were charged slowly at rates less than one vertical foot per minute, better quality pipe resulted.

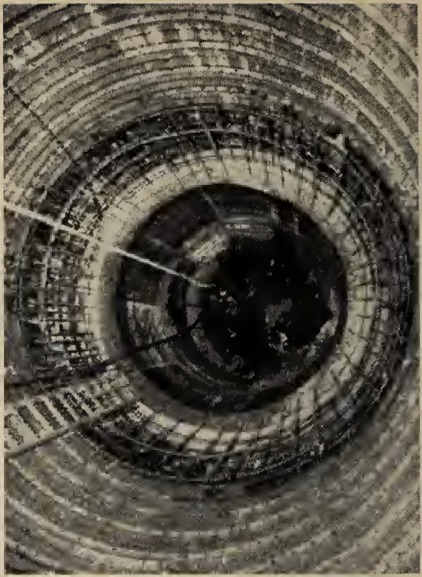


Fig. 5. Stripping forms from concrete shell east shaft, Red River Tunnel prior to commencing rock excavation.

The first pipe was laid on May 22nd, 1959 and pipe laying was essentially completed, other than for certain connections at Deacon and miscellaneous structures, by Christmas, 1959. To meet the District's rigid specifications for vertical trench walls, the Contractor devised an ingenious steel box or sled which was put in the trench wherever bad ground was encountered and slid along as each pipe was laid.

Another departure from standard practice was the method used by the Contractor to compact the granular backfill material. This material was placed uniformly on either side of the pipe to the required level of one foot above the centre line of the pipe and then jetted with a one inch water pipe and vibrated with a heavy duty concrete vibrator. This provided very good consolidation and was used even in the late fall with the onset of cold weather.

Notwithstanding the abnormally wet spring, summer and fall, with rainfall of 21.85 in. compared with the normal of 15.52 in., the Contractor was able to maintain exceptionally good progress. The best day of pipe laying saw 63 pipes installed and backfilled, or a total of 1,008 ft. of pipe laid. This was done with only one spread working.

The railway companies insisted that the pipe be encased where the line passed under all existing tracks. 96 in. tunnel liner was installed ahead of the pipe laying crew. The same method was used in crossing under two paved trunk highways.

Very few municipal utilities were encountered but those that were had to be relaid so as to permit the installation of the large pipeline. Water mains varying in size from 6 in. to 14 in. were relaid as were sewers varying from 8 in. to 30 in. The Seine River was crossed by a depressed section, using concrete pipe laid within steel sheet piling which was intended to aid the construction as well as serve to prevent any future scour of the river bed. Because of the wet season, abnormally high flows prevailed throughout the summer and it was not until late November that the Contractor was able to divert the stream and lay the pipe. Once flows had dropped to normal, no great difficulties were encountered.

The contractor was permitted to continue working during the cold weather, but heated backfill material was required and extra precautions to warm the ends of the pipe as well as the interior were required to permit mortaring of the joints. A small crew worked throughout the winter of 1959-60 completing miscellaneous concrete structures and the connection to the main aqueduct at Deacon. Pressure testing will be completed this spring but due to the fact that the City of Winnipeg reservoirs and pumping station will not be available until mid-summer of 1960, it will not be possible to complete flow and acceptance tests until that time.

As mentioned, weather conditions were abnormal with precipitation being much heavier and more frequent than normal. However, both the prime contractor and the pipe laying sub-contractor, by bringing in top flight supervisory personnel and adequate equipment and by excellent job organization, were able to maintain their schedule. All concrete pipe for the line, as well as for the Red River Tunnel, and some 2,750 ft. for the City of Winnipeg reservoirs were manufactured by October 31st, 1959. The contract called for 60,000 ft. of pipe to be laid by November 15th and the job completed by July 1st, 1960. Actually the job was completed in March, 1960, with the exception of testing and cleanup work.

Red River Tunnel Crossing

Design: Branch I crosses the Red River by means of vertical shafts 75 ft. deep on each side of the Red River, joined together by a horizontal tunnel through the limestone bedrock underlying Winnipeg. 60 in. diameter cast iron pipe was installed in the vertical shafts and in the horizontal tunnel, with the space between the exterior of the pipe and the tunnel backfilled with concrete grout. Since this crossing has proven eminently satisfactory, having been in continuous operation without any maintenance whatsoever for more than 40 years, it was felt that the same procedure should be followed again. It was nevertheless decided to consider the only two other alternatives:

(1) a pipe crossing laid on the bed of the river,

(2) a pipe crossing supported on a bridge.

The Greater Winnipeg Sanitary District and the City of Winnipeg have constructed numerous crossings of both the Red and Assiniboine Rivers by laying pipe, usually cast iron, on the river bed. However, particularly in recent years, there have been numerous failures which have been caused by the movement of the banks and in some cases, scour of the river itself. Recently the practice has been adopted of using steel pipe, bedded in a trench, with approximately 4 ft. of cover. The Winnipeg & Central Gas Company has recently installed similar crossings. However, the largest of these pipes has been 24 in. in diameter and when the size of this particular pipe was taken into consideration and the fact that this would form one of the two supply mains to Greater Winnipeg across the Red River, it was felt that this method was not suitable.

The practice of supporting mains on bridges has been used fairly generally and in some cases, special bridges have been built for this purpose. Mr. William Walkden, M.E.I.C., was asked to make a preliminary report on such a bridge for the District. This report indicated that without taking maintenance costs or possibility of damage into consideration, the initial capital cost would result in very little, if any, saving over a tunnel crossing in bed rock. However, when the final hydraulic gradient was developed, it ruled out the bridge crossing since the pipe elevation to meet high water flow conditions in the river, as well as to clear navigation, would have had to be at an elevation only slightly under the hydraulic gradient line at maximum design flow, which could have meant syphoning and difficult operating problems. It was then decided to base the design on two vertical shafts and a rock tunnel. (See Fig. 4)

The original 20 ft. diam. shafts had been constructed by casting reinforced concrete sections at ground level and sinking them in place. This method had also been used successfully in constructing the surge well at the Sewage Disposal Plant and by the City on a somewhat similar water main installation. The District therefore suggested a similar method but did permit contractors to bid on other alternatives in addition to this method. As will be described later, the successful contractor subsequently asked for and was granted permission to use a different method of constructing the shafts.

As a contract had been awarded for the construction of the pipeline proper by using reinforced concrete pipe, it was felt that this would probably prove cheaper for the tunnel crossing, but the specifications nevertheless did permit the steel pipe alternative. The lowest tender submitted for the crossing was based on the use of prestressed embedded cylinder concrete pressure pipe.

The cast iron pipe in Branch I had been grouted by pumping grout into the tunnel from pipes driven down through the river bed. In the specifications for the second branch, two alternatives were given and the contractors asked to quote on each of them. In one case, grout holes were to be provided in the pipes themselves, with the grouting being done from the inside. The alternative to this called for concrete backing to be placed around each pipe as it was laid. Subsequently the low bidder's figure for the second alternative was $18,000 less and the District accepted that procedure.

Diamond drill cores taken from the ice indicated that water would be encountered at certain elevations in the limestone. A tunnel profile was established which the District's Engineers thought should present the least difficulty with this water, but the Contractor was offered the option of lowering the tunnel centre line up to 10 ft. if he felt that this would mean more favorable conditions in the tunnel. Once construction was started and the east shaft had been sunk, the contractor decided to follow the line selected by the District.

Six tenders were received, ranging from $357,325.00 to $646,459.00, the contract being awarded to the lowest bidder. The bid was made on using the District's suggested method of sinking the shafts, but subsequently the contractor asked permission to use a modified method.

Construction: The contractor felt that it would be quicker to sink the vertical shaft, lining it with tunnel liner and grouting in behind the liner, then pour the required reinforced concrete shell from the bottom up. While the District had some qualifications about this method, particularly in regard to water, and felt that the original method was safer, the contractor was granted permission to use his proposed alternative. The shaft was sunk quickly, due to the novel method the contractor used. Seven 36 in. diam. holes were augered to bedrock and the remaining earth removed by clamshell bucket. Augering these holes saved a great deal of time and excavation in mucking the excavation. (See Fig. 5).

As had been feared by the District, a considerable quantity of water was encountered as the shaft entered the rock. In order to seal off this flow of water, the contractor felt it necessary to pour a thick mat of concrete, which was then pierced by 2 in. holes through which grout was pumped under pressure to seal off the crevices in the rock before excavation continued.

No great difficulty was encountered with the west shaft, which was excavated following a similar procedure as no water was encountered at the base of the west shaft.

The horizontal tunnel was driven as one heading, under atmospheric pressure from the east shaft westerly, advancing about 8 ft. per shift. The upper 3 ft. of the heading was in tight, white limestone but below this was a 2 ft. seam of fractured, water bearing red shale. This was underlain by 3 to 4 ft. of grey, highly fractured flow. No attempt to grout was made until the entire tunnel had been completed. Once the tunnel had been driven to a point beneath the base of the west shaft, a vertical shaft was driven up to complete the rock work.

The specifications required that the pipe be placed in the dry. As an attempt to reduce the flow of water, the contractor poured a primary concrete lining to seal off the fissured rock in the lower 4 ft. of the walls and confine the flow to drains in the floor, which was partially concreted. This was not sufficient to stop the flow of water completely and it was necessary to grout fairly extensively before the flow was reduced to the District's satisfaction.

Because of the nature of the rock and the way in which it was bedded, it was virtually impossible to eliminate overbreak, so that a tunnel roughly 9 ft. square resulted. Arrangements were made with the contractor to install a 24 in. water main in the tunnel, which could be used as a future high pressure feeder main crossing. (See Fig. 6).

Laying of the 5 ft. 6 in. concrete pipe commenced at the west shaft. Pipes were used to confine the water flow, while solid concrete was placed in the annular space between the outside of the pipe and the rock face by means of a Pendell pneumatic concrete placer. Periodically these pipe drains would be grouted off. One pipe was laid and backfilled with concrete before the next pipe was laid. In this way, the water was completely stopped and a satisfactory pipe laying operation was possible.

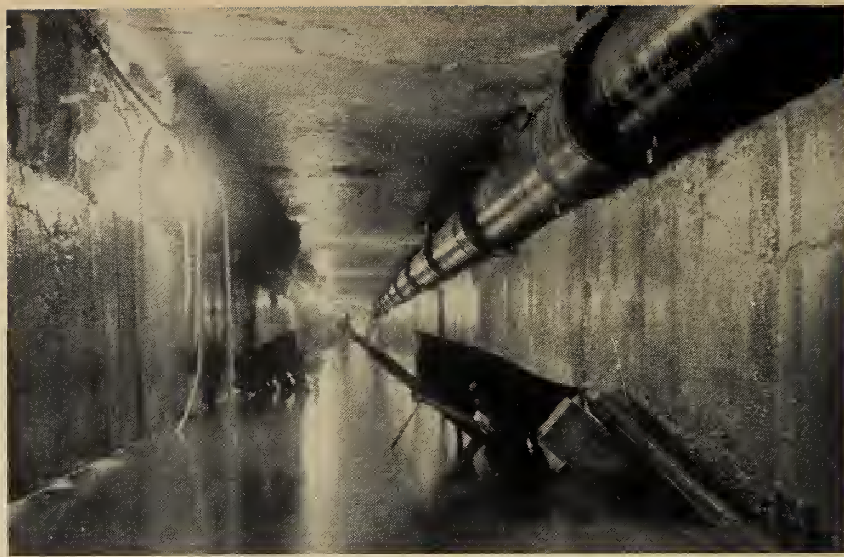

Fig. 6. Twenty-four inch cast iron pipe in place.

Work on the Red River Crossing commenced on February 23rd, 1959 and pipe laying was virtually complete by Christmas 1959. Concrete work around the top of the shaft and the valve chamber was completed in January and February of 1960, but testing of the completed crossing was deferred until the spring.

Indian Bay Low Lift Pumping Station

Necessity of Maintaining Lake Levels: The capacity of the gravity flow section of the aqueduct depends on the water level in Shoal Lake, as shown in Fig. 7. A level of 1058.3 is required to deliver 85 m.g.d. The District's records indicate that between 1918 and 1959, the lake levels fell below 1058.3 in 16 years and that in 1931 it fell to 1056, which would only permit delivery of 45 m.g.d.

Lake of the Woods drains into Lake Winnipeg through the Winnipeg River, the flow being controlled by a dam at Norman, near Kenora, Ontario. As the Winnipeg River is still the major source of power for Manitoba and since Lake of the Woods is an international body of water, the matter of lake levels is of great importance. As long as the levels are between 1056 and 1061.25, control lies with the Lake of the Woods Control Board, a Canadian body with representatives of the Federal Ontario and Manitoba Governments. However, if either of these limits is exceeded, control passes to the International Joint Commission.

Both the Manitoba and Western Ontario power systems now have substantial thermal generating capacity which will allow more efficient use of the hydro sources of the Winnipeg River. New patterns of river flow regulations will probably evolve, resulting in lower average levels on Lake of the Woods. Consequently there is a good possibility that Shoal Lake levels will fall below 1058.3 much more frequently.

With the construction of the second branch aqueduct, the question of lake levels became a matter of prime importance and measures had to be taken to make sure that 85 m.g.d. could be introduced into the aqueduct at the Intake under all conditions.

While the Board of Consulting Engineers who were responsible for the design and construction of the original works did an outstanding job, making provisions for future additions to be constructed as demand required and as witnessed by the fact that our present projects could be fitted in some 40 years later without undue difficulty, they made no provision for the construction of a low lift pumping station to maintain the required 85 m.g.d., although they had considered the possibility of pumping at a later date to increase the flow to some 120 m.g.d. when required.

Preliminary investigation indicated two possibilities of assuring this required flow, as follows:

(a) the construction of a dam and lock at Ash Rapids in order to maintain the level of Shoal Lake itself above 1058.3.

(b) The construction of a low lift pumping station at the Intake to lift the required amount of water into the Intake, regardless of the level of Shoal Lake.

Ash Rapids Dam and Lock: The Lake of the Woods, including Shoal Lake, has a water area of 1,500 sq. miles with a drainage basin of some 27,700 sq. miles. Shoal Lake itself has a water area of 107 sq. miles with a drainage basin of 360 sq. miles. Shoal Lake is interconnected with the Lake of the Woods proper through a very narrow channel some 2,000 ft. in length known as Shoal Lake Narrows. The actual passage at either end of these narrows is very much restricted with a rapids being located on the eastern end. Preliminary survey work indicated that it would be quite feasible engineering-wise, to construct a dam at the latter location. However, a lock would also be required to permit navigation through it. This scheme would only be feasible if the drainage area of Shoal Lake itself was sufficiently large and could be depended upon to maintain a lake level of 1058.3 under all climatic conditions with a draw of 85 m.g.d. or more in the future. From original reports on the District's files, it appeared that there was some considerable difference of opinion on whether Shoal Lake alone could provide the water required. The District therefore requested the Water Resources Branch of the Provincial Government to make a study of this problem.

Pumping Station: While the construction of a low lift pumping station would be a relatively simple project in itself and would obviously permit any quantity of water to be pumped into the aqueduct under any conditions of lake level, there were certain problems involved, as follows:

(1) Only a limited amount of single phase power is available and this comes to the site over a 15 mile long line. Discussions with the Manitoba Power Commission indicated that the construction of a new transmission line from West Hawk Lake and the necessary ancillary construction would make this scheme economically impractical. Auxiliary power was therefore the only answer.

(2) No provision had been made in the design of the original Intake for the construction of a pumping station, and as three municipalities served have virtually no storage capacity, the flow of water could only be interrupted for very short periods.

(3) The pumping equipment itself would have to be very carefully chosen and probably specially designed since it would have to be capable of pumping quantities varying from 40 to 85 m.g.d. under heads which might range from 4 ft. to 9 ft.

A preliminary comparison of the various factors involved indicated that the construction of a pumping station at the Intake would prove to be the most suitable scheme. The report received from the Water Resources Branch indicated that from the little information available, it was doubtful that the required lake elevation could be maintained in a prolonged dry period. Aside from the construction and operational problems which would entail staffing and operating the locks at an extremely remote location, the Ash Rapids scheme would entail considerable negotiation with Provincial, Dominion and United States authorities. It was therefore decided to proceed with the design of the low lift pumping station at Indian Bay.

As mentioned, the construction work had to be carried out and connected with the existing facilities without interrupting the flow of water for more than a few hours. Furthermore, it was not possible to interfere with the flow for even this short period during peak flow conditions, between May 15th and October 30th, so that the timing of construction was one of the important factors to be taken into consideration in the design. The existing gate house, shown in Fig. 8, consists of a submerged intake to prevent flow of ice into the channel during the winter months. From this Intake the flow divides into two channels, passing through trashracks just as it enters the gatehouse structure. The water then passes through screens and through control gates before flowing into the aqueduct proper. The thoroughness of the design by the original engineers is indicated by the measures which were adopted to prevent debris, leaves, grass and other materials getting into the Intake. This was accomplished by locating the intake opposite a small island several hundred yards out in Indian Bay and providing two gravel and rock dykes which extend out 200 ft. into the Bay.

Initially, consideration was given to the construction of the pumping station as a separate structure ahead of the intake itself, in the area between the two dykes mentioned above. Investigation indicated that this was not the best solution, chiefly because the dykes themselves had been constructed of loose rock material and there was some doubt of their stability under flow with differential heads of up to 10 ft. Furthermore, there could be construction problems in coffer damming while maintaining a flow of water into the aqueduct.

A location immediately north of the present intake structure was then

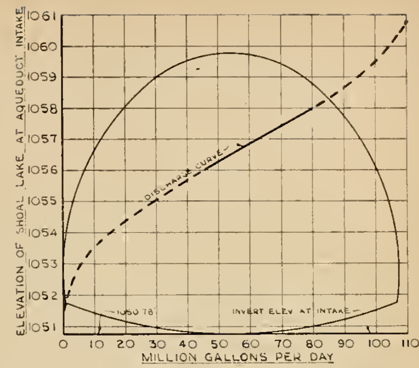

Fig. 7. Discharge capacity of Aqueduct.

considered and was finally adopted. Even here, however, there were a considerable number of problems to be overcome, chiefly that of diverting the water from both of the channels into the pumping station, through the pumps and back into those same channels, downstream from the existing gates. Since this total distance was only 132 ft., it meant that very careful design had to be given to the water passageways. A basic condition to be met by the pump manufacturers when tenders were called for the pumps was that they approve the arrangement of the pumphouse and passages.

Pumps and Prime Movers: Since the extreme low recorded water level for Indian Bay is elevation 1056.0 and since the hydraulic grade line required for a flow of 85 m.g.d. in the arch section of the aqueduct is 1058.3, a static lift of only 2.3 ft. is required. However, a designed low water level of 1055.0 was decided upon. Once the station design was worked out, it was found that it was necessary to have a static lift of up to 9.16 ft. at maximum pumping rate and extreme low suction well level.

Axial flow pumps were the obvious choice and a rather novel type was selected after a good deal of discussion with two manufacturers. This pump consists simply of a steel tube, belled out at the bottom, in which is mounted a propeller with the water flowing over a circular discharge weir.

As it was not economically practical to bring in a new electric power transmission line, diesel generators and electric motors were considered for drives, but after a good deal of consideration, were ruled out in favor of direct diesel drive. It was found that the speed of the diesels could be varied to regulate the capacity of the pumps over a sufficiently wide range without going to the added expense of adjustable bladed impellers, which had been considered.

It was felt that the installation of dual pumps was warranted, but due to the unorthodox nature and size of the pumping equipment, it was not possible to secure sufficiently accurate estimating prices on which to base an economic comparison. Tenders were therefore called for two sizes of pumps, with the District having the option of selecting any combination of the units tendered upon. Five tenders were received, none of which complied completely with the specifications.

The specifications were then revised slightly and tenders again called, with the result that four bids were received, three of which could be considered as formal tenders. After discussions with the two lowest tenderers, the contract was awarded for the design, supply and delivery of one 85 m.g.d. and one 60 m.g.d. pump, together with diesel engines and right angle drives, for the price of $88,680.00.

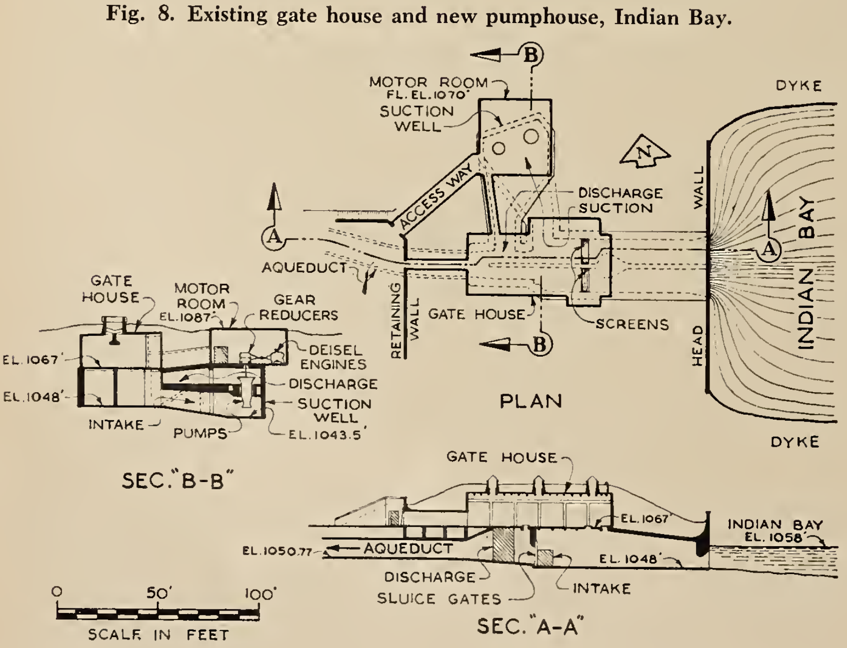
While the upper 9 miles of the aqueduct is designed to carry a flow of 120 m.g.d. with a 4 ft. surcharge on the arch, it was felt necessary to protect the unreinforced concrete section against any higher head. Overflow weirs were considered but due to the swampy terrain which the aqueduct traverses at this location, great difficulty would be encountered in keeping high water out of the pipeline during certain periods of the year. Electrode type high and low level recorders were therefore installed in the suction well and in the discharge flume, which will automatically shut off the prime movers in the event of an abnormal water level.

Mechanically Cleaned Screens: In the original construction of the Gate House, fixed water screens were installed. These screens have a maximum square opening size of 3/32 in. and each of the 10 sets of screen panels have to be removed by means of hooks and overhead cranes. The water is normally fairly clear but occasionally, during the spring and fall turnover of the lake, large quantities of weeds and debris are carried into the Gate House and cleaning of the screens becomes a considerable problem. The Intake staff consists of an Operator and Assistant and at these times of the year their enitre time is devoted to cleaning the fixed screens. The construction of Branch II and the installation of low lift pumps will result in increased flows and higher velocities which will aggravate this problem.

It was therefore decided to install travelling water screens at the same time as the new pump house was being constructed to house the low lift pumps. Two sets of 10 ft. wide mechanical screens are to be installed with screen openings of ⅛ in. square. Tenders were called for stainless steel, bronze or galvanized steel screens and stainless steel was selected as the most economical choice.

Because only single phase power is available at the site, it was necessary to install phase converters to provide three phase power to drive the 15 hp. turbine type wash water pumps. Single phase motors were also considered but because of the difficulty of securing hollow shaft single phase motors of this size, were ruled out. A standby generator was also installed which will be driven from the shaft of one of the diesel pump engines.

Fig. 8. Existing gate house and new pumphouse, Indian Bay.



Pump House Structure: Once the details of the mechanical equipment were available, the detailed design was prepared of the low lift pump house structure and tenders were called. Four tenders were received, with the contract being awarded to the lowest bidder at $190,576.00. Construction commenced on June 22nd, 1959. The pump house is situated in a solid rock ridge immediately north of the existing Gate House. Extreme caution had to be exercised by the contractor in blasting the rock, but nevertheless an unknown fault in the rock resulted in a rock shift which caused extensive damage to the north wall of the Gate House so that the roof had to be shored up and the entire wall repoured.

Conclusion

It might be worth repeating that the Consulting and Construction Engineers responsible for the original works did an outstanding job. The aqueduct has been serving Greater Winnipeg for more than 41 years and with the construction of Branch II, for which they had provided, will continue to serve more than half the population of Manitoba for many more years.

In the 46 years since work started on the aqueduct, the great majority of those responsible for this major project have passed away, but the authors would like to conclude by acknowledging the extremely valuable contribution made by three of the "originals" in the additions described in this paper:

Mr. Harold Shand, Asst. General Manager and Asst. Chief Engineer of the Greater Winnipeg Water and Sanitary District, who actively participated in both the design and construction of the additions and who was Office Engineer during the original construction.

Mr. Douglas L. McLean, Project Engineer on the construction of Branch II, who was Division Engineer on the original construction.

Mr. J. C. D. Taylor was mainly responsible for the design of the Low Lift Pumping Station before he passed away in December, 1958, and was Office Engineer on the original construction.

THE KHULNA NEWSPRINT PROJECT

D. P. Wyness,
Project Engineer,
Sandwell & Company Limited,
Consulting Engineers,
Vancouver.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The surge of nationalism sweeping the world today has brought into being many new countries. Most of these countries are underdeveloped and must be helped in their efforts to stabilize their economies and to raise their standards of living. Help has been given to these peoples by such organizations as the United Nations, the Colombo Plan of the British Commonwealth, and the International Co-operative Administration of the United States. In some instances, these agencies have helped by sending out experts in the fields of economics, education, and engineering, to name a few, to advise the peoples on how to deal with their particular problems. In other instances the aid has been solely financial, or has been a combination of both expert advice and financial aid.

Pakistan is one of the underdeveloped countries receiving aid from these agencies. The Khulna Newsprint Project is of particular interest, however, because the Pakistanis financed it from their national income with a minimum of outside aid, and engaged experts in the appropriate field to study and overcome the problems of establishing a newsprint industry from indigenous raw materials. That the enterprise was brought to a successful conclusion on schedule during times of both internal and external strife is a remarkable achievement and a tribute to the patriotic and tenacious spirit of the leaders of the Pakistan Industrial Development Corporation. No less is it a tribute to the drive and initiative of the Canadian Engineers and Contractors who were entrusted with the responsibility of establishing a new industry in Pakistan.

IT IS believed that the Khulna Newsprint Project in Pakistan is the only project for which a Canadian company has had complete responsibility not only for the engineering but also for the operation of an overseas pulp and paper enterprise. The responsibilities embraced all phases of the work from feasibility and economic studies to forest management, mill operation, and finally to sale of the finished product.

Not too much is generally known about Pakistan; some knowledge of the country, her people, and her history is essential to an understanding of the project.

Background

Geography: East Pakistan which lies north of the Bay of Bengal between India and Burma, occupies the delta of two great rivers, the Ganges and the Brahmaputra. When the rivers are in spate, there is a positive flow to the Bay of Bengal through the larger channels but during the dry season most of the waterways become little more than tidal sloughs. Khulna is a growing industrial town centrally located on this vast delta.

People: In an area of 60,000 sq. miles are crowded about 45 million people, predominantly Moslem — a population density of 775 people to the square mile. (By comparison, British Columbia occupies 366,000 sq. miles with 1.3 million people — a population density of 3.6 per sq. mile.) Life expectancy is 31 years and literacy is about 15%. About 95% of the people live in small villages of twelve to fifteen hundred people.

Transportation: Transportation is mainly by water on the numerous waterways that interlace the country. Most of the roads are little more than dirt tracks that become impassable during the rainy season. One system of the East Bengal Railway connects the Khulna area with the northwestern parts of the country. Another connects Chittagong, the only deep sea port, with Dacca, the capital city on the east. An anchorage for deep sea ships has been developed at Chalna on the Pusser River about 30 miles from the Bay of Bengal and 20 to 30 miles from Khulna. Shipments of materials and machinery from overseas to the central part of the country are off-loaded at Chalna to river barges which are towed to their destination by tug.

Climate: Temperatures range from about 55°F on a cold winter morning to as high as 110°F on a hot summer day. Prior to and during the monsoon rains that occur during the months June to September the relative humidities commonly range between 95 and 100%.

History: Since coming into being on the partition of the Indian Sub-Continent in 1947, Pakistan has been faced with tremendous difficulties in stabilizing her government and in rounding out her economy.

During partition people fled by the millions to the country of their choice — the Moslems to Pakistan; the Hindus to India. Some 3½ million people were killed and Pakistan alone had 7 million refugees. Many of the key administration positions at all levels of government and industry had been held by non-Moslems who fled to escape the carnage, with the result that many of the government offices and commercial establishments could not function.

Prior to partition, the area that is now Pakistan was wholly agricultural, and the industries dependent upon the resources of the area were located in the area that was allotted to India. In the early years the Pakistan government realized that industries utilizing the natural resources of the country would have to be established if favourable trade balances were to be built up and the country's position consolidated as an independent nation. To this end the Pakistan Industrial Development Corporation — a government sponsored body — was entrusted with the job of establishing basic industries. During the last decade about 10 or 12 basic industries have been established at a cost of about $190 million. The Khulna newsprint mill was a part of this overall industrialization program.

Feasibility Studies

Before a new industry can be established, several conditions must be satisfied. There must be an adequate supply of raw materials and a suitable process for converting them to a useful product; adequate markets on which to profitably sell the product; reliable facilities for transporting raw materials and finished products; and land available suitable for an industrial site — land that is close to the transportation facilities and to an adequate source of relatively pure water.

In addition to the physical requirements there must be sufficient capital to finance the enterprise and carry it into production.

The first phase of the engineering work embraced studies of these physical requirements. Some of the pertinent information was obtained from reports previously made by others and some was obtained by investigations carried out prior to and during construction.

Forest Resources: Of the three forested areas in Pakistan one lies in the Kagan Valley of West Pakistan. The other two are in East Pakistan, one on the delta of the Ganges River — an area known as the Sundarbans Forest, and the other in the Chittagong Hill Tracts, east of the Bay of Bengal. Bamboo in the Chittagong Hill Tracts had already been reserved for an existing sulphate mill and other species in this area were neither suitable nor in sufficient quantity to support a paper mill. Investigations proved that although the softwoods in the Kagan would be well suited to conventional pulping processes, they were inaccessible and their exploitation would be uneconomical. On the other hand the hardwoods in the Sundarbans were readily accessible and, in view of recent developments in hardwood pulping processes, looked more promising as an economic source of raw material. The Pakistan Industrial Development Corporation decided, therefore, to concentrate on the hardwoods in the Sundarbans.

Of the two dominant species, Sundri is dark in colour and heavy, and Gewa is light in both colour and weight and more suitable for pulping. Early surveys by the Indian Forest Service in 1931, inspections by the United States Technical Co-operation Administration in 1953, and advice from the East Bengal Conservator of Forests in 1954, placed the annual yield of Gewa between 35,000 and 47,000 air dry long tons, which would be sufficient for a mill producing 100 tons a day. The annual yield of Sundri, a possible fuel, was estimated at 100,000 air dry long tons.

In November, 1955, we commissioned engineers to analyze methods of extracting and transporting Gewa wood and to determine whether or not previous estimates of wood supply were correct. They were also to investigate the economics of extracting Sundri wood for fuel.

These studies were completed by June, 1956. The engineers found no reason to dispute the previous assessments of the amounts of Gewa and Sundri available and believed that the extraction methods currently in use could be expanded to ensure that the supply of Gewa would be sufficient to meet planned pulp mill needs. However, they recommended that the use of Sundri as a fuel be postponed until more suitable extraction methods could be developed to handle the large volume required. They also recommended that an independent detailed forest survey be conducted in the Sundarbans to provide the basis for a five year cutting program, and that steps be taken to increase the yield of Gewa. This survey was subsequently made and although the final results are not yet available the yield figures previously mentioned have been confirmed.

Process: Between the years 1948 and 1954, the making of suitable paper pulp from Gewa was investi-

Fig. 1. View of the Steam and Power Generating Plant with Water Treatment Plant in foreground.

gated in the leading experimental laboratories of the pulp and paper industry in the United Kingdom, Scandinavia and Germany. All met with limited success. In 1954, however, the New York State College of Forestry produced handsheets from mixtures of spruce sulphite and Gewa groundwood that were comparable to conventional newsprint. The need for further investigation was clearly indicated.

Under our supervision a comprehensive testing program was carried out by the U.S. Forest Products Laboratory at Madison, Wisconsin in the autumn of 1954. Papers were made from four different pulp types; chemi-groundwood, neutral sulphite semi-chemical, cold soda, and sulphate. The sulphate process was eliminated on the basis that it was not suitable for the small tonnages required. The cold soda process offered no advantage over the chemi-groundwood and neutral sulphite semi-chemical processes. As there was less mill scale experience on the cold soda process than the others the cold soda process was eliminated. The differences between the chemi-groundwood and neutral sulphite pulps were negligible insofar as quality was concerned. Although estimates showed no difference in the direct manufacturing costs they did show that the capital required for the neutral sulphite would be much higher than for the chemi-groundwood. Thus the chemi-groundwood process was determined to be best suited to the Khulna Project.

Markets: The market analysis was taken primarily from reports made in 1953 by the Technical Co-operation Administration of the United States and the Food and Agriculture Organization of the United Nations. These reports showed that the annual per capita consumption of newsprint in Pakistan was 2½ lb. as compared to 280 in Canada and 26 in Mexico, and that 30,000 tons of newsprint and printing papers were imported into Pakistan in 1952 at a cost of $8 million. They predicted that the population would increase to 88 million in 1962 and 100 million in 1972. Further they predicted that, with the accelerated educational program then in the planning stage, literacy would increase to 30% and 50% by the years 1962 and '72 respectively. Should these predictions come true, the demand for newsprint would be 23,000 and 56,000 tons, and for printings 41,000 and 99,000 tons by 1962 and '72, respectively. In the event that actual figures fell short of those predicted, it was believed that export markets could be found in the neighbouring countries of Burma, Ceylon, India and Malaya.

Fig. 2. General view of mill during construction. Note that concrete was delivered by mobile mixer but placed by "human bucket elevator".

Transportation: The abundant waterways of Pakistan proved very convenient for transport of wood from forest to mill. Logs were collected in bundles and in large rafts in the water and towing distances were reasonably short. Getting other materials and equipment to the mill and the finished products to West Pakistan was not quite so simple. Deep sea ships could only come up river as far as the anchorage, Chalna. Here the cargoes were transferred to river barges and towed to the mill. Finished paper is currently being shipped in the reverse manner to West Pakistan and by river steamer throughout East Pakistan. Should markets develop in India, a spur of the East Bengal Railway connects the mill with the distributing centre, Calcutta.

Site and Foundations: East Pakistan is very flat and low lying and most areas in the southern and central portions are subject to flooding. Surveys by the Pakistan Industrial Development Corporation indicated that an area near Khulna on the Bhairab River was the best available for those industries drawing their raw materials from the southern parts of the country. Construction of several jute mills and a shipyard had been either started or completed in this locality by 1954, and an area of 65 acres had been reserved for the projected newsprint mill.

Records of previous borings in this vicinity showed that the general area was built up of successive layers of silt, clay and sand to a depth of 1,000 ft. No rock or gravel strata have been discovered by the borings done to date. It was necessary, therefore, to carry out investigations of a specialized nature to determine the best type of foundations for the mill. Mr. Paul Cook of Vancouver, a specialist in foundation analysis, was commissioned to outline a plan of investigation that could be carried out by the engineers on site, to analyze the results, and to recommend the most economic type of foundation.

In accordance with Mr. Cook's instructions, two series of test holes were drilled. Analyses showed that the only layer that might be considered compressible was too deep to be affected by the loads imposed by the mill and that the sub-soil structures were sufficiently uniform to allow complete freedom in locating the buildings on the site.

Soil bearing tests determined that the maximum allowable load for spread footings was 1,200 p.s.f. Therefore, spread footings could not be used to support the heavier loads of the main mill buildings without excessive settlement, but would be suitable for the lighter structures where a small amount of settlement could be tolerated.

It appeared that heavier loads would have to be supported on piles. Precast concrete piles were considered to be most satisfactory, and test piles were cast. These were driven into a layer of relatively coarse sand which lay at a depth of about 20 ft. Calculations based on the driving test predicted that piles 25 to 30 ft. long would support loads of 50 tons without undue settlement. Loading tests on these piles, however, showed that safe loading was nearer 30 than 50 tons per pile. Footing designs were consequently based on the 30 ton figure, and the number of piles increased from 1,200 to 1,700.

Water: Perhaps more than any other industry, the manufacture of pulp and paper requires a large amount of relatively pure water. The obvious source was the Bhairab River. However, since the Bhairab River water was heavily laden with silt and suspected of being contaminated with sea water, it was considered necessary to embark on a program of testing and to investigate alternative sources. As the only alternative appeared to be wells, test wells were drilled and samples were taken from the wells and from the river. The results of these tests showed that the river water contained much less of the harmful chemical components than did the well water. Further, these tests showed that the only treatment required of the river water was the removal of the suspended material — a relatively simple matter.

As various patented treatment systems were found to be unnecessarily complex and costly, a simplified system using standard equipment was adopted at the suggestion of the water consultant. The treatment plant reduces the suspended matter to 6-10 parts per million which is sufficiently clear for newsprint and mechanical printing papers.

Capacity: From studies of the amount of raw material available and the predicted demands for newsprint and printing papers in Pakistan, the capacity of the mill was set at 35,000 tons per year of which 23,000 would be newsprint and 12,000 printings.

Economics: Even though there were raw materials, process, markets, site and transportation, the venture had to be analyzed to determine whether or not it would be profitable. To this end, preliminary designs were prepared in sufficient detail to estimate the capital and operating costs. The selling price for the products on world markets was well known, and the annual earnings were estimated from them and from the operating costs.

Stated briefly, the estimates placed the capital costs at $20 million and the annual return before depreciation and taxes at about 20%.

Authorization: Our report on the feasibility and economics of the Khulna Newsprint Project was presented to the P.I.D.C. in December, 1954. In July, 1955, the venture was given government approval and we were instructed to proceed with the detailed engineering. Preliminary designs and equipment selection were nearly complete when word was received that the project had to be temporarily postponed. Work was resumed in April of 1956 and the last detail drawings were issued from Vancouver in July, 1958.

Finance: The project was financed by the P.I.D.C. with government funds, although toward the end of the construction program some financial assistance was received from the United States through their International Co-operation Administration for the purchase of some equipment, spare parts and operating supplies.

There were periods when the foreign currencies needed by the project were diverted to other needs. This was particularly so in the fall of 1958 when the army expelled the president, took over the running of the government, and saved the country from going bankrupt. The first action of the new regime was to freeze the expenditure of foreign currencies — a freeze that was in effect for about four months during which the supply of materials to the project was suspended.

Payment for the various phases of the work was by irrevocable letters of credit deposited at the banks named by the suppliers of equipment and services.

Construction

Materials: Materials for building construction in East Pakistan were generally more costly than in other parts of the world. In addition, quality tended to be unsatisfactory. Special measures often had to be taken to develop a supply and to check the quality of the material when received. Keeping the project supplied with materials required constant vigilance. Frequently, the project was kept in motion only by borrowing or trading materials with other projects in the area.

Concrete: Cement, although manufactured in West Pakistan, could not be landed at site for less than double the factory price. Nevertheless, this price was far less than would have been paid for imported cement, and justified the trouble taken to keep the project supplied. It was fortunately of satisfactory quality.

Coarse aggregate was not available in the area and local sand was not acceptable for concrete on the basis of sieve analysis. It was, therefore, necessary to freight these materials by country boat through a tortuous river channel system roughly 400 miles from a source of supply in the northern provinces of Sylhet and Chattak or, alternatively, by rail from India over a similar distance.

Steel: Neither reinforcing steel nor structural steel shapes were available in Pakistan although a rolling mill in Chittagong did roll a portion of reinforcing requirements for the project from billet steel imported from Europe. Because the resulting reinforcing rods were not of uniform cross section, they were used only where stresses were low. Swedish reinforcing rod was employed in all highly stressed concrete, although much of this type of concrete construction was delayed by late deliveries of the material.

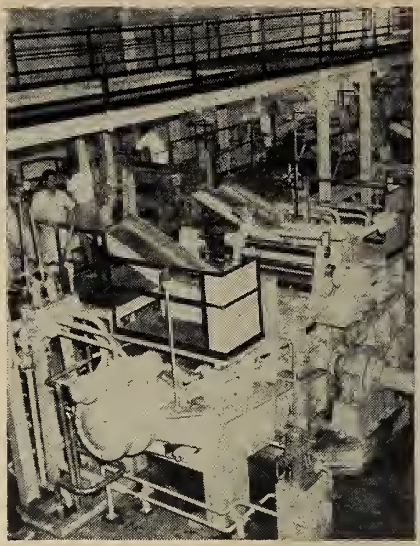

Fig. 3. General view of Grinder Plant showing Pakistanis operating the pulpwood grinders.

Roof trusses for mill buildings and structural steel framing for the Boiler House were fabricated and imported from North America. All structural steel shapes such as angles, channels, and beams for miscellaneous light framing were imported in bulk and fabricated on site.

Lumber: Lumber for formwork was so scarce that it was necessary to improvise a sawmill to cut form lumber from logs, and to use the lumber from packing cases for formwork. Most of the local sawmills were strictly hand operations which could not begin to meet the project demand for sawn lumber. The most popular woods for formwork were Keora from the Sundarbans Forest, and Gurjun from the Chittagong area. Both of these are dense hardwoods difficult to work, and susceptible to warping and checking. Where appearance was a factor, forms were lined with imported hardboard to avoid an unsightly finish resulting from shrinkage cracks and warping of form lumber. Fabrication and erection of concrete formwork was further handicapped by the fact that lumber was only available in short lengths, generally 6 to 8 ft, and numerous splices were necessary. In spite of the difficulty experienced in salvaging and redressing form lumber, every possible means was used to ensure a maximum re-use factor compatible with the construction schedule, and an average usage factor of approximately 1.5 was in fact achieved for the entire project.

Site Work: Work performed on site which would be considered unusual in North America included cutting and bending of all reinforcing steel, fabrication of miscellaneous steel platforms, brackets and handrail, fabrication of all pipe hangers and supports other than special spring hangers, fabrication of numerous items of handling and rigging equipment and, of course, performing the sawmill function in addition to normal wood framing yard work.

Labour: Manual labour was used almost exclusively for earth moving and for a major part of all materials handling where this was physically practical. Cost checks indicated that such methods were as cheap as mechanical handling and released equipment for tasks which could not be handled manually. An efficient dry-batch concrete plant and three 3½ cu. yd. motor truck mixers permitted an average weekly concrete pour of about 500 cu. yd. throughout the main concrete pouring schedule. Sufficient modern construction equipment was available to permit most elevated concrete pours to be made by conventional crane bucket or skip hoist and concrete buggy. From time to time a human chain, conveying concrete in metal head pans, was organized for certain types of pour where a good deal of framing to prepare for concrete buggies would otherwise have been necessary. Many of the columns were poured in this manner.

Equipment Installation: Equipment installation commenced in September, 1958, with erection of No. 1 Boiler, and No. 1 Paper Machine and was completed by July, 1959. Effective erection time for each boiler was approximately 5 months and for each paper machine 7 months. Mechanical tradesmen available locally were sufficiently skilled for most equipment installations if carefully supervised by European foremen and Vendors' representatives. Vendors' erection engineers supervised Pakistani erection crews directly in erection of the boilers, installation of process instruments, application of tank lining and in fact wherever there were special erection problems.

Piping: A start on piping work was made in September, 1958, when a small initial order of pipe and fittings arrived on site. Prefabrication work with these stocks commenced immediately and no doubt provided a useful training period for Pakistani tradesmen. Piping work could not proceed at the desired rate, however, until the main orders of pipe and fittings arrived during the latter part of October. Pipe fitting progress was greatly hampered throughout the programme by shortages of materials and many temporary substitutions had to be made to keep the job rolling. Valve substitutions were quite common and where this was not possible, piping was erected with spacers to maintain gaps equal to face-to-face dimensions of the missing valves. Because of a shortage of ready-trained tradesmen, pipefitting workmanship was, generally speaking, of lower quality than that of other trades, but was nevertheless satisfactory for the project.

Electrical Work: Electrical work was carried out by the contractor with a small supervisory force directing a larger crew of Pakistani tradesmen at times augmented by working foremen provided by the suppliers of electrical equipment. The Pakistani personnel were not particularly well trained when they arrived on the job, but as a result of intensive on-the-job training, the work went very well. Owing to late delivery, installation of electrical equipment and lighting did not commence until mid-October, 1958. Electrical crews reached a peak of about 240 Pakistanis and 12 Europeans in March to April, 1959.

Mill Services: The water supply and distribution system was the first of the mill services to be completed. This service was required, of course, before either steam or site-generated power could be produced to permit checking out of equipment and start-up of the mill. The water treatment plant was placed in operation in early April and, through the temporary installation of a stock pump in the system, provided the initial water supplies for flushing and testing mill process equipment. Early in May the proper water pumps arrived and the permanent water distribution system was placed in operation.

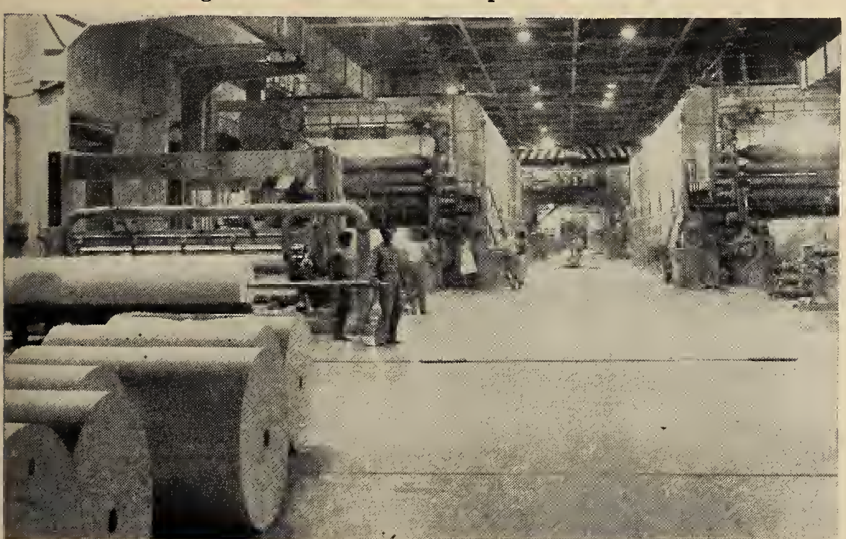
Following completion of the permanent water supply to the Boiler House and testing of boiler feed-water treatment equipment, the first boiler was fired on May 10 and the first electricity was generated on site on May 22, 1959. Electricity for construction power, colony service and equipment testing was produced on site continuously from this date.

Procurement: Each important item of equipment was selected only after competitive bids had been received.

It was then necessary to get permission in the form of an import licence to pay for the equipment with foreign exchange, and to get an irrevocable letter of credit deposited in the Vendor's bank. The purpose of the import licence was to control the expenditure of foreign exchange, and these licences were, by necessity, rationed. It is not surprising therefore that import licences often took months to secure. Nor is it surprising that the expiration date of licences was often approached before letters of credit were established, or that licences expired before goods were manufactured and shipped.

That the inevitable delays inherent in such a necessarily restrictive program were kept to a minimum is a tribute to the officials of the Pakistan Government and of the Pakistan Industrial Development Corporation as well as to the engineer, contractors and suppliers.

Fig. 4. General view of the Paper Machine Room.



Project Completion

Construction Schedule: The construction schedule for the Khulna Newsprint project as initially conceived in 1955 required site clearing to commence in November, 1956, mill construction in March, 1957, and equipment installation in December, 1957, to meet a scheduled start-up in May, 1959.

Owing to initial delays in implementing the construction programme, site clearing did not commence until December, 1956, mill construction until September, 1957, and equipment installation until September, 1958, nine months behind schedule. In spite of this and the delays in allocation of import licences, the first paper was manufactured on Paper Machine No. 1 on June 30, 1959, basically on schedule.

Equipment Testing: As mechanical and electrical installation work neared completion, a plan for testing the equipment was evolved. Check lists were prepared, itemizing faulty or incomplete work in each of the major mill systems. A segment of the contractor's work force was then allocated to correct all listed defects in logical sequence, so that each piece of equipment within a system was ready for testing in the proper order. After re-checking, the equipment was tested.

Operating Personnel: Because trained personnel to operate the paper mill were not available in Pakistan, the P.I.D.C. appointed us Mill Management Consultants for the Khulna Project in 1957 with the responsibility of hiring and training the necessary European and Pakistani personnel to start up the mill and operate it for approximately 18 months. As part of the training program, several key Pakistani personnel were sent to North America for training courses at various operating mills. Key personnel were brought to the site 8 or 9 months before the scheduled start-up date, so that they would have time in which to become thoroughly familiar with the mill, and to ensure that they would have arranged for an ample supply of spare parts and operating materials. In addition, key operating personnel cooperated in the final checking out and testing of mill equipment.

All other personnel were engaged in East Pakistan by more or less normal hiring procedures modified to conform with local custom. Key operating personnel were of great assistance in scrutinizing the hundreds of applications received. It is perhaps interesting to note that the work force eventually hired for the mill was drawn almost exclusively from the literate component of the population.

Between 40 and 50 key people, mostly from the United Kingdom and Canada, are at present employed at the mill supervising the operation of equipment and carrying out the training of approximately 850 Pakistanis who make up the working force.

Start-up: The start-up of the mill, though not entirely without incident, was surprisingly trouble-free, and the success of this phase of the project may be attributed at least in part to the comprehensive testing and checking procedures.

Perhaps the most serious trouble during start-up resulted from undersizing the motors on the fresh water pumps. One motor burned out and it appeared that the other two would follow. To prevent this from happening, one of the 4 impellers on each of the 2 remaining pumps was removed, thus reducing the load to within the limits of the motor. As a result, design heads and capacities were not reached. However, since the water demand had not built up to its peak, we were able to limp along until larger motors could be delivered. These motors have since been installed and, with the impellers replaced, the pumps are functioning well.

Another trouble spot occurred in the speed reduction unit coupled to the induced draft fan on No. 2 Boiler. Excessive vibration and heating caused us to examine the individual gears and one of them was found to be imperfect. To correct the imperfection was beyond the scope of the shop facilities in the country and we were forced to wait about 6 weeks until a spare arrived from the United Kingdom. Once again we were able to get by on one boiler during the first weeks of operation when the steam and power demands were below normal.

The first paper was produced on Paper Machine No. 1 on June 30, 1959, and on Paper Machine No. 2 on July 31, 1959. For initial runs, the furnish consisted of a mixture of imported chemical pulp and Gewa groundwood pulp. The percentage of long fibered chemical pulp was kept large in order to provide a strong sheet and minimize breakages. After the machine had been thoroughly tested on this rich mixture, the content of chemical pulp was reduced to about 20%, and, with the addition of chemi-ground pulp, reduced still further to about 7% — well within design figures.

Both machines are operating at about 70% of their design speeds and little trouble is anticipated in reaching or even exceeding design speeds when market conditions dictate.

The quality of the newsprint and printing papers so far produced at the Khulna mill is good and the forecast is that there will be little difficulty in selling the capacity output of the mill.

Conclusion

Canadian Engineers can be proud of the Khulna Newsprint Project because it is believed to be the first newsprint project in which they have been concerned with every phase from start to finish.

There are other reasons for being pleased with the results. The preliminary engineering work carried out for the purpose of determining economic feasibility turned out to be sound. Detailed engineering failed to reveal a single important instance in which final design principles departed from those envisaged in the preliminary stages. Perhaps the most significant change was in the layout of the mill buildings on the site, which in the final arrangement was at 90° to that of the preliminary plan.

Despite a six month delay in the start of the construction program and a four month freeze on foreign exchange during the program, the job was finished essentially on schedule.

THE ECONOMICS OF AN INDUSTRIAL GAS TURBINE

David Panar, M.E.I.C.,
Associate Professor of Mechanical Engineering, University of Alberta, Edmonton.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The use of large size gas turbines for peaking power is not a new application for electrical utilities. The Port Mann Station[1] of the B.C. Electric Company and the City of Edmonton Power Plant are two notable examples in Western Canada. The gas turbine in the smaller sizes (5,000 kw. and less) has been mainly used for process work such as oil field pressuration and natural gas transmission line pumping. Smaller sizes have also been used as base power plants at isolated independent plants such as Fort Stockton Texas[2]. The use of the small size gas turbine as a source of peak electrical power in conjunction with purchased and steam generated power in the industrial installation has not been too common. At the University of Alberta we have, we believe, Canada's first such use of an industrial gas turbine. It will be the subject of this paper to briefly discuss the economics involved and to describe the installation.

TYPICAL daily load curves of the needs of the University of Alberta are indicated in Fig. 1. It will be noticed that the summer and winter curves exhibit similar trends and it can be seen that the load factor, typical for an industrial installation, is quite poor. This is caused primarily because the University is an eight hour a day institution. While there are the occasional evening classes and night laboratories, the bulk of the work is done during the normal working day. This rather poor load factor is reflected in the electrical charges which are made by the City of Edmonton for power supply to the institution. Appendix 1 is a copy of the City of Edmonton rates and the rather severe penalty for high demand is indicated in the rate structure. The demand meter is reset once a year so that the worst condition which occurs demand wise is reflected in the payment for the entire twelve months. Justification for this charge by the City of Edmonton can be seen if we briefly review the actual costs of producing power.

Power Costs

Many[3] authorities divide the cost of electrical power into three main elements. The fixed element, the energy element and the customer element. The fixed element includes the capital cost of the plant distribution system as well as the depreciation and taxation which these are subjected to. This is usually expressed as a percentage of the total cost of the plant and the total cost of the plant in turn is influenced by the maximum power which it must produce; the charges of depreciation, taxation, management and other fixed elements of cost do not vary as the load is reduced. The energy element which will include fuel costs, labor costs, supplies and maintenance are influenced by the actual energy produced but in turn also these have a fixed element. The cost of supplies and maintenance of a turbine running lightly loaded are very close to those of the same turbine running under a normal or even heavy load. The customer element of cost which includes the distribution system, transformers, meters and so forth is again influenced by the maximum demand which the customer uses even though it may be for a very short time.

It therefore seems reasonable if a customer is attempting to reduce the electrical energy charge that the first approach should be made at reducing the demand and the demand charges. Of course, if some electricity can be produced as a by-product during a process, less electricity need be purchased and electrical utility charges will be reduced. This approach is quite common in a number of industries which require process steam and it is felt that the details of this technique have been efficiently covered in other literature[4] to require no more than a brief résumé.

By-Product Power

Many industrial plants require steam for their processes and/or heating purposes. If the steam is required at a pressure below that which can be readily produced, an industrial steam power plant is operated at a pressure somewhat higher than the process requirement so that a steam turbine or engine may be used as a reducing valve and in turn electrical energy is produced. Since the added thermal energy required to produce the higher pressure steam is usually quite small, electricity produced in this manner is very economical. Unfortunately the production of electrical energy in this manner, in many cases, is more simple than the accountants determination of the cost. It is this writer's opinion that since electricity is essentially a by-product, the costs which be attributed to it are those which can be actually charged to it; namely, the additional costs for boilers to produce the higher pressure steam, the additional cost for fuel to produce the higher enthalpy, the wages of the engineers necessary for the steam power plant but not those for the steam heating plant (unless a higher certificate is necessary—and then only the difference should be charged). In many cases, these costs are difficult to determine and approximations are used in order to apply interplant accounting procedures. At the University of Alberta, the electricity is charged to the various departments and buildings at the City utility rate and the cost of heating steam is reduced so that the power plant operation is basically nonprofit. The rationalization here, while there may be an overcharge for electrical energy, there is a corresponding undercharge for the steam and therefore the total cost of each department will be equalized.

This technique, however, does not overcome the high demand costs because unfortunately, the production of electrical energy is dependent by the use of the process steam, and if this steam is used basically for heating, a considerable energy charge can occur during the nonheating periods of operation. There are also periods, during extremely cold weather, where additional steam is needed beyond what can be passed through the turbines, and this represents an additional cost since the steam no longer has a by-product credit and the full cost of steam generation must be applied.

Gas Turbine Power

The industrial gas turbine seems to supplement the steam turbine in the above regard. We have a machine which produces electricity as its main product and steam as the by-product. Electricity can be produced at all times of the year and when the by-product steam is needed, it can be produced with very little additional cost. The type of gas turbine and its arrangement will determine the ratio of fuel costs to electricity and steam produced. While the large number of combinations which are available in the larger sizes have not yet been used in the smaller gas turbines, there are several distinct choices which can be made. (See Fig. 2).

Single Shaft

The single shaft compressor—turbine—alternator with possibly reduction gear between the turbine and the alternator, is perhaps the simplest to construct and operate. There is one operating speed, namely the synchronous speed of the alternator. This has a rather sharp efficiency curve and is best suited for design load.

Series Shaft Machine

The usual arrangement of this type is that the gas compressor and its turbine (called the charging set) are mounted on one shaft and the power turbine which is connected to the alternator is on a second shaft in line with, but not connected to, the charging set. This allows the charging set to vary in speed while the power turbine and its geared alternator operate at the synchronous speed. Efficiencies are somewhat higher over the usual operating range and the starting motor does not have the added load of rotating a fairly large alternator.

The Two Shaft Machine

This type is more commonly employed in larger machines where there are two stages of compression and expansion. This allows intercooling between the first and second stage of compression and also allows reheat between the high pressure and the low pressure turbine. We now have basically two gas turbines, two compressors, one low pressure and one high pressure. This also has two combustion chambers, one high pressure and one low.

All of the above can be equipped with regenerators which allow the exhaust heat to preheat the compressed mixture before it enters the combustion chamber and/or waste heat boilers which allow the exhaust gases to supply process steam. The turbine at the University of Alberta is of the second classification, equipped with both a regenerator and a waste heat boiler. The regenerator, in preheating the compressed gases, increases the thermal efficiency a significant percentage (16 to 23%) and yet the exhaust gas temperature is still sufficiently high to produce heating steam. Let us examine more closely the University of Alberta installation.

Gas Turbine Power Plant

The design of a gas turbine power plant does not differ materially from any other type of power plant. It has the problem of supplying the raw materials, eliminating or transferring the waste products and transmission of the power produced. There is one rather significant additional problem with gas turbines of the open cycle type. Due to the fact that the working substance is air in rather large quantities, almost 15 cu. ft. per min. for each horsepower produced, and that this same weight of air (with some additional burnt fuel) must also be exhausted to the atmosphere and in many cases at quite a high temperature, we find that a new parameter has been in-

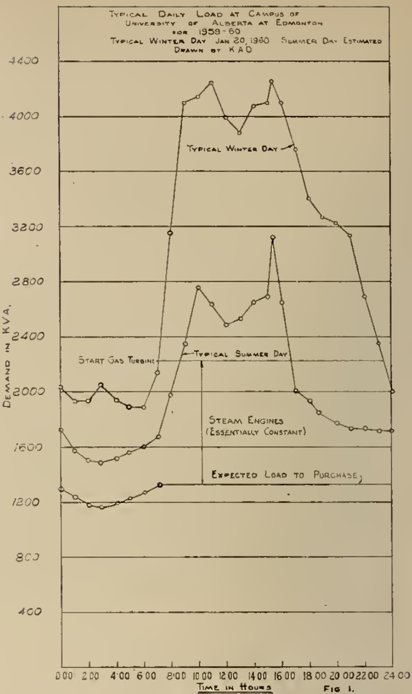

Fig. 1. Typical Daily Load Chart.

troduced into design consideration, namely, that of sound. The gas turbine at the University of Alberta area has been installed in a residential-hospital-teaching zone which has made the sound problem one of paramount importance. The gas turbine heat exchanger duct work, and waste heat boiler have been placed towards one end of the power plant and the wall behind the turbine houses the air intake duct. The north side was selected for the air intake in order to obtain the coolest air possible and this orientation allows the longest clear distance before any buildings or reflecting surfaces are encountered. In order to keep duct lengths as short as possible, the exhaust stack is also on the north side. Fig. 3 is a view of the intake silencers from the downstream side and shows the rather successful straight line flow type of silencer which has absorbent vertical members that absorb the sound energy with minimum pressure drop. The air intake filters are shown in Fig. 4. It might be added that no special silencing treatment was carried out on the exhaust since it was felt that sufficient attenuation would occur as the exhaust gases passed through the heat exchanger and the waste heat boiler. While one of the theoretical advantages of the gas turbine is that no cooling water is needed, in practice some cooling is necessary to remove the heat from the lubricating oil of the gas turbine. This oil in turn has cooled the gas turbine bearings and removed some of the heat which has been transmitted to the bearings by the high temperature blading and discs fastened to the shaft. Cooling water was also necessary for the gas compressor and the generator. In order to make this power plant as self sufficient as possible and to keep the water charges at a minimum, a cooling tower has been also installed in this installation. Year round operation of the plant being mandatory, the cooling tower was installed indoors. This is a standard outdoor type of cooling tower which has been selected oversize and installed in an upper corner room of the power plant building. Louvers are installed in the two walls as well as the roof and these are automatically operated as the temperature of the cooling water increases. All louvers are metal and while severe frosting has been encountered on the roof or upper louvers, these are of the locomotive type with very powerful actuators which can be opened even though they are heavily covered with frost. Once the roof louvers are opened, natural draft through the wall louvers tends to remove the frosting formed and these are opened by normally sized motors. Unfortunately, we have been unable to test the cooling tower under summer conditions and therefore the actual reduction in capacity due to this indoor installation cannot be given.

Special Instrumentation

While the power plant is south of the actual campus, extensive instrumentation has been provided by the manufacturer for student testing. This includes a 24 manometer panel with mercury or colored water as the indicator fluid allowing students to determine the pressures of the operating gas turbines at the various significant points. A sixteen point temperature recorder is also included with the student instrumentation and this automatically indicates and records the temperatures at the significant points. Further instrumentation such as gas flow, steam output, intake temperatures, are installed around the walls in the area of the gas turbine.

This rather complete instrumentation has allowed senior and graduate students of the University of Alberta, to observe an industrial gas turbine under actual operating conditions. The proximity of this power plant to the University and its instrumentation will allow a most interesting and informative group of tests to be conducted by the students. To the best of this author's knowledge this installation is the world's first for students in a regular mechanical engineering degree pattern. Perhaps one should now look at the economic factors.

Economic Feasibility

In the economic justification of a gas turbine installation one must consider possible savings against probable costs. The yearly electrical charge for the university area if all power were purchased would be \$231,000. This is for 20.1 $\times 10^6$ kwh. at a load factor of 0.55 and a power factor of 0.80, resulting in a kilowatt-hour charge of 1.15 cents. The present steam generating plant (assumed to operate at 100% utilization factor for 6 months of the year) can produce 3.33 $\times 10^6$ kwh. per year. The gas turbine used as a peak load generator can produce 5.27 $\times 10^6$ kwh., which means that the City of Edmonton will then supply 11.4 $\times 10^6$ at a load factor of 0.98. This power will cost 1.01 cents per kwh. (compared to 1.15) and the steam produced power should be evaluated at 1.01 (it can be produced for much less, but this is to the credit of the steam plant—not the gas turbine) and the break-even summary of costs will be as follows.

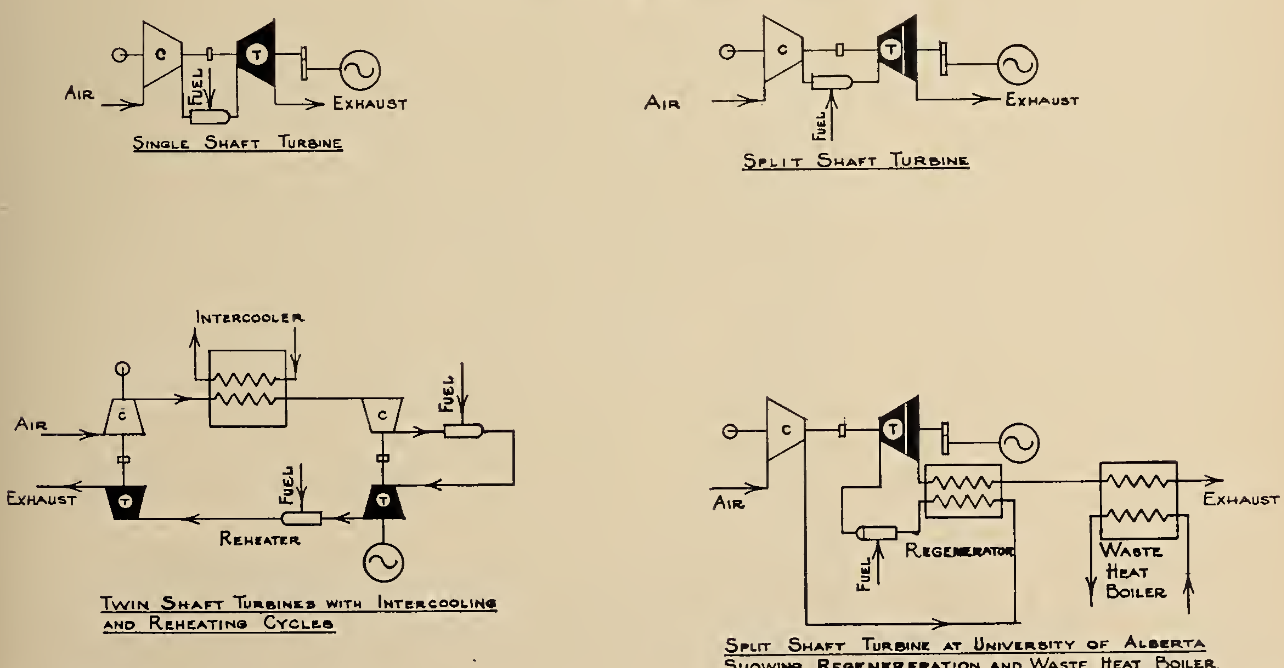
Purchasing all Electrical Energy

20.0 $\times 10^6$ kwh. at 1.15c (load factor 0.55), annual electrical charge		\$230,000

Gas Turbine, Steam Engine plus Purchased Electrical Energy

Purchased, 11.4 $\times 10^6$ kwh. at 1.01c (load factor 0.98)	\$115,200	
Steam Engine Production, 3.33 $\times 10^6$ kwh. at 1.01c	33,700	
Gas Turbine Production, 5.27 $\times 10^6$ kwh. at 1.54c	81,100	
		\$230,000

Fig. 2. Open cycle gas turbine variations.



In other words the gas turbine should be able to produce its power for less than 1.54 cents per kwh. before it becomes economically feasible.

Gas Turbine Costs

The gas turbine purchased by the Government of the Province of Alberta procured on a combination purchase-gift was evaluated at $300,000. It has a guaranteed output of 1980 kw. at 48°F, and supplied with a 2200 kw alternator to take advantage of greater power outputs at lower ambient temperature. The cost per kilowatt hour of capacity is very close to $150. In addition to the turbine there must be supplied a cooling tower, gas compressor, intake silencers, and electrical switch gear. These items are 10 per cent. or an additional $30,000. The building space occupied by the gas turbine and its auxiliaries is approximately 75,000 cu. ft. at $1.00 per cu. ft. or $75,000. Thus the total capital costs are approximately $405,000 or slightly more than $200 per kilowatt of capacity.

Operating Costs

Natural gas is the cheapest fuel available in the City of Edmonton, costing 2.3 cents per therm (100,000 B.t.u.) or 23 cents 10^6 B.t.u. Bunker "C" oil is approximately 40 cents per 10^6 B.t.u. Also there is no storage cost associated with natural gas and while there is a minimum demand charge of $100 per month, this is assumed to be borne by the steam plant.

No additional staff are to be employed for the gas turbine, and since it is to be operated in conjunction with two steam turbines, but only for 8 or 10 hours per day, it was felt that one-third the cost of two shifts should be charged to the gas turbine. With supervision, the hourly cost of shift engineers is $3.20 per hour.

There has not been sufficient running time to establish the cost of supplies, oil, minor repairs, etc., but it is anticipated that this will be fairly small, somewhat comparable to a steam turbine, oil consumption being negligible, $300 per month is the value used. There may be the repair of a larger nature or other unpredictable, and therefore a contingency sum of $1,000 per year is also provided.

Depreciation Allowances

It is estimated that the gas turbine and its auxiliaries, will have a life of 20 yr. (reblading is recommended by the manufacturer at 40,000 hr.) and the building will have a life of 40 yr. The depreciation values are therefore 5% and 2½%.

Total Operating Costs

The yearly operating costs with an average thermal efficiency of 20% may be summarized as follows.

			Mills per kilowatt-hour
Fuel	$\frac{5.27 \times 10^6 \times 341.3}{0.20 \times 100,000} \times 2.3$	$20,700	3.96
Labour	$\frac{16 \times 365 \times 3.20}{3}$	6,230	1.18
Supplies	300 × 12	3,600	.87
Contingency		1,000	
Depreciation	Gas turbine, and auxiliaries, 5% of $330,000	16,500	
	Building, 2½% of $75,000	1,870	3.46
	Total	$49,900	9.47

Return on Capital

It was noted previously that the power could be purchased for $81,100, therefore the saving, using the gas turbine, is $31,200. With a total investment of $405,000, this represents a return of

$$\frac{\$31,200}{\$405,000} \text{ of } 7.7\%$$

Waste Heat Boiler

If the value of the steam produced by the waste heat boiler is credited to the gas turbine a greater return is shown. The minimum steam consumption at the university area is over 10,000 lb. per hr., and therefore it is theoretically possible to produce steam at all time, however, the steam engines are of the back pressure type and in order to allow them to produce electricity, steam would only be produced by the waste heat boiler when the steam engines are at their maximum, namely the winter months. On this basis it is estimated steam will be required for 4 months. The waste heat boiler has a capacity of 10,000 lb. per hr., therefore the annual waste heat boiler production will be in the vicinity of 4 × 30 × 8 × 10,000 or nearly 10 million lb. of steam. The steam generating plant pay 2.3 cents per therm for natural gas and with an efficiency of 80% steam has a cost of 28.8 cents per 1,000 lb. The waste heat boiler therefore will save an additional

$$28.8 \times \frac{10,000,000}{1,000} = \$2880$$

The rate of return is now

$$\frac{\$3,1200 + \$2880}{\$405,000} = 8.45\%$$

If the waste heat saving is credited to the gas turbine generation costs, the cost per kwh. is

$$\frac{\$49,900 - \$2,880}{5.27 \times 10^6} = 0.895 \text{ cents.}$$

If money is borrowed at 6%, and this cost is added to the yearly production cost, we find the cost per kilowatt hour is

$$\frac{\$47,200 + \$24,300}{5.27 \times 10^6} = 1.35 \text{ cents,}$$

which is still below the "break even" charge of 1.54 cents per kwh. The charge of this borrowed money would be 4.56 mills per kwh., which represents the largest single item of electrical cost.

Other Economic Considerations

Naturally, if the hours of operation of the turbine are increased as load increases, greater savings are possible since the fixed charges at present make up the major share of the overall costs. There is also the possibility of operating the gas turbine (or perhaps a second one) as a base plant and purchase peak power from the City of Edmonton.

The use of the exhaust gas which still has a temperature of 310°F. after leaving the waste heat boiler as combustion air for the steam boiler plant has been considered. However, this will require considerable correlation between steam plant and gas turbine loads and operation. The design of the existing exhaust duct work is such, that should this interconnection prove feasible, it can easily be done.

One other possibility for considerable saving is due to the price structure of natural gas. Since this fuel is also used for steam production, the cost used in the calculations has been the normal commercial rate. In order to encourage high load factor of the installed gas transmission line, customers are offered an "optional" or high load factor rate which can be requested by industrial gas users whose summer consumption is at least forty percent of the yearly total. Thus, by operating the gas turbine for a greater period during the summer months, the annual gas costs may be reduced a significant amount. This phase will also be examined during the current summer's operation.

There is one other asset to this installation other than its economic and instructive possibilities. The university area power plant serves a hospital area, which includes University Hospital and its associated clinics as well as the Aberhart Memorial Sanatorium. The supply of continuous electrical power to hospitals is a problem most of us can readily appreciate, and while certain very strategic areas such as operating room lighting, poliomyelitis patients, iron lungs and other more dramatic areas, may be served by storage batteries or emergency diesel electric sets, it is very difficult to isolate any area in a hospital and say that continuous electrical energy is not necessary, and while the continuity of energy as supplied by the City of Edmonton has been very good, there has been and will be outages of some duration. The gas turbine can be started cold to full power in eight minutes and for this purpose a diesel electric plant is installed in power plant and this automatically comes on the line with the City of Edmonton voltage drops.

Commissioning of gas turbine has not been without the usual frustrations and delays. But the dependability and reliability of this source of power is now an established fact. The noise problem appears to be solved. There seems to be a large and growing need for the flexibility and diversity of the gas turbine.

It is felt that installation of the type described herein, with perhaps some modification will become more common as our needs for economic and supplementary power grow.

APPENDIX No. 1

The City of Edmonton Electric Light and Power Distribution System

NETWORK POWER RATES 1956

Commercial Power—4,160 Volt Service, 75 kva. or over.

Customer supplying All Transformers, Switching Equipment, etc., Service to be taken at 2,300 Volt, balanced three phase and having a measured maximum demand of not less than 75 kva. taking a minimum consumption of 10,000 kwh. per month.

First 100 hours use of kva. of demand at 1.1c per kwh.

Next 100 hours use of kva of demand at 1.0c per kwh.

Next 200 hours use of kva. of demand at 0.09c per kwh.

Over 400 hours use of kva. of demand at 0.08c per kwh.

Plus a Service Charge of 50c per kva. of demand taken at the highest 15 minute interval in any one month, and this shall be accepted as the maximum demand for the succeeding twelve months, or until a greater demand is established.

Minimum Bill $145.00 per Month.

JOINTS IN PRECAST CONCRETE BUILDING FRAMES

E. M. Rensaa, M.E.I.C.,
Rensaa & Minsos,
Architects and Consulting Engineers,
Edmonton.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

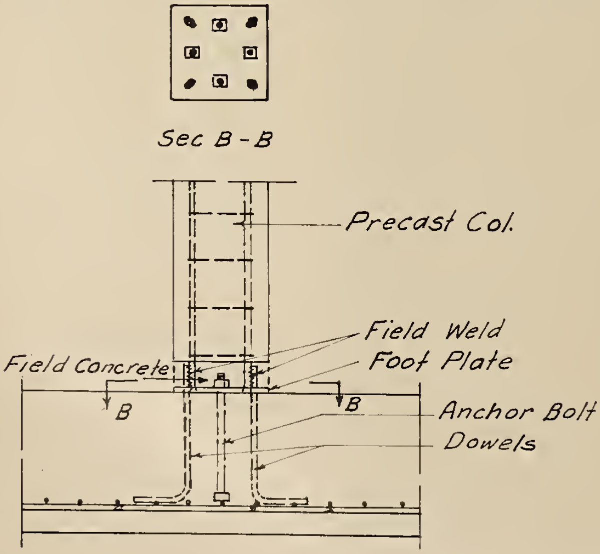
This paper discusses the technical and economical aspects of joining together precast reinforced concrete beams and the fixing of columns to their supports. Methods and details of jointing which have been worked out during the last 12 years by the writer are described. Basic principles in the development of suitable joints are discussed. The discussion also deals with jointing under winter conditions.

BOTH STRUCTURAL sufficiency and the economy of precast reinforced concrete building frames depend largely on methods of joining the individual members together. There is generally little or no saving of materials involved in precasting beams and columns and any saving obtainable must, therefore, be in connection with form work and labour. Precasting is for this reason justified only in cases where the combined cost of casting, transport, erection and joining is less than the cost of casting the members in place, or where saving of time is an important consideration.

Forming and casting a reinforced concrete member at the ground level can always be done more cheaply than up in the air where the member needs special support. This is the chief source of saving by precasting. From this saving must be deducted the cost of transport from the factory to the site if the members are factory made and the extra profit to the factory. In addition to this comes the cost of placing the precast members and the cost of joining them together. An engineer who is designing on the basis of economy must consider the different phases of all these aspects and find out which method of casting is most profitable. Consideration must, of course, also be given to structural sufficiency which is not always easy to obtain in precast frames. It should also be noted that methods of casting in place have been considerably improved during the last decade.

The most variable and difficult problem to solve economically is the jointing of precast members. It is nearly always possible to design a joint which is sufficiently strong if little regard is paid to cost, but to obtain the proper combination of simplicity, economy and strength is often an extremely difficult problem. There has not been much to learn from what has been practised in North America in that respect. In most cases, joints used here have been of a simple type providing little or no continuity and quite often no other anchorage than that provided by bond and friction. The writer has not been satisfied with such simple joints and has tried to work out details which would make a structural precast concrete frame comparable in continuity with a cast-in-place frame. European practice as described in literature on precasting has been studied in this connection. The most advanced methods seem to be those used in Russia and the countries under its sphere of influence. The details used there, however, would not generally be economical under North American conditions. The reason for this is that we

Fig. 1. Departure from the pocket type column connection



do not use so much mass production of similar elements as in Russia and, therefore, cannot employ special equipment and devices repeatedly to the same extent. An even more important difference is our relatively higher labour cost which makes it unprofitable to use labour absorbing methods even if some saving of material can be achieved. Some of the joints developed and described in the paper, however, will hardly require any extra material in spite of their simplicities. A general discussion of the suitability of precasting may be found in an earlier paper by the writer.[1]

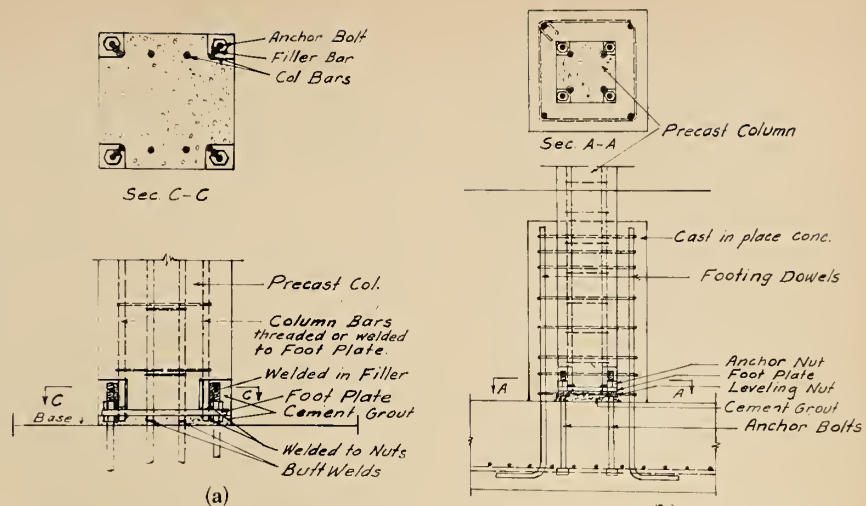


Fig. 2. (a) Screwed and welded joint. (b) Screwed and welded joint with collar reinforcement.

Column to Footing Connection

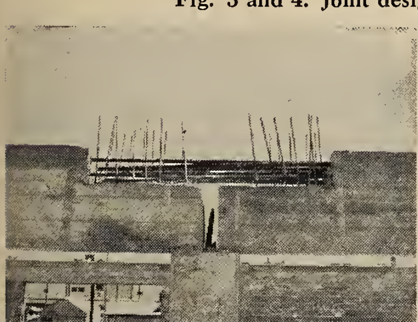
The providing of lateral stability in large industrial buildings or buildings of considerable length quite often constitutes a problem if no interior cross wall or bracing is feasible. In many cases the simplest solution is to fix the columns to their foundation so that these will resist the overturning moment from lateral loading. The bending stresses will under such circumstances often be much greater than the direct stresses from vertical column loads. About the simplest connection that can be used for obtaining bending moment resistance is to form a pocket hole in the foundation block into which the lower end of the column can be set. The hole is usually made about 2 in. larger on all sides than the column and should also be about 2 in. deeper than the lower end of the precast column. In practice, it is found to be almost impossible to finish off the bottom of a hole at correct elevation and level at the same time as the foundation block is cast. Before the columns are erected a pad smaller than the column cross section should be cast at the bottom of the hole and finished off at the correct level.

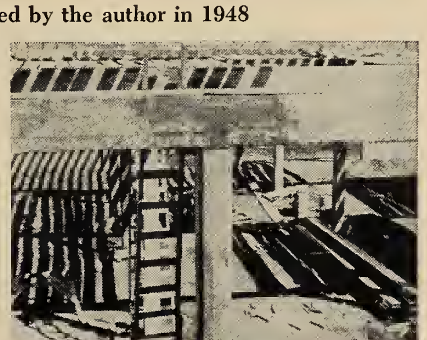
When the precast column is placed it must be held temporarily in place by means of wood wedges. Plumbing of columns can be made by adjusting these wedges. The space between the foundation block and the precast column is then filled with well packed cement mortar.

This type of column connection is very strong provided the pocket hole is sufficiently deep and the mortar packing has been well done. But it is a crude piece of work requiring much labour in forming, wedging, plumbing of column and packing of mortar. It is not cheap in material either and is not suitable if there is a basement under the floor where the footing is placed. This type of column base was copied from German practice and was used on our two first precast frame buildings before more suitable footing connections were developed.

The first departure from the pocket type column connection is shown on Fig. 1. and together with some later developments and improvements are covered by Canadian and U.S.A. patents. The idea with this connection was the cutting of labour cost, speed of erection, economy of material and unrestricted usability. There is no method which will allow a faster fixing of a column to its foundation than a screw connection. No temporary shoring is required and plumbing can be done at any time after erection so that the expensive erection work is done in the shortest possible time. It was found to be desirable and economical to get a direct connection between the anchor bars and the column bars. This would lessen the dependence on the bending strength of the foot plate so it could be cut down to a thickness just sufficient for erection. The most suitable way of obtaining a direct connection between upper and lower bars is by means of welding.

Fig. 3 and 4. Joint designed by the author in 1948





Apart from the work of welding there was some work required in packing the spaces left in the column with cement mortar. This work must, however, be done to a certain extent even with steel columns. An expanding agent put into the mortar is desirable. It is not likely that such a mortar joint will weaken the concrete section materially if it is well done and of uniform depth.

Plumbing is greatly facilitated by means of levelling nuts such as are sometimes used in steel construction. This feature has been included on all later designs. To cut work on mortar packing a special type of joint was developed where only small parts of the concrete corners above the foot plate were removed. This will constitute a weakening of the concrete section even when filled in later, because it is hardly possible to obtain the same strength as for a more homogeneous concrete section. The weakening in most cases will not be very important, however, if the column has a reasonably large cross section (Fig. 2(a)). The vertical steel bars can take considerable load without help from the concrete. Concreting may, therefore, be postponed and this makes the joint suitable for winter construction.

An alternative without direct connection between lower and upper bars, not a patented design, requires a thicker foot plate and the concrete section is weakened to an even greater extent than is the case where only the concrete corners are removed. The column section would undoubtedly be stronger if the remaining part of the concrete section were removed and later replaced with expanding cement mortar. We have not used this type of connection.

It might look as if the most advantageous design would be to use a larger foot plate than the column section so that the anchor bolts could be placed outside the column because no concrete would then need to be removed. The use of such a large plate is, of course, possible, but is inconvenient to include in the casting of a column. This is most often done on a platform and it is inconvenient to have any projection attached to a member which will necessitate the cutting of recesses in the casting platform. The cheapest method of casting is to use members of such a form that every second piece is first formed and cast. The forms are then removed, a bond breaking agent is put on the side surfaces and the sides of the first cast members are used as forms for similar members cast in between the first ones. It is, of course, possible to fasten a steel foot plate to the column bars after casting but this is not convenient and the foot plate needs to be extra strong. Any projection from a precast member which cannot be placed upwards during casting will increase the forming cost.

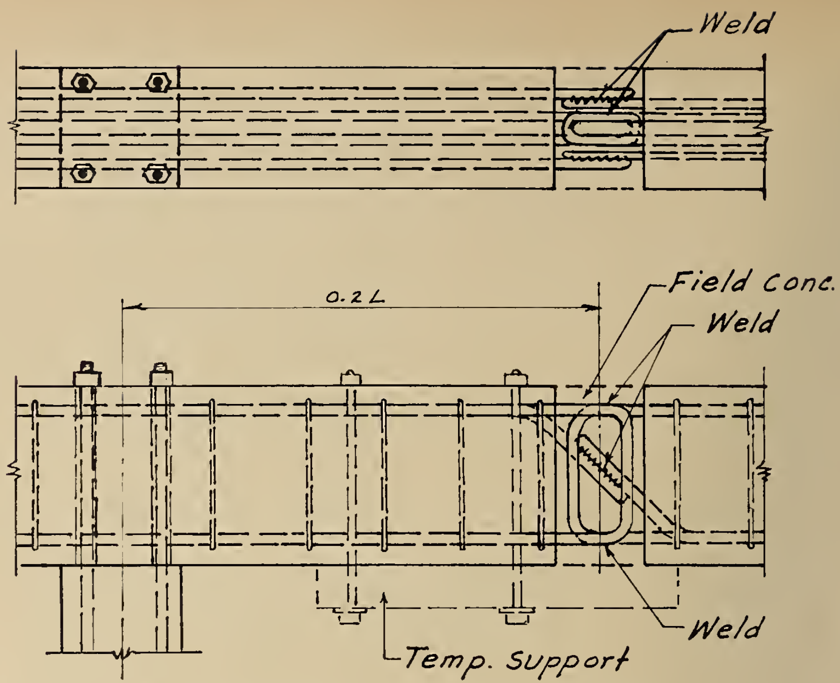


Fig. 5. Joint requiring temporary support until both horizontal bars and the diagonal shear bars have been welded together

Fig. 6. Structure with joints of the type described in Fig. 5.

In the case where the column is very high and has to resist considerable lateral loads from wind and crane impact, the writer has been reluctant to depend on the sufficiency of a welded and screwed connection. In a recent industrial building the lateral loading became quite great. A combination connection was, therefore, developed (Fig. 2(b)) where the usual screw connection would provide all advantages of initial fixing. A form for a concrete enclosing box was then placed around the column and filled with concrete. This concrete box is heavily reinforced with dowels projecting from the footing and with strong ties. The labour involved is much less than for the hollow foundation type, but the same strength as with this can easily be obtained.

Joints in Precast Beams

When our first precast frame was designed in 1948 the problem of joining precast beams had to be solved. The writer wanted to obtain continuity, but this was not economically feasible by such types of joints as were found described in European literature. A joint as shown on Figs. 3 and 4 was, therefore, designed and at the time was thought to be an innovation. Some years later, it was found that similar joints had been developed and tested in Russia. Tests there showed that lap splicing of the reinforcing bars at point of maximum negative bending moment did not cause lower ultimate strength than for a comparable case with fully continuous bars.[2] The reason for this is undoubtedly that at the section of maximum bending moment the amount of steel due to lapping is really doubled and that at the end of the laps where the amount of steel corresponds to the full bending moment, the actual bending moment has decreased considerably. These test results constitute an exception to the rule that reinforcement should not be spliced at points of maximum stress. It is, of course, not certain that tests would show the same result for shorter laps as might be employed with deformed bars.

We have used this type of joint in a large number of cases and never experienced any difficulties. The joint has the advantage that beam lengths correspond approximately to the distances between columns. No temporary supports are required for the beams which can be hoisted up and placed directly on the columns. As disadvantages might be mentioned, the considerable amount of labour required to bend the stirrup ends down and the proper packing of the joint concrete. The joint is not very suitable for a second story design and not really adaptable to winter construction.

A joint which requires considerably less labour is shown on Figs. 5 and 6. The joint can most conveniently be placed near the point of inflection. It requires a temporary support until both the horizontal bars and the diagonal shear bars have been welded together. The complete maximum shear should, of course, be taken by the diagonal bars. The centre suspended beam is stable after welding without any temporary support, but should not be subjected to heavy torsion before the joint is concreted. Filling the space between the beam ends with concrete is easily done and the finished joint is then hardly noticeable (see Fig. 6). The concreting might even be postponed until heating of the building has started and the joint may, therefore, be used for winter construction. We have used this joint in several cases with complete success.

A beam joint based on somewhat similar ideas is shown on Fig. 7. This joint will not require any temporary support and can be filled in with concrete at any convenient time. Labour involved is quite small and the joint is very suitable for winter construction.

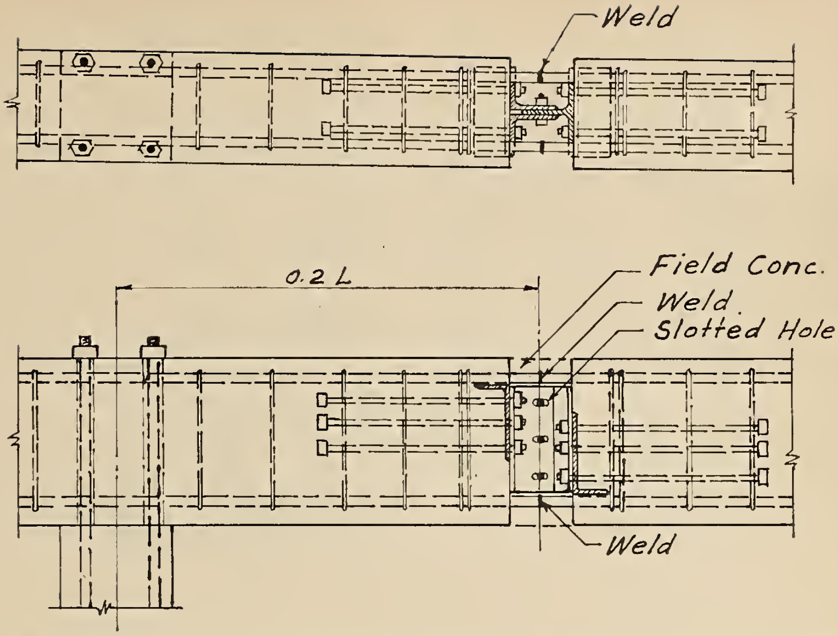

Fig. 7. Joint which does not require any temporary support and can be filled with concrete at any convenient time.

Joints Between Steel Sections and Concrete Members

A combination of steel and precast concrete members may sometimes form an economical and easily constructed building frame. Precast concrete columns are usually cheaper than steel columns if they have to be designed to take both vertical and lateral loads. Steel may on the other hand be more suitable for long spans. There is no special difficulty in designing such a combination structure and our firm has built several of them. It is much easier to design a joint between a steel member and one of concrete than it is to design a good joint between two precast concrete members. For this reason and because of the large number of possible variations, examples of such joints will not be given in this paper. It is important also in this case that the design should be such that there are projections only on one side (upwards) when the concrete member is cast. This will facilitate the side by side casting mentioned previously. Fig. 8 shows part of such combination steel-precast concrete structures.

Conclusion

The question may be asked what further developments are possible in the jointing of precast concrete members. The writer thinks that this will depend largely on the increased use of welding of reinforcing bars. At the present time welding of reinforcing bars for taking tension is seldom used in North America. Comparatively little attention has been given to the weldability of reinforcing steel and there are not even any suitable code provisions as far as the writer knows. Until further investigations have been made it seems risky to depend unduly on a welded splice and especially on the butt welded type. Steel with high carbon content is difficult to weld without considerable loss of tensile strength. Undesirable as the lap splice is in many respects, it is probably still the most reliable form for a splice. It is for the above reasons urgently required that a thorough investigation be made of the possibilities and limitations of welding of steel reinforcement.

K_2O

WESTERN CANADA POTASH AND ITS FUTURE PROSPECTS

W. J. Pearson, M.E.I.C.
Geologist, Department of Mineral Resources, Province of Saskatchewan.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The term "potash" is applied to the compounds of the element potassium and is expressed in the term of potassium oxide (K_2O). Potassium oxide is not found in nature nor produced by man, but is used as a basis for comparison of all potassium compounds and is applied generally to the various compounds of potassium used by agriculture and industry. Potassium is one of the most essential chemical elements used by man. In 1959, 95% of the potash consumed in North America was used for fertilizer and the balance for industrial and chemical uses. Potassium chloride, known commercially as muriate, is the major potash compound used in fertilizer, the other compounds used are sulphate of potash and sulphate of magnesia. Chemical grade potassium chloride containing over 99.9% KC1 is the basic compound for most chemical and industrial uses. Potassium hydroxide, produced from potassium chloride, serves as the basic chemical for manufacturing many potassium compounds. The major industrial uses of potash are in detergents and soaps, glass and ceramics, textiles and dyes, chemicals and drugs, and refining and purification processes.

THE GREATER part of the world's supply of potash is derived from deposits of soluble potassium minerals such as occur in western Canada and New Mexico. There is, however, some production from concentrated surface brines, for example, at Searles Lake, California; Salduro Marsh, Utah; the Dead Sea; and from well brines in Michigan.

Up to the outbreak of World War I the German potash industry, which was developed in the period 1861-1865, was the sole source of potash for North American agriculture and industry. During the war years the United States was forced to get what potash it could from a number of expensive sources such as brine lake, distillery wastes, flue dust and seaweeds. The price rose from $35 a ton to almost $500 a ton. In 1925 while exploring for oil east of Carlsbad, New Mexico, the Snowden and McSweeny Company discovered potash salts. The United States Potash Company was formed to develop the deposit and production of potash began in 1931. At the present time there are six mines in operation in the Carlsbad area of New Mexico with an annual production in excess or two million tons K_2O. The mine production from this area for 1958 was 2,309,000 tons K_2O.

Discovery of Potash in Saskatchewan

Potash mineralization in Saskatchewan was first recognized in a core from the Norcanols Radville No. 1 well (Lsd. 36-5-19-W2), drilled early in 1943 near Radville in southeastern Saskatchewan. In the same year, potash was observed in Norcanols Ogema No. 1 well (Lsd. 24-7-23-W2). The potash-bearing beds occurred in these wells at depths of 7,653 ft. and 7,420 ft. respectively, and the discoveries were not of interest for commercial production of potash. In 1946 core grading 21.6% K_2O over 11 ft. was recorded from Verbata No. 2 (Lsd. 24-21-24-W3), drilled near Unity in west central Saskatchewan. In this well the potash was encountered at a depth of 3,466 ft. and the possibility of commercial production was considered.

In 1950 companies engaged in oil exploration began running logs measuring the natural radioactivity of the formations penetrated and this provided a new tool for the search of potash. Potassium has one isotope K_{40} which emits intense gamma rays (Ahrens and Evans, 1948) which give rise to high radio activity being recorded on the log opposite potash bearing formations. These logs indicated the existence of potash-rich beds over a large area of southern Saskatchewan.

Geology and Mineralogy of the Saskatchewan Deposits

The potash in Saskatchewan is of Middle Devonian age and occurs in beds near the top of the Prairie Evaporite formation of the Elk Point group. A Middle Devonian age has been confirmed by potassium dating methods (Folinsbee, Lipson, and Reynolds, 1956). The Prairie Evaporite formation was deposited in the Elk Point basin (Baillie, 1953), which trends northwest-southeast from North Dakota and southwestern Manitoba into eastern Alberta. The basin is structurally closed except to the northwest.

The Elk Point group consists of, in ascending order, the *Ashern formation* (shale: red and green shale, subordinate gray shale, dolomitic and calcereous); the *Winnipegosis formation* (Dolomite: tan saccharoidal dolomite, minor standard carbonate, sporadic inclusions of evaporite near top); and the *Prairie Evaporite formation*

(Evaporite: potash, salt, and anhydrite). The group is underlain by older Paleozoic formations and overlain by the *Second Red Bed* of the Dawson Bay formation. The Second Red Bed, which is an argillaceous layer consisting of red and green shale and subordinate gray shale (dolomitic and calcereous), forms a distinctive marker horizon above the Prairie Evaporites.

The Prairie Evaporite formation consists mainly of massive halite with clay and anhydrite interbedded throughout. Varying amounts of anhydrite and dolomite occur near the base. The salts vary in texture from fine grained to very coarse grained, the latter being found chiefly in the upper part of the formation. The formation extends from northern Alberta, across central and southern Saskatchewan, and into Manitoba for a few miles. In the south central part of the area there is a section in which the salt has been removed by solution and the younger formations above have collapsed. Geophysical data indicate that there are solution channels in the salt formation. The Prairie Evaporite formation is over 600 ft. near the centre of the basin and thins to less than 50 ft. around the margins. The formation does not outcrop and at the northern edge the salt is found at depths of 2,500 to 2,800 ft. below the surface. The beds generally dip gently in a southerly direction.

The potash mineralization occurs within the upper 200 ft. of the Prairie Evaporite formation. Information obtained from bore holes drilled specifically for potash indicate that there are several distinct potash-bearing horizons or zones. Goudie (1957) identified three major zones. In addition to these there may be one or more lesser ones. Each zone contains one or more potash-rich beds interlayered with barren salt or beds with low potash content. However, the three major zones are not encountered in all test holes. The available well information indicates that the area of deposition of the earliest potash zone was more restricted than the later ones. A number of sub-basins developed in the Elk Point basin. According to Goudie (1957) during the first major period of potash deposition, three of these, designated as the Esterhazy, Ellisboro, and Moose Jaw-Regina sub-basins, appear to have been in existence. Others developed during the other major cycles of potash deposition.

There are three predominant minerals occurring in the potash-bearing formation, halite (NaCl), sylvite (KCl), and carnallite ($KCl.MgCl_2.6H_2O$). Halite and sylvite occur together as the mechanical mixture known as sylvinite. Sylvite is the desirable mineral from the point of economics as it contains 63.2% K_2O equivalent, while carnallite contains only 16.9% K_2O. Polyhalite ($K_2SO_4.MgSo_4.2CaSO_4.2H_2O$) and leonite $MgSo_4.K_2SO_4.4H_2O$) have been reported from a few wells. The main potash minerals, sylvite and carnallite, occur separately and in close association. In different localities or areas the sequence of occurrence is not always the same. In some wells the upper beds may be predominantly carnallite grading down into those higher in sylvite, while in others the sylvite occurs predominantly above the carnallite-bearing beds, or sylvite may be the main mineral throughout. For example in the wells, Quill Lake No. 1 and Quill Lake No. 2, just to the west of the Quill Lakes, the uppermost bed contains mainly sylvite and halite and the lower beds contain essentially carnalite, while in a well, Flint Edmore Crown No. 2, about 25 miles southeast of Big Quill Lake, carnallite occurs in the upper bed and sylvite with carnallite appears below. Generally the clay content appears to be higher in the western and central parts of the potash area than in the eastern section.

Grades and Reserves

The grade of potash found in Saskatchewan and Manitoba is generally higher than the potash being mined in New Mexico and Europe. The best ore of New Mexico grades from 20 to 25% K_2O. However, as mining is carried on, the higher grade ores are depleted first. The United States Bureau of Mines reports that the calculated grade of the crude salts mined in 1958 was 18.89% K_2O compared with 19.30% in 1956 and 20.7% in 1947. The grades in the Stassfurt deposits in Germany range from 10 to 20% K_2O. The commercial grade in Saskatchewan probably will be in the 25 to 35% range.

Drilling to date had indicated that the potash deposits in Saskatchewan are very extensive and that the total potash in the Prairie Evaporite formation probably exceeds previously known world reserves. In Saskatchewan the recoverable reserves at depths of less than 3,500 ft. and grading 25% or better, with bed thicknesses limited to 5-10 ft. have been estimated at 6.4 billion tons. In making this estimate a recovery of 40% of the ore from only one bed in zones of multiple beds and 90% mill efficiency was assumed. However, if a brining technique can be developed which will extract potash economically, potash-bearing deposits at greater depths than 3,500 ft. will become commercial reserves and the economic potash reserves of the province will be increased greatly.

Development of Potash in Saskatchewan

The first commercial production of potash in Saskatchewan was attempted by Western Potash Corporation Limited (Continental Potash Corporation Limited, 1955) on land acquired in the Unity district approximately 100 miles west of Saskatoon. The company attempted to develop a method of mining potash salts by solution similar to that used in producing comon salt, but the experiment proved unsuccessful. A shaft located approximately eight miles northwest of Unity, was begun and by February 1958, when operations ceased, had reached the top of the Blairmore formation at a depth of 1,675 ft. In June 1959, operations on the shaft were resumed. A test hole was drilled 230 ft. west of the shaft for the purpose of making a study of the Blairmore formation. Tests carried out on sections of this formation indicate that the shaft can be extended successfully through it.

Potash Company of America was the first of the producers from New Mexico to begin exploration in Saskatchewan. By the end of 1953 the company had selected an area east of Saskatoon and from that time exploration for potash accelerated rapidly. In 1954 Potash Company of America started preparations for shaft sinking, which included freezing the shaft area to a depth of 3,000 ft. at Patience Lake, approximately 16 miles east-southeast of Saskatoon. The shaft was completed in June 1958 to the 3,450 ft. level and the main operating level was established at 3,333 ft. Production began in November 1958 and the first shipment of muriate of potash was made in March 1959. The plant continued to operate until November 1959 when production was suspended due to water seepage into the shaft. A program of grouting and shaft repairs was initiated, which entails the gradual thawing of the frozen area surrounding the concrete shaft lining and grouting as the thaw takes place. The grouting program may take up to one year to complete.

International Mineral & Chemical Corp. (Canada) Ltd. which holds a reservation and lease on the east side of the province in the Esterhazy area, entered the field in 1955 and shaft sinking was begun in the spring of 1957 at a site approximately 12 miles northeast of Esterhazy. By June, 1958 the shaft had reached the top of the Blairmore formation at a depth of

1,200 ft. An attempt was made to sink the shaft through the Blairmore without prefreezing the shaft area and by using a grouting technique, but this method proved unsuccessful. The present operations involve freezing of the Blairmore to —50° F. and when this is completed the shaft sinking will be resumed using a technique called "tubbing". This involves lining the shaft through the water-bearing formation with a water-tight cast iron lining, composed of a series of 65 rings, each 5 ft. high, about 4 in. wall thickness, and 18 ft. diameter, which will be joined and sealed with lead and bitumen. When the cast iron section has been completed the frozen area will be permitted to thaw out. Haniel and Lueg, a German engineering firm, will direct the installation. It is expected that potash production will begin in late 1961.

The water-bearing Blairmore formation so far has been one of the main problems in shaft sinking and shaft construction. However, by employing shaft-sinking methods used with success in other parts of the world where similar conditions exist there is not much doubt that this problem can be overcome by future producers in the potash field.

As of May 1, 1960 there were 15 companies representing Canadian, American, British, German and French interests holding a total of 1,326,590 acres under potash disposition.

With the extensive exploration for potash that has been carried on in the last few years the main activity is centered in two areas. The one area extends from about 30 miles west of Saskatoon to the Quill Lakes in a belt 30 to 35 miles wide, and the other extends from south and southwest of Yorkton, southeast across the Saskatchewan-Manitoba boundary into Manitoba for a few miles over an approximate width of 25 to 30 miles. However, the most recent withdrawals of potash lands have been in an area between Moose Jaw and Regina, and one west of the northern part of Last Mountain Lake about 46 miles north of Moose Jaw. One potash permit is held in the Unity area.

World Production and Consumption of Potash

The first recorded production of potash was in Italy in 1816, where alunite $(K_2Al_6.(OH)_{12}(SO_4)_4$ was mined to produce alum. Potash salts were noted in Poland at Kalsz in 1854, but continuous production from Polish deposits did not begin until 1920. Soluble potash salts were first produced in Germany in 1861 and by 1865 Germany had developed a potash industry. Alsace began production of potash salts in 1910, Spain in 1925, Russia in 1930, and the United States in 1931 (although potash production from brines had begun in the United States in 1915 when the potash supply was cut off from Germany during World War 1). There was some production from brines from the Dead Sea in 1930. In addition, Japan, China, Ethiopia, Italy and Korea are reported to produce minor amounts of potash salts. Production in Europe had dropped from approximately 3,520,000 short tons K_2O in 1941 to about 1,500,000 short tons by the end of World War II. However, since then there has been a steady increase in potash production. Table I gives the world production of marketable potash in equivalent K_2O by main producing countries from 1949 to 1958. World production of potash in 1958 totalled approximately 8.8 million short tons.

Free world consumption of potash increased from 2,776,000 short tons in 1938 to 7,666,000 tons in 1957. The North American consumption in 1938 was 428,178 short tons and by the end of 1959 the total consumption had risen to 2,787,367 tons, approximately 6.5 times what it was in 1938. Canadian consumption in 1950 was 62,181 tons while in 1959 it was 96,411 tons, of which 29,441 tons were imported from Europe. In 1958 the United States imported 237,269 tons K_20 and in 1959, 268,002 tons K_2O equivalent. Exports of North American potash to other countries in 1959 showed an increase of 36% over the previous year. Deliveries of potash in 1959 for agricultural pur-

TABLE I

World production of potash (marketable, unless otherwise stated) in equivalent K_2O, by countries

(1) 1949-53 (average) and 1954-58, in short tons (2) (Compiled by Helen L. Hunt and Bernice B. Mitchell) (Modified) Foreign Statistics, Division of Foreign Activities, Bureau of Mines, May 4, 1959

Country (1)	*1949-53 (average)*	*1954*	*1955*	*1956*	*1957*	*1958*	*% of World Production*
North America: United States	1,480,689	1,948,721	2,066,706	2,171,584	2,266,481	2,147,670	24.4
Crude (including brines) (3)	1,619,004	2,170,969	2,326,946	2,479,463	2,615,808	2,478,724	
South America: Chile	3,650	550	11,000	12,000	11,000	(4) 11,000	
Europe:							
France	1,191,387	1,192,083	1,310,961	1,463,006	1,545,267	(4) 1,613,000	18.3
Crude (3)	1,099,382	1,361,734	1,490,764	1,653,465	1,736,800	1,882,039	
Germany:							
East (4)	1,387,800	1,488,000	1,582,000	1,598,000	1,653,000	1,700,000	19.3
Crude (3) (4)	1,602,800	1,720,000	1,820,000	1,840,000	1,900,000	1,960,000	
West	1,189,900	1,783,394	1,870,848	1,823,000	1,862,000	1,892,000	21.5
Crude (3)	1,420,650	2,135,000	2,227,000	2,166,000	2,190,000	2,222,000	
Spain	187,626	243,166	242,539	263,468	251,460	(4) 236,000	2.7
U.S.S.R. (4)	377,600	593,700	870,500	983,600	1,040,000	1,100,000	12.5
Asia:							
Israel	683	(4) 12,000	(4) 12,000	(4) 31,000	(4) 50,000	(4) 80,000	0.9
Japan	234	454	461	474	(4) 1,650	(4) 1,900	
Africa: Eritrea	786	—	—	—	—	—	
Oceana: Australia	369	—	—	—	—	—	
World Total (marketable) (estimate)(1) (2)	5,800,000	7,300,000	8,000,000	8,300,000	8,700,000	8,800,000	

(1) In addition to countries listed China, Ethiopia, Italy, Korea, and Poland are reported to produce potash salts, but statistics of production are not available, estimates are included in totals.
(2) Data do not add exactly to totals shown because of rounding where estimated figures are included in the detail.
(3) To avoid duplication of figures, data on crude potash are not included in the total.
(4) Estimate.

poses in the United States, Canada, Cuba, Puerto Rico, and Hawaii were four per cent higher than in 1958 and deliveries for non-agricultural purposes were 24% higher. Total deliveries for all purposes, containing 2,787,367 tons K_2O, were 8% higher. The potash consumption in parts of Asia is extremely low and no doubt will have to be increased greatly in the near future if sufficient food is to be supplied to ever growing populations. For example, in 1950, India consumed 2,205 tons of potash and by 1957 the consumption had increased to 29,106 short tons, which is still a small amount for a country of that size.

Grades and Prices of Potash Marketed

In 1959 in North America muriate of potash (KCl) comprised 94% of the agricultural potash. Sulphate of potash and sulphate of potash-magnesia accounted for the remaining 6% of agricultural deliveries. The potassium chloride, as the 60-63% muriate, is produced in three grain sizes — standard (28— to 150 mesh), coarse (10— to 28— mesh) and granular (8— to 20 mesh) and as manure salts containing 20 to 22% K_2O. The potassium sulphate contains a minimum of 50% K_2O and the potassium-magnesium sulphate (Sul Po-Mag) contains 22% K_2O and 18% MgO. A chemical grade of potassium chloride with less than 1% impurities is also produced and is used as the basic material for the production of other potassium compounds used by the chemical industry.

Prior to the development of the potash industry in the U.S. importers sold potash on the basis of 60% K_2O with adjustments if the K_2O content were more or less. Shipping costs were equalized at the Atlantic and Gulf ports. There were discounts for quantity, which were discontinued prior to 1930, and seasonal discounts for deliveries between July 1 and October 1.

When the U.S. producers went into production this price structure was in existence, but in 1934 the 60% K_2O basis was increased to 62½%. The "20-lb unit" basis replaced the tonnage basis. On this basis the price per ton is calculated by multiplying the percentage of K_2O by the price per unit. At the present time different prices are in effect for different times of the year. This pricing system promotes early contracting, enabling the producers to schedule the output more evenly throughout the year. Since the development of the potash industry in New Mexico potash prices have remained relatively stable.

All the producers in the U.S. issue price schedules annually. Prices are for minimum 40 ton lots, f.o.b. mine per unit K_2O. For example, the following prices were quoted for agricultural potash for the season July, 1958 through June 30, 1959:

For Shipment	*Standard*		*Granular*		*Sulphate of Potash 50% K_2O Min.*
	Muriate-bulk 60% Min. K_2O-per unit	*Bagged 60% Min. per ton*	*Muriate-bulk 60% Min. K_2O-per unit*	*Bagged 60% Min. per ton*	
July, 1958	30c	$22.90	30.5c	$23.20	59.5c
August, 1958	30c	$22.90	30.5c	$23.20	59.5c
September, 1958	31c	$23.50	31.5c	$23.80	59.5c
October, 1958	31c	$23.50	31.5c	$23.80	64.5c
November, 1958	32c	$24.10	32.5c	$24.40	64.5c
December, 1958	32c	$24.10	32.5c	$24.40	64.5c
Jan. thru May incl. 1959	34.5c	$25.60	35.0c	$25.90	67.5c
June, 1959	30c	$22.90	30.5c	$23.20	64.5c

Source: Potash Company of America Limited.

The prices above applied only to tonnage contracted for prior to July 1, 1958. On tonnage contracted after July 1, 1958 the basic price was increased by 2c per unit K_2O on bulk shipments and $1.20 per ton on bagged shipments. The price of mine-run salts, 22% K_2O minimum, per unit of K_2O for shipment in any month regardless of when contracted is 17.65c. All the prices are f.o.b. cars, Carlsbad, New Mexico, or f.o.b. cars P.C.A. Siding, Saskatchewan, with shipment from either point at seller's option. The freight charges were to be equalized if the freight rates from the Canadian shipping point to points in the United States were higher than from the Carlsbad seller.

Recently one U.S. company announced that it will increase prices on all its agricultural grades of potash after July 1, 1960. The prices will be as follows:

For shipment	*Standard Muriate "Higran" (62%-63% K_2O) per unit*	*Coarse Muriate "Hygran" (62%-63% K_2O granular Muriate (60% K_2O) per unit*
July-Aug., 1960	33c	34c
Sept.-Oct., 1960	34c	35c
Nov.-Dec., 1960	35c	36c
Jan.-June, 1960	37½c	38½c

Bag prices for all grades are $5 ton higher.

Markets and Future Outlook

The greatest demand for potash will continue to be for fertilizers and the demand may be expected to increase with the long term growth in agriculture. The potash industry in the United States predicts that the North American capacity will more than double by 1970-71. Thus it can be expected that approximately 4,700,000 tons K_2O will be consumed annually by that time on this continent. Further, The Royal Commission on Canada's Economic Prospects states that "A minimum of eight million and a maximum of ten million tons K_2O must be supplied if Canadians and Americans are to counteract soil losses twenty-five years hence". Thus the predicted minimum requirement for Canada and the United States in 25 years is only slightly less than the total world production of potash for 1958 (8.8 million tons).

The Western Canada potash industry should compete well in the world market with the established potash industries in the United States, Germany, Russia, Israel-Jordan, France, and Spain. Saskatchewan and Manitoba are in a preferred location to supply the American Midwest market because potash from these provinces will be competitive with the New Mexico deposits as far south as Virgina. The United States Midwest is one of the largest concentrated markets for potash in the world. In 1959 six midwest states accounted for the consumption of 797,870 tons K_2O out of a total of 2,165,581 consumed by the whole United States. Potash consumption in each of these states was as follows:

State	*Tons K_2O**
Illinois	227,039
Indiana	180,459
Iowa	66,434
Minnesota	76,200
Ohio	174,516
Wisconsin	73,322
Total	797,870

* American Potash Institute (to nearest ton)

Other states in this area which would become markets for Canadian potash are North Dakota, South Dakota, and parts of Montana. Western Canada can compete with New Mexico for at least 40% of the U.S. potash market.

The expansion of the Canadian potash industry will be dependent on developments in other potash producing countries and potential producing territories, such as Germany, and Utah in the United States, and also on the expansion of the consuming areas which are deficient in potash such as parts of Asia, Africa, Australia and New Zealand. Areas in Asia which particularly will require potash are Japan, India, Pakistan and China. Japan could become a large market for Saskatchewan potash. The major factor determining Saskatchewan's competitive position relative to West Germany in supplying the Asiatic market will be the cost of the rail haul to Vancouver. During 1959 Potash Company of America Limited completed contracts for bulk sales to Japan. The first shipment of Canadian potash to Japan was scheduled for last July. The construction of a bulk loading dock at Vancouver, should improve Saskatchewan potash producers' competitive position in Far East markets. Other potential markets are Australia, New Zealand and other Asiatic countries such as Korea and parts of China. Too much cannot be expected in the European markets because the potash deposits in Germany and Israel-Jordan are well situated to serve these.

Factors Conducive to Increased Potash Consumption

There are a number of factors which will have a pronounced influence on the future of potash production and consumption, not only in Western Canada but in other potash-producing countries. Some of these are listed below:

1. There will be a considerable increase in the populations' total needs. As population growth continues upward, farmers must produce more out of each crop;

2. Movement of farm labour to cities will deplete farm manpower to the extent that greater mechanization must be used and therefore greater quantities of fertilizer;

3. Expanding cities and towns will decrease the number of acres of land under cultivation. As a result there must be more intensive cultivation of the remaining acreage;

4. India and Pakistan, trying to overcome food shortages for their extremely large and ever growing populations, will require large quantities of fertilizer;

5. The communization program in China will probably be responsible for large increases in the amount of farm mechanization, which in turn will require greatly increased amounts of potash;

6. The nationalization of many African territories could call for more intensive agricultural programs involving greater use of potash;

7. Programs which are advocated in the United States and might well be adopted in other countries which will help boost potash consumption are as follows:

(a) Forage crop fertilization: As the population increases more meat is required, which in turn requires more forage crops;

(b) Forest fertilization: As the country's lumber and paper mills and cellulose manufacturers use more and more fibres, forest growth must be accelerated by using fertilizer application;

(c) Non-farm fertilization: With the expansion of the suburban population there will be more emphasis on space in parks and around public buildings requiring heavy landscaping expenditures and as a result an increase in fertilizer consumption can be expected in the future.

Summary

The long term prospects for potash in general are good. Factors such as the fast-growing populations in various countries, particularly those of Asia, and the nationalization of many African territories, combined with rapid growth rates, will call for more extensive agricultural programs, involving greater use of potash to increase food production.

The future of the Western Canadian potash industry is very promising. The immense reserves and high grade of the potash, as well as the favourable location with respect to some of the large markets and potential markets make the Canadian deposits very attractive to potash producers from other countries. Apart from the fact that there will be an increase in potash consumption in many parts of the world in the years ahead, the reserves of a number of the other potash-producing countries are decreasing. The grade of the reserves in some of these countries is becoming lower. For example, in New Mexico the grade in 1947 was 20.7% K_2O and by 1958 is was 18.89% K_2O. Therefore as the reserves decrease and grades become lower potash producers will eventually have to seek new sources from which they can carry on production. Western Canada will be the obvious choice because of the size of the commercial reserves and the grade of potash which is higher than the best both in Europe and the United States. Because of the higher grade of the Canadian ore, production costs should be less than those in New Mexico, particularly. A further inducement making potash mining in Canada attractive is that there is an exemption from taxes the first three years after commencement of production.

IRRIGATION LAND DEVELOPMENT POLICIES FOR SASKATCHEWAN

C. D. Stewart, M.E.I.C.
Head of Agricultural Engineering Department, University of Saskatchewan, Chairman of the South Saskatchewan River Development Commission.

Presented at the E.I.C. Technical Conference, Banff, Oct. 1959.

Although Jacobson[1] under experimental control on the Bow River Irrigation Project at Vauxhall, Alberta was able to produce in excess of 5 tons (Fig. 1) of alfalfa per acre the average yield on the project itself was in the neighborhood of 1.7 tons. Stewart[2] in 1953 therefore planned Farm Use of Water Studies in an attempt to determine the cause of this low production. This project was laid out in such a manner that it was possible to determine approximately the amount of water delivered, moisture holding capacity of the soil at the time of irrigation, runoff, and to a limited degree deep percolation and water distribution on the field. After only two summers it was concluded to obtain accurate results was almost an impossibility as less than 25% of the water diverted was going to plant use and the remainder to runoff or deep percolation. The efficiency of application was therefore less than 25%.

ENGINEERS for decades have used the term efficiency to convey to their associates a measure of performance of men, machines or equipment. It is therefore not surprising to find that Israelsen[3] a pioneer in the irrigation field proposed the term *Water Application Efficiency* and defined it as follows:

$$\text{W.A.E.} = 100\,\frac{\text{Stored Water}}{\text{Delivered Water}}$$

or in algebraic terms

$$E_a = 100\,\frac{W_s}{W_f}$$

where
E_a = water application efficiency
W_s = water stored in soil root zone during irrigation
W_f = water delivered to the farm.

This concept has been widely accepted and is now in general use.

As Irrigation Science has advanced over the decades and more and more emphasis placed on increased production Israelsen's definition has been found quite inadequate. Situations where the water distribution was uneven, or where insufficient irrigation water was applied at any particular irrigation, were not evaluated realistically. This was the situation at Vauxhall, Alberta although the runoff and deep percolation were so large it was difficult to assess the magnitude of poor distribution on the field and throughout the season. Insufficient irrigation water was also common. Considering the former, it was possible and indeed quite a reality on the rougher land to obtain an efficiency of 50% for the average of the field and at the same time to reach 100% in areas of low application. For the latter it was apparent that any amount diverted which is less than the storage capacity of the soil gives 100% efficiency. The less the amount diverted the greater the probability of reaching 100% even though this type of water application would not provide a suitable moisture environment for the crop nor would it be desirable from the standpoint of the efficient use of labour.

The growing scarcity of water in the United States and the desire for irrigation and drainage improvement prompted Hansen[4] to present three new irrigation efficiency concepts, *Water Storage Efficiency, Water Distribution Efficiency* and *Consumptive Use Efficiency*, defined as follows:

Water Storage Efficiency (W.S.E.) —

$$100\,\frac{\text{Stored Water}}{\text{Needed Water}}$$

algebraically $E_s = 100\,\dfrac{W_s}{W_n}$

where
E_s = water storage efficiency
W_s = water stored in root zone during irrigation
W_n = water needed in the root zone prior to irrigation

Water distribution efficiency (W.D.E.)

$$= 100\left(1 - \frac{\text{average deviation}}{\text{average strength applied}}\right)$$

or $E_d = (1 - y/d)$
where
E_d = water distribution
y = average numerical deviation in depth of water stored from average depth of water stored during the irrigation.
d = average depth of water stored during the irrigation

Consumptive use Efficiency (C.U.E.)

$$= 100\,\frac{\text{Consumptively use water}}{\text{depleted water}}$$

or $E_u = 100\,\dfrac{W_u}{W_d}$

where
E_u = consumptive use efficiency
W_u = water used consumptively
W_d = depleted water

Experimental Observations

An irrigation project to be a success not only to those involved in the planning but also to the farmer who is directly associated with the water application must produce substantially higher yields than neighbouring dry land farms. To obtain this high degree of production it is essential that the growing crops receive moisture according to their consumptive use requirements. In the Prairie Region this involves, on the average, three irrigations per year and further requires the supplemental water be applied uniformly throughout the field, neither a shortage nor an excess. In other words, it is essential that not only the water application efficiency should be a high percentage but the water storage efficiency, the water distribution efficiency and the consumptive use efficiency should likewise be of a realistic magnitude.

In addition to these low efficiencies on the Bow River Project irrigation water was applied at the average rate of five acres per day. The farmer who had 160 acres required 30 days to irrigate once and 90 days for the required three irrigations or 120 days for four applications of water. Consequently, not many farmers applied more than a single irrigation. The major reasons for this alarming situation were:

1. Land requiring up to 500 yd. of levelling per acre was under the ditch. The difficulty of attempting to surface irrigate land with no preparation and requiring this amount of levelling would appear to be fairly obvious;

2. Farms have adopted practices for applying water which were outdated. It is rather difficult to interest farmers, for that matter any one, to change their technique when considerable capital investment is required;

3. Farmers had insufficient knowledge about irrigation. In comparison with the knowledge farmers have of livestock, machinery, etc. they knew very little about modern methods of the artificial application of water, infiltration, water storage in the soil, crop requirements, etc;

4. The farm distribution systems were undersigned. This requires greater correlation on the part of the designing engineers and those operating the project. Farmers of the future should look forward to applying three inch irrigations to 30 acres per 8 hour day, with an application efficiency of 75%.

Land Preparation and Crop Returns

Insufficient surface and subsurface drainage, poor land preparation, low water application efficiency, salinity, and net farm income were so complexly related that it was difficult to explain their interrelation without at least two or three graphs. Unfortunately, sufficient scientific data is not available in Western Canada to compile these graphs accurately. The following have, however, been compiled from the available scientific data plus scientific observation from Alberta projects.

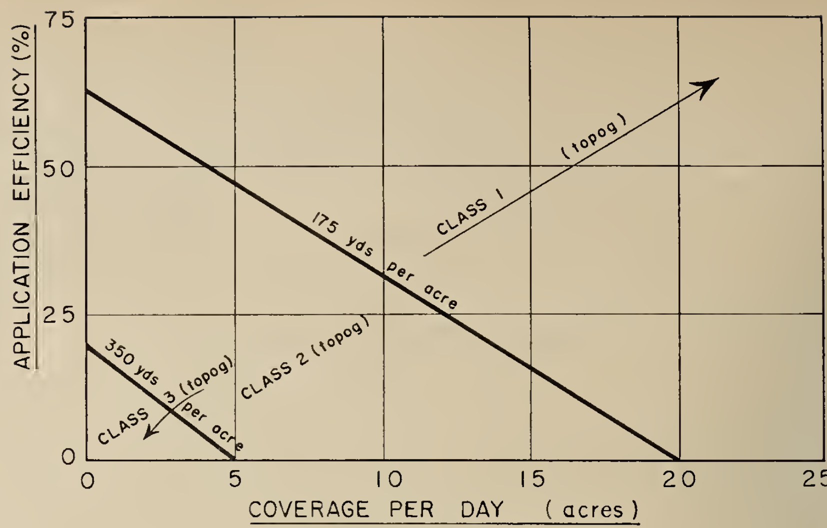

Fig. 2.

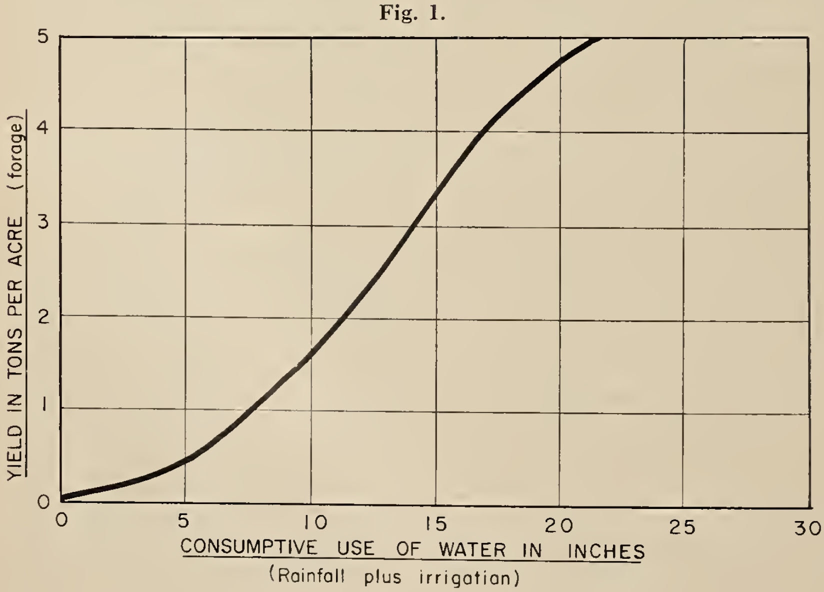
Fig. 2 and Fig. 3 make use of the United States Bureau of Reclamation topographic classification — Class 1 topography up to 175 yd. per acre, Class 2 topography from 175 to 350 yd. per acre, and Class 3 from 350 to 650 yd. per acre.

Fig. 2 is intended to convey the relationship between the three variables application efficiency, coverage per day and topography in a more or less qualitative manner only. It is not possible to say just how accurate this graph is over the ranges indicated but from experience in Alberta these concepts are sufficiently important in dealing with irrigation problems that an attempt should be made to express them.

Fig. 3 is based on the costs of moving earth at 20c per yd. for average cuts. When the yardage per acre increases to the upper limit the costs drop to about 16c per yd.; when the yardage per acre decreases to the lower limit the costs rise considerably above 20c. Levelling in the range of Class 1 seldom requires an additional finishing in succeeding years of use as does Class 2; this accounts for a larger area for Class 2 than Class 1. The additional cost required to handle 30 acres per day in lieu of fifteen at the same efficiency is due to the greater precision required in finish levelling. In other words where an accuracy of cut or fill of two-tenths may be sufficient for a coverage of 15 acres per day less than one-tenth would be required for 30 acres per day. This finish levelling is expensive on a yardage basis.

Fig. 1.



Consider three farms each of 160 acres with three farmers of identical managerial capacity. Farm A requires 350 yd. per acre land levelling, farm B 175 yd. per acre and Farm C 100 yd. per acre. These yardages are considered necessary to bring each farm to optimum preparation.

Farm A — 350 yd. per acre preparation: If four acres are irrigated per day (Fig. 2) the efficiency is approximately 10%. If 10 in. is diverted then 1 in. is stored and 9 in. created a surface and sub-surface drainage problem. At four acres per day it requires 40 days to irrigate, consequently the farm is irrigated only once. From Fig. 1, ten inches of rain *plus one inch irrigation gives a net return of 1.7 tons per acre.

Farm B — 175 yd. per acre preparation: If four acres irrigated per day (Fig. 2) with an efficiency of 50% and 6 in. diverted, then 3 in. is stored and only 3 in. contribute to drainage. With one irrigation (ten inches of rain plus three inches irrigation) a net return of 2.5 tons per acre is possible. With two irrigations and eight acres per day, returns are the same.

* Assuming effective rainfall for consumption use of ten inches.

Farm C — 100 yd. per acre preparation: If ten acres are irrigated per day (Fig. 2) with an efficiency of 50% and 6 in. diverted, 3 in. are stored and 3 in. create a drainage problem. If ten acres are irrigated per day it requires only 16 days to irrigate and no doubt two irrigations will be applied. Ten inches of rainfall plus two 3 in. irrigations (total 16 in.) gives a return of 3½ tons per acre. In general more water is diverted for each irrigation as the topography becomes poorer.

Consider that the three farms are prepared to good standards and the efficiency will approach 75%, also that four irrigations are applied. If each irrigation stores three inches (10 in. rain plus 12 in. irrigation) the returns are better than five tons per acre. The effects of removing surface soil through levelling and not replacing it are of considerable concern at the present time to Soil Scientists. Experience in Alberta on the 20,000 acres levelled would indicate the greatest problem occurs when the lime zone becomes the new surface. These effects however disappear in about three to five years. Many authorities feel levelling is essential even with its adverse effect on structure and fertility due to the improved application efficiency, labour efficiency and the resultant decrease in drainage problems.

There are an unlimited number of these combinations of variables and assumptions which can be considered. The same conclusions would be evident.

1. Efficiency falls off with poor preparation. As the need for heavy levelling and improved surface preparation increases the application efficiency, distribution efficiency, storage efficiency and possibly the consumptive use efficiency fall off;

2. Number of irrigations per year decreases with increased need for preparation. As the need for preparation increases so does the length of time required to apply water until such time as the coverage per day decreases to 2 or 3 acres. If the farmer has a reasonable number of so called irrigable acres it eventually becomes a physical impossibility to cover the area more than once if he is to give any attention to other farm operations;

3. Surface and sub-surface drainage problems are aggrevated by poor land preparation. As the efficiency decreases the surplus water is removed either by surface or sub-surface methods. Surface water is perhaps the least serious as the main consideration is waste of water. Sub-surface drainage however, is much more of a problem as the cost of sub-surface drainage varies almost directly with the amount of water to be removed. If the contribution of sub-surface water is extreme it becomes physically impossible to supply sufficient artificial sub-surface drainage;

4. Low returns on land which is difficult to irrigate. It is rather difficult to assess all the factors causing low returns such as physical, chemical, managerial, etc. but it would appear that in general the high areas suffer an extreme lack of irrigation water, the low areas an extreme excess and the fairly uniform areas a deficiency of water mainly from an insufficient number of irrigations;

5. Unless some adjustment is made in price of land, or water rate, then the farmer on Farm C has a decided advantage. Farm C would provide the optimum gross returns with $50 per acre land preparations whereas Farm B would require $100 per acre and Farm A $150 per acre.

Recommendations and Development Policies

It would appear that the following recommendation would alleviate on the South Saskatchewan Project most of the above difficulties which are common to irrigation projects in Western Canada.

1. Establish a South Saskatchewan River Irrigation Board, which would be responsible for the correlation of the dam construction, land classification, land acquisition and allocation, distribution system, land development policy, extension, and administration until approximately ten years after the project is in operation;

2. Irrigate only land that can be developed for a maximum of $100 per acre (this would give an average cost of approximately $75 per acre). If the cost of land preparation decreased due to new types of earth moving equipment now on the market it would be expected that larger yardages per acre could be handled;

3. As far as possible have each farmer gain experience in irrigation before he has water delivered to his farm;

4. Develop forty acres per farm unit before the farmer has his first water delivery. Not only will he develop good irrigation practices but it will encourage him rather than discourage him as is so often the case when his land is not prepared;

5. A complete surface drainage system which will permit an outlet to each farm unit to be installed at the time of construction of the distribution system;

6. Provide outlets for farm tile drains, which will be required in a portion of the project area after it is in operation;

7. Establish a charge for a water right in accordance with the class of topography. ($30 per acre — Class 1, $20 per acre — Class 2, $10 per acre — Class 3).

Discussion

THE POTENTIAL IN THE FREE PISTON ENGINE PRINCIPLE.

A. Braun, *Vice President,*
Free Piston Development Company, Ltd., Kingston, Ont.
The Engineering Journal, July, 1960, p. 57.

Discussion by James D. Fleming.

In the past five years, many papers have been written about free piston gasifiers. In most of these papers, the advantages of the gasifiers have been oversold. The disadvantages or the difficulties generally go unmentioned. As a result, gasifier performance does not come up to the expectations and the performance of several installations has been disappointing.

In Mr. Braun's paper, the calculated efficiency based on the air standard cycle far exceeds the actual gasifier efficiency. The compressor and turbine efficiencies are completely ignored. The cycle shown in Fig. 3 cannot be used alone. The so-called "by-pass gas" is also part of the working mass and in fact represents a major portion of the energy available. Flow losses, compressor efficiency, and turbine efficiency must be considered for this gas.

The gasifiers now in use run with a volumetric compression ratio of 30 and under. A common error is to multiply the compressor pressure-ratio by the volumetric compression ratio of the diesel section and call this the overall volumetric compression ratio. The relationship is shown below:

$p_r = (cr)^n$
$p_r = 4.5$ (pressure-ratio for the compressor)
$n = 1.38$ (for the compressor)
$cr = 2.98$ (compression ratio for compressor)

Thus when the pressure-ratio for the compressor is 4.5, the compression ratio is 2.98. The compression ratio in the diesel section of commercial gasifiers ranges from a minimum of 6 to a maximum of 10 at full load. The overall compression ratio would then be 29.8 at full load and not 45. The approximate compression pressures for various compression ratios are shown below:

Compression Ratio	Compression Pressure
40	2000 psi
60	3400
80	5000

Compression ratios of 60 and 80, as shown in the paper, are unreasonable. The maximum pressures and temperatures after combustion would be extremely high. The maximum combustion pressures in the GM-14 range from 1500 to 2000 p.s.i.

Mr. Braun has pointed out that the gasifiers will burn a wide range of fuel; however, for efficient operation, the injection system must be tailored for the fuel. Many difficulties have been experienced in using Bunker "C" fuel and the gasifiers will not necessarily run satisfactorily on any fuel that can be injected. Additional equipment such as fuel heaters and centrifuges are required. When heavy fuel is used, wear rates increase.

The "simplicity" of the machine actually complicates its use. There are no rotating parts from which to drive cooling oil pumps, cooling water pumps, fuel transfer pumps, and air compressors. The auxiliary equipment required for a gasifier can be one of the major factors in determining the minimum feasible size for the machine. The turbine cost is also a major factor in determining minimum economical size for a gasifier.

Multiple gasifier installations appear to offer many advantages, especially in flexibility. However, problems of control, line losses, line pulsations, intake pulsations and engine room noise occur. If complete flexibility is to be obtained then each engine room installation which differs from the original poses a new engineering problem.

The gasifiers do have advantages as well as disadvantages and the machines certainly have their place in the power field. The selection of an engine for any application requires a careful analysis of the job requirements and of the operating characteristics of the engines available.

GEOLOGICAL FEATURES AND FOUNDATION TREATMENT AT THE BEECHWOOD DEVELOPMENT

I. D. MacKenzie, M.E.I.C., *Geologist*
E. L. Brown, M.E.I.C., *Field Engineer,*
The Shawinigan Engineering Company Limited, Montreal, Que.
The Engineering Journal, 1959, December, p. 54.

Further discussion: by M. A. J. Matich, M.E.I.C.

The authors are to be commended on a fine paper which is particularly interesting from a foundation engineer's point of view since it describes the course of the work in its entirety, from the geological study of the area and initial exploratory drilling to the completion of the grouting, with even comments on the actual performance of the foundations after treatment.

The data so presented are a useful addition to available information on rock consolidation by cement grouting and it is interesting to compare the results obtained and methods used with the experience of others, including several examples from the records of the firm with which I am associated and which carried out the grouting work in this case. Perhaps a few comments along these lines would be in order.

The information on the pressures used for grouting is of value because it represents a safe departure on the high side from the rule of thumb that the pressure at any elevation should be equal to 1 p.s.i. per ft. of depth. A comparison of the criteria used for the project with published guides for grouting pressure, as apparently employed by the U.S. Corps of Engineers for example, shows that the pressures that actually could be adopted were considerably higher at depths of up to 30 feet than those given in the guides, especially in the stage grouting case. It is recognized of course that the rules of thumb are probably conservative since they do not take into account the physical conditions of the foundation rock and a number of other significant factors such as consistency of the grout and degree of tightness of the hole. Our experience elsewhere in a limited number of cases confirms that pressures considerably in excess of those derived by

Automation and Control Engineering in Canada

Gas Sampling in the Steel Industry

E. T. W. Bailey

Chief Fuel Research Engineer
The Steel Company of Canada, Limited, Hamilton

Presented at the ISA Symposium on Instrumental Methods of Analysis, Montreal, June 1960.

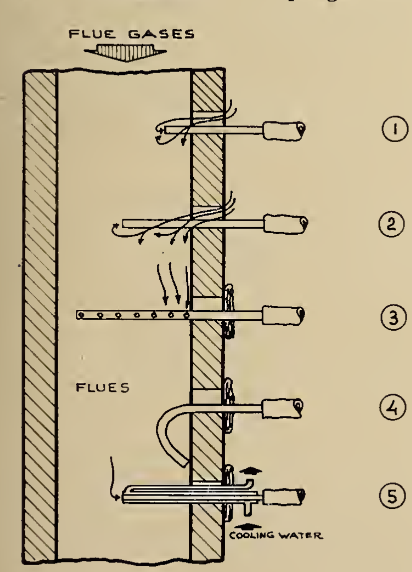
THE principal reasons for gas sampling in the steel industry are the safety of personnel involving the detection of explosive or toxic gases and vapours; the determination of combustion efficiency, air infiltration, dust loading and complete chemical analyses of gaseous mixtures.

Sampling for Safety Tests

In the steel industry the dangerous gases are limited mainly to carbon monoxide. This gas can be present in the fuel or be formed wherever there is incomplete combustion of carbon.

Gases containing carbon monoxide are used in the steel plant for heating purposes. Therefore, it is piped to all sections of the plant, creating plenty of opportunities for contamination of the air in various departments.

Fig. 1. Arrangement of Sampling Tubes.



The following percentage of carbon monoxide is found in the listed fuels:

	Percentage CO
Blast furnace gas	27.7
Bessemer gas	25.0
Open Hearth tap hole	27.0
Cupola gas	17.0
Coke Oven gas	5.9
Mixed Coke Oven and blast furnace gas	8.1
Exhaust from automobile	7.0

Since it is a fact that breathing only four parts of carbon monoxide in 10,000 parts of air can cause collapse in less than two hours and death in three to four hours, the great care that has to be taken can at once be appreciated.

When it comes to sampling, no matter for what purpose, there are truths that must be fully appreciated by those directing the tests. The persons making the tests must have extensive training and experience in order to safely apply the best means to secure a truly representative sample. Any instrument analyser, whether it costs $30 or $3000, is incapable of producing accurate results unless it receives an uncontaminated representative sample.

Before anyone rushes in to secure a sample of atmosphere in any area every care must be exercised that the sampler does not get trapped. Unless he is very familiar with the aspects of the job area where only a gradual build up is possible he should first equip himself with a respirator.

Sampling with such devices as the MSA or Drager carbon monoxide detector tubes can be dangerous. We would very much like to see the manufacturers of this equipment design so samples could be secured from enclosures through a suitable length of tubing without requiring the operator to enter them.

Other precautions must also be taken. For example, a few years ago a steelworker went into a manhole tunnel to open a gas valve. After he failed to appear his partner rushed to get a gas detector. When the detector showed negative results he entered the tunnel. After some time the foreman went to see what caused the delay. He noted the gas detector at the manhole. He cautiously entered holding his breath. His flashlight showed the two men on the floor. He climbed out and sent for a respirator. Both men were dead before they could be removed. It seems the gas main had been purged with nitrogen gas which had escaped into the tunnel when blown out of the pipe. Here is a case where a knowledge of what was going on would have indicated that oxygen content should be tested as well as other toxic gases.

Frequently gas testers have to enter looping pits. These are holes in the ground 80 ft. deep and are used to provide a means of supplying continuous annealing and galvanizing lines with material while one end is stopped to weld on the next coil. Permanent sampling piping is being installed as it is quite a feat to work in them hampered by respirator equipment.

Construction areas frequently require tests to determine carbon monoxide accumulations from trucks, engine driven compressors, heating furnaces and salamanders. Many electrical manholes, pipes, tanks and like enclosures require testing, not only for personnel toxic safety but also for infammable gases and vapours. Any work requiring use of cutting or welding torches on such equipment must be preceded by safety tests. The MSA Explosimeter is the favourite instrument for such tests. It is equipped with means for securing a sample at a safe distance.

Sampling for Combustion Efficiency

In all test sampling of hot gases whether for combustion or air infiltration determinations, it is very necessary to select suitable sampling tube materials.

Steel tubes are not satisfactory when temperature of the gas is above 400 D.F. An Inconel tube is satisfactory for all temperatures below 1000 D.F. For temperatures between 1000 and 2400 D.F. porcelain or fused quartz tubes are used. Above 2400 D.F. one must resort to water cooled probes.

For continuous sampling of hot dusty gases, such as leave an open hearth furnace, special systems have to be used. One of these, designed by the Bailey Meter Company is fully described in their bulletin E65-6.

In all testing pains must be taken to secure a representative sample. This means, that in many cases, considerable study has to be given to the flow pattern of the gases in their enclosure. It is necessary to have the end of the probe in the centre of a fast moving core of gas. Eddies, back flows and openings which could influence the composition of the gaseous mixture must be avoided.

Where a furnace or waste gas flue system is under a slight pressure with respect to atmosphere, selection of a suitable sampling point is greatly simplified.

Quite often sampling points have to be chosen in zones where the pressure is lower than the atmosphere. Great care must be taken in selecting the position and arranging the insertion of the sampling tube. Referring to Fig. 1; arrangement (1) indicates air being infiltrated through the sampling hole and a portion entering the tube. The tube is not only too short but care hasn't been taken to seal the sampling hole with clay. Arrangement (2) indicates a longer tube but the high velocity of the flue gases in a downward direction creates a zone of low pressure on the underside of the tube. Air entering the sampling hole flows along the reduced pressure zone and can enter the end of the tube. Arrangement (3) shows a sampling tube having an arrangement of several sampling holes along its length. It was expected that in this way a representative average sample could be secured. It is a means frequently used to sample waste gas from boilers. Unless it is used with a very powerful aspirator it is useless for such purpose. When used with a hand bulb or a low capacity suction device the greater portion of the sample enters through the hole nearest the exhausting end of the tube. Illustration (4) shows what happens if the sampling tube cannot retain its rigidity due to high temperatures. Tests taken through a tube in this condition can show 100% air. It is a fact that there is a layer of air along the inside of many refractory furnace and duct walls. The arrangement (5) illustrates a water cooled probe. It points out the need to make all joints very tight and avoid pockets which can collect condensed vapours. Drip legs should be provided.

There are other precautions one must take, some of which are almost too obvious to mention. The furnace must be operating in a normal manner. Doors should be all closed and fuel input rates held at the desired point. In cases where gases are being given off from the materials being heated combustion tests should be deferred or special means taken to evaluate. Examples are open hearth furnace and lime kiln.

In general probes should be slanted to place the opening upstream from the sampling hole. This helps reduce the possibility of air being drawn into the entrance.

When measuring the amount of air infiltering into a furnace exhaust duct system, the same precautions mentioned above have to be observed. As most tests require simultaneous sampling uniform procedure is essential. An example of this in the steel industry is in determining the air leakage through all the cleaning and inspection openings at a waste heat boiler.

The chief instruments used to analyse combustion products encountered in a steel plant are the "Heat Prover" and "Fyrite". The orsat has all but disappeared for on-location analysing. Samples of gas prior to entering the Heat Prover are passed through silica jell for drying and horse hair filter to remove dust.

Most furnaces have permanent sampling stations built in at locations chosen from previous studies. Gas flow channels are plotted and confirmed from brick wear patterns. Each year thousands of routine samples are taken for setting combustion efficiency and locating sources of air infiltration. Crews are constantly sealing openings in refractories. Close attention to these items can lead to substantial money savings by reducing fuel and increasing production. Sampling must obviously be consistantly accurate. To insure tight sampling connections frequent tests are made using the familiar under water bubble method.

Sampling for Dust Loading

Some operations in a primary steel plant produce gases containing varying amounts of metallurgical dust. From time to time it is necessary to determine the concentration in a gas stream as well as the physical, chemical and electrical properties of the dust.

Before test locations can be selected certain factors must be carefully reviewed.

Sampling points should be located in a straight duct section with no obstructions in the gas stream for at least the equivalent of eight duct diameters preceding them. Compressed air, water and electrical facilities must be within easy reach. All necessary safety precautions must be taken for sampling personnel.

A testing plan would include the determination of the number of sampling points required to effectively traverse the cross section of the duct. These would vary with the dimensions of the duct, the nature of the gas flow and the distribution of the dust in the duct.

The next step is to determine the velocity pattern of the gas stream at each selected sampling point. This is done using a standard pitot tube. A velocity profile is next prepared for the cross section of the duct. If the flow is variable, as often happens, a velocity profile is prepared for different flows.

The standard method of determining the dust concentration in a gas stream is the probe and filter method. A metered volume of gas is drawn through a filter and the amount of dust deposited on the filter is determined. Dust concentrations are then computed and expressed in unit weight per unit weight of gas.

In sampling the gas an iso-kinetic sampling rate must be maintained. (The velocity through the sampling nozzle must be equal to the prevailing velocity in the gas stream being sampled). If the sampling nozzle velocity is lower than in the duct, collected dust weights will be higher than would have resulted from an iso-kinetic rate. This would produce results indicating higher dust loadings than actually existed. The opposite result is obtained if high nozzle velocities exist. Traverse sampling is necessary when the dust is unevenly distributed throughout the gas stream.

The most common means used to insure iso-kinetic sampling rates is the balanced tube method. This uses the principle that if the velocity through the sampling nozzle is equal to the velocity in the duct the static pressures in both will be equal. Thus if the static pressures in the nozzle and duct are maintained equal iso-kinetic sampling rate will be maintained.

Other precautions that must be observed during sampling are:

1. Carefully check all connections for leaks;
2. Clean probe before and after each test;
3. Allow probe to warm up before commencing to withdraw sample. This is to prevent dust from sticking to condensate on the inside of a cold tube. Point nozzle down stream;
4. Make very sure nozzle is pointing directly into the stream during sampling;
5. Keep the filter above the dew point temperature of the gas. In some cases it may be necessary to electrically heat the filter holder.

Sampling for Temperature Measurements

While the vast majority of temperature measurements are satisfactorily met by the insertion of a thermocouple or radiation station, it is frequently necessary to know the temperature of the gases themselves without having the sensing device influenced by cold and or hot refractories or product being heated.

To accomplish this a special probe is used called a multiple shield high velocity thermocouple. A powerful aspirator is used to withdraw a generous volume of gas from the furnace or flue. This passes over the shielded couple and gives an accurate temperature sensing arrangement. In general, the same rules and precautions used in analyses sampling must be followed for best results.

Sampling for Complete Chemical Analysis

Under this general heading one could list almost every gas encountered in a steel plant. Normally most sampling deals with on-the-spot analyses of one or more gas constituents. Occasionally a complete analysis is required including dew point determinations. These have to be carried out in the laboratory. Examples are fuel and prepared atmosphere gases used for heat treating operations.

For collecting accumulative samples a mercury displacement type of container is recommended. Water is the most convenient medium for displacement sampling, but due to the solubility of carbon dioxide, it should be saturated with gas before use. A salt solution can frequently be used to advantage.

Sample containers — usually glass with seal cocks at each end — can be filled by air or gas displacement. This is essentially a process of sweeping out the original gas content by allowing the sample to stream through the container a sufficient length of time. This is easily done when the gas is under a pressure. A good sample is usually obtained when at least 20 times the sample container volume has passed through.

Once again, all the rules and precautions used in sampling must be followed with special emphasis for gases under less than atmospheric pressure.

Canadian Developments

Kelsey Generating Station Goes On Stream

The Manitoba Hydro-Electric Board's Kelsey Generating Station, the first on the Nelson River, began delivery of power to The International Nickel Company of Canada Limited at Thompson, Manitoba on June 22, 1960. It was a victorious day for engineers and contractors who less than five months before had seen fire levy damages of more than $1 million on this same powerhouse.

Quite a number of steel members have had to be replaced or straightened. The walls and roof are in process of being completely replaced and more than 1000 cu. yds. of concrete have been removed and replaced in the scroll case roof of Unit No. 5.

Work on the Kelsey Generating Station site began in June, 1957 and by the end of June this year two of the five 42,000 H.P. units had been installed. Provision has been made for the addition of a sixth unit.

Convey Speaks on Methods of Reducing Iron Ores

Canada's future will depend to a considerable extent on her iron industry, according to a paper presented by John Convey, Director of the Mines Branch of the Canada Department of Mines and Technical Surveys, Ottawa. Dr. Convey made this remark in a paper delivered at the Conference on "Methods of Reducing Iron Ores" held in Chicago, May 3-5, 1960. Over 50 Canadians were in attendance.

By 1957, he pointed out, Canada's annual iron ore production had increased to ten times the 1949 volume. Since by 1965 it is expected to be in the order of 55,000,000 tons per year, iron ore processing methods are of considerable interest. The blast furnace method of producing iron, Dr. Convey predicts, will continue to be used for the greater part of the iron production in large centres of population and industry. However, in various other parts of the country where the ore is available electric smelting and direct reduction plants will be put into operation.

It is to be noted that although Canada's stores of iron ore are of generous proportions, many parts of Canada are a long distance from any important body of the ore. Likewise, although her coal reserves are more than adequate, much of them lies a long distance from the deposits of iron ore. The opening of the seaway, construction of long-distance pipelines, and the Government's policy of building roads and railways to resources are helping to bridge these gaps.

Athlone Fellowship Recipients Named

Forty Canadian engineers have been awarded Athlone Fellowships by the British Government to study, research, or work in industry in the U.K. during the period 1960-62. They are:

J. A. Abbott, Montreal; E. M. Aziz, London, Ont; H. D. Barber, Saskaoon; P. R. Barnard, Oakville, Ont; T. W. Bremner, Ottawa; D. W. Brown, Victoria; H. F. Button, Regina; S. H. Chisholm, Dorval, Que.; F. A. Christie, Halifax; F. E. Collins, Toronto; T. A. Croil, Edmonton; J. G. Descary, Lachine, Que.; D. Dueck, Toronto; R. M. Duncan, Transcona, Man.; C. Ferland, Drummondville, Que.; R. F. Frindt, Edmonton; T. Garrett, Vancouver; P. M. Gratton, Shefford, Que.; M. Guay, Quebec City; L. P. Haberman, Winnipeg; W. Hanuschak, Transcona, Man.; C. R. Huntley, Vancouver; R. V. L'Archeveque, Montreal; G. M. Lindberg, Edmonton; S. M. Lyle, St. Lambert, Que.; F. W. Maine, Kingston, Ont.; A. A. Marsan, Montreal; J. A. Nilson, Saskatoon; R. B. L. Ross, Toronto; J. P. Y. Rouette, Montreal; R. P. D. Round, Victoria; D. J. Skinner, Halifax; W. D. Smythe, Ottawa; R. J. Taborek, Toronto; A. S. Taylor, Lachute, Que.; G. W. Toop, Vancouver; W. R. Tucker, Montreal; M. A. Ward, Toronto; W. E. Watt, Sudbury, Ont.; C. M. Woodside, Toronto.

Official Opening of the K.W. Neatby Building

A new building dedicated to the memory of the late Dr. Kenneth William

Kelsey Generating Station: (left) view of upstream side of powerhouse during fire, January 30, 1960. (Right) downstream side, showing cofferdam removal and dykes, rockfill dam and sluiceway, June 15, 1960.

Neatby was opened at the Central Experimental Farm, Carling Avenue, Ottawa on June 16, 1960. A commemorative plaque in memory of Dr. Neatby was also unveiled.

Among the distinguished guests at this ceremony was the Minister of Agriculture for Canada, The Honourable Douglas L. Harkness.

Study of Drifting Sand in Lake Ontario Harbours

A group of scientists at Queen's University, Kingston are constructing a model of Cobourg Harbour to scale as part of a more extensive study of drifting sand in Lake Ontario harbours. They have secured a large stone building formerly used as an RCNVR barracks to house their project and have already completed a concrete basin, 51′ x 50′ and 1′ deep. The model harbour, complete with breakwater and other works, will be erected along one side of the basin. On the other side a movable wave-making machine capable of producing waves of different heights and intensities will be constructed. Artificial storms will pound the Cobourg Harbour works from various angles, and the effects of the waves on the sand floor of the harbour will be recorded by various instruments. The principle purpose of the model is to determine what causes navigation channels to become clogged with sand and silt, and what engineers can do about it.

The project is sponsored by the Associate Committee on Waves and Littoral Drift of the National Research Council, Ottawa, in the hope that future harbour works can be designed to decrease or eliminate movement of silt and sand into harbour channels. The work is directed by Professor R. J. Kennedy, Queen's civil engineering professor, and Dr. Arthur Brebner and Dr. B. LeMehaute have charge of particular sections of the program.

Encouragement of Sewage Treatment Plant Installations

The Southern Canada Power Company has recently extended its offer to all municipalities in the service area to pay for the electricity used in the first five years' operation of a sewage treatment plant. In view of the increasing seriousness of the water pollution menace, the company has agreed to supply and pay for the electricity for lighting and the motive force needed to operate a sewage treatment plant for these first five years. The offer is effective until April 1, 1962.

Canadian Institute of Surveying and the International Photogrammetric Congress

The International Society for Photogrammetry is holding its IXth quadrennial congress in September 1960 at London, England, where the latest achievements in aerial surveying and photogrammetric applications in various engineering fields will be discussed. The Canadian Institute of Surveying, one of the most active members of this international photogrammetric association, will be represented at the Congress. Canadian delegates will chair several discussions on the results of international experiments directed from Canada and on important instrumental and theoretical developments. Some recent Canadian achievements are most spectacular and in the opinion of experts will have a great influence on the future development of aerial surveying and mapping methods.

The Canadian Institute of Surveying will be represented by scientists and engineers engaged in photogrammetric work with federal and provincial departments, research agencies, universities, and with commercial photogrammetric companies. An interesting exhibit illustrating the vast application of modern electronic means in Canadian surveying and mapping will be displayed at the Congress. The Canadian Institute of Surveying has also published a special Congress issue of its official journal, The Canadian Surveyor, which describes photogrammetric activities in Canada during the past four years. The contents of this issue will be included in the Archives, the official publication of the International Society for Photogrammetry.

International News

U.S. Breakthrough in Conversion of Nuclear Fission Heat

Scientists at the Westinghouse Testing Reactor, Waltz Mill, Pennsylvania have succeeded in uniting two advanced forms of power generation to convert the heat of fission inside a nuclear reactor directly into electricity. This combination of thermionic and thermoelectric generators in one fuel assembly for insertion in the reactor represents a major step toward using untapped energy inside a reactor.

John W. Simpson, Vice-President and General Manager of the Westinghouse Atomic Power Division, asserts that development work may produce high temperature thermionic-thermoelectric generators for satellite power supplies or other situations where modest amounts of power must be got from light, small equipment. He also suggests that nuclear powered generating stations may in future have three operational stages — thermionic elements to convert the high temperatures in a reactor into electricity, thermoelectric elements to utilize the more moderate temperatures and conventional generating equipment for lower temperatures.

Expansion of Electric Power in Peru and Honduras

On June 29th the World Bank made loans of $24 million and $8.8 million to Peru and Honduras respectively for the development of their electric power supplies. Power in Lima, the administrative, commercial and industrial capital of Peru, will be increased by 70%. Honduras will have its first centralized power system when the 27,000 kw. hydroelectric power plant, provided for by the loan, is completed.

Two separate projects are anticipated in the Lima area. Waters from lakes and rivers on the eastern slopes of the Andes are to be diverted to the Sarnia Eulalia River Basin in the west and a 120,000 kw. power plant will be built at Huinco on the Santa Eulalia.

The power potential of Lake Yojoa and Rio Lindo in Honduras will be developed by construction of dikes, a three-mile canal, an intake structure and penstocks to bring water from the lake to a powerhouse which will be built near the village of Canaveral. The new station is to be installed with two 13,500 kw. generating units and provision for a third. Approximately 175 miles of transmission lines will be built to connect the plant with towns of the northwest.

Sweden Supplies Pulp and Paper Mill Machinery

Rayon silk manufacturers in India have ordered machinery from Sweden for a new mill they are building which will produce 150 tons of bleached pulp per 24 hours. It will be the first rayon pulp mill in the world to use bamboo as raw material. A chip preparation plant is among the units being supplied by Sweden, as well as a cooking plant with compound digestors and a soda recovery boiler.

In Africa a new sulphate mill, based on eucalyptus, with a soda recovery plant is being equipped by Swedish firms. A powerhouse, turbine, two wood-fired steam boilers and a friction debarking plant are on order.

Machinery is also being purchased by Argentina for a rayon sulphite mill, with eucalyptus as raw material, in one area and complete paper factory in another.

UK Industrial Research and Development

The United Kingdom Department of Scientific and Industrial Research has published a report on expenditure by British industry in 1958. It indicates that the U.K. manufacturing industry spent approximately $900 million on research in 1958 compared to some $570 million in 1955. Whereas in 1955 about two-thirds of the research and development expenditure in the manufacturing industry's own establishments was from defence contracts, less than half the expenditure in 1958 was military. Expenditure on non-military research doubled between these years.

Aircraft had the biggest research budget (about $300 million), while electrical engineering spent $192 million and chemicals, $129 million.

(Continued on page 89)

New **Portable Gas Station:** During a recent special demonstration nine F-100 Super Sabres, under test by the Tactical Air Command of the U.S. Air Force, were landed, refueled and ready for flight in less than 30 minutes. The 50,000 gal. station, developed by the Goodyear Tire and Rubber Company and Bowser, Inc., can fuel all types of jet aircraft at a rate of 150-600 gal. per min., servicing as many as six aircraft simultaneously.

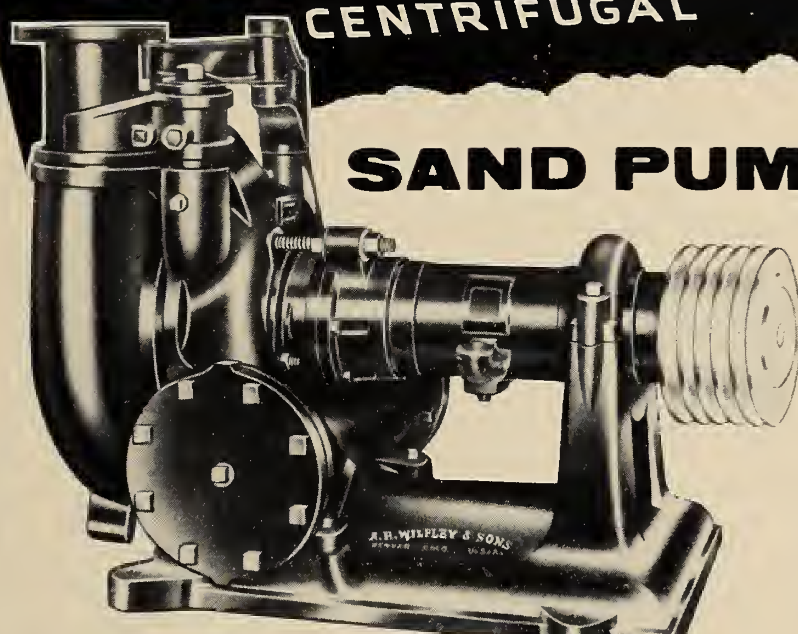
FOR SAND, SLUDGE, SLURRIES, SLIME & ABRASIVES

THE NEW MODEL "K"

WILFLEY

CENTRIFUGAL

SAND PUMPS



For dependable, low cost, trouble free operation and easy maintenance

We manufacture the new high efficiency Wilfley Model K sand pumps in 9 sizes. Capacities range from 20 to 2300 G.P.M., depending on the intake head and density of pulp. **Write for information.**

Improved features of the new Model K include: The remarkable new Wilfley seal — eliminates stuffing box troubles, making the pump especially adaptable to handling gritty pulps, slurries, sludges, hot solutions and eliminates air traps in the runner. Solution slippage is reduced between the runner and follower plate because minimum clearance can be maintained by simple adjustment thereby eliminating over speeding. The four wear parts — case, runner, die ring and follower plate can be changed in minutes without disturbing intake or discharge pipe, saving valuable time. Rubber covered, Ni-Hard and special acid resisting alloy wear parts can be furnished when required.

Month to Month

Employment and Earnings, 1959

The Economics and Research Branch of the Department of Labour has compiled comprehensive statistics and analyses of Canada's manpower resources in the scientific and technical professions during 1959. Results of their survey show that median earnings were $7,900. Twenty-five percent of those surveyed were earning less than $6,400 and 25% were earning more than $10,100. The median was highest for architects, followed by engineers, among the five major professions tabulated on the basis of academic specialization.

TABLE I

Quartile and Median Earnings, 1959

Scientific and Technical Professions

*Specialization**	*First Quartile*	*Median*	*Third Quartile*
	$	$	$
Agriculture	5,400	6,450	7,750
Architecture	6,300	8,750	13,950
Engineering	6,800	8,300	10,550
Natural Science	6,150	7,600	9,500
Veterinary Science	6,200	7,350	8,800
TOTAL	6,400	7,900	10,100

*The academic specializations shown in this report are based on undergraduate courses. Forestry and mathematics are included under the heading "natural science" for the purposes of this report.

Regionally, earnings for those employed in Canada were highest in Ontario and Quebec. Canadian citizens working in other countries were also included in this survey, but the respondents from the U.S. were an older group than those in Canada and this is reflected in the higher median earnings for the U.S.

TABLE II

Median Earnings by Specialization and Place of Employment, 1959*

Scientific and Technical Professions

	Place of Employment						
Specialization	*Canada*	*Atlantic*	*Quebec*	*Ontario*	*Prairies*	*B.C.*	*U.S.*
	$	$	$	$	$	$	$
Agriculture	6,450	5,700	5,850	6,900	6,500	6,200	—
Architecture	8,850	—	9,150	9,200	8,350	8,050	—
Engineering	8,250	7,400	8,500	8,300	7,900	8,250	9,600
Natural Science	7,450	6,550	7,600	8,000	7,300	6,950	9,300
Veterinary Science	7,350	—	6,500	7,550	7,750	—	—
TOTAL	7,850	6,900	7,900	8,050	7,450	7,650	—

*Dashes are shown where there were insufficient data to compute medians.

Luncheon for Norman G. Allen

Mr. H. Norman G. Allen, Vice-President of the Institution of Mechanical Engineers of Great Britain, was guest of honour at a luncheon given by The Institute at the Engineers Club, Montreal, on June 17, before returning to London. Mr. Allen was in Canada to attend the E.I.C. Annual General Meeting.

The luncheon was presided over by the President, George McKinstry Dick, M.E.I.C., who took the opportunity, on behalf of the Institute and the assembled group, to thank Mr. Allen for his kindness in coming to Canada at this time. The guests included: Hugh G. Conn, M.E.I.C.; A. Robert Edis, M.E.I.C.; W. P. Ferguson, M.E.I.C.; Henri Gaudefroy, M.E.I.C.; William Milne, M.E.I.C.; D. Gray-Donald, M.E.I.C.; S. Howe; J. R. Y. Johnston; E. B. Jubien, M.E.I.C.; T. R. McLagen, M.E.I.C.; Donald L. Mordell, M.E.I.C.; W. J. Paton; P. W. Gooch, M.E.I.C.; Harold Hurdle, M.E.I.C.; H. Ulman, M.E.I.C.; J. A. Watson; D. L. Spanjer, M.E.I.C. Garnet T. Page and George M. Dick were hosts.

CTF Mathematics Seminar

The professions which make day-to-day use of mathematics could contribute significantly to better curriculum planning for the schools. This was the sentiment brought forth in the early-summer CTF Seminar on "New Thinking in School Mathematics", held at the Chateau Laurier, Ottawa.

An informal survey made by the CTF in advance of the seminar indicated that in many parts of Canada highly trained mathematics teachers are not available. It also showed that the requirements for mathematics teaching are not generally high. Neither is the student of high mathematical ability provided for by present school curricula. The seminar made clear that where curriculum planning was possible on a provincial level, with representation from the department of education, teachers, university faculty, educational psychologists and professionals using mathematics, the results were good.

Professor J. E. Ruptash, Director of Engineering School, Carleton University, Ottawa, represented the Institute at the seminar.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on May 24, 1960.

Member: E. P. Boddaert, Montreal; D. B. Chamney, Calgary; F. S. Clark, Toronto; N. Devich, Iroquois Falls; J. J. Fedy, Kitchener; J. A. G. Hunter, Montreal; J. E. Hutton, Calgary; B. H. Lloyd, Montreal; J. R. McEachern, Sarnia; J. H. McGuire, Ottawa; M. J. Salm, Edmonton; J. L. Seychuk, Toronto; J. L. Simard, Montreal; W. P. Steele, Vancouver; E. J. Wiggans, Arvida.

Junior: P. F. Bacave, Montreal; A. C. Kanen, Welland; F. J. Mayer, Hamilton; D. V. Sedlak, Montreal; C. Soydemir, Boston, Mass.

Junior to Member: D. L. Aker, Arvida; G. T. Alexander, Montreal; A. J. Arcand, Camp Valcartier; A. F. Avant, Toronto; S. J. Babin, N. Weymouth, Mass.; A. H. Baker, North Bay; W. K. Baldwin, Sherbrooke; W. R. Ball, Toronto; R. G. Barbour, Granby; E. A. Beaumont, Prince George; A. P. V. Bennett, Montreal; J. M. Bentham, Montreal; J. M. Bird, Vancouver; R. A. Blount, Montreal; M. G. Bolstad, Caledonia; J. D. Booth, Montreal; D. T. Bourke, Montreal; K. B. Bourne, Brownsburg; P. R. Brais, Arvida; N. B. Breen, Kingston; T. E. Buck, Don Mills; R. F. Cairns, Toronto; D. S. Cameron, Montreal; E. G. Capling, Calgary; J. E. Cash, St. Catharines; S. Cherry, Vancouver; W. I. W. E. Christmas, Montreal; J. L. Clark, San Francisco; L. W. Clark, Ottawa; R. H. Clawson, Halifax; J. Corey, Montreal; J. P. R. Cristel, Montreal; G. V. D. Crombie, Toronto; G. H. Curtis, Toronto; C. V. Davies, Walkerville; R. I. Davis, Peterborough; J. T. Denley, Campbell River, B.C.; W. J. Dickson, Camp Valcartier; T. T. Dobie, Trail; J. Dubuc, Montreal; G. Ducharme, Montreal; P. T. Duff, Toronto; E. W. Dunlap, Guelph; J. J. Eatock, Edmonton; C. R. Eaton, Peterborough; W. J. Eden, Ottawa; J. A. Eddleston, Vancouver; D. W. Ellis, Sarnia; G. E. Estey, Otter Rapids; E. R. Evans, Burlington, Ont.; W. L. J. Fallow, Calgary; D. U. Findlay, Brownsburg; A. D. Finlayson, Copper Cliff; B. H. Fleming, Vancouver; C. G. Forberg, London; C. D. Forbes, Vancouver; J. Forte, Montreal; G. Fournier, Acton Vale; F. H. Frappier, Ottawa; A. Ganton, Niagara Falls; R. I. Gilchrist, Montreal; H. F. Godin, Montreal; K. P. Gould, Montreal; J. A. Gurnham, Preston; H. M. Hadley, Montreal; D. J. Hains, Toronto; R. Haliburton, Deep River; J. M. Hall, Toronto; T. P. Halley, Port Cartier; P. N. Hanson, Grand'Mere; D. M. Harris, Owen Sound; E. W. Hayes, Kitchener; H. V. Henderson, Toronto; A. D. Heron, Montreal; E. T. Hilbig, Belleville; R. C. Hodge, Smooth Rock Falls; S. A. Hudson, Toronto; J. G. Irving, Bridgewater; G. P. Kemp, Toronto; R. E. Keyes, Calgary; W. R. Kinnear, Toronto; A. Kriger, Ottawa; J. J. Larocque, Montreal; H. K. Larsen, St. John, N.B.; F. J. Le Blanc, Montreal; H. J. H. A. Lee, Guelph; J. M. Leger, Montreal; W. F. Light, Montreal; R. H. Little, Montreal; C. C. Louttit, Arvida; E. A. A. Love, Shawinigan; G. O. Lucas, Edmonton; R. W. Ly, Peterborough; C. H. Maartman, Vancouver; K. C. Mackenzie, Ottawa; L. S. Maclure, Niagara Falls; N. McCarthy, Hamilton; A. D. McCutcheon, Spragge, Ont.; J. B. McLaren, Vancouver; J. M. McLaughlin, Sarnia; J. W. McNaughton, Montreal; F. R. Mehling, Vancouver; E. L. Mercer, Toronto; F. S. Miller, Montreal; J. G. Mitchell, Hamilton; C. W. Morgan, Windsor; M. Murchison, Montreal; M. P. Murphy, Montreal; J. S. Mutchmor, Arvida; F. W. New, Winnipeg; R. C. Newman, Dundas; B. L. Nugent, Edmonton; E. E. Paine, Arvida; E. G. Parker, Vancouver; W. A. D. Parratt, Toronto; W. F. Patterson, Montreal; L. A. Pattison, Three Rivers; G. K. F. Pepper, Toronto; C. H. Perreault, Kenogami; G. H. Perron, Chicoutimi; J. E. Pescod, Cornwall; A. B. Platt, Sudbury; W. H. Potts, Toronto; S. R. Price, Niagara Falls; R. Proudfoot, Windsor; L. Putsep, Montreal; G. A. Read, Montreal; J. Renchko, Niagara Falls; A. G. Ringuette, Granby; A. E. Risk, Montreal; G. C. Ritcey, Pembroke; I. C. Rogers, Toronto; R. J. Ross, Toronto; W. G. Rowan, Montreal; M. L. Rush, Taylor; A. Ryttel, Montreal; J. R. Sabourin, Montreal; E. C. Scott, Montreal; K. W. Short, Willowdale; N. D. Simmons, Hamilton; J. T. Sinclair, Sarnia; G. L. Smith, Saint John, N.B.; A. E. Speers, Toronto; J. A. Spinney, Copper Cliff; K. W. Stairs, Ottawa; H. A. Stevenson, Vancouver; W. L. Stewart, Montreal; A. R. Stienstra, Hamilton; J. G. Sutherland, Kingston; E. G. F. Sweet, Brantford; R. B. Sweet, Windsor Mills; P. J. Tansey, Montreal; J. S. Taylor, Beauharnois; D. S. Templeton, St. John's, Nfld.; J. Thibaudeau, Montreal; D. L. Townsend, Kingston; N. G. Trower, Oromocto, N.B.; H. J. Tucker, Montreal; A. G. Turton, Ottawa; R. G. Urquhart, Castlegar, B.C.; J. van Beck, Cornwall; J. Veilleux, Quebec; G. S. Warner, Montreal; L. J. Westwood, Toronto; H. M. Whittles, Sudbury; J. E. Wilson, Toronto; R. E. Winter, Toronto; D. M. Wishart, Edmonton; W. R. M. Wood, Montreal; L. H. Yeomans, Toronto; H. N. Young, Thetford Mines.

Student to Junior: M. J. Heuer, Toronto; A. M. McMahon, North Bay; J. M. R. Thomson, Montreal; D. R. Turnbull, London.

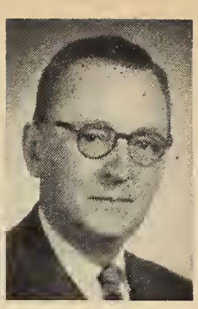
STUDENTS ADMITTED

University of Waterloo: J. D. Balfour, C. G. Edgar, S. Ferrero, R. S. Goodall, R.

(Continued on page 89)

The DUGGAN MEDAL and PRIZE

was awarded by the Institute to A. G. Davenport, JR.E.I.C., now at the University of Bristol, England. It was presented to him last month at the Institution of Electrical Engineers in London by Mr. F. L. Lawton, Vice-President, Montreal.



President's Column

IMMEDIATELY following his return from Winnipeg, your President started off his time honoured duties by visiting, with his wife, his home Branch, the Eastern Townships Branch, where the Chairman, James Davidson, presided at their Annual meeting and Ladies' Night at Hovey Manor, North Hatley, Quebec. A good attendance of members and their wives from Sherbrooke and district, together with a fine respresentation from Montreal, permitted the new President to extend his personal thanks to the Branch for their part in the Presidential nomination. During his initial speech the President emphasized the important part which the Canadian Engineer must take in the future development of this country, and made a plea for continued technical growth of each engineer by extended interest in such spheres over and beyond the normal composite of his regular duties.

Presidential visits to Branches will commence in early September, with attendance at the Maritime Professional Engineers' Conference at St. Andrews, New Brunswick, where your President will be the guest speaker at one of the principal events. Visits to the Newfoundland Branches will follow.

Summer activities at the Engineering Institute include studies by a special Committee of the membership structure, and procedures, of the Engineering Institute. It is hoped that we can find methods of handling membership activities which will improve member relationships with the Institute.

The Engineering Council for Professional Development, of which E.I.C. is a member, is holding its Annual Meeting in Montreal on October 3rd and 4th. It is expected that a wide representation of interested Engineers from both United States and Canada will be present.

Joint meetings of ASME-EIC on Engineering education, scheduled to be held at Ecole Polytechnique, October 5th and 6th, under the guidance of a Committee under Dean Mordell of McGill University, should prove interesting and of considerable value in analyzing Engineering education requirements and what steps are necessary to improve this important feature.

The first of the newly authorized Executive Committee meetings will be held in Montreal, July 22nd. This new departure is a novel development in E. I. C. administration and will be watched with interest both by Council and the membership at large.

H. HAWRYLUK

THE Cook at Crane

FOLLOWS HIS RECIPES CAREFULLY

The ingredients for Crane valve metal are scientifically specified — so much pig iron, so much scrap iron, so much limestone and other materials. Harry Hawryluk weighs these ingredients carefully to make sure that the correct charges go to the cupolas for "cooking". His work is vital to valve quality — the care he takes is typical at Crane.

1 out of every 12 employees at Crane's Montreal plant is a tester or inspector. They test raw materials — metals, sand — continuously...they subject finished valves to tests 2½ to 3 times as severe as they'll meet in normal service. The PAINS they take form one of the reasons why a Crane valve is the best buy in the long run.

Another reason: PEOPLE. The Crane technical people (at your service anywhere in Canada) have heard just about everything there is to hear about valves. They can give you PRACTICAL advice on valve selection, use and maintenance — whatever your business. Crane Head Office: 1170 Beaver Hall Square, Montreal.

SUCCESS STORY: CRANE VALVE STILL SERVES AFTER 70 YEARS!

Recently — in the course of routine maintenance at the Petrolia, Ontario, Waterworks — a trench was dug. It uncovered a 12″ Crane waterworks valve that had been installed in 1890. We can't show you a picture of the actual valve because the investigators found that it was still doing its job perfectly so they simply covered it up again. Crane care makes today's valves just as reliable.

CRANE VALVES • PIPING • PLUMBING • HEATING • AIR-CONDITIONING

(Continued from page 82)

New European Federation on Corrosion

Fifty scientific and engineering associations have joined in a European Federation on Corrosion which held its first symposium in Frankfurt recently. Cathodic protection from corrosion was the subject of discussion, including the most recent German research on electric anti-corrosion measures.

Dr. E. Eberius, of Duisburg, explained that it has long been known that iron is corroded by the formation of tiny electric elements on its surface. Corrosion consists of an exodus of iron ions. The traditional method of making an iron surface into a cathode by applying a baser metal such as zinc or magnesium is being replaced in some instances now by connecting the iron to the negative pole of a source of direct current.

The German Federal Republic, said Dr. Eberius, has some 2000 miles of pipelines protected cathodically at present, including the water supply line from Lake Constance to Stuttgart.

SIR CASIMIR STANISLAUS GZOWSKI

a biography

by Ludwick Kos-Rabcewicz-Zubkowski, L.L.D.

and

William Edward Greening, M.A.

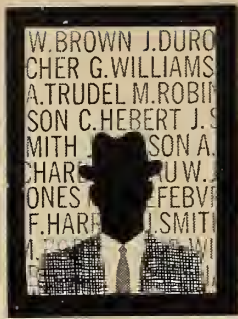
(Published under the auspices of the Engineering Institute of Canada)

This volume may be ordered from the E.I.C. Library.

When ordered for a member of the Institute the regular retail price of $4.75 is reduced to $3.80.

The volume describes the background and achievements of one of Canada's outstanding engineers.

Personals



Geoffrey A. Gaherty, M.E.I.C. (Dalhousie '09), President of the Montreal Engineering Company and a director of Atomic Energy of Canada Ltd., was awarded an honorary Doctor of Engineering degree at the N.S.T.C. convocation.

T. R. McLagan, M.E.I.C. (McGill '23), President and General Manager of Canada Steamship Lines Ltd., Montreal, was recently elected 1960-61 President of the Canadian Manufacturers' Association.

Charles H. Pigot, M.E.I.C. (McGill '26) has been appointed Assistant Chief Engineer of the Power Development Division of Hydro-Quebec.

The following are to be recipients of Canadian Good Roads Association fellowships: **Paul-Henri Durand**, JR.E.I.C. (Laval '58), of the Quebec Department of Roads, to study at Purdue University; **K. G. C. Smith**, JR.E.I.C. (Toronto '53), of Proctor & Redfern, Toronto, to study at the University of California; **J. A. Knowles**, S.E.I.C. (Manitoba '60) to study at the University of Alberta; and **Y. I. Fellman**, JR.E.I.C. (Queen's University, Belfast '56), of the Newfoundland Department of Highways, to study at Queen's University.

P. H. Durand, JR.E.I.C.

K. G. C. Smith, JR.E.I.C.

F. Russell Stone, M.E.I.C. (Toronto '30) has been appointed District Representative in Eastern Canada for North American Refractories Ltd., to be located in Montreal.

C. B. Jackson, M.E.I.C. (Saskatchewan '31) has been appointed Vice-President of Alchem Ltd., Burlington, Ont.

Austin D. Misener, M.E.I.C. (Toronto '33) has been appointed F.R.S.C. Director of the Ontario Research Foundation. Since 1949 Mr. Misener has headed the Department of Physics at the University of Western Ontario.

Mortimer A. Montgomery, M.E.I.C. (Saskatchewan '34) has been elected Vice-President of Sales for The Canadian Blower & Forge Company Ltd., Kitchener, Ont.

E. L. Neal, M.E.I.C. (Queen's '38) has been elected a director of Anglo-Newfoundland Development Company Ltd. He is President and General Manager of Gaspesia Sulphite Company Ltd. of which he is also a member of the board.

J. A. Knowles, S.E.I.C.

Y. I. Fellman, JR.E.I.C.

H. P. Hershman, M.E.I.C. (McGill '45), formerly of J. Becker Inc., has opened his own air-conditioning business, Airco Installations Ltd., and is acting as its President.

J. Terence Gregg, M.E.I.C. (Queen's University, Belfast '49) has been appointed Chief Engineer and a director of Morrison, Hershfield, Millman and Huggins, Ltd., Consulting Engineers, Toronto. For the past six years he has been Supervising Bridge Engineer for the Foundation Engineering Corporation Ltd.

W. H. Nord, M.E.I.C. (Toronto '48) has been made Plant Manager of the Northern Pigment Company Ltd., New Toronto, Ont.

A. Ray Dow, M.E.I.C. (Toronto '49) has been named General Sales Manager of British Oxygen Canada Ltd.

F. M. McGuire, JR.E.I.C. (U.N.B. '50) has been appointed Manager of Dominion Structural Steel Company's operations in the Winnipeg-St. Boniface area.

W. P. London, M.E.I.C.

W. P. London, M.E.I.C. (New Brunswick '34), formerly Chief Engineer, Thermal Division, H. G. Acres & Company Ltd., announces the formation of the firm of W. P. London and Partners, Consulting Engineers, Niagara Falls, Ontario. A complete range of engineering services in the mechanical, civil, and electrical fields is offered by the firm.

P. A. Pasquet, M.E.I.C. (Queen's '42), A. C. Shamess, M.E.I.C. (Toronto '46), and **Harold Jones**, M.E.I.C. (Manchester College of Technology '33), all formerly with H. G. Acres & Company Ltd., have joined the firm of W. P. London and Partners, Consulting Engineers, Niagara Falls, Ontario, as partners.

Donald Robson, M.E.I.C. (N.S.T.C. '50) has recently joined the staff of the National Research Council, Division of Building Research, as a member of its Atlantic Regional Station in Halifax.

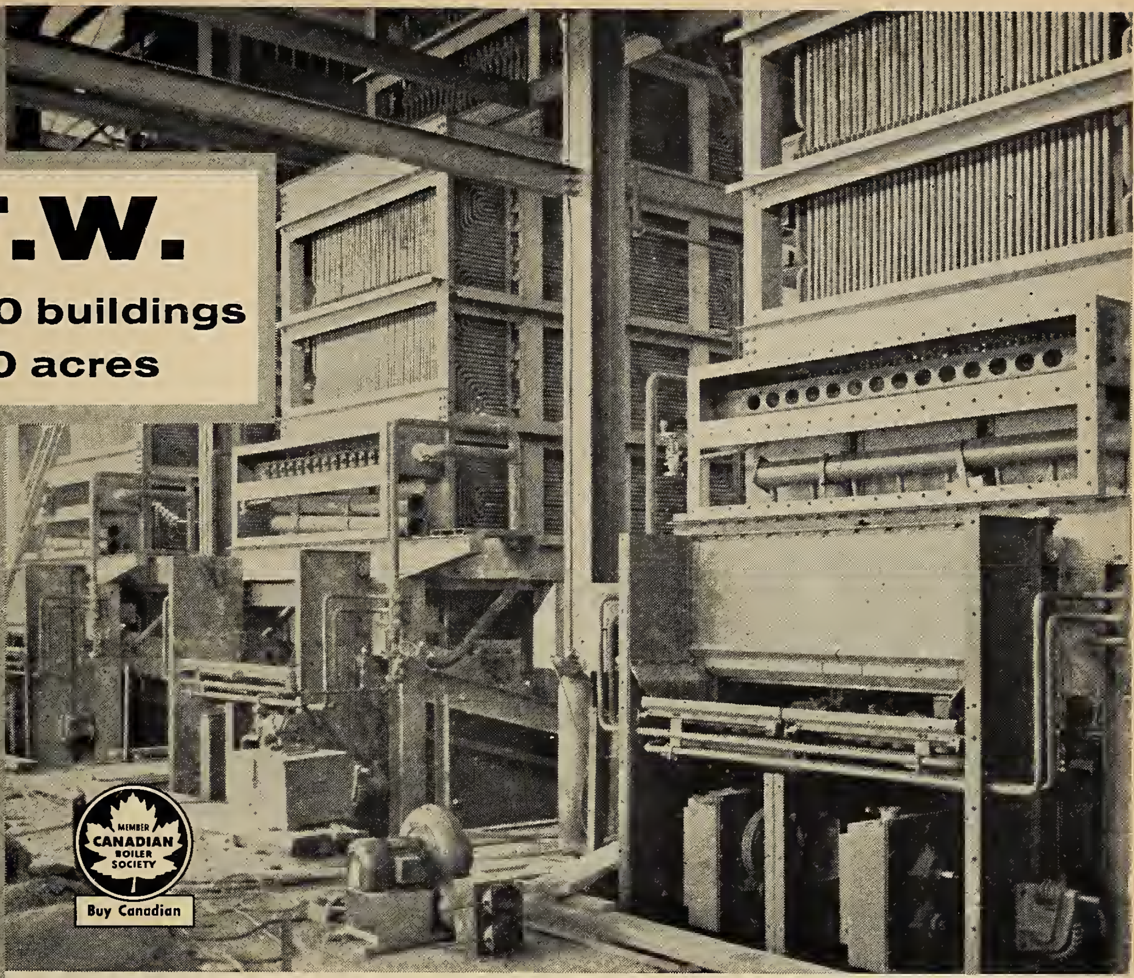
A. E. Insley, JR.E.I.C. (U.B.C. '53) has been named Soils Engineer with R. C. Thurber and Associates, consulting civil engineers, Victoria, B.C.

Lester L. Atkinson, JR.E.I.C. (N.S.T.C. '53), of Kingsport, N.S., has been appointed the first Analytical Services Officer of Canadian National Railways Atlantic Region, with headquarters in Moncton.

Karl Van Dalen, JR.E.I.C. (Queen's '57) has returned to Canada after two years at Imperial College of Science and Technology, London, on an Athlone Fellowship. He will take up duties as a lecturer in civil engineering at Carleton University, Ottawa.

H.T.W.

heats 20 buildings on 1,200 acres



At the Central Experimental Farm Ottawa three Dominion Bridge 30,000,000 btu *high temperature water* boilers have been installed to satisfy the varied heating requirements of twenty buildings spread over some 1,200 acres. The installation provides for space heating and domestic hot water, and low pressure steam for a large number of special applications such as air-conditioning, autoclaves, sterilizers, pressure cookers, laboratory outlets, etc.

Each boiler is equipped with a fully water-cooled Vibra-grate stoker designed to burn Canadian bituminous coal and provision is made for alternative oil firing. The system is pressurized by nitrogen in an expansion tank and the water temperature is maintained at 366°F.

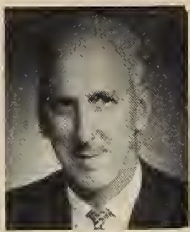
In applications of this kind, where heat must be distributed over a wide area, H.T.W. offers very definite advantages. These are evident in lower overall costs due largely to the absence of corrosion, the elimination of condensate traps and separators, and the fact that mains pipes may be laid without regard for levels or grades. Because of the high thermal storage of the system a smaller capacity plant is possible, an advantage that reduces fluctuation in the firing rate to give better overall efficiency. Capital costs are comparable with H.P.S. installations.

Dominion Bridge designs and manufactures watertube and firetube boilers for a wide variety of applications. A call to the Boiler Products Division at any of its offices across the country will put their long experience at your service.

49

Boiler Products Division **DOMINION BRIDGE**

DOMINION BRIDGE COMPANY LIMITED - FIFTEEN PLANTS COAST-TO-COAST



C. A. Peachey, M.E.I.C.

C. A. Peachey, M.E.I.C. (Toronto '27), General Manager of the Communications Equipment Division, Northern Electric Company Ltd., has been appointed to the Defence Research Board.

L. Donald Sanderson, S.E.I.C. (Manitoba '60) has begun work as a mechanical engineer with the Aluminum Company of Canada at the Arvida works.

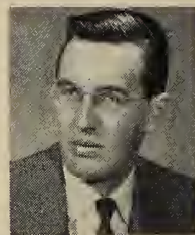
William J. Gibson, S.E.I.C. (N.S.T.C. '60) has accepted a position with the Aluminum Company of Canada as process engineer at the Arvida works.

A. C. Ridgers, M.E.I.C. has been appointed Assistant to the Manager of the Engineering Division of The Consolidated Mining and Smelting Company, Trail, B.C.

Edward A. Silver S.E.I.C. (McGill '59) is working toward an M.Sc. in Operations Research at the Massachusetts Institute of Technology.

E. H. Martin, M.E.I.C.

Eric H. Martin, M.E.I.C. (Manitoba '47) has been appointed to head the construction division of the British Columbia Power Commission.



H. J. T. Patterson, M.E.I.C.

H. J. T. Patterson, M.E.I.C. (McGill '48) has been appointed District Sales Manager for Dominion Structural Steel Ltd., Montreal.

Ken W. Short, JR.E.I.C. (Toronto '48) has formed a new partnership for the practice of engineering and architecture in Willowdale, Ontario, which is to be known as Ball, Craig, Short & Strong, engineers and architect.

John T. Dyment, M.E.I.C. (Toronto '29), Chief Engineer for Trans-Canada Air Lines, has been elected to the board of directors of the Society of Automotive Engineers.

A. G. Murphy, M.E.I.C.

A. Gordon Murphy, M.E.I.C. (McGill '22), Chief Engineer for The St. Lawrence Seaway Authority, had an honorary degree of Doctor of Laws bestowed upon him at the McGill University spring convocation.

James Douglas Robertson, M.E.I.C. (Manitoba '45) is Head of Electrical Engineering with I.O.R.C. in South Iran.

Clarence A. Parker, S.E.I.C. (N.S.T.C. '60) has taken up a position as process engineer at the Arvida works of the Aluminum Company of Canada.

(more Personals on page 125)

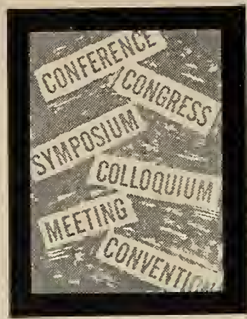
(Continued from page 76)

the rule of thumb can be safely used, especially where relatively massive and other than horizontally stratified rock was involved.

The authors mention that, as a result of comparison between water test data and grout acceptance, a mix of one part of cement to six parts of water was found suitable for sealing the fine seams in the bed rock. It would be interesting to know whether co-efficients of "secondary" permeability, K, for the rock were computed from the results of the water testing, and if there was any correlation between such coefficients and grout acceptance. It is recognized that with so many variables involved, a simple correlation between secondary permeability and grout acceptance would probably not be possible, but at least such studies may have yielded information as to the lower limit of the co-efficient of secondary permeability at which acceptance of grout will take place. It has been suggested that this lower limit is represented by a K value for the rock of 10^{-4} cms. per second, although based on a limited number of tests our experience would indicate that the lower limit of K is even less than this. (The co-efficients in the tests mentioned being computed from pressure pumping test data using methods outlined in the U.S. Department of the Interior, Bureau of Reclamation, "Earch Manual"). In this connection it is worth noting that research carried out by the U.S. Corps of Engineers has apparently shown that it is doubtful whether grouting would be at all effective in any fissures which are smaller than 3 times the maximum particle size in the cement. It would be interesting to know also, if the results of other work on this project, such as an examination of rock cores taken after grouting, confirmed the above criterion.

The data on the actual acceptance of grout per foot of hole in order to give a water-tight foundation in this case is useful information. Merely by way of comparison, it may be worth adding that published precedent and our experience elsewhere in foundation rock consisting of sandstones and limestones indicates that acceptances of between 0.05 and about 2.0 bags of cement per foot of hole can be expected. In one case involving sandstone rock acceptances of 0.06 to 0.30 bags per foot of hole were obtained, while to consolidate a limestone and shale foundation in another instance between about 0.5 to 1.0 bags of cement per foot of hole were required. In both of the above-mentioned examples, the grout acceptance at various locations on the site varied considerably, and this, according to published data, seems to be often the case. The variation seemed to be greater than was apparently experienced on the project discussed in the paper. The generally low average acceptance of the grout and the general uniformity of the foundation rock across the site as indicated by the grout acceptance results, point to a good final choice of site from the point of view of foundations.

Other Societies



1960 Canadian Trade Fairs

The Foreign Trade Service of the Canadian Department of Trade and Commerce has published a schedule of Canadian Trade Fairs for the remainder of 1960. Among the 70 trade fairs to be held in many different parts of the country are: 3rd Canadian National Material Handling Show and Conference, Montreal, September 26-30; Montreal International Trade Fair, October 25-November 6; Canada's Great Eastern Exhibition, Sherbrooke, August 26-September 1; Canadian National Exhibition, Toronto, August 24-September 10; Pacific National Exhibition, Vancouver, August 20-September 5.

Canadian Copper and Brass Association

A new quarterly bulletin "Canadian Copper & Brass" is being published in February, May, September, and November, to give up-to-date information on copper, copper alloys and copper compounds. It can be obtained free by contacting the Association, Room 1101, 55 Yonge Street, Toronto 1. The Association has also published its first book, entitled "Copper in Canada".

International Society of Soil Mechanics and Foundation Engineering

The proceedings of the First Asian Regional Conference of the International Society of Soil Mechanics and Foundation Engineering, arranged by the Indian National Society of Soil Mechanics and Foundation Engineering and held at New Delhi, February 4-7, 1960, are being published. The volume will be ready by Fall and can be ordered from the Indian Society, c/o Central Board of Irrigation and Power, Curzon Road, New Delhi 1, for $11.

Attending the conference were scientists and engineers from India, Israel, Japan and the U.S.S.R. The construction and behaviour of earthen embankments, the foundations of structures other than hydraulic structures, general soil stabilization techniques and field measurement and sampling were discussed.

American Welding Society

Recommended Practices for Metallizing Shafts or Similar Objects, a publication of the American Welding Society, has been revised, introducing a new section on surface preparation for metallizing. The 32-page booklet is available for $1 from the American Welding Society, Dept. T, 33 West 39th Street, New York 18, N.Y.

The Society of Naval Architects and Marine Engineers

Four graduate scholarships for the coming academic year have been awarded by The Society of Naval Architects and Marine Engineers, New York. The two recipients of awards for marine engineering study are George Webb, to study at the Virginia Polytechnic Institute and Roy L. Harrington, to study at the University of Michigan. All four scholarships are for two semesters' tuition and living expenses.

Industrial Education Institute

Among the summer and fall seminars scheduled by the Industrial Education Institute, Boston, are: "More Effective Problem Solving in Engineering, Manufacturing and Marketing", August 15; "Measuring and Improving the Effectiveness of the Maintenance Department", August 30; "Inventory Control", September 22: "Calculating the Return on Proposed Projects, Equipment or Plant Facilities", all to be held at the Sheraton-Mt. Royal Hotel, Montreal.

American Welding Society Bibliographies

The AWS has announced the availability of the 1959 supplement to the AWS Bibliographies. The original publication contained bibliographies of articles which appeared in the Welding Journal from 1937 through 1957, and each year a supplement is compiled listing the previous year's articles. Copies may be obtained from the American Welding Society, Department T., 33 West 39th Street, New York 18, N.Y. The cost is $1.50.

Water Pollution Control Federation

"Design and Construction of Sanitary and Storm Sewers," the Water Pollution Control Federation's latest edition to its Manual of Practice Series, is now available. Popularly known as "The Sewer Manual", this publication is the result of several years' joint effort by the Federation and the American Society of

(Continued on page 101)

The Associations and Corporation

The April Issue of *The Professional Engineer*, the Journal of the Association of Professional Engineers of Ontario, listed a number of correspondence courses which would be available to members if enough interest were shown. Returns from the questionnaire on this subject have indicated that courses in Advanced Mathematics and Engineering Computer Programming are most sought after. The current issue of *The Professional Engineer* lists the courses to be offered and required tests and registration forms. The Ontario Professional Engineers Foundation has agreed to underwrite losses up to $500 for the course in Engineer Computer Programming which is expensive both to prepare and to operate. Exercises submitted by students will be put through the computers at the University of Toronto and incorrect solutions will probably be returned to students for correction, then put through the computers a second time.

The original date of the Annual Convention of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. has been changed to September 22-24. It is to be held, as planned, at Trail, B.C. Among the papers to be delivered are: "Street Markings and Signs", J. H. Harding, B.C. Department of Highways; "Chemical Aids to Municipal Engineers", F. J. L. Miller, Cominco; "Smoke Control", J. F. Snowball, Cominco; "Urban Redevelopment", H. Peter Oberlander, U.B.C.; "Asphalt", N. M. McCallum, Willis & Cunliffe Engineering Ltd., Victoria.

● OTHER SOCIETIES

(Continued from page 98)

Civil Engineers. Orders should be placed with the Water Pollution Control Federation 4435 Wisconsin Avenue, N.W., Washington 16, D.C.

Coming Events:

A Symposium on "Stereochemistry in Organic Reactions", University of Alberta, Edmonton — September 6-7.

Symposium on Fundamental Aspects of Atomic Reactions (The Chemical Institute of Canada), McGill University, Montreal — September 6-7.

Symposium on Nuclear and Radio-Chemistry (The Chemical Institute of Canada and AECL), Chalk River, Ont. — September 6-8.

1st Joint Automatic Control Conference (ISA, AIChE, AIEE, ASME, IRE), M.I.T., Cambridge, Mass. — September 7-9.

ISA Fall Instrumentation-Automation Conference & Exhibit and ISA Annual Meeting, New York Colliseum, N.Y. — September 26-30.

13th Annual Conference on Electrical Techniques in Medicine and Biology (ISA, AIEE, IRE), Sheraton Park Hotel, Washington, D.C. — October 31-November 2.

Coal Meeting (Society of Mining Engineers of the American Institute of Mining, Metallurgical, and Petroleum Engineers), Chase Park Plaza Hotel, St. Louis, Mo. — September 8-9.

4th Annual Joint Military-Industrial Electronic Test Equipment Symposium (Office of the Director of Defense Research and Engineering and the Department of the Army Signal Corps), Museum of Science and Industry, Illinois Institute of Technology, Chicago — September 14-15.

8th Annual Engineering Management Conference, Chicago — September 15-16.

4th International Industrial & Technical Exhibition, Charleroi, Belgium — September 15-26.

Symposium on the Numerical Treatment of Ordinary Differential, Integral and Integro-Differential Equations (International Computation Centre, Rome), University of Rome—September 20-24.

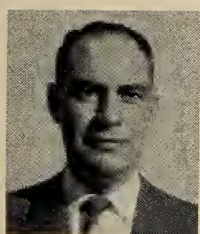
Conference on Problems of Power Generation and Transmission (ASME, AIEE), Philadelphia — September 21-23.

3rd Annual Meeting of the Water Pollution Control Federation, Philadelphia — October 2-6.

7th Annual Meeting of the Professional Group on Nuclear Science of the Institute of Radio Engineers (PGNS and Oak Ridge National Laboratory), Gatlinburg, Tenn. — October 3-5.

MARITIME PROFESSIONAL ENGINEERS' CONVENTION
Algonquin Hotel
St. Andrew's, N.B.
September 8-10

News of the Branches



New Chairmen: *(left to right)* M. Perley Estey, M.E.I.C., Fredericton; J. Longworth, M.E.I.C., Edmonton; F. R. Denham, M.E.I.C., Niagara Peninsula; J. A. Webb, M.E.I.C., Calgary.

Halifax

H. F. Peters, M.E.I.C., ***Correspondent***

TWO LARGE LOBSTERS were the delight of each member and guest at the social evening held on June 24 at the Shore Club, Hubbards. After dinner the Engineers' Wives provided entertainment for the group. Mr. H. A. Marshal, chairman of the branch, welcomed the ladies and said that it was the general feeling of the executive that there should be more such evenings.

Baie Comeau

G. W. Scott, M.E.I.C., ***Correspondent***

THE OIL INDUSTRY—from its general organization and economy in Canada to the detailed solution of technical problems associated with a modern refinery—was described colourfully by Mr. John J. Rowan, M.E.I.C., Refinery Manager of Imperial Oil Limited, Montreal, at the April 21st meeting.

Mr. Rowan's address was supported by some excellent colour slides and a sound film entitled "Refinery At Work" made at the Fawley Refinery of the Esso Petroleum Company of England.

Guest of honour at the Annual Dinner-Dance of the Baie Comeau Branch, held at Manoir Comeau, June 15th, was Mr. W. J. Thomas, M.I.E.E., M.I.Mech.E., Managing Director of The British Aluminium Company. In a spontaneous after-dinner speech, Mr. Thomas paid tribute to the engineering profession and engineers throughout the world, singling out Canadian engineers for their foresighted policy concerning the status and recognition of their profession in Canada.

Mr. Thomas was introduced by Mr. Charles Miller, vice-president of the Institute representing the Province of Quebec. Approximately 76 members were in attendance.

Brockville

D. B. Ashenden, JR.E.I.C., ***Correspondent***

THE MANY FACETS of the St. Lawrence Generating Station were explored by E.I.C. members on June 11. Accompanied by their families, 21 members and guests were introduced to the building layout by a film on the Seaway and Power Dam and then taken on tour.

The Canadian Power Station consists of 16 units of 75,000 HP, and control of the whole operation is in the hands of two control room operators. The latest in electrical switchgear and controls and a large gantry crane for maintenance services are in use.

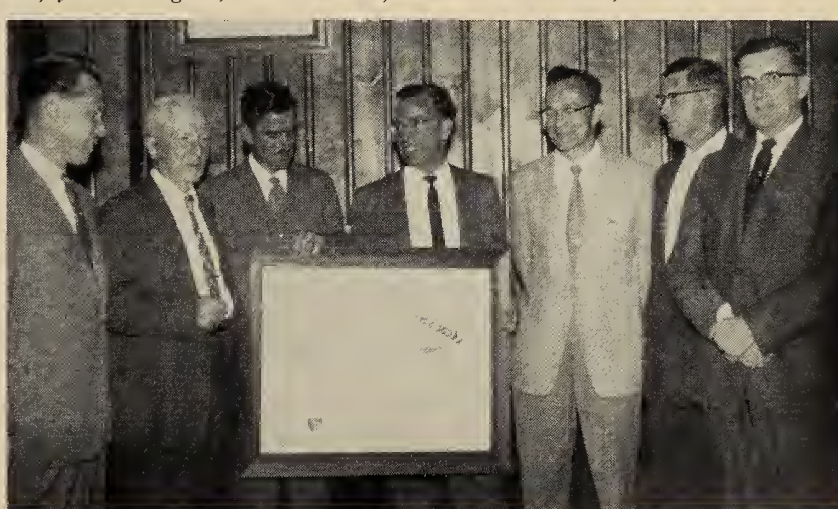
The excellent commentary and able response to questions by the Ontario Hydro engineers who acted as guides made this tour a memorable and worthwhile experience.

Niagara Peninsula

E. C. Little, M.E.I.C., ***Correspondent***

THE INTAKE STRUCTURE above the falls was the take-off point for a tour of Niagara Power Project of the Power Authority of the State of New York on June 16th. Proceeding north by bus along the twin cut for the two tubes (each about 44′ wide by 60′ high), members saw the dykes which have been partly completed and will provide a reservoir. The reservoir will be pumped up during the night by a mechanism which will also act as turbines for peak power. The forebay is well advanced and work is proceed-

The present executive of the Moncton Branch takes a look at its Charter: (left to right) D. A. Foster, vice-chairman; V. C. Blackett, secretary-treasurer; W. M. Steeves, immediate past chairman; R. F. Weir, chairman; L. R. Wadlyn, committeeman; J. F. Callaghan, committeeman; and C. L. Trenholm, councillor.



ing on the power house. The buses continued along the gorge to Lewiston where the soil disposal area is situated. During the trip guides explained each project and answered questions about the work.

North Shore Lower St. Lawrence

L. E. Fischer, M.E.I.C., *Correspondent*
NEW OFFICERS of the branch, to serve until the Fall elections in October, were elected at the April 11th meeting. They include: R. W. Pryer, chairman; R. Herbert, vice-chairman; L. Fischer, secretary-treasurer; D. O'Connor, L. Freddi, M. Storrier, D. Manston, B. Kelly and J. C. Garneau, executive members.

Ottawa

H. P. Ristow, JR.E.I.C., *Correspondent*
THE AIR TERMINAL BUILDING at Uplands was inspected by members on May 19th, through the courtesy of Mr. H. J. Connolly of the Department of Transport.

The Annual Ottawa Valley Engineers' Golf Tournament drew players from the Ottawa Branch of E.I.C. and the Professional Engineers Associations of Quebec and Ontario to compete at Arnprior Golf Club, June 24th. Ninety-eight members managed to complete the course by evening and top golfer of the day was Bob Watson from Deep River with 4-over-par 74.

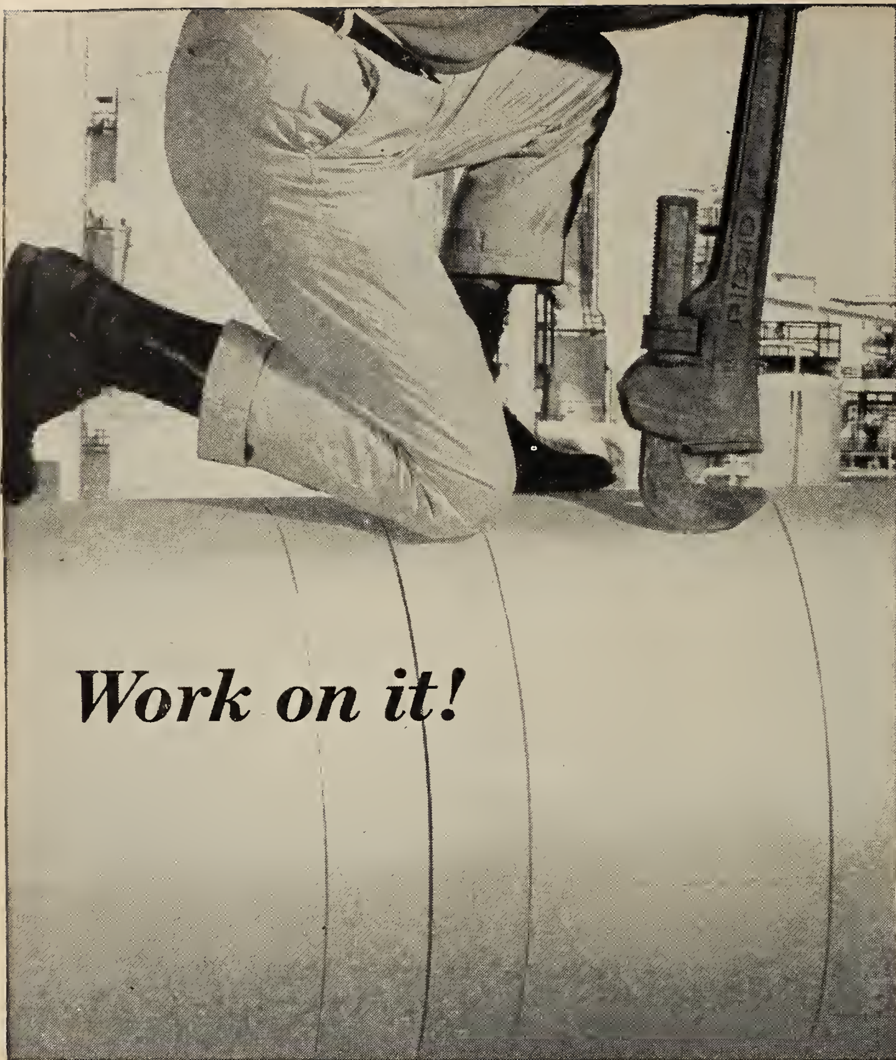
Sarnia

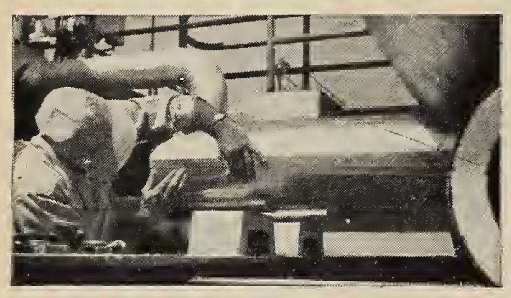
Paul Donato, M.E.I.C., *Correspondent*
ENGINEERING KNOW-HOW, according to Mr. R. A. Frigon, M.E.I.C., speaker at the May 17th meeting, could make the difference to Canada in world competition by increasing productivity through the proper employment of machinery, automation and manpower. Mr. Frigon is with the Federal Department of Trade and Commerce.

Vancouver

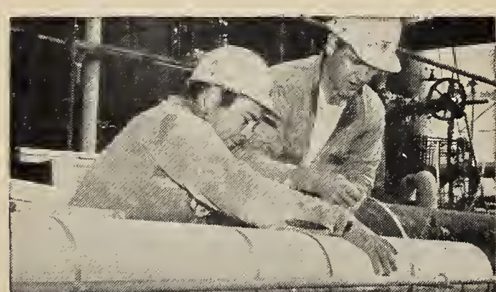
D. R. Bakewell, M.E.I.C., *Correspondent*
SEATTLE was the destination of 15 members and their wives attending the Annual Joint Meeting with the Seattle Chapter of the American Society of Civil Engineers on May 21st.

The new executive of the Vancouver Branch is: J. H. Swerdferger, chairman; C. H. White, vice-chairman and program manager; R. C. Clough, secretary; R. H. Carswell, treasurer; D. R. Bakewell, publicity and student guidance; S. W. Faliszewski, student guidance; H. Lillie, professional development; G. A. Antenbring, professional development; A. W. Greenius, membership; A. A. Kay, technical sections; C. H. Maartman, entertainment and field trips; C. P. Jones, past chairman; P. W. Bland, councillor; and W. G. Heslop, councillor.





J-M's new Metal-On® insulation is Thermobestos prejacketed in aluminum. Snaps on pipe quickly . . . surely. Saves the time and cost of separate on-the-job metal application.



J-M Thermobestos is quick, easy to apply . . . its strength makes it particularly adaptable to time-saving prefabrication of fittings and bends. Furnished in large sections, Thermobestos reduces the number of joints needed.

It's tough, durable Johns-Manville

Here's why Thermobestos is the preferred high-temperature calcium-silicate insulation . . . to 1200 F

You know the kind of treatment pipe insulation must take . . . day after day, year after year!

There's no better reason than this for the spiraling growth in Thermobestos® applications throughout the process and power generation industries — an insulation so strong and rigid, so resistant to crushing and compression it is almost structural.

THERMOBESTOS insulation!

Equally important is the ability of Thermobestos to keep fuel costs low. Its *k* factor is the lowest of all insulations generally accepted for process applications. Its moisture resistance, unsurpassed.

Furnished in large, lightweight sections, precision-molded to unusually close tolerances, Thermobestos is easy to handle and install . . . readily adaptable to shop fabrication of fittings and bonds. Large selection of sizes, thicknesses (and quads up to 33″ pipe size) permit calcium-silicate installations that are entirely Thermobestos insulation.

You'll want the new Thermobestos booklet for your technical file. It contains complete information on prefabricating and installation practices . . . specification data . . . heat transmission tables . . . and physical and thermal characteristics. Write for it today. Ask for booklet IN-169A. Address Canadian Johns-Manville Co. Limited, 565 Lakeshore Rd. East, Port Credit, Ontario.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*PROCEEDINGS OF THE SYMPOSIUM ON MILLIMETER WAVES. (MICROWAVE RESEARCH INSTITUTE SYMPOSIA SERIES, VOL. IX)
The forty papers here published include nine not presented at the symposium. Participating were scientists from England, France, Japan, Israel, the Netherlands, the U.S.S.R., and the U.S.A. The papers discuss the present state of the use of millimeter waves in such fields as physics, communication, solid state research and metallurgy; dielectric, power, and electron profile measurements; the generation of millimeter and submillimeter waves by undulator, Cerenkov, and Purcell radiation, as well as by other means; multimodes and components; and future trends and applications of millimeter wave research. (Ed. by J. Fox. Sponsored by the Polytechnic Institute of Brooklyn. New York, Interscience, 1960. 656 p., $8.00.)

*DIRECT CONVERSION OF HEAT TO ELECTRICITY.
An edited collection of papers originally presented at the M.I.T. 1959 "Direct Conversion" program, which discuss thermionic engines, both high vacuum and low pressure, magnetohydrodynamic conversion, semiconductor devices in thermoelectrics, and fuel cells as energy converters. (Ed. by J. Kaye and J. A. Walsh. New York, Wiley, 1960. Various pagings, $8.75.)

*BEACHES AND COASTS.
The main factors on which the character of a beach depends include beach material, waves, tides, and winds; the inter-relationships between these elements are the subject of this book. The movement and grading of material and its effect on the changing profile of the beach is the main theme, and wave actions, both constructive and destructive, are covered thoroughly. Coastal types are classified and described and historical data on coastal change is given. Most examples are of English beaches, but coasts of the whole world are also included. (C. A. M. King. Toronto, MacMillan, 1959. 403 p., $11.25.)

*THE CORROSION AND OXIDATION OF METALS.
This work represents the conclusions reached by the author in his investigations into corrosion, as well as providing a summary of other experimental work which has influenced him in reaching these conclusions. The topics discussed include simple oxidation of single metals, electrochemical corrosion, soluble inhibitors, bimetallic contacts and crevice corrosion, anodic corrosion and passivation, hydrogen evolution and acid corrosion, crystallographic corrosion, and atmospheric corrosion. In addition a number of industrial aspects relating to boilers and condensers and to various types of coatings are discussed. (U. R. Evans. Toronto, Macmillan, 1959. 1094 p., $24.00.)

*SYMPOSIUM ON PLASMA DYNAMICS.
This volume is based on the 1958 Woods Hole international symposium on the variously-named science which deals with the interaction of deformable conducting materials and the electromagnetic field. The material has been arranged in individually-edited chapters synthesizing the transcript of the symposium in areas such as experimental research on high-temperature plasmas, thermonuclear fusion and high-temperature plasmas, gaseous electric phenomena, the dynamics of electron beams, statistical and continuum plasma dynamics, and flight, solar, planetary, interplanetary and cosmical magnetohydro-dynamics. (Ed. by F. H. Clauser. Reading, Addison-Wesley, 1960. 369 p., $12.50.)

*SURFACE EFFECTS ON SPACECRAFT MATERIALS.
These are the transactions of the first symposium on the requirements of materials for temperature-control surfaces of spacecraft and the behavior of material surfaces in space. Methods of calculation and measurement are first presented; the remainder of the book deals with the effects of space on the surface and structural properties of materials, and covers the sublimation of material into ultra-high vacuum, the effects of high vacuum on mechanical properties, friction and wear under ultrahigh vacuum, ultraviolet radiation in space, interplanetary dust distribution, and atomic and molecular sputtering. (Ed. by F. J. Clauss. New York, Wiley, 1960. 404 p., $11.50.)

*PROCESS ENGINEERING CALCULATIONS.
The concern of this book is the application of the laws of conservation of matter and of energy to the solution of industrial chemical process problems by the freshmen engineering student. The principles of process material and energy balance are applied here to the feed preparation, chemical reaction, and separation steps of industrial processes, but are applicable to all process operations. (M. Tyner. New York, Ronald, 1960. 402 p., $8.50.)

*THE AMERICAN CIVIL ENGINEER.
This study of the American engineer from the late 1700's through the 1840's examines the organizational pattern of nineteenth century life by describing the emergence of the civil branch as a recognized specialization in engineering. The author concentrates on those engineers who worked on internal improvements, mainly canals and railroads. He traces the careers of such men as Latrobe, Baldwin, and Brindley, the history of early New York and New Jersey canals, railroads, and such projects, and the development of the national professional association, the American Society of Civil Engineers. (D. H. Calhoun, Toronto, Saunders, 1960. 295 p., $6.35.)

*PHOTOCONDUCTIVITY OF SOLIDS.
This discussion relies more on physical description than mathematical analyses in order to foster quantitative understanding of photoconductivity. Other photoeffects in solids, such as photovoltaic and photoelectromagnetic effects are covered, and

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Summer Library hours are: Monday to Friday: 2 p.m. to 5 p.m.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

description of the chemical preparation and properties of photoconductors is included. The text ranges from discussion of the basic concepts, to detailed treatment of current theoretical understanding of the mechanisms of photoconductivity and description of particular phenomena illustrating the variety of characteristics available. (R. H. Bube. New York, Wiley, 1960. 461 p., $14.75.)

***INTRODUCTION TO MODERN NETWORK SYNTHESIS.**

An undergraduate text which follows a middle path between rigorous mathematical exposition and practical applications. Among the many possible topics selection was made to ensure presentation of each in sufficient detail. Those selected include positive real functons, synthesis procedures for LC, RC and RL, and RLC cases, approximation methods, one and two terminal-pair network synthesis, and synthesis by image parameters. (M. E. Van Valkenburg. New York, Wiley, 1960. 498 p., $11.75.)

***STRUCTURAL MECHANICS.**

This book presents fundamental principles, emphasizing the mathematical treatment of structural theory bearing on indeterminate structures. It introduces advanced strength of materials, topics such as finite difference approximations, Fourier series, and structural dynamics and stability, and includes consideration of beam columns, moment distribution for axially loaded members, and numerical method for deflections and buckling. Intended primarily as an undergraduate text, but designed also to be of use for more advanced study. (S. T. Carpenter. New York, Wiley, 1960. 538 p., $9.50.)

***SYMPOSIUM ON RADIOISOTOPES IN METALS ANALYSIS AND TESTING.**

Four survey papers discuss general types of analysis using radioisotopes, such as thickness gaging, absorptiometry, radiometry, activation and isotope dilution essays, and the proper instrumentation for these methods. The remaining four papers describe current industrial activity, including the analysis of tungsten and of aluminum for trace impurities, and the training of personnel in the utlization of radioisotopes. (Philadelphia, American Society for Testing Materials, 1960. 62 p., $2.75. s.t.p. 261.)

***SYMPOSIUM ON HYDRAULIC FLUIDS.**

There are three papers on problems and trends in the use of hydraulic fluids—a general survey, and automotive and aircraft hydraulic systems, and also papers on new development and evaluation methods for marine, aircraft and industrial hydraulic fluids, including fire-resistant fluids. (Philadelphia, American Society for Testing Materials, 1960. 102 p., $3.75. s.t.p. 267.)

***LITERATURE SURVEYS ON INFLUENCE OF STRESS CONCENTRATIONS AT ELEVATED TEMPERATURES and THE EFFECTS OF NONSTEADY LOAD AND TEMPERATURE CONDITIONS ON THE CREEP OF METALS.**

The survey on stress concentration covers 1926-1957. It reviews the available notch-rupture data with the idea of establishing fundamental influences of stress concentrations, testing variables, and the influence of alloy compositions, and deals with the application of notch data to the problem of component design. The survey on cyclic loading covers 1937-1956, and describes the fundamental investigations, summarizes data on alloys under complex variations of load and temperature, and reviews several analytical procedures for calculating nonsteady behavior from steady-state stress tests. (Philadelphia, American Society for Testing Materials, 1959. 104 p., $4.50. s.t.p. 260.)

***IONIZATION PHENOMENA IN GASES.**

This graduate-level text complements others by concentrating on those discharges not previously treated collectively. The first two chapters provide a general background in describing the nucleus, ionization and excitation of the atom, spectra, conduction of electricity in a gas, and the fundamental processes of ionization and de-ionization. The remaining chapters discuss the similarity principle as applied to discharges, alternating, high current and high frequency discharges, thermonuclear effects, ionization in the upper atmosphere, and plasma oscillations and waves. Periodic tables, critical potentials, and physical constants are included in appendices. (G. Francis. New York, Academic, 1960. 300 p., $10.50.)

***HIGH PRODUCTIVITY IN HEAVY ENGINEERING.**

A book for anyone involved in the fabrication of metal by welding. The features of the different arc-welding processes are listed, with detailed consideration only of slag welding and welding of thick plate. Major consideration is given the machines for cutting and welding, methods of dimensioning, assembling, handling and inspection, and plant layout. Four final chapters discuss time standards, the use of cost data, the relation of cost to output, and productivity improvement. (A. G. Thompson. Toronto, British Book Service, 1960. 339 p., $15.50.)

***LE BOULONNAGE DES ROCHES EN SOUTERRAIN.**

The "boulonnage" or "bolting" discussed is a new technique for shoring roofs and walls of underground excavations in rock. Long bolts driven into the rock face outwards from the excavation secure flat, metal washers and often a large-mesh heavy metal screen against the rock face. The advantages, methods and materials of this technique are given, with illustrations of applications. The mathematical theory basic to it also is given, permitting assessment of its value in any specific application, and selection of the most effective type of bolt. (A. Hugon and A. Costes. Paris, Editions Eyrolles, 1959. 179p., 3035 fr.)

***TIN AND ITS ALLOYS.**

An organized compilation of eleven chapters by five British experts on the properties and applications of tin and its alloys. Describes the tin industry in general, the versatility, physical and chemical properties of the materials, their chemical behaviour during electro-deposition, hot-tinning and corrosion, and their practical uses. (Ed. by E. S. Hedges. Toronto, Macmillan, 1960. 424p., $21.50.)

***MATHEMATICAL METHODS FOR DIGITAL COMPUTERS.**

The first chapter describes methods of generation of elementary functions on digital computers. The remaining chapters each present a mathematical discussion of a particular method followed by related papers of special interest, all by authors in close contact with latest developments. The areas covered in these chapters are matrices and linear equations; ordinary differential equations; partial differential equations; and statistics. The final chapter contains six papers on miscellaneous methods, including those for numerical and multiple quadrature, and Fourier and network analyses. (Ed. by A. Ralston and H. S. Wilf. New York, Wiley, 1960. 293p., $9.00.)

*FLUID POWER CONTROL.

Following a review of fluid properties and fluid mechanics, the theory and practice of hydraulic control components, emphasizing control valves, is covered in detail. Recent progress with gaseous working fluids, particularly high- pressure pneumatics, is discussed in the final section, including systems analysis and design. Overall emphasis is on conversions, transmission, and control of fluid power under conditions for which gravitational effects are negligible. Topics discussed include flow of fluids through closed circuits, orifices and valves, variable-volume chambers, pumps, motors and accumulators. (Ed. by J. F. Blackburn and others. New York, Wiley, 1960. 710p., $17.50.)

*THE INTERNAL COMBUSTION ENGINE IN THEORY AND PRACTICE, VOLUME 1.

Volume one of this two-volume work is devoted to establishing a rational quantitative basis for design and development, and for analysis of performance. Design information in the form of curves, charts, and tables, is included for solution of practical design problems. Also covered in detail is engine friction, the relation of actual engine to ideal fuel-air cycles, air-capacity and fluid-flow characteristics of four- and two-stroke engines, and the influence of cylinder size on engine characteristics. (C. F. Taylor. New York, Wiley, 1960. 574p., $16.00.)

*INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING, PUBLICATIONS 1959. NINETEENTH VOLUME.

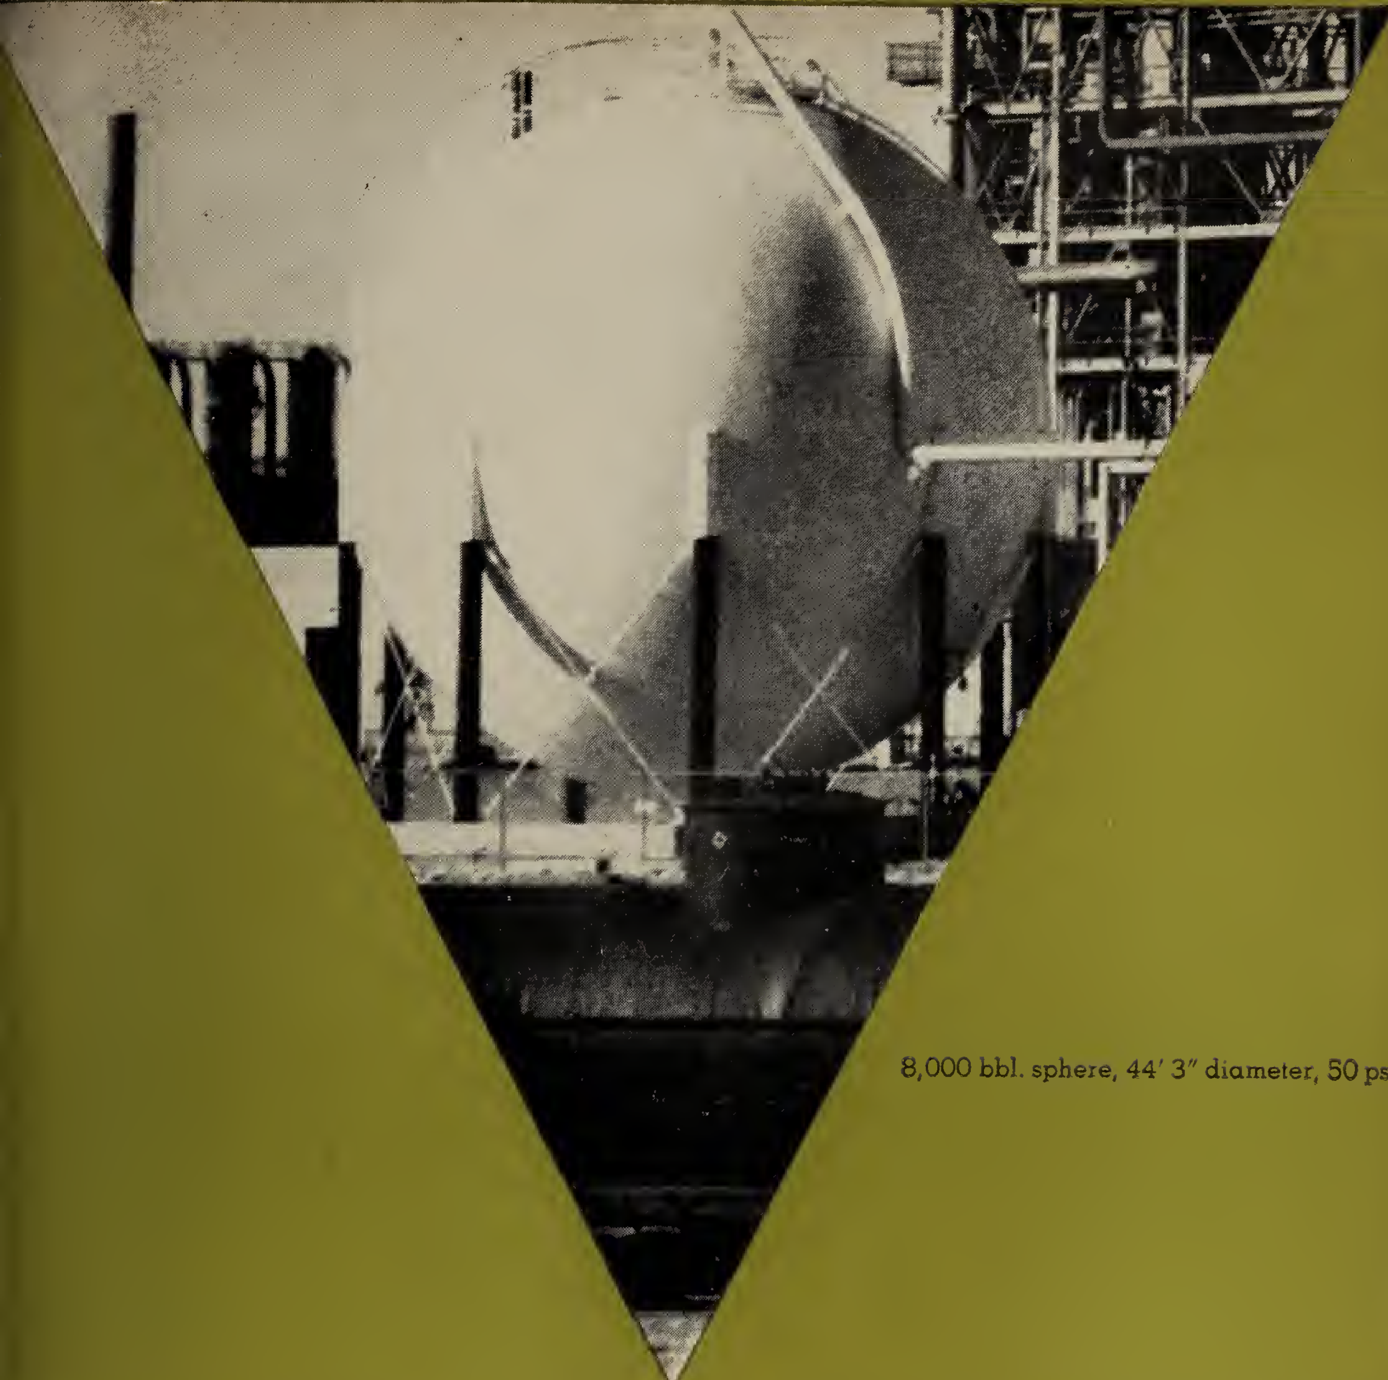
Various aspects of steel and reinforced concrete construction falling within the Association's province are the subjects of these 15 papers: the theory of trusses, of cylindrical shells, and of orthotropic plates; the plastic theory of structures; buckling loads, deformation of ring girders, boundary conditions; analysis of a skew girder bridge, design of frameworks for specific deflections; etc. Most of the papers are in English; the others have English summaries. (Zurich, Leeman, 1959. 296p., Sw. Fr. 40.00.)

*CERTAIN DYNAMIC PROBLEMS OF THE THEORY OF SHELLS.

This translation from the Russian discusses the vibrations, the dynamic stability, and the resistance-to-earthquakes of thin-walled shells, used primarily as roofs and ceilings in industrial and domestic buildings. Included is an explanation of the hypotheses and most important relations of the Vlasov engineering moment theory of shallow shells. (O. D. Oniashvili. West Newton, Massachusetts, M. D. Friedman, 1957. 178p., no price given.)

*ELEKTRISCHE ISOLIERSTOFFE, 2ND. ED.

Describes with scientific accuracy the installation, properties, manufacture and treatment of insulating materials in electrical engineering. Particular emphasis has been put on practical use in constructing machines and equipment, and typical problems are worked out in detail. There are diagrams, drawings and tables and electric stress formulas in an appendix. (A. Imhof. Zurich, Orell Fussli Verlag, 1949. 272p., 18.50 Sw. Fr.)



8,000 bbl. sphere, 44' 3" diameter, 50 psi.

*VENTILATION DES SOUTERRAINS EN CONSTRUCTION.

General material on the characteristics of and conditions in subways under construction, and the overall principles of ventilation are presented, including discussion of fans and vents. Several specific methods of ventilation, based on rigid scientific principles and experimentally proven for a wide variety of tunnel-types are described fully, along with discussion of the materials used, working conditions extant, and the economic aspects of ventilation. (P. Expilly. Paris, Editions Eyrolles, 1960. 274p., 36.55 N.Fr.)

*ARTIFICIAL EARTH SATELLITES.

Translation of information on the results of the Soviet Union's first three earth satellites. Separate papers include the data obtained in orbit, discussing methods of observation, cosmic-ray measurements, upper atmosphere and electron density, orbit parameters and other areas of upper atmosphere research. Volume I includes space biology and data on Laika, the first astronaut. Volume 2 includes discussion of similar investigations carried out with rockets. (Ed. by L. V. Kurnosova. New York, Plenum, 1960. 107p., $9.50. 2 vols. in one.)

*QUANTUM ELECTRONICS.

Advanced papers from seven nations, fully one-third of which deals with masers, their properties, types, and uses such as in amplification, pumping, time standards spectroscopy, and millimeter wave generation. Other topics discussed include relaxation processes and methods, paramagnetism, electro-magnetic amplification, molecular beams, and atomic clocks. (Ed. by C. H. Townes. New York, Columbia University Press, 1960. 606p., $15.00.)

*CHEMICAL ANALYSIS, VOLUME X: THE CHEMICAL ANALYSIS OF AIR POLLUTANTS.

Methods given here for the determination of the kind of air contaminants include general methods for sampling and for determination of volume, quantity and velocity of air and gas; analysis of settled and of suspended particulate matter; and analysis of gaseous and vapor contaminants. Methods also are given for determination of the amount of pollution emitted by any given source, such as chimneys, motor vehicles, and incinerators, and evaluation of effectiveness of abatement devices. The final chapter examines air pollution monitoring devices such as sequence absorbers, multiple gas samplers, and autometers. (M. B. Jacobs. New York, Interscience, 1960. 430p., $13.50.)

*ELECTROPOLISHING, ANODIZING AND ELECTROLYTIC PICKLING OF METALS.

This translation gives an insight into the present state of Russian technology in the metal-finishing field, giving equal emphasis to practice, application and theory, for both ferrous and non-ferrous metals. The section on electropolishing of steels reveals an advanced stage of development and of industrial application. (N. P. Fedot'ev and S. Ya. Grilikhes. Teddington, Middlesex, Eng., Robert Draper, 1959. 285p., $8.40.)

*TELEMETERING SYSTEMS.

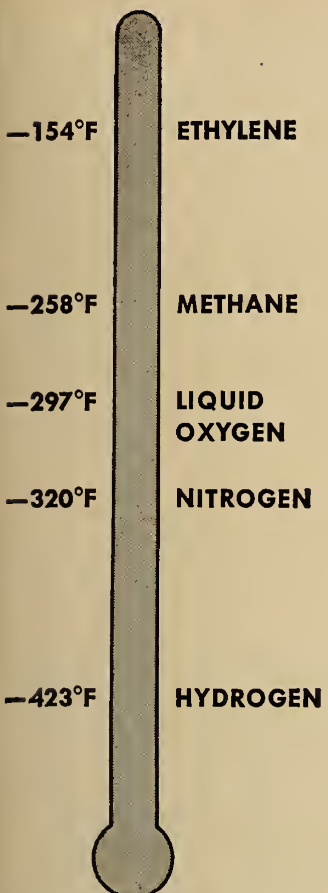
Here are presented the practical aspects and possibilities of both stationary and mobile telemetering. The latter phase, now so important in rocketry, is entirely new to this edition and is based on information in telemetering used by weapon research programs which was hitherto classified. The authors stress the similarities between the two methods of telemetering in order to point out their increasing mutual dependencies in regard to practice and techniques. The types and principles of various systems are explained: current system, voltage system, a-c and d-c position systems, and impulse systems. Pickups and channels are included, as well as the selection, application, coordination, reading, computing, and integrating of the systems. (P. A. Borden and W. J. Mayo-Wells. New York, Reinhold, 1959. 349p., $8.50.)

*BRITISH ELECTRICAL POWER CONVENTION; PROCEEDINGS, ELEVENTH, 1959.

The five long papers included in these proceedings deal with the design and growth of four British nuclear power stations, the public electricity supply and its place in the British community, the scope of installation engineering, the National Inspection Council for Electrical Installation Contracting, and the technological development in lamps and lighting. (London, The Convention, 1960. 472p., no price given.)

For safety and economy in LOW TEMPERATURE STORAGE

HORTON CRYOGENIC VESSELS



In the chemical process, steel and gas utility industries, the problem of storing low boiling point materials is best handled with CRYOGENIC STORAGE. Cryogenic storage vessels are actually vessels within vessels which minimize heat transfer to the inner sphere with powdered insulation placed between the inner and outer shell. Large savings result through economy in storage space.

Cryogenic storage calls for vessels of special design — and quality steel plate fabrication, metallurgical testing and control facilities. For nearly 50 years, Horton's quality code of workmanship and experience in engineering, fabricating and erecting special storage structures assures dependable cryogenic construction — to the most rigid code or customer specifications. Write today for complete details.

HORTON DESIGNS IN CRYOGENIC VESSELS VARY TO MEET SPECIFIC NEEDS. LET US RECOMMEND A TYPE TO SOLVE YOUR PROBLEM.

• LIBRARY NOTES

***ELECTRONIC COMPUTERS, 2ND. ED.**

A British book also published in the United States, this book gives a non-mathematical general introduction to the principles and applications of computers employing tubes, transistors and other electronic devices. Almost entirely re-written with new diagrams and equipment photographs, this edition includes new chapters dealing with analog computer circuits, the programming of digital computers, and the evolution of the "intelligent" machines of the future. (T. E. Ivall. New York, Philosophical, 1960. 263p., $6.00.)

***ANALOG COMPUTATION.**

This college-level text does not require a specialized electronics background. Its general purpose is an appreciation of systems analysis, and the value of analog computation in comparison with analytical and numerical procedures. The subjects covered are: basic analog computer concepts, elements and components available, design philosophy and operating characteristics; magnitude and time scaling; solution of statistical problems and mathematical models; simulation of system adjoints; operational amplifier design problems; and detailed examples and representative applications, including combined digital analog computations. (A. S. Jackson. Toronto, McGraw-Hill, 1960. 652p., $15.55.)

***TREATISE ON THE LAW OF SURVEYING AND BOUNDARIES, 3RD. ED.**

While much of the information on surveying and boundaries in the previous edition of Clark is still applicable, changes and additional statutes and court decisions have made a new edition necessary. The chapters on public land surveys, the restoration of lost or obliterated corners, and government rules for lots and subdivisions have been considerably revised. The tracking of surveys; reading instruments of conveyance; boundaries and rights concerned with highways, lakes, streams, and rivers; pertinent state laws and court decisions, and the Canadian rectangular system of determination are other important topics covered. Footnotes referring to court decisions have been practically eliminated from this edition to save space. (F. E. Clark. 3rd. ed. by J. S. Grimes. Indiana, Bobbs-Merrill, 1959. 1031p., $12.50.)

***ELECTRONIC ENGINEER'S REFERENCE BOOK, 2ND. ED.**

This revision comes close on the heels of the first edition, published in 1958, but it has been revised and has 350 additional pages. Included are new sections on nondestructive testing, components, radiation detection, digital computer applications, simulators and electronic telephone exchanges. (Ed. by L. E. C. Hughes. Galt, Brett-Macmillan, 1959. 1588p., $18.00.)

NOTE: During the Summer months, Library hours are Monday to Friday, 2 p.m. to 5 p.m. only.

C22.2 No. 18-1960: Construction and test of outlet boxes, conduit boxes, and fittings. (Third edition) $1.50.

C22.2 No. 21-1960: Construction and test of cord sets and power-supply cords. (Fourth edition) $1.00.

C22.2 No. 75-1960: Construction and test of thermoplastic-insulated wires and cables. (Fifth edition) $1.50.

C22.2 No. 117-1960: Construction and test of room air conditioners. $1.50.

• LIBRARY NOTES

°PLASMA PHYSICS.

A graduate-level summary of current plasma physics. The behavior of plasmas is described first by the analysis of a single particle and then using the fluid model. These two models of description are then applied to plasma processes such as equilibrium configurations, wave-motion, instabilities and shocks, motion of plasma bunches, and the various collision, diffusion, and radiation processes operative in arriving at equilibrium. Finally, some of the applications of plasma physics to the research on the controlled fusion of light nuclei, to electronics, and to other problems in applied physics and engineering are described. (J. G. Linhart, New York, Interscience, 1960. 278p., $7.00.)

°MONORAILS.

This brief survey of monorail transportation opens with an historical account, and then discusses types of monorails, cars, track, structures, location and construction, operating characteristics, wayside equipment, and the economics of this means of transportation. There are very useful appendices, including chronological lists of constructed and proposed monorail systems, a tabulation of the dimensions and other characteristics of cars in use, diagrams of rail cross-section and rail supports, and an extensive biography. (H. S. D. Botzow, Jr. New York, Simmons-Boardman, 1960. 104p., $3.95.)

°RESIDENTIAL CONSTRUCTION MANAGEMENT.

The dramatic changes taking place in residential construction as it evolves from a trade to an industry present a range of management and construction problems. The structure of organization follows a statistical background and projection; the author then examines methods of preparing land for construction, development of land, plans, specifications, estimates and budgets. Construction scheduling is examined, with one system described in detail, and with emphasis on work control. Other chapters deal with subcontracts, material control, sales, and cost accounting, discussing general concepts together with suggestions for specific procedures. (E. L. Buckley. New York, Wiley, 1959. 193p., $7.95.)

°THEORIE DER ELASTISCHEN VERFORMUNG.

The elastic deformation of basic structural elements is thoroughly analyzed from the mathematical point of view. Section I covers the general development of elastomechanics-distortion and stresses and the relation between them, energy of deformation, etc. Section II presents analyses of some nine different types of problems dealing with torsion and bending of rods and plates, shell theory, elastic stability, vibration problems, and wave phenomena. (W. Muller. Leipzig, Germany, Akademische Verlagsgesellschaft, 1959. 327p., 31.50 DM.)

°RADIATION PYROMETRY AND ITS UNDERLYING PRINCIPLES OF RADIANT HEAT TRANSFER.

The first three chapters discuss the principles of the emission, absorption, reflection, and transmission of thermal radiation, excluding aspects not particularly applicable in pyrometry. The characteristics of high and low temperature radiation pyrometers then are dealt with, including calibration, lenses, mirror design, field of view, and ambient temperature variation effects and compensations. The application of emittance corrections then are described, and the final chapter contains tables, such as of relevant mathematical relationships, calibrations, optical characteristics of some substances, and radiation functions. (T. R. Harrison. New York, Wiley, 1960. 234p., $12.00.)

°REPORT ON MARINE ATMOSPHERE EXPOSURE OF GALVANIC COUPLES INVOLVING MAGNESIUM.

This publication reports the results of exposure tests of protective systems for magnesium, including chromate conversion, anodic coatings, and paint systems of chromate prime and alkyd, phenolic, and epoxy resins. (A. Galleccio and I. Cornet. Philadelphia, American Society for Testing Materials, 1959. 26p., $2.25. s.t.p. no. 255.)

PRODUCT DESIGNERS

Interesting positions are now available in our product development Engineering Group. These positions, located in Toronto, involve the design and development of new products in the Plumbing and Heating field.

We are a large, multi-plant manufacturing firm making boilers, furnaces and plumbing ware. University Graduates in Engineering or equivalent with 1 to 3 years experience preferably familiar with plumbing and heating products, are required. Good starting salary and many employee welfare benefits. Reply in confidence, enclosing resume, to File No. 7060-V.

nical institute in the field of mining and civil engineering. All further details may be obtained by contacting directly, Bureau of Personnel, UNESCO, Place de Fontenoy, Paris 7, France, or by applying to File No. 7091-V.

SALES ENGINEERS required by a leading member of the compressed gas industry. Applicants should have graduated 5 to 10 years ago, preferably in Chemical, Electrical, Metallurgical or Mechanical engineering. Subsequent experience in the welding industry or in metal fabrication desirable. These are challenging positions in our Head Office, Montreal. Replies will be kept in strict confidence. A resume stating business experience, education, salary requirements, etc., should be sent to File No. 7092-V.

SALES ENGINEER as Montreal Branch Manager, handling air and dust filtering and other industrial equipment. Bilingual preferred. Three to five years' sales experience. Salary plus commission. Interviews Montreal and Toronto. File No. 7094-V.

SALES ENGINEERS, three recent graduates, mechanical, electrical or chemical required by leading manufacturer of air conditioning and ventilating equipment, shell and tube heat exchangers and related engineered products. Following completion of Company training course successful applicants will be assigned to Hamilton and Montreal Branch Sales Offices. Attractive starting salary and wide range of Company welfare benefits. Send complete resume and salary requirements. File No. 6923-V.

ELECTRICAL ENGINEER

The CITY OF REGINA has an opening for a Graduate Electrical Engineer with one or two years' experience, preferably in the Light and Power field. Salary Range: $5,040 to $6,432 per annum, commensurate with qualifications of successful applicant.

Applications and enquiries should be directed to the PERSONNEL DEPARTMENT, CITY HALL, REGINA, SASK.

ENGINEERING SALES

Positions open in a rapidly growing company for high calibre sales representatives.
A degree in Engineering or Science, preferably emphasizing Chemistry and obtained since 1955, is desirable. Relocation and travelling required.
Remuneration above average and advancement possibilities good.
Kindly apply in writing, outlining academic qualifications, experience and interview availability.

ALCHEM LIMITED
Burlington, Ontario
Offices from coast to coast

Water Conditioning Chemicals & Services • Coagulants • Petroleum Chemicals • Corrosion Inhibitors • Antifoams • Microbiocides.

OPPORTUNITY FOR

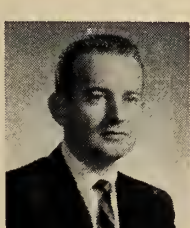
CHIEF ELECTRICAL ENGINEER

Electrical engineer required with wide experience in electrical design of hydro-electric stations and transmission lines, to take charge of electrical design department. Ability to organize an effective engineering team is important. Reply to:

SANDWELL INTERNATIONAL LIMITED
1512 ALBERNI STREET, VANCOUVER, B.C., CANADA

• MORE PERSONALS

W. James Bichan, M.E.I.C. (Royal School of Mines '32), Vice-President, Mining and Geological Divisions of Beaco Ltd., has been in the West Indies for Canadian Engineering (International) Ltd. as technical adviser to the Government of Trinidad and Tobago.

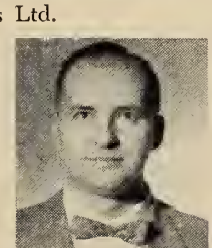


W. D. West, JR.E.I.C.

W. D. West, JR.E.I.C. (Queen's '55) has been appointed Technical Representative, special accounts, for the Marketing Division of the RCA Victor Company Ltd., Montreal.

D. F. Coates, M.E.I.C.

D. F. Coates, M.E.I.C. (McGill '48), consulting civil engineer, has been appointed a director of W. S. Atkins and Associates Ltd.



J. B. Herbich, M.E.I.C.

John B. Herbich, M.E.I.C. (Edinburgh '49) has been promoted to the rank of Associate Professor in the Department of Civil Engineering, Fritz Engineering Laboratory, Lehigh University, Bethlehem, Pennsylvania.

Murray Zides, M.E.I.C. (New Brunswick '44), Director of the Town Planning Commission of Metropolitan Saint John, was recently elected to the presidency of the Town Planning Institute of Canada.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Address all information to: *The Engineering Journal,* Editorial, 2050 Mansfield Street, Montreal, Que.

Business and Industrial Briefs

Appointments and Transfers

F. Gordon Holroyd has been appointed Operations Manager of Macdonald & Macdonald Ltd., Inspection and Testing Engineers.

James Warren Quarles has been named Technical Sales Representative to the Eastern Sales District of Carbide Chemicals Company, Division of Union Carbide Canada Limited. He will be handling the sales of "Union Carbide" Brand polyethylene resins and compounds.

The appointment of **R. J. Norton** as Ontario Regional Manager, Technical Products Marketing Division, RCA Victor Company, Ltd., has been announced.

L. Grant Bragg has been appointed Manager of the Toronto office of Research-Cottrell (Canada) Ltd., manufacturers and distributors of industrial gas cleaning equipment.

H. J. Cameron has been appointed Product Manager, Pipe Department, of Atlas Asbestos Co. Ltd., Montreal. He will be responsible for merchandising "Turnall" Asbestos-Cement Pressure and Sewer Pipes throughout Canada.

Paul N. Heald has been appointed Manager, manufacturing operations, of Shell Oil Company of Canada, Limited, and will make his headquarters at the head office in Toronto.

Douglas Lee has been made Manager of the Canadian Westinghouse power transformer and circuit breaker division, Hamilton.

C. Wondolowski has been appointed Works Manager of the Toronto Eastern Avenue Plant of Canadian Iron Foundries, Limited. **Arnold Henry** is the new Works Manager of the St. Thomas Plant.

W. H. Irwin, vice-president of the Canada Metal Co. Ltd., was recently elected a director of the Canadian Copper & Brass Development Association.

Establishment of Washington representation for the Aeronautical Group of companies of A. V. Roe Canada Limited has been announced. **John R. Douglas**, formerly the Canadian Government's Washington Representative for the Department of Defense Production, has been appointed to administer the new office.

Patrick E. Cavanagh has been appointed President and a director of Premium Iron Ores Limited, Montreal. The company is engaged in studies of an iron ore reduction plant to produce metallic iron at the Lakehead with natural gas.

CANADIAN PERSONNEL and equipment will be at work on a project in the United States for the U.S. Atomic Energy Commission. The American subsidiary of the Cementation Company (Canada) Limited. has been awarded a $765,000 contract by the Commission foı shaft-sinking and tunnelling in connection with an atomic explosion designed to further the peaceful uses of nuclear energy. The explosion is expected to create an underground storehouse of heat from which energy will be derived. T. H. Blair, executive vice-president of both the Canadian company and the U.S. subsidiary, said his firm had won out over eight others because of its experience in dealing with water-bearing strata which are anticipated in the first section of the shaft sinking. Personnel of the Canadian firm are already at work in uranium deposits at Grants, New Mexico, and in a salt mine at Cleveland, Ohio.

A MEMORY UNIT of the magnetic core type used in high speed electronic computors has been installed at the University of Houston as an experimentation and training aid in computor technology. Presented by Telemeter Magnetics, Inc., and valued at nearly $10,000, the unit has 24 core arrays, each with over 4,000 cores, and provides storage for 100,000 information items. It is wired to provide for writing and reading information into and out of the unit at rates up to 125,000 operations per second.

New Developments

THE DEEP-PLEAT design of Farr's new HP series of folding, disposable media filters provides larger media area in a compact, preformed, folding filter cartridge. The new filters were especially developed to operate at the lowest pressure drop without loss of efficiency or dirt holding capacity, and are designed for any commercial or industrial ventilating or air conditioning system requiring high efficiency air filtration with low maintenance costs.

CORKTITE, normally an underfloor insulation and cushion where concrete is placed directly on the ground has been employed as an insulating material for a stainless steel curtain wall in Toronto's new Union Carbide building. The architects had specified insulation between interior structural steel mullions and the extruded aluminum exterior mullion, to ensure a positive thermal barrier by isolating the interior and exterior metals.

MINIATURE SOLDERING INSTRUMENTS are the business of Len Finkler Ltd. of Toronto. A new addition to their Oryx line is claimed to be the smallest 115V iron in the world. It comes in two models — the 115-10 which heats to 672°F. in 70 seconds with a 3/32 in. tip and 115-15 w. which heats to 717°F. in 50 seconds with a 7/32 in. tip. No transformer is required.

A SINGLE ELECTRON is now made visible by means of a small electronic tube with a light-sensitive screen at its input end. Individual particles of light, photons, are directed onto this screen, strike its surface and eject electrons from it. Each ejected electron is accelerated forward by 2000 volts and strikes head-on into a thin two-layer film, penetrating its insulator layer and releasing four or five additional electrons. The resulting electrons are aimed at a thin layer of fluorescent material at the output end of the tube. Thus the light striking the input photosurface is reproduced thousands of times brighter at the output end. The tube, designated as the Astracon, is a Canadian Westinghouse product.

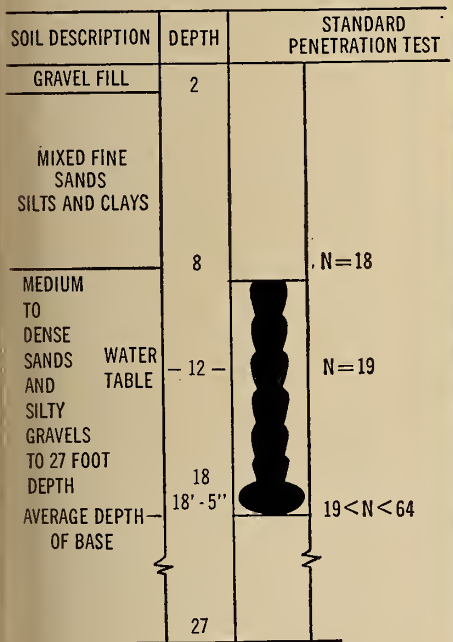
Franki caissons provide uniform bearing in erratic melt water deposits

TYPICAL BORING LOG



NOTE: 19<N<64 means "N" is more than 19 and less than 64

Problem

The site of the new BIG FOUR BUILDING at the Calgary Exhibition and Stampede Grounds lies in an old glacial melt water channel where the soil profile shows considerable variation in horizontal stratification normally found with river deposition. Test holes indicated a wide range in density in the interbedded layers of water bearing gravels, sands, silts and clays with no correlation between the test holes. This two story structure, designed to accommodate 48 sheets of curling ice, could not tolerate even the smallest differential settlement. Column loads up to 210 tons had to be transferred to a suitable bearing deposit.

Solution

Franki Caissons were chosen to support the structure as the Franki method alone can provide uniform bearing at a given depth in granular soils, regardless of the relative density of the deposit in which the base is made. This bearing is guaranteed by measuring the amount of energy expended in ramming into a bearing deposit, 5 cu. ft. batches of zero slump concrete. Concrete charges of this volume are added until 20 blows of 140,000 ft. lbs. are attained to expel the last 5 cu. ft. This criteria provides 120 ton bearing capacity.

Compaction of the granular deposits, which varied widely in density, provided even bearing throughout the site at medium depths, thereby affording the owner a safe economic foundation.

Literature-This series of job highlights, as well as other descriptive literature, will be sent to you upon request to Franki of Canada Ltd., 187 Graham Blvd., Montreal 16, P.Q.

SPRAY METHOD ROOFING of flat and free-form surfaces was publicly demonstrated for the first time recently by The Flintkote Company at its research laboratory in Whippany, N.J. The Sealzit Spray Gun jet installs roofing in a single operation rather than by the ordinary method of building up layers of roofing. A three-man crew using the gun can install between 15,000 and 18,000 sq. ft. of material a day.

BULLETIN 175, just published by Clark Bros. Co., N.Y., one of the Dresser Industries, introduces the "Isotemp" Packaged Centrifugal Air Compressor line for air separation plants and industrial use. These compressors are built in six frame sizes with horsepowers ranging from 1000 to 8000 and capacities from 5000 to 38,000 cfm.

COMPONENT MINIATURIZATION has shown new possibilities in a compact servo amplifier produced by Lear Incorporated, Grand Rapids, Michigan, which can perform reliably under severe environmental conditions. The module, contained in a package with a total volume of less than a cubic inch, is being used at Lear for positioning gimbals, gyros, platforms, and compass systems.

THE SWITCHING SURGES and high reverse voltage stresses previously met in T.V. H.T. circuits have been overcome by a new 1000 volt-tested SIMET Silicon Rectifier put out by The Plessey Company Ltd., England. The 1000 volt test gives almost 50% over-voltage protection against the normal 700 P.I.V. maximum obtained in a television receiver on 250 V. AC mains.

A LOW-BED TRAILER for heavy duty work is announced by LaCrosse Trailer Corporation, LaCrosse, Wisconsin. The three-axle trailer is of single point suspension design. LaCrosse's thru axle tandem assembly is coupled to the third axle by a walking beam and two-way oscillation provides uniform distribution of weight even when single wheels are raised or lowered by uneven ground.

A CHIMNEY 490 ft. high is rising on the lakefront just west of Metropolitan Toronto. The first of three such chimneys, it marks Ontario Hydro's coal-fired Lakeview generating station, the largest thermal-electric power project in the world. Each stack will effectively disperse combustion gases from two of the plant's generating units. The $250,000,000 station will be operating in 1960 with an expected capacity of 1,800,000 kw. from six units.

LOW TEMPERATURE IMPACT upon four nickel steels is outlined in a 32-page booklet distributed by The International Nickel Company of Canada, Limited. It points out that since nickel in normalized steels effectively lowers the impact transition temperature, these steels are ideally suited for handling liquified gases at low temperatures.

ELASTOMERIC ROOFS, their coatings made from neoprene and synthetic rubber, have recently been introduced into Canada by Dupont of Canada Limited. They have demonstrated exceptional resistance to weather, abrasion, chemicals, ozone and the ultra violet rays of the sun. Applied in fluid form, these roofs lend themselves to the unusual geometric forms of modern building. They are non-inflammable.

GROUT FAILURE is most frequently caused by shrinkage. The Master Builders Company has published a 16-page booklet on grouting techniques with *Ebeco* non-shrink grout — common methods of grouting different types of equipment, the mixing and placing of grout, and cold and hot weather grouting. Bulletin E-1d can be obtained from: The Master Builders Company, Ltd., Toronto 15, Ontario.

EXPANDING motor control facilities are being made available at Canadian Allis-Chalmers' St. Thomas, Ontario plant with the completion of the new $100,000 addition. A line of 0 to 4 low voltage motor control will be manufactured there and distributed by Canmark Services Limited. Unitized construction in the new line of contactors allows building-block modification, and standard, special design, and accessory control devices are available for application from 110 to 600 volts for fractional to 200 hp. motors.

FLOODLIGHTING is the subject of a recent 61-page Canadian General Electric catalogue. PAR, general purpose heavy duty, underwater, fluorescent and mercury floodlights are described in this book, as well as mercury ballasts and mercury lamps. One section deals with calculating lighting requirements and laying out good lighting installations. Catalogue No. FL-60 can be procured from: Lighting Equipment Sales, Canadian General Electric Company Limited, 830 Lansdowne Avenue, Toronto 4, Ontario.

CONTROL REQUIREMENTS of hydraulic machinery may be met by a new solenoid operated 4-way directional control valve which is being produced by Vickers Incorporated, Detroit, Michigan, Division of Sperry Rand Corporation. Furnished with ⅜ in. ports (or ½ in. to take advantage of larger flows), the valve has a nominal rating of 8 gpm and can handle flows up to 12 gpm. It is rated for 115 volt, 50 or 60 cycle a-c service.

A PNEUMATIC CONTROLLER regulates the new Wallace and Tiernan metering pump. In response to an air signal from a W&T Merchen gravimeter feeder caused by varying the flow rate of dry solids through the feeder, the controller will automatically adjust the pump's stroke length to give varying rates of flow of the metered liquid. It bolts onto any run-adjust model of W&T Series 200, 400 or 600 pump, in place of the normal adjusting handle, and makes the process entirely automatic.

A NEW REFINERY at Rimbey, Alberta is to be equipped with 18 industrial steam turbines from Canadian Westinghouse, including the two largest compressor-drive turbines ever built in Canada for this type of application — rated 2500 hp. at 7500 rpm. Also among the 18 units are three 1250 kw. turbine-generators. The plant, owned by 25 companies, will process up to 326 million cu. ft. of gas daily from the Homeglen-Rimbey and Dick Lake fields.

AN INERTIAL DAMPER that can be coupled to the mating servo motor in a matter of seconds is being produced by the Industrial Control Company, Inc. The motor's mounting register fits into the rear of the damper and its pinion drives the damper element. The 1D-15-100 can be used without mechanical changes in an existing gear train to raise the loop performance above that possible with a simple motor.

A FLOATING COVER for sewage digesters, composed of rectangular steel plates field-welded into a single deck without trusses, is being put out by Infilco Inc., manufacturers of water, sewage and waste treating equipment. The steel plates are ¼ in. thick, while insulation is of 1½ in. thick fibreglass material. A weighted pontoon around the periphery gives torsion, bending and compression.

A BALLOON-PARACHUTE system has been developed by Goodyear Aircraft Corporation for the Air Research and Development Command's Wright Air Development Division. The spherical drag balloons are to be used to retard tumbling and to control speed of instrumented nose cones, manned escape capsules and other orbital vehicles during re-entry through the heat barrier of the earth's upper atmosphere.

ELECTRONIC COOLING is achieved by a new refrigeration unit which has been produced by The Garrett Corporation's AIResearch Manufacturing Division at Los Angeles. The Peltier cooling device dissipates 65.3 watts of heat to ambient air at 140°F. at sea level, maintaining temperatures below 110°F. Heat generated by gyro servo components is transferred via internal air and conduction to a stable platform aluminum housing from which it is drawn out by thermoelectric couples and vented overboard through a plate and fin heat exchanger.

A CAM PROGRAMMER coordinates the operations of the new high temperature furnace being produced by The Electric Hotpack Company, Inc., Philadelphia. High retention insulation keeps thermal levels even, and a high velocity blower and counter-weighted exhaust stack facilitate rapid evacuation of heat from the chamber during cooling cycles. Both the wattage selector switch and timer and the blower switch are synchronized to the programmer for automatic cooling cycles.

RECLAIMING CRANKSHAFTS — grinding, shot peening, chrome plating and balancing extra large shafts of the size used in diesel engines and big compressors — are all operations of the new facilities at Montreal Locomotive Works, Limited. A huge crankshaft grinder equipped with automatic load compensators, weighing over 15 tons, is one of the new pieces of equipment at the Longue Pointe plant.

A CIRCUIT BREAKER, half the size of previous breakers, has been announced by Eastern Power Devices Limited, Toronto. The new moulded case circuit breaker, designated FJ-frame, provides the ratings and features of the J-frame, but is 4½ in. x 10 in. while the J-frame is 9" x 11". It is available in two- and three-pole construction in current ratings of 70 to 225 amperes, 600 volts a-c and 250 volts d-c.

SATIN FINISHES in the metal industries can be achieved with no special equipment or compounds with a finishing material produced by Minnesota Mining and Manufacturing of Canada Limited. This "Scotch-Brite Brand" finishing material is made of non-woven nylon web ¼ in. thick impregnated with fine abrasive grains.

A NON-HARDENING glazing compound, "Speedglaze", has been developed by Stelco. Tested under radiation conditions approximating noon June sunlight with periodic spraying of water at controlled temperature and pressure, the new product has proved its ability to resist long periods of outdoor exposure. It adheres well to metal or wood and will resist wrinkling and cracking.

THE GENERAL OFFICES of the Linde Gases Division of Union Carbide Canada Limited are now situated in the Union Carbide Building, 123 Eglinton Avenue East, Toronto 12.

A CANADIAN COMPANY, Multitone of Canada Limited, supplied a unique pocket paging system for use at the Democratic National Convention in Los Angeles. Delegates, officials and TV network and news service personnel were provided with tiny pocket receivers enabling them to be called at any point in the proceedings regardless of their location. A closed radio circuit with a central transmitter and as many receivers as needed (each on its own separate wave length), the Multitone Personal Call System has already been installed widely in hospitals and factories.

A CHANGE of name has been effected in F.S.B. Heward & Company Ltd., 3285 Cavendish Boulevard, Montreal 28, and the company is now Canapower Thermal Specialties Ltd. It continues to represent leading manufacturers for the sale, service, installation and operation of steam plant, industrial and marine equipment.

WANTED

July 1960 issue of

THE ENGINEERING JOURNAL

The Engineering Institute has received so many requests for additional copies of the July issue of The Engineering Journal that the available supply has been exhausted.

It will be greatly appreciated if readers who do not keep their copies on permanent file, will return them to the editorial office at 900 Sherbrooke Street West, Montreal 2, Que.

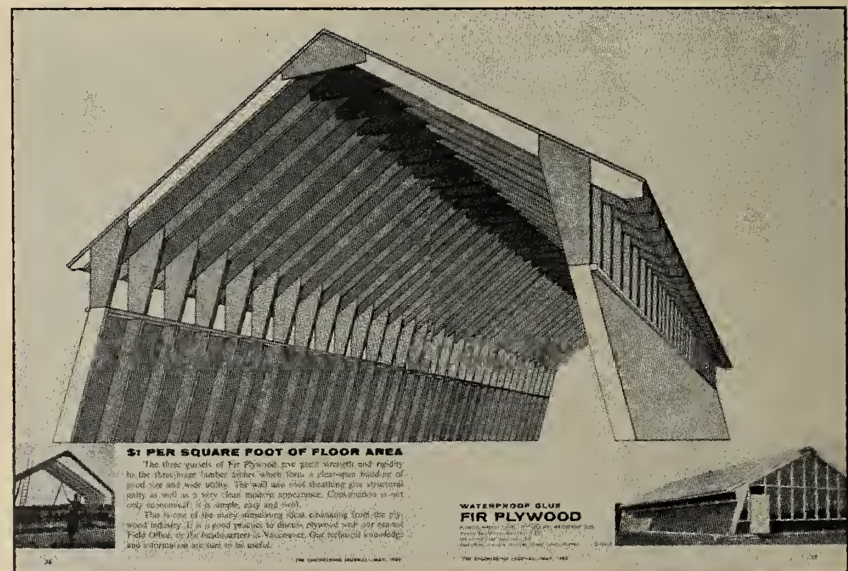
E.I.C. CERTIFICATE OF ADVERTISING MERIT

PLYWOOD MANUFACTURERS ASSOCIATION OF BRITISH COLUMBIA WINS CERTIFICATE

A two page, two color, advertisement prepared by the Vancouver office of McConnell, Eastman & Co. Ltd. for the Plywood Manufacturers Association of British Columbia was judged the "best" in the May issue by a jury of fifty readers. Judging was based on ACCURACY–INFORMATION and ATTRACTION and the jurors represented every province of Canada.

The advertisement presents a striking two color line drawing and is headed: "$ PER SQUARE FOOT OF FLOOR AREA". The copy describes the type of construction illustrated in the advertisement. The advertiser will be pleased to send readers of the "Journal" copies of literature illustrating and describing the various uses of plywood for engineering work.

The Advertising & Publicity Manager of the Company is Mr. C. J. Hempsall and the Advertising Agency who placed the winning advertisement is McConnell, Eastman & Co. Ltd., Vancouver, B.C. — Mr. Clarke Wallace, Vice-President.



Reproduced above, on a greatly reduced scale, is the two page, two color advertisement of the Plywood Manufacturers Association of British Columbia which was judged the "best" in the May issue. It appeared as pages 36 & 37 of the issue.

● MORE BRIEFS

A TRANSISTORIZED SHIRT-POCKET RECEIVER applicable to any situation where instantaneous verbal contact is required—general manufacturing, agriculture, construction and mining, to take but a few examples—is being produced by Canadian General Electric. The person wearing the 12-ounce receiver can be contacted instantly by a base station transmitter, a two-way radio car or by a portable unit, all operating at the same frequency.

EXPLORATION AND SURVEY FLYING will be performed across Canada by the new company Survair Limited, with home base at Uplands Airport, Ottawa. Their S-55 Sikorsky helicopter, two Piper Apaches, and a Cessna 182, equipped with the newest Swiss mapping cameras and airborne geophysical instruments, will do the job.

CONTINUOUS BRIGHT ANNEALING of stainless steel strip is made possible by the new high-production furnace produced by Canadian General Electric. A cost-lowering is promised by improved surface appearance, corrosion resistance and physical properties of the annealed strip. Through utilization of very pure and dry hydrogen or dissociated ammonia atmosphere, the bright annealing furnace prevents the formation of scale on the strip.

MATERIAL PREPARATION OPERATIONS and warehouse functions will be carried out by the new addition to the St. Thomas, Ontario Works of Canadian Allis-Chalmers completed in June. A new line of low voltage motor control will be processed there, motor and switchgear assembly facilities will be expanded and the present lines manufactured by the St. Thomas plant will be increased.

AN OPEN STEEL PLANK which will combine with Dexion angles to provide strong, load-bearing floors, ramps, catwalks, stair-treads, mezzanines and platforms is the newest product to be added to the Dexion (Canada) Ltd. slotted angle construction system. Available in 4′6″ or 6′ lengths, each unit is 9″ wide, pressed from a single slab of 16-gauge mild steel.

THE INSTRUCTIONAL SERVO SYSTEM manufactured by Feedback Ltd. of Servomex Controls Ltd. is being used in many universities and technical schools in the U.K. to demonstrate control system theory. The Servo Control Unit and Servo Assembly can be used directly to work out important aspects of basic theory and, with additional test equipment, can take detailed measurements on frequency response and transient response in both openloop and closed-loop conditions.

A CURLING AGENT and seal for concrete floors, eliminating constant wetting down of concrete during the curing stage, is being produced by The Tremco Manufacturing Company, Cleveland and Toronto. In one application this new product gives a high degree of water retention in the concrete while the proper cure takes place. The agent, "Tremcrete", permits application of paint, linoleum, asphalt tile and other materials. It dries to tack-free stage in two to three hours.

A MORE POWERFUL VERSION of the Bristol Siddeley Olympus turbojet, the standard engine for the RAF's Vulcan V-bomber, has been announced by the company. The engine has a thrust without reheat of 20,000 lbs. and is the most powerful British military aircraft engine in existence today. Developed from the earlier 17,000 lb. Olympus 201, this latest engine has an extra stage on the front of the low pressure compressor and a shorter air intake.

THE CREOSOTE INFORMATION BULLETIN prepared monthly discusses the nature and application of the wood preservative Creosote, a product of the Coal Tar Products Division, Dominion Tar & Chemical Company, Limited. More than 100 chemicals toxic to fungi are combined in Creosote; thus although living matter in time becomes immune to the harmful effects of a single chemical, it is unlikely that fungi could overcome the multiplicity of toxic ingredients.

EPOXY COATING has been used on the 42-inch-diameter steel pipes being laid for the fast growing community atop Hamilton, Ontario's mountain. The pipes, forming a water main which runs some 900 ft. horizontally into the face of the mountain and approximately 200 ft. vertically to the summit, are prepaired for coating by a fine sand blast and kept at a temperature not less than 50 degrees F. for application of the resin paint. Sparling Tank & Manufacturing Co., New Toronto, supplied the pipe and did the inside and outside welds.

NEW MANUFACTURING FACILITIES for cylinders have been established by Vickers Incorporated, Division of Sperry Rand Corporation, in Waterbury, Connecticut. Designed for manufacturing standard hydraulic cylinders for the industrial and marine and ordnance fields, the new plant includes complete engineering, manufacturing, processing, raw stores, and warehousing facilities.

A LIFE SCIENCES DIVISION has been added to the facilities of Arthur D. Little, Inc., large private industrial research company with headquarters in Cambridge, Mass. Under the direction of Dr. Charles J. Kensler, the new division will investigate uses of biology in industrial processes and in evaluating effects on man and animals of industrial products.

STEEL RINGS are being used rather than conventional cast-iron tunnel supports in construction of the Callahan Tunnel under Boston Harbour. Use of the rings was made practicable by applying a protective coating of Bitumastic 70-B coal-tar enamel, developed by Koppers Company, Inc., to the eleven steel plates which make up a ring section.

Meet the Authors

Arthur Porter, M.E.I.C., M.Sc. (Manchester '34), Ph.D., Dean of Engineering, The University of Saskatchewan, Saskatoon *(The Principles of Automatic Control).*

Dean Porter was an assistant lecturer in physics at the University of Manchester, England prior to attending M.I.T. as a Commonwealth Fellow in 1937. He was subsequently employed by the British Admiralty Research Laboratories, and then the Ministry of Supply. In 1946 Dean Porter joined the Royal Military College of Science, Shrivenham, England as Professor of Instrument Technology, and in 1949 he came to Toronto as head of the Research Division of Ferranti Electric. He later joined the staff of the Imperial College of Science & Technology and in 1958, the University of Saskatchewan.

Harold P. Klassen, M.E.I.C., B.Sc. Civil (Saskatchewan '49), Chief Municipal Engineer, Underwood McLellan & Associates Limited, Saskatoon *(Water Supply and Sewerage at Uranium City).*

After graduation Mr. Klassen joined his present firm as field engineer in charge of construction of utilities for the R.C.A.F. Station, Rivers, Manitoba. He later became an associate member of Underwood McLellan and Associates Ltd. and was appointed to their board of directors in 1959. Mr. Klassen is a member of the Association of Professional Engineers both in Manitoba and Saskatchewan.

John Convey, B.Sc. (Alberta) M.Sc., Ph.D., Director, Mines Branch, Department of Mines and Technical Surveys, Ottawa *(Mineral Resource Development in North and West).*

Dr. Convey served with the Scientific Research Department of the Royal Navy and spent six years in Sheffield laboratories in charge of metal physics. He returned to Canada in 1946 as associate professor at the University of Toronto. Two years later Dr. Convey joined the Mines Branch staff as Chief of the Physical Metallurgy Division. He has been the recipient of the C.I.M. Blaylock Medal for contributions in the development of atomic energy in Canada.

J. D. Mollard, M.E.I.C., B.Sc. Civil (Saskatchewan '45), M.Sc., Ph.D., President, J. D. Mollard and Associates Limited, Regina. **H. E. Dishaw,** M.E.I.C., B.Sc. Civil (Saskatchewan '51), Consulting Engineer, J. D. Mollard and Associates Limited, Regina *(Airphoto Interpretation in Municipal Engineering).*

Before setting up his own consulting practice Dr. Mollard was with the Saskatchewan Department of Highways as resident engineer and with the Prairie Farm Rehabilitation Association as air surveys engineer. He is a former councillor of the Association of Professional Engineers of Saskatchewan.

Until 1956 Mr. Dishaw was soils engineer and special projects engineer of the Materials Branch, Saskatchewan Department of Highways. He now specializes in airphoto interpretation as applied to preliminary engineering and engineering-geology investigations.

Thomas Lamb, M.E.I.C., B.Sc. Civil (Manitoba '41), President and Resident Partner, T. Lamb, McManus & Associates Ltd., Consulting Engineers, Calgary. **Ralph N. McManus,** M.E.I.C., B.Sc., Civil (Alberta '42), M.Sc., Ph.D., Principal, T. Lamb, McManus & Associates Ltd., Consulting Engineers, Calgary *(The Dunvegan Suspension Bridge).*

For eleven years Mr. Lamb was employed by the Highways Branch, Manitoba Department of Public Works. His positions there included Assistant Bridge Engineer, Assistant District Engineer, Executive Assistant to the Deputy Minister, and Bridge Engineer. He set up his consulting practice in 1952.

In 1956 Dr. McManus resigned from the University of Alberta, where he had served for 14 years, to devote full time to his consulting practice. Dr. McManus is also a principal of Structural Engineering Services Ltd. He is a member of the Association of Professional Engineers of Alberta.

H. N. G. Allen, M.A. (Cambridge '33), Joint Managing Director, W. H. Allen Sons & Company Ltd., Bedford, England. **T. P. Jones,** Chief Engineer and Manager, Gearing Department, W. H. Allen Sons & Company Ltd., Worcestershire, England. *(Marine and Industrial High Powered Epicyclic Gearing).*

Mr. Allen is a Member of Council and past chairman of the British Internal Combustion Engine Research Association; a Member of Council of the British Hydro-mechanics Research Association; a Governor of the College of Aeronautics, Cranfield; a Member of the British Transport Commission Research Advisory Council; and Vice-Chairman of the Council of Mander College, Bedford.

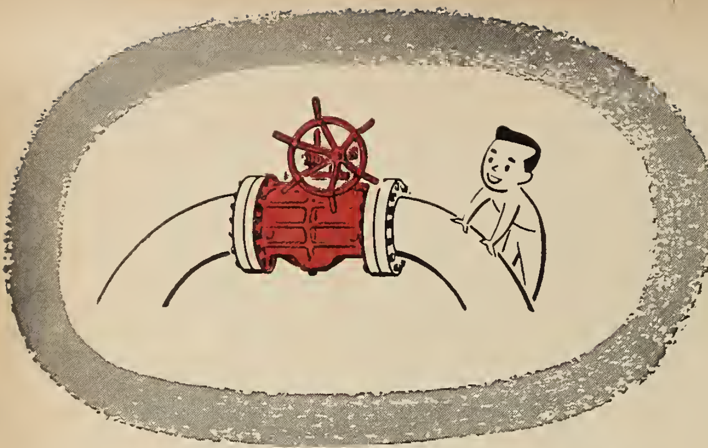
Mr. Jones received his general and technical education at Newport College, Monmouthshire, and after an apprenticeship with W. H. Allen Sons & Co., Ltd., and further technical study at Newcastle-upon-Tyne, was awarded a Higher National Certificate. He was subsequently engaged on the installation of Allen auxiliary machinery on both Naval and Mercantile vessels.

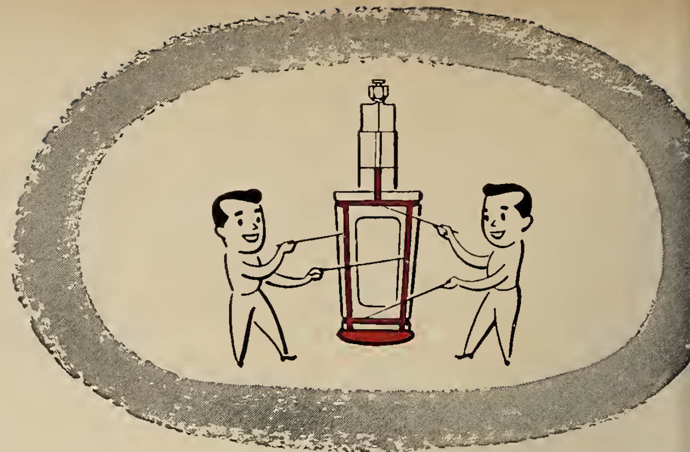
Lt. Col. Lyndall F. Urwick, B.A., (Oxford '13), M.A., Chairman of the Board, Urwick, Orr & Partners Limited, Management Consultants, London, England *(Management—Horse Trading or Trusteeship?).*

Colonel Urwick, a pioneer and authority in scientific management, is a well known lecturer and author in this field. From 1928-33 he was Director of the International Management Institute at Geneva. His positions in public service, both in Britain and internationally, have been extremely varied and include, among others: Colombo Plan advisor to the Indian Government; past-chairman of the Education Committee, Institute of Industrial Administration; and Director, American Management Association's Inquiry into Management Development.

COVER ILLUSTRATION

Automatic control, discussed by Dr. Arthur Porter in this issue, can invest machines with certain powers evident in man and associated with his capacity for thought. This type of brain function is demonstrated as the tennis player calculates the factors involved in the successful interception and return of the ball.

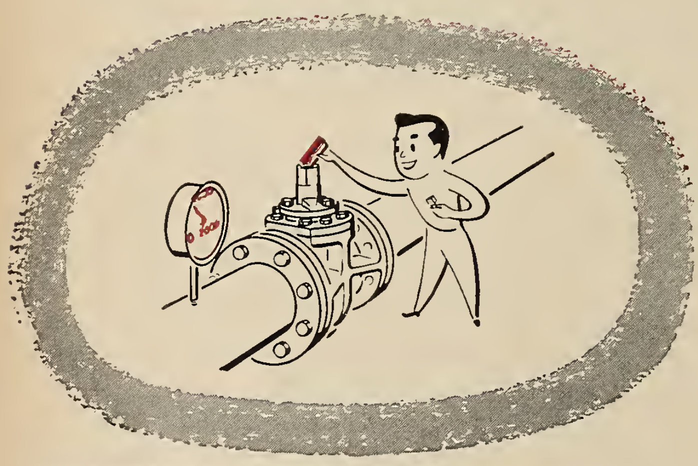


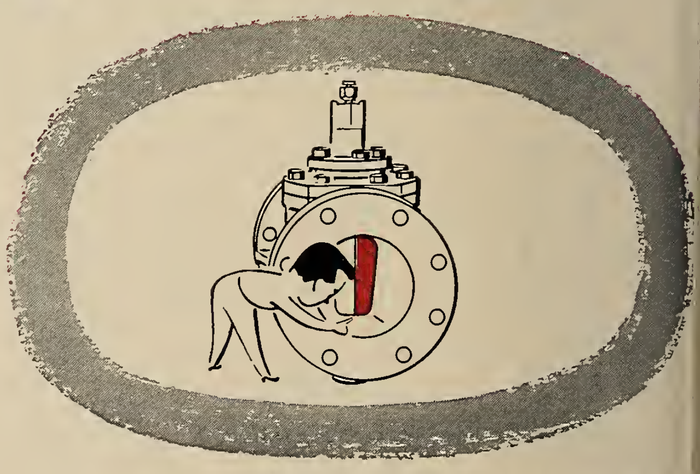


WHAT IS THE ADVANTAGE OF A LUBRICATED VALVE? —The most important advantage of a lubricated valve is that it *seals far tighter* than ordinary valves. The thin film of plastic lubricant forced into the ports of the plug is a pressure seal in itself. And the possibility of seizing or galling is eliminated because the plug can be hydraulically jacked for instant operation. Lubrication is also *preventive maintenance* against down time.

WHAT DOES THE LUBRICANT DO?—In a Rockwell-Nordstrom valve, lubricant is forced through grooves surrounding the plug ports where it acts as a *double seal* against leakage. By hydraulic action, lubricant under pressure also jacks up the plug keeping it free for *instant quarter-turn* operation. And lubrication means that operation is smooth and easy. Finally, lubricant prevents grinding wear for longer valve life at lowest cost.

DOES VALVE LUBRICATION ? ? ?





WHAT LUBRICANTS SHOULD BE USED?—Insist on genuine Rockwell lubricants—Rockwell is the largest and most experienced manufacturer of valve lubricants in the world. Rockwell lubricants are the result of years of field experience with nearly every process condition. For many services, there are variations of Rockwell lubricants compounded to offset specific line conditions. See your Peacock sales engineer or write for Bulletin V-220 for complete details.

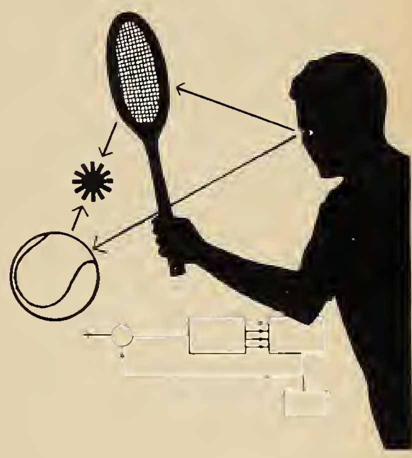
HOW LONG WILL PROPERLY LUBRICATED ROCKWELL-NORDSTROM VALVES LAST?—Many of the first Nordstrom valves put in service are still going strong. In gas distribution installations there are many valves with more than 30 years service. In a two-year paint plant study, Rockwell-Nordstrom valves were the only ones that did not need to be replaced because of leakage. Lubricant assures extra years of perfect service you can't expect from "dry" valves.

ROCKWELL-Nordstrom **VALVES**

THE PRINCIPLES OF AUTOMATIC CONTROL

Arthur Porter, M.E.I.C.
Dean of Engineering, University of Saskatchewan, Saskatoon

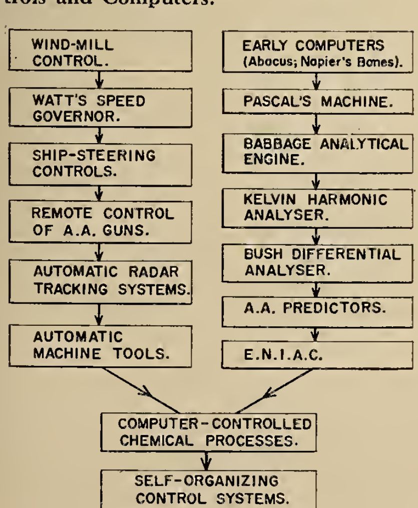
Presented at the 74th E.I.C. Annual General Meeting, May 1960.



In common with all fields of applied science, control system technology has undergone a profound change during the past two decades. Some of the major influences have been the applications of analogue and digital computers, the increased reliability and efficiency of electronic components (e.g. semi-conductor devices), the evolution of a comprehensive theory of linear systems, and the recognition that certain classes of non-linear control systems can be designed scientifically. But perhaps the most significant development has been the formulation of control problems on the basis of system optimization. The object of this paper is to re-evaluate the basic principles of automatic control in the light of this trend. System optimization is synonymous essentially with the optimum utilization of information and the necessity for feedback processes in automatic control follows directly from this concept. On the other hand, simple first-order feedback loops are usually inadequate to optimize complex processes, and second-order and perhaps a hierarchy of control loops are required. This principle is illustrated by the evolutionary operational method introduced by Box. A further significant factor in the control of multi-variable processes is the optimal coding of information which may, in some cases, involve carrying out correlation analyses. Coding is an essential prerequisite for the basically important procedure referred to as information classification which, considered in terms of probability, leads to the concept of pattern recognition. And pattern recognition determines the degree of programmed, as opposed to plastic, control required for a specific process; the biological model provides important analogies in this connection. Some consideration is given in the paper to the associated problems of decision-taking and logical goal-seeking. The requirements of automatic controls based on the principle of self-organization (i.e. heuristic systems) are discussed briefly.

THE REMARKABLE advances in the theory and design of servomechanisms and automatic process controllers have had a considerable impact on all branches of applied science and technology during the past two decades. And there has been a growing realization that electronic computers and computer techniques have an important part to play in the future evolution of automatic control. Many first-class books, some of massive proportions, have been written on the subject recently, and it might appear impracticable for a single paper to give an adequate introduction to automatic control principles. On the other hand, the increasing importance of systems engineering is accenting the need for a re-evaluation of these principles. In particular, the goal of the systems engineer must essentially be to optimize the performance of a system. And if control, as such, is limited merely to the stabilization of a system with adequate speed of response, it usually will not embrace the concept of optimization. Moreover, it is well known that the impact of automatic control principles in such fields as economics, management, marketing research, etc., is already considerable, and these offshoots of servomechanism theory are already having an important influence on the basic philosophy of automatic control. And this is consistent with the whole feedback principle.

Fig. 1. The Evolution of Automatic Controls and Computers.



A brief review of the evolution of automatic control may be helpful. In the light of recent developments there are clearly two main branches, one concerned essentially with automatic control systems and the other with analogue and digital computer techniques, and recently these branches have coalesced. The major landmarks in the evolution of both branches are indicated in Fig. 1. Many notable names have been omitted from the diagram which is intended as a guide and not as a comprehensive genealogical tree.

It is notable that, although the branches of automatic control and automatic computation were complementary for many years, it remained for the designers of automatic fire control equipment, during World War II, to introduce the concept of the integrated design of systems involving both servomechanisms and complex automatic computers. These computers were essentially analogues which solved the geometry of the fire control problem. The complete systems were based on physical models, and they exemplified the important principle that the optimization of a process can often be facilitated by setting up models as controllers.

The process of optimization involves the optimum utilization of information, and it is not surprising that a recent trend in process control is the use of computers and data-processing equipment to achieve the desired goals. Thus, during the comparatively short span of twelve years both analogue and digital computers have been brought within the orbit of the control system engineer. And the present trend is for computers to be integrated into complex automatic control systems. While recognizing the high importance of these machines in the design of automatic controllers, this paper, being involved with basic principles rather than techniques, does not consider specific computer applications.

Computers are only capable of handling information which has been coded into "machine language", and as far as digital machines are concerned this involves a binary coding procedure. Several basic measuring instruments are at present being modified so that analogue outputs can be converted into digital outputs for communication and computational requirements. On the other hand, there appears to be some evidence that the evolution of automatic controllers will not be solely in the direction of digital control but rather that combinations of analogue and digital systems will be required.

Feedback

The fundamental characteristic of all control systems is feedback. Even in the cases of control systems which may be regarded as "open loop" systems there is necessarily, considering the system as a whole, some monitoring process involved. It is sometimes convenient, however, to consider the control system as a programmed control, cf. the programming of a digital computer. And the nature of a control system will normally be a compromise between fully-programmed and completely non-programmed depending upon the process under control. From the point of view of information theory, the more programming involved in a process, the more redundancy of information is implied and hence, the greater the degree of predictability.

It is convenient to consider the fundamental physical control processes* in which feedback is an essential feature. These processes shown schematically in Fig. 2 (a), (b) and (c) are:

(i) system protection;
(ii) system regulation;
(iii) system optimization.

Items (i) and (ii) may be integrated into a single over-all controller although it is convenient to consider them here as independent processes. In the case of protection systems the feedback only comes into action when certain plant conditions satisfy a set of logical rules or constraints which are designed to prevent accidents or damage in the operation of the plant. In this respect the plant protection system is analogous in the human nervous system to "pain" which can be regarded as a warning signal. The principles upon which protection systems are based reduce to the principles of logic and as such are beyond the scope of this paper.

*Note that feedback is a basic characteristic of the majority of biological mechanisms, of economics, of communications, etc.

Fig. 2 (b) shows a simple process regulating control in which it is required to keep two control variables p and q at the desired values p_0 and q_0. In practice many variables may be involved and the objective is to constrain these variables to depart as little as possible from their desired values in spite of internal and external disturbances. A considerable portion of the literature on automatic control is devoted to the theory of automatic process regulation.

The principle of optimization is illustrated in Fig. 2 (c). It is assumed that a regulation system is associated with each significant control variable, the object of which is to ensure that the commands of the "optimizing controller" are obeyed. It is assumed further that the criteria for optimum behaviour of the process have been adequately stated in symbolic form and that suitable instrumentation for measuring the optimizing variables is provided. As in protection and regulation processes, feedback is fundamental in all optimization procedures in order to handle unpredictable disturbances.

In addition to the three basic applications of feedback, considered above, the principle is also used to produce special transfer functions and to minimize the effect of certain nonlinearities. It is also used to modify impedances at certain points in network structures, and to provide control over the variation of parameters due to extraneous influences. But these applications are essentially manifestations of the fundamental idea that feedback is introduced to deal with unpredictable disturbances.

Prediction and Feedback

Information theory indicates that the more predictable a process the less information is available at a specific time. In the limit, for example, a process whose behaviour is fully predictable will not require monitoring feedback. Most processes by their nature are to some extent predictable, otherwise automatic control of the process would be impossible; they are in fact stochastic in nature. Three special techniques which illustrate the relationship between predictability and feedback are considered below.

In the systems described by Lang and Ham,[1] i.e. conditional feedback systems, and the system described by Reswick,[2] i.e. disturbance response feedback, the basic idea is to utilize all known information concerning the process and to build dynamic models

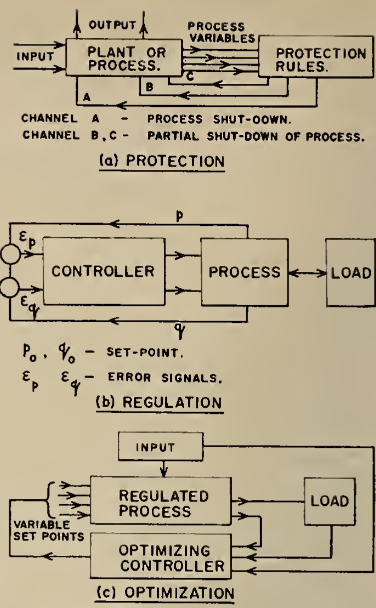


Fig. 2. Classes of Automatic Control Systems.

for use as "model-controllers". For example, in Fig. 3, which represents a simplified form of the Lang-Ham system, the transfer function of the model is designed to match the transfer function of the main servo loop (this assumes no control element is introduced into the portion of the loop marked X). Clearly, if M(s) is the transfer function of the model and KG(s) is the open-loop transfer function of the servo system, and if

$$M(s) = KG(s) \qquad (1)$$

then, assuming no disturbances are involved such as, for example, saturation of amplifiers and motor, it will be seen that the control signal is zero. Only when disturbances are present will the error signal be finite. Moreover, the forward gain of this class of system can be made extremely high because the anti-stabilizing effect of disturbances can be handled by a compensating network at X. Thus, the intelligent use of information in the design of servomechanisms leads to enhanced predictability which, in turn, minimizes the possibility of unstable behaviour.

The Reswick disturbance-response feedback technique also involves the concept of the model-controller, although in this case the technique is applicable to regulators while the previous method applies essentially to servo-mechanisms. The method is illustrated in Fig. 4 in which the controller has the transfer function,

$$\frac{\lambda(s)}{\epsilon(s)} = \frac{k_1}{1 - k_2KG(s)} \qquad (2)$$

The controller transfer function involves two variable parameters k_1

and k_2 and it is not difficult to show that the value of k_2 is determined by the requirement that the steady-state error in the system must be zero. This leaves a single parameter k_1 as the basic control parameter. In a later section a generalized version of the Reswick model-controller is used to introduce the principle of self-organization.

The third technique arises in the design of a basic class of sampled-data control systems, first described by Porter and Stoneman.[3] In this case information is utilized to predict continuously the behaviour of the controlled variable rather than, as in the previous two cases, to predict system transfer functions. The system is shown schematically in Fig. 5.

The basis of the method is a system for automatically generating polynomials, the output of which is compared at sampling instants with the corresponding input, and the error signal is used to modify the coefficients of the polynomial output function progressively. Clearly, this system must be inherently stable because the feelback loop is open most of the time. The system handles initial transient conditions by successively switching in additional terms of the polynomial. In principle, this system assumes that the behaviour of the controlled quantity in any automatic control system can be represented in terms of a sequence of overlapping polynomials of order three or four. Again, the system differs from conventional control systems in so far as the feedback loop is only open at sampling instants and operates to determine the effect of disturbances which may have occurred since the previous sampling point.

Evolutionary Operation

The previous examples of feedback have dealt with simple first-order feedback loops as exemplified by Fig. 2(b). In practice, multi-loop systems, which may involve a hierarchy of loops, are common and the process of optimizing such systems involves the correlation of a large amount of information and the taking of decisions concerning the best operating conditions for a process at a particular time. In these complex systems the all-embracing feedback is essentially the decision-taking loop which determines such parameters as process set-points.

Some of the most fundamental work on the optimization of chemical processes has been due to Box.[4] The method has been described as "evolutionary operation" on account of its close parallelism with the process of natural selection in the evolution of biological species.

Box considered comparatively simple processes and based his method essentially on the exploration and exploitation of response surfaces. He was concerned with the yield of a chemical process, which perhaps depended on the pressure and temperature at which the process was operated, and also on the concentration of various chemical reagents. The response surface can be obtained by plotting yield on a vertical scale against temperature, pressure, etc. as shown in Fig. 6. An important consequence of the Box method is the fact that it is not profitable to consider each variable at a time when deciding on optimum values, and the method depends on simultaneous variation of the key parameters in such a way that the yield tends to climb the slope of the contours.

At present the evolutionary operation procedure is carried out for the most part by a combination of man and machine. All the relevant information concerning the past history of a process is available to a small group of specialists and, on the basis of certain statistical analyses, (usually carried out by a digital computer), this group decides how most effectively to change the values of the control parameters in order to climb the slope on a line of steepest ascent.

It transpires that the nature of the calculations involved in investigations of this kind is that of operations involving linear algebra. And perhaps the most significant technique is the application of "linear programming"[5]. These procedures are admirably suited to the high-speed digital computer. It is probable in the future that all manual aspects of evolutionary operation will be eliminated and the whole optimization process will become automatic.

Mathematically, the optimization procedure, when handled in terms of evolutionary operation, reduces to the problem of maximizing a linear function of control parameters which are subject to constraints which usually involve given inequalities. For example, one such inequality would arise from the fact that the temperature at which a given reaction must be carried out must in no circumstances exceed a stated value.

Coding and Classification of Information

Note on Information Theory: An important recent development has been the growth of information theory based on the classical work of Shannon[6] and Wiener.[7] Although at first sight information theory, which provides a scientific measure for certain basic types of information, is applicable for the most part to communication systems, there is little doubt that its impact on automatic control theory will be profound. The relationship between communication channel capacity, transmitter power, signal to noise ratio and bandwidth is particularly significant and has led, during the past few years, to new and more scientific methods of specifying the behaviour of control systems in terms of information handling capacity. But it is in the fundamental approach to the problem of coding information that the impact of information theory on automatic control is likely to be appreciable in the future. In this respect the optimal coding procedures of Shannon[8] and Huffman[9] are significant, not only in treating automatic control systems as communications channels, but also as means of reducing redundancy to an absolute minimum, bearing in mind the fact that a certain degree of redundancy is essential for error-free operation.

Nor should the physical process of coding be considered solely as the quantization of information, e.g., binary coding, etc., because, fundamentally, coding implies translating information into another language. And, since many data-handling processes can still be carried out most effectively by analogue methods, it is important not to neglect these in the study of control optimization procedures. For example, one of the most important methods available for analysing data is through correlation techniques, and these can usually be carried out much more effectively when the data is in analogue form rather than binary-coded form. The following section summarizes the importance of correlation processes in the synthesis of transfer functions of processes, and illustrates how information can be most effectively used in certain circumstances.

Correlation as a Coding Technique: For a simple linear control system, the output function for any bounded input function can be expressed as

$$\theta_0(t) = \int_0^t w(\tau)\theta_i(t-\tau)d\tau \qquad (3)$$

where $w(\tau)$ is the weighting function of the linear system.

Alternatively, it is sometimes convenient to regard the input and output functions of time as a time sequence of values, (with period T) in this case the above relationship is written,

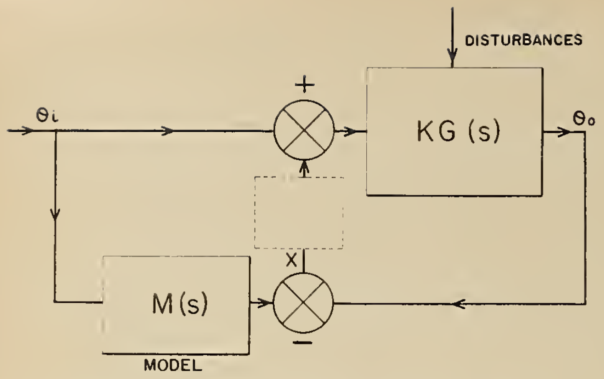

Fig. 3. Lang-Ham Conditional Feedback System.

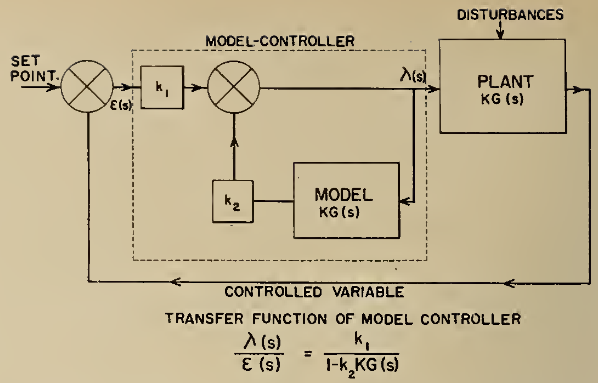

Fig. 4. Reswick Disturbance-Response Feedback.

$$\theta_0(t) = \sum_{n=0}^{k} w_n \theta_i(t-nT) \qquad (4)$$

Frequently the input and output functions are given in sampled-data form and it is required to determine the corresponding weighting function $w(\tau)$ of the linear process. Goodman and Reswick[10] have devised a so-called "delay-line synthesiser" to determine weighting functions in such cases. However, the major difficulty is to deal with the effect of extraneous disturbances which make prohibitive the determination of realistic weighting functions in the majority of cases. To overcome this difficulty it can be shown that if*

$$A_{ii}(\tau) = \overline{\theta_i(t) \cdot \theta_i(t+\tau)} \qquad (5)$$

is the auto correlation function of the input quantity θ_i(t), and

$$C_{i0}(\tau) = \overline{\theta_i(t) \cdot \theta_0(t+\tau)} \qquad (6)$$

is the cross-correlation function of θ_i(t) with θ_0(t), then,

$$C_{i0}(\tau) = \sum_{n=0}^{k} w_n \cdot A_{ii}(\tau-nT) \quad (7)$$

And this relationship can be used to determine w_n given A_{ii} and C_{io}, whereas the application of (4) directly is impractical. The significant point is that when the system output is perturbed by noise, which is not caused by the input, and hence not correlated with it, this noise is not included in the cross-correlation function. In fact, the correlation processes have effectively acted as an information filter and removed much extraneous information. Moreover, apart from the contributions of noise, all the statistical information contained in the time functions is still available in the auto and cross-correlation functions.

The above process illustrates a most significant trend in the development of automatic control systems. In order to predict system behaviour, a prerequisite of effective automatic control, it is necessary to disregard, as much as possible, all random and near-random information such as that introduced by noise. And correlation procedures are highly effective for this purpose. In the present context analogue correlation analyses may be described as coding processes.

Pattern Recognition: The requirement, in automatic control, that the process should be predictable to some degree is almost synonymous with the requirement that the system should incorporate a pattern recognition capability. In straightforward cases such as simple single-loop servomechanisms the pattern is inherent in the design of the system. For example, the ability of the system to determine the "direction and distance to go", and to recognize relative rates of change of θ_i(t) and θ_o(t) constitute properties which may be described as pattern recognition properties. But in more complex systems the patterns of behaviour are usually more obscure and it is necessary to explore all the information available in order to determine them. In some systems correlation procedures help considerably to minimize the deleterious effects of extraneous and irrelevant information,[11] and the application of elementary probability theory is of fundamental importance.

Pattern recognition necessarily involves the classification of information, and for simplicity it is convenient to consider control variables which are two-valued—i.e. the temperature (or pressure) is high or low. Following the work of Uttley,[12] and considering four binary variables A, B, C, D, a classification based on the conjunctions of the variables is shown in Fig. 7. The binary variables may be regarded as states, and it is required to classify these states over a given period of time during which it is assumed that the system is subject to dynamic modifications. Classification in this simple example is concerned essentially with "spatial" classification as opposed to "temporal". Each conjunction unit AB; BC; etc., is considered to incorporate a counter so that in the course of time the coincidences between state combinations can be determined and a "weighing factor" for each conjunction established. And the "value" of any conjunction unit will change continually with time if there is a high degree of randomness involved in the process on the one hand, and will reach a steady-state value if there is a high degree of redundancy on the other. In effect patterns of behaviour have been established based essentially on a spatial distribution of states—perhaps this simple classification process can be regarded as an elementary exercise in topology.

In some processes relationships between present and previous states are important. For example, in Fig. 8, although only one variable is involved, the significant factor is the temporal pattern of behaviour of this variable. The classification process relates to the present state, say A, to the three previous states, A^1, A^{11} and A^{111} — the *delta* symbols in Fig. 8 correspond to unit delays which may be regarded as short-term memories.

If n delay units are involved, with the corresponding circuits and conjunction units, the system is capable of handling patterns involving the previous (n-1) states. The process is essentially an auto-correlation process. Spatial-temporal patterns may be obtained using a combination of the systems shown in Figs. 7 and 8.

The type of patterns arising out of such classification procedures may be

*In equations (5) and (6) the bar indicates "average value".

regarded as probability patterns. And it is possible to represent them in terms of transition matrices, assuming that, in general, these matrices will change with time, and, in most practical systems, except those of a very simple kind, a steady-state will never be reached. But most processes can be described as ergodic, in so far as the variations in patterns occur over comparatively long periods of time compared with, for example, the time constants of the system.

Conditional Probability Considerations: The binary classification process introduced in the previous section has been utilized by Uttley[13] in the design of a conditional probability computer. This machine incorporates 32 conjunction units capable of handling 5 binary values. And a duplicate set of units is available which indicates conditionally the probability that the system will behave in a prescribed manner in the future. The coincidence units not only count conjunctions but also incorporate the characteristic of weighting information in such a way as to give recent events great weight and past events less weight on an exponential scale. Accordingly, the "strength" of a particular unit decrease exponentially with time unless it is stimulated externally—i.e. the unit possesses the property of "forgetting".

The conditional probability of two events A and B occurring together, given that A occurs is written as $P(AB/A) = P(B/A)$* and if this corresponds to a probability $>\frac{1}{2}$, the unit AB is excited when A alone is stimulated.

This class of machine has the property of prediction based on probability, and has in fact been applied by Uttley and Russell[14] to the control of simple processes. It has been demonstrated, moreover, that conditional probability machines have a learning capability which is closely parallel to simple biological learning processes. Thus, it has been shown that automatic control systems based on the conditional probability principle have the capability of learning from past experiences[15] although at the present stage of development this learning capability is almost trivial. It should be noted, however, that the classical experiments of Pavlov[16] on conditioned reflexes in dogs can be simulated using a simple conditional probability computer.

*The conditional probability of B given A is defined as

$$p(B/A) = \frac{p(A \text{ and } B)}{p(A)}$$

provided that $p(A) \neq 0$.

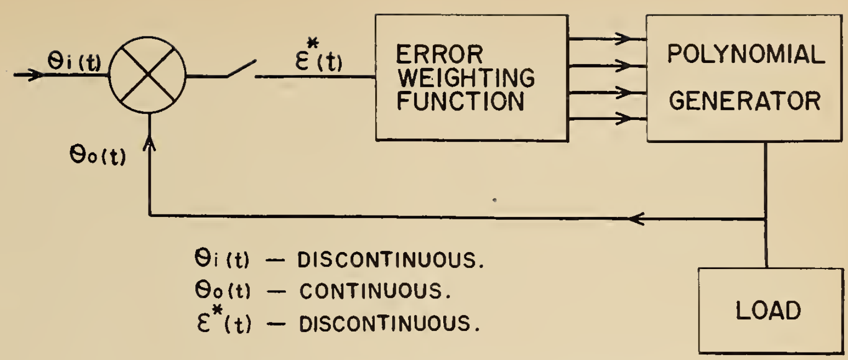

Fig. 5. A Sampled-Data Control System.

A basic limitation of conditional probability machines is their impracticability when the number of variables involved is greater than 6 or 7; for example, 20 variables would involve a total of more than 1 million coincidence units. It would be necessary, therefore, before applying this important principle to the control of complex processes, to introduce a pre-filtering unit which discards non-significant data. This presupposes that methods are at present available for carrying out this information filtering economically—unfortunately no satisfactory method has yet been devised, although the human nervous system handles the problem very effectively. A significant factor is that the more random the process, the more equipment will be required in order to establish probability patterns, and this implies that the complex processes in which we are interested must involve much redundant information.

The conditional probability approach to the problem of control can accordingly be applied to comparatively redundant stochastic processes, and fortunately, in practice most processes would appear to fall into this category. And this implies that the patterns of behaviour of these systems can be determined by such techniques as correlation and conditional probability and these in turn will provide the basis for process optimization.

Note on Decision-taking and Logical Goal-seeking

The feedback property in a system implies decision-taking. And it may not be out of place to examine briefly the role of decision-taking in automatic control. In simple servomechanisms the comparator unit can be regarded as a decision-taking unit and the rules upon which decisions are based are both simple and concise. Further, the inherent goal-seeking nature of simple servomechanisms is obvious. But in multi-variable processes it may be impossible to define the overall control problem in terms of simple decision-elements and the adequate specification of the goals may not be straightforward.

Decision-taking implies the existence of given rules of behaviour and, in order to be meaningful, these must be stated in logical form. For example, if the system variables are binary in nature, the rules may be stated in terms of two-valued logic, while, on the other hand, if many-valued variables are involved, it may be necessary to formulate the rules in terms of many-valued logics.[17]

Again, the basic nature of the rules is not likely to differ appreciably from that of the rules involved in the protection of a process, and certainly the same variables will be involved. But protection as such is a very crude form of control, and if process optimization is required more sophisticated rules must be formulated. Another important point is that if the rules of operation are stated completely, thereby leaving no room for probability and past history considerations, the automatic control of the process is essentially a deterministic operation in spite of the fact that the actual goal-seeking procedures may involve random search methods. Summing up, therefore, in order to carry out optimization procedures it is necessary to state certain basic operating rules, and to build these into the control system,* and, in addition, to provide the facility of taking into account the past history of the process. As a result a degree of indeterminancy will be introduced into the automatic control.

The mechanization of logical rules can be readily achieved,[18] and it is in this connection that electronic computer techniques will be of high im-

*This is an alternative way of saying that the goals must be specified and introduced into the system in a practical way. In a simple regulator the goal is to maintain a control variable at a given value — physically, the goal may be introduced into the system as a fixed voltage level.

portance in the future development of automatic control systems. The deterministic portion of the system will inevitably be "programmed" in much the same way as a digital computer is programmed to solve mathematical problems. Moreover, it has been demonstrated recently that topological patterns representing basic logical and arithmetical operations, can be converted directly into logical circuits and this sort of technique may have increasing importance in the control of processes.[19] It should also be noted that the term "process" in this connection can be interpreted in the widest possible sense. For example, processes such as the automatic control of air traffic; the scheduling of operations in a production line; the control of railway traffic and road traffic; the control of complex communications systems; etc., are included. Indeed, the majority of problems involving time-tabling can be stated in terms of logical connectives.

The Principle of Self-organization

Although feedback is recognized as the fundamental characteristic of automatic control systems, the principle of self-organization may be regarded as of almost comparable significance. For example, the majority of biological processes are self-organizing, otherwise life would be impossible. The concept of self-organization is associated with "plastic", as opposed to "programmed" behaviour, and as such it is of great importance in the optimization of processes. Elementary self-adapting systems have been known for several years, e.g. automatic gain control in radio receivers, but the broader implications of the idea have not been exploited in the optimization of control systems.

One generic class of self-organizing regulators is that proposed by Reswick[20] in connection with the application of the delay-line synthesiser as a model-controller in the automatic regulation of a process. Although this system is not intended as a practical proposal the basic idea is sufficiently important to justify special mention. The system is shown schematically in Fig. 9. To minimize the effects of noise introduced in the process the delay-line synthesiser operates on the auto-correlation function of the control variable $\theta_i(t)$ and the cross-correlation function of $\theta_i(t)$ with $\theta_0(t)$. An approximation of the equivalent weighting function of the process can then be obtained manually. However, in the hypothetical system shown in Fig. 9, automatic operation is assumed.

The key feature of the Reswick self-adapting regulator is the fact that the system takes into account the possibility of changes in the process weighting function with time. Undoubtedly, this system would give very accurate regulation although its complexity (assuming the weighting function is synthesized from 20 ordinates, 20 independent servomechanisms would be required in addition to the other equipment), would be prohibitive.

Several other classes of self-adapting regulators and servo-mechanisms have been investigated recently.[21] Such systems, of which the servo system incorporating automatic gain control is the most elementary, will find increasing applications in such problems as automatic machine tool control, the control of space vehicles, the control of aircraft control surfaces, etc. These classes of control systems involve environmental changes which cannot be handled by classical feedback techniques and in almost all cases it is necessary to modify automatically the controller transfer function as a function of the environment. It is not unlikely moreover, that the principle of self-organization will be utilized widely in all automatic control systems where high accuracy is required. But in general the principle of self-adaption as applied to single loop and to three and four variable control problems is not adequate to deal with the problem of process optimization.

The major limitations of such simple self-adapting systems are:

(i) Each control variable requires a separate control system and the problem of handling inter-action effects may be extremely difficult;

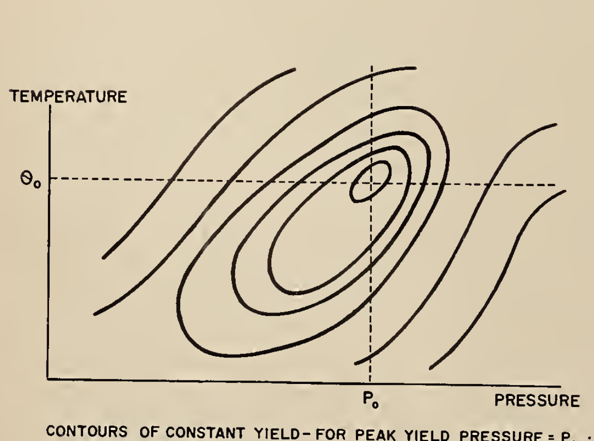
(ii) Although the internal loops of a process can be optimized by such methods as the Reswick self-adapting regulator, the same principle is not applicable to the optimization of the process as a whole. In other words, the major problem is the optimization of the outer loops which involve the difficult decision-taking requirements.

Further, in spite of the many successes of the process of evolutionary operation, it must be noted that the method is applicable essentially to processes involving no more than 3 or 4 key control variables. Additional control variables would so complicate the slope-climbing process, and would involve such large-scale computing facilities, that the effectiveness of the method as a process optimization procedure is limited. The method necessarily involves programmed techniques while the methods we seek must essentially be of a plastic character.

Requirements: The basic requirements of a fully automatic self-organizing process are:

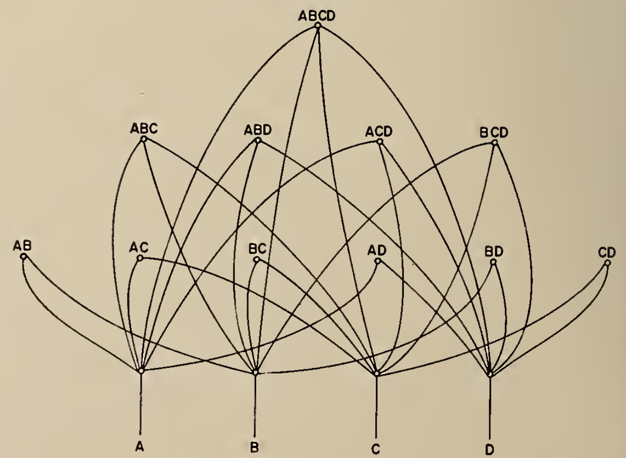
(i) An adequate statement of the process goals (i.e. the criteria of performance) and the means whereby these can be converted into machine language. This requirement may be

Fig. 6.



CONTOURS OF CONSTANT YIELD-FOR PEAK YIELD PRESSURE = P_0 ; TEMPERATURE = Θ_0.

Fig. 7. Spatial Classification of Four Bi-Valued Variables (after Uttley)



regarded as "specification of the rules of the game";

(ii) An inherent capability of adjusting key process variables in order to achieve the process goals in spite of continuously changing environmental conditions.

It has already been mentioned that although the statement and practical manifestation of the goal in simple servomechanisms and regulators is straightforward, the problem may be difficult in complex multi-variable processes. One reason is that goals may be incompatible e.g. the maximization of yield combined with the minimization of cost and customer satisfaction considerations. Further, unpredictable market conditions must, if possible, be taken into account, although this important aspect is likely to be handled by plant managers for several years to come. And, given the goals, there remains their interpretation into machine language. In this latter connection the language will almost certainly be that of (a) symbolic logic and (b) conditional probability. Thus, at a particular time, the goal and constraints may perhaps be expressed as in (8), where A, B, C . . .* are variables which describe the state of the process, and α, β, γ, δ . . . are values of set-points. The logical relationship (i) defines the goal and (ii), (iii), etc., process constraints based on past behaviour.

$$\text{(i)}\quad A \cdot B \cdot \overline{C} \cdot D \cdot \overline{E} \cdot \overline{F} \cdot G \cdot H$$

$$\text{(ii)}\quad p(A \cdot B \cdot C)/(\alpha \cdot \beta \cdot \gamma)] = 0.7$$

$$\text{(iii)}\quad p(\overline{C} \cdot D \cdot \overline{B} \cdot H)/(\alpha \cdot \delta \cdot \xi)] = 0.9 \qquad (8)$$

These rules are hypothetical but suggest nevertheless the general nature of the self-organizing problem — they imply basically that information must be stored, classified and conditional probability computations carried out. The mechanization of the rules corresponds to the motivation of the controller so that the system is always constrained to seek the goals. The latter may change from time to time and will be assigned by human operators. In biological processes the relationships between specified goals and the corresponding motivations are usually clearly defined and in simple cases may be reduced to such relationships as (8)—cf. the Pavlov experiments. However, in these cases the goals, usually complex functions of the environment, are established automatically.

*2-valued logic is assumed and standard symbols are used—however, there is no fundamental reason why the rules should not be stated in terms of many-valued logics. The classification process may involve not only conjunctions but also disjunctions (cf. rule (ii),), and other logical operations.

The fundamental nature of a self-organizing control system is illustrated in Fig. 10; the main operations are outlined briefly below. It should be stressed that this type of controller has not, except in simple cases, been built and tested. However, considerable theoretical work, including digital computer simulations, is in progress and there is little doubt that practical systems, based on these principles, will be available within a few years.

Learning Capability: All self-organizing systems must incorporate a learning capability which necessitates adequate storage of past behaviour.* In this context, learning is essentially learning through association, and this suggests that the controller must be conditioned in a similar way to the Pavlov dog. This learning, or conditioning process requires first, the classification of available information and second, the extrapolation of the inherent patterns in the information on the basis of conditional probability determinations. And in these terms the approximate future behaviour of a process can be predicted.

Consider the nature of the patterns which may be obtained during the operation of a simple process. Suppose the process can be regarded as a simple Markov chain process[22] having four states A, B, C, and D. The probability that state A will follow state D, or state A will follow state A etc. can be represented as a probability transition matrix i.e.

$$P = \begin{array}{c|cccc|} & A & B & C & D \\ A & P_{AA} & P_{AB} & P_{AC} & P_{AD} \\ B & P_{BA} & P_{BB} & P_{BC} & P_{BD} \\ C & P_{CA} & P_{CB} & P_{CC} & P_{CD} \\ D & P_{DA} & P_{DB} & P_{DC} & P_{DD} \end{array} \qquad (9)$$

If the process is ideally ergodic, a future state can be predicted on the basis of fixed probability laws. But normally the transition matrix will not reach a steady-state and prediction must be based on changing probability laws. For example, if the present state is C, the probability that the following states will be A, D, B is clearly,

$$P_{CADB} = P_{CA} \cdot P_{AD} \cdot P_{DB} \qquad (10)$$

* Since this article was written an important contribution to the field of mechanized learning has been published by Professor Dennis Gabor and his co-workers at Imperial College, London.[23] This paper describes a self-organizing system based on a learning process.

And patterns of behaviour in this form can readily be determined. Note that each row of (9) is a probability vector since the sum of the individual elements is unity.

Now consider the more general case of a process whose behaviour depends on many previous states, not one state as above, and in which spatial and temporal patterns are required. A convenient method of describing the past and present behaviour of such a process is in terms of conditional probability matrices. Suppose the state of the process is characterized by three bi-valued variables A, B, C, the matrices are,

$$P_1 = \begin{array}{c|ccc|} & A \cdot B & A \cdot C & B \cdot C \\ A & p(B/A) & p(C/A) & p(BC/A) \\ B & p(A/B) & p(AC/B) & p(C/B) \\ C & p(AB/C) & p(A/C) & p(B/C) \end{array} \qquad (11)$$

$$P_2 = \begin{array}{c|c|} & A \cdot B \cdot C \\ A & p(BC/A) \\ B & p(AC/B) \\ C & p(AB/C) \end{array} \qquad (12)$$

Note that the following simple relationships exist between conjoint and conditional probabilities.

$$\begin{aligned} p(A \cdot B) &= p(A) \cdot p(B/A) \\ &= p(B) \cdot p(A/B) \qquad (13) \\ p(A \cdot B/A) &= p(B/A) \end{aligned}$$

The above matrices supply the behaviour patterns of the process upon which prediction can be based, and they must be kept continuously up-to-date. Moreover, it is assumed as indicated in Fig. 10 that the information has been suitably weighted. Clearly, the determination of all conditional probabilities involved in a process with more than eight control variables is prohibitive. In practice, however, complex processes may involve many variables and the object of the data coder is to select, by weighting procedures, the key variables, and to keep continuous surveillance over the incoming information to ensure that significant data is not discarded. In this way, only "profitable" combinations of variables are involved in the conditional probability computations. This procedure can be considered as "concept forming" and it constitutes the outstanding problem to be solved in the development of self-organizing systems.

The noise generator: In Fig. 10, the unit described on the "random-

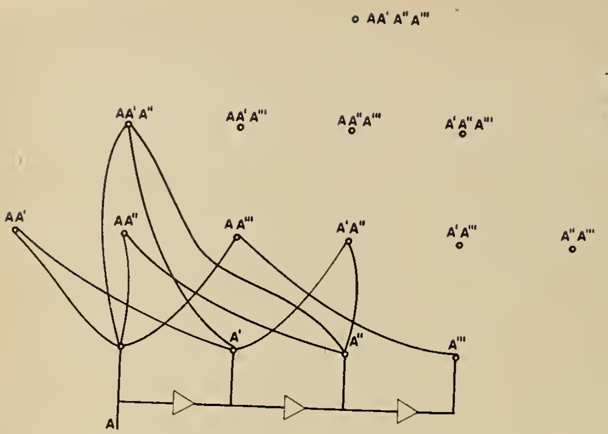


Fig. 8. Temporal Classification of a Bi-Valued Variables (after Uttley)

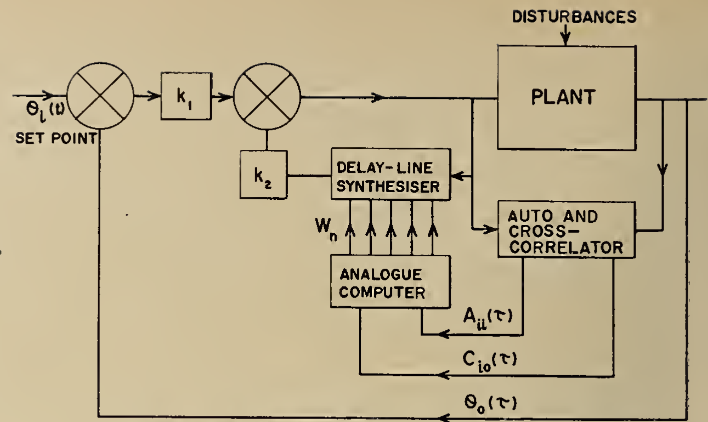

ANALOGUE COMPUTER DETERMINES W_n FROM THE RELATIONSHIP,

$$C_{io}(\tau) = \sum_{n=0}^{n=k} W_n A_{ii}(\tau - nT).$$

Fig. 9.

izer" needs explanation because it introduces an essential, and fundamental, characteristic of all self-organizing systems (both physical and biological). In seeking a goal a non-deterministic process must inevitably be guided by information obtained on a trial and error basis—the only basis upon which the "direction in which to go" can be determined.

For example, combinations of control parameters must be chosen to satisfy the optimization rules, but, since the environment is assumed to be dynamic and the rules are stated in probability terms, there is never a unique solution. It is necessary, therefore, to select a combination of parameters, on a random, or weighted average basis, from a given set of combinations which satisfy the requirements.

Another way of interpreting the randomizer requirement is to note that the environment is continuously changing in a partially random manner, and the optimum method of ensuring goal-directed behaviour, on the part of the process, is to search continuously for conditions which are most satisfactory. The only means available for achieving this objective is for the process to collect new information continuously about the present state and thereby to keep the patterns up-to-date. This suggests that a stochastic control process is required to handle a stochastic environment and accordingly a randomizer is a basic requirement.

There is already evidence that biological self-organizing processes incorporate noise generators and it can be concluded that feedback and noise generators are the fundamental requirements of all self-organizing systems. And this important new principle in automatic control engineering will no doubt facilitate the optimization of complex multi-variable control systems.

MAJOR UNITS IN SELF-ORGANIZING PROCESS CONTROLLER

WATER SUPPLY AND SEWERAGE AT URANIUM CITY

H. P. Klassen, M.E.I.C.,
Chief Municipal Engineer, Underwood McLellan & Associates Limited, Saskatoon.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

This paper deals with the design and construction problems encountered in providing a complete water and sewerage system in the precambrian regions of northern Saskatchewan. The unusual factors to be considered both in design and construction practices require both the engineers and contractors to be resourceful in their approach to the problems confronting them due to a lack of authentic data, transportation problems and climatic conditions.

The author has tried to present some of the problems and their solutions in such a manner that engineers who are presently engaged in northern development may benefit from these experiences.

URANIUM CITY, the hub of uranium mining operations in northern Saskatchewan, is a planned townsite on Martin Lake north of Lake Athabasca at approximately 59° 34′ north latitude and 108° 37′ west longitude. This is in the Precambrian Shield of Canada. As early as 1951 the growth and importance of the community was apparent and steps were taken by the Provincial Government to provide a well planned townsite with complete modern services comparable to those of any other community in Canada, thereby eliminating slums, shacktowns, etc. which usually accompany unorganized development. The Department of Natural Resources selected the site of Uranium City in 1951 and surveyed the property. In 1952 the Government of Saskatchewan requested the National Research Council to determine soil temperature conditions and the probable occurrence of permafrost. The work was undertaken by the National Research Council under the direction of Mr. R. F. Legget. A Progress Report[1] was issued by Mr. Legget in 1955 covering the Climate and Soil Conditions, permafrost and details of Soil Temperatures recorded during their investigation.

Access to the Uranium City area is unusual in that no road or railway exists within several hundred miles. Heavy bulk freight is shipped in by rail through Edmonton via the Northern Alberta Railways to Waterways on the Athabasca River. At Waterways the freight is transferred from the railway cars to barges. The barges are hauled by diesel tugs down the Athabasca River and across Lake Athabasca to a wharf at Bushell. A road connects Bushell with Uranium City and several uranium mines and mills in the district. All other transport services are by air from both Edmonton, Alberta and Prince Albert, Saskatchewan. Personnel are all transported in and out of the district by air as well as many thousands of tons of perishable goods and other urgent materials. It must be pointed out that the water transport season is very short, usually beginning in the first or second week of June and ending by mid-September.

The local geology is typical of the Precambrian geology of Canada. The topography consists of glaciated bedrock, giving a rolling terrain with depressions between rocky hills having glacial soils and muskeg in them. The country is well covered by jack pine, aspen and white birch and some spruce trees. The local soil in Uranium City is generally a clear sand and gravel mixture, with only a thin vegetal cover. Low-lying areas are often covered with thick layers of muskeg underlain with fine silts described best as "glacial rock flour".

Climatic conditions at Uranium City were not recorded but fortunately regular weather observations have been recorded for Fond Du Lac, 50 miles to the east, by the Meteorological Division, Department of Transport, since 1905.

In 1953 the Provincial Government requested a preliminary report on the possibilities of providing water and sewer services for this community. Preliminary surveys were carried out in the fall of that year and a report on a possible system and its costs was submitted in January 1954. Due to the limited time available and the very limited information at hand, this report was of necessity incomplete but it outlined possible sources of water supply, methods of water distribution, sewage collection and disposal. Fortunately from the engineer's standpoint, no action was taken by the government until 1955. By this time the population of Uranium City had more than doubled and the need for a complete review of the project was evident. Early in 1956 the Municipal Corporation of Uranium City and District was incorporated and the newly formed corporation engaged the consulting engineers to design a water and sewerage system and to supervise its construction.

The data gathered by the National Research Council[1] was available by this time. This information resolved many of the problems relating to the temperature degree and variations in the soils in question. In his report, Mr. Legget points out that the soil temperature observations were limited in quantity so that definite conclusions about the soil temperature could not be reached. The report clearly shows that permafrost exists under muskeg cover and that temperatures in the sandy and gravel soils were well below freezing even at depths of 12 ft. The observations clearly indicated that the grain size of the soil affected the temperature penetration appreciably. This was illustrated in two separate observations, one in damp, uniform, compact sand, the other in dry sand and gravel. In the latter installation, the minimum winter temperatures at 6, 9 and 12 ft. were 24°F, 26°F and 29°F respectively, whereas at the former location readings of 31°F, 32°F and 37°F respectively, were recorded at depths of 8, 10 and 13 ft. It is also shown that the minimum soil temperatures at the 8 to 13 ft. depth are reached in April and May whereas minimum air temperatures of −40°F range were reached in January. From this data, a reconstructed soil temperature profile indicates that at depths exceeding 10 ft. the average minimum soil temperatures should be above freezing. Comparisons and studies were made on two pipe recirculation systems at Flin Flon, Manitoba and Yellowknife, N.W.T., as well as the single pipe recirculation system at Fairbanks, Alaska. The relative advantages and disadvantages were considered in the selection of the system at Uranium City.

Establishing Design Criteria

The water distribution system selected for Uranium City was a single pipe recirculating system. As mentioned previously, the Townsite was planned by the provincial Government and streets had been laid out along valleys between ridges of rock outcroppings. Differences in elevation were extensive, varying from a minimum of 30 ft. (above Martin Lake) to 260 ft. The layout adapted itself to the use of 3 separate loops and in this way pressures were held within reasonable limits throughout the system. Separating the town into these individual loops furthermore provided for shorter runs and more positive recirculation.

The design of a recirculation system must be based on sound engineering principles involving heat transfer between the water and the surrounding medium. It is, therefore, necessary to utilize the heat contained in the water and add additional heat as required to prevent freezing. Since water contains both specific heat and latent heat, it is possible to remove all the specific heat of the water above the freezing point before freezing in the mains occurs. By recirculating the water throughout the system from the source of heat addition to distribution and back again to the heat source, it is possible to prevent freezing by controlling the rate of recirculation and the amount of heat added. To determine the rate of recirculation and the heat required it is necessary to calculate the heat losses in each loop under foreseen conditions.

In calculating the heat losses from the water it is necessary to determine the factors affecting the heat loss. The factors considered were:

(a) Temperature of Water;

(b) Film coefficient between fluid and pipe;

(c) Conductivity of pipe material;

(d) Conductivity of soil surrounding the pipe;

(e) Temperature of soil surrounding the pipe;

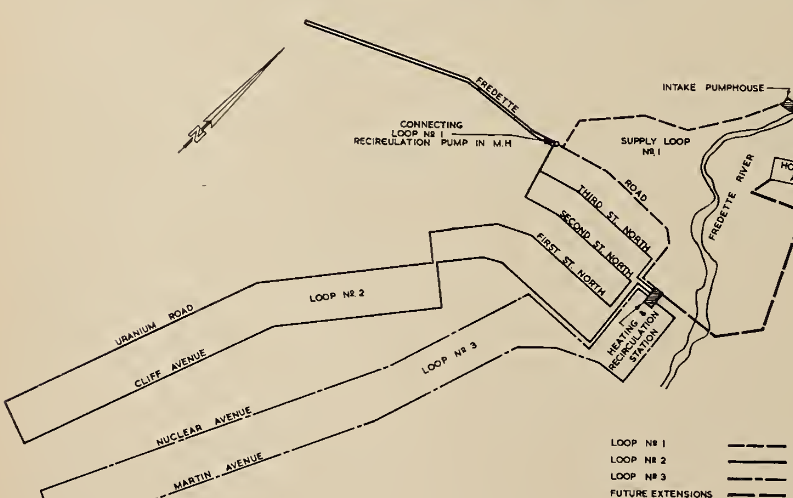
(f) Depth of bury;

(g) Conductivity of insulating materials.

The conductivity and temperature of the soil are probably the most important and most variable factors which require attention of the designer. Miles S. Kersten in his *Thermal Properties of Soils*[2] provides extensive information on the behaviour of temperature in soils. R. F. Legget and C. B. Crawford in *Soils Temperatures in Water Works Practice*[3] show the many factors influencing soil temperature. It is, therefore, necessary for the engineer to make several basic assumptions in order to complete his analysis.

In our design, the raw water was assumed to reach an average low temperature of 34°F. From Kersten[2], the thermal conductivity of the average soil was taken as 12 B.t.u. per hr. per sq. ft. per inch thickness and the mean air temperature of −35°F during the month of January was assumed to be equivalent to a soil temperature of 30°F at a depth of 9 ft. In a recirculation system it is our practice to use average values instead of maximum values for the factors affecting the operation of the system, that is, since the ground temperatures lag behind the air temperature from 2 to 3 months water temperatures may be

Fig. 1. Method of Looping Water Mains



increasing by the time minimum temperatures exist outside the pipes. Furthermore, although a 9 ft. bury is specified, except in rock, this is considered as the minimum depth and in many instances the depth will be greater so that the average minimum temperatures at the pipe will be increasingly warmer.

Having established these basic design criteria a minimum recirculation rate and heat requirements were calculated for each recirculation loop using both the minimum demand and the maximum demand which would occur during a fire. Since the separate loop system eliminated nearly all parallel lines and cross connections, calculations on flows were made by the Hardy Cross Method.

The demand for water and the ultimate extent of the system was based on existing population forecasts which indicated a growth to 6,000 persons when the peak capacity of uranium production would be developed. The Townsite had been planned accordingly. Should growth and development exceed the forecast, it would in all probability take place in other directions or in other areas.

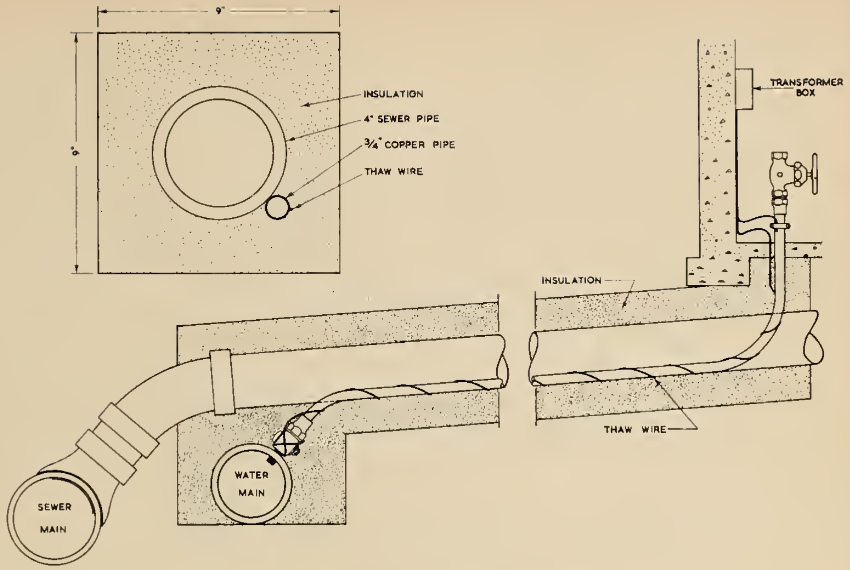


Fig. 2. Building Service Connection

Description of Water Supply and Distribution System

The water supply selected originates with Fredette Lake located approximately 3 miles north of the townsite and approximately 250 ft. higher than Martin Lake. The Fredette River connects Fredette Lake to Martin Lake and passes through the east part of the townsite. Consideration was given to constructing a pipeline to Fredette Lake but in view of the high cost, it was decided to take the water directly from the river just north of the townsite.

Twin intakes were constructed at a point on the Fredette River where a natural rock formation had created a pool approximately 6 ft. deep. A pumphouse equipped with both electric driven pumps and gasoline driven standby units was constructed and a 10 in. supply main 4,200 ft. long was built to the heating and recirculation station located in the townsite. The supply main was located so that it would also service property along most of its length. Future plans allow for completion of a recirculation loop through an area which will be developed for residential purposes if the growth continues. At the time of construction, provision was made to bleed water from the supply main and waste to the Fredette River at the heating and recirculation station since no heat was being added at the source.

The heating and recirculation site was selected so that separate loops could be laid out without excessive duplication of mains. Two distribution loops have been constructed in addition to the supply main. The pipe is 6 and 8 in. diam. spun cast-iron of the mechanical joint type. Each loop is provided with a recirculation pump and heat exchanger. The pumps have been sized so that the temperature differential can be maintained at a maximum drop of 5°F. Heat is provided by two 40 b.h.p. boilers which are equipped to burn Bunker "C" type fuel.

It is pointed out here that the recirculation pumps provide only the minimum circulation requirements. The make-up water is supplied from pumps at the Intake Pumphouse which were selected to meet the minimum and maximum domestic consumption, and the maximum fire demand. One distinct advantage in the single pipe recirculation system is that in the event of fire, water can be delivered through both the feed and return mains and this results in smaller pipe sizes to meet the fire demand.

Construction and Installation

The design of the system was completed during 1956. Due to the transportation problem and since it was desired to begin construction as early as possible in 1957, much of the material was purchased in 1956 and shipped to Uranium City during shipping season.

A contract was awarded in May of 1957 the work proceeded on schedule until freeze-up. The work had been prepared in two stages to be completed in 1957 and 1958.

The first stage consisted of the construction of all buildings and installation of the equipment, construction of the intakes, water supply main, trunk sewer and outfall and the water distribution mains and collecting sewers for the central area of the townsite. The second stage, completed in 1958, consisted of extension of the distribution and collection system for the remaining built-up areas.

The intake pumphouse has a reinforced concrete wet well approximately 20 ft. deep which is filled by gravity through two 12 in cast-iron intake pipes, from the river. Excavation was mainly solid rock which had to be blasted. The superstructure is of woodframe construction with an exterior finish of asbestos cement clapboard and Trafford Tile. The equipment consists of 3 vertical turbine pumps electrically driven. The 2 service pumps are rated at 150 g.p.m. and 300 g.p.m. The fire pump is rated at 1,200 g.p.m. and is equipped with an auxiliary gasoline engine. A chlorinator has been provided for water treatment.

The Heating and Recirculation building covers an area of 2,075 sq. ft. and houses 2-40 b.h.p. boilers, heat exchangers and recirculation pumps. Adequate office space for the operator and a workshop have been provided. Reinforced concrete was used to construct the foundations and piping chamber. The superstructure is wood frame construction with a cement-asbestos clapboard exterior finish. Asbestos flexboard interior finish was used to provide a fire resistant and serviceable structure. Materials which were readily available were selected so that the contracts should not be held up for lack of supply.

The Cutting and Metering station was constructed of materials similar to the others. This building holds a bar-screen, barminutor and a Parshall-flume for measuring the sewage. Adequate room has been provided for further chlorination equipment if and when it is required.

Soil conditions were such that very few unusual problems were encountered during the installation of the water and sewer mains. As previously outlined, much of the overburden was granular material with the result that most of the trenching was not costly. Due to the granular condition, water and sewer mains were laid in common trench. Where gravel or rock was encountered, sand backfill was placed around and over the pipe before backfilling with the excavated material. Where rock was encountered along the line of the trench, the outcrop was exposed in preparation for drilling and blasting. Where the trenches were less than 12 ft. deep, the trench was completely backfilled before detonating the charge and then re-excavated. In places where the rock was encountered at depths greater than 12 ft., only sufficient backfill was replaced, before blasting, to prevent damage to adjacent property. The blasted rock and fill material was then removed by a clamshell bucket.

The most difficult trenching was encountered in the installation of the trunk sewer which passed through a low lying area partially covered by muskeg. Permafrost occurred under this cover. The muskeg cover was stripped off in the spring and the permafrost was allowed to thaw out. This made it virtually impossible to bring in the excavating equipment until late in the season when the surface had frozen over. No special effort was made to insulate the pipe from the natural material except to provide a granular bed under and around the pipe. Some difficulty has been experienced with this line in that silt has entered and blocked the flow, but this has not been particularly due to the materials and methods prescribed but rather to insufficient care in making the joints watertight. Some cracking of manholes, which were constructed of concrete block, also has permitted the silt to enter the sewer. From observations to date, indications are that granular bedding and backfill would prevent misalignment if placed with due care. This project has also shown, however, that materials must be selected for ease in assembly to prevent unsatisfactory workmanship.

The water mains were installed without incident.

Since the townsite was laid out between rock ridges and the greater part of the system was buried to a depth of 9 ft. in sandy materials, rock excavation could not be avoided entirely. As is typical of the Precambrian Shield, rock outcroppings were encountered frequently. Where this occurred, it was not always considered economical to bury pipes as described. In this case, it was necessary that earth cover be replaced by insulation. For this purpose we selected a product which has been used extensively in the Fairbanks system. It consists of a mixture of vermiculite and asphalt which is readily applied in the field. It is economical and has sufficient insulating qualities for this application. The thickness of application was dependent upon the depth of bury. Pipes on or near the surface were given protection to external loads by constructing a wooden box around the pipe.

Description of Building Services

Probably the greatest difference in the Uranium City system from standard systems and others constructed in arctic regions was the method used to protect the building service connection. We have called this method a "Heat Storage System". In two pipe recirculating systems as well as in some one pipe systems the water service connection has consisted of two pipes and recirculation was provided to keep the lines from freezing. In two pipe systems the rate of flow was controlled by orifices placed in the line. These orifices are known to have plugged frequently and if recirculation is decreased appreciably, entire sections of a system may freeze up. At Fairbanks double service lines were used and pitorifices used to set up sufficient differential to cause circulation.[5] This requires velocities approaching 3 f.p.s. and increases the pumping costs. The heat storage method is a standard service connection which has been insulated and has an external heating device. In this case, the water pipe was wrapped with an electrical wire fastened at the main stop and taken into the building. The pipe was then firmly taped to the sewer pipe and the whole insulated The cost of the electrical wire was only 1½c per ft. and it was estimated that an average service line would only require 30 to 60 w. of energy which is taken from the household by means of an inexpensive transformer.

To place the insulation, two outside forms were placed along the desired grade and alignment of the service connection. A 3 in. layer of insulation was placed in the bottom of the form. The sewer pipe was then placed on the insulation and the water pipe, wrapped with the thaw wire, was placed adjacent to the sewer pipe and secured. Insulation was then packed around the pipes to the top of the forms which were removed when the insulation had cooled sufficiently so that the insulation did not adhere to them. This was followed by mopping the top and sides of the insulation with a hot asphalt coating to prevent water absorption.

Operation

The system has now been operating for two full years. An analysis of the first year's operation shows that the design criteria used have been reasonable. It has been fairly well established that heating is required from approximately December 1st to the beginning of May with recirculation commencing about two weeks earlier and stopping early in June when the raw water temperatures reach 40°F. Records show that the raw water temperature reaches 34°F in November, 33°F in January through to March, and in April and May an average 34°F again is reached. In June when the break up occurs, temperatures rise rapidly, reaching a maximum of 60°F by the end of July.

A considerable number of service freeze-ups were experienced during the first full winter's operation but by far the majority were due to the neglect on the part of the owners to connect the electrical protection wire in time or at all. This was no doubt due to a lack of familiarity with the system. Where repetitions occurred, it was noted that the pipes were entirely unprotected within the building. This situation is rapidly being corrected and satisfactory operation is almost ensured. The electrical wire makes thawing in case of freeze-up a very simple operation although the current applied must be limited to prevent damaging the wire permanently.

During the first year of operation, a gross fuel consumption of 6,000 gal. of oil was recorded. It is estimated that approximately 1,000 gal. were used for heating the structure and that 5,000 gal. were used up for heating the water. This represents a cost of $1,000 to heat approximately 7,500,000 gal. of water or 13c per thousand. Recirculation and heating both were started on December 18th and heating was discontinued on June 6th and recirculation stopped June 13th. It is noted here that during the first year of operation, only 125 services were in use. This has

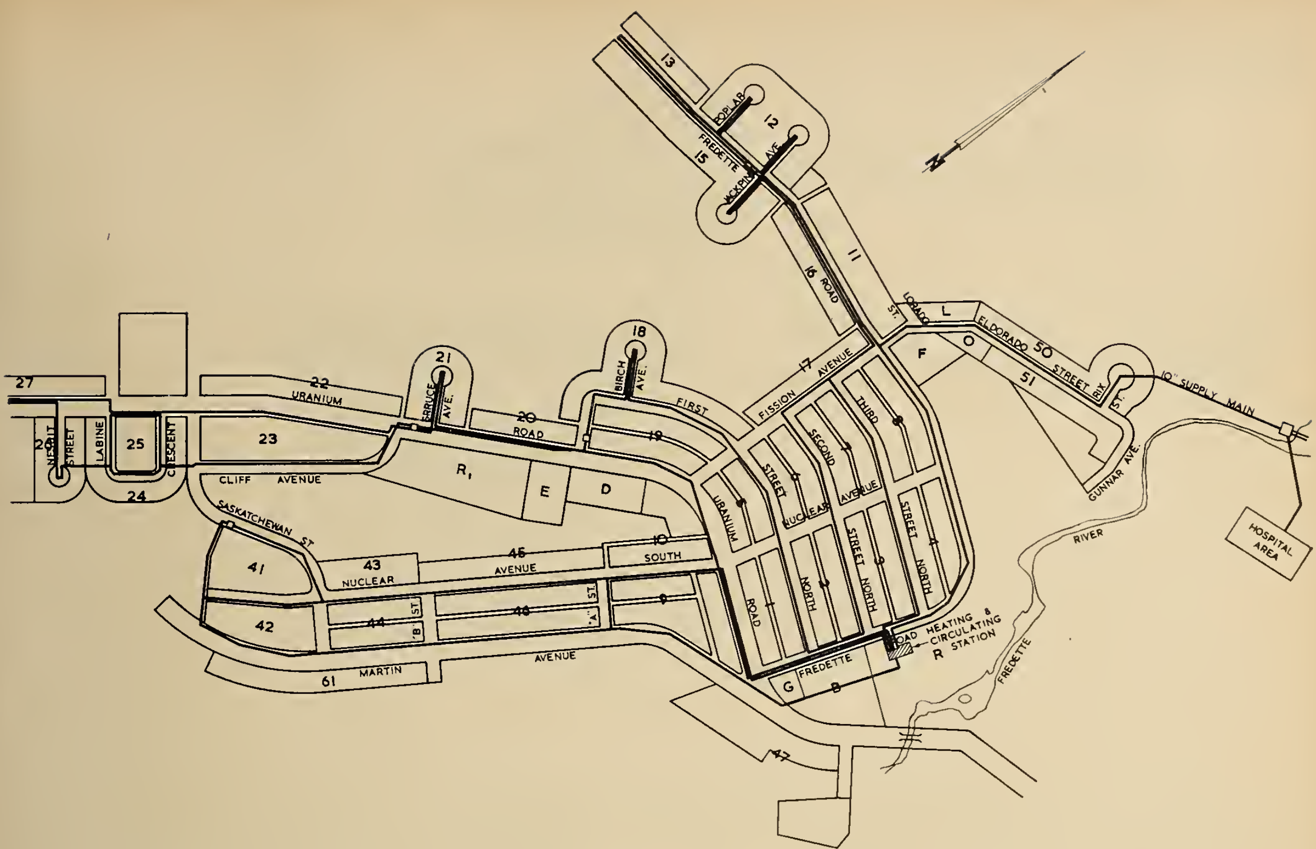

Fig. 3. Distribution System

now increased to approximately 350. It is felt that with the increased consumption, recirculation only will be required for a longer period in the early winter as well as in spring after the raw water temperatures begin to rise.

The following data will indicate the extent of the project and the costs of a water system for arctic regions. The total length of water mains installed was 38,500 ft. consisting of 4, 6, 8 and 10 in. cast-iron pipe. 3,800 cu. ft. of insulation was used on these water mains, 7.850 bd. ft. of lumber was used for boxing and 2,940 cu. yd. of rock was excavated. In addition, there were 32,875 ft. of 8, 10, 12 and 15 in. sewer main and over 300 service connections. The total cost of the project including structures, equipment and pipelines was approximately $1,123,000 including engineering costs. The average cost per foot for water mains was $11.20 and for sewer mains was $12.80. We feel that these costs show that arctic regions can be served at reasonable costs and that with improved materials and transportation facilities future costs will be less.

In conclusion, the Uranium City water system provides a positive circulation of water and the control affords minimum heat addition without waste. House services are economical and well protected against freezing, and the danger of plugging and contamination factors has been minimized if not eliminated. In this system we have eliminated the disadvantages of the two pipe recirculation principle, that is, short circuiting circulation and the double pipe installation. We have used the advantages of one pipe recirculation and eliminated the high pumping costs necessary to provide circulation in house service connections. Two disadvantages that the householder must be relied upon to assure protection of service lines and that there is some inflexibility for extension or revision to the system. Since this system has been in operation a similar system has been designed and installed at Thompson, Manitoba, for the International Nickel Company of Canada, with modifications and improvements. At present, two other installations of this type are at the design stage and it is apparent that northern Canada can be developed and provided with the modern facilities so vital to the personnel who are going to settle there with their families and make it their home.

Acknowledgements

The information presented in this paper represents the results of a large amount of work by other members of our organization and the author is indebted to them for much of the information. We wish to express our thanks to Mr. G. J. Darychuk, Manager of the Municipal Corporation of Uranium City and District and the members of Council for their kind permission to present this paper and for the co-operation they have shown in providing records of the operations.

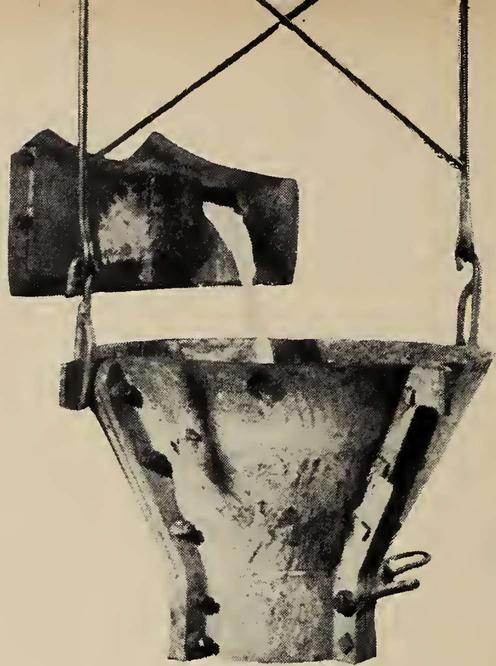
MINERAL RESOURCE DEVELOPMENT IN NORTH AND WEST



John Convey,
Director, Mines Branch,
Department of Mines and Technical Surveys,
Ottawa.

In man's everlasting struggle to control and improve his environment, engineers and scientists contribute more to the success of this struggle than any other group of men. An engineer, we are told, is an applied scientist who makes use of knowledge supplied by science and by applying this knowledge to the forces and materials of nature, he has created a very comfortable place for humans to live.

THE DEVELOPMENT of Canada has been a colossal undertaking in engineering; first, there has been the problem of communications, the spanning of the continent by telegraph and telephone and lately a multi-channel micro-wave system. Then there have been the problems of transportation, the building of two trans-Canada railway systems, a transcontinental highway, and an inland water route up the St. Lawrence into the heart of the continent. The development of our forests, minerals and water power resources has called on the skills of the structural engineer, the mining engineer and the metallurgical engineer. These people have built our hydro stations, sometimes in remote parts of the country such as at Reindeer Lake in Saskatchewan and have shown how our mineral wealth can be extracted from solid rock at reasonable costs and converted into concentrates and finished products. Mechanical engineers have improved machinery so that one can do easily the work which formerly was difficult for many, making our industries and our farms efficient to a point unimaginable to our fore-fathers. More recently chemical and petroleum engineers have played essential parts in our growing petroleum and petrochemical industries, and most recently of all, electronics engineers are promising us automatic factories operating twenty-four hours a day seven days a week producing a stream of products while a few maintenance men look on.

However, Canada is a large and often difficult country and many areas are still either frontier areas or nearly so. Historically Canada was opened up by the fur traders, whose exploratory activities have been consolidated by the miners and by the farmers and ranchers.

With the increasing complexity of modern technology, engineers like other professional people have had to specialize. I would like to discuss with you now the accomplishments of a dedicated group of scientists and engineers who are specialists and compose the Mines Branch at Ottawa.

Deposits of metal ores, industrial minerals and fossil fuels are of little use in the ground. After discovery these resources must be developed into economic feed materials for Canadian industry. This has been the prime function of the Mines Branch since its founding in 1907.

The Mines Branch embraces five Divisions: Mineral Processing; Extraction Metallurgy; Mineral Sciences; Fuels and Mining Practice; and Physical Metallurgy.

The known mineral resources of an area that comprises about two-thirds of Canada, from the Canada-U.S. border to the Arctic and from Winnipeg to the Pacific, have at one time or another come under the scrutiny of the engineers and scientists of the above mentioned Divisions.

Since a very large proportion of the mineral resources of Western Canada is represented by fossil fuels it may be appropriate to emphasize the work done by the Mines Branch on fuels.

During the period 1930-33, a survey of the coking coals of Western Canada was carried out in a 2 ton capacity oven designed and operated by the Mines Branch. The studies, during this period and subsequent investigations in two ovens of 500 lb. capacity each, demonstrated the application of Canadian coals to the industry in the production of domestic coke, which was supplying an expanding market in the 1930's, and also for the manufacture of metallurgical coke suitable for use in the non-ferrous industry of Western Canada.

Most of the coking coals in Western Canada are in the medium volatile range and, in some cases, there may be dangerous expansion when the coals are carbonized in slot-type ovens. This known fact lead to the development of equipment for the measurement of expansion pressures during the coking cycle, this work being instrumental to a considerable degree in the formation of a sub-committee of ASTH Committee D-5 on Coal and Coke.

In 1939 the Mines Branch co-operated in a study to demonstrate the feasibility of carbonizing coal from the Michel Colliery of the Crow's Nest Pass Coal Company in Curran Knowles ovens. These ovens are a radical departure from the conventional slot-type of oven as they apply sole heating to a bed of coal. The adaption of the process to the Michel coal was advantageous in allowing more economical processing of small tonnages than in the conventional slot-type oven and the mode of carbonization was suitable for an expanding coal. The results of the investigation led to the installation of a battery of 10 ovens and their success may be judged by the expansion to the present installation of 52 ovens.

With the recent interest in the development of an integrated steel industry in Western Canada, requests have been made to evaluate specific seams of Western Canada for use in the manufacture of coke suitable for consumption in a high-shaft blast furnace. Samples from the Crowsnest, Mountain Park, and Comox areas were tested in a 500 lb. capacity movable-wall oven at Montreal. The cokes produced were evaluated for physical and chemical properties by standard methods of testing.

In view of the current market for coking coal in Japan, the Mines Branch, during the past year, has conducted an intensive carbonization program to demonstrate the potentialities of Western Canadian coals for the produetion of metallurgical coke suitable for the Japanese steel industry. The program included the production of test-oven coke from coals and coal blends using Canadian, Japanese and American coals. The evaluation of the samples of coke produeed was made by standard methods in use in North American and Japanese steel practices.

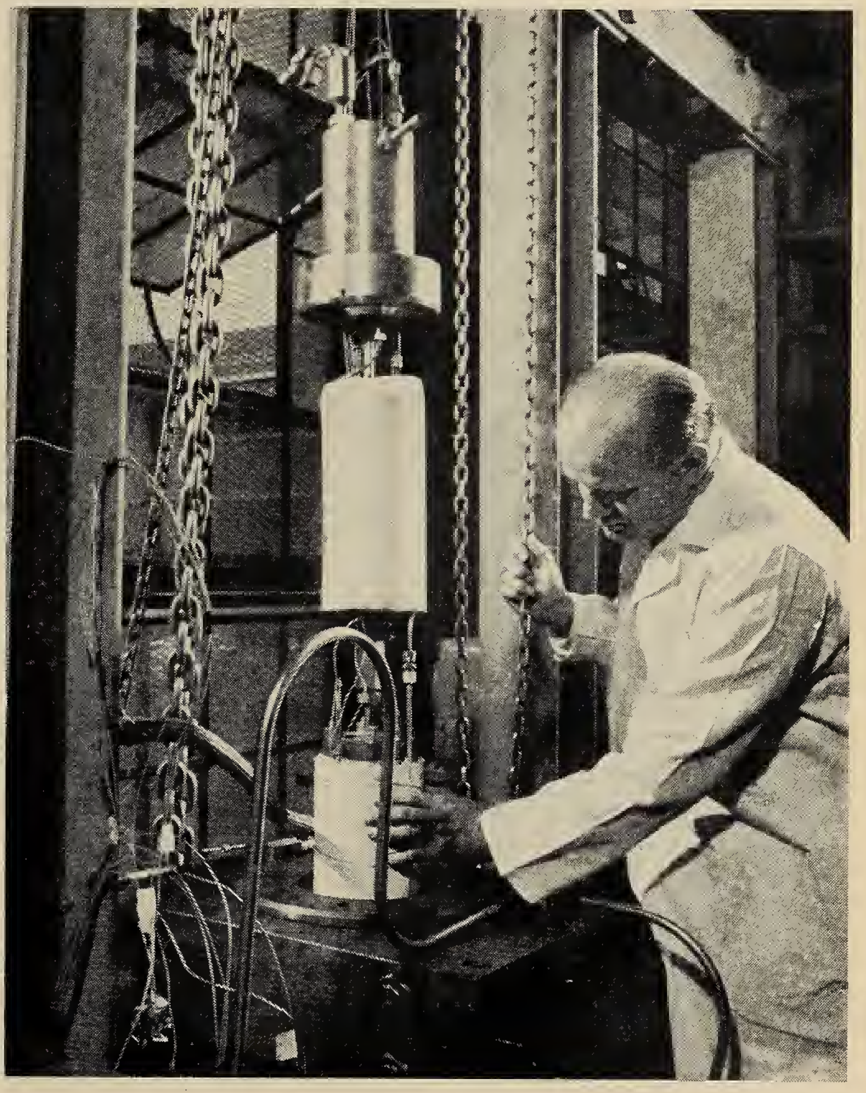
Guaranteed ash contents of Western coking coals for export has stimulated interest in cleaning of fine sizes of coal not amenable to treatment by jigs. A four-tons-per-hour pilot plant for cleaning of slack coals in cyclones using water only has been installed at the Western Regional Laboratory of Mines Branch in Edmonton, in co-operation with the Research Council of Alberta. A two-tons-per-hour pilot plant for cleaning coal in heavy medium cyclones is under construction. Furthermore, research in the dry cleaning of fines is being conducted by studying the interaction of vibratory and centrifugal forces in a pilot machine.

The Mines Branch has recognized the importance of petroleum in the Western Canadian economy for many years, long before the conversion of the railways to diesel oil. Today transportation, which is the life blood of Western Canada, depends entirely on petroleum, and we are indeed fortunate that petroleum discoveries have been able to keep pace with the modern developments in this industry. The relative abundance of petroleum in Western Canada has not always prevailed. During World War II the acute shortage of oil in the Western provinces led to a program of drilling under the direction of Mines Branch to explore the magnitude of the Tar Sands deposits of Alberta. After outlining in one small area a deposit containing a billion barrels of oil the emphasis of the Mines Branch was shifted to problems related to its separation and refining.

The interest of the Mines Branch in the heavy oils of high sulphur content goes far beyond the Tar Sands of Alberta. Experience has shown that the high quality oils are used first and that with the progress of time oils of lower and lower quality must be used. The rate at which this trend affects Canada can be gauged by detailed study of the quality of Canadian oil resources. The Mines Branch performs such a service by analysing oils and natural gases from all the significant Canadian discoveries.

As improved methods of conserva-

Fig. 1. Mines Branch engineer guides the electrically-heated inner reaction chamber into the pressure vessel of the hydrogenation pilot plant.



tion and utilization play a dominant part in the outlook of the Mines Branch, much present research effort is directed to finding new methods to improve the product of Western Canadian heavy crude oils so that these oils may be in a better position to find more stable markets in the face of keen competition.

The conversion of petroleum to refined products using high pressure hydrogen is but one aspect of petroleum refining, and facilities are under construction to provide a balanced pilot plant laboratory for the production of a wide range of commercial products from crude oils which today have limited scope within the famework of the present day refinery technology.

In petroleum technology as in other areas the Mines Branch has an interest in making fundamental contributions to science. In this particular area significant contributions have been made in understanding the structure of petroleum, bitumen, and a wide variety of naturally occurring organic residues that are of interest to the petroleum geologist and those in search of oil.

Mines Branch worked out a cold water process for the economic recovery of bitumen from the bituminous sands of Alberta. The separated bitumen is not, however, a marketable product, and Fuels Division is carrying out a long-term hydrogenation program on the desulphurization of the bitumen and of high sulphur crude oils for the production of marketable products. In this connection, our engineers in 1955 completed the construction of a high-pressure pilot plant which will operate at pressures up to 20,000 p.s.i. They have shown that high-quality diesel oil can be produced at 10,000 p.s.i. Part of the program is directed to the development of suitable catalysts.

Today we are in the era of nuclear fuels and by way of contrast with the mineral dressing problem on tar sands, the present concentration techniques of radioactive ores are chemical in nature.

The Canadian uranium industry began with the Eldorado mine at Port Radium and the Mines Branch developed the process to treat the ore. The original process developed in the early thirties was to recover radium from the uranium-bearing gravity concentrates and later when uranium became important the Mines Branch developed the more efficient acid leaching processes to recover the uranium. The Port Radium leaching plant built in 1952 utilized the processes developed at the Mines Branch. The Mines Branch shared in the development of the high pressure carbonate leach process for the Eldorado Beaverlodge mine, and also developed the atmospheric pressure leach process which was later incorporated into the mill there.

The first private company to develop a uranium mine, Gunnar Mines Ltd., was assisted by the Mines Branch in selecting and modifying suitable processes for its ore. The leaching process selected was a modification of the original processes worked out for the Port Radium mine, and the uranium extraction process chosen was ion exchange, originally developed by the Americans for South Africa. The whole process was tested and piloted in the Mines Branch laboratories.

A number of other Western ores from uranium properties were investigated both on laboratory and pilot scale, but only two, Lorado and Rayrock, reached production. The development of uranium ore processing methods has been a major activity at Mines Branch for well over a decade and has included the processes used in Eastern Canada, in the Blind River and Bancroft areas. Currently extensive research is being applied to means to reduce the cost of uranium.

Today our main extensive work on metallic ores concerns the concentration of low-grade iron ores. Canada has great tonnages of low-grade concentrating iron ores. These have gained much popularity with the steel industry because the use of beneficiated ores has made possible an increase of as much as 50 percent in blast furnace output. Some of the iron ore projects from Western Canada are:

1. Electric smelting of iron ore from Texada Island, B.C.;
2. The direct reduction of sponge iron of oolitic iron ore from Clear Hills, Alberta.

One of our recent and most interesting projects was a joint laboratory investigation by Consolidated Mining and Smelting Company of Canada and the Mines Branch to determine the feasibility of making satisfactory steel from the pig iron which Comico could produce from heretofore waste sulphides. After an elaborate series of experiments on manufacture and testing of steel made from varying amounts of Cominco pig iron, no significant differences could be found from standard steel.

The current development of missiles, ultra high speed air vehicles and atomic energy power plants emphasizes the need for highly specialized alloys, possessing premium properties of high strength-to-weight ratio, high strength at elevated temperatures, and high corrosion resistance. These requirements, as well as many technological problems of the metals industries in Canada and of the Armed Forces, occupy the attention of a large staff of research scientists in the Physical Metallurgy Division.

This short account of the activities and facilities of the Mines Branch should enable you to understand how our engineers and scientists have assisted and are assisting in the development of Canada's wealth of metals, minerals and fuels. I think I should mention that the Mines Branch has a staff of 650, of whom 250 are scientists and engineers. The Branch is located in a large group of buildings in Central Ottawa, in the Booth Street area, and has recently occupied new laboratories devoted to mineral sciences and the development of extraction metallurgy. During the last few years there has been tremendous extension of facilities, to place emphasis on research for the development of new sciences and methods in order to expand Canada's position and importance in the mineral world. This new approach has required the recruiting of numerous research scientists, many with doctor's degrees, and the obtaining of very much new and ultra-modern research equipment. To the question of why all this is being done, I might say that while Canada is endowed with a plethora of mineral resources, comparatively few of these resources can be regarded as in the bonanza class. We are faced with the innumerable problems of dealing with complex and often very low-grade resources which cannot be converted to marketable products without such facilities as exist at Mines Branch to assist Canadian industry in its contribution to the economy.

AIRPHOTO INTERPRETATION IN MUNICIPAL ENGINEERING

J. D. Mollard, M.E.I.C.
H. E. Dishaw, M.E.I.C.

J. D. Mollard and Associates Limited, Regina, Saskatchewan.

Presented at The Engineering Institute of Canada Western Technical Conference, Banff, Alberta, October, 1959.

This paper is not a review of the techniques of interpreting aerial photographs. Rather, it concerns the applications of airphoto interpretation studies in the initial planning stages of municipal-engineering investigations. The authors describe landscape features often assessed on municipal engineering projects. Information in the paper is based on the last 3½ years work; during this time the authors have carried out 42 airphoto interpretation assignments covering a wide variety of municipal engineering projects. This paper is directed principally toward engineers who are not specialists in airphoto interpretation but who can make good use of information derived from airphotos. It is hoped that information in the paper will help these engineers to know when to recommend air photo studies, know what to ask for, and know how to use the data to advantage when it is received.

ALMOST every major construction project undertaken today considers one or more aspects of the landscape. Commonly it is the type and condition of soil or rock materials in the near-surface zone. In this connection it is often the pattern, depth and variability of different soil deposits, related in turn o their parent geologic landform.[1] On the other hand the aspect of greatest importance may be topography or, in certain areas, surface and subsurface drainage. Less frequently native vegetation is important. Particularly in and around metropolitan centres it is the type and pattern of present land use. Of course it may actually be changes in vegetative cover and changes in land use.

Normally one map is required to show each set of information—be this information on soils, drainage, topography or land use. To the specialist in photo interpretation, however, the airphoto reveals certain data on all of these, and in a single aerial view.[2,4,6] Of course, adjoining photos may be viewed in three dimensions and when this is done a small-scale relief model of natural and man-made features can be seen.

In municipal work it is usually the interrelationship among topography, drainage, different soil deposits, and the distribution of vegetation and land-use patterns that is most significant. Obviously this interrelationship is best appreciated when all these data can be simultaneously integrated and studied at length in a single view, rather than as a series of separate maps placed side by side.

To the analyst who can confidently identify and interpret natural and man-made detail in airphotos, to a large extent the airphoto takes the place of several maps placed side by side or, alternatively, a series of superimposed maps.[7] If the airphoto is properly interpreted it is indeed several maps "rolled up" in one. But the interpreter must be able to correctly identify and evaluate recorded photographic detail.

In selecting new townsites and new resort areas (as well as in assessing peripheral extensions to existing communities) a large proportion of the data needed for decision-making purposes can be extracted from the same set of aerial photos. Sometimes, of course, more than one scale of photography is desirable. And sometimes photographs taken at different times of the year or periodically over several years are especially helpful.

In any event several maps, each map showing a different set of data, can be made from the same aerial photograph (Fig. 1).

Applications of Photo-Interpretation in Municipal Engineering

Selection of New Townsites and New Resort Areas: Following is an assignment the airphoto interpreter is frequently asked to carry out:

In an area select the three best townsites available for new development. Rate these selected area according to first, second, and third choice and give the reasons for your rating. Prepare a set of maps that show a) the general nature of soil conditions and the distribution of significant geologic landforms in each area-of-interest; b) a visual-type classification of topography (e.g., depressional vs nearly level vs hummocky vs gently sloping and so forth); c) drainage characteristics (indicate both surface hydrographic features such as rivers, creeks, draws, lakes and sloughs as well as predicted internal drainage characteritics for different areas); d) the distribution and character (type, density and height) of natural vegetation; e) all cultural or man-made features including transportation and communication facilities, if the latter exist in the area-of-interest.

In addition to the preparation of the above maps, depending on geographical location of the new development, the airphoto interpreter may be asked to make[13]:

1. A regional search to determine whether or not ample supplies of

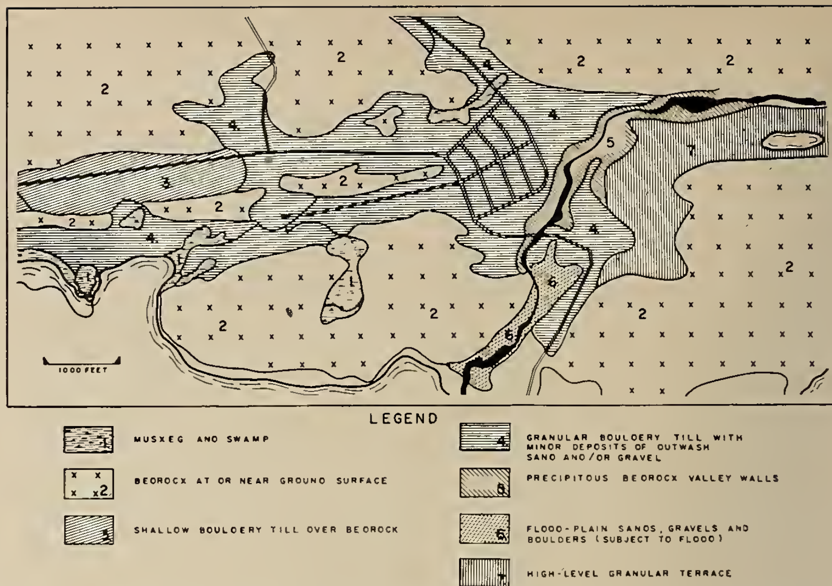


Fig. 2. This reconnaissance map of the Uranium City area shows broad yet important terrain delineations made by studying airphotos. These terrain types influence new housing development and the installation of underground utilities. This map was prepared in connection with planning new development extensions in the vicinity of the townsite.

aggregate materials exist in the area;

2. A study of the possibilities of obtaining surface water or groundwater supplies, suitable in quality and quantity for domestic and industrial use as well as for the disposal of indutrial wastes and sewage;

3. An assessment of the broader phyical environment expressed in mosaics in order to appraise the possibility of hazards to life and property. For instance, consider the possible occurrence of fires and floods, snow avalanches, rock slides and landslides, accelerated erosion and sedimentation problems, permafrost,[3] deep muskeg, volcanic activity or earthquakes caused by recurrent movement along "active" faults. The possibility of any of these or other hazards actually occurring is of course subject to geographic limitations. But certainly the hazards pertinent to any region should not be overlooked in any preliminary examination;

4. An appraisal of prospective earthwork and foundation problems at potential building-site areas—for example, depth to substrata capable of sustaining heavy buildings, the assessment of excavation problems (groundwater, bedrock, highly compressible soils) associated with the installation of underground utilities and deep basements for tall buildings;

5. A general layout of transportation systems, including accessibility to the new site by water, air, rail and highway;

6. An appraisal of natural landscape features, particularly as they affect storm-sewer design, location of playgrounds and parks and the pattern of street layout;

7. An estimate of the fertility of soils in the vicinity as this might affect lawns, gardens, vegetable and other crops grown for local consumption.

In each of these studies the photo analyst usually works for or with a specialist who is responsible for carrying out detailed work on the ground. Especially in little-known, unmapped areas the photo-analyst specialist can do much to simplify and expedite the ground observer's task by compiling pertinent information and by systematically preparing sketch maps showing relevant physical and cultural features (see Figs. 2, 3).

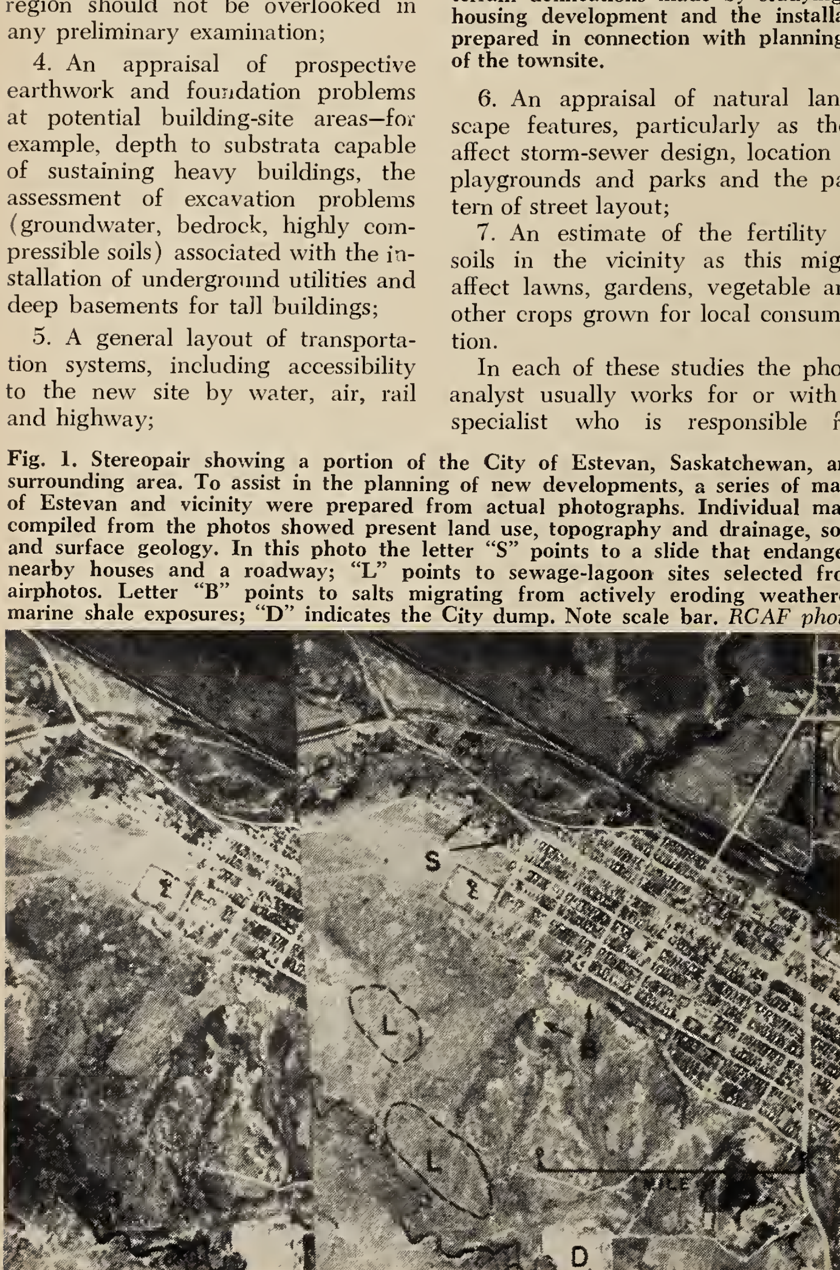
Specification-Material Searches: No single airphoto study is requested more often than the search for undeveloped sources of sand and gravel.[10]

Searches may be made for materials that must meet high-quality standards, such as coarse-aggregate deposits for making concrete (Fig. 4). Or the searches may be made for materials to be used as subbase on paved streets, in which case the governing specifications are considerably less rigid.[11] In most search areas studied on the prairies, deposits suitable for subbase far outnumber those deposits that are suitable for concrete aggregate. A knowledge of the location of all prospects is needed to determine the most economic deposit to develop.

Airphoto studies have been carried out in search of clay deposits for lining sewage-lagoons and town reservoirs and for clay materials for capping streets and roads wherever cohesionless sand is the subgrade material. Filler sand for use in bituminous paving mixtures has been sought and discovered from airphoto study. Organic deposits for application to lawns and gardens may also be located.

Groundwater Appraisals for Cities

Fig. 1. Stereopair showing a portion of the City of Estevan, Saskatchewan, and surrounding area. To assist in the planning of new developments, a series of maps of Estevan and vicinity were prepared from actual photographs. Individual maps compiled from the photos showed present land use, topography and drainage, soils and surface geology. In this photo the letter "S" points to a slide that endangers nearby houses and a roadway; "L" points to sewage-lagoon sites selected from airphotos. Letter "B" points to salts migrating from actively eroding weathered marine shale exposures; "D" indicates the City dump. Note scale bar. ***RCAF photo.***



and New Industries: In addition to selecting potentially favorable groundwater environments to drill and test (Fig. 5), the airphotos are commonly studied in an effort to a) detect springs (Fig. 6), b) appraise the salinity and mineralization potential of the groundwater in the locality under study, c) determine the possibility of recharging near-surface aquifiers (Fig. 7), d) identify water-bearing fissures in sandstones, limestones and Shield areas, even where these rocks in some instances are masked below surficial deposits.[13]

In mountain and foothill areas containing alluvial fans and valley-fill deposits it is often possible to locate areas where water-bearing strata are confined between impervious soil or bedrock materials.

Buried preglacial valleys in glaciated country occasionally show up on aerial mosaics owing to a regional slight darkening in airphoto tones.

High costs of groundwater exploration associated with random drilling methods point out the need for some reasonably cheap means for isolating the most promising places in which to concentrate subsurface explorations, including earth-resistivity surveys. Airphotos, properly used, are such a medium. But airphoto studies should always be followed by field examination. The photos should be analyzed in the light of all pertinent available subsurface data.

Airphoto interpretation for groundwater prospecting must be done with a good appreciation of factors that control the availability of groundwater. In this connection three factors

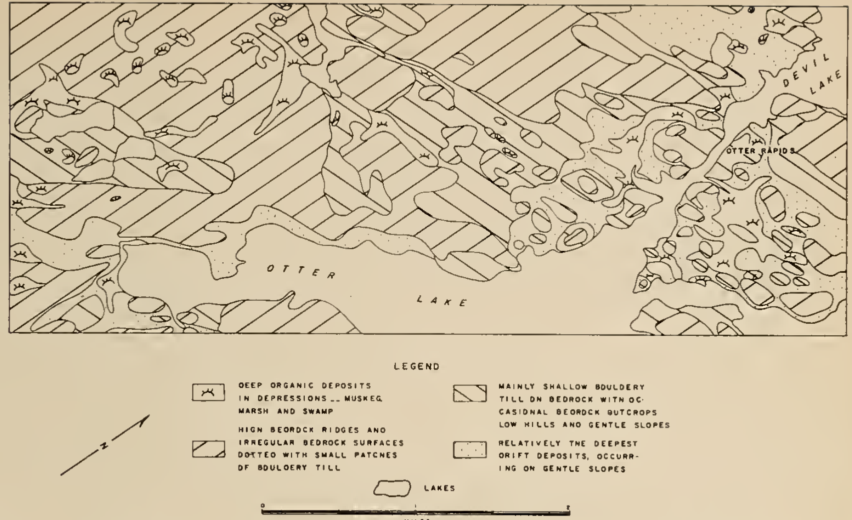


Fig. 3. This figure shows a generalized terrain classification map prepared from four inch equals one mile scale aerial photographs. A forty acre tract of land was desired for a new townsite in this rugged Precambrian Shield country. The terrain found here consists of lakes and muskeg interspersed with high rock hills. Actually very small areas of land are available for new townsite development; and what land is available is irregular shaped, small in extent, and consequently of little value. The better prospective townsites were selected and rated as first, second and third choice. Reasons for this rating were detailed in the report. No areas can be considered as even "fair" townsites. This sort of map is usually prepared before field investigations commence. See scale bar for size of area mapped.

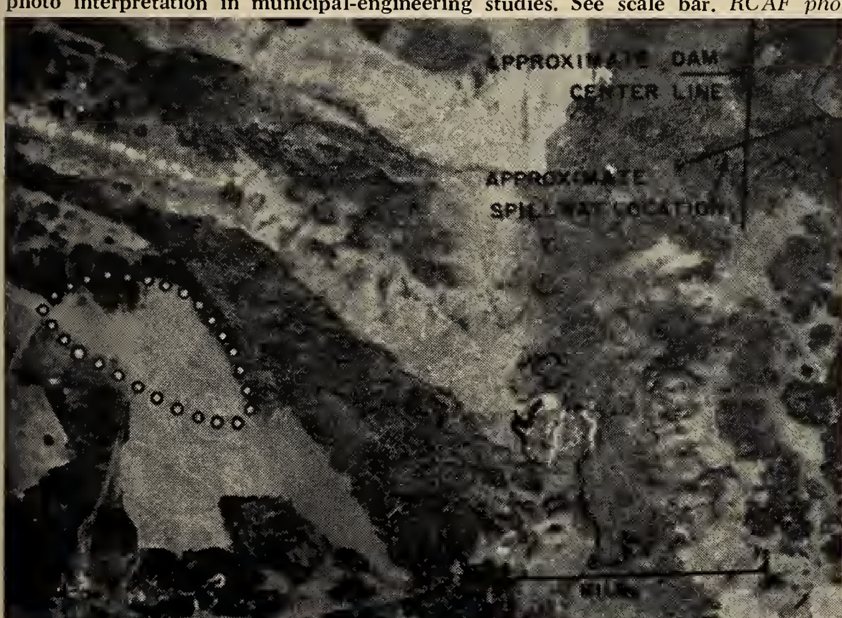
are of prime importance. They are a) the character of the near-surface deposit—whether, for instance, it is bedrock, sand and gravel, or a clayey type of material; b) the availability of water which infiltrates into the groundwater reservoir—a function of climate, drainage-basin size, shape and characteristics; and c) possible underground movement of water—a function of local relief and variations in the character of the subsurface materials.[13]

Indicator clues to possible groundwater sources decipherable in aerial photos vary from region to region. The clue observed in photos may be a deep sand or gravel bed that extends back from a river or other large body of water; an old valley that has been deeply infilled with glacial drift or alluvium; deep sand dunes resting on bowl-shaped impervious strata at depth; or well-defined seepages on valley slopes and hillsides. The observer must recognize these features in photos. And he must be able to interpret their significance in laying out a drilling and aquifer-testing program.

Fig. 4. This photo illustrates a coarse gravel deposit discovered originally from aerial photographs. This subtle-appearing deposit was used in the construction of a concrete spillway (see upper right). Reservoir water impounded by the dam is used as a town water supply and for recreational purposes.

Location of constuction aggregates is one of the principal applications of photo interpretation in municipal-engineering studies. See scale bar. ***RCAF photo.***



Assessing Surface Water Supply Possibilities: The interpreter undertaking a study of surface water sources is usually given a radius around a town or city that he must "size up" and report on (Fig. 5). The observer should have an idea of the economic distance he can go for a municipal water supply and an estimate of the quantity of water required to meet future demands. Normally this information is supplied to the photo interpreter.

In such a study aerial mosaics covering large areas are first inspected with a view to selecting reservoir sites capable of storing sufficient water to satisfy present and future demands.

Where stream-flow records for small creeks are few or not available, it may be necessary to measure the size of drainage basin and make an estimate of the actual area contributing to stream flow. On the prairies it is well known that in many areas most of the spring and rainwater runoff discharges in sloughs, so that only a

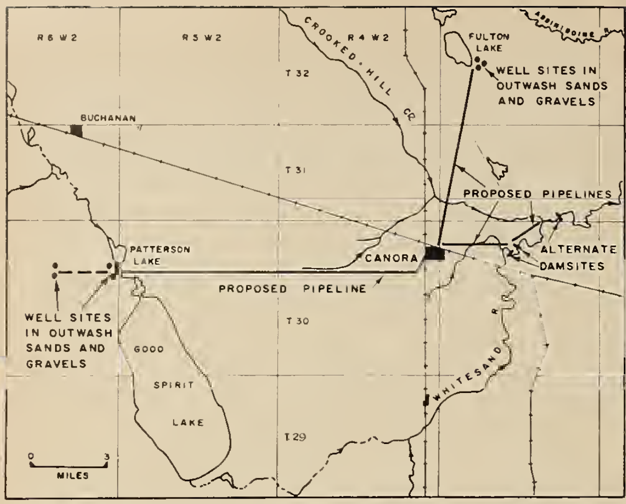


Fig. 5. This key map shows the results of an area-wide airphoto study in search of potential ground-water and surface-water schemes in the vicinity of Canora, Saskatchewan. Once all promising-looking sites for ground-water development and surface water storage were identified, the conditions at each site were in turn studied in detail in the airphotos.

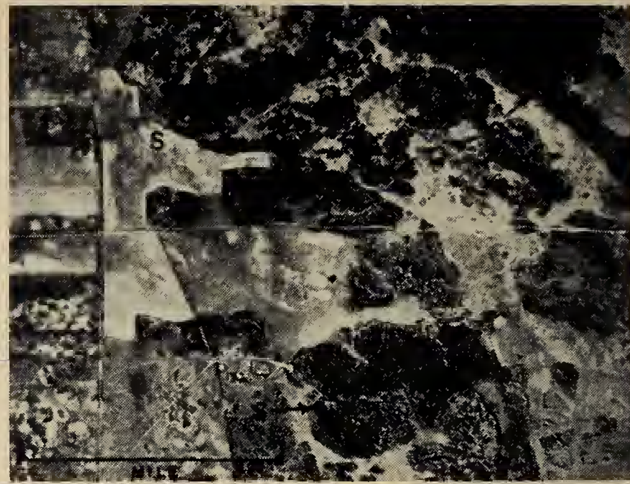

Fig. 6. This portion of an airphoto shows a series of large springs east of Rosthern, Saskatchewan. They were identified in connection with a regional search for a suitable town water supply. Note their characteristic shape. Blowouts in the lower left corner of this photo (small dark-toned areas) indicate that the surficial materials here are sands. See scale bar. ***RCAF photo.***

small percentage of the runoff actually reaches creeks and rivers. When considering the character of the drainage basin, usually all that is required is a general statement on topography as it effects runoff; subsoil permeability; vegetative cover; and cultivated versus uncultivated land.

In a few instances runoff from one drainage system can be diverted into a second drainage network and so increase the amount of water available. Close liaison with a hydrologist is desirable.

After assessing possible yields to prospective town reservoirs and ways of augmenting this yield, the damsite and reservoir areas are considered.[9] If the dam being considered is a large and important structure, then the following features should be reported on in an airphoto appreciation[13]:

a) Deductions and inferences concerning the geologic origin of the valley at the potential site—in particular, its erosional and infilling history. This prefield study serves as an excellent basis for future closeup studies on the ground;

b) Composition and probabe character of materials in the dam abutments and in the valley bottom with special emphasis on mode of deposition of the unconsolidated materials as well as on any apparent structural defects or detectable seepage channels in the underlying bedrock—should the character of bedrock be significant because of its proximity to ground surface;

c) Delineation of all bedrock outcrops, areas of shallow cover, and a qualitative estimate of depth to sound bedrock or other competent material, where surface features, geologic setting and observable outcrops permit a reasonable estimation. The disposition of rock outcrops along valley sides often suggests a tentative dam centerline as well as the possible layout of appurtenant structures;

d) Location of probable routes of excess seepage in the immediate vicinity of the dam and around the reservoir rim;

e) Detection of old and recent earth movements and other structural weaknesses (faults and joints) in the vicinity of the damsite and appurtenant works and around the reservoir rim,[15]

f) Determination of the availability and prospective suitability of various types of construction materials in the vicinity, pinpointing locations to check in the field;

g) Suggestions as to the type of dam to construct in view of the above considerations;

h) Suggested preliminary layout of appurtenant structures, taking into account natural topographic features and prospective foundation conditions, where these are to some extent assessable. Structures ordinarily included in this appraisal are diversion works, spillway, powerhouse, penstocks and canal structures where required. For each structure, alternative layouts may be suggested to take advantage of certain natural conditions—e.g., tunnels versus cut-and-cover conduits;

i) Determination of approximate storage capacity and flooded area where existing topographic maps and form-line construction from aerial photos make this a feasible proposition;

j) Search for evidence indicating the probability of accelerated sedimentation in the reservoir; also, evidence suggesting possible retrogression of the river-bed downstream from the dam;

k) Appraisal of flood damage to existing transportation and communication systems, to valley farm and pasture lands, stands of merchantable timber, farmsteads, population centers.

Selection of Sewage-Lagoon Sites: To make a worthwhile airphoto assessment of potential sewage-lagoon sites around a town or city the interpreter should have some idea of regional slopes so that sewage wastes flow by gravity from town to lagoon sites (Fig. 1).

Requests for the location of suitable lagoon sites frequently call for alternate locations and a statement of the pros and cons of each site that is chosen.

In selecting a lagoon site from aerial photos, other things being equal, the photo interpreter derives information on the following:

a) Size of tracts of non-commercial land that are available for development and the possibilities for future extensions to selected lagoon sites;

b) Type of excavation (e.g., large boulders vs till);

c) Subsoil permeability (e.g., heavy clay vs clean sands and gravels);

d) Type of borrow material available for dike construction;

e) Proximity to farmsteads or other dwellings;

f) Relative amounts of organic topsoil that must be removed from the site;

g) Comparative volumes of grading required to level different sites;

h) Comparative elevations of the

townsite and the proposed sewage-lagoon site;

i) Existence of natural channels leading away from proposed lagoon sites;

j) Prevailing wind direction;

k) Present use and value of land that must be acquired;

l) Pipeline length from town to the lagoon and terrain conditions along the selected route.[12]

In selecting alternate sites and assessing their relative merits the photo interpreter will often list the above points, item by item, and then comment on each. As with all airphoto-based studies, places to field check and features to field check are noted directly on plans accompanying the report.

For most towns, an airphoto study for possible lagoon sites can be completed in one day.

Less Common Applications: In the 42 individual airphoto studies carried out in connection with municipal-engineering investigations and used as a basis for this paper, as mentioned previously some studies were requested much more frequently than others. The more common applications are covered above. Contained in the list below are less common studies in which we have been requested to:

a) Select a cemetery site;

b) Map and classify slump and landslide features adjoining built-up city property as well as near proposed new townsites (Fig. 9);

c) Assess the relative stability of proposed alternate town reservoir sites where situated on former landslide or slump topography;

d) Select dugout locations for use as a town reservoir;

e) Locate clay materials for lining a sewage lagoon situated in an area underlain by sands (Fig. 8);

f) Locate the best site for a river intake, considering foundation problems and the possibility of erosion or sedimentation taking place at the intake;

g) Assess the likely quality of surface water supplies (lakes, for example) from an inspection of indicators suggesting contamination by chemical wastes, high concentrations of "alkali" salts[8] or undesirable algae growth around lake shores;

h) Locate a sewage outfall main to avoid as much as possible the following: muskeg, permafrost, large boulders, and bedrock;

i) Detect the most likely course of a deeply drift-filled valley in shale bedrock, using as a clue the presence or absence of major slumps that have in the past been induced by movement in the weathered surface of shale bedrock—where, also, the shale surface lies above the base of the valley floor;

j) Locate a pipeline route between a group of wells yielding groundwater and a townsite;[12]

k) Map drainage conditions as they affect new housing and industrial development.

When to Make Airphoto Studies

To be most useful, the airphoto study should be made before any appreciable amount of field work is undertaken. Very often, unfavorable terrain situations can be avoided and field work concentrated in places where it will do the most good. In addition the field engineer, who may or may not be the photo interpreter, visits selected points with a view to obtaining specific and detailed information. Of course his first job is to confirm or disprove data and inferences resulting from his photo study.

By carrying out photo studies at an early stage during an investigation the engineer not only economizes on field work—today becoming more and more costly—he also makes sure that favorable situations are not overlooked just because they are not apparent from the limited perspective so often accorded a person on the ground. The method also provides a way of developing preliminary information for design purposes at a relatively low cost.

Determining What Data Are Required

Municipal engineers and consulting engineers doing municipal work are best qualified to assess the sort of information they would like to get from an airphoto study. This task is naturally much simplified if the engineer requiring scattered terrain data has a general appreciation of what can and cannot be interpreted from the pictures. To solve this, one method that has worked well is for the photo analyst and the engineer requiring data to get together and list, point by point, all information desired and also information that exists and may be procurable. Until the photos are examined, even a competent specialist with considerable experience does not know precisely what and how much data can be obtained.

Fig. 7. A map prepared from a study of airphotos. In the search for water supplies the airphoto interpreter must always be alerted to the possibility of recharging potential near-surface acquifers. First of all the interpreter must determine whether or not a potential acquifer exists; subsequently, determine its characteristics. Then he must ascertain whether or not an assured source of recharge water is available nearby. A good example of this development on the prairies is the present Camrose water-supply system in Alberta.

In the area shown here the granular material in locality "A" is both coarser textured and deeper than in area "B".

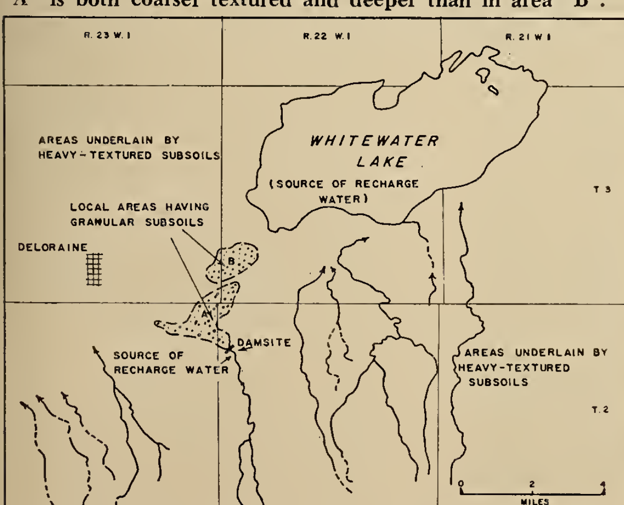

Fig. 8. Photo showing landscape features north of Saskatchewan Hospital, A, located near North Battleford. Purpose of the airphoto study was to locate impervious lining materials for a nearby sewage lagoon situated in sandy soils. Surface deposits here are shallow sands, which, in turn, overlie glacial till. Area "B" was selected as first choice for a clay borrow pit. Letter "C" shows a low cigar-shaped ridge, indicating here the local direction of glacier ice movement. See scale bar. *RCAF photo.*

The Use of Reference Material

For reference purposes the interpreter of aerial photographs should have an up-to-date library of published maps showing the surface geology, agricultural soils, drainage, contours, and the rest. Usually each map adds something to the overall picture and makes the final product just that much more complete and meaningful. But many times the objectives of these maps, their early date of publication, or their small scale may mean that they can be used as a guide only. Even so they often lend assurance to the digested airphoto detail or, on the contrary, arouse suspicion of possible errors in photo interpretation. No procurable map that shows landscape information should be overlooked.

How Data Are Shown

Where the magnitude of a job warrants the added expenditure for mosaic preparation, the photo-derived data should be shown either on the mosaics directly or on mosaic overlays. That is to say, data are best shown on transparent tracings to the same scale as the mosaics they overlay. Otherwise, the information may be shown on small-scale township plots or small-scale regional maps.

The more information that can be shown directly on plans, the more useful the results. Pertinent notes are also best recorded right on the plans. If the interpreter is unsure of his interpretation, where this uncertainty applies it must be clearly expressed. Field check points should always be indicated on the prints. And the sort of information the aerial observer expects to find on the ground should be appropriately noted.

How Data Are Used

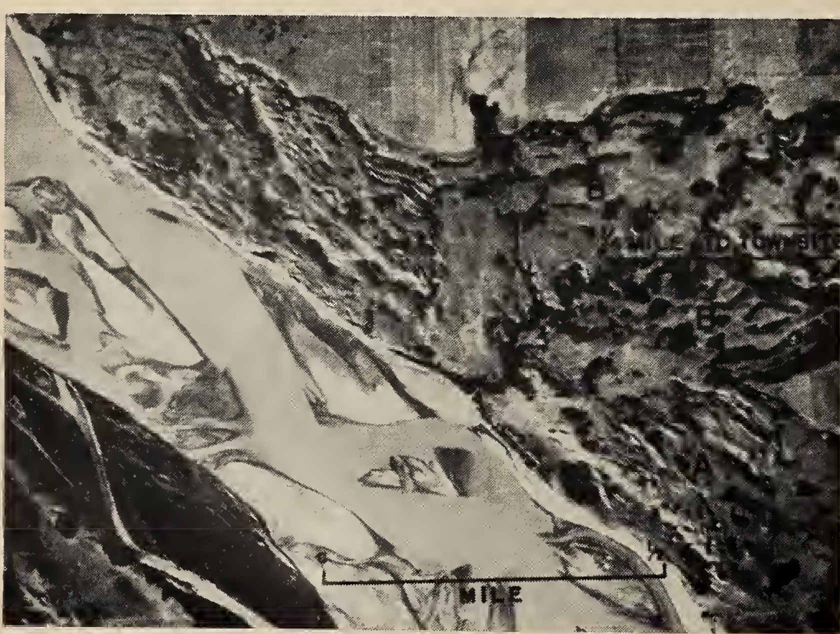
Aerial prints or tracings showing interpreted airphoto information are commonly taken to the field. Depending on the development stage of the project under consideration, the data shown may be used in preliminary design work, for preliminary cost calculations, assessment of relative costs of different alternatives, appraisals of problems and an estimate of their probable magnitude, and in some instances recommendation for possible solutions.

Preliminary estimates may be used in determining rough earthwork quantities for a dam, the approximate amount of storage capacity in a reservoir, the length of pipeline between a reservoir city and the town it serves, comparative costs of trucking aggregates from different sources.

Conclusions

The relative success of an airphoto undertaking depends not only upon the quality of tools at the disposal of the interpreter (good reference maps and scale and quality of airphotos, for instance) and the personal capabilities and experience of the analyst, but also the whims of nature.

Fig. 9. A new town has been recently built on level ground just a short distance to the east of the area seen in this airphoto (see arrow). Water supply and sewage disposal systems for the new community rest in part on valley-side topography, which as seen here shows a great many slump features. Areas marked "A" show features associated with relatively recent dislocation of slope-forming materials. Areas marked "B" appear more stable and do not reveal the preponderance of "active-looking" slope-instability features. The critical nature of all these slopes is of course well known and their condition is carefully considered wherever new construction on them is contemplated. *RCAF photo.*



Airphoto data should be derived as quickly as possible and should be presented in usable form just as concisely as possible.

Facts, inferences, and speculations should be separated and these different degrees of certainty should be plainly labelled on maps and in reports. Statements should be qualified where inferences replace facts and where speculation replaces inferences. These three degrees of certainty should not be confused.

Success in this work demands a working knowledge in the field of application; background training in soil mechanics, engineering geology and geomorphology; and widespread experience in airphoto interpretation. Careful observation and the interpretation of significant facts, however subtle, play an essential part of this work. Although field work may be drastically reduced, airphoto interpretation by itself is seldom a substitute for field study. Usually both are necessary to carry out any regional program involving appraisal of landscape factors.

THE DUNVEGAN SUSPENSION BRIDGE

T. Lamb, M.E.I.C.,
R. N. McManus, M.E.I.C.,
T. Lamb, McManus & Associates Ltd., Consulting Engineers, Edmonton.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

In June of 1956 the Alberta Department of Highways decided that the ferry across the Peace River at Dunvegan, Alberta should be replaced by a permanent two-lane highway bridge. The crossing is located about midway on the river between the bridges at Taylor Flats, B.C. and Peace River, Alberta and on the main highway connecting Grande Prairie and Peace River.

THE CHOICE of site was not limited to the immediate vicinity of the existing ferry crossing but several factors ruled in favor of this location. A great deal of money had already been spent by the Department of Highways stabilizing the north hill approaches and there appeared to be no better potential outlet to the south than Dunvegan Creek. The Peace River valley is about 800 ft. deep in this area so that exit on a reasonable grade could only be attained by use of an existing drainage channel. An evaluation of all these factors led to selecting a site about 500 ft. upstream from the existing ferry crossing on a skew of about 30°. Preliminary foundation investigations showed that the river had been scoured into over-consolidated clay previously loaded by glaciers. The main river channel near the south shore is about 15 ft. deep at low water and the bed is about 15 ft. above the hard clay. The north side of the river bed consists of 70 ft. of sand and gravel overlaying the over-consolidated clay. The thickness of the gravel bed decreases uniformly towards the south shore. The river bank on the south side rises quite steeply in the same material as the river bed for some distance with beds of highly compressed sand and finally gravel deposits about 100 ft. above river level. The north river bank consists of about 30 ft. of river deposited silt on top of the same layer of river deposited sand and gravel found in the river bed. Fig. 1. shows the foundation profile at the crossing.

Scour

Scour studies based on flood records, bed material and percentage of stream area affected indicated the river might scour around the large piers as much as 80 ft. below maximum flood level (determined as about elevation 1145). Normal flow in the Peace River is approximately 30,000 c.f.s. with a maximum recorded flood in excess of 400,000 c.f.s. in May, 1948.

In view of this fact it was undesirable to locate the pier bases on river deposits and the decision was made to locate the river pier bases at elevation 1065 or at the level of the hard clay, whichever was the deeper. Stream bed is about 1100 in the main channel, low water is around 1113 which is slightly below stream bed near the north shore and the north bank is slightly above maximum expected flood level.

Foundations

Field and laboratory investigations showed that the bearing capacity of the over-consolidated clay would be determined by elastic deformation rather than ultimate strength. A compromise figure of 10 tons per square foot was selected for the design of foundations on the over-consolidated clay with smaller values on the normally consolidated clays.

Recommendations

Preliminary cost estimates showed that expensive river piers would dictate relatively long spans. Various types and spans were investigated with the final choice falling between either a suspension bridge with two river piers or a cantilever truss bridge with four river piers.

The suspension bridge was recommended rather than the cantilever because it contained less structural steel (which was in short supply at the time of the preliminary investigation) and because half as much river work would be involved. Generally the unknowns and hazards of river work are greater than work on dry land or above water and therefore the cost of deep piers is less subject to close analysis than the cost of superstructure or land anchors. The contractors appeared to agree with the latter conclusions since no bids were received until the deep river pier foundations were put on a force account basis.

Project Layout

The minimum length of bridge which would clear the river on the 30° skew with land based foundations a safe distance from the river, was 1800 ft. The suspension bridge was therefore laid out with 900 ft. center span and 450 ft. side spans. The north anchorage was to be carried to gravel so was located only 100 ft. back from the river bank and could carry the north cable saddle and rocker. The south anchorage had to be located in over-consolidated clay so was kept back 250 ft. from the river's edge. The south cable saddle and rocker were carried on a separate steel bent near the edge of the river. The north end of the crossing was kept at a reasonably low elevation since the silt could not be expected to carry a very high fill. However a grade of approximately plus 3% to the south, together with 575 ft. of approach span including 150 ft. of spiral and 194 ft. of 4° curve, not only improved alignment at the south end but made the new approach road cross the old ferry road near the end of the bridge. This is considered important since any approach road along the banks of Dunvegan Creek is bound to require time for stabilization. In the meantime the existing exit, which is steep and not subject to slides since it follows contours, will be available for emergency use.

Model Study

In view of the size of the project it was decided that a model study of the principal structure would be justified. The preliminary design, and hence the model, used a cable sag of 110 ft. which was later changed to 100 ft. for the final design. Space does not permit a full discussion of the design and testing of the model but certain features are of interest. Briefly a linear reduction factor of 180 was used together with a slicing factor of 4. The towers and stiffening trusses were simulated by solid steel members carefully machined to account for proposed changes in stiffness. The bases of the towers were notched to simulate pins and piano wire was used for main and hanger cables. The piano wire was clamped at the tower tops and at the end of the span while the hangers were run through the stiffening truss and clamped below. Dead weight cans, partially filled with lead to match dead load, were attached at the panels point and lead shot was added to represent live load. The whole model was then mounted on a laminated wooden base to keep temperature movements of the base to a minimum. The base had provision for the proposed change of grade from one end of the bridge to the other. Ames dials capable of reading movements directly to the nearest 1/1000th inch were located at mid-span of the side spans and at the mid and quarter points of the center span. Duplicate sets of readings were then taken with all design combinations of live load. Observations were also taken at nine different locations to one side of center under the condition of a single moving concentration. Observations were also taken of the movements which occurred during a 50°F change in temperature. In addition the wind load on the towers and trusses was simulated by lateral spring loads and the corresponding lateral deflections observed. The deflection readings were all converted to prototype and from these bending moments and shears checked.

Agreement between deflections obtained from the model and theoretically computed ones was well within the limits of experimental error. Fig. 2 shows a photo of the model while Fig. 3 shows several deflection curves obtained by converting readings on the model to prototype. Lack of symmetry due to the fact that the bridge is on a grade caused the low point on the cables to shift about a panel off of center line. The influence lines for points symmetrically located as to distance will not be exactly the same.

Readings taken for the points located symmetrically with respect to the towers show that the maximum deflection reading can vary as much as 10% apparently due to lack of symmetry of the cables. This lack of symmetry makes the conversion of model deflection to prototype moments and shears difficult. However calculations to a sufficient accuracy for preliminary investigations were very useful.

Final Design

The knowledge obtained from the model study showed that the general dimensions chosen for the bridge were of a satisfactory order as were all likely deformations due to load, temperature and wind. The detailed designs of the bridge and its foundations could therefore proceed.

Substructure

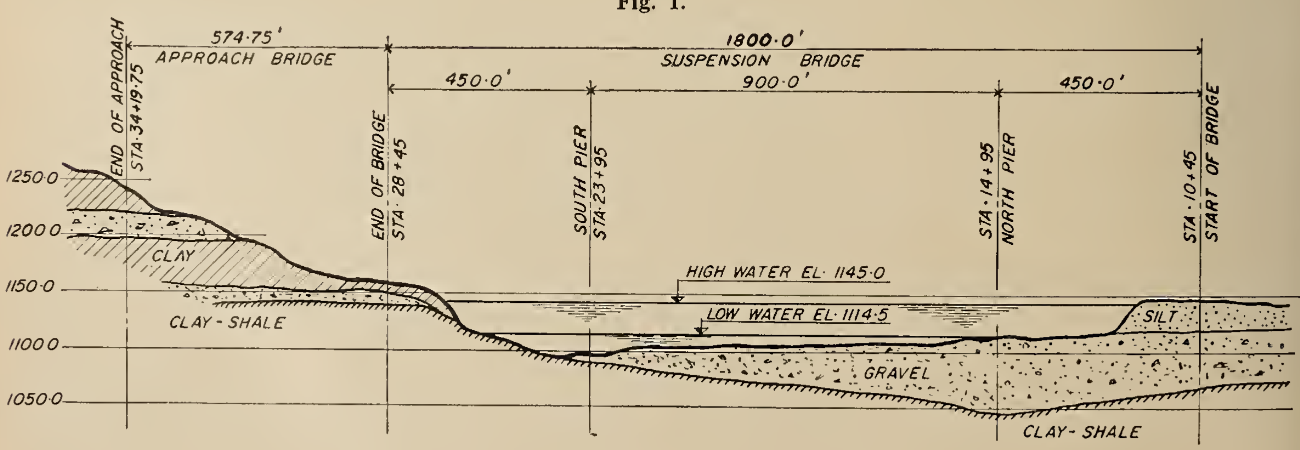
The design of the foundations resolved itself into two principal problems, viz. the underwater pier bases and the pier tops and land based foundations.

The north anchorage was carried down through the silt into the sand and gravel to elevation 1106 at the back side and stepped to 1112 at the front. The sand and gravel base was consolidated by driving steel H-piling and during high water it was necessary to install well points to maintain this consolidation until after the dead load of the concrete was in place. The total dead weight of the north anchorage is 18,400 tons with a net effective submerged weight of approximately 14,000 tons. The maximum horizontal component of cable tension is approximately 3500 tons due to the combined effect of live and dead load which means a coefficient of friction of approximately 0.25 was used. The anchorage is made up of cellular construction with gravel ballast as economical dead weight. The south anchorage being completely above high water has a gross weight of concrete and ballast of 14,000 tons and is of similar concrete cell construction to the north anchorage. The cables entering the south anchorage have a vertical component which is offset by the dead load reaction of the towers carried on the anchorage.

The design and construction of the two river piers cannot be covered in detail. Briefly it can be said that standard cofferdam procedure was abandoned for the north pier early in the preliminary investigations on the realization that sheet piling could not be driven through the sand and gravel to the shale. In any case the bracing for such a cofferdam would be extremely expensive.

The decision was reached to design a caisson which would be sunk

Fig. 1.



FOUNDATION PROFILE

SCALES: HORIZ· = 1" = 250'-0
VERT· = 1" = 100'-0

through the sand and gravel by dredging until it reached the over-consolidated clay below. The design conditions were an assumed ice force of 1500 kips acting at elevation 1115 together with the effects of dead load, live load and wind. These requirements called for a pier base of almost 2,600 sq. ft. from the point of view of stability and permissible bearing. The final design was a three cell hollow caisson 86 ft. by 30 ft. with 5 ft. reinforced concrete walls analyzed by moment distribution for lateral pressures and checked by the coefficients published by the Portland Cement Association for a 3 cell box culvert. The cutting edge was reinforced by steel plate and the walls were notched to key a concrete seal 20 ft. thick in the bottom after the caisson was in place. It was proposed to fill only the upstream cell with ballast in order to offset the fact that the pier shaft had to be located off center to permit the construction of the starling. The top was also notched to provide support for the framework on which to pour a 5 ft. thick slab. This slab was intended to be left at elevation 1105 above which the pier shaft and cap would be constructed. The caisson was designed on the assumption of an average side friction of approximately 750 p.s.f. It was assumed that it would be necessary to "glory hole" or remove the sand and gravel for about 15 ft. deep around the caisson and load with about 700 tons of ballast to sink the caisson to the required elevation 1048. In addition holes were cast in the walls of the caisson clear to the cutting edge and lubricating holes were connected to the side so that water or mechanical means might be used to help loosen rocks or gravel.

Side friction is very difficult to estimate since it is a function not only of the density but the composition of the material. The preliminary investigations could not possibly evaluate these accurately throughout the depth so assumptions had to be made. Lee[1] shows in his Table XI, Page 129 the highest average value of skin friction for a mixture of sand and boulders and a depth of 100 ft. below low water as 660 lbs. p.s.f.

The caisson was constructed on a gravel island and launched by building the first 11 ft. high section on a concrete pad temporarily reinforced by removable bolts. When the concrete had cured sufficiently the launching was accomplished by removing the reinforcing and dynamiting the thin concrete slab. Excavation inside the cells was accomplished at first by clam shell and later supplemented by an air-lift pump consisting of 10 in. pipe, fed at the bottom by a 2 in. air line hooked to two 600 c.f.m. compressors.

Fig. 2. Photo of Model

Very little trouble was encountered until the caisson reached about elevation 1065. Although side friction had naturally increased it became evident that a region of higher than normal friction had been encountered. At this time bison head was brought up during excavation which indicated that the river had run for some appreciable length of time near this level. This is significant from two points of view. Firstly, the increase in friction meant that a well graded mixture of boulders, sand and gravel resulted in a layer of maximum density. Secondly, the fact that no other dense layers had been encountered on the way down meant that most of the upper 50 ft. was in a relatively loose state. If this is the case it is possible that the river could scour in a single major flood to elevation 1065. The original design had assumed that approximately 15 ft. of "glory holing" plus a surcharge of 700 tons would be required to sink the caisson. In actual fact more than 30 ft. of "glory holing" plus 1800 tons of ballast were required to sink the caisson. This works out to an average skin friction value of 1300 p.s.f. or almost double the design value. The caisson was maintained within an inch or two of its final lateral position throughout its descent so no problems arose there. Shale was encountered in one corner of the excavation 3 ft. higher than indicated in the test hole log so the caisson was halted at this level. The bottoms of all cells were cleaned out down to shale and the seal concrete poured in contact with the shale over the full area. It is believed that this is one of the largest open caissons sunk in Western Canada and perhaps the largest ever on the prairies.

The south pier was designed as a conventional spread footing to be carried about 15 ft. into hard shale to elevation 1065. The design was therefore not unusual but the construction was very unusual and worth brief mention. Due to the very hard shale it was recognized that although the material would scour in time it nevertheless would not permit sheet piling to be driven to the bottom of the excavation. The final cofferdam design called for a very heavy sheet piling to be driven as far as possible into the shale (about elevation 1080) in a rectangle stepped back about 6 ft. from the neat lines of the footing. Bracing frames were designed to drop into the cofferdam and be wedged in place as excavation proceeded and it was then proposed to excavate to the neat lines of the footing for 15 ft. below the bottom of the sheet piling. The bottom frame was jacked tightly against the shale to prevent leakage, which proved useful before completion of the base pour. Excavation in the shale was carried out by air hammers and clam shell. An innovation which worked well was the use of a small caterpillar front end loader. This machine moved all loose material to one corner of the excavation so the clam shell always lifted a full load. Confining the operations of the clam to one spot was also a safety measure since it was less likely to damage the bracing.

The south anchorage is similar in design to the north anchorage except that it is smaller since it is above high water. Since the base of the south anchorage is resting on the over-consolidated clay it was decided to take precautions against seepage pressures building up. The plans therefore called for the front of the anchorage to be poured to the neat lines of the excavation for the bottom ten feet while the back has a two foot thick gravel backfill connected to a drain at elevation 1145. The drain is piped to the river bank in a 6 in. sub-drain pipe. The upper 6 ft. of the backfill behind the anchorage is mechanically compacted clay so that

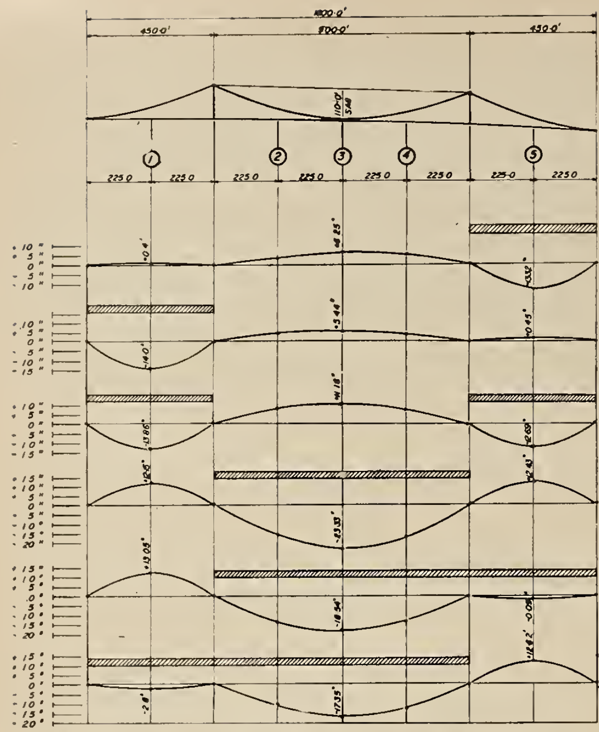


Fig. 3. Live Load Deflection—Curves for Prototype

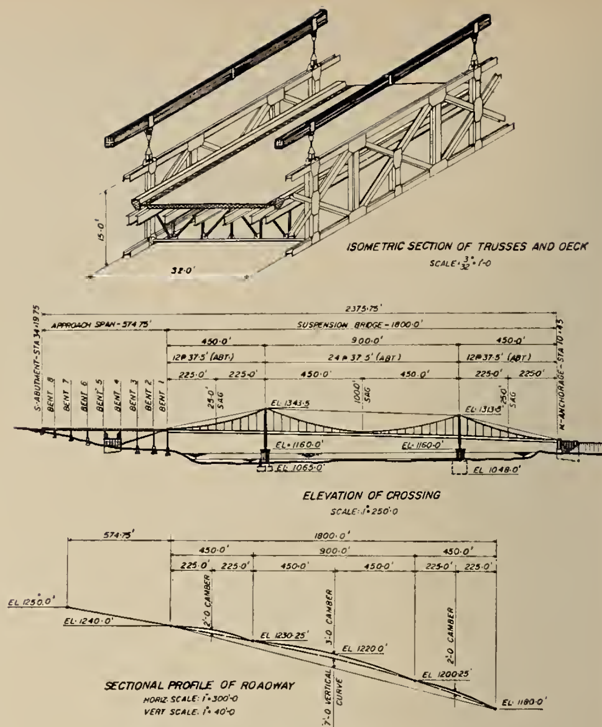

Fig. 4. General Layout and Section

most of the surface water will not be carried into the sub-drain near the anchorage.

The construction of the foundations for the Dunvegan Bridge was unusual and difficult. However the caisson was launched and sunk successfully in accordance with the original scheme. The south pier base was a very difficult problem since it required an open cofferdam 42 ft. by 97 ft. 60 ft. deep. This pier was completed in accordance with the original design and the excavation was carried out in the dry. In both cases the problems encountered were within the range of what might be expected any time work is carried out at great depths in large rivers. As mentioned previously the river work below elevation 1105 was constructed on a force account basis. The cost of this force account portion of the work was within range of the engineering estimates. The total cost of the two river piers was less than $1 million which is slightly less than the engineering estimates at the time of the preliminary investigation.

Superstructure

The tops of the piers were located at elevation 1160 approximately 15 ft. above maximum high water. The only exposed structural steel below 1160 is the cable anchorage at the north anchor. This is not considered serious since this steel is above high water and not in the path of floating debris. Fig. 4 shows the general layout of the project with important dimensions, elevations and a typical cross-section near the center of the suspension bridge.

All structural design is in accordance with the American Association of State Highway Officials Standard Specifications for Bridges, 1953 edition, insofar as these specifications can be applied to the design of a suspension bridge. Permissible stresses in cables, factor of safety against sliding of anchorages, required vibrational stiffness (both vertical and torsional) and many other features of suspension bridge design are not covered in the A.A.S.H.O. Specifications. It was therefore necessary to rely on experience and the recommendations of other designers of suspension bridges for limitations and recommendations. In this connection Mr. G. B. Woodruff was consulted and made recommendations with regard to live loads, wind loads, etc. that should be provided for.

The approach spans at the south end of the crossing are unique only in that they are partly on a 4° curve, partly on a spiral and finally approach the suspension bridge proper on tangent. These are girder spans designed for composite action in regions of positive bending moment. The girders are continuous over the supports and have articulation pins and expansion links at points where the girders must change direction as well as in the straight portion of the bridge. The girders were set to take care of the super-elevation of the curved roadway as well as possible but the concrete deck had to take care of the refinements. In all cases the bottom of the deck followed the line of the girder flanges in order to simplify the formwork. In deference to the area served by the bridge where snow removal would be a problem, continuous snow slot grating about 21 in. wide runs the full length of the bridge adjacent to each curb. On the approach spans the guard rail posts require a moment connection which was obtained by breaking the snow slot grating and making a continuous deck and curb section at each post. This was unnecessary on the suspension bridge so the snow slot grating runs continuously where it will not only be useful from the point of view of snow removal but also will improve the wind resisting qualities of the structure.

The suspension bridge design was based on certain requirements, limitations, assumptions and decisions. Some of these were supplied by the Bridge Branch of the Alberta Department of Highways, such as the 27 ft. clear roadway between curbs, the snow slot grating, the 18 in. minimum safety curbs (wide enough for use as emergency sidewalks) and H20-S16-44 highway loading. In addition it was decided that since lane loading would govern on the long spans for the design of the main elements it would be good economy to increase the stringer, floorbeam and approach span capacity to take care of a single heavy load. Alberta with its oil and gas exploration activity is particularly subject to heavy loads. The load selected was one H40-S32 truck plus impact with rear axles spaced at 24 ft., the truck confined to the centre of the bridge and stresses permitted at 125% of basic unit stress. The main cables, towers and stiffening trusses, so far as live load are concerned are designed for H20-S16-44 with no impact. Suspenders and members of the stiffening truss taking suspender or floor truss reactions are designed for H20-S16-44 plus 30% impact. Stringers and floor trusses not governed by the single heavy truck are also designed for H20-S16-44 plus 30% impact. The structure was designed for a lateral wind load of more than 500 lb. per linear foot on the truss, 100 lb. per linear foot on the cables and 200 lb. per linear foot on the live load.

The bridge is designed on the assumption that under dead load only at +30°F the stiffening truss is unstressed. In order to assure this, closure will not be permitted until the dead load is all in place and the temperature is between 30°F and 35°F.

The design load combinations of significance in the design of the superstructure are:

Case I — Dead + Live + Temperature + Impact @ 100% B.U.S.

Case II — Dead + Full Wind @ 125% B.U.S.

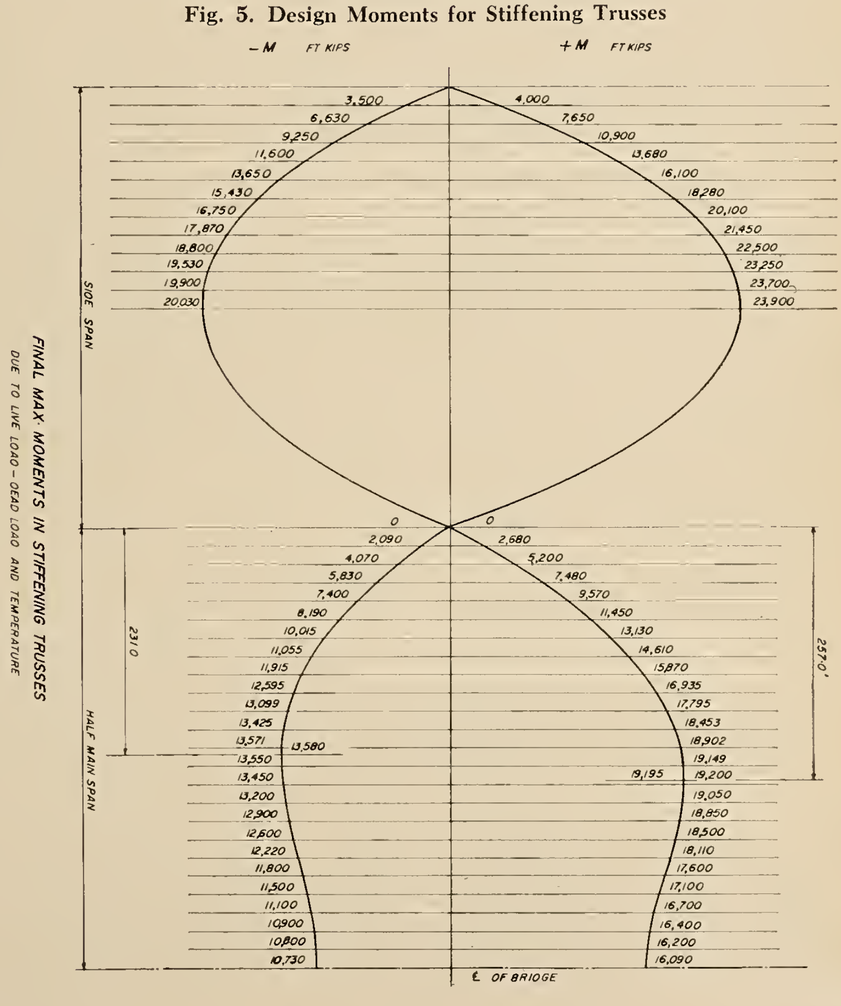
Case III — Case I + 15# Wind + ½ Wind on Live Load + Longitudinal Force for Live Load at 125% B.U.S.

Each main cable for the suspension bridge is made up of 20 — 2⅛ in. bridge strand while the suspenders are 2¼ in. bridge strand. Each 2⅛ in. strand is made up of one 0.207 in. diam. galvanized wire and 90 — 0.193 in. diam. galvanized wire. All wires are full length with no splicing permitted. All strands were required to be prestressed to one-half their specified ultimate strength and held at this load for at least 4 hrs. The tension load was then to be relaxed to the average dead load tension at 30°F and marked for the positions of all hangers, saddles, etc. Actually the suspender locations were marked on only four of the twenty strands since the other strands were erected to match the four guide strands. Modulus of elasticity was determined for each strand and was required to be a minimum of 23.5 x 10^6 p.s.i. Special castings engage the strands and keep them separate at each hanger point. Wooden separators are bolted to the cables mid-way between hanger clamps to stop flutter which could cause fatigue in the outer wires of the strand. Considering the relatively dry climate and the space between strands for air circulation, corrosion of the zinc plated strands is not considered serious. However if inspection in later years shows corrosion is actually occurring there is space enough to apply a corrosion inhibitor.

The structure as a whole has been analysed by the so-called deflection theory first developed by Melan[2] and translated by Steinman.[3] This has been a standard approach to all modern suspension bridge design. The actual analysis was somewhat shortened by following the procedure outlined by Ling-Hi-Tsien[4]. The important constants and other factors necessary for this analysis and belonging to this particular structure are outlined in Appendix 1.

There are several unusual features in the design of this structure which are worthy of discussion. The stiffening truss is a Warren type with double intersecting diagonals and with the wind system and deck at mid-depth. The truss is fairly deep for the relatively short centre span of 900 ft. (short for suspension bridges that is) but there are several good reasons for the choice. Basically it was decided early in the design to attempt to make full use of both top and bottom chords in the lateral wind system. This could only be attained by placing the wind system near mid-depth of the truss. The relatively small towers and narrow sidewalks meant that the hanger cables only clear the roadway by 2½ ft. on either side. It was therefore desirable to keep the upper chord and hence the hanger cables at least five feet above the roadway. These factors led to the choice of a 15 ft. depth of stiffening truss which at 1/60th of the span was considered very satisfactory. The double intersecting diagonals were used to assist in transferring the wind shears to the chords and actually reduce the slenderness ratio of the diagonals to where there is a net saving in weight. The criterion chosen for wind was to limit the lateral deflection to a maximum of three feet under full wind load. Participation between cables and stiffening truss was based on the simplified distribution suggested by Pavlo.[5] A d/l ratio of 1/60 is considered very stiff for suspension bridges but this is particularly desirable when the wind system and deck are at mid-depth rather than at the top or bottom of the stiffening truss. In order to further improve the

Fig. 5. Design Moments for Stiffening Trusses



torsional stability and decrease the wind area floor trusses were used rather than girders.

Analysis of this suspension bridge from the point of view of aerodynamic stability based on Steinman's[6] criteria shows that the mean effective ratio of the distributed force of restitution to the displacement is approximately 450 p.s.f. per cable where he recommends more than 120 p.s.f. for open web stiffening trusses. The ratio per foot of width is approximately 28 lb. per cu. ft. where he recommends not less than six. The proportion of the ratio due to the stiffening trusses is 0.70 where he recommends not less than 0.25. On this basis the aerodynamic stability seems assured. Normally it would be desirable to inhibit relative longitudinal motion between the stiffening trusses and cables at the center of the main span since this is one place where torsional motions can initiate. In view of the exceptional stiffness in all respects of this structure it was decided that this feature was unnecessary. In comparison to the first Tacoma Narrows Suspension Bridge the ratio per cable was about one-seventh that of the Dunvegan Bridge and only 0.015 of this ratio was due to the stiffening girder. The ratio per foot of width of the Tacoma Narrows Suspension Bridge was approximately one-eighth of the Dunvegan Bridge. Compared to the Lion's Gate Bridge the ratio for Dunvegan is about four times as high, the ratio per foot about five times as high and the proportion due to the stiffening trusses about twice as high. This exceptional stiffness was obtained without sacrifice of steel quantities by using the double intersecting Warren system. Fig. 5 and 6 show the bending moments and shearing forces for which the stiffening trusses are designed.

The towers of the Dunvegan Suspension Bridge are unusual in that it was decided to use pinned bases. The reasoning behind this is that in the northern area where the temperature range is ± 80°F from the vertical position of the towers, about twenty percent of the maximum stress in a fixed base tower is due to longitudinal movement of the tower top. A unique approach was also taken to check the stability of the towers. The A.A.S.H.O. establishes permissible unit stresses for compression members on the basis of slenderness ratio. The slenderness ratio cannot be obtained for a tapered column of varying cross-section. On the assumption that the slenderness ratio has significance only from the point of view of decreased stability for

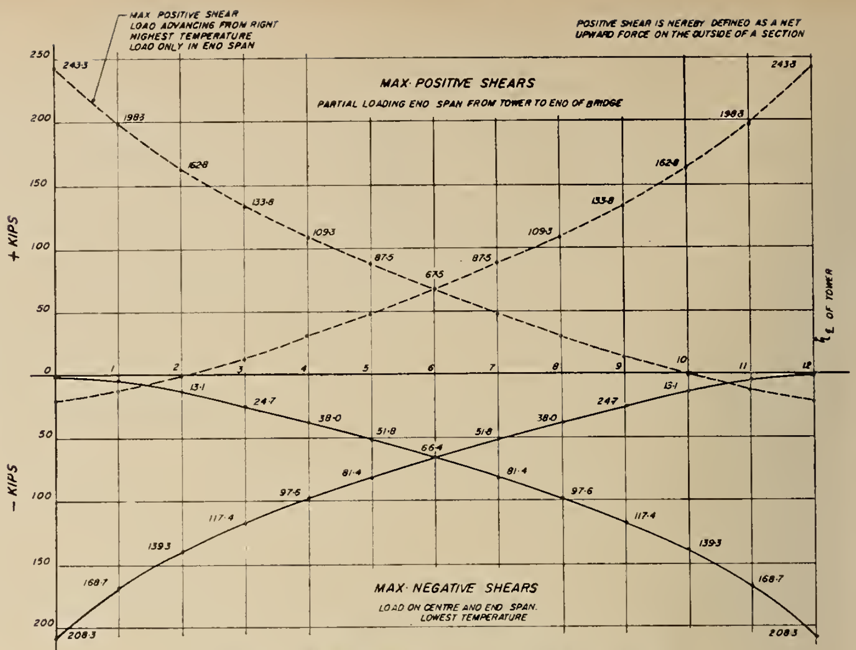


Fig. 6. Design Shears for Stiffening Trusses

greater ratios the problem was approached on the basis of comparing the stability of the tower column with one of the same height and theoretical ultimate capacity but with regular cross-section. The theoretical buckling load for the tower column was computed by means of Newmark's[7] numerical procedures and converted to critical unit stress for the mid-portion of the column. The slenderness ratio of a column of the same length and theoretical buckling stress was then computed and the permissible unit stresses in the tower column reduced the same as would be required by A.A.S.H.O. for the uniform column of equal stability. Although the buckling load on the tower column could never be reached since the yield strength of the steel would be reached first this technique permitted a reduction in permissible load consistent with that which would be required in a uniform compression member of equal stability. Appendix 2 shows a typical calculation for this approach. As it turned out the critical case arose from the combination of direct stress and moment due to lateral forces.

The tower sections were erected in rather unusual fashion by a creeper with a travelling hoist on rails at the top. The roadway on the suspension bridge is set on a camber between towers such that under maximum live load and maximum temperature the deck would theoretically form a straight line between towers. All field assembly is accomplished by high tensile bolting and no field welding has been permitted.

The stiffening truss has been assembled in 37 ft-6 in. sections at the site and will be erected one section at a time. Articulation is to be provided by loose bolting the chords at 75 ft. intervals while pouring the deck and the last work required will be tightening up the gussets at these points.

The Dunvegan Bridge is scheduled for opening in the fall of 1960, and at the time of writing this schedule appears likely to be met. The fabrication is complete on all steel; the towers, cables and hangers are in place and the schedule called for the stiffening trusses to be lifted from the ice to their position in the structure starting the last week of January, 1960. This schedule has been met and at the time of writing it appears certain the structure will be ready for deck forming to commence by March 1, 1960. Fig. 7 shows some progress photos taken during erection of the stiffening trusses. Forming and pouring the concrete and asphalt deck will take most of the summer with closure of the articulation points and paint touch-up the last operation.

Conclusions

The Dunvegan Suspension Bridge is Alberta's longest clear span and the fourth largest suspension bridge in Canada. The use of a suspension bridge for the relatively short clear span of 900 ft. might be considered marginal but the cost of the crossing and the quantities of materials used have justified the choice. The superstructure of the suspension bridge contains 2620 tons of structural steel and 509 tons of cables and fittings. Cables and fittings cost approximately fifty percent more than structural steel in the suspension bridge proper. The snow slot grating, the extra structural steel required due to the grating and the extra steel in the stringers and floor trusses due to the single heavy truck amount to approximately 350 tons which reduces the equivalent quantity of steel to approximately 3,000 tons. Comparison with other structures is difficult, because design requirements and class of structure enter the picture. The structural steel quantity of 0.83 tons per lane per foot of bridge is almost identical with the quantity in the former Taylor Flats Suspension Bridge. This structure however was designed for only H15-S12 live loading and a lateral wind force of 270 lb. per ft. which is less than half that provided for in the Dunvegan design. Other structures with similiar clear spans appear to run between 0.85 and one ton per lane per foot of span depending on location, facilities provided and class of structure. The overall cost of the crossing including the 575 ft. of approach span will be approximately $4.5 million which compares favourably with other projects of a similar nature in the same general area.

APPENDIX 1

Design Constants

The stiffening trusses were analyzed by the Deflection Theory using the simplified methods of Ling-Hi-Tsien.[4] The numerical values from which the constants were computed together with the constants which apply to this structure are presented using the nomenclature of his paper, as a matter of interest. Finally Fig. 6 and No. 7 show the design values of maximum moment and maximum shears for which the stiffening trusses were designed.

APPENDIX 2

Tower Design

The towers may be considered as pinned top and bottom in the longitudinal direction with unsupported length from the base pin to the P.I. of the cables. In the lateral direction the columns are continuous and have lateral support as individual members at each of the cross beams. The loading cases, discussed in the test are

Case I — Dead + Live + Temperature + Impact @ 100% B.U.S.

Case II — Dead + Full Wind @ 125% B.U.S.

Case III — Case I + 15# Wind + ½ Wind on Live Load + Longitudinal Force from Live Load @ 125% B.U.S.

in which B.U.S. stands for Basic Unit Stress.

The stability of the towers needs to be investigated in the direction of the span under Case I loading while the stability perpendicular to the span will depend on Case II or Case III loading. Case II loading gave the worst combination of direct stress and bending in a lateral direction of the tower and the sections were selected to satisfy this condition. For example the section of south tower between the bottom strut and rocker beam carries end moments of +4150 ft. kips and -2702 ft. kips together with an axial load of 3210 kips. When designed according to Appendix "B" of the A.A.S.H.O. this section would require 338 sq. in. at 9.5 k.s.i. (125 x B.U.S. of 7.6 k.s.i.).

The final choice of section based on considerations throughout the length of the tower resulted in a constant section with an area of 398 sq. in. throughout the middle portion of the tower with constant depth perpendicular to the span and with the ends tapered in the other direction.

An analysis of this tower to determine the theoretical critical buckling load for one leg (see Fig. 8) using Newmark's[7] numerical procedures shows after three successive rounds that the theoretical critical buckling load is close to 16,400 kips. A uniform column of equal length, area and stability would have a slenderness ratio of 84.5. According to A.A.S.H.O. such a column would have a permissible unit stress in axial compression of 12.6 k.s.i. Since this is greater than the 9.5 k.s.i. required for the combination of loads under Case II the latter was the governing case.

The foundation investigation and recommendations were under the supervision of Dr. R. M. Hardy and the precautions against scour were based on the recommendations of Dr. T. Blench of the University of Alberta. C. B. Woodruff of San Francisco was consulted regarding suspension bridge design in general and recommended live and wind loads. G. D. Morrison and R. M. Morison, resident engineers on the substructure and superstructure respectively have played important parts in the success

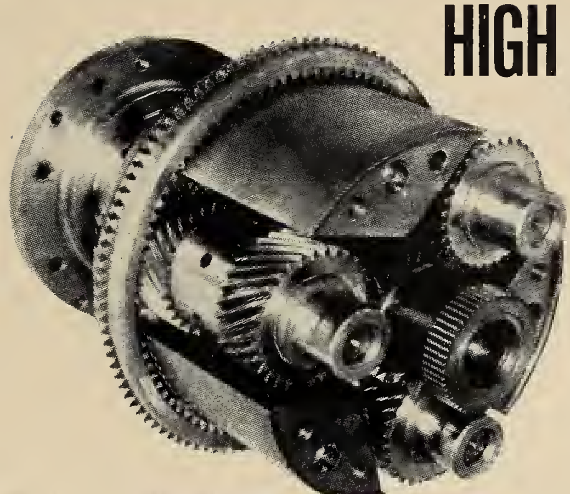
MARINE AND INDUSTRIAL HIGH POWERED EPICYCLIC GEARING



H. Norman G. Allen,
Joint Managing Director,
W. H. Allen Sons & Company Ltd.,
Bedford, England.

T. P. Jones,
Chief Engineer and Manager,
Gearing Department,
W. H. Allen Sons & Company Ltd.,
Bedford, England.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

Shortly after the war, great interest was aroused in work which had been taking place in Germany on epicyclic gearing designed to the principles of Dipl.-Ing. W. Stoeckicht of Munich. Work commenced in England on gearing to these principles in 1946 and a paper was written on the subject by the authors in 1952. At that time there were critics and doubts were expressed in many quarters concerning these developments. This paper, presented eight years later, describes the rapid progress which has in fact taken place in the application of epicyclic gearing for use in high speed, high torque and high powered applications, and is based upon highly successful results. The gearing described is equally suitable for speed reducing or speed increasing applications and attention is drawn to developments for speed change, reduction-reverse and for de-clutchable applications. The use of combined co-axial and parallel axis gearing is discussed. Reasons are given for such gearing to be able to deal with high speeds and torques without exceeding recognised maximum permissible tooth speeds and stresses. An unusual form of hardening the toothed components is described with reasons for its adoption. Results are compared with those obtained by the more usual carburising method. The paper is illustrated with reference to many different types of installation and application.

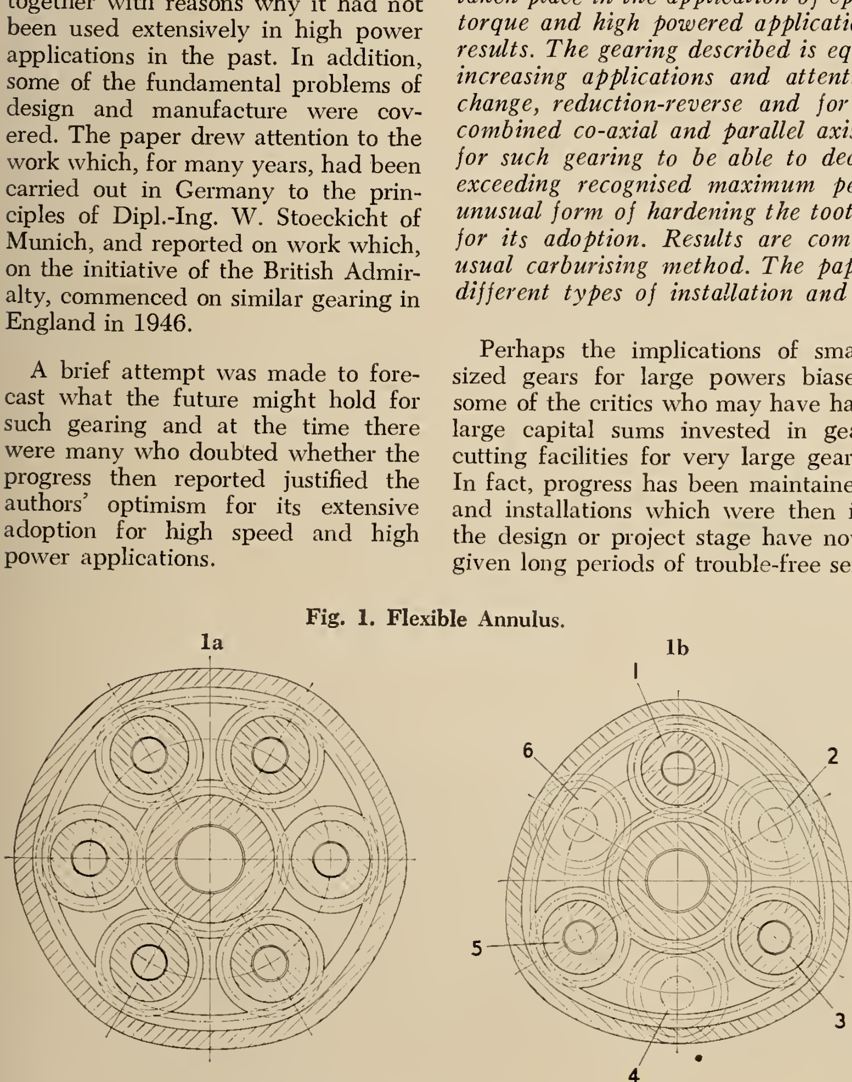
EIGHT YEARS ago the authors presented a paper to the Institute of Marine Engineers in London, England,[1] outlining many types of epicyclic gearing for industrial and marine applications. A brief historical survey of epicyclic gearing was given, together with reasons why it had not been used extensively in high power applications in the past. In addition, some of the fundamental problems of design and manufacture were covered. The paper drew attention to the work which, for many years, had been carried out in Germany to the principles of Dipl.-Ing. W. Stoeckicht of Munich, and reported on work which, on the initiative of the British Admiralty, commenced on similar gearing in England in 1946.

A brief attempt was made to forecast what the future might hold for such gearing and at the time there were many who doubted whether the progress then reported justified the authors' optimism for its extensive adoption for high speed and high power applications.

Perhaps the implications of small sized gears for large powers biased some of the critics who may have had large capital sums invested in gear cutting facilities for very large gears. In fact, progress has been maintained and installations which were then in the design or project stage have now given long periods of trouble-free service. A great deal of what was described has become even more firmly established practice. It is thought that the present paper which reports on some of the many successful applications which have taken place may be of wide interest because it shows not only that doubts which have been expressed about the suitability of such gearing for high power applications have proved to be unfounded but also indicates that further developments are to be expected.

The authors have tried to give what they consider to be an unprejudiced view of interesting and significant developments in epicyclic gearing, and hope that what they have to say may be strengthened by the fact that they still maintain an interest in the type of gearing which was formerly used in many of the applications quoted, and which still has an important part to play. All forms of gearing are but a means to an end, and each application needs to be engineered according to the merits of the case.

Fig. 1. Flexible Annulus.



Growth in Size and Numbers of Double Helical Epicyclic Gears

In any type of gearing the advantages to be gained from the use of helical teeth, compared with spur teeth, for the transmission of large powers are well-known. Amongst them, particularly in high speed applications, one of the more important is that of noise. It is found almost invariably that high speed gearing with helical teeth is quieter than gearing made with spur teeth. In many cases the use of double helical, as distinct from single helical, gearing is considered desirable.

Stoeckicht gears in which the sunwheel has no bearings have been successfully made with spur and single helical teeth, but the use of double helical gearing gives further advantages from this point of view. There is a better support for the floating sunwheel because the radial components of the tooth forces act in two separate planes and the equal and opposite axial forces on the sunwheel teeth also tend to have a steadying influence. Further, there is no tipping moment—as would be the case with single helical gears—to be resisted by the planet wheel bearings.

It is not surprising, therefore, that the most rapid and extensive progress with Stoeckicht gearing has been made with the double helical form which was introduced some ten years ago. This type has proved to be much more suitable for the majority of industrial and marine applications than earlier forms of epicyclic gearing using spur or single helical teeth. The paper amplified some of the reasons for the rapid growth in the use of such gearing from 1951 to the end of 1959.

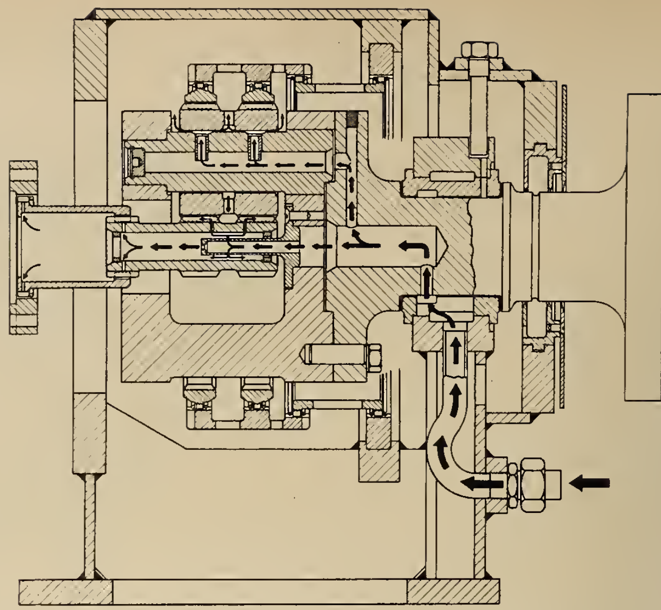


Fig. 4. Sectional Arrangement of a Typical Epicyclic Gear showing Flow of Lubricating Oil.

In 1951 there were very few applications and the total horsepower involved was quite small, but by the end of 1959 there were 2050 applications with a total horsepower of more than 4,400,000. This is an average of 2100 hp. for each gear, but in fact the powers vary from just over 100 hp. to 20,000 hp. The input speeds vary from a few revolutions per minute up to 45,000 r.p.m., but even in the gears with high input speeds the pitch line velocity is relatively low as this is, of course, one of the inherent advantages of epicyclic gearing.

The gears include speed-reduction and speed-increasing gears, change-speed gears, reduction-reverse gears and also de-clutchable gears. There is a wide variety of industrial and marine applications, and a number of these will be described in some detail in this paper in an attempt to illustrate the extensive field in which high power epicyclic gearing is now playing a part.

Mechanical Considerations

The Importance of Load Sharing between Planet Wheels: The main difference between parallel shaft gearing and epicyclic gearing is that, in

Fig. 2. Load Sharing Between Planet Wheels.

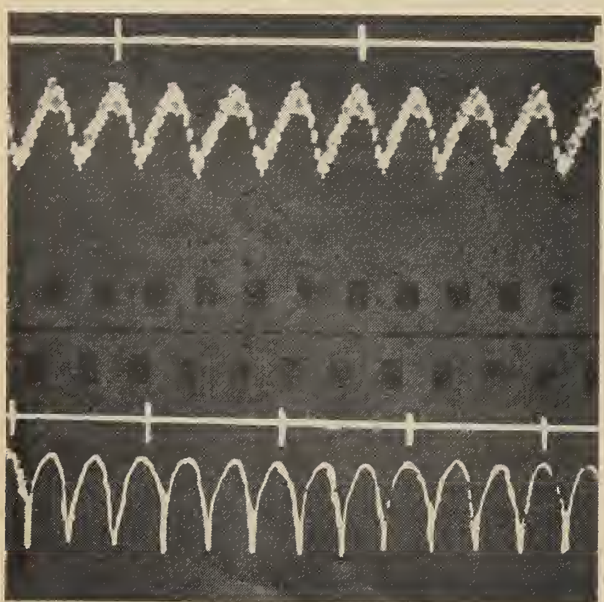

Fig. 3. Principal Components.

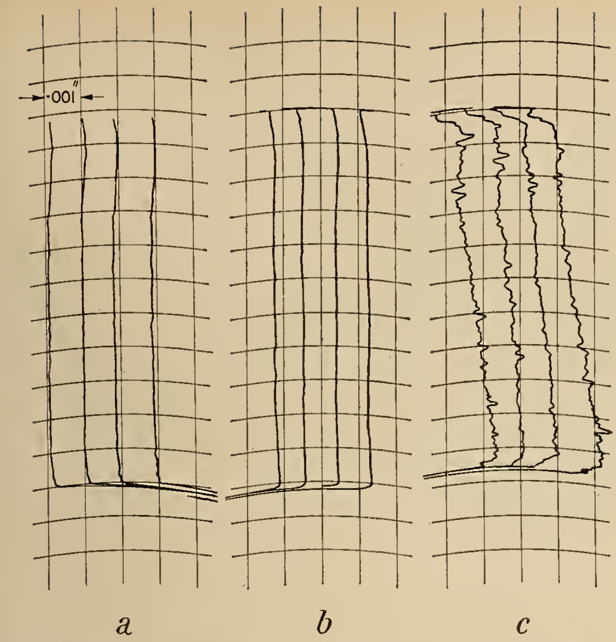

Fig. 5. Check Results on Helix Angle of Carburised and Nitrided Wheels.

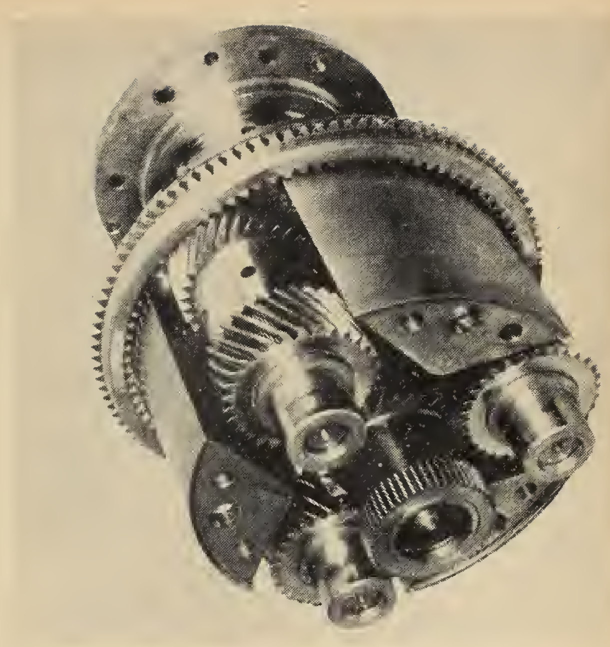

Fig. 6. 1450 hp. Double Helical Epicyclic Gear, Using Hardened and Ground Planet Wheels.

the latter, the load is transmitted by more than one set of tooth contacts, but in order to take advantage of this, it is, of course, essential to ensure that the load is equally divided between all planet wheels. It may not be out of place to re-state the now well-known Stoeckicht principles for ensuring automatic load sharing, as these are so essential for the success of large power epicyclic gearing. This recapitulation of the principles may be particularly desirable as other attempts have been made, without their use, which have not been so successful.

It is easy to understand that if torque is applied to an epicyclic gear with three planet wheels whilst it is prevented from rotating, and one of the co-axial members, either the sunwheel or the annulus or the planet carrier, is allowed to float, the tooth forces involved will move the floating member until equilibrium is obtained. It is not possible, however, to demonstrate this feature theoretically when more than three planet wheels are used. Moreover, under running conditions the problem becomes more complicated, particularly as it is impossible to manufacture components which are perfectly accurate. However, experience has shown that the problems involved can be overcome and the following free translation from a paper by Barwig[2] amplifies these points with particular reference to double helical gears.

"In parallel shaft double helical gearing the gears are usually located axially by one of the wheels, and because this wheel is fixed axially the inertia forces which arise from unavoidable tooth errors, and which work against equal loading between the helices, may sometimes be greatly increased even at moderate speeds. In double helical Stoeckicht gearing, one of the two co-axial members, usually the annulus, is made divided. There are two identical single helical annuli with opposite helix angles which are connected together and to the torque reaction member by means of gear-toothed couplings. The freedom achieved by these means ensures uniform division of the load between both helices, undisturbed by additional dynamic forces. Balancing achieved by these means is not enough in itself when more than three planet wheels are used, nor at very high speeds. Therefore, as an additional measure, allowance is made for a predetermined elastic deformation of the annulus under load. This is achieved by correctly dimensioning the annulus, and Fig. 1a shows a section through a Stoeckicht gear with six planet wheels. The figure gives an exaggerated indication of the elastic deformation of the annulus. This annulus would be freely connected to the torque reaction member by means of a gear-toothed coupling not shown in the figure.

Since free suspension of the annulus is generally sufficient for equal load sharing between three planet wheels, it is arbitrarily assumed that due to tooth errors only three planet wheels (1, 3, and 5) are sharing in the transmission of power. Immediately the radial components of the circumferential forces try to bend the annulus into the form of a triangle as shown in Fig. 1b. As a result of this the annulus approaches the planet wheels (2, 4 and 6), which so far have not been in engagement. In them, the backlash which was formerly too great, is reduced, whilst in the remaining wheels the backlash is at the same time increased. Since all the errors occurring in epicyclic gears, including the pitch and concentricity errors of the planet carrier, eventually affect the toothed components, the problem to be overcome is the elimination of the effects of the errors which periodically add up to a maximum. This difficulty is overcome by making the annulus with the requisite degree of flexibility."

As evidence that a freely supported annulus with the requisite degree of flexibility does, in fact, ensure equal load sharing, Fig. 2 shows oscilloscope readings of strain gauges fitted to annulus systems with three and four planet wheels. Successive peaks on the graph indicate the strain induced in the annulus by successive planet wheels passing the same point. Perhaps even more conclusive evidence comes from the very large number of Stoeckicht gears which have now given long periods of entirely trouble-free service. The number of planet wheels which may be used is dependent on the gear ratio, and although in practice gears using up to eight planet wheels have proved quite satisfactory, in the majority of installations only three are used.

Manufacturing Advantages arising from Reduction in Size and in the Use of Internal Teeth: So much for the fundamental necessity of ensuring that the planet wheels share the load. Once this is established, advantage may be taken of the fact that more than one set of toothed components is used in the transmission of power to give considerable reductions in the size of gearing needed for any given application.

The reduction in size which is possible makes it easier to control accuracy in the manufacture of gear components. It is also helpful in considering the use of hardened sun and planet wheels, and all the epicyclic gearing, to which reference is made in this paper, takes advantage of this fact.

If one considers a 10 : 1 ratio conventional parallel shaft gear, the wheel would be ten times as large as the pinion, but in a planetary gear for the same ratio the planet wheel is only four times the size of the sunwheel. The sunwheel itself would be smaller than the pinion of a parallel shaft gear for the same duty, because instead of just one set of tooth contacts being usefully employed three would be used. In other words, in the epicyclic gear the largest gear wheel to be hardened is only four times as large as the smallest, compared with ten times in the case of the parallel shaft gear.

The surface stress between internal and external teeth running together is less than that between external teeth. It is, therefore, usually unnecessary to harden the annulus when taking advantage of the use of hardened sun and planet wheels. A further important consideration in design is that the internal teeth of the annulus are stronger in bending than would be corresponding external teeth in a wheel of similar size. The annulus, therefore, may be made in material of a lower tensile strength than that of the material in which the sun and planet wheels are made.

Principal Components: The principal components of a high power Stoeckicht gear are illustrated in Fig. 3. The teeth of the wheels are, of course, most important and must be correctly designed and manufactured, but it is also essential to make sure that the planet carrier is made accurately and that the planet wheels spindles are correctly spaced. The planet carrier is of particularly robust construction.

Fig. 4 shows a cross sectional arrangement of these components assembled to form a complete gear.

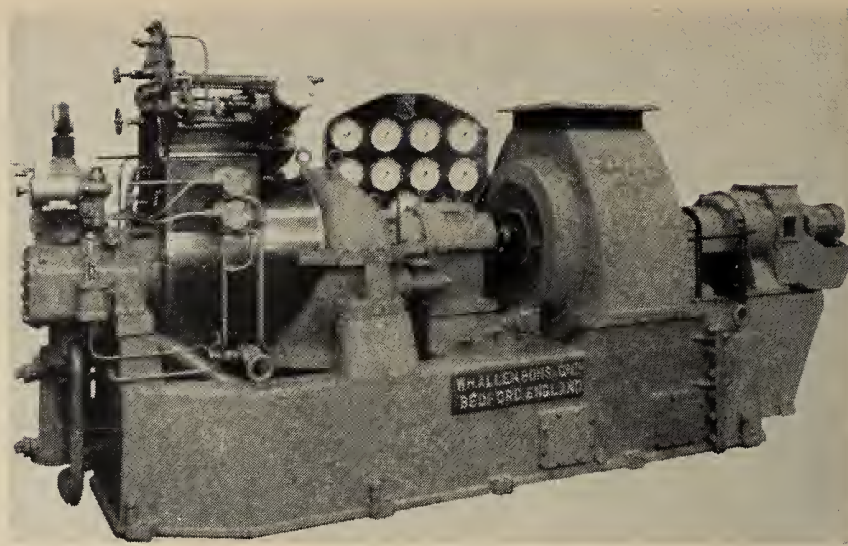

Fig. 8. Turbo-Alternator for C.S.L. *Fort Henry.*

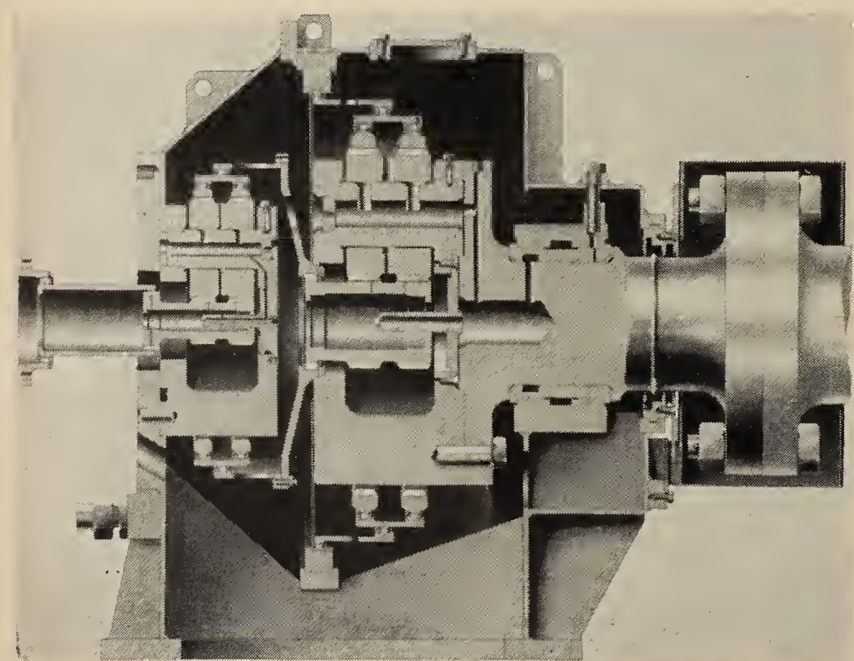
Reference has already been made to the fact that all the epicyclic gears mentioned in this paper use hardened sun and planet wheels, and over 95% of them have these components hardened by the nitriding process (See Appendix II). A great advantage of this method of hardening, compared with others, is that virtually no distortion takes place during hardening, and it is unnecessary to carry out any post-hardening correction processes on the teeth. Fig. 5a, b and c illustrate check results (from a Maag P.H. 60 measuring machine) on the helix angle of two identical components each having 21 teeth of 8 d.p. and a face width of 2 in. Tests of profile, carried out on the same machine gave similar results. Fig. 5a shows the result obtained on a nitrided wheel after nitriding. Fig. 5b is a check from a similar wheel before hardening by the normal pack carburising method. Fig. 5c is the same wheel after carburising and quenching. It will be apparent immediately that whereas Fig. 5a shows a wheel which will be quite suitable for use and is, in fact, very good, it would be essential to grind the wheel which is illustrated in Fig. 5c before it could be put into service. Grinding is a long and expensive process. The nitriding steel used by the authors gives a surface hardness similar to that obtained by pack carburising and, although the case depth of the nitrided wheel may be less than that of the carburised wheel, in practice it has always been found adequate.

Fig. 7. 27:1 500 hp. Double Reduction Gear 16,500/600 r.p.m. Largest Annulus Diameter 14 in.



No radial or transverse forces from epicyclic gears act on the gearcase except the torque reaction which may be taken up on the circumference of the gearcase. Stresses on the casing arising from outside sources cannot affect the tooth contacts unfavourably. This is particularly important in marine applications where it is sometimes difficult to ensure that the gear casing will be completely free from stresses and deflections induced by the hull. The fact that the gearcase is small and, therefore, can be much stiffer than the considerably larger case needed for parallel shaft gearing is, of course, a further advantage.

The planet wheel bearings of an epicyclic gear are particularly interesting and in most cases the best bearing is obtained by using a spindle faced with white metal on which the planet wheels rotate. This form of bearing has several advantages, amongst which is the fact that the load on the white metal is always in the same direction and consequently there is less chance of the bearing failing by fatigue than if a bush lined with white metal were used in the wheel. When a white metal facing is used it is possible to finish the bore of the wheel before the teeth are finished and this makes it easier to ensure that the teeth are true with the bore. Examination of spindles of this type made after 33,000 hours running shows no sign of wear.

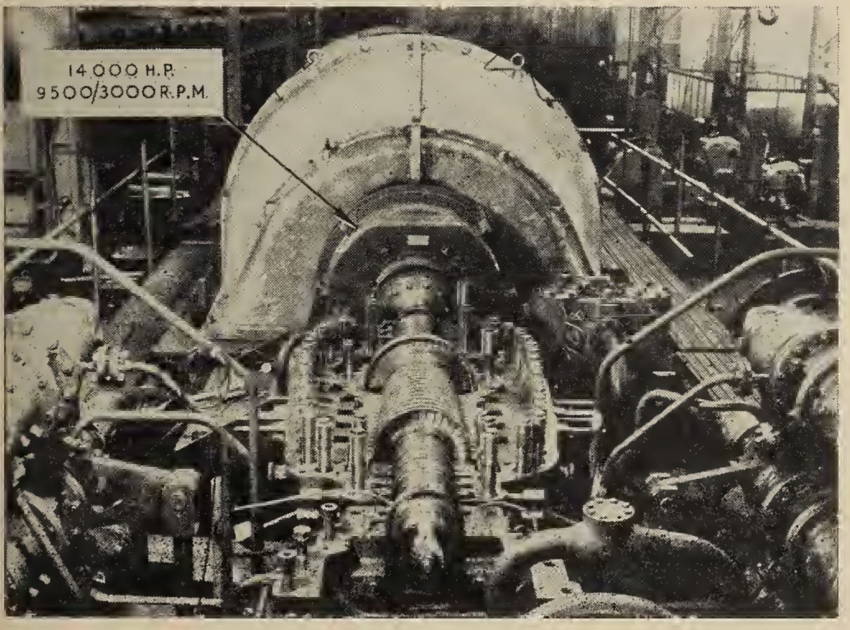
Lubrication: The arrows in Fig. 4 illustrate the method of lubricating a typical epicyclic gear. The planet wheel bearings are fed with oil led into the centre of the low speed shaft and then by radial holes via the centre of the planet wheel spindles, to the bearings. The sun-wheel/planet contacts are lubricated by oil led into the centre of the sun-wheel, from which it flows by radial holes in a number of tooth spaces, the planet/annulus contacts by the oil mist present in the gearcase and the gear tooth type flexible coupling by radial holes in each tooth space. Precautions are taken in gears where the planet carrier revolves to see that any sludge in the lubricating oil is retained inside the spindle and not allowed to centrifuge out onto the planet wheel bearing surfaces. The bores of the spindles may be cleaned during periodical inspection of the complete unit.

The gear may be lubricated either by means of filtered oil from the prime mover lubricating oil system, or by oil supplied by a pump mounted on the casing, and driven through gearing from the low speed shaft. Where the authors have freedom of choice, normal geared-turbine oils with no special extreme pressure additives are used. However, in order to avoid the necessity for various oils in an installation, it is usually found possible to use whatever oil is required by the prime mover.

Efficiency: Epicyclic gearing is at least as efficient as parallel shaft gearing, and a number of factors which are inherent in epicyclic gearing make it even slightly better. In applications where the planet carrier revolves, the relative pitch line velocity between the sun and planet wheels is reduced and this leads to an increase in efficiency in the tooth engagements. The elimination of bearings completely from the high speed rotating member removes the most prolific sources of loss in any form of gearing. In fact, with epicyclic gears the losses in some cases may be as little as half those with parallel shaft gears.

Accessibility: Epicyclic gears are sometimes criticised as being inaccessible compared with parallel shaft gears, and it is true that on lifting the top cover of an epicyclic gear very little can be seen of the principal components. However, it is easily possible to arrange such gearing so that the whole rotating assembly can be conveniently removed without affecting the alignment of the bearings of the driving or driven machines. Once the rotating assembly has been removed it can quickly and easily be dismantled completely. Having done this, it is, in fact, easier to examine the teeth and planet wheel bearings in greater detail than is sometimes possible with the teeth and bottom half bearings of large parallel shaft gears.

Fig. 9. Super-critical Steam Turbine Incorporating 14,000 hp. Epicyclic Gear to give a Speed Reduction from 9500 to 3000 r.p.m.



Co-axial and Parallel Shaft Arrangements: Not only are reductions in size obviously advantageous from the point of view of savings in weight and space and ease of handling, but also the co-axial arrangement of input and output shafts often leads to an improved arrangement of machinery installation. However, it is clear that a co-axial arrangement of the shafts does not always meet requirements, and in installations where a change of centre between driving and driven members is desirable, parallel shaft gears are obviously more suitable than epicyclic gears. Moreover, there are a number of applications where a combination of epicyclic gears with parallel shaft gears can give the best answer for the overall requirements of the installation. One example will be given later in this paper, and it is possible that in the future further advances will be made in the combination of both types of gearing, to the overall improvement of the complete installation, particularly for the propulsion gearing of large power Merchant and Naval vessels.

Epicyclic gearing can be used most conveniently for reversing, and can be useful in cases (such as manoeuvring in icy conditions) where it is sometimes desirable to be able to de-clutch the engine from the propeller shaft. A most important aspect where changes of speed or direction or rotation are concerned is that not only have the rotating parts of epicyclic gearing a lower weight, but also their inertia is much reduced. An example illustrating this reduction of inertia is given later, where the gears being compared both use hardened components and have comparable specific loads.

Representative Applications

Gas Turbines: It was not surprising that when Stoeckicht double helical gears were first introduced they were regarded with suspicion by some engineers. This was natural as previous attempts to introduce high power epicyclic gearing had not been successful. This form of gearing had established itself firmly in the automobile and aircraft industries, but in aircraft there had been considerable difficulties.

However, at the time many gas turbine designers were pioneers, ap-

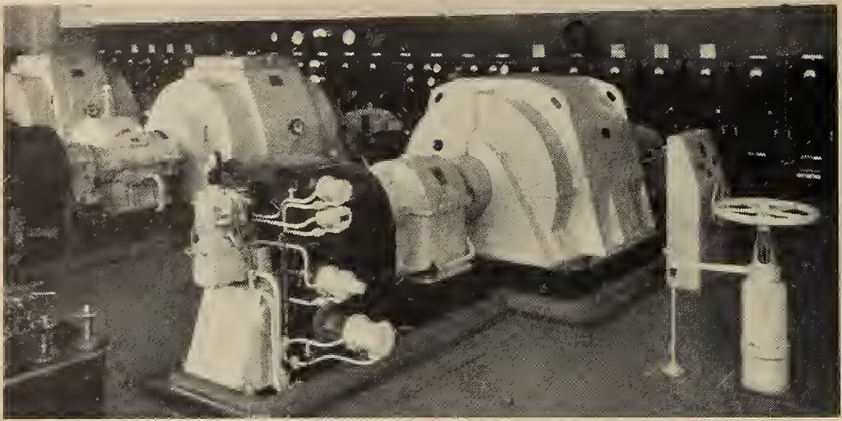


Fig. 10. Turbo-Alternator Incorporating 5000 hp. Epicyclic Gear giving a Reduction Ratio from 9500 to 1500 r.p.m.

plying aircraft techniques to industrial and marine fields, and some were quick to appreciate the advantages of a compact gear scientifically designed and accurately made and furthermore generally in keeping with their own advanced engineering thought and action. Their foresight with regard to epicyclic gears proved correct and they have been able to fit and forget them.

Fig. 6 illustrates the basic rotating elements of a gear designed for the Ruston and Hornsby T.A. 1450 hp. unit which has had over ten years' experience. 125 of these units have been supplied for service all over the world, some in oil pumping installations in the Middle East operating under very primitive conditions. The illustration shows clearly the excessive gap which must be left between the two helices of double helical gears to facilitate grinding. Such a gap is, of course, unnecessary with the shaved and nitrided gear technique introduced since these particular gears were designed. The annulus pitch circle diameter is 14 in. and the reduction in speed is from 6000 to 1500 giving a ratio of 4.0:1.

The English Electric Company of England have standardised on this form of gearing and a turbo-alternator from their range incorporating a 3250 hp. gear has recently been installed in the University of Alberta.

A further interesting example is to be found in the Allen 750 hp. Naval compound intercooled gas turbine driven alternator where two gears are used in series to give a reduction of 26,000/1800 r.p.m., i.e. a ratio of 19.5 : 1. The planet carrier provides the drive for the following pumps — cooling water, fuel, servo and lubricating oil. All this is achieved in a length of 24 in. and an outside diameter of 20 in. A gear of this type is shown in section in Fig. 7.

Steam Turbines: In most classes of ship, be they Naval or Merchant Marine, the demand for electrical power is rapidly increasing at a time when engine room spaces are being cut down. The advantages of saving in length given by the small sizes of epicyclic gears have been quickly appreciated and an increasing number of ship owners now regard their use as conventional, particularly for larger ratios.

The Canadian Pacific Railways ships *Empress of Britain* and *Empress of England* include turbo generators incorporating epicyclic gears to transmit 1600 hp. reducing 7000 to 600 r.p.m.

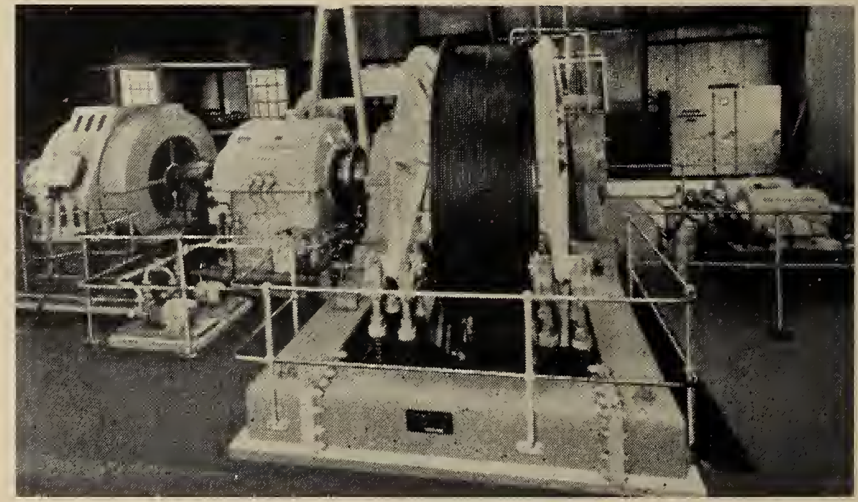
Fig. 8 shows a 450 hp. turbo-alternator for the Canada Steamship Lines *Fort Henry* which has been in service for five years. The gear has an annulus diameter of only 9 in., speeds 9000/1800 r.p.m. On one occasion this set was accidentally short-circuited. Inspection showed no damage to the gear except for a slight shoulder on the dowels which transmit the torque from the planet carrier to the low speed shaft. In installations where a short-circuit test is specified as part of the acceptance trials, loads of up to twelve times full load torque may be suffered by the gearing. In the authors' experience, the flexible system of the epicyclic gear stands up to these conditions better than parallel shaft gearing. In the latter, permanent damage has on occasion been observed.

The Steel Company of Wales are at present installing a high pressure/back pressure topping turbine manufactured by Richardson Westgarth (Hartlepool) Ltd. under licence from Brown Boveri & Co. Ltd. of Switzerland. The inlet steam conditions are 3000 p.s.i., 1050°F and the back pressure can vary from 620 to 670 p.s.i. The turbine runs at 9500 r.p.m. and the 9500 kw. alternator at 3000 r.p.m.

It will be appreciated that the steam conditions called for particular care in design. The turbine speed was chosen to keep down the mass of the turbine casing to minimise the effects of temperature gradient. Fig. 9 shows the neat solution to the gearing problem as photographed on the test bed. A star gear of 20 in. diameter was used to transmit 14,000 hp. One of the alternator bearings is housed in the gearbox and the rotating annulus of the gear is connected to the alternator shaft by the double tooth couplings which is an essential feature of the gear design.

From a very large variety of land installations, an interesting example is illustrated in Fig. 10 showing the arrangement of an Allen back pressure turbo alternator of 5000 h.p

Fig. 11. Mine Hoist Equipment incorporating Allen-Stoeckicht Epicyclic Gear.



reducing the turbine speed of 9500 r.p.m. to the alternator speeed of 1500 r.p.m.

General Industrial Transmissions: All the applications to which reference has so far been made have been for gearing driven either by steam or gas turbines. However, the use of epicyclic gearing is by no means confined to use with these particular prime movers. At the time of writing, the gear illustrated in Fig. 11 is the largest dimensioned Stoeckicht gear in service, although larger gears have been constructed and tested. It is capable of transmitting 3200 hp. with a reduction ratio from 486 to 64 r.p.m. i.e. a torque on the low speed shaft of over 260,000 lb.ft. The annulus diameter is 43 in. and the weight of the gear is 9 tons. It has been in service for four years on sinking duty at the Monktonhall Colliery of the U.K. National Coal Board. When the 3450 ft. shaft has been completed, the gear will be used for normal winding duty in a tower mounted motor driven friction hoist.

The small size and weight, compared with a parallel shaft gear, saved some $20,000 in the civil costs of the tower. Not only were the savings in weight and space advantageous but a further important consideration was that the inertia of the rotating parts of the epicyclic gear was only 687 lb.ft.sec.^{2} compared with 3478 lb.ft.sec.^{2} for a concentric parallel shaft gear for the same duty. This factor is particularly important in the acceleration, retardation and reversing of winding equipment and is by no means confined to this particular type of application. Special means were incorporated within the gear to enable it to operate as a temporary measure under conditions which could cause gross malalignment between the motor and winder drum. These conditions might occur during an excessive overwind on the adjacent winder mounted in the same tower.

A further illustration of the application of epicyclic gearing for low speed and high torque is given by the 160 hp. two-speed, triple reduction gear shown in Fig. 12. The maximum overall ratio of this gear is just over 80 : 1 and it is driven by a two-speed motor at 1500 or 750 r.p.m. These speeds, combined with the two-speed reduction of the gear, give output speeds of 24, 18, 12 or 9 r.p.m. At the lowest speed the output torque is 110,000 lb.ft. The high reduction and large torque are obtained from a gear which is only 6 ft. long and which weighs only 5½ tons. The diameter of the largest annulus is 30 in. The gear is to be installed in a new machine where space, weight and reliability are all equally important. This example illustrates the convenient way in which epicyclic gearing may be used for speed changing or reversing since the two-speed gear could easily be arranged to give opposite rotation.

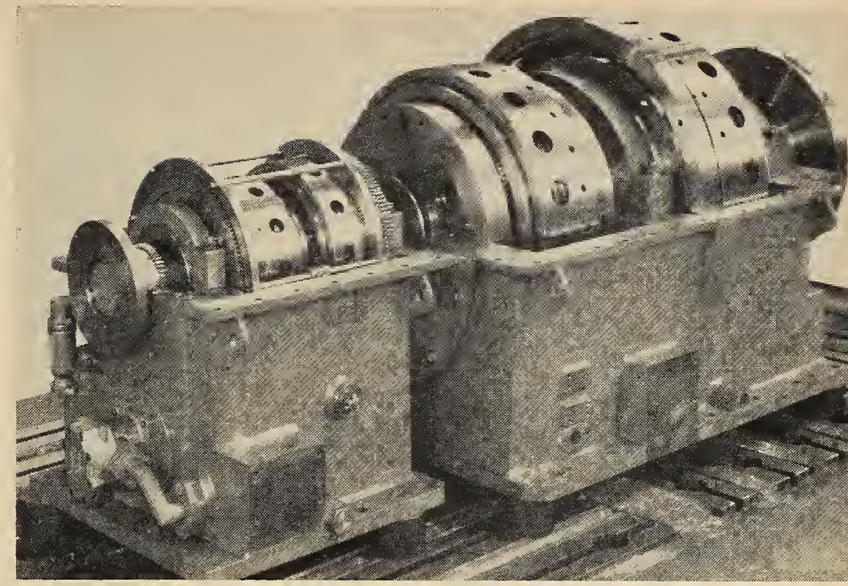


Fig. 12. Two Speed Triple Reduction Gear. Maximum Overall Ratio 80:1. Maximum Low Speed Torque 110,000 lb.ft. at 9 r.p.m.

Mention has already been made of the ease with which epicyclic gears may be used in installations where conditions are such that it may be desirable to de-clutch the prime mover from the driven member. Such gears are arranged so that the fixed member is held stationary by an hydraulic brake instead of being mechanically connected to the gear case. Release of the oil pressure in the brake de-clutches the gear. This operation may be carried out manually or arranged to work automatically due to an overspeed of the prime mover, e.g., an overspeeded turbine, or due to the application of excessive torque, e.g. a fouled propellor of a ship. Fig. 13 shows a submersible water turbine alternator manufactured by Escher Wyss and incorporating a B.H.S.-Stoeckicht speed increasing de-clutchable gear to transmit 1750 hp. from 165 to 1000 r.p.m. The gear has been in service for three years. It is arranged to de-clutch the alternator automatically in the event of a turbine overspeed. Such turbines are being increasingly used in Europe and de-clutchable gears of this type up to 7200 hp. have been made for them.

The National Aeronautical Establishment of Canada's wind tunnel at Ottawa, Ontario, will make use of an 11,000 hp. G.E.C. of England compressor. The 11,000 hp. synchronous motor runs at 1200 r.p.m. and drives the LP and HP compressors in tandem through epicyclic gearing as shown in Fig. 14. The speed increasing gear between the motor and LP compressor transmits the full horsepower and increases the motor speed from 1200 to 4500 r.p.m. It has an annulus diameter of only 27 in. The gear between the LP and HP compressors transmits 3600 hp. and increases the speed from 4500 to10,000 r.p.m. Its annulus diameter is 13 in. It will be noticed that both gears—of the star type—are housed in pedestals which contain the adjacent bearing for the motor and/or compressors. The only bearings in the gears are those for the star wheels. The gear tooth couplings which are incorporated in the gear eliminate the need for external flexible couplings. The use of epicyclic gears allowed each part of the installation to run at its best speed and at the same time maintained the desired in-line arrangement.

Reflections and Projections

The beginning of the last decade saw the introduction of Stoeckicht double helical gears and in this paper the authors have attempted to report on the successful application of these gears in a wide variety of installations. Progress has been most rapid in general industrial applications and in constant speed turbo drives. There is no indication that the limits of power, torque or speed are in sight and the authors believe that the new decade will see further development in all these respects.

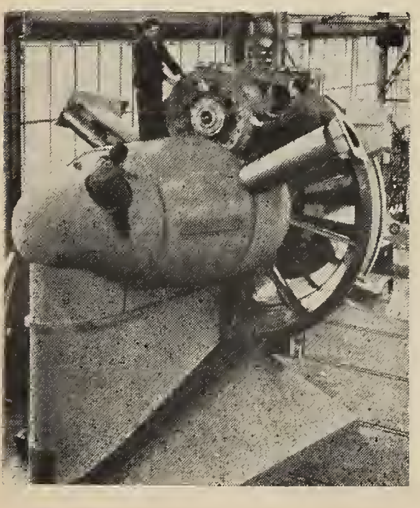
Possibly the next major progress can be expected in marine propulsion gearing. There are many ships operating at shaft horsepowers up to 10,000 which is well within established experience, whilst results obtained from such applications as mine hoist gears give confidence in meeting the type of loading to be expected in marine propulsion gearing.

The limited but important work already done in the marine propulsion field is, therefore, the note on which the authors would like to conclude this paper, with the same conviction that they showed eight years ago in predicting progress to date.

The experience so far with this type of gearing for main propulsion is largely confined to that obtained with Diesel engine ships of comparatively low power. The authors' own experience in this respect is limited, with one noteworthy exception, to gears for twin screw Seaward Defence Vessels in which reduction-reverse gearing to transmit 550 hp. giving a reduction ratio from 1000 to 625 r.p.m. ahead and 1000 to 500 r.p.m. astern has been extensively used.

H.M.S. *Brave Borderer*, a fast patrol boat designed and built by Vosper Ltd., of Portsmouth, England, and recently commissioned in the Royal Navy had a recorded speed of over 50 knots during her trials. The authors made use of epicyclic gearing not only to give a primary reduction between the Bristol-Siddeley Marine Proteus gas turbine and the flexible cardan shaft but also in the reduction-reversing gearbox which incorporates an hardened and ground E.N.V. spiral

Fig. 13. B.H.S.-Stoeckicht De-clutchable Speed Increasing Gear being erected in an Ascher Wyss Submersible Water Turbine-Alternator.



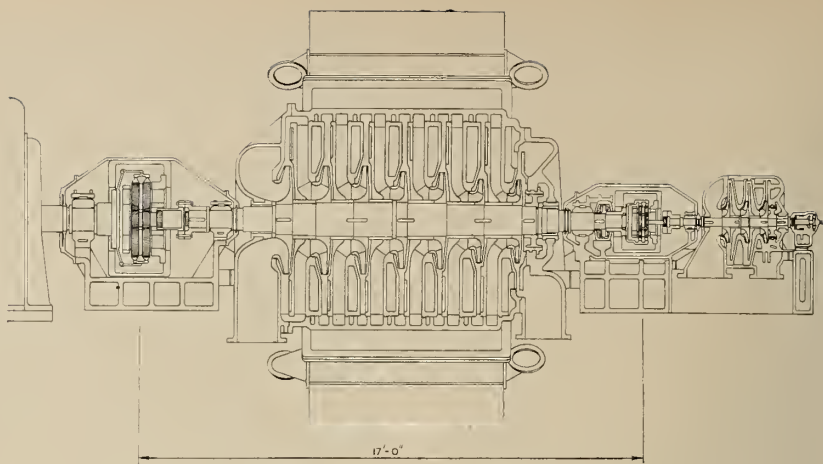


Fig. 14. 11,000 hp. Compressor incorporating Two Allen-Stoeckicht Speed Increasing Gears.

bevel vee drive. The maximum power transmitted is 3500 hp. and an idea of the size of the epicyclic gearing may be obtained from the fact that the annulus diameter is only 14 in. The total weight of the gear shown in Fig. 15, is less than two tons. In the author's opinion, the reduction-reversing epicyclic gearing could be most suitably applied in very much larger sizes to meet the requirements of many merchant vessels.

Other main propulsion gearing has already been built and tested and will shortly be in service at sea. Fig. 16 shows the Allen-Stoeckicht double reduction gearing to be fitted in M.V. *Bass Trader,* which will be in service this year as a cargo vehicle ferry between Australia and Tasmania. The gear, which meets Lloyds requirements, transmits 2200 hp. from a Deltic turbo-blown Diesel engine with a reduction ratio of 1630 to 180 r.p.m.

A description of the propulsion machinery for the new German Frigates has been given in The Marine Engineer and Naval Architect.[3] The only detailed information on the gear which has been released is as follows. For cruising, two speed de-clutchable epicyclic gears are used between the two 3000 hp. MAN Diesel engines and the propeller shaft. For full power, the second of the two available speeds from the two speed gearbox is used and in addition a large de-clutchable epicyclic gear transmits a further 13,000 hp. from a Brown Boveri gas turbine. Fig. 17 shows the gears following successful shore tests at B.H.S. Sonthofen.

In the future the authors consider that not only will epicyclic gears be used as straight reduction gears, multi-speed gears, reduction-reverse gears and de-clutchable gears, but in their opinion epicyclic gearing has a part to play in combination with very large parallel shaft gears. Increasing speeds of prime movers and increasing powers required — for example, by very large tankers – make the gear problem such that possibly the limit is being reached with parallel shaft gearing and, already, hardened gears are being considered. In this connection, epicyclic gearing can probably play a most useful part to give in a very compact way the initial reduction in, say, applications where two turbines are combined through a parallel shaft gear to drive one propeller shaft.

Finally, the authors would like to emphasise that they do not claim progress and development during the last ten years has taken place solely in epicyclic gearing. They do feel, however, that what has happened is not nearly so widely known as developments in parallel shaft gearing which have, of course, been taking place continually for a much longer period of time. In many spheres of engineering involving high powers it is not practicable for the prime mover and driven member to rotate at the same speed—from time to time engineers, both designers and users, are faced with transmission problems. If, on such occasions, this paper helps in some small way to stimulate thought and discussion on the possibilities of epicyclic gearing, compared with other types, then the authors will consider their efforts have been well worthwhile.

Acknowledgments

The authors wish to thank W. H. Allen Sons & Company Ltd. for permission to publish information given in the paper and for the facilities made available in the preparation of material. They are most grateful for the willing help of many of their colleagues without which the paper could not have been completed.

All the epicyclic gearing developments described are based on the principles of Dipl.-Ing. W. Stoeckicht, who kindly agreed to the paper being written.

Thanks are also due to Dipl.-Ing H. Barwig and to "Konstruktion", Springeh-Verlag, Berlin, for permission to use a translation of material taken from "Stoeckicht-Getriebe" by Dipl.-Ing. H. Barwig published in "Konstruktion" in 1954 and for the use of Fig. 1a and 1b. Mr. C. L. Deveson gave a great deal of help in the translation.

The authors are particularly grateful to Messrs. Ruston & Hornsby Ltd., Lincoln, England, for the early encouragement given by them in the standardisation of Allen-Stoeckicht epicyclic gears in their T.A. gas turbine. Fig. 6 was kindly supplied by them.

The Steel Company of Wales kindly agreed to Messrs. Richardson Westgarth (Hartlepool) Ltd. supplying information about their plant illustrated in Fig. 9.

B.H.S., Sonthofen, Germany, were kind enough to provide information and photographs for the applications illustrated in Fig. 13 and 17.

Fig. 14 and information about the installation of the compressor at Ottawa were kindly supplied by the General Electric Company of England.

APPENDIX I

Types of Epicyclic Gears and Formulae for Ratios

Planetary Gear: In this type of gear the annulus is fixed to the casing and the planet carrier rotates in the same direction as the sunwheel. The sunwheel is connected to the high speed shaft and the planet carrier to the low speed shaft. This configuration is suitable for gear ratios between approximately 2.5 : 1 and 12 : 1.

The ratio is given by (A/S) + 1
Where
A = the number of teeth on the annulus.

S = the number of teeth on the sunwheel.

Star Gear: In this type of gear the planet carrier is fixed to the casing and the annulus rotates in the opposite direction to the sunwheel. The sunwheel is connected to the high speed shaft and the annulus to the low speed shaft. This configuration is suitable for gear ratios of between approximately 1.7 : 1 and 11 : 1.

The ratio is given by A/S.
Where
A = the number of teeth on the annulus.

S = the number of teeth on the sunwheel.

Solar Gear: In this type of gear the sunwheel is fixed to the casing and the annulus rotates in the same direction as the planet carrier. The annulus is connected to the high speed shaft and the planet carrier to the low speed shaft. This type is suitable for gear ratios between approximately 1.2 :1 and 1.7 : 1.

Solar gears are most generally used as one train in double reduction gears for special applications, of which the reverse reduction gear in Fig. 17 is an example.

The ratio is given by (S/A) + 1
Where
A = the number of teeth on the annulus.

S = the number of teeth on the sunwheel.

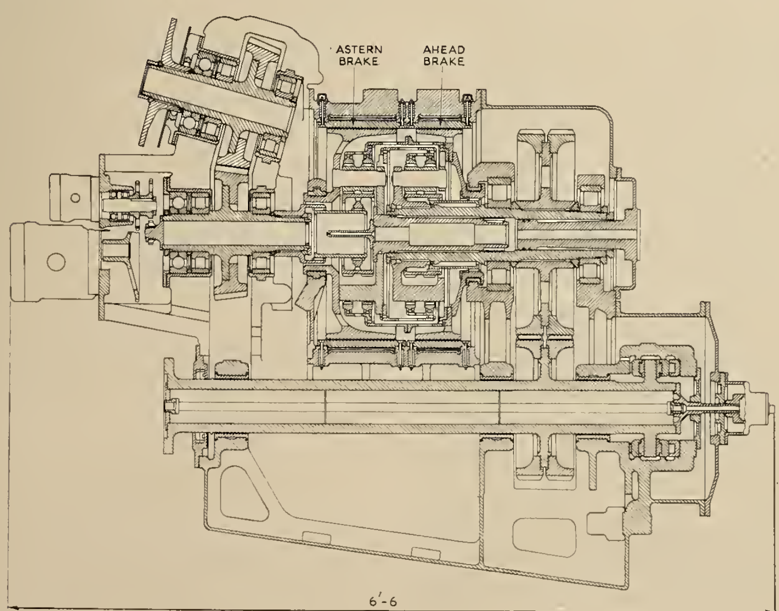
Any of the above types may be connected to achieve higher ratios than those obtainable in a single train.

APPENDIX II

The Nitriding Method of Case Hardening

Ordinary case hardening leads to troubles from distortion, from quenching cracks and from cracks developing during grinding operations. These sources of trouble are completely eliminated by the use of nitriding. In this process various alloy steels are used. The authors do not propose to discuss these except to say that they have experienced difficulties with nitriding steels containing aluminium, although these give the maximum hardness obtainable by this process (1,100 diamond point hardness, which is in excess of 65 Rockwell C). Further, these aluminium alloy steels have, after nitriding, a very brittle surface film which can easily lead to cracking and spalling, although this film may be removed by grinding or lapping before the parts are put into service. The authors noted with interest at the 1958 International Conference on Gearing held by the Institution of Mechanical Engineers in London,[4] that one European firm appears to be using such steels very successfully in gearing applications. The authors' experience is confined to nitriding steel not containing aluminium and giving a hardness of 700 to 750 diamond point hardness, approxi-

Fig. 15. Sectional Arrangement of Allen-Stoeckicht Reduction-Reverse Gear for H.M.S. *Brave Borderer*.



mately 60 Rockwell C. With this steel they have experienced no difficulty with the surface film, and, in fact, carry out no post-nitriding processes on the teeth of the gears. The surface film is very thin and soft and is not harmful in any way. In fact, it may aid running-in.

The hardness achieved by nitriding comes from heating the components for some 40 to 90 hr. in an atmosphere of ammonia gas at a temperature of about 500°C. The gas dissociates and some of the atomic nitrogen which is formed diffuses into the steel to form alloy nitrides. These are stable and give rise to a hard case without the need for further treatment. During the process the parts increase in size slightly to the extent of some .0005 in. per side, but this expansion is quite uniform so that due allowance can be made for it in machining. By reason of the growth freedom from distortion cannot be absolute, but for practical purposes it can be taken as being so.

The gradual diminution of hardness of the case as it merges into the core is considered by the authors to be most advantageous for hardened gear wheels. It is generally recognized that the fatigue resistance of steel is materially enhanced by nitriding. Its effect is to increase the strength of the surface layer and leave this layer in a state of compression. Again, this is advantageous in considering the alternating stresses which take place in gear teeth. A further advantage of nitriding steel is that it retains a very high degree of hardness up to the temperature at which the process is originally carried out. It will be appreciated, therefore, that any overheating caused by a temporary lack of lubrication is much less likely to result in seizing or scuffing than would be the case with ordinary case-hardened materials.

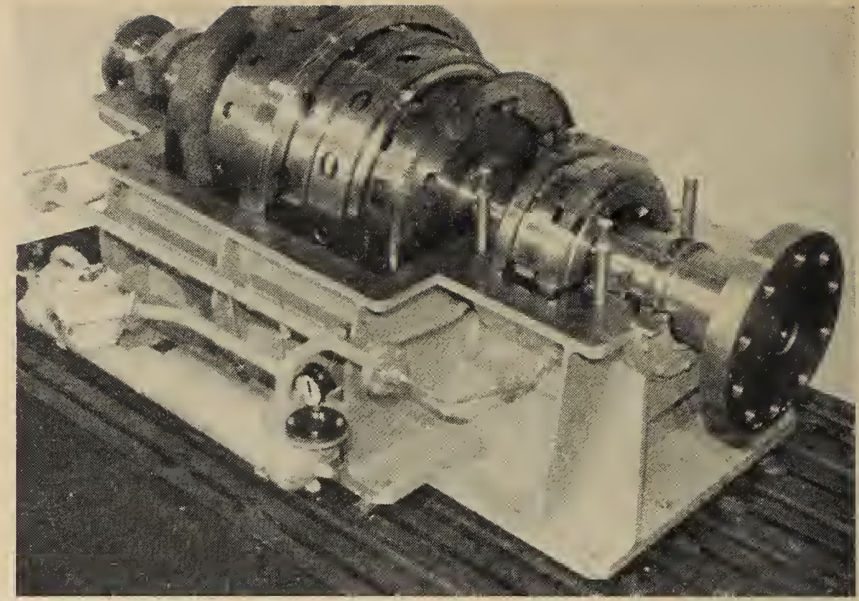


Fig. 16. Main propulsion gears transmitting 2200 hp. from 1630 to 180 r.p.m. Deltic engines Tasmanian Ferry of Australian National Line.

The components to be nitrided are machined in the hardened and tempered condition before nitriding, and the actual process is of a comparatively simple nature. The components are thoroughly cleaned to ensure removal of dirt and grease in a degreasing plant using Trichloroethylene. After this preparation the parts are placed in a box of special material which, in addition to being heat resisting, is also resistant to the action of ammonia gas. The components are packed in such a manner as to ensure free circulation of the ammonia gas throughout the charge, after which the cover is placed in position, a gas-tight seal being obtained by means of an asbestos and aluminium gasket. The sealed box is then enclosed in a suitable furnace which is maintained at a temperature between 500 and 510°C. The box containing the parts to be nitrided is fitted with inlet and outlet tubes for the ammonia gas which is circulated throughout the period of treatment. At regular intervals during this period a test is made on the exhaust gas in order to check the percentage of dissociation, the supply of ammonia gas being regulated according to the results of the test. The depth of the case depends on the period of nitriding; for most gear components the period is approximately 50 hr., but larger components may have this increased up to a maximum of approximately 90 hr. in order to achieve the greatest possible depth of case. When the period of nitriding has elapsed the box is withdrawn from the furnace and allowed to cool down, the circulation of ammonia gas being maintained until the temperature has fallen to about 80°C, when the cover is removed.

Any parts of the components which are not required to have a nitrided surface are protected by tinning prior to the nitriding treatment. The bores of planet wheels are polished by honing as a final operation.

MANAGEMENT—HORSE TRADING OR TRUSTEESHIP?

Lt. Col. L. F. Urwick,
Chairman of the Board, Urwick, Currie Limited, Toronto and Montreal

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

THE *Concise Oxford Dictionary* has a somewhat astonishing definition of the word *management*—

"**Management,** noun. In verbal senses; also, or especially, trickery, deceitful contrivance; **the Management,** governing body, board of directors."[1]

Of course, the *Concise Oxford Dictionary* was compiled by the late H. W. Fowler. And those who have enjoyed his *Modern English Usage* and his *The King's* (now, presumably, "the Queen's") *English* will be aware that he liked his little joke.[2] Possibly the association of boards of directors with 'deceitful contrivance' is just another of them.

But, if the investigation is pushed back a step further to Murray's full Oxford Dictionary, light begins to dawn.[3] The word management is derived from the French *manege*, a stable. In other words it has something to do with horses. Indeed in one local dialect use in Great Britain management still means manure. Now dealing in horses is traditionally a dishonest business. It is one in which the old adage *caveat emptor* still makes sense. If A tries to sell B a horse the popular assumptions are simple. They run like this:

i. If it was really a good horse A wouldn't want to sell it.

ii. Therefore there is probably something wrong with the horse.

iii. In consequence—

a. A's description of the horse is presumably false.

b. The price he is asking for the horse is certainly greater than its value.

c. While he may produce a veterinary certificate there are all kinds of possible snags which a cursory veterinary examination can't unearth, a vicious temperament or a preference for going through obstacles instead of over them.

iv. The deal therefore reduces itself to a battle of wits. B pits his knowledge of horses against A's anxiety to get rid of that particular animal. And if B is 'had for a mug' he more or less blames himself.

One of the difficulties of discussing management is that many people don't seem to have made up their minds whether *all* business behaviour is, or should be, on this horse-trading basis or not.

Arthur Bryant in his *English Saga* has a brilliant description of the small employers of the early industrial revolution—

"Though men often of splendid vigour, courage and independence, they were without the ruling tradition of responsibility and *noblesse oblige,* and the professors of economic science told them that such scruples were in any case antiquated and useless. They had one main concern, to get rich, and by every legitimate method available. As is often the way with servants turned master, they tended to confuse discipline with terror. Their own manners were rough and brutal, and they saw no reason to soften them in their relations with employees."[4]

That is from a chapter headed Dark Satanic Mills. In it he refers later to "the dual nature of early nineteenth century Britain and the legacy of discontent and social division we still inherit from its tragic dualism."[5]

It may well be argued 'All that's far away and long ago. It has nothing to do with us today. Ideas have changed.' But this is not so certain. There is current writing which is not so far removed from "the professors of economic science" to whom Bryant refers. One author, on the staff of *The Economist*, has argued:—

"It is noticeable that all discussions on the nature of management . . . consistently play down its *business* side—its money-making function. . . . The professional man is conservative and cautious by nature; the business man ought to (but now seldom does) think in terms of bold innovation—he must rush in wherever money can be made."[6]

Presumably that includes rushing into "betting, black-marketing, bucket-shops and brothels". The writer understands—he has no personal experience —that money can be made in these occupations in all countries.

Enterprise

Nor is the author quoted content to say that people who are interested in the art of managing are insufficiently interested in the financial side of business. He is quite clear that the economists' theories should come first and the actual behaviour of business people second. For instance, in a subsequent work he discusses the tendency for the entrepreneurial element in business to become specialized:— "The word 'enterprise' is often used to describe business, and quite often entirely falsely. Modern economists recognize this, and the Americans are even distinguishing 'entrepreneurial drones' among firms or business men. Such subtleties are all very well, but they leave the nature of the business man no longer entrepreneurial, and *hence play havoc with the neat rationalism of business behaviour, based solely on the profit motive, which is the starting point of almost all economic analysis.*"[7]

That is quite clear. 'The neat rationalism of business behaviour, based solely on the profit motive' which nineteenth century economists invented, must come first. Our job is to study, not how business people actually behave, still less how they should behave to be most effective. We must confine ourselves to seeing how far their actual behaviour squares with that theoretical stereotype.

It is 'beating the air' to discuss

management without clearing this central issue. The writer quoted is saying that the first requirement in every person who professes to be in business is that he should be 'on the make', personally and individually, as well as on behalf of the undertaking which employs him. That is "the neat rationalism of business behaviour, based solely on the profit motive", to which he refers.

That formula, in the actual conditions in which we live today, is not only misleading; it is dangerously misleading. It is perpetuating the "tragic dualism" to which Bryant refers. As a description of human behaviour it was admirably suited to the period in which it was evolved—the tail-end of a handicraft economy and the tentative beginnings of a machine economy. Then the one thing that mattered was that men should have the vigour and courage to make the transition, to pile up the much greater capital resources which a machine economy required. If the only way to do that was an all-out reliance on personal greed, if the only way to persuade the mass of the population to face the change was to threaten the individual with starvation if he was unadaptable, then perhaps the professors of economic science were right for their period.

For today they are utterly and tragically wrong. A number of things have occurred in the last century and a half.

a. Broadly speaking, the capital has been found. While the world is still in the middle of a technological revolution, the great mass of the people engaged in business are in comparatively large organizations. In any event they are wage and salary-earning employees. It is useless to talk to them about the *profit motive*. They do not participate in profit directly. And if there is one thing for which no-one in the world feels any interest and enthusiasm, it is that someone else should enjoy a larger income than he does. To quote Peter Drucker, whose *The Practice of Management*[8] is the best book on the subject which has come out of the U.S.A. in the last decade,

"It is irrelevant for an understanding of business behaviour, including an understanding of profit and profitability, whether there is a profit motive or not. That Jim Smith is in business to make a profit concerns only him and the Recording Angel."[9]

b. Because men and women do work in large organizations they have quite inevitably organized to protect their common interests as producers or as workers in the distribution trades. They are also consumers. But in this capacity they are what has been described as " a disordered dust of individuals". They have no daily contact to enforce association.

c. Owners and managers on the other hand are compelled by the logic of a free economy to give first attention to the interests of consumers. While Jim Smith or a group of anonymous stockholders may be in business to make a profit, they can only do so on one condition, that they supply at a price which consumers are prepared to pay, goods and services which consumers need. To quote Drucker again, "there is only one valid definition of business purpose, *to create a customer*."[10]

d. It is therefore not surprising that there has been a certain amount of friction between organized workers, concentrated on their interests as producers, and owners and managers, who are trustees, willy-nilly, for the interests of consumers. This friction is no-one's fault. To ascribe it to "blood-sucking capitalists" or to "irresponsible trade union agitators" is a piece of primitive animism. It is on a par with thinking that disease is caused by the wrath of some god or other or with making a wax doll, representing your 'enemy', and sticking pins into it accompanied by the prescribed imprecations.

e. There is only one way out of this impasse, for owners and managers to reassert the leadership of the people working in business undertakings which, owing to circumstances, has been assumed by others. Today, the very phrase "the men's leaders" means trade union officials, not the owners and managers, the officers, of the organizations in which they work.

f. To do this they must clear away one more handicap imposed by false economic thinking, the idea that the relations between the employee and the employing agency are exclusively an individual contract. That is another of the bulwarks of individualist *laissez faire* economics which circumstance has washed away. We talk as though it were still there—of the law of master and servant, for instance. But the mere fact that men and women are associated in business undertakings means that such undertakings are systems of *social* co-operation. It is not suggested that managers should fail to consider and to understand each individual working with them. Of course they must do so. But, beyond and additional to this, they should cultivate understanding of the social sentiments of the groups for which they are responsible.

This is the most serious handicap that the persistence of economic theory which no longer corresponds with the facts has laid upon the free societies. Many people still insist on talking and acting as if they had only to deal with a series of individuals and their motives, each considered as an individual. And it is often argued that these individual motives are what make men tick—the predominant issue. Nothing could be further from the truth. It is fatally easy to be cynical about this, to say that 'every man has his price', 'all that the worker cares about is what's in the pay packet at the end of the week', and so on. The answer to the first fallacy is a question—'What is *your* price, my friend?' The answer to the second is equally simple. If all the worker cares about is his personal gain, why is industry troubled with persistent restriction of output, both conscious and unconscious? The fact is that the vast majority of human beings care far more for social approval, and are more deterred by fear of social disapproval than by any individual reward or penalty. There are a small minority in most populations who really are indifferent to social disapproval; an appreciable percentage of them are in prison.

Six Points

These are six points which every manager should keep in mind:—

1. Except for those who start businesses or who are shareholders, there is no such thing as the profit motive;
2. Men and women who work in close association will organize inevitably to protect their common interests as producers;
3. In a free and competitive economy owners and managers must act as trustees for the interests of consumers. To supply goods or services which the community needs is the purpose of business;
4. There is bound to be some conflict between representatives of the wage-earning group protecting their producer-interests and the managers. But there is no need to personalize this conflict. It is merely a demarcation dispute;
5. It will disappear if owners and managers will recognize that they have a duty to *lead* those they manage;
6. They should make a start in this task by realizing that they are concerned not only with the right relations with each individual employed, but with the social sentiments of the whole group with whom they have to work. They should not neglect the individual. They must attend to both.

If it is the duty of every manager to lead the members of the group for which he is responsible, what is leadership? Chester Barnard has said "leadership has been the subject of an extraordinary amount of dogmatically-stated nonsense".[11] As soon as the word is mentioned men's minds jump to a Napoleon or a Churchill, just as they find it difficult to use the word poetry without thinking of Shakespeare, or music without thinking of Bach or Beethoven. But that is misleading. The world is full of poetry and music: these things are not only the privilege of giants.

It is so with leadership. Properly understood it is near to a universal activity; almost everyone leads in something. It is particularly important in business today for the reasons I have given. The task facing owners and managers is to change men's minds, to persuade them to abandon the sour, cynical attitude to business which circumstances reinforced by the persistence of *laissez-faire* individualist economics in circumstances to which it was no longer applicable, have stamped on their consciousness.

Business is a social activity: every business is a system of human co-operation. And men cannot co-operate together effectively *in action* without leadership. They can decide *what* they want to do by talking about it. But when it comes to doing it, they must have a leader. The reason is simple. Without a leader they cannot keep time; their efforts become dis-synchronized and therefore ineffective. An orchestra needs a conductor. That is why there are positions of authority in business. Men can't see the conductor all the time. He has to communicate with them. And they need to know that each communication is authentic. It comes from a position which is entitled to communicate with them on that subject.[12] That is what a position of authority, any manager's position, is—a clearing-house in a system of communication.

Authority, however, depends for its effect on the recipient. If he refuses to act on a communication, its authority is gone as far as he is concerned.[13] The formal organization—the kind of thing shown on an organization chart—is never, by itself, enough. It is formal, impersonal. If men are to breathe life into it, it has to be supplemented by leadership. Leadership is really a very simple idea. It is a kind of behaviour, the kind of behaviour on the part of an individual in a position of authority which inclines others to accept his guidance. It is a catalyst. It transforms authority—"the formal right to require action of others" into power —"the ability to make things happen". Those definitions are from Mary Parker Follett.[14] Everyone in a position of authority exercises leadership. The problem is whether it is effective or ineffective. Every subaltern officer, every manager has to be a leader: the only question is 'how good or how bad a leader?'

What does a leader do? Broadly, four things:—

i. He *represents* the purpose of the system of co-operation, the group, both to those inside it and to the outside world. Men cannot co-operate together effectively unless they are agreed as to the purpose for which they are co-operating. He is the personal embodiment of the common purpose.

ii. He *initiates* or causes to be initiated the changes which are necessary to keep the group effort in line with that common purpose. No group, by itself, precipitates change except very slowly. It always prefers its current social pattern, its way of life.

iii. He *administers* the group. He keeps its routines tidy and economical. There is an old Latin motto *Ubi ordo deficit, nulla virtus sufficit*. It may be translated freely "No high quality avails, where the rule of order fails". No business can function without routines.

iv. That means that much of a leader's time must be preempted in his fourth duty—*interpretation*. He has to be perpetually explaining to those associated with him the *reasons* for things.[15]

In short the manager as a leader has a good many other things to do besides managing. Managing, administration, in the strict sense, is only a quarter of his job. That is not surprising. Competitive business is a form of warfare. And no less an authority than Napoleon once observed that "in war, the moral is to the material as three is to one".[16] What qualities does a leader need? Field Marshal Sir William Slim—Bill Slim who made the 14th, "the forgotten army", into an army which those who fought with it will never forget—says five:—

Courage because it is the basis of all virtues in man and beast. But the higher you are in an organization, the more must your courage be moral courage.

Will-Power because it is extraordinary the amount of opposition you will meet when you want to do anything. This will come especially from your own staff who will be convinced that they are protecting your best interests. You have to get over that one.

Flexibility of Mind because we live in a changing world and without flexibility of mind strength of will may become a danger.

Knowledge, not of how to do the other fellow's job, but enough to appreciate the difficulties subordinates will meet, the time it will take them to do things and the sort of help they will want.

If he has these four qualities, he continued, a man will be a leader. But he will only be a leader for good if he adds a fifth. "The last quality on which all the other qualities have to be based, is:—*Integrity*—the thing that makes people trust you."[17]

Emphasis on Integrity

It is interesting to note that a man as different from Slim in experience and outlook as Peter Drucker places the same emphasis on Integrity. In his book, already quoted, he mentions the word no less than 20 times as *the* quality essential in a manager. For instance, "the best practices will fail to breed the right spirit unless management bears witness for its own professed beliefs every time it appoints a man to a management job. The final proof of its sincerity and seriousness is uncompromising insistence on integrity of character."[13]

This is the reason why every manager has got to make a choice, a choice between the sour, cynical, traditional, horse-trading view of business already described, in which we assume that every man is out for his own advantage, and the modern, the management view, which regards the manager as a trustee for the interests of all concerned in the system of co-operation.

This latter view has been well described by Ralph Cordiner, Chairman of the General Electric Company:

"The General Electric Company is managed by professional managers. These managers, including myself, are not the owners of the business, but employees hired by the share owners through their elected directors to manage their business in the best balanced interests of all concerned . . . The work of managing is tending to become professional, as a distinct kind of work in itself. It is becoming a job that requires a great amount of thought, effort, and training in the principles as well as the techniques of management . . . . This professional approach requires, in fact, a dedication of the man's self and service not only to the owners of the business through his Board of Directors, but also as a steward to the Company's customers, its industry, its employees, and to the community at large. The professional manager must consciously place the balanced best interests of these ahead of his own personal interests. The corporate manager today thus has an opportunity and an obligation for service comparable to the highest traditions of any profession in the past."[19]

To be appointed a manager is to

fulfil Robert Louis Stevenson's epigram about matrimony; it is indeed "to domesticate the Recording Angel".[21]

A manager is in a fiduciary position, as Cordiner has emphasized. He is appointed by a corporation to assume some of the responsibility of ensuring that a group of persons, part of the system of co-operation, work unitedly and enthusiastically to realize the corporate purpose. If he puts himself and his interests first and the corporate purpose second, the members of that group will be the first people to know it. And they will react accordingly. They will rate him as lacking in integrity.

It may be, it frequently is, argued that this view of management as a trust undermines the whole philosophy of capitalism and makes nonsense of a free enterprise system. But to argue in this way is to fail to make a number of essential distinctions. These are:—

i. The difference between the profit of an institution and acquisitiveness of an individual;

ii. The difference between profit as a measuring device and profit as a purpose;

iii. The difference between profit as an insurance and profit as a purpose;

iv. The difference between starting a business and managing an established business;

v. The difference between managerial positions which call for entrepreneurial skill and those which do not;

vi. The difference between competition and co-operation.

Profit

Profit as a measure of the success of a business institution as a social entity is one thing: profit in the sense of an exceptionally high pecuniary reward to the individual working within such an institution is another. The first is a sign of well-being; the second is a symptom of weakness. As Drucker records, one of the most venerable and successful banks in the U.S.A. set its research department the problem of determining significant indices of whether the management of a corporation was good or bad. After investigating hundreds of companies the research team came up with one totally unexpected clue—"If the top executive in a company gets a salary several times as large as the salaries paid to Number Two, Three and Four men, you can be pretty sure that the firm is badly managed. But if the salary levels of the four or five men at the head of the ladder are all close together, then the performance and morale of the entire management group is likely to be high."[22]

From the standpoint adopted in this paper the result is not so totally unexpected. A man in a position of authority who uses the opportunity to 'feather his own nest' and to secure personal and pecuniary advantages conspicuously larger than those of his immediate colleagues will attract envy rather than loyalty. He will be lacking as a leader. But there could be no clearer piece of evidence than this opinion of a sober New York bank that institutional profit and personal pecuniary gain are in different categories. The latter is no measure of success as a manager.

Profit is an invaluable measuring device for measuring that a business undertaking is, in fact, fulfilling its social purpose by supplying consumers with goods or services which they need at the right prices. If an undertaking fails to do so it will cease to make a profit and, ultimately, go bankrupt. But a measuring device, a weighing-machine, for instance—we talk about a balance sheet—cannot be a purpose. Races are run against a stop-watch. But, the stop-watch is not the purpose of the race. It merely records the runners' performances.

Profit has other important social functions. It provides the new development and replacement capital without which business enterprises could not expand or, indeed, remain in being. But its functions, in this capacity, are analagous to those of insurance. And, once again, an insurance policy is not a purpose.

So long as it remains possible in any society for the individual to start up a business enterprise of any kind and, by producing or distributing goods or services more economically than his competitors to secure a share of the market, so long will that society have a free enterprise system. And so long will individuals who have enterpreneurial ability be stimulated by the large rewards resulting from success in such initiatives to instil a life-giving flow of new ideas and exceptional energy into its economic life. Such men are valuable to the society and merit both honour and high pecuniary rewards. But again, the competitive element in their conduct, while invaluable in starting new enterprises, is a passport to disaster when applied to a managerial position in an established business.

To be sure, the established enterprise needs entrepreneurial skills and initiative if it is to maintain its place in the market. But it needs these skills in only a proportion, and that not usually a large proportion, of its managerial personnel. In common with almost all the other functions of business, entrepreneurial skill has become increasingly specialized during the present century. Its locus in any established business tends to be primarily with those concerned with merchandising, selling and the design of new products in engineering and research departments.

The great majority of managers in an established business are concerned particularly with organizing collaboration not competition. And even those whose functions are predominantly entrepreneurial have to remember continuously that they are units in an *organized* system of co-operation. Personal conduct which is geared too manifestly to the furtherance of individual ideas and, still more, to the attainment of personal advantage, whether social or pecuniary, is bound to put them at odds with their colleagues and to weaken the solidarity and team-spirit of the group. Indeed, one of the most difficult problems facing the chief executive, the principal manager, in any large modern business undertaking is to reconcile his initiators, the men who are fertile in new ideas, the men with the entrepreneurial outlook, with his faithful administrators, the men who keep the established routines of the undertaking running smoothly, day in and day out, year in and year out.[23]

Profit Motive

In sum the so-called profit motive and the competition between business undertakings which are characteristic of a free economy have important limitations. If they are applied to the conduct of individuals within an established undertaking:—

a. the profit motive is ineffective with those who do not participate directly in ownership and may, in the form of conspicuously high salaries or special bonuses to those who are supposed by ownership to contribute particularly to profitability, be translated by associates and subordinates into an expression of the corruption of power, which undermines rather than reinforces authority;

b. Individual competitiveness is not only directly deleterious to co-operation. The belief among subordinates that it is a principal concern of a superior or superiors will issue in a cynical and sceptical attitude which will render it impossible to generate a high morale in any group so affected.

These considerations are merely a restatement from a particular angle of the general principle stated earlier in this paper that the manager must be concerned with the social sentiments of the group responsible to him as well as with their individual reactions. Profit and competitiveness are both stimuli which operate on the individual. From the standpoint of group feeling and morale they have different effects. A good profit showing may have a positive effect on a group which does not participate directly in the financial rewards involved, merely as evidence that they have done a useful job collectively. But, after over a century of socialist propaganda, to place too much reliance on this as a factor in stimulating morale is optimistic. The reverse argument that ownership is appropriating an illegitimate proportion of the results of the co-operative effort is too easy to advance and too difficult to answer convincingly. Individual competitiveness always undermines co-operation. Group sentiment is almost invariably hostile to those who seem to be exceptionally endowed: the individuals sufficiently generous-minded to welcome the accelerated promotion of others are a small minority.[24]

Hitherto the free societies have failed to distinguish clearly between the different functions of profit. They have used the blanket phrase, the profit motive, without sufficient analysis of who is motivated and how to do what. Similarly they have talked glibly about competition without distinguishing competition between business undertakings from competition between individuals employed by the same undertaking who are supposed to be co-operating. Consequently there has been no sufficient analysis of the differences in ethical attitude appropriate in an entrepreneur and in the salaried manager in an established undertaking. Relying on an outworn economic theory long after the objective circumstances which justified it had passed, free enterprise has been brought into question among large elements of the population in most of the industrialized countries.

Owing to confusion between corporate objectives and individual ambitions, too many managers have talked as though business existed for the few, the privileged. In consequence they have lost the support and interest of the many. Because they have been hard-boiled, or, as many would say, realistic, about the right of those with the power of ownership to be as tough as they please with those who have not that power, they have brought ownership itself into disrepute. Again, Drucker has the pertinent phrase, "capitalism is being attacked not because it is inefficient or misgoverned, but because it is cynical."[25] That is a position which, if it is allowed to continue in a political democracy can have only one end—the expropriation of the property-owning and managerial classes.

If that position is to be corrected two things are essential:—

1. A *common purpose* for all those who co-operate in economic undertakings. To supply goods and services which the community needs effectively and economically is capable of being elevated into such a common purpose. Realizing a larger profit for a group of anonymous stockholders is not.

2. Constructive and ethically defensible *leadership* in pursuit of that common purpose by all those in a position of responsibility in economic life. A manager has only two means open to him of convincing those under his authority that he is a leader and not merely a person in a position of authority. These are:—

a. absolute integrity in pursuit of the common purpose;

b. within the limits imposed by that purpose, a real concern for the well-being and development of each individual responsible to him and for the social sentiments of the group.

He can only approach these tasks if he is clear that he is a trustee for the interests of all concerned in the system of co-operation and not merely a horse-trader. In other words, "the tradition of responsibility and *noblesse oblige*" which the professors of economic science rejected has become, once again, 'the headstone in the corner'.

Conclusion

For generations the cynic's answer to this challenge to leadership has been "I'm not in business for my health". That is perhaps the silliest phrase that has ever been invented to bolster an obsolete philosophy. The individual whose daily occupation is not good for his health is sickening for one of the occupational diseases of the rat race in early middle age. How come people call the big-shot row "ulcer gulch" instead of the old "front office"?[26] That may be his affair, as an individual. But as a citizen, a member of a community, he has some responsibility for the health of his society. The majority of the citizens of the modern industrial nations are engaged in business. If men and women are not in business for their health our hopes of social progress are an illusion. To quote Drucker once more, "in a lasting society the public good must always rest on private virtue".[27]

The alternative creed has been stated succinctly by one of the most profound thinkers Great Britain has fathered in the last century, the late Professor Alfred North Whitehead, O.M.—"a great society is a society in which its men of business think greatly of their functions".[28]

24. An example is the poor early academic showing and almost fantastic unpopularity at every stage of his career till he was 66 years of age, of the greatest man of the 20th century, Sir Winston Churchill. It has been recorded of him in 1940 "His life had scarcely brought him personal popularity on a wide scale till now. But there could be no mistaking what they felt about him as the cheers rang out; and then the hat came off in a wide sweep and a shy smile appeared. That, perhaps, was his reward after a long career in which he had so often stood alone." (Philip Guedalla, **Mr. Churchill**, London, Hodder and Stoughton, 1941, p. 310). Yet even Churchill's immense popularity and tremendous services in the second World War were no bulwark against the mounting dissatisfaction with laissez-faire economics which is the subject of this paper. In 1945 at the very hour of his triumph his party lost office, largely because the people of Great Britain mistrusted a capitalism which appeared to them untempered with a corresponding responsibility.

Discussion

THE POTENTIAL IN THE FREE-PISTON ENGINE PRINCIPLE

A. Braun,

Free Piston Development Company, Kingston.

The Engineering Journal, July, 1960, p. 57.

Author's reply

The idea of Mr. Martin Berlyn, with regard to the application of an aftercooled supercharger upstream or ahead of the compressor sections of free piston engines has quite recently been given considerable attention by several research and development groups. An excellent appraisal of its merits and shortcomings can be found in the ASME paper No. 55-A-147 by A. L. London. Mr. Berlyn's assumptions of the various r_v values are correct as well as his conclusion that the critical compressor discharge pressure can be raised by means of supercharging. The author did not stress this fact specifically but it was one of the points implied in the conclusion that in the FP field only the first steps have been undertaken and so many roads for its full exploration are still offering great promise.

Supercharging has been applied in recent designs and one of the main advantages is the reduction of weight and size per HP. In dealing with points like this one such important benefits as pointed out by Mr. Berlyn are often overlooked, whereas it has to be pointed out that a complication of the overall installation as well as higher SFC is the price one has to pay for these advantages. Therefore, as long as the initial pressure ratio is not reached, the designer should try to find ways that result in the same advantages and eliminate the complication of the whole power plant. Much development work can be eliminated in this process by suggestions such as Mr. Berlyn's which point out desirable engine characteristics which are seldom found in text books.

A lower r_v in the combustion chamber as pointed out in the discussion can in the case of FP engines be achieved, without sacrifice, by other means and moreover with higher ignition temperatures at the same ignition pressure. Another most important characteristic, namely starting, improves considerably under these conditions. Once the critical pressure ratio will be reached it remains a question whether or not to intercool between supercharger and compressor or even compressor and combustion cylinder but this question might better be answered at such time.

Mr. R. G. Fuller has been associated with FP engines for a considerable number of years and has during this time had the opportunity to follow closely the performance of numerous installations under many different conditions and his remarks in this regard should accordingly be given careful consideration. An interesting point in his discussion is the comparison of FP and Open Cycle or G.T. marine installations particularly since in this field some of the advantages that the FP engine offers have not even been utilized as yet, such as after-burning for above rated load conditions etc.

Referring to Fig. 1 in Mr. Fuller's discussion it should be emphasized again that the temperatures quoted are maximum **cycle** temperatures which occur only intermittently in a FP engine, whereas they would be continuous in the combustion chamber and turbine entry of the gas turbine. The gas turbine is therefore again depending much more on high grade and expensive materials than any reciprocating engine (see Fig. 4 of author's paper).

Another point that is most interesting is the insensitivity of FP engines to ambient conditions and the difficulties in this regard that were experienced particularly with supercharged Diesel engines might well be remembered here.

In connection with marine FP turbines employing an astern wheel it comes to the author's mind that an often used argument against the application of FP engines to road vehicles is that the braking effort from the FP turbine would be so small, once the fuel lever is shut off, that extremely large brakes would be required. A relative simple solution to obtain an unusually high braking effect from this very turbine is to connect to the fuel lever a valve that opens at O-delivery and which diverts the gas from the forward nozzles to a reversed nozzle which blows on the back side of the turbine blading and which results in a similar situation as described by Mr. Fuller but on a turbine without astern wheel.

It can only be hoped that Mr. Fuller's suggestions with regard to Locomotive applications of FP engines will be given appropriate consideration in this country since the experiences in France and Russia in this field have been very successful (see paper by R. G. Fuller "The Free-Piston Gas Turbine" published by The Engineering Institute of Canada, June 1960).

As Mr. Cockshutt points out the air standard cycle approach of the author was taken to present the case of the FP engine on as simple a basis as possible and certainly in terms of actual engine behaviour caution is always required when applying any air standard cycle to study the effect of certain variables. It should be noted however that for related types of engines, such as reciprocating types, the conclusions out of such studies have also certainly their validity as apparent for example if one compares the average superiority of the diesel engine over the spark ignition engine, which is in this case primarily due to the higher possible compression ratio level in the diesel

Automation and Control Engineering in Canada

Automatic Control of Machining Operations

PARTICULARLY in North America, great interest has been shown in the automation of operations involving machine tools. Perhaps the obvious field for application of automatic machining processes is that of high-speed mass-production of standard parts. Certainly control of such operations has been practised very successfully, but generally speaking the majority of machining work done by industry is on quite small lots of separate items. Automatic control is equally applicable to such short-run work, and can show considerable savings over conventional methods, provided it is applied with common sense.

Numerical Control

The term numerical control is used to indicate the use of numbers to describe a part that is to be made on a machine. The information represented by these numbers can then be fed on to a punched tape or other control medium, which is used to direct the operation of the machine.

Instead of the machine operator having to interpret a blueprint and convert dimensions into machine operations to achieve the desired result from the original workpiece, all data can be handled in advance by an engineer who converts dimensions, machine operating data, and tool information into numerical data that are transferred to the control medium. A reader on the machine converts the numerical data to instructions to the machine.

A part may be described numerically by using the conventional X, Y, Z co-ordinated together with mutual planes and angles. A corresponding system is used for machine axes.

Simple Operations

The simplest method of control is referred to as the positioning or point-to-point system. In this, the part and the tool are brought into the required relative positions in a controlled sequence. Thus, for example, to drill a series of holes in sheet metal a drill press can be provided with a table that is moveable in two directions by, say, feed screws and servo drives. The positions of the required holes can be referred to simply in terms of X and Y ordinates, and provided the workpiece reaches the correct position in the correct sequence it does not matter essentially whether it is moved first along the X or Y axis.

The control medium can also be used to start the drill when the workpiece is in position, and the positioning system can also be used to control vertical turret lathes, jig bores or similar more complicated machines.

Complex Operations

In the relatively simple positioning system it does not matter what path the workpiece or tool takes between each position. This path can, however, be controlled with great accuracy over its entire length, however complex the path may be. The system is known as a continuous path or contouring method and, as the name applies, can be applied to profiling or contouring operations.

The amount of data involved is much greater than in the simple positioning system, and may include reference to the three main axes and several angles and attitudes of tool and workpiece. With many continuous path systems a computer is used to handle the data; for example, to calculate the points around a circle. From these data, the dimensions and tolerances, the computer can provide necessary tool data and a tape that will control production of the circle to the required limits.

Control Data

The control medium to store data for either the positioning or contouring system may be punched cards or tape, or magnetic tape. Several commercial systems use 8-channel punched tape, but other numbers of channels and other media have their particular applications.

The simpler systems may use dimensions directly as control data, but the continuous path or contouring methods usually require binary coding. A check may be made on the machine by incorporation of a gauging system that continuously supplies data to correcting loops..

Applications

Numerical control has spread to almost all conventional machining operations both singly and in combination. Contour grinders can be controlled to finish such complex surfaces as turbine blades to dimensions of the order of several millionths of an inch.

Control has also extended beyond machining work into such fields as joining by riveting or welding, assembly of small components, and tube-bending.

Economic Advantages

The use of numerical control has obvious advantages in relieving the operating staff from the responsibility of interpreting written or diagramatic data into practical results, and in avoiding human fatigue or error with greater possibilty of increased accuracy in the final product. The main attraction of such a control system, however, is most likely an economic one.

Expensive machine tools give returns only when they are producing, and the working time of machines in a 'conventional' shop is often an alarmingly low proportion of the overall work-period. It has been shown in practice that machine tools that have been adapted for use with numerical control can be in productive use three to five times more than under a conventional set-up.

One big advantage of numerical control is that it can eliminate jigs, templates, holding fixtures, and other expensive tools that take a lot of time to prepare. For example, in the manufacture of a honeycomb die cavity, a comparison has been given of 122 hours lead time by numerical control compared with 550 hours by conventional methods. By numerical control, the initial stages of planning, calculating, and tape preparation occupy 68 hours, compared with 28 hours planning and calculating conventionally (no tape preparation required). From then on, however, the conventional method requires 482 hours for seven operations that are eliminated by numerical control: loft drawing, station master template, plaster mould template, rigging template and fairing, plaster splash, male casting from plaster splash, and casting metal die. From this point the conventional method ends with 60 hours to finish grinding of the die, whereas the numerical control system proceeds directly from its prepared tape to machine the die (24 hours) and finish grind it (30 hours).

This great reduction in lead time indicates some of the fields that are promising for application of numerical control, and emphasises that it is not only the long-run mass-produced work that can benefit. Reduction of lead time may be one of the main reasons for applying numerical control. Others include: large numbers of machine operations or set-ups; complicated machining operations; short machining time but long set-up time; short runs and multiple variations in a complex part; to reduce human error, particularly with very complicated operations; to produce more or less to order parts that are normally so involved that it is uneconomical to provide a sufficiently large stock of them as spares.

Examples of Controls

An idea of the scope of automatic control systems for machine operations can be gained from the general outline given so far. As in most cases of automatic control applications, it is possible to automate almost any required work, but how much can be achieved in practice depends on how much the operator can afford to pay, in relation to the advantages that might be obtained.

Relatively simple control systems may cost something of the order of \$3000 to \$9000; continuous path systems and other special installations may run to ten times these figures or even considerably more for special-purpose systems.

At the lower end of the scale, one example is the case of conversion of a standard capstan lathe to automatic operation by a stepping relay control system. Control includes a stepping relay and a patchcord programming panel, of which the interconnections are set to control certain functions of the lathe; for example, open and close chuck jaws, feed-in bar, change spindle speed and turret head position, adjust cross-slide and capstan slide feed rates. The conversion involved no major alteration beyond addition of actuating mechanisms, including air cylinders, hydraulic check cylinders, and necessary drives.

A much more sophisticated specially-designed machine that has recently been described is a turret lathe that starts as a manually-operated machine and can be developed by addition of control blocks until it can perform very complex operations by numerical control. The basic machine is equipped with the necessary servo-feeds, and even manual operation is controlled through servo links. Numerical control blocks can be added to provide positioning control and contour control of the machine's two turrets. The contour or continuous path control receives pre-calculated data recorded on a punched tape. Positioning control data are stored in a 10,000-bit magnetic core memory, in which the instructions are recorded during an initial manual machining operation. It is proposed to provide the means of reading instructions into the magnetic core matrix from another punched tape prepared in advance of the machining operation.

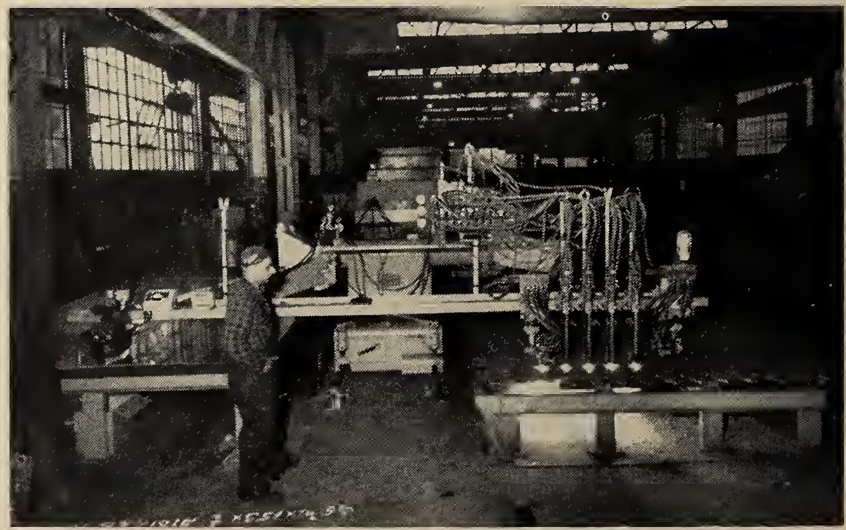
Automatic Inspection

With proper attention to all phases of an automatic program, great accuracy can be obtained; the system just mentioned is said to be accurate within 0.0005 in. However, inspection is still necessary and may become a problem when parts are being turned out at very high rates from an automatic system.

Various means of automatic inspection have been devised to help the job of the human inspector, who still has the final word on acceptance. One such system of automatic inspection is applied to a positioning system used in production of parts in large quantities, to accuracies of 0.001 in. The positioning system incorporates a servo-controlled table with movement along the X and Y axes. A punched tape is used to position selected inspection points at the tip of a stationary air probe sensing unit; any departures from correct size are indicated by extent and type, in thousandths of an inch, on a pneumatic gauge.

In the particular system mentioned here, vertical dimensions are checked by replacing the air probe with the arm of a mechanical dial indicator and manually checking thicknesses at at each of the stopping points on the tape-controlled inspection program. Such a system can obviously be developed further to permit inspection of more variables by automatic means.

The Travograph. By this ultra-modern method, an electronic "eye" guides four oxy-acetylene torches along the face of the material to follow a prepared design. Many intricate patterns can thus be cut, fast and with great accuracy—several thicknesses at one time, if required. *Photo courtesy Toronto Iron Works Limited*



Canadian Developments

New Use of Aluminum

Perfection of the extrusion process in the aluminum industry has made possible products as diverse as construction sections and aerosol containers. The construction sections, extruded with bulb corners, attain close to the full strength of steel and have only half its weight. They have been put to use extensively in modern power line towers, where they give an impression of giant bird wings.

The aerosol containers, on the other hand, are hand-size, compact objects. The lacework of the power towers contrasts sharply with their solid, seamless character. They have a bright, anodized surface.

Welding at high speed has also opened up a new terrain for aluminum. Pipe lines for oil fields, conveying oil, gas and water are being laid in the Western provinces, perhaps the longest of which is a 17-mile line in Alberta.

Another product of high-speed welding is the aluminum tank hopper car with a single hopper in the center, a design which has been unfeasible in the traditional rectangular hopper car.

The Methane Pioneer

Aluminum's ability to withstand extremely low temperatures has made it highly suitable for vessels carrying liquid gas. In 1959 the Methane Pioneer, a 3,000-ton tanker, was converted to carry 2,000 tons of liquid natural gas. Five aluminum cargo tanks insulated with balsa wood were installed in the ship to transport the liquid gas at a constant temperature of approximately -258° F. It was found that the aluminum could withstand both the low temperatures and variations in temperature from liquification and re-gasification. The ship departed from Texas and upon arrival in Great Britain had its cargo transferred to high storage tanks consisting of an aluminum container, insulation and an outer shell. An extruded aluminum pipe was used for the transfer.

Aluminum has found application in Arctic building for these same cold-resisting characteristics, as well as in Alpine snow fences. Shelters against avalanches have been built out of extruded aluminum tubing and formed sheet.

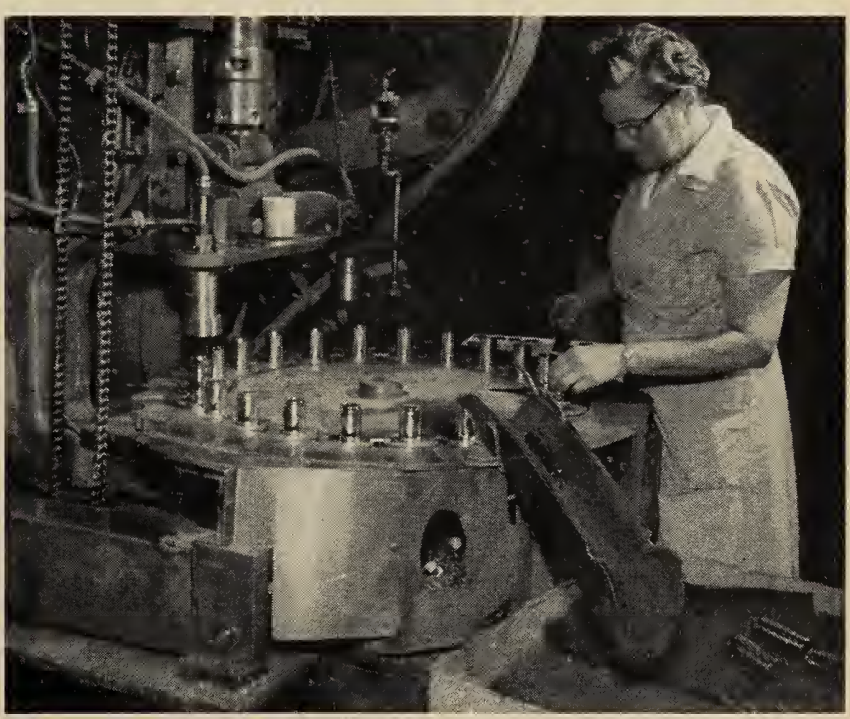
Effects of Anodizing

Anodizing has various effects upon aluminum, among them the acceleration of aluminum oxide formation. It gives a slightly milky appearance to the surface of most aluminum alloys, but in the case of silicon, gives a handsome dark grey tone to the alloy. The new Mackenzie building in Toronto is composed of grey anodized aluminum frames around modular panels of coloured glass, clear aluminum window sections and steel. Exposure to oxygen causes an oxide layer to form on the surface of these aluminum frames which, with anodizing, thickens and hardens giving protection to the metal.

The development of aluminum-magnesium alloys, as well as perfection of welding procedures, has produced an aluminum off-highway rock body for

trucks. In this vehicle the usual combination of steel with oak cushions is replaced by a single 1¼ in. aluminum plate, the aluminum absorbing the impact.

Preparation of impact extruded aluminum aerosol containers to take valve caps.



Uses of Copper

Generally speaking, copper and its alloys are not used for structural strength. Their appeal is in their design value, particularly their colour which ranges from pure copper to red brass, through architectural bronze to yellow brass, and to the white metal, nickel-silver.

Copper in building may appear in two general forms—as thin facing over steel sheet, tubes and structural shapes or as exterior curtain walls of bronze and other copper alloys. Bronze mullions and bronze-coloured Muntz metal spandrels have recently been used in combination to make a curtain wall. Bronze mullions give sharp edges which create a kind of shadow which lends a third dimension to a structure.

The Queen Elizabeth Hotel in Montreal drew heavily upon nickel-silver for ornamentation. Thirty-eight thousand pounds were used in door and window frames, stairway handrails, and the panels and ceiling in front of the main elevator doors.

Completed steelwork for TCA's 836 ft. x 175 ft. hangar at Montreal Airport. It is believed to be the longest cantilever roof in North America.

Radiant heating and air-conditioning

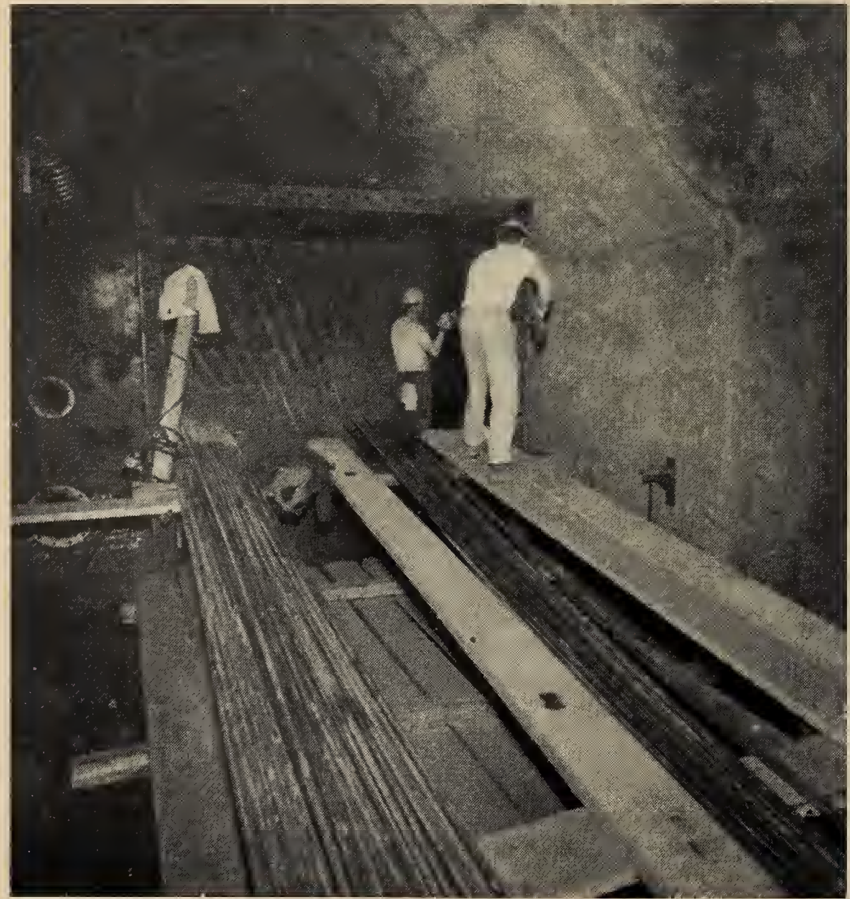
Copper is being used increasingly for radiant heating installations, where radiant panels decrease temperature variations in a room heated by convection currents from 10° F. to approximately ½° F. The Workmen's Compensation Hospital and Rehabilitation Centre in Toronto has such a system. Eight miles of copper tube were used in this building for hot and cold water lines as well as the radiant heating panels. The copper tube has virtually

no maintenance, low head loss due to friction and high resistance to corrosion.

Air-conditioning installations have also come to use copper more. Copper tubes are used in control and supply lines for test rigs as well as hydraulic and pneumatic control mechanisms. For control panel piping small-bore copper tube is used, and polyvinyl chloride clad tube where corrosion threatens.

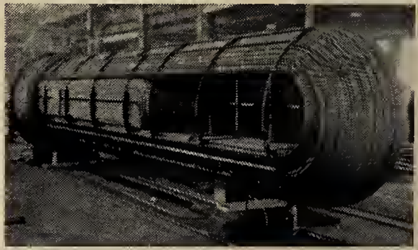
In hospitals and various medical facilities copper tube is used for carrying gases in surgery, therapy and resuscitation. Steam cleaned and capped until installation, oxygen tube draws from a central gas supply and runs into every room for use beside the patient's bed. In this way transport of heavy cylinders is eliminated and explosion hazards are reduced.

Installation of brass tubes in condensers, Richard L. Hearn Generating Station.



Generating Stations

While considering the uses of copper and copper alloys in the structural design of commercial buildings, it would be an error to overlook their use in electrical generating stations, since over 50% of the copper used in Canada is used in power-generating systems. The water-driven generating system of the St. Lawrence Seaway Power Project uses alone over 2,000,000 lb. of copper. Canada's largest steam-power station, the Richard L. Hearn Generating Station, uses vast quantities of cupro-nickel and



brass tubes for the feedwater heaters and condensers, not to speak of the generators.

One last application which is interesting to consider is sewage treatment plants. A copper-silicon alloy was specified for many parts of the Humber Sewage Treatment Plant — the weir plates, the guides for sluice gates, nuts, bolts and even the fixtures in the aeration tanks. It is copper's resistence to corrosion which makes it so valuable in this field.

International News

Uses of Stainless Steel

Stainless steel will sheath the $12 million United Engineering Building in New York City and many other modern metal and glass structures. It will take to the air in planes and in missiles. It will even line the nuclear reactors which may explode the limitations of conventional power sources.

The hardenable "Austenitic" stainless alloys are becoming ever more important to the aircraft industry. One of these alloys, for example, is the main constructional material in the B-70 Valkyrie chemical bomber, an aircraft which travels at speeds up to 2700 m.p.h. without damage from intense air friction heat. Semi-austenitic stainless steels resist corrosion exceptionally and can be hardened at temperatures low enough to minimize distortion and oxidation.

United Engineering Building

The problem of steel's high density has been met in the B-70 by a honeycomb sandwich structure. The stainless steel used in the Atlas ICBM airframe is of such a thin gauge that manufacturers refer to the missile as a stainless steel balloon. Resistance welding is possible on this hard-rolled type of stainless steel, whereas the heat treatable stainless steel used in the B-70 honeycombs calls for other welding methods.

Nuclear Reactor Applications

The development of a number of new stainless steel alloys has given rise to nuclear reactor applications. Low cobalt and boronated stainless are but two of these, the latter being an exceptionally good neutron absorber and thus a natural material for reactor shielding The combination of nitrogen, chromium, nickel and manganese in a fixed proportion gives an alloy which may be useful in many applications where there is a high temperature environment. It resists erosion, oxidation and corrosion at high temperatures and has a tensile strength in excess of 162,000 psi. at room temperature.

Slag washing of stainless steels has been developed to a point where the metal is applicable to fabrication of hot sections of jet aircraft, high temperature steam boilers and turbines, and nuclear reactors. Spinning, drawing, machining and polishing of slag-washed stainless is now possible.

Use in Instrumentation

Stainless steel foil can be made to a thickness of .0005 in. and it is thought that refinements are still ahead. Electronic tubes, missile and satellite instrumentation and honeycomb skin will all call increasingly upon this form of stainless steel. Foil 2 mils. thick, coated with radioactive tritinated titanium, has been used as an irradiation source in static eliminators and other instruments.

New Fabrication Techniques

Extrusion of stainless steels is an important development in that it will allow the fabrication of complex contours in stainless steel products. The extruded forms lend themselves to greater freedom of section design, their integral complex shapes replacing two or three traditional component parts. With extrusion, machining operations can be appreciably reduced and economy can be had in short run production when demand does not justify roll forming.

Roll forming has also been perfected as a stainless steel fabricating technique. Whereas earlier it was thought suitable only for mass production of standard sections, standard stainless steel shapes are now being produced at a relatively low cost on a job shop basis.

Fusion welding, because of the delicate technical applications to which stainless is put, must reach a high state of perfection. Severe standards are being met in the fusion of nuclear reactor components and the joining of stainless pressure vessels, chemical process piping and load-bearing aircraft parts.

Redstone Missile

Month to Month

Municipalities Urged to Speed up Planning of Winter Work's Program

The Chairman of the National Joint Committee on Wintertime Construction and Past-President of the Canadian Construction Association, Raymond Brunet, said recently that his committee had made a recommendation to the Federal Government that the scope of municipal projects eligible for assistance be increased. The committee also has asked that an earlier announcement be given than in the past so that municipal authorities have more time to prepare plans and specifications for the winter program.

Mr. Brunet pointed out that new regulations provide the municipalities with new incentives for wintertime work on municipal buildings other than schools and hospitals. He also said that engineering projects with subsidies for labour costs have been expanded to include above-ground sewage and water installations, as well as below-surface work, street lights and traffic signals.

"This program will of course not in itself solve the seasonal unemployment problem for the construction industry and there will be many municipalities who will be unable to participate, but it should provide very useful assistance to this end. Last winter the program expanded by roughly 50% over that of the initial program in the previous December-to-May period. This winter with the expanded scope of the scheme, more advance notice and more experience on the part of the municipalities, the program's usefulness should grow still more," said Mr. Brunet.

New American Institute for Certification Established

Establisment of an Institute for the Certification of Engineering Technicians and Technologists has been approved by the Board of Directors of the National Society of Professional Engineers, U.S.A.

The National Society will organize and operate the Institute to:

a. Determine by examination, endorsement, or otherwise, the qualifications of all persons who apply for certification.

b. Grant a certificate in the appropriate grade to applicants who successfully meet the criteria for certification.

The Institute, which is to be exclusively an examining body, will be operated by a board of directors comprising equal numbers of registered professional engineers and certified engineering technologists.

A. C. Friel, Midland, Michigan, chairman of the National Society's Committee on Engineering Technicians, told the group's Board of Directors that the establishment of the Institute "should provide a much needed means of recognizing the status of technician members of the technological team."

Friel pointed out that the Institute "should also lead to the upgrading of the education and work experience, as well as the continued self-development of the technician."

Advisory Committee at Essex College

The Advisory Committee to the Faculty of Applied Science at Essex College, Assumption University of Windsor is composed of practising professional engineers representing various branches of engineering and is a sub-committee of the Academic and Personnel Committee of the Board of Directors of Essex College.

It is basically the re-organization of the former Engineering Education Committee originally formed in October 1956 to recommend to the Board whether or not the university might establish a complete accredited program leading to the engineering degree in a minimum of four branches, namely, chemical, civil, electrical and mechanical engineering.

As a direct result of this recommendation, three degree courses were inaugurated at Essex College by the Board of Directors in 1957. This led to the establishment of the Faculty of Applied Science by the University Senate in the fall of 1959.

Registration for the 1959-60 term comprised 52 engineering students in the first year, 40 in the second and 26 in the third, for a total of 118 students. The first crop of graduates will receive their B.A.Sc. degree in the spring of 1961.

The Committee functions as an advisory group to the faculty, expressing the practical viewpoint of professional engineers on all phases of the applied science program. Among its immediate objectives are the placement of graduates in 1961, assistance to undergraduates in finding summer employment, and a continuing intensive public relations program.

As of May, based on a committee recommendation, a "placement package" consisting of pertinent information relative to the faculty and students was mailed to 319 industries and 60 consulting engineers mainly located in Southern Ontario and Western Quebec.

Mr. R. T. Waddington, Riverside, Ont., is chairman and Mr. D. D. Duquette, Windsor, Ont., is secretary.

E.I.C. Elections and Transfers

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers became effective July 22, 1960.

ALBERTA

Members: K. J. Bates, R. G. Erikson, P. H. Hwang, D. K. MacDonald.
Juniors: J. D. H. McMillan, R. W. Nichols.
Student: G. Zieffle.
Junior to Member: R. E. Bailey, R. D. Hall, F. B. Matthews, H. Nahaiowski, A. Wilumsen.
Student to Member: D. W. Russell.

SASKATCHEWAN

Member: G. E. Ellingham, F. E. Fernyhough, P. L. Money, W. A. Padgham, D. Sawatzky, R. Shklanka, K. H. C. Un.
Junior: P. deWolf.
Junior to Member: D. G. Bishop, B. G. Brown, G. C. Burns, D. G. Delparte, W. A. Derry, R. N. Filson, J. A. J. Kavanagh, R. W. Kyle, S. E. Lawrence, M. F. Main, J. E. McGuire, D. G. Olafson, J. H. Peterson, A. Shklanka, G. R. Ursenbach, D. W. Wilson, J. E. Zuk.
Student to Member: L. E. Brown, N. A. Mackenzie.
Student to Junior: L. P. Benoit, R. L. Blanchette, E. A. Cochrane.
Student: G. H. Morris.

NOVA SCOTIA

Members: T. G. Burton, P. B. Corkum, C. J. Courtney, R. A. MacRae, A. D. Oliver, H. D. Tanner, R. L. Vatcher.
Junior to Member: K. H. W. Barrett, D. G. Lordly, R. N. Pereira, G. B. Weld.

NEW BRUNSWICK

Member: D. M. Dexter.

MANITOBA

Member: F. S. Bolton.

THE ENGINEERING INSTITUTE OF CANADA

President's Column

DURING the summer months, Presidential visits are being arranged to a number of important Canadian engineering organizations, such as the Department of Mines and Technical Surveys in Ottawa; National Research Laboratories, Ottawa; Ontario Research Foundation, Toronto; CARDE, Valcartier; etc. The purpose of these visits is to bring a closer liaison between these organizations and The Engineering Institute of Canada, because it is felt that the future development of Canadian engineering depends to quite a large extent on the fundamental work by these groups.

Courtesy visits were also made to the Ontario Association of Professional Engineers in Toronto and to the Corporation of Professional Engineers of Quebec.

The newly formed Executive Committee of Council met in Montreal on July 22nd for the first time, with the President, four Vice-Presidents, Treasurer, and several Councillors present. A considerable volume of Institute business was transacted and numerous reports of Committee and other groups were presented. The second meeting of the Executive Committee was held in St. Andrews, N.B. on September 9th.

At the bienniel Maritime Professional Engineers Meeting which was held in St. Andrews, N.B., September 7, 8 and 9th, your President was the guest speaker at one of the functions. An interesting program was arranged for this Maritime Meeting, which provided an excellent opportunity for the Engineering Institute Officers to meet the Maritime Engineers.

The various Committees of the Engineers Confederation Commission are energetically at work during these summer months, busily engaged with their respective assignments.

The Institute's delegates to the first Pan American Congress on Engineering Education being held in Buenos Aires, September 12th to September 18th, are Dean McLaughlin of Toronto and Dean Conn of Queen's.

The above Congress will be followed by the Sixth UPADI Congress, also at Buenos Aires, at which the Engineering Institute will be represented by a suitable delegation.

Encouraging responses are being obtained by the President in his communications with Vice-Presidents and Branch Chairmen regarding Branch activities being organized well in advance of the inauguration of fall programs. Now is the time to do the advance planning necessary to get interesting and attractive meetings for the coming season.

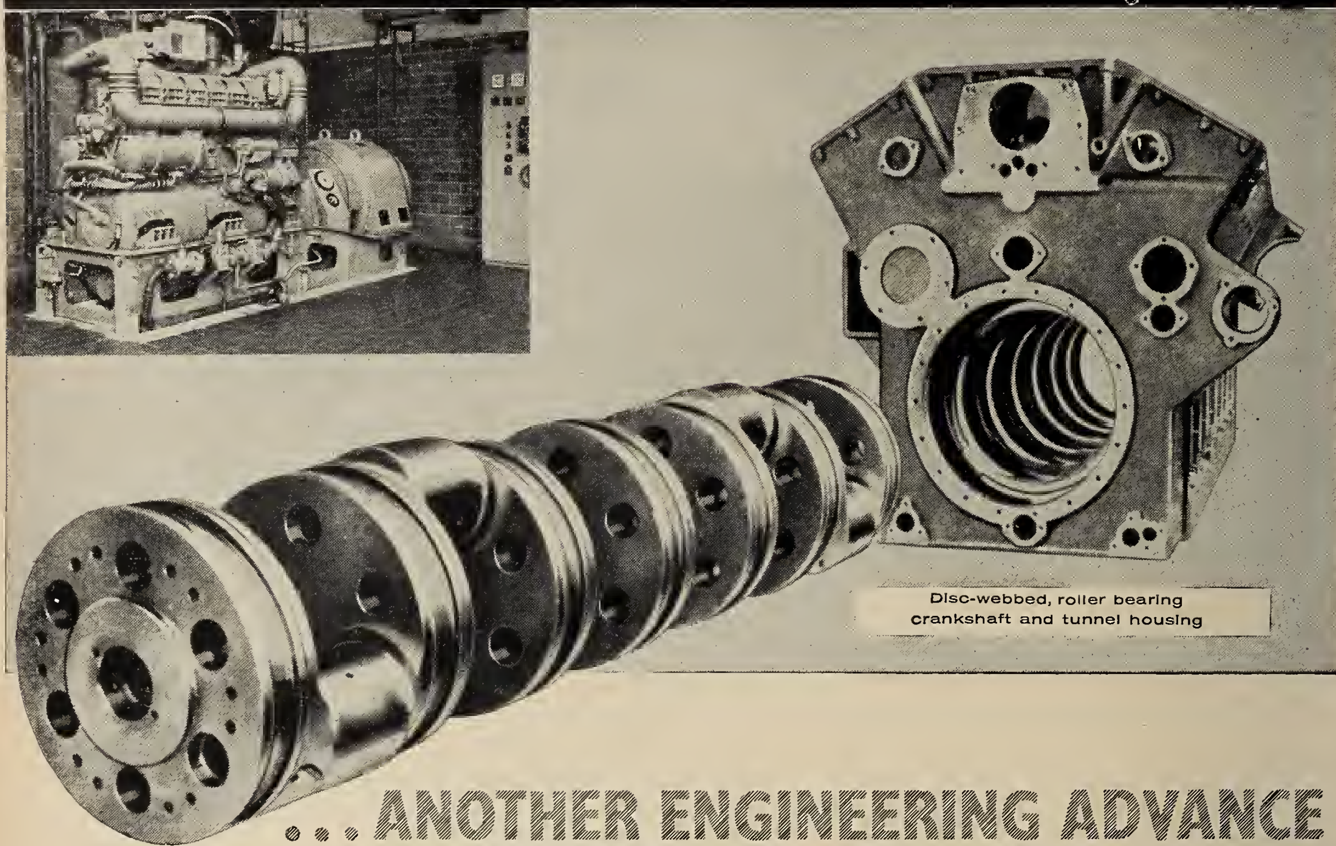
Maybach industrial diesel engines—from 300 to 1,800 hp—can achieve 16,000 hours between major overhauls . . .



Disc-webbed, roller bearing crankshaft and tunnel housing

. . . ANOTHER ENGINEERING ADVANCE FROM BRISTOL SIDDELEY

Bristol Siddeley Engines Limited produce Maybach* diesel engines. Covering a power range from 300 to 1,800 hp, Maybach diesels are amazingly reliable and have shown that they can achieve major overhaul lives of between 12,000 and 16,000 hours.

The *proven* basic design features of the whole range (straight 4 to 16-cylinder V) are the same, and each unit can be turbo-charged, or turbo-charged and intercooled. The range operates up to 1,600 rpm and *combines the best performance and design qualities of high, medium and low-speed diesel engines:* light weight and compactness; excellent thermal efficiency; and extremely long life.

Advanced design features

The pistons are pressure-oil cooled. This gives very efficient heat dissipation and reduces liner and gas ring wear to a minimum. The roller bearing, disc-webbed crankshaft is exceptionally rigid within its tunnel housing, and in practice withdrawal is not normally necessary before 12,000 hours running. So low is big end bearing wear that in some cases the protective lead flash has been found intact when examined after 15,000 hours running!

Since the cylinder bore and stroke, and the majority of components, are identical in all models, spares stocks are considerably reduced. And during servicing semi-skilled labour can be used because great thought has been given to easy accessibility and removal of components.

World-wide application

Bristol Siddeley Maybach diesel engines are designed for a wide variety of industrial applications, from stationary and mobile light and power generator sets to oil-drilling rigs and pumping stations. Maybach diesel engines are in service all over the world and have built up an unrivalled record for reliable and economic operation.

For further information please write to: Bristol Aero-Industries Limited, 200 International Aviation Building, Montreal 3. Tel.: UNiversity 6-5471.

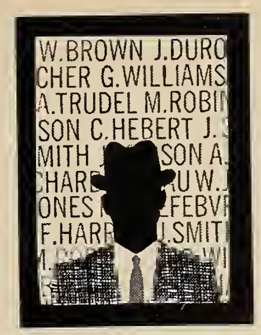
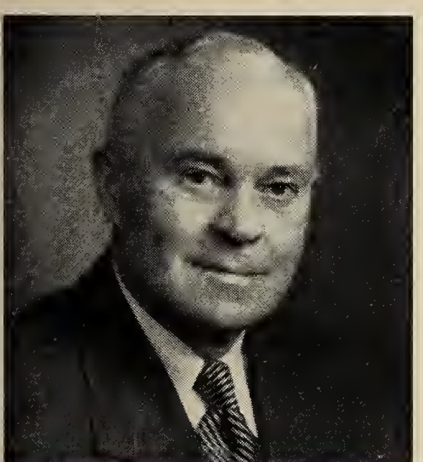
BS BRISTOL SIDDELEY ENGINES LIMITED



Personals

Otto Holden, Hon. M.E.I.C. (Toronto '13), chief engineer of the Hydro-Electric Power Commission of Ontario, has retired after 47 years of service. A major influence in hydro-electric development throughout Ontario, Dr. Holden has been intimately associated with the design and construction of over 300 hydraulic projects in the province. Significantly, he leaves the work at which he has had such success after completing the largest project of his career, the long-term planning and design of the St. Lawrence power project.

Dr. Holden began his career with the Commission in 1913, the year he graduated from the University of Toronto. In 1918 he was placed in charge of the design of hydraulic plants, the most outstanding of which were the Nipigon River plant at Cameron Falls and the Sir Adam Beck-Niagara generating station No. 1 at Queenston. Named deputy head of the hydraulic department in 1924, he supervised the first complete development of an interprovincial power site, on the Ottawa River at Chats Falls.



Dr. Otto Holden, HON. M.E.I.C.

As chief hydraulic engineer from 1937-47, Dr. Holden served with distinction on the International Committee, charged with the design and construction of the remedial works in the Niagara River. In 1947, appointed assistant general manager of engineering, he continued to develop Ontario's water power resources and in the following ten years played a key role in speeding some 14 new major power sources into operation. In renaming the La Cave generating station The Otto Holden Generating Station in 1952, the Commission signally recognized Dr. Holden's important contribution. He was appointed to succeed Richard L. Hearn as chief engineer in 1957.

A distinguished professional engineer, Dr. Holden has been honoured with positions of leadership in professional societies for many years. He is a past councillor of the Institute; a past director of the American Society of Civil Engineers, of the American Institute of Electrical Engineers, and of the Senate of the University of Toronto. He is also a past president of the Engineering Alumni Association of the University of Toronto and a past president of the Royal Canadian Institute.

Dr. Holden was awarded Honorary Membership in the Institute in 1960.

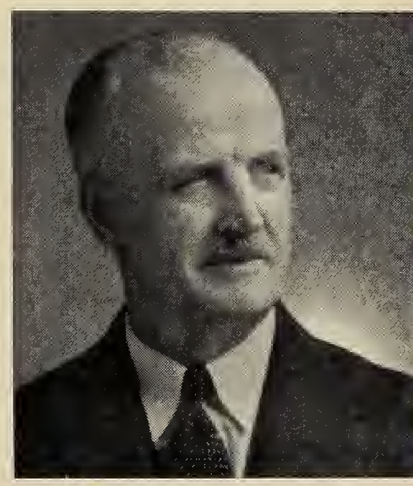
Huet Massue, M.E.I.C. (Ecole Polytechnique '13), General Manager of the Lower St. Lawrence Gulf Development Association and former director of Atomic Energy of Canada Limited, was recently elected to the board of EDITORIAL ASSOCIATES LIMITED, public relations counsel.

E. D. Gray-Donald, M.E.I.C., (McGill '26), Vice-President, Administrative Services, The Shawinigan Water and Power Company, has been elected an HONORARY MEMBER of the Canadian Transit Association for "outstanding service to the Canadian transit industry". Mr. Gray-Donald first became associated with the Canadian Transit Association while with the Quebec Railway, Light and Power Company and was subsequently elected to the Executive Committee and served as President from 1946 to 1948.

Charles H. Pigot, M.E.I.C. (McGill '26) has been named ASSISTANT CHIEF ENGINEER of the Power Development Division of the Quebec Hydro-Electric Commission.

T. W. B. Lazenby, M.E.I.C., has been made DESIGN ENGINEER III in the Engineering Division of The Consolidated Mining and Smelting Company at Trail, B.C.

C. J. MacKenzie, Hon. M.E.I.C. (Dalhousie '09), a past president of the Engineering Institute of Canada and former president of the National Research Council, has been appointed to the Ottawa Advisory Board of The Toronto General Trusts Corporation. Dr. MacKenzie has



C. J. MacKenzie, HON. M.E.I.C.

had a distinguished career, as dean of the faculty of engineering at the University of Saskatchewan, president of the National Research Council, president of Atomic Energy of Canada Ltd., and, currently, chancellor of Carleton University.

Dr. MacKenzie has been the recipient of honorary degrees from the universities of Dalhousie, Queen's, Western Ontario, Algiers, Saskatchewan, McGill, Laval, Cambridge, British Columbia, Princeton, Toronto, Nova Scotia Technical College, and the University of Montreal.

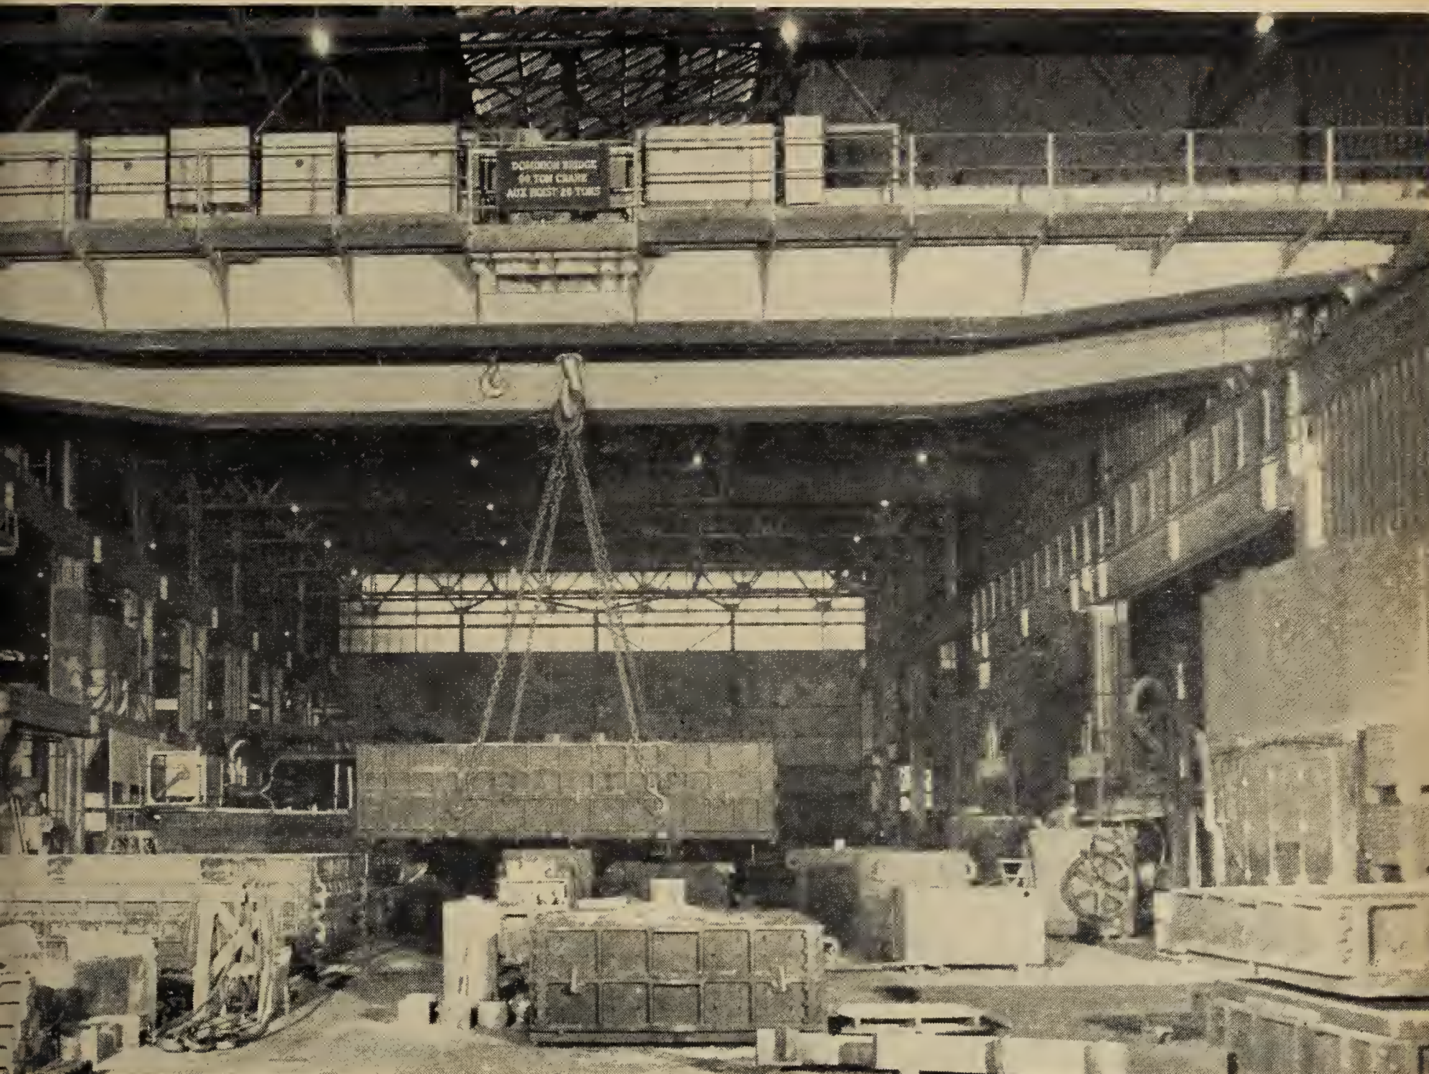
Ronald W. Dunlop, M.E.I.C. (Toronto '27) has been appointed GENERAL MANAGER of the manufacturing department, Imperial Oil Limited.

Wilfred N. Hall, M.E.I.C. (U.B.C. '29), President of Dominion Tar and Chemical Co. Limited, Montreal, has been elected PRESIDENT of The Chemical Institute of Canada.

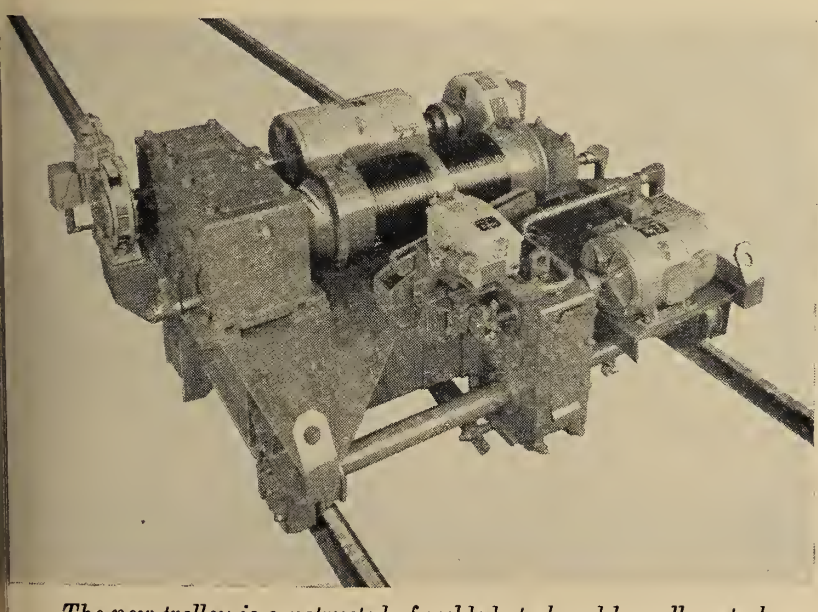
Dwight S. Simmons, M.E.I.C. (Queen's '32), President of the Association of Pro-

(more Personals on page 112)

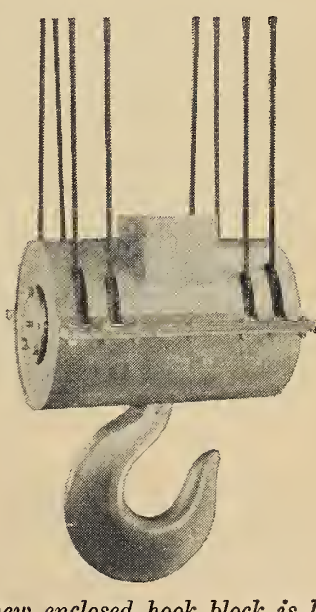
with new standards



One of the new cranes installed in a foundry. This 90-ton unit, equipped with open type cab incorporates an auxiliary 20-ton hoist.



The new trolley is constructed of welded steel and has alloy steel gearing. Split oil seals are used on projecting shafts and the drum. Large gear case inspection cover simplifies maintenance.



The new enclosed hook block is lighter and more compact.

• PERSONALS

(Continued from page 109)

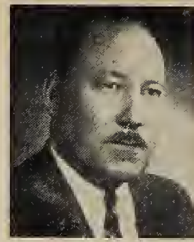
fessional Engineers of Ontario, has been named a DIRECTOR of Imperial Oil Limited.

J. H. Palmason, M.E.I.C. (Manitoba '33) is the EXECUTIVE VICE-PRESIDENT of L. Gordon Tarlton Ltd., general contractors, Montreal, by recent appointment. Mr. Palmason was formerly Vice-President and General Manager of Siporex Ltd., a subsidiary of Dominion Tar & Chemical Co. Ltd.

J. E. Dumontier, M.E.I.C. (Ecole Polytechnique '35), Director of the Engineering Branch of the Board of Transport Commissioners, has been appointed DEPUTY CHIEF COMMISSIONER of the Board.

Andrew M. Swan, M.E.I.C. (Manitoba '39) is RESIDENT MANAGER of the Richmond Pulp and Paper Co. of Canada, Ltd. mill at Bromptonville, Quebec by recent appointment.

E. Rohatynski, JR.E.I.C. (Manitoba '50) has been appointed CONSTRUCTION ENGINEER IV in the Engineering Division of The Consolidated Mining and Smelting Company, Kimberley, B.C.



G. E. Humphries, M.E.I.C.

W. L. Wardrop, M.E.I.C.

George E. Humphries, M.E.I.C., and W. L. Wardrop, M.E.I.C. (Manitoba 39), Presidents respectively of M. M. Dillon and Company Limited and W. L. Wardrop and Associates (Management) Limited, announce the formation of DILLON - WARDROP ASSOCIATES, Consulting Engineers, Winnipeg. The two firms will continue to operate independently as in the past but will combine in the new firm for large engineering projects in Western Canada.

A. J. Groleau, M.E.I.C.

A. J. Groleau, M.E.I.C (McGill '28), vice-president of the Corporation of Professional Engineers of Quebec, has been named VICE-CHAIRMAN of the Trans-Canada Telephone System. Mr. Groleau is Vice-President and General Manager of Bell Telephone's Toll Area.

John A. McRae, M.E.I.C. (Toronto '49) has taken up the duties of CHIEF ENGINEER with the Noront Steel Construction Co. Ltd., Sudbury, Ont. He was formerly with the Dominion Bridge Co. Ltd.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Address all information to: *The Engineering Journal,* Editorial, 2050 Mansfield Street, Montreal, Que.

Lloyd K. Hart, M.E.I.C. (Toronto '40) has been appointed GENERAL MANAGER of Regent Electric Supply Company, Division of Union Electric Supply Co. Limited, Toronto.

L. K. Hart, M.E.I.C.

Donald A. Burris, M.E.I.C. (N.S.T.C. '45) is GENERAL SALES MANAGER, Canadian Ingersoll-Rand Co. Limited, following a recent appointment.

D. A. Burris, M.E.I.C.

R. J. Balfour, M.E.I.C. (McGill '46), formerly with Fraser-Brace Engineering Company Ltd., has opened a new construction office for BROWN & ROOT, LTD., Montreal.

R. J. Balfour, M.E.I.C.

J. B. Goodfellow, M.E.I.C. (McGill '46) has been elected ALDERMAN in the City of Dorval, Quebec. Mr. Goodfellow is Transite Pipe Staff Manager of the Montreal branch, Canadian Johns-Manville Co. Limited.

J. B. Goodfellow, M.E.I.C.

Glenn C. Ritcey, M.E.I.C. (McGill '48) is VICE-PRESIDENT AND GENERAL MANAGER of Radar Pneumatics (Eastern) Ltd. following a recent appointment.

L. S. Love, JR.E.I.C.

L. S. Love, JR.E.I.C. (McGill '51) has been appointed EASTERN SALES ENGINEER for Separator Engineering Ltd. He was previously associated with General Electric and Infilco as Canadian District Manager.

R. G. Gallinger, JR.E.I.C. (Toronto '56) has been transferred from the RCAF 4(F) Wing in Germany to the Central Experimental and Proving Establishment, Ottawa, where he will act as a pilot on test and development projects. He has recently been promoted to the rank of FLIGHT LIEUTENANT.

P. E. Coulter, JR.E.I.C.

Philip E. Coulter, JR.E.I.C. (McGill '56) has been appointed Canadian DESIGN AND SALES ENGINEER for Waterman-Waterbury Co., Minneapolis, Minn.

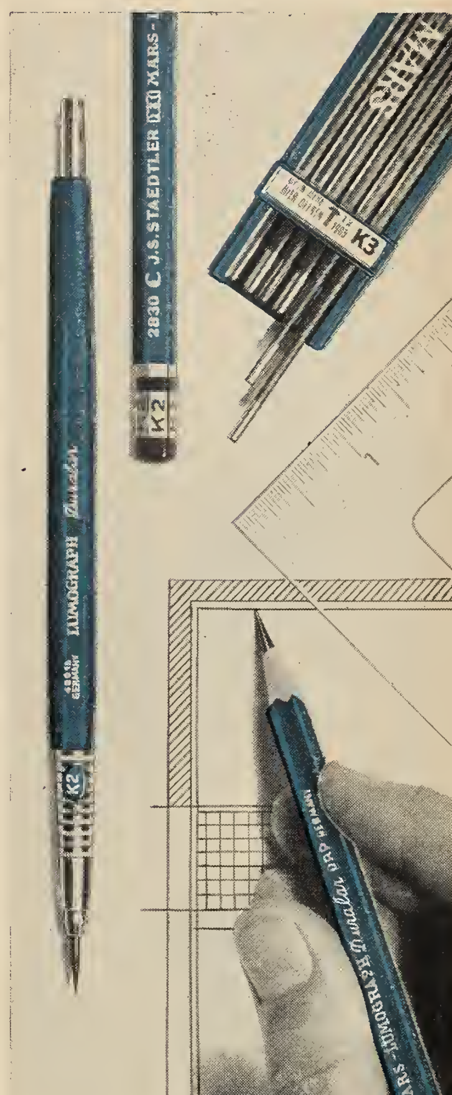
D. B. Barry, M.E.I.C.

Donald B. Barry, M.E.I.C. has been appointed MANAGER OF PLANT ENGINEERING for Dominion Engineering Works Ltd., Montreal.

Frederic Dreville, M.E.I.C. has been appointed CHIEF ENGINEER of the hydraulics department, Surveyer, Nenninger & Chenevert, Montreal.

Richard J. Joy, M.E.I.C. (McGill '45) has joined the INDUSTRIAL DEVELOPMENT BANK as an Investigating Officer and is now attached to their Montreal office.

Maurice Decarie, M.E.I.C. (McGill '45) has been appointed VICE-PRESIDENT AND GENERAL MANAGER of Domaine d'Esterel Inc. Mr. Decarie is President of Omega Construction Company Limited.



Other Societies

New Volume of Dechema Monographs

"Fortschritte der Destilliertechnik" (Progress in Distillation Engineering) is the title of Volume 37 of the Dechema Monographs. It contains an account of three comprehensive experimental investigations on rectifying columns—the first, on the properties of two-phase flow in rectification in packed columns; the second, on control problems in continuous distillation columns; the third, on application of the similarity theory to the processes in rectification columns.

French Magazine on Industrial Design

A magazine on industrial design, published in Paris, is available for circulation in Canada. Entitled "Esthetique Industrielle", the publication includes photographs and documentation on new designs and discussion of design problems.

Soviet Research Published in Translation by ASME

Recent Soviet engineering research is described in a new translation entitled **Friction and Wear in Machinery**, published by the American Society of Mechanical Engineers. Included in the volume are fifteen articles on a wide range of topics from hydrodynamic lubrication and bearing performance to boundary lubrication, dry friction and wear. Copies are available at $7.50 per copy from the Order Department, ASME, 29 West 39th Street, New York 18, New York.

World Conference on Earthquake Engineering

Organized by the Science Council of Japan, the Second World Conference on Earthquake Engineering was held at Tokyo and Kyoto, Japan, July 11-18. Dr. Sheldon Cherry, Civil Engineering Department, University of British Columbia, participated in the conference, representing the National Research Council of Canada.

AIEE Pacific General Meeting

The 1960 Pacific General Meeting of the American Institute of Electrical Engineers was held in San Diego, California, August 8-12. One of the chief items on the technical program was the meeting of the Aero-Space Committee and their discussion of "Electrical Frontiers of the Space Age". Technical papers were presented in three general groups: Communication and Electronics; Applications and Industry; Power Apparatus and Systems.

Joint Automatic Control Conference

Massachusetts Institute of Technology, Cambridge was the scene of this year's Joint Automatic Control Conference, September 7-9, sponsored by the American Society of Mechanical Engineers with the cooperation of the Boston section and participating societies. Conceived to reduce the overlap of conferences on control sponsored by individual societies, it is understood that there will be no other national conferences on control. At this conference a report was delivered on the First IFAC Congress held in Moscow, June 27 to July 2.

Ready-Mixed Concrete Convention

The first convention of the Ready-Mixed Concrete Association of Ontario was held September 18-20 at Delawana Inn, Honey Harbour, on Georgian Bay, about 100 miles north of Toronto. One of the highlights of the convention was an equipment display by associate members.

Brno Trade Fair, September 11-25

The gates of the International Trade Fair in Brno, Czechoslovakia opened on September 11 to a giant exhibition of machine tools, electrical and electronic devices, raw materials, semi-products and various products of the engineering and metallurgical industries. More than 30 countries, including Canada, are exhibiting at the fair. AECL is displaying a wide range of special instruments which it has developed.

Coming Events

Power Conference (ASME with AIEE), Philadelphia, Bellevue Stratford Hotel, September 21-23.

3rd Canadian National Material Handling Show and Conference, Montreal, Show Mart, September 26-30.

(Continued on page 116)

The Associations and Corporation

The winners of this year's undergraduate scholarships awarded by the Association of Professional Engineers of Ontario for study at the University of Toronto and Queen's University, Kingston have been announced.

The scholarships, of $250 each, are awarded annually in the first three years at Toronto and Queen's to the student who, taking honours in engineering, obtains the highest standing in his work in the academic year.

The University of Toronto scholarship winners this year are:

First Year: Yiu Chung Li, Toronto, civil

Second Year: G. M. Bragg, Islington, mechanical

Third Year: J. G. Heller, Toronto, engineering physics.

Recipients of A.P.E.O. scholarships at Queen's University are:

First Year: Edward Langstaff, Rainy River

Second Year: Stanley E. Frost, Port Hope

Third Year: D. Russell Morton, Kingston.

Obituaries

William Douglas Adams, M.E.I.C., a member of the Institute since 1908, died in Toronto on June 30, 1960.

Mr. Adams received his degree in engineering from the Royal Military College of Canada in 1908. After work on various engineering projects, Mr. Adams enlisted in the Victoria Rifles of Canada and went overseas. In April of 1917 he was appointed Brigade Major of the First Canadian Infantry Brigade where he served until May 1918. At this time he was promoted to General Staff Officer, Fifth Canadian Division. He took a staff course at Cambridge and acted as second-in-command of Canadian headquarters at Seaford.

Returning to Canada Mr. Adams became a partner of Adams Brothers in Toronto, later joining the Toronto Transportation Commission. Subsequently he was associated with Walter J. Francis and Company of Montreal, and with A. Bentley & Sons, Toledo. Mr. Adams joined the Algoma Steel Corporation, Toronto in 1939 and retired as a piling engineer from that company in 1957.

A Member of the Council of the Institute from the Sault Ste. Marie Branch in 1958-60, Mr. Adams was a Life Member of both E.I.C. and the Association of Professional Engineers of Ontario.

Robert W. Angus, Hon. M.E.I.C., a Life member of the Institute, former senior professor at the Faculty of Applied Science, University of Toronto, and distinguished consulting engineer, died June 30, 1960.

Professor Angus graduated from the School of Practical Science in 1894. Appointed lecturer at the University of Toronto in 1900, he enjoyed 47 years of association with the university and carried on an active consulting practice until last year. He was instrumental in establishing the mechanical engineering department as a separate entity at the University of Toronto, and during his early years there was responsible for the design and equipment of the mechanical laboratories. Professor Angus directed all the heat-engine and hydraulic work done at the university.

A pioneer in the use of models for the study of water flow and elimination of ice troubles in hydraulic plants, Professor Angus maintained a large consulting practice, specializing in pumps and turbines. His published works include "Theory of Machines" (1915), "Hydraulics for Engineers" (1931), and numerous technical papers.

Over the years Professor Angus' distinction in the profession has been repeatedly recognized. Honorary Memberships were bestowed upon him by the Engineering Institute of Canada, in 1937; the American Society of Mechanical Engineers, in 1940; and the American Water Works Association, in 1945. The latter association honoured Professor Angus in 1942 with its George Warren Fuller Award for his contributions to the field of hydraulics. In 1957 The Engineering Institute of Canada established a medal to commemorate his name.

Ernest E. Brydone-Jack, M.E.I.C., former professor of civil engineering at the University of New Brunswick, Dalhousie University, and the University of Manitoba, died at his home in Joshua Tree, California, on May 23, 1960.

A graduate in Arts from the University of New Brunswick, Mr. Brydone-Jack received his civil engineering degree from Rensselaer Polytechnic Institute in 1894. From 1901-05 he was professor of engineering and Dean of the Engineering Faculty at the University of New Brunswick; during the period 1905-07 he held a professorship at Dalhousie; and from 1907-17 he was at the University of Manitoba.

For the next seventeen years, 1917-34, Mr. Brydone-Jack acted as Superintending Engineer, Public Works of Canada, for the Prairie Provinces, British Columbia, the Northwest Territories and the Yukon. In 1926 his Alma Mater, the University of New Brunswick, conferred the Honorary Degree of Doctor of Science upon him.

Mr. Brydone-Jack was granted Life Membership in the Institute in 1938. He was a Past President and Life Member of the Association of Professional Engineers of British Columbia and a Life Member of the American Society of Civil Engineers.

Charles Peter Edwards, M.E.I.C., former Deputy Minister of Air Services, Ottawa, and a key figure in the establishment of Canada's radio and wireless networks, died in Ottawa, July 14, 1960. He was 74.

Born and educated in Wales, Mr. Edwards' experience in wireless communication began in 1903 when Guglielmo Marconi erected a demonstration station at Chester, England. He became a Junior Technical Assistant on Marconi's staff and, in 1904, came to Canada to supervise the construction of stations at Camperdown, Nova Scotia and Sable Island. In 1909 he was appointed director of radio in the old Marine Department, later becoming director of the Radio Branch of the Department of Marine and Fisheries, and subsequently Director of Radio for the Dominion Government.

During World War I he held the rank of lieutenant-commander with the Naval Vounteer Reserve.

In 1941 Mr. Edwards was appointed Deputy Minister of Air Services for the Department of Transport, Ottawa, to direct the radio, civil aviation and meteorological services of Canada. He played a large part in establishing the Commonwealth Air Training Plan during World War II.

Mr. Edwards retired from his post as deputy minister of Air Services in 1951 after 41 years of government service. In that year he was also made a Life Member of the Institute.

James John Haffey, M.E.I.C., resident manager at the Valleyfield plant of Canadian Schenley Ltd., died suddenly on July 10, 1960, at the age of 43.

A 1939 graduate in chemical engineering from the University of Toronto, Mr. Haffey later became chief chemist with Canadian Industries Ltd. He subsequently joined Defence Industries Ltd. in Valleyfield as laboratory supervisor. In 1943 he was employed by the Polymer Corporation, and was made assistant mechanical engineer at the Sarnia, Ontario plant. He became associated with Canadian Schenely in 1945.

Mr. Haffey held memberships in the Corporation of Professional Engineers of Quebec and the Chemical Institute of Canada.

J. Donald Rice, M.E.I.C., Assistant Chief Engineer of the Pipe Line Division of Imperial Oil Ltd., died on June 11, 1960. He was 47.

Educated in Montreal and Welland, Mr. Rice graduated from McGill University in 1935 with a degree in civil engineering. Before joining the International Petroleum Co. Ltd., Peru in 1938, he worked in various survey parties and for the civil service in Ottawa.

In 1950 Mr. Rice returned to Canada from South America and worked on the Sarnia Products Pipe Line, for Imperial Oil, Toronto, as Chief Dispatcher. He spent five years in Waterdown, Ontario and then was transferred to Toronto in 1957, as Chief Engineer of the Pipe Line Division.

News of the Branches

Cape Breton

L. R. Boutilier, M.E.I.C., *Correspondent*

A LOBSTER PARTY, an annual affair at this time of year, brought 85 members and guests together on June 15, for an evening of feasting, cards, and good fellowship.

This outing at the Y.M.C.A. camp at Barrachois, about 20 miles from Sydney, was the final meeting of the season.

Lakehead

P. W. Pinn, M.E.I.C., *Correspondent*

THE ANNUAL MEETING of the Lakehead Branch was held on June 20 at the Port Arthur Country Club, and the following people were elected to the 1960-61 executive of the branch: John A. Brown, chairman; Philip W. Pinn, vice-chairman; Ernest B. Cashton, secretary-treasurer; Wayne P. Cheney, A. E. Meade, and Bruce P. Menlove, Fort William directors; Laurie E. Hardman, John C. Gilmore, Reginald Williamson, Port Arthur directors; Robert Hamilton, Eastern representative.

Mr. Douglas Fisher, Member of Parliament from Port Arthur, discussed the subject The Engineer and The Politician, stressing the need for more participation of engineers in public life.

Niagara Peninsula

THE SEVENTH ANNUAL Professional Engineers' Ball will be held again this year at Prudhommes' Garden Hotel on the Queen Elizabeth Way at Vineland, on Friday, September 30, 1960.

Mart Kenney and his orchestra will provide the dance music and there will be organ music during the cocktail and dinner hours. The floor show at intermission will be given by the Paul Brothers and Shirley.

The program is to start with cocktails at 6:00 p.m., followed by dinner at 7:00 p.m. and dancing at 9:00 p.m. Tickets will be $10.00 per couple.

J. H. Travers, JR.E.I.C.

Sarnia

Paul Donato, M.E.I.C., *Correspondent*

A FIELD TRIP to London, Ontario, June 16, allowed 38 members to visit the plants of the Wolverine Tube Mill of Calumet and Hecla and the Canada Vulcanizer Equipment Company. Groups of four and five engineers were guided around the plants to see first the extrusion and drawing processes in the Wolverine Tube Mill, then the production of Lo-Fin and Hi-Fin tubes at the C.V.E. plant.

A dinner at a London Golf Club followed, where the Calumet and Hecla personnel acted as hosts. Many who took the trip expressed the hope that more trips of a similar nature could be had in the future.

Engineers' Wives' Associations

THE FOURTH ANNUAL MEETING of the Associations, held in Winnipeg at the time of the Annual General Meeting of the Institute, brought 100 ladies together at the Royal Alexandria Hotel, May 27th.

Mrs. W. L. Bunting, Past President of the Winnipeg Professional Engineers' Wives Association and Chairman of the meeting, welcomed the many members and guests and asked for a reading of the annual reports from the different associations.

A number of interesting facets in association activities were illuminated by these reports. Mrs. R. H. Stevenson, speaking for the Hamilton Branch, discussed their bursary fund, pointing out that no fund-raising is done but $1 of the $5 fees is put aside for the bursary fund. A $50 bursary for a McMaster student in engineering has been made available each year until this year. With accumulated surpluses, it is possible to celebrate the 10th Anniversary of the branch with two $50 bursaries to engineering students.

The Penticton Branch, represented for the first time at the Annual Meeting. has an active membership of 12 ladies. It has been in existence for six years. No large projects are undertaken by the group, but social evenings are held every two months, sometimes with a speaker. The branch was represented by Mrs. Amudson, President, and Mrs. R. Price, Secretary-Treasurer.

Reports were also presented by: Mrs. J. M. Reid, Border Cities; Mrs. Stuart Neil, Calgary; Mrs. E. M. Rensaa, Edmonton; Mrs. M. A. Montgomery, Kitchener; Mrs. George Hayman, London; Mrs. P. A. Lovett, Halifax; Mrs. T. F. Holmes, Montreal; Mrs. P. M. Sauder, Lethbridge; Mrs. Rex Williamson, Lakehead; Mrs. T. Foulkes, Ottawa; Mrs. R. R. Keith, Regina; Mrs. G. V. Meagher, Toronto; Mrs. R. O. Jonasson, Winnipeg.

The 20th Anniversary Luncheon of the Winnipeg Professional Engineers' Wives Association, directly following the Annual Meeting, was the occasion of an address by Mrs. E. P. Featherstonaugh. Several excerpts from the historical sketch of the Winnipeg association follow.

My interest in Engineers' Wives goes back many years, for throughout my married life my husband and I entered wholeheartedly into the University functions planned by the students; we chaperoned countless dances, and many were the romances that budded before our eyes. Thus it was that when a group decided to form their own club and asked me to act as their first President, I was very proud and happy to do so. This was to be a purely social organization, we had a little fun together, and we wanted to get to know each other better. If at any time Engineering Conventions were to be held in Winnipeg, we would have our Committees standing by ready to help in the entertainment of visiting ladies.

However, to go back to 1940 and those early days of war, it was not long before an appeal came to us from the Red Cross, and we decided that we must do something. We started two sewing groups and a knitting group, and in the first two years turned in 442 pair of pajamas and 310 articles.

Perhaps the only way in which I can possibly cover the work accomplished over the past twenty years is by simply stating facts without elaboration. Our war work, in addition to the sewing and knitting groups, included Volunteer Service given to the United Services Centre: The Blood Donor Clinic; the Men's Service Lodge. From 1940-48 we raised over $1200 to purchase flannelette and wool. From 1945-47 we purchased twenty-four radios at a cost of $543, a gift to Deer Lodge Hospital for the use of wounded veterans. We set aside $50 as a wedding gift for Princess Elizabeth. In 1950 when Winnipeg was facing a major catastrophe, we gave $300 to the Flood Relief Fund.

In January 1951, we came to the decision that as Engineers' Wives, we would further the cause of Engineering education in this province; we undertook to endow one Bursary, and in 1951, we awarded our first Bursary of $100 to an Engineering student in the University of Manitoba. Since this time, we have built up a Trust Fund of $3,550. This money has been raised by our Annual Coffee Party held in February or March. The average net take in the past five years has been $630, with a high of $780 in 1959. Thus with our Trust Fund behind us, we have doubled and quadrupled our bursaries. In 1956, 1957 and 1958 we gave two Bursaries of $100 each, and in 1959 and this year two bursaries of $200 each.

"Pyrotenax" was used for interior and exterior wiring at the O'Keefe Centre, Toronto.

• DISCUSSION

(Continued from page 98)

engine. In this sense then the use of the same basis is justified for a comparative study of the free piston engine relative to diesel and spark ignition engines. With regard to the gas turbine Mr. Cockshutt's point that the use of regenerators will greatly offset the results of a study made on the basis of the Brayton cycle is quite true. It is obvious however that with the use of such regenerators the most appealing characteristic of the gas turbine namely its simplicity is lost. It was for this reason that the author limited his study to the simple gas turbine cycle as represented on the air standard basis by the Brayton cycle.

Mr. Cockshutt's way of plotting the data from Professor London's paper was most interesting but in this connection it has to be pointed out that even in reference 15 (Professor London's paper) from which the data was taken a number of design parameters had to be neglected for the sake of clarity of representation. Fig. 1 in Mr. Cockshutt's discussion may furthermore be easily offset by the influence which the compressor compression ratio has on turbine efficiency in the low and medium power range as pointed out in the last parts of his own discussion. By increasing the compressor compression ratio for instance the turbine expansion ratio increases simultaneously which for the same power output results in more dense turbine inlet conditions and consequently lower turbine blades, therefore higher clearance loss and lower turbine and overall powerplant efficiency. If on the other hand from design considerations a higher maximum pressure is tolerable one can select a low compressor compression ratio and apply the possible increase in overall compression ratio to the diesel section only, which will not alter turbine inlet conditions appreciably but will result in a higher overall efficiency. These considerations however do not dispute the validity of Mr. Cockshutt's remarks in general.

In regards to scavenging temperatures it might first of all be pointed out that conditions in actual engines according to the assumed values are for several reasons not quite as severe as quoted. Taking nevertheless these quoted figures the challenging of the term 'cooling' air when this air is 600° hot is surely justified when speaking in terms of lubricating conditions. On the other hand this air is still considerably cooler than the exhaust gases and does therefore an efficent cooling job when considering materials being subjected to the mean gas temperature within the engine.

Referring to the turbine design it seems appropriate to consider present day gasifiers with present day turbines. Since the average expansion pressure ratio is 4 instead of 7 the turbine inlet temperatures are approximately 900° and the enthalpy drop across the turbine is lower, resulting in a smaller number of turbine stages and moreover on account of the larger specific volume at the turbine inlet, the first stage blade length for otherwise same conditions will go up and so will the efficiency as a result of this. If this should not be enough it is quite possible to reduce the turbine diameter somewhat resulting in a higher speed which according to the author's experience should not present any serious problem.

It might be stated in this connection that the best turbine the author has heard of was installed in a free piston installation having in a 2,000 hp. installation an overall efficiency of about 89% (see ref. 6). This turbine at 2,000 hp. is running with 8000 r.p.m. and installed in a German Heck-trawler requiring a very low propeller speed. It has been operated over the past two years quite successfully and it seems therefore quite reasonable to drive for instance a 500 hp. turbine, as shown in Fig. 2 of Mr. Cockshutt's discussion, at say 30,000 r.p.m.

In regards to after burning it might be pointed out that the author's designs are considerably less sensitive to downstream conditions than other designs which indicates that the designer has considerable freedom in solving new problems that may come up in the development of this new engine principle. Tests run in regard to this question indicate that a sudden reduction of the nozzle area down to 50% does not create any trouble with the designs mentioned.

MARINE AND INDUSTRIAL HIGH POWERED EPICYCLE GEARING

H. N. G. Allen and D. P. Jones,
W. H. Allen Sons & Co. Ltd., Bedford, England.
The Engineering Journal, September 1960, p. 83.

Discussion by Professor J. S. Campbell.

You have discussed how the flexible nature of the annulus enables you to secure a distributed load to several pinions. Some concern has been expressed about the possibility of failure due to fatigue under this flexing. An article entitled "Breakthrough in Mechanical Drive Design, The Harmonic Drive" by C. W. Musser in Machine Design April 14, 1960, describes a design that incorporates a flexing annulus many times as severe and it is claimed fatigue is not a particular problem. If this be true then your design is very safe.

I would be interested in an application at the other extreme end of the range, namely to accept 180 shaft horse power at 50,000 r.p.m. and convert it to an output speed of 200 r.p.m.

This application is for a marine drive, the high speed is developed by a turbine, the output speed is the desired propeller speed.

It will be necessary to provide for reversing either by (a) reversing the turbine, (b) incorporating a reverse in the gearing or (c) utilizing a fully reversing variable pitch propeller.

Keeping in mind reliability, cost, weight and size, what would be your general recommendation?

Reply by the authors

We have not read Mr. Musser's article but we can confirm that our design is safe. We have never had an annulus failure and the comparatively minute, but nevertheless necessary degree of flexibility in the rings themselves ensures that the stresses induced are very much lower than those likely to cause fatigue failure.

An application such as that suggested by Professor Campbell would involve two epicyclic gears each of about 12 in. annulus diameter. From the aspects of reliability, weight and size, reversing epicyclic gears would compare favourably with any other proposition. So far as cost is concerned, they might, in this small power, prove to be more expensive than other alternatives.

If a gas turbine is involved, direct reversing of the turbine might be difficult but a full reversing propeller is within the range of existing experience.

Again depending on the particular circumstances, a small de-clutchable Diesel engine might be incorporated for reversing only.

It is impossible to give specific recommendations without knowing the relative importance of all the factors involved.

Discussion by Professor J. F. Muir

You show an epicyclic gear connecting an axial flow water turbine and an electric generator.

1. Could you give the horsepower and speed of these units?
2. Could such a gear be designed to transmit power from a 100,000 hp. axial flow turbine running at about 85 r.p.m. to an electric generator running at faster speed?

Reply by the authors

1. 1750 hp. 165/1000 r.p.m. (See Fig. 13).
2. The largest gears of this type which have already been built are to transmit 7200 hp. with a ratio of 78/750 r.p.m. A gear to transmit 100,000 hp. at 85 r.p.m. would be much beyond present experience and might prove to be impossible.

MANAGEMENT—HORSE TRADING OR TRUSTEESHIP?

Lt. Col. L. F. Urwick,
Urwick, Currie Limited, Montreal & Toronto
The Engineering Journal, September 1960, p. 93.

Author's reply

I suspect that Mr. Gray-Donald overemphasizes the extent to which individuals in the ordinary business enterprise are motivated by consideration of profit. My experience suggests that in most enterprises these considerations are far removed from the daily routine of the individual members.

Of course profit is important. The ability to continue making a profit is a condition of survival for the business enterprise. But that does not prove that profit is the primary purpose and motivating factor of business institutions. It is, as I have pointed out, a means of measuring their success.

Mr. Gray-Donald's extension of the concept of profit motive to include most of the basic social desires which people seek to satisfy in their work has interesting implications in relation to government enterprises, military forces, charitable institutions and so on. Members of such institutions cannot be inspired by the profit motive as defined by Mr. Gray-Donald and his argument seems to imply that it is therefore impossible to have a successful management team in such cases. However, there is no lack of examples showing that in practice this is not true.

LIQUID PETROLEUM GASES AS FUELS FOR AUTOMOTIVE ENGINES

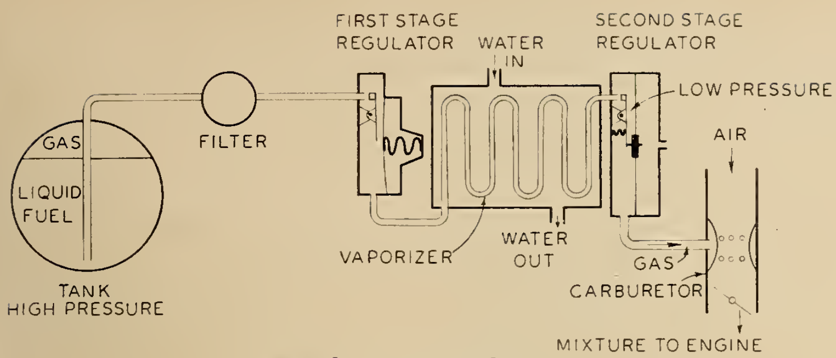
H. A. Spencer, M.E.I.C.,
Research Council of Alberta, Edmonton.
The Engineering Journal, July 1960, p. 62.

Author's reply:

Prof. MacHardy very kindly points out the main advantage of the LPG carburetion which gives it its good burning qualities and ideal distribution through the various cylinders. With regard to the lean quality of the propane in a dual-fuel situation it appears to me that a slightly greater quantity of a diesel fuel may be necessary to support combustion adequately, that is during idling the relative proportion of diesel to propane might be higher than it would be during the full load condition, and it will be interesting to do further research on the subject to discover what proportions of propane and diesel will be necessary to achieve ideal burning characteristics under all conditions. Mr. MacHardy's further suggestion of utilizing a fuel injection system appears to be the ideal answer to problems in pressure control, but necessarily poses other problems in metering a non-lubricating material.

Prof. Green asks why power increases were so large in dual-fuel installations. As mentioned in the paper the 55 HP and 103 HP each were obtained on a wheel dynamometer at 30 MPH. Power was transmitted through a torque converter to the rear wheels and actual engine horsepowers may have been within the range of 125 to 165 HP. Also in this regard the usual high peak of pressure which is associated with diesel engines directly after injection

FIGURE I. LPG CARBURETION



A revised Figure 1. is shown.

was flattened off to a certain extent and the engines sounded much smoother. It is the intention during further research to investigate the pressure phenomenon of combustion under both conditions. Also Mr. Green suggests that one would use the cheaper fuel as much as possible. However there are maintenance costs and installation costs which must be added to the cost of the cheaper propane. Three criteria are important in the consideration of this technique— 1. Fuel cost, 2. Power, and 3. Smoke production. Probably a proper balance between all three cannot be achieved by utilizing the maximum quantity of propane and it therefore will be necessary to discover the optimum conditions.

JOINTS IN PRECAST CONCRETE BUILDING FRAMES

E. M. Rensaa, M.E.I.C.,
Rensaa & Minsos, Edmonton.
The Engineering Journal, August 1960, p. 64.

Author's reply

The two points mentioned by Dean A. E. Macdonald are well worth consideration and may be answered as follows:

The type of temporary support shown was decided on after comparison with some other alternatives. It has the advantage of providing automatically the same elevation of both ends to be spliced without any special adjustment. Exactness in that respect is very important for providing good appearance. Furthermore, the time required by the erection crew for placing the centre beam is an absolute minimum. It is also thought that a bottom support gives less obstruction to welding work.

There is no doubt that the type of temporary support mentioned by Dean Macdonald would work too. It is more difficult to say what the comparative costs of the two alternatives would be.

Regarding welding of reinforcing bars, the same concern indicated by Dean Macdonald is shared by the writer. There is considerable uncertainty of how much stress can safely be allowed in a welded reinforcing bar of unknown carbon content and especially when field welded. The writer has, therefore,

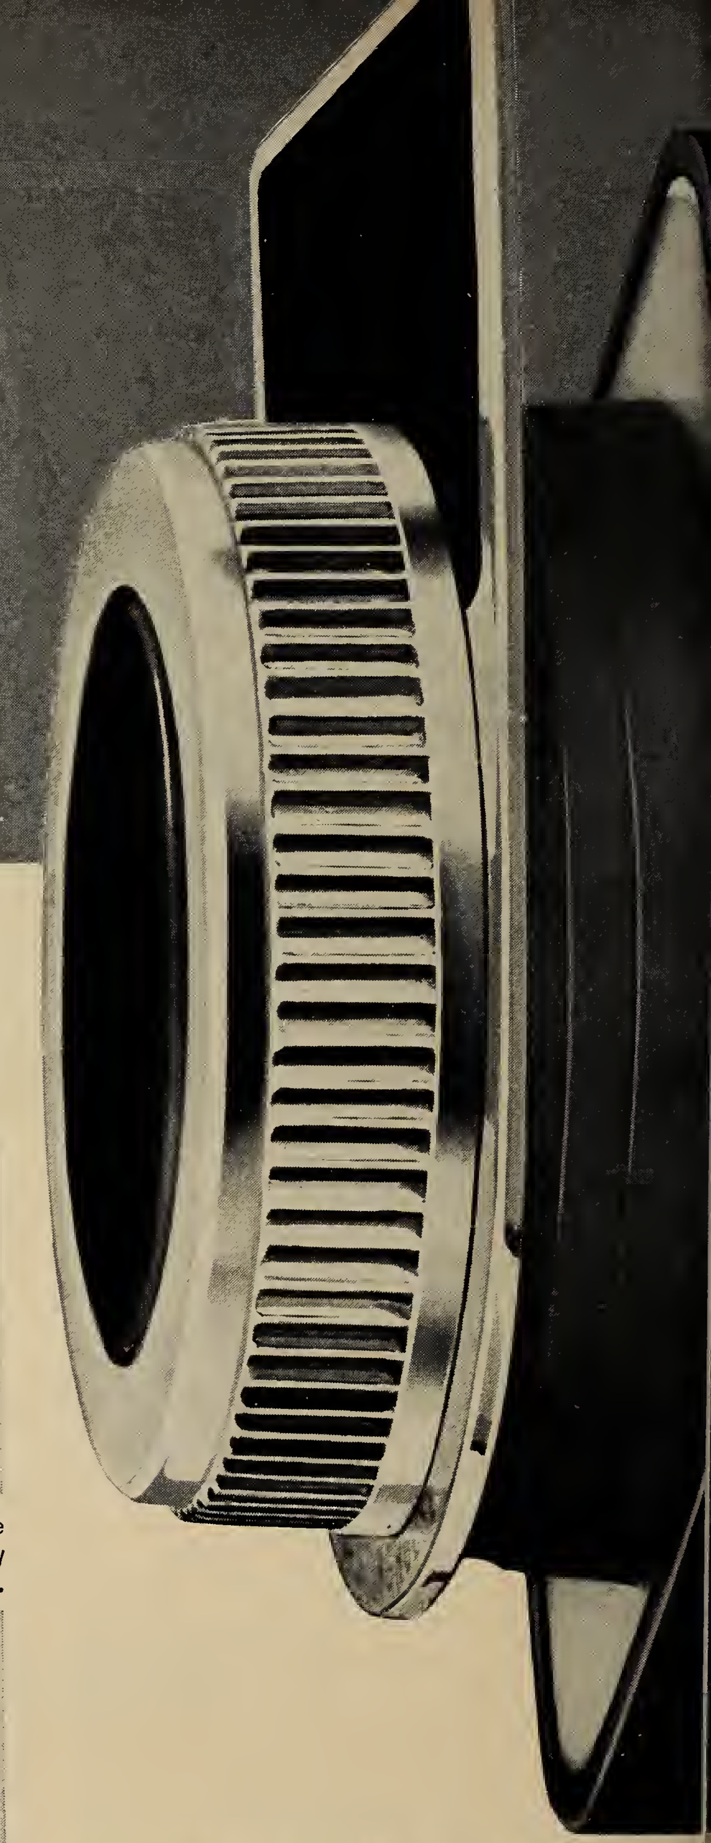
not used welding when the tensile stress in the bar would be near the ordinary allowable for reinforcing steel. At or near the point of inflection, however, the maximum stresses in horizontal bars are generally low. The same applies also to bars bent up for taking shear. All these bars are in most cases oversized at this point. Since the unit stresses in these bars are generally low, the writer has considered it safe to allow welding. If high stresses were to be allowed, it should only be based on results of tests with the kind of steel used and special precautions should be taken in all cases especially for field welding.

In connection with welding of reinforcing steel, it might be of interest to read a paper, "Composite Construction in Precast and Cast-in-place Concrete" for March 1960 in Civil Engineering, A.S.C.E., by Arthur F. Anderson, F., A.S.C.E. He reports some strength tests showing that it is possible to obtain the full tensile yield point stress for bars of intermediate grade and with carbon contents from 0.3 to 0.6%. Special electrodes are necessary and preheating and controlled cooling is also important to obtain such good results. The writer thinks it might often be difficult to obtain sufficiently good field practice with such welding.

It is generally assumed that welding becomes difficult when the carbon content of steel exceeds about 25%. Other alloy additives such as Manganese have also an influence on weldability. If welding or reinforcing steel becomes more common than at present, it will be necessary for the rolling mills to pay more attention to the chemical composition of reinforcing steel.

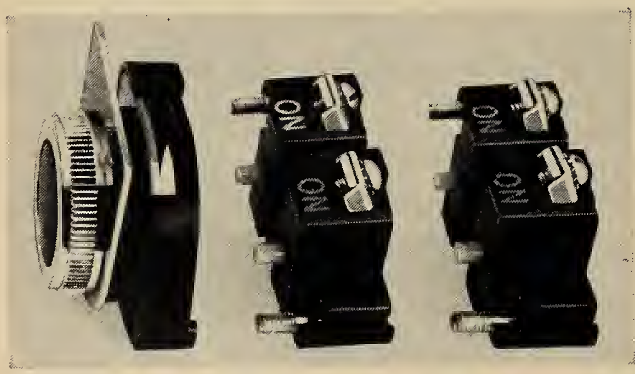
Even when the ordinary intermediate grade reinforcing steel is used for the ordinary beam reinforcement and welding of such steel is considered inadvisable, it would be possible to use this type of joint. The ordinary intermediate grade reinforcing could be stopped at the end of the precast members, and special splice bars of structural grade or milder could be used for the welded connection. These splice bars needed only to extend far enough into the beam ends to develop the bar strengths by bond. Plain bars, not necessarily of circular cross section, could be used for that purpose. The quantity of such splice steel would not be very high and should not be unduly difficult to obtain. It is, therefore, clear that the type of joint shown could be used also in such cases where stresses are so high that welding must develop almost the full bar strengths.

Announcing FLUSH PUSH-BUTTONS



The newest addition to the complete Westinghouse line

Westinghouse flush pushbuttons are the thinnest from front to back . . . engineered to meet the most exacting requirements.



New shallow contact blocks can be easily stacked to give you multiple control circuits. Terminals are angled . . . easy to get at with a screwdriver, even when blocks are stacked.

And only Westinghouse flush pushbuttons let you change the colour without changing the button. Colour-coded, snap-on caps come in red, black, blue, green, gray, yellow and brown.

Contact your nearest Westinghouse Sales Office, or write to Canadian Westinghouse Company Limited, Hamilton, Canada.

YOU CAN BE SURE...IF IT'S

Westinghouse

COMPANY – PEEL CONSTRUCTION CO. LTD.

PROBLEM – ON-THE-JOB STORAGE

SOLUTION – NEW **PORTABLE** ASPHALT STORAGE TANKS by **KING**

Asphalt supply is no longer a problem for Peel Construction Co., Ltd., of Brampton. Equipped with this new storage unit, the company can now store over 30,000 gallons of heated, ready-to-use asphalt on the job. Shown here coupled to the Mixing plant, the tanks can be detached and moved to a new job site in a matter of hours.

The trailerized tanks measure 40′ long by 10′ wide by 12′10″ high. Each has been insulated with 2″ fibre glass and fitted with a hot oil heating coil. One tank will hold 18,950 gallons of asphalt. The other tank is separated into two compartments one of which contains 11,750 gallons of asphalt, the other 7,000 gallons of Bunker C. fuel oil which is used for heating the asphalt, and keeping it in a fluid state.

This is only one of many specialized jobs completed by King in the past year. If you have a problem in moving heavy equipment or storage where semi-trailers can be utilized, consult King.

Tanks being built at the Woodstock plant of Truck Engineering Ltd. Heating coil is shown on the bottom of the tank.

REMEMBER, IF YOU CAN MOVE IT OVER LAND, KING CAN BUILD THE TRAILER TO DO YOUR JOB. Write to:

TRUCK ENGINEERING LIMITED **WOODSTOCK • Toronto**
Montreal • Ottawa • Edmonton

Made in Canada to Meet Canadian Needs

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

THERMODYNAMICS.

A graduate, or advanced undergraduate, introduction to thermodynamics, using a postulational approach, rather than the conventional inductive presentation. The author proceeds from a few basic concepts and postulates to develop a self-contained, simple, logical theory of thermodynamics. He shows how the whole subject is a direct consequence of these postulates. In addition to the traditional topics of thermodynamics, the author also covers such subjects as stability, second-order phase transitions, fluctuations, and irreversible thermodynamics. (H. B. Callen. New York, Wiley, 1960. 376 p., $8.75.)

BASICS OF FRACTIONAL HORSEPOWER AND REPAIR.

A working explanation of the principles of operation of the fractional horsepower motors in such common use, and the basic procedures for servicing and maintaining them. The types of motor covered include; split-phase, capacitor, repulsion, shaded-pole, universal, and three-phase. Other chapters discuss: enclosure and mounting characteristics; windings; testing; care and maintenance; control devices; motor protective devices.

The material is presented in the "picture-book" method often used by this publisher. (Gerald Schweitzer. New York, Rider, 1960. 168 p., $3.90.)

STRENGTH OF MATERIALS.

An introduction, at the undergraduate level, to the problems of stress analysis. Worked examples and problems are included. Both elastic and plastic strains are discussed, and other topics covered include problems of thin walled tubes in bending and torsion; the principle of virtual work; strain and complimentary energy, vibrations and impact stresses.

This is the first part of a completely revised edition of Case's Strength of Materials. A second volume, Advanced Strength of Materials, is to be published later. (John Case and A. H. Chilver. Toronto, Macmillan, 1959. 390 p., $6.00.)

NUCLEAR ENGINEERING MONOGRAPHS.

The volumes listed below are three in a series intended for students and others requiring a broad understanding of the topics of nuclear engineering outside their own field of study.

APPROACHES TO THERMONUCLEAR POWER.

The points in favour of the thermonuclear reactor for economic power production are discussed. An account is given of the experimental approaches to this problem, and the results obtained, including the linear pinch, the toroidal machine and the mirror machine. Methods of heating, confining and isolating the hot fuel are explained, as are the methods used to reduce the effects of the instabilities developed. A bibliography is included. (R. F. Saxe. London, Temple, 1960. 65 p., 12/6.)

NUCLEAR RADIATION MEASUREMENT.

The ways in which nuclear radiations interact with matter to provide energy which can be detected, and the use of this energy for detection, are covered in detail. The basic physics of detectors are also given in detail, and the design of detectors is discussed. A final chapter covers the applications of detectors for specific radiation. A bibliography is included. (J. Sharpe. London, Temple, 1960. 71 p., 12/6.)

NUCLEAR REACTOR OPTIMIZATION.

Most reactor types have ten or more independent variables, but only one combination of values will produce electricity at the lowest cost. This monograph describes the systematic methods which must be used to achieve this optimization of the reactor, and illustrates by giving a complete worked example on the design and optimization of a nuclear station. (P. H. Morgen. London, Temple, 1960. 81 p., 12/6.)

KEMPE'S ENGINEERS YEAR-BOOK, 65TH ED., 1960.

Once again, the Year-book has been extensively revised, and new sections included on electronic engineering, nuclear power, prestressed concrete, diesel locomotives and railcars, railway brakes, railways signalling and naval architecture. Various shorter additions have been made, and reference is made to new and revised British Standards. Brief bibliographies are included, and the detailed index contains over 100 pages.

The Year-book is written by specialists, and its volumes are invaluable to any engineer. (Ed. by C. E. Prockter. London, Morgan, 1960. 2 vols., 87/6.)

*APPLICATIONS OF THERMOELECTRICITY.

An elementary account of the applications of thermoelectricity in semiconductors and the uses of the Peltier effect for refrigeration. The theory of thermoelectricity is outlined; the thermoelectric properties of semiconductors, selection of semiconductors, properties of semiconductor alloys, the preparation and evaluation of materials for conductivity, and thermoelectric generation comprise the rest of the book. (H. J. Goldsmid. Toronto, Ryerson, 1960. 118 p., $2.25. Methuen's monographs on physical subjects series.)

MATHEMATICS FOR ENGINEERS.

Volume 1, now in its 9th edition, covers the fundamental rules and processes of algebra, plane trigonometry, mensuration and graphs. There are chapters on the application of difficult curve equations, the determination of laws, and the construction of practical charts.

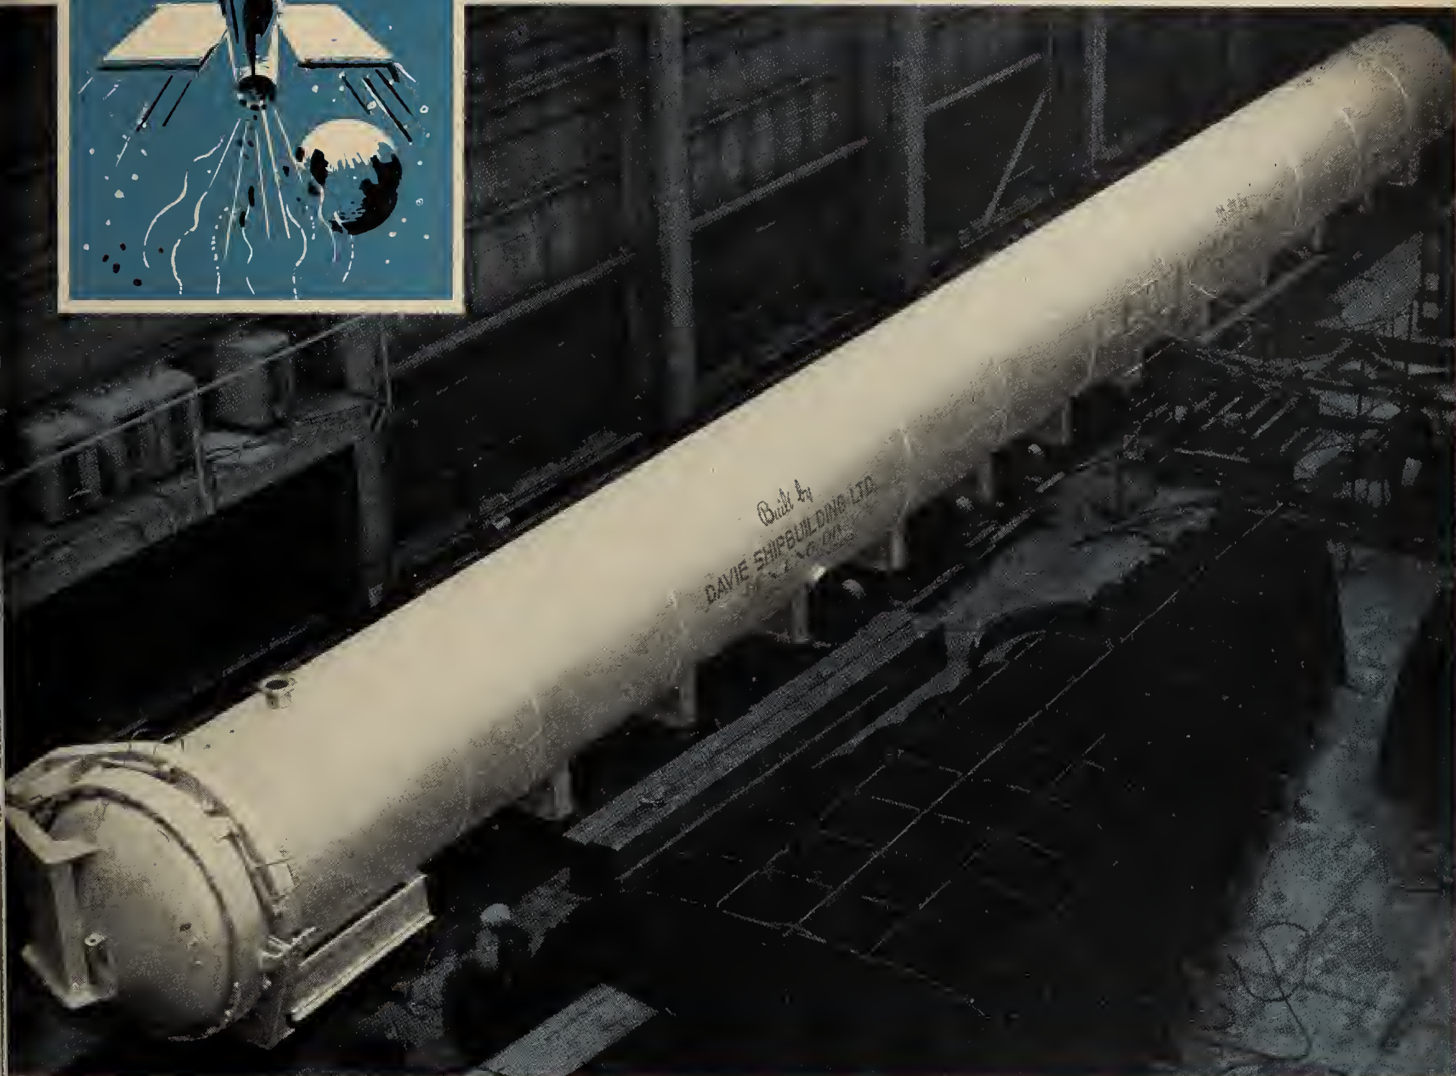
The 5th edition of volume two is concerned with differential and integral calculus and its applications, particu-

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

No, this is not a rocket-in-the making but...



DAVIESHIP can build any size or shape of engineering structure you may require!

The huge earth-bound shell above is a 100-ton AUTOCLAVE. It is only one example of the numerous giant engineering jobs performed regularly by DAVIESHIP. And just as DAVIE craftsmen are past masters in the construction of all types of ships, the ENGINEERING DIVISION is expert in the shaping, fabricating, welding and handling of steel construction in just about any size, shape or form. Give us a call — we'll be glad to discuss your construction problems with you at any time.

D
DAVIESHIP

BIG 'D' STANDS FOR 'BIG DAVIE'

DAVIE SHIPBUILDING LIMITED, LAUZON, QUE.

SHIP BUILDING · SHIP REPAIRING · PRESSURE VESSELS · PENSTOCKS
GATES · STEEL STRUCTURES · INDUSTRIAL MACHINERY & EQUIPMENT

larly in the engineering field. Chapters on spherical trigonometry and mathematical probability are also included. Worked examples and problems are included throughout both volumes. (W. N. Rose. New York, Rider, 1958. 2 vols., $6.60 per vol.)

DIRECT CURRENT ELECTRICITY.

Intended for the student and general reader, this volume discusses the fundamentals of direct current electricity in terms of the Franklinian approach, that is, plus to minus flow of current. The topics covered include electrochemistry, series and parallel circuits, electrical measuring instruments, electrical heat, and the generation of electromotive force by electromagnetic induction. (Alexander Efron. New York, Rider, 1960. 91 p., $2.25.)

UNDERSTANDING MICROWAVES.

A discussion of the fundamentals of microwaves, their generation, transmission and application. It includes an explanation of electromagnetic and electrostatic fields, radiation and reflection, Poynting's vector and Maxwell's equations, wave guides, coaxial lines, resonant cavities, and antennas.

This is an abridged reprint from which are omitted the sections on the elaboration of microwave terms, ideas and theorems. (V. J. Yound, New York, Rider, 1960. 292 p., $3.50.)

*FOUNDATION DESIGN AND PRACTICE.

Economy in the design and building of foundations is stressed. Beginning with the choice of site and a consideration of the demands of the superstructure, the author then describes various foundation types and how they are installed. He continues with laboratory and field testing of soil and foundation units, specifications and contracts, and building codes. A basic design procedure is proposed and described in the concluding section. The efficiency of this procedure is based in large part on the frequent use of battered pile and caissons and tension units. (J. N. Thornley. New York, Columbia University, 1959. 296 p., $15.00.)

RIVER STUDIES.

A report prepared for the Government of Nigeria by NEDECO (Netherlands Engineering Consultants) on the conditions in the 3000-mile long Niger and Benue River systems, with the object of determining how navigation could be improved.

The investigation lasted three years, and covered many aspects of the river system. The first part of the report gives a summary of the studies, a description of the rivers, information on present navigability, etc. In Part II a detailed description of the actual investigation is given, including planning, staff and equipment, measurements taken. Part III deals with the rivers, explaining their hydrological and morphological regime, and describing their other characteristics. Part IV includes information on transport in general, the rivers as navigable waterways, and navigation and shipping in Nigeria. Part V summarizes the defects of navigability.

The final section, Part VI contains the consultants' recommendations for improving navigability.

This is a well-written, well-printed report, containing innumerable illustrations, charts and diagrams, together with a bibliography. It necessarily includes much information on Nigeria in addition to that on the river system. The sections on the characteristics of the rivers, and possible river-engineering works are sufficiently detailed to be used as a textbook for the Nigeria Inland Waterways Department. (NEDECO. Amsterdam, North-Holland, 1959. 1000 p., £7.)

*HYDROMAGNETIC CHANNEL FLOWS.

This book presents analyses for three flows of viscous, incompressible, electrically conducting fluids in high-aspect-ration rectangular channels subjected to transverse magnetic fields, using methods based on hydro-magnetic equations, dimensional analysis, and experiment. Principal results of this study include a scheme for correlating experimental friction-factor data and methods for computing mean-velocity profiles, mean magnetic-field distortion, current distributions and turbulent-shear distributions in the d-c turbulent flow. (L. P. Harris. New York, Wiley, 1960. 90 p., $2.75.)

SURVEY OF OILS, 1960.

The basic reference book on the Canadian oil and gas industry contains all the information needed by the investor. Reviews of active and inactive Canadian companies occupy most of the book giving data on property acreages and locations, production, finances, officers, etc. Also included are maps of oil and gas fields, lists of producing fields, production reserves, price range of stocks, etc. (Financial Post. Toronto, Maclean-Hunter, 1960. 248 p., $4.00.)

COLOUR IN INDUSTRY TODAY.

Concerned with the functional use of colour, the author in this volume explains in detail the theory of colour psychology. He shows the many benefits which can accrue from carefully planned colour schemes, and gives examples from his own experience in factories, offices, schools and hospitals. The relationship between colour and light is also discussed. Coloured plates illustrate the points made in the text. The author was a leading colour consultant, and Art Director of the British Colour Council for 25 years. (R. F. Wilson. London, Allen and Upwin, 1960. 90 p., 35/-.)

SHORTHAND FOR THE MIND.

Always remember the face but never the name? Forget your own telephone number? The five lessons in memory training in this book will show how you can remember hundreds of names, telephone numbers, addresses, statistics, etc. As the shorthand writer uses written symbols, so Mr. Wermont's method uses mental symbols to make remembering almost automatic.

This is an interesting book. (I. Wermont. Dorchester, Mass., the Author, 1955. 64 p.)

*TORSION DEVICES.

This book reviews the design, construction, and application in instruments of torsion devices used as frictionless suspensions for the moving parts of sensitive instruments, as hinges for levers and the like, and for the magnification of small displacements and the indication of small forces. Included are a forty-page annotated bibliography and a numerical index to British, French, German, Swiss, Swedish and American patents. Part No. 5 in the B.S.I.R.A. Survey of Instrument Parts. (P. J. Geary, Chiselhurst, Kent, England, 1960. 142 p., 23/6.)

AMERICAN BUILDING ART: THE NINETEENTH CENTURY.

The nineteenth was a century of great changes in building construction, which became a science rather than an art. The coming of the railroad had a great effect on the number and types of structures to be built, and the author deals with the wooden bridge truss, the iron bridge truss, the suspension bridge, the iron arch bridge, and the railway trainshed. He also covers wood and iron framing, and concrete construction. Many illustrations and a useful bibliography are included. The author has also written the Rise of the Skyscraper, a study of the Chicago school of architecture. (C. W. Condit. Toronto, Oxford, 1960. 371 p., $12.50.)

THEORIES OF SCIENTIFIC METHOD: THE RENAISSANCE THROUGH THE NINETEENTH CENTURY.

Thirteen studies of the philosophy of science, as expressed by some of the leading thinkers over a period of five centuries. The topics and problems with which these writers were primarily concerned were: theory construction; hypothesis; casuality; lawfulness; probability; the problem of induction; the universality of casuality; the problem of discriminating the a priori and the empirical elements of science. Ideas of many philosophers are discussed, and quotations from their writings given, and particular attention is paid to Bacon, Descartes, Hobbes, Newton, Hume, Herschel, Whewell, Mill, Jevons, Peirce and Wright.

This should prove a useful reference tool, as well as being interesting reading. (Ed. by E. H. Madden. Seattle, Univ. of Washington Press, 1960. 346 p., $6.50.)

CHARACTERISTICS OF ENGINEERS AND SCIENTISTS.

The findings of a study made to try and determine the characteristics of engineers and scientists as a group, compared to other groups of employees. The study also enquired into job activities

(continued on page 138)

Improve product performance, cut costs with 3M Adhesives, Coatings and Sealers

VIBRATION RESISTANT. Tough aluminum strips (bonded in the middle, above) tear before 3M Brand EC-801 bond separates! This versatile sealer is especially suited for integral fuel tanks, keeps them tightly sealed in spite of vibration and flexing. Highly resistant to aircraft fuels; adheres firmly to metals at temperatures from −65°F. to 180°F.

MOISTURE RESISTANT. 3M Brand EC-1300 grips like a bear while wet, speeds rubber-to-metal bonding. Synthetic rubber base has light colour for less clean up. EC-1300 sets fast, bonds tightly with no cold flow under pressure. Bonds foam, sponge, extruded and mechanical rubbers fast with moisture-resistant, flexible film.

FIRE RESISTANT. This Bunsen burner can't ignite wet, 3M Brand Adhesive EC-321—proof this adhesive can safely be used anywhere on the assembly line. Ideal for bonding sound deadening pads, insulation batts and lightweight padding. High wet strength allows production to continue as adhesive dries. Apply with spray gun, brush or roller.

CORROSION RESISTANT. Rugged torture test! 2000 hours exposure to salt spray; 20 weeks submersion in 20% solution of hydrochloric acid; six-month weather exposure in Miami, Florida proved CORO-GARD* 1706 Brand Protective Coating resists abrasion and corrosion. For steel, aluminum, wood, concrete, cloth and some plastics.

(continued from page 134)

and satisfaction, and the problems facing young professionals.

It is a qualitative study, and is based on some four hundred interviews conducted in ten companies. It summarizes and discusses the results of the interviews, and provides a series of recommendations for management for using the data, and for young engineers and scientists. (L. E. Danielson. Ann Arbor, Univ. of Michigan, Bureau of Industrial Relations, 1960. 136 p., $4.00.)

MECHANICS OF MATERIALS.

Designed for a first course in mathematics, this volume puts its emphasis on the elastic range of stress. It presents the fundamental principles, and shows how these are applied to develop logical methods of procedure. The subjects covered include centric, torsional and flexural loading; statically indeterminate beams; combined loading; columns;; repeated and dynamic loading; connections. Problems are included. (A. Higdon, E. H. Olsen and W. B. Stiles. New York, Wiley, 1960. 502 p., $7.75.)

*BERYLLIUM.

A collection of present information on beryllium, giving its properties in detail, a summary of the different fabrication and extraction routes for the metal, and special attention to such increasingly important uses of beryllium as in aircraft, missiles, and nuclear reactors; as an alloy base or additive; and in the preparation and use of the oxide beryllia. In cases where results are contradictory in this rapidly developing field, the fullest amount of experimental details are given. (G. E. Darwin and J. H. Buddery. Toronto, Butterworth, 1960. 392 p., $13.50.)

CONCRETE FORMWORK DESIGNER'S HANDBOOK.

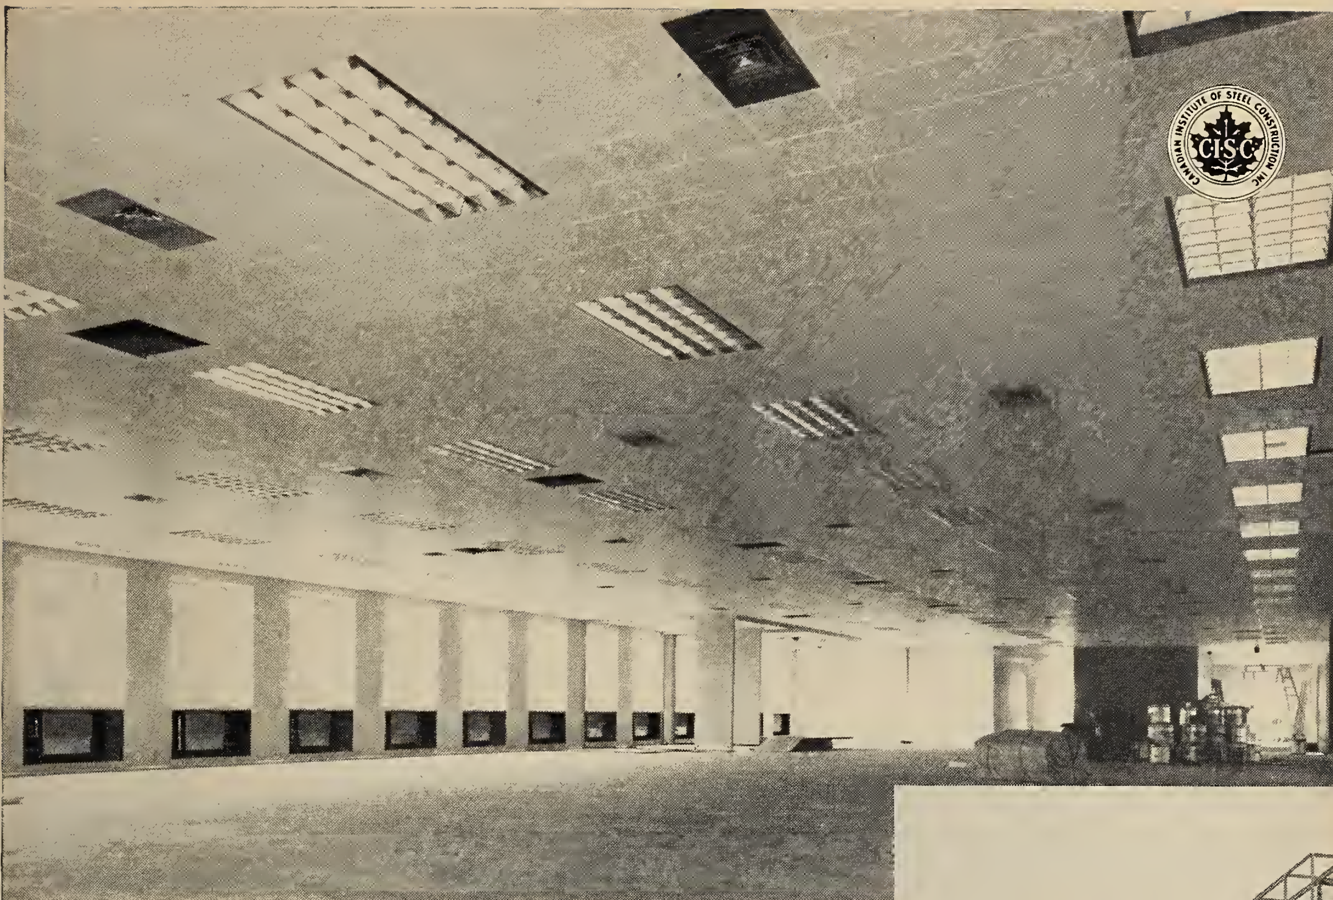
Concerned with the structural design of formwork in timber and steel, this handbook includes over fifty nomograms, tables and charts for the rapid design of formwork for various types of construction. The factors affecting the pressure of concrete against the forms are discussed, as are permissible stresses in the formwork materials. Several worked examples explain the use of the nomograms, charts, etc., and a brief bibliography is included. (H. R. Gill. London, Concrete Publications, 1960. 153 p., $3.50.)

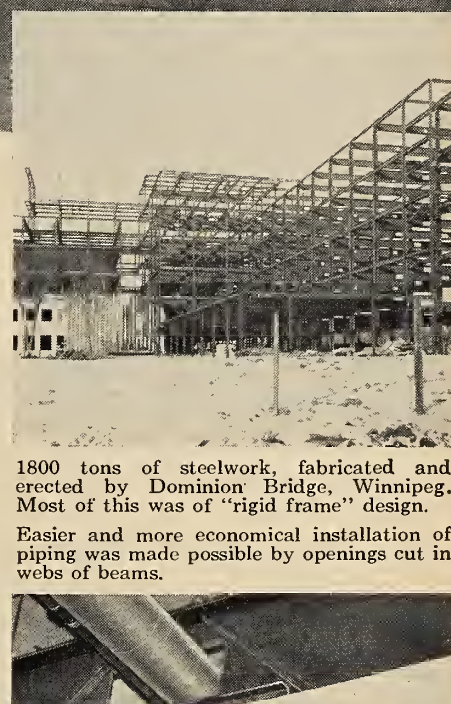
BASIC ULTRASONICS.

A simple introduction, in the Rider "pictured text" series, to the subject of ultrasonics. The first section of the book covers the general theory of ultrasonics, particularly the nature of sound and ultrasound waves. The second section describes the basic types of ultrasonic equipment, and the third discusses applications, including sonar, nondestructive testing, cleaning, welding, cameras, instrumentation, and biological and chemical effects. (Cyrus Glickstein. New York, Rider, 1960. 137 p., $3.50.)

TEXTBOOK OF METALLURGY, 2ND ED.

In this second edition, many sections have been re-written, in particular those on crystallization, plastic deformation and the benefication of iron ores. Information has been added on the metallography of radio-active metals, zone-re-





fining, blast-furnace production of zinc and the extraction of titanium and uranium.

The book covers the nature, structure and properties of metals and alloys; the examination of metallic structures; the theoretical and practical aspects of metal production; the production of ingots and castings; metal working; metal testing. Problems and suggestions for further reading are included. (A. R. Bailey. Toronto, Macmillan, 1960. 561 p., $5.00.)

RADIO CONTROL FOR MODEL BUILDERS.

Intended for those whose hobby is model building, and who are interested in learning how they can use radio-control, this volume tries to give an overall picture of the subject of remote control. It explains the control systems available, and discusses transmitters, receivers, actuators, installation, batteries, meters, relays, etc. It covers particularly radio-controlled planes and boats. (William Winter. New York, Rider, 1960. 220 p., $4.25.)

CHEMISTRY FOR ENGINEERS.

An introductory course, intended both for students and those needing a "refresher," some previous knowledge of chemistry being assumed. The two main themes in the text are the chemistry of power production and chemistry of materials. The ten chapters cover nuclear chemistry; atoms and molecules; chemical reactions; chemical fuels; metals; acids and bases; corrosion; water treatment; plastics; friction and lubrication. (Edward Cartmell. Toronto, Butterworths, 1959. 172 p., $5.00.)

PRINCIPALS OF CHEMICAL THERMODYNAMICS.

Intended for an introductory thermodynamics course at the graduate level, the text stresses the principles of thermodynamics, in a logical and critical manner, and shows their application to chemistry. The topics covered include conditions of equilibrium and the free energy functions; gases and vapors; thermochemistry; statistical thermodynamics; mixtures and solutions; chemical and phase equilibria; electrolytic solutions and electro-chemical cells; thermodynamics of surfaces; systematic methods of deriving thermodynamic relations. (C. E. Reid. New York, Reinhold, 1960. 306 p., $7.80.)

CANADIAN TRADE INDEX, 1960.

A directory of products manufactured in Canada, listed under some 10,000 headings and an alphabetical listing of more than 11,000 Canadian manufacturers. There is a French index to the headings used in the classified section. Many new firms and products are included in this edition of the Index, which is an essential volume for anyone concerned with purchasing. (Toronto, Canadian Manufacturers Assoc., 1960. 1150 p., $12.50.)

***THE DYNAMIC BEHAVIOR OF THERMOELECTRIC DEVICES.**

This is the report of a study of the dynamic behaviour of thermoelectric heat pumps and generators, made by means of a small-signal analysis of linear models. This analysis produces small-signal transfer functions that can be used to compute the response of devices in the frequency domain or in the time domain. Here, the small-signal analysis for the heat pump and for the thermoelectric generator and measurement of the small-signal response of a heat pump are described. There is also a chapter examining the modification of the heat-pump analysis to include a temperature-dependent resistivity. (P. E. Gray. New York, Wiley, 1960. 136 p., $3.50.)

***SPECTROCHEMICAL ABSTRACTS, VOL. VI, 1954-1955.**

The 460 abstracts in the current issue of this biennial publication are arranged for the first time by subject rather than by author. Abstracts cover methods of analysis of mineral, metal, gaseous, liquid, and biological substances, the apparatus and techniques, and a few reviews of books, bibliographies, and charts. (E. H. S. Van Someren and F. Lachman, London, Hilger & Watts, 1960. 100 p., 25/-.)

***AERO-THERMODYNAMICS AND FLOW IN TURBOMACHINES.**

In Part 1 the fundamental relations for the analysis of arbitrary flows are derived from the general principles of fluid mechanics and thermodynamics applicable to the flow of any compressible media. This derivation employs vector and dyadic analysis, the elements of which are summarized in appendices A and B. Part 2 treats flows which are idealized either with respect to the properties of the fluids or the thermodynamics process they undergo. Part 3 discusses flows in turbomachines wherein the concepts of Parts 1 and 2 are affected by the primary function of turbomachines, which is to change the energy level of fluids, and because the members guiding the flow in turbomachines are surfaces of revolution. (M. H. Vavra. New York, Wiley, 1960. 609 p., $14.50.)

***SCHUTZE UND SCHUTZENSTEUERUNGEN.**

A treatise on contactors, covering basic principles, behavior under abnormal conditions, and the great variety of control devices and protective equipment utilizing contactors. Separate chapters are devoted to special types, durability, selection criteria, control methods, signal equipment, and test methods. There is an extensive bibliography including a scattering of English references. (Herbert Franken. Berlin, Springer-Verlag, 1959. 382 p., DM 42.00.)

***SEMICONDUCTOR ABSTRACTS, Volume V-1957 issue.**

Some 1700 references are listed in the new volume of this useful and thorough compilation. Most of the entries are from 1957 with a scattering of earlier ones from a few foreign journals. Through

1951 Graduates – Please Note

According to amended Institute regulations covering Junior membership, 1951 graduates must apply for transfer (by written application form) to the grade of Member during 1960, if they wish to avoid payment of a transfer fee.

The applicable sections are as follows:—

"———— he shall not remain in the class of Junior beyond the end of the tenth year after graduation.

A Junior may be transferred to Member without payment of a transfer fee providing he makes application before the end of the ninth year after graduation ————"

intensive editing, more cross-references, reduction of duplication, and elimination of phenomena of lesser relevance like organic ferroelectrics and solution luminescence, this edition of the abstracts is smaller and the coverage more intensive than previous ones. Arrangement is by subject with four main divisions: elemental semiconductors; compound semiconductors; theory; and general applications. (Ed. by G. S. Peet. New York, Wiley, 1960. 449 p., $12.00.)

STANDARDS RECEIVED

Aluminum Association standards.
The Aluminum Association,
420 Lexington Ave., New York 17, N.Y.

Supplement to drafting standards—aluminum extruded and tubular products. 3d ed. 1960.

CSA standards. Canadian Standards Association, 235 Montreal Road, Ottawa 2.

Business and Industrial Briefs

Appointments and Transfers

MANAGEMENT SERVICES is a new department at C.I.L. It will consist of existing staff functions under one jurisdiction and will maintain a staff trained in industrial engineering, operations research, office systems and procedures, statistics, and other management skills. The manager will be **M. S. Macgillivray**, formerly head of engineering services.

Joseph Gilbert has been named SECRETARY AND GENERAL MANAGER of the Society of Automotive Engineers (SAE). He has served in the Society's Publication Division as managing editor of the SAE Journal and for the past three years has been assistant general manager of SAE, which has more than 24,000 members among engineers engaged in the design, development and manufacture of motor vehicles, farm tractors, earthmoving machinery, aircraft and space vehicles.

John B. Jolley, native of Hamilton and graduate of McMaster and Osgoode Hall Law School, is MANAGER OF PERSONNEL for B. F. Goodrich Canada Limited. His new assignment will include both manufacturing and salaried employee relations activities.

Sika Chemical Canada Limited announces the appointment of **W. E. (Bill) Murray** as Western Ontario DISTRICT SALES MANAGER.

Joseph E. Wolfe becomes INDUSTRIAL PRODUCTS REPRESENTATIVE at Sun Oil. Mr. Wolfe is a mining engineer B.A.Sc. and former instructor at the University of Toronto.

Robert W. Reinicke, a mechanical engineering graduate of Ohio State, has been named VICE-PRESIDENT OF OPERATIONS at Ansul Chemical Company, Marinette, Wisconsin.

New Developments

POSITIVE SHUTOFF and freedom from galling are the features of a new "floating cone" ¼ in. hand valve announced by The Foxboro Company, Massachusetts. Recommended for liquid or gas service on meter manifolds, seal chambers, hydraulic equipment and similar applications, the new valve is supplied in five variations of globe and angle types, accommodating line pressures up to 3000 p.s.i.

THE CUTTING HEAD is replaceable on a new masonry core drill announced by Canadian General Electric's Carboloy Section. One drill body and separate cutting heads will do the work of several complete drills, reducing delays and inventory costs. Heads are easily attached or removed and the drills can be had in standard sizes from 1⅜ in. to 6 in. diameter for use on cement and cinder block, plaster, brick, tile, slate, marble, stone, concrete, even reinforced concrete.

EARNINGS WERE UP in the first half of 1960 according to a statement issued by Shawinigan. Consolidated earnings of Shawinigan Water and Power, St. Maurice Power and Southern Canada Power amounted to 80.07 cents per common share, compared with 70.80 cents for the first half of 1959.

THE LARGEST manganese steel mantle ever cast in Canada was poured on May 21 in Joliette, Quebec for a 689 Superior gyratory crusher. Canadian Allis-Chalmers is building the machine for the Iron Ore Company of Canada's Carol Lake project. Largest crusher to be made in Canada, it will rise more than 30 ft. and weigh 400 tons. The mantle itself weighed over 23,000 lb. Overall measurements were about 12 ft. high by 7 ft. 5 in. in diameter.

PLEASURE BOATING has been revolutionized by the Dowty Turbocraft, which in tests has taken rapids, marsh lands, sandbars and even a neck of dry land in its stride. Weeds are chopped up and churned out. The boat's jet unit sucks in water through a grille in the bottom of the hull and ejects it above the water line through a nozzle in the transom. The reaction to the outgoing jet stream provides the forward thrust. Deflecting the jet stream by means of hinged plates steers the boat to right or left, and lowering a metal gate deflects the jet forward to reverse the boat.

LIGHTWEIGHT CONCRETE as a strong, durable structural material for columns, beams and floor slabs, multi-story structures, and bridge decks is featured in a new Master Builders Company publication. Thirteen construction projects are discussed with the aid of photographs and job reports.

THE COMPACTRON is a new electronic device that combines into one unit the functions now performed by several components and will enable manufacturers to reduce the size of radios, television, high-fidelity sets and electronic organs. Canadian General Electric recently displayed a two-compactron radio which was 2½ in. high, 2½ in. deep and 10½ in. wide—the width being dictated by the generous size of the speaker. Underlying metallurgical developments include a new anode material that reduces heater power requirements of the cathode and a clad material that improves the hot strength and thermal efficiency of cathode elements.

ALUMINUM CAN take the stresses and shocks of mining operations. Two aluminum off-highway dump bodies which are mounted on the largest single rear axle chassis in the world have been ordered by Canadian Johns-Manville. When tests were made last summer, rocks weighing up to 6 tons were dumped into aluminum units from 10 ft. heights over a two-day period.

18,000,000 GALLONS DAILY is the volume handled by Fairbanks-Morse Pumping Equipment installed at Cornwall's new filtration and water purification plant. A Model 5813 high lift pump supplies the volume against a total dynamic head of 190 ft. It is driven by an F-M type QZK–400 hp. motor. Two other Model 5813 high lift pumps provide 5,000,000 IMP/GPD each against a total dynamic head of 180 ft. They are powered by F-M type QZK–250 hp. motors.

FORD HAS been able to produce tractor linkage bars at a lower cost and feature furthermore increase output by using a British Oxygen Bison profile cutting machine at Imperial Foundry in England. The machine cuts the steel bars to length with extremely fine tolerances for final flash-butt welding. In addition, there is a longitudinal cutting operation

NUCLEAR POWER NEEDS LOOKING AFTER . . .

Horton knows how!

Nuclear power, mighty power source of the future, needs looking after. Nuclear Reactors have to be thoroughly protected to avoid radio-active contamination of people and property. Constructing special steel plate Reactor Containment Vessels requires great skill and vast engineering experience. Horton has the skill and engineering background to erect these special vessels because they have been fabricating and erecting all types of quality steel plate structures throughout Canada for many years. Horton will be pleased to supply you with further information on request.

TANKS AND STEEL PLATE WORK FOR MUNICIPALITIES, PETROLEUM AND OIL, CHEMICAL PROCESS, MINING, PULP AND PAPER, AIRCRAFT . . . AND INDUSTRY AT LARGE.

on the bars, this being a straightforward profiling process.

DEAD ENDS are stronger if forged. This component of a compression assembly used with high tension electrical lines must provide strength and dependable service over long periods. Stelco drop-forges these parts by modern techniques and produces complicated shapes to close tolerances.

TUNNEL SHIELDS for use in the construction of Toronto's new subway are nearing completion at the Trois Rivieres plant of Canada Iron Foundries. The six massive shields are the first to be designed and built in this country. Four of the shields, weighing 70 tons each, are for the running tunnels and two larger shields of about 130 tons are for tunneling two subway stations.

LIVE CARGO presents many problems to trucking companies. Shifting loadweight can cause uneconomic conditions when payload is reduced to prevent excess maintenance and repairs, and transports used for cattle are not readily adaptable to dry freight. A new series of pusher-tandem diesels, developed by the White Motor Company, will haul the first tri-level livestock unit built by the Freuhauf Trailer Company. The trailer provides for control of weight distribution and will hold an average of 40 head of cattle based on an approximate weight of 1000 lb. per animal. This compares with 27 cattle previously carried in trailers.

ZOOMING SALES of Mimik hydraulic machine tool tracer attachments in the U.S.A. have led Retor Developments Limited, a wholly Canadian owned company with head office and plant at Galt, Ont., to incorporate an American subsidiary which will be located at Buffalo, N.Y. The Mimik is a high precision hydraulically operated tracer which can be attached to any standard machine tool.

AIR CONDITIONING and refrigeration are the principal concerns of the Frick Company, which has established a Canadian subsidiary, Frick of Canada Limited, Montreal.

FOR SITE WORK in oil fields and on construction projects, Chamberlain Industries of London, England have introduced a completely new type of bender in their extensive range of "Staffa" tube and pipe bending machines. The "Field" bender has been especially designed as a lightweight two-stage hydraulic unit and is supplied in two sizes, one with a range of formers for bending pipe from 2 in. to 4 in. bore and the other for bending pipe from 4 in. to 8 in. bore.

POCKET MAGNIFIERS with built-in graticules are now on the market. A model that folds into a neat unit measuring only 2⅛ in. by 1 7/16 in. by 9/16 in. has been designed to permit more precise measurement with a highly portable instrument. The micrometer, which is on glass, is mounted in the base of a low-powered folding magnifier, the whole frame being made of aluminum cut away to give maximum visibility on a field of view 1 in. square.

THE ONLY TOOL needed to make a perfect connection every time with "RED-E" lugs and splicers to welding and power cables is a hammer. Bernard Welding of Chicago introduced these lugs and splicers which eliminate special crimping tools, wrenches, and soldering equipment.

CORRECT EXPOSURE in aerial photography is easier with Kodak's two-dial computer. The Kodak Aerial Exposure Computer has just been published in the form of a six-page folder which contains the computing dials, instructions for their use, a typical aerial exposure problem and its solution with the computer, and tables which give the altitude of the sun above the horizon in degrees for any point in the world at any time.

A DISTRIBUTING PLANT has just been opened in the London, Ontario area by the St. Lawrence Cement Company. The aerated storage silo and warehouse will supply high quality cement in bulk and bag. The company

E.I.C. CERTIFICATE OF ADVERTISING MERIT — WINNING ADVERTISEMENT

For the fourth time in a twelve month period, a Honeywell Controls Limited advertisement has been judged the "best" in an issue of The Engineering Journal by a fifty reader jury.

Tabulations of the jurors' appraisals of the advertising in the June 1960 issue —from the viewpoints of ACCURACY— INFORMATION and ATTRACTION— showed votes very much in favour of the 4-page, 3-color Honeywell Controls Limited insert headed: "MODULAR DESIGN MAKES 1960 ELECTRONIK POTENTIOMETERS A GREATER VALUE THAN EVER".

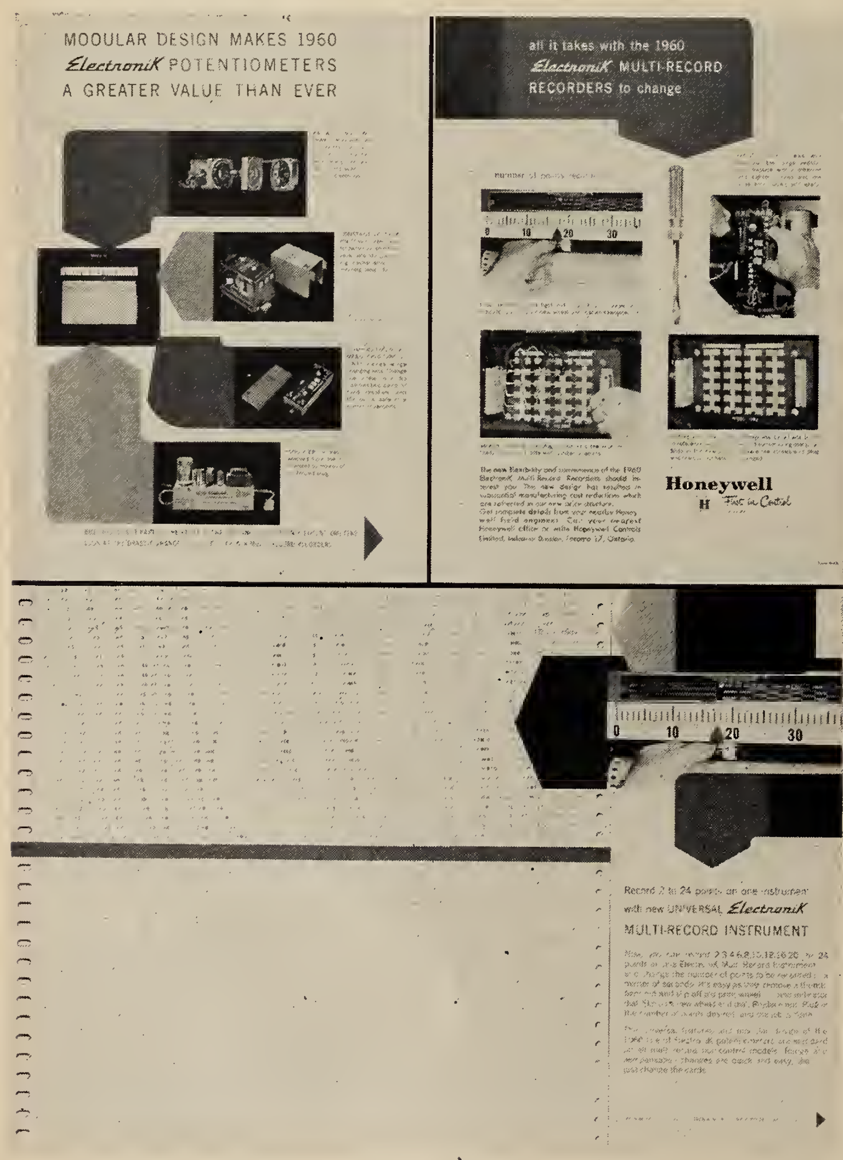
The judicious use of color, pleasing layout and concise, informative copy, coupled with descriptive illustrations, are features of this insert as was the case in previous Honeywell Controls Limited winning advertisements.

K. K. Warne, of Toronto, is in charge of the company's Canadian advertising arrangements and the advertisement was prepared and placed by the Toronto office of Cockfield, Brown & Co. Ltd.— A. D. Black—Account Executive.

HONEYWELL CONTROLS LIMITED WINS CERTIFICATE

This reduced-scale, monotone, reproduction of the 4-page, 3-color Honeywell Controls Limited insert in the June 1960 issue does not do justice to the pleasing appearance of the original advertisement. Interested readers are advised to look at a copy of the original which appeared on pages 33-36.

FRONT BACK



CENTRE SPREAD

• MORE BRIEFS

has recently acquired another quarry near Colborne, Ontario which will provide aggregates for their Clarkson manufacturing plant.

A PLASTIC SECTOR which replaces the traditional wooden sector and offers advantages both in durability and in less frequent shutting down for maintenance is now being produced by the Mechanical Goods Division of Dominion Rubber Company Limited. It is available for 6 ft. diameter fillers and will soon be available for larger sizes. Smooth and non-splintering, it is non-porous, and will neither warp nor swell.

RANGE AND FLEXIBILITY for all types of noise measurement have been increased in the new soundscope produced by Mine Safety Appliances Company, Toronto. Two alternate microphone systems have been incorporated in the new model — one a condenser microphone extending the sound level range up to 200 db.; the other a dynamic microphone designed for use under conditions of extreme heat or humidity. The M-S-A Soundscope provides noise survey data in three areas of interest to industrial hygienists, safety engineers and acoustic specialists.

FASTENINGS INTO BRICK, concrete, metal and wood can be accomplished with the new all-metal thread screw anchor produced by Rawlplug Products (Canada) Limited, Montreal. Designed for 3/16 in. screws, the manufacturers claim the "Rawlset" can easily support 150 lbs. in direct pull in brickwork. The tough brass shell, theaded internally to receive the screw and knurled externally to give extra grip when tightened in position, is split at one end into four sections and contains a special aluminum expander shaped so that when the screw is driven in the sections expand and grip the sides of the hole firmly.

A RETRAC BIT and coupling sleeve which can be used together or separately are being manufactured by Sandvik and distributed in Canada by Atlas Copco. The detachable bit and sleeve, particularly effective in rock where there is difficulty in withdrawing drill rods from drill holes, are designed to achieve straight, round holes even in loose rock. The retrac bit has edges which allow it to cut backwards and the sleeve has four ridges to prevent reduction of hole diameter caused by cuttings settling on the wall of the hole.

SIX THOUSAND FEET of penstock liners, valued at $1.2 million, are to be fabricated for the Coteau Creek development project of the Saskatchewan Power Commission. Sparling Tank & Mfg. Co., Toronto, a division of Products Tank Line of Canada, Ltd., will do the on-site fabricating with steel from the new Interprovincial Steel Company Ltd. mill at Regina.

● MORE BRIEFS

THE APPOINTMENT of A. C. Leslie & Co. Ltd., a Canadian steel service centre firm headquartered in Montreal, to market a new family of high strength, heat-treated steels is announced by Great Lakes Steel, Detroit-based division of National Steel Corporation. The Canadian organization will direct distribution of the new specialty steels throughout Canada.

DEARCLAD 765, a new epoxy pipe coating announced by Dearborn Chemical Company, Chicago, has a rapid curing rate, exceptional resistance to physical impact, abrasion and moisture absorption. The product retains its physical properties over the temperature range of −40°F. to +250°F.

A NEW METHOD for detecting aerial film distortions as small as one five-thousandths of an inch wide was revealed recently by a team of Kodak scientists. The technique is based on an effect known as the moire pattern, a network of wavy lines.

CONSTRUCTION WILL BEGIN in September on the first phase of a $93 million natural gas pipeline system in northeastern British Columbia. Gas Trunk Line of British Columbia Ltd. announced the pipeline, to be completed in December 1961, will deliver gas from the newly-discovered fields in the vicinity of Fort Nelson, B.C., to markets in southern B.C. and the U.S. Initial capacity of the new trunk line will be 350 million cu. ft. per day and this can be increased to 650 million cu. ft. with additional compression. It will connect with the existing Westcoast Transmission pipeline near Chetwynd, B.C.

A REMOTELY CONTROLLED DEVICE with applications in many fields where it is required to rotate a shaft with a high degree of accuracy has been developed by The Plessey Company Limited of England. The unit, designed to rotate a shaft to any one of 12 positions set up independently, with an accuracy of within six minutes of arc, is available for 12-48 volt d-c operation in two panel sizes and with a torque of either 35 oz-in. or 60 oz-in.

CANADIAN DISTRIBUTOR for Boving Butterfly Valves is now James Howden and Company of Canada Limited of Scarborough, Ontario. Basic standard range will comprise valves of from 18 in. to 72 in. diam., but larger units are available.

PLANS for a method of constructing a unique type of underground sewage lift station employing electric submersible pumps are available from Flygt Canada Limited of Montreal. The station is CSA-approved and its design enables maintenance to be carried out without anyone entering the sump.

WELDING POWER SOURCES for use with manual and automatic gas-shielded metal-arc welding equipment have been recently marketed by Air Reduction Canada Limited of Montreal. These new welders are capable of providing constant arc voltage output, or varying degrees of down slope. The machines are rated at 300 amp., 100% duty cycle and 500 amp., 100% duty cycle. The 300 amp. d-c rectifier Aircomatic CV welder is of vertical design and provides continuous infinite down slope adjustment through a hand wheel. The 500 amp. d-c rectifier is of horizontal design and can be used for welding with all diameter wires where conventional constant arc voltage or down slope is required. Fourteen different down slope adjustments are obtainable by reconnection of leads accessible through a panel on the side of the welder.

EFFICIENCY can normally be increased 5 to 20% by properly converting coal and oil designed equipment to natural gas. This is the theme demonstrated by a mobile training and display unit designed and built by Northern Ontario Natural Gas Company. Efficiency tests

(More Briefs on page 167)

are run for the purpose of proving the economy of converting existing heating plants to natural gas by the installation of low cost natural gas conversion burners.

COLUMN RESEARCH COUNCIL announces the publication of its Guide to Design Criteria for Metal Compression Members. This 112-page book presents a condensed summary of design criteria based upon recent and past research on metal compression members in building and bridges. It is written specifically for the engineer who either meets special problems not covered by standard specifications or is himself engaged in the preparation of specifications for such structures. The price of the book is $5 and it may be ordered from the Column Research Council, University of Michigan, Ann Arbor.

A HEATLESS, reactivating dehydrator which produces ultra-dry air or gas equivalent to a dewpoint of −180°F. is being marketed by Lear Industrial Products of Grand Rapids, Michigan. Unlike other heatless, continuous-duty dehydrators, this dehydrator cycles only as required for maintaining the flow of dry air. It is simple to install and operates on 115-a-c, 60 cycle current. The system provides up to 25 SCFM of air so dry that it contains less than 1/10 part per million water vapour by volume. Since the dehydrator filters as well as dehumidifies, its use is ideal for mermetically sealed instruments and for equipment such as bombsights, gyros, optics and cameras.

THE AMERICAN DRAFTING STANDARDS Manual, Section 15, Electrical Diagrams has been approved by the American Standards Association and published by The American Society of Mechanical Engineers. This is the first American Standard to deal with the actual preparation of electrical diagrams. It includes detailed recommendations on preferred practices for use in the preparation of electrical diagrams. This standard represents the first part of the work on electrical diagrams of the type used by the electronics and communications industries. Price is $1.50 per copy.

STRAPPING TENSIONERS of new design have been released by the Signode Steel Strapping Company of Chicago. They apply the principle of the self-energized feed wheel to manual heavy duty strapping operations. Grip of the new tools enables them to apply 1 to 1½ tons of tension per strap. They use coil-fed strapping to eliminate additional waste inherent in cut-to-length strapping, and are designed to slide easily from under the strap after sealing.

AN AIR OPERATED Sliding Gate and Plate Pressure Reducing Valve, with a capacity of 50,000 lb. of steam per hour or 2,500 g.p.m. of water, is now available in 4 in. and 6 in. sizes from OPW-Jordan Corporation of Cincinnati. The

valve is used to reduce pressure wherever large capacities, accurate control and tight shut-off are required. The system is suitable for pressure to 250 p.s.i. and temperatures to 500°F. The sliding gate and plate seats are self cleaning and self-lapping to give tight shut-off and minimum maintenance.

LABORATORIES which need to cap relatively few concrete cylinders will be interested in the new basic cylinder capping set for preparing compression test specimens designed by Soiltest Inc., of Chicago. The new set, for vertical type capping, includes all items needed for efficient capping of 6 in. by 12 in. cylinders. The sets are in conformity with ASTM test methods C-31 and C-192 and AASHO test procedures T-23 and T-126.

GAS-FIRED INFRA-RED burners with controlled-wavelength radiant emission for high-efficiency heat transfer have been designed specifically for low-temperature industrial processing applications. Bryant Industrial Products Corporation of Cleveland reveal the face temperature of the 4 in. by 18 in. burner screen is 1200 to 1800°F. The nominal heat output is 30,000 B.t.u. per hr. per unit; each unit has a built-in flame adjustment—the first adjustable infra-red burner available. Applications for the new burner include drying metals, curing shell molds and foundry cores, drying porcelain enamel frit on metals, drying moist fabrics, paint and enamed baking and radiant heating for any other low-temperature processing need.

HIGHWAY CONSTRUCTION COSTS are dropping slightly, reports the U.S. Bureau of Public Roads. Notes, comments, and statistics pertaining to highways are reported by the Better Highways Information Foundation, organized recently in Washington, D.C. The Foundation is a non-profit, educational organization established to develop wider understanding of the need for and benefits of modern highways.

FRIGIDAIRE

Meet the Authors

John S. G. Shotwell, M.E.I.C., B.Sc. (McGill '25), M.Sc., Ph.D., President, John S. G. Shotwell & Associates, Ltd., Ottawa *(Canada's Energy Sources to 1989 — A Forecast).*

Following his Ph.D. at Columbia Mr. Shotwell was a research engineer with Price Bros. & Co., Ltd. and later Vacuum Oil Company in Paulsboro, N.J. In 1934 he established a consulting practice and in 1958 organized his present firm which this year became affiliated with William H. Byrne, P.E. Consulting Engineers, N.Y.

Wojciech A. Grobicki, B.Sc. Electrical (Polish University College, London, England '51), Electrical Project Engineer, Ewbank & Partners (Canada) Limited, Toronto; **David K. Whish,** B.Sc. (Newport Technical College, England '44), Senior Mechanical Engineer, Ewbank & Partners (Canada) Limited, Toronto *(Saskatchewan Power's Boundary Dam Generating Station).*

Mr. Grobicki worked for one year for Balfour, Beatty Co. on power station design. After coming to Canada in 1952 he was with the telecommunication equipment division of Northern Electric in Montreal until 1956.

Mr. Whish served three years with the Royal Engineers. He spent two years on design and field construction of high-pressure water tube boilers and other plants for steam power stations with Mitchell Engineering Limited. He joined Ewbank & Partners in 1950.

J. Lawrence A. Carey, M.E.I.C., B.Sc. Civil (U.N.B. '49), Engineer on Special Projects, Montreal Engineering Company, Limited, Calgary. *(Whitehorse Rapids Power Development).*

Mr. Carey was Montreal Engineering resident engineer on the Menihek Hydro Development in Laborator, the Whitehorse Rapids Development in the Yukon and the Brazeau Hydro Project in Alberta. He was also the Canadian liaison engineer on the Umtru Hydro Project in Assam, India.

R. A. Pillman, JR.E.I.C., B.A.Sc. Civil (U.B.C. '48), Executive Engineer, H. G. Acres & Company Limited, Niagara Falls; **H. R. Hopper,** JR.E.I.C., B.Sc. Civil (Manitoba '50), Project Engineer, Kelsey Generating Station, Manitoba Hydro Electric Board, Winnipeg; **D. H. MacDonald,** M.E.I.C., B.A.Sc. Civil (Toronto '45), Ph.D., Geotechnical Engineer, H. G. Acres & Company Limited, Niagara Falls. *(Kelsey Generating Station Dam and Dykes).*

Mr. Pillman has been with his present firm since 1948, and has in recent years been in charge of the co-ordination of engineering for large hydro-electric projects.

Mr. Hopper was with the Manitoba Department of Highways for a short while after he graduated. In 1951 he worked on the Red River Basin Investigation for the Water Resources Division, Department of Resources and Development. He joined the M.H.E.B. early in 1952

Mr. MacDonald was a structural engineer and testing engineer on the Yonge Street Subway for the Toronto Transportation Commission. After obtaining his Ph.D. from the University of London, England, he joined H. G. Acres and is now in charge of their Geotechnical Department.

H. Brian White, M.E.I.C., B.Sc. Civil (Toronto '44), Sales Development Division, Transmission Structures, Aluminum Company of Canada, Limited, Montreal. *(Chute-des-Passes 345 K.V. Transmission Line).*

Mr. White lectured in Civil Engineering at the University of Toronto for three years before joining B.C. International Engineering Company. He joined Alcan in 1954 in the Conductor Division, and was later transmission engineer responsible for the design and construction of the Chute-des-Passes transmission line.

Alastair R. Scott, B.Sc. (Edinburgh '44), Power Systems Application Engineer, Canadian General Electric Company Limited, Peterborough. *(Automation in Thermal Power Plants).*

Following technical service in the R.N.V.R. Mr. Scott joined the British Electricity Authority in Glasgow. He came to Canada in 1955 and joined Canadian General Electric. His present work includes application problems on utility and industrial power systems.

James R. McMullan, B.A.Sc. Electrical (Toronto '49), Design and Application Engineer, James R. Kearney Corporation of Canada Limited, Guelph, **J. Howard Myers,** Manager of Engineering, James R. Kearney Corporation, Guelph *(Standard Aluminum Substation Structures).*

Mr. McMullan was in the Engineering Department of Eastern Power Devices Ltd. of Toronto from his graduation to 1955. He then joined his present firm.

Mr. Myers spent six years with Reliance Electric prior to eighteen years on transformer design with English Electric. He joined his present firm last year.

Leonard A. Bateman, M.E.I.C., B.Sc. Electrical (Manitoba '42), M.Sc., System Planning Engineer, The Manitoba Hydro-Electric Board, Winnipeg. *(Long Range Hydro Planning for Manitoba).*

Mr. Bateman started in the design office of the City of Winnipeg Hydro-Electric System as a junior engineer and was subsequently appointed operating engineer, and general superintendent in charge of production. He resigned from the latter position in 1956 to take his present job.

W. F. Allen Jr., B.Sc. (Brown University '41), M.Sc., Mechanical Engineer, Stone & Webster Canada Limited, Toronto; **H. A. Smith,** B.Sc. Electrical (Queen's '40), Assistant General Manager of Engineering, The Hydro Electric Power Commission of Ontario, Toronto *(Lakeview and R. L. Hearn Generating Stations Design).*

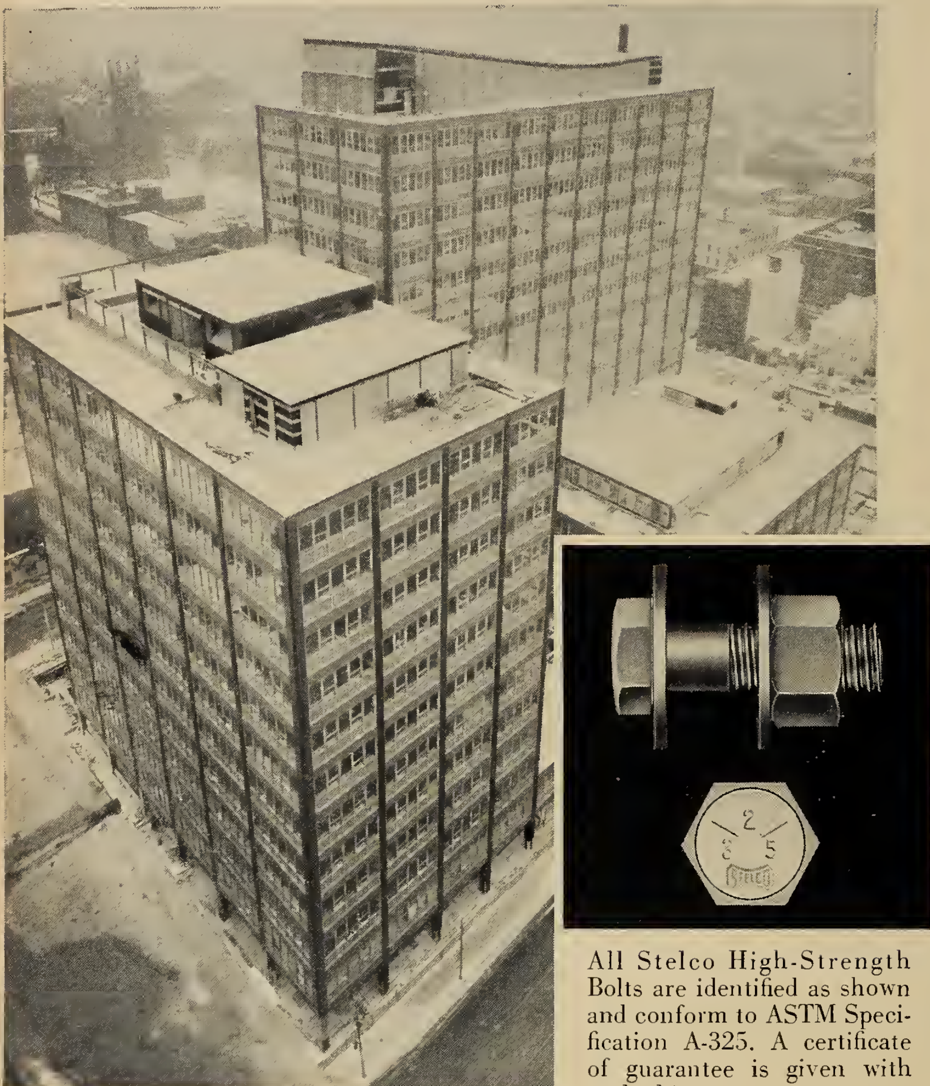
Mr. Allen was a Teaching Fellow at Harvard in 1947 and then joined the Boston engineering department of Stone & Webster. From 1950-54 he was in charge of the Heat Cycle and Special Studies Group. He has recently been project engineer on major steam-electric generating stations.

Mr. Smith's former positions with Ontario Hydro include assistant to the assistant electrical engineer; assistant to the director of engineering; frequency standardization engineer; co-ordinator nuclear power group; and director of nuclear power project. At Chalk River he initially served as project co-ordinator of a team carrying out joint studies on the feasibility of generating power from nuclear reactors.

COVER ILLUSTRATION

Symbolizing Power in Canada is this section of an air blast circuit breaker in the Cornwall switching station of the Hydro Electric Power Commission of Ontario's St. Lawrence Seaway development.

BOLTED BEAM AND COLUMN CONNECTIONS



All Stelco High-Strength Bolts are identified as shown and conform to ASTM Specification A-325. A certificate of guarantee is given with each shipment.

In Modern Downtown Office Building

MACKENZIE BUILDING, TORONTO, ONTARIO

OWNERS: Dept. of Public Works, Ottawa, Building Construction Branch, *E. A. Gardner, Chief Architect.*

ARCHITECTS: Shore & Moffat, Toronto.

GENERAL CONTRACTORS: Redfern Construction Company, Limited, Toronto.

STEEL FABRICATORS and ERECTORS: Frankel Steel Construction Limited, Toronto.

High-strength bolting and welding were employed to erect the steel framework of this modern Canadian Government Building which houses a Post Office and other Federal Offices.

29,245 Stelco High-Strength Bolts were used in the building shown here. Present regulations require one bolt for one rivet, but a 2-man crew with an air wrench and a holding wrench can install 3 bolts in the same time it takes a heavily equipped 4-man riveting crew to install 2 rivets. Stelco High-Strength Bolts are stronger than rivets in both tension and shear. Bolting has important advantages in almost any structural job, but, as bolts are installed cold and with relative quiet, this method is particularly desirable in built-up areas, and in school and hospital zones.

STELCO **HIGH-STRENGTH BOLTS**

THE STEEL COMPANY OF CANADA, LIMITED

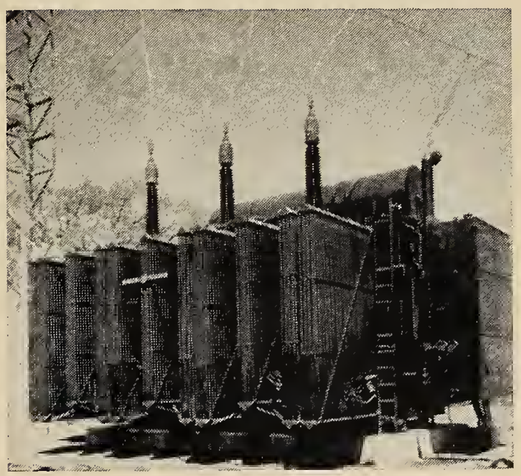
STELCO 50 YEARS OF PROGRESS 1910-1960

60181.B

POWER IN CANADA



POWER PRODUCTION in Canada continues to increase. Through the first six months of 1960 total net generation of electric energy rose 10.2% above the corresponding period the previous year.

The Dominion Bureau of Statistics, reporting on firms which produce 10 million kwh. a year, said that in June power production totalled 9,132,588 Mwh. This compares with 8,289,846 Mwh. being generated in the corresponding period in 1959.

Generation by utilities rose 9.7% to 7,162,722 Mwh., while produetion by industrial establishments increased 12% to 1,969,866 Mwh.

Of the net generation between December 1959, and July, about 78% was produced by utilities. Utilities produced 44,895,987 Mwh., including 2,699,842 Mwh. of thermal power. The remainder was hydro.

Industry produced 12,419,424 Mwh., including 11,246,746 Mwh. of hydro and 1,172,678 Mwh. of thermal power.

Net generation of power has more than doubled in the last 11 years. Respective totals in 1949 and 1959 were 50,064,048 and 103,843,029 Mwh. last year. This trend is continuing in 1960.

Thermal and Hydro Power

Installed capacity of water-power plants at the end of 1959 totalled 24,888,426 hp. The total for thermal generating plants was about 3,785,979 hp.

For the second consecutive year a record was established for the amount of new hydro power brought into operation. A total of 2,508,800 hp. of new capacity was added. Major installations during 1959 were made at the Robert H. Saunders-St. Lawrence Generating Station of the Hydro-Electric Power Commission of Ontario where the nine remaining units totalling 675,000 hp. were placed in service, at the Chute des Passes generating station of the Aluminum Company of Canada, Limited, where three units totalling 600,000 hp. started operating, and at the Bersimis II generating station of thc Quebec Hydro-Electric Commission where three units totalling 513,000 hp. were placed in service.

Canada's total installed hydro capacity remains at less than 30% of the feasible turbine installation based on the country's estimated water power resources.

New thermal developments, or extensions to existing facilities, were under construction in nine of the provinces and in the Yukon and Northwest Terrtories. Significant increases in thermal installations were made in Alberta, Saskatchewan, New Brunswick and Nova Scotia where the greater part of the total requirements is derived from thermal plants.

Another significant increase in thermal power was made in British Columbia, where the first major thermal installation started operating in 1958.

Ontario showed the greatest increase, however, as the development of principal hydro-electrie sites within economic transmission distance of present load centres has largely been completed.

This growing tendency towards increased thermal-electric generation in various provinces reflects not only the fulfilment of the rapidly-increasing energy demand, but also the benefits of resources conservation which may be derived through the operation of an integrated power system supplied by both hydro-electric and thermal-electric plants.

Following is an outline of the main features of power in Canada, dealt with province by province.

BRITISH COLUMBIA

At the end of 1959 the west coast province was third in installed capacity of hydro power with turbine capacity of 3,509,460 hp. and fifth in thermal power with an installed capacity of 319,247 hp. British Columbia ranks second in recorded available hydro resources.

Considerable power potential exists principally in such rivers as the Columbia, Fraser, Peace and the Stikine. Much of the present development is in southern B.C., but the largest single development is the Kemano plant of the Aluminum Company of Canada with a present capacity of 1,050,000 hp. The British Columbia Electric Company, Limited is the major hydro producer and distributor in the province. The British Columbia Power Commission, organized in 1945, also has become an important power producing and distributing agency.

During 1959 a total of 199,000 hp. of new capacity was put into operation. Another 198,000 hp. are scheduled by the end of this year while various projects totalling 229,200 hp. are planned for development in later years.

B.C. Power put its new 35,000 hp. hydro development on the Ash River, Vancouver Island, into operation last year. In the planning stage are the Commission's Kokish River development on Vancouver Island where a development of 51,500 hp. is anticipated, and the Pyramid Mountain-Murtle River development which will consist initially of one unit with a turbine rating of 43,000 hp. It is proposed that this project eventually will consist of four 43,000 hp. units.

In the thermal-electric field the Commission finished its Georgia Generating Station at Chemainus, Vancouver Island. The plant consists of four gas turbines connected to identical generators, each rated at about 29,168 hp. at 85% power factor.

Work continued on the final phase of development of B.C. Electric's Bridge River No. 2, including construction of Mission Dam on the Bridge River. Initial operation of the new power house started late in 1959 with the completion of two 82,000 hp. units. Two similar units are to be added this year. Mission Dam will raise the head at Bridge River No. 1, increasing its output to 276,000 hp. from 248,000 hp.

Installation of a 6,000 hp. unit is planned this autumn at the Falls River development, Big Falls Creek. This will raise to 12,000 hp. the total installed capacity of the Northern British Columbia Power Company Limited plant.

The City of Revelstoke is planning to install a 5,700 hp. unit on Cranberry Creek, about 15 miles south of Revelstoke. Provision will be made for a second similar unit.

The Peace River Develpoment Company continued its planning of a project above Hudson Hope. Preliminary plans indicate this project will consist in part of a main storage dam where hydro-electric facilities under a maximum operating head of 600 ft. will provide a generating capacity of about 3,350,000 hp. A second dam and hydro-electric plant are expected to be developed downstream from the main dam.

Northwest Power Industries Limited maintained an active interest in the Yukon River power project and in the Nass River project. Review of main features of the Nass River project was undertaken and estimates for both projects were revised.

The governments of Canada, the United States and British Columbia continued active negotiations toward early development of the Columbia River in Canada.

ALBERTA

Alberta ranks sixth in installed capacity of hydro-electric power with 312,595 hp. at the end of 1959, and second in thermal capacity with 680,157 hp.

Principal hydro-electric developments from which Calgary Power Limited serves a large part of the southern portion of the province, are located on the Bow River and its tributaries. A substantial share of the water power resources are located in the northern half of the province, rather remote from present population centres. Large reserves of coal, oil and natural gas in the province supply a substantial portion of its power requirements.

In the thermal field Calgary Power began installing this year a 201,072 hp. steam turbine in addition to its Wabamun plant where two units with generating capacities of 88,472 hp. each are currently in operation. The new unit is expected to be in operation late next year. Late last year the City of Edmonton brought into operation a new 40,214 hp. Brown Boveri gas turbine unit at its municipally-owned thermal-electric plant. Addition of the new unit raises the plant capacity to 241,-287 hp.

Canadian Sugar Factories Limited installed a 2,245 hp. unit at Taber. Canadian Utilities Limited installed a 683 hp. diesel generating unit at the new town site of Swan Hills in northern Alberta. Northland Utilities Limited installed a new 670 hp. generating unit at its diesel plant at Lac La Biche.

No new hydro units were brought into operation last year but 102,000 hp. of new capacity are expected to be in operation by the end of 1960, and considerably more in later years.

Calgary Power resumed construction of extensions to its Spray and Rundle plants in the upper Bow River basin. This work started in 1957 but was suspended in 1958. Capacity of the Spray plant is being doubled by the addition of a 62,000 hp. unit while a 40,000 hp. unit is being added to the Rundle plant which now has a capacity of 23,000 hp. Both are scheduled to be finished this autumn.

Calgary Power also has started a new hydro development on the Brazeau River at Big Bend, about 15 miles upstream from where it joins the North Saskatchewan River. The first unit will have a 200,000 hp. capacity and plans call for construction of three additional 200,000 hp. units.

The company also is investigating a hydro-electric development at the Brazeau Forks site on the North Saskatchewan River, below its confluence with the Brazeau River.

SASKATCHEWAN

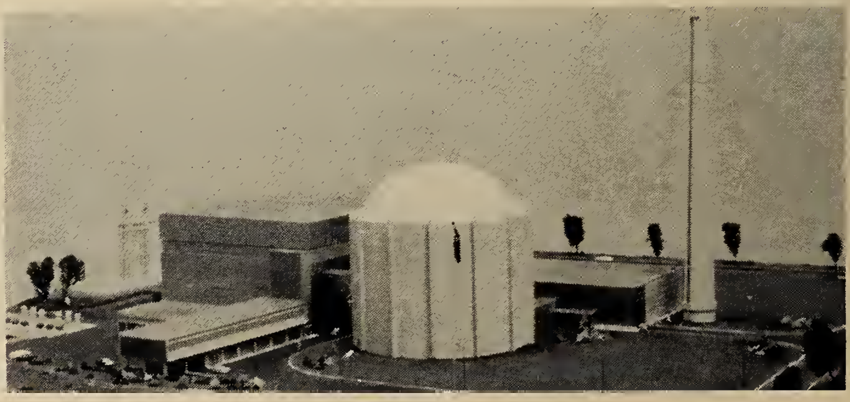
Saskatchewan is ninth among the provinces and territories in hydro-electric capacity and ranks third in thermal capacity. Installed hydro capacity is 128,835 hp., and installed thermal capacity is 622,524 hp.

Abundant water power resources are located in the northern part of the province, principally on the Churchill and Fond du Lac Rivers and on the Saskatchewan River. Existing water power developments now are confined to mining uses in northern areas. However, new developments now under construction on the Saskatchewan River will be tied into the transmission network of the Saskatchewan Power Corporation of the provincial government. The Corporation serves the more settled areas and now is supplied exclusively by thermal-electric plants. As in Alberta the substantial reserves of coal, oil and natural gas located in the province supply much of its power requirements, particularly in southern Saskatchewan.

The Churchill River Power Company Limited, a subsidiary of the Hudson Bay Mining and Smelting Company, Limited, completed last year the installation of a 19,000 hp. unit, increasing to 125,500 hp. the installed turbine capacity in seven units. Work on Saskatchewan Power's Coteau Creek site on the South Saskatchewan River continues. The Corporation plans to install hydro-electric facilities at the earth-fill dam which the Prairie Farm Rehabilitaton Administration is building as an irrigation aid.

Initially the hydro development is expected to consist of three units of 50,000 to 60,000 hp. each. Two similar units will be added at a later date. The complete project is scheduled to be finished in 1966.

Model of the Douglas Point Nuclear Power Station



Another Saskatchewan Power Corporation project, this one at Squaw Rapids on the Saskatchewan River, has started. Four 46,000 hp. units are planned for service by 1963 and the remaining two by 1964.

Last year the Corporation doubled the capacity of its Queen Elizabeth Steam Turbine Plant at Saskatoon with the addition of a second 88,472 hp. steam turbine and generator. At the new Boundary Dam Generating Station at Estevan, the Corporation installed the first unit, a steam turbine of 88,472 hp. and now is building a second, similar unit at this plant.

Northland Utilities installed a new 670 hp. unit at its diesel plant at Uranium City, Sask.

MANITOBA

Manitoba is the most generously endowed of the Prairie provinces in the field of hydro-electric capacity. With an installed capacity of 778,900 hp. the province ranks fourth in hydro. Manitoba has an installed capacity of thermal-electric power of 252,990 hp. and ranks seventh.

Manitoba also has the largest water power resources among the Prairie provinces with great potential on the Churchill, Nelson and Saskatchewan Rivers.

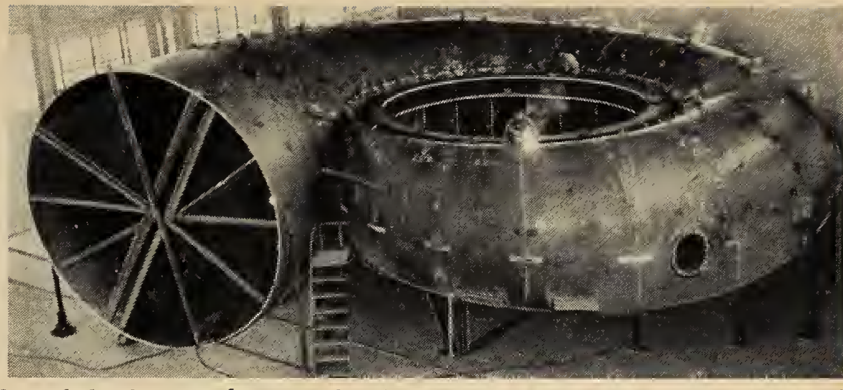
The larger present developments are on the Winnipeg River, now fully developed, and serve greater Winnipeg and the transmission network of the Manitoba Power Commission. Increasing amounts of thermal-electric power are being used to meet the increasing demands of the southern part of the province.

Construction continues at the Manitoba Hydro-Electric Board's Kelsey Generating Station on the Nelson River. Five 42,000 hp. units are scheduled for completion by the end of this year and provisions are being made for a sixth, similar unit. Also to be completed by this autumn for the Board are two 88,472 hp. steam turbine units at the Selkirk Generating Station.

ONTARIO

Ontario, which has developed the greater part of its recorded available hydro-electric power, ranks second with an installed capacity of 7,982,151 hp. It is first in thermal-electric power capacity with 1,080,303 hp.

The Hydro-Electric Power Commission of Ontario is the greatest power producing and distributing organization in Canada. It operates 69 hydro-electric stations with a total installed capacity of more than seven million hp. and two thermal-electric stations with a combined generating capacity of more than 900,000 hp. Its largest water power development is located on the Niagara River at Queenston where the total capacity of the Sid Adam Beck-Niagara Generating Stations No. 1 and 2, and associated pumping-generating stations is 2,521,000 hp. The Commission also buys about one million hp. on contract.



One of the four spiral casings for the Otter Rapids development on the Abitibi River.

Several major developments were completed for the Commission last year. They were: the Robert H. Saunders-St. Lawrence Generating Stations on the St. Lawrence River with seven units of 75,000 hp. each, increasing to 1,200,000 hp. the total installed capacity at the plant; Abitibi Canyon on the Abitibi River, a fifth unit of 66,000 hp.; Silver Falls, Kaministikwia River, the installation of a single 60,000 hp. unit.

At Red Rock Falls on the Mississagi River construction for the Commission continued for the installation of two 26,500 hp. units. The first is scheduled for service this December. At Otter Rapids on the Abitibi River work continued for the installation of four 60,000 hp. units, with minimum provision being made for the addition of four other units. Two units are scheduled for service next year.

Also completed last year was a single 30,300 hp. unit for the Great Lakes Power Company at Cat Falls on the Michipicoten River.

Thermal and Nuclear Power

A vital factor in the Commission's future plans is the development of power resources other than hydraulic. At the Richard L. Hearn Generating Station located in the eastern area of the Toronto waterfront the Commission plans to have all four additional steam turbines, each with a capacity of 268,000 hp. in operation by the end of this year. When finished the plant will have eight units totalling 1,608,000 hp. The Commission's thermal-electric capacity in southern Ontario will be further augmented by the installation of four 402,000 hp. units at the Lakeview Generating Station, now being built near Toronto. The first unit will be put in service in 1961 and the fourth unit is scheduled for completion in 1964. Plans now call for a total installation of 2,400,000 hp. at the station.

In conjunction with Atomic Energy of Canada Limited and the Canadian General Electric Company Limited the Commission is building a 26,800 hp. Nuclear Power Demonstration plant near Des Joachims Generating Station on the Ontario side of the Ottawa River. Atomic Energy of Canada Limited will build a 268,000 hp. nuclear-electric generating station on a 2,300-acre site between Kincardine and Port Elgin, on Lake Huron. When it has been demonstrated to be a satisfactory power source it has been proposed that the Commission buy the station at a price which will permit the production of energy at competitive cost.

QUEBEC

Quebec is the wealthiest of the provinces in water power resources, containing more than 30% of the total recorded for Canada. Quebec also ranks highest in developed power. Its present installation of 11,315,407 hp. is about 45% of the total for all provinces and represents the development of probably less than 40% of its feasible turbine installation.

In thermal-electric capacity Quebec ranks eighth, with 84,906 hp.

The largest single hydro-electric installation in Canada is the Quebec Hydro-Electric Commission's Beauharnois development on the St. Lawrence River with a capacity of 1,718,800 hp. installed to date. Also notable are the Commission's Bersimis I development on the Bersimis River with an installed capacity of 1,200,000 hp. and the Shipsaw plant of the Aluminum Company of Canada Limited on the Saguenay River which is rated at 1,200,000 hp.

Power production in the province is greatly facilitated by the regulation of stream flow by the Quebec Department of Hydraulic Resources through the storage dams it operates or controls.

The remaining two of Quebec Hydro's five 171,000 hp. units at Bersimis II were scheduled to have gone into service this month. At Beauharnois construction continued on the third and final section of the power house to contain 11 units of 73,700 hp. each. Operation of the third section started last year with the installation of four units totalling 294,800 hp. The remaining units were to have been installed at 2 1/2-month intervals and by 1961 the entire plant with a total rated capacity of 2,234,700 hp. is scheduled to be finished. Construction of Quebec Hydro's Carillon development on the Ottawa River started. There will be 14 units, each rated at 60,000 hp.

Alcan's Chute des Passes development on the Peribonka River was virtually completed early this year when the last three of five 200,000 hp. units were placed in operation.

Quebec Cartier Mining Company's Hart Jaune River development continues. Three 22,000 hp. units are scheduled for completion this autumn.

The Quebec Department of Hydraulic Resources continued its water power investigations on the Broadback, Rupert, Eastmain, Great Whale and Fort George Rivers in the James Bay watershed; on the Kaniapiskau River in the Lake St. John watershed and the Moisie, Sault-au-Cochon, Sault-au-Mouton, Portneuf and Escoumain Rivers on the north shore of the lower St. Lawrence River.

NEW BRUNSWICK

New Brunswick has about equal amounts of hydro-electric and thermal-electric capacity. It ranks sixth in thermal capacity with 258,066 hp., and is seventh in hydro capacity with 254,875 hp.

Although its water power resources are small compared with some of the other provinces they constitute a valuable power source of which considerable use is being made. As is the case with Nova Scotia it is favoured with abundant indigenous coal supplies.

The New Brunswick Electric Power Commission acquired ownership last year of the Grand Falls generating station on the Saint John River. Acquisition of this development from Gatineau Power Company Limited increased the Commission's generating capacity by 84,453 hp.

At Milltown on the St. Croix River, a reconditioned 500 hp. unit originally installed in 1910 and retired in 1920 was placed in operation last year by the Commission.

NOVA SCOTIA

Nova Scotia is in a power situation similar to that of New Brunswick. While it ranks fourth in thermal-electric capacity with 393,425 hp., it stands eighth in hydro capacity, with 183,168 hp.

As its neighbor, Nova Scotia has numerous rivers upon which moderate-sized power sites exist within economic transmission distance of principal cities and towns. Other sites are advantageously situated for use in development of timber and mineral resources.

The Nova Scotia Power Commission completed two developments on the Sissiboo River this year. There was an 8,000 hp. installation at Sissiboo Falls and a 12,000 hp. installation at Wymouth Falls. Developments by the Commission at Riverdale on the Sissiboo River and at Wreck Cove on Wreck Cove Brook are in active prospect with proposed installations of 10,800 hp. and 90,000 hp. respectively.

At Lequille on the Lequille River the Nova Scotia Light and Power Company Limited is building a single-unit 7,500 hp. development. This is scheduled to be finished next year. A single-unit 6,500 hp. development at Alpena on the Nictaux River is an active prospect for the Company, with completion expected in 1962.

PRINCE EDWARD ISLAND

Prince Edward Island suffers from the lack of large streams and consequently water power sites are limitted in size to those used for small mills. It ranks last in hydro capacity with 1,660 hp. and is 10th in thermal capacity with 34,023 hp.

The Maritime Electric Company is adding a 13,405 hp. unit for operation late in 1961 at its Charlottetown steam plant.

NEWFOUNDLAND and LABRADOR

On the basis of the limited streamflow data available Newfoundland's water power resources are estimated to be of considerable magnitude. On the Island, although the rivers are short, topography and run-off conditions are favorable to power development. The Hamilton River in Labrador is considered one of the largest undeveloped sources of water power in Canada.

Newfoundland ranks fifth in hydro capacity with 370,135 hp., and its thermal capacity of 55,981 hp. places it fifth in that category.

United Towns Electric Company Limited completed two installations, one late last year and one in 1960. At Pitmans Pond, New Chelsea Brook, a single 1,200 hp. unit was finished last November. The other project, installation of a single-unit 3,200 hp. development, was at Heart's Content on the Heart's Content River.

At Menihek Rapids on the Ashuanipi River in Labrador the Iron Ore Company of Canada this year doubled the existing plant capacity by the addition of a 12,000 hp. unit. For the Newfoundland Light and Power Company Limited installation of a single-unit 6,500 hp. development is in active prospect at Middle Brook near Gambo.

Also in active prospect as part of an ultimate development of 350,000 hp. is the installation of two 38,500 hp. units at Bay d'Espoir for Southern Newfoundland Power and Development Limited. In the same category is Hamilton Falls Power Corporation Limited's Scott Fall project on Labrador's Unknown River. Two 25,000 hp. units would be part of an ultimate development of 300,000 hp. This development on a tributary of the Hamilton River is one of three subsidiary projects which may be built prior to construction of the main features included in the plan for Hamilton River developments.

YUKON and NORTHWEST TERRITORIES

The two Territories which comprise Canada's vast northland possess extensive water power resources. But owing to light precipitation the favorable sites are dependent upon large storage facilities. In the Yukon Territory most of the resources are located on the Yukon River and its tributaries. There exists the possibility of diverting the headwaters of the Yukon River through the Coast Mountains to utilize a high head near tidewater in northern British Columbia. Such a development, however, would affect adversely the power potential of the Yukon River in the Yukon Territory. In the Northwest Territory resources are large, with more than one-half the total occurring in rivers flowing into Great Slave Lake. Present development is limited to local mining uses and the supply of attendant settlements.

The Territories now rank 10th in hydro capacity with 51,240 hp. and are 11th in thermal capacity with 4,357 hp.

At Snare Falls on the Snare River, N.W.T., the Northern Canada Power Commission is working on installation of a single 9,200 hp. unit with provision for a second similar unit. The first unit is scheduled for operation in November. The Commission also has added or is planning 1,340 hp. diesel units at Yellowknife, Frobisher Bay and Fort Smith.

CANADA'S ENERGY SOURCES TO 1989 — A FORECAST

John S. G. Shotwell, M.E.I.C.
President, John S. G. Shotwell & Associates, Ltd., Ottawa.

Presented to Power Section, E.I.C. Toronto Branch, September, 1959.

Canada's power engineers must face, at the present time, the problem of deciding what sources of energy the country will be using for its power plants, industries and other purposes in 1980. At first, 1980 seems a long way off and any attempt to forecast the principal sources of energy used then is a very wild guess. A second look at the engineering picture quickly reveals that this is not so.

A LARGE proportion of 1980's power plants are either already built, under construction or on the drawing boards at the present time.

This may seem strange until we remember that we usually design power plants to have a useful life of from 20 to 30 years and that it often requires from 10 to 15 years to transform somebody's dream into a major operating project.

Such "lead time" may seem long to some people; but, they must remember that every stage from the first hazy concept, through its design and construction to its acceptance and getting it into service takes time. First the engineers and economists make feasibility studies and site selections and prepare preliminary plans with estimates of cost and time required to build the project. These go to the Board of Directors and generally require several revisions before receiving approval. Then the engineers must prepare the contract drawing and specifications and get these approved before calling for tenders. Next we take time off while the various contractors study the documents, prepare their estimates and submit their bids. The owner and his engineers now require some time to review the bids, after which the construction contract is awarded, and construction drawings prepared and approved. All these stages require considerable time to complete before a single sod is turned or item fabricated. The actual construction of the plant, the fabrication and erection of equipment require time, although some of this may be saved through careful scheduling of the combined operations so that several operations which do not conflict will proceed at the same time.

If a major technological development occurs before the fabrication and erection of the equipment has proceeded too far; the owner, the engineers and the designers may decide to redesign the plant and equipment to take advantage of these advances. In so doing, they will set back the completion time and hold up the final acceptance of the plant.

The Long Branch Station of the Ontario Hydro-Electric Power Commission is an example of these time-consuming progresses. Although this plant was designed by 1958 it is only scheduled for full operation in 1968, ten years later. An examination of the Commission's records would probably show that the total time between the initial studies leading to the decision for a second thermal plant in the Toronto area to the final acceptance of the station at full operating capacity will exceed 15 years.

Thus, we may assume that any new large thermal power project conceived during the winter of 1959-1960 will be lucky if it reaches full productive capacity by 1975. And, if it incorporates any radically new engineering concepts and techniques it may not reach the full operational state until 1980. This will be the case, especially, if the new techniques, pressures, temperatures or fuels require the use of new alloys or ceramics.

The generally-accepted economic doctrines consider that because energy multiplies man's effort many fold energy and industry are synonymous. The wide use of inanimate energy to furnish light, heat and power for factories and to convert matter from one form to another strengthens the general acceptance of this concept. Modern industry, however, uses sources of energy both directly and through converting them into new materials on a much wider application then is generally conceived. It does this through the use of energy sources in the trades and services and also as raw materials in many new chemical and physical processes.

New commercial sources of energy, technological advances and improved designs will affect the trends and modify the consumption of every type of "fuel" used for any specific purpose. Nevertheless, 1980's newest heating units and power plants will be modifications of and forecastable improvements of those in use, under construction or on the drawing boards in 1959 and 1960. Exceptions to this broad statement may take place due to the rapid technological application of some process which is presently barely a passing idle fancy in some physicist's mind or a stray reaction in some chemist's test tupe. Or, somebody may develop a new alloy, ceramic material or plastic which will permit the use of higher temperatures and pressures, faster speeds or it may eliminate corrosion and erosion.

Assuming the above premises to be correct, the author will attempt in this paper to study the trends and forecast Canada's probable utilization of all sources of energy during the next 20 years. He will do this through consideration of the trends in: (1) the consumption of energy, (2) the various energy sources, and (3) the indicated technological advances during the next few years.

The Gordon Commission[1] thoroughly investigated the existing[2] and future use of fuels, power and energy by the various segments of Canada's economy. John Davis, the Commission's economic expert on energy matters, frequently reiterated that each energy-consuming segment of the community selects the course of energy it uses according to the suitability of the source for the particular end use and its technological advantages, the reliability of the source at the point of consumption and the economic factors of each application.[3] We shall discuss later these various factors and the changes which result when new sources of energy become available to any using sector of the community.

The pattern of Canada's economic development is changing rapidly and with the changes come alterations in the consumption and end use of each of the enercy sources. The transformation of Canada's economy from an agrarian to a heavily industrialized one has resulted in the discovery of many new sources of energy together with new uses for the old ones. The next 20 years will see these trends increase and, while many result in the conversion of a source of energy into a new material without the release of useful energy in the form of power or heat which may be transported and used elsewhere, these uses of energy sources must be included in our study because they may assist us to clarify our thinking and also they may disclose possible new fuels.

Thirty years ago space heating and transportation utilized nearly two thirds of the total energy used in Canada. At present these uses of energy have dropped to about 58% and by 1980 they will have dropped still farther to about 47%.

Although the percentage of the total energy used for these purposes (space heating & transportation) is dropping, the quantity of the fuel used is increasing (Table II & Fig. 2.) An examination of these show that the total fuel used for the two purposes has increased from the equivalent of 32.6 million tons of coal[4] in 1926 to 60 millions tons of coal at the present time and it will reach approximately 150 million by 1980.

At the time the percentage of the total energy and the quantity consumed by the public utilities in the production of power have increased from 7% to 15% and from 3.5 million tons in 1926 to 60 million tons in 1980. Similar increases are noted in the use of self-generated power by the mining and manufacturing segments of the community whose energy demand increased from 8.9 million tons last year and will probably reach 104 million tons in 1980. The non-fuel uses of the energy sources from coal, to oil and gas will rise from 3.0 million tons to 31 million tons of coal equivalent not including the employment of wood as the raw material.

We shall examine the various consuming segments of the economy and the various sources of energy in detail later; but first we shall review the bases for making predictions on the future uses of energy.

First we shall consider probable population increases, because the expansion of the country's industries and the country's demand for additional sources of energy depend largely upon population increase. We all recognize that population shifts affect the energy consumed of the country. For instance when large numbers of farm workers moved into urban areas and became industrial employees there was an increase in the total energy consumption. This increase is important, but it does not have the overall irresistible impact of an additional one or two million in population added to both industry and agriculture. Further, we must recognize the steady movement of industry into rural areas with the subsequent part-time employment of large numbers of farm works and the combined mechanization and electrification of the farms.

Fig. 3 shows the population increase based upon the figures given in the Gordon Report, the Canada Year Book and the reports of the Dominion Bureau of Statistics. The forecasts follow those of the Gordon Report using four premises. (1) All population growth is due to the natural rate of increase with no immigration; (2) the population based upon the assumed rate of increase chosen by the Gordon Commission (100,000 net immigration); (3) population growth continuing as the 1955-1959 rate of increase; and (4) the same as (3) but with the immigration to the United States and other countries stopped through the combined efforts of leaders in government, business and stopped through the combined efforts of leaders in government, business and labor circles. The curves in Fig. 3 indicated that according to these assumptions we should have a total population of (1) 24 million, (2) 27.5 million, (3) 32 million and (4) 33.5 million and possibly due to the added incentives nearly 40 million.

The simple increase in the population does not of itself, make radical changes in the energy demand. It will, of course, increase the energy demand proportionately with the population. If the population increase is accompanied by revisions in the country's economic structure such that the per capita consumption of energy is increased then we find that the final energy demand far exceeds that usually estimated. Hence, before we can make any reasonable predictions of the consumption of any energy source we must first examine the trends in the country's economic development, the various potential sources of energy (with their advantages and disadvantages) the cost of each source with its availability and reliability at any given point.

The close relationship between a country's economic growth and its

TABLE I

Canada's Changing Pattern in Energy Use

(As percentages of total energy used)

Consumption Sector	*1926*	*1958*	*1980*
Energy Industries	7	10	17
Mining and Manufacturing	18	24	29
Res. and Comm. Heating	37	28	23
Transportation	29	29	21
Non-fuel Uses*	3	5	9
Waste and Other	6	4	1
Total	100	100	100

* Non-fuel uses include those where the source is changed into another such as: matallurgical coke, coal tars, dyes, petrochemicals, lubricants, etc. It should include pulp, paper and other wood derivatives.

TABLE II

Canada's Changing Pattern in Energy Use

(As million tons of coal equivalent)

Consumption Sector	*1926*	*1958*	*1980*
Energy Industries	3.5	8.6	60
Mining and Manufacturing	8.9	30.0	104
Rest. and Comm. Heating	18.3	34.5	81
Transportation	14.3	35.0	74
Non-fuel Uses	3.0	6.5	31
Waste and Other	1.4	4.2	6
Total	49.4	118.8	356

energy consumption is well recognized. The wealthier and more industrialized countries have relatively high rates of energy use, while the poor countries with little or no industry have low rates of energy use and there is a parallel between the industrial development, the national income and the energy consumption of those in between. (Fig. 4 & 5).

While acknowledging the general relationship between economic development and energy consumption, we must realize that it is not universally apparent. It is often obscured by such factors as the non-commercial sources of energy used; changes in efficiency due to the conversion from one fuel to another; the losses involved in converting a source of energy to a more highly processed form (which may of course give greater useful efficiencies) and the conversion of energy sources into non-fuel uses.

The replacement of wood and agricultural wastes by the fossil fuels and water power often accounts for a rapid rise in measured energy consumption which may be misleading. This does not constitute a major problem in forecasting Canada's future energy requirements, because the non-commercial sources of fuel and energy do not form an appreciable percentage of the total requirements. There are two factors which we must consider later and those are the large quantities of wood which are destroyed by fire and the also large volumes of wood which are transformed into other and more-refined forms including alcohol and other chemicals.

The overall cost of energy affects a nation's economic development in the same manner that the cost of a particular energy source may affect its selection for a specific use. Fuel costs are an important factor in the power and the primary industries and may decide in the selection between two types. However, availability, quality and dependability of supply and flexibility in use are often far more important factors than mere cost in the final selection.

Each source of energy has specific purposes for which it is the most efficient and most economical. Even so, the improved methods of transportation and distribution of "Fuels" have widened the choice in energy sources available to Canadian consumers. The pipe lines and high tension transmission lines have released huge quantities of natural gas, oil and electricity from the restrictions of local demands to supplying the markets of almost country-wide extent.

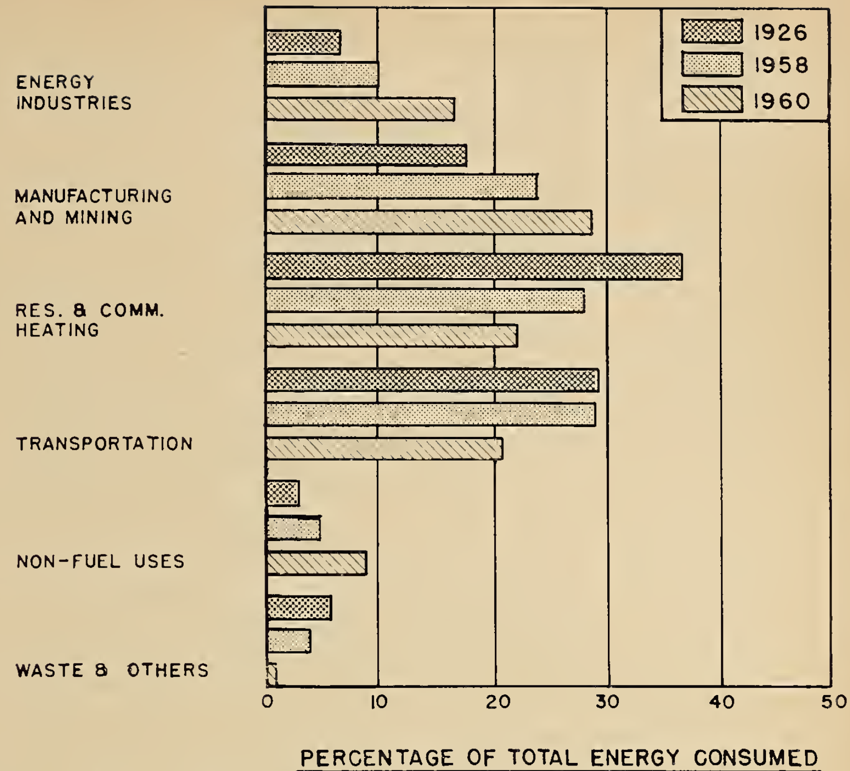


Fig. 1. Canada's changing pattern is energy use—energy consumed.

The past, present and future consumption of Canada's energy sources are shown in Tables III & IV, these are taken from the Gordon Commission Reports and are based on present marketing techniques. They further include the "non'-fuel" uses for coal, Petroleum and natural gas but only the direct fuel uses for wood. We shall later consider the effect of including the similar "non-fuel" uses for wood.

Many factors can alter the trends shown in the above tables. Changes in the merchandizing techniques of an industry can alter the picture completely. This is the case, especially, when the changes are the result of a long-range co-operative program of applied research. The petroleum and gas industries have shown the benefits of such long-range research programs which have developed new products, more-efficient methods of refining and transportation and more effective means of utilizing the products. The coal industry has just initiated a similar program and may regain some of its lost markets when the results of this research begins to seep down to the salesmen and users.

Again the enforcement of waste treatment legislation may result in the utilization of a waste for some useful purpose (many of the petroleum products such as gasoline were originally by-products) or it may result in the development of some new material from the wastes. Thus the pulp industry might enter the energy market with extremely cheap alcohol. This could completely alter the existing balance and force the gas and oil industries to re-assess their marketing policies.

Any well-planned concentrated drive for new markets brings interesting side chain reactions. This is so especially when the drive means the opening up of a new territory to new centrally, distributed fuels. For instance, the recent opening up of

Northern Ontario by the natural gas industry suddenly multiplied the sales of liquified petroleum gas (LPG), which the gas was expected to replace.

We shall now examine the main sources of energy in the country and after taking them in detail we shall consider how they may change their importance to the future.

Water power (hydro-electric power) has been the touch stone to Canada's industrial revolution. It is the key to the transformation of a fur trading and agricultural land into the world's fifth industrial nation within a space of 40 years. It will remain an important factor in the future, but undeveloped water power is no longer the sole key to the country's industrial expansion.

Ontario has already developed the last great hydro site within her confines. There are still some small projects which may utilize the potential energy of the few remaining unharnessed rivers; but, the majority of the future added requirements will come from thermal electric power stations, and by 1980 the Ontario Hydro expects nuclear stations will furnish one-third of its demand.

Quebec has only developed 40% of her water powers and so has considerable potential room for expansion before becoming entirely dependent upon thermal stations for new sources. The Ottawa, St. Maurice and Saguenay Rivers and their tributaries can still produce some 2.5 million kw. while the rivers of the North Shore of the St. Lawrence and those flowing into Hudson and Ungava Bays are barely reconnoitred. Even with these opportunities for hydro expansion, Quebec may need thermal or nuclear power stations in the near future to meet the demands for additional power in the congested Montreal district and in some of the remote Arctic sites.

Newfoundland possesses few undeveloped hydro power sites on the island itself, but the large Labrador rivers have over 5.0 million kw. of undeveloped potential water power. The British-Newfoundland Corporation is presently developing a 4 million kva. project at Grand Falls on the Hamilton River and other groups are investigating other sites.[5] These locations are so remote from the normal markets for power that they will require the development of the region before they can truly utilize their full potential.

Prince Edward Island possesses no undeveloped water power and the provinces of Nova Scotia and New Brunswick have a few of any magnitude, hence, these provinces must rely upon thermal stations to meet any large future demand unless they develop efficient and economical tidal-power stations.

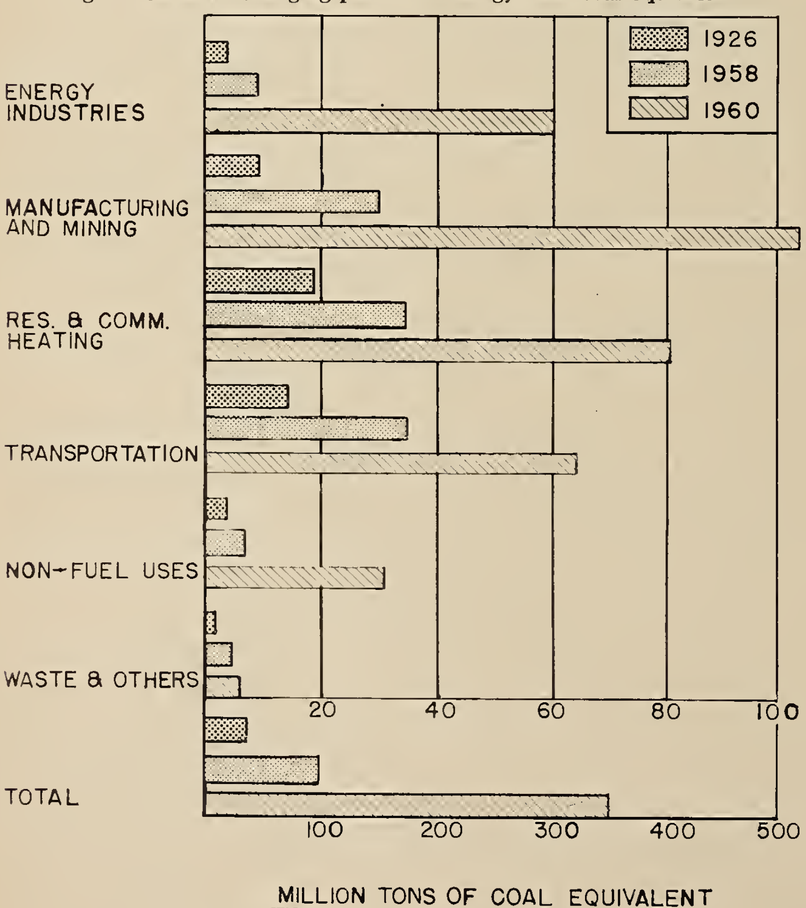
Tidal power is a form of hydro power and extensive research has been carried out by both American and Canadian bodies which have reported that tidal-power can operate effectively in the Bay of Fundy. At the same time, the need for furnishing markets for Maritime coal may well force the utilities to build thermal stations in these provinces.

Manitoba has sufficient undeveloped hydro sites on the Nelson, Saskatchewan and Churchill Rivers to assist in the development of the northern section of the province, the rich mineral region. The southern section of the province where its present population and industries occur possesses little undeveloped water power sites and this area will require thermal stations to meet any new demands.

Saskatchewan and Alberta possess little undeveloped water power and most of this is on rivers which are international in character and require the *approval of the International Joint Commission*. However, that body has recommended several projects and the Government of Canada has agreed with the province concerned to jointly build some of these developments.

British Columbia and the Yukon possess many large undeveloped water power sites. Unfortunately, most of these occur in remote areas so that their construction would probably be limited in usefulness to the development of restricted regions.

Fig. 2. Canada's changing pattern in energy use—coal equivalent.



This situation is apparent in the decision of the British Columbia Electric Company to build a large thermal-electric station to meet the growing demands of the Vancouver area.

The domestic use of electricity has risen rapidly in the last 15 years with the great increase in the use of electric washing machines, driers, stoves and refrigerators. The general use of blowers, or oil burners for house heating has added to the demand. While the Canadian householder pays approximately the same proportion of his usable income for power and fuel, as his American confrere, he uses about 1.6 times the amount of electricity as does the householder south of the border.

The industrial demands are increasing with the growth of industry as is shown in Table VI.

The forecast by Mr. Davis[6] was prepared on the basis of usages in 1955. Recent developments in the commercial and domestic electric loads indicate that the total demands for these classes of customers will be much higher than anticipated.

The current practice of commercial lighting is to use 100-150 ft. candles instead of the 20-50 ft. candles used at the time of the forecast. This will probably increase the commercial demand in 1965 and 1980 by at least 25%. In addition the heat given by this lighting necessitates cooling of the lighting fixtures and dissipation to either the outside of the buildings or at least to the areas adjacent to the exterior walls and may even eliminate the need for supplying any other heat even during extreme winter weather.

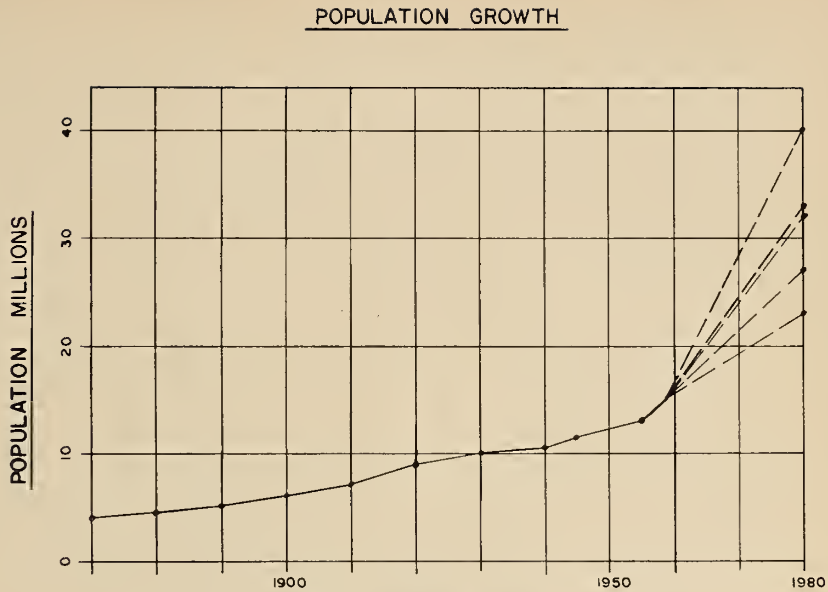

Fig. 3. Population growth.

The electric industry is taking advantage of the trend to radiant heating in both commercial and domestic fields. With the 90% efficiency of transforming electric power at the bus bar to heating in the store, office or home, electricity can compete economically with the other forms of fuel when power is available. The public utilities are taking this into consideration in their expansion plans. This is evidenced in a speech made by a Vice-President[7] of the West. Penn Power Company of Pittsburgh in June 1958, in which he stated his company was experimenting with electric home heating commercially and that they expected to have their share of this market by 1965 and at least 40% of the new homes by 1970.[7]

Coal will continue to supply an increasing amount of the country's energy supply through 1980, even though the percentage of the total energy demand supplied by coal gets smaller. The total tonnage of coal used in Canada in 1958 was 3.0 million tons greater than that used in 1926 although the percentage had shrunk from 69% in 1926 to 29.9% in 1958. It is expected that the nation's coal requirements will grow so that in 1965, 37.4 million tons and in 1980 78.5 million tons will be used. These increased tonnages will, however, only mean 26.1% and 21% of the total energy used in all forms.

The amount of coal used for domestic heating and for transportation decreased by approximately 6.1 million tons between 1926 and 1953 but this loss plus nearly six million more tons was made up by the additional coal used by the iron and steel plants, industry in general and the thermal electric power stations.

The forecasts by the Gordon Commission and the Dominion Coal Board estimate that by 1975 the an-

nual coal, requirements for Canada's thermal-electric plants will reach 27 million tons and that by 1980 the demands may reach 40 million tons. In addition industry will use 26 million tons in 1975 and 28 million tons in 1980. Thus, the combined total coal used by industry and the production of electricity in 1975 will be 156% of the 1926 total for all purposes and that for 1980 will be 200% of the 1926 grand total. Table VII shows the estimated demands by their principal uses.

The rapid expansion of thermal electric generation is the direct result of the nation's demand for more power than hydro-electric development can supply and this has resulted in a growing demand for more and more coal. The public utility companies, after carefully surveying the fuel situation, designed the central stations to operate at near critical pressures and temperatures with burners which can be operated on coal, oil or gas. In most cases the operators select coal as their regular fuel, although it requires expensive coal and ash handling equipment and space for large storage piles but, it is economical, reliable and less subject to interruption in supply provided that the plant has sufficient storage.

Thermal power stations will furnish nearly one-third of the additional generative capacity and 30% of the total generative capacity required to meet Canada's power demands by 1980. These plants will be built in all provinces.[8,9].

Coal will maintain, generally, its use as the fuel for space heating and process steam plants, which due to size or pressure require the full-time employment of a boiler room attendant. These larger plants usually find the fuel economics for coal, except for Alberta and Saskatchewan, outweigh the apparent advantages for oil and gas. It might be pointed out here that several large chemical plants are presently converting to and using gas with the intention of establishing a present demand for this material so that they can use it as a raw material for synthetics in a few years when the Canadian demand for those materials warrants their production in Canada.

Coal — high grade coking coal — is an essential major raw material for the rapidly-expanding iron and steel industry. Steel mills require continuous supplies of suitable coal in very large tonnages. This demand has restricted the industry to sites which are easily, economically and continuously supplied with iron ore, coal, limestone, and fantastic quantities of water. Hence the industry's major expansion will probably continue along the shores of the Great Lakes, the Upper St. Lawrence and in Nova Scotia. However, it is extremely possible that Provincial and Dominion policy may result in steel mills in Labrador, the Lower St. Lawrence and Ungava. This action might be accelerated by the development of commercial direct reduction of the ores by hydrogen in electric furnaces.

Petroleum products have replaced solid fuels in many fields, thanks to their ease of storage and the close quality control maintained in their preparation and manufacture. They have dominated the transportation field through their many advantages. In ships the elimination of "wing" and "cross" coal bunkers has liberated space for valuable cargo carrying; and double bottom tanks largely devoted to carrying ballast water can now carry the ship's requisite fuel oil. They can fill their tanks in less than a quarter of the time required for coaling and they can trim ship easily by pumping oil from one tank to another. Finally, they can store more heat units in the same space than they can with coal.

This employment of waste space has less apparent effect on land than its greater flexibility and the greater efficiency of the diesel-electric locomotive and truck over coal-fired steam driven ones. The flexibility of the internal combustion engine and the ease of storing fuel are factors in the domination of petroleum fueled buses, trucks and cars for highway traffic. Without oil and the internal combustion engine, man could never have conquered the air.

Oil's freedom from dust and ashes and its small space requirements for storage combined with the easy application for automation makes it an ideal domestic heating fuel. This has assisted it to replace solid fuels for domestic heating, as it is presently being supplanted by gas and, to a limited extent, by electricity.

In addition to its advantages in fuel fields, oil has become the important raw material in the manufacturer of an ever-widening range of chemical-products. This use of oil has risen from 6,000 barrels a day in 1956 to 13,000 barrels a day in 1958 and may reach 60,000 barrels per day by 1980.

Eastern Canada's reliance upon foreign sources of crude oil may effect the ultimate development of this source of energy. This may be overcome through the construction of pipelines to carry Western Canadian crudes to Sarnia, Toronto and Montreal. The Borden Commission did not bring down a definite and clear-cut recommendation on this point. Even so, the 1980 demand for the country should exceed 1,753,000 barrels per day.

From the above, we can expect that by 1980 petroleum products will fill the following uses:

(a) Space heating: oil will increase for this use, although the proportion of its use for this purpose will decrease both within the petroleum products and in comparison with other fuels after 1960;

(b) Transportation: It is the fuel for highway and air transportation

and the railways will complete their dieselization by 1960. Marine operators are converting the remaining ships to oil and, except a few special cases, oil will be the marine fuel of 1980;

(c) Industrial fuels: Oil is presently used in those places where it can offer ease in automation, flexibility and the savings resulting in storing it in waste space or underground tanks and where the cost per million Btu. is lower than other fuels. These factors will increase its demand for many industrial purposes in the future;

(d) Petrochemical industry: Petroleum products will increase in demand as a raw material for the petrochemical, synthetic chemical and plastics industries.

Natural gas has become a major source of energy across Canada from British Columbia to Montreal and the Eastern townships. The construction of a network of transmission lines has brought the gas from the extensive fields in Alberta and Saskatchewan to British Columbia, Manitoba, Ontario and Quebec.

This energy source will largely confine its use to those fields where its extremely great adaptability to automation is a great factor, and where its cost per million Btu. is less than coal and oil.

Gas will capture the bulk of the domestic heatings field by 1965 as far east as Montreal. It will also make heavy inroads into the industrial space heating and process steam fields where there are enough transmission mains to warrant an uninterrupted flow and where the costs are lower than coal and oil. During the next five years, numerous plants will connect gas to their boilers to secure a firm supply of the material and then utilize it as a raw material while returning to coal or oil for fuel purposes. Even now natural gas is an important raw material in the chemical fields.

Natural gas is the fuel used to drive the thermal-electric plants in Alberta and Saskatchewan and the B.C. Electric Company is installing gas-fired boilers in their new steam plant near Vancouver. Several western companies are using this fuel to drive gas turbines, direct connected to electric generators.

No eastern power company is presently considering using gas as the principal fuel for a major power station, although several may connect it up as an off-peak load fuel. Of course, a station such as the Hydro's Richard H. Hearn or Long Branch would require the complete capacity of the Trans Canada Pipe Line and in addition would demand that a second pipe line of equal size be held in reserve.

Nuclear energy is not a commercial source of power in Canada at the present time although several units are in commercial operation in Great Britain and the United States. One semi-commercial 20,000 kw. nuclear powered electric unit is nearing completion and the Ontario Hydro and AECL are building a 200,000 kw. unit for commercial operation in 1965.

The Gordon Commission forecast that nuclear energy would furnish 5% of the nation's power requirements in 1975 and that by 1980 this figure would increase to 12.9%. However, the Ontario Hydro forecast that by 1975 they would use nuclear energy to produce 26% of Ontario's demands and

Total...	100.0	100.0	100.0	100.0

that by 1980 this percentage would reach 31.75%. It is interesting to note in the Hydro's forecast that they figured nuclear energy would produce 133% as much power as would water power and 70.7% as much as the conventional thermal electric stations.

There is no question that nuclear energy is the ideal fuel to operate installations where the cost of transporting the fuel is extremely high and where the load factor will be above 75%.

On the other side of the picture, the nuclear power proponents have discussed the use of low-pressure saturated steam and before this source of energy can thoroughly compete with the conventional fuels some means of raising pressures and temperatures must be found or else all the advances in steam turbine design and power plant operation will be overlooked.

Generally economists consider firewood as the only energy source derived from our forest industries and report this a dwindling factor in modern industrial economy. They report the non-fuel uses of all the fossil fuels and trees are increasing with the growing industrialization of our civilization. Now let us see what results when we consider the non-fuel uses of Canada's forest products.

The conversion of wood into chemical pulp leaves about half the wood dissolved in the cooking liquors and disposed in various manners. That contained in the alkaline liquors is concentrated and burnt with the recovery of heat so that this would be added to our energy uses in addition to those normally shown. The acid liquors from the bisulphite processes are generally dumped into the streams to the annoyance of the conversationists. Several suggestions have been proposed to treat these liquors and recover saleable materials. Vanalin is being recovered at Thorold, alcohol at several mills and several lignin chemicals at others.

The production of alcohol might prove to be a valuable outlet for these wastes if costs including taxes could be reduced. Alcohol selling for ten cents a gallon, or even somewhat higher would have a definite market as fuel in several chemical fields. It has the advantage of burning with a non-smoky flame and containing few if any of the detrimental impurities which many of the petroleum and natural gases have. The large-scale production of cheap alcohol and allied compounds would force the present fuel distributors to seriously revise their marketing policies.

Conclusions

Canada's sources of energy during the next 20 years will be substantially the same as those presently used in increasing amounts although the percentages used will be substantially different.

Oil and natural gas will tend to replace coal and other solid fuels for domestic space heating and will furnish approximately 100% of the energy used for this purpose by 1965. During this period there will be a definite trend to the employment of radiant heat for space heating with increased efficient in the use of the energy. After 1965 electricity will begin to cut into this field, and by 1970 may attain as much as 40% of the space heating for domestic and commercial purposes.

In the large power plant field the 1980 load will be well distributed among water power, coal and nuclear energy; with natural gas and oil furnishing the most fuel in the prairie provinces. It must be remembered that in this field the demands for cooling water are enormous and at present this energy is lost. We expect that by 1980 methods of utilizing this waste heat for space heating will have reduced the losses considerably.

In addition direct connected gas turbines using gas, oil and powered coal will produce appreciable percentages of the power.

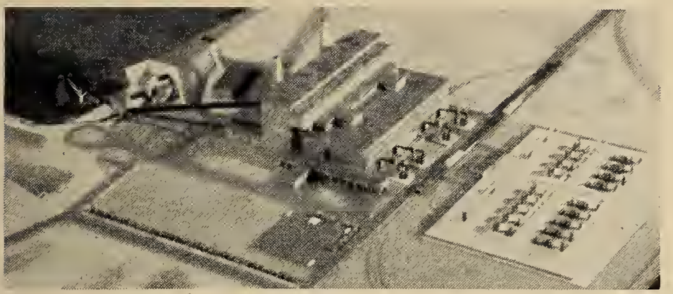
SASKATCHEWAN POWER'S BOUNDARY DAM GENERATING STATION



D. K. Whish,
W. A. Grobicki,
Ewbank & Partners (Canada) Limited, Toronto.

Paper presented at a meeting of the Power Group, Toronto Branch, Engineering Institute of Canada, November, 1959.

The Boundary Dam Generating Station is a fairly conventional Thermal Power Station. Emphasis is given to two aspects which are of unusual interest in this instance, namely: (a) Problems of ensuring adequate cooling water supply; (b) Problems of mining, handling and burning Souris lignite. The total electrical load in Saskatchewan up to 1955 was increasing at over 20% per annum—an integrated provincial system with two large steam stations was then undertaken. Vast quantities of lignite in the south-eastern corner of the province led to the decision to build onelarge thermal plant there. Within a four mile radius of the chosen site there is 100 million tons of lignite which can be economically mined. The fuel has an average calorific value of only around 7,000 B.t.u/lb. and a moisture content, of over 30%, but can be delivered at about $1.30 per ton. An artificial lake formed by construction of an earth dam in the Long Creek valley near Estevan provides adequate cooling water storage and evaporative cooling surface. Mining, transporting, unloading, conveying, storing and burning of lignite is discussed with reference to the problems of high moisture content, and the danger of fires under certain conditions. The turbo-generator plant and other main equipment is then briefly described. Some of the difficulties encountered during construction and commissioning are covered and the paper concludes with a note on station cost.

BOUNDARY DAM Generating Station is a fairly conventional thermal power plant. We propose to give a brief general description of the first two units in the station and to bring out points of particular interest relative to the location in southern Saskatchewan, where problems of water supply and fuel supply are of particular importance.

The post-war growth of electric load in Saskatchewan has been around 20% per annum and up to 1955 was tending to exceed this figure. Saskatchewan Power Corporation decided to proceed with an integrated transmission and generation network covering most of the populated part of the province including provision of a large thermal plant in the southern part of the province in addition to the new Queen Elizabeth Generating Station at Saskatoon. Although the centres of load are around Saskatoon and Regina, extensive lignite fuel deposits in the south-east led to consideration of construction of a large station there.

Within a five mile radius of the chosen site for the generating station there are around 100 million tons of lignite which can be mined economically by the strip-mining process. The great problem, however, was the lack of large areas of water in this part of the province which could be used for cooling.

The generating costs were calculated to be lower than the costs of transportation of the fuel to sites where the water supply situation was more favourable.

Extensive studies were made of suitable sites for construction of a dam which would form an artificial lake adequate for the anticipated size of the station. The final site chosen was on Long Creek, about 4 miles south of Estevan. Long Creek is a tributary of the Souris River which drains a watershed extending to near Moose Jaw, enters North Dakota and returns across the border to join the Souris River at Estevan. Long Creek was very shallow and sometimes dry in the summer, but examination of the topography of the valley above the dam site showed that a lake of some 48,000 acre-feet could be impounded.

With the decision to build the station in the Estevan area studies were made of various sizes of units and steam conditions to meet the anticipated load growth and a decision was made to install initially two 66 Mw. units, with turbine stop-valve conditions 850 p.s.i., 900°F.

Design was started at the beginning of 1956 and construction work for the generating station started on the site in October of that year. The first unit at the station was commissioned in the spring of 1959 and the second unit early in 1960.

Water Supply Problems

A detailed study was carried out, in conjunction with the Water Resources Board of the Federal Department of Agriculture and the Prairie Farmers Rehabilitation Administration, of the run-off in various creeks and of suitable sites for construction of a dam. Once the present site was chosen as the most feasible a submission had to be made to the International Joint Commission for their approval.

The dam was designed by P.F.R.A. on behalf of Saskatchewan Power Corporation and is of earth construction with a clay seal extending deep into the bank on either side. The dam is approximately 1,000 ft. long and 80 ft. high above the original stream level. The dam was completed in time to catch the 1958 spring run-off and, by commissioning date, the 1959 spring run-off was also impounded. Neither of these were very heavy run-offs, but a lake was formed sufficient for the present installed capacity with about 9,000 acre-feet of water which gives 22 ft. submergence over the bell of the vertical-spindle C.W. pumps.

When the lake reaches normal full level, it will extend for some five miles south to the North Dakota boundary. The artificial lake has become quite a feature in the area with boating activity and increased wild life. Scrub was cleared from the valley for the length of the lake and very few homes, bridges or other structures were affected.

Once the position of the dam was known, considerable study took place on methods of locating the circulating water pumps relative to the dam. From the cost and layout points of view, a conventional pumphouse below the dam with horizontal-spindle pumps was desirable. However, the very large intakes necessary through the earth dam to get the water to the pumphouse were a major design problem due to possibilities of settlement of the dam, danger of leaks causing erosion, etc. A final decision was made to construct the pumphouse upstream of the dam.

A 4 ft. square concrete tunnel through the dam with a shut-off gate lets water through for downstream users. From the lake end of the tunnel a separate pipe supplies a Fire Pumphouse below the dam. This pipe may be used in the future to take water to the City of Estevan water plant so that the reservoir is directly connected to the city water system.

A 125 ft. wide concrete spillway in the bank adjacent to the dam has five 10 ft. high radial gates, 25 ft. long, electrically operated.

The main access road to the site goes across the top of the dam.

Some water is let down occasionally to augment the very limited supplies in the Souris River for Saskatchewan Power's existing Estevan Generating Station.

Cooling water is pumped from the pumphouse adjacent to the dam to the station and then back to the canal intake chamber with a syphon seal pit adjacent to the station building. A long canal returns the cooling water to a discharge structure on the bank of the valley some 11,000 ft. from the dam. The surface area for cooling purposes on the lake from the discharge point back to the intake will be around 300 acres at half of maximum level.

From the canal intake structure a 48 in. pipe for recirculation, with a shut-off gate, has been taken back to the main intake, so that some, or all, of the cooling water can be returned direct when winter conditions demand.

One interesting feature of the valley was the many small coal mining operations into the bank. Coal seams are exposed along the valley sides and numerous workings had been dug into the banks by small operators. These disused workings and air vents from them had to be avoided in construction near the valley.

The anticipated final size of the generating station is 332 Mw. with the present two 66 Mw. units followed by two 100 Mw. (or possibly 120 Mw.) units. For the four units a total quantity of 200,000 Imp. gal. per minute of cooling water would be required.

For design purposes the lake level has been assumed to range from a minimum of 1790 ft. to a maximum of 1840 ft. Present level is 1802 ft. Prairie level is 1850 ft.

The design water temperature was taken as 65°F., but due to the possibility of having to operate at low lake levels with a very limited cooling circuit, allowances were made for inlet temperatures up to 85°F. for auxiliary cooling purposes.

With a minimum working lake level of 1790 ft., a pumphouse had to be built with the pumpwell floor below that level and at a level to give the pumps adequate submergence. The floor of the pumphouse is at 1780 ft., while the motor floor is at 1846 ft., in order to be above the maximum possible flood level.

Fig. 1 shows the side elevation of the pumphouse.

The pumphouse is a reinforced concrete structure, built now to house pumps for the final four units and has a conventional pumphouse building on top of the concrete foundation. It includes a concrete intake culvert with a rough bar screen at the inlet, three screen wells and three separate pumpwells, each housing two vertical-spindle pumps. The structure is 100 ft. long, 60 ft wide, and is 66 ft. from the pumpwell floor to the motor floor.

With the vertical-spindle pumps necessary in such a design, considerable care was taken in ensuring that the dimensions of the pumpwell were suitable for correct suction conditions to the pumps. Model tests were carried out to ensure that the structure was properly dimensioned.

Gates have been provided to allow isolation of any screen well or pumpwell.

The three travelling water screens are each 10 ft. wide with 68 ft. centres. No differential level control was included. It was anticipated that once the initial spring run-off had cleared the sides of the valley there would be little trouble from further debris.

Three pumps have been installed for the present two units, with provision for three more when the station is completed with the additional two units.

The final scheme will have three pumps supplying Nos. 1 and 3 units and three pumps supplying Nos. 2 and 4 units. To keep down initial construction costs the first three pumps are supplying No. 1 unit and No. 2, through a temporary cross-connection of the supply mains.

The three pumps at present installed are vertical-spindle mixed-flow centrifugal pumps, each capable of pumping 33,300 Imp. g.p.m. with differential head of 95 ft. They are constant speed pumps, speed 590 r.p.m., with a 42 in. column 66 ft. long. They have below-floor discharges and are driven by 1250 hp. electric motors.

The three pumps now installed are capable of supplying all the water required by one 66 Mw. and one 100 Mw. unit with water at 65° and machines at full load.

Water temperature and lake level are appreciable additional variables in this instance, so that pump operating conditions vary considerably. With winter temperatures one pump will be adequate for the two 66 Mw. units now installed.

The 50 ft. variation from minimum to maximum lake level explains the high differential head of the C.W. pumps applicable at Boundary Dam compared with stations on lakeshore or river bank sites.

The C.W. pumphouse is 1600 ft. from the main building and all pump controls are arranged for remote operation from the Plant Control Room in the main building. Local controls are included for use where necessary.

The pumps are oil lubricated with the thrust bearing at the top of the motor. The 1250 hp. motors are water-cooled, but can be used with air cooling if required, the discharged air being used to warm the pumphouse.

Each pump has a 42 in. tilting disc check valve and an automatically-operated butterfly valve at the discharge. When starting a pump the equipment is arranged so that the pump starts first and runs up to speed before the butterfly valve starts to open. On stopping the equipment is arranged so that the butterfly valve is closed before the pump is tripped.

The three C.W. pump discharges are all connected into one 72 in. diam. steel main which supplies the water to the main buildings. In the future a second 72 in. main will connect the future pumps to Nos. 2 and 4 units.

The return pipes from each condenser lead individually into the canal intake structure. An effective syphon of about 10 ft. exists through the condenser part of the circuit.

The canal to the discharge at the far end of the lake was constructed by digging a wide trench and using the material excavated to form additional dykes at each side. Velocity through the canal with maximum flow is kept below 2 f.p.s.

Losses from the water system are those due to seepage, evaporation, water for ash handling (part of this is returned), boiler blowdown, water treatment effluents, etc.

Given reasonable fortune in non-occurrence of successive seasons of very low run-off in the Long Creek drainage basin, no difficulty should be encountered in keeping four units fully loaded.

Lignite Mining

A special feature of this project is the very large quantity of lignite fuel required, and methods used to handle and burn this. The fuel has an average calorific value of only 6,000 to 7,000 B.t.u. per lb., and has a very high moisture content of 30-35%. Fixed carbon is around 31%, volatile matter 25% and ash 10%.

The Corporation's plans for burning large quantities of lignite were co-ordinated with invitations to various coal mining companies to mine the coal under a direct contract.

The successful bidder is now operating under an 11-year contract to supply all the coal required by the station. A shovel with a 20 cu. yd. bucket is used for removing overburden with depths down to 70 ft. Seams now being worked are from 8 to 25 ft. below surface. The large shovel removes the overburden and piles it up on one side of the cut. When the top of the coal seam is exposed it is cleaned and the coal is then removed and loaded by smaller shovels at the bottom of the cut. The coal-mining shovels and excavators are electric driven. Explosive charges are used when necessary to break the coal. Run-of-mine coal is delivered direct to the station, the equipment there being designed to take lumps up to 4 ft. cube.

Forty-ton bottom dump trucks are being used at present. The intake equipment has been designed for the 50 ton trucks which will be used when deliveries are increased.

Eventual coal consumption will rise to more than 1.5 million tons per annum.

A large garage and maintenance shop with all the necessary services for the coal mining operation was constructed adjacent to the power station buildings.

Coal costs approximately $1.30 per ton delivered at the intake hopper.

Coal Handling

The coal handling equipment at present installed is designed to handle 400 tons per hour of run-of-mine coal to the bunkers, or to stockpile. Reclaimed coal from the stockpile is bulldozed into the main intake hoppers. The eventual capacity of the coal handling plant will be 800 tons per hour. This is based upon the coal being taken in on an 8 hr. shift in a normal five-day week. The stockpile is planned to be adequate to cover periods in fall and spring when trucks may be unable to move.

Trucks delivering coal from the mine are weighed on a 100 ton capacity scale and then bottom-unload into one of two 120 ton capacity intake hoppers. Breaker beams are set in the concrete hoppers to break large lumps and protect the reciprocating feeders which feed from the hoppers into the primary crushers. The primary crusher is a double-roll toothed type, 30 in. diam., 72 in. wide, which crushes up to 400 tons an hour of run-of-mine coal and breaks it down to minus 6 in.

Secondary crushers located in the crusher house reduce up to 400 tons per hour of minus 6 in. coal to minus ¾ in. A magnetic pulley above the secondary crusher removes tramp iron.

From the crusher house belt conveyors carry coal to the transfer house from which it can pass to the long conveyor to the bunkers, or to the stocking-out pile, or to a loading point for deliveries elsewhere. Sampling equipment is located within the transfer house.

The duplicate conveyor belts from the intake pocket to the transfer house are each 36 in. wide, travelling at 265 f.p.m. The main conveyor from the transfer house to the bunker room is a 48 in. wide belt, travelling at 265 f.p.m. In the future, for its final capacity of 800 tons an hour, this belt will run at 530 f.p.m.

A telescopic chute on the stocking-out conveyor retracts as the pile rises. A stockpile of 100,000 tons has been formed with no difficulties to date from fires.

A continuous weigher is fitted on the main belt to the bunkers with the instrument located in a coal-handling control room adjacent to the crusher house. In this control room all control functions are combined on a desk which has a mimic diagram of the complete system. The entire coal-handling plant is operable from the desk.

The tripper is motor-driven and controlled automatically by bunker level switches and limit switches. The coal-handling equipment is generally conventional in its components, but particular care had to be taken with this fuel to avoid hang-up in chutes feeding crushers and transfer points.

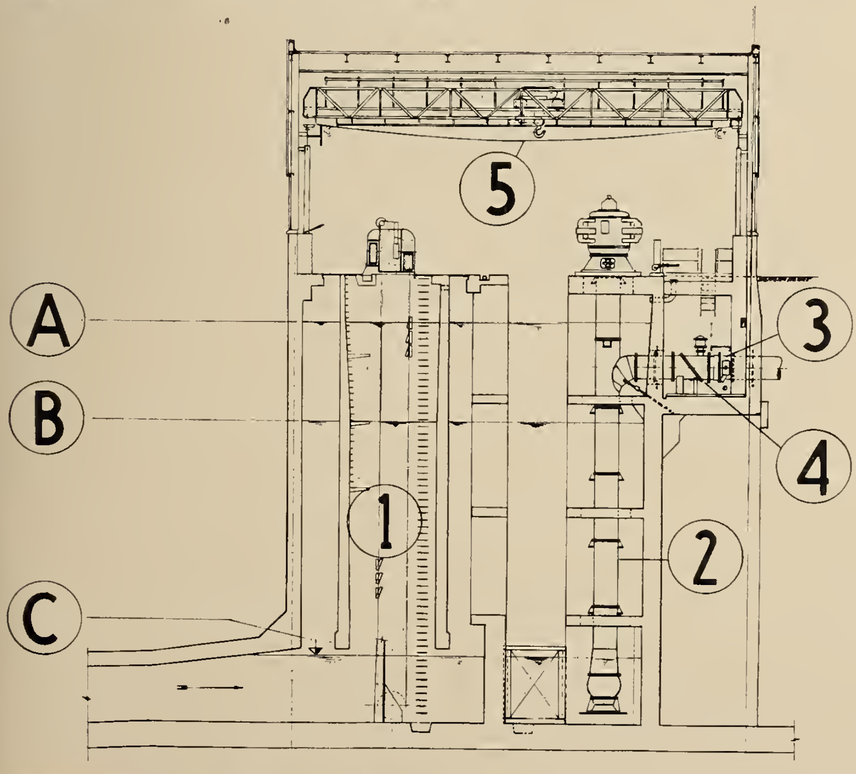
The coal-handling system is interlocked in sequence and an emergency safety stop system has been incorporated throughout.

Fig. 1. Side Elevation, C. W. Pumphouse

Legend:

A — high water level — 1840 ft. el.; B — normal water level — 1825 ft. el.;
C — low water level — 1790 ft. el.

(1) travelling water screens; (2) C. W. pumps; (3) 42 in. butterfly valve; (4) 42 in. tilting disc check valve; (5) 30 ton travelling crane.



Due to the high moisture content of the fuel all the coal-handling equipment is enclosed and heated.

The coal as delivered can vary considerably in surface moisture.

When the coal is dry, dust is a fire hazard. A spray system has been installed at all transfer points using, at the moment, service water. If adequate dust suppression is found impossible one of the proprietary wetting agents may be tried or cyclone type exhausters fitted on the bunkers.

In view of the known tendency of the fuel to hang-up, particular care was given to main bunker design. It was decided to install circular storage bunkers with stainless-clad double outlet cones. The cylindrical part of each bunker is 31 ft. in diameter. Each boiler has two bunkers with a total capacity per boiler of 1500 tons or 24 hr. capacity at full load.

Boilers

The two boilers now installed each are of maximum continuous rating 600,000 lb. per hr. with superheater outlet conditions 875 p.s.i., 915°F.

No. 1 Boiler is of radiant type with single drum, an economiser, and little boiler convection surface. Tangential tubes form an entirely water-cooled furnace of liberal dimensions which is front-fired by twelve burners.

Special attention was paid to the design of superheater surfaces to prevent bridging by the lignite ash. The first platens of tubes are widely spaced at 18 in. centres and the second bank at 9 in. centres. The superheater is of the self-draining type with considerable radiant heating to effect control of steam temperature at all loads. Steam temperature control is completed by attemporation by spraying feed-water into the intermediate attemporator headers. The spray water is used as a vernier control to effect the slight adjustment necessary.

Due to the low calorific value of the fuel, four very large mills are necessary for these units. On the boiler four EL 70 mills, each capable of crushing 38,000 lb. per hr. of lignite are installed. Full load is carried on three mills, except when the fuel is at the lowest specified calorific value of around 4,500 B.t.u. per lb.

Due to the high moisture content a very high air temperature for drying in the mills is required. The air temperature leaving the air heater at full load is 534°F and little or no use of tempering air is anticipated.

The disposition of heating surfaces on this boiler is as follows:—

Furnace	30,160 sq.ft.
Boiler	10,894 sq.ft.
Superheater	17,800 sq.ft.
Economizer	23,800 sq.ft.
Air Preheaters	69,000 sq.ft.

Each of the mills supplies three burners, each of which has an oil igniter adjacent to it. All functions for the igniters, impellers, coal/air gates, hot air gates, etc., are controlled remotely from the Plant Control Room.

Each boiler has two air heaters, two dust collectors, two F.D. fans and two I.D. fans.

An automatic sequential sootblower system uses steam for blowing. Particular care was taken in locating the blowers to ensure that fly-ash accumulations were not possible. Any horizontal surface causes progressive build-up of this fly-ash and all flues have been designed to avoid "ledges."

A water-impounded ash hopper collects bottom ash below the furnace.

The No. 2 boiler is of the same capacity and steam conditions, but is different in several features. It is corner-fired with sixteen burners of the tilting type, with steam temperature controlled by tilting the burners. Four bowl mills are included and again three of them are expected to carry full load. Each mill supplies one tier of four burners.

This unit has a large boiler convection section with a mud drum and has no economiser. The superheater in this case is of the pendant type in two stages. Similar design features for avoidance of fly-ash problems have been incorporated.

The furnace volume and dimensions generally are rather smaller than those on the No. 1 boiler. The fans and other auxiliaries are similar.

No. 2 oil is used for lighting-up purposes and for maintenance of flame when required on both units.

Turbo-Generators

Both turbo-generators have a continuous maximum and most economical rating of 66,000 kw. The turbines are two-cylinder 3600 r.p.m. machines with twin steam chests, a single flow HP cylinder and double flow LP cylinder.

The generator is cooled by hydrogen at 30 p.s.i. and has the exciter gear-driven from the main shaft.

The hydrogen coolers use distilled water which in turn is cooled in raw water heat exchangers.

The turbine and generator auxiliary equipment is quite typical.

The condenser is in two halves and of total surface 48,000 sq.ft. Each half of the condenser can be shut down for cleaning purposes while the set is on load.

Feed System

The feed heating system comprises five stages as follows: L.P. heater; Deaerating heater; and three high pressure heaters.

The extraction pump discharges through condensate oil coolers, through the main ejectors, through a drain cooler and the L.P. heater to the deaerator.

From the deaerator storage tank feedwater goes to the suction of the boiler feed pumps and then through the three H.P. heaters to the boilers. Final feed temperature at full load is 388°F.

Make-up to the system is controlled by the level in the deaerator storage tank. Controls are arranged to divert condensate through a 3-way valve after the ejectors, up to a high-level reserve feed tank when the deaerator level is high. When the deaerator level is low and make-up is required, the controls cause condensate to flow from the high-level storage tank to the condenser. Additional condensate is stored in low-level storage tanks which are arranged to automatically replenish the high-level tanks when required.

Each unit has three boiler feed pumps, each 50% capacity and electric motor driven. Each pump can be put on automatic standby and arranged to start automatically if the pressure from the running pump or pumps falls to a set value. The pumps are 8-stage and driven by 700 hp. motors. Controls for the feed pumps are in the Plant Control Room and on panels adjacent to the pumps.

Automatic Controls and Instrumentation

Air-operated controls are arranged to perform the following functions:

(a) Master steam pressure controls air flow to the mills and thus fuel flow. A mill proportioning controller for all four mills ensures that the total fuel flow is correct as called for by the master controller. Individual control stations with a bias feature allow the load per mill to be adjusted as required;

On the No. 1 mills a feeder controller automatically controls the feeder according to the primary air flow to the mill and the mill differential. On the No. 2 mills the signal from the master controller goes direct to the feeder and to the exhauster control damper;

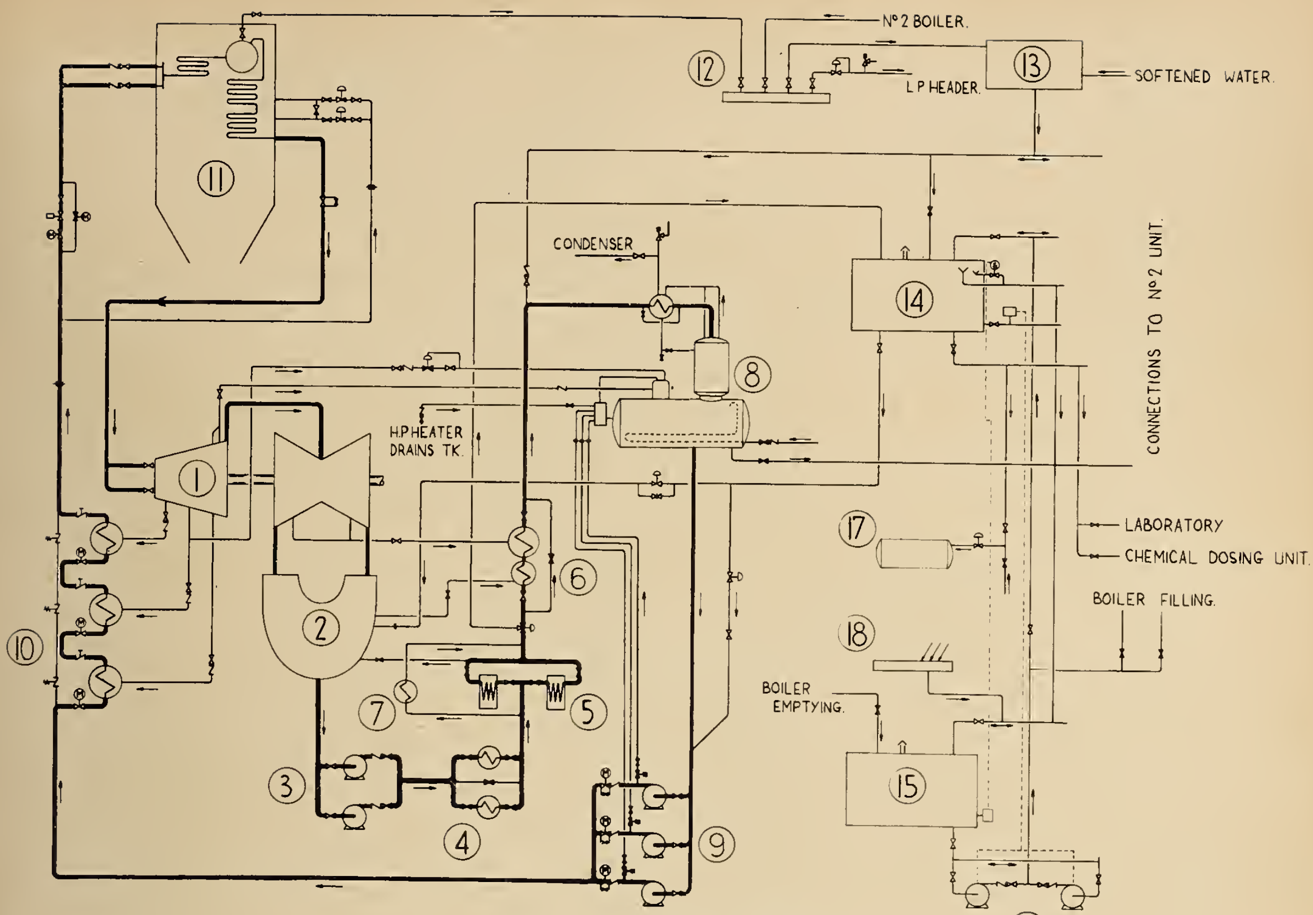


Fig. 2. Steam and Feed Diagram

Legend:

(1) 66Mw. turbo-generator; (2) condenser; (3) extraction pumps—2/100%; (4) lub. oil coolers; (5) air ejectors; (6) drains cooler and l.p. heater; (7) gland steam condenser; (8) deaerator; (9) boiler feed pumps — 3/50%; (10) hp. feed heaters; (11) 600,-000 lb./hr. boiler; (12) hp. steam header; (13) 35,000 lb./hr. evaporator; (14) high level reserve feed tank; (15) low level reserve feed tank; (16) reserve feed transfer pumps; (17) aux. boiler feed tank; (18) heating system condensate header.

(b) Combustion efficiency is controlled by a regulating steam flow/air flow ratio controller which controls the F.D. fan intake dampers.

A flue gas oxygen indicator recorder on the Plant Control Room panel informs the operator when adjustment of the steam flow/air flow ratio is necessary. An oxygen trim control on the panel allows direct adjustment of steam flow/air flow ratio;

(c) Furnace draft is controlled by I.D. fan speed and I.D. fan outlet dampers. Small fluctuations are corrected on the dampers and sustained load changes by automatic adjustment of the fluid couplings;

(d) Drum level is controlled by a three - element system comprising steam flow, feed flow and drum level transmitters which feed a computer relay designed to give an output signal which is governed by the relationship between the three variables. The output signal passes through an auto-manual station to the feedwater regulating valve;

(e) Steam temperature on No. 1 Boiler is controlled over the range where attemporation is necessary by control valves on the feedwater supply to each of two attemporator headers.

A casade system of control measures steam temperature at the attemporator outlets and at the secondary superheater outlet. The control point of the attemporator outlet controllers varies in accordance with final steam temperature so that attemporation responds quickly to changes.

All controls for normal operation of both units are combined in a single panel in the plant control room.

The room is located at operating floor level between the two units and between the turbine house and boiler house and is completely enclosed and air conditioned.

The main panel has five sections housing, from left to right:

1. No. 1 Boiler — Mill and P.A. Fan controls and instruments and burner pattern lights;

2. No. 1 Unit — Instruments and Controls for Boiler Draft, master pressure, megawatts, flue gas oxygen, final steam temperature, drum level, furnace pressure, steam flow/air flow, feedwater flow, boiler stop valves, I.D. and F.D. fans, air preheaters, boiler feed pumps, and for limiting maximum generator load;

3. A central section including, for both units:

Tank level gauges, condenser absolute pressure, circulating water pressure at condenser, fuel oil pressure and pump controls, heating steam pressure, dissolved oxygen recorder, conductivity recorder, air pressure and compessor pilot lights, controls for the remote C.W. pumps, controls for electric operation of the condenser inlet valves, synchronizing switches and electrical instruments relative to the station and unit switchboards.

4 & 5. Similar sections to Sections 1 & 2 for No. 2 Unit.

Annunciators for all important functions such as bearing tempera-

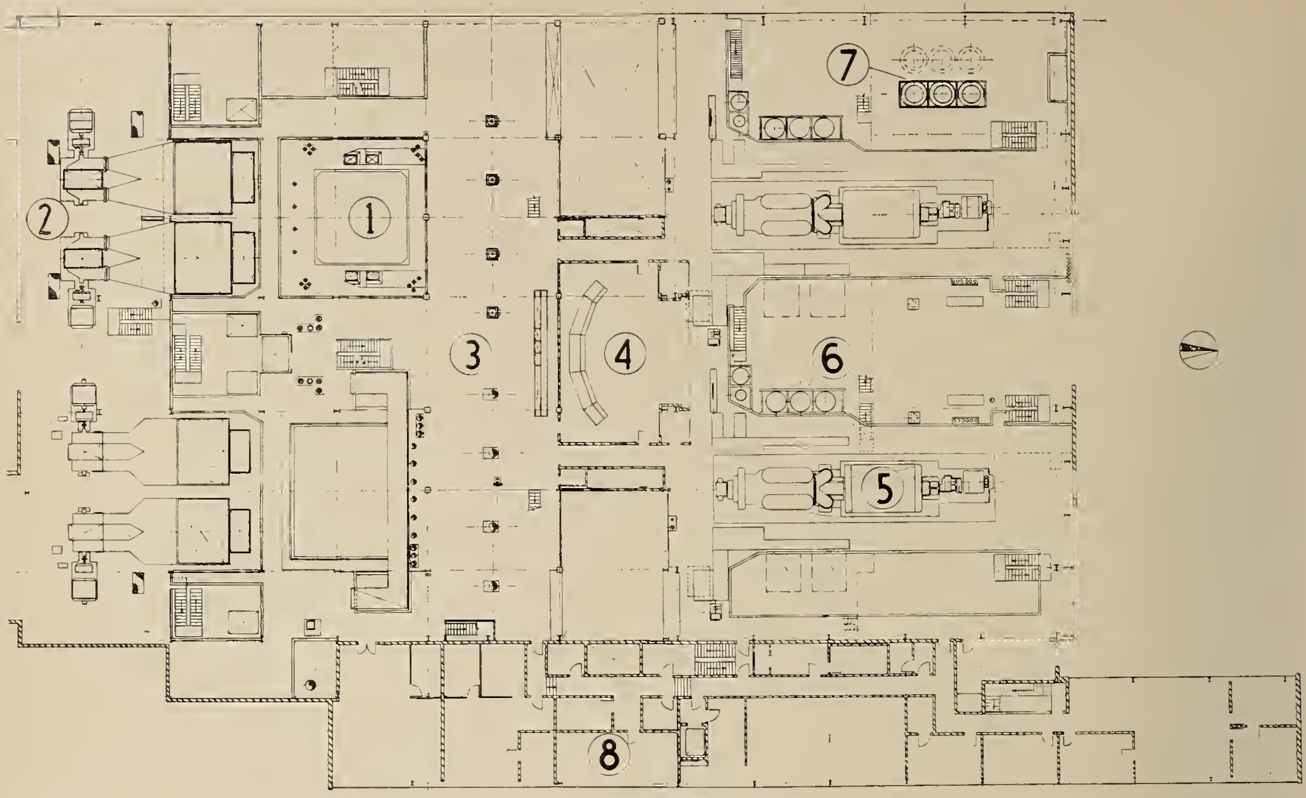

Fig. 3. Operating Floor Plan.

Legend:

tures, trip of remote auxiliaries etc. are mounted on the panel. Where a remote station such as the C.W. pumphouse has several local annunciators a single common alarm on the plant control room panel is actuated when any one of the local alarms is actuated.

The main panel was designed to afford compact grouping of the various controls and instruments. The majority of the switches for routine operation are mounted on the protruding desk part of the panel. The protrusion was kept to 18 in. to ensure easy access to the equipment on the vertical part of the panel.

Each unit has a desk for the operator located in front of the main panel. Each desk includes a multipoint temperature indicator for routine checking of temperatures throughout the unit.

All variables are transmitted to the instruments within the plant control room and no high pressure or high temperature connections are brought in.

Direct pressure and level indicators for each boiler are visible outside protective windows at each side of the control room.

Loading of the generator is carried out from the system control room. A maximum load limiting device is included on the plant control room panel.

Each turbo-generator has a gauge board with all indicators for local operation together with indicators for the supervisory equipment. The turbine gauge boards are located adjacent to each turbine and outside the plant control room.

Inside the plant control room a further panel for each machine houses the recorders for the supervisory gear and a multipoint instrument for monitoring stator temperatures.

Adjacent to the plant control room in the bunker bay, panels have been located for sootblower equipment and ash handling equipment.

Electrical System

The electrical design of the station is based on the usual unit layout, Fig. 5 and 6 show simplified one-line diagrams of the power distribution system within the station and the connections in the switchyard.

Each 66 Mw., 0.85 p.f. 14.4 kv. hydrogen-cooled generator is connected directly, by means of isolated phase bus, to its 75 mva., 14.4/138 kv. generator transformer and 7.5 mva., 14.4/4.16 kv., Unit Transformer, the transformers being located outside the turbine house.

The generator transformers are oil-immersed forced-oil water cooled units. Each is equipped with on-load-tap-changing equipment. Two 100% oil pumps and coolers are provided per transformer, the oil pumps are arranged for automatic change-over in case of failure of the unit in service. The coolers are located indoors to facilitate maintenance.

On the high voltage side, the generator transformers are connected by overhead lines to the switchyard, which links them with the provincial power system.

The unit transformers are oil-immersed self-cooled units equipped with off-load tap changing gear. Their 4160 volt windings are connected, by means of cables, to the unit switchboards. Neutral grounding resistors are incorporated in the neutral connections to limit ground fault currents.

A 10 mva. 138/4.16 kv. oil-immersed self-cooled station transformer supplies power for starting-up and for station auxiliaries which are not directly associated with either Unit. This transformer, is equipped with on-load-tap-changing gear, and connected to the 138 kv. busbars in the switchyard and the 4160 volt station switchboard. A grounding resistor is incorporated in the neutral connection.

The 30/40 mva., 72/138 kv. auto-transformer provides means of interconnection between the 138 kv. switchyard and the 72 kv. provincial power system. A short 72 kv. transmission line to the switchyard of the Estevan generating station completes this link, the purpose of which is to provide for starting-up either of the two stations, to improve voltage conditions on the systems and to increase the stability of the systems. The auto-transformer is an oil-immersed self-cooled/forced-air-cooled unit, equipped with on-load-tap-changing gear.

Unit and Station Auxiliaries

Under normal operating conditions the generators supply their own power requirements for auxiliary equipment, through the Unit Switchboards connected to the Unit Transformers. The two unit switchboards, with the station switchboard connected between them, form a common line-up of switchgear located on the switchgear floor facing the Turbine House.

The station switchboard can be connected to either or both unit switchboards by means of bus-tie circuit breakers. Under normal operating conditions the bus-tie breakers are open, and are used only for starting-up or during emergency conditions. A synchronism check system prevents paralleling any two sources of supply at the 4160 v. voltage level when synchronism obtained at the 138 kv. voltage level is not maintained by the interconnections.

The unit and station switchboards are of the metal-clad type with 1200A and 2000A, 250 mva. electrically-operated air circuit breakers.

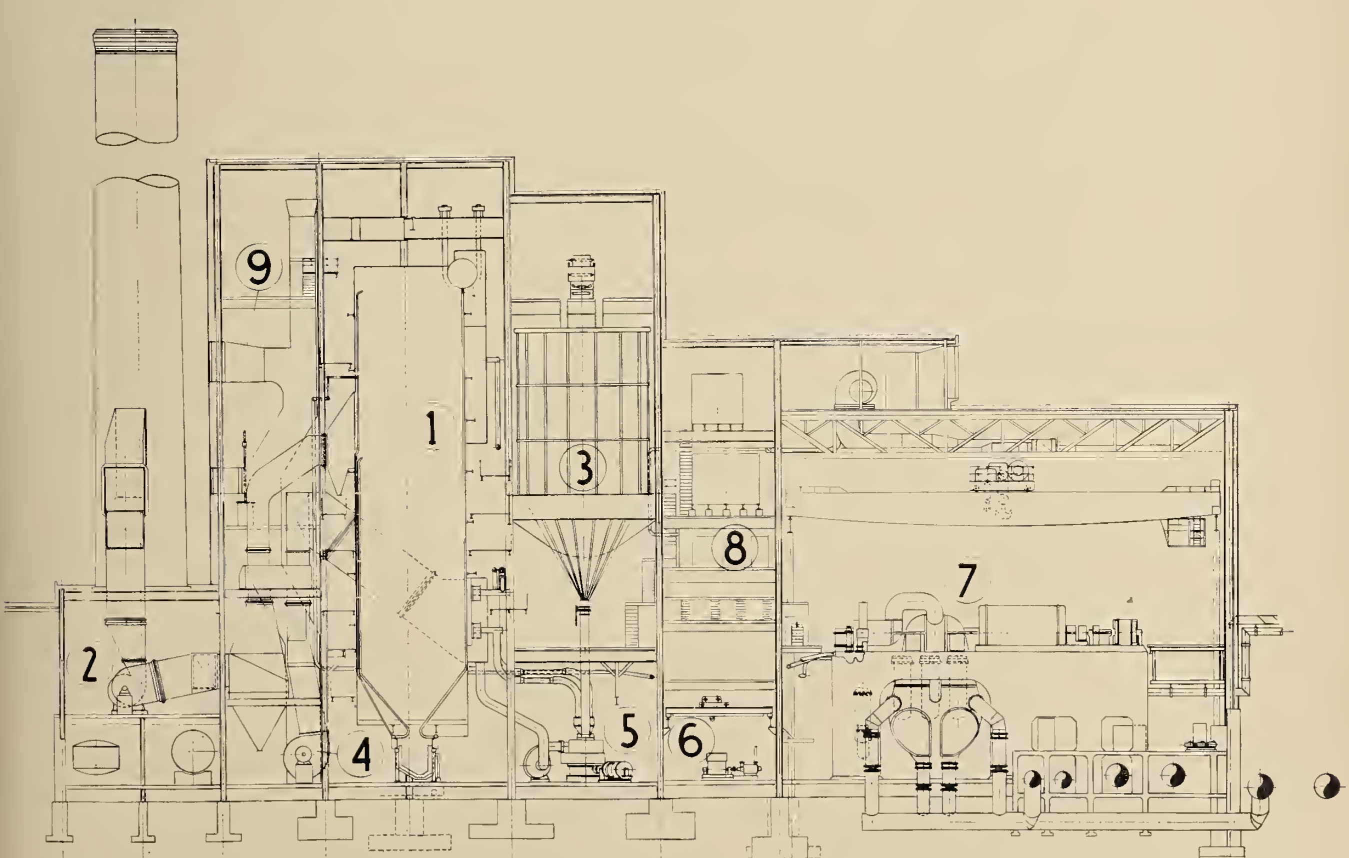
All electric motors driving unit auxiliary equipment which are over 100 hp. are supplied at 4,160 v. from the unit switchboards. This group includes the I.D. and F.D. fans, the mills and the boiler feed pumps. Also connected to each unit switchboard is one C.W. pump and one ash sluicing pump.

The station switchboard feeds the third C.W. pump, the coal handling plant and, through unit substations, all 480 v. auxiliary equipment which is common to both units. It also feeds unit substations which provide duplicate 480 v. supplies for unit auxiliaries and essential station auxiliaries.

The second voltage level of power distribution within the station is a 480 v. system originating at the unit substations also located on the switchgear floor. These are metal enclosed switchboards with dry type air-cooled transformers and manually operated, draw-out type air circuit breakers. Two of these, with 600 kva. transformers, are fed from the 4160 v. unit switchboards and supply turbine and boiler motor control centres. The remaining three (two 1000 kwa. and one 600 kva.), supplied from the 4160 v. station switchboard, feed motor control centres which control equipment common to both units and provide duplicate feeders to boiler turbine and essential station services

Fig. 4. Cross-section through the main building

Legend:
(1) 600,000 p.p.h. steam generator; (2) induced draft fans; (3) coal bunkers; (4) forced draft fans; (5) P.F. mills; (6) feed pumps; (7) 66 Mw. turbine generator; (8) switchgear; (9) combustion air intake ducts.



motor control centres. The following 480 v. services are typical for this group: lighting, air compressors, circulating water auxiliaries, water treatment plant, heating, ventilating, air conditioning, fire pump, system control building, workshop, etc.

Motor control centres located throughout the station at their respective load centres provide mounting space for all 480 v. combination magnetic starters used for the control of 480 v. motors. Small 115/230 v. panelboards also mounted in the motor control centres, supply small single phase auxiliary motors and solenoid valves.

Lighting

All lighting panelboards are supplied from identical single-phase 37.5 kva. 480-115/230 v. dry type transformers fed from the station services unit substations. The transformers are mounted in three-unit assemblies with common enclosures and are located on the switchgear floor, feeding strategically-located panelboards, equipped with molded case circuit breakers.

Color-corrected mercury vapour lamps are used for lighting the high-bay areas (turbine room, workshop, circulating water pumphouse). Fluorescent lighting is used extensively, typical areas being switchgear floor, plant control room, offices, feed pump aisle, boiler operating floor, coal handling plant operating areas. Incandescent lighting is also used, the system control room and boiler house galleries being typical areas.

Mercury vapour road lighting, controlled by solar clocks, has been used. Levels of illumination are in keeping with modern practice.

Particular attention has been paid to the lighting layout in the control rooms in order to avoid specular reflections from instruments and to provide a high level of illumination on the vertical surfaces of the switchboards.

D-C. System

Except for the internal telephones and the hydrogen alarm panel (which require a separate 50 v. d-c. supply) all station d-c. loads are supplied from a 125 v. switchboard located on the switchgear floor. The switchboard is connected to an 860 Ah lead-acid battery and two constant voltage regulated battery chargers. Normally one charger supplies the continuous d-c. load and float-charges the battery, the second one being used as a stand-by and for giving equalizing charges, when both chargers are used in parallel.

The main d-c. connected loads consist of control and indication or 4160 v. circuit breakers, emergency seal oil and lubricating pumps of both turbogenerators and the emergency lighting.

A separate 125 v. battery, chargers and distribution board are used for the d-c. loads associated with the switchyard.

Cabling

All 4160 v. cables are paper insulated, mass-impregnated non-darining, lead covered type. Single conductor cables have an overall neoprene jacket.

480 v. cables are either butyl rubber insulated, neoprene jacketed, or mineral insulated copper sheathed type, depending on the location of the cable run.

Thermocouple extension connections are made with mineral insulated steel sheathed cable with iron/constantan conductors. Within the station the cables are routed on cable trays. Cables outside the building are in fibre duct banks encased in concrete.

Communications

A 100 line private automatic exchange is installed to provide for direct communication between operating personnel and for administrative personnel in the main plant building and outbuildings. The system features executive right-of-way, conference calls and direct dialling to the plant control room for a fire alarm.

A staff locating system is provided for in the initial installation of the PAX, and will either be accomplished by a Morse code calling system.

Switchyard

The switchyard arrangement is based on the so-called breaker-and-one-half scheme with two main buses. (Fig. 6 is a simplified one-line diagram of connections). It provides two circuit breakers for each feeder and affords much flexibility and reliability. Normally both main busses are energized and all circuit breakers closed. However, either bus, or any circuit breaker can be removed from service without interrupting service or disruption of protection.

The 138 kv. circuit breakers are rated 1200 amp., 3500 mva. and are of air-blast type. Compressed air is supplied by two 30 c.f.m. 900 p.s.i.g. compressors through dryers, a storage bottle system, filters and reducing valves to a dual radial air supply distribution system in the switchyard, with air to the breakers at 350 p.s.i.g.

The disconnecting switches are of the group-operated 3-pole, vertical break type. The feeder and generator switches are motor operated.

The connections in the switchyard are made with either copper tube (for low level buses) or stranded copper conductor (high level buses).

Insulation coordination is based on apparatus impulse level of 650 kv., which is the full level for 138 kv. service voltage. 80% lightning arresters were used for the solidly grounded system.

An interesting feature of the switchyard is the 18.5 mvar. shunt reactor connected to the 138 kv. busbars. Its purpose is to compensate for the large charging current of the long transmission lines and thus improve the stability of the system.

A 72 kv. feeder shown in Fig. 6 supplies the 2,500 kva. coal mining substation. 4,160 v. feeders from this substation, located near the stripping operations, supply the draglines and shovels.

5 kv. trailing cables, portable switchhouses and portable substations provide means of power distribution in the coal mining areas.

The system control building, located between the turbine house and the switchyard, houses all equipment for the control, indication and protection of the turbo generators, main transformers and switchyard equipment.

Water Treatment

Make-up water for the units is taken from the C.W. supply mains to water treatment equipment located in an annex to the boiler house. The equipment comprises a clarifier for removal of dissolved and suspended solids, followed by sand bed filters and a zeolite softener. Softened water is pumped to a storage tank at high level which then feeds a central evaporator plant.

The central evaporator plant takes softened water and distills it for both units. The plant has a capacity of 35,000 lb. per hr. of distillate and uses about 1 lb. of steam to produce 6-7 lb. of distillate. High pressure saturated steam from the boiler drums is used for the inlet nozzle of the evaporator plant, which is of the thermo-compressor type.

The make-up enters the feed system at the inlet to the deaerating heater for each unit.

Miscellaneous Services

For general services such as cooling bearings, compressor aftercoolers, etc., filtered lake water is used. Raw water from the C.W. supply mains is pumped through sand bed filters to a high level tank which feeds the various services around the station.

A fire-protection system has been installed with a small fire pumphouse located below the dam in the valley where the most assured source of water is available. The pressure system has automatic starting of an electric pump followed by a diesel pump if the electric one does not start. An external ring main supplies hydrants at various key locations and an internal ring main supplies the various areas needing protection. Turbine oil equipment, seal oil equipment, generator and unit transformers, etc., are protected by deluge type equipment. Coal handling plant is protected throughout by a sprinkler system.

Two auxiliary boilers each of 10,000 lb. per hr. capacity, fired by No. 2 oil, were installed early in the project for heating during construction and for availability of steam if necessary for emergency heating and re-starting. A steam heating system for the plant and out-buildings uses 100 p.s.i. steam which normally is taken from the main boiler drums.

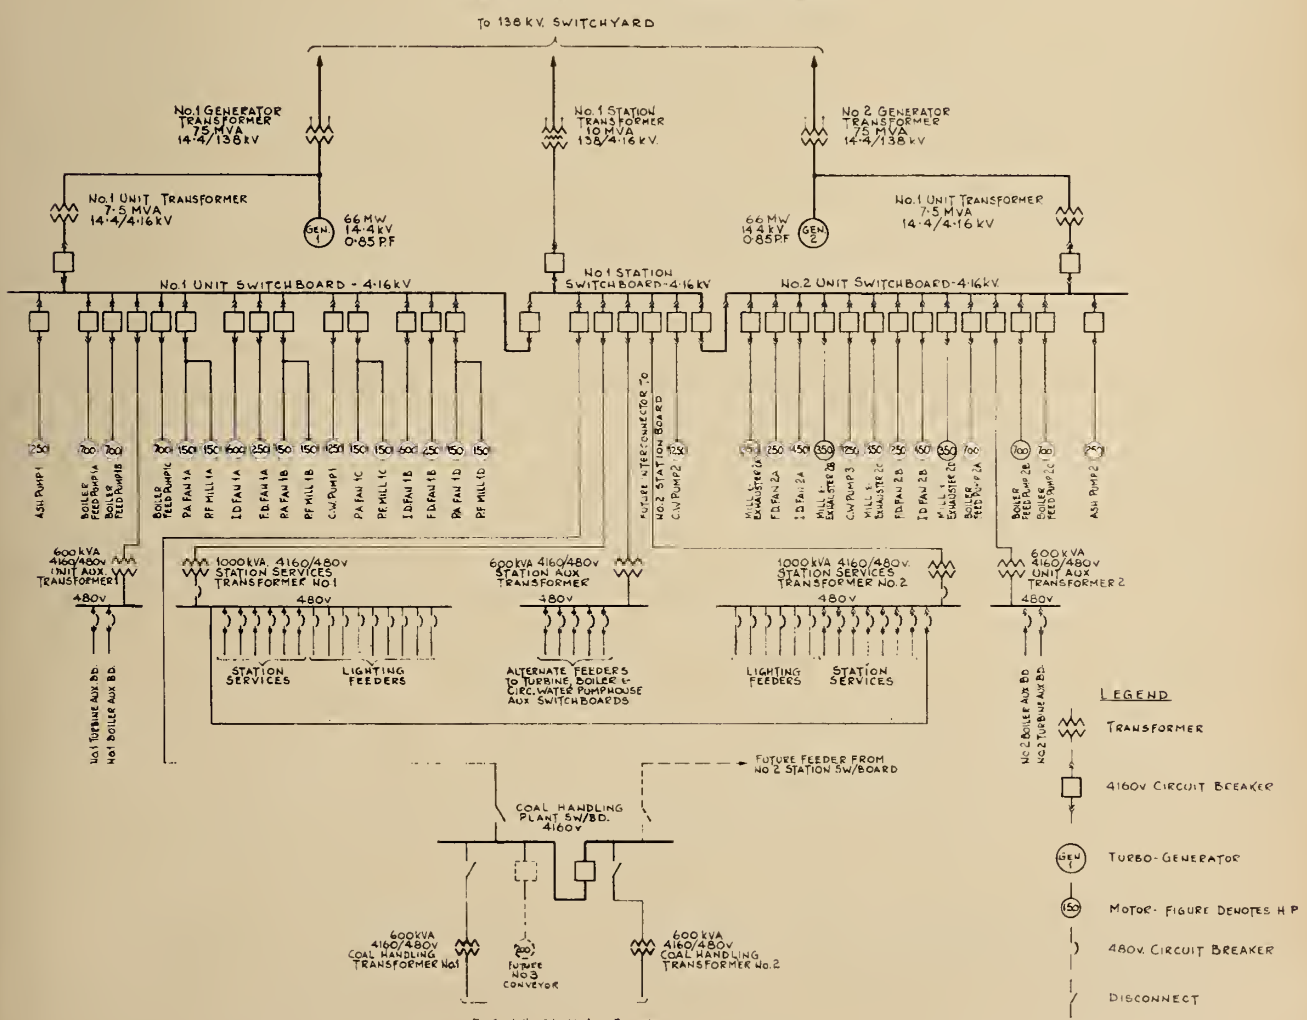
The main building ventilation system includes heating of the incoming air in winter and is independent of the combustion air intake system. Combustion air is taken separately through heating coils direct to the F.D. fans. Ventilation air passes through its own plenum room and into the building.

Ash handling equipment for the station required careful consideration due to trouble experienced by Saskatchewan Power Corporation at other plants with fly-ash from lignite fuel. The fly-ash has the characteristics and behaviour of cement and has been found very difficult to load into vehicles by dustless unloaders. Bottom ash is collected in water-impounded hoppers under the boilers and pumped to ash ponds. Fly-ash is withdrawn dry by a vacuum system operated by a hydraulic jet. The fly-ash plus water from the hydraulic jet flows by gravity through the same discharge line to the ash ponds.

As disposal of the ash is a problem in the area and as much water as possible must be returned to the lake, it was decided to build large lagoons or ponds adjacent to the coal pile and to drain these into a further settling pond from which clean water flows into the C.W. canal and thence back to the lake. Each pond is capable of storing 6 to 8 months' capacity of the two-unit station at full load. Each boiler produces about 6 tons an hour of ash at full load. Ash in the ponds will be removed by clamshell once a year.

Cranes in the plant are conventional. Consideration was given initially to installation of a crane of capacity sufficient to handle the generator rotor in the turbine house rather than one capable of lifting the heaviest load, the stator. A 50

Fig. 5. Station A. C. one-line diagram



ton crane would then be satisfactory instead of a 125 ton. In other stations it has been found more economical to provide special lifting gear for the few occasions when a stator has to be handled and to size the turbine house crane only for normal weights to be handled during maintenance of the machines. In this case a 125 ton turbine house crane has been installed.

Office accommodation including a general office, superintendent's office, workshop, laboratory, instrument shop, etc., are housed in an annex adjacent to and attached to the main building.

A garage building adjacent to the station is used for servicing corporation vehicles associated with the station and in general use in the Estevan area.

Layout and Building Finish

The general layout of the station is quite typical except for the circular bunkers.

Studies of foundation conditions showed the existence of several coal seams which played a part in dictating footing levels. Some trouble was experienced during construction of foundations due to coal seams dipping and rising from one part of the site to another. A final compromise of layout and foundation conditions was made whereby the basement was 16 ft. below prairie level. This allowed the footings to rest on a bed of shale. Individual footings for each column were used and no piles were necessary.

The general positioning of the buildings relative to the area was determined by the location of the dam, which dictated the lay-out of the C.W. system, and the location of the coal mines which dictated the direction from which the incoming fuel would come. There is ample space for further extension beyond four units provided the water supply allows such expansion.

The buildings are of insulated aluminum siding with metal deck roofs.

The single chimney for the two units is of radial brick construction located on the roof of the I.D. fan annex at the rear of the boiler house.

Construction

Some of the construction problems in the area were unusual. Winter conditions are, of course, very severe for erection of steel work and external work on concrete work and buildings. Some difficulties were experienced with early concrete work under winter conditions. Construction proceeded non-stop however, from commencement in October 1956 to completion early in 1958. Difficulty was experienced in obtaining good-quality aggregate for concrete construction within reasonable distance of the site. Prior to completion of the dam, a spring provided abundant water for concrete.

Cost

The approximate total cost of the present installation housing two units is $22 million or $167 per kilowatt of installed capacity. This sum does not include the cost of the dam itself nor the coal rights, nor the coal mining equipment contract. It does include, however, the high voltage switchyard and considerable civil costs associated with the future units, particularly for the C.W. system. The anticipated final cost for the four-unit station is $136 per kilowatt.

Operation

Operation to date on No. 1 Unit has been normal except for the following points of interest.

Trouble was experienced after a few months' operation with the C.W. system. Severe water hammer occurred when one of the vertical-spindle C.W. pumps was stopped and damage was caused to cast iron components of the system. A detailed study of the hydraulics of the system took place and the conclusion reached that the trouble was due to separation and rejoining of the water column near the condenser due to the rapid decay in pressure when a pump is tripped. Additional vacuum-breaking valves were added at key locations and no further trouble has been experienced.

Some initial troubles were anticipated with the coal-handling equipment due to the sticky nature of the fuel. After some minor troubles and minor adjustments to the components, however, this works satisfactorily.

One pre-commissioning worry was the known tendency of the fuel to cause fly-ash build-up in the boiler and particularly to cause of clogging of the mechanical dust collectors.

Experience to date, however, has been reassuring, with the boiler surfaces remaining clean and no trouble experienced at the dust collectors.

The ash system has worked satisfactorily to date with no trouble experienced handling the fly-ash.

The pulverisers required several field adjustments to suit them to the unusual characteristics of the lignite fuel.

Conclusion

The brief account above has, of necessity, been only superficial relative to the equipment installed at this station. It is felt, however, that to give a vast list of design data would be of less interest and give less scope for discussion than a brief summary of some of the highlights.

Our thanks are extended to Saskatchewan Power Corporation for permission to issue this description.

WHITEHORSE RAPIDS POWER DEVELOPMENT

L. A. Carey, M.E.I.C.,
Resident Engineer, Montreal Engineering Co. Ltd., Calgary

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

This development is located about one mile upstream from the City of Whitehorse on the Yukon River, where an ancient lava flow created the Whitehorse Rapids. The turbulent waters of these rapids, together with those of Miles Canyon some three miles upstream, were the major obstacles to water transport on the "Trail of 98", and originally a wooden railroad was built to portage this dangerous reach of the river. Remnants of this railroad were still in evidence when the development was started. Downstream from the Whitehorse Rapids the river is navigable to the ocean, and with the coming of the gold rush Whitehorse became the head of navigation. It was joined to the Pacific Coast by rail with the completion in 1902 of the White Pass and Yukon Route Railway to Skagway, Alaska. The next major land access route into the Yukon came into being during World War II, when the 1,500 mile Alaska Highway was built from Dawson Creek, B.C. to Fairbanks, Alaska. Whitehorse is at milepost 917 on this road.

THIS PARTICULAR area of the Yukon is semi-arid, with an average annual precipitation of about 10½ in. Although Whitehorse is only 100 miles from the Pacific Ocean, the climate is mainly continental, with cold winters and warm, dry summers. The St. Elias and Coast Ranges act as a barrier to coastal weather entering the Yukon. The Whitehorse area is generally warmer than the rest of the Yukon Territory because of the milder Pacific air masses which move in through the White Pass (maximum elevation 2,915). Snow has been observed in every month of the year in this area, although it is a rare occurrence in the months of June, July, and August. The mean annual temperature at Whitehorse is 30.8°F. The maximum and minimum temperatures recorded during the construction of the Whitehorse Rapids Power Development were 85°F and —47°F.

Site Selection

The hydro plant was built to serve the growing power requirements of the Whitehorse area. It will provide for the load growth of the Yukon Electric Company, Ltd., and will supply the requirements of the Department of National Defence and of the new hospital of the Department of Health and Welfare. Some 5000 kw. of diesel plant capacity, operated by the Department of National Defence and Yukon Electric Company, was retired when the new hydro plant came into operation.

Three hydro sites were considered by the Northern Canada Power Commission in the initial investigation in 1955: the Whitehorse Rapids, the outlet of Kusawa Lake, and the outlet of Aishihik Lake. All three sites were within 75 miles of Whitehorse. Some consideration was also given to a steam plant to burn coal from Carmacks, about 100 miles north of Whitehorse. The Whitehorse Rapids site was found best suited to the development of the region. It offered the prospect of meeting present load requirements at reasonable cost, and could be expanded to meet future growth. After a study of load requirements and water available, it was decided to install two 7,500 hp. units in the initial development, and to leave space for the addition of a third 7,500 hp. unit in the future.

Hydrology

The Whitehorse Rapids Hydro-Electric Development utilizes water from 7,500 sq. miles of drainage area comprising the headwaters of the Yukon River (formerly called the Lewes River). Most of this drainage area consists of high mountainous country lying to the east of the Coast Range and gives rise to many small streams and several large lakes. This area contains some of the largest ice-fields in North America. The principal lakes in the upper watershed (Bennet, Tutshi, Atlin, Tagish and Marsh) have a combined surface area of approximately 430 sq. miles, or about 6% of the total drainage area. The Yukon River proper comes into being at the outlet of Marsh Lake, and the power site is about 17 miles downstream from this point.

River stage and discharge measurements of the Yukon River have been made at Whitehorse for more than 50 years, and were available as follows:

(a) Miscellaneous discharge measurements—1915;

(b) River gauge heights, May to October—1902 to 1928;

(c) River gauge heights, continuous —1928 to 1943;

(d) Continuous daily discharge in c.f.s.—October 1943 to September 1954.

A hydrograph of mean monthly discharge derived from the daily flow data for the 11 years October 1943 to September 1954 is given in Fig. 3. An examination of this hydrograph will show that the Yukon River is extremely well regulated by the large lakes in the upstream reaches, and the annual flow patterns are remarkably uniform. Conversion of the earlier gauge records to flow indicates that this uniformity of flow has existed throughout the 52 years for which data were available.

As a further illustration of the uniformity of the annual flow distribution, flood peaks in excess of 20,000 c.f.s. have occurred twice since 1943 and it is estimated that this peak was exceeded six times between 1902 and 1943. However, the highest peak discharge recorded is only 22,800 c.f.s. on August 9th and 10th 1953.

In order to determine what the maximum capability of the drainage area might be, it was decided to make flood routing analyses of hypothetical floods. The maximum recorded precipitation in the watershed area is 4 in. Assuming:

(1) that this entire rainfall could occur in a single storm;

(2) that 100% run off would take place in a period of about two weeks;

(3) that the instantaneous peak flow would be equivalent to 30 c.f.s. per sq. mile of drainage area; and

(4) that a base flow, originating from snow melt, of 15,000 c.f.s. existed in the river at Whitehorse at the time the storm began;

hypothetical flood hydrographs were derived.

Floods were assumed as originating on:

(a) the entire drainage area;

(b) the lower portions of the drainage area.

It was found that the flood storage on the lakes is so great that the calculated peak flow in the river would not exceed 30,000 c.f.s. even under these conditions. A flood of this magnitude can be discharged through either one of the two main sluice gates provided in the dam—in addition, there is a regulating gate of 3,200 c.f.s. capacity for fine adjustments of the discharge.

An installation of two 7,500 hp. units was desired to supply the electrical load in Whitehorse at an average winter load-factor of 65%. Examination of the water records shows that the flow has seldom, if ever, fallen below 1,600 c.f.s. A net head of 61 ft. would therefore be sufficient to supply the required power with 1,600 c.f.s. through the plant. It could be developed by raising the water level at the head of the Whitehorse Rapids to elevation 2141 and leading the water along the left bank of the river in a canal and penstocks to a powerhouse discharging at a minimum tailwater level of 2078. Two feet of pondage has been anticipated on the forebay to meet daily load fluctuations. Provision has also been made in the powerhouse for the future addition of a third 7,500 hp. unit, to bring the total installation to 22,500 turbine horsepower. Addition of this unit would require a minimum winter flow of 2,400 c.f.s. The large area of the upstream lakes will permit a relatively economical development of the storage necessary to guarantee this flow. For example, a useful storage range of only three feet on Marsh Lake is estimated to be adequate to provide this additional regulation.

General

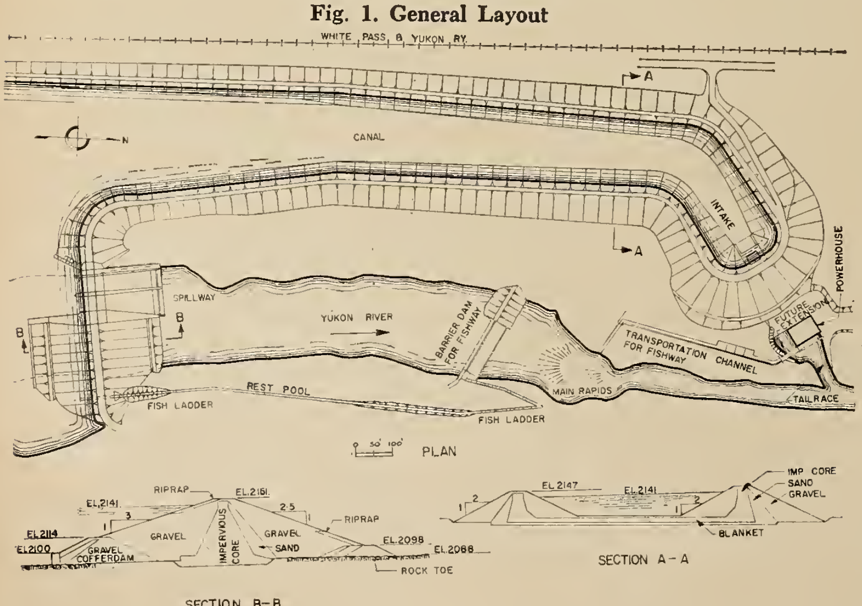
The decision to proceed with this development was made in August 1956. The first unit generated power for the local system on November 15, 1958.

The general layout of the development is shown in Fig. 1, and consists of the following structures: main dam, spillway, canal, intake, penstocks and powerhouse. The fishway facilities consist of a collection system and transportation channel at the powerhouse, a barrier dam, a fish ladder, and a concrete box culvert through the dam. A two transformer step-up substation is located adjacent to the powerhouse.

River Diversion

The Whitehorse Rapids gorge has a drop of some 12 ft. in about 1,500 ft., hence violent flow conditions exist at all river stages. In winter, prior to the construction of the power development, the Miles Canyon to Whitehorse Rapids reach of the Yukon River produced frazil ice for some 4 to 6 weeks before the rapids froze over. The ice pack, under severe winter temperatures, inched up the rapids creating, at the dam site, backwater conditions raising the water level some eight to ten feet higher than that of peak summer flows.

Fig. 1. General Layout



A major problem on the project was the diversion of the river during the various construction stages. Fig. 4 shows cofferdam stages 1 and 2 for the spillway structure and the main dam, and cofferdam stages 3 and 4 for the barrier dam. All diversions were carried out within the confines of the existing gorge.

Generally, rockfilled timber cribs were used in the cofferdams, because of space limitations and swift water. The contractor developed the timber crib shown in Fig. 4, Section A-A, for the longitudinal section of the cofferdam, which was exposed to high velocity water in the first stage of the construction. The two interior compartments were rock filled, leaving a 2 ft. void adjacent to the exterior sheathing. Two feet of the concrete was placed under water at the bottom of this void to effectively seal the contact of the sheathing with the bedrock. The remaining space was then rockfilled to complete the crib. Water velocities in the narrowed section of the river were estimated to be about 20 f.p.s. at the high summer stage in 1957.

Work on the first stage cofferdam was started in January 1957. Timber cribs were pushed out some 150 ft. in the river, leaving a width of about 130 ft. to pass the peak flow of the following summer. The water level rose some 10 ft. by the end of January as a result of backwater conditions caused by the ice pack gradually moving up the gorge. Timber cribs therefore had to be launched in water up to 16 ft. deep. The contractor used discarded tractor tracks as weights on the cribs to overcome the buoyancy problem in the deep water. The weights were also very helpful in placing timber cribs in fast water. Wakefield piling, made up on the site, and 4 in. tongue and groove were used for the exterior sheathing of the timber cribs. A buffer crib was put in at the upstream corner to protect the sheathing from the ice run. The first stage cofferdam was completed in early May. Two 10 in. diesel pumps and two 6 in. gas pumps handled the leakage inside this cofferdam, caused by a maximum head of 18 ft. of water against the upstream cribs. The first stage cofferdam was removed in late 1957.

The low height of the second stage upstream cofferdam was made possible by leaving unpoured, in the 1957 phase of the spillway construction, the top 16 ft. of the concrete ogees in the main sluices. The second stage cofferdam is shown in Section

B-B of Fig. 1. An 8 ft. wide, rock-filled timber crib built to elevation 2100 was used to divert the river through the sluices at the low stage in April 1958. Behind this low crib, a gravel dyke was built to elevation 2114, sufficient to handle the expected peak flow in the following summer. This upstream cofferdam became an integral part of the main dam. The rock toe of the main dam, sealed with gravel and silt on the inside, was used as the downstream cofferdam. This silt was removed and replaced with pervious gravel, after the core section of the main dam rose above the water level adjacent to the rock toe. The concrete transition wall at the east side of the spillway completed the enclosure.

The final steps in the unwatering of the main dam spillway required the closure of one 40 ft. sluice opening to complete the ogee and flip bucket concrete, while the river was passed in the other 40 ft. opening. The second sluice was then closed, and the river allowed to rise over the previously completed ogee. The sluice gate stop logs were used for these operations in construction checks located upstream of the ogees. These steel logs were handled by a 20 ton hoist mounted on a monorail. Arrangements were made in the gate superstructure to install the monorail temporarily over the construction checks. The logs are normally lowered by gravity, and are intended to be placed in still water, with the gate closed. In this case, however, they had to be placed in high velocity water, and there was danger that the friction between the logs and the guides would prevent the former reaching the bottom of the opening. It was thus imperative that the closure be made at as low a river stage as possible. This was particularly true when closing the second sluice, as the flow had to be diverted over the completed ogee of the first sluice. In order to obtain a sufficiently low stage of the river for this operation, the small storage dam at the outlet of Marsh Lake was used to regulate the flow.

The Lewes River dam at the outlet of Marsh Lake is a pile bent structure with 7 flash-board sluices and 21 gate openings. It was normally left fully open during the summer, and was closed in late fall, after the natural river flow dropped to about 8,000 c.f.s., leaving a residual flow of about 4,000 c.f.s. in the river. Water thus stored on Marsh Lake by this dam during the winter was released in quantity in the early spring.

A test closure on the Lewes River dam in early October 1957, with the river flow at 17,500 c.f.s., indicated that the closure of the dam would not be effective, unless the natural outflow from Marsh Lake was less than 15,000 c.f.s., otherwise, the gates of the control dam would be overtopped.

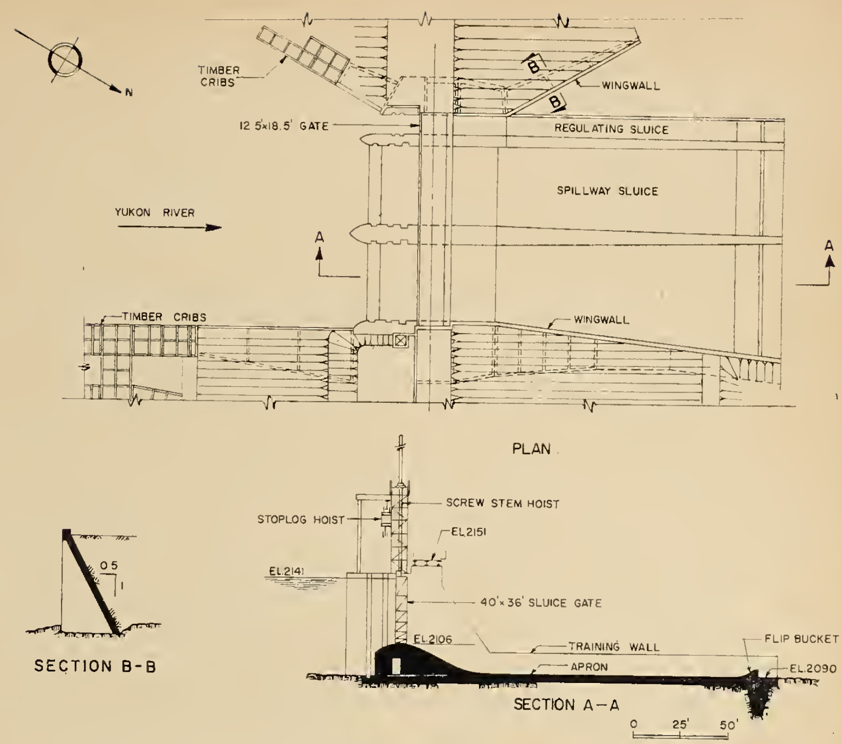


Fig. 2. Spillway Dam

On September 21st, 1958 the river flow at the power site was reduced from 14,500 c.f.s. to 6,200 c.f.s. by a fairly complete closure of the Lewes River dam. The first sluice at the spillway was unwatered on September 22nd without incident. The Lewes River dam was reopened on the same day, in order to lower the water level in Marsh Lake. The unwatering of the second sluice was carried out in late October, with the river flow temporarily reduced from 9,400 to 3,200 c.f.s., again by the closure of the Lewes River dam.

The third stage cofferdam for the fishway barrier dam was started in early August 1958, and completed in September. The river flow varied from 16,500 c.f.s. to about 15,000 c.f.s. while this cofferdam was being built. The contractor showed great ingenuity in launching timber cribs in 8 to 9 feet of water having velocities approaching 15 f.p.s. This cofferdam was removed in early October, and stage four cofferdam was started from the east bank, diverting the river between the completed transition wall and the west bank. The fourth stage cofferdam was removed in late April 1959, and the diversion channel was closed with a rockfill at the low river stage in May.

Spillway

The spillway, shown in Fig. 2, consists of two 40 ft. wide sluice openings and one 12 ft. 6 in. wide regulating sluice. The National Research Council tested a model of the spillway in 1957. The model study indicated the need of considerable downstream protection to avoid undermining the spillway structure and main dam transition wall. The concrete apron at the sluice exit was extended downstream some 130 ft. Flip buckets were provided at the end of the apron to throw the water clear of the structure, and hence avoid undermining. Training walls were required between the sluices to maintain the flow normal to the flip bucket when one sluice only was operating, and to permit unwatering of the apron for inspection and maintenance. A deep cutoff was provided under the flip bucket, as an added protection against the erosion which might occur at low flows, when the velocity is insufficient to throw the stream clear of the structure. The model also indicated the best operating procedure for the gates under various discharge conditions in order to minimize the erosion.

The transition walls between the spillway and earth fill structure are of counterfort construction with the slabs varying in thickness from 1 ft. 6 in. to 2 ft. 6 in.

The volcano which formed the river bed of the Rapids in geological times laid down successive layers of lava, varying from volcanic ash to dense basalt. A good deal of the lava was scoriaceous, that is, it was filled with air pockets up to ¼ in. diam. Laboratory tests proved that the voids were not interconnected and the rock was impervious. The rock loading was limited to 10 tons per sq. ft. in the design of the structures. The occasional strata were hard and appeared stable when first uncovered, but deteriorated to ash when exposed to air for some time. This was caused by hydration of the rock. The contractor experienced difficulty in clean-up prior to placing of concrete, when these strata were encountered.

Two sluice gates are provided, each 40 ft. wide by 36 ft. deep, and weighing some 80 tons. They are raised and lowered by electrically operated screw-stem hoists. The regulating gate 12 ft. 6 in. by 18 ft. 6 in. is cable-suspended and electrically operated. A 20 ton electrically operated cable hoist is mounted on a monorail upstream of the gates to raise and lower the steel stoplogs.

An access bridge across the spillway downstream of the gate structure was used for the gate erection. Heating elements were installed in the sills, guides and gates of the west sluice and the regulating sluice, to permit operation of these gates in winter.

Main Dam

The main dam is shown on Fig. 1, Section B-B. It is a conventional earth fill consisting of an impervious silt core, with a sand filter on the downstream of the core, and pervious gravel flanks. Riprap was applied to the top sections of the upstream flank and the lower section of the downstream flank, to afford protection from ice and wave action. The contractor used shovels and 12 cu. yd. trucks to handle the materials for this structure. The main dam was constructed in about five months in 1958.

The east bank of the river at the main dam consisted of bedrock, overlain with glacial till up to elevation 2120. The glacial till was covered to a depth of some 100 ft. with fine gravel and sand. The dam was tied into the east bank by means of steel sheet piling driven through the nearly completed core section into the glacial till contact at elevation 2120. The tie had to be effective against a head of 21 ft. of water. The sheet piling was carried into the bank some 25 ft. beyond the end of the impervious core, thus increasing the seepage path and insuring against any leaching of the impervious core at the contact with the sand of the east bank. This was more economical than a conventional blanketing operation.

A small spring developed about 400 ft. downstream from the dam centreline after the forebay was brought up to full supply level, but the water is clear, and no increase in flow has been noted.

Canal

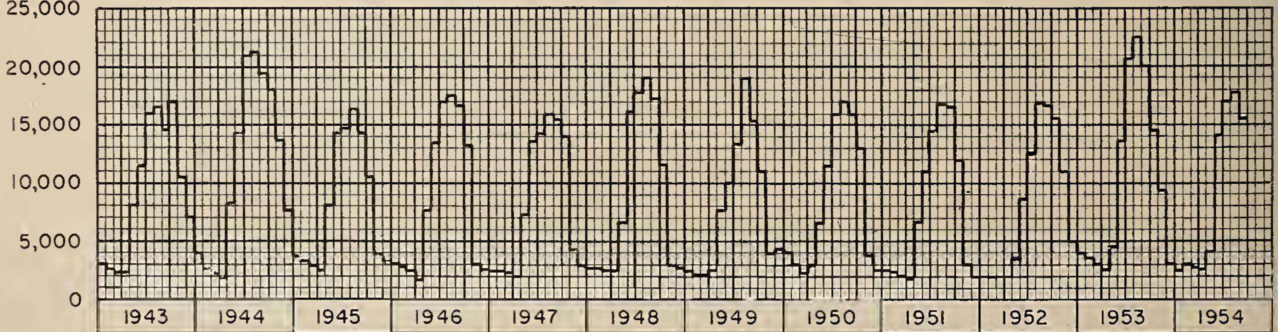
The canal layout is shown in Fig. 1. Its downstream end is founded mainly on pervious gravels, so that an impervious lining on the bottom was necessary. Laboratory tests of the local silts, made during the preliminary investigations, indicated their suitability for use in earthfill structures. The impervious layer of the canal blanket varied from a minimum thickness of 3 ft. to a maximum of 7 ft. 6 in., depending on the head. The gravels uncovered in the canal excavation were compacted "in situ", just prior to placing a 1 ft. thick layer of compacted sand. The impervious blanket was then placed to the designed depth, and covered with an inverted filter consisting of 1 ft. of compacted sand and 1 ft. of gravel. The blanket was carried across the canal and tied into the impervious core of the canal embankments. It was also tied into bedrock across the entrance to the canal proper, thus giving continuous protection from loss of water through the canal bottom.

A good deal of the local drainage from an area west of the canal percolates through the gravels on which the canal was built. The rock along the west bank of the river dips generally to the west. An overlay of fine sand over the bedrock adjacent to the slightly higher ground near the river resulted in a high water table at the downstream end of the canal. In 1957, a deep drain was cut from the river into this area, about 200 ft. upstream of the intake, and extended across the canal right-of-way. This lowered the water table some 6 ft. and permitted the contractor to excavate this area in the dry. The ditch was back-filled with oversize gravel from the aggregate screening operations. This drain functioned effectively throughout the winter of 1957-58. The only precaution taken before placing the canal blanket over the drain area was that 3 ft. of compacted sand was placed over the drainage ditch instead of the customary 1 ft. filter layer over the compacted gravel. A V-notch weir was installed at the outlet of this drain, and periodic flow measurements were made. This drain ran about 45 g.p.m. with little or no variation before and after the canal was filled with water.

Due to the gradient on the bottom of the canal (some 25 ft. in 2,000 ft.) special care had to be taken during the initial filling to prevent scouring of the canal blanket. Water was therefore pumped from the forebay (using a 10 in. diesel pump) into a stilling basin located at the head of the canal and constructed from a discarded section of the temporary fish ladder. From here 2,150 ft. of 1 ft. by 3 ft. wooden flume laid on an even gradient conveyed the water to the concrete intake slab, where it was discharged. As the water rose in the canal, the downstream end of the flume floated. The canal was filled in 5 ft. increments until the water level at the intake was raised 24 ft. to elevation 2129, about 1 ft. below the canal entrance. After each increment, readings were made on the drain discharge as described above and water levels were taken in the canal proper to check on possible water losses through the canal lining. This initial filling covered practically the entire bottom of the canal, thus protecting it from any frost penetration. It also gave a reasonable assurance that there were no major faults in the canal blanket.

It was not possible to raise the river to the level of the canal entrance

Fig. 3. Monthly Hydrograph of Yukon River at Whitehorse



until after the closure of the second sluice, in late October. The forebay level was raised to elevation 2134 early in November, and work was caried on in the sluiceway behind 46 ft. of steel stoplogs. The first unit was put into operation on November 15, with the forebay being maintained between elevations 2134 and 2135.

Intake

A three conduit intake was built in the initial stage, but head gates and trash racks were installed for conduits 1 and 2 only. The conduit for the future unit No. 3 was closed off by a bulkhead in the penstock. The hoist house is mounted on a slab supported on columns, high enough so that the headgates may be hoisted clear of the checks for inspection and maintenance. The head gates are operated electrically. Stoplog checks are provided upstream of the gate slots. The one set of steel stoplogs is handled by a manually operated monorail hoist. The same logs and hoist can also be used, if and when required, upstream of the regulating gate at the spillway.

The intake structure rests on undisturbed sand, covered by a layer of compacted gravel. The tie between the impervious layer in the canal blanket and the intake was effected with a special, ⅛ in. rubber sheet. The rubber sheet was placed on a compacted sand base and fastened to the intake base slab and to the base slabs of the two upstream retaining walls with bolted 3 in. angles. The sheet was extended upstream and embedded in the silt. At the intake entrance, a 6 in concrete wearing slab was placed directly on the compacted silt over the rubber sheet and the standard canal blanket was constructed immediately upstream.

Penstocks

All three penstocks, which are 12½ ft. diam., were installed. This will avoid the necessity of breaching the canal embankment when the third unit is added. The horizontal sections of the penstocks adjoining the intake and the powerhouse were embedded in concrete. The sloped sections were erected on a compacted sand base. The exterior surfaces of the penstocks, when not embedded in concrete were treated with a bitumastic coating. All penstocks were backfilled with gravel, after precautions were taken to avoid damaging the bitumastic coating. The penstocks were erected in the late summer of 1957, and two sliding joints were left in each penstock to allow for movements due to settlement. The sliding joints were welded in 1958, after the canal embankment was near completion. Settlement of

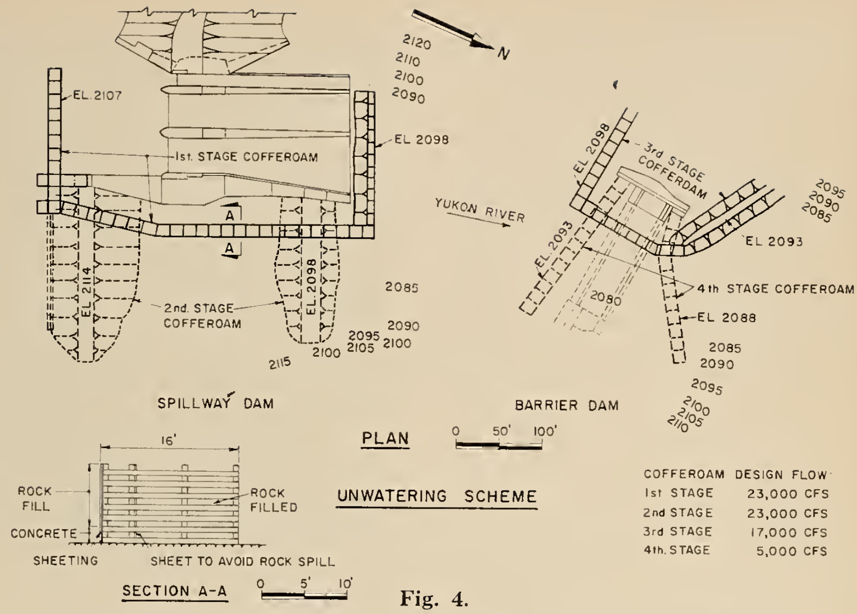


Fig. 4.

⅜ in. was observed at one joint only. Movement, if any, was longitudinal at the remaining joints.

No. 3 penstock will not be in actual use until the third unit is added. A timber bulkhead suitably backed with steel and designed for the full head on the plant was installed at the downstream end of the penstock. Two 2 in. pipes were put through the bulkhead and valved on the downstream side. The valves were left open, thus maintaining a small but continuous flow through this penstock. It is expected that this circulation will avoid major temperature fluctuations and prevent any significant icing in this penstock. The valves discharge some ten feet below the minimum tailwater level and are thus constantly submerged.

Powerhouse

The powerhouse excavation was completed for three units, but the substructure was built for the initial two units only. When starting the excavation, it was found that the bedrock was overlaid with a fine, saturated sand up to a maximum depth of 14 ft. The sand would not stand for any length of time, on a slope of less than 4:1, and it also went to a quicksand condition as soon as equipment worked on it. The excavation of this material was done by a 1½ cu. yd. dragline standing above, on the firm ground. A gravel dyke was carried around the perimeter of the excavation, directly behind the excavating equipment, thus trapping the sand before it could slough. Provisions were made to facilitate the unwatering of the excavation for the third unit at some future date, without interfering with the operation of the existing units.

The initial powerhouse structure contains two 7,500 hp. 300 r.p.m. Kaplan turbines which operate under a maximum gross head of 63 ft. Power is generated at 6900 v. by two 6700 kva., 300 r.p.m. generators. This voltage is stepped up to 34.5 kv. by two 5000/6667 kva. three-phase transformers for transmission to Whitehorse.

Some unusual difficulties were experienced with the governing of the turbines when they first started to take on load. Normally, load fluctuations on the Whitehorse system are small. However, during the commissioning of the plant the 3000 kva. electric boilers in the hospital were also being commissioned and, occasionally, the individual generating units had sudden load increases in excess of 1000 kw., or about 20% of their full load rating. When this occurred, governor action degenerated into violent hunting and, on occasion, the governors "locked out". On the other hand, performance during load rejection was satisfactory.

Mr. L. Avery was called to the site and during his investigation he noted that when load increases of over 1000 kw. occurred, the compensating dashpot on the governor was bypassed. This happened each time the opening movement of the big plunger of the dashpot was large enough to move the small plunger so near the end of its stroke as to uncover a slot on the opening end, and bypass the oil. The small plunger movement then ceased to have any compensating effect, and the unit began to hunt. Such bypassing of the dashpot is a desirable feature on sudden load-off, and a slot is provided for this purpose on the closing end of the small plunger. It was, however, the presence of the similar slot on the opening end of the small plunger, that was the cause of the trouble in this case. If the machine had formed part of the usual interconnected power system with abundant WR^2 stability, the trouble would not have arisen.

In order to prevent this hunting action, the pilot valve was centered with 5/16 in. blocks under the fly balls, instead of the ½ in. blocks usually used. This adjustment is such that, when the fly balls are forcibly collapsed against the spindle and the dashpot plunger held just clear of the bypass point, the distributing valve does not move beyond its centering point and, consequently, the gates do not open. At the same time the dashpot needle valve was set for maximum stability. Following these adjustments the performance of the governors was satisfactory. Loads of 2000 kw. were then "dumped" from one unit to the other without exceeding expected speed regulation. This was the maximum load available at the time for testing without using the town load.

On one occasion during the tests, with Mr. Avery present, the machine locked out. It was apparent to him that the lock-out was associated with hunting and low oil pressure. Evidently, under these conditions an accumulation of air collected behind the plunger of the automatic shut off valve causing the unscheduled closure. It was expected that with the elimination of the hunting this trouble would also disappear, but in order to make sure the drain line from the automatic shut off valve was modified to discharge directly into the oil sump above the oil level, where it would have free venting at all times.

Fish Facilities

At the start of the construction, in 1956, the decision as to the need for structures to facilitate the movement of anadromous fish was postponed. Meanwhile, the Department of Fisheries began an intensive investigation of the situation, and, as a result of their studies, it was decided in the spring of 1958 that a fishway should be provided. The Engineering Division, Pacific Area, Department of Fisheries then prepared a functional design which was incorporated into the project.

The fishway structures are shown in plan on Fig. 1. They are divided into two groups. One consists of a barrier dam to prevent the fish from reaching the confusing turbulence below the spillway flip bucket, and the ladder connecting the west end of the dam with the forebay. The other is a collection structure on the downstream wall of the powerhouse, and a transportation channel connecting this structure with the river below the barrier dam. The object of these structures is to return to the river those fish which swim up the tailrace.

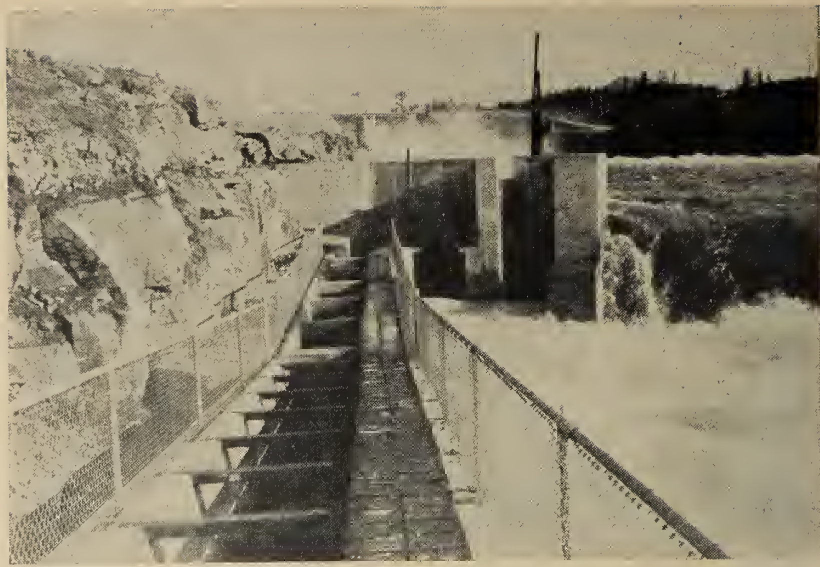

Fig. 5. Barrier Dam and downstream end of the Fish Ladder looking upstream.

Powerhouse Collection System and Transportation Channel

A collection chamber in the form of a timber flume with 3 submerged orifices was constructed on the downstream face of the powerhouse, above the draft tube openings. This chamber was connected to the transportation channel by means of a steel and timber aqueduct across the excavation for the future third unit. This will allow the fish facilities to operate without interruption, when the third unit is added. The transportation channel extends several hundred feet upstream to the head of the Rapids. Water at the higher elevation in the river flows down the transportation channel and passes into the tailrace via the submerged openings of the collection chamber. Fish entering the tailrace are attracted through these openings by the outflow, and ascend through the system back to the river to rejoin those that had proceeded directly upstream. The flow into the collection chamber is self-regulated by a system of slotted concrete baffles, which are adjusted to maintain the discharge and velocity within a specified operating range for all river stages between 10,000 and 25,000 c.f.s.

Barrier Dam

The barrier dam is located about 200 ft. upstream of the main rapids. A positive barrier was required, with a minimum surface drop of 8 ft., and a flow pattern of the overfall such that fish could not surmount it.

The structure was angled across the river in such a way that the fish would be led to the east bank, where the collection facilities for entrance to the ladder are located. Water is supplied to the collection system from the fish ladder, and an auxiliary supply of up to 600 c.f.s. is available, through a 6 ft. square slide gate in the east abutment of the barrier dam.

The west end of the barrier dam is a rock fill section constructed by end dumping. The final closure was made at low river stage, after closing the spillway gates for a few hours.

The design of the barrier dam and transportation channel was checked by a model study made prior to construction in the LaSalle Hydraulic Laboratory, Montreal.

Timber Fishladder

The fishladder, constructed of creosoted timber and reinforced concrete, approximately 1200 ft. long, and having a vertical rise of nearly 50 ft., allows the fish to swim from the collection facilities of the barrier dam to the forebay.

All of the fish facilities were placed in service on June 26th, 1959. During that year 1,054 Spring Salmon were counted going into the forebay.

Cost

The estimate for the power project was $7 million before construction was started, and the work was completed for $7.2 million. The fish facilities were estimated at just under $1 million and constructed for some $875,000.

Acknowledgements

The Whitehorse project was constructed for the Northern Canada Power Commission. The author acknowledges with thanks, the permission of Mr. E. W. Humphrys, General Manager of Northern Canada Power Commission, to present this paper and reproduce pictures taken during the progress of the work. He also wishes to express his appreciation to fellow members of the Montreal Engineering Company, who have assisted in the preparation of this paper. Special thanks are due Engineer R. N. Gordon of the Fisheries Department for data connected with the fishway facilities. EIC

KELSEY GENERATING STATION DAM and DYKES

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

For the Kelsey Generating Station, the first hydro-electric development on the Nelson River, economic and schedule considerations dictated that a rock-fill dam be constructed on bedrock across the river and that dykes be constructed upon both unfrozen and permanently frozen foundations. For design of the 120 ft. high, 955 ft. long rock-fill sloping core dam, extensive laboratory testing was performed on the highly plastic core material. Construction delays and inclement weather conditions necessitated slight design modification, and it was also necessary to complete construction of the core within heated enclosures placed upon the dam. Dykes upon permanently frozen ground were constructed in winter, of sand brought to the site by rail. It is expected that the foundations will thaw gradually due to heat from the reservoir. Sand drains have been provided in the foundations to facilitate drainage and accelerate consolidation during thawing. Virtually no precedence was available and design had to be based qualitatively upon theoretical heat transfer and consolidation considerations. The latter involved testing, under carefully controlled conditions, samples of frozen and thawed foundation material. Sensitive temperature and settlement measurement devices have been installed in the foundations to check performance and design assumptions. These observations will serve to give warning of any impending troubles and will provide valuable information for the design of future water impounding structures on permanently frozen foundations. Considerable settlement is expected and periodical or continuing maintenance may be necessary on these dykes.

THE KELSEY Generating Station is a hydro-electric power development situated on the Nelson River, approximately 425 miles due north of Winnipeg, Manitoba. The station is owned by The Manitoba Hydro-Electric Board and was constructed for the purpose of supplying power for the mining and smelting operations of The International Nickel Company of Canada, Limited, some 60 miles distant at Thompson, Manitoba. The locations of the Kelsey development and Thompson are shown in Fig. 1. Construction began at Kelsey in June, 1957 and will be substantially completed during the summer of 1960. The initial installed capacity is 210,000 hp. The general arrangement of the development is shown in Fig. 2, and the pertinent statistics are given in Table I.

The Kelsey project involved the construction of a small rock-fill dam and a number of dykes which, because of the climatic and geological conditions at the site and the schedule requirements, gave rise to some geotechnical problems of unusual interest. The most significant factors were the low mean annual temperature, the short annual period of temperature favourable to earthwork construction, and the existence of appreciable but sporadic permafrost throughout the site. Construction of the main dam was governed by a reasonably tight diversion schedule and a short construction period; some difficulty was experienced in the use of a fairly plastic wet clay for core construction, and extreme difficulty was encountered with the very low temperatures existing during the later stages of its construction.

Two of the dykes, here referred to as sand dykes, had to be constructed in low swampy areas which were underlain by appreciable depths of permafrost. These were built directly upon the permafrost, an approach without any known precedent. Precautions were taken to ensure stability and the performance of these dykes will be watched with interest. For ease of access these dykes were constructed in winter; consequently they were built as homogenous sand fills rather than of rolled clay construction.

The remaining dykes were of more conventional types and presented no serious design or construction problems. They are here referred to as the clay dykes. Construction of one form or another was carried out during all seasons of the year.

Topography and Geology

The Kelsey site lies within the geological region known as the Canadian Shield,[1] which in Manitoba, as in most other parts, is a comparatively featureless region peneplained by erosion and several glaciations to its present surface of comparatively low relief. The bedrocks are of Precambrian age, and in the Manitoba area they are generally igneous or metamorphic types. During Pleistocene times this bedrock surface was eroded by the Laurentide ice sheet which covered most of Eastern Canada and gave to the area its comparatively thin cover of overburden consisting of glacial tills, glacial outwash deposits, and post-glacial lacustrine deposits. Since the relatively recent disappearance of the last glacier, the formation of a new surface drainage system has been progressing but, because of the flat topography and the nature of the overburden, this system is still highly disorganized and contains innumerable lakes, rivers, and swampy areas. The Nelson River threads its course for 375 miles from Lake Winnipeg to Hudson Bay and drops in elevation a total of 712 ft.

From the outlet of Lake Sipiwesk to the inlet of Split Lake, the Nelson River flows in an almost due north direction. The Kelsey power site is located four miles upstream from Split Lake at a point where the river turns through almost 90° and descends about 20 ft. through a narrow gorge, formerly known as Grand Rapid. Immediately below the rapid, the river turns through 180°, flows westerly about one mile, then continues its northerly flow into Split Lake. In following this course, the river has left a small rock-controlled peninsula separating the river at the two elevations. Above the falls, the normal summer river elevation was about 573 ft. and the deepest sounding was to elevation 530 ft.; the comparable figures below the falls are 553 ft. and 460 ft. Ground surface maximum elevation in the vicinit of the development is about 635 ft.

Rock outcrops are almost invariably confined to the shores of the river and the surrounding overburden is made up of varying thicknesses of glacially derived soils. The area is generally tree covered, with small to moderate sized growth and, as a result of the poor drainage, swampy areas and muskeg are common. Occasionally the latter are as great as 15 ft. in depth. Beneath the general cover of 1 to 3 ft. of organic topsoil, grey varved clays and silts occur which usually become less plastic and siltier with depth. In the top 6 ft. these are usually weathered to a brownish colour. These clays, which may exceed 25 ft. in thickness, were deposited in the post-glacial Lake Agassiz which formed behind the retreating ice sheet.[2] They are underlain by a glacially deposited ground moraine of sand, gravel, and granular till which varies in thickness from zero to more than 20 ft. The total thickness of overburden may vary from several feet to more than 50 ft., with the greater thicknesses occurring as infilling in depressions in the rock surface.

The country rock at the site is a medium to dark grey paragneiss which is thought to be a granitized sedimentary complex.[3] This has been

Fig. 1. Location of the development

intruded by acidic granite gneisses and by basic gabbro dykes and sills, the latter being in some cases of fairly massive proportions. The gabbros have been intruded by minor dykes of diabase and lamprophyre, whereas the gneisses contain a number of small pegmatite dykes. The major rock outcrops occur near the rapid and on the peninsula immediately north of the rapid. In the latter location the gabbroic rocks predominate.

The regional strike of the gneissic rocks is in the east-west direction, but at the Kelsey site there are some local deviations of a minor nature from this trend, probably associated with the basic intrusions. The principal jointing parallels the foliation, striking east-west and dipping to the south at 50° to 70°. Minor sets of jointing strike northwest-southeast and north-south and dip at very steep angles. Known structural weaknesses at the site are of a comparatively minor nature, the largest one being a small shear zone or fault in the riverbed at the rapid. Topographic evidence does, however, suggest that this may be associated with a larger fault parallel to it and in the river on the north side of the peninsula. Those shear zones found in the exploratory drilling are recemented, and it may be safely assumed that those faults which do exist in the region are inactive. Moreover, the Canadian Shield is considered to be among the world's most seismically stable areas,[4] and the probability of the Kelsey structures being subjected to earthquake loadings is extremely slight. The bedrock was found to be of a highly competent nature, capable of supporting all structures safely and of providing supplies of rockfill and concrete aggregate.

Permafrost

In the Kelsey area the mean annual temperature is 25° F and the mean January and July daily temperatures are respectively minus 15° F and plus 59° F.[5] The site experiences, on the average, only about 140 frost-free days each year.[6] The mean annual total precipitation is 16 in., about a third of which occurs as snow. Approximately a half of the total precipitation occurs during the months of June, July, and August.[5]

The Kelsey site is very near the southerly boundary of the permafrost region; that is, the region in which ground still remains frozen as a result of the last glaciation. Permafrost was encountered in some shape, manner, or form, during construction in approximately 70% of the entire area. Its occurrence was, however, found to be sporadic in both the

vertical and horizontal directions, and over only a small percentage of area was the soil found frozen completely down to the rock surface. In general, the zone of active frost was 2 ft. to 3 ft. thick in the swampy areas and where organic cover existed, and 5 ft. to 6 ft. on the more exposed higher ground. Beneath the active zone, the varved clay and sandy moraine were found frozen to depths as great as 35 ft. below ground surface and at some locations it was found within 25 ft. of the Nelson River. In some cases permafrost was found in the rock. Where permafrost was encountered in the clays, the frozen pore water occurred in several forms from evenly distributed minute ice crystals to lenses of clear ice as great as 7 in. thick. Ice lenses of such thickness were exceptional and were found mainly in the sluiceway area. The most common form consisted of thin threadlike ice stringers at the contacts between the light and dark layers of the varved clay. The temperatures in the permafrost were found to vary between 29.5° and 32° F.

Natural Construction Materials

At Kelsey the only two materials economically available in any quantity within the immediate area were the bedrock and the plastic varved clays. Suitable rockfill for the dam, dykes, cofferdams, roads and for concrete aggregate were obtained from the various excavations and the quarries shown in Fig. 2. As a well-graded glacial till material could not be found at or near the site, the varved clays had to be used for construction of the impervious zones in the dam and dykes and for sealing the cofferdams. While this clay is abundant at the site, its use was at times made difficult by the existence of permafrost, by its high natural moisture content, and by its relative thinness in some locations. Suitable sand and gravel deposits were not found at the site and both screened and unscreened sand for concrete aggregate and for dam and dyke construction had to be brought in to the site by rail.

Explorations

Preliminary site surveys were made by the Water Resources Branch of the Department of Mines and Natural Resources, Province of Manitoba, in the summer of 1955 and the winter of 1955-6. Hand auger holes were drilled in some locations to determine the nature and depth of the overburden. Preliminary field geological mapping was done in 1956 by The Canadian Nickel Company Limited, and a number of wash borings were made the same year by The Manitoba Hydro-Electric Board to determine overburden thicknesses. These were followed in late 1956 by photogeologic studies of the power site and the route of the railway line from Pit Siding to Grand Rapid. Additional explorations by diamond drilling and auger boring methods and more detailed geological mapping were begun in April, 1957, and were carried out intermittently until 1959 While most of the drilling was done by conventional exploratory methods, a departure from the normal was made in the investigation of the foundations for the sand dykes. Permafrost was known to exist at the locations of these two structures and it was considered necessary to obtain a reasonably complete picture of the foundation conditions. Continuous core from the frozen varved clay was obtained fairly successfully in the winter by the use of a double-tube, swivel-head core barrel with fuel oil as the drilling fluid.

Arrangement and Schedule of Development

The arrangement of the Kelsey development is shown in Fig. 2. The powerhouse is located to the west of the rapid on the north side of the peninsula. Water is supplied to the powerhouse through an intake channel which has been cut across the neck of the peninsula. The sluiceway is located in a cut made through another peninsula, that immediately southeast of the rapid. The river is blocked at the rapid by a rockfill dam. The dam extends from the sluiceway structure to the centre dyke which runs along the peninsula to high ground. Dyke No. 1 west extends from the west end of the powerhouse to high ground to the southwest. At the east end of the sluiceway, dyke No. 1 east provides a seal between the concrete bulkhead of the sluiceway and high ground in this area. South of the main structures two sand dykes, both founded on permafrost, one on each side of the reservoir, close low gaps around the reservoir. Several small freeboard dykes are located south of dyke No. 2 west on the west side of the reservoir.

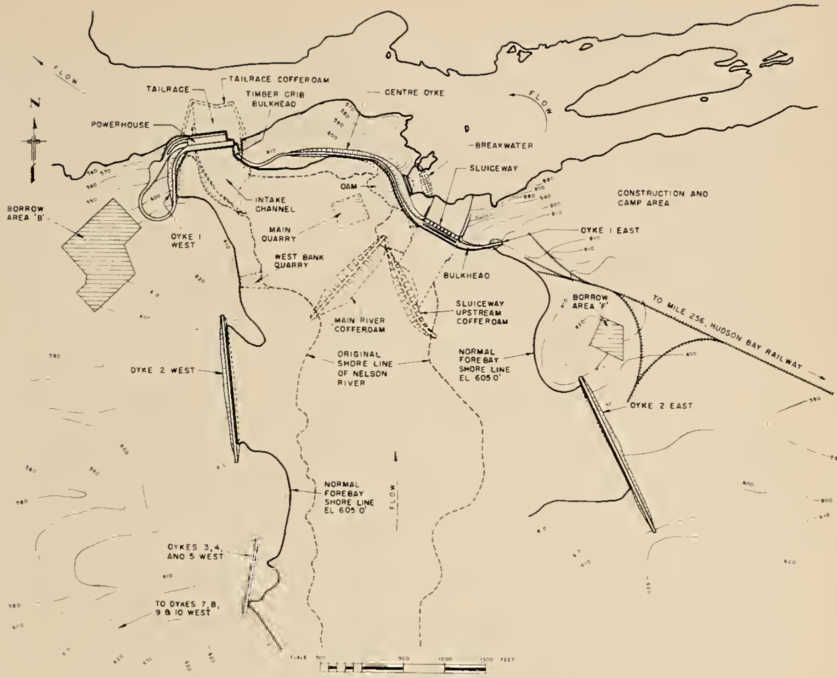

Fig. 2. General arrangement of the development

The operating level of the forebay will be elevation 605 ft., a level approximately 30 ft. above natural river level. This increase in water level plus the natural drop of approximately 20 ft. which existed at the rapid, provides an operating head of 50 to 55 ft. at the powerhouse. Under normal operation, the forebay level will be relatively constant; that is, it will fluctuate not more than 1 or 2 ft.

Access to the site is by a railway spur from the Hudson Bay Railway to the east or sluiceway side of the site. To obtain access to the west side of the river during construction, a temporary precast post-tensioned concrete bridge was erected to span the river immediately downstream from the main dam location.[7]

The construction schedule required that the sluiceway cut be excavated during the summer, fall, and winter of 1957, that the sluiceway structure be constructed during the year 1958, and that the Nelson River be diverted through the sluiceway during the low flow period in early spring 1959. Diversion of the river was accomplished by building a cofferdam across the river just west of the sluiceway intake at the location shown in Fig. 2. Construction of the rockfill dam was begun immediately after diversion and was completed by the end of 1959. The two longest clay dykes (the centre dyke and dyke No. 1 west) were constructed during the summer of 1959; the sand dykes during the winters of 1957-1958 and 1958-1959. Scheduling of powerhouse construction was relatively independent of that of other structures, except for dyke No. 1 west which abuts it.

The unwatering and diversion sequence involved the construction and removal or partial removal of some large cofferdams. A rockfill clay-sealed cofferdam was constructed immediately upstream from the sluiceway intake. This permitted excavation of the cut and construction of the sluiceway structure to be done in the dry. After completion of this work, this cofferdam was removed to the sluiceway cut invert level. The main river cofferdam, similar in construction to the sluiceway cofferdam, was then advanced north-eastward a total of 1300 ft. across the river to divert the entire flow through the sluiceway. The potentially difficult closure of this cofferdam was achieved with comparative ease, as the river flow at the time of closure was down to 45,000 c.f.s. from a flow of 80,000 c.f.s., which was the maximum likely to occur at this time of year. This cofferdam served as the upstream cofferdam for the construction of the dam and also for completion of excavation of the powerhouse intake cut. The downstream cofferdam for the dam consisted of the first stage of the dam rockfill, sealed on its downstream side by clay. The cofferdam for unwatering the powerhouse and tailrace was a rockfilled timber crib with steel pile sheeting.

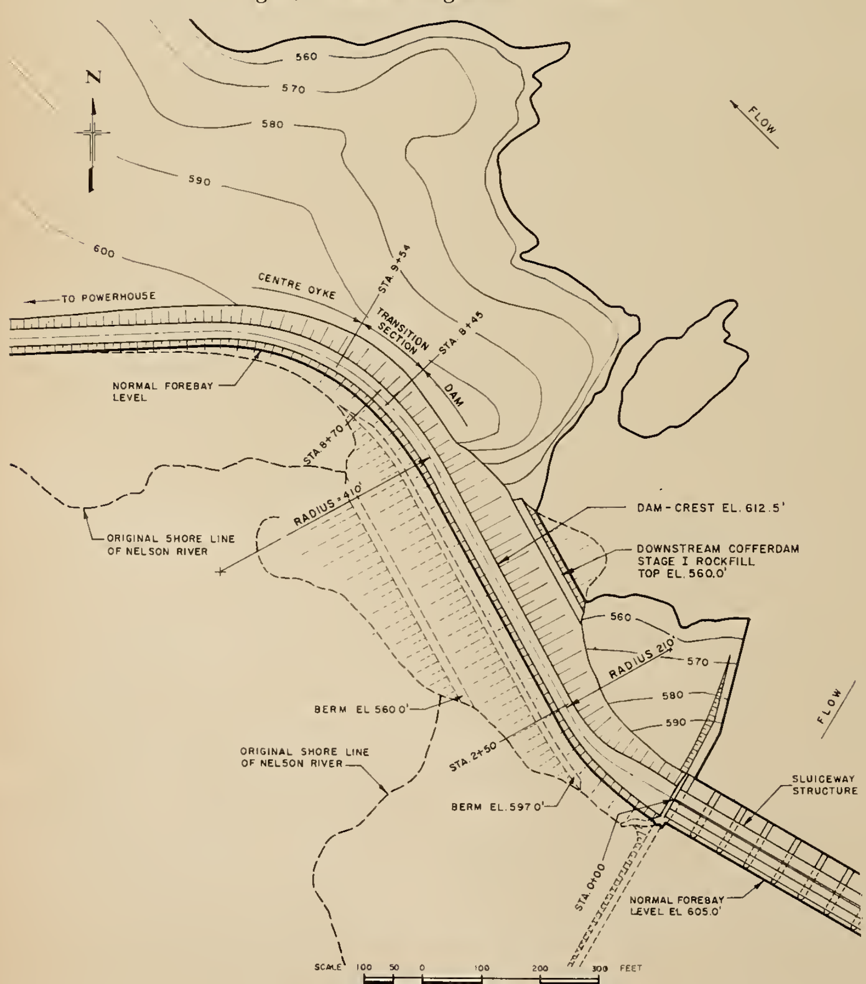
Dam Design

Arrangement and Type:

The approximate locations of the major structures were determined by the general arrangement of the project which required that the Nelson River be blocked by a dam about 120 ft. high at, or very near, the rapid. The exact location and the orientation of this structure were determined in such a way that the volume of materials required would be as small as possible and that the permanent access provisions would be both satisfactory and consistent with the greatest overall economy. These considerations resulted in the dam being located so that, together with the sluiceway to which it abuts on the south bank, and the centre dyke which it joins on the north bank, it describes a long reverse curve with the main portion of the dam occupying a straight section, about 480 ft. long, in the centre. The general arrangement of the dam is shown in Fig. 3.

The dam is of the rockfill type with an upstream impervious sloping core. It has a crest length of 955 ft., a maximum height of 120 ft., and contains 288,300 cu. yd. of material. Sound rock existed at the surface or at a very shallow depth throughout the actual damsite, and foundation conditions were suitable for the construction of several types of concrete or rockfill dams. Consideration was given to a concrete gravity structure, but in view of the availability of good quality rockfill from either structural excavations or from quarries, a rockfill dam proved to be appreciably more economical and was consequently adopted.

Fig. 3. General arrangement of the dam



The sloping core design was chosen in preference to one with a vertical or near-vertical core, chiefly because of the greater flexibility in construction scheduling that is achieved with it. The downstream cofferdam is an integral part of the dam and was designed to be constructed as stage one of the main rockfill placing operation. The remainder of the main rockfill was designed to be placed in one high lift at a rapid rate in order to permit the construction of transition zones, impervious core, and supporting zone to proceed independently. Where a short construction season and uncertain weather conditions are encountered, this flexibility in scheduling the material placing is advantageous. A typical cross section of the dam is shown in Fig. 4.

Dam Materials: Rock for both stages of the main rockfill and for the supporting zone was permitted by the specifications to vary in size from rock dust, which together with rock smaller than 4 in., unsound rock, and soil, was not allowed to constitute more than 15% of any load, to a maximum size which was to be determined only by the capacity of the loading and hauling equipment. These specifications were rigidly enforced for the main rockfill, but for the supporting zone these were relaxed somewhat to allow the use of finer rock which was produced in the sluiceway excavation.

The impervious core is protected by three transition zones on the downstream side and two on the upstream side. The material for zones A and D was a natural sand, and those for zones B, C, and E, were produced by crushing and screening rock at the site, and were broadly specified as follows:

Zone B — 1½ in. to ¼ in.
Zone C — 7 in. to 3 in.
Zone E — 7 in. to 1½ in.

The gradation ranges of the impervious core material and the transition materials actually used are shown in Fig. 5.

Borrow pit explorations indicated that the varved clay deposits con-

tained soil of varying properties. The upper 4 ft. to 8 ft. consisted of a brown plastic clay. Beneath this upper layer, the clay became less plastic with depth and more greyish in colour. Underneath this grey silty clay, and just above the rock surface, there was a layer of almost pure silt which was not used in the dam or dyke construction. The comparative properties of the brown plastic clay and the grey silty clay shown in Table II were determined during borrow pit investigations prior to construction.

Early considerations suggested that the brown plastic clay would, because of the greater plasticity and smaller disparity between the natural and optimum water contents, be more easily handled and placed by the construction equipment. The design of the upstream slope of the dam was, therefore, based upon the assumption that this brown plastic clay would be used. Accordingly, a complete set of triaxial compression tests including consolidated undrained, unconsolidated undrained, drained, controlled stress ratio, and pore pressure dissipation tests, was performed on a sample of this clay with the properties shown in Table III.

Stability, Settlement, and Seepage: Stability calculations were made by the slices method[8] for varying geometrical shapes of the upstream slope. These analyses were made in terms of effective stresses and were two-dimensional in scope.

TABLE III

Properties of Brown Plastic Clay

Specific gravity	2.70

Activity	0.59
*Optimum water content	24.7%
*Maximum dry density (pcf)	96.8
Coefficient of permeability (f.p.m.)	3×10^{-8}
Shear strength parameters—see following discussion.	

*As determined by the Standard Proctor Compaction test.

Three conditions of loading were considered, the construction case, the steady seepage case, and the drawdown case. The placement water content was assumed to be 31% and from the triaxial tests the effective shear strength parameters for the construction case, c' and $\varnothing'$, were determined to be 150 p.s.f. and 24° respectively. The pore pressure parameter $\bar{B}$[9] was estimated from the triaxial tests to be 0.55. Using these values, the minimum overall safety factor for a slope of 2.25 to 1 above elevation 590 ft., and 3.0 to 1 below elevation 590 ft. with a 15-ft. berm at elevation 560 ft., was calculated to be 1.52 for the case where the dam was completed to full height and the rising reservoir had reached elevation 565 ft.

For the steady seepage case, it was assumed that the core was completely saturated and that the steady seepage flow net for a reservoir elevation of 605 ft. had been established. The pore pressures were determined from this flow net and c' and $\varnothing'$ were determined from the triaxial tests to be 70 p.s.f. and 23° respectively. The minimum safety factor for the same upstream slope for this condition was determined to be 1.90.

For the drawdown case, it was assumed that steady seepage conditions had been established and that drawdown took place instantaneously $\bar{B}$ was therefore assumed to be 1.0 and the minimum safety factor was found to be 1.45 for the maximum possible drawdown to elevation 570 ft.

The material actually used for core construction consisted largely of the grey silty clay with the properties shown in Table V. Laboratory tests had shown that the effective strength parameters of this material differed only slightly from those determined for the brown plastic clay, c' and $\bar{B}$ being slightly higher and $\varnothing'$ remaining essentially the same. However, the very wet state of the material which resulted from the borrow pit conditions and the necessity to complete the dam in 1959, led to the conclusion that pore pressures higher than those assumed would occur. In order to maintain the same minimum overall safety factor of about 1.5, the upstream slope was modified to that shown in Fig. 4 by the continuation of the 3.0 to 1 slope up to elevation 597 ft., and the addition of a 10-ft. berm at that level. The dam was constructed to this section.

The rockfill and the transition materials were assumed to have the properties shown in Table IV.

TABLE IV

Properties of Rockfill and Transition Materials

	Rockfill	*Transition Materials*
Porosity	29%	26%
Moist density (pcf)	120	125
Submerged density (pcf)	76	75
Angle of shearing resistance ($\varnothing$ in degrees)	45	40

In a sloping core rockfill dam of the Kelsey type, settlement of the crest can be expected to occur as a result of the adjustment of the rockfill to the increasing load. The magnitude of this settlement is impossible to calculate rationally but, on the basis of past experience, it is expected to be very small and to take place largely during construction. An allowance of 18 in. was made by superelevation of the crest; that is, 1.25% of the height of dam. Monuments were established along the crest to determine the movements of the dam.

Seepage from the reservoir through the impervious core will be negligible in view of the extremely low permeability of the clay. The downstream transition zones A, B, and C, have, however, been designed in accordance with accepted practice and, where applicable, established filter criteria[10] to prevent migration of particles from one to the next.

To control seepage through the rock beneath the dam, blanket and curtain grouting was performed, and consisted of three rows of holes beneath the core and extending from Station 0+00 to Station 8+70. The outer two rows consisted of 15 ft. deep holes at 20 ft. spacings, whereas the centre row consisted of holes varying in depth from 15 ft. on the abutments to 50 ft. at the deepest part of the dam foundation. These holes were also spaced at 20 ft. centres. Additional grouting to treat zones of fractured rock was specified as required.

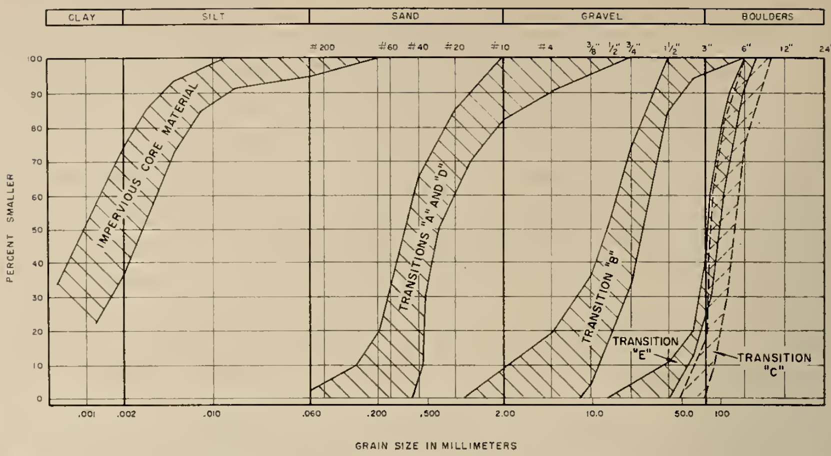

Fig. 5. Particle size distribution of impervious core and transition materials in the main dam

Dam Construction

Unwatering: The upstream cofferdam across the Nelson River was constructed as described previously. It was closed in February, 1959 and effectively sealed in June, 1959. A small secondary upstream cofferdam was built just upstream from the riverbed quarry to facilitate unwatering of the immediate area of the dam. The downstream cofferdam across the river was, for reasons of economy and because of space restrictions, incorporated as stage one into the construction of the rockfill. This rockfill was completed in April, 1959 and was effectively sealed in July, 1959. The design of the downstream cofferdam was similar to the one upstream in the main river, and consisted only of a layer of clay deposited in water on the face of the rockfill. Considerable difficulty was encountered in producing an effective blanket seal, and this was attributed to the erosive action of the flow through the sluiceway as it emerged in close proximity to the toe of the cofferdam. This difficulty was eventually overcome by the construction of a rockfill breakwater immediately downstream from the cofferdam.

Seepage into the immediate area of the dam was collected in two natural sumps, one on each side of the impervious core. The larger amount of seepage was collected in the downstream sump and this was removed by a submersible pump installed at the bottom of a 30 in. diam. corrugated steel pipe, laid between the main rockfill and transition zone C and running up to about elevation 595 ft., to discharge outside the downstream cofferdam. Pumping on the downstream side of the core was continued until construction was sufficiently advanced to allow the water pressures on both sides of the core to be equalized. Pumping was then discontinued and the 30 in. pipe was filled with concrete.

Foundation Treatment: The abutments of the dam above water level were generally covered with clay varying in depth from 3 ft. to 15 ft., whereas beneath the river level the rock surface was relatively clean and smooth, although highly irregular. As much as 15 ft. of sand, gravel, and boulders, were found in the deepest part of the riverbed, and boulders up to 6 ft. diam. were found on the south bank. The rock was mainly a hornblende-biotite gneiss which was cut by numerous vertically dipping pegmatite and gabbro dykes. Surface weathering of the rock was of very limited depth, but weathering along joints particularly near the former water line, extended to depths as great as 8 ft. The rock surface beneath the river contained many shallow potholes and a number of larger ones ranging up to 10 ft. diam. and 10 ft. deep. Steep rock faces had been formed along both sides of the river in its deepest part because of the nearly vertical dip of the foliation joints, and along the south bank this face was overhanging. Near the foot of this south wall, a steeply dipping 9 ft. wide shear zone was found striking in an east-west direction. Several other minor shear zones were found, but all such structural weaknesses were tight.

The specifications required that the area beneath the impervious core and transition zones A, B, and D, be excavated to sound rock. The initial stripping was done with a bulldozer and a dragline and the final cleaning was done by sluicing and hand labour. About 3600 cu. yd. of loose and overhanging rock were removed by trimming back the walls to slopes of 1 horizontal on 2 vertical. The previously mentioned shear zone, the potholes, and the badly weathered joints, were dug out to depths which reached a maximum of 8 ft. in the shear zone, and were subsequently filled with concrete to provide a conveniently smooth area upon which to place the clay core material. Approximately 900 cu. yd. of concrete were thus placed. The minimum rock elevation reached was 492 ft.

Beneath the main rockfill, the supporting zone, and transition zones C and E, pockets of gravel and boulders were allowed to remain in place, and cleaning of the rock was confined to the removal of clay and sand and the cleaning of the larger potholes which were subsequently refilled with graded rock.

After the cleaning and surface concreting had been completed in the core area, the grouting of the rock was begun. The two outer rows of blanket holes and the shallower holes in the centre row were drilled with jackhammers, whereas the deeper curtain holes were diamond drilled with AX size bits. One hundred and forty-nine holes with a total length of 2816 ft. were drilled, pressure washed and pressure tested prior to grouting. Cement grout was used throughout and was injected into the holes in stages from the bottom of the hole up, using a single expander. Grouting pressures were limited to 20 p.s.i.g. at the surface and increased by 1.5 p.s.i.g. for each foot depth of rock and concrete. Of the 149 holes drilled, 80 accepted no grout and the remaining 69 accepted a total of only 123 bags of cement. Most of this grout penetrated the jointing in the upper 3 ft. of rock, and virtually no grout was consumed at the lower elevations in the curtain holes. In view of this experience in the first few 50 ft. long holes, the length of the remaining holes was reduced to 30 ft.

Rockfill: The rockfill placing was divided into three parts: stage one, which constituted the downstream cofferdam, stage two or the main rockfill, and the upstream supporting zone. The rockfill was obtained from the excavations of the sluiceway channel, the intake channel, and the powerhouse, and from two quarries, one on the west bank about 1800 ft. southwest of the dam, and the other in the riverbed immediately upstream from the dam. In the riverbed quarrying operation, a 20 ft. to 35 ft. face was worked, and drilling of 2.5 in. diam. holes on a 7 ft. by 7 ft. spacing was done with wagon and track-mounted percussion drills. The loading of rock was done with 2½ and 1½ yd. shovels. Hauling was done by 15 ton and 18 ton trucks and 34 ton PR20 and PR21 rock wagons. The greatest number of hauling units working at any one time was eight trucks and six rock wagons.

The stage one rockfill was obtained directly from the powerhouse excavation and from stockpiles of rock from the sluiceway channel. It was end-dumped into the river from a 35 ft. to 40 ft. wide crest at an elevation of 560 ft. The maximum height of this fill is about 65 ft. and, although it could not be sluiced during placing, it is considered that adequate compaction was achieved by virtue of the water flowing through the fill at the time of placement.

The stage two rockfill was obtained from stockpiles of rock excavated from the sluiceway channel, the powerhouse, and both quarries. It was deposited in three lifts, the first of which progressed outwards from the north abutment at a crest elevation of 586 to 590 ft. The maximum height of this lift was, therefore, about 90 ft. The lift was sluiced during placing with a water jet directed from a manually controlled monitor mounted at the end of a 50 ft. long cable-controlled boom attached to a D-6 bulldozer. The nozzle pressure was 125 p.s.i.g., and the volume of sluicing water was four times the volume of dumped rock.

Following the completion of the first lift, a layer of up to 3 ft. of fines was removed from the crest by backhoe and sluicing. A second lift of about 10 ft. in height was placed using selected rock with no sluicing. The final lift of about 3 ft. was placed at the same time as the upper portion of the impervious core to bring the main rockfill up the finished elevation of 596-598 ft.

The supporting zone rockfill was obtained from the stockpiled sluiceway channel rock and from the riverbed quarry. For reasons of stability, its top elevation during construction was maintained very nearly equal to that of the impervious core. This was done by placing a zone of small rock adjacent to transition zone E in 2 ft. to 3 ft. lifts and by end-dumping large rock on the upstream face of this zone. The upstream face of the dam was trimmed to its final lines and grades with a bulldozer and a backhoe. No sluicing was done on the supporting zones.

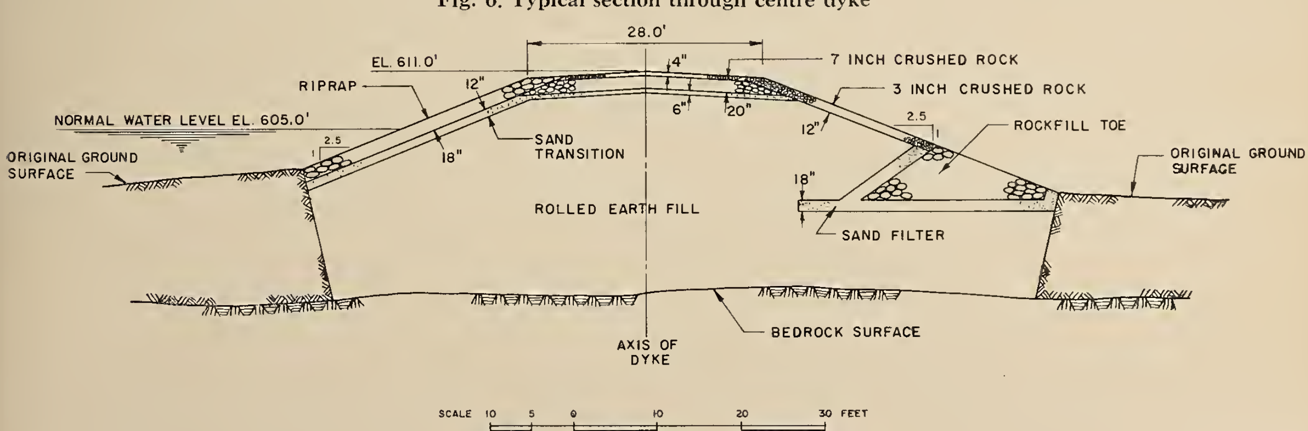
Transition Zones: The material for transition zones C and E was produced at the site by crushing and screening rock from the various excavations and the two quarries. Some of this was stockpiled and used later, while some was taken directly from the crusher to the dam. The transition C material which had a 7-in. to 3-in. grading was, for reasons of access, placed by dumping from the top of the rockfill. Despite the heights of dumping, which exceeded 70 ft., segregation of the material was not appreciable. The transition E material had a 7 in. to 1½ in. grading, although above elevation 590 ft., some 3 in. to ¼ in. was substituted. Transition E was placed in 1 ft. thick lifts which were never more than about 2 ft. below the adjacent transition D level.

Transition B material was produced by crushing and screening excavated and quarried rock at the site. A temporary shortage of this material developed during August and September of 1959, and approximately 8,000 cu. yd. of crushed and screened gravel were brought in by rail from Thompson. The transition B material was deposited in the deep channel section from the south wall by a chute, then spread by bulldozer. Above elevation 550 ft. it was dumped at various points from the top of the rockfill and spread and compacted by bulldozer. Placing of this zone was allowed, for convenience in construction, to reach a level as much as 15 ft. in advance of transition A.

The sand for transitions A and D was a selected pit-run material obtained from a large excavation previously established at pit siding. It was excavated in the pit by a dragline and hauled in rock wagons and trucks to the rail spur where it was stockpiled. It was then loaded into gondola railway cars with a dragline and hauled the 13 miles to the site where it was unloaded with a clam bucket and taken to the dam in trucks. At the lower elevations the sand was placed through a 24 in. diam. pipe located on the south bank, while above elevation 540 ft., the pipe was located on the main rockfill. The material was spread and compacted with D-6 and D-4 bulldozers. To achieve the specified 75% of relative density, material was placed in layers less than 6 in. thickness. Difficulty was experienced in late 1959 with freezing of the sand, and calcium chloride was added in amounts up to 10 lb. per cu. yd. of sand to allow placing at temperatures down to 0° F. Transitions A and D were both maintained at all times within a few feet of the elevation of the impervious core.

Impervious Core: The clay material for impervious core construction was present in almost unlimited quantities near the site and a number of potential borrow pits were demarcated. It proved necessary, however, to use only two of these, borrow areas B and F. Most of the material for the dam came from area B, with area F being used near the end of construction when continued

Fig. 6. Typical section through centre dyke



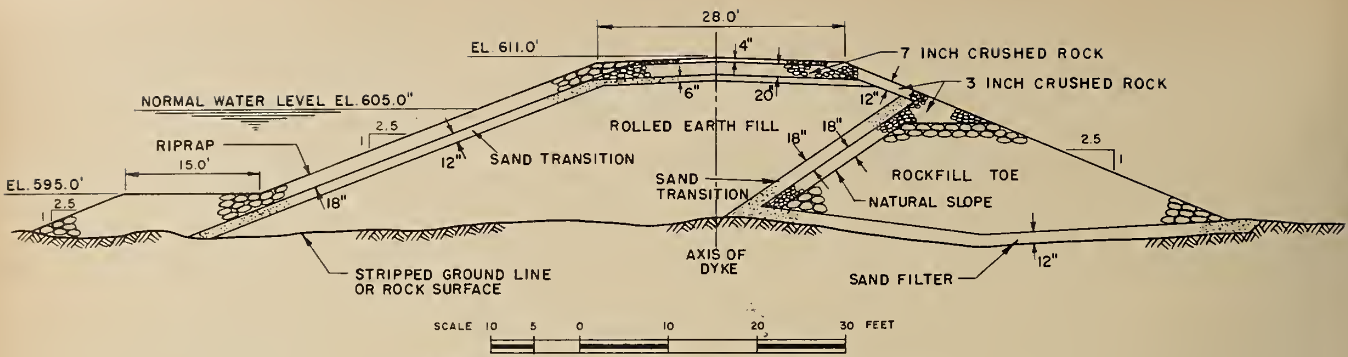


Fig. 7. Typical section through Dyke No. 1 West

operation in area B became difficult.

Stripping of the borrow areas was done as much as possible in the early spring months before the ground and organic cover thawed. Access into the pit was made difficult by the highly plastic nature of the clay, by its high natural water content, and by the occurrence of frequent rain. Consequently it was necessary to build good rockfill roads into the pit. The material was excavated with a 1½ yd. dragline and hauled to the dam in 10 ton tandem dump trucks. The maximum length of haul was almost one mile.

The clay was spread along the core with D-6 and HD-21 bulldozers and compacted in 6 in. layers with a four-wheel pneumatic-tired roller, ballasted only to a total weight of 13 tons. Above elevation 590 ft. the lifts were made thinner and compacted only with bulldozers. Pneumatic hand compactors were used in locations near rock surfaces and structures which were inaccessible to the roller. It was hoped that it would be possible to use only clay with a water content less than 120% of the standard Proctor optimum value and to obtain densities in excess of 95% of the standard Proctor maximum. However, in spite of attempts to drain the borrow pit and promote rapid drying of the material, it proved impossible to meet these requirements. Clay with a water content up to 130% of Proctor optimum was allowed to be used and densities as low as 90% of Proctor maximum were accepted. The average values were respectively 123% and 92%. To compensate for these lower densities, the upstream slope was further flattened and another berm was added at elevation 597 ft. as mentioned previously under "Design".

In late September, when the fill had reached elevation 588 ft., difficulty was experienced with freezing of the clay and, to overcome this, 78% fused-flake calcium chloride was added to the fill as it was loaded into the trucks at the pit in amounts of 5 lb. per cu. yd. of clay. Placing at any time was restricted to small areas of the core but freezing of the fill continued and frequent delays resulted from the need to stop placing and scrape off as much as 6 in. of frozen clay from the surface. In this manner the elevation of the fill was brought up to 591 ft. by October 7, at which time the daily range of temperatures was approximately 22° to 35° F.

The temperatures continued to drop, but the need to complete the dam and dykes before March 1960 led to the decision to finish the core placing under a heated enclosure. A timber framework, 19 ft. wide by 96 ft. long, was built and covered with polyethylene tarpaulins. Heat was supplied within this cover, and placing of fill beneath it was begun on November 6, at which time the daily range of temperatures was approximately 0° to 15° F. Placing within this enclosure continued as it was moved along the dam, and the fill was completed on November 22. Clay was not placed when the outside temperature fell below 0°, and the temperatures within the enclosure were maintained between 25° and 35° F. during this period. The calcium chloride content was increased to 10-15 lb. per cu. yd. and the trucks were covered with tarpaulins during transit. At the same time, it became necessary to remove the frozen surface material in the borrow pit by drilling and blasting.

Construction Statistics: The necessity to provide access at the north end of the sluiceway deck prior to the diversion through the sluiceway required the construction of a portion of the main dam between Stations 0+00 and 2+50 in the autumn of 1958. This was accomplished in August, September, and October, of that year. The stage one rockfill was completed in April, 1959, and stage two was completed near the end of August. Considerable difficulty was experienced in gaining access to the river channel after unwatering and it was not until August 13 that a road was cut through the steep rock bank to the riverbed. Foundation treatment and grouting proceeded throughout July, August, and the first half of September, and it was not until August 30 that the first clay was placed in the core. Between that date and November 22 the core, transition zones, and supporting zone were raised from about elevation 500 ft. to the finished elevation of 612.5 ft. A summary of the quantities of materials placed appears in Table VI.

Clay Dykes

Centre Dyke: Early explorations in the centre dyke area showed that the overburden consisted of a varved clay underlain by a thin layer of sand and gravel. Bedrock, which was mainly granite gneiss with numerous gabbro dykes, lay beneath the sand and gravel. Extensive zones of permafrost were found in the overburden. Subsequent excavation confirmed the widespread existence of permafrost with ice lenses up to ½ in. in thickness in the varved clay. It was concluded that the filling of the reservoir would change the existing thermal regime sufficiently to produce extensive thawing of the permafrost and that this would probably result in critical stability conditions in the dyke foundation. It was, therefore, decided to remove the overburden down to bedrock from beneath the dyke and to replace it with compacted unfrozen clay. This was done for a distance of approximately 850 ft. beyond the end of the dam, to the point where the natural ground surface reached elevation 605 ft. At this point, the height of the dyke is approximately 5 ft. and it was placed directly upon the stripped overburden. For this dyke, a homogeneous rolled earth-fill section was chosen because abundant impervious clay was available and no problem in connection with access for construction equipment was anticipated. A typical section of this centre dyke is shown in Fig. 6.

The clay fill was obtained from the upper layers of borrow area B. The properties of this clay are shown in Table V. It was placed several per cent wet of optimum and the resulting densities were somewhat lower than the maximum values. However, these variations from optimum placing conditions were insufficient to require any modifications in the comparatively flat slopes of the original design. Settlement within the dyke is expected to be small because of the low height, and virtually no seepage will occur through it because of the low permeability of the clay. A rockfill toe draining into the rockfill of the dam was incorporated to take care of surface runoff.

Sand for the transition layer and the toe filter was obtained from pit siding while the crushed rock for road dressing and downstream slope protection was obtained from the same sources as the comparably sized dam transitions. The riprap and the rockfill toe material were obtained from excavations and the quarries.

The overburden was stripped with a dragline after attempts to remove it with bulldozers proved unsuccessful, and the frozen material was disposed of close by, on the upstream side of the dyke. The bedrock was found to be sound and the joints tight. The surface was sluiced clean and the potholes were thoroughly cleaned, but no excavation of rock and no contact grouting were considered necessary. The excavation for the dike was made in the summer of 1958 and the side slopes were cut to, and left at a very steep angle until the placing of fill began in the early summer of 1959. Some difficulty was encountered with the thawing and sloughing of these slopes during placing operations. This was overcome by packing clay fill against them temporarily and subsequently removing this just prior to the placing of the permanent fill. The clay was hauled in 10 ton and 15 ton trucks, spread by bulldozers, and compacted in 6 inch lifts with loaded 10 ton and 15 ton rubber-tired trucks.

The junctions between the sloping core and the transitions of the dam and the corresponding zones of the homogeneous section of the centre dyke were unavoidably complex. The transition between the two types of section was accomplished over a length of about 90 ft. The visualization of the transition was facilitated, both in the design office and at the site, by the use of a block model.

Overburden excavation and foundation preparation were done mainly in August and September, 1958, and were finally completed in July, 1959. Fill placing began in May, 1959, and was completed in mid-November of that year under very severe conditions of freezing weather. Construction on this dyke was suspended during the period of intensive work on the dam when all available equipment was diverted to that structure. The quantities of material in this dyke are shown in Table VI.

Dyke No. 1 West: Dyke No. 1 west provides closure between the west end of the powerhouse headblock and the high ground to the southwest. The overburden in the area of this dyke consists mainly of a varved silty clay which is successively underlain by a silty sand layer containing sand and gravel lenses, a layer of relatively impervious sandy till of local extent, and bedrock. The permafrost in this area occurred sporadically and it was decided to excavate the overburden to bedrock only for a distance of approximately 100 ft. from the powerhouse. The remainder of the dyke was placed directly upon the varved clay.

The dyke was designed as a homogeneous rolled earth-filled section with slopes of 2.5 to 1 and a large rock toe on the downstream side. The clay fill was obtained from borrow area B and its properties are listed in Table V. It was placed several per cent wet of optimum with densities that were slightly below maximum values. Stability of this dyke was generally not critical in view of its small height, but because of the lower strength of the clay resulting from the wet placing conditions, a 15 ft. wide rockfill berm was added below elevation 595 ft. at the section of greatest height near the headblock. At this junction the clay fill was butted against, and wrapped around, a stub concrete wall extending from the headblock.

The other materials in dyke No. 1 west were obtained from the same sources as the comparable materials in the centre dyke.

The clay fill was hauled in 10 ton and 15 ton trucks, spread by bulldozers, and compacted in 6 inch lifts with 10 ton and 15 ton rubber-tired trucks ballasted to the point where they could just be operated without seriously rutting the fill. Aside from some trouble with locally thawed-out soft spots and poor drainage in the foundation beneath the first lift, no construction difficulties were experienced on this dyke.

The possibility of seepage occurring through the more pervious layers of silty sand with the reservoir filled, was considered sufficiently strong to justify the blanketing of these layered exposures in the overburden slope excavated for the intake channel. This blanket consisted of a 3 ft. thickness of rolled clay fill covered by a 1 ft. sand transition and an 18 in. layer of riprap. Subsequent excavation along the slope showed that these pervious layers were not as extensive as had been originally supposed and the blanket was extended only about 350 ft. upstream from the headblock.

Foundation excavation at the headblock was done in the late summer and autumn of 1958 and stripping of the dyke foundation began in February, 1959. Clay fill placing began in June, 1959, and the trimming of slopes to their final grades was completed in November, 1959. The quantities of materials in this dyke are shown in Table VI.

Dyke No. 1 East: In the area to the east of the sluiceway, the over-

*As determined in the Standard Proctor Compaction test.

burden consisted of silty varved clay with a maximum thickness of 30-35 ft. This clay contained extensive permafrost, the progressive thawing and sloughing of which, in the future reservoir, would have constituted a hazard to any structure founded directly upon it. It was, therefore, decided to remove all of the overburden above bedrock for a distance of 465 ft. from the sluiceway to the point at which it intersected the natural 605 ft. contour. A concrete gravity bulkhead was built in this section and dyke No. 1 east provides the closure from the end of the bulkhead to the 611 ft. contour.

Clay fill from borrow area F was used in a homogeneous section which was protected on both sides by a transition zone and riprap. The dyke was constructed in October and November, 1959, at which time difficulty with freezing temperatures was encountered. Excavation of sloughed-in material and placing of fresh clay fill within a heated enclosure was finally restored to, and the dyke was successfully completed in this manner.

Freeboard Dykes: Several very small dykes were required on the west side of the river to provide complete closure to elevation 610 ft. around the reservoir. The maximum height of these dykes is 6 ft. and their total volume is about 5400 cu. yd. As these dykes were all located in low swampy areas where access with conventional equipment during the summer months was difficult, it was decided to construct them in the winter. This was successfully accomplished during February and March, 1958.

The dykes were made of clay fill obtained from small borrow pits located near the dykes. Stripping of the frozen organic surface cover was done immediately ahead of the placing of the clay fill. The fill was obtained and placed in an essentially unfrozen state, although it was found impossible in a winter operation such as this to eliminate all frozen lumps. Those that were included in the fill were broken up during compaction by the bulldozer so that a fairly homogeneous fill was produced. Following the placing of the fill, the stripped organic material was pushed back onto the dykes to provide them with thermal and erosion protection.

Sand Dykes

Design: Approximately 3000 ft. upstream from the dam on either side of the river, there were two low-lying swampy areas which, in order to complete the closure of the reservoir, required the construction of two dykes each about 2000 ft. long and with maximum heights of 20 ft. These are indicated as dykes Nos. 2 east and 2 west in Fig. 2.

At both locations, the surface was covered by a layer of muskeg and topsoil from 1 to 4 ft. deep which made access to the sites very difficult in the summer months. This surface cover was successively underlain by a layer of varved silty clay of variable thickness, a sandy till or moraine layer with maximum thickness of 20 ft., and bedrock. The maximum measured depth to rock was about 45 ft. and the average depth was about 20 to 25 ft.

Permafrost occurred generally throughout both dyke areas in all forms from the fairly plastic type containing minute ice crystals, to the very hard lenticular type containing lenses as thick as 6 in. Numerous pockets of unfrozen soil did occur but, with the exception of two areas near both ends of dyke No. 2 east, these were generally neither extensive nor continuous. The permafrost extended to within 3 ft. of the surface and downwards to, and into, the bedrock.

This permafrost condition extended from the dyke location to within a very short distance of the river, and no suitable dyke line free from permafrost could be established. Consideration had to be given, therefore, to the effect of the creation of the reservoir on the existing thermal regime in the ground that would eventually be submerged. Such considerations indicated that thawing of the permafrost beneath the reservoir is inevitable. Calculations showed that the top few feet of frozen soil will thaw within the first few years of submergence, but that the rate of thawing will progressively decrease with depth. The exact pattern of thawing along the edges of the reservoir is virtually impossible to predict because of the

TABLE VI

Summary of Quantities of Materials in Dam and Dykes

Material	*Dam*	*Centre Dyke*	*Dyke No. 1 East*	*Dyke No. 1 West*	*Dyke No. 2 East*	*Dyke No. 2 West*	*Freeboard Dykes*	*Totals*

Totals	288,300	36,500	2,800	46,900	48,200	49,300	5,400	477,400

All quantities are in cubic yards

complexity of the boundary and initial conditions, but there appears to be little doubt that the thawed zone will extend beneath dykes Nos. 2 east and 2 west.

The design and construction of structures in permafrost regions customarily involves one of the following alternative proceedures:

(a) Locating the structure on material which will not become troublesome upon thawing;

(b) Removal of potentially troublesome overburden;

(c) Preservation of the existing thermal regime by natural or artificial means.

In the case of these two structures, alternative (a) did not exist, and studies showed that alternatives (b) and (c) would have been excessively costly and relatively impracticable. These approaches were rejected, therefore, in favour of a design which has no known precedent. This provides for the construction of the dykes upon the existing overburden and incorporates features intended to allow the dykes to accommodate the movements, and to be stable under the conditions that will probably result from the thermal changes in their foundations.

Because of the high ice content in the varved clay, its thawing will produce a large amount of free water and, by virtue of the clay's low permeability, this water will not readily escape. It was considered that the existence of this free water, together with the softening of the surrounding clay to which it would contribute, might result in critical foundation stability conditions, even though the height of the dykes is very small and the surrounding natural slopes are comparatively flat. As the rate of consolidation of the varved clay, subsequent to its thawing, might well be the determining factor in this stability condition, it was decided to facilitate the drainage of the foundation by the use of vertical sand drains.

Beneath each dyke a grid pattern of sand drains was laid out to extend from the downstream toe to a distance of approximately 50 ft. beyond the upstream toe. The spacing of the rows of drains varied from 10 ft. centres beneath dykes greater than 15 ft. in height, to 20 ft. centres beneath dykes less than 10 ft. The drains were 14 in. and 16 in. in diameter and extended to a depth of 25 ft. or to refusal of the drill. In the row farthest downstream, the maximum depth was increased to 40 ft.

The two dykes have identical cross sections, as shown in Fig. 8, and consist of homogeneous fill of compacted sand with upstream and downstream slopes of 4 to 1 and 2.5 to 1, respectively. These are protected by transition zones and coarse rock. The exterior slopes of the dykes are 4 to 1 on the upstream side and 3 to 1 on the downstream side. The use of sand, rather than clay, for the main body of the dyke section was determined primarily by the important advantage that could be gained by building these structures during the winter, when the freezing of the ground cover virtually eliminated the difficulties of access and mobility that would have been encountered by conventional construction equipment in the summer months. Moreover, there was the consideration that a sand fill could accommodate itself to the inevitable differential settlements more readily than could a clay fill.

The sand fill is a pit-run material and the sand transition is a coarser unscreened material selected from the same pit. The coarse transition and filter is a crushed rock grading from 3 in. to ¼ in., and the maximum size of the riprap was about 18 in. The particle-size distributions of these various materials are shown in Fig. 9.

As the slopes on these dykes are appreciably flatter than those required for limiting equilibrium in a granular fill, the only possible sliding failure that can occur is a foundation failure. Such a failure on the downstream side is virtually impossible because the thawing of the permafrost will not extend beyond the downstream toe, nor even reach this area for many years. A foundation failure can occur only on the upstream side and here the safety factor at any time will depend on a number of factors. These are:

(a) The loss in shear strength of the varved clay due to the thawing process;

(b) The rate at which the free water released by thawing can escape;

(c) The rate at which the varved clay can gain in shear strength as a result of consolidation.

Quantitative evaluation of the effects and interrelationships of these factors has been possible only in an elementary form, but the results of triaxial consolidation testing of frozen and thawed soil cores indicate that the consolidation process can be expected to keep pace with the thawing. Under such conditions, it is expected that little loss of strength will occur, and the stability of the dykes will, therefore, be assured.

Settlement of the dyke crests is inevitable and will result from the following four causes:

(1) The escape of the free water produced by thawing of the clear ice in the large voids;

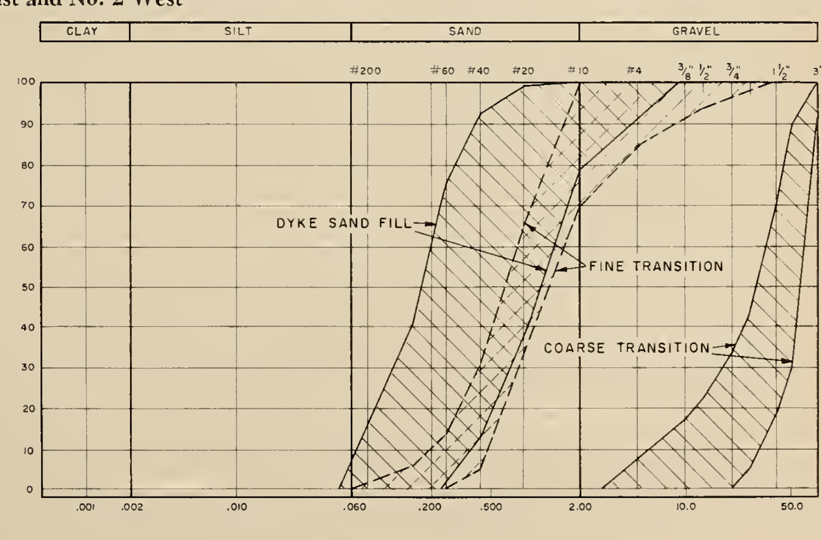
(2) The decrease in volume resulting from the thawing of the ice in the minute voids;

(3) The consolidation of the unfrozen and thawed clay in the foundation;

(4) The consolidation of the sand fill in the dyke.

The total settlement at any point will be largely governed by the depth and nature of the perma-frost at that point and, as these are both highly variable, considerable differential settlements are expected. Estimates indicate that the maximum ultimate settlement will be of the order of 5 ft. As some future maintenance to take care of this setttlement is to be expected, no superelevation allowance was made in the original construc-

Fig. 9. Particle size distribution for sand fill and transition materials in Dykes No. 2 East and No. 2 West



tion. The dyke crests were designed to facilitate future extension upwards, and a stockpile of sand has been provided at the site for such future use.

Because of the highly impervious nature of the varved clay, no foundation underseepage should occur. The comparatively pervious nature of the sand fill will, however, result in steady seepage through the dyke. This seepage has been estimated by flow net analysis and use of a coefficient of permeability equal to 10^{-2}, cm. per sec. to be approximately 0.8 c.f.s. for the entire 2000 ft. of each dyke. Collection ditches were provided on the downstream side of each dyke to facilitate the discharge of seepage into natural water courses, thereby preventing the ponding of it behind the dykes where its presence might disturb the downstream thermal regime of the soil and cause undesirable thawing.

Construction: Stripping of organic matter and topsoil from the dyke foundations was done during March and December, 1958. Almost all of the stripping was done by bulldozer. This operation was difficult because of the hard frozen condition of the topsoil and because of a swampy area at each dyke, which was too soft to support even tracked vehicles. These latter areas were stripped by blasting and with the use of a 1½ cu. yd. dragline.

The holes for the sand pile drains were drilled by two truck-mounted power augers, a 16 in. diam. machine, and a 14 in. diam machine. Approximately 59,000 lin. ft. of drilling was accomplished at an average rate of 38.6 ft. per hr., all of it being done during the winter months with no difficulty. Drilling through the frozen clay proved easy, but a number of the holes were stopped slightly short of their designed depth by boulders in the underlying sandy till which the augers could not penetrate. The drilling statistics are presented in Table VII.

TABLE VII

Summary of Drilling Data for Sand Drains in Dykes Nos. 2 East and 2 West

	Dyke No. 2 East	*Dyke No. 2 West*	*Both Dykes*
Number of holes	1,165	1,456	2,621
Linear feet drilled	24,383	34,578	58,961
Average length of hole (feet)	20.9	23.7	22.5
Rate of drilling (feet per hour)	34.6	42.1	38.6

The holes were filled with sand, similar to the dyke fill sand, deposited in them in a loose state. The drains upstream from the dyke were topped off above ground surface with about a cubic yard of sand each, in order to assure good drainage in future.

The sand fill and sand filter material were obtained from pit siding in the same operation described previously for transitions A and D of the dam. The sand for these various uses was classified and stockpiled according to grading at the pit. After being unloaded from railway cars at Kelsey, it was hauled in 15 ton to 18 ton Euclid and 10 ton tandem trucks to the dykes where it was spread and compacted in 12 in. layers with HD-21 tractors. No measurements of the density of the fill were made, but the compaction methods used produced very dense fills.

Materials for the upstream coarse transition and the downstream slope protection were obtained by crushing of excavated rock and were deposited and spread by bulldozers operating up and down the dyke slopes. The upstream riprap layer was material selected for size from the excavated rock stockpiles.

Excavation of the drainage ditches and channels was done in winter and was accomplished by blasting and the use of a dragline and hand labour. Subsequent sloughing of the slopes necessitated a cleaning out of these channels.

On dyke No. 2 west, the stripping and sand drain construction was carried out in March and April, 1958, and the sand fill was placed in April, 1958, and January, 1959. On dyke No. 2 east, the stripping was done in March and December, 1958, while the sand drains were installed in January and February, 1959. The sand fill in this dyke was placed in February and March, 1959. Excavation of the downstream drainage ditches for both dykes was done in November and December, 1958. The quantities of the various materials used in these dykes are shown in Table VI.

Performance: As the construction of water-retaining earthworks, such as dykes No. 2 east and No. 2 west, directly upon permanently frozen overburden is, to the best of the authors' knowledge, without precedent, considerable interest in their future performance has already arisen. In the hope that careful observation of these dykes will provide valuable data for use in similar problems in the future, a program of instrumentation designed to measure the changes in the thermal regime and the resultant settlements of the varved clay foundation beneath dyke No. 2 east, has been undertaken by the Division of Building Research of the National Research Council of Canada in conjunction with The Manitoba Hydro-Electric Board. The significance of the results being obtained from this program probably will not become apparent for some time, but when it is sufficiently clear to allow a fair appraisal of the performance of these structures, the results will be made available through publication.

Acknowledgements

The design and the supervision of construction for the Kelsey Generating Station were done by H. G. Acres & Company Limited for The Manitoba Hydro-Electric Board. The general contractor for the project was McNamara-Brown & Root. Mr. R. Peterson, acting in an advisory capacity to The Manitoba Hydro-Electric Board, reviewed the designs of the dam and dykes. Helpful discussions concerning the permafrost aspects of the earthworks were given by members of the staffs of the Division of Building Research of the National Research Council of Canada, and of the Arctic Construction and Frost Effects Laboratory of the U.S. Army Corps of Engineers.

The authors are grateful to The Manitoba Hydro-Electric Board and to H. G. Acres & Company Limited for their permission to present this paper, and they wish to thank their colleagues in these two organizations for their assistance in its preparation.

CHUTE-DES-PASSES 345 KV TRANSMISSION LINE

H. B. White, M.E.I.C.,
Development Engineer—Transmission Structures, Aluminum Company of Canada, Limited, Montreal.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

The Chute-des-Passes generating station of the Aluminum Company of Canada, Limited, was completed early in 1960 with the installation of the last of five 200,000 hp. units. A 345 kv. transmission system was built to transmit this power a distance of 91.2 miles to the south for interconnection with the existing 2.6 million hp. Saugenay Hydro-Electric System. Design and construction features of this transmission system are recorded in this paper along with data on a new type of aluminum guyed tower that was installed in a short section of one of the lines.

THE storage dams at Lac Manouan and Passes Dangereuses were built in 1940-1943 to provide regulation of the Peribonka River, a main contributor to the flow of the Saguenay River which serves the Isle Maligne, Chute-a-Caron and Shipshaw power plants. This control of the Peribonka River also made power generation on the Lower Peribonka practical, and installation of the Chute-a-la-Savanne and Chute-du-Diable plants followed in 1951-1953.

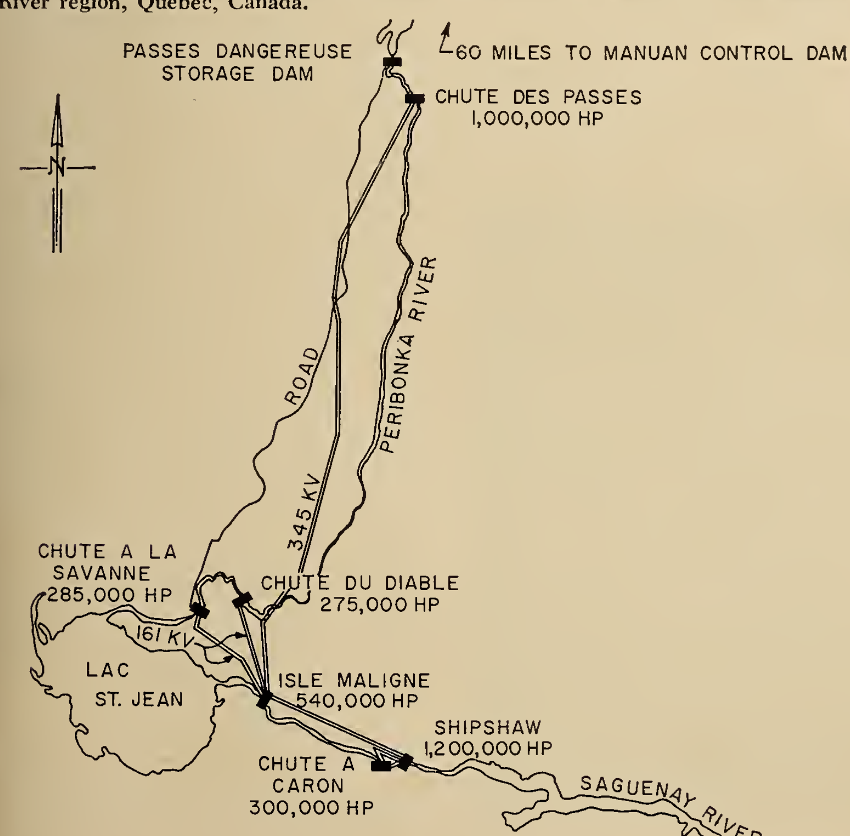
The Passes Dangereuses storage dam has a head of only 135 ft. but by skirting the dam with an 8 mile long system of intake and discharge tunnels, it is possible to add about 500 ft. of static head due to the rapid fall of the river below the dam and develop at Chute-des-Passes a maximum output of about 750 Mw.

System Voltage

The lower twelve miles of the Chute-des-Passes transmission line route between Isle Maligne and the crossing of the Lower Peribonka is through flat and often swampy marginal farm lands with easy access. The remainder of the route varies from mountains to swamps with difficult access.

The full load of 750 Mw. was considered to be too large and important for one tower line in view of the problems of quick access for maintenance and as prolonged loss of the entire load could not be tolerated. On the other hand, transmission at the existing system voltage of 161 kv. would have required an excessively large and costly number of circuits and was ruled out. A system of two double circuit 230 kv. tower lines (4 circuits) was a possibility but was estimated to cost considerably more than a system of two single circuit 345 kv. bundled conductor lines which was selected.

Fig. 1. Map showing principal hydro-electric stations in Lake St. John-Saguenay River region, Quebec, Canada.



Under normal full load conditions, each circuit of the 345 kv. system will carry 375 Mw. with sending and receiving voltages of 370 kv. and 350 kv. With one circuit shut down, the remaining half of the system will be able to carry about 700 Mw. with the addition of some reactive capacity from the remainder of the system. This overload capacity of one tower line of the 345 kv. system was much greater than that of one double circuit tower line of the 230 kv. system being studied, and was an added factor in the decision to go to the 345 kv. system.

Transformation at Isle Maligne will reduce the voltage to 161 kv. for connection to the existing Saguenay network. Due to present reduced power requirements, initial operation of the lines will be at 161 kv. bypassing the Isle Maligne transformer station which will not be built until required.

Radio Interference and Corona Losses

The selection of 345 kv. as the system voltage introduced the question of radio influence or interference, commonly called RI, and the possibility of excessive power losses due to corona generation.

Test data at hand during line design in 1955-1956 indicated that satisfactory RI and corona performance would be obtained from a bundle of two 1.1 in. diam. conductors, spaced 16 in. horizontally and would in fact be equal to or less than that of a single 1.1 in. diam. conductor at 230 kv., a utility standard for many years.

There was also preliminary test and experience data available at the time to indicate that control rings could not be justified at suspension and dead end points and that no special treatment of the conductor surface was required during stringing.

Control rings were not used although all hardware at conductor attachment points was designed so that rings could be added at a later date if initial operation indicates the need for them.

The importance of the RI problem was tempered by the fact that all but the lower short section of the lines lie through uninhabitable terrain and even the lower section is in marginal farm land with only scattered farms.

Conductor Loadings

Although the area north of the Saguenay River and away from the influence of the St. Lawrence River is specified as a low to medium loading area, a heavier conductor loading of ½ in. radial ice and 5 p.s.f. wind at 0°F, was selected and the following limiting conductor tensions were set:

Unloaded initial	at 0°F	less than 33% UTS
Unloaded final	at 0°F	less than 25% UTS
Loaded	at 0°F	less than 50% UTS

The limiting conditions for each of the two ruling spans of 1400 and 1650 ft. was the final unloaded tension of 25%, although for both spans the loaded tension reaches very close to the 50% limit.

Conductor Design

In the evaluation of optimum conductor aluminum area versus value of power losses, values of from $0.60 to $2.00 per thousand circular mils (MCM) per phase mile were added to the basic conductor cost to represent the incremental costs of towers, footings, transport, erection and stringing that can vary with a change in conductor size.

This study indicated an aluminum area per sub-conductor of from 800-900 MCM and the RI study mentioned above pointed to a conductor diameter of approximately 1.1 in.

A 45/7 stranding ACSR of 850 MCM aluminum area, with a rated ultimate tensile strength of 23,900 lb. and a diameter of 1.099 in. was selected and appeared to provide the lowest overall line cost.

In anticipation of a possible future increase in transmission line load, all towers and suspension assemblies were designed so that a third conductor can be added to the present bundle of two, thereby increasing the transmission capacity of the system without addition of a new tower line.

Insulation and Hardware

Suspension assemblies consist of a single string of eighteen 5¾ in. by 10 in. porcelain or glass 25,000 lb. M. and E. strength insulators, with a simple yoke at the lower end for attachment to the suspension clamps.

Fig. 3. Spring type spacer.

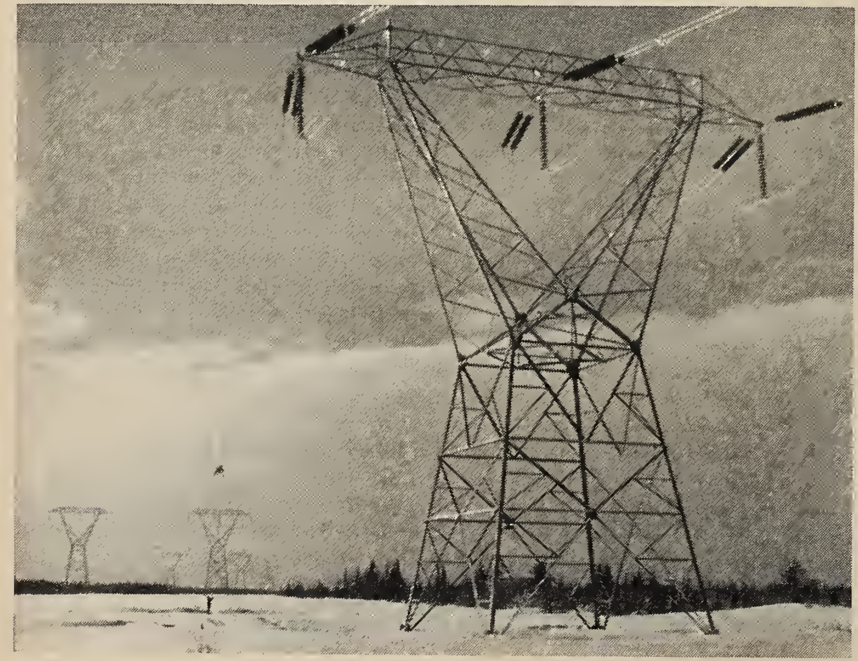


Fig. 2. Deadend assemblies on 20° strain tower. Note mid-span installation of spacers.

The deadend assemblies shown in Fig. 2 have a single string of 20 insulators for each conductor, the extra two units being expendable to permit installation of the longer yoking hardware that will be necessary if a three conductor bundle is ever installed.

A 6 in. turnbuckle was placed at the tower end of each insulator string to permit correction of any minor errors in the deadening operation. This adjustment was only used at about one deadend tower in four and the amount of adjustment never reached the full range available from the two turnbuckles. Omission of one of the turnbuckles might be warranted in the future.

Conductor Hardware

Tubular type compression joints and deadends were used throughout. Conductor support points were reinforced with formed armour rods and Stockbridge dampers were placed at each end of each span of conductor.

Recent experimental and field test work by others has indicated rather convincingly that vibration of bundled conductors is usually less than that of single conductors. It was not considered advisable to omit vibration dampers on these lines, however, as the evidence was not conclusive at the time of stringing and, as shown above, everyday conductor tensions are not low enough to justify the risk of such full scale experimentation.

Conductors are positioned in the bundle with a spring type spacer (Fig. 3) that permits restrained movement in any direction but has no moving parts to wear. The clamp action produces a good grip on the conductor and permits easy mid-span installation as there are no loose nuts, washers or small pieces to handle.

The first spacers were placed 50 ft. from the tower and out in the span were set a minimum of 225 ft. and a maximum of 300 ft. apart.

Protection and Communication

The power line carrier system has four parallel 20w. single-sideband links providing duplex voice communication with superimposed audio frequency shift channels for transfer

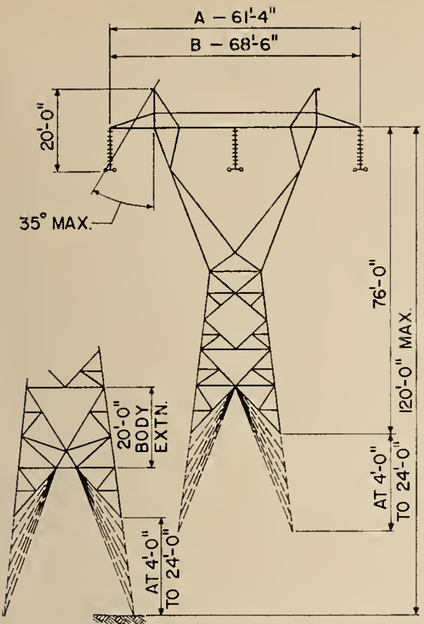

Fig. 4. Outline dimensions of A and B suspension towers.

trip protection relaying, telemetering and teletype. Two of these links are coupled phase to ground of phase A of one line and two to phase A of the other line. The equipment is coupled to the lines by 400 kv. coupling capacitors which also act as potential devices. A 2000 amp., 0.165 millihenry band-tuned wave trap is used at each coupling point.

The use of multi-purpose carrier equipment with a gross band width of 4 kc. in each direction permitted a most reliable arrangement by carrying the protection relaying channels in parallel over two separate links. A relaying signal for one of the two transmission lines is thus always transmitted over both transmission lines.

The 4 duplex voice links, 2 duplex relaying channels, 1 duplex teletype channel, 3 continuous telemetering channels and 1 simplex voice channel between either terminal station and a mobile carrier set only occupy a total gross band width of 37 kc. Each of the 4 links occupies 8 kc. for both directions and each link permits allocation of several additional narrow band channels above the voice band for future requirements.

The high speed distance relays work on a modified impedance principle on phase as well as ground faults. Each protection terminal consists essentially of one one-cycle relay for instantaneous one-zone coverage and one relay for multi-zone back-up protection. Faults outside the instantaneous zone of one terminal are detected and relayed over the carrier system by the opposite terminal.

Operation with single phase and/or three phase high speed reclosing or operation without reclosing can be selected by means of a switch located in the relay panel. Phase selection in the case of the single phase reclosing with carrier tripping is provided by the impedance starting elements under-voltage relays. Mechanical targets and remote annunciators assist in analysing faults.

The line breakers at each end are the air blast type with a rating of 2,000 amp., 15,000/18,000 MVA three phase interrupting capacity, with a BIL of 1,550 kv. Initially, the lines are to be operated at half-voltage, obtained by connecting the high voltage windings of the transformers in parallel. This connection allows the use of only the highest off-load tap and the bank ratio is then 13.8-192.5 kv. and the test BIL of the high voltage winding is 750 kv.

The transformer banks are protected by lightning arrestors with a rating of 308 kv.

Ground wires of ACSR Partridge conductors are carried for about one mile at each end of the lines to protect the terminal equipment. The low isokeraunic level of the area indicated they could be omitted for the remainder of the lines, although all towers were designed and detailed so that ground wire horns can be added in the future.

Tower Loadings

Three types of towers were used with the loading limits shown below:

Towers and footings were designed

	Number in Line	*Wt. Span*	*Wind Span*	*Max. Line Angle*
Suspension A	298	2400 ft.	1600 ft.	1°
Suspension B	272	3000 ft.	2000 ft.	3°
Light Angle Strain	32	3000 ft.	2000 ft.	20°

for the loads resulting from a triple bundle of loaded conductors in applications as stated above, all with a factor of safety of 1.5. Both A and B suspension towers can also carry vertical overloads of 40%.

A longitudinal or broken wire loading of 65% of the unloaded final 30° tension of the three conductors in the bundle was applied at any one suspension point of the A and B towers, combined with vertical and transverse loads resulting from no ice and 3 p.s.f. wind on the conductors, all with a factor of safety of 1.5.

The 20° strain type towers are designed for longitudinal loads at all three attachment points equal to 16,000 lb., which approximate unloaded conductors in the span on one side of the tower with no conductors on the other side or loaded conductors on one side and unloaded on the other.

An additional wind load of 20 p.s.f. was applied to one face of the towers loaded with ½ in. ice coincident with the maximum ice and wind loads on the conductors.

Construction

A 115 mile system of bush roads had to be built for the sections of the transmission line that were not served by the local roads or the main project road.

During the winter months, line materials and heavy equipment were moved easily with trucks, tractors and sleds and the lighter haulage was done with snowmobiles, muskeg tractors and jeeps.

Once the snow roads disappeared, transport was limited to tracked equipment and the terrain was so rough, and swamp and muskeg sections so extensive, that only very slow speeds could be maintained and the equipment required extensive maintenance.

Reference to the Construction Progress Chart, Fig. 5, will show that a major part of those items requiring heavy transport of men and materials were concentrated in the winter months. The experience on the project indicates that with such a road system in similar difficult terrain, an even greater portion of the work might well be attempted during the winter.

The contractor established his main camp and material yard at the Isle Maligne railhead at the southern end of the line, and a second semi-permanent camp, complete with equipment repair facilities, was set up adjacent to the main road near the mid-point of the line.

Two other camps were set up at quarter points and between these temporary camps moved with the work.

Clearing

The normal clearing requirement was for a 300 ft. strip that permitted 75 ft. on the outside and 150 ft. between the two lines of towers. Trees outside these limits which were so high that they could strike the conductors in falling were classified as danger trees and were also cut.

Stumps of 12 in. were permitted and all brush and logs that were not merchantable as pulp wood had to be burnt or removed from the right-of-way with the exception of logs of more than 15 in. diam. which could be cut in 10 ft. lengths and left to rot in contact with the ground.

Material Transport

Ninety percent of the tower steel was scheduled to arrive at Port Alfred on the Saguenay River before freeze-up in 1957 and this was yarded and sorted and then delivered along the line to the individual tower sites during the following winter.

A small tonnage had been retained for Spring 1958 delivery to accommodate last minute changes of requirements and this was taken to site at the northern end of the line during the following winter.

Conductor was shipped at regular intervals through the winter of 1957-1958 and immediately dispersed along the line. The reels were carefully grouped according to length and as the reel length was nominally 7850 ft., caches of 24 reels were established approximately three miles apart to permit pulling both ways on both lines from the same point.

Insulators and hardware were distributed to the tower sites at the same time.

Footings

The steel grillage for normal soil conditions was a quadruped shape utilizing a technique of assembly requiring few bolts which is best described by reference to Fig. 6.

Rock anchorages consisted of a steel weldment on a small concrete pad and held down by a set of four bolts grouted into the rock. Split wedges at the lower ends of the bolts were used to increase pull-out resistance.

Unfortunately, ground conditions were such that straight forward installation of footings was possible at less than a third of the tower sites.

Water was encountered at more than 70% of the footings, and where a permanent high water table was indicated, a pattern of 8 ft. long red spruce logs was laid across the top of the grillage to increase the volume of soil above the grillage and counteract the decrease in uplift resistance brought about by buoyancy.

Very poor bearing values were obtained at several sites and at one, where suitable resistance to drilling could be obtained at about 30 ft., timber pile footings capped with concrete were used. At other sites where piles would have been 90 ft. in length or more, timber mats up to 16 ft. square were used to reduce the pressure on the soil to values found suitable by tests.

The installation of rock footings was complicated by the large quantities of shattered rock found when footings were opened up. Where extensive, the broken rock was removed and a grillage installed.

Surface examination of the tower sites proved to be a very unsatisfactory aid in scheduling equipment

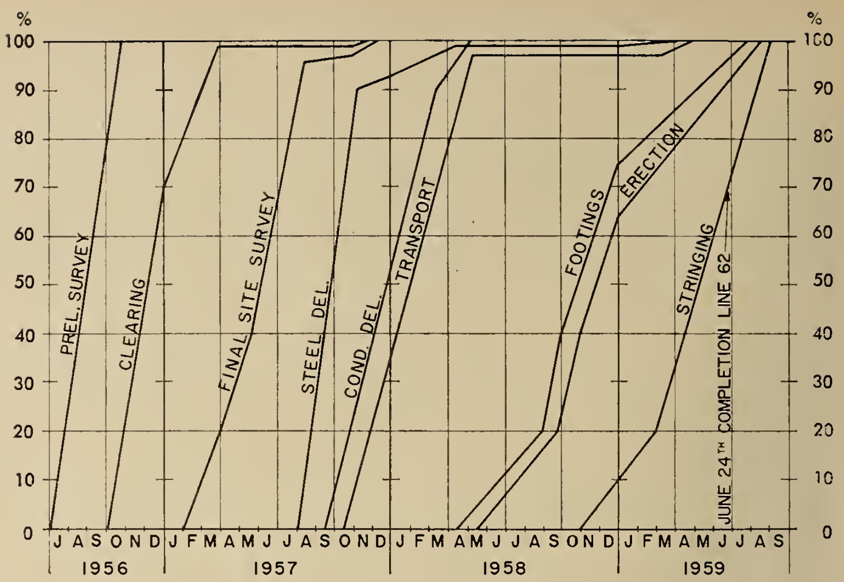

Fig. 5. Construction Progress Chart.

deployment. Frequently a backhoe was set to work to open what appeared to be a standard grillage excavation, a compressor and drill would be moved in to break up loose rock or boulders too large to remove whole and then a ledge of solid rock would be encountered requiring further drilling and the erection of a rock footing on a concrete pedestal.

This led to considerable interchange of grillages and rock anchors from tower to tower and the original dispersal of leg extensions, based on individual tower site surveys, had to be changed frequently as the footing work proceeded.

Footing installation continued at a reduced rate through the winter. Temperatures reached —55°F but an early heavy snow fall proved to be sufficient insulation to limit frost penetration to from one to two feet.

In setting grillages in the winter an attempt was made to complete excavation, setting and backfill in one day so that the backfill material did not freeze. Care was taken to ensure that the material below the grillage did not freeze before setting and that no snow, ice or frozen material got mixed in the backfill. The latter was not always possible and in the early summer a cleanup crew went back to such towers to bring the backfill up to grade. No cases of heaving of footings before or after tower erection were reported by the inspection personnel.

Materials for concrete work on the rock footings required heating. Concrete additives were used to create added heat during set-up and when combined with the use of rock-wool insulating bats and wind protective covers, good curing of the concrete was obtained.

The problem of the "Peribonka Sands", peculiar to the area, forced the contractor to produce his own concrete aggregates for a considerable section of the line. Methane gases, released from underlying beds of decaying organic materials have over the centuries risen into the surface deposits of sand and gravel and coated the grains with a product that dissolves during the making of concrete. An unpredictable and damaging degree of aeration occurs that can be chemically controlled on large concrete operations but which is almost impossible to combat on small quantity work such as tower footings where there is frequent opening of new gravel or sand pits as the crews move along the line.

Tower Erection

The towers were pre-assembled by a crew that worked about 2 weeks ahead of the erection crews. Side panels of the body of the tower, the two arms and the complete crossarm were ground assembled.

The following 9 man erection crew, equipped with a 72 ft. sectional aluminum gin pole, could, where the terrain was favourable, erect more than two 96 ft. towers in one day. Difficulty in guying the gin pole and very uneven terrain that made it impossible to locate the pre-assembled sections in good positions for raising could cut the efficiency of this operation greatly.

A follow-up crew accompanied by an Alcan inspector later checked every tower to ensure that all nuts were tight and that all threads were punched.

Before the onset of winter, the pre-assembly crews were increased so that a heavy snowfall would not cover the piles of tower material.

However, the very good progress of the stringing crews following close behind made desirable the winter erection of a greater number of towers than originally scheduled. A considerable amount of steel for these extra towers could not be found and replacement material had to be drawn from the yards. Cleanup crews in the spring picked up the lost material which was used in the last 80 towers that were erected during the summer of 1959.

Fig. 7. Mid-winter stringing operations.

Stringing and Sagging

The stringing specification did not call for special treatment of the conductor surface and techniques satisfactory for stringing 795 MCM ACSR for 230 kv. were considered adequate. At his option, the contractor decided against tension stringing in favour of the method of pulling the conductor along the ground, using timber lagging where necessary to prevent damage to the outer aluminum strands. About 75% of the stringing was done while there was sufficient snow to minimize the danger of conductor damage and cut down on the placing of lagging. Two 50-60 man stringing crews were employed. The first started near the lower end late in 1958 working north and the second crew started in mid-February 1959, working north from near the midpoint of the line.

The group pulling out and stringing conductor worked from 1 to 3 weeks ahead of the sagging-in crew. The conductor was pulled up to about 60-70% stringing tension so that it was well free of the ground and in no danger of getting 'frozen in'. An allowance for creep during this time in the air before sagging-in was made and added to the initial sag data. This creep correction was standard for all spans and contained little error as long as the period in the air while awaiting sagging-in was more than 3 days and less than 3 weeks.

The only exception to this was during the stringing of the very first section of line south from the Peribonka River in November 1958. The first 4 miles of conductor in one line was off the ground and 2 miles of this had been sagged-in and checked when a severe ice storm hit the area depositing a 1 in. thick coating of clear ice on one side of the conductors, a load of approximately 0.7 lb. per ft.

A recheck of sags on the sagged-in portion indicated an increase of from 2.5 to 3.0 ft. which checked very closely with that to be expected from such a loading. The contractor was then told to make a similar compensation when sagging-in the other conductor that had been in the air awaiting sagging-in.

A wind of from 20 to 30 m.p.h. that followed this ice storm produced galloping on one phase of one span of the sagged-in section. A vertical movement of from 6 to 9 ft. in three loops at about 40 cycles per minute was observed. The two conductors of the bundle, that were already fitted with spacers, moved together and maintained their horizontal position at all times.

In order that the conductors of a bundle should maintain equal sags after being sagged-in it was necessary to ensure that they both had the same stress histories before sagging. The contractor always handled the conductors of a bundle at the same time and under approximately the same tensions, and checks of the sags up to 12 months after sagging have disclosed no new differences between the sags of the bundle.

Precision control of the sagging was obtained by use of small high ratio manually operated winches that were clamped to the legs of the tower at one end of the sagging section. Within 10 days of sagging, a follow-up crew installed dampers and spacers.

Fig. 6. Quadruped grillage being set. Bearing angles are placed in the triangular slots in channels. Broken rock is typical of conditions encountered at tower sites.

Aluminum Guyed Towers

During initial studies, consideration was given to the possibility of using guyed mast type suspension towers. They were rejected in favour of conventional rigid towers as the project schedule did not afford sufficient time for the thorough investigation necessary for such a radical departure from standard North American practice.

The investigation of guyed towers continued, however, and before completion of the project, authorization was given for the design, fabrication and testing of one full scale prototype of strength and size equivalent to the A type rigid tower. The program of tests, described briefly below, proved the structural adequacy of the towers and four towers, three 76 ft. to crossarm and one 97 ft. to crossarm, were installed in the lower end of one of the Chute-des-Passes circuits, and have been carrying power since September 1959.

Design

The two masts and the crossarm were fabricated of B51S-T6 structural aluminum alloy (Am. des. AA6351-T6) with the following design stresses:

Tension = 26,000 p.s.i.
Compression = 25,000 − 140 $k(1/r)$
to be $\leq$24,000 for $k(1/r) < 64$

$$\frac{6.6 \times 10^7}{(k1/r)^2} \text{ for } k1/r > 64$$

Where k is an end fixity factor.
Bearing = 35,000 p.s.i. on 1.25D edge distance to
50,000 p.s.i. on 2D edge distance

Plain extruded equal leg angles were used for many of the members but special shapes were designed for the principal compression members. A bulb angle was used for the main struts in the masts and a lipped channel in the lower chord of the crossarm. All nuts, bolts and washers are galvanized steel.

The mast is made up of sections 21 ft. long weighing 170 lb. complete with bolts.

The aluminum in the 97 ft. tower weighs 2755 lb. to which must be added the nuts and bolts, guys and anchorage material which are of steel.

The main tower footing is a 5 ft. by 7 ft. rectangular grillage buried 6 ft. to ensure security from frost heave. The only loads on this footing are thrust and shear with no possibility of uplift.

Guys and Anchorages

The guys consist of a stranding of 19 wires of 0.1052 in. diam. aluminized ACSR core wire with an OD of 0.526 in.

A double guy is used passing around a thimble at the top end and the two guys are then twisted about each other to eliminate the possibility of vibration trouble. Each guy wire is terminated with a compression sleeve.

When sound rock is present, guys are anchored to an eye bolt grouted into place. The threaded U-bolt arrangement is used for final adjustment and pretensioning of the guy wires.

A variety of types of guy anchors for normal soil conditions have been considered and at the present time, dished and flanged steel boiler ends appear to be satisfactory and they are the least expensive of any alternatives considered to date. They can be obtained in a range of diameters and thicknesses to suit the guy loadings. A long U-bolt is used as a guy rod and threads at the upper open end permit adjustment of the guys as with the rock anchors.

Test Program

Compression tests were carried out on complete legs to determine the behaviour of the joints and suitability of the bracing system as applied to columns of these proportions.

A 103 ft. 4 in. leg, weighing 8.5 lb. per ft., carried a compressive load of 80,000 lb. without failure and a shorter leg of 82 ft., composed of the same elements, reached 93,000 lb. before failure.

A complete tower, 76 ft. to crossarm, was then erected on a rocky site near Arvida, Quebec, and subjected to loadings equal to 1.5 times the design loads. Difficulty was experienced with details at the conductor attachment points but these were readily corrected.

The full vertical and transverse loadings were carried with no signs of distress in the tower. Failure did occur at 135% of the design longitudinal load in a member of the mast

Fig. 8. Erection of 76 ft. guyed tower.

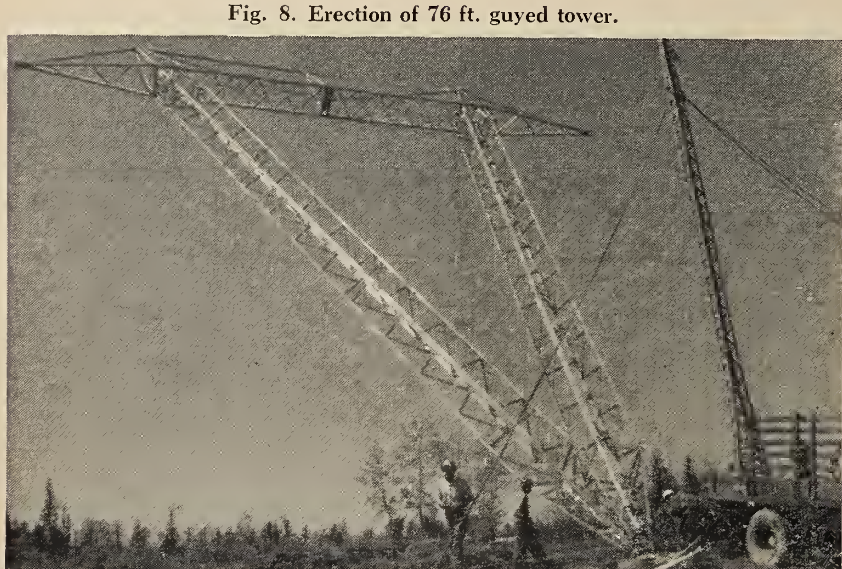

Fig. 9. Guyed aluminum tower—76 ft. to crossarm.

section between the crossarm and the point of attachment of the guys. The arrangement of members at this point has been changed in later designs of the tower.

A series of tests on uplift capacity of large guy anchors embedded in a variety of soils at varying depths has been started and will continue.

Creep of anchors is being measured on two of the line towers that were located in a swamp. Guys of these towers received pretensioning and levels of the tops of the anchor rods and the grillages are being recorded periodically.

In order to obtain a better impression of the stability of the tower, a guy was removed from one of the four line towers after stringing was completed. Adjacent spans were 1150 ft. and 1550 ft. A transverse load of 2,400 lb. (equivalent to a 3°—4° line angle or a wind of 45 m.p.h.) was applied to the tower on the opposite side of the removed guy. The unrestrained end of the crossarm moved less than 2 ft. along the line and about 6 in. across the line. This small movement is a good indication of the restraint offered by the conductors and ground wires.

Logie contributed to the section on Protection and Communication. Power Lines Construction Limited were principal contractors for the construction of the transmission line. EIC

AUTOMATION IN THERMAL POWER PLANTS

A. R. Scott,
Power Systems Application Engineer,
Canadian General Electric Company, Peterborough

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

In the operation of both thermal and hydraulic generating stations Utilities have long been leading users of automatic controls. These have been applied both to control the quality of the finished product, electrical energy, and to control the mechanical parameters of the plant. Thermal generation is of course the more complex process, and we have gone a long way since hand fired boilers and manual control of combustion and feedwater could be relied upon to raise steam.

THE BASIC automatic controls which have been developed to a high level of efficiency are —

(1) Combustion control;

(2) Feedwater level control;

(3) Steam temperature control;

(4) Speed governor;

(5) Voltage regulator.

(1), (2) and (3) have the main responsibility for the safety and economic operation of the thermal portion of the plant while (4) and (5) control the quality of electrical output. There has been a recent trend to the use of electrical controllers for (1), (2) and (3) in place of pneumatic devices.[5] In this field of power generation it is clear that automation is no stranger.

Utilities have also been quick to take advantage of progress in other fields, notably in the use of automatic computing facilities. Network and transient analysers have long been used but more recently the availability of high speed digital computers has found ready response amongst utility engineers as is shown by the approximately 200 digital computer programs recorded in ref. (3).

These programs include such items as transmission line performance, economics of system expansion and system operation, structural design of transmission lines, load forecasting and steam station heat balance and incremental heat rate. This paper will review the progress being made in combining the best features of existing automatic controls with the powerful features of digital data handling equipment to take another large step forward in improved operation of thermal generating stations.

Analog and Digital Measurement & Control

It would be well at this stage to clarify the two main classes of measurement and control. Most conventional controls operate on an analog basis. This means that a quantity is represented by a physical variable such as rotation, translation, voltage, or resistance. This analog may be used to record for example on a chart recorder or it may be used in conjunction with other analog quantities to carry out a computation and produce a resulting analog output for actuation of a control. An example of the latter is the three element feedwater control which uses analogs of steam flow, feedwater flow and drum level to produce as output a signal to adjust feedwater flow control valves. The digital approach is to represent a quantity by a number in some suitable system, decimal or otherwise. Any necessary computation is carried out on the number or numbers. The raw data will often be in analog form and must be converted to digital form. The output may be in digital form punched on tape or typed.

Where the output is used for control purposes it may be convenient to restore the quantity to analog form. We will consider later how the choice may be made between analog and digital methods for measurement, recording or control in a given case.

Computers for Control

While digital computers of various sorts have been used for a considerable number of years for processing a variety of business data and for engineering design purposes, it is only recently that this type of equipment has found a place in industrial process control. This may at first seem strange since many control problems can be expressed in mathematical terms and solved by a calculating machine. To carry out complex procedures the equipment must be able to carry out a programmed sequence of calculation which it has remembered. For business and engineering purposes a computer is presented with instructions and data in numerical form usually on cards or punched tape. This is stored in a memory and, after completing the calculation, the answers are fed out again in numerical form on punched cards or tapes. If occasional maintenance is required this can be done at prescheduled hours. A failure of equipment may be an annoyance but aside from delaying computation and possibly requiring the re-run of the program in progress at the time of failure, no harm results. Thus many computers used in business and scientific work do require appreciable amounts of maintenance and checking time and employ hot cathode tubes which require routine replacement. Often, too, business calculations involve handling large volumes of data and performing comparatively simple mathematical processing. The amount of data and instructions to be stored by the machine may be comparatively small for any one program and when a new problem is to be solved the machine can have a fresh set of instructions loaded in. If one computer will not handle all the work, this can be shared between two or more.

If we are to use digital equipment for control purposes much more stringent requirements must be met. Since a process may operate 24 hrs. a day, 7 days a week without shutdown for long periods, so must the computer. Speed of computing is no longer simply a question of the economics of how much one computer will handle but of keeping up with the process and doing all of the necessary calculation in a time limited by process characteristics.

All of the necessary information and instructions must be available in the computer memory for every phase of its operation. Data is not available directly in numerical form but must be obtained by the computer from sensing devices which measure process parameters and which provide analog quantities which must be converted to the computer language of "bits" or "digits".

These differences in requirement have led to the development of computing equipment specially designed for industrial process control. This equipment uses static devices throughout and components used at only a fraction of their rating in order to achieve reliability of the highest possible order. Facilities are incorporated for the computer to read analog quantities representing process parameters. Large memory capacity permits storing large quantities of recorded data and instructions which are required.

High operating speeds are necessary both in carrying out calculations and in gaining access to information stored in memory. On the other hand accuracy in the order of 1 part in 1000 will usually be adequate to match accuracy in available measuring devices. More than 3 significant decimals may be necessary to ensure accuracy through calculation procedures but the use of 10 decimal digit accuracy common in business computers may be unnecessary.

Constructional techniques and component design are tailored to suit industrial environment conditions rather than the "ideal" environment often afforded to other types of computers. Only recently have components, particularly the transistor, become available to meet these exacting performance and reliability requirements for industrial process control computers.

Computers in Thermal Generating Stations

A thermal station is an example of a complex industrial process for which such computers have been designed. That this process is already largely automated has been mentioned earlier but we can note the following manual processes which are still carried out in most existing stations.

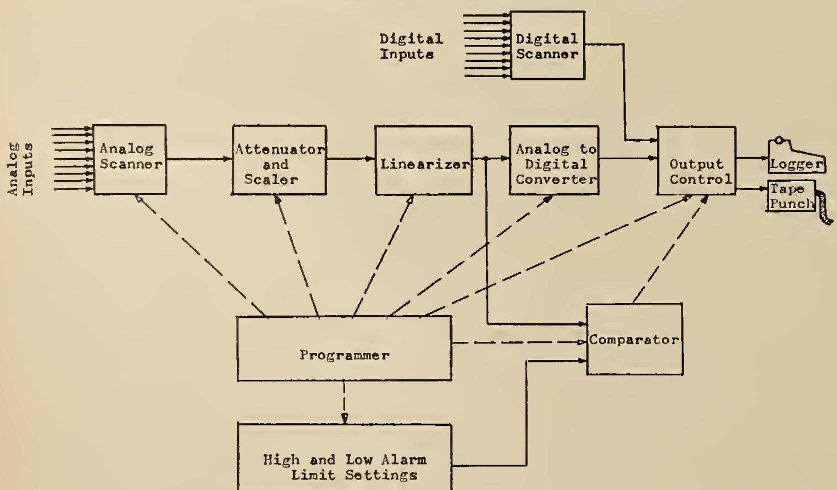
(1) Much of the operating data is still collected by hand logging of instrument readings. This collection of data serves as a means of regular supervision of process conditions as well as providing historical data.

(2) The results from logged readings together with information extracted from chart records is manually processed to give performance information such as overall heat rate and component efficiencies.

(3) Minute-to-minute supervision of the plant combines a check of readings of a few vital quantities, together with review of the more occasional data which is logged. In addition a variety of quantities is provided with alarm annunciation from relays or other devices.

(4) Further to the functions above relating generally to steady state operation the operator must perform a variety of functions and provide special supervision during process changes such as start-up, load increase or decrease, and shut down of the unit.

Fig. 1. Block Diagram of 310 Data Acquisition System



Improvements in station design have generally led to concentrating vital instrumentation in a central control room and to the unit approach to generator and boiler construction. By this means the operator is presented with all pertinent information within easy reach. This has made possible not only the improvement in the quality of supervision needed for modern high performance station equipment but also the reduction in total manpower requirements.

Data Logging

Taking the manual functions listed above in the order given, computer techniques are being applied to take over these requirements.

Fig. 1 shows in block diagram form a data logging equipment designed to take over the manual logging noted in paragraph (1) above. The data is obtained from suitable sensors similar to those used for analog measurement. These provide a millivolt or other signal equivalent to the primary quantity and this is converted into digital form which suits the handling process and output. A program in the data logger controls the scanning of quantities to be recorded. The program is arranged also to provide the necessary scale factors to suit various full scale inputs from sensors and if necessary to linearize inputs from sensors such as thermocouples. This permits the digital output to be in engineering units and the quantities are typed out on a logging typewriter as required or on a regular timed basis such as every hour.

Data loggers can also be readily arranged to provide alarms when a quantity exceeds or falls below the preset limit specified for each point. Scanning for alarm purposes is done frequently and for example a data logging system of 100 points could scan each quantity every 10 to 20 sec. Print-out of information will occur only when a point exceeds its assigned limit or when complete print-out is called for at regular intervals or on demand by the operator.

Equipment used for data logging and alarm is not strictly a computer since it does not include arithmetic facilities or memory except in the limited sense of its program. This may take the form of a pin board programmer as illustrated in Fig. 2. The data logger has thus taken over the manual fnuctions listed under item (1) but with the following improvements.

(1) The log is available in more legible and accurate form;

(2) The log can be recorded ac-

curately during periods of system or equipment disturbance when the operator may be distracted by more urgent tasks;

(3) The degree of alarm supervision is close to that provided by individual alarm relays and individual annunciators for each point and far superior to the supervision associated with manual logging;

(4) Annunciator and indication or recording instrumentation costs and space requirements are reduced.

Since much of the collected data is of historical interest only, the operator can confine his attention primarily to the alarm information which is listed on an alarm printer separate from the logging typewriter. This extends the existing trend of giving the operator only the essential minimum of data.

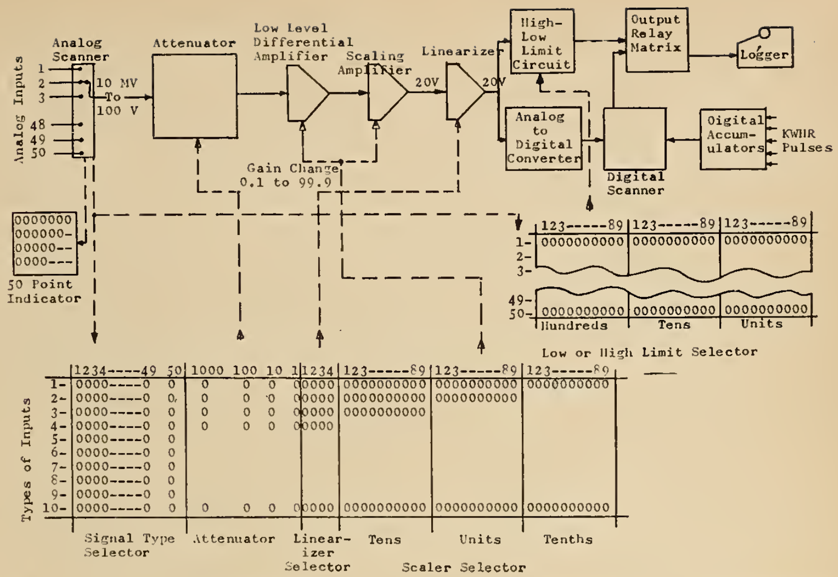


Fig. 2. Functional Diagram of the 310 Data Logging System With Its Pinboard Programmer

Performance Calculation

When historical data is used to calculate performance this can be done manually from the typewritten log in the same way as is commonly done from the handwritten log. Programs have been developed (Ref. 3) to make performance calculation on business type computers which may be available in the plant or elsewhere. In this case it may be convenient for the data logger to prepare a punched tape which can be processed directly as computer input.

An alternative arrangement is to use an industrial process computer associated directly with the generator unit to combine the functions of data logging and performance calculation. The initial advantage of this arrangement is that, with the facility of rapid calculation, the computer can make available performance results at regular intervals within a second or so of the end of the period reviewed. This may be done on an hourly and daily basis. This in itself is enough to justify the extra equipment on a large unit but of equal benefit are the extra facilities which can be provided with the high speed arithmetic abilities and memory capacity of a computer. Alarm limits need no longer be fixed by operator's selection but may be programmed as a function of some process variable such as load.

The computer can also be instructed to scan points at varying rates depending on the importance of the measured variable. Speed of alarm scanning and comparison with limits is raised to hundreds per second. Storage in memory provides the necessary buffer to allow printout of alarm and logging information at speeds within typewriter capability without interrupting the other scanning and calculation functions. Thus logging speed is no longer limited to typing speed as with a simple data logger. Alarms for calculated quantities can be provided as for example when heat rate falls below a reasonable value for the operating conditions.

Typical performance calculations used for a turbine-generator unit are:

(1) Overall Boiler-Turbine-Generator Heat Rate;
(2) Turbine-Generator Heat Rate;
(3) Boiler Efficiency;
(4) Monitor Extraction Feedwater Heaters;
(5) Condenser Performance;
(6) Air pre-heater, economizer monitoring;
(7) Generator field temperature from field volts and amp.

With such calculations the computer reviews overall performance of the unit and also checks individual component performance for deterioration. These results are available rapidly so that corrective action on components or operating practice can be taken to improve operating efficiency.

The computer scans and stores the quantities required to calculate performance. In the memory are loaded the calculation instructions and such basic data as steam tables which are necessary during the calculation. Quantities used in performance calculation are scanned every few minutes and averaged over the review period such as one hour.

It will be helpful to consider two of the performance calculations in some detail to illustrate the procedure. In calculating boiler efficiency the input-output method could be used. This involves measuring the quantity of fuel and for gas and oil fired stations the available flow measuring equipment is not ideal. Coal fired stations present an even greater problem in accurate weighing particularly over short periods such as one hour. A more suitable method based on the ASME Boiler Test Code is the heat loss summation procedure for boiler efficiency; this is recommended for computer calculation. The losses are estimated on a B.t.u./lb. of fuel basis. Efficiency is calculated

$$\text{from} \left(1.00 - \frac{\text{lost B.t.u./lb.}}{\text{B.t.u./lb.}} \right) \times 100\%$$

The computer is supplied with B.t.u./lb. based on fuel sampling. Losses included are:

a) Heat loss in dry gases (based on gas temp. - air temp.);
b) Heat loss due to moisture (based on sampled moisture per lb. and measured gas temp.);
c) Heat loss due to hydrogen;
d) Heat loss due to CO;
e) Heat loss due to combustibles in ash;
f) Heat loss due to radiation (stored in computer as table based on gross heat input).

With a small empirical addition for unaccounted losses the total loss is used for boiler efficiency without the necessity of fuel weighing. Another advantage to this method is that errors in loss estimates have only a second order effect on calculated efficiency.

Turbine generator efficiency calculation illustrated in Fig. 3 shows that net turbine input is measured at points of heat transfer between boiler and turbine. Pressure and temperature sensors plus steam tables stored in memory provide the computer

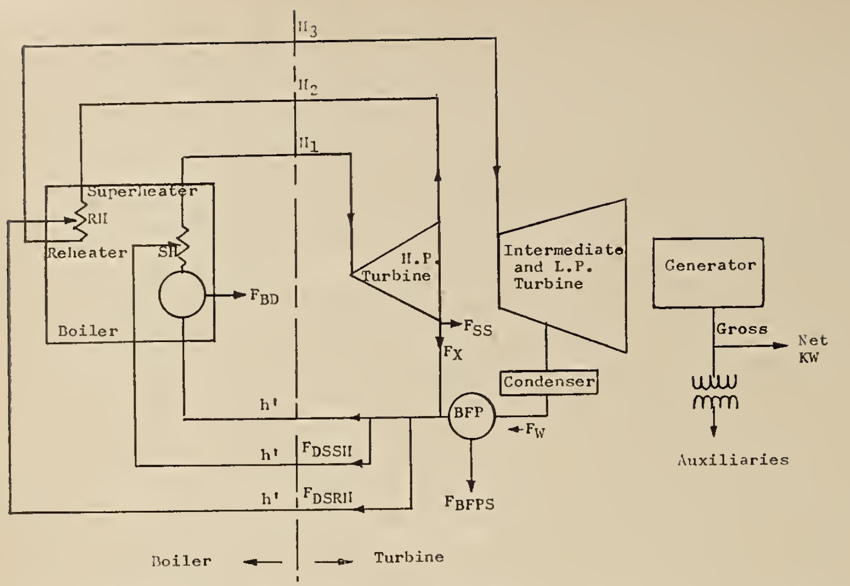

Fig. 3. Thermal Quantities for Turbine Generator Net Heat Rate Calculations

with the raw materials for heat calculation. Flow is conveniently measured at the input to the boiler feed pump where pressure and temperature conditions are most suitable.

Having measured net heat input to the turbine generator, its heat rate is established by comparing this with gross or net kwh. output. Overall heat rate is then computed by dividing the net turbine generator heat rate by boiler efficiency calculated as described previously. The value of these performance calculations can be increased by having the computer estimate "bogey" heat rate for the plant loading and operating conditions during the period reviewed. If required, an alarm can be provided when the difference between bogey and actual performance exceeds a predetermined limit.

Fig. 4 shows the method of checking performance of a component such as a feedwater heater. The input-output difference in feed and extraction flows is compared against normal conditions for the flow or load conditions at the time. Thus any deterioration in the component is rapidly shown up before it seriously affects plant performance.

We have to this point reviewed the application of computer techniques to automate the first three of the manual items listed earlier for conventional stations. In addition to the advantages listed for automatic data logging, the further benefits from using a computer for performance calculation are:

1) Performance results available more quickly — in seconds instead of days or weeks;
2) More flexible alarm structure as a function of loading or other process variable;
3) Higher scanning speeds and rate of scanning adjusted to suit importance of quantity measured;
4) Performance variation alarms available.

Computer Control

With the facilities previously described the operator's manual tasks would reduce to —

1) Taking corrective action when alarms from computer or other source indicated an abnormality;
2) Adjusting unit loading to suit system conditions;
3) Controlling the sequence of start-up and shut-down procedures.

Since the computer already has most of the *information* from the process it would seem logical to add to the computer the necessary *instructions* to carry out these routines. This is currently being done. Computer requirements in terms of memory capacity are considerably increased since more instructions must be provided and more information from the process collected and stored. The computer will be required to scan many contact inputs and some additional analog quantities to determine the state or position of auxiliary components. Routines which are provided include:

1) Start-up from cold;
2) Hot start-up (following short duration shut-down);
3) Normal shut-down;
4) Emergency shut-down;
5) Incremental loading;
6) System diagnostic and corrective action.

Fig. 5 shows in block diagram form the layout of a control computer for a thermal generating unit. It will be seen that analog quantities and contact positions are scanned to provide input information for control, performance calculation and logging. Output consists of contact closures for direct control and analog outputs where control is achieved by varying the set point of analog sub-loops. In addition, print-out of logged readings, alarm indication and performance results is supplied on typewriter, printers, paper tape or annunciator as required.

Fig. 6 shows a short portion of one of the many sections of a start-up routine to illustrate the type of checking and decision making which a computer is programmed to make. The logic of diagnostic and corrective action routine shows how a computer can handle minor or major emergencies arising under normal steady loading conditions.

The flexibility inherent in a stored program control computer allows maximum use to be made of the speed of a computer in decision making as well as in actual calculation. Complex start-up and shut-down routines which must in any case be setup for guidance of operators are stored in the computer memory and carried out step by step. Each operation is checked for satisfactory completion before a subsequent operation is initiated. Where close checking of some quantity is required during a phase of the start-up cycle, rapid scanning of the analog output from the appropriate sensor is initiated to give maximum supervision with alarm facilities during critical periods.

The program required for each portion of station operation is controlled by an executive program which selects the appropriate subroutine for control, scanning, logging or performance calculation. Since, while the speed of the computer may give the impression of doing many jobs simultaneously, it is in fact a sequential device, the executive program acts to give priority to more important functions if any possibility of conflict exists. Equally, the executive program by-passes any portion of scanning or checking which is not required for a particular operating condition.

A computer actuated control offers, in addition to the advantages listed for automated data logging and performance calculation, a reliable, unemotional control which will carry through preprogrammed sequences of operation with all necessary checks at each stage. Even under conditions of emergency when an operator may be distracted, the computer will not depart from the correct program. The ability of the computer to scan and compute the most essential quantities at each stage of a change in the state of the unit enables the timing of start-up and shut-down sequences to be linked more closely to equipment stress limits and the optimum times can be achieved without endangering equipment.

The Computer and Conventional Controls

It has been shown that computers applied for data handling and control of a thermal station will take over some or all of the manual processes which remain. We will eonsider now the relationship of the computer to existing controls. Both digital and analog controllers rely on the same types of sensors to measure the quantities upon which any control must be based. In general sensors are available to cover adequately the requirements. The trend to electrical controllers and away from pneumatic control has already produced sensors with electrical outputs which are suited to computer input. Typical of these sensors are:

Pressure: Strain bridges, transducers;
Temperature: Thermocouples, resistance thermometers;
Flows: Orifices plus differential pressure transducers.

Other areas where sensors are available but additional work is needed include flame detection, chemical measurement, specific gravity measurement, slag detection. These do not in general impose any serious obstacle to automating steam plants.

Having suitable sensing equipment there remains the choice of control by analog or by digital methods. At the moment the choice is to retain the present, well-tried analog controllers for the functions for which they have been used sueh as control of combustion, feedwater, temperature and for voltage regulation. These tasks are well suited to the analog controller since they involve two or three analog inputs and require an analog output to the actuator. For other tasks which have been mentioned, the digital approach is generally superior. The effectiveness of the analog controllers noted above may be increased in some cases by set point adjustment provided as output from the digital controller. This is used for example during start-up when boiler load is below the range of the analog controller. Analog devices which have been used for recording purposes may in many cases be replaced by digital display or recording of the quantity. Some analog records will be retained when trend information is important. Generally economics will play a key part in the choice between analog and digital methods and the analog approach is more suited for those portions of control which require continuous supervision. Where time sharing is possible between functions, when complex calculation is necessary or when complex sequences are to be carried out, a digital controller is indicated.

Why Automate?

So far we have described and illustrated the method of automatic control as applied to a thermal generating unit. Let us now review why such equipment should be considered. We have reviewed the improvements in operating characteristics achieved in each stage of progressive automation comprizing these categories:

1) Data Logging and Alarm;
2) Performance Calculation;
3) Automatic Control.

While these performance improvements may be satisfying aesthetically this will rarely be enough to justify additional expenditure to management. When we review the economic gains which may result, the subject can be properly appraised. The gains from complete automation are listed below.

1) Reduction in fuel costs: continous monitoring of performance and precise control can improve plant efficiency.

2) Improved continuity of service: constant scanning and prompt corrective action in emergency will reduce the number of unit outages.

3) Increased safety to personnel and equipment: continuous supervision will reduce the possibility of a major accident. Higher costs, larger size and more critical pressure and temperature conditions have increased the economic penalty of an operating error.

At the present time the items noted above have been the main justification for automation. A number of others can be listed and some of these may with further experience prove to be a major justification for equipment installation. These are:

1) Reduced operating costs: through more efficient use of manpower;

2) Reduced maintenance cost: through reduced equipment stresses;

3) Reduced auxiliary power: auxiliaries brought into use only when load conditions demand;

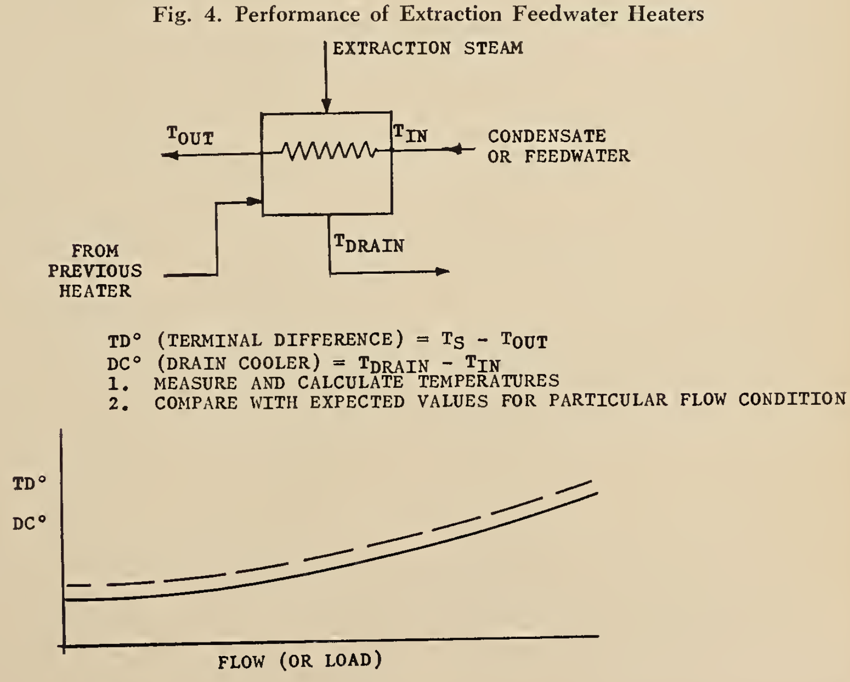
4) Reduced expenditure on control room and conventional instrumentation;

5) Removal of the need for periodic boiler and turbine tests: up-to-date performance values aid accurate load dispatching on incremental cost basis.

Some of these gains may be achieved at least in part by investing in less than complete automation. Where data logging and alarm alone is required, the equipment will not require the calculating or memory features of a computer. It may also be uneconomic to expand later and retain appreciable amounts of apparatus. On the other hand equipment to provide performance calculation does require memory and arithmetic features and may be quite practical to expand to complete automation.

The possible savings in some of these items are remarkably large when capitalized. For example with fuel costs of 30¢ per million B.t.u., capitalized savings from a ½% improvement in heat rate in a 2-unit

Fig. 4. Performance of Extraction Feedwater Heaters



average size plant may run to $150,000. As average unit sizes increase, such savings will grow.

Equipment Characteristics & Reliability

We have already noted that the reliability requirements for computers used for process control are much higher than for business or scientific calculation purposes. Three requirements must be met for satisfactory use in a control scheme.

1) Equipment must be designed to reduce component failure to an absolute minimum.
2) Failures must be detected rapidly and prevented from affecting the safe operation of the process.
3) Repair of the equipment must be made in the shortest possible time.

To meet requirement 1) the availability of transistors has been a major factor in permitting equipments to be constructed from almost entirely static components. This in itself is no magic guarantee of reliability but, combined with conservative application practices in which the transistors, diodes, resistors, capacitors, transformers and so on are used at a fraction of their normal ratings, a high order of freedom from failure can be obtained. These ratings range from one-tenth to one-half of normal depending on the device.

Another factor noted in reliability was rapid detection of failure. This is catered for in digital equipment by frequent self-checking routines called for by the executive program. When the self-check reveals an error the computer can set its output information to values safe for the process and commence to perform diagnostic routines which will inform the operator of the location of the fault. This facility is supplemented by the wide use of plug-in cards and other components so that faulted elements may be rapidly replaced from spare stock. To ensure that plug-in connections do not create more unreliability than they seek to cure, close attention must be paid to the design of the plug connection itself.

Scanning of input points is achieved by mechanical means using high reliability mercury wetted contact relays which are suited to the low level signal inputs encountered in industrial applications. By using a relay matrix, a high degree of flexibility in the sequence of input selection is achieved when compared with a sequential scanning device. At the same time equipment common to a large number of scanned points is avoided.

Memory requirements for an industrial computer can be provided in a number of ways but magnetic drum storage offers a number of advantages. The memory consists of a drum rotating at high speeds with information written on magnetized spots on the drum surface in much the same way as a tape recording. A number of recording heads spaced at the periphery of the drum provide writing and reading facilities. A magnetic drum offers large storage capacity at reasonable cost and is less sensitive to disturbance from power failure or system transients than some other types of memory. It does have a disadvantage that access to a particular piece of information may take time since one might have to wait until the drum rotates to the point that the information lies under a reading head. With a typical drum speed this could average 6-10 milliseconds but by careful programming, these access times can be reduced to much smaller values. The drum has far fewer components than other types of memory with equivalent capacity and is thus theoretically more reliable and easier to maintain.

Other Applications for Automation

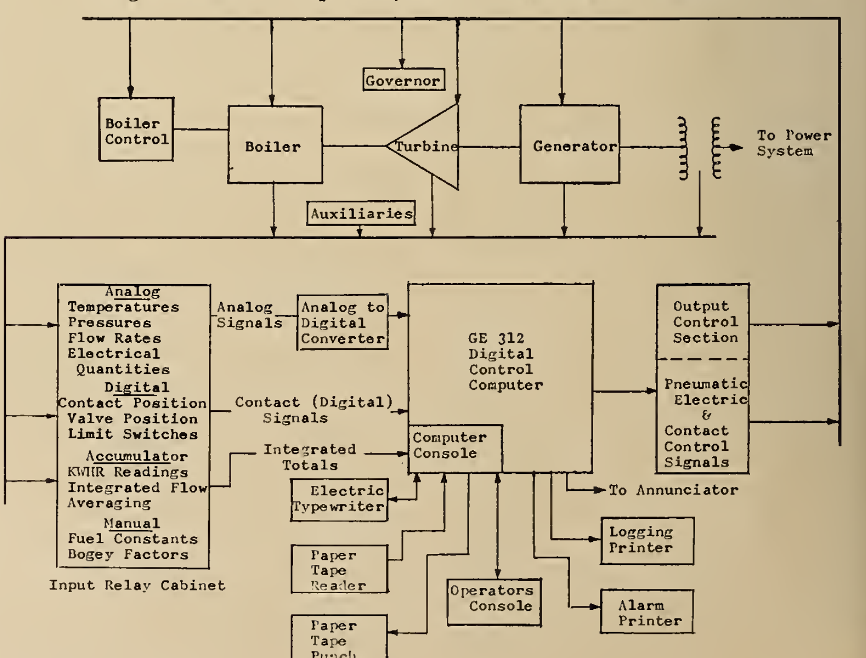
To place the automation of steam stations through the use of digital equipment in proper perspective, it may be useful to remark briefly on other industrial applications of automation. Steel production has in common with electric power generation the need for continuously reliable equipment to ensure high availability and maximum output from high capital investment. In steel also is a need for consistent high quality and uniformity in the end product. Thus it is not surprising that this industry has also been in the forefront in applying the facilities of high speed digital equipment for data collection, recording and control.

The data accumulation is used on a tinning line to measure and record defects on the strip. These defects are detected by a variety of sensors to show pinholes, off gauge sheet, and coating thickness. Coil identification is inserted manually.

Some special problems in memory arise since defects must be recorded in relation to the exact foot of strip in which they occur to permit totalizing prime strip footage free of defects. Results are recorded for each finished coil giving a record of quality which could not be produced by any other means.

Another example shows a fine match between analog control and digital control. Each stand of the hot strip mill has its own analog gauge control scheme. The computer is designed to optimize analog settings to produce the best load division between stands for optimum quality. It does this by estimating from incoming strip temperature the appropriate setting. This is a coarse calculation. It is based on assumed strip temperature from a surface temperature measurement and estimated hardness of incoming steel. By measuring actual power input to the first stand and comparing this with the computer's estimate, any deviations in temperature and hardness as they affect rolling quality are evaluated. These variations are used to repeat the calculations for the remaining stands in time to adjust the analog set-points of the

Fig. 5. Control Computer System for Steam Plant Automation



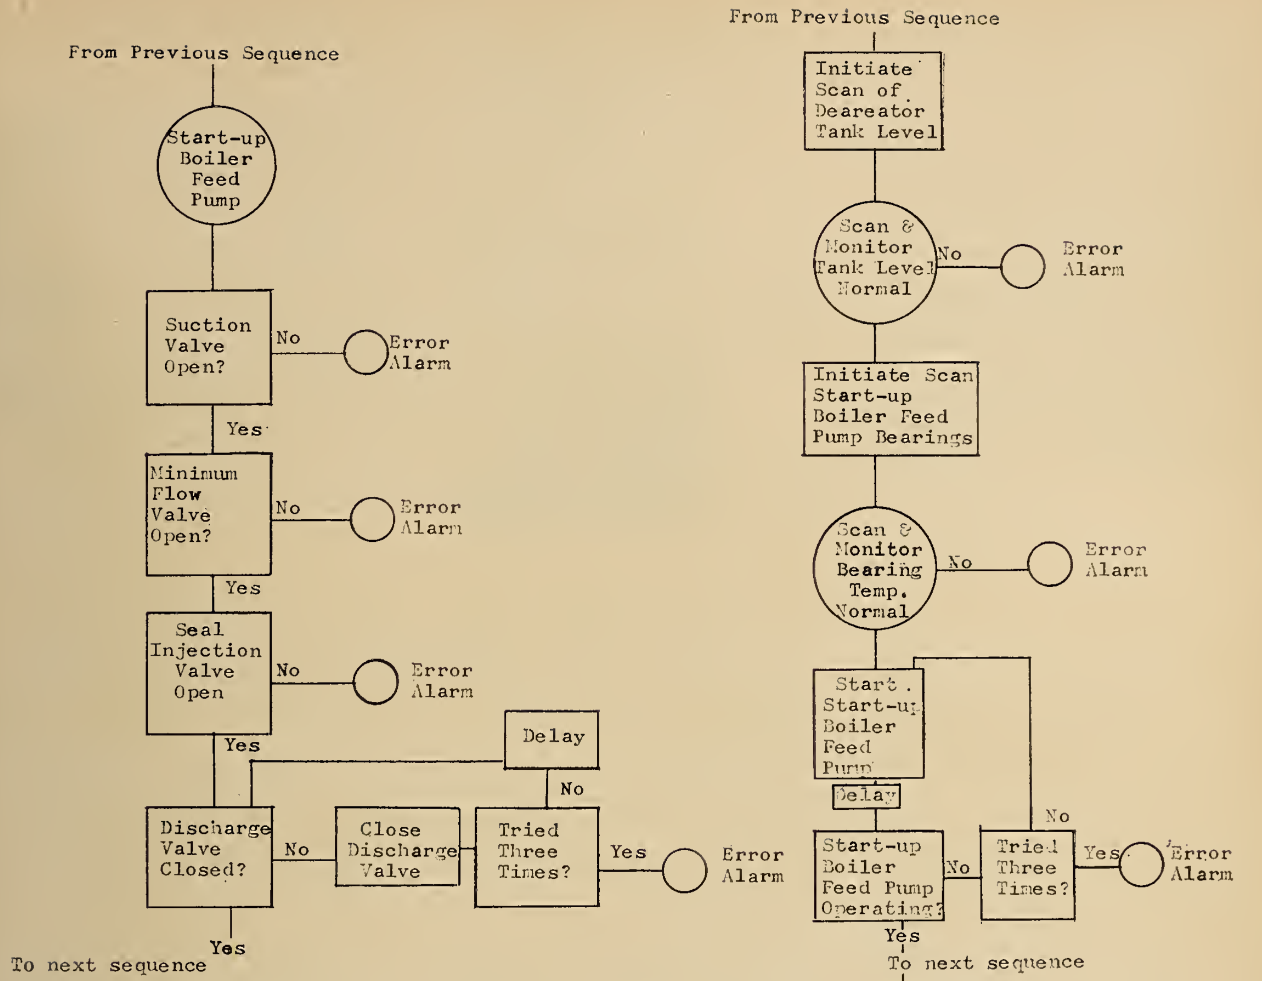


Fig. 6. Portions of Computer Orientated Start-up Sequence: Boiler Feed Pump

gauge controls even closer to ideal values. This is a good example of computer optimizing and "self education" in which it improves on its own best guess.

These necessarily brief remarks on two other industrial process applications serve to indicate how experience in many fields is being obtained and this all helps to ensure the best equipment quality and application techniques.

Conclusion

Steam station automation is but one example of the application of techniques and equipment which are producing an industrial revolution as significant as the introduction of steam power.

New apparatus does not change the basis of process control but merely expands the horizons of what can be achieved. Proper choice and good application depend on a review of the broad economic benefits which can be obtained. Justification may hinge upon lower costs of production, higher utilization of the investment in plant and better quality of output.

Computers permit higher speeds of calculation, more rapid corrective action and in many cases closer control. Computers require reliable apparatus, expert programming and full understanding of the process to be controlled.

A computer can help solve some of its own problems by collecting data and providing performance results from processes which are insufficiently understood. Further, by programming on an optimizing basis, a computer can improve upon the initial results much as a human being gains skill as he becomes more familiar with his job.

Best results will follow if the computer is designed into the process rather than by being superimposed upon it. A clear philosophy of application should be allowed to permeate the programming of the computer, the application of conventional control and the provision of conventional instrumentation. In general the operator should be presented only with information upon which he is required to make decisions. Data of historical value should be recorded separately. Where computed results give significant indication of process conditions, the raw data used in the calculation need not be preserved.

While automatic control of a thermal generating unit may require the scanning of 300 to 600 analog quantities and up to 600 contact inputs, the historical record may contain only 10 to 50 items. Thus what may seem to have started out as the compounding of complication upon an already complex process has resulted in opportunity for improved performance and at the same time reduces significantly the information which the plant operator must review to provide effective supervision.

A substation in popular use by electrical utilities in Ontario[1] is the outdoor open construction with the high and low voltage lines overhead. This type of substation is used in areas with low load densities such as rural or suburban localities. It has a simple layout with lightning arrestors, an air-break switch and fuses on the supply line to the high voltage side of the transformer, and fuses on the low voltage feeders. The design provides for oil circuit breakers and load interrupter switches which are commonly used in addition to the low voltage fuses. Separate structures for the high voltage and low voltage equipment give a maximum of flexibility in the layout. The transformer bank, one 3 phase or three single phase units, is located between the two structures. The station is used with supply voltages up to 44 kv. and up to 12 kv. on the feeders.

THE DESIGN of the low voltage side of this station is very flexible. The secondary switches, fusing, metering, voltage regulation and number of feeder circuits can be varied to suit the load requirements. The overhead feeders can be taken off in several directions without extreme changes in the secondary structure. Where the right of way for overhead lines is restricted, the high voltage line can enter from the street and the secondary lines can leave the station in the same direction. They may even be mounted on the same pole. With such a versatile station design, the structures must be designed to accommodate a great variation in equipment.

The demand for this type of station increased with the steady load growth in the rural and suburban areas. The versatility of the station design presents the manufacturer with the problem of producing a standard structure to meet the exact requirements of the purchaser.

Bolted Steel Structures

An early design consisted of an H-frame structure for the high voltage equipment and a four column box structure for the low voltage equipment with all members made from single channels and angles of galvanized steel. The individual pieces were cut and holes were punched before galvanizing. In a bolted structure of this type all connections are made in the field. The weight of the steel for the high voltage structure is 2,500 lb. and for the low voltage structure is 3,000 lb.

There are several disadvantages to the bolted steel structure. Each non-identical piece of the structure requires a detail drawing before it can be manufactured. The length of members is limited by the available galvanizing facilities. Galvanizing tends to block holes making extra work for the erectors. The need for enough material around bolt holes limits the minimum size of members. The main disadvantage of this type of construction is the large number of bolted connections that must be made during the field erection.

Welded Steel Structures

To reduce the number of field connections, a welded type of structure was developed. Columns and girders, consisting of four chord angles with lacing of rods and light angle, are shop-welded. By restricting the overall dimension to a few common sizes, standard methods can be used for manufacturing the structural members. Dimensional tolerances can be maintained. Component parts can be kept in stock. Engineering time is reduced.

The use of shop-welded columns and girders is ideal for the standard substation structure. The basic design work is done in advance of an order. The designer selects the correct size of members from stock and adds only the extra parts necessary to adapt the standard structure to the special requirements of the station. As we have seen above, many variations of equipment are mounted on the low voltage structure. It is here that the designer may, of necessity, deviate from standard members.

The field erection is simplified, because of the fewer number of pieces. The parts are easier to identify and locate in the structure.

A typical example of this type of station is shown in Fig. 1. It was erected in July, 1958. This station has a 13.8 kv. high voltage line entering the primary structure at a height of 31 ft. above grade. The high voltage equipment mounted on the structure consists of: 3 pole gang operated switch, 3 lightning arrestors, 3 power fuses and bus supports. The 3000 kva., 3 phase transformer is located between the high voltage structure and the 4.16 kv. secondary structure. Two, four-wire, feeder circuits are strained off the secondary structure in two directions with provision for adding a third circuit. The low voltage equipment consists of load interrupter switches and fuses on each feeder circuit.

The primary H-frame structure is made from only 7 shop-welded assemblies and weighs 2,500 lb. The secondary structure weighs 4,100 lb.

Standard welded columns used in the station are 12 in. x 12 in. and 12 in. x 30 in.

The use of steel, in the welded assemblies, presented a number of difficulties. The length of the members was still limited by the galvanizing facilities. The maximum length of a 12 in. x 30 in. column that could be galvanized was 20 ft. The weight and bulk of the welded member prevented the shaking of excess galvanizing from it, so that build-up was common in holes and sharp tips were left to cut the hands and belts of the erection crew. Twisting and bending, resulting from the heat of the galvanizing process, made it necessary to straighten the welded assembly before it could be erected.

This substation design, using prefabricated steel members, was accepted by users as being a great improvement. Many industrial and utility stations of this type were erected and are still in service throughout Ontario.

Why Aluminum

Investigations, however, continued in an attempt to reduce the difficulties encountered in galvanized steel substation structures. These led to the examination of aluminum as an alternative to steel.

Aluminum as a structural material has many features to recommend its use in outdoor substations. One of its salient properties is resistance to most atmospheric environments. Because of the natural affinity of aluminum for oxygen, an oxide film is always present on the surface of the metal. This thin, dense film is tenacious and self-healing and provides the key to aluminum's ability to resist attack by various corrosive agents.

The structural aluminum alloys are practically impervious to sulphur-contaminated industrial atmospheres as well as salt-laden coastal air, or even a combination of both. Tests by the Alcoa Research Laboratories[2] indicate that ⅛ in. and 3/16 in. material after 20 yr. exposure to a severe industrial atmosphere (at New Kensington, Pa.) would suffer a loss of tensile strength of approximately 1.5% and 1% respectively. In a coastal atmosphere (Pt. Judith, R.I.), the loss would be even less. The good corrosion resistance of aluminum is a significant factor in reducing maintenance and enhancing appearance.

Structural aluminum alloys perform satisfactorily adjacent to such alkaline materials as concrete.[3,4] Likewise, no detrimental effect results from contact with hot dipped galvanized items encountered in substations such as insulator pins, caps, switch bases, line hardware, splice or anchor bolts.

The aluminum alloys normally specified for structural use, compared with steel, have ultimate tensile strengths ranging from 63% to 100%. However, the tensile yield strengths vary from 66% to 140% of the yield strength of steel. All aluminum alloys exhibit a narrower spread between the ultimate tensile and yield strengths than does structural steel. That is to say, the yield strength of a structural aluminum alloy is a greater percentage of ultimate strength than is the case with structural steel.

The coefficient of linear expansion is approximately twice that of steel while the modulus of elasticity is three times. The result is that stresses, due to temperature changes, are less in aluminum than in steel. Because of the lower modulus of elasticity, deflections in aluminum are approximately three times that of steel under identical conditions.

Aluminum can be readily extruded using relatively inexpensive dies. This means that special shapes, which make the most efficient use of the material for any particular design, are both practical and economical. To take advantage of maximum economies it is, however, necessary to purchase in large quantities. The lengths of members are limited only by handling and transportation considerations, rather than by the length of galvanizing tanks as is often the case with galvanized steel members.

Frequently, it is necessary, or desirable, to make alterations at the site. These may result from design changes or additions to the station. Aluminum can be drilled without difficulty and without impairing its corrosion protection.

Bolted Aluminum Structures

The first attempts, at the utilization of aluminum in substations, involved standard structural shapes. It has been common practice for designers to substitute aluminum for steel structural shapes, increasing the size of the aluminum members to obtain comparable rigidity. These structures were either bolted or rivetted and were almost exact copies of their steel counterparts. This design method did not result in the most economical aluminum structures. The weight of the
