CLEVELAND SPEED VARIATOR

Accurately Provides Dependable, Infinitely Variable Speed Control

ANNOUNCED late in 1954, the new Cleveland Speed Variator met instant, enthusiastic acceptance. Engineers and designers of industrial equipment already have put thousands of units into use on such varied equipment as cigarette making machines, textile machinery, metalworking machinery, pharmaceutical equipment, transfer tables, conveyors and experimental and testing equipment of many types.

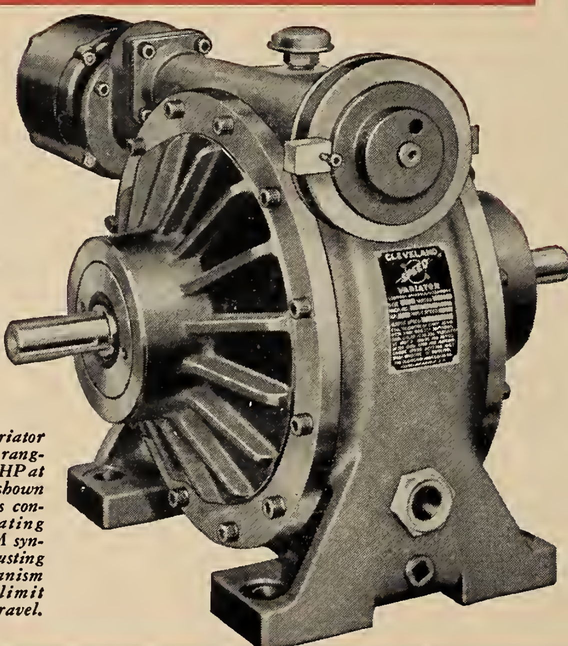
Infinitely variable, the Cleveland Speed Variator gives stepless speed over a full 9:1 range—from ⅓ to 3 times input speed. Output speed can be adjusted by either a hand wheel on the Variator or by manual or automatic remote control.

The Cleveland Speed Variator offers these major advantages:

1. An extremely compact unit with input and output shafts in line and rotating in the same direction.
2. Almost any input speed up to 1800 RPM can be used—either clockwise or counterclockwise rotation.
3. Rated for constant horsepower output over a 9:1 or 6:1 range; or for constant output torque over a 6:1 range.
4. Speeds infinitely variable over entire range of adjustment.
5. No slippage—positive torque response mechanism adjusts in direct proportion to the loads encountered.
6. Long life and minimum maintenance due to absence of belts or complicated linkages.
7. Ample bearing support for overhung pulleys on both input and output shafts.

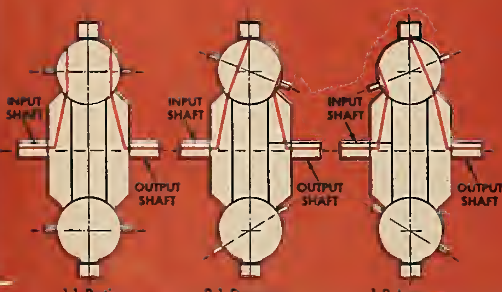
Write for Bulletin K-200 for detailed description with photographs, sectional drawings, rating tables and specifications.

Typical speed regulation curves for the Types K and KL Variators. Type KL offers a linear speed regulating pattern, often an advantage in automatic control applications. Output speed regulation of the Type K Variator follows a geometric progression pattern. Starting at the minimum output speed, each turn of the speed regulating wheel produces a fixed percentage increase in output shaft speed.



The Cleveland Speed Variator is available in 18 models ranging from fractional to 16 HP at 1750 input RPM. Unit shown at right, used in process control, has speed regulating worm driven by 75 RPM synchronous motor, with adjusting shaft indicating mechanism modified to actuate limit switches to prevent overtravel.

HOW THE CLEVELAND SPEED VARIATOR WORKS



Power is transmitted from input shaft to output shaft through alloy steel driving balls which are in pressure contact with discs attached to the two shafts.

Relative speeds of the shafts are adjusted by changing the positioning of axles on which the balls rotate (diagram, right, shows cutaway Variator with hand regulating wheel).

"It's the Drive That's on the Ball."

MEET THE AUTHORS

F. T. Matthias, director of engineering and construction, Aluminum Company of Canada, Limited, Montreal *(Planning and Construction of the Chute-des-Passes Hydroelectric Power Project).*

Mr. Matthias received his B.S. degree in civil engineering from the University of Wisconsin in 1931, and an M.S. degree in 1933. From 1931 to 1935 Mr. Matthias was an instructor at that university. He worked with the Tennessee Valley Authority for four years and later with Johnson Construction Company and the Dravo Corporation. In 1941 Mr. Matthias joined the U.S. military service and after five years in the forces worked in Brazil on hydroelectric design and construction. He became assistant manager of Alcan's B.C. Project in 1952 and was appointed chief engineer in 1956. In 1957 he was promoted to his present position.

F. J. Travers, M.E.I.C., senior project engineer, H. G. Acres and Company Limited, Niagara Falls, Ont. *(Planning and Construction of the Chute-des-Passes Hydroelectric Power Project).*

Mr. Travers received his B.A.Sc. in civil engineering in 1944 and after graduation joined McColl-Frontenac Oil Company Limited in Montreal. He worked for the Hydro-Electric Power Commission of Ontario from 1947 to 1955 co-ordinating the construction of generating stations and the activities of the joint power development in Cornwall. In 1955 he became a senior project engineer for H. G. Acres and Company.

J. W. L. Duncan, administrative representative for the installation of all electrical and mechanical equipment, Aluminum Company of Canada, Limited, Chute-des-Passes, Que. *(Planning and Construction of the Chute-des-Passes Hydroelectric Power Project).*

Mr. Duncan obtained an M.A.Sc. degree from the University of Toronto in 1950 and joined the Aluminum Company of Canada, Limited the same year. Working on the Chute-des-Passes project, Mr. Duncan was involved in the initial hydraulic and power studies and later in equipment specifications.

C. L. Merrill, district administrator, Fort Smith, Department of Northern Affairs and National Resources *(The New Aklavik—Search for the Site).*

Mr. Merrill studied geology at Western University and continued with post-graduate studies in geography from 1945 to 1950. He participated in the sea-borne expeditions, "NAUJA" and "CANCOLIM". As project manager from 1954 to 1956 Mr. Merrill was in charge of siting and development work at the New Aklavik.

J. A. Pihlainen, JR.E.I.C., Northern Building Section, Division of Building Research, National Research Council, Ottawa *(The New Aklavik—Search for the Site).*

Mr. Pihlainen received a B.Eng. from McGill University in 1950 and his M.S. in civil engineering from Purdue University in 1952. For the past ten field seasons he has been carrying out research for the N.R.C. on permafrost, engineering site investigations and building foundations, principally in the Mackenzie River district of the N.W.T.

Robert F. Legget, M.E.I.C., director, Division of Building Research, National Research Council of Canada, Ottawa *(The New Aklavik—Search for the Site).*

Mr. Legget graduated from the University of Liverpool, England in 1925 and received the degree of Master of Engineering from the same institution in 1927. He came to Canada in 1929 and was engaged in heavy construction engineering until 1936 when he entered the educational field. Mr. Legget was on the Queen's University staff for two years and then on the University of Toronto faculty until 1947 when he was appointed by the National Research Council to head the new Division of Building Research.

G. L. Tiley, application engineer, Mining, Petroleum and Chemical Division, Canadian Westinghouse Company Limited *(Industrial Uses for an Auxiliary Low Frequency Supply).*

Mr. Tiley was born and educated in South Africa and received his B.Sc. in electrical engineering from the University of Witwatersrand in 1941. In 1946 he was awarded a B.Sc. in Mechanical engineering from the same university. From 1942-1945 he served as a radar officer with the Royal Navy. He was employed as an engineer on the Gold Mines of Witwatersrand before coming to Canada to his present position.

E. Oldfield, application engineer, Mining, Petroleum and Chemical Division, Canadian Westinghouse Company Limited *(Industrial Uses for an Auxiliary Low Frequency Supply).*

Mr. Oldfield was educated in Manchester, England and received the higher National Certificate (Electrical) from Manchester College of Technology in 1943. He was apprenticed at Metropolitan-Vickers Electric Company Limited during the war, working in the mine hoist electrics division.

K. A. Henry, JR.E.I.C., river control engineer, The Hydro-Electric Power Commission of Ontario *(River Control in the International Rapids Section — St. Lawrence Power Project).*

Mr. Henry graduated from the University of Alberta in 1948 with a B.Sc. in civil engineering. He was supervisor of hydraulic operations during construction at Rolphton, Ontario, then spent five years in the Ontario Hydro's hydraulic model laboratory at Islington and the University of Toronto, constructing and testing models of the Niagara and St. Lawrence Hydro-Electric projects.

J. A. Reid, JR.E.I.C., manager of motor sales, motor and Generator Division, Canadian Westinghouse Company Limited, Hamilton *(Voluntary Standards—Vital to Progress).*

Mr. Reid graduated in electrical engineering from the University of Manitoba in 1949 and joined Canadian Westinghouse Company Limited the same year on the graduate student program.

General view of power development looking upstream

Extensive Dominion Bridge Equipment Now In Operation at the Beaumont Power Project

The Shawinigan Water and Power Company's hydro-electric developments on the St. Maurice River in the province of Quebec, designed and constructed by The Shawinigan Engineering Company, Limited are now providing a power capacity in excess of two million horsepower. Seven sites have been developed and the Beaumont power project is the latest. Three more usable sites remain.

The Beaumont development is located ten miles above La Tuque and provides 330,000 horsepower from six 55,000 horsepower Francis turbines.

The development included numerous major projects: construction of access roads; erecting construction plant and housing; excavating over 11,000,000 tons of earth and rock and building and equipping the dam and power station; erecting a 90-mile transmission line; relocating a 10-mile stretch of railway; building two railway bridges; and driving a 700-foot railway tunnel.

WINNIPEG — CITY OF FORTS

1960 CONVENTION CENTRE

Lower Fort Garry, now one of Winnipeg's major tourist attractions, was once the seat of government. Almost all of what now is Canada was ruled from this fort. It was also, for a while, headquarters of the Hudson's Bay Company. A corner of the old fort is shown below.

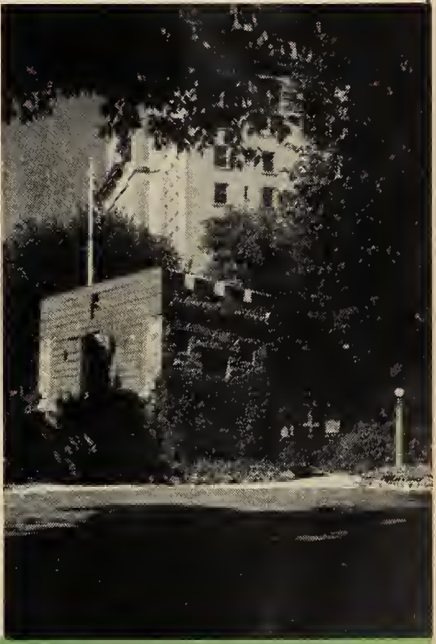
Lower Fort Garry, built 1832, is the only stone fort of the fur trade regime still intact anywhere in North America. It is now a museum and home of the Winnipeg Motor Country Club. Superb food and golf have replaced beaver tail and pemmican, and the rough games of the Indians and fur traders.

The original Upper Fort Garry was built in 1821, was reconstructed and enlarged in 1839, and finally dismantled in 1882. The North Gate, below, is all that remains of the proud old fort which was occupied by Louis Riel's forces and later by Wolseley's Red River Settlement volunteers.

Three famous forts once stood at the forks of the Red and Assiniboine Rivers: Fort Rouge, the first structure built on the site of the present city of Winnipeg; Fort Gibraltar of the North West Company, and Upper Fort Garry of the Hudson's Bay Company.

Within their thick walls, as well as at Lower Fort Garry (18 miles north of Winnipeg), members of the governing bodies made the policies and took the actions which decided the future not only of the West but of Canada as a whole.

The old forts and their purpose have long been gone but the City of Winnipeg remains as a bastion of economic and cultural development.



PLAN NOW TO ATTEND the 74th ANNUAL MEETING

Royal Alexandra Hotel — MAY 24-27, 1960 - WINNIPEG

A MESSAGE

FROM

THE PRESIDENT

It is a pleasure and a privilege to announce that, effective with this issue, The Engineering Institute of Canada will send *The Engineering Journal* each month to over 32,000 engineers in this country.

For many months, the Council of the Institute considered ways and means of obtaining wider dissemination of the technical articles and news items which *The Engineering Journal* contains, to ensure the maximum effectiveness of the publication as an essential service to Canadian engineers.

The Engineering Journal will be sent without charge to over 32,000 engineers in Canada, and to members of the Institute outside the country. All other subscribers will be required to pay the regular subscription rate.

It is the Institute's aim to make every issue topical and highly informative. An even balance between reading and advertising content will be maintained.

Obviously, to ensure the success of this venture, we must have the full co-operation of the recipients of the publication. We hope that they will keep the Institute informed of their changes in address and occupation so that the mailing lists may be kept up-to-date.

We are always happy to have comments and suggestions from our readers for further improvements.

J. J. Hanna

J. J. HANNA, M.E.I.C.

PLANNING AND CONSTRUCTION OF THE CHUTE-DES-PASSES HYDROELECTRIC POWER PROJECT

F. T. Matthias, *Director of Engineering and Construction Aluminum Company of Canada Limited, Montreal, Que.*

F. J. Travers, M.E.I.C., *Senior Project Engineer at Chute-des-Passes, for H. G. Acres & Company Limited Consulting Engineers, Niagara Falls, Ont.*

J. W. L. Duncan, *Electrical Engineer Aluminum Company of Canada Limited, Isle Maligne, Que.*

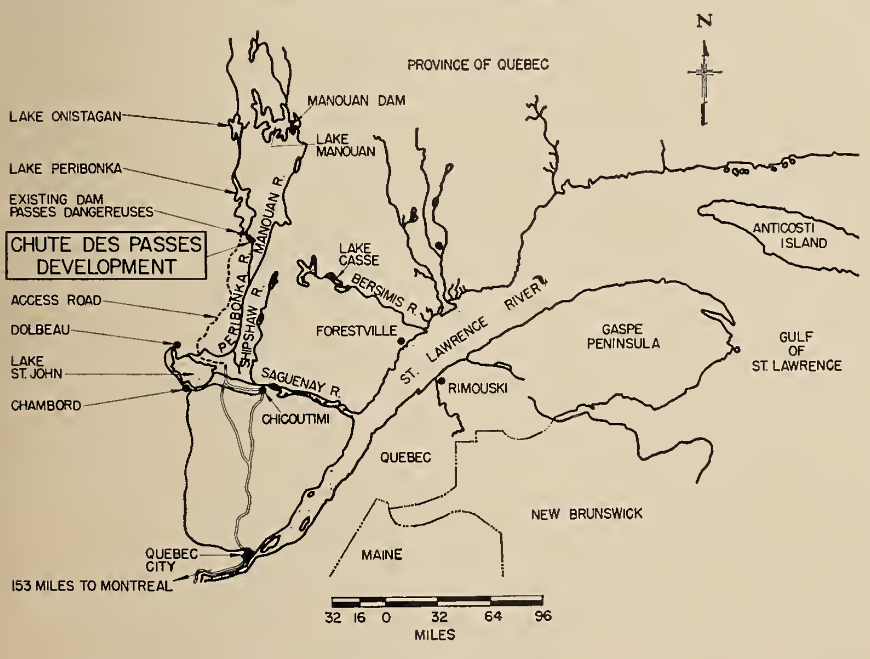
THE SAGUENAY and Peribonka Rivers are famous in the annals of early Canadian exploration and fur trade, this course being a main route from the St. Lawrence River to Lake Mistassini and thence to James Bay. This district is known generally as the Saguenay area and is shown in Fig. 1.

The power potential in the Saguenay has been recognized for a long time and the first grant for a power development was issued in 1900. After a series of surveys by various interested parties over the years, actual construction of the Isle Maligne development was started in 1922 and ultimately grew to an installed capacity of 540,000 h.p. Subsequent projects on the Saguenay system were the 300,000 h.p. Chute-a-Caron development completed in 1931, the Shipshaw 1,200,000 h.p. development completed in 1942, the Chute-du-Diable development completed in 1952 and the Chute-à-la-Savane development completed in 1953. In 1941 the Aluminum Company of Canada, Limited, completed construction of the Lake Manouan Storage Dam and in 1943 the Passes Dangereuse Dam was put into operation. The waters impounded in these two reservoirs, together with that stored in the older reservoir, Lake St. John, effect the required hydraulic regulation for the existing power system of some 2,600,000 h.p. of installed capacity. The system is operated jointly by the Aluminum Company of Canada, Limited and the Saguenay Power Company, Limited.

While no physical facilities were built into the Passes Dangereuse Dam towards utilization of the head developed by the dam and the steep fall of the Peribonka River through a 6½-mile reach downstream, the power potential was recognized and planning and studies were carried on. In 1955, as load growths indicated need for additional power, a comprehensive preliminary engineering study of the project was made and a report issued in January, 1956. Detailed studies continued and by middle 1956 the general design had been established.

The drainage area above the Passes Dangereuses Dam is 4,787 square miles, and the Lake Manouan Dam controls storage from an additional 1,920 square miles. Unfortunately, however, the natural outlet of Lake Manouan discharges into the Peribonka River some thirty miles downstream from the Chutes-des-Passes development. To utilize the Lake Man-

Fig. 1. Location of development.



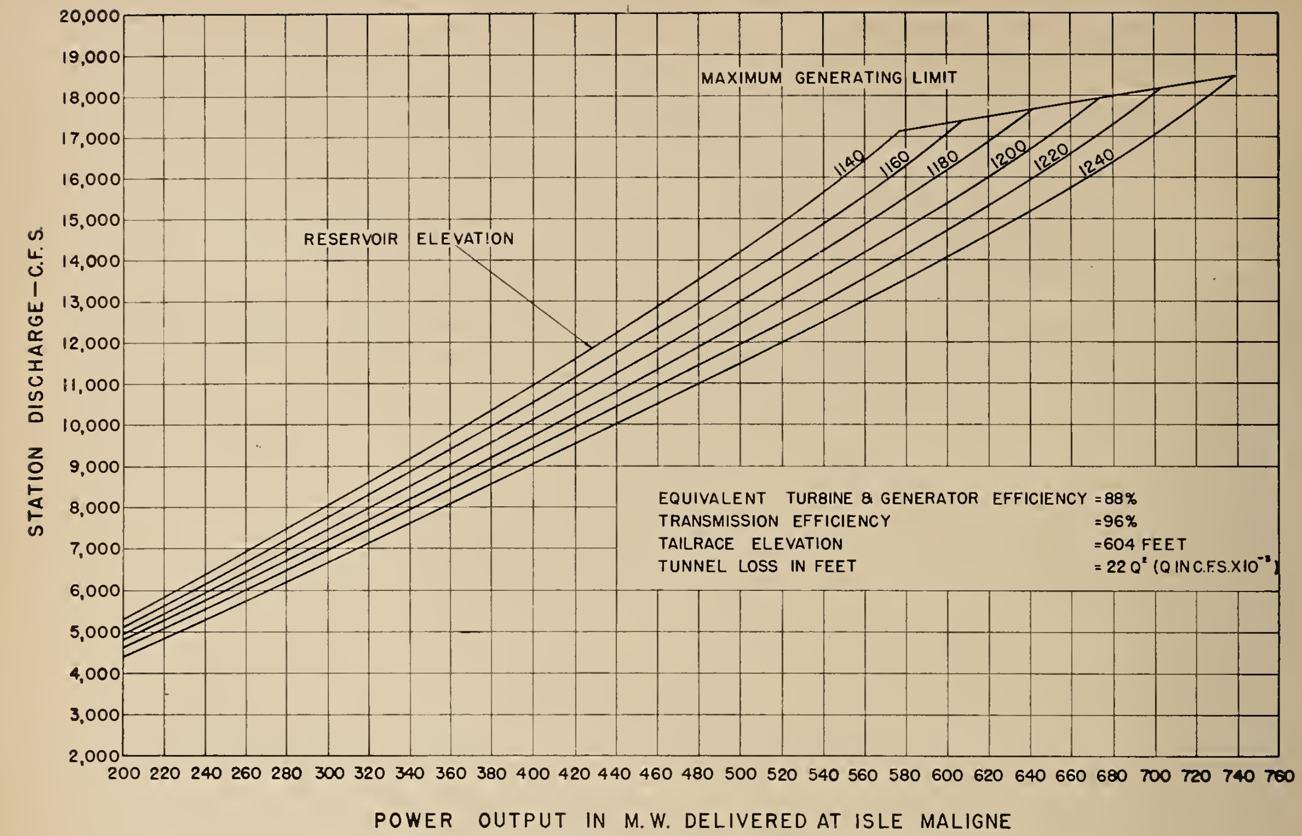


Fig. 2. Power at Isle Maligne v. station discharge at Chute-des-Passes.

ouan water through Chutes-des-Passes Powerhouse requires a controlled outlet and channel to the reservoir above Passes Dangereuse Dam. The plan to accomplish this is to build a concrete control structure near the western end of Lake Manouan and a channel about 2-miles long into the Bonnard River which is part of the Passes Dangereuse drainage area. Studies indicated that with such a diversion the Chute-des-Passes Project would increase the "Firm Generation" of the Saguenay Power System by some 675,000 h.p. The studies further indicated that a station would be required having a nominal capacity of 1,000,000 h.p. with the reservoir near the top elevation of 1,240 ft. and a capacity of 800,000 h.p. at an elevation of 1,140 ft. With such an installation the installed capacity of the Saguenay Power System would be about 3,600,000 h.p.

General Design

Consideration of topography and geology indicated that an underground development would be the most practicable and economical. Several arrangements of intake tunnel, powerhouse and discharge tunnel were considered during the early stages of design. For an underground station the powerhouse must be under enough good rock cover to be safe under the hydraulic and rock pressures existing. The elevation of the powerhouse had to be established relative to the tailrace discharge, so factors determining location involved tunnel location, position of powerhouse along the tunnel and the rock topography.

Core drill sub-surface investigations indicated that the rock was generally sound. The drilling confirmed the presence of a short but major fault section between the powerhouse and the reservoir that had been identified as a probability from surface geological exploration. Careful attention during core drilling was paid to the bedding planes and joint systems of the rock as well as to the general character of the material. As a result of these investigations the powerhouse was changed 90° in orientation to improve the strength of the side walls. In its revised location, the longitudinal line of the powerhoure is approximately at right angles to the strike of the bedding planes of the rock. This orientation minimizes the possibility that rock might slide out of the side walls which could weaken the haunch that supports the concrete arch of the powerhouse.

Core drilling information also confirmed surface indications of extensive faults along the east side of the Peribonka River, originally selected as the line for the tailrace tunnel. This poor rock was certain to cause serious excavation problems and surface geological indications were carefully studied to determine likely alternate routes. The more favourable route followed crossed under the Peribonka River below the powerhouse and then back into the river from the west side. Core drilling done along this route confirmed its desirability.

The intake structure will take water from the Passes Dangereuse reservoir adjacent to the dam on the left bank. This intake will provide for 100 ft. drawdown from elevation 1240 to 1140 in the reservoir. The tailrace elevation is approximately at elevation 604 ft. Because of the depth and size of gates required and the large drawdown, the intake gate structure presented problems in design almost without precedent. The bottom of the intake gates is about 160 ft. below the maximum reservoir surface.

Description and Layout

Starting at the intake, water will be taken from the Passes Dangereuse Reservoir into an intake tunnel leading to the intake structure. Thence the water is carried in a concrete-lined supply tunnel, 31,000 ft. long, to a penstock manifold. From this point the water is lead to each unit through steel-lined penstocks and is then discharged from the units into the draft tube manifold. The water is then carried in an unlined discharge tunnel some 9100 ft. in length leading back to the Peribonka River.

Power will be generated at a nominal voltage of 14.4 kv., transformed to 385 kv. in a surface switching station and transmitted to Isle Maligne some 90 miles distant. The original power studies were based upon curves such as those shown on Fig. 2 but these curves will require modification subsequent to the completion of the station when the actual hydraulic losses and equipment efficiencies will be known.

Construction at Chute-des-Passes was begun in the summer of 1956 and the initial power output is expected to be in September, 1959.

Intake

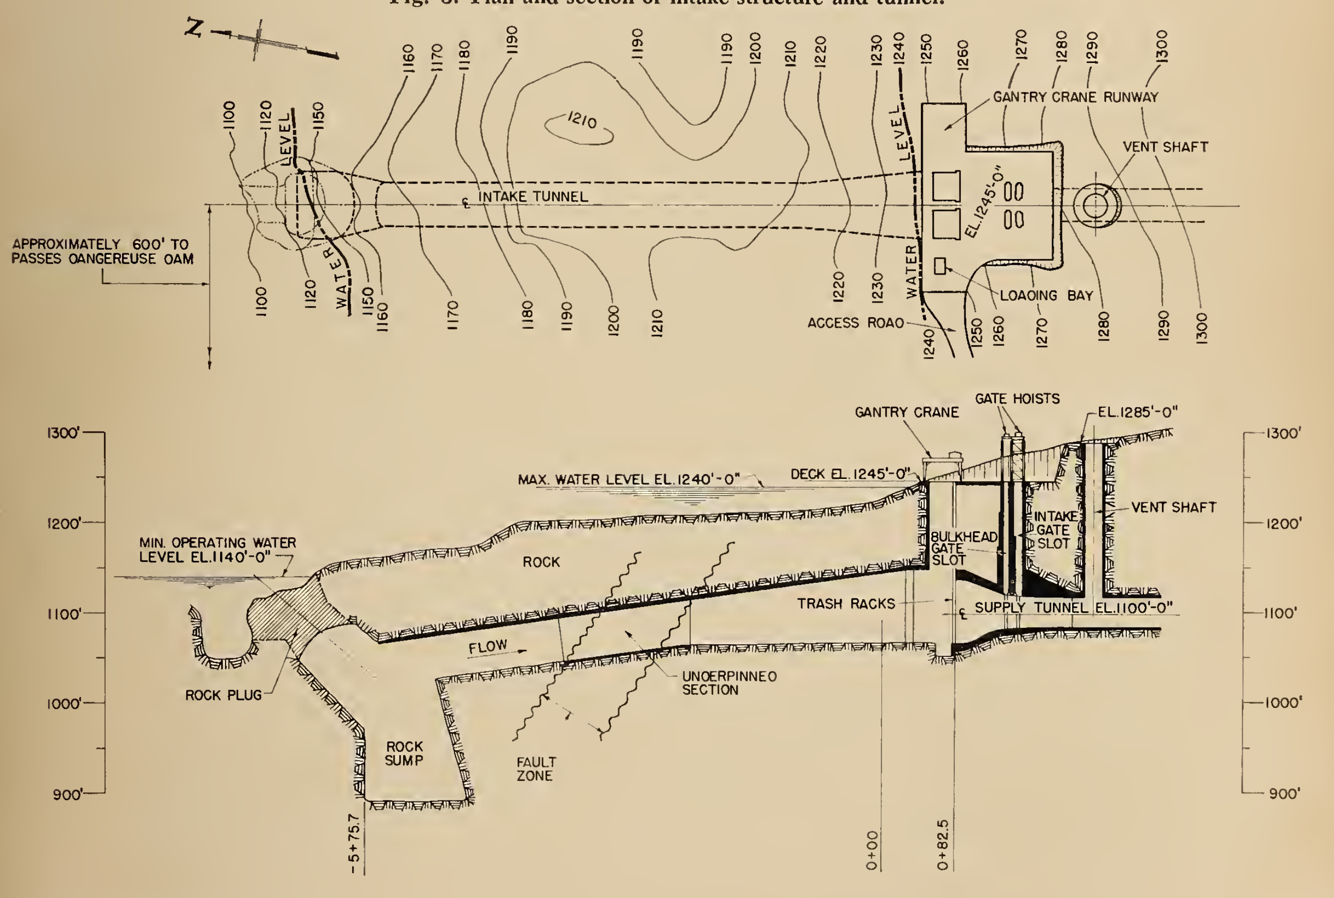
Referring to Fig. 3, the intake as a whole consists of a tunnel intake at the bottom of the reservoir, an intake tunnel and a reinforced concrete structure incorporating trash racks, one bulkhead gate, two intake gates and a vent shaft.

Ingress of water to the intake and other workings downstream was blocked by a rock plug which was removed on 19th April, 1959. Removal of this plug was contingent on low water levels in the reservoir and optimum conditions for the operation did occur just before the Spring breakup which takes place sometime between 1st April and 10th May of each year. Models were built to determine the shape and location of the inlet from the bottom of the reservoir and extensive tests were carried out utilizing different shapes to arrive at an optimum design. Associated with this design, other studies were carried out to determine the shape and size of the sump required to catch the rock from the plug when it was blasted. After numerous experiments utilizing various combinations of plug and sump shapes, it was possible to determine the behaviour of falling rock so that a minimum quantity of rock would be carried down the intake tunnel by the inrush of water.

Water will be led to the intake structure by means of a partially-lined intake tunnel about 600 ft. long. The lining consists essentially of a concrete arch which will offer permanent support to the rock above the tunnel. One of the two major faults encountered in the underground work on the project was in this tunnel upstream from the intake and the arch in the area is underpinned with reinforced concrete. Further protection of the rock is afforded by a reinforced concrete floor extending the full length of the faulted area. The intake tunnel is horseshoe shaped in cross-section and over its greater length is 50-ft. wide and about 50-ft. high. At a point approximately 300 ft. upstream from the trash racks the floor of the tunnel changes grade and the height of the tunnel begins to increase as it approaches the intake structure. Referring to the plan view, the tunnel begins to widen 176 ft. upstream from the trash racks and reaches a maximum width of 70 ft. and is about 80 ft. high as it enters the trash rack shaft. The form and extent of the transition were determined from model studies performed to establish an arrangement giving an even distribution of flow across the trash racks. Velocities through the intake tunnel are in the order of 9 or 10 ft. per second under maximum flow conditions. With all five units operating the average net velocity of the water between the trash rack bars will be approximately 6 ft. per second which will uniformly accelerate to a velocity of 18.6 ft. per second in the supply tunnel.

The intake structure is located in open rock cut about 80-ft. wide, 110-ft. long and about 215-ft. deep. The

Fig. 3. Plan and section of intake structure and tunnel.



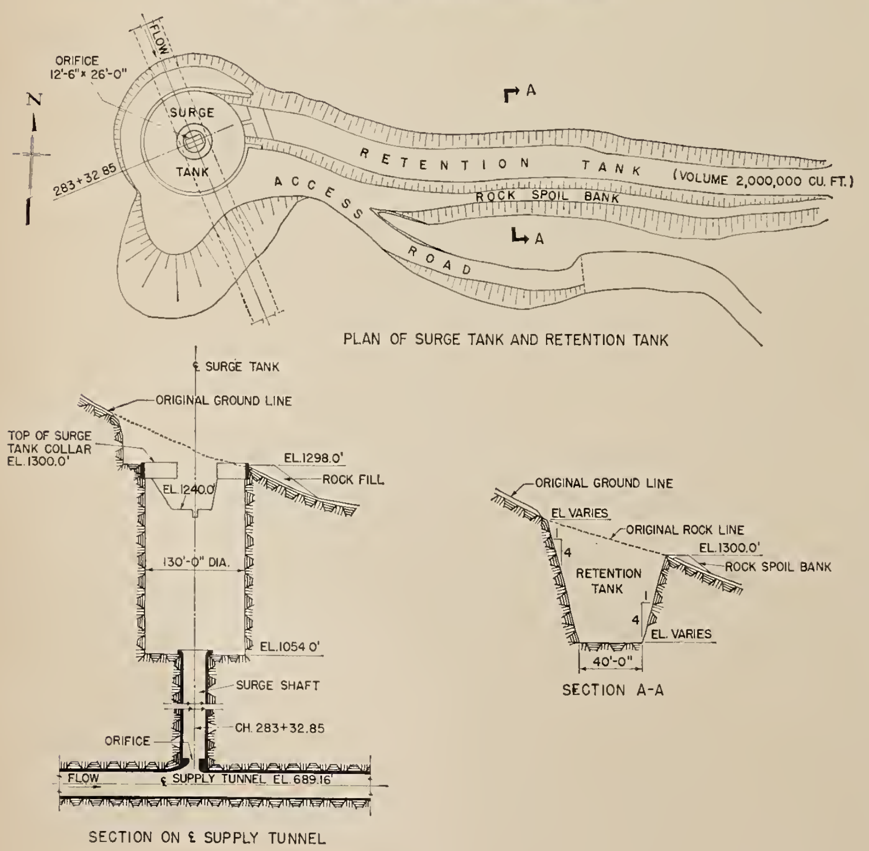
flow of water approaching the structure is divided by a central pier which extends 18 ft. upstream into the intake tunnel, thus providing additional support for the wide tunnel arch span at this location. The central pier terminates about 60 ft. downstream from the intake gates. Essentially the basic requirements for an intake of this type is to have a streamlined intake tube which will accelerate the water from the trash racks to the junction of the intake with the supply tunnel, keeping hydraulic losses to a minimum. This requires a properly designed transition. The entire transition from the trash racks to the beginning of the supply tunnel is 125 ft. in length.

The trash racks are made up of 6-in. by ½-in. bars, with a spacing of 5½ in. The bars are fabricated into panels 33 ft.-10 in. wide and 8 ft.-10 in. high with eight such panels comprising a whole trash rack. The racks are designed for a differential head of 35-ft. within normal design stress limits. A deflector will be provided to rest on the top panel of each opening to prevent the accumulation of trash on the top of the racks. The trash racks will be serviced by a gantry crane operating over the trash rack opening. Cleaning of the racks will be accomplished by utilizing a clam bucket operated by a gantry crane to remove trash accumulated in the sump located immediately upstream from the racks.

Guides for one bulkhead gate are provided in each water passage and the gate can be lowered into either passage by a hoist located on a steel superstructure which also incorporates the fixed hoists for the two intake gates. The bulkhead gate is a sliding type of gate with downstream seals and can be lowered only under static water conditions. Under emergency conditions with one intake gate lowered and the bulkhead gate positioned in the other water passage, access can be gained to the embedded parts and sealing faces of the second intake gate. The bulkhead gate is 40 ft.-3 in. high by 19 ft.-6 in. wide.

The two intake gates are of the fixed roller type with upstream seals. The gates are 16 ft.-10 in. centre to centre of the rollers and 38 ft.-5½ in. high and are operated by fixed hoists located on the deck superstructure. The lowering rate of the gates is one foot per minute, a limitation imposed by hydraulic considerations associated with surges in the supply tunnel. These gates can be lowered under full flow conditions should the need arise. During normal operating conditions, both gates will be stored just above the lintel of the gate opening and will be suspended by steel links pinned together.

Fig. 4. Surge tank and retention tank.



Supply Tunnel

The supply tunnel will be concrete-lined through its entire length and is a modified horseshoe shape in cross-section. This tunnel was driven from the three adits and five headings were in progress simultaneously. The finished tunnel will have a nominal diameter of 35 ft., or in other words the cross-section is equivalent to circular tunnel of this diameter. Actually the diameter of the top half tunnel is 34 ft.-7 in., the remaining equivalent area being made up by flattening the invert and extending the sides to meet the short radius fillets in the lower corners. This shape was mainly chosen for convenience of construction and afforded the contractor a relatively flat area to work from. The thickness of the concrete lining averages about 1 ft.-9 in. and the minimum distance allowed between the points of rock and the inside face of the concrete is 12 in. Where support was required in faulted areas, steel sets were employed. Any voids between the concrete lining and the rock will be filled with grout, and where rock support is necessary a program of consolidation grouting will be performed. Areas associated with water seepage will also be grouted to prevent undue external water pressure coming to bear on the lining in the event of the tunnel being dewatered. Manning's 'n' of 0.012 was used in hydraulic studies of the concrete-lined tunnel to estimate the losses therein.

Large pressure conduits excavated in rock rely on the overlying rock to provide resistance against bursting under pressure. The criterion adopted for the location of the Chute-des-Passes tunnel was to maintain at least 50% of the maximum head of water in feet, in rock cover. Actually the specific gravity of the rock encountered averaged about 2.7.

Surge Tank

Ideally, the surge tank should be located as close to the powerhouse as possible, but the topography dictated that it be placed some 2,800 ft. upstream from the penstock manifold. The general arrangement is shown in Fig. 4. The unlined tank, except for a concrete collar at the top, was constructed in sound bedrock and is 130-ft. in diameter and approximately 250-ft. deep. A 30-ft. diameter concrete-lined surge shaft leads vertically from the supply tunnel and enters the surge tank through a reinforced concrete annulus 6 ft. high which serves as a rock trap. A reinforced orifice is located at the bottom of the surge shaft just above the crown of the tunnel.

It has long been understood that regulation of flow at surge tanks could result in unstable oscillations in the surge tank if the areas were too small in relation to that of the conduits. To supply a constant load, turbines will pass more water when the level in the surge tank is low than when the level is high. This condition accentuates the potential surge and requires a careful study. As discussed later, the draft tube manifold acts as a surge tank for the discharge tunnel. Chute-des-Passes is therefore unique in that a surge shaft is required both upstream and downstream from the powerhouse. Stability limits for initial design were most easily obtained using "Routhe's" discriminate to determine the stable tank areas, as indicated in Fig. 5. However, as the hydraulic transients associated with this double surge tank development are quite complicated, the final diameter of 130 ft. for the upstream surge tank was adopted only after extensive analog computer studies, which examined in detail the regulating qualities of this tank.

The design condition of a full load rejection also required careful consideration. If the upstream surge tank diameter of 130 ft. had been kept uniform, the surge height on full load rejection could have reached elevation 1,342 ft., which would have caused serious over-pressures in the tunnel and other hydraulic equipment. This led to the provision of the retention tank to store the water overflowing from the surge tank following a full load rejection.

With five units operating and the Passes Dangereuse Reservoir at 1,240 ft., a maximum surge level of 1,290 ft. can be reached in the retention tank. One minute after full load rejection under these circumstances, the water level in the surge tank would rise to elevation 1,263 ft. with the water level in the retention tank gradually rising and attaining an equal and higher level two minutes after load rejection. The period of the surge from maximum to minimum elevation and back to maximum is about 18 minutes under this extreme condition.

With an operating level of 1,140 ft. at Passes Dangereuse, the maximum surge level in the surge tank will be 1,250 ft. after a full load rejection with no spillage into the retention tank. The period of oscillation in this case is about 10 minutes. Under this operating condition, if one unit were put back on the line with the transient elevation in the surge tank dropping, the worse point of load acceptance would result in an even lower drop in the surge level. To aid the operators in avoiding conditions such as this, a surge level indicator and recorder will be placed in the control room to ensure that load acceptance is made during a rise in the transient water level in the surge tank.

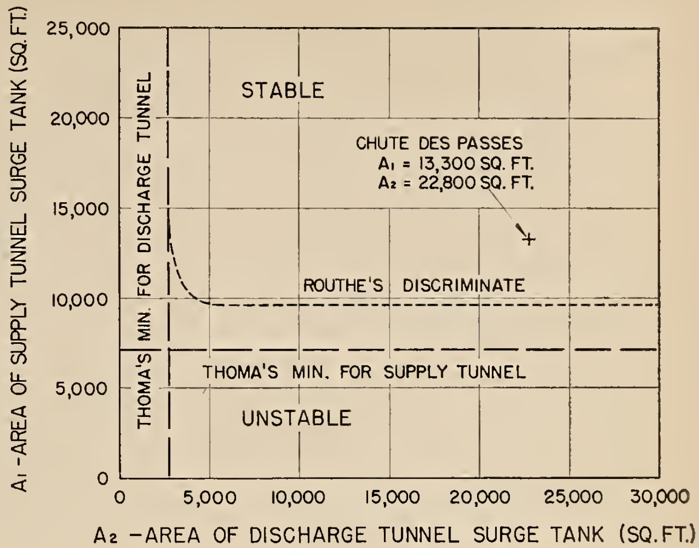


Fig. 5. Minimum areas for surge tank stability.

Penstocks

There are five steel-lined penstocks leading from the penstock manifold, each penstock serving one unit. They vary in length from 256 ft. to 394 ft. and are steel-lined throughout their entire length. Fig. 6 shows the general arrangement of the penstock manifold and the penstocks. The inside diameter of each penstock varies from 15 ft. at the upstream end to 11 ft. at the downstream end. The design of the turbine inlet dictated the 11-ft. diameter, and the diameter was increased in three stages, namely 12 ft., 14 ft. and finally 15 ft. Anchorage for the 11-ft. diameter spherical valves is obtained by these transitions.

Particular emphasis was given in preparing the specifications for the steel liners to eliminate, to as high a degree as practically possible, failures due to brittle factures of the steel. The steel plate thickness varied from 1½ in. to 3 in., which is matter for much consideration where brittle failure is likely to occur. Every plate was subjected to Charpy impact tests and all welds were low temperature stress relieved followed by full radiography.

Due to shipping limitations, the larger sections were made up in cans about 8 ft. long at the place of manufacture and then were assembled into 30-ft. sections at Isle Maligne, Quebec. Final assembly of the penstocks was accomplished by transporting the 30-ft. sections by truck to Chute-des-Passes, placing them directly into the excavations, and then hand welding the final circumferential seams. Excellent results were obtained from all welding with less than 1% of cutout and repair.

The liners were finally encased in concrete and grouted to ensure full contact between the surrounding concrete and rock.

It is interesting to note that the minimum steel thickness of 1½ in. was determined solely from the anticipated effects of external water pressure which may occur upon dewatering of the tunnel and penstocks.

Powerhouse

The power station proper is in an excavated cavern 473-ft. long, 65-ft. wide, 105-ft. high, and located some 450-ft. below the earth surface. Access to the station will be either through a 36-ft. diameter adit tunnel 2,400-ft. long or by means of a passenger-freight elevator running between the control block floors and a surface entrance building.

There will be a passenger elevator operating between floors at the control block end. To reduce the fire hazard, the oil storage tanks will be placed in an oil storage room having fireproof doors, the whole being located in a tunnel leading off from the main access tunnel. In addition, a transformer to be repaired can be lowered into a fireproof vault located below the service bay floor. These areas are covered by sprinkler systems. Fig. 7 is a cross-sectional view of the powerhouse in which can be seen the inlet valve, turbine, draft tube and manifold, generator and generator bus shafts leading to the surface. The draft tube manifold is a chamber 410-ft. long, 62-ft. wide and 102-ft. high, nearly as large as the powerhouse chamber, and is vented to the surface by a vertical shaft about 450 ft. high. Each of two over-head cranes has a rated capacity of 210 tons on the main hook and 25 tons on the auxiliary hook. The two cranes can be interconnected through an equalizer beam for lifts heavier than the capacity of one unit. The 25-ft. high by 30-ft. wide draft tube discharge openings are equipped with gate guides and one gate is provided to permit unwatering each unit separately.

The ventilating system is divided between the powerhouse proper and the control block. The powerhouse is supplied with air by two 100,000 c.f.m. centrifugal fans located on the machine shop floor, which will draw air from the surface through the main access tunnel, the air afterwards being united with a controlled portion of recirculated air, and discharged into a room in which cooling coils may be installed in the future. From the coil room the air enters a passageway, also used as a cable gallery, along the downstream side of the turbine floor and from there is distributed to the various sections of the powerhouse. During the warm seasons, when only outside air would be utilized with no recirculation, all surplus air will be discharged through the bus shafts. During the colder seasons not less than 10,000 c.f.m. will be discharged through the bus shafts to provide necessary cooling.

The transformer repair room, welding hoods, and oil storage room exhaust into the tailrace chamber and thence up the vent to the surface. Such provision is effected after consideration of both safety measures and disagreeable fumes.

The control block is supplied with outside air from the entrance building on the surface by way of the elevator and stairwell. After mixing with recirculated air, it passes through a system of air conditioning before being delivered to the various rooms. A duct located in the elevator shaftway exhausts to atmosphere air from the washrooms, locker rooms, lunch room, and battery room.

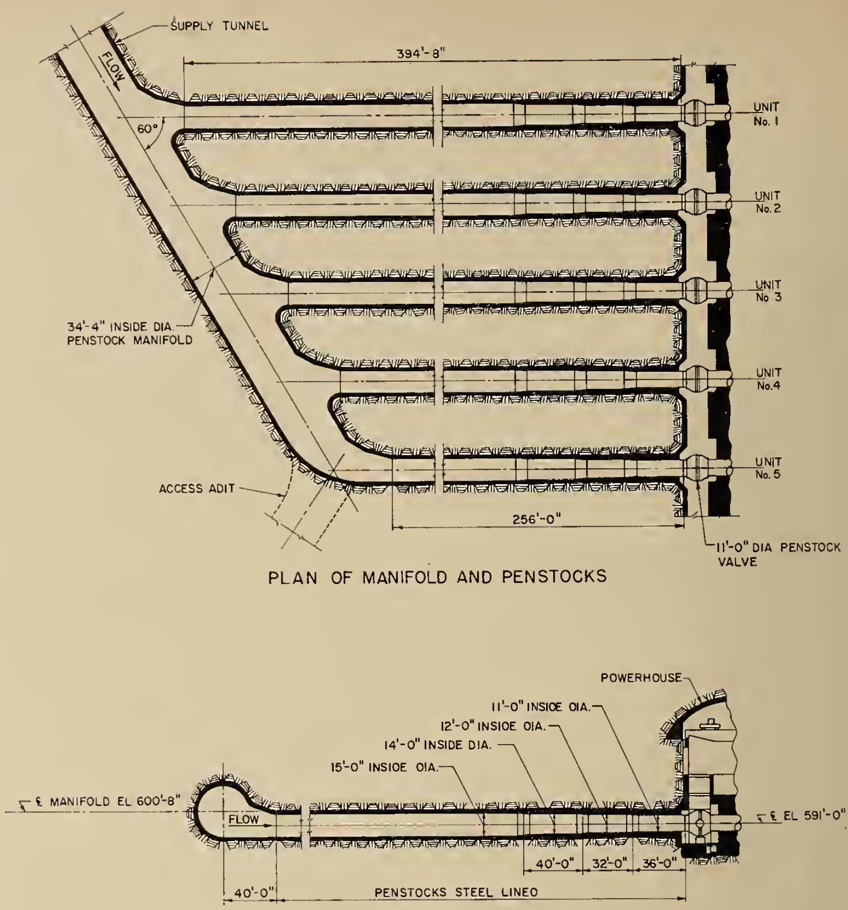

Fig. 6. Plan and profile of penstocks.

Discharge Tunnel and Tailrace

The tunnel, leading from the draft tube manifold to the tailrace is unlined and is 48 ft. in diameter. For construction convenience the circular cross-section was modified giving a relatively flat bottom to permit construction equipment to pass. As with the supply tunnel, the discharge tunnel was driven by the heading and bench method. The only major fault associated with the discharge tunnel was located by means of drilling, and occurred near the exit portal of the tunnel to the tailrace. This required a minor alteration in the location of the exit portal, allowing the fault to fall in the open cut of the tailrace where support can be more easily obtained.

Aside from rock bolting, which was carried out by the contractor during construction, this tunnel required very little support. It is interesting to note that aluminum rock bolts were used extensively in this part of the work to provide permanent support without fear of eventual loss of bolts through corrosion. In addition there are four or five areas where the tunnel passes through narrow bands of altered rock resulting from minor shears. None of these sections is serious enough to warrant extensive support and it has been decided that protection in the form of reinforced gunite keyed into the rock will be sufficient.

The tailrace consists of a large cut through bedrock and extends to the Peribonka River ending at a sill with elevation at 585 ft.

As mentioned previously the draft tube manifold acts as a surge tank for the discharge tunnel which will operate as a low pressure conduit. Thus the tunnel will always flow full under normal conditions. Due, however, to the possible surge conditions, it was found necessary to utilize an unlined tunnel of 48-ft. diameter to minimize the velocities and the magnitudes of the surges. Although the surface area of the tailrace tunnel surge tank is far above that required for stability at normal turbine setting (See Fig. 5) it was not sufficient to prevent the draft tubes from being unwatered under full load rejection. Providing additional area or lowering the turbine setting would have been expensive. Resort was therefore made to constructing a flat weir in the discharge tunnel downstream from the draft tube manifold. The height of this weir will prevent unwatering of the draft tubes.

Table I lists the hydraulic losses associated with each part of the project and the criteria used in determining these losses.

Table I—Hydraulic Losses (Discharge 14,750 C.F.S.)

	Loss (*Feet of Head*)	
Intake		
Entrance—Intake Tunnel ($0.5v^2/2g$)	0.44

Electrical Abstract

The electrical portion of the project involves the following:

1. An underground turbine-generator station having a nominal capacity of 1,000,000 h.p. in five units.
2. A surface switching station including transformers.
3. Two single circuit transmission lines to interconnect with the present Saguenay Power System at Isle Maligne, Quebec.

Station & Equipment

Valves—There is one hydraulically-operated spherical turbine shutoff valve of 11-ft. nominal diameter for each unit as indicated on Fig. 6. The valves consist of a valve body or casing in which a plug rotates to open or close the valve to the flow of water. Two sets of seals are supplied with each valve. The main seal is on the downstream end and will close after the plug is rotated to the closed position. Means are supplied through dismantling sections for replacement of this seal without dewatering the penstock. During such operation the second or emergency seal can be applied on the upstream end of the valve.

The valves are designed for a maximum working pressure of 400 p.s.i. with satisfactory operation at any pressure between 190 p.s.i. and 400 p.s.i. The acceptance test for the valves stipulated a pressure of 600 p.s.i.

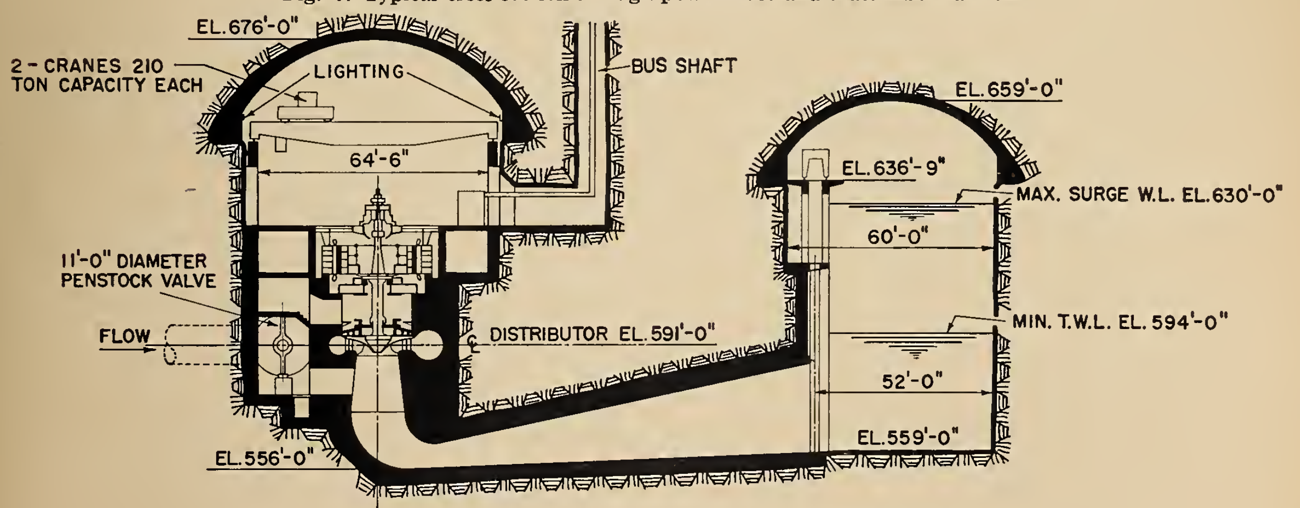
The valves will normally be operated remotely but provision is made for mechanical local operation. The time required to fully open or fully close a valve is approximately 30 seconds and each valve is designed to close against the maximum full gate turbine discharge. It is interesting to note that cooling water for the units and the powerhouse service water is supplied by an eductor system pumping from the tailrace manifold, the high pressure connection being taken from the valve by-pass piping which is normally used to equalize pressure before the opening of the valve.

Turbines—The turbines are of the Francis type, each having a guaranteed capacity of not less than 200,000 h.p. at a net head of 540-ft., and of not less than 165,000 h.p. when operating under a net head of 470 ft. The turbine efficiencies are guaranteed at several net heads ranging from 470 ft. to 590 ft. The foregoing two characteristic criteria are necessary since the elevation of the reservoir, from which the supply tunnel leads, can vary over approximately 100 ft. The turbines have the usual protection against overspeed, loss of governor oil pressure, excessive bearing temperature, low oil or cooling water flow. Table II lists some of the turbine data while the guaranteed efficiency curves are indicated in Fig. 8.

The turbines will be controlled by electro-hydraulic type governors in which a tuned inductance-capacitance circuit and phase-sensing rectifiers replace the normal fly-ball arrangement.

The direct-current output of magnetic amplifiers following the above-mentioned rectifiers operates a moving coil actuator to control the first stage

Fig. 7. Typical cross section through powerhouse and draft tube manifold.



of a hydraulic amplifier system, the final stage of which is the distribution valve controlling the rate of movement of the servo-motor for the turbine wicket gates. With this type of governor the transient response of the units is easily controlled, e.g., by turning a small knob an operator can change the damping from very heavy, which would be suitable for units parallel on the bus but off-load, to very light which would correspond to the on-load condition. It will be possible to operate any number of the units under one joint control with the remaining units, if any, being individually operated.

Generators—The generators are of the umbrella type with the thrust bearing located below the rotor and using the edge of the thrust block as a journal for the guide bearing. The generators are of unfamiliar design in that the generator shaft is merely a stub shaft for carrying the exciter and has no function in relation to the rotor proper. There is a guide bearing at the upper end of this stub shaft. Furthermore, there is no rotor spider in the normal sense of the word. Instead a rotor ring is built up of laminations or rim plates to which the pole pieces are keyed. The rotor ring is keyed to a bracket which in turn is fastened to the thrust block. There is no connection between the bracket and the generator stub shaft.

Table II—Turbine Data

Efficiency and Output	See Fig. 8
Weight of Shaft (pounds)	66,000
Weight of Runner (pounds)	60,000
Weight of Complete Turbine (pounds)	850,000
Turbine W R^2 (pounds Ft.^{2})	1,190,000
Runner Inlet Diameter (inches)	162.5
Runner Discharge Diameter (inches)	145.0
Type of Runner	Cast Steel
Runaway Speed at Max. Head (r.p.m.)	376
Bearing	Self Lubricated

The generators have direct-connected main exciters and voltage regulation is effected through automatic high-speed continuously acting regulators of the static type using rotating amplifiers. Six phase leads are brought out of the unit for split phase protection. The generators will be grounded through a distribution transformer loaded with a resistance such that with a ground fault at the machine terminals the maximum fault current will be about 15 amperes. This should prohibit significant iron burning due to ground faults. Cooling of the generator is accomplished by passing the ventilating air through air-to-water heat exchangers located in each corner of the concrete enclosure. Air-water fog fire protection manifolds are located at the top and bottom of each machine. The usual temperature-detecting elements are located in the stator windings, in the bearings and in the cooling air, and the usual flow alarms in the cooling water lines for the air coolers and bearing. Table III shows the relevant generator data.

As indicated on the foregoing station layout diagrams, the generators are connected to the transformers by means of buses located in shafts rising some 480-ft. to the surface. There is one bus shaft for each generator. Each phase bus is constructed of two 12-in. aluminum channels placed together on edge and supported by post-type insulators. Additional insulators act as spacers between the three phases. The aluminum channel is of 19-ft. sections with expansion joints between adjacent sections. There will be a ladder with safety hoops running the full length of each shaft, with landings at 20-ft. intervals.

As previously mentioned, should a total load rejection occur, the resulting water pressure surge has a period of 10 to 18 minutes. Should load acceptance be attempted on more than one unit when the surge is reaching its minimum level in the surge tank, the water level in the surge tank would drop down into the surge shaft below the minimum acceptable level established for the surge tank design. As an aid to the operators, a surge tank water level indicator and recorder will be incorporated in the control room to enable the operator to determine the existing water level in the surge tank and also the direction of the transient pressure.

the five main transformer banks consists of three single-phase transformers rated 33/44/55/66-mva, type ONS /ONP/OFP/OFFP, that is, the natural cooling for the minimum transformer rating will be augmented by fans mounted on each bank of radiators and by oil pumps between the bottom headers of the coolers and the transformer tank to give the other ratings specified. The coolers are separately mounted from the transformers and are self supporting, being connected to the transformer by flexible connections. Thus a faulted transformer could be moved exclusive of the coolers, or conversely a complete cooler or individual radiators could be removed for repair with the transformer operating at a load suitable to the cooling means remaining in service. The bank ratio, when the three units are connected delta-wye, is 13.8-385/222.3-kv., with four 2½% full capacity off-load taps below the 385 kv. level. This wide range of voltage control is required to cover the divergent conditions of (a) sending almost the complete station output over one circuit, and (b) two very lightly loaded lines with the generators operating at a slightly leading power factor.

The high-voltage winding is graded from a BIL of 1,300 kv. at the line end to 110 kv. at the neutral point, which will be solidly grounded. The BIL of the low-voltage winding is 150 kv. throughout. All transformers will be constructed with aluminum windings.

It is intended to operate the transmission circuits initially at half-voltage which will permit them to be connected directly to the existing power system without stepdown transformers at the receiving end of the lines. To effect this it will be possible to connect the high-voltage windings of the Chute-des-Passes transformers in a parallel connection rather than in a series connection. With the parallel connection, however, no off-load taps will be available, the bank ratio being 13.8-192.5 kv., the BIL of the high-voltage winding is 650 kv. and the bank capacity is somewhat reduced. The transformer data are shown in Table IV.

High-Voltage Switchgear—The high-voltage circuit breakers are of the air-blast type rated 380 kv., 1,550 kv. BIL and are of the 3-cycle opening class. The interrupting capacity on a symmetrical basis is 15,000 mva for the line breakers and 8,000 mva for the unit breakers. The maximum fault duty will be about 3,300 mva. The breakers will be equipped for either single-pole or three-pole reclosing.

The high-voltage disconnects are standard units with grading rings, with the provision that they are guaranteed to interrupt one ampere of charging current at normal voltage. This will ensure that the various bus sections can be de-energized through a disconnect.

A set of lightning arrestors will be connected to each of the high-tension buses. However, as a load rejection at the receiving end of the lines will result in considerable overvoltage on the Chute-des-Passes bus, the arrestor rating was carefully chosen. For example, under the condition of only two units operating at their nominal rating and supplying both transmission circuits through transformers set on mid-tap, the power frequency voltage would instantly increase to a theoretical value of about 508 kv. L-L or 293 kv. L-N following a load rejection. A rating of 308 kv. was chosen to ensure that the arrestor will be able to reseal should it be required to discharge a surge under such overvoltage conditions.

There will be two single-circuit steel tower lines about 91-miles long, using double conductors per phase of 850-mcm ACSR. A spacing of 16 in. will be maintained between the two conductors of a phase by means of spacing devices located approximately 250 ft. apart. The tower strength was designed so that a third phase conductor could be added at a later date if so desired. The circuits will be protected by double ground wires extending only about one mile from each end of the lines, although continuous ground wire protection could be added if required. Line insulation will consist of eighteen insulators of 10-in. diameter at 5¾ in. spacing, giving a critical impulse insulation level of about 1,600 kv. As the surge impedance loading per circuit at 385 kv. is some 485 Mw, each circuit will be capable of carrying approximately the complete station output.

Table IV—Main Transformer Data
(Series connection of H.V. Winding)

Rating According to Operation (k.v.a.)	
ONS-No Auxiliary Cooling	33,000

Weight of Tank and Fittings (Pounds Approx.)	66,500
Total Weight (Pounds Approx.)	237,000

Relaying

The generator and transformer protection provided is in accordance with modern accepted practice for such large units. All of the protection operates one of two trip relays, both of which trip the generator field breaker, trip off the voltage regulator, trip the high-tension breaker, and operate the governor to bring the unit to speed-no-load. On units No. 1 and No. 5, from which the station service is provided, the low-tension breakers corresponding thereto are also tripped. The objective is to have some fundamental protection for each piece of equipment on each trip relay. Table V shows the various relays and their distribution between the trip relays. The operation of either the emergency shut-down switch, the unit overspeed relay set at 150% speed, or the loss of governor oil pressure relay, shuts down the unit and closes the penstock valve.

Differential protection will be provided for the high-tension bus. Carrier current relaying of the transfer trip type using impedance relays with overcurrent backup will provide protection for the transmission lines. A complete system of annunciators will be available to monitor the above protective relays as well as those protective devices mentioned previously with the equipment pieces.

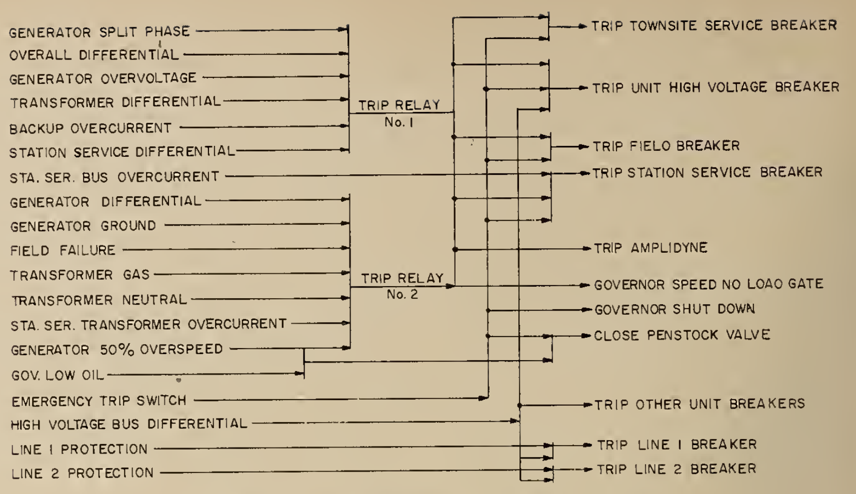

Table V—Arrangement of protective relays

Communications

The primary communication between the Chute-des-Passes station and the remainder of the system will be effected through power line carrier of the single side-band type. There will be four audio frequency channels, three telemetering channels, and one teletype channel. The coupling is phase-to-phase, that is, to one conductor on each of the two transmission circuits. It is believed that this type of coupling results in a lower loss in case of icing conditions on the transmission line and furthermore the loss of one circuit still permits operation phase to ground, although with considerable transmission loss. At three points along the transmission line it will be possible to plug a mobile set into a line coupler and thereby permit communication with either the power station or the dispatching office which is located near the receiving end of the lines. This provision should facilitate line maintenance.

The carrier communication system will be supplemented by normal telephone lines which will also serve the Chute-des-Passes community.

Station Service

The powerhouse a-c. station service will be supplied by either or both of two 1,200 kva., 13,800/575 volt dry type transformers located in generator terminal cubicles No. 1 and No. 5 Each transformer is equipped with a dry type on-load tap changing mechanism covering the range of 11,000 to 15,200 volts. These two sources feed a central distribution board equipped with an automatic throw-over device such that should one source fail, its load is picked up by the second source.

The switching station a-c. station service will be supplied by either or both of two 750 kva., 4160/575 volt dry type transformers located in the surface entrance building. These two transformers are in turn supplied from either or both of two 5,000 kva. 13,800 /4160 volt townsite transformers equipped with on-load tap changing mechanisms located in the switchyard and connected to the buses of units No. 1 and No. 5. An automatic throw-over scheme, similar to that described in the previous paragraph, is also incorporated for this station service supply.

The d-c. control is taken from a 250 volt station battery located in the powerhouse control block. This battery also provides emergency lighting power which automatically comes into force in the event of failure of the a-c. power.

Construction Planning

Located some 90 air miles north of Isle Maligne, the project area was accessible by a road unimproved over the north 100 miles of its 145-mile length and incapable of handling the passage of heavy equipment and other heavy traffic. This north 100 miles was rebuilt and much of it relocated. Work on the road actually began in June, 1956 but as the road was the key to the success of the whole project, the road work was pushed vigorously. By November, 1956 the work was essentially complete and the road had carried heavy traffic long before that date. Bridges and other traffic facilities were designed to carry up to 60-ton net load and this limitation did influence the design of some of the power station equipment. The lower 40 miles of road is public and the bridges there were strengthened as a cooperative effort with Provincial authorities.

While access facilities were being provided, work was going on leading towards contracts for the main project. A unit price or lump sum contract was desired if such could be obtained on attractive terms. The alternative was a cost-plus fixed-fee-type contract. Because it was certain that it would take some time to develop satisfactory project contracts. Alcan assumed direct responsibility to build access roads to within 1,000 ft. of the various working areas of the project, to build an airstrip, to furnish construction power, and to purchase the permanent equipment. Permanent equipment in this case was construed to mean almost everything that would be specified on a construction drawing. Alcan also accepted the responsibility of providing housing for Alcan employees on the job and for the consulting engineer's staff. Review of preliminary proposals from contractors in mid-1956 provided confirmation of early planning and early scheduling and gave better information about probable costs but none were sufficiently firm to be acceptable. In the meantime, much more design information had been developed.

Discussions with contract bidders and analysis of information given in their preliminary proposals led to changes in the final contract bid invitation terms that clarified the more difficult points of uncertainty and probably led to more favourable bidding. The contract was a unit-price contract with lump-sum bids for camp, plant and equipment. The contractor was responsible for all of the construction areas and for construction materials not furnished by Alcan. The contractor started field work in September, 1956.

Certain extra work items were anticipated but not included specifically in the contract, anticipating negotiation of unit prices later. Failing negotiation the work could either be awarded to an outside contractor or performed by the general contractor on a cost-plus fixed-fee basis with a predetermined schedule of fees. Certain items, such as tunnel supports, grouting and guniting were intentionally omitted from the contract on the basis that too little was known to establish firm unit prices at the time of the contract award. Subsequently, firm unit prices were negotiated.

Construction power was originally planned to be furnished by Alcan but this was added to the general contract. Twelve diesel electric sets of 1,000 kw. capacity each were purchased and set up at the job site. Further studies indicated economies in provision of hydroelectric power for temporary construction services.

Two small hydro units, totalling 10,000 kva. rated capacity had been used by Quebec-Hydro for construction of the Bersimis No. 1 Project. These units were more than fifty years old. They were moved to Chute-des-Passes and installed on the Peribonka River near Adit No. 2 where approximately 50 ft. of head was readily available for development.

Access to underground work was through three separate adits. The first adit (No. 1) was located near the north end of the project, about 7,500 ft. south of the tunnel intake, the second adit (No. 2) 15,000 ft. farther south, and the third adit (No. 3) led directly into the powerhouse, nearly 31,000 ft. from the tunnel intake. Branches from No. 3 adit near the powerhouse provided access to the penstock manifold and main tunnel upstream and to the draft tube manifold and discharge tunnel downstream. The intake areas were accessible from the surface. It was planned that the intake tunnel would be constructed through Adit 1 with alternative access through the intake excavation when this excavation was down to tunnel invert grade. Normal access to the short tailrace channel was through the discharge tunnel as this site was across the river from the other construction sites.

Construction Operations

At each of the three adits to the underground workings a construction camp was built. Each camp, located as close to the portal as practicable, was self-contained and controlled by the superintendent responsible for the work through or near that adit. Each camp had its own construction services. Adit No. 3, the powerhouse adit, was the general headquarters for the field operation by the general contractor, by Alcan and by the consulting engineers.

The underground excavation of the project was the biggest single item. More than three million cu. yds. of rock were taken out from underground.

The contractor started driving the supply tunnel as a fullface heading. Subsequently, he found that there was room for his equipment to operate taking less than the full heading and he changed to a top heading leaving about 12 ft. of the tunnel section as a lower bench to be taken out later. This change in program permitted faster driving and opened up the entire main tunnel quicker, permitting an earlier start on concrete lining. It also improved ventilation sooner. All of the excavation was handled by crawler shovels and truck or trailer units. No railroad equipment was provided at any point. Heavy drifter type drills, mounted on Jumbos that were moved by crawler tractors, did the drilling. The drills were semi-automatically controlled with long-travel feed that permitted drilling with not more than one steel change for the normal driving operation. Muck was loaded by power shovels into dump trailer units with a capacity of 18 cu. yds. These rubber-tired tractor-trailer units proved particularly effective as their ability to make short radius turns and their maneuverability proved an extremely important factor in the very impressive production that has been attained on this job. Two headings were driven from the No. 1 adit and two from No. 2 adit, and some of the tunnel was excavated from No. 3 adit.

Services such as compressed air, water and ventilation air were provided by plants at each adit portal. As Adit No. 1 is 2,283 ft. long, adit

Table VI—Summary of Principal Features, Chute-des-Passes Project

Location	On Peribonka River, 90 air miles north of Isle Maligne, P.Q.
Capacity	One million horsepower.
Water Elevations	*Reservoir* 1240 to 1140 *Discharge* 604, modified by flow conditions in the natural river.
Intake Structure	Located in the bank of the Passes Dangereuse Reservoir where excavation and construction can be done without cofferdam. The Intake Tunnel extends 600 ft. upstream from the gates to deep water in the reservoir. *Bottom of Intake Structure*—160 ft. below high reservoir elevation. *Gates*—2 roller gates 15 ft. wide by 38 ft. high operated by fixed hoists elevated from the deck of the intake structure. *Bulkhead Gate*—Gate slots upstream from operating gate to accommodate bulkhead gate for emergency service to operating gate. One bulkhead gate to be provided. *Trash Racks*—2 sets of trash racks to be provided, serviced by gantry crane.
Tunnels	*Permanent and Construction Access Tunnels*—various sizes, but generally 38 ft. wide—Total length 10,427 ft.
Supply Tunnel	Concrete lined, nominal diameter 35 ft. inside concrete lining; length 30,854 ft.
Discharge Tunnel	Unlined diameter 50 ft.; length 9,137 ft.
Power Chamber	465 ft. long, 65 ft. wide, 48 ft. high from generator floor, but 120 ft. from low point in draft tube. Located about 450 ft. below the surface.
Draft Tube Manifold—Chamber 410 ft. long, 60 ft. wide, 102 ft. high. Draft tube discharge openings 25 ft. high by 30 ft. wide arranged to permit insertion of Closure Gate.	
Surge Chamber	130 ft. diameter by 250 ft. deep connected to power tunnel through 30 ft. diameter shaft and located 2,800 ft. upstream from Power Chamber
Penstocks	5 steel penstocks, 15 ft. diameter to 11 ft. diameter branch from concrete-lined tunnel to each of the turbines. Average length is 325 ft. Centreline Elevation is 591.
Penstock Valves	5 double seal, hydraulically-operated sphere, 11 ft. diameter one for each unit. Valves located just inside upstream power chamber wall.
Generating Units	5 turbine-generators, vertical shaft Francis type, 200,000 h.p. each, controlled by electro-hydraulic governors. Low tension power from each generator will be carried through rigid buses through a vertical bus shaft to the substation at the surface 450 ft. above.
Powerhouse Cranes—2 travelling bridge cranes, each with a 210-ton hook and auxiliary 25-ton hook. Crane rails supported on concrete beams carried by concrete columns from powerhouse floor.	

No. 2 is 4,376 ft. long and adit No. 3 is 2,600 ft. long, the service lines are extensive. The compressed-air supply provided at each adit was sufficient to operate only one heading for drilling, so drilling and mucking cycles for the two headings at each adit were carefully planned and controlled to achieve the best production.

Compressed air plants at the three adits had a combined capacity of 28,680 c.f.m. provided by 37 stationary compressors, of which 3 were diesel driven and the rest electrically driven. The maximum connected construction power load was 14,200 kw., of which more than half was for supply of compressed air and ventilating air to the underground work.

To excavate the powerhouse, the access tunnel was ramped up to about the spring line of the powerhouse and the arch excavated. As soon as the excavation was done, this arch was concreted to offer protection for the subsequent excavation work; then the main body of the rock was removed. Excavation of the powerhouse was essentially complete in February, 1958. The zone above the concrete arch was pressure grouted.

The draft tube manifold, just downstream from the powerhouse, is also a very large structure and was excavated in the same manner as the powerhouse. The elevator shaft, the five bus shafts and the vent shaft, that rise from the powerhouse area to the surface nearly 500 ft. above, were all raised from the bottom up.

The surge chamber, located about 2,000 ft. upstream from the powerhouse, was excavated by raising a centre shaft, then expanding downward from the top with the muck fed down through the centre shaft and taken out through the tunnel. To permit simultaneous drilling and mucking during the expanding operations, spiral steps were developed in the main body of the 130-ft. diameter surge chamber. Drilling was done on one step while muck was shoved down the centre hole from another step.

The tailrace tunnel, 48 ft. in diameter, was driven entirely from the powerhouse end of the tunnel. A top heading was driven full length then the bench was removed as a second operation. Loading and hauling of muck was by the same type units as were used in the supply tunnel.

Tunnel driving progress was spectacular. The best week for all four headings of the supply tunnel showed an advance of 1,138 ft. and removal of about 38,000 cu. yds. of rock.

Through weak fault zones in the granite rock of the main tunnel a total of about 700 linear ft. of tunnel was protected by steel arch ribs. Steel rib supports were also used for 466 ft. of construction adit tunnel. Elsewhere, extensive use of rock bolts provided effective protection. Where concrete lining is planned, as in the supply tunnel and in the powerhouse and draft tube manifold arches, the rock bolts are embedded in concrete and the corrosive properties of the steel bolts used were not considered serious. For the tailrace tunnel, after satisfactory field tests, aluminum alloy rock bolts were used to eliminate the corrosion inhibiting measures necessary to preserve rock bolts made of steel.

Concrete was supplied by a central mixing plant located above the tunnel near adit No. 2. A hole was driven below the concrete plant down into the tunnel and mixed concrete dropped through it to the tunnel level to save hauling distance and to achieve additional freedom from outside weather. It was originally estimated that the total project would require 420,000 cu. yd. of concrete but the actual quantity will be about 580,000 cu. yd. The biggest item of concrete is in tunnel lining of the pressure tunnel, which started on 30th April, 1958. Tunnel arch concrete was placed by pumpcrete into a movable form 160 ft. long. Concrete was hauled in bulk in the end dump trailer units from the drop pipe near Adit No. 2 to pumpcrete machines at the form. The concrete supply system and equipment at the form, all mounted on wheels, was impressive. To the 160-ft. long steel arch form and carrier was attached a ramp, a turning table, concrete remix and pumpcrete machines. The whole assembly was some 370 ft. in length, mounted on wheels and moved as a unit. The volume of pours behind this form varied from 1,200 to 1,500 cu. yds. Normally this assembly placed one 160-ft. section each day.

The concrete lining procedure was to place curbs on each side of the tunnel to accurate line and grade. These curbs had embedded inserts to which the arch form section could be bolted tightly against the vertical curb faces. The concreting equipment rolled on the top of the curbs. The arch concrete was then completed. Invert concrete was hauled in bulk by the end dump tractor-trailer units and delivered to a travelling screed by belt conveyor. The bulk of the concrete placed on the project was delivered to forms by pumpcrete machines. In the intake and low sections of the powerhouse and a few other miscellaneous sections, concrete was delivered to forms in buckets.

The surge shaft lining was placed as a continuous operation through the entire 350 ft. height.

The aluminum switchyard structure had to be located on a hillside requiring heavy fill. This fill was provided almost entirely from the material excavated from the surge chamber retention tank nearby.

Installation of the major items of equipment such as turbines, generators, valves, gates and penstocks is being done by the suppliers of this equipment. By far the major part of the work has been done by the General Contractor or his sub-contractors, but a fair amount of work is being done by local area specialty contractors working directly for Alcan. Progress has been very close to schedules prepared early in the program.

Construction of the intake tunnel (See Fig 3) presented unusual problems. Tunnel driving proceeded from Adit No. 1 through the intake to the intake tunnel. The rock fault was encountered when the tunnel heading was under the reservoir and the structure of the rock there was sufficiently

broken to give concern that major leakage through the tunnel arch might develop. This concern led to the decision to construct a concrete bulkhead downstream from the intake with a removable gate to be closed when blasting and opened for access. It also led to excavating a small exploratory heading all the way upstream to the bottom of the rock plug planned for removal by a single blast to admit water to the tunnel system. This small heading was then expanded in short sections to the arch excavation line. As excavation of each section was finished, the concrete arch was placed and the process repeated until the arch was concreted up to the plug. Through the fault zone, the arch was supported on concrete walls placed by "underpinning" technique. Slots were expanded outward from the centre of the tunnel and concrete placed under the arch. Then adjacent slots were expanded until the underpinning required was complete.

The development, drilling and blasting of the rock plug is a story in itself. Briefly, the procedure followed was to extend inclined access shafts upward into the mass. Holes were drilled upward through the rock plug into the reservoir to check the location and character of the rock at the bottom of the reservoir. This exploration showed deep crevassing and the average thickness originally estimated as safe for the plug was increased to 50 ft. to insure safety of the operation. The result was that the sump planned to receive the blasted rock had to be substantially larger than previously planned. The sump volume required was set at 22,000 cu. yd. and the shape of the top half of the opening was determined as the result of model tests.

The contractor developed and built a nearly vertical skip hoist to lift this rock out of the sump and this skip dumped directly to the end dump trailer units. A diesel shovel and bulldozer were fitted with armor and remained in the hole as blasting was carried on. The equipment was then disassembled and lifted out of the 150-ft. deep hole.

Fig. 9. The blast on 19th April, 1959, removed the rock plug, and water filled the intake tunnel. 60,000 pounds of explosive removed 13,000 cu. yd. of rock (rapid sequence film).

The plug was loaded with explosives placed in drill holes and in coyote concentrations in the interior of the mass. The shot effectively removed the plug on 19th April, 1959, filling the intake tunnel with water as far down as the concrete bulkhead. After cleanup of the gate area and diver inspections, the gates were closed and the concrete bulkhead removed.

Plans have been made for permanent housing for operators on a hillside directly above the powerhouse. The site, topographically, is as good as any in the vicinty and offers further advantages of proximity to the powerhouse and a very attractive vista toward the south. Planned to serve an ultimate 80 homes, with schools, commercial and other community needs, roads have been graded and underground water and sewer lines have been placed for the first 40 units and community buildings. Part of the school and 6 permanent houses are completed as part of the initial project.

Procurement

Alcan supplies permanent materials and equipment at the railhead at Isle Maligne where nearly all of the materials for the project are delivered and despatched the 140 miles to the Chute-des-Passes project by truck. The trucking operation is a sub-contract of the general contractor. Storages for cement, diesel oil, grease, fuels and general construction supplies are provided at the site by the contractor.

Manouan Diversion

The project described above does not include one of the important parts of the Chute-des-Passes power project. Lake Manouan above the present reservoir is controlled, and water releases generate power through the existing Peribonka plants and the other plants downstream. Manouan Lake water will be further controlled and released into the Passes Dangereuse reservoir so that it can generate also through the Chute-des-Passes plant. This requires a substantial canal-excavation job, about 1.5 million cu. yds. and a control structure for which surveys have been largely completed and for which some preliminary work has been done. It was originally planned to do this work immediately, but completion has been postponed until after the power plant goes into operation. The proposed Lake Manouan-Bonnard River canal is located almost 100 miles north of Passes Dangereuse Dam and access is by water and road, or by air.

Table VIII—Major Construction Quantities, Chute-des-Passes Project

Underground Rock Excavation	
Tunnels and Surge Chamber	2,620,000 cu. yd.
Powerhouse and Draft Tube Manifold	240,000 cu. yd.
Intake	200,000 cu. yd.
	3,060,000 cu. yd.
Surface Rock Excavation	260,000 cu. yd.

This paper was presented to the Ottawa Branch of The Engineering Institute of Canada on September 18, 1956; to the Montreal Branch on March 20, 1957; and to the Cornwall Branch on April 17, 1957.

AKLAVIK, the main settlement of Northwestern Canada, is located in the delta of the Mackenzie River about 68°N. (Fig. 1). This places it in approximately the same relation to the Arctic Circle as Fairbanks in Alaska (65°N), Reykjavik in Iceland (64°N), Narvik in Norway (68°N) and Murmansk in the USSR (69°N). Compared to these other cities, Aklavik is a relatively small place with a permanent population of about 400, which increases to possibly 1500 during the short summer season when Indians and Eskimo come to visit the settlement. Despite this it is the most important Canadian outpost north of the Arctic Circle, and it will almost certainly steadily increase in importance with the development of the Canadian North.

The decision of the Government of Canada in 1953 to move the entire settlement to a new site is a matter of importance to all Canadians. This was the first step in a development in connection with a town which is almost without precedent, apart from such special operations as the move of some mining communities (notably Sherridon to Lynn Lake) and the current work in relocating some of the municipalities on the Canadian side of the St. Lawrence River. The decision to make the move was taken only after the most exhaustive studies. The selection of a new site was correspondingly made only after a most thorough investigation. It is the purpose of this paper to explain briefly the reasons for the move of Aklavik, the requirements for the new site, and the means employed in carrying out the field survey work which eventually resulted in the selection of a new location for this northern outpost.

The start of Aklavik can be dated as recently as 1912 when a small fur trading post was established. In 1919 the famous Anglican Mission was started. The R.C.M.P. established a detachment at Aklavik in 1922 and the first building of the signal station of the Royal Canadian Corps of Signals was built in 1925. The Roman Catholic Mission was started in 1926 and in this same year the adjacent post of the Hudson's Bay Company (on the Pokiak Channel) was relocated. By 1931 population of the settlement and the surrounding area had reached about 400. Today the population of the town and the surrounding delta country exceeds 2000, of whom about 30% are white, 20% Indian and 50% Eskimo; many of the Indian and Eskimo children live in the schools operated by the two churches.

In addition to being the location of the agencies already noted, the town is an important administrative centre for the Department of Northern Affairs and National Resources which is responsible for the administration of the Northwest Territories. More recent establishments have included a Department of Transport radiosonde station and a naval signal station. The town is supplied with electric power by a local power company and is served by two river transportation companies. A scheduled mail and freight air service from Edmonton is operated by Pacific Western Airlines.

The Mackenzie Delta

Aklavik owes its strategic location to the fact that it is on one of the main navigation channels in the delta of the Mackenzie River (Fig. 2). This is one of the greatest rivers of the world, eighth in order of magnitude based on discharge, eleventh in the size of its drainage area and so about 50% larger than the St. Lawrence. The Mackenzie System is navigable by shallow draft boats for 1600 miles from rail head on the Clearwater River at Waterways, Alberta, to the Arctic Ocean, with only one break—the 12-mile stretch of rapids on the Slave River between Fort Fitzgerald and Fort Smith at the northern boundary of Alberta. River transport is therefore operated in two stages on the upper and lower sections of the river system.

Because of the great load of sediment which the river carries, its delta is spectacular (Fig. 3). It is one of the most remarkable physiographic features of Canada, but because of its location it is not as well known as some other major river deltas of the world, even though it is the twelfth largest. From Point Separation, where the delta properly starts, it is approximately 150 miles to the Arctic Ocean. Unlike other deltas it is confined—on the west by the Richardson Mountains and on the east by the Caribou Hills and other high land that is a result of glacial action. Its maximum width is about 50 miles. Of this immense area about one half is water in the form of meandering channels and backwaters, small ponds, and many cut-off *(oxbow)* lakes.

The level area of the delta is nowhere more than from 10 to 15 ft. above normal river level, and much of the area is flooded during high water in the spring. Such land as there is appears generally to consist of silt covered by the inevitable muskeg growth so typical of the North. This makes an ideal area for the breeding of muskrat and the delta is well known as a muskrat hunting area. In the 5,275 square miles of the delta there are over 900 people dependent on trapping. Income from muskrat furs has been declining during recent years and this is creating a local problem. This is only one of the many problems regarding the future of Aklavik, however, which have had to be faced by those responsible for its administration.

Reasons for the Move of Aklavik

The entire delta area is perennially frozen so that the ground consists of material that can be described by the popular name *permafrost*. This condition indicates that the temperature of the ground for an appreciable distance beneath the surface (possibly 1000 ft.) is below freezing temperature, apart from the upper few inches which may thaw during the heat of summer. The soil on which Aklavik rests is an organic silt with a very high natural moisture content. Subsurface investigations for the formation of a new school, which were carried out in 1953, showed that about 60% by volume of the frozen fine-grained soil consisted of ice. If, therefore, the old town site were further developed with a further clearing of the muskeg cover and the installation of heated buildings, ground subsidence would occur with serious results.

The old town site is located on a bend in one of the navigation channels. The entire area adjacent to this site is flat and drainage has always been a particularly difficult problem. One feature of the area is stagnant pools of water formed by the melting of permafrost. Subsurface drainage is impossible and the ditches that are dug for surface drainage tend to complicate the drainage problem by causing still more thawing of the permafrost.

Because of the subsurface conditions, the laying of sewers or watermains beneath the surface would similarly create serious problems. To locate them above ground level and then to connect them to existing buildings would be costly and unsatisfactory for the existing town conditions.

The area used for the town is hemmed in by the bend of the river and by swamps and ponds. There is, therefore, no practical way for the town to expand, and expansion is vital if Aklavik is to fulfil its role as the centre of administration for northwest Canada. Not only is the present site restricted but it is even getting smaller because for some time the river bank has been eroding badly near the Roman Catholic Mission. Works to stop this natural action have been estimated to cost several million dollars and their success would be questionable.

Finally, if Aklavik is to serve properly the expanding needs of the North, it is essential that it should have available to it an airport that could be used throughout the year. Now each year, during the break-up period in the spring and the freeze-up period in the fall, the town is cut off from all flying services. Attempts have been made to construct an airstrip adjacent to the present town but the subsurface conditions are such that this has proved impracticable. A small strip for very light planes does exist, but only with the expenditure of vast sums of money could a major airstrip be developed.

These were the main factors that had to be considered with regard to the future of Aklavik as an expanding community of the North. Confirmation by detailed soil testing of what had been suspected about subsurface soil conditions finally showed the need for over-all consideration of the entire problem. It was this study that finally led to the decision that the only possible solution was to find a new site for the town.

Requirements for the New Site

Before any work could be done in attempting to locate a new site a clear picture had to be developed of the requirements that any such site would have to meet. These could then provide the guide posts for those who were to conduct the actual survey.

The essential factors for any new town site were determined as follows:

(a) the site must be suitable from economic and social points of view;

(b) the site should be suitable for the installation of permanent sewer and water systems, building foundations, and roads;

(c) the site should be on, or very close to, a good navigation channel within the delta;

(d) the site must have reasonably close to it a suitable area for the construction of a permanent first-class air field;

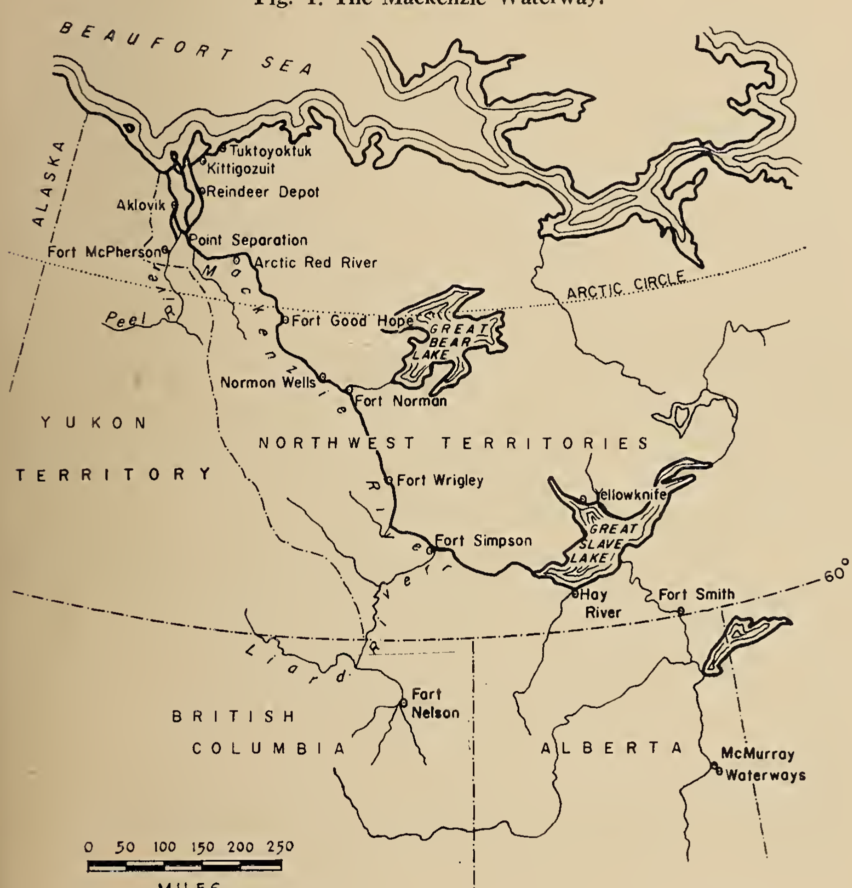
(e) there should be, within economical distance, a suitable public water supply.

The following were regarded as highly desirable features but were not quite so important as those already listed:

(f) the site should provide for economical and convenient disposal of sewerage;

(g) it would be convenient if there were a good supply of gravel and sand

Fig. 1. The Mackenzie Waterway.



nearby for building purposes;

(h) from the navigation point of view it would be desirable if the wharf facilities could be used as a trans-shipment point for freight from river vessels to sea-going vessels which could sail out into the Arctic Ocean.

Finally, the following three factors had to be kept in view as desirable but in no way essential:

(i) availability of a good wood supply;

(j) availability of coal for heating purposes, and

(k) if possible, availability of water power which could be used for the generation of power for public supply.

Organization of the Survey Team

In January, 1954, when the requirements for the new site were specified, the agencies to be represented on the survey team were selected. These agencies were the Department of National Health and Welfare, the National Research Council (Division of Building Research), the Department of Northern Affairs and National Resources, the Department of Mines and Technical Surveys, the Department of Public Works, and the Department of Transport. To the Department of Northern Affairs was assigned the task of placing a team on the ground by March 15, 1954. The survey was to extend through late winter, spring, and summer and the team was to report its findings by August 1, 1954.

The personnel included men trained in the social and physical aspects of the geographic, geologic, and engineering sciences. (See Appendix A for members of the team.) Each agency had responsibilities in the Aklavik area. The Department of Northern Affairs, with the primary administrative responsibility, provided the project manager, C. L. Merrill.

In the few weeks during which the team was recruited, winter clothing, rations, camping and surveying equipment were obtained and, when necessary, shipped to Aklavik. During the winter the only means of getting in supplies was by air. At the same time, relevant information was obtained from reports of earlier expeditions and from representatives of the Royal Canadian Mounted Police and other organizations in Ottawa. Studies of air photographs, already initiated at the National Research Council, were continued in Ottawa until the time of departure of the team, and thereafter in the field.

In addition to the representatives

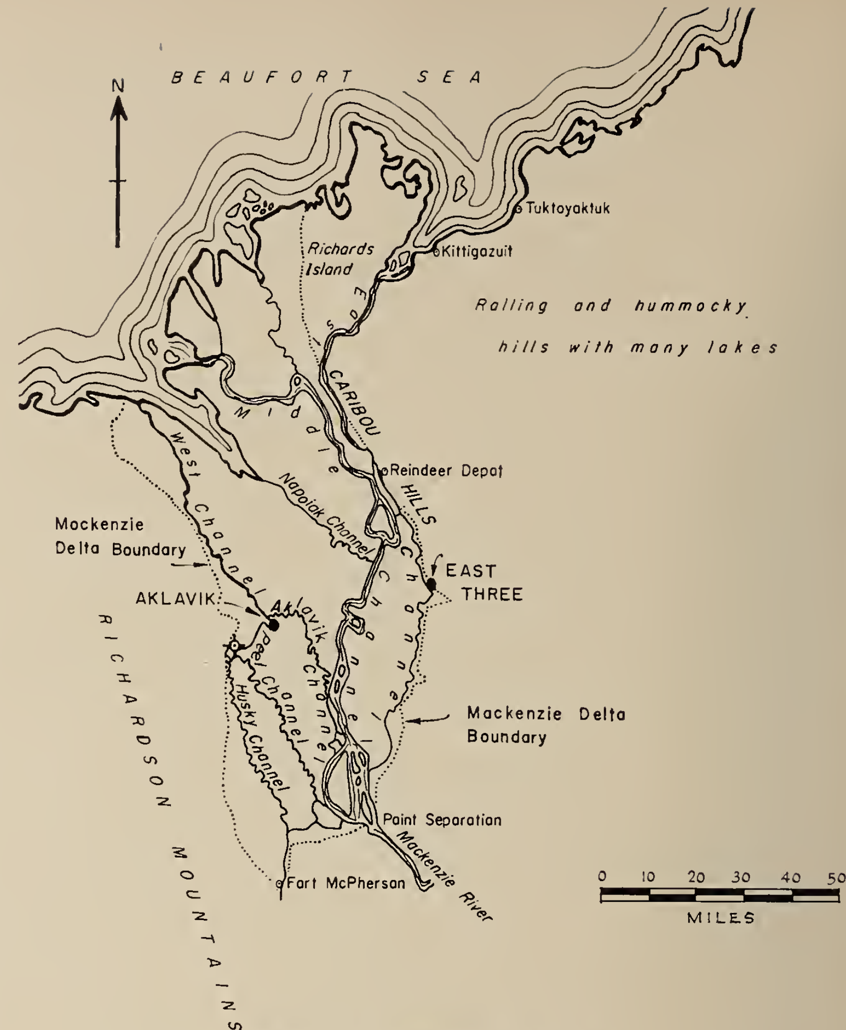


Fig. 2. The Mackenzie River Delta.

already mentioned who were recruited from personnel located at Ottawa and Edmonton, the team was assisted by local departmental representatives "ex officio". The Department of National Defence and the R.C.M.P. unit at Aklavik provided advisory members to the team. Their expert local knowledge proved to be of great value.

The benefit of other local experience was obtained through a Local Advisory Committee. This Committee included representatives from each racial group and from the traders and missions. The first meeting was held before the team established a camp; other meetings were called at intervals as required. In this way, not only was local experience made available to the survey team, but the residents of Aklavik were kept directly advised of the survey's progress.

The Use of Air Photographs

One of the most important early tasks of the survey party was the examination of air photographs covering the entire delta of the Mackenzie River. The techniques of air photo interpretation and identification are increasing in use, especially for the North. The advantages of using air photographs for a preliminary view of the field terrain conditions were appreciated by the survey team. Thus by examining in Ottawa the terrain to be covered by the survey, a preliminary appraisal was made of the problems that would be encountered.

An air photograph records every surface feature to which it is exposed. At first sight this can be confusing since the photograph records these details in many shades of black and white. If, however, the air photographs are viewed stereoscopically (three - dimensionally) the various land forms, and to some extent the variations in the vegetal cover, are soon apparent. After the air photographs are thus examined, similarities in terrain soon become clear. These terrain similarities or *patterns*, as they are most commonly described, are recognized by means of land form, vegetal cover, and photographic tones in a manner similar to the way in which one identifies various acquaintances by their stature and facial features. The land form patterns are then roughly delineated and sampling is carried out in each pattern. If the interest of the observer is the engineering use of soils, the identification of soils in various patterns is attempted. Thus instead of taking soil samples at regular intervals, samples are taken in strategically located positions in the land form and similar soil conditions are assumed for similar patterns. In this way preliminary sampling is greatly reduced.

Using these techniques, members of the survey team, working in the Building Research Centre in Ottawa, carefully examined aerial photographs of the entire area of the Mackenzie Delta. Twelve sites were selected as worthy of detailed study in the field. Their locations were accurately determined and salient features were noted for investigation in the field. The actual saving in time and money which this use of aerial photographs effected cannot be estimated with any accuracy but it is safe to say that, without this preliminary office work, the survey could have been only partially completed in one working season.

Fig. 3. A typical view of the Mackenzie River delta looking west at the Richardson Mountains.

The Survey: Aerial Reconnaissance

The survey party assembled at Aklavik during March 1954. This early field arrival date was fixed so that observations at potential townsite areas could be made under late winter conditions, during spring break-up, and during the summer season. Spring break-up records for the Mackenzie River delta are virtually non-existent and since this period is critical for any town, a helicopter was chartered for the survey period until well after break-up (Fig. 4). The helicopter was first used to make a winter reconnaissance of the potential site areas selected in Ottawa by the use of air photographs. The original selection of twelve sites was quickly pared down to six since some of the potential sites were obviously unsuitable when examined in the field. During these initial helicopter reconnaissance flights, notes were also made on the depth of snow cover and ice thicknesses of the river channels at the sites.

The helicopter had to be maintained remote from repair facilities, with a staff of only one pilot-mechanic, in air temperatures as low as −30°F (in April 1954). During its service of 73 days, flights were logged on 69 days. (The machine was out of service for one day due to mechanical difficulty and for three days because of unsuitable weather.) A total of 201 sorties was flown for a total of 164 flying hours. Although the three-seat *Hiller* machine could carry the pilot and two passengers, it was found that the pilot and one passenger, usually with some survey or other gear, proved to be more effective in the work. The aircraft had a flying speed of 70 miles per hour and carried sufficient fuel for 3 hours flying with one passenger. All parts of the area under investigation were accessible in less than one hour from one of the base camps established.

Fig. 4. Spring break-up at Aklavik, June 5, 1954.

Field Investigation at Four Sites

The survey was conducted from a series of base camps from which investigations were carried out at each prospective townsite as the season progressed. Base camps were located in turn at four of the possible townsites. The more time-consuming operations, such as topographic and hydrographic studies, and soils investigations, were conducted when the base camp was at, or near, the site of the work. Use of the helicopter, and in summer a fast boat, made it possible to carry out some work at each potential townsite throughout the field season, regardless of the location of the base camp. In the course of field investigations the team was housed in tents. The cook, a driller's assistant, and several labourers were hired locally. The base camp was moved by tractor train, dog team, and by a small barge and scows, all obtained locally, as seasonal conditions dictated.

The first base camp was set up at

a potential site approximately 12 miles southwest of Aklavik. This site was located on the alluvial fans of the Richardson Mountains. The camp was located at the junction of the delta and the fans near the Husky Channel and so was called the Husky Site. The camp was set up during the beginning of April and consisted of two 16 x 16 ft. tents and some other smaller tents. All of the camp equipment was brought to this site by tractor from Aklavik.

Unfortunately the region experienced one of its coldest Aprils on record and this restricted much of the soil sampling. For the first two weeks in camp, the temperature rarely rose above 0°F and went down at night to as low as −30°F. An attempt was made to drill during this interval but the problems of supplying drilling wash water soon forced its abandonment until air temperatures rose above 10°F.

The drilling equipment used was a modified version of a permafrost drill developed by the U.S. Corps of Engineers (Fig. 5). It is essentially similar to a diamond drill using wash water to carry away bit cuttings, but uses a hard metal insert bit (*carballoy*) instead of a diamond bit. A notable feature of the rig is that it is made of lightweight materials and can be broken down into small light components for easy transportation by bush aircraft. The special feature of drilling and sampling in permafrost is not the equipment used but the amount of wash water and the skill with which it is used. If too much wash water is fed to the face of the bit to carry away frozen soil chips, there is a danger of melting and washing away the core, even though a double-tube type of core barrel is used. On the other hand, if too little wash water is used, the frozen soil cuttings soon form a slush with the wash water which can quickly freeze in the core barrel. No rules can be formulated for the amount of wash water to use and the correct amount is best determined in the field.

After the samples were obtained from the drilling, representative split cores were photographed in colour before soil samples were taken. These photographs were invaluable later when the soil test results were available and references were required to the types of frozen soil encountered. The samples were shipped to Norman Wells for routine engineering soil identification tests including determinations of moisture content, grain size, Atterberg limits, and natural densities.

Fig. 5. Drill rig operation before airlift to next drilling location. Tent in background provides shelter for soil sampling and photographing frozen cones.

Break-up observations were started during May. These consisted of establishing observers at the potential townsites to record channel water levels and to assess the damage, if any, caused by the moving ice. During the break-up interval of the delta, daily reconnaissance flights were made with the helicopter and the rate of progress of the moving ice and general water levels was observed.

After break-up, the survey party proceeded to the east side of the delta and carried out terrain studies at two potential sites known as *East Three* and *East Four*. Two more of the east channel sites were eliminated as potential townsites because of their low-lying topography and possible difficulties in reaching them by river transport. After the east channel sites had been investigated, the party completed its investigations at another site on the west channel. This site was purposely left until the end of the survey since snow cover remained at this location until June and made terrain investigations difficult.

After the four finally selected sites had been investigated, the survey completed its field reports. A preliminary appraisal indicated the site known as *East Three* to be the most favourable. Even though a final decision on the new townsite could not be made until the fall of the year, the need for design data from the chosen site was anticipated. Accordingly the month of August and part of September were spent in making a detailed terrain analysis of *East Three* and collecting soil samples for a better understanding of the soils at this site.

Description of New Site: East Three

The central part of the eastern delta flank is predominantly a huge glacial moraine. In the southern part, bedrock is exposed through the glacial deposits; in the northern part, in the latitude of the Reindeer Station, the moraine is built up around the Caribou Hills. *East Three* is located between the areas of bedrock to the south and the Caribou Hills to the north where the East Channel flows along or close to high ground of glacial origin.

The relief of the area is one of flats at varying elevations, gentle undulations separated by shallow swales, rounded knolls, hummocky hills and ridges of varying heights and lengths. To the north are two terraces at elevations of 60 and 150 ft., and to the south a series of elongated smoothly rounded hills (drumlins) aligned in an east-and-west direction, with a swing to the north as the channel is approached. Some of the low-lying areas between the hills are occupied by small lakes.

East Three is drained to the west and northwest by streams which emanate from deep gullies in the high interior upland. The drainage is controlled by the relief, especially in the southern part of the area where the streams flow in parallel courses between the ridges. As a rule the ridges, knolls, and undulations are well drained although some of the relatively lower areas are not.

Spruce and birch are the dominant tree types, with secondary stands of willow and alder. The ground is generally hummocky with a varying cover of moss and shrubs. Birch predominates on the south-facing slopes and on well-drained areas. Spruce predominates on the north-facing slopes; stunted spruce, willow, and alder are found on more poorly drained areas.

Few trees grow on the low flat areas except along stream courses where there are dense thickets of willow and alder.

At *East Three,* frozen ground was encountered in September at depths varying from 6 in. to 4 ft. 3 in. below the ground surface. Surface cover of living organic material is 3 to 9 in. in depth. Soils range from fluvioglacial gravels to glacial till (stoney, silty clays with varying amounts of organic material, with the fine-grained material deposits being of greater extent). The largest deposits of coarse-grained materials (sandy gravels) are found on the northern portion of the site on the lower terrace immediately north of Boot Lake. Granular deposits are also found along the east and north banks of Twin Lake and to a lesser extent on knolls south of Boot Lake. Finer grained soils (stoney silt clays) are found in the ridges and in the lower areas over the rest of the site area.

It must be emphasized that the new town will still be founded on permafrost. It would be impossible to find any site in the delta area that was not underlain by perennially frozen material. In the development of the new townsite, therefore, every necessary precaution against disturbing the general permafrost condition will have to be taken. The topographical relief of the new site, however, will facilitate all surface drainage arrangements. The glacial origin of the underlying soils will yield more satisfactory foundation conditions than at the old site, and should provide reasonable supplies of road building material and gravel. At the same time, the glacial character of the local soils almost inevitably means that some massive ground-ice (in the form of *ice-boulders* in the glacial till) is present beneath the site so that some eventual ground subsidence is to be expected.

The site is a beautiful one, especially in summer, and spreads over rolling hills that are enlivened with small lakes. From the site there is a striking view of the low-lying delta to the west. With the careful town planning that is intended for the new settlement, the Aklavik of the future should be as attractive physically as the old Aklavik was disappointing.

Conclusion

Despite all difficulties the survey team completed their main assignment by the scheduled date, their findings pointing to *East Three* as the most desirable site for the new Aklavik. The third author had the privilege of visiting all four sites, in the company of his fellow authors and of other members of the team, in late July 1954. Two weeks later, the sites were visited by the then Minister of Northern Affairs and National Resources and by Mr. R. G. Robertson, his Deputy Minister. This is believed to be one of the first occasions when the Federal Minister responsible for Northern Canada has been able to study in the field, and far to the north of the Arctic Circle, the facts upon which a major policy decision was to be based.

The results of the survey were reported to the Advisory Committee on Northern Development, of which Mr. Robertson is the Chairman. The Committee endorsed the selection of *East Three* as the location for the new Aklavik and on November 18, 1954 the Federal Cabinet, upon the recommendation of the Minister of Northern Affairs and National Resources, officially decided that the town of Aklavik should be moved to this new site. Responsibility for the vast amount of work which the implementing of this decision involved is being shared by the Department of Northern Affairs and National Resources and the Department of Public Works. Preliminary planning has been done; work is actively proceeding at the site. Within a few years the new town will be a reality gracing its fine new location.

The authors are indebted to all the members of the survey team not only for their good work in the field but for demonstrating so well what can be achieved by real team-work in the interests of the awakening North.

Appendix B

Survey Costs

Staff salaries	$13,000
Personnel transport: Ottawa to Aklavik (Return) Edmonton to Aklavik (Return)	3,500
Rations (Purchased locally: 1440 man days at $3 a day)	4,320
Helicopter service	20,000
Labour (local)	2,857
Services (local)	468
Rental of equipment (local)	1,200
Camp fuel, 615 gallons heating oil at $0.26	160
Fuel for boats, 1277 gallons at $0.34	434
Oil for boats, 55 gallons at $2.50	137
Freight for initial camp, 3,000 lb.	3,630
Freight for drill rig*, 2,000 lb.	2,000
	$51,706

*N.R.C. property so no rental charges

INDUSTRIAL USES FOR AN AUXILIARY LOW FREQUENCY SUPPLY

G. L. Tiley, *Application Engineer*
Mining, Petroleum and Chemical Division

Canadian Westinghouse Company Limited, Hamilton, Ont.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June, 1959.

THE A-C INDUCTION MOTOR is the simplest and cheapest electrical rotating machine for industrial drives and is ideally suited to constant speed applications. Pole changing may be used to obtain a two or three to one speed ratio, but for higher ratios it becomes impracticable and a wound rotor motor must be used. The well known speed-torque curves of a wound rotor motor (Fig. 1) and h.p. diagram (Fig. 2) point out its fundamental disadvantages, viz.

1) If torque is to be maintained reasonably constant between standstill and full speed, the amount of external secondary resistance in circuit must be varied over a wide range. This can be done either with a liquid rheostat or metallic grids and contactors.

2) It is wasteful of power. At 50% speed, say, half of the power supplied appears as heat in the secondary resistors.

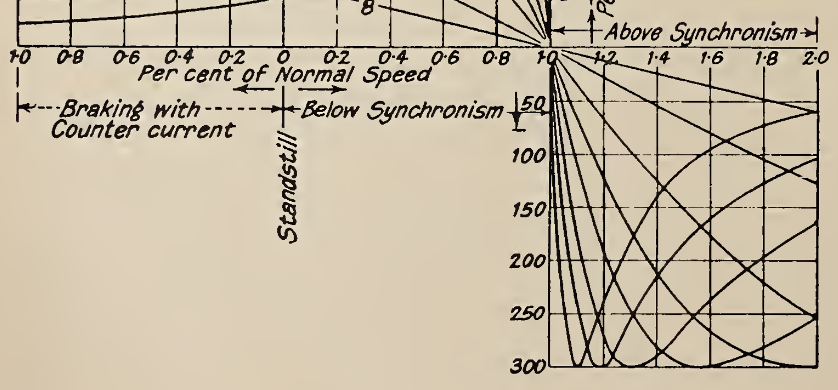
3) Regenerative torques, obtainable by reversing the stator supply, are not easy to control. Also, three times as much power is wasted in the secondary resistors as is usefully employed.

4) Accurate speed control at low speeds is very difficult, because the speed varies considerably with load in this region.

In addition to adjustable speed drives, there are many applications where two widely different speeds of operation are required — a very slow speed for creeping and a normal speed for running.

It is the purpose of this paper to show how an auxiliary low frequency a-c. supply can overcome some of the above mentioned drawbacks, thereby broadening the range over which the induction motor can be economically and satisfactorily applied in industry.

Fig. 1. Curves connecting speed and torque for several values of rotor resistance.



Low Frequency Equipment In The Rotor Circuit

The low frequency generator was originally developed for use in the rotor circuit of an induction motor. With such a scheme, the speed may be controlled at speeds near the synchronous and without the losses associated with secondary resistors. The power factor of the induction motor can also be controlled by injecting voltages of the correct frequency and phase angle into the rotor circuit.

Fig. 3 shows the schematic layout of the system, designed to give shunt characteristics to the drive, i.e. the speed of the induction motor will not vary greatly with load, but the set speed will be adjustable.

Field coils F are fed from taps of an auto transformer B, whose terminals are across the sliprings of the induction motor. The flux in this auto transformer remains constant at all slips, because when the voltage across the rings increases, the frequency in the rotor circuit increases at the same time. For a given setting of the taps the flux in the field coils F1, F2 and F3 will, for the same reason, be constant and independent of frequency. The amount of flux F1, F2 and F3 can, however, be adjusted by altering the position of the tappings.

The armature A of the low frequency generator is also connected across the sliprings through the compensating and interpole windings C and will always generate a back e.m.f. at the same frequency as the slipring frequency.

At speeds below synchronism the low frequency generator acts as a motor to drive the induction motor E at above its synchronous speed. Power taken from the rotor circuit is thus returned to the lines. Speed is controlled by adjusting the auto transformer taps.

The greater the speed range required, the higher will be the voltage and frequency to be handled by the low frequency generator. Economic considerations limit the speed range to about 15% below synchronism.

The addition of an ohmic drop exciter, which is nothing more than a frequency converter mounted on the shaft of the main induction motor, enables the speed to be taken above synchronism. In this case, power is fed into both the stator and rotor of the main induction motor.

Low Frequency Supply To The Stator

Recent developments in the application of low frequency equipment have been directed towards its use in the stator circuit of induction motors. This work has been pioneered in Germany, particularly for automatic mine hoist control. A brief description of some of these applications follows:

1) *Mine Hoists*—A typical production drum hoist duty cycle is shown in Fig. 4. The a-c. drive is considerably cheaper to install than the equivalent d-c. drive for horsepowers below about three thousand. Where the full speed time is long in comparison with the accelerating and decelerating times, running costs may also favour the use of an induction motor.

To maintain optimum duty cycles and accurate stopping, deceleration and creeping speeds must be consistent and independent of load. Prolonged operation at creep speed during shaft and rope inspection trips must not overheat the motor or the resistors.

Manually controlled a-c. hoists are in use all over the world, but usually the operator must use the mechanical brakes to "trim" the speed during deceleration and creeping. Often a shaft inspection trip must be interrupted while the rotor resistors cool off.

A semi-automatic hoist using a low frequency supply for braking and slow speed operation has recently been installed. Fig. 5 shows the speed torque curves obtained during tests on the 1250 h.p., 4160 volt hoist motor, when supplied with 60 and 4 cycles power and the rotor short-circuited. The proportional voltage at 4 cycles would be 4160/15-277 volts. It will be seen that for comparable performance the motoring voltage should be increased to 390 volts and the braking voltage reduced to 175.

When motoring on 4 cycles, maximum torque is developed at standstill with the rotor short-circuited. As rotor resistance is added, the torque falls away, as shown in Fig. 6.

Accurate control of braking torque is obtainable by adjusting the value of the rotor resistance at any speed. Moreover, shorting out steps of resistance by means of timed contactors as the speed falls, produces a certain amount of self correction of torque with load, in the same way that timed acceleration on 60 cycles tends to maintain constant acceleration, independent of the load. During automatic operation the hoist to which reference is made operates as follows:

Just before deceleration is due to commence, the power being taken by the hoist motor is measured. This gives an indication of the load in the skip. The deceleration programme is set up accordingly, so that when the skip reaches a certain position in the shaft, the normal frequency supply is removed and replaced by the low frequency supply at braking voltage. Simultaneously a pre-determined amount of rotor resistance is introduced. As the hoist decelerates, other contacts of the limit switch cut out rotor resistance. As the skip is about to enter the horns, the rotor is short-circuited and the low frequency voltage increased to the motoring voltage. Creep speed is maintained accurately, and independent of skip loading, by virtue of the "stiff" speed torque characteristics obtained once the slip rings are shorted.

Low frequency is also used for manoeuvring and for shaft inspection runs. Under these conditions no power is dissipated in the rotor resistors. The frequency of the supply is chosen to give the desired creep speed. In the case under discussion, either three or four cycles may be selected manually on a two speed gear box.

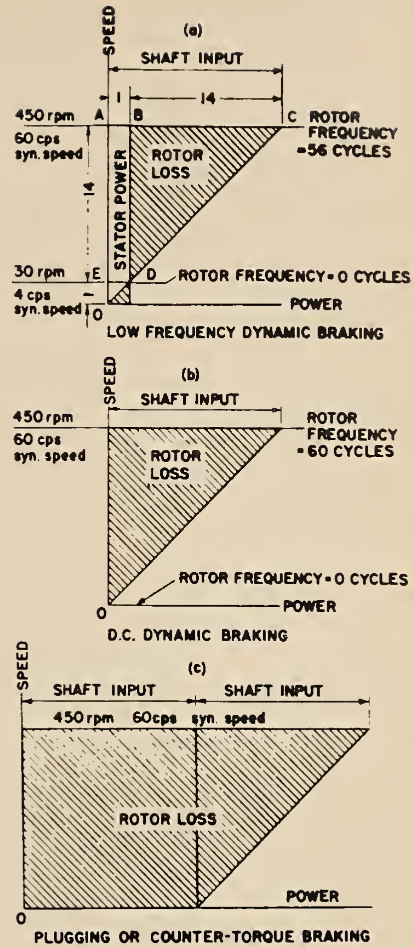


Fig. 2. Power and energy relations during braking.

2) *Use of Low Frequency for Starting and Barring of Ball, Tube and Rod Mills*—The torque required to start rotation of a ball, tube or rod mill is relatively high when compared with the running torque. The reasons for this high starting torque requirement are:

1) Friction is high until such time as an oil film has been established under the bearing journals by rotation.

2) If the mill is stopped without first emptying the charge the material will settle and harden, and the torque required to rotate the drum and its out-of-balance load is high until the point is reached at which the load starts to cascade and break up. Once the load has been broken up by cascading, the mill can be stopped and if started up again soon enough there-

after, a much lower starting torque will be required.

Starting presents no great problem when wound rotor induction motors are used, as the rotor resistance can be adjusted to give maximum torque at standstill, and then reduced progressively as the mill speeds up.

If synchronous or squirrel cage motors are used, however, they must have a high starting torque for the reasons given above. They must also deliver high torques in the neighbourhood of full speed; the synchronous motor must be able to pull the high inertia mill into synchronism and the squirrel cage motor must run at low slips to be efficient. These two requirements are mutually incompatible and, in practice, it is necessary to use a motor about 40% larger in size than is actually required for continuous running.

The motor can be of smaller size if a slip coupling of suitable rating is interposed between the motor and the mill, but such couplings are relatively expensive and introduce continuous losses while running.

An auxiliary low frequency supply can be used to advantage in reducing starting torques, as will now be explained. One set of low frequency equipment may be used to start a number of mills if arrangements are made to start only one mill at a time. Each mill will have two starters, one connected to the main and the other to the low frequency bus.

When the low frequency contactor is closed, the motor will develop practically maximum available torque on low frequency at standstill as illustrated in Fig. 6 and the mill will start to rotate. If a synchronous motor is employed, the synchronizing relay will operate almost immediately to apply the field as it is usually set to detect a rotor frequency of about 3 cycles/sec. The motor will then continue to rotate with full available torque as a synchronous machine.

Tests on a typical synchronous motor driving a ball mill gave the following figures:

- Starting Inrush on 2200 V, 60 cycles—1100 amperes
- Starting Inrush on 175 V, 4 cycles —350 amperes
- Full load current at 2200 V, 60 cycles—200 amperes
- Running current on 175 V, 4 cycles —160 amperes

A mill can thus be barred over at low frequency and run until the bearings are lubricated, and the charge is broken up. It will then start very easily if immediately switched over to normal frequency.

In an alternative method of operation, the low frequency power is applied to rotate the mill in the re-reverse of its normal direction of rotation. When transferring to normal frequency in the correct direction, the out-of-balance load will assist the mill to get up to speed, and so further reduce the required starting torque.

The low frequency supply is also used for turning the mill over slowly during maintenance operations. Very accurate spotting is possible and the stresses caused by the high starting inrush current on normal frequency are eliminated.

3) *The Use of Secondary Reactors with Low Frequency*—The use of resistors and reactors in the rotor circuit of an induction motor can produce some interesting results.

This system has recently received much attention, chiefly because computers are now available to the design engineer. Previously, the ultimate performance of an induction motor with resistor-reactor secondary control could only be predicted after many hours of tedious slide rule computations. The expense of engineering was an economic deterrent.

Fig. 7a illustrates how a substantially constant torque may be achieved between standstill and full speed by the judicious use of reactors and resistors with only two secondary contactors, when a motor is supplied with 60 cycles.

With low frequency supplied to the same machine, the dynamic braking characteristics for any particular value of applied voltage will similarly be essentially flat, as shown in Fig. 7b. It now becomes practicable to control the rotor circuit automatically, by means of one- or two-speed, or frequency-sensitive switches, and still maintain the torque constant within a few percent between standstill and full speed.

To control the torque, it is only necessary to vary the voltage applied to the stator.

Fig. 8 shows a system developed for controlling a mine hoist by this means. A variable voltage, low frequency supply is generated by a fre-

Fig. 3. Low frequency M.G. set.

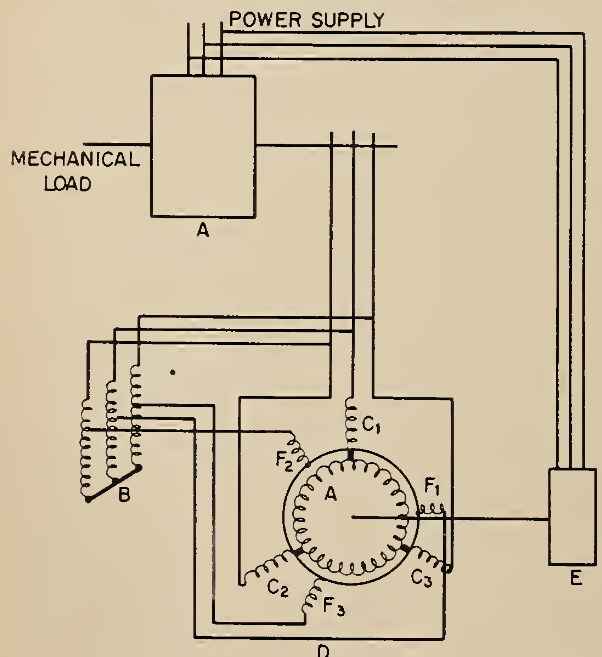

Fig. 4. Drums hoist duty cycle.

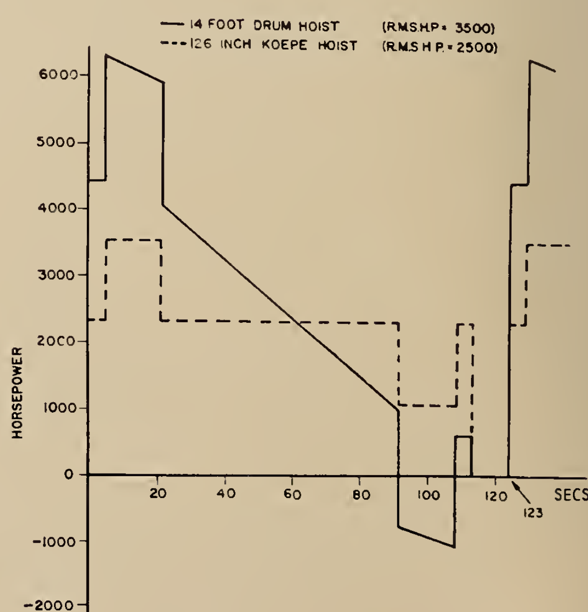

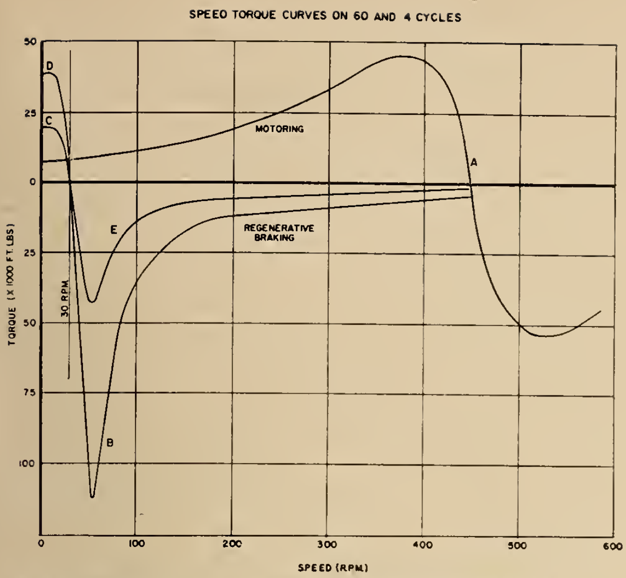

Fig. 5. Speed torque curves (zero external resistance): (A) 4160 volts 60 cycles; (B) 277 volts 4 cycles braking; (C) 277 volts 4 cycles motoring; (D) 390 volts 4 cycles motoring; (E) 175 volts 4 cycles braking.

Fig. 6. Speed/torque curves—induction motor 4 cycle motoring.

quency changer that is fed from a small alternator mounted on the same mg. set. This mg. set may be driven by a standard squirrel cage induction motor because the slip frequency is determined primarily by the gear box ratio and not by the speed of the set. The size of the hoist motor necessitates the use of a low frequency mg. set.

Provided the duty cycle always calls for braking torques during the decelerating period, this system gives stepless control of deceleration and creeping speeds. At the beginning of the deceleration cycle, the normal frequency supply to the motor stator is replaced by a low frequency supply of the same phase rotation. At the same time, a secondary contactor closes to introduce the reactors and an auxiliary contact completes the circuit to the alternator field.

The alternator voltage is now a function of the speed-error signal and controls the braking torque in such a manner as to keep the hoist to the preset speed program down to creep speed. When creep speed is reached, the rotor is automatically short-circuited and the low frequency voltage increased.

Use Of Low Frequency For Anodizing Aluminum

An interesting and rather unusual application of low frequency was recently investigated. This concerned the anodizing of aluminum. Anodizing may be defined as the electrochemical conversion of the surface of aluminum to aluminum oxide, the aluminum serving as an anode in an aqueous electrolyte and the oxygen being provided by the electrolytic dissociation of water.

The aluminum oxide film is extremely hard and is highly resistant to corrosion and wear. Attempts to produce a thick anodized coating by conventional d-c. electrolysis however, resulted in a high percentage of rejections due to "burning".

The oxide film has a high specific resistance so high voltages have to be used when thick layers are required. "Burning' occurs when a local weakness of the film results in the concentration of current at that point. The resultant heating causes the film to break down and "burning", or local melting, takes place almost instantaneously.

It was found that periodic current reversal reduced the occurrence of burning by producing a more homogeneous surface film.

One method of current reversal involves the use of reversing contactors with a d-c. supply source. In another method, reversal of current is effected by injecting a-c. at mains frequency into the d-c. supply. This system requires the use of enormous capacitors and chokes to isolate the two supplies. Both of these methods become expensive when large powers have to be handled.

A standard d-c. generator will satisfactorily commutate frequencies up to 3 or 4 cycles and it was also found that the frequency changer commutator could handle a d-c. component. Two standard machines connected in series have been used to produce a d-c. supply that can be modulated to effect periodical reversal of polarity.

Performance of a pilot installation has been excellent. It was primarily intended for hard anodizing of high copper aluminum alloy components for aircraft. The high copper content had prohibited the use of conventional d-c., and the parts had previously been shipped to Great Britain for processing in a mains frequency-modulated system. The use of low frequency modulated d-c. now permits these alloys to be anodized locally and much more economically.

Standard anodizing process times were cut by as much 60%, proving the value of a low frequency supply in commercial anodizing.

Low Frequency Generating Equipment

Very expensive, low speed machines would be required if a frequency of 3-5 cycles per second were to be generated by conventional alternators. If a commutator is used, the speed of rotation can be much higher than the output frequency and economical machines are possible.

There are two main types of low frequency generating machines, i.e.

a) Frequency Converters
b) Low Frequency Generators

In general, frequency converters can be used in those applications requiring less than 20 kw. and less than 100 volts, and low frequency generators are required for higher powers.

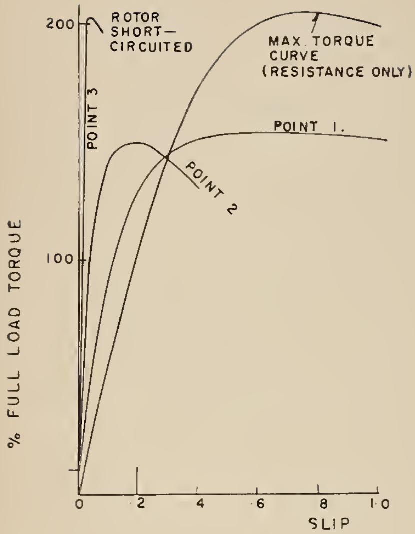

Fig. 7(a). left — Speed/torque curves — induction motor — 60 cycle motoring resistor — reactor rotor control.

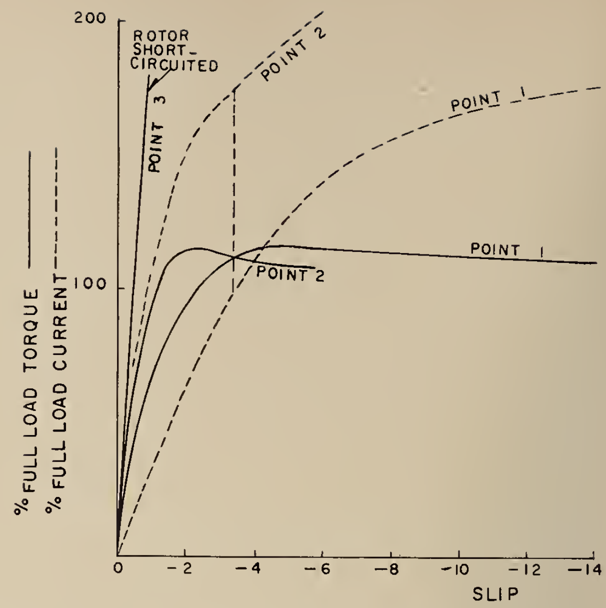
Fig. 7(b). right — Speed/torque curves — induction motor — 4 cycle dynamic braking resistor — reactor rotor control.



The design and peformance of these machines has already been described in detail in several papers, and only a brief outline will be attempted here.

1) *Low Frequency Converters*—Consider an ordinary 2 pole d-c. armature, provided with a commutator at one end and three sliprings tapped into the winding at three equally spaced points at the other. Let the armature at first be stationary, and let the rings be fed with 3 phase currents at 60 cycles. The currents will produce a magnetic field revolving anticlockwise, let us say, looking at the commutator end, at a speed of 3600 r.p.m. This will set up a back e.m.f. to balance the e.m.f. of the supply. The flow of current will be limited mainly by inductance of the winding and it will lag behind the applied e.m.f. If there are three brushes spaced 120° apart on the commutator, the voltage between these will alternate at 60 cycles and will have the same virtual value as on the rings.

Now, make the armature rotate in a direction opposite to the magnetic field. The speed of the field relative to the tappings remains the same, i.e. 3600 r.p.m., but the speed relative to the stationary brushes becomes less and less as the speed increases up to 3600 r.p.m. The value of voltage across the brushes remains the same, but the frequency decreases.

At 3600 r.p.m., the field becomes stationary relative to the brushes which have a steady voltage across them. The machine is then a synchronous converter and may be used to yield d-c. current from an a-c. supply.

At speeds either above or below synchronism, the apparatus operates as a frequency converter, yielding at the brushes a frequency that is the difference between the frequency of the supply and the frequency of rotation. *(Continued on page 68)*

RIVER CONTROL IN THE INTERNATIONAL RAPIDS SECTION THE ST. LAWRENCE POWER PROJECT

K. A. Henry, Jr.E.I.C., *River Control Engineer*

The Hydro-Electric Power Commission of Ontario

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June, 1959.

The paper describes the rather unusual circumstances which arose in the International Rapids Section during construction of the St. Lawrence Power Project, where numerous agencies and their many contractors all were engaged in works affecting river conditions. The need for an all-embracing control of operations affecting river conditions, and the administrative arrangements for this unification, are outlined. The actual field control system and the necessity for continued use of models in construction as well as design are shown by describing how some of the more interesting problems were handled.

The Need for a River Control System

THE ST. LAWRENCE POWER PROJECT and associated Seaway work in the International Rapids section of the St. Lawrence River between Cornwall and Prescott presented an exceedingly complex construction problem. From the beginning the power entities, Ontario Hydro and the Power Authority of the State of New York, as well as the two seaway groups, Canada's St. Lawrence Seaway Authority and the United States Seaway Development Corporation, were all at work on the same reach of river and were continually faced with the possibility of adversely affecting each other's working conditions. Also the Order of Approval by the International Joint Commission for construction of the Power Project required that the construction proceed without adversely affecting upstream or downstream conditions, which in effect meant that Lake Ontario levels and St. Lawrence flows must be maintained in accord with the levels which would have occurred had no project been built, as well as requiring maintenance of satisfactory navigation conditions for the existing 14 ft. draft shipping.

Engineers of the power entities, using both topographic and structural hydraulic models as the chief tool, started from studies and reports dating back many years, and evolved a basic design for the International Rapids section. Once the basic design was settled, a working sequence was determined and from these two bases a series of contracts were developed, of which the starting and finishing dates were vitally interlocked.

It was readily apparent from the early stages of planning that to comply with the Order of Approval would require some unified control of operations affecting the river. In April 1955 at a meeting in Montreal, The St. Lawrence River Joint Board of Engineers, appointed by the governments of Canada and the United States to supervise the project for the Federal governments during the construction period, expressed concern over this feature. It was then learned that the Power Entities proposed to prepare and submit for approval an overall method of River Control. This method would outline all the steps in the construction procedure which might affect the river regimen. To ensure proper implementation of this plan a River Control Engineer, familiar with the work and planning, would be appointed and placed on the site to advise the Project Director for Ontario Hydro and the Project Manager for the consultants to the Power Authority, on all matters pertaining to levels, flows, currents and navigation. This then was the background for the creation of River Control and the author was appointed River Control Engineer in the spring of 1955, following several years of work on the planning stages of the project at the Hydraulic Model Laboratory in Toronto.

Fig. 1.

The conception of a St. Lawrence Power Project in the International Rapids area probably dates back as far as the beginning of hydro-electric generation. Certainly when the last barriers to construction were removed in 1953, designers had a wealth of earlier studies to draw from. Starting from these original conceptions and using new design techniques, particularly hydraulic models, they completed hydraulic design for the combined shipping and power channels.

In all the design work, one of the more fundamental considerations was the sequence and method of work to ensure that no material change in river flows or Lake Ontario levels would occur and that the existing 14-ft. draft navigation could continue uninterrupted. It was no easy matter to produce such a sequence under the simplest of construction concepts, but when the work was finally divided amongst the four responsible agencies, and each had divided its share into manageable sections for the calling of contracts, a vastly complicated pattern of starting and finishing dates for the contracts arose. Nearly all the work depended on river diversions and cofferdamming operations. It was essential that the effects of work by different contractors balance one another producing as small a total change as possible. This required a close, comprehensive system of control. Also essential was a comprehensive inspection of work progress and continual measurement of effects of work and operation of control structures on the critical aspects of river regimen and navigation. As the job progressed this measurement of effect became more important, since the natural controls of the river were eventually completely removed and replaced by man-made and man-operated structures.

The concern of this paper will be with the system of inspection, measurement and control used to ensure the high degree of co-ordination and co-operation that was essential.

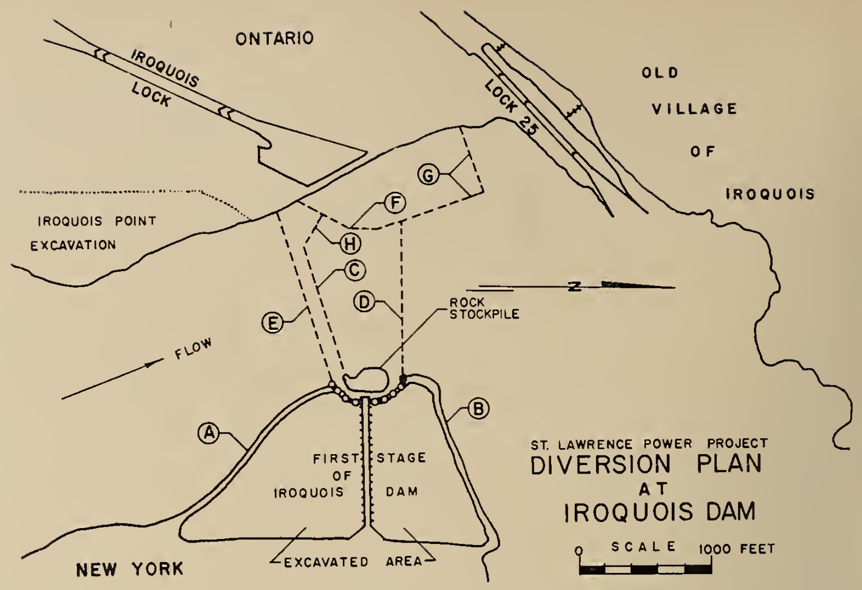

Fig. 2.

The Gathering of River Control Data

To keep track of what is happening in a river, the most readily available measurement is that of water levels. For this purpose, prior to the construction period, the power entities established a series of more than thirty continuously recording gauges, in consultation with, and to the satisfaction of, the governmental supervising agencies concerned. The locations of these are shown in Fig. 1. Some of the gauges were duplicates of long established measuring points but most of them were new. Analysis of the levels at these points made possible the determination of construction effects in the whole reach. Use could be made of the services of a large and expert hydraulic surveying crew from Ontario Hydro, equipped for precise current metering and accurate echo sounding, with all the necessary radio communication for rapid determination of flow conditions other than levels.

Also available, of course, was all the information from the very co-operative field engineering services of the consultants and of Ontario Hydro, as to progress by the various contractors and predictions of the likely course and rate of construction.

From the beginning it was evident that gauge records collected and tabulated once a week would not provide the necessary data for control of operations quickly enough. As work progressed, the need for quicker reporting of conditions would become more urgent. Therefore, certain critical gauge levels were telemetered, via standard telephone service, to control centres. At first, since work at the two ends of the project was generally unconnected, two separate centres were used, one at the east end of the area and one at the west end; but as the work progressed and became more closely integrated and as operation of the river became more artificial, a single central control with a sub-centre was set up. Five of the six gauges telemetered to the Cornwall Control Centre are indicated in Fig. 1. The sixth gauge was located some eighty miles west of Prescott, at Kingston on Lake Ontario. The gauge at Massena Intake was only available at the Massena sub-centre, where the Dickinson Landing and South Shore gauges were repeated.

In order to provide a flexible and reliable means of emergency communication, a radio network was set up with four fixed stations as indicated in Fig. 1. There were also four radio-equipped vehicles, two working out of Massena sub-center, one from Cornwall and one from the North Channel Office. The fixed stations could all reach each other, while the mobile sets had a sure range of some thirty miles. In addition, a number of portable battery sets with ranges from one to ten miles, normally used for survey co-ordination, could be diverted to control use when required.

This, then, with the men to operate and service it, was the equipment used for river control.

The Procedure for Construction Problems

At first all the problems were in connection with the construction work. Contractors changed their methods of operation or the engineers varied the locations of channels. Every variation in scheduling, for these or any other reason, involved a whole chain of subordinate effects, so throughout the length of the river and for all the construction period, a constant series of changes and improvisations had to be evaluated and co-ordinated.

Project Directors were, of course, responsible for prosecuting the work. In cases where variations from the specified plans might affect the river in any way other than that planned initially, the variation was referred by the Director concerned to the River Control Engineer. The River Control Engineer reviewed the proposal and passed it on to the Hydraulic Engineer for evaluation, at the same time bringing the matter to the attention of the St. Lawrence River Joint Board of Engineers, and, if it could in any way affect navigation, the appropriate Department of Transport agency. After review by everyone concerned, if any appreciable change in overall effects appeared likely, the proposal, often in modified form, was submitted to the Joint Board of Engineers for approval, and upon approval was incorporated into the construction sequence.

There were of course many variations in the size and importance of the changes, from those conceived, presented, evaluated, approved and completed in a day, to others requiring months of model testing and formal submission for approval, affecting the whole construction procedure.

Construction operations were planned in as much detail as possible ahead of time, but naturally a good deal of the final timing depended on work progress. Such operations as the diversion of the river from its course to the man-made channels and control structures at Iroquois Dam and Long Sault Dam were of this nature, and control of them was accomplished through the River Control system.

The Procedure for Operational Problems

As work progressed, the river gradually became more and more artificially controlled. The artificial reproduction of natural conditions was a continually growing part of river control throughout the job. 'Natural conditions' is a rather difficult term to define, and it is evident that the reproduction of a damaging storm-bred seiche would not be at all desirable from any point of view. Proper modification of natural phenomena to improve the conditions for everyone in the river was inevitable. The operation of control structures to provide these modified natural conditions was carried out from the River Control Centre at Cornwall with operation orders to contractors and structures controlled by the consultants being transmitted through the Massena sub-centre.

Under artificial control, the river required continual surveillance at a period long prior to establishment of a proper operating staff on round-the-clock duty. This surveillance was obtained by painting directly on the visual record telemeter charts colored areas depicting dangerous levels or conditions. The security patrol on its hourly rounds checked each gauge and called the engineer on duty if anything appeared to be amiss. This economical system worked satisfactorily for over a year until the plant operators appeared on the scene.

The River Control system as described above worked satisfactorily throughout the construction period, culminating in the filling of the forebay to create Lake St. Lawrence in July of 1958 when, with greatly increased equipment and personnel, the system served as the basic method of control for that complex operation. The gradual switch in emphasis from control of construction operations to straight operation of a power plant is now nearly complete, but the basic system will always continue in operation.

Fig. 3. Iroquois dam just before flooding of first stage (October 11, 1956).

A Construction Problem — Diversion at Iroquois

A rather complex operation, in the fall of 1956, the diversion of the river at the site of Iroquois Dam from its natural course to the completed first half of the Dam, affords a good example of the type of construction problem which required the exercise of River Control facilities.

Construction of Stage 1 of the dam had been completed early in October. On October 22 the area was flooded and the diversion began. The map in Fig. 2 indicates the items of work mentioned below while Fig. 3 and 4 show the area at the beginning and end of the diversion.

The diversion plan consisted of the following steps:

1. Remove cofferdams A & B
2. Construct rock groin C
3. Construct earth fill F with rock kick dyke H for protection if needed.
4. Complete cofferdams D & E and unwater.

If it had been possible to work the above steps in sequence no problems would have been presented, but the exigencies of a very tight schedule compelled the contractor to overlap the steps so that in fact all were under way at once.

The factor controlling the rate of diversion was the removal of cofferdams A and B to provide new area for flow. Gates in the dam could, of course, readily be opened to accommodate diverted water. As quickly as new area for flow could be provided, the rock groin C was to be extended, until a closure against H was effected, whereupon the second stage cofferdams E and D could be completed. Throughout the operation flows of just under 250,000 c.f.s. were handled, but in view of the possibility of seiches it was necessary to be prepared at all times to handle 300,000 c.f.s.

Rock groin C, the primary closing structure, was built of rock excavated in Stage 1 and stockpiled for this purpose. It was a straightforward end dumping proposition, necessary because the construction of the final cellular cofferdam, E, in the swift currents which would be encountered was impossible.

A large number of factors, some of which are listed below, made necessary the most rigid control of every part of the work:

1) It was desired that as little raising of levels as possible occur upstream because part of such a rise would be transmitted right up the river, reducing flows from Lake Ontario. The local raising effect was

measured at a gauge about a mile upstream;

2) It was essential, in view of the near-capacity operation of the existing canal system, that the downstream navigation be carried through the river channel as long as possible with as little velocity change as possible and no lowering of levels;

3) No excessive drop in levels through the work area could be tolerated because the associated high velocities might cause wash to occur at cofferdams A or B with the material being deposited in areas where excavation was complete. Also, dyke F was built of dumped till and no increase in velocities could be tolerated, because even under the best balanced conditions velocities of 12 ft. per second along the exposed side were expected;

4) It was quite easy for an excessive drop to be created because the contractor had available sizeable stone for the rock groin C and could push this out to cut off more flow area than had been excavated at cofferdams A & B;

5) The approach to Lock 25 from downstream had always been difficult in the fast current and the moving of the whole river to a new location changed the currents considerably so that a varying effect was felt. The high velocity jet from increased head drop would aggravate this effect.

In the summer of 1956 the contractor and engineers had collaborated in extensive model studies to determine the best balanced conditions satisfying the strict criteria of proper functioning and limited time. As a result of these studies, the contractor was made aware of the items likely to limit his progress.

The method of control adopted for the operation was to limit the length of the rock groin C and the gate openings in the completed first half of the dam. The contractors were all allowed to press work as quickly as possible in all other items. A careful check was kept on the stage upstream and no appreciable increase above normal was permitted. As velocities built up along dyke F with the approach of rock groin C some material was washed away, but a closure was effected in mid-December.

Some difficulties in navigation arose, but careful arrangement of gate openings according to improvements noted by the ship captains allowed navigation to continue uninterrupted.

This brief description of a rather straightforward problem affords an illustration of the construction end of river control.

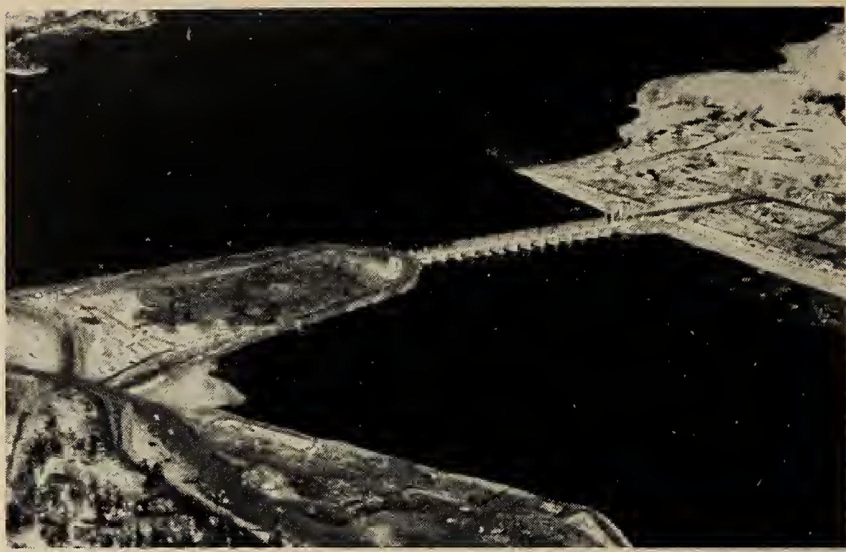

Fig. 4. Iroquois dam with cofferdams for second stage complete (February 5, 1957).

Operational Control of Seiches

Any description of the normal operation of control structures to produce the desired modified natural conditions in the river would make singularly unexciting reading. The feature of this part of river control which did cause some excitement on occasion was the operational procedure during seiches.

Seiches themselves are an interesting phenomenon in the St. Lawrence River, the word itself being mysterious enough to alarm the uninitiated. The St. Lawrence is normally considered to be a very stable river, and so it is. Many rivers can quickly increase their flow by two or three times and often much more. A change of 20% in the St. Lawrence is abnormal, and a good thing it is, too, when it is realized that even this represents something like forty to fifty thousand c.f.s. A good example of such a change happened on November 17, 1955, when the flow, which had been averaging some 255,000 c.f.s. rose to 293,000 c.f.s. for a day, and was actually well over 300,000 c.f.s. for some hours. This type of phenomenon is known as a positive seiche.

Observations so far have indicated that seiches are always linked to weather disturbances. In general, south-west winds pile water up at the east end of Lake Ontario spilling extra water into the St. Lawrence River, and as the extra water passes down into the more constricted sections, the rise in level increases. Negative seiches occur under the influence of northeast winds. The seiches seem to be linked also to barometric pressure differences and sometimes occur without too much wind.

Under artificial control conditions with the gates at Iroquois Dam set partly open, as they had to be through the summer of 1957 on account of navigation conditions at Lock 25 just downstream of the Dam, the gates were, in effect, orifices, and the rise in Lake Ontario at Kingston might be exaggerated as much as four times just upstream of the Dam. Additionally, as mentioned previously, it was not in the best interests of all concerned to pass a seiche downstream. For flood routing the storage had to take place above Iroquois Dam, causing an exaggerated rise in levels. A seiche might of course be too large to be routed, and the hazard of starting a routing program and then having to let go was that downstream conditions might worsen.

The most effective defense against seiches is an efficient warning service. This should provide two items of information: primarily, notice that a seiche is imminent; and secondarily, the size of the seiche.

The Ontario Hydro has developed a weather watching section to assist operation of the Niagara plants where the large Lake Erie level variations affect flows drastically. Because St. Lawrence River seiches are dependent on large scale weather systems and not on local weather, a minor extension of the standard watching procedure has provided warning of serious seiches. On the other hand, it has not been possible so far to invariably distinguish between disturbances which will cause a sizeable seiche and others which have very little effect.

In general the first warning of a

seiche comes from the Hydro's Toronto weather centre. Once an alert has been given the next indication shows up on the local barograph. Seriousness of seiches is usually indicated by the lowness of pressure, the steepness of the drop and duration of the minimum pressure. The Kingston telemeter shows the actual beginning of the seiche, and here again size is indicated by the rate of rise, the height of rise and the duration of the elevated levels. In general, fast short term rises dissipate rather quickly, while the slow long-lasting rises multiply as they come into the project area. The height of rise is of course directly related to the seriousness of the seiche.

Let us look at a particular case. At noon, Friday, November 8, 1957, a warning was received from Toronto that all necessary conditions preliminary to a seiche existed. This confirmed the indications of a steeply falling barometer, which at that moment stood at 29.62 in. The barometer continued falling till a low of 29.29 was reached at eight o'clock p.m. Meanwhile a small rise in level occurred at Kingston between three and four o'clock in the afternoon, which seemed unlikely to cause trouble. The continued barometric drop indicated that there might be more to come, and indeed, between eight and eleven p.m., the level at Kingston rose to a foot above normal. It was decided that this seiche would be too large to route, so orders for opening three gates at Iroquois Dam were given at eleven o'clock, which stopped further rise above the dam.

However, the level at Iroquois Dam did rise over 3 ft., approaching very closely the maximum permissible height at certain construction sites. The flow, which had been averaging some 220,000 c.f.s., was allowed to increase to 250,000 c.f.s. by the opening at Iroquois. Downstream at Long Sault Dam, matching changes in gate settings were required to prevent damage because at this point a rise of a foot would have exceeded the maximum permissible level at the Cornwall Canal Locks. Further gate openings were required on Saturday but by Sunday afternoon everything could be returned to normal.

This seiche was typical of a dozen or more which occur each year, and which will continue to be a feature of the operation of control structures in the upper St. Lawrence River. Creation of Lake St. Lawrence in the summer of 1958 has made it possible to route larger seiches and increased operating experience is gradually making the control of levels and flows more precise.

The Creation of Lake St. Lawrence

The creation of Lake St. Lawrence took place from July 1 to July 3, 1958 and this complicated operation, the culmination of three years of intense construction effort, called for a great temporary elaboration and amplification of the River Control System.

Toward the end of June all the necessary clean-up work possible was completed in the area to be flooded. Long Sault Dam was substantially complete and ready to act as the valve for controlling flow out of the pool while Iroquois Dam was ready to control the inflow. All dykes and other structures were completed and awaiting the rise of water. The powerhouse itself was ready to be flooded, but the upstream cofferdam was still in place and had to remain so because its removal would cause flooding of the 14 ft. canal near the powerhouse. Navigation had continued uninterrupted up to this time, passing up and down the canals and locks as usual, slipping through the Cornwall dyke by means of a 50 ft. wide concrete slot known as the Closure Structure. The new locks, which were to lift shipping from Lake St. Francis into the new lake, stood ready.

The flooding procedure consisted first of all of clearing the reach of all ships, closing the hole through the dyke at the Closure Structure and clearing out the last-minute power and telephone lines and canal fixtures. Then with everything ready, the upstream cofferdam was to be removed by blasting and erosion, inflow to the pool was to be increased, the outflow reduced and the level raised. Every effort was made to reduce the time of the operation to the absolute minimum in order to have as little delay to shipping as possible, and so the various items overlapped, making rigid adherence to a very careful schedule essential.

The operation was carried out under the direction of the Project Directors; the river control system provided the necessary data, analysis and communications to make this direction effective.

A Central Control Room was established where all data was collected by radio, telephone or telemeter. A staff of three men well versed in the required work was on hand round-the-clock to process the data, and the Project Directors or their responsible agents were continually present or immediately available. It would be overambitious to attempt to describe all the changes in the gauging system needed during this period. Many gauges were removed just prior to flooding and new gauges were ready to go into action when the water reached them. At telemeter sites where information was needed continuously, staff gauges with readers radioing information were used until the level climbed to the waiting new installations. In case of telemeter failures, standby telephone communication and radio sets were on hand. Because of the large numbers of people in the area, a helicopter was kept ready to ensure that emergency transportation needs would not be interrupted by traffic snarls. For the transmission of orders for gate operations, direct telephone lines were set up with standby telephone arrangements and a radio link as a third line if needed.

The plan for the flooding operation was governed by two principal features. The rate at which water could be impounded was limited because upstream considerations imposed a maximum on the rate of inflow and downstream considerations made necessary certain minimum outflows. The necessity of providing 14 ft. draft navigation facilities right up to the last possible minute before flooding meant that the old locks must be left substantially unimpaired and that some power and telephone lines in the area to be flooded had to be maintained.

After nearly six months of planning and co-ordination between the power entities and navigation interests, a plan was settled on. All planning was done to an H-hour which eventually was set at 4 a.m. on July 1, 1958. At this critical time, the gates at Iroquois Dam were to be opened to let in extra water thereby beginning the actual filling of the pool. Events occurred in about the following sequence:

1) At 4 a.m. June 30, shipping was stopped from entering the area to be flooded, and by about noon the reach was clear.

2) Shortly after dawn on June 30, removal of power lines to locks and telephone lines started; it was finished well before flooding took place.

3) Dismantling of the lock equipment began as soon as shipping cleared the various locks, and was completed in good time ahead of flooding.

4) When the last ship had cleared the Closure Structure in the Cornwall Dyke, the steel stop logs were set in place completing the last plug in the pool except for the Long Sault Dam.

5) At July 1, the Iroquois Dam was opened and a total of some 310,000 c.f.s. began to spill in the pool.

6) At 7 a.m. the first port at Long Sault Dam was closed reducing the outflow to about 220,000 c.f.s.

7) At 8 a.m. after construction crews had left the danger area and the Provincial Police had made sure that no one else was too near, the upstream cofferdam at the powerhouse was blasted and within a short time the water had removed a large part of this earth structure, at the same time beginning to fill the pool just above the powerhouse.

From this time on the hydraulic features of the flooding governed all operations. As the water level rose, ports were closed at Long Sault Dam to produce a reasonably constant flow downstream. When the level reached the sills of the permanent sluices, water was spilled there too, until after closing all the ports some of the sluiceways were also closed bringing the water up to its final level. At Iroquois Dam, as the tailwater rose, more gates were opened to maintain the high flow to the pool until flooding was complete, when the gates were set to pass the natural flow of the river.

In the Central Control Room, the numerous gauge levels gathered there were used to compute the flows and flooding progress every few minutes. This progress was constantly compared with the planned rate, and at the appropriate times orders were despatched for gate movements to Iroquois Dam and to Long Sault Dam via the consultant's offices at Massena.

On July 2, both the Canadian and United States powerhouses began to use water for turning generating units. On July 3, navigation authorities began the placement of new aids to navigation in the new channels and on July 4, the mass of shipping tied up during the flooding began to move through the new facilities.

It is with no small amount of admiration that the author takes this opportunity to pay tribute to the splendid spirit of co-operation between Power and Seaway entities and between Canadian and United States engineers which made the job a success.

INDUSTRIAL USES FOR AN AUXILIARY LOW FREQUENCY SUPPLY

(Continued from page 62)

It should be noted that no stator is necessary. In practice, the armature is surrounded by a laminated iron stator in order to decrease the magnetizing current required.

The 4 pole armature is driven through a reducing gear box by an 1800 r.p.m. reluctance type synchronous motor. This motor has only to supply friction and windage losses. The commutator is provided with 6 sets of brushes. If the gear is 1800/1710 r.p.m. the output frequency will be 3 cycles. For 4 cycle output, the required gear ratio is 1800/1680 r.p.m. In the frequency converter a manual changeover allows either frequency to be selected.

Commutation limited the output of the machine illustrated to about 35 volts, 4 cycles. On test, sparking was found to be a function of voltage rather than current i.e. it was caused by the voltage induced by the rotating field in the coil sides being commutated. The maximum output was raised to about 55 volts by machining axial slots in the stator: these slots were spaced so that they were opposite the coil sides being commutated, and so reduced the flux at these points.

An alternative design of frequency converter has a similar rotor. A 3 phase winding is added to the stator, and the stator leads are connected through resistors. The machine then behaves like a wound rotor induction motor turned inside out, and is self-driven. Sixty cycle power is fed to the slip rings and slip frequency appears at the brushes. However, such a machine is very sensitive to changes in the supply voltage. Stability may be improved by artificially loading the armature with a fan or a brake.

2) *Low Frequency Generator* If outputs greater than about 20 kw. at 100 volts are required, the frequency converter is used to excite a low frequency generator.

Such a machine was originally developed by Scherbius and bears his name. In appearance it is very similar to a d-c. generator. Fig. 9 is a photograph of a Scherbius generator.

The stator has some multiple of three semi-selient main poles that carry shunt fields. Interpoles are fitted between the main poles, and a compensating winding is wound on the faces of the main poles.

In order to keep down eddy current losses, the stator iron is laminated.

The armature carries a conventional lap wound d-c. winding, connected to a commutator. Its brushes are arranged in multiples of three and commutate the coils under the interpoles exactly as in a d-c. machine.

The machine differs from a d-c. machine in that the currents and fluxes are 3 phase and must be summed as vectors and not algebraically. This leads to some complication in the arrangement of the pole-face and compensating windings. Armature currents over any portion of the armature are compensated by currents from all 3 phases.

As the stator frame is laminated, it is not possible to adjust the interpole field strength by varying the interpole airgap. Coarse adjustment is achieved by adding or removing turns from the interpole windings. The interpole teeth laminations can be broken off to obtain finer adjustment.

A Scherbius generator has only about 70% of the output of a d-c. machine of similar frame size. The reasons for this are:

1) The iron circuit has to carry the peak values of flux, whereas the output is expressed in terms of the RMS value.

2) The currents are added vectorially and not algebraically.

At 3 or 4 cycles, the low frequency generator has been built to deliver up to 400 volts and to commutate 400 amps. satisfactorily. Such a machine is capable of handling a 1600 h.p., 4160 volt, 3 phase, 60 cycle motor with peaks of at least twice full load current. The practical output frequency of a Scherbius generator is about 10 cycles, because of commutation difficulties.

Conclusions

Commutator a-c. machines have been used quite extensively in Europe for many years for rolling mill, mine hoist, railway locomotive, and many other industrial drives. Low frequency equipment has already proved its worth in Canadian mines and new applications for it are continually arising. This paper has attempted to enumerate some of the characteristics and limitations of low frequency machinery and applications. The authors are confident that commutator a-c. machines can and will find increasing popularity in Canadian industry.

VOLUNTARY STANDARDS — VITAL TO PROGRESS

J. A. Reid, Jr.E.I.C., *Manager of Motor Sales*
Motor and Generator Division
Canadian Westinghouse Company Limited, Hamilton, Ont.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

The economic progress of Canada is dependent to a large degree upon the use of voluntary standards in industry. Two of the most important social-economic developments of the past century, interchangeability and mass production, were based on standardization. Measurable dollar savings and many broader benefits have arisen from the use of standards on an industry-wide or national basis. The savings and benefits are: fewer parts and finished goods inventory; more continuous employment by manufacturing for stock; longer, smoother production runs; and reduced training time of employees.

INDUSTRIAL standardization is a motivating force used by modern management to increase productivity. Productivity is the key to increased earnings and standard of living in an industrial economy. Productivity is achieved by simplification, which in turn is achieved by standardization of parts, finished goods and processes. Standardized products are lower in cost and selling price per unit, are easier to sell and easier for the purchasing agent to buy.

Voluntary standards are used internally by companies, by nations on an industry-wide basis and in the international field. A voluntary standard can be defined as a democratic organized solution to a recurring problem. Voluntary standards must be alive and subject to gradual change. They are non-mandatory and must not be detailed to the point where they hinder progress. Because it relegates solved problems to the field of routine, standardization frees creative facilities and human energies for the infinity of other industrial problems awaiting solution.

History

Standards have been with us since the stone age. Unfortunately they have have developed in a haphazard manner, unguided by those who are eventually affected by them. It is only during the past 85 years that organizations have been created to guide the formation of standards. It is worthwhile to briefly review the history of standards to bring into focus the importance of an organized standards movement. If we are to reap the benefits of new products and processes yet undiscovered management and its delegates need to increase their interest in and support of standards organizations in the national and international fields.

In ancient Egypt and Mesopotamia a brick maker made standard sun-dried bricks with the aid of a simple form. Until the form wore out the bricks produced had substantially the same dimensions. As time progressed other standards evolved. In 1101 A.D. Henry I of England proclaimed that the yard constituted the distance from his arm pit to the tip of his longest finger. This was an adequate standard at the time but is inadequate for to-day's precision requirements. Besides, none of us can remember the length of King Henry's arm! However, by common usage the yard has become a standard measure which is still used to-day, except that its length is now compared to the standard meter which is based on the length of green light produced by a neutron of mercury with an atomic weight of 198 when added to an atom of gold. 1,831,249.21 of these wave lengths equals a standard meter.

In the seventeenth century the idea of production of standard objects by the use of machinery and automatic processes hailed the beginning of the decline of the artisan. Little progress was made in this regard until the beginning of the nineteenth century when Eli Whitney, the inventor of the cotton gin and manufacturer of fire arms, applied the idea of interchangeable parts manufacture. With the aid of the U.S. Army and government officials, Whitney worked painstakingly for twenty years to smooth out the path for a new way of making guns. In 1824, the year of accomplishment, one hundred rifles were stripped and reassembled, proving that the parts were interchangeable. This was in effect the beginning of national standardization in modern industry. Probably the most significant development in the standards field took place in England in 1841 with the development of the screw thread standards. American screw thread standards had their beginning in 1864 and unfortunately differed basically from the screw thread standards in England, with subsequent disastrous results.

Standards Organizations

Standards organizations had their beginning on the international scene. In 1875 about twenty nations formed a General Postal Union, subsequently renamed the Universal Postal Union, and signed the International Postal Convention — the first general agreement standardizing and simplifying international postal rates. The same year the International Bureau of Weights and Measures was formed.

Prior to World War I the only national standards agency in existence was the British Standards Institution. World War I gave impetus to national standardization in all countries involved in that struggle and at the same time established the need for an international standards movement.

The oldest organization in the national standardization field in Canada is the Canadian Standards Association. Its formation was promoted in 1917 by the Engineering Institute of Canada and incorporated in 1919 by Letters patent under the Dominion Companies Act and named the "Canadian Engineering Standards Association". In 1944 the term "Engineering" was dropped. It is a non-profit, non-governmental organization which provides a national standardization body for Canada.

CSA has two subsidiary divisions, the CSA Testing Laboratories and the Canadian Welding Bureau. CSA works closely with other organizations which are interested in or devote all or part of their efforts to standardization. Some of the organizations in Canada interested in standards are:

- Canadian Electrical Manufacturers Association
- Canadian Electrical Association
- Canadian Government Specification Board
- Department of Trade and Commerce—Standards Division
- Department of Transport
- Associate Committee on National Building Code — National Research Council
- Electronic Industries Association
- Specification Writers of Canada Association.

CSA Standards and Codes of Practice are prepared by committees having diversified interest to ensure that the views of all interested parties are considered. It is significant to note that all standards issued by CSA are voluntary. They become mandatory only when adopted by an authority having jurisdiction such as a provincial government. For instance the Canadian Electrical Code which is strictly a safety code prepared by CSA is mandatory in the majority of provinces in Canada since it has been adopted by its governments. Regulations based on this code but with slight modifications are mandatory in the majority of the other provinces.

The International Picture

Standardization activity in the international field is still in its infancy despite ample evidence of its economic value. An immediate expansion is vital, and complacency and lack of foresight must be replaced by strong management support and awareness.

The penalties for lack of action in international standardization have been dramatically illustrated in the past. Chaos existed during World War II when ammunition used by the Americans could not be used in British and Canadian weapons and, naturally, vice versa. The position of the allies in North Africa was in peril at one stage because of the lack of screw thread standards. Damaged equipment lay idle and useless. An American Air Force mechanic characterized the situation when he exclaimed, "We can't borrow parts from the British. We can't even steal them. THEY DON'T FIT". Because of the difference between American and British threads it has been estimated that about 600 million dollars in the form of extra screws, nuts, bolts and spare parts were shipped abroad during World War II.

Lack of consideration of the importance of national and international standards resulted in an island of 25 cycle electric power in the industrial part of Ontario. At that time 25 cycle electric power had many benefits to heavy industry, which since have virtually disappeared. The conversion to 60 cycle was a costly changeover — approximately 375 million dollars.

Painful experiences like this undoubtedly contributed to recognition of the need for international standardization bodies such as those now in existence. Of notable importance are: International Organization for Standardization (ISO) of which the International Electro-Technical Commission (IEC) is a branch; the ABC organization which was formed by the United States, Britain and Canada primarily to standardize screw threads. By 1948, only a few years after its formation, the ABC team signed a Declaration of Accord which adopted a unified thread standard. This was a momentous step. These standards were published in the United States and Canada in 1949 and by the British Standards Institution in 1953. The ABC team has expanded its activities into other fields such as drawing practices and limits and fits. Considerable progress has been made in these two fields and in the near future common standards will materialize within the English speaking countries. Through the efforts of ISO these standards and many others eventually will become world wide standards.

The Canadian Standards Association is very active in ISO, IEC and ABC standardization bodies.

CEMA

A significant example of the benefits and economics obtained through national standardization are the standards which have evolved for electric motors and generators over the past fifty years. The guiding force behind these standards in Canada is the Canadian Electrical Manufacturers Association, commonly known as CEMA, of which the Motor and Generator Section is one of the largest groups. The standards which they publish are strictly voluntary standards.

CEMA was formed in 1944 when it was recognized that there was a need for an organization in Canada similar to the National Electrical Manufacturers Association (NEMA) in the United States. One of its prime functions is to guide the standardization of electrical products in Canada. Through CEMA assistance is given to CSA in formulating safety standards for electrical equipment and to other organizations in developing standard practices in the electrical field.

There are 31 product sections and divisions operating in CEMA and several standing committees. Its Codes and Standards Committee is the clearing house for all standards proposed by the various sections and divisions. This committee approves all standards before they are adopted and it approves recommendations for standards which are made to other organizations. All CEMA standards are submitted to CSA before they are published to ensure they do not conflict with existing CSA standards.

Standards for electric motors and generators were initiated about 1910, by AIEE in the United States. At that time no agreement existed among the various manufacturers as to what constituted a 5 h.p. motor or a 200 kw. generator. In competitive selling a salesman could claim that a 5 h.p. motor would carry twice the load. Purchasing agents had no way of knowing which manufacturers' motor was the best buy, short of carrying out complete tests. The standards developed in the initial stages were a system of ratings based on specified tests and accurate measurements of temperature at rated load. Permissible temperature rise was standardized for each type of insulation. These first standards were the result of industrial co-operation and many of the tests established at that time are still used to-day.

By 1926 the National Electrical Manufacturers Association was formed in the United States and took over the standardization of electric motors and generators. By the late '20s it developed a system of frame assignments for each horsepower and speed rating and standardized the critical dimensions for each frame. This was a great benefit to the industry as a whole. The user achieved interchangebility of all motors of the same rating in his plant allowing him to reduce the number of spares required and to purchase from several manufacturers. On the other hand the manufacturer benefited too. He no longer needed to supply motors which he considered non-standard to replace another manufacturer's make. Standardization encouraged him to stock completed motors since he was assured that all motor purchasers could use his product. Manufacturing in quantity for stock resulted in lower cost.

By eliminating the necessity of designing a motor for each order received, the design engineer redirected his energies to developing a full line of motors with the resulting reward of economies to his company and the user industry, as well as personal satisfaction to himself.

Some people may think that such a standardization program would retard advancement. Such is not the case since the only dimensions standardized were those which affect the mounting of the motor to equipment such as the shaft diameter, foot dimensions and shaft height. A great deal of scope was left for the ingenious design engineer to achieve the economies of the latest materials and processes developed. At the time this first standardization of frames was made, the ratings applied to each were the maximum achievable by the NEMA member companies.

Due to further advancement in materials and processes the industry was ready and preparing for a re-rating program when the second World War broke out. Naturally all energies turned to the war effort and the program was shelved. However in 1948 it was re-activated by NEMA and also by CEMA which was then in existence. All the latest advancements, ingenuity and experience were utilized in the new designs. This resulted in some frame sizes being dropped entirely, others were created, and the balance were up-rated considerably. The program resulted in considerable design and re-tooling expense to the CEMA member companies, but the economies and improved designs obtained justified the program.

Such a changeover program cannot be achieved without the utmost co-operation amongst the manufacturers and from the user industries. This co-operation was achieved and the transition made without chaos, in fact with only a few murmurs of dissent.

If there were no national standards for electric motors it is estimated that the selling price would be about four times greater than it is. This represents a saving to the Canadian economy of 100 million dollars per year. Add to this the savings realized by the thousands of other products and processes in Canada which are standardized on a national basis and you will appreciate the significance of the standards movement.

With the rapid advancement in insulation systems and materials and improvements in electrical sheet steel it may not be too many years before there is another re-rating program. When this takes place the temperature rise limit of the standard motor will probably also be increased provided the user industries will accept motors with higher operating temperatures.

There are some instances where CEMA has sought agreement with other industries with little success. For instance they have endeavoured to promote a standard oil burner motor in the industry but are continually receiving requests from oil burner manufacturers for special features peculiar to their own needs. Most close-coupled pump manufacturers have different motor shaft size requirements. The pump industry has not achieved agreement on a standard size. The electric utilities in Canada do not have a national standard for maximum and minimum voltage limits for each nominal voltage as do the electric utilities in the United States. The utilities in different parts of Canada maintain their voltage levels within their own chosen limits, some of which may be reasonable and others not. As a result electrical manufacturers often receive complaints that equipment supplied is not operating properly as a result of voltages which are too high or too low as compared to the nominal design voltage of the equipment supplied. As a result some users buy equipment having a special design voltage to meet the peculiar voltage conditions of their plant, at a price premium for the extra design and manufacturing expenses involved.

Eventually these differences will be resolved but in the meantime they are a problem to the user as well as the manufacturer. Manufacturing expenses go up and hence the selling price. Quality control suffers. Manufacturers cannot stock the user's requirements and hence deliveries are extended.

Conclusion

The standards movement, however, has shown marked progress during the past ten years. It must continue to progress and broaden its scope if we are to take full advantage of the benefits of automation and new products and processes. No longer must a statement made by a leading industrialist in the late 1930's be permitted to find application. He declared, "Where proper standardization has been delayed beyond the time when it should have been done, the very turmoil and chaos of the resulting situation almost automatically impelled conflicting interests to seek a common meeting ground. Further, from the welter of confused experience there is much material that can be salvaged in the making of a standard".

Today, strong measures must be exerted because of a common recognition of advantages to be gained — not because of a welter of confused and costly experiences. To quote Robert E. Gay of the U.S. Department of Defense, "Automation is in a transitional phase as is our entire system of production. In the early course of this phase, new processes, new products, and whole new industries are springing up, pushing back our horizons into new worlds. There is an opportunity here to do what we have never done before: To standardize in advance of need, to use standards in accordance to their proper, creative, pre-planning functions, instead of as correctives of serious trouble".

Future economic progress in this country will depend upon Canadian industries' ability, on a voluntary basis, to modify existing standards to take advantage of new products and processes; to create standards for existing products where benefit to the economy will be realized and to create standards for new products as they are developed. The program of achievement rests on the shoulders of industry management. The producer and user industries must work together in teams to achieve the common goal — progress.

Authors' Reply

The authors agree with Mr. Dye that the possibility of providing steam and power for industry from a plant owned and operated by a utility presents interesting possibilities.

In working out the most economical design of such a plant there are, as he points out, a number of problems which were not touched upon in the paper. We would certainly agree that the proportioning of the exhaust end of the turbine and condenser so as to give optimum economy is one of the more important. As to the use of a steam air heater to improve cycle efficiency, this arrangement can be and is used, not only in by-product power installations, but in conventional generating stations as well. For one installation with which the authors are familiar where a cold end temperature of 250° F is necessary, it has been found economical to heat the combustion air to 150° F and the overall reduction in plant heat rate amounts to 9.0 B.t.u. per kilowatthour. In a by-product power plant, due to the higher ratio of steam production to energy output, the saving expressed in the same terms would, of course, be somewhat greater.

THE FIRST CYCLONE FIRED BOILERS IN CANADA

Authors' Reply

Mr. Hymmen in his discussion has asked a number of questions, some of which must be answered in a general way since our records in some cases are not extensive enough to give a definite answer.

With regard to the questions:

(1) What capital expenditure is justified for a unit of this size *due to fuel saving alone,* for each 1% gain in efficiency at the prevailing capacity factor and fuel cost?

Evaluating this on the basis of 60% capacity factor and our present high cost of coal an additional expenditure of about $110,000.00 would be justified for each 1% gain in efficiency.

(2) Are predicted results being achieved with respect to:

(a) low excess air—Yes, we are able to follow closely;
(b) Low exit gas temp.—Yes, with air heater and boiler surfaces kept clean;
(c) Low carbon loss—carbon loss is very low on any checks made, less than ¼ of 1% in slag.

(3) What maintenance problems and expenses are being experienced?

Not able to give definite figures but maintenance has been reasonable. Original wear blocks still in primary burner scroll of No. 6 unit. Surfaces built up by welding on several occasions.

One slag spout cooling coil burnt out. Both oxygen probes replaced, also a number of spray tips. An accounting system is being set up to keep better records.

(4) Has the pressurized method of firing caused abnormal difficulty or expense in operation?

No particular difficulty with pressure firing. A few casing leaks developed in the early stages.

The air requirements for the aspirated observation doors have added to the expense as additional compressor plant was required.

(5) Has the low exit gas temperature caused any fouling or corrosion in the expendable cold end section of the air preheater?

I am happy to say that to date there has not been any corrosion or sulphur deposits in the air heaters. There has been some tube plugging with loose and dry fly ash, possibly due to light load operation and low velocity.

(6) Additional information and test data has been requested when using the high level burners for boosting steam temperature for two shift operation.

The high level burners have been found very effective for boosting steam temperature. However, our experience in their use has been rather limited, as we have had very little 2-shift operation. One of the difficulties has been measuring the gas temperature entering the superheater tube bank, i.e. to get a representative temperature or to locate the highest temperature zone. Further studies will be carried out when the plant is called on for 2-shift operation.

Mr. Broad asked what percentage of total power is required to drive the forced draft blowers.

I am not able to give the percentage figure but the overall figure for station service including all auxiliary power is 6.5 to 7.5%, or about the same range as our pulverized fuel fired boilers using the same class of fuel.

Mr. Broad stated that in Cyclone Firing, since all of the air must be raised to a static pressure of 30 in. or more, the power required to sup-

(Continued on page 83)

AUTOMATION AND CONTROL ENGINEERING IN CANADA

Introduction

THROUGHOUT 1959, *The Engineering Journal* featured a series of articles on "Instrumentation in Industry". These articles were based on the replies to a questionnaire which was distributed widely to users of instruments in a number of industrial classifications. The material received was tabulated to give background reference figures, and the various remarks advanced by respondents were incorporated into a short text. It is hoped that, by confining the questionnaire to persons interested only in the use of instruments, a general picture of instrument usage in the industrial classifications chosen would emerge.

There is evidence that this objective was partly met in the 1959 program, but it is also evident that there were serious deficiencies in the method chosen. The title "Instrumentation in Industry" was so broad that it proved impossible to cover it adequately in a simple questionnaire. As a result, many of the questions were interpretive, and the pattern which emerged was far from satisfactory from the technical point of view.

Editorial investigation into the matter by the editorial staff and the various committees of the Institute resulted in the recommendation that a new approach be investigated for 1960, and the series which will follow in the next eleven months is the result. We hope that it will prove to be a significant contribution to this field of engineering activity, which is rapidly assuming vital importance in Canada's industrial future. We already have in this country some of the most advanced automated industrial plants in the western world, and experience gained in them will help to shape usage in other countries. Our economy, with the high labour costs inherent in our advanced standard of living, demand that we utilize the most advanced concepts of modern technology if we are to retain a satisfactory position in world markets. In no direction is there greater promise than in the wise and ingenious use of automation and control engineering techniques.

There have been many vital and interesting developments in this field during the past few years, and not all of them passed the final tests of wide acceptance in industry. Static switching has not yet fulfilled its early promise but it has been gaining important support in the United States as a technique for controlling complex processes in the steel industry and in warehousing. The main drawback seems to lie in the complex circuitry of static switching systems, which points to a new requirement for better testing and fault locating devices, and more convenient "packaged" replacement units. Machine tool controls, which were originally regarded as the natural outlet for static switching, have been recovering from the depressed activity experienced during 1958 and early 1959, and a great deal of attention is being given to the production of cheaper controls tailored for the small and medium-sized machine shop. A number of people engaged in this field inform us that their objective is to market machine controls which small shops cannot afford to do without, and they are making considerable progress towards this goal.

A great deal of interest is being shown these days in the extension of the power handling capacity of control equipment. Extensive investigation is being made which shows promise of extending the range of d.c. Servos and servomotors up to 1½ or 2 horsepower.

In the fields of closed-loop control, there is still a considerable amount of controversy over the relative merits of electronic systems versus hydraulic or pneumatic systems, or combinations of the two. It depends to some extent upon the control problem at hand, and there is understandable reluctance in some quarters to invest heavily in electronic systems when the cost is usually quite high, the maintenance problems considerable, and the advance in technology so rapidly changing. The development of transistors compatible with control requirements make some of the older amplifiers and circuit elements appear less attractive, and general advances in solid state techniques have been so startling that the control engineer contemplating new installations is confronted with a very complex problem. On the other hand, hydraulic and pneumatic systems have been improving steadily, some of it due to the need for better systems for high performance aircraft and missiles. Military research has conquered many problems which promise to extend the line of usage for industrial equipment using hydraulic or pneumatic techniques.

These are but a few of the items which will be discussed from the users point of view in the coming months. Through the cooperation of local branches of the Instrument Society of America, we have invited a number of outstanding Industrial Control Engineers to contribute one or more articles on the state of automation and control in their industry. We have given them a free hand in the presentation of their subject, but we hope to obtain a series of "inside" articles which will explore the viewpoints of a number of persons whose speciality lies in the application of better control methods to process and manufacturing industries. We hope that they will describe what they have done, will outline some of the philosophy which has guided their choices, and will give us some idea of what we should expect in their industry during the next few years.

Canadian Developments

Metropolitan area, exurbia, suburbia—perhaps these are all terms which need never have come into being. Two possibilities come to mind. The first is that the city might have remained in concept what it was some 700 years ago. At that time tradesmen referred to the "liberty" of the city which allowed them to market their skills and wares more swiftly and simply than the country ever had. One asks then, why didn't the city grow up as a dynamic but self-contained market-place and leave the country for living?

Again, an alternative to our sprawling cities might have been metropolises built for living as well as working. William Zeckendorf, noted planner of central development, has spoken of cities rotting at the core. Others have assailed the method so far used to stop the rot—that is, the move to build great apartment blocks in the very centre of the city. The truly residential city would have to be made up of apartment houses conceived as dwellings, not as adjuncts to commercial buildings, with exteriors like banks and interiors like executive suites.

But we have a distinct, essentially non-residential metropolitan area. We have ever-extending suburbia. And the latest development is a new limbo beyond the circumference of suburbia — the self-sufficient unit known as exurbia. Engineers, in town planning and building, are as responsible as the architects and the sociologists. They have helped to make what we have now and will have a hand in deciding how it is to be transformed for the future.

The engineer enters the picture only in so far as he builds these structures and in so doing puts the final stamp on any construction project. As a mechanical engineer he is likely, if informed of the aesthetic considerations, to be able to abet the architect's knowledge of what in design is practicable. However, to some this divergence from specialization may seem pure folly. For them municipal planning still holds one consideration and perhaps it is the most important of all — the integration of many and various plans for a single city.

Municipal Planning

Integration of Montreal Planning

David Owen, vice-president of Webb & Knapp (Canada) Ltd. who are building the Place Ville Marie Development at the corner of Dorchester and University Streets in downtown Montreal, has outlined an integration program which he considers essential to Montreal's future vitality. The steps are: to determine an adequate means of public transportation to accommodate a growing public; to discover a means for bringing the increased volume of passenger cars into the city and getting them parked; to plan for a route to carry vehicles going from West to East (or vice versa) but not stopping in the downtown area; and to modernize the waterfront so that it can serve the city economically.

Place Ville Marie had its beginnings over 30 years ago, when the management of the CNR began to look for ways to rebuild "the Dorchester Street hole" and unite it with the surrounding area. The 313,000 sq. ft. tract circumscribed by Dorchester on the South, Mansfield on the West, Cathcart on the North, and University Street on the East, went under development in late 1958. The

(Continued on page 76)

The new mining town of Gagnon 150 miles northwest of Sept Iles, Quebec, is composed of a group of multiple dwellings (left); bungalows and facilities for unmarried personnel including five dormitories, recreation hall and dining hall (center); and shops and temporary barracks for the 700 men working on the construction program. The entire project calls for an investment of approximately $200,000,000 and should be completed in the Fall of 1960.

(Continued from page 74)

main building is to be the 42-storey cruciform office building. Six acres of plate glass and an equal amount of anodized aluminum will go into the construction of its exterior walls.

Excavation began in September for another skyscraper on the Dorchester Street-University Street site. The 31-storey C-I-L House will house 5,000 office workers and provide an additional rentable area of 600,000 sq. ft. Canadian Industries Limited will occupy 12 to 14 floors of the new building. Among outstanding architectural features will be a 41 ft. base which will eliminate most of the interior structural columns and provide underground parking facilities for 400 cars.

Also under construction at this site, and due to be completed in May, 1961, is the Canadian National Railway's 17-storey headquarters office and garage building on Lagauchetiere and Mansfield Streets. This is the fourth building in a long-range Canadian National program which includes Central Station, the International Aviation Building and the Queen Elizabeth Hotel.

One of Montreal's more stagnated areas, just four blocks east of the city's central shopping district, is to be transformed by a new building for the performing arts, the Sir Georges-Etienne Cartier Centre, more commonly known as Place Des Arts. One proposal made by the municipal planners has been to make the property a block south of the prospective Place Des Arts site available to the Canadian Broadcasting Corporation for construction of a new centre for its activities. If the CBC were to accept the idea, planners contemplate the possibility of a midtown park area and mall to connect the two properties.

The subway system which Montrealers have talked of for several decades is still far from realization according to the present signs. Although a private organization, La Societe d'Expansion Metropolitaine, proposed a $163,000,000 subway project to the city administration in early November, little headway has been made toward its acceptance. At present neither the City of Montreal, the Montreal Transportation Commission, nor the Montreal Metropolitan Corporation has the power to build or participate in the construction of a subway. However, both the city and the Metropolitan Corporation are seeking appropriate legislative authority.

Survey of Drumheller, Alberta

The City of Drumheller, Alberta is to be the subject of a survey by an independent firm of business consultants and engineers to determine the industrial and economic potential of the municipality and district. Under the auspices of the Industrial Development Branch of the Department of Industry of Alberta, the private firm will establish the physical area of influence of the city to allow a close evaluation of marketing and other potentials. The assets and liabilities of the community will be clearly set out to permit an impartial consideration by potential new industries.

Residential Planning

Enquiry Into Canadian Residential Design

The Royal Architectural Institute of Canada, with $30,000 support from the federal government, has launched a full-scale enquiry into the design of residential areas in Canada. Four prominent Canadian architects, Peter Dobush, of Montreal, John C. Parkin, of Toronto, C. E. Pratt, of Vancouver, and Robert Cripps, of Toronto, will complete their 17-week tour of Canada in January, having travelled 9,000 miles and visited 15 major centres from Victoria to St. Johns.

As well as making this visual survey of the nation's residential areas, the committee has invited a wide variety of opinions and advice in the form of briefs and submissions from the house-building industry, lending institutions, transportation consultants and consumer groups.

While visiting Montreal on November 10, the committee heard a brief describing the kind of apartment buildings being built in the area of Guy, Atwater, Sherbrooke and St. Catherine Streets as "haphazardly constructed and located in such a way as to destroy each other's amenities." A plan was proposed as a possible solution to the downtown residential problem which included: provision for sunlight and fresh air, adequate recreation space, proper parking facilities and reduction of the effects of traffic on the inhabitants. The basic plan called for the residential block to be built one level above the street so that normal traffic and parking facilities could be maintained while the apartment units would be above traffic noise. They would be spaced to provide maximum air between units.

The C-I-L House will rear its head high at the corner of Dorchester and University Streets, Montreal, by mid-1962. The downtown section of Dorchester Street is undergoing extensive redevelopment and the thoroughfare itself is to be widened and somewhat rerouted west of Guy Street.

Communications

Toronto's Solution to Traffic Problem

Metropolitan Toronto Traffic Director, Sam Cass, reports that the city's traffic has reached the chaotic stage. While auto registration continues to increase at a rate of 5% a year, the roads system increases at a meagre 1%. In the last three years the volume of traffic pouring into Toronto from other points in the province has doubled. A Metro technical committee has been established to consider three possible solutions: an additional five or six new roadways from the suburbs into the city; conversion of many roads in the 260-mile Metro road system into one-way routes, allowance for exclusive TTC bus lanes and widening of roads; or special subsidization of railway lines and TTC bus lines to draw motorists off the roadways in rush hours.

A network of six expressways is provided for, and two are already under construction, as part of a 10-year program, but they will be only beginning in the relief of extensive traffic congestion.

Ottawa Initiates Interconnected Traffic Signals

Traffic signals at fifty intersections in Ottawa's central business district were recently interconnected to form a single traffic control system. The master-controller in Ottawa's city hall automatically selects the signal timing best suited to prevailing traffic conditions. Intensive studies of traffic flow conditions will permit the city's traffic engineering department to establish a timing program which can be followed each day throughout the year. The program can be changed 60 times during one day. The system also permits central control of other illuminated signals such as "no left turn" signs, directional arrows and pedestrian signals. Provision has been made to establish emergency routes for the fire department and evacuation routes for civil defence.

Many cities have had small interconnected systems for some time, but the coordination of 50 intersections gives such a plan much greater scope. The cost of installing the cable to make such an interconnection has long been prohibitive, but the Ottawa network utilizes telephone lines for transmission of messages.

Vancouver Proposes More Freeways

Vancouver's answer to increasingly large traffic problems is to build more freeways. The traffic planners predict that over the next 17 years their construction will take $374,000,000. Many commuters have been opposed to the $23,000,000 expenditure on the nearly completed Second Narrows Bridge because it leads to a part of town which they do not need to go to. They have also opposed the suggestion that they revert to public transportation. The planning experts propose a system of freeways which would bring an area of 200 sq. mi. within 30 minutes' travelling distance of the downtown area.

The Finance of Planning

Hamilton Publishes Five-Year Report

A report and analysis of Hamilton's five-year capital budget prepared by

• CANADIAN DEVELOPMENTS

Dr. C. C. Potter of McMaster University has recently been made public. Financed by the city's chamber of commerce, the report shows how one major city is handling the problem of financing and planning its capital expansion projects.

Toronto's 1960 Budget

Metro Toronto's Roads Committee has recently approved a 1960 budget of $25,010,000, an increase of $6,540,000 over 1959. It includes: $9,000,000 for the Gardiner Expressway, $5,000,000 for the Don Valley Parkway, and $300,000 for preliminary engineering on the proposed Spadina Expressway.

Municipalities Ask For Federal Aid

The Canadian Federation of Mayors and Municipalities has been urging the federal government to implement policies which would enable them to carry out more heavy construction projects. In a brief submitted to the federal government they stated: "Unless there is a marked change from the present situation and outlook there could develop a serious setback to the progressive effort which municipal governments have been making in an endeavour to keep pace with their urban growth requirements." The federation asked that a national municipal loan fund also be established.

Planned Communities

Summer Cottage Developments

Saskatchewan residents are being urged to build their summer cottages in a planned resort. Mr. Z. Bakun, director of the Community Planning Branch of the Department of Municipal Affairs, points out that summer cottage developments are urban in nature and therefore require controls of an urban community. He believes that it is in the builders' interest that cottages should be constructed in properly planned subdivisions, developed in suitable areas and served with proper facilities.

Newfoundland Establishes New Towns

The Newfoundland government has instituted a program to establish centralized communities complete with churches, schools and hospitals as well as housing to replace the scattered and isolated settlements characteristic of the province. Numerous sites have been opened for development in the St. John's area as a start.

Current Events

Seaway Season Closes

The Rockcliffe Hall, a 252 ft. Canadian canaller, was the last ship to go through the St. Lawrence Seaway this year. With its passage on December 4 the first full season of operation of the locks and channels between Lake Ontario and Montreal came to a close.

Preliminary traffic statistics issued by the Canadian and United States seaway authorities show that 17,400,000 tons of cargo were carried through the St. Lawrence Seaway (Montreal-Lake Ontario) in the current navigation season to the end of October. This figure is 7,300,000 tons, or 72%, in excess of the quantity of cargo carried by the old St. Lawrence canals in the corresponding period of 1958. The upbound movement increased by 5,500,000 tons (128%) and the downbound by 1,800,000 tons (31%).

INTERNATIONAL NEWS

A town where pedestrians never meet traffic, where cars are allowed only on roof tops and people travel from one area to another by water bus has been envisaged by a group of London architects. Requisite to the building of their city, however, is a network of flat, 50-ft-high roofs, and this removes the plan from the realm of immediate feasibility. "Motopia" might be a prototype for the cities of the 1980's, but we are at present faced with quite a different picture. In most of our cities the system of roads needs untangling and many of the buildings themselves must be redesigned or replaced.

Since the end of the war France has built 1,620,000 housing units of which only 300,000 have been reconstructions. Her average rate of population increase (300,000 per year) has been the greatest of any country in Western Europe, and she has had to try and meet the demand. The capital for this development has had to come largely from the government. With this financial support, the French construction industry has taken long strides to cut down the need for large labour forces and to increase the on-the-site productivity rate. Prefabrication and assembly-line construction have been her methods.

France has made notable progress in developing building systems using steel, aluminum, clay blocks, and precast concrete. Two such systems are the Fillod System of steel sheeting for outer walls and the Phenix System, a combination of light steel and framework and concrete block filler.

The Paris headquarters of the Federation Nationale du Batiment is an admirable example of France's recent work in aluminum. The internal and external walls were constructed separately and connected by small insulated straps to prevent any transmission of heat through the metal. Between the walls is a soft 20 mm thick "Isorel" sheet and on either side of that a creased 4/100 mm thick aluminum coated paper. The wall reflects both internal and external radiations and assures thorough interior ventilation.

London Continues to Expand

A British government research officer fears that before long London may become a solid urban concentration at least 100 miles across. According to him, "The geographic and economic attractions of the metropolis are too strong to be controlled by planners." He cites the fact that over the last seven years 40% of the national increase in employment has taken place in the London region. In the nine square miles of Central London 200,000 new jobs are being created yearly. The population of the area at a radius of 12 miles from the city's centre has increased some 660,000 since 1951.

Two situations emerge. Towns near London, like Brighton, Luton, Reading and Southend, risk being swallowed up. At the same time more people are building well out of London and buying cars to bring them to their London jobs. The country is taking on a suburban air as new "dormitory" towns grow up by the sea.

In London, as in all the big cities, concentration and centralization are the motifs in commercial building. The British Broadcasting Corporation is building a new television centre at Shepherds Bush Green next to the White City Stadium, at one of the city's worse congestion points. The building presumably replaces countless theatres scattered around the city by one consolidated unit. The traffic problem is all too apparent.

"Motopia" is the name given to a revolutionary town designed by London's Glass Age Development Committee to house 30,000 people. In the foreground is a road linking the ground-level network with the rooftop road system. The low building under the overpass is a station with its own roof parking area. Above the shopping area looms a 20-storey block of administration offices for 3,000 workers. The roof level is a uniform 50 ft. high and traffic on it is made invisible by hedges, inaudible by special ceiling insulation.

Sweden Excels in Self-service Stores

Recent figures show that Sweden leads Western Europe in the field of self-service stores. Her one self-service store for every 1,800 inhabitants can be compared with Switzerland's one to every 3,400 people and West Germany's one to every 5,900. In Sweden the proportion of food turnover handled by self-service stores is estimated at over 20%.

The Swedish Institute of Economic Research has calculated that 69,000 housing units were built in Sweden in 1959. In 1957 and 1958 alike about 60,000 houses were constructed, an increase of 10,000 over preceding years.

Germans Convert Munitions Factories

Not long ago the West German community of Espelkamp-Mittwald was granted the status of a town by the

(Continued on page 82)

• INTERNATIONAL NEWS

(Continued from page 80)

North Rhine-Westphalian government. Just twelve years before, in 1947, it had been nothing but a collection of old ammunition factories and explosives depots about to be demolished. A Swedish visitor, the Reverend Birger Forell, in Germany after the war to discover ways of housing prisoners-of-war and refugees, had the idea of converting the ruins of Espelkamp into a residential community. Today more than 2,000 living quarters have been constructed there and 5,000 people earn a living in the community.

Danish Apartments Erected in Germany

Danish builders have put up 116 pre-assembled apartment units in Hamburg, Germany during the last quarter of 1959. A growing housing shortage and a lack of skilled construction workers led the city authorities to survey the European scene for a quick remedy. A Copenhagen firm was contracted to produce all the apartment components in their home plant and ship them to the site ready for quick erection. Floor and ceiling slabs, complete with all necessary horizontal utility lines, door frames, doors, and hardware were prepared in Copenhagen. Windows arrived with glass in them. Bathroom units were equipped with plumbing fixtures ready to be hooked up. Two apartments a day were completely assembled ready for heating, and the whole job was overseen by three skilled workers — the crane operator and two supervisors from the Copenhagen plant.

Pittsburgh Sets Planning Precedent

The Allegheny Conference on Community Development went to work to rejuvenate Pittsburgh in 1947. In the twelve-year period, working through citizens' committees, they have succeeded in ridding the city of its smoke problem; constructing flood protection; clearing traffic congestion through a system of freeways; and building up a complex of modern office buildings and parks. Corporations, foundations and individuals have supplied the funds for Pittsburgh's momentous redevelopment.

One of the many new buildings reaching completion in downtown Pittsburgh is the $20,000,000 public auditorium. It is part of a cultural centre which is to occupy the city's Lower Hill area. An open-air amphitheatre and sports arena, a convention hall and an exhibition centre will be housed in the new circular structure under a retractable steel dome. Its seating capacity will be close to 14,000, including one section of 2,100 permanent seats covering the stage. These can be tilted out of the way hydraulically when the 119 x 64 ft. stage is needed.

The dome, composed of six movable sections and two fixed, rolls along rails anchored to a 20 ft. wide concrete ring girder which encircles the auditorium. It takes only a push-button to put it in motion.

Soviet Envisages Dam Across Bering Strait

Melting the ice sheet of the Arctic Ocean is the task Soviet Engineer and Stalin Prize Winner Pyotr Borisov has set for himself. According to Borisov, if the Gulf Stream's warm currents were allowed to flow into the Arctic Ocean from the Atlantic the ice would thaw in no time. At present the Labrador and East Greenland currents render the Gulf Stream cold and impotent. Together they run under the ice sheet without affecting it.

If a dam with pumps were built across the Bering Strait, he maintains, the water from the Arctic Ocean could be directed into the Pacific, leaving the Gulf Stream to flow warm under the ice sheet. Once the ice was melted, up to 90% of the sun's warmth now reflected into space would be retrieved. Immense areas of tundraland in the U.S.S.R., Alaska, and Canada would thus be made habitable, says Borisov.

Reconstruction in Peiping

The population of the capital city of Communist China has doubled during the last five years and the increase has resulted in a drastic housing shortage. Occupancy standards have been set at 10 sq. ft. minimum floor space per person to meet the problem of housing 5.5 million people. As a point of comparison: the Philadelphia Housing Code requires 150 sq. ft. for the first occupant, 100 for the second, and 75 for each ensuing.

The government has been granting loans to repair some 40,000 rooms in Peiping and to build 46 million sq. ft. of new housing space. Twenty-eight new industrial plants have sprung up in the southeast area of the city. Perhaps the most dramatic step has been the demolition of the old city walls to allow the East and West Chagnon Boulevards, modern eight-lane thoroughfares, to meet.

Electrification of Southern India

The following is a summary of a talk given by Messrs. P. S. Subramanian and A. Subramanian of the Madras State Electricity Board at the October 20 meeting of the Saguenay branch of E.I.C.

J. R. Easton, Correspondent

Electrical power first became available in 1909 and then only to the few wealthy people in Madras City. Expansion was slow until 1925 when the first big hydroelectric development took place — big for that period and part of the world. In 1947 the Madras State Electricity System was nationalized and since then has expanded at a tremendous rate. Since 1950 its installed generating capacity has increased by 400% to 600 megawatts.

The expansion of the Madras State Electricity Board has been organized into 5-year plans. The second such plan is drawing to a close now. In each of the first two, installed generating capacity has doubled and during the third plan it is to almost double once again.

Hydroelectric installations are accounting for roughly three-quarters of the expansion. However, at the end of the third 5-year plan all available potential hydro sites will have been exploited. The Board is now looking elsewhere for more sources of power.

States to the west and northwest of Madras have large potential sources of hydroelectric power — more than they need for their own development. Madras is negotiating for the development of particular sites within these states and the diversion of water eastward into Madras State.

The Central Government of India is developing large lignite coal fields in the State of Madras, creating several new chemical industries and work for many people. It is also building a large thermal electric power station. The Central Government is also considering the construction of two atomic power stations — one in the north and one in the south, the latter in the City of Madras.

So much recent and proposed electrical development and expansion in Southern India has led to a council being formed. It will organize the interconnection of the power systems that exist in the several states concerned. This will benefit those states which are very heavily populated and are short of power.

The major portion of the power consumed is used in the pumping of water for irrigation to increase the production of food. All other uses are secondary to this. Approximately 70,000 pumping units exist today and this is expected to reach 100,000 within a few years. This power demand is greatest during the dry season months of April, May and June as rice-growing requires a constant 8-9 inches of stagnant water on the fields during this interval.

Because of the shortage of power at normal peak load times, work within industries is scheduled carefully. The Board has over 11,300 miles of high voltage transmission line and 15,000 miles of low voltage transmission line. Electricity is supplied to power consumers at 400 volts and to domestic at 200 volts. If a customer has an electrical load of 75 kilowatts or higher, the customer is supplied power at high voltage and must instal his own transformers and switch gear.

(Continued on page 86)

• DISCUSSION

(Continued from page 72)

ply the air at this high pressure offset any saving made by not having to pulverize the coal.

Data gathered from various boiler installations indicates that the auxiliary power requirements for a cyclone fired unit and a pulverized fuel fired boiler are approximately the same when burning coal having a grindability of about 55. The compressor effect of the blowers operating at high static pressure adds 20° to 30° to the air temperature. This gain in temperature is recovered and represents an increase in efficiency of about ½ of 1%.

Mr. Broad's comments regarding the suitability of various coals for cyclone firing certainly raise an important consideration. Generally speaking most coals having an ash softening temperature of 2400° F or less are suitable for cyclone firing. However, samples must be analyzed to determine the suitability of any particular coal. The greater percentage of the coals mined in Canada and the United States fall within the requirements for cyclone firing.

LITTORAL DRIFT IN LAKE ONTARIO HARBOURS

A. Brebner, A.M.I.C.E. and
R. J. Kennedy, M.E.I.C.
Queen's University, Kingston, Ont.

The Engineering Journal,
1959, September, p. 85
(Further discussion)

Dr. Brebner's reply to points raised by Mr. E. S. Bell.

1) Fig. 12 Caption should read "typical off-shore Breakwaters"

2) On Figs. 2 and 6 the ordinate should read "Percentage Retained On" not "Percentage Finer Than"

3) With regard to part 2) in the reader's criticism — which may be in the discussion?—my answer would be:

Fig. 2 definitely indicates a well graded sand from a soils point of view whereas Fig. 6 indicates a uniform but poor grading from a soils viewpoint. The "excellent" in the text was meant to refer to Fig. 2 but the authors realize the ambiguity of this statement.

Month to Month

McGill's McConnell Engineering Building Opened by Governor-General

The official opening of McGill University's McConnell Engineering Building on November 30 by the Queen's representative is a fitting tribute to the growth of engineering education in Canada begun at that university one hundred and four years ago. At 12:15 p.m. the Governor General, His Excellency Georges P. Vanier turned a ceremonial key, thus unveiling a commemorative plaque in the main lobby and an array of decorative flags. The General Secretary of the Institute, Garnet T. Page, and Dean Henri Gaudefroy of Ecole Polytechnique attended the ceremony, Dean Gaudefroy representing President J. J. Hanna who was unable to be there.

The central spine of the new building, rising eight storeys, houses the highly specialized research facilities of the Electrical Engineering Department as well as staff offices and a conference room. The rest of the building, two five-storey wings, is for general use and includes two large auditoria, thirteen classrooms and eight drafting rooms. Of particular interest is the Computer Centre on the fourth floor which houses an IBM 160 digital computer. The Anechoic Room in the basement of the building, one of very few such chambers in Canada, provides an opportunity for acoustical research.

Fiftieth Anniversary of South African Institute

The Golden Jubilee of the South African Institute of Electrical Engineers, held in Johannesburg from September 5 to 9, comprised a full-day trip to the Premier Diamond Mine in the Transvaal, another to the West Driefontein Gold Mines near Carletonnville in the Western Rand, the Bernard Price Memorial Lecture, "Fission and Fusion" by Dr. T. E. Allibone, director of the research laboratory of Associated Electrical Industries Ltd. (England), and a finale banquet at which Sir John Maud, United Kingdom High Commissioner, spoke to the gathering of more than 500 members, delegates and special guests. F. H. Chapman, M.E.I.C., represented the Institute at the fiftieth anniversary festivities.

First Pan American Congress

Dr. Luis Migone, founder of the Pan American Federation of Engineering Societies (UPADI) and president of the Argentine Union of Engineering Associations and the South American Union of Engineers, was the guest of the Institute at a special luncheon held at the University Club in Montreal on November 3. Dr. Migone has been delegated by the Argentine government as its envoy extraordinary to establish contacts with "the highest authorities of the government, the universities and the professional groups of America in order to invite them to send not only representative delegations but also studies related to the agenda of the First Pan American Congress of the Teaching of Engineering, which is to be held in Buenos Aires in September 1960."

Toronto Quality Control Society

The Toronto Quality Control Society has scheduled two meetings this month, a panel on tool engineering, January 6, and a discussion of tolerancing led by Stan Prout of Canadian Controllers Ltd., January 19. This second meeting will be held in the Canadian General Electric Auditorium, 214 King Street West, Toronto, and will begin at 8 p.m.

Queen's Graduate Program in Nuclear Engineering

Queen's University is offering a one-year graduate program in nuclear engineering "to familiarize engineers with the basic concepts of nuclear energy and with the special problems that arise in the design of nuclear reactors and in the industrial applications of nuclear radiations." The course is restricted to graduates in engineering and engineering physics. Applications must be filed before April 1, addressed to The Dean, Faculty of Applied Science, Queen's University, Kingston, Ont.

Industrial Lubrication Course

The next course in Industrial Lubrication sponsored by the Toronto Section of the American Society of Lubrication Engineers is being offered through the extension department at Ryerson Institute of Technology, Toronto. Six lectures of two hours each will be given on consecutive Wednesday evenings starting January 27. The sessions, conducted by prominent members of industry and the teaching profession, will stress the basic principles and practical knowledge of lubricants and lubrication. Requests for further information regarding the sessions should be sent to Mr. K. J. Dean, Shell Oil Company of Canada Ltd. or Mr. H. S. Ostrander, Sun Oil Company Ltd., both of Toronto.

Traffic Engineering Course at Toronto

The University of Toronto's University Extension Section has recently announced an introductory course in traffic engineering to be conducted during the winter term, 1960. Beginning on January 21 and continuing to March 24, the lectures will be given each Thursday evening at 7:30 p.m. in room 128 of the Mining Building at the university. The course will attempt to give a basic introduction into the problems of traffic movement, control and planning. Registration may be made through the director, University Extension, 65 St. George Street, Toronto 5.

Middle East Technical University

In March, 1960, the charter of the Middle East Technical University at Ankara will come into final and effective operation and the university will cease to be under the aegis of the civil service administration. The university now has 500 students, and architecture, engineering and physical and administrative sciences are its specialties. The charter underlines that it is important for all concerned with the university to keep in mind the long range program which envisages, after 10 to 20 years, a university of 20,000 students with numerous research facilities. The Middle East Technical University is financed in large part by the Turkish government and by organizations such as the United Nations' Special Fund Committee.

Rewording of Certificates of Approval

The Inter-Service Equivalents Board, as a result of apparent misunderstanding concerning the Certificates of Approval issued by that body, has amended them with the following: "This Certificate is valid only for the project shown, and for the specific use indicated by the specification reference. Unauthorized use of this certificate for advertising or promotional purposes is not permitted."

New Australian Trade Commissioner

The Australian government has recently established the post of Senior Trade Commissioner in Canada and named W. Rupert Hudspeth to fill it. Mr. Hudspeth has had extensive chemical and engineering experience in Australian industry and was leader of an Australian Government Trade Mission to South-East Asia in 1955.

1960 Nuclear Congress

A partial program of sessions planned for the 1960 Nuclear Congress to be held in the New York Coliseum April 4 to 7 has been announced by Dr. Clarke Williams, chairman of the Nuclear Engineering Department of Brookhaven National Laboratory, Upton, New York, and chairman of the Congress. It includes: Problems of Fuel Technology; Development of Nuclear Standards; Industrial Applications of Isotopes; Nuclear Propelled Aircraft and Space Vehicles; Research Reactors and Radiation Facilities; Progress in Reactor Instrumentation; and Advanced Reactors and Fuel Cycles. The Congress is sponsored by 28 leading engineering, scientific, management and technical organizations. It consists of the 6th Nuclear Engineering and Science Conference, the 8th NICB Atomic Energy in Industry Conference and the 6th International Atomic Exposition.

Engineers' Wives' Association News

The E.I.C. Wives' Club of Calgary recently awarded its annual $100 scholarship to Clifford David Friesen, a graduate of the Collegiate Institute of Swift Current, Sask. studying engineering at the University of Alberta.

The London section closed the year 1959 with 144 members. A group of members from Woodstock are considering organizing their own group, but for the coming year the program will be chosen and details handled by zone groups.

The Sarnia group pays no membership fee. The membership list is compiled from the E.I.C. membership list which numbers approximately 140 and the wives' membership is estimated at about 125. In the Spring a special meeting is held — usually a tea — to raise a small sum of money for current expenses.

The Toronto Wives' Auxiliary of E.I.C. has established five area groups in lieu of the one large group so that members can become acquainted more easily.

Secretaries for the different sections of the Engineers' Wives' Association for 1959-60 are:

Border Cities — Mrs. J. E. Sinnott, 21 Spring Court, Windsor, Ont.

Calgary — Mrs. J. A. Lamb, 1601 9th Street, N.W., Calgary, Alta.

Cape Breton — Mrs. Gordon W. Ross, 40 Ankerville Street, Sydney, N.S.

Edmonton — (Liaison Member), Mrs. R. C. B. Jarvis, 13211 - 104th Avenue, Edmonton, Alta.

Halifax — Mrs. C. D. Martin, 33 Mumford Road, Halifax, N.S.

Hamilton — Mrs. E. R. Dixon, 16 Wilmar Court, Dundas, Ont.

Kitchener — Mrs. M. A. Montgomery, 162 East Avenue, Kitchener, Ont.

Lakehead—Mrs. Ronald P. Holmes, 1821 Walsh Street, Fort William, Ont.

Lethbridge — Mrs. N. H. Bradley, 2205 - 9th Avenue South, Lethbridge, Alta.

London — Mrs. D. W. Harvey, 33 Croxton Road West, London, Ont.

Manitoba — Mrs. R. O. Jonasson, 51 Rowand Avenue, Winnipeg 12, Man.

Moncton — Mrs. V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

Newfoundland (St. John's) — Mrs. F. G. Vivian, 23 O'Reilly Street, St. St. John's, Nfld.

Niagara Peninsula — Mrs. D. O. D. Ramsdale, 157 Highland Avenue, St. Catharines, Ont.

Nipissing & Upper Ottawa — Mrs. R. R. Prescott, Temiskaming, P.Q.

Ottawa — Mrs. G. E. Martin, Apartment 9, 280 Carling Avenue, Ottawa, Ont.

Peterborough: Mrs. T. J. Halme, 455 Albertus Avenue, Peterborough, Ont.

Port Hope — Mrs. H. A. Gadd, 779 Division Street, Cobourg, Ont.

Regina — Mrs. J. S. Anderson, 62 Motherwell Crescent, Regina, Sask.

Sarnia — Mrs. J. C. Harris, 575 Cathcart Blvd., Sarnia, Ont.

Saskatoon — Mrs. W. G. McKay, 413 Hilliard Street East, Saskatoon, Sask.

Sault Ste. Marie — Mrs. V. A. Graham, 135 McMeekin Street, Sault Ste. Marie, Ont.

Toronto — Mrs. G. V. Meagher, 97 Great Oak Drive, Islington, Ont.

Vancouver — Mrs. P. N. Bland, 1996 Trutch Street, Vancouver, B.C.

Victoria — Mrs. O. J. Wilkie, 2046 Carrick Street, Victoria, B.C.

• INTERNATIONAL NEWS

(Continued from page 82)

Silicones Developed to Make Walls Watertight

Scientists in West Germany have a process for treating outer surfaces of houses with silicones to protect them from moisture seepage. They have found that siliconisation of mortar, roughcasting or varnish saves an extra process of silicone application, and that combined with any of these materials the silicones provide six to seven years' protection against water absorption.

Central Air-conditioning Systems for Shopping Centres

A speaker at the recent exposition of the Air Conditioning and Refrigeration Institute in New York stressed the considerable saving which can be made by installing central air-conditioning systems in shopping centres. Initial costs, operating expenses and maintenance charges can all be curtailed. He cited the Southdale Shopping Center in Minneapolis, Minnesota, an 800,000 sq. ft. multi-level structure with two department stores, 70 other shops, and numerous walking and sitting areas, which is entirely enclosed and air-conditioned.

TRIDENT WATER METERS

. . . safeguard against the threat of water shortage

Neptune's strict policy of interchangeability makes possible the use of improved parts in Trident meters of the oldest manufacture. Maintenance is easy and economical. Inventory is kept at a minimum. Every unit, register, gear train, and measuring chamber is stamped with the date of manufacture.

Trident meters conserve water, halt water waste. This means important savings in power, chemical and capital investment, providing efficient, economical operation of water and sewerage systems, now and for years to come.

FROST PROOF
with breakable bottom. Sizes ⅝″ to 1″.

STYLE 3
For medium-class service. 1½″ to 6″ flange end.

CREST
Velocity or inferential type, with turbine or propeller, for high rates of flow. Sizes 1½″ and 2″ screw end. 1½″ to 16″ flange end.

THE TRIDENT METER IS NEVER OBSOLETE

PROTECTUS
NOTE:—Clear waterway. Sizes 3″ to 10″.

PROTECTUS
For fire service. First to be approved by Underwriters Laboratories Inc.

COMPOUND
For both large and small flows. 3″ to 10″ sizes.

Personals

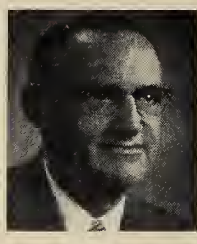
Robert O. King, M.E.I.C. (McGill '95), head of the Defence Research Board's Combustion Research Section, has retired after 65 years of full-time scientific research. Mr. King, who is believed to be Canada's oldest research engineer, will continue his interest in combustion investigations as a consultant to the Board.

For the last ten years Mr. King has been investigating the processes associated with fuel burning in internal combustion engines and has been particularly successful in advancing scientific understanding of these phenomena.

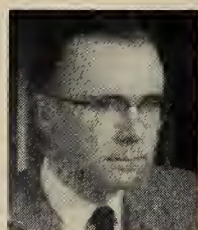
R. W. Diamond, Hon. M.E.I.C., (Toronto '13) has received the highest award of the Association of Professional Engineers of B.C., an honorary life membership, for his distinguished contribution to the engineering profession.

R. W. Diamond, Hon. M.E.I.C.

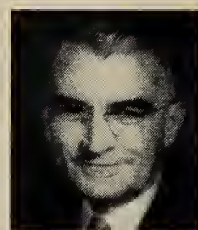
Clement Matthew Anson, M.E.I.C. (McGill '25), a past president of E.I.C., is the new vice-president and general manager of steel operations for the Dominion Steel and Coal Corporation.



C. M. Anson, M.E.I.C.



L. F. Kirkpatrick, M.E.I.C.



S. L. Fultz, M.E.I.C.

A. G. Mahon, M.E.I.C.

Thomas Blench, M.E.I.C. (Glasgow '27), professor of civil engineering at the University of Alberta, has been awarded the degree of Doctor of Science by that university.

Dr. A. Hartley Zimmerman, chairman of the Defence Research Board, presents Robert O. King, M.E.I.C., retiring head of the board's Combustion Research Section, with a bound volume of scientific papers published by Mr. King and his associates.

L. F. Kirkpatrick, M.E.I.C. (Nova Scotia '38) has been appointed manager of the Nova Scotia Power Commission. **S. L. Fultz**, M.E.I.C. (Nova Scotia '20) is the new administrative assistant and **A. G. Mahon**, M.E.I.C. (Nova Scotia '29) succeeds Mr. Fultz as director of operations.

W. L. Wardrop, M.E.I.C. (Manitoba '39) took over the presidency of the Canadian Institute on Sewage and Sanitation in October. He is also president of the Manitoba Association of Professional Engineers and chairman of the Winnipeg branch of E.I.C.

S. M. Breuning, M.E.I.C. (Stuttgart '49) has accepted a position as associate professor of civil engineering with Michigan State University in Lansing, Mich. He will teach and do research in connection with the Highway Traffic Safety Center.

(Continued on page 90)

Beaco Limited and Canengco Limited

We hope that two of the Institute's more distinguished Honorary Members, John Bertram Stirling, Hon. M.E.I.C. and L. Austin Wright, Hon. M.E.I.C., will forgive our apparent disregard of their proper names and designations. This was a most regrettable consequence of haste in the preparation of the December issue.

• • •

• PERSONALS

(Continued from page 88)

Lt.-Col. Donald H. Rochester, M.E.I.C. (Toronto '41) has been made chief of the Canadian section, U.S. Army Command and General Staff College, Fort Leavenworth, Kansas. Canada has not been represented on the faculty of the college previously.

Lt. Col. D. H. Rochester, M.E.I.C.

John Renchko, JR.E.I.C. (Saskatchewan '49) is employed with Emerson-Day, Niagara Falls, New York, as electrical engineer on construction of the Niagara Switchyard power project.

Donald C. Cullingham, M.E.I.C. (Toronto '50) has been appointed process engineer at the new MgO process dissolving pulp mill in Sitka, Alaska.

S. K. McMillan, M.E.I.C. (Saskatchewan '50) is now employed as mechanical superintendent, architectural branch, Department of Public Works, Province of Manitoba, with residence in Winnipeg.

James R. Wallace, JR.E.I.C. (Alberta '52) has been appointed chief metallurgist for the Dominion Steel and Coal Corporation's steel operations from Montreal to Aguathuna, Newfoundland.

J. A. Walsworth, JR.E.I.C. (Queen's '53) has left Canadian Westinghouse to take a position with Dupar Canada Limited in Kitchener, Ont.

Donald M. Onysko, JR.E.I.C. (Manitoba '57) is working for T. Lamb, McMannus and Associates Ltd. in Winnipeg after two years in England on an Athlone Fellowship.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Address all information to: *The Engineering Journal,* Editorial, 2050 Mansfield Street, Montreal, Que.

NEWS OF THE BRANCHES

Assumption University

William Pulleyblank, S.E.I.C.,
Correspondent

William Arison, M.E.I.C., past chairman of the board of directors of Essex College and assistant production manager of Hiram Walker & Sons Ltd., Walkerville, Ontario, spoke to students at a dinner on November 28 forecasting what the first graduating class in engineering at Assumption University should expect from industry.

A dance followed the dinner and students and faculty had a most enjoyable evening. The idea of a dinner-dance to make students and faculty become better acquainted is likely to become an annual affair.

Belleville

D. A. Law, JR.E.I.C.,
Correspondent

Mr. Joseph Steven of Ontario Hydro's planning department outlined the growth of his company from the early 1900's to the present at the December 7 meeting. In 1910, he pointed out, Ontario Hydro was serving eight municipalities. Today it is the second largest power utility in North America. Mr. Steven explained that today's peak loads are being met by supplementing hydraulic installations with thermal power.

Border Cities

R. L. Kennedy, JR.E.I.C.,
Correspondent

About 55 branch members heard a panel discuss the erection of the Princess Margaret Bridge in New Brunswick on November 19. Victor Davies, M.E.I.C., of Dosco, chaired the panel which included Walter Macdonald, Jr.E.I.C., and Dick Cranker, M.E.I.C.

Calgary

Herbert Bailey, M.E.I.C.,
Correspondent

City Traffic Supervisor Robert Bailey spoke to members on November 3, discussing the chronic traffic difficulties with which Calgary is faced. He showed graphs of traffic patterns which had been made following 1,000 interviews and also presented maps indicating the future system of freeways and throughways through the city. He suggested that Calgary may before long see elevated pedestrian crosswalks at major intersections, particularly over one-way streets. A series of graphic, colored photographs of traffic accidents brought about a lively discussion of traffic control safety in the city.

Cape Breton

Harold M. Aspinall, M.E.I.C.,
Correspondent

Sir Charles Goodeve, director of the British Iron and Steel Research Association, London, spoke to Cape Breton members at a meeting in the Isle Royale Hotel, Sydney, on November 30. He described the tonnage oxygen development and L.D. steel processing as revolutionizers of today's industry but pointed out that the process still had one sizable disadvantage. The extensive fuming which occurs, he explained, necessitates the use of costly cleaning equipment.

Central B.C.

A. F. Joplin, M.E.I.C.,
Correspondent

Mel J. Shelly, M.E.I.C., was elected chairman of the branch on November 27. Serving with Mr. Shelley on the executive will be H. A. Price, J. W. Nelson, R. C. Wannop, E. R. Gayfer and B. Harvey.

Mr. P. Tassie, retiring chairman of the branch, reviewed the year's accomplishments and singled out the completion of the memorial cairns erected by the Central B.C. branch to the memory of our pioneer engineers and the field trip through Rogers Pass as the outstanding events of 1959. Following the dinner, Mr. Bruno Engler, a professional photographer for the Trans Canada Highway, showed films of mountain work in the vicinity of Banff.

Chalk River

G. R. Fanjoy, JR.E.I.C.,
Correspondent

Members heard Professor K. B. Jackson, head of the department of applied physics, University of Toronto, give a talk on photogrammetry, November 3. Research into the question of how much information can be gleaned from these photographs has occupied much of Professor Jackson's time. He showed several pictures of the model which he built for photographing from the air. From these photographs he is able to check resolution, colour graduation from white to black, and the effect of haze on shadows produced.

St. Dunstan's University (Charlottetown)

Francis S. S. Tam, S.E.I.C.,
Correspondent

On October 30 the third year engineering students accompanied by Mr. D. Kawaja, Jr.E.I.C., faculty representative, went to Halifax to visit the Nova Scotia Technical College. They were met by faculty and students of N.S.T.C. and shown the different buildings and departments. The detailed explanations from both faculty members and senior students contributed to one of the most interesting educational tours that St. Dunstan's students have had.

Francis S. S. Tam, S.E.I.C., was elected student representative to E.I.C. at the November 4 meeting.

Cornwall

H. S. Johnston, JR.E.I.C.,
Correspondent

J. L. Olsen of the civil atomic power section of Canadian General Electric gave members a review of the nuclear energy business on November 17. He explained that a program of nuclear power plant development is under way, sponsored jointly by the Canadian government, Ontario Hydro and Canadian General Electric. Mr. Olsen stated that nuclear power plants are economically competitive now with coal and oil-fired plants but require approximately five to seven years' development work to overcome operational problems.

Corner Brook

H. A. Hinton, JR.E.I.C.,
Correspondent

On Wednesday evening, November 25, members were taken on a conducted tour of the recently opened CBC radio and television station here. Besides demonstrating the modern equipment, staff members answered many questions on operation of the station.

Fredericton

John Burrows, JR.E.I.C.,
Correspondent

The November joint meeting of the Fredericton branch of E.I.C. and members of the Association of Professional Engineers of the Province of New Brunswick was held on November 16 in the banquet rooms of The Paradise Restaurant. Dr. R. B. Banerji of the department of engineering and mathematics, University of New Brunswick, spoke to the group on electronic computers.

Hamilton

Charles A. McCurdy, JR.E.I.C.,
Correspondent

The first dinner meeting of the 1959-60 season was held at the Argyle and Sutherland Highlanders Officers Mess where the famous hot roast beef and mushroom gravy dinner was served in buffet style. L. C. Sentance, M.E.I.C., manager of the Atomic Energy Division of the Canadian Westinghouse Co., gave an illustrated lecture on atomic marine propulsion.

The chairman announced the formation of a new group within the branch, the "Civils Group", open to all members who are interested in any aspect of civil engineering. Their first meeting will be on winter construction, January 14.

President J. J. Hanna visited the branch on January 22 and presented his report on E.I.C. affairs. The ladies were present and a buffet luncheon and entertainment by the Hamilton Theatre Guild followed the president's talk.

Kingston

D. I. Ourom, JR.E.I.C.,
Correspondent

"Some Applications of Modern Computer Techniques" was the title of a speech given by Mr. Radford, director of systems evaluation at R.C.A.F. Headquarters in Ottawa, on November 17.

Kitchener

John F. Runge, M.E.I.C.,
Correspondent

I. Needles, chairman of the board of directors of B. F. Goodrich Canada Ltd., gave an outstanding general talk at the November 3 meeting about the engineer in industry and his opportunities for advancement to management and executive positions.

Although some engineers in their present positions are limited in seope, Mr. Needles maintained, they have every chance to gain experience in public speaking, accounting, salesmanship and administration by taking part in community and service club functions.

Kootenay

Ian Waterlow, JR.E.I.C.,
Correspondent

Mr. E. Rohatynski, Jr.E.I.C., liaison engineer with Cominco's iron and steel project, read a paper on "Model Studies leading to Modification of Waneta Dam" at the November 19 meeting. The paper, presented at the Western Zone Technical Conference, dealt with changes made in the No. 1 Spillway of the Waneta Dam brought about by extensive studies of the flow and jump pattern on the spillway outflow.

Lakehead

G. O. Hanson, JR.E.I.C.,
Correspondent

Members visited the central control system of the Canadian National Railways on the evening of November 18. Vern McGregor, signals department engineer, gave an illustrated talk on the growth of railroad signal systems from the early days of hand signals up to the present situation where one dispatcher can control trains 400 miles way. He noted that the installation at the Lakehead, controlling the movement of trains from here to Atikokan, is typical of modern installations.

Loyola (Montreal)

The Dominion Steel and Coal Company in Verdun, Que., was host to our group on November 25. Students were impressed by the vastness of the 25-acre plant but were glad to find an excellent ¼" to 1' scale model in the plant office for an appreciation of the general layout of the building. Safety is an important consideration in the Dosco works and students were given special safety glasses before starting the tour of the plant.

University of Manitoba

D. W. Brown, S.E.I.C.,
Correspondent

The membership drive held from November 2 to 6 resulted in approximately 190 new members.

Each Thursday films are being presented in the noon hour at the Engineering Building. About 200 student engineers have attended these sessions.

McGill University (Montreal)

R. D. Hatfield, S.E.I.C.,
Correspondent

One hundred and fifty-five engineering students became S.E.I.C.'s in the Fall drive for membership.

The Montreal branch Students' Night, January 27, will completely change its pattern this year. Included in the technical papers' competition will be delegates from Laval and Sherbrooke Universities. The McGill organizing committee expects to have an E.I.C. member address the students on the function of E.I.C.

Moose Jaw

T. L. Salmon, M.E.I.C.,
Correspondent

J. A. Beveridge, city commissioner of Moose Jaw, discussed the five-year development plan for the city on November 18.

Officers for 1959-60 elected at the meeting are: H. Kindred, chairman; J. MacKay, vice-chairman; T. L. Salmon, secretary-treasurer; and R. Grant, member of the executive.

Saguenay

Maurice Lavallee, JR.E.I.C.,
Correspondent

The November 3 meeting of the Saguenay branch, to which members of the Corporation of Professional Engineers of Quebec and the Chemical Institute of Canada were invited, was addressed by Dr. J. M. Zarzycki. Dr. Zarzycki is chief engineer of the Engineering Services Division of Canadian Aero Service Ltd. and he spoke on "Photogrammetry in Engineering and Science".

At the general meeting on November 27, held at the Saguenay Inn, Arvida, members had the honour of hearing President Hanna talk about his recent tour through Canada. Mr. Hanna recommended that engineers should give more attention to economic and financial conditions and suggested a program of education toward this end.

Saint John

Harley K. Larsen, JR.E.I.C.,
Correspondent

James E. Isbester, resident engineer of H. G. Acres Co. Ltd., consulting engineers on the East Saint John thermal power plant, spoke to members on December 8 on his experiences working in Pakistan under the Colombo Plan.

The following were elected to the executive for the coming year: J. B. Eldridge, chairman; P. W. Hastings, vice-chairman; J. P. Mooney, secretary treasurer; Gordon Bayne and M. C. Schofield, councillors.

(Continued on page 103)

OBITUARIES

L. MacC. Allison, M.E.I.C., of Armdale, Nova Scotia died on September 24, 1959. Mr. Allison was associated for many years with the Department of Public Works of Canada and worked on many of the larger public works projects in Nova Scotia from 1924 until his retirement in 1957.

Born in Halifax in 1892, Mr. Allison received his engineering education from Dalhousie University and graduated from that institution in 1911. He began his career with the Department of Railways and Canals on railway construction and in 1920 and 1921 worked on the Saint Lawrence Improvement Survey.

In 1924, after two years with the Nova Scotia Provincial Highway Board, Mr. Allison entered the Federal Department of Public Works. As area engineer for Lunenburg, Queens, Shelburne and Yarmouth counties in Nova Scotia, Mr. Allison contributed to a great variety of construction projects.

Harry Holborn Angus, M.E.I.C., past president of the Association of Consulting Engineers of Canada and head of two Canadian engineering firms, died in Toronto on November 3, 1959.

Mr. Angus was born in London, Ontario and graduated from the University of Toronto in 1904. Before organizing his own consulting business in Toronto in 1922, he worked with Bethlehem Steel, Westinghouse and Western Electric in the United States.

As president of H. H. Angus and Associates Ltd., Toronto, and Angus, Butler & Associates, Edmonton, Mr. Angus gained widespread recognition through his work on many commercial buildings and hospitals, among them the Toronto General.

He was a past chairman of the Ontario section, American Society of Mechanical Engineers and a life member and past chairman of the American Society of Heating and Ventilating Engineers.

Morris A. Bohn, JR.E.I.C., has died at the engineers' camp of B.C. & B.B. Power Consultants in British Columbia.

Mr. Bohn, who obtained his civil engineering B.Sc. at Queen's in 1957, joined the Institute as a student that year. He subsequently worked as a research assistant in the department of civil engineering at the University of Illinois.

Frank Charles Graham, M.E.I.C., city engineer at Port Arthur, Ontario, died on November 20, 1959. He was 68.

Mr. Graham was born in Broadview, Saskatchewan. In 1907 he came to Port Arthur and began work in the city's engineering department. For 47 years he

L. M. Allison, M.E.I.C.

A. A. Murphy, M.E.I.C.

H. M. Olssen, M.E.I.C.

worked in this department and in 1954 he retired as city engineer.

A past chairman of the Lakehead Branch of the Institute, Mr. Graham was granted Life Membership on January 1, 1957.

Harry Louis Hayne, M.E.I.C., a Life Member of the Institute, died suddenly on September 7, 1959.

Construction work for the Canadian Pacific Railway in the West was the first engineering assignment for Mr. Hayne, whose birthplace was London, Ontario. From 1910 to 1912 he was resident engineer for construction on the Esquimalt & Nanaimo Railway, and on his return from overseas service he worked for this line again until 1921. That year Mr. Hayne joined the British Columbia Department of Public Works, and when he retired twenty-nine years later he was its chief construction engineer at Kamloops.

Mr. Hayne joined the Institute in 1920 as an Associate Member, and was active in the Central British Columbia Branch from the time of its inauguration. In 1950 he was elected to represent this branch on the Council, and his Life Membership was conferred four years later.

James Frederick Lester M.E.I.C., a member of the Institute for thirty-nine years, died on October 10, 1959.

Mr. Lester had retired only two months earlier after a long and varied career as a professional engineer. His service with the Canadian Pacific Railway as a construction engineer from 1911 to 1934 was interrupted only by a period overseas with the Canadian Army. In 1934 Mr. Lester joined the Ontario Department of Highways as resident and location engineer. The Second World War took him overseas again, and after serving with the Air Ministry in Britain as resident engineer and works officer on airport and ancillary works, he remained in England on various civil engineering construction projects for Sir Robert McAlpine & Son Limited.

In 1948 Mr. Lester returned to this country and joined the Alberta Department of Highways. He was appointed Chief Location Engineer when the location branch was formed in 1953.

Adelbert Arthur Murphy, M.E.I.C., died on December 2, 1959 at the age of 75. A recognized leader in Canadian broadcasting, Mr. Murphy established CFQC Radio in Saskatoon in 1923 and just five years ago, in 1954, CFQC-TV.

Born in Portland, Ontario in 1884, Mr. Murphy earned science degrees from both Queen's and McGill Universities. He was a partner in a firm of Saskatoon consulting engineers from 1911 to 1920 and then spent two years in the electrical business before establishing his radio station.

In 1936 Mr. Murphy was vice-president of the Canadian Association of Broadcasters. He also served as president of the Western Association of Broadcasters.

Harald Matias Olsson, M.E.I.C., died on October 19, 1959 in Port Arthur, Ontario. He was 61. Born in Sweden in 1898, Mr. Olsson was educated in Sweden and Germany and came to Canada in 1925.

Mr. Olsson's first employment in Canada was with the Canadian National Railways in Winnipeg. In 1926 he went to work as a draughtsman for the Dominion Bridge Company and later in that same year joined the staff of the C. D. Howe Company in Port Arthur, Ontario.

In 1946 he was made their chief engineer and in 1950 became manager of the Port Arthur office, which post he held until the time of his death. The design of grain terminals in Port Arthur, Sas-

News of Other Societies

R.C.E.M.E. Corps. Celebrates 14th. Year

The R.C.E.M.E. School at Barriefield, Ontario was the meeting and dining place for the Royal Canadian Electrical and Mechanical Engineers Corps Association on October 24. Seventy-five members from across Canada attended the meeting and heard speeches by Lt. Col. F. N. Pope, acting director of militia and cadets, and Col. R. A. Campbell, director of the Corps. Officers elected for the 1959-60 term are: president, Lt. Col. E. D. Gray-Donald (Montreal); first vice-president, Major A. Anderson (Hamilton); secretary-treasurer, Lt. Col. LeSueur Brodie (Toronto).

Professor John Dunbar of McGill University's zoology department addressed 150 members at the dinner on "Problems and Prospects of the Canadian Arctic".

An illuminated scroll honouring the memory of the late Colonel H. G. Thompson was presented to Mrs. H. G. Thompson by Lt. Col. A. G. Edward of Montreal on behalf of the Royal Canadian Electrical and Mechanical Engineers Corps Association. A past executive assistant general secretary of E.I.C., Mr. Thompson organized the R.C.E.M.E., served as its president for three years, and was active in it until his death.

American Institute of Chemical Engineers

Jet and rocket combustion, heavy water production, pulp and paper processing, electrochemical equipment and liquid purification by solvent extraction—these are but a few of the subjects dealt with at the annual meeting of the American Institute of Chemical Engineers in San Francisco on December 6-9.

The Society of Petroleum Engineers joined in sponsoring three sessions on petroleum recovery methods, underground combustion and displacement by liquefied hydrocarbon gases.

Institution of Electrical Engineers, Britain

The Impact of Nuclear Development on Electricity Supply and on Instrument Techniques is the theme for the September 1961 Convention which is to be organized by the Measurement and Control Section of The Institution of Electrical Engineers, London.

The organizing committee will be pleased to receive offers of papers which might be included in the Convention's program.

Gas Dynamics Colloquium, 1959-60

The Department of Mechanical Engineering of The Technological Institute at Northwestern University, Evanston, Illinois is sponsoring a colloquium on gas dynamics from October 15, 1959 to May 26, 1960. The schedule for the next month reads: Feb. 4—Steady State Magnetohydro-dynamic Experiments; Feb. 11—Departures From Equilibrium in Mixing Regions; Feb. 18—Relaxation Times in Gases; Feb. 25—A New Application for the Hydraulic Analogy.

1961 Congress of Chemical Engineering

The 13th Exhibition Congress of Chemical Engineering organized by the DECHEMA will be held in Frankfurt from June 9 to 17, 1961. It will include the following groups of exhibits: research and literature, new chemical substances, nuclear science and techniques, laboratory techniques, measurement control and automation techniques, structural materials techniques, works mechanics, pumps and fittings, packaging techniques, auxiliary materials and consumable stores, accident prevention and works safety precautions.

World Conference on Earthquake Engineering

The Science Council of Japan in cooperation with the Japan Society of Civil Engineers, the Architectural Institute of Japan, and the Seismological Society of Japan is planning a second World Conference on Earthquake Engineering, to be held in Tokyo and Kyoto, Japan on July 11-18, 1960.

National Concrete Products Manitoba Conference

The National Concrete Products Association will hold its annual convention in Winnipeg on January 18-20, 1960. Indicative of the growing potential of the association is the fact that this is the first time in its eleven-year history that the convention has been held outside Quebec and Ontario.

Coming Events:

Conference on Automatic Computing and Data Processing in Australia

Sponsored by The Australian National Committee on Computation and Automatic Control
The Universities of Sydney and New South Wales
May 24-27, 1960.

Symposium on Plastics in Domestic Refrigeration

Presented by The Society of the Plastics Industry, Inc.
Dallas, Texas
February 1-4, 1960.

International Congress of Scientific Management

Organized by the International Committee of Scientific Management
Sydney, Australia Session: February 22-26, 1960.
"Management Methods in the Next Decade"
Melbourne, Australia Session: February 29 to March 4, 1960.
"Management in a Developing Country".

1960 Pacific Northwest Metals and Minerals Conference

Sponsored by The American Institute of Mining, Metallurgical and Petroleum Engineers
Portland, Oregon
April 28-30, 1960.

Seventh Commonwealth Mining and Metallurgical Congress

Union of South Africa, Northern and Southern Rhodesia
April 10 to May 21, 1960.

Conference on Coastal Engineering

Council on Wave Research of the Engineering Foundation (USA) and the Rijkswaterstaat of the Netherlands
The Hague, Netherlands
August 22-27, 1960.

Third International Conference on Nondestructive Testing

Organized by the Science Council of Japan in cooperation with the Japanese Society for Nondestructive Inspection
Tokyo: March 15-18, 1960.
Osaka: March 21, 1960.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

UNEMPLOYMENT: THE PROBLEM OF INDUSTRIAL NATIONS

The author, a member of the Engineering Institute of Canada, has compiled this volume largely from material presented to the Montreal Branch in the past. He presents his views on the causes of unemployment, superfluous manpower created by the harnessing of the forces of nature, and the boom and depression cycle, and considers ways of combatting this by social, fiscal, tax and monetary reform. (P. Ackerman. Montreal, the author, 1959. 75p., $4.00. Special price to E.I.C. members $2.50.)

GATEWAY TO THE WORLD

A pictorial record in photograph and water-colour of the construction of the St. Lawrence Seaway, both the ship canal and the power project. Mr. van der Aa has taken some wonderful photographs, and the descriptive text by Donald M. Ripley, a member of the Institute, provides enough information to place them in their context. (Hans van de Aa. Montreal, Robson Printers, 1959. 184p., $3.95 hard cover, $2.50 soft.)

THE MODERN SLIDE RULE

In this description of his new method of using the slide rule, by which the position of the decimal point is fixed exactly in all operations, without approximate calculations having to be made, the author lists all the operations which can be performed with a slide rule, and explains how they are done. (Stefan Rudolf. New York, William-Frederick, 1959. 68pp., $5.00.)

LES ENERGIES DE LA MER

The recent report on the Passamaquoddy power project increases the interest of these proceedings of a conference held in 1956 on energy from the sea. The papers are divided into eight groups, covering: the natural state of the mechanical energy of waves and tides; scale model tests of the mechanical energy of waves and tides; harnessing tidal and wave energy; harmful effect of waves and tides, tidal bores, etc., and protective structures; utilization of the sea's thermal energy, the equipment used and general conclusions. (Grenoble, la Houille Blanche, 1958. 2 vols., no price given.)

*MODERN AIR CONDITIONING, HEATING AND VENTILATING, 3rd ed.

This edition presents a thorough revision of all chapters where significant advances have been made in the past decade. Additions to the volume include a section on psychrometric processes, new material on factors influencing comfort, and an expanded treatment of basic cycle theory. Also added are a section on high-velocity air duct design and a chapter on industrial systems. Volumetric efficiency, work and horsepower receive a more theoretical treatment, while the chapter on the heat pump has been expanded and given more rigorous theoretical treatment. The appendix includes many new tables such as solar azimuth angles and intensity data, summer degree-days for cooling, and properties of refrigerants 113 and 500. (W. H. Carrier and others. Toronto, Pitman, 1959. 592p., $12.00.)

*STEAM TURBINE OPERATION, 6th ed.

Thermal and mechancial considerations which effect the operation and handling of larger steam turbines are described. Topics discussed include installation, heating and drainage of turbines, lubrication, thrust bearings and their adjustment, governors and governing, starting and stopping of turbines, inspection and overhauling, regenerative feed-heating, erosion of blading in low-pressure stages, supervisory and protective equipment for turbines, and turbine testing. (W. J. Kearton. Toronto, Pitman, 1958. 453p., 35/-.)

*TELEGRAPHY

The theory and principles of telegraphy upon which practical systems and equipment are based is explained. Detailed information is given on the equipment used by the British Post Office for its inland and oversease public telegraph services and for private wires and telex. Aspects discussed are electromagnetic relays, line plant, manual switching telegraph systems, automatic switching of telegraph circuits, multi-channel voice-frequency systems, start-stop instruments, facsimile and picture telegraph systems, teleprinter private wires and telex service, and submarine cable telegraphy. (J. W. Freebody. Toronto, Pitman, 1959. 738p., 80/-.)

*FUELS AND LUBRICANTS

Summarizing material from a great many sources, the authors discuss the important fuels, including boiler, internal combustion engine, and jet fuels, as well as rocket propellants and nuclear fuels. Emphasis is placed on the correlation between the properties of fuels and lubricants and their performance in an engine or machine, as well as on the significance of the standard tests that are conducted on these materials. Particular features of the volume include discussions on synthetic lubricating oils, and a tabulation of octane numbers of many pure hydrocarbons. (M. Popovich and C. Hering. New York, Wiley, 1959. 312p., $8.50.)

(Continued on page 98)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 A.M. to 5 P.M.; Saturday: 9 A.M. — 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

appearance and dependability...

NORANDA BRASS

More than a half century of manufacturing and designing experience stands behind the new Lustre-Line by Wallaceburg Brass Limited.
A special survey of housewives across Canada determined the choice of exterior (chrome-plated) controls for appearance and ease of operation.
Noranda Brass was selected by Wallaceburg for the "working parts" of the entire fixture. Ease and speed of fabrication, corrosion resistance and consistent quality make Noranda copper and copper base alloys the outstanding choice for all your fabricating needs. Call your nearest Noranda sales office for information or technical assistance.

THE KEY TO THE BEST IN METALS

Noranda Copper and Brass Limited

SALES OFFICES: Montreal • Toronto • Edmonton • London • Vancouver

● LIBRARY NOTES

(Continued from page 96)

*FUNDAMENTALS OF ELECTRON DEVICES AND CIRCUITS

Survey of electron devices that gives an analysis of newer devices such as transistors, diodes, and magnetic amplifiers as well as conventional vacuum and gas tubes. A thorough analytical approach stressing physical phenomena is used where possible. Topics discussed include electron emission and acceleration; single-phase and poly-phase rectifiers; diodes, triodes, and multigrid tubes; class A amplifiers; push-pull and feedback amplfiers; transistor circuits; magnetic amplifiers; gaseous tube circuits; controlled rectifiers and inverters; regulators; operational amplifiers, and oscillators. (N. R. Wood and W. L. Davis. Englewood Cliffs, Prentice-Hall, 1959. 591p., $9.50.)

*BALL AND ROLLER BEARINGS

Translated from the German edition, this book represents the experience of a large ball and roller bearing company. The types, materials, dimensions, and tolerances of the important bearings manufactured in Europe are presented. This is followed by a discussion of bearing stresses and kinematic phenomena with consideration of the basic relationships between carrying capacity, load, and life. A series of individual problems is then used to illustrate design principles and the practical aspects associated with them. (P. Eschmann and others. London, Heyden, 1958. 375p., $8.75.)

*APPLIED HYDRODYNAMICS

A practical approach to the theory of hydrodynamics which stresses the adaptation of non-viscous flow theory to the analysis of real, or viscous, fluid flow. Topics discussed include flow of an ideal and a real fluid; graphical flow nets, numerical analysis, and experimental analogies; standard patterns of flow; conformal transformation; and three-dimensional irrotational flow. Emphasis is paid in the text to detailed physical explanations of such concepts as stream functions, potential function and conformal transformation. (H. R. Vallentine. Toronto, Butterworth, 1959. 272p., $10.00.)

*INTRODUCTION TO THE DYNAMICS OF FRAMED STRUCTURES

Using two mathematical tools, matrices and orthogonal functions, the author presents the analytical aspects of dynamic disturbances in structures. Lumped parameter and distributed parameter systems are discussed, and the classical formulation of problems based on direct application of Newton's laws of equilibrium are considered. Particular applications dealt with include stresses and strains in structures during and after earthquakes and atomic blasts, action of moving loads such as highway and railroad bridge loadings, deflections and bending movements, and velocities and shear forces in structures acted upon by dynamic disturbances. (G. L. Rogers. New York, Wiley, 1959. 355p., $10.25.)

*SYMPOSIUM (INTERNATIONAL) ON COMBUSTION, SEVENTH, 1958

A comprehensive survey that begins with detonation, and in particular the transition from flame propagation to detonation. It continues with spectroscopy and the structure of flames in which modern methods of following the change of composition through a flame front are described. A substantial part of the book is then devoted to the mechanism of combustion reactions, both hydrocarbons and other substances being considered. Also investigated are ignition and limits of inflammability, combustion in practical flowing systems, special fuels, and instrumentation. (Toronto, Butterworth, 1959. 959p., $28.00.)

*MASERS

A study of quantum mechanical amplifiers that approaches the subject from both the classical and quantum mechanical points of view. Beginning with a discussion of the ammonia maser and of the magnetic atomic beam system, there is a section on an optically pumped frequency standard and a description of electron paramagnetic resonance. Two level masers are then treated with emphasis on their possibilities for millimeter and submillimeter wave generation, and numerical illustrations are employed in an examination of three level cavity masers. The book concludes with the theory and experimental results of the travelling wave masers. (J. R. Singer. New York, Wiley, 1959. 147p., $6.50.)

PULP AND PAPER MANUAL OF CANADA, 1959

This twenty-seventh edition follows the same plan as previous ones. The first section contains general information on the industry in Canada, the second contains brief technical articles, this year on cost reduction techniques, the third lists mill operating personnel and gives flow sheets for pulp and paper mills, and the last section is a classified buyers' guide. (Ed. by J. N. Stephenson. Gardenvale, National Business Pubs., 1959. 480p.)

SURVEY OF INDUSTRIALS, 1959

Hundreds of companies covering all types of Canadian industry are reviewed in this edition. The information given for each includes earning statements and balance sheets, working capital position, dividend history, funded debt, directors and subsidiaries. The price range of Canadian stocks over the last eight years is included. This is a valuable reference tool. (Toronto, Financial Post, 1959. 400p., $4.00.)

NATIONAL REFERENCE BOOK, 1959-60

Almost 1300 biographies of Canadians prominent in the commercial field are included in this new edition, many of them being accompanied by photographs.

The second section of the volume contains useful information about Canada, including geography, national parks, government, sources of official information, population, a business directory, and a classified index to the biographies. (L. M. Durant, ed. Montreal, Canadian Newspaper Service, 1959. 1707pp., no price given.)

FRASER'S CANADIAN TRADE DIRECTORY, 1959

In this 46th edition of an invaluable directory, 10 percent of the brand and trade names appear for the first time. Over 12,500 firms are listed alphabetically, and their products shown under 6,500 headings. Over 12,000 foreign companies and their Canadian representatives are listed.

The market section contains valuable data for those companies interested in foreign trade, as well as a list of cities and towns over 2,000 population, transportation companies, utilities, banks, telephone and telegraph companies etc. (Montreal, Fraser's, 1959. 1880pp., $10.00.)

CANADIAN TRADE INDEX, 1959

The major section of this index is a classified list of Canadian products and their manufacturers, with a French index. There is an alphabetical listing of over 11,000 Canadian manufacturers, a section of information for exporters, and a produce section. (Toronto, Canadian Manufacturers' Association, 1959. 1071p., $12.50.)

*AUTOMATION TODAY AND TOMORROW

The field of automation is surveyed and some of its important aspects are described. These include sales and distribution, building design, computer control of processes, instrumentation in the process industries, processing methods and automatic assembly, industrial finishing, and inspection and testing. In addition, automation in specific industries is discussed, and an extensive bibliography is provided which includes references to books and articles covering many of the advances in automation. (L. L. Goodman. London, Newman Neame, 1958. 158p., £2.)

*PROCESS EQUIPMENT DESIGN: VESSEL DESIGN

The basic concepts, industrial practices, and theoretical relationships useful in the design of processing equipment are presented with particular reference to pressure vessels. Beginning with a review of elementary theories of mechanics and strength of materials, the material covered ranges from simple vessels for low pressure service to thick-walled vessels for high pressure applications. Advanced theory is developed as needed and is integrated with design practice. (L. E. Brownell and E. H. Young. New York, Wiley, 1959. 408 p., $18.00.)

*RIVER POLLUTION. 1: CHEMICAL ANALYSIS

The present volume constitutes an expansion of chapters 9 and 10 of the author's previous work "Aspects of River

(Continued on page 104)

Employment Bulletin No. 60-1

EMPLOYMENT SERVICE

SITUATIONS WANTED

CIVIL ENGINEER, Jr.E.I.C., M.S. Princeton 1952, B.Sc. London 1951. Age 29, married, one child. Desires structural design position with consulting engineer. Particularly interested in prestressed concrete. 3 years experience at site of construction of large hydro-electric development. 1½ years experience in structural design for industrial plant buildings. Present location Quebec. Prefers to remain in Eastern Canada. Available on reasonable notice to present employer. File No. 5610-W.

M.B.A. AND MECHANICAL ENGINEER. Postgraduate M.B.A. from U.S. University 1956, B.Eng., mechanical McGill 1954, Jr.E.I.C., P.Eng., age 28, single. Three years experience conducting studies preparing reports for senior management on economic appraisals of process, plant expansions, development of production, distribution costs, market research, budget preparation. Seeking position where strong analytical ability together with engineering and economics background is needed. Speak French. Will relocate. Complete resume on request. Located Central Canada. File No. 5638-W.

SENIOR PROFESSIONAL ENGINEER, M.E.I.C., specializing in project engineering, production planning, production set-up design, methods, work simplification. Production administration and management. Location in or around Toronto preferred. Located Central Canada. File No. 5642-W.

CIVIL ENGINEER, M.E.I.C., P.Eng., (Ont.) B.A.Sc. University of Toronto 1948. Age 33, married with family. Twelve years experience in construction industry, six in field and six in office management position. Available for management position with an excellent future. Present location Southern Ontario. File No. 5663-W.

MECHANICAL ENGINEER, P.Eng., Jr.-E.I.C., Grad. I. Mech. E., age 28. Experience includes five years comprehensive training rubber industry. Special purpose machine design, plant layout, two years gas turbine, fuel equipment. Also project and field engineer on diversified hydraulic schemes, construction and research. Presently design, estimate engineer, plumbing, heating, ventilating systems. Seeks permanent position in small or medium development organization. Presently located Central Canada. File No. 5683-W.

HYDRO ELECTRIC ENGINEER, P.Eng., M.E.I.C., B.Sc., London 1952. Age 39, with seven years experience in the electrical and mechanical aspects of the design, construction, contract administration, operation, and maintenance of large hydro electric stations, seeks responsibility for the contract administration of a hydro project with consulting engineers or utility, at home or abroad. Located Central Canada. File No. 5685-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc. Queen's 1948, veteran, age 41, married with family. Experience since graduation five years plant engineering and six years welding engineer with a firm producing medium heavy custom fabrications including unfired pressure vessels. Wishes to continue in the welding field. Located South East Ontario but prepared to relocate preferably Eastern Ontario or Montreal area. Immediately available. File No. 5717-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng. Age 35, married. Graduate of University of Toronto. 10½ years experience in the pulp and paper industry. Wish to relocate with a progressive manufacturing company or enter sales and service field. Montreal area preferred. Located Central Canada. File No. 5718-W.

CIVIL ENGINEER, P.Eng. (Que). Jr.E.I.C., B.Eng., in applied mechanics McGill 1957. 2 years experience in systems analysis and evaluation. Age 25 years, single. Seeking employment in mechanical or structural field, preferably in a research and development role. Located Atlantic Province. File No. 5719-W.

CIVIL ENGINEER, Jr.E.I.C., P.Eng. (Ont.) age 37. Nine years field and office experience in heavy and general construction. Experience includes municipal works, hydro projects, townsite and subdivision construction, radar and microwave projects, highway construction and industrial construction. Three years professional Development Course of the E.I.C. Interest lies in municipal or general engineering administration. Resume on request. Located Central Ontario. File No. 5720-W.

CIVIL ENGINEER, P.Eng., M.E.I.C., age 44, with extensive experience in senior administrative posts in municipal engineering in Canadian Cities, and in the design and construction of major arterial roadways, sewers, drainage systems and water works. Seeks challenging position with a consultant firm in the Maritimes or Eastern Canada. Located Central Canada. File No. 5721-W.

CHEMICAL ENGINEER, B.Sc.Ch.E., 1942, M.E.I.C., M.A.I.Ch.E. Seventeen years experience process, project and sales engineer for petroleum refineries and petrochemical plants. Perfect German, some Dutch and Russian. Presently in Europe as Project Manager. Seeks senior position in Vancouver with engineering, petroleum refining, or petrochemical company. Located W. Germany. File No. 5722-W.

ELECTRICAL ENGINEER, M.E.I.C., P.Eng. (Ont.) McGill 1951, married. Diversified experience includes; CGE Test Course; electrical manufacturing, plant engineering; consulting and project engineering in the chemical, industrial and commercial fields. Seeking a responsible industrial job where this experience can be effectively utilized. Preferred location Ontario. Located Central Canada. File No. 5723-W.

YOUNG CANADIAN MECHANICAL ENGINEER, Jr.E.I.C., (age 26, single) presently being turned into an organization man by a large Montreal aircraft manufacturing firm, wants to get off the design board and do some active work requiring a P.Eng., fluent bilingualism, imagination, individuality, and a liking for travel. Prefer Montreal as base of operations. Four years of Canadian and British industrial experience. Located Central Canada. File No. 5725-W.

CIVIL ENGINEER, P.Eng., (Alta.) B.Sc., A.R.C.S.T. Jr.E.I.C., (University of Glasgow) 1951, age 30, professional experience with Canadian consulting engineers in structural design, completed course requirements for Master's degree 1958 (structures, soils), at present on graduate scholarship and teaching assistantship, studying advanced mathematics, engineering mechanics, technical French, German; desires university teaching position in strength of materials, structural design or structures. Located U.S.A. File No. 5726-W.

MECHANICAL ENGINEER, P.Eng., M.E.-I.C. Long experience in design of heavy machinery, fabricated products, pressure vessels, would like position of engineering or administrative responsibility involving liaison work, use of mathematics. Likes travelling. Preferred location Southern Ontario. Located Central Canada. File No. 5727-W.

CIVIL ENGINEER, Jr.E.I.C., P.Eng., (Ont.) age 39, Veteran. Several years experience in responsible positions in the construction industry. Four years experience with consulting engineers as resident engineer and as design co-ordinator. Seeks permanent position with progressive and growing firm, preferably engineering consultants or general contractors. Available on reasonable notice. Location preferred Ontario or Western Canada. Located Central Canada. File No. 5728-W.

AGRICULTURAL ENGINEER, B.E., S.E.I.C., 1959 graduate of the University of Saskatchewan age, 23, single. Desires agricultural engineering position preferably in Manitoba. Especially interested in structures, irrigation, or hydraulics. Available on reasonable notice to present employer. Located Prairie Province. File No. 5729-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., (Ont.) presently Executive Director of Technical Association overseas wishes similar promotional work in Canada. Experienced in technical sales and practical maintenance and construction work. Available on short notice. Located Prairie Province. File No. 5730-W.

THE ENGINEERING INSTITUTE OF CANADA

This service is operated for the benefit of members of the Engineering Institute of Canada and for organizations employing engineers.

SITUATIONS WANTED

Advertisements are inserted free of charge for members of all classes. Maximum length is 60 words, and repeat insertions must be separately requested in writing for each desired appearance.

SITUATIONS VACANT

Rate: Six dollars per column-half-inch per insertion.

Replies to advertisements should be addressed to the file number, Employment Service, 2050 Mansfield Street. Montreal. Interviews with the Employment Service may be arranged by calling VI 2-5078 at the above address.

ures and non-destructive testing. If interested write giving particulars of qualifications: Supervisor, Staff Department, The Consolidated Mining and Smelting Company of Canada Limited, Trail, B.C. File No. 6838-V.

TWO GRADUATE ENGINEERS, Electrical or mechanical for application sales work in electrical machinery. Good opportunity with expanding company in Southwestern Ontario. Reply in full confidence giving all necessary personal data. File No. 6874-V.

MANUFACTURER OF SCIENTIFIC lighting equipment requires two sales representatives for Ontario and Quebec Territories. Applicants should be graduate engineers or the equivalent in experience and possess a high degree of sales aptitude. Salary, commission, expenses and company paid pension. All replies held in strictest confidence. File No. 6890-V.

MECHANICAL AND ELECTRICAL ENGINEERS for design of services in commercial and institutional buildings. Excellent salary and full Associate for right man in three years. Preferably someone between 25 and 40 years of age with 3 to 5 years applicable experience. Consulting Office. Ottawa, File No. 6899-V.

UNIVERSITY OF QUEENSLAND, AUSTRALIA. Applications are invited for the position of SENIOR LECTURER IN INDUSTRIAL ENGINEERING: Salary £A2160/£A2510 p.a. Applicants should have an Honours Degree or higher Degree of a recognized university, together with industrial experience in both the technical and administrative fields. The applicant will be required to assist in the research and teaching work in Industrial Engineering at both undergraduate and post-graduate level. Further particulars may be obtained from the Registrar, University of Queensland, Brisbane, Australia, with whom applications close on 30th January, 1960. File No. 6910-V.

MECHANICAL or CIVIL ENGINEER required for sales organization. Preferably bilingual, experience in sewage disposal or water supply an asset. Some out-of-town travel will be required. File No. 6913-V.

TECHNICAL SALES & SERVICE ENGINEER. Recent graduate to manage sales territory. Montreal area marketing petroleum products to industry. File No. 6914-V.

INDUSTRIAL ENGINEER. Well known and long established Canadian organization with offices from coast to coast, seeks a capable and imaginative industrial engineer for a career position on its Montreal consulting staff. Close association with industrial engineers and other qualified professional consultants will provide the successful candidate with exceptionally interesting experience in working on a wide variety of industrial problems. Preference given to graduate engineers aged 25/30 having a minimum of three years industrial experience in work measurement and related areas of industrial engineering. Attractive compensation range. Applications should provide full particulars and will be held in strict confidence. File No. 6915-V.

CHIEF ENGINEER — to supervise engineering activities and serve as staff engineer of multi-plant operation in Eastern Canada. In order to carry out expansion plans, executive must be familiar with steel plant design and construction, as well as equipment. All replies will be held in confidence by consulting firm. Please send resume to File No. 6918-V.

SALES ENGINEER — Excellent opportunity for aggressive graduate. Mechanical or Chemical engineer, 25-35 years of age who is interested in selling engineered equipment to Pulp & Paper Industry. Some experience in Pulp & Paper Industry desirable. Reply in confidence to File No. 6921-V.

SALES ENGINEERS, two recent graduates, Mechanical or Electrical required by progressive manufacturer of ventilating, air conditioning and related engineered products. Some experience preferred, but not essential. Following completion of Company training course successful candidates will be assigned to Hamilton and Montreal Branch Sales Offices. Wide range of employee benefits and attractive starting salary. Send complete resume and salary requirements. File No. 6923-V.

PRODUCT DEVELOPMENT ENGINEER. Are you the man we are looking for? Age 25-35 years. Education — Graduate of a recognized university in engineering. Experience — 4 to 7 years' professional experience in design, project or development engineering. Position—Engineer in charge of product development function. The successful applicant will be expected to work independently with his technical group in the design, construction of prototypes, testing and preparation of engineering specifications and data, within policy guidance. Our fields of activity include vulcanizing and tire service equipment, and finned tube heat transfer equipment. This is a key position in a small company with excellent growth potential. The location is London, Ontario. Please apply in confidence to: Mr. F. S. Brown, Canada Vulcanizer and Equipment Company Limited, P.O. Box 7, London, Ontario. File No. 6924-V.

OBITUARIES

(Continued from page 94)

katoon, Vancouver, Toronto and Montreal as well as numerous other buildings in the Port Arthur area, was under his jurisdiction.

An active member of the Institute, Mr. Olsson was chairman of the Lakehead Branch in 1949.

Lieutenant Colonel Harold Lyndridge Trotter, M.E.I.C., a partner in the firm of Trotter & Cate (Montreal) for many years, died on December 12, 1959 at the age of 77.

Colonel Trotter earned his degree in military and civil engineering from the Royal Miltary College in Kingston. Prior to World War I he practised engineering with the firm of Ross & Holgate. During the war he served as a lieutenant with the Canadian Royal Engineers (now the Royal Canadian Engineers) and was awarded the DSO.

Upon his return to Canada, Colonel Trotter went into partnership with Carol Cate, forming the engineering firm Trotter & Cate, specialists in hydraulic engineering.

During World War II Colonel Trotter was district military engineer in Halifax, Montreal, and Ottawa. He retired from business five years ago.

The death is announced of Ernest Owen Way, M.E.I.C., a member of the Institute for forty years.

Mr. Way was one of the three Members who became Companions of the Imperial Service Order (I.S.O.) in the Dominion Day Honours of 1946. Six years later the Institute made him a Life Member.

NEWS OF THE BRANCHES

(Continued from page 92)

St. Maurice

William B. Scott, JR.E.I.C.,
Correspondent

On December 8 Dr. David Bate of Atomic Energy of Canada Limited addressed the branch on "Plans for CANDU Nuclear Power Station" which will be constructed shortly on Douglas Point, Lake Huron, near Kincardine, Ontario. As senior design coordinating engineer on this project, Dr. Bates discussed factors affecting site selection, general plant layout, building and equipment design, operating procedures and safety precautions necessary with the use of radioactive materials.

Toronto

D. R. Abbey, M.E.I.C.,
Correspondent

E. B. Griffith, general manager of the Toronto Harbour Commission, outlined the events of the first year of seaway operation at the November 26 meeting. He explained that berthing space is still limited for deep sea ships but that planning is in progress for additional space. He predicted that the Welland Canal would be sufficient for several years to come upon completion of the present improvements.

The October 29 symposium on engineering ethics, moderated by Professor C. A. Morrison, head of the department of civil engineering at the University of Toronto, proved very interesting and informative.

● LIBRARY NOTES

(Continued from page 99)

Pollution", and provides a chemical background for analytical methods used in river pollution. Topics discussed are physical and chemical methods; dissolved oxygen and oxygen demand tests; combined nitrogen; sulphur compounds; alkalinity, acidity, free carbon dioxide, free chlorine, chloride, fluoride; metallic contaminants; various carbon compounds. (Louis Klein. Toronto, Butterworth, 1959. 206p., $6.00.)

*MATHEMATICS APPLIED TO ELECTRICAL ENGINEERING, 2ND. ED.

A comprehensive survey of the mathematics used in electrical engineering. In this edition the two chapters on operational calculus and Fourier Analysis have been completely rewritten and a new chapter on functions of a complex variable has been added. Other new or rewritten sections discuss analogs, eddy current methods of non-destructive testing, and modulation, as well as material on the use of analog computers to solve differential equations. (A. G. Warren. London, Chapman and Hall, New York, Plenum, 1958. 464p., $11.50.)

*FEEDBACK CONTROL SYSTEMS

A synthesis of the field of servomechanisms that combines in a single volume a description of the overall theory, both linear and nonlinear, and of the components used. The subject matter included falls into two categories, the first constituting a text-book on the basic theory of servomechanisms, and the second dealing with additional data on particular and more advanced methods. Special topics discussed are structural stability, transient response of servo with any nonlinear component, stability of nonlinear systems on the verge of instability, forced oscillations of nonlinear servos, Liapunov's direct method, and describing function with statistical input. (J.-G. Gille and others. Toronto, McGraw-Hill, 1959. 793p., $19.00.)

*INDEX TO THE LITERATURE ON SPECTRO-CHEMICAL ANALYSIS. PART IV, 1951-1955.

The fourth part in this series contains 1892 abstracts. They are largely quoted from Chemical Abstracts, although there are occasional quotations from other sources. Although efforts have been made to attain completeness, references to papers containing only a few qualitative results have been generally omitted. (Philadelphia, American Society for Testing Materials, 1959. 314p., $6.50. S.t.p. no. 41-D.)

*SYMPOSIUM ON BULK SAMPLING, 1958.

Among the topics discussed are measurement error factors in bulk sampling, the problems faced in sampling a particular class of bulk material, and the sampling of coal and similar materials.

(Continued on page 110)

E.I.C. CERTIFICATE OF ADVERTISING MERIT

Northern Electric Company Limited have won the E.I.C. Certificate of Advertising Merit for the second time this year. The winning advertisement appeared in the October issue. It is a 4-page, two-colour, insert, black and orange, titled "Northern Electric Serving Canada's Communication and Power Systems". The insert covers a variety of services and products made available to engineers through the company and lists some of the firms Northern Electric represents. The advertisement occupies pages 33, 34, 35 & 36.

Mr. E. H. Woodley is the Advertising Manager of Northern Electric Company Limited and the Montreal office of Foster Advertising Limited, (Account Executive Frank Thompson) placed the business with us.

The selection, as usual, was made by 50 readers of the *The Engineering Journal* who were asked to evaluate the advertisements in the issue from the viewpoints of ACCURACY – INFORMATION and ATTRACTION. The advertisement was repeated in the November issue.

NORTHERN ELECTRIC COMPANY LIMITED WINNING INSERT

The above illustration is a reduction, to a small scale, of the 4-page, 2-colour advertisement which fifty readers selected, from the viewpoints of ACCURACY – INFORMATION and ATTRACTION as the "best" in the October issue. The original advertisement, on pages 33, 34, 35 & 36 of the issue was printed in black and orange on heavy white stock.

the world is 3" in diameter

Six Continents lie within the dial of your telephone. By raising your finger you can call any of them. This phenomenon has been created by communications engineers—those men who develop this equipment that shrinks the earth and by those who manufacture and install it. Continuing research is constantly being carried on in the field of communications. Northern Electric designs, manufactures and installs a large proportion of Canada's telephone communication systems and equipment. The experience gained in this field is being utilized in the challenging sphere of Canada's Defence Communications. Northern's experience is all-embracing and includes the manufacture of electrical wires and cables for communications and power transmission. At Northern Electric, product research and development never stops and advances are continually being made.

Business and Industrial Briefs

Appointments and Transfers

Boyles Bros. Drilling Company Limited announces the appointment of Mr. J. D. Campbell to the position of vice-president and general manager of the firm's head office in Vancouver, to meet expansion in both the contract drilling and manufacturing divisions of the business.

James Howden and Company of Canada Limited announces the appointment of E. A. Burgess as eastern area manager. An expanding sales and service program will be directed from the firm's Montreal Office, 1255 University Street.

Research Development and Surveys Associates, Toronto, announces the appointment of Charles Newbury, B.Sc., as senior associate in charge of the newly-formed combustion and pollution division.

Dresser Manufacturing Company, Ltd., Toronto, announces the appointment of J. G. Cushing as manager of operations with headquarters at 21 Coronet Road, Toronto 18.

Watson Jack-Hopkins Limited, suppliers of construction, mining railway and forest fire fighting equipment has appointed R. W. Chorlton as general manager and D. J. Brule as Quebec regional manager.

United Steel Corporation Limited has announced that L. F. Harrison will take charge of the operation of the Standard Steel Construction Company, a division of the corporation.

Canada Wire and Cable Company Limited, Toronto, announces the appointment of J. A. McCrodan as a senior sales representative and that of H. E. Horrocks as sales representative, northern district. Mr. Horrocks will be located in Kirkland Lake, Ontario.

Canadian Liquid Air Company announces the appointment of D. F. McLeod as manager of the purchasing and stores department.

Noranda Copper and Brass Limited has recently appointed M. A. Vachon to the position of chief sales metallurgist.

Hewitt Equipment Company Limited has appointed A. Blouin regional sales manager for Eastern Quebec. He will direct the activities of his region from Quebec City.

General Motors Diesel Limited, London, Ontario, has announced two appointments to the Mobile Training Unit to be taken across Canada. They are P. Marani, supervisor of mobile training and J. Lantagne, instructor in the training activity.

The Hydro-Electric Power Commission of Ontario has announced the appointment of J. M. Hambley as general manager. He succeeds A. W. Manby.

Herbert Morris Crane & Hoist Company, Limited, Niagara Falls, Ontario has appointed R. G. Bonneau as manager of the Company's Montreal Branch at 55 Decarie Boulevard, St. Laurent.

Vickers-Sperry of Canada Limited has appointed B. C. French as district sales manager at Toronto.

Du Pont of Canada Limited has appointed E. T. Challacombe as a technical sales representative for elastomers, which include neoprene newer synthetic rubbers and the basic ingredients of the new urethane materials.

R-O-R Associates Limited, electronics engineers, 3333 Cavendish Blvd., Montreal, announces the appointment of W. W. Hastings to their sales engineering staff.

Hewitt Equipment Limited announces the appointment of J. C. Ackle as regional sales manager for part of Montreal and North-Western Quebec and R. Moreault as regional sales manager for part of Montreal, South Shore and Eastern Townships.

Barber-Greene Canada Ltd. has announced the appointment of F. G. LeDez as manager of its Technical Services Division.

Canada Iron Foundries, Limited has appointed A. G. McNichol manager of Industrial Engineering. Mr. McNichol will make his headquarters in Toronto.

Canadian Industries Limitel has appointed Dr. S. S. Grimley as research manager. He succeeds Dr. I. R. McHaffie whose retirement was recently announced.

Spartan Air Services Limited announces that arrangements have been made with The Bristol Aeroplane Company of Canada Limited whereby V. V. R. Symonds is being released by Bristol to take over as general manager of Spartan.

Business News

Chemesco Limited of Hamilton, Ontario, has designed and built a butane and olefin liquid drier which is being shipped to a western refinery for removal of water, both free and soluble, from butane and olefin foods to an alkylation unit.

Air Reduction Canada Limited has placed on the market two new automatic units for use with Airco's Heliweld welding process. The units are specifically designed for long-run production Heliwelding applications on all ferrous and non-ferrous metals where good weld appearance is necessary or where stringent specifications must be met. For further information contact the company at 905 Hodge Street, Montreal.

Vickers Incorporated recently announced a new deceleration valve for hydraulically actuated machinery. For further information contact Gray & Kilgore, Inc., 18845 West McNichols Road, Detroit 19, Mich.

Metalbestos Manufacturing Company, Brockeville, Ont. has introduced a new chimney of double-wall steel construction designed for every fuel. The chimneys are available in 18-inch and 30-inch lengths.

Toronto Iron Works Limited announces that they have entered into an agreement with British Boiler Accessories Limited of London, England for the manufacture and sale in Canada of British Boiler Accessories Limited products, including B.B.A. steam accumulators and B.B.A. "Helitube" heat exchangers. The B.B.A. accumulator, it is claimed, saves overdriving boilers, decreases fuel and production losses due to steam pressure failure; avoids offensive smoke emission and reduces costs of operation and maintenance of boilers, stokers and burners.

International Business Machines officially opened their 704 electronic computer centre recently in Toronto. Actually, the 704 computer is a series of separate machines packed with 25 miles of wire, more than 4,000 electronic tubes and 13,000 germanium diodes. The machines are linked by the central brain which draws power and information from them and directs the work. Initial cost of the machine is around $1,500,000, but it can be rented for about $35,000 a month.

● LIBRARY NOTES

(Continued from page 104)

(Philadelphia, American Society for testing Materials, 1959. 60p., $2.25. S.t.p. no. 242.)

*SYMPOSIUM ON BULK QUANTITY MEASUREMENT

Papers discussing the use of bulk measurement devices in the petroleum industry. These include hand gage, automatic tank gages, temperature equipment, and positive displacement meters. (Philadelphia, American Society for Testing Materials, 1959. 50p., $2.25. S.t.p. no. 249.)

*SYMPOSIUM ON INSTRUMENTATION IN ATMOSPHERIC ANALYSIS

It has been recognized that continuous analysis and recording of pollutants is necessary for an adequate appraisal of the hazards of pollutants and the effectiveness of any remedial measures taken. With this in mind, the papers included deal with the development of instrumentation to analyse the atmosphere for many compounds and classes of compounds. (Philadelphia, American Society for Testing Materials, 1959. 57p., $2.25. S.t.p. no. 250.)

*FRAMES AND ARCHES

Presents a solution to the analysis of frames or arches of constant or variable cross-section which is based on the classical method and is presented in a convenient, practical form. Time required for frame analysis is considerably reduced. Over 400 condensed solutions for twenty principal types of statically indeterminate frames and arches are given, each solution applying to a particular structure anl load. The solutions allow almost limitless variation in members' shape or cross-section, and can be used in steel, concrete, and wood design. Also included are comprehensive tables and charts to facilitate the analysis of haunched frames and arches. A volume in the Engineering Societies Monographs Series. (Valerian Leontovich. Toronto, McGraw-Hill, 1959. 472p., $23.00.)

*NON-DESTRUCTIVE TESTING

A broad survey of the field of non-destructive testing is made in this volume which discusses such aspects as the production and properties of x-rays, gamma rays, radiological examination, ultrasonic vibrations and testing, surface flaw detection with and without magnetic particles, sorting of mixed materials, and miscellaneous methods of non-destructive testing. In addition there is a discussion of diffraction, safety precautions in radiological laboratories, and the interpretation and presentation of test results. (J. F. Hinsley. London, Macdonald and Evans, 1959. 495p., 75/—.)

*ELECTRICAL SAFETY

Although particularly related to British practice as exemplified in the Factory Acts, there is a considerable amount of information in this volume which is general in nature. Topics discussed include physical aspects of electricity; adequacy and maintenance; cables and lines; automatic protection; switchboards; inflammable surroundings; static electrification in relation to fire and explosion risks. (H. W. Swann. London, Macdonald, 1959. 292p., £2.)

*HELICOPTER DYNAMICS AND AERODYNAMICS

A comprehensive treatment of helicopter theory from the viewpoint of the practicing aerodynamicist and project designer. Aspects discussed are induced aerodynamics, rotor dynamics, dynamics of rotors with hinge constraint, flapping stability and blade movements in gusts, stability and control, rotor vibration, ground resonance and vibration due to rotor resonance, control loads and vibration, blade flutter and rotor weaving, and blade flexing and resonance. A feature of the volume is the recent information on the cantilever, stiff-hinged, high flapping pin offset and other advanced forms of rotor. (P. R. Payne. Toronto, Pitman, 1959. 442p., $17.00.)

*ELEMENTS OF REINFORCED CONCRETE

Featuring an approach combining theory and practical application, methods for both design and detailing are presented. Among the topics covered by the author are flexural stresses in timber, plain-concrete, and reinforced-concrete beams; bond, shear, and diagonal tension; anchorage, embedment, and anchor bolts; reinforced concrete colmuns; retaining walls; foundation design for a steel-framed building; and detailing and drafting of reinforced concrete structures. (S. S. Stern. Englewood Cliffs, N. J., Prentice-Hall, 1959. 444p., $10.60.)

*LINGUISTIC AND ENGINEERING STUDIES IN THE AUTOMATIC TRANSLATION OF SCIENTIFIC RUSSIAN INTO ENGLISH

A report on research done in the field of automatic language translation of scientific Russian into English. An extensive linguistic study of Russian literature was made in about forty scientific fields and resulted in the development of an operational lexicon of about 14,000 semantic units. This lexicon was prepared for use in a photoscopic memory device and translation system developed by the International Telemeter Corporation. Part one is concerned with the linguistic analysis of the problem while part two is concerned with the engineering analysis. (Seattle, Univ. of Washington Press, 1959. Various pagings, $10.00.)

*ADVANCED STRUCTURAL ANALYSIS

A comprehensive analysis of structural theory and its applications. A discussion of the various methods for determining deflections and for solving statically indeterminate structures is first presented, and then followed by advanced topics of current interest such as the theory of arches with reference to the deflection theory, numerical and approximate methods of analysis, torsion analysis, limit design, and temperature analysis. Special chapters deal with the basic theory and design methods of shell structures and with the use of electronic computers to solve structural problems. Throughout the book, an attempt is made to present the basic theory as completely as possible, and then to show the actual engineering applications of the theory. (S. F. Borg and J. J. Gennaro. Toronto, Van Nostrand, 1959. 368p., $8.00.)

*CONTROL ENGINEERING

Modern automatic control theory is covered at an intermediate level. Following a discussion of time response, including a development of Laplace transformations, the characteristics of a large number of control-system components are described, and design in the complex domain covered. The use of frequency-response techniques, a complete treatment of a-c carrier systems, and the analysis of systems with time lag are then presented, and followed by sampled-data systems and the statistical analysis of linear control systems. Concluding sections deal with non-linear control theory and the use of describing functions and the phase plane. (G. J. Murphy. Toronto, Van Nostrand, 1959. 385 p., $8.00.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Aircraft

Organization of a large computation in aircraft stress analysis, by A. L. M. Grzedzielski. Ottawa, N.R.C., 1959. (Aeronautical Report LR-257.)

Metods of measurement of aircraft dynamic stability derivatives, by K. Orlik-Ruckemann. Ottawa, N.R.C., 1959. (Aeronautical Report LR-254.)

Bridges

Deflections of an abutment wingwall considered as a thin trapezoidal plate, by H. J. Weiss. Ames, Iowa, Iowa Engineering Experiment Station, 1959. (Bulletin No. 185.) 50c.

Moment analysis for bridge abutment wingwalls of variable thickness, by C. L. Hulsbos and Ti-ta Lee. Ames, Iowa, Iowa Engineering Experiment Station, 1959. (Bulletin No. 184.) 75c.

Canada. Iron and steel industry.

Survey of the Canadian iron ore industry during 1958, by T. H. Janes and R. B. Elver. Ottawa, Dept. of Mines and Technical Surveys, Mineral Resources Division, 1959. (Mineral Information Bulletin MR 31). 50c.

Canada. Zinc and alloys.

Survey of the primary zinc industry in Canada in 1958, by D. B. Fraser. Ottawa, Dept. of Mines and Technical Surveys, Mineral Resources Division, 1959. (Mineral Information Bulletin MR 32.) 50c.

MEET THE AUTHORS

G. D. H. Ganong, M.E.I.C., B.Sc.E.E. '49(UNB), Engineer in charge of Hydro-Electric Production, New Brunswick Electrical Power Commission (*Electro-Hydraulic Governors at Beechwood Generating Station*).

Mr. Ganong served with the Royal Canadian Corps of Signals in W. W. II and then returned to university. He joined the Canadian General Electric Co. after graduation and the N.B.E.P.C.-Hydro-Production Division, a year later.

P. G. Fazzari, Dr.ING '49 (Milan), Canadian ASEA Electric Limited, Montreal (*Electro-Hydraulic Governors at Beech-Wood Generating Station*).

After graduating in Electrical engineering, Mr. Fazzari worked six years in research and application for ASEA of Västeras (Sweden); two years with ASEA of Brussels, Belgium; and joined Canadian ASEA in 1957, where he is at present in charge of special projects.

A. Bernups, M.E.I.C., Civil Eng. '38 (Latvia) Senior Civil Engineer, Aluminum Company of Canada, Limited, Montreal (*Mooring Dolphins for the Harbour at Kitimat, B.C.*)

After graduation Mr. Bernups worked nine years in construction and design of cement and other industrial plants. In 1947 he joined the Building Department of Simon-Carves Ltd., and worked on the design of structures for coal industry and gas producer plants. Since 1951 he has been engaged in structures design for Aluminum Smelters and Harbours. Mr. Bernups is a member of the Corporation of Professional Engineers of Quebec, and the Canadian Standards Association.

A. E. Berry, M.E.I.C., (B.A.Sc. '17, M.A.Sc. '21, C.E. '23, Ph.D. '26 — Toronto), General Manager and Chief Engineer, Ontario Water and Resources Commission, Toronto, (*Development of Water Resources in Ontario*).

After serving with the Royal Canadian Engineers in World War I, Mr. Berry joined the Ontario Department of Health as a Sanitary Engineer and was Director of Sanitary Engineering from 1926 to 1957.

Secretary-Treasurer of the Canadian Section of the American Water Works Assoc. and of the Canadian Institute of Sewage and Sanitation for almost thirty years and Vice-President of the E.I.C. 1952-54, he is also a member of the Assoc. of Professional Engineers of Ontario. He is a past president of the Federation of Sewage and Industrial Wastes Assoc.; The Fuller Award Society; The A.W.W.A.; and at present is chairman of the Pollution Control Board of Ontario and a member of the Advisory Board to the International Joint Commission on Pollution of Boundary Waters. Mr. Berry has received several awards for his activities in the field of water supply and sanitation.

H. W. Lea, M.E.I.C., B.Sc.(C.E.) '31 (McGill), Consulting Engineer, Montreal and Ottawa (*Hydraulic Problems in Connection with the Development of the St. Lawrence River*).

Mr. Lea was with the Montreal Sewers Commission for five years prior to joining Philips Electrical Works Ltd., and later Automatic Electric (Canada) Ltd. He was on loan to the Canadian Gov't as Director of Wartime Bureau of Technical Personnel, Dept. of Labour; and subsequently Co-ordinator of Public Projects, Dept. of Reconstruction and Supply. Mr. Lea went into practice as a consulting engineer in 1947, specializing in hydraulic and municipal problems. He is a member of the Corporation of Professional Engineers of Quebec; Assoc. of Professional Engineers of Ontario, Nova Scotia, New Brunswick, and P.E.I.; the American Waterworks Assoc.; the Canadian Institute of Sewage and Sanitation; and the Assoc. of Consulting Engineers of Canada.

H. M. McFarlane, BScME '37 (Queen's) MASc. '50 (Tor), Hydraulic Design Engineer, The Hydro Electric Power Commission of Ontario. (*Backwater Computations for the St. Lawrence Power Project — Part A — Hydraulic Engineering Aspects of Computations*)

Mr. McFarlane took a post graduate course in Commerce at Queen's in 1937-38, then spent four years with Trane Company of Canada, Ltd., designing heating and air conditioning layouts equipment. For three years he worked in various war industries; from '46-'50 lectured in Hydraulics at the University of Toronto; and joined Ontario Hydro in 1950. Mr. McFarlane is a member of the Assoc. of Professional Engineers of Ontario.

C. G. Gotlieb, BA '42, PhD '47 (Tor), Associate Professor of Physics and Chief Computer, Computation Centre, University of Toronto (*Backwater Computations for the St. Lawrence Power Project — Part B — Backwater Calculations on the Ferranti Digital Computer*).

During the war Dr. Gotlieb worked on the Proximity Fuse Project for the NRC in Canada and England. He has been associated with U. of T's Computation Centre since its establishment in 1948. He is a member of the Canadian Society for Computing and Data Processing, the Operations Research Society of Toronto, and the Association for Computing Machinery. Dr. Gotlieb is also co-author with J.N.P. Hume of "High Speed Data Processing" (McGraw Hill, N.Y. 1938).

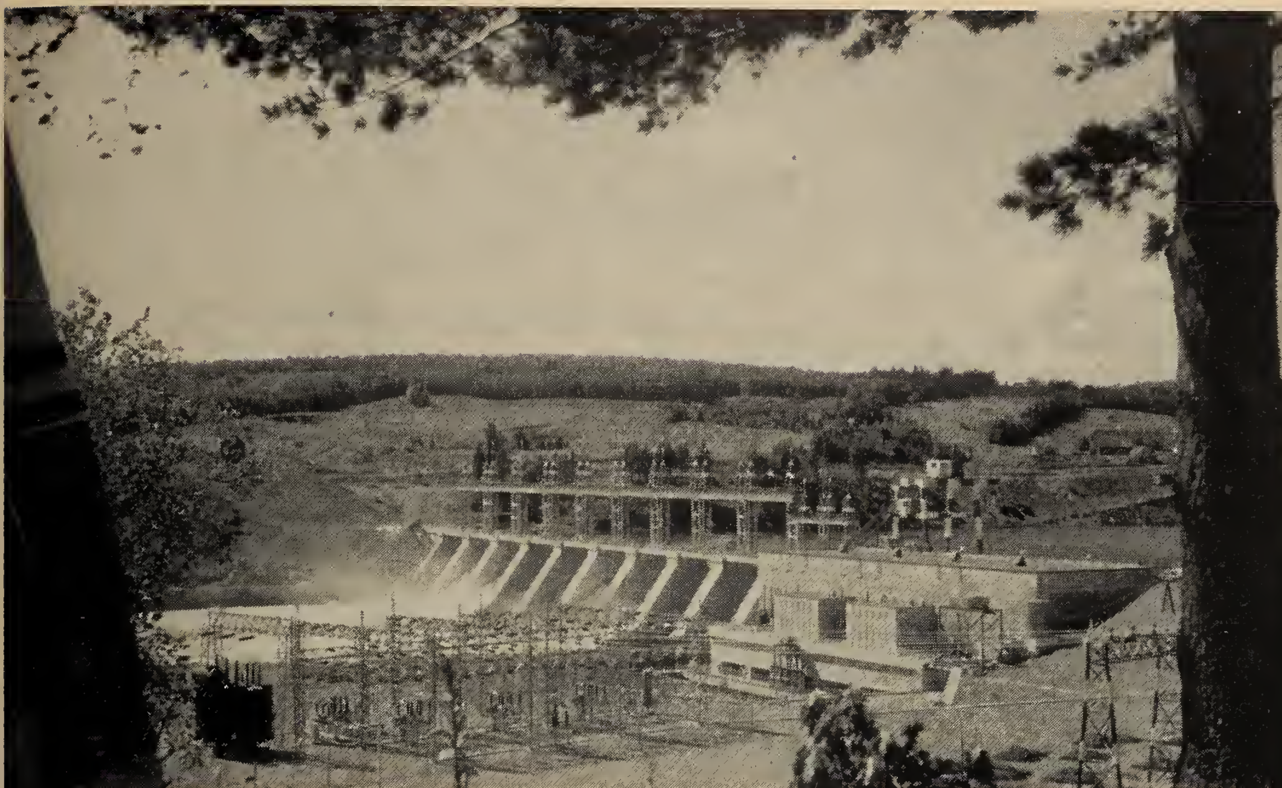
J. H. Jackson, M.E.I.C., BASc (Civil) '47 (Tor), Construction Manager of Otter Rapids Project, Hydro Electric Power Commission of Ontario (*The St. Lawrence Power Project — Rehabilitation — A Review of Major Features*).

Mr. Jackson has been with the Ontario Hydro since graduation. He has been Construction Engineer — Pine Portage Development; Division Construction Superintendent — Sir Adam Beck NGS No. 2; Generation Construction Engineer — Toronto; and Rehabilitation Engineer — St. Lawrence Power Project.

Mervyn Woods, B.A., LL.B. (Sask.) LL.M. (N.Y.), Q.C., Professor of Law at the University of Saskatchewan (*A Professional Outlook*).

Mr. Woods practiced law eleven years in Saskatoon and was made Queen's Counsel in 1956. He served six years with the R.C.N.V.R. during the Second World War and was awarded an M.B.E. for war services.

"Electro-Hydraulic Governors at Beechwood Generating Station". G. H. D. Ganong, M.E.I.C., examines starting mechanism in the main valve cabinet. He is accompanied by Cecil Jackson, chief operator at Beechwood.



Shown above is a view of the New Brunswick Electric Power Commission's 72.000 K.W. hydroelectric generating station at Beechwood on the St. John River. Plans are at present under way for the future installation of an additional 36,000 K.W. unit.

ELECTROHYDRAULIC GOVERNORS AT BEECHWOOD GENERATING STATION

System governing requirements

THE NEW BRUNSWICK Electric Power Commission owns and operates five hydro and four thermal generating stations. The power produced represents about 90% of the provincial requirement and is distributed throughout the province via a 138 kv. and a 69 kv. transmission system.

The Commission's newest and largest hydro development is situated on the Saint John River at Beechwood, whence it gets its name. The Beechwood site was selected from a number of possible choices as the second step in the power development of the Saint John River Basin. Altogether there is a potential of about 434,000 kw. of undeveloped capacity in five sites exclusive of Beechwood.

The load growth today throughout the utility industry is, of course, also being felt by the N.B.E.P.C. Consequently, system planning indicated previous to construction, that this entire potential would probably be required to meet the demand well within the life of the Beechwood station. In addition, it was felt that as the system grew, interconnections would be made with neighbouring utilities. As a matter of fact, the Commission has completed interconnections with The Maine Public Service Co. and The Eastern Maine Cooperative since the completion of the Beechwood station. In addition interconnections have been made with a number of internal power producers. Discussions have taken place with utilities in the Province of Quebec and an interconnection with utilities in Nova Scotia is under construction.

With these considerations in mind, it was anticipated that the Beechwood station would be required to serve initially as a peaking plant and system frequency regulator during periods of low river flow and as a base plant during the higher run-off periods. As the development of further power sites and interconnections progressed, the regulating duty of the plant would shift from a flat frequency requirement to regulation of local or remote tie line power either independent of frequency variations (Flat Tie Line Control) or with frequency biased regulation (Tie Line Bias Control). In other words, a governor was required at Beechwood which could be easily adapted to all these regulating requirements.

The Beechwood development represents approximately 23% of the total generation of the N.B.E.P.C. system with its interconnections. The nature of the system load varies from time to time and from season to season. It is, therefore, desirable to have an accurate and readily available method of altering governor characteristics to match system conditions. The ease of adjustment and the possibility of operating the entire station through a single set of controls is a distinctive feature of the ASEA electro-hydraulic governor. Controls of damping, output and frequency for each machine are available on the bench board. A finger tip motion through an angle of about 270° will change the loading from zero to full capacity. The joint operation feature brings the same finger tip control of the entire station to the operator's desk making station frequency, station output and regulating capacity available for adjustment or alteration as the situation may require without the necessity of moving about the control room.

The above considerations together with the successful application of the of the ASEA governor on the large integrated Swedish system led the designers of the Beechwood station to recommend its use to N.B.E.P.C.

The governor equipment

The governor equipment consists of the following main elements:

The Permanent Magnet Generator;

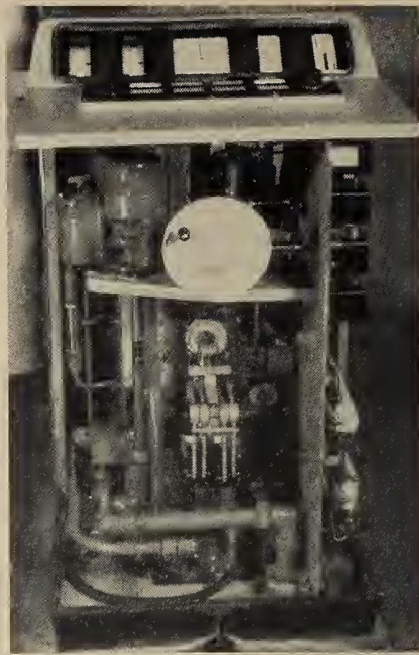
The Regulator Cubicle, containing the electric components, such as the speed sensing circuit, the electric amplifier and various protective relays;

The Actuator cabinet, containing the mechanical parts such as the Transducer, the hydraulic amplifier and associated devices;

The Main Valve Cabinet, controlling the oil admission to the Turbine Servomotors;

The Control switches and selectors to be incorporated in the Control board.

The design and operation of the principal regulating elements are outlined below, followed by sections dealing specially with the control and protective features characteristic of the ASEA Electrohydraulic Governors.



Actuator cabinet with top down showing gauges.

(a) *The Permanent Magnet Generator* — The primary necessity in any governor is, of course, a device capable of supplying the governor proper with an accurate indication of speed. The ASEA governor uses a 60

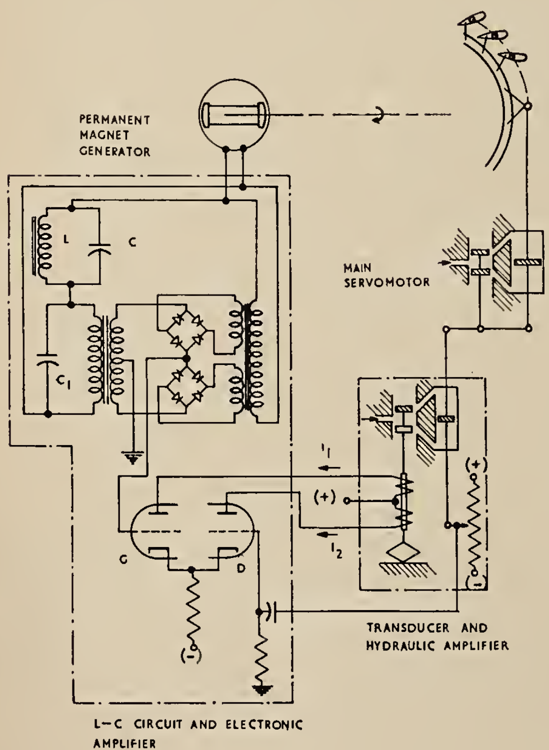


Fig. 1 ***left:*** **Governor schematic**

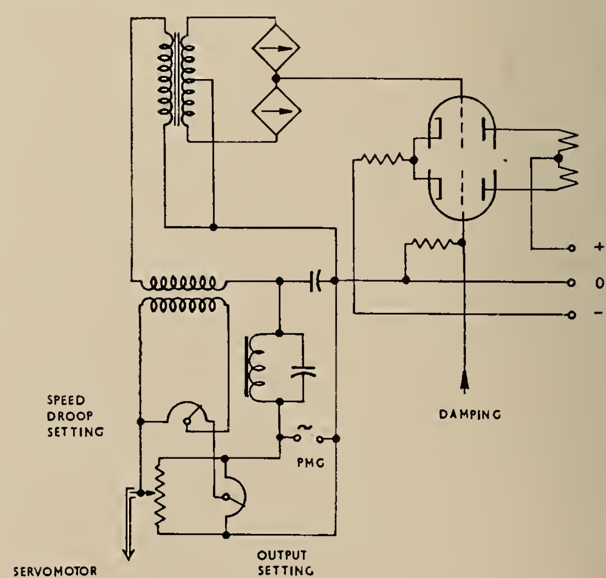
Fig. 2 ***below:*** **Output and speed droop control circuit**



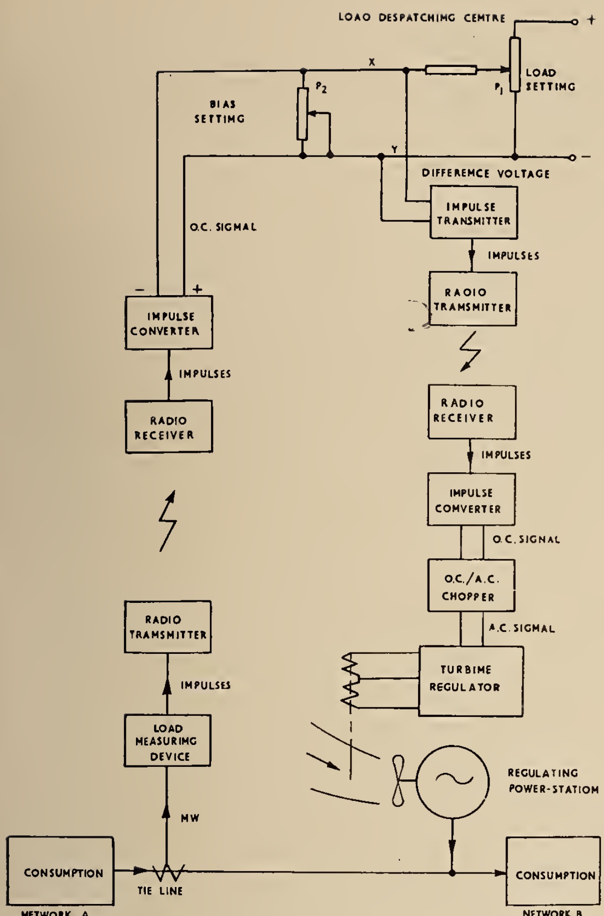


Fig. 3 Schematic for tie line bias control

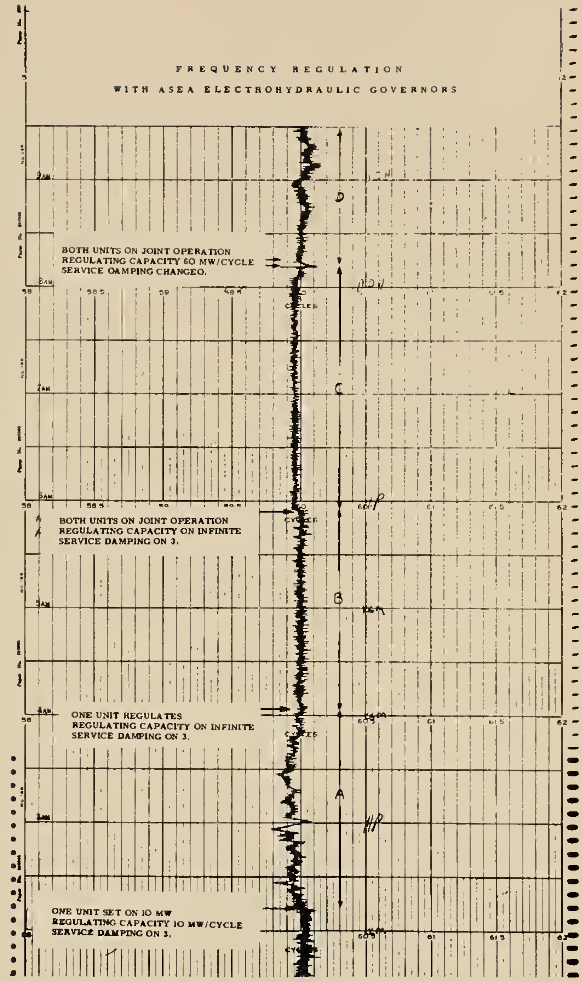

Fig. 4 Frequency chart

cycle threephase Permanent Magnet Generator for this purpose. This PMG is wound with the same number of poles as the main unit. The rotor is of salient pole design and is split to facilitate mounting on the main shaft.

(b) *The Speed Sensing Circuit* — The speed sensing component is a parallel resonant (L—C) circuit tuned at 60 cycles. The PMG frequency is applied to this circuit (see Fig. 1) and as long as it stays at exactly 60 cycles no current will flow through it, the current through the inductance L being equal and opposite to the current through the capacitor C.

If the frequency increases the capacitor current increases and inductance current decreases. The resultant current when passed through another capacitor C_1 produces a voltage drop across C_1 in phase with the PMG voltage. Similarly a drop in frequency produces a voltage drop across capacitor C_1 180° out of phase with the PMG voltage.

In order to make use of this phase angle difference as a governing impulse it must be used to produce a d-c. voltage of suitable polarity. This is achieved by two phase-sensitive rectifiers R. These rectifiers are biased by the PMG voltage and so connected as to act as switches. When the voltage across C_1 is in phase with their bias voltage the rectifying circuit will produce a negative voltage while if the C_1 voltage is 180° out of phase the rectified voltage will be positive. This voltage has thus a polarity depending upon whether the frequency is too low or too high and its amplitude will be proportional to the difference between the actual and the resonant frequency.

(c) *The Electronic Amplifier* — We have shown in the preceding paragraph how a voltage dependent on the frequency deviation is obtained; the next step is to amplify this signal to a suitable power level, introduce the necessary feedback, and use it as a governing signal in the transducer. However, before describing the amplifier it must be pointed out that the frequency signal is only one of the signals that are fed into the amplifier.

A signal dependent upon the output of the unit and the speed droop is superimposed on the frequency signal when the unit is running in separate operation. When in joint operation a signal representing the total output of the power station, a load division signal and the regulating capacity signal (equivalent to the inverse of the station speed droop) are added. Other signals are superimposed to allow the unit to run as a synchronous condenser. Any other variables whether measured locally (e.g. water level) or transmitted through a remote control link (such as a tie line output) can be introduced as regulating signals, the sole condition being that each can be represented by a proportional 60 cycle voltage. These additional control signals are simply introduced into the circuit of the phase-sensitive rectifier by transformers connected in series with the transformer for the frequency signals.

Such control signals can be obtained in a relatively simple way and we will describe the arrangement for the output control. An induction device, fed by the PMG voltage, is built into the actuator cabinet and will produce a voltage dependent on the position of the wicket gates and, therefore, proportional to the output of the unit. The output setting device is a potentiometer fed by the same PMG voltage. The difference between the voltage set on the output setting potentiometer and the voltage from the induction device (representing the output of the unit) is the desired output regulating signal.

To adjust the speed droop, this output regulating signal can be reduced in an adjustable proportion by passing it through another potentiometer before feeding it into the amplifier. If the whole output regulating signal is admitted into the amplifier (maximum speed droop) the governor performance will be very dependent on the output. Reducing the speed droop means adjusting the corresponding potentiometer so that the influence of the output is decreased until, at zero speed droop, no part of the output regulating signal is admitted and the governor becomes dependent upon the frequency only. The same principle is applied to regulation by other variables. In water level regulation the voltage from the output setting potentiometer would be replaced by a voltage proportional to the water level. In tie line regulation a voltage dependent on the power flow of the line would substitute the output setting potentiometer and so on. The additions required to adapt the governor to these other kinds of regulation are always of a very minor nature.

The amplifier proper contains a double triode symmetrically connected as a balanced differential amplifier, (see schematic circuit on Fig. 1). The plate current of the tubes will flow through the two halves of the transducer solenoid and cause it to move in one or the other direction, depending on which current prevails. At rest, i.e. with both grids at zero potential, the plate currents of the two halves of the tube are the same and, since they act in opposite directions on the transducer solenoid, the resultant ampere turns and force will be zero. The cathode resistor is so chosen that the voltage drop across it equals the negative d-c. supply.

When a small voltage signal from the sensing circuit alters the grid potential of triode G, its plate current I_1 will change. The current I_2 in the triode D (its grid still at zero potential) will change in the other direction so as to maintain the sum $I_1 + I_{r2}$ constant; this is because the total cathode current $I_1 + I_2$ is mainly determined by the value of the cathode resistor and the negative d-c. supply. The difference $I_1 - I_2$ will now act upon the transducer solenoid and cause it to move; the hydraulic amplifier and wicket gates will follow.

A d-c. voltage of opposite polarity on the grid of tube D would have had the same result due to the symmetry of the arrangement. If triode G is used to amplify the governing signal, triode D can conveniently be used for feedback or damping.

The damping circuit fulfils, in the electric governor, the same function as the dashpot in a mechanical governor, that is it prevents overshoot and gives a smoother regulation. A d-c. voltage proportional to the movement of the actuator rod (which in the ASEA governor is precisely followed by the wicket gate servomotors) is used to charge a capacitor and fed into the grid of tube D; the electrical connections are such that the current induced in the triode (and transducer solenoid) will counteract the movement that has caused it. In short, a governing impulse through triode G will cause a movement of the actuator rod and gates that through the damping circuit and triode D will work against the original impulse and try to stop the movement before any overshoot appears. The damping circuit is only shown as one capacitor and one resistor on the schematic of Fig. I, but it is actually somewhat more complex. Various selectors are provided to permit choice over a very wide range of the voltage to be fed into grid D and the discharge time of the capacitors of the circuits. By suitably selecting the size of the damping voltage and the length of time during which it is allowed to act on the grid, it is possible to obtain very fast and stable regulation. Further, the damping can be changed at will during on-the-line operation without any disturbance. When running at no-load a considerably higher damping is required than when running in parallel with other machines. The change over to no-load damping is carried out automatically and instantaneously when needed.

The components of the governor described above are purely electric and are housed in the regulator cubicle together with protective relays and other electric devices (such as equipment for spinning reserve operation) that may be connected with the governor. The location of this cubicle can be chosen independently of the location of the other elements of the governor equipment, since the only connections between them are electrical. In Beechwood the governor cubicle is placed beside the voltage regulator equipment.

(d) *The Transducer and the Hydraulic Amplifier* — The hydraulic and mechanical parts of the governor are placed together in the so called actuator cabinet on the generator floor. This contains the transducer, the hydraulic amplifier as well as indicating gauges and facilities for hand control. The actuator cabinet is the link between the purely electric components of the governor and the relay valves which in turn act on the servomotors.

The transducer, as mentioned previously, consists of a small solenoid that can move in a permanent magnetic field and controls a small pilot valve. The whole assembly is machined with the utmost precision and designed for maximum reliability and sensitivity. There are no bearings and the movable parts are positioned by one spring at one end and by oil streams at the other end. This design eliminates both friction and wear. The d-c. current from the electronic amplifier causes the transducer solenoid to move in the magnetic field and displaces the pilot valve from its neutral position. This valve then admits oil to a hydraulic amplifier that finally determines the movement of the actuator rod. This rod is connected to the pilot valve in the main valve cabinet and decides the position of the turbine servomotors. A position indication is obtained from the actuator rod and is used both for damping and as a restoring signal for the output. While the speed of response of the transducer to governing impulses is inherently very high, the operating times of the hydraulic amplifier are adjusted so as to be only slightly smaller than the main servomotor operating times.

The gate limiter is designed as a mechanical device to limit the travel of the actuator rod. When hand operation is desired, the gate limiter is used as a gate setting device.

Another important detail is the actuator lock, a cam and ratchet device that locks the actuator rod and thus puts the governor temporarily out of action.

For operating convenience the actuator cabinet contains the brake controls and various gauges and indicators, i.e.

Speed meter
Governor balance meter
Gate and gate limiter position
Accumulator and actuator oil pressure
Servomotor oil pressure

While the transducer is of ASEA manufacture, the hydraulic amplifier and the rest of the actuator cabinet has been supplied by Messrs. KMW.

(e) *The Main Valve* — The main valve is the final stage of amplification. Governing signals originating at the transducer are amplified in the actuator cabinet and are transmitted to the main valve pilot through the elastic actuator rod. Displacement of the main valve pilot causes oil under pressure to be admitted to the unit servomotors through the main valve. The restoring cable recentres the pilot as soon as the wicket gates have reached the required position.

The main valve cabinet also contains the blade valve. This is operated through a cam follower which follows the wicket gate position.

Maximum efficiency is obtained when the blade gate relation follows the pattern ascertained through Index tests. The relationship alters appreciably with a change in net head, consequently a three dimensional cam is provided to produce the required relationship through a head range from 45 to 65 ft.

At start, however, the relationship set forth by the cam surface does not give the maximum starting torque. A starter device is, therefore, provided to make the turbine start with fully open blades and to bring back the blades to the optimum efficiency position after a few seconds. An additional three-way solenoid insures the correct positioning of the blades while running as spinning reserve.

The start and stop solenoid for the turbine is also located in the main valve cabinet. It acts directly on the pilot valves and is, therefore, completely independent from the governor itself. The main valve cabinet is also of KMW manufacture.

Control Features

Control of the turbine may be exercised manually from either the actuator cabinet located on the generator floor or from the control room where remote indications of speed, gate and gate limiter position are available.

The controls for automatic operation are located on the benchboard or control panel in the control room together with the other voltage regulation and circuit breaker controls of the unit. They are:

Frequency setting knob;
Output setting knob;
Damping switch and selector;
Joint operation switch;
Actuator lock switch.

The unit is started up by opening the gates with the gate limiter (manual control). At about 85% of rated speed the governor will automatically take over and bring the unit to the speed set on the frequency setting knob; the unit can now be synchronized. After closing the line breaker the required output is set on the output setting knob and the damping of the governor can be changed from its no-load value to a suitable service value.

If it is so desired, the entire station may be operated as a single unit from the operator's desk. This feature of the ASEA governor is called "joint operation" and Frequency, Regulating Capacity and Station Output controls are within easy reach on the operator's desk.

In our particular case the load is shared equally between the machines during "joint-operation" since the units are similar. However, a different load division could be arranged if desired. While on "joint-operation" the damping of the two units may be either set to the same value, thus allowing a maximum of regulating capacity for both fringe and sustained load changes or, they may be set so that one unit responds to fringe swings and the other to sustained load changes. However, they will both return to the preset load division within a very short time.

Before being synchronized the transient behaviour of the unit was determined by the no-load damping. (This damping is chosen and set with the aim of obtaining quiet and stable running at no-load and at load rejection). It is, therefore, a considerably higher damping than what would be required when running in parallel with the system. After synchronizing, the link with the system contributes towards damping whatever oscillations may be induced in the units by load or frequency variations and so a considerably lower degree of damping can be used on the governor. The service damping is, therefore, switched in to substitute the no-load damping and its value may be selected from a wide range and changed at will during operation.

On conventional mechanical governors there is one dashpot for the service damping and its characteristics cannot easily be modified. This new flexibility of damping, as afforded by the electrohydraulic governor, has been found very valuable and is extensively used to adapt the performance of the units to the varying requirements of the system.

The actuator lock is another convenient feature of this governor. It is possible to lock the actuator mechanically and thus hold the gates in any position, irrespective of subsequent governor signals. If the system frequency should deviate more than 0.5 cycle from the set value a frequency relay will release the actuator lock automatically and restore the governor control.

The spinning reserve—synchronous condensing feature of the Beechwood development is perhaps unusual and, for that reason, may be of interest. The control circuits are so arranged that turning a switch labelled "Motoring—Generating" places a closing signal on the electric-hydraulic transducer. This results in the wicket gates being closed and held closed as long as the signal is maintained. In addition air is admitted below the head cover depressing the water in the draft tube to a point below the turbine runner. The runner blades go to the fully closed position through the action of a three-way solenoid valve located in the main valve cabinet. All losses are, therefore, reduced to a minimum.

In the event of a system disturbance resulting in a frequency dip below a predetermined minimum, a frequency relay operates placing an opening signal on the transducer and closing the air inlet below the head cover. The wicket gate will then go to full load position unless prevented from doing so due to system frequency correction. The unit is considered spinning reserve even though it is being used for condensing purposes since it will pick up to full load within about six seconds after a frequency dip has been experienced.

Protective features

Since the PMG gives a very reliable and exact indication of the speed of the machine, an electromagnetic relay is used as overspeed switch. This has the advantage that the operation of this relay and connected circuits can be checked at will by applying a suitable voltage without having to raise the speed of the machine. This must be considered as an advantage over mechanical overspeed switches that are practically never tested after installation.

Other speed relays are used for the brake circuit and creep indication. Magneto electric relays with very low power consumption are used for this application; they have a very high accuracy and their setting can be altered over a considerable range. There is no limit to the number of relays that can be installed or added later and their operating values can be chosen and altered at will. Furthermore, these relays can be tested independently from the PMG.

The governor equipment is self-protecting to the greatest possible extent. Relay protections are designed so that a minimum of disturbance will result from a failure of any component part. The protective functions included in the Beechwood equipment are:

(1) Abnormal PMG voltage;
(2) PMG overload;
(3) Amplifier failure;
(4) Governor hunting;
(5) Low oil pressure;
(6) High and low frequency;
(7) Automatic damping change over.

In the event of a regulator fault, such as tube failure or loss of PMG output, the actuator lock is automatically applied through one of the above relays.

If at the same time or subsequently the PMG frequency should become appreciably higher than normal, a signal is applied to the transducer to guide the gates to no-load position.

If, while on system regulating duty, the unit breaker should be tripped due to either line or generator protection, the governor concerned is automatically disconnected from joint operation and the damping is increased to the preset no-load value.

The stop-start solenoid operates directly on the main valve and is located in the main valve cabinet. It is, therefore, independent of the transducer and will act directly on the hydraulic system should it be so required through the operation of any associated unit protection device such as loss of excitation or generator differential protection.

In the electric circuits no fuses are used. All circuits are protected by no-fuse breakers with instantaneous and thermal overcurrent relays. These breakers are provided with an alarm contact to attract the operator's attention immediately upon the failure of one circuit. As mentioned, the governing and the protecting circuits of the PMG are electrically separated. Auxiliary DC is used for the operating and indicating circuits of the governor equipment. While the operating and protective circuits of the governor are dependent upon the auxiliary DC supply, the regulating circuits are fed only by the PMG. A momentary failure of either of these circuits will not affect the output of the power station.

Operating experience

The Beechwood governors have now been in operation approximately a year and a half, and have performed in a very satisfactory way. This refers both to the performance and to the maintenance record.

The primary objective of good frequency regulation has been achieved as illustrated in the frequency chart shown on fig. 4.

On the first section from the bottom (marked A) the frequency is shown with one unit connected to the system and set for a regulating capacity of 10 Mw./cycle. At this value the unit runs practically at a constant output and the governor is made rather insensitive to the frequency variations. The frequency is controlled by other units on the system and the frequency variations are rather noticeable.

On the second part (marked B) of the chart the regulating capacity has been increased to infinite. (This is equivalent to saying that the speed droop is zero). The unit is then on flat frequency control and it can be seen that the frequency variations stay within ±0.05 of a cycle. It should be noted that these variations are the transient variations due to the load changes. The centre line around which the frequency oscillates has a constant value and no deadband can be detected within the accuracy limits of the measuring instruments.

On the third section (marked C) of the chart both units are connected to the system in joint-operation and regulate the frequency with infinite regulating capacity. The band of the transient frequency variation has been narrowed down to about ±0.03 cycles.

In the fourth section (marked D) both units have been kept on the line but the regulating capacity has been reduced from infinity to 60 Mw. per cycle. It is readily seen that the frequency now fluctuates considerably following the load variations.

From the description of the governor design and control characteristics, it is apparent that it differs considerably from the conventional mechanical type. The most salient differences are:

the possibility of setting the output independently of the frequency setting;

the possibility of running the units in joint-operation;

the flexibility attained through having adjustable speed droop of each unit when they are in separate operation and in addition adjustable regulating capacity (the inverse of speed droop) of the whole power station in joint operation;

the possibility of varying the transient behaviour of the units through the damping adjustment.

We wish to point out, however, that although the ASEA electrohydraulic governor offers greater flexibility than conventional governors, the station operators' task has not been made more complex.

The operating staff soon became familiar with the additional features afforded by these governors. The use of these controls is now a matter of routine and it would probably be difficult to satisfy the operators with a governor lacking these novel features.

As far as maintenance is concerned, it can be safely stated that there is none for the electrical part. Wherever possible induction devices have been used instead of potentiometers, in order to eliminate a possible wear problem. The contact wear on relays is quite insignificant, due to the very ample design. For the hydraulic part, the filters are periodically cleaned, but apart from this, no other measures are recommended nor have been required.

Summing up, in the light of the operating and maintenance experience of this first year and a half of operation, it can be said that the ASEA electrohydraulic governors have fulfilled all the expectations and have completely justified the bold decision of the New Brunswick Electric Power Commission in installing this new device.

MOORING DOLPHINS FOR THE HARBOUR OF KITIMAT

A. Bernups, M.E.I.C., *Senior Civil Engineer,*
General Engineering Department, Aluminum Company of Canada, Ltd.

Application of large diameter high tensile, low alloy tubular steel piles made possible the design and construction of flexible type mooring dolphins for Kitimat Harbour. The flexibility of long vertical piles was utilized to absorb the berthing impact energy of large cargo vessels and also to resist the static mooring loads. Unconventional pile handling and driving methods facilitated the execution of work in the harbour with 20 ft. tidal variations. Simplicity of the design and a careful scheduling of all construction phases were two governing requirements.

GROWING ALUMINUM smelter capacity necessitated in 1956 the planning of additional harbour facilities at Kitimat. The first harbour structure built at the early stage of the development was a temporary timber pile wharf which served mainly for plant construction purposes. Subsequently this wharf was used for handling coastal traffic for Kitimat Townsite. A reinforced concrete caisson type wharf was constructed in 1953, providing berthing space for ocean-going cargo vessels up to 30 ft. draft. This structure which is 760 ft. long is known as Terminal Wharf No. 1 and is equipped to handle all inbound shipments of raw material as well as outbound shipments of metal.

Fig. 1. shows the existing and planned possible future harbour development, including the mooring dolphins, installed in 1958.

Requirements

At the end of 1956 the Terminal Wharf already had a berth occupancy figure of 40% and with additional new potlines under construction it was necessary to plan an extension for the berthing of cargo vessels.

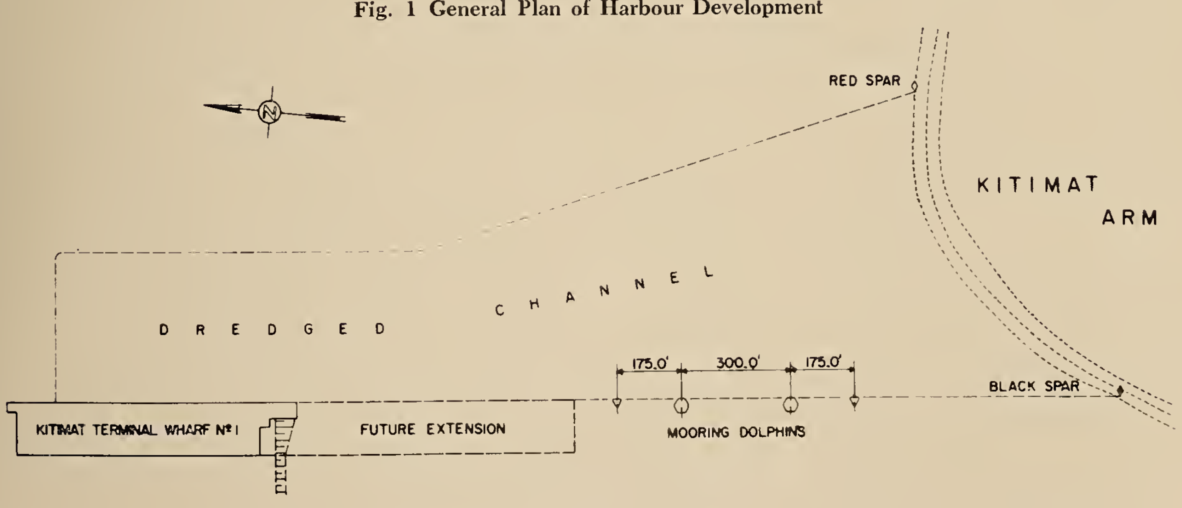
Fig. 1. shows that the original wharf was designed and located so that a future extension southward was possible. However, an expensive wharf extension did not appear economically justified in 1957; therefore, to cope with the immediate future requirements, an installation of mooring dolphins was decided upon. The dolphins had to provide safe mooring for a vessel arriving in the harbour while the wharf was occupied. For any cargo handling operations the vessels had to be moved to the Terminal Wharf as soon as a berth became available.

From consultations with officials of Saguenay Shipping Ltd., who operate most of the ships using Kitimat Harbour facilities, the following requirements were established. Two main dolphins or "strength dolphins" were to be designed to resist impact forces resulting from the berthing of a ship. The same structures were to resist afterwards the pull of the ship's spring and breast lines. Apart from that it was found necessary to install two "end dolphins" to hold the bow and stern mooring lines after the berthing of the ship and to provide some additional resistance along the line of dolphins.

Parallel with the design of the mooring dolphins, the planning of the ultimate harbour development was advanced and the dolphins were located to allow for a future Terminal Wharf extension of 750 ft. As shown in Fig. 1., the dolphins are situated south of the wharf at the entrance to the dredged harbour basin and only some 500 ft. away from the deep water of Kitimat Arm.

The prevailing winds are nearly due north or due south, following the direction of the valley. This factor had already been considered in the original harbour design. The mountain ranges offer some wind protection, particularly from the West; however, wind velocities up to 60 m.p.h.

Fig. 1 General Plan of Harbour Development



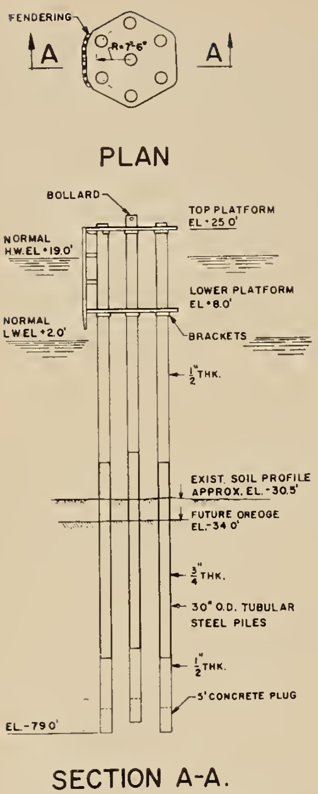


Fig. 2 *above:* Main Dolphin

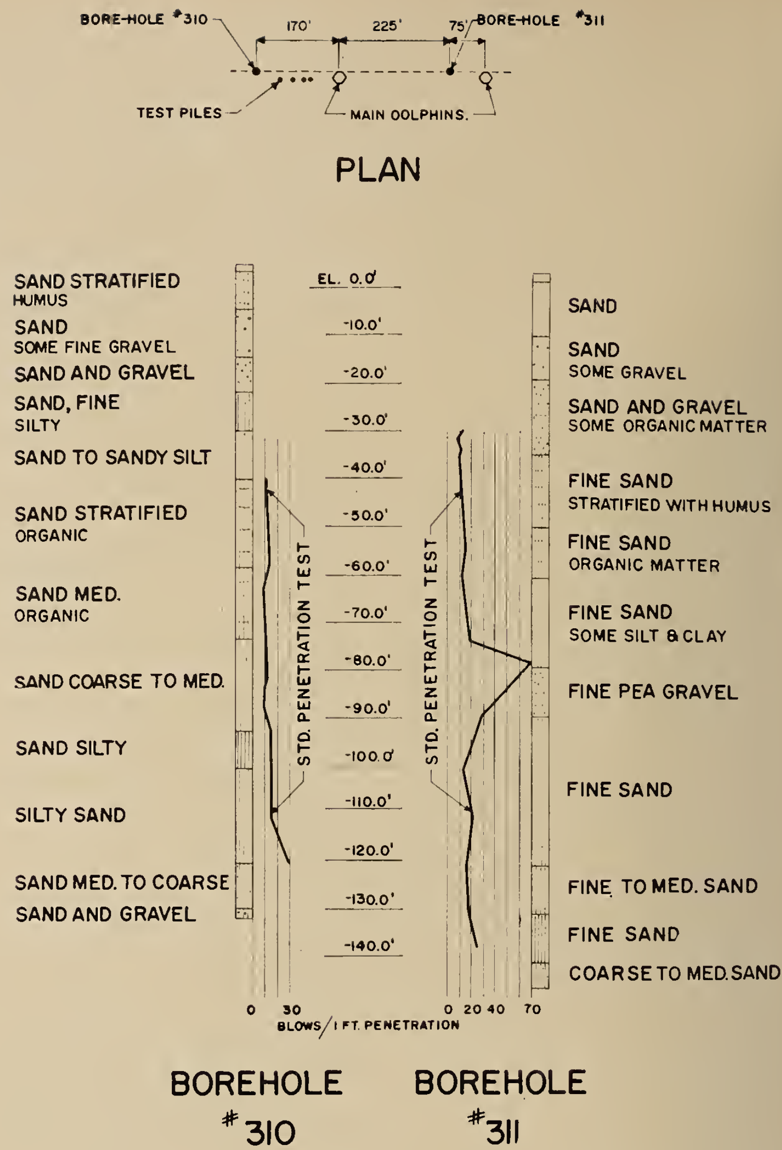

Fig. 3 *right:* Soil Stratigraphy and Penetration Resistance

have been recorded and during several storms velocities up to 80 m.p.h. have been estimated. The effect of such winds had to be considered.

The axis of the installation was selected so that the fendering of the dolphins lines up with the fendering of the wharf. The centre-to-centre distances of the dolphins were chosen to allow for mooring of vessels from 10,000 to 16,000 T.D.Wt.

As the basis for the design the following data were to be used:

Load displacement of ship, representing the moving mass of a 16,000 T.D.Wt. cargo vessel: . . . . 24,000 sh.t.
Maximum angle between ships approach line and line of dolphins . . . . 15°
Maximum approach speed of a vessel normal to the dolphins . . . . 0.5 ft/sec
Wind pressure . . . . 20 lb/sq.ft.

Selection of Dolphin Type

Prior to the selection of mooring dolphins a mooring buoy alternative was investigated. The depth of water at the possible location of a mooring buoy in Kitimat Arm is about 60 fathoms and the bottom consists of silt. Detailed studies showed that the ground anchorage and the methods for laying the ground tackle would be complicated. This alternative also had the disadvantage that extended pilot service would be required while the ships were at the anchorage, some 5,000 ft. away from the wharf. The scheme was abandoned finally.

Several dolphin arrangements and types of pile construction were studied before the final design was adopted.

The construction methods had to be as simple as possible to cope with the extreme tide conditions varying between elevations of +0.58 ft. and +23.08 ft.

Pressure creosoted timber piles were considered first but it was soon realized that the scheme was not very feasible, because of the great number of batter piles required to resist the impact and wind loads. Also a concrete capping would be required to engage the resistance of all dolphin piles. Such concrete work would be very difficult because of the tide conditions.

Steel sheet pile cells 27 ft. in diameter, penetrating the soil for some 40 ft. and gravel filled above the bed elevation, offered reasonable factors of safety but the costs involved were found to be high compared to other choices.

Further studies revealed that flexible vertical steel piles could be used with advantage to absorb impact energy of a vessel, although this flexibility has some disadvantage for resistance to static mooring loads.

The selection of this dolphin type was influenced also by technical articles, describing successful flexible dolphin installations of similar type at the Port of Amsterdam.

As shown in Fig. 2., the final design used long, vertical, tubular steel piles as flexible members to absorb the ships' kinetic energy.

Seven piles were used for each main dolphin and three piles of the same type were used for each of the end dolphins. Two horizontal steel platforms for each dolphin were introduced to provide the tie between the piles. As the platforms are supported loosely on the brackets at the piles, the lateral loads do not cause any appreciable axial pile loads. The tubular piles offer equal resistance to lateral forces from any direction and each pile is acting essentially as a long cantilever. It was proved later that the fabrication and erection of steel platforms was a comparatively easy job, considering the tidal conditions, while the handling and particularly the driving of tubular piles involved some problems.

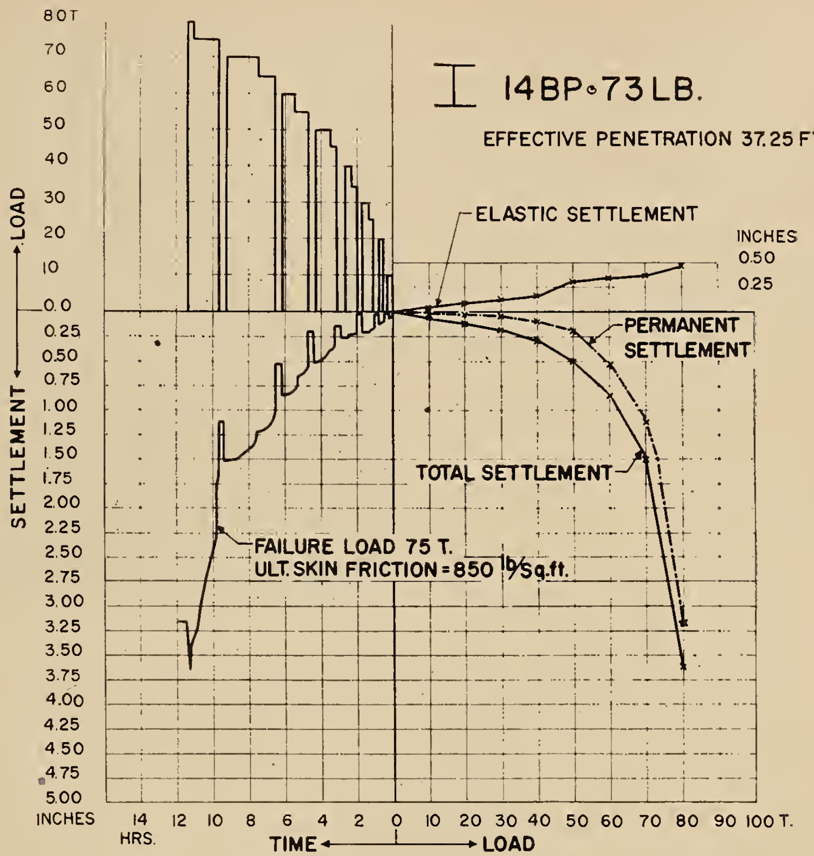

Fig. 4 Pile Loading Test Data

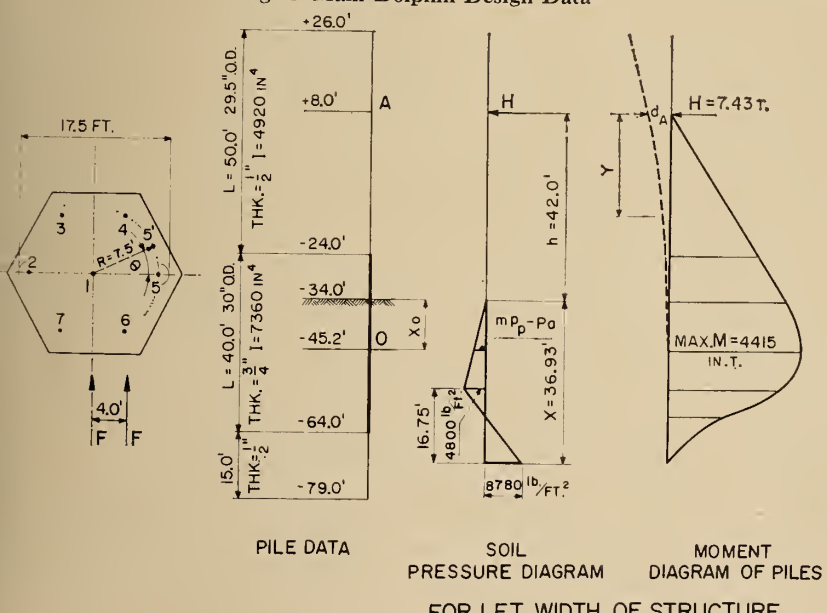
Soil conditions

The topography of the Kitimat area is characterized by high peaks and low valleys. A large delta area with tidal flats has been formed by the Kitimat River which empties into a fjord known as Kitimat Arm. The floor of this valley is at great depth and bedrock beneath the tidal flats is covered by post-glacial sediments, varying in thickness up to a maximum of 450 ft. The deposition of these sediments has been affected by fluctuating coastline and ocean levels.

Extensive soil investigation was carried out in the harbour area in 1952 before the construction of the Terminal Wharf. Altogether twelve borings were made at that time to determine the soil profile, the penetration resistance, and to obtain the necessary soil samples for laboratory testing. The borings covered the area of the initial wharf site as well as the future wharf extension area and the site of the present mooring dolphins. Fig. 3. shows stratigraphy and penetration resistance of soil from the two borings nearest to the site of the dolphins.

The soil below the dredged bottom elevation—31.0 ft. can be classified as complex granular non-cohesive material, consisting mainly of fine silty sand of medium density. Consolidated undrained tests indicated an angle of internal friction varying from 20° to 43°, with an average of 30°. Most of the soil samples had little or no cohesion with a maximum value of 1,000 lbs. per sq. ft. The in-situ dry density of the soils varied between 80 and 95 lbs. per cu. ft., while the water content varied between 30% and 43%.

Fig. 5 Main Dolphin Design Data



Pile loading tests were carried out in the harbour area in 1957, with the main purpose of determining the permissible pile loads for a possible future wharf extension on piles. The tests supplied also some information for the dolphin pile design.

A characteristic time-load-settlement graph for one of the test piles is shown in Fig. 4. Altogether six loading tests were carried out with four piles.

Ultimate loads yielded average skin friction resistances of 750 lb. per sq. ft. for 14 in. H piles and 1,000 lb. per sq. ft. for a 12 in. diameter tubular steel pile with a conical tip, assuming that in both cases the loads were transmitted to the soil entirely by skin friction.

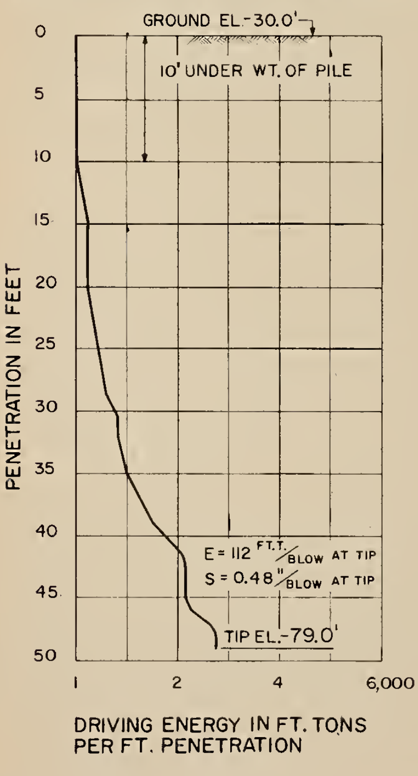
It was apparent that the shape of the pile had some effect on the pile resistance. While the H pile was merely cutting the soil, the cylindrical pile acted as a soil displacing pile. It was further observed that an increase in penetration depth of the piles within the same soil layer did not produce a proportional increase in driving resistance. This leads to the conclusion that the prolonged driving affected the pore pressure of the surrounding soil and reduced the shear resistance of it. On the other hand, piles regained driving resistance after some period of rest and nearly became "frozen". This was evidenced during the redriving of piles and after field splicing of piles.

Apart from supplying information on possible frictional values, the tests gave an indication of the difficulties which could be expected when driving large diameter piles. Suitable equipment had to be chosen to overcome the frictional and end resistances of the piles and the driving methods had to be planned to ensure continuous driving for each pile. Splicing of piles during the driving was ruled out completely because of the danger that they might become "frozen".

Design of Dolphins

The design took into account the future planned dredging of the harbour basin down to El.-34.0 ft.

Fig. 7 Diagram of Pile Driving Energy Used



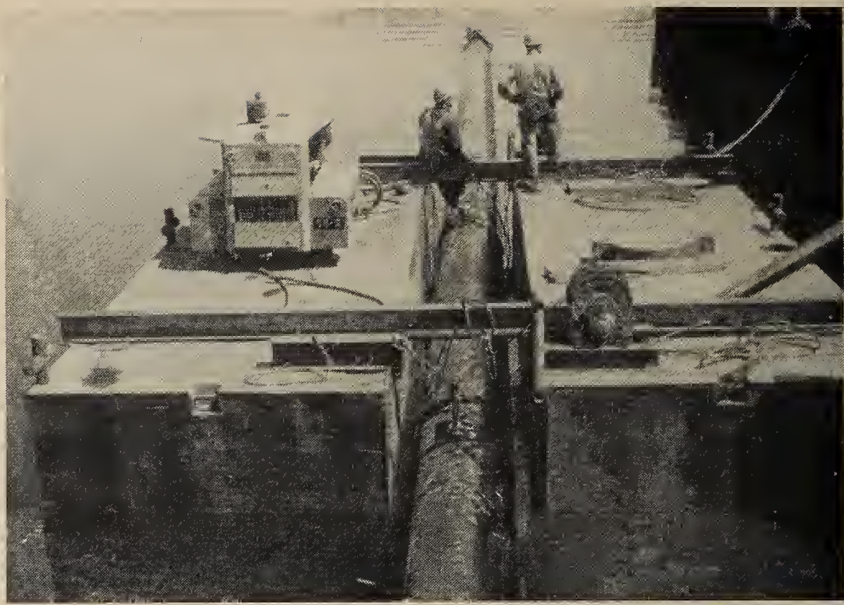


Fig. 6 Floating of Piles to Site

Loaded and unloaded vessels were considered in determination of the wind force on the ship. Further, it was assumed that from the total kinetic energy of the berthing ship only 50% will be absorbed by the two main dolphins, while the rest of the energy will be lost due to the water displacement in a broadside movement towards the dolphins, and due to the loss of energy on first impact.

Two cases of berthing were considered:

(a) Broadside collision of the vessel with the main dolphins, engaging both structures simultaneously. In this case the energy to be absorbed was considered equally distributed to both structures;

(b) Collision with only one of the main dolphins. Because this type of impact is unlikely to occur amidships, a reduction coefficient of 0.5 was used for the moving mass.

Hence, in either case, the energy to be absorbed by one main dolphin was the same. It follows that in case (a) the dolphin absorbs the energy in pure bending, while in case (b) the structure may be also subjected to torsion, caused by a glancing blow.

Comparative design studies revealed that high tensile, low alloy steel piles can be utilized better than medium structural grade steel pipes to resist the cantilever moments for this particular structure. Welded steel pipes of 30 in. diameter, complying with ASTM Specification A-252, Grade 3, were selected, having an ultimate tensile strength of 75,000 psi. and an ultimate yield stress of 45,000 psi. The use of this steel offered considerable saving in pile transport, handling, field welding and driving costs as compared with medium structural grade steel piles.

Considering the nature of the design loads it was decided to use a maximum working stress of 37,500 psi. for cases of pile bending. This means a theoretical factor of safety of 1.2 against yield failure and a factor of safety of 2.0 considering the ultimate strength. Actually the inspection tests during the fabrication of the piles showed that the ultimate stress of the material varied between 78,000 and 89,000 psi. and the yield stress was between 52,000 and 59,000 psi. Test specimens from welded joints had an ultimate strength of 81,000 to 84,000 psi. and a yield stress of 53,000 to 56,000 psi.

As the platforms are resting loosely on brackets welded onto the piles, all connections can be considered as hinges. The structure is so flexible, that under the maximum forces the slope of the timber fendering exceeds the probable tilt of the ship. For this reason it was assumed that the point of load application for wind thrust and impact forces will shift to the elevation of the lower platform.

Except for loading Case (b), the loads have been assumed uniformly distributed to all dolphin piles.

The penetration depth of the piles was determined following the methods used for cantilevered steel sheet piling. The soil between the piles was included in the effective width which appeared to be a justified assumption considering the 7 ft.-6 in. centre-to-centre spacing of the piles.

For calculations of the soil resistance the following soil properties were used: *(see equation I)*

In order to have a consistent overall factor of safety, the penetration depth was designed for a theoretical lateral force on structure, required to produce simultaneous yield of steel and ultimate soil resistance.

A summary of calculations for the main dolphins is shown in equation II as well as in Fig. 5.

Actually the specified penetration depth was made 8 ft. greater than the theoretically calculated 37 ft., to provide some allowance for the uncertainties in soil conditions.

The bending moment diagram, shown for 1 ft. width of structure, allows to compute moments and corresponding deflections and stresses for various design loads by use of coefficients.

The greatest lateral force was found to be a wind thrust of 90 T. per dolphin. Corresponding maximum bending moment per pile:

Equation III

$$M = 4415 \frac{17.5 \times 90}{7 \times 130} = 7640 \text{ in. t.}$$

Stress

$$f = 31200 \text{ psi.}$$

Deflection $$d_A = \int_0^A \frac{M_y Y dy}{EI_y} = 11.3'$$

It was found convenient to determine first the deflection for a load of 1T per pile $d_{A1} = 0.88''$ and use it as a basis for further calculations.

The highest stresses in piles were found to be due to eccentric impact forces. *(see equation IV)*

The twist of the structure is represented by an angle θ. Except for the center pile, all other piles undergo a displacement of $R \times \theta = 90\,\theta$ in. Total torsional moment on six piles. *(see equation V)*

Since the structure undergoes torsion and bending at the same time, the sum of both energy quantities represents the total energy absorbed by the structure. *(see equation VI)*

It should be noted that the deflections were defined assuming that the effective point of fixation coincides with the point of maximum moment. It could be expected that the effective resistance of the soil changes as the lateral load is increased. Although the point of maximum moment remains at essentially a fixed elevation, the effective point of fixation moves downward as larger loads are applied. Consequently the extreme

Equation I

Submerged weight of soil	$w = 65$ lbs. per cu. ft.
Angle of internal friction	$\phi = 30$ degrees
Cohesion	$c = 0$
Factor to allow for wall friction in Rankine's value of coefficient of passive earth resistance	$m = 1.33$

Equation II

Soil pressure increment per 1 ft. of depth	$mp_p - p_a = 238$ lb./ft.²
Effective width	$B = 17.5$ ft.
Required M.R. of soil for 1 ft. width, based on yield strength of piles	$M_r = 736{,}000$ ft. lb.
Maximum bending moment for piles is at depth	

$$X_0 = \sqrt{\frac{2H}{mp_p - p_a}}$$

$$\max M = M_r = H\left(42 + \sqrt{\frac{H}{119}}\right) - \frac{238}{6}\left(\sqrt{\frac{H}{119}}\right)^3 = 736{,}000 \text{ ft. lb.}$$

$H = 14860$ lb. $= 7.43$ T. $\qquad X_0 = 11.2$ ft.

Corresponding force on structure $\qquad F = 7.43 \times 17.5 = 130$ T.

From equation

$$X^4 - \frac{8H}{mp_p - p_a}X^2 - \frac{12Hh}{mp_p - p_a}X - \left(\frac{2H}{mp_p - p_a}\right)^2 = 0$$

necessary penetration $\qquad X = 36.93$ ft.

Equation IV

Energy absorbed by structure in bending only $\qquad E_B = 0.5\frac{0.88}{7}F^2 = 0.0629F^2$ in. t.

Energy absorbed by six piles in torsion $\qquad E_T = 0.5 M_T \theta$

Assuming force F acting on structure with 4 ft. eccentricity $\qquad M_T = 48F$ in. t.

Equation V

$$M_T = 6\frac{90\theta}{0.88} \times 90 = 55300\theta \text{ in. t.} = 48F \qquad \theta = 0.00087F \text{ (Radians)}$$

$$E_T = 0.5 \times 48F \times 0.00087F = 0.0209F^2 \text{ in. t.}$$

Equation VI

$$E = E_B + E_T = (0.0629 + 0.0209)F^2 = 0.0838F^2 \text{ in. t.}$$

Energy from ships impact

$$E = 0.5 \times 0.5 \times \frac{mv^2}{2g} = 23.4 \text{ ft. t.} = 282 \text{ in. t.}$$

say 300 in. t.

Force on structure $$F = \sqrt{\frac{300}{0.0838}} = 59.9T$$

Maximum displacement of a pile at EL. + 8.0 ft.

$$d = \frac{0.88}{7}59.9 + 0.00087 \times 59.9 \times 90 = 12.22 \text{ in.}$$

Maximum force on a pile $$F = \frac{12.22}{0.88} = 13.9T$$

Maximum stress $\qquad f = 36200$ psi.

deflections could be expected larger than calculated.

For the design of end dolphins a static pull, governed by the breaking strength of 8 in. ropes was considered. According to the marine experts a vessel may have up to three 8 in. manilla ropes tied on a bollard of the dolphin. The breaking strength of one rope is 21 tons. Since it is unlikely that all ropes will be stressed to the same extent and near their breaking strength, it appeared to be justified to use a design load of 30 tons. The calculated maximum bending stress from this load was 36,000 psi. and the maximum deflection for the structure at El. + 26.0 ft. was 20". Comparative calculations were made combining the effect of a wind force on ship and the drag from a current of 3.5 knots. Assuming this force equally distributed to one main dolphin and one end dolphin, the resulting force on an end dolphin was 28 tons.

The platforms were designed as diaphragms, each made up of a single ⅜ in. thick checkered steel plate with stiffeners. A tolerance of ±6 in. was allowed for locating each individual pile in plan, which later proved to be adequate. Creosoted B.C. fir timber fendering was used in front of the dolphins as shown in Fig. 2. To lessen the effect of glancing blows on the structure, the fendering was curved towards the sides of the dolphins. Each dolphin was also equipped with steel ladders and handrailing.

Construction of Dolphins

The main construction problem was the driving of the large diameter piles. Ultimate pile resistance was expected in the range of 200 to 300 tons, therefore, driving equipment had to be of the heaviest type.

An open end tubular pile may act during driving like a closed one, because of the clogging of soil inside the cylinder. The jetting of piles was not desirable because of possible soil disturbance. The heaviest locally available double acting steam hammer with 20,000 ft. lb. energy per blow was considered to be inadequate for this job. For all practical purposes, driving with a heavy drop hammer appeared to be the best solution. In order to avoid reinforcing the pile head, the driving was carried out with a hammer, dropping inside the pile cylinder and delivering the blows to a 5 ft. long concrete plug, poured at the bottom of the pile.

Fig. 8 Complete Installation of Mooring Dolphins

This method offered good control over the plumbness of the pile during driving. Also, the energy of the hammer was used more efficiently when applied at the pile tip. In some respects this unconventional driving method is associated with the principles used for caisson-pile driving. In fact, the largest type pile driving rig, equipped with a hammer of 8,000 lbs. weight, was used for the job. The method chosen simplified the pile preparation and generally proved to be successful. As it was not certain that a conical pile tip would ease the expected heavy driving the pile was constructed for simplicity and economy with a flat end.

The 105 ft. long piles were fabricated and shipped to the site in units of 50 ft. and 55 ft. lengths. Concrete of 3,000 lb. strength with 15% additive by weight of cement was used for the plugging of the 55 ft. long bottom units. After a hardening period of 3 days the pile units were moved to the welding bed for splicing. Prior to welding, the material was preheated to 450°F. by means of a burner coil. The preheating temperature was controlled by use of heat sensitive crayons. To slow down the cooling of the material, the joint was kept covered with asbestos blankets for 2 hrs. after welding. All field welding was carefully inspected and a number of radiograph films were made to check the quality of the welding.

The upper end of the pile was temporarily sealed off and the whole pile assembly weighing 12 tons was floated to the site at high tide by use of two pontoons equipped with air winches as illustrated in Fig. 8.

Fairly accurate location of the piles was obtained by means of markers on the shore and markers and templates fixed on the barge. The barge, carrying the driving rig, was moved into the final accurate location by use of four air winches, adjusting the length of four anchor cables from the barge. Prior to the pile driving, a packing of sand and crushed stone was placed on top of the concrete plug to cushion the hammer blows. More packing was added from time to time during the driving as soon as it was noticed by sound that the packing had been pulverized and compacted to the point where it no longer acted as a cushion. Up to 16 ft. of packing was used for some of the piles.

In general, the hardest driving was experienced for the last 20 ft. of the total penetration of approximately 50 ft. Fig. 7. shows the driving energy used for penetration of one of the main dolphin piles, which may be considered as typical for the majority of the piles. It is questionable whether any of the known dynamic pile driving formulae is applicable in this particular case. It could be expected that a great deal of energy was absorbed by compaction of the packing and elastic deformations of the pile. It was estimated that the ultimate resistance of a pile is in the neighbourhood of 300 tons. Several piles were inspected visually from the inside after completion of the driving. Inspection did not reveal any sign of damage to the pile, nor any noticeable deformations. The average time for locating and driving of a pile was one day. Most of the driving was accomplished in 4 hours per pile. Templates were made to fit the as-driven pile locations. The platforms were then assembled on the shore from prefabricated elements using these templates.

The platforms and all external surfaces of the piles were painted with a coal tar paint applied in two coats. In addition to that, a sacrificial magnesium anode system was installed. It is expected that this system will be replaced by an impressed current

DEVELOPMENT OF WATER RESOURCES IN ONTARIO

Dr. A. E. Berry, M.E.I.C. *General Manager and Chief Engineer*
Ontario Water Resources Commission, Toronto, Ont.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June, 1959.

A MAJOR CHANGE in the administration of water and sewage works has been introduced in Ontario. It involved the creation of a Water Resources Commission, along with the adoption of appropriate legislation. Since this Act came into force in 1956, the program of the Commission has expanded and it is now feasible to assess what has been accomplished, as well as to discuss some of the plans proposed for the future. It is believed that this program in Ontario is unique, both on this continent and elsewhere. It recognizes certain principles which are of the utmost importance in the development and orderly progress of any country. An outline of the Commission's program and objectives is included in this paper.

This new procedure in Ontario recognizes the important role played by water resources. The events preceding this action pointed clearly to the significant requirements of the Province for water supply for all areas where growth is to be expected. It showed clearly that water resources must be conserved against the ravages of pollution from sewage, industrial wastes and other substances, which may impair water quality and interfere with repeated use. The relationship between water supply and pollution is made clear by the overall objectives of the Commission.

This new program resulted from a number of factors which had developed over a period of time. A better understanding of this activity may be had through an analysis of some of the conditions which brought about this change in policy. Ontario has a population in excess of 5½ millions. It covers an area of 412,582 square miles, out of a total of 3,845,794 square miles for all Canada. The scattered distribution of population creates problems where community projects are involved. Southern Ontario has the highest concentration of population and has been a focal point for industrial growth. Opportunities for this continued growth are great, but the associated problems also are great.

It is recognized that growth and human betterment cannot be sustained unless there are adequate water supplies. These supplies are one of the greatest national assets, and the quality must be protected at all costs. The importance of the Great Lakes system to southern Ontario is clearly evident. Large communities and industries have been attracted to these waters over a period of many years. Now as the growth moves inland, the adequacy of water and the prevention of pollution take on new significance.

Inland communities in much of southern Ontario are faced with water problems including quantity, quality and pollution control. Rapid run-off and resulting low stream flows in the summer months, combine to make pollution a serious problem when these watercourses are needed to serve their normal functions. Costs for the development and transportation of water have risen sharply, and high interest rates have added further to this difficulty. It is even more essential to protect local water supplies from pollution when the expenditure for others is so great. When water must be piped long distances, or when the most economical arrangement is necessary in sewage and waste disposal, there is an advantage in dealing with these on a regional basis for a number of municipalities rather than having each attempt to solve its own problems separately. Individual efforts in the past have not led to the most effective solutions.

By 1955, the need for water supply and sewage treatment works was sufficiently urgent to call for action at the Provincial level. This was especially true in southern Ontario where a major post-war growth had been experienced, and where there was every promise of a continuance of this expansion if no serious restrictions or barriers were placed in the way. Adequate water resources of good quality were recognized as a primary need for insuring this continued growth and the welfare of the Province. The interrelationship of waste disposal and availability of water supplies was conceded in the program which was to be adopted by the Province.

Action by the Government

The adverse conditions which might well develop in relation to water resources were foreseen by the Government of the Province, and a Water Resources and Supply Committee was appointed in 1955 to inquire into and to advise on a constructive program. The Committee consisted of five members under the chairmanship of Mr. A. M. Snider. The Committee's report of that same year was followed immediately by legislation made effective in April of 1956, and through which a Water Resources Commission was appointed consisting of five men under the same Chairman. This first legislative enactment authorized the development of an organization and necessary procedures for carrying out the program. This bill was considerably altered in April of 1957 under the title "The Ontario Water Resources Commission Act, 1957". Some further amendments were made in 1958. These various actions provided the means for the Commission to proceed aggressively on its objectives.

The Ontario Water Resources Act

The broad scope of the authority given to the Commission is set out in Section 16 of The Ontario Water Resources Commission Act, which reads as follows:

"Notwithstanding any other Act, it is the function of the Commission and it has power,

(a) to control and regulate the collection, production, treatment, storage, transmission, distribution and use of water for public purposes and to make orders with respect thereto;

(b) to construct, acquire, provide, operate and maintain water works and to develop and make available supplies of water to municipalities and persons;

(c) to construct, acquire, provide, operate and maintain sewage works and to receive, treat and dispose of sewage delivered by municipalities and persons;

(d) to make agreements with any one or more municipalities or persons with respect to a supply of water or the reception, treatment and disposal of sewage;

(e) to conduct research programs and to prepare statistics for its purposes; and

(f) to perform such other functions or discharge such other duties as may be assigned to it from time to time by the Lieutenant-Governor in Council. 1957, c.88, s.16".

The major features of this legislation may be considered under two parts, one dealing with the supervision by the Commission over all water and sewage works in the Province; the other having to do with the construction of water and sewage projects by the Commission for municipalities and others. Some features of these two parts of the program may be of interest at this time.

For many years the Ontario Department of Health under public health legislation had exercised supervision over public water and sewage works built and maintained by municipalities or persons. This was similar to what was done in other provinces of Canada, and in most of the States. Under The Water Resources Commission Act, legislation contained in The Public Health Act was not only transferred to the Commission, but was considerably expanded and altered to permit more effective control. This was especially so in relation to stream pollution.

This new program for water and sewage works construction is a distinct departure from the procedures of the past. It is believed to be also different from practices followed in other countries. The object was to help municipalities meet their demands for these utilities. The Commission offers financial advantages as well as expert technical assistance in the planning, construction, and operation of the works. This procedure obviates the need of the municipality to issue any bonds or to borrow any money for the works.

Construction Procedures Under the OWRC

The procedure followed by the Commission in its program of constructing these water and sewage projects has several new features not otherwise utilized in Ontario.

1. In the first place, any municipality is free to decide whether it wishes to do its own work, or whether it desires to place this under the Commission. The services of the Commission are available to any municipality, but there is no effort made to urge a municipality to place a project under the OWRC. The chief desire of the Commission is to see that the work goes forward. If the municipality so requests, an agreement can be made between the corporation and the Commission under which the latter undertakes to design, build, finance, and operate the water or sewage project. A standard form of agreement is used, subject to minor alterations to meet local conditions. This agreement on a project may involve one or several municipalities as well as industries. It may concern very small works or very large ones. Particular emphasis is placed on joint projects which will serve a number of municipalities, whether these be for water supply or sewage disposal.

2. Projects undertaken by the Commission are, in general, confined to works for the supply, purification, and delivery of water through feeder mains to the contracting party's distribution system, or to trunk sewers, treatment works and sewer outfalls. It is only in the case of small communities that the Commission undertakes the construction of the local water distribution mains or the sewage collection system. In those instances there is a definite advantage to have all the work done under the one contract and under one management.

3. When the agreement has been approved by both parties, the Commission goes forward on the necessary plans and specifications. The policy of the Commission has been to appoint consulting engineers to do the design work and also to do field supervision during construction. Thus, the consulting engineer is an employee of the Commission rather than the municipality. He engages the resident engineers and field staff to supervise construction. The Commission on its own maintains a construction branch to deal with this work and to ensure that the project is carried out to its satisfaction.

4. All contracts for these projects are awarded by the Commission, and the complete program is under the direct responsibility of the Commission. Payments are made to the contractor as work progresses, also to the suppliers of equipment and to the consulting engineers. In this way, no payments are made by the contracting municipality until the works are in operation.

5. The agreement between a municipality and the Commission is based on the latter assuming responsibility for the operation and maintenance of the works during the lifetime of the debt. When the project is constructed, the responsibility of this passes from the construction division of the Commission to the operating division. The personnel for these operations are engaged by and paid for by the Commission. Where there are small works, and these do not require the services of a full-time staff, arrangements may be made to employ on a part-time basis some of the local employees of the municipality or others as the case may be.

6. The agreement between the municipality and the Commission contains a clause whereby at the termination of the debt, the works may be returned to the municipality at the request of either party. Extensions or enlargements of the works may be made by the Commission at the request of the municipality and in this way, the debt retirement period may be extended for a longer period. Each of these extensions involves a new agreement between the Commission and the municipality, and the Commission would not have the right to extend the original works under the terms of the first agreement.

7. An important part of this entire program is the means for co-operation between the Commission and the municipalities served. Each municipality is asked to appoint a local advisory committee to work with the Commission and to deal with all aspects of

the program. In this way there is a local direction for such matters as appointment of employees, wages paid, and many other features of administration. This tends to relate the activity to local conditions rather than having one set of standards or requirements for the entire Province.

8. The Commission offers to each municipality extensive services in the operation of the works. There is the closest co-ordination of all technical matters in which the advice of the local engineering staff is combined with the specialized training of the Commission's personnel. In small municipalities where new works are being installed and where there has been little local experience on such matters the Commission advises on all aspects of the administration, including rate structures, bookkeeping, records, etc. In this way, full use is accorded each municipality of the Commission's laboratory facilities and its technical staff without cost to that community.

Financing Commission Projects

The financial arrangements for the projects constructed and operated by the Commission are an important part of the overall program. Stringent money conditions including difficulty of raising loans, and high interest rates have added to the burdens of municipalities in financing undertakings on their own. Under the plan offered by the Commission, the municipality does not issue or sell any debentures or bonds. Money is advanced by the Commission, and the credit of the Province is pledged for this. The debt is paid back over a long period, 30 years in most instances but varied according to the wishes of the municipality. The interest rate is the actual cost of money borrowed by the Province. This rate is normally lower than it is possible for the municipality to obtain on the open market. The indebtedness of the Commission can be met by the sale of its own bonds, which are guaranteed by the Province, or it can horrow directly, as it has to date, from the Provincial Treasurer, thereby gaining the advantage of borrowings on a large scale.

A number of advantages can be found in this method of financing in addition to the more favourable interest rate. One is the flexibility of the agreement. The municipality makes no payment to the Commission until the work is put into operation. The debenture period may be made to suit local needs. Principal payments may be deferred at the outset and up to a period of five years after the work is completed. The interest rate will vary each year, and as the prevailing high interest rate is lowered, the municipality obtains this advantage of further saving.

In Ontario, all financial obligations to be incurred by municipalities come under the supervision of the Ontario Municipal Board. The Board thus determines whether the obligation is within the ability of the municipality to carry. This same requirement applies whether the municipality is doing the work on its own, or whether the work is under The Ontario Water Resources Commission. In the latter instance, the Commission deals directly with the Board for the municipality.

Where a number of municipalities or other parties are concerned with a single project, the agreement provides for allocation to each of these that part of the capital debt for which they will be responsible to the Commission. The cost of the water delivered or the sewage treated is based on this and the actual cost of operation. At present, the Commission is undertaking sewage projects in which a number of municipalities will be provided joint service including the trunk sewers and the treatment facilities.

The basis of all financial agreements with municipalities is that they shall pay to the Commission the actual cost of the debt and service rendered. The latter does not include the supervisory services of the Commission, but only those operators actually engaged on the project. No money grants are involved in these programs. The contracting municipality will pay quarterly to the Commission the estimated amount of capital and operating charges as well as a reserve fund for contingencies, repairs and replacements. At the end of the year an adjustment is made with the actual costs for that period. These financial procedures relieve the municipality of all details involved in borrowing money for capital works.

Sanitary Supervision over Sewage Works

The other part of the Commission's program involving sanitary supervision over sewage plants as well as water utilities is similar to that which is normally carried out under a Provincial health department. All plans for water and sewage works installations, or extensions to existing works require the approval of the Commission before construction is undertaken. In this way, the Commission is given wide powers to deal with the water resources of the Province, and has the right to regulate water use.

Great emphasis is placed on the control of stream pollution. If water resources are to be made available for the maximum use and public benefit pollution control must be exercised rigidly. The Commission, under the legislation is empowered to deal with the protection of all water supplies. Heavy penalties are provided for infringement of this. A departure from the usual public health provision against pollution is that under the Commission's program this is not to be confined to something which may only affect public health, but rather is it widened to include anything which may impair the quality of the receiving watercourse. A good deal of the activity of the Commission since its inception has been devoted to sewage and waste disposal and to the abatement of stream pollution.

Organization of the Commission

The Commission's program has been organized to give effect to these various activities. The Commission, at present consisting of six members, decides on all matters of policy. The administration of these policies comes under a General Manager acting through six divisions or branches. These consist of Administration, Laboratories & Research, Construction, Plant Operations, Sanitary Engineering, and Water Resources. The staff has grown at a rapid rate, and at present is nearly 200. A new laboratory is near completion to serve the needs of the Commission and to give service to all municipalities operating water and sewage works. Research programs will be emphasized in this laboratory, and there will be full co-operation with industry and with municipalities.

Progress Under the Commission

The program of the Commission is as yet in its early stages. The act of the Legislature came into effect only in April 1957. Since that time it is gratifying to note the number of projects which have been undertaken. To date agreements have been made with municipalities for 65 projects for works involving an estimated expenditure of approximately $33,500,000. These include 32 water projects and 33 sewage works. Twenty-one of these are already in operation, others are in various stages of development. In many other instances agreements

HYDRAULIC PROBLEMS IN CONNECTION WITH THE DEVELOPMENT OF THE ST. LAWRENCE RIVER

H. W. Lea, M.E.I.C., *Consulting Engineer, formerly Alternate Member, Canadian Section, St. Lawrence River Joint Board of Engineers.*

ALTHOUGH the St. Lawrence River is noted amongst the larger rivers of the world for the fact that its maximum discharge is only about twice the minimum discharge, nevertheless many useful purposes would be served by the achievement of greater regularity of flow by some practical and suitable means of control.

Disregarding for the present purpose the fluctuations in water levels of the four Great Lakes upstream from Lake Ontario with the consequent storage which results, it became apparent from study of records which have been kept for the past 100 years, that there has been continuous variation in the level of Lake Ontario which has shown a total range of about six and a half feet. This represents a very large volume of water when translated into terms of river flow, and if advantage, so far as practical, is taken of that storage the regime of the river can be materially improved, particularly during periods of low natural discharge.

The portion of the water shed of the St. Lawrence tributary to the Great Lakes is international in character and this situation persists in the International Rapids Reach where the river itself is the international boundary until the latter deviates to the southward away from the river, near the head of Lake St. Francis just downstream from Cornwall. A plan of this reach is given in Fig. 1.

Any actions taken which will interfere with the natural flow of the St. Lawrence upstream from where it ceases to be the international boun-

Fig. 1. St. Lawrence project—International Rapids section.

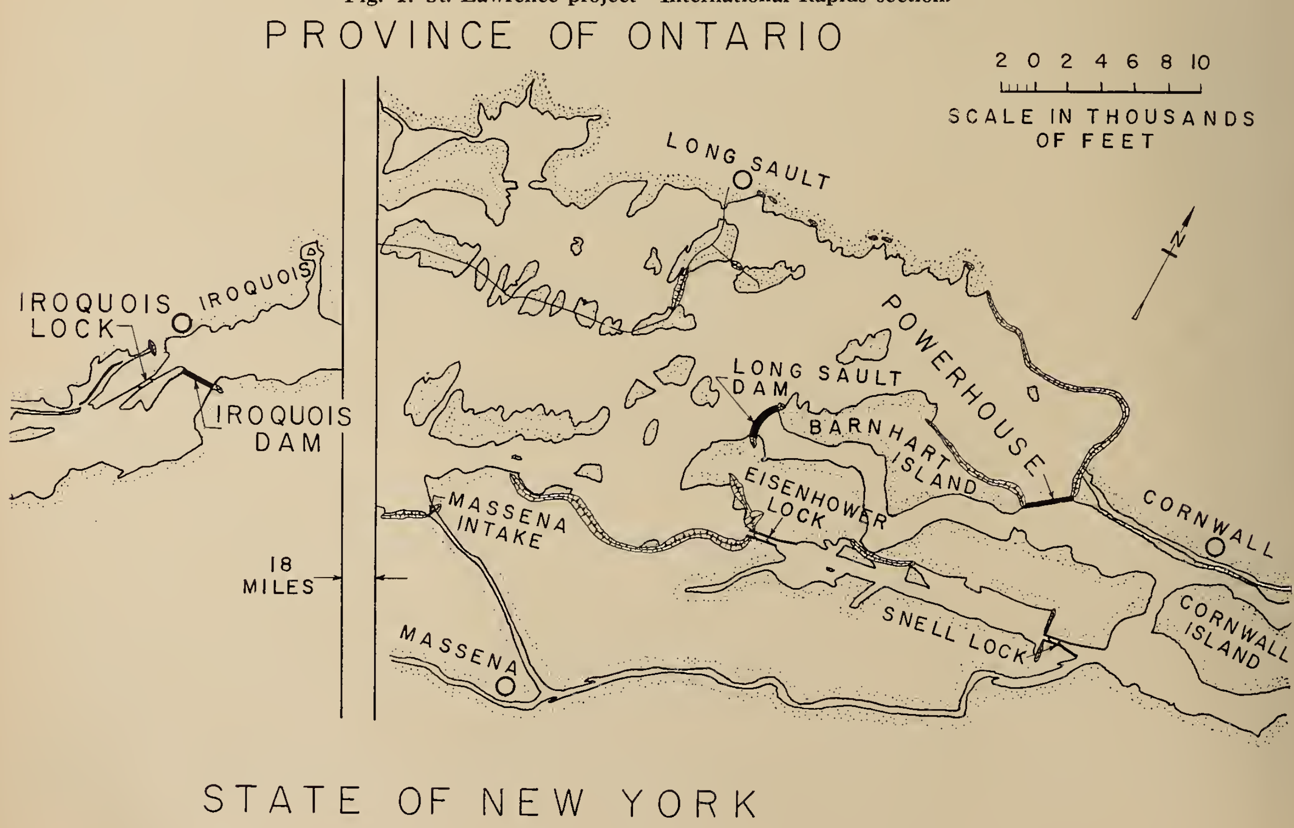

Fig. 2. St. Lawrence project—Soulanges section.

dary must be in accordance with the wishes of the people of the two nations as agreed upon by their governments. It will also be understood that any measures of control which are initiated in the international section of the river must be so devised that they would do no harm to any legitimate interest on that portion of the river downstream from the international boundary, which is an exclusively Canadian river.

The problem of development of the international section of the St. Lawrence for navigation and power had been under active study for more than half a century and many attempts had been made to secure agreement between the United States and Canada on a joint scheme of development. Eventually, lacking achievement of such agreement, Canada decided to proceed with an all-Canadian seaway which provided for such canal sections and locks as would be required in the international section of the river to be constructed on the Canadian side. At the same time there was an urgent demand for hydro-electric power from both sides of the border and it was recognized that the development of such power in the international section would greatly reduce the problem of design and construction of deep-draft navigation facilities. Consequently the two national Governments decided to refer the question of development of the International Rapids Section of the river for both navigation and power to the International Joint Commission with the objective of the issuance of an Order of Approval by that Commission on the premise that the construction of all navigation facilities would be on the Canadian side and would proceed concurrently with those for hydro-electric power development.

An Order of Approval was issued by the IJC in the fall of 1952 and when it became patent that Canada intended to complete the navigation facilities as quickly as possible the United States decided, as was the right of that country, to participate in the navigation development, and the United States Wiley-Dondero Bill which was passed in 1954 provided for construction of a canal on the American side of the river leading downstream from the power pool above Long Sault Dam to the international channel south of Cornwall Island, which leads into Lake St. Francis.

As a result of many representations from both countries over the years with respect to control of the levels of Lake Ontario and the outflows through the St. Lawrence River the two Governments, previous to the joint submission on development of the International Rapids Section, decided upon a reference to the International Joint Commission requesting a study and report on those subjects. The International Joint Commission thereupon established a Lake Ontario Board of Engineers to investigate and report to the Commission on the engineering aspects of the problem. This engineering study had hardly begun at the time of the joint submission to the Commission of the St. Lawrence Project in the International Rapids Section.

Many complaints had been received by both countries on both high water levels and low water levels on Lake Ontario and on low flows in the river. Since the maximum natural range of stage in Lake Ontario, as previously noted, is not more than about six and a half feet it was necessary to approach with extreme care the feasibility of reducing this range of stage in order to satisfy in part the wishes of all the complainants regarding extreme high and low lake levels, and variations in river flows. Eventually, the Lake Ontario Board of Engineers reported that it would be possible under regulation to reduce the range of stage of Lake Ontario to about four feet and the IJC accepted the advice of its Board and set the range of stage at, from a minimum of elevation 244, during the navigation period, to a maximum of elevation 248.0, as near as may be.

These figures may be compared with a recorded minimum elevation of 242.7 during the navigation season and a maximum elevation of 249.3.

The original IJC Order of Approval provided for the establishment of two international engineering boards and set out the duties and responsibilities of these boards in connection with the development of the international section of the river and operation of the control facilities:—

The St. Lawrence River Joint Board of Engineers.

This Board was established in late 1953 and is composed of 2 members and 2 Alternate Members for each country, whose duties are to review, co-ordinate, and approve on behalf of the two Governments the plans, specifications and schedules of construction of the works to be constructed by the Power Entities in the International Rapids Reach and to ensure their construction in accordance therewith.

The International St. Lawrence River Board of Control.

This Board, established in late 1953, is composed of 4 Canadian and 4 U.S. Members—increased from 3 from each country in 1958—which during the construction period is keeping the International Joint Commission informed as to the outflow and levels of Lake Ontario and co-operating to this end with the St. Lawrence River Joint Board of Engineers, and upon completion of the works is to insure that the provisions of the Order relating to water levels and the regulation of the discharge from Lake Ontario and the flow of the water through the International Rapids Section, as set out therein, are complied with. Later, in 1956, this Board was instructed to take over the study of the regulation of Lake Ontario, which until that time had been carried on by the International Lake Ontario Board of Engineers.

Subsequent to the issuance of the original IJC Order of Approval, which was accepted by both Governments, as a result of detailed investigations and studies by the Lake Ontario Board of Engineers and by the Board of Control which led to engineering recommendations to the IJC, a Supplementary Order of Approval was issued in the summer of 1956. This Supplementary Order set out a series of detailed criteria which were designed for appropriate and reasonable protection of all legitimate interests on the river both upstream and downstream from the works to be constructed, and detailed regulation of the flow of the river must at all times fulfil the conditions set out in the criteria.

These criteria are as follows:—

(a) The regulated outflow from Lake Ontario from 1 April to 15 December shall be such as not to reduce the minimum level of Montreal harbour below that which would have occurred in the past with the supplies to Lake Ontario since 1860 adjusted to a condition assuming a continuous diversion out of the Great Lakes Basin of 3,100 c.f.s. at Chicago and a continuous diversion into the Great Lakes Basin of 5,000 cubic feet per second from the Albany River Basin (hereinafter called the "supplies of the past as adjusted").

(b) The regulated winter outflows from Lake Ontario from 15 December to 31 March shall be as large as feasible and shall be maintained so that the difficulties of winter power operation are minimized.

(c) The regulated outflow from Lake Ontario during the annual spring break-up in Montreal Harbour and in the river downstream shall not be greater than would have occurred assuming supplies of the past as adjusted.

(d) The regulated outflow from Lake Ontario during the annual flood discharge from the Ottawa River shall not be greater than would have occurred assuming supplies of the past as adjusted.

(e) Consistent with other requirements, the minimum regulated monthly outflow from Lake Ontario shall be such as to secure the maximum dependable flow for power.

(f) Consistent with other requirements, the maximum regulated outflow from Lake Ontario shall be maintained as low as possible to reduce channel excavations to a minimum.

(g) Consistent with other requirements, the levels of Lake Ontario shall be regulated for the benefit of property owners on the shores of Lake Ontario in the United States and Canada so as to reduce the extremes of stage which have been experienced.

(h) The regulated monthly mean level of Lake Ontario shall not exceed elevation 248.0 with the supplies of the past as adjusted.

(i) Under regulation, the frequency of occurrences of monthly mean elevations of approximately 247.0 and higher on Lake Ontario shall be less than would have occurred in the past with the supplies of the past as adjusted and with present channel conditions in the Galops Rapids Section of the Saint Lawrence River. ("present channel conditions" refers to conditions as of March 1955.)

(j) The regulated level of Lake Ontario on 1 April shall not be lower than elevation 244.0. The regulated monthly mean level of the lake from 1 April to 30 November shall be maintained at or above elevation 244.0.

(k) In the event of supplies in excess of the supplies of the past as adjusted, the works in the International Rapids Section shall be operated to provide all possible relief to the riparian owners upstream and downstream. In the event of supplies less than the supplies of the past as adjusted, the works in the International Rapids Section shall be operated to provide all possible relief to navigation and power interests.

It should be noted at this point that the various bodies that have been referred to herein have been concerned exclusively with development of the international section and control of the levels of Lake Ontario and St. Lawrence River flows. With respect to navigation, construction and maintenance of the St. Lawrence channel below Montreal has been for many years the responsibility of the St. Lawrence Ship Channel Service of the Department of Transport and ships with draft up to 35 ft. are using the Port of Montreal regularly. Above Montreal the St. Lawrence Seaway, which has previously been the subject of numerous papers and articles, envisages a channel depth of 27 ft. and maximum ship draft of 25 ft. up to Lake Ontario, and through the Welland Canal to Lake Erie; while additional programs are under way to provide for these depths up to the head of the Lakes. The St. Lawrence Seaway Authority is charged with responsibility for construction, maintenance and operation of the Canadian portion of the seaway while the St. Lawrence Seaway Development Corporation is the parallel United States organization.

In the international section basic requirements of navigation channels are contained in the IJC Order of Approval and the details of the channels are being completed along lines which have been approved by the Joint Board of Engineers. In the Canadian section of the river the Government of Canada is directly concerned only with navigation matters and consequently the St. Law-

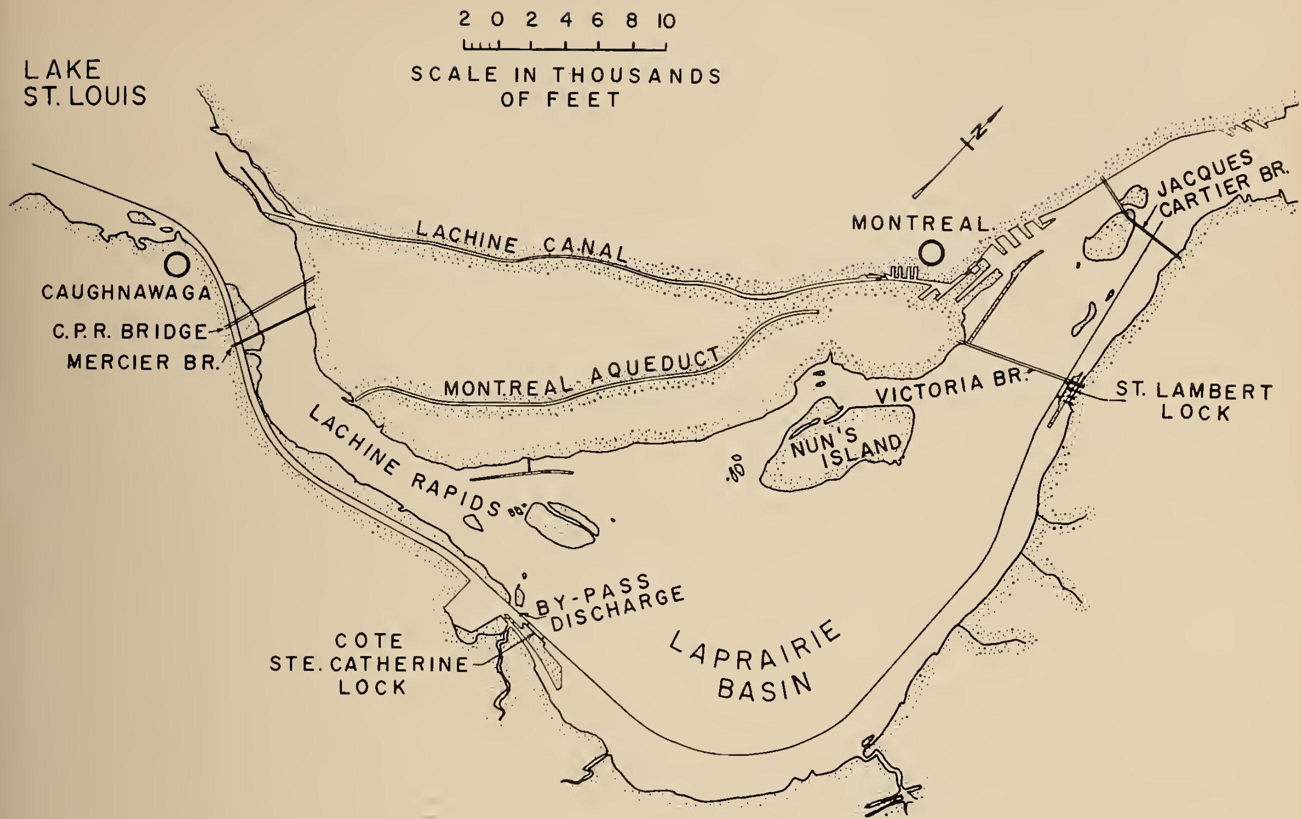

Fig. 3. St. Lawrence project—Lachine section.

rence Seaway Authority has worked closely with Quebec-Hydro wherever each body has an interest in the program.

Insofar as the international section is concerned, the IJC Order of Approval requires that average velocity in the navigation channel shall not exceed 4 feet per second during the navigation season, and shall not exceed 2¼ ft. per second during the ice-forming period. Generally speaking, channel improvements which fulfil the second requirement mentioned above also fulfil the first. Therefore no substantial problem has been met in creating a satisfactory navigation channel while work is being carried out for the purpose of providing satisfactory hydraulic conditions.

Below the Long Sault Dam and the Powerhouses the river divides into two channels flowing to the north and to the south of Cornwall Island. The large scale excavations which were required to provide a seaway channel south of Cornwall Island, which became necessary when it was decided to install locks on the United States side of the river, altered the balance of discharge of the two channels. Thus compensatory excavation was required in the channel north of Cornwall Island in order to maintain the natural distribution of flow. These operations lowered the average elevation of the tailrace at the Powerhouses by more than a foot, which increased dependable power production by a substantial amount. By agreement between the Power and the Seaway Entities the former undertook to pay to the latter a lump sum of 12 million dollars in recognition of the increased head made available on the turbines. At this point, it may be of interest to remark that Canada has also agreed to pay a lump sum of 15 million dollars to the Power Entities towards the cost of navigation improvements in the International Rapids Section.

When the Beauharnois power development was begun the power company undertook to provide a depth of 27 ft. in a section of the power canal 600 ft. in width, throughout its length and this channel has now been incorporated in the St. Lawrence Seaway by the installation by the St. Lawrence Seaway Authority of locks adjacent to the Powerhouse leading from the canal to Lake St. Louis. Fig. 2 shows a plan of the Beauharnois Canal.

When hydro-electric power is developed at Lachine Rapids it will be necessary to undertake a large scale excavation program above the existing rapids in order to reduce forebay velocities during the ice-forming period to the extent which will ensure formation of a suitable and satisfactory ice cover. Ledge rock is found at or near ground surface throughout this area and excavation will be costly. The Seaway, as it leaves Lake St. Louis is located very close to the south bank of the river and restricts the width to which excavation could be conveniently carried out in the dry along that shore. Consequently, when constructing that portion of the canal which extends from Lake St. Louis to Laprairie Basin the St. Lawrence Seaway Authority, at its own expense, designed the canal prism to be capable of carrying a flow of 40,000 c.f.s. from Lake St. Louis, and provided the necessary structures above Cote Ste. Catherine Lock to discharge this flow into Laprairie Basin. There will be no interference with navigation since the ice-forming period does not occur until after the annual navigation season is finished. Thus Quebec-Hydro will be relieved of excavation which otherwise would be required to carry a flow of 40,000 c.f.s. A plan of the Lachine Section is shown in Fig. 3.

Optimum requirements for Domestic Use, Navigation and Power, and protection of Riparian Owners, as well as economic considerations were frequently at variance during solution of these hydraulic problems. Careful analysis and considerable give and take were required to reach fair and reasonable decisions. The study of some of these problems must be continued with a view to improvement in procedures as more knowledge is gained and it may be anticipated that such studies will continue for many years before all the problems are finally resolved.

MOORING DOLPHINS *(Continued from page 46)*

cathodic protection installation, following the construction of any future wharf extension.

The B.C. Fir pressure creosoted timber fendering units were prefabricated on the shore and later fastened on brackets of the dolphin steelwork.

The field work for all four dolphins, including the pile preparation, required three months' time. The work on water was very much affected by the tide conditions.

The installation was completed on 25th July 1958. Fig. 8. shows a general view of the completed mooring installation.

Since the completion of installation several ships have used the new mooring facilities. None of the ships has been moored during extremely rough weather, but moderate winds have been experienced. During one of the mooring operations, repetitive pulling forces due to the tightening and slackening of lines produced 18" deflection of the northern end dolphin. However, no permanent deflections have been observed. It could be expected that the 300 ft. distance between the main dolphins will be to greater advantage for the future large cargo vessels than for the present ships of medium size. The present general experience indicates that the installation provides a satisfactory service.

Acknowledgments

The design and detail construction drawings were prepared by the General Engineering Department staff of the Aluminum Company of Canada, Limited, under general direction of J. F. Braun, M.E.I.C., Chief Civil Engineer. The General Contractor for this work was Saguenay-Kitimat Company. Mr. H. C. Jenkinson, Vice President of the company, directed the work in field. Franki of Canada Limited was engaged as subcontractor for the pile driving work and Mr. L. A. Fraikin, Managing Director of Franki, contributed useful ideas for the execution of the work. Mr. H. Jomini was Alcan's resident engineer in Kitimat.

DEVELOPMENT OF WATER RESOURCES *(Continued from page 49)*

are pending, and preliminary engineering work is being done. These include both small and large works. Water supplies will be pumped considerable distances. Sources of water supply, both surface and underground, will be developed wherever they are considered most advantageous. Sewage treatment will be provided to suit the local needs, and trunk sewers will be constructed to treatment plant sites or to outlets. Municipal boundaries are not to be regarded as the basis for the treatment of sewage, but rather this is considered to be an area problem, so that regardless of the municipality in which the area is situated it may be combined with the adjacent area to advantage and to economy to all concerned.

The boundary waters between Ontario and the United States offer a challenge in the effective control of pollution. These waters with unsurpassed international value must possess high quality to serve their many functions. The International Joint Commission has made surveys and has maintained close contact with conditions. Enforcement of quality standards set by the International Joint Commission has been carried out on the Canadian side by the Ontario Water Resources Commission. This is a co-operative effort designed to reach the desired objective of good stream sanitation.

Good progress is being made on pollution abatement in the boundary waters. The OWRC is participating in the building of municipal plants, and is co-operating closely with industry in their waste treatment problems. Joint efforts can be most effective, and in the boundary waters there is every expectation that the desired results will be a reality in the near future.

Summary

A review of the program of the Ontario Water Resources Commission at this time emphasizes the significance of the original objective to facilitate the development of water supplies and sewage disposal for all municipalities whether they be inland or on large bodies of water. The Province has adopted a program for the development and conservation of water resources and for pollution abatement with full protection of all watercourses in the Province. This pertains to municipalities and industries. A great deal of effort is being devoted to surveys of all water sources, and for determination of discharges to watercourses. Special efforts are being directed to the control of drainage outfalls in small municipalities as well as large ones. In this way, it is hoped to be able to clear all streams of pollution. This is a further step in a program aimed at close co-operation between the Province and the municipalities. The results obtained to date have been most gratifying in spite of the heavy expenditures required for these works. It is not possible to predict with accuracy, the length of time needed to deal with these major programs and especially all sources of pollution now reaching the streams, but the work is proceeding at a rapid pace. There has been splendid co-operation from municipalities and from industry.

Modern methods of water purification are employed, and the degree of treatment of sewage and industrial waste is aimed at the protection required for the watercourse. Naturally this will vary according to local conditions. The trend, however, is definitely towards more complete treatment and for raising the standard of stream sanitation throughout the Province. As the treatment works come into operation, rigid control will be exercised by the Commission to prevent the discharge of untreated or inadequately treated wastes or further pollution of any stream. In this objective, it is felt that the population growth can go forward, and industry can expand while at the same time streams can be utilized fully for disposal of these effluents without undue impairment of their quality or their usefulness. Co-operation of all concerned, which is the basis of this program, cannot fail to achieve the desired results.

BACKWATER COMPUTATIONS FOR THE ST. LAWRENCE POWER PROJECT

Part A — Hydraulic Engineering Aspects of Computations

H. M. McFarlane, *Hydraulic Design Engineer*
The Hydro-Electric Power Commission of Ontario
Toronto, Ont.

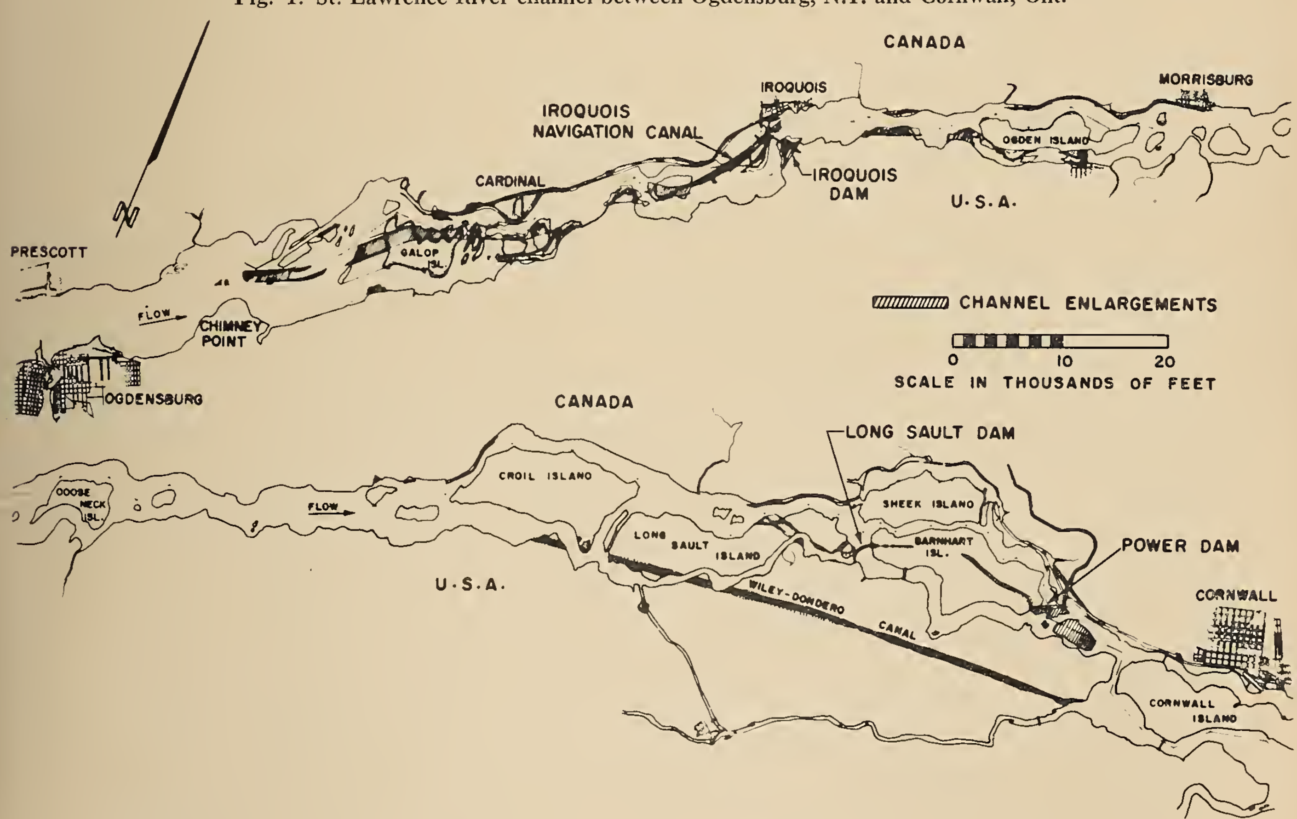
Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June, 1959.

Introduction

EARLY in 1952 the decision was made to begin preparing preliminary designs for construction of the St. Lawrence Power Project. From the hydraulic standpoint it was necessary to determine the operating head on the turbine in the power dam, as well as to establish the size of the water passages in the power dam and other control structures. Designs also were required for channel enlargements, and for the rehabilitation of the flooded headpond area. As a consequence, it became necessary immediately to know the range of water levels which eventually would be experienced under operation in the headpond reservoir, to serve as a basis of hydraulic design.

At the same time it appeared that construction of the 27-ft. Seaway between Montreal and Lake Ontario was imminent. Since the headpond of the Power Project would form part of this navigation system, the range of water levels in the headpond was

Fig. 1. St. Lawrence River channel between Ogdensburg, N.Y. and Cornwall, Ont.



required also by the Seaway entities to design the navigation facilities in the headpond area.

On several occasions prior to 1952, studies had been initiated to develop plans for the Power and Seaway projects. Although these plans had not been completely detailed, sufficient progress had been made to indicate the desirability of carrying out channel enlargements in the International Rapids section of the river. These enlargements would remove a considerable part of the natural shelf which controlled the outflow from Lake Ontario. Thus the headpond of the Power project would in effect extend upstream to Lake Ontario, and the water levels in the headpond would depend upon the levels to be maintained on Lake Ontario. As a result, when the need arose in 1952 for a knowledge of the range of water levels in the headpond reservoir, it was decided that backwater computations would be made for this purpose, and that water surface profiles would be prepared for the river reaches extending from the power dam site near Cornwall, Ontario, upstream to Lake Ontario.

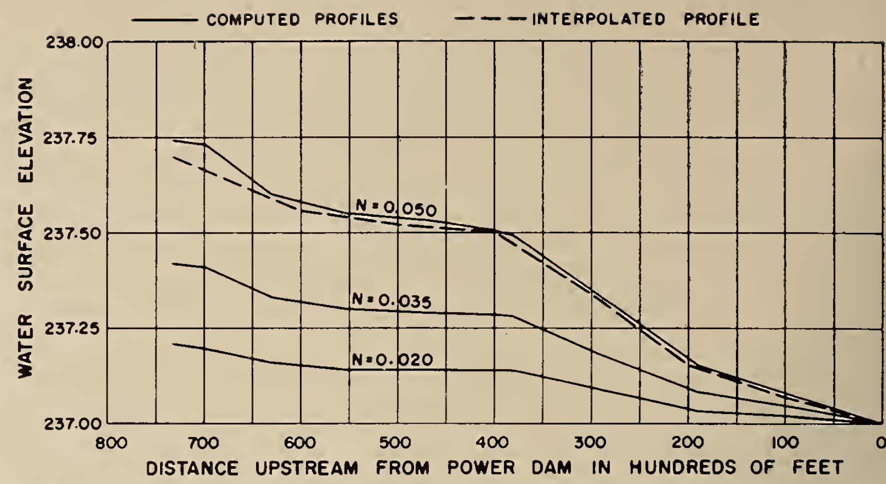


Fig. 2. Computed and interpolated backwater profiles between power dam and head of Croil Island open water condition.

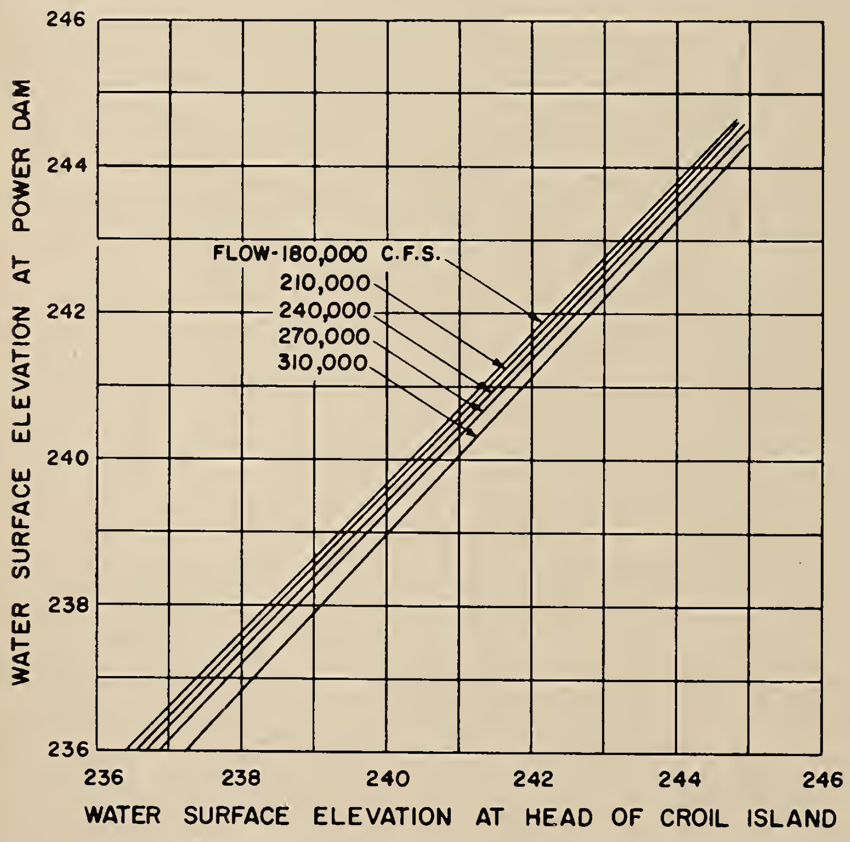
Basic Data

Fundamental requirements for an accurate, comprehensive backwater study include a set of contour maps of the river shores and channel, and stage-discharge relationships at sufficient points along the channel to provide the means for determining the channel roughness. From earlier surveys, a set of maps had been produced, giving subaqueous contours and shore topography between the power dam and Chimney Point. Limited soundings from navigation charts were available for the reaches from Chimney Point to Lake Ontario. However, very few up-to-date water-level records were available to provide channel roughness, and an extensive program of gauging was established immediately on the river to provide the necessary information. Since a considerable period of time would be required to obtain sufficient gauge records to establish the channel roughness, and since it was felt that the backwater computations should not be delayed, it was decided to proceed with the computations using a range of channel roughnesses which, it was hoped, would be sufficiently wide to bracket the values eventually selected.

Fig. 3. Computed backwater slopes-power dam to head of Croil Island open water condition.



Variables Selected

Two general channel conditions were assumed for carrying out backwater computations. In the first, no channel enlargements were assumed, and in the second, enlargements were assumed between the power dam and Chimney Point, which is approximately four miles east of Ogdensburg, N.Y., as shown in Fig. 1. For the most part, these enlargements were taken from reports summarizing earlier studies by the Corps of Engineers, U.S. Army. Additional enlargements in the vicinity of Iroquois were included to correspond with studies made by the Canadian Department of Transport. It was decided also that backwater slopes should be computed assuming open water conditions for the unimproved river channel, and open water and ice cover conditions for the improved river channel.

As indicated earlier, the proposed scheme of channel enlargements would largely eliminate the effects of the natural control section on the outflows from Lake Ontario. As a result, it had been accepted that some method would be adopted to regulate Lake Ontario elevations and outflows. Early in 1952, when the decision was made to proceed with the backwater computations, it appeared that Method No. 5, prepared by the Canadian Department of Transport, might be selected subsequently for this purpose. Under this regulation method, the range of outflows would be from 180,000 c.f.s. to 310,000 c.f.s. and from 180,000 c.f.s. to 260,000 c.f.s. for open water and ice-covered conditions respectively. Consequently, the following discharges were selected for the backwater computations:

Open water conditions
180,000, 240,000 and 310,000 c.f.s.

Ice-cover conditions
180,000, 220,000 and 260,000 c.f.s.

The assumed channel roughness, stated in terms of Manning's "n", were as follows:

Natural river channel
0.020, 0.035 and 0.050

Channel enlargements
0.020 and 0.035

Ice cover 0.025

The composite values of "n" for a channel with ice cover were obtained by averaging the values of "n" for ice cover and for the channel bed on the basis of the proportion of the wetted perimeter. When these discharges and roughnesses were combined with three assumed starting elevations at the power dam for each condition of the two general schemes, a total of 99 backwater cases resulted.

	250	304,700	6.235

Methods Used

In the pre-project state, there was a difference of approximately 85 ft. at mean discharge between the water levels at Lake Ontario and at the site of the power dam near Cornwall. All but about one ft. of this fall was concentrated in the reaches between the power dam and Chimney Point. With the Power project in operation, the flooding from the forebay would extend upstream approximately to Chimney Point, but in the channel between Chimney Point and Lake Ontario, stages would remain substantially unaltered.

n = Roughness of natural portion of channel
i = Roughness of improved portion of channel

Between the power dam and Chimney Point, where the greatest change in water levels would be effected, it was decided to perform the backwater computations by means of the standard-step method, using an adaptation of the Chezy-Manning equation proposed by Leach[1]. This method provides a convenient solution for problems dealing with channel cross-sections having a submerged flood plain, or other irregular conditions such as an artificial enlargement in part of the section, which necessitates separate computations. The discharge in open channels by the Chezy-Manning formula is:

$$Q = \frac{1.486}{n} AR^{2/3} S^{1/2}$$

or, putting $K_d = \dfrac{1.486}{n} AR^{2/3}$

$$Q = K_d S^{1/2}$$

For a constant "n", K_d varies only with the stage. Thus at a channel cross-section where the flow must be subdivided, K_d is obtained for each sub-section using the area, hydraulic radius and roughness applying to the sub-section. The sum of these values of K_d is the value of K_d applying to the entire cross-section. Hence at any cross-section, the slope of the hydraulic gradient is given by the equation

$$S = \frac{(Q)^2}{(K_d)^2}$$

by averaging the slopes at two ends of a reach, the friction loss in the reach is found by multiplying its length by the mean of the slopes.

In addition to friction losses, bend and expansion losses were included where applicable. Bend losses were computed when the total bend angle was greater than 45°, and expansion losses when the velocity at the upstream end of a reach exceeded the velocity at the downstream end. The equations used for these minor losses were as follows:

$$\text{Bend Loss} = \frac{1}{2} K_b \left(\frac{V_1^2}{2g} + \frac{V_2^2}{2g}\right)$$

$$\text{Expansion Loss} = \frac{1}{2} \left(\frac{V_2^2}{2g} - \frac{V_1^2}{2g}\right)$$

where:—V_1 and V_2 are the velocities in feet per second at the downstream and upstream ends of the reaches, respectively.

—K_b is a coefficient depending on the bend angle.

For want of better information on open channel bend losses, the results of model tests on pipe bends were used. Based on these tests the following bend loss coefficients were selected:

Bend Angle in Degrees	*Bend Loss Coefficients K_b*
45	0.18
60	0.22
75	0.26
90	0.29
105	0.31

The length of the main river channel between the power dam and Chimney Point is slightly more than 40 miles. In about 4/5 of this distance, large islands divide the river channel, and in about 2/3 of the distance, groups of islands form complicated channel networks. Because of the length and complexity of the river channel, and since backwater profiles were urgently required for 99 cases, it was decided to carry out the computations by means of a Ferranti digital computer at the University of Toronto Computation Centre.

Between Chimney Point and Lake Ontario, where stages during operation of the Power project would be practically unchanged from pre-project conditions, backwater slopes would be obtained by means of the unit fall - discharge method using recorded pre-project elevations and flows.

Preparation of Data

Using the contour maps of the river between the power dam and Chimney Point, approximately 230 channel cross-sections were selected. For each of these sections, the areas and conveyance factors were computed as a function of the water surface elevation. For the ice cover condition, an ice thickness of one foot was assumed, with the water surface coinciding with the top of the ice sheet.

In the case of the open water unimproved channel, the conveyance factor was left in the form nK_d

(where $nK_d = 1.486AR^{2/3}$)

Since the same value of "n" would apply at all cross-sections for each open water unimproved backwater case, only one set of conveyance factors was prepared in the above form. When the backwater computations were being performed on the Ferranti computer, one of the necessary operations was the division of the quantity "nK" by the appropriate value of "n". However, when channel enlargement and/or ice cover were included, it was found desirable to compute values of K_d manually for the various assumed combinations of "n". Sample tabulations of these data supplied to the Computation Centre are shown in Tables I, II and III.

The inclusion of channel enlargements was found to have an appreciable effect on the reach lengths and bend loss coefficients. Hence two sets of these data were required, as shown in Tables IV and V.

Selection of Actual Channel Roughnesses

While water surface profiles for the 99 backwater cases were being determined at the Computation Centre,

n = Roughness of natural portion of channel
i = Roughness of improved portion of channel

data from the gauging programme on the river were being processed. Stage-discharge relationships at the newly-selected gauge locations were determined by relating the water surface elevations at these points with those at long-term gauge installations having established stage-discharge relationships. Distribution of the total river discharge around islands was determined from flow measurements obtained by current meters. Using recorded water levels and the corresponding discharges, backwater effects between several gauges were calculated to determine the channel roughness which would produce the observed slope. These computations were made for channels carrying the full river flow, and also for divided channels formed by islands. Bend and expansion losses were calculated and deducted so that the true channel roughness could be established as nearly as possible.

Since these calculations were based on pre-project water levels, and since the final backwater slopes were required for the flooded reservoir, the computed roughnesses were modified[2] to apply to the channel when water levels were raised. The values of Manning's "n" finally selected for the flooded channels were as follows:

	Open Water Conditions	*Channels with Ice Cover*
Natural Channel		
Channels without islands	0.032	0.0285
Split channels formed by islands	0.044	0.0345
Channel Enlargements	0.025	0.025

In the foregoing tabulation, the values of "n" for channels with ice cover assumed a roughness of 0.025 for the ice sheet. This value was based on operating experience in the canals supplying water to the Beauharnois plant of the Quebec Hydro-Electric Commission, and to Ontario Hydro's Sir Adam Beck-Niagara Generating Station No. 1.

The roughness values selected for the natural channels were the average of two groups each containing several modified values of "n" based on pre-project water levels and discharge. It is, perhaps, worthy of note that the individual values of "n" comprising each group showed a remarkable consistency.

Interpolation of Computations

When the flooded channel roughnesses had been decided, it was necessary to interpolate the profiles produced by the Computation Centre, for which the previously chosen ranges of roughness had been used. The following equations were developed:

(a) In a reach consisting of cross-sections having a single value of "n" for each backwater profile, the friction loss for the desired value of "n" was given by the equation:

$$hf_2 = \left(\frac{2n_2}{(n_1/hf_1^{1/2}) + (n_3/hf_3^{1/2})}\right)^2 \quad \text{(a)}$$

where hf_1 and hf_3 are computed friction losses for assumed roughnesses of n_1 and n_3 respectively.
n_2 is the selected roughness for which friction loss hf_2 is required.
n_1 and n_3 bracket n_2.

(b) When cross-sections in a reach include channel enlargements, and separate values of "n" were assigned to the natural and improved portion, the friction losses for the desired "n" values were given by the equation:

$$\frac{1}{(hfn_3/i_3)^{1/2}} = \left(\frac{(1/n_3) - (1/n_2)}{(1/n_1) - (1/n_2)}\right)\frac{1}{(hfn_1/i_1)^{1/2}} + \left(\frac{(1/i_1) - (1/i_3)}{(1/i_1) - (1/i_2)}\right)\frac{1}{(hfn_2/i_2)^{1/2}} + \left(\frac{(1/n_1) - (1/n_3)}{(1/n_1) - (1/n_2)} + \frac{(1/i_3) - (1/i_2)}{(1/i_1) - (1/i_2)} - 1\right)\frac{1}{(hfn_2/i_1)^{1/2}} \quad \text{....(b)}$$

where hfn_3/i_3 is the required friction loss in a reach in which the natural and improved roughnesses are n_3 and i_3 respectively.
hfn_1/i_1, hfn_2/i_1 and hfn_2/i_2 are known friction losses, computed using the indicated natural and improved roughness combinations.

To obtain the interpolated backwater slopes, the channel between the power dam and Chimney Point was divided into 22 reaches averaging about 10,000 ft. in length. Losses in these reaches were taken from the backwater slopes computed by the Ferranti computer, and were modified by applying the above equations to obtain slopes for the values of "n" established from studies based on recorded water levels. Computed backwater profiles and the resulting interpolated profile for a typical reach are given in Fig. 2.

It was realized that interpolation by the above equations would be strictly accurate only if applied to pure friction losses in the reach. The actual losses included not only friction losses, but also bend and expansion losses which would be independent of the friction loss. Thus the interpolation process introduced a possible source of error, since bend and expansion losses were modified as well as friction losses. However, no practical method of separating these losses was evident and since these minor losses represented a small percentage of the total, it was decided to interpolate the total loss and to make several check computations to determine whether a serious error resulted.

Checks on Machine Accuracy and Interpolation Methods

To ensure that the calculations by the Ferranti computer were accurate and that the interpolation methods were reasonably correct, the following manual computations were made:

(a) Solution of the Goose Neck Island networks
(b) Solution of the Galop Island network
(c) Computation in South Galop channel
(d), (e) and (f) Solution of the Galop Island network for flows of 310,000 c.f.s., 240,000 c.f.s. and 180,000 c.f.s.
(h)-(k) incl. Computations in the vicinity of the Iroquois Dam, with and without ice cover.

Of the above checks, (a), (b) and (c) were made to determine the accuracy of the machine in solving networks and in computing losses in a channel. In each of these checks, the same values of "n" was used in the manual check as in the machine computation so that the results were directly comparable. Checks (d)-(k) were for verification of the interpolated results, and in each case the value of "n" used was the one for which the interpolated curves were obtained. It was found that the machine and manual computations agreed very closely, but that the interpolated profiles indicated slightly higher losses than the manual computations. Since the maximum discrepancy occurred at a discharge of 240,000 c.f.s. it was decided to compute a complete profile at that discharge. This computed profile was practically identical with the interpolated profile between the power dam and Morrisburg. Between Morrisburg and Chimney Point, the profiles diverged, with the interpolated profile being 0.24 ft. higher at Chimney Point. Since this cumulative difference occurred in a distance of approximately 18 miles, it was considered that the interpolation methods gave results which were reasonably free from error. Furthermore, it was realized that hydraulic models would be constructed to investigate the design of channel enlargements in the reaches between Morrisburg and Chimney Point, and that these models would be used to verify the backwater slopes.

Preparation of Final Backwater Curves

Although water surface profiles were computed and interpolated for the channels with and without enlargements, final backwater curves were prepared only for the channels with enlargements. To isolate and permit detailed studies of various groups of channel enlargements, the river channel between the power dam and Chimney Point was divided into six reaches. From cross-plots of the interpolated backwater profiles, slopes for open water and for ice cover were obtained for each of these reaches. The open water losses between Lake Ontario and Chimney Point were derived from a unit fall-discharge curve based on pre-project water levels for summer months. Ice cover losses in this reach were assumed to be 0.25 foot higher than for open water as indicated by comparing gauge-relation curves for summer and winter months. Overall losses between Lake Ontario and the power dam were derived by including losses through the Iroquois Dam as computed by the Canadian Department of Transport. Drawings then were prepared to show the water level at the head and foot of the reaches as a function of the river discharge. Curves for a typical reach are given in Fig. 3.

Uses of Backwater Curves

The design and construction of the St. Lawrence Power Project was a joint venture undertaken by the Power Authority of the State of New York, and Ontario Hydro. The hydraulic design of the project was allotted to Ontario Hydro, and as a result, the engineering staff of that organization has used the backwater

(Continued on page 66)

BACKWATER COMPUTATIONS FOR THE ST. LAWRENCE POWER PROJECT

Part B. Backwater Calculations on the Ferranti Digital Computer.

C. C. Gotlieb, *Associate Professor of Physics and Chief Computer Computation Centre, University of Toronto, Ont.*

Presented at the 73rd Annual General and Professional Meeting of The Enginering Institute of Canada, Toronto, Ont., June 1959.

Formulation of Basic Reach Equation

IN BACKWATER calculations as described in part A of this paper by H. M. McFarlane, certain parameters of a river are assigned, e.g. its course (including branches), the profile of its bed, roughness of channels, discharge of water, etc., and the problem is to compute the water elevations along its course for these conditions. The basic equation assumes steady state flow and relates the water levels at two stations (i.e. the two ends) of a reach (i.e. a channel of uniform cross-section, A).

Let E_1 be the energy per unit mass of the water at station 1,

E_2 be the energy per unit mass of the water at station 2,

assumed to be upstream from station 1. Then $E_2 = E_1 +$ energy loss between 1 and 2.

Now $E_1 = gW_1 + \frac{1}{2}v_1^2$

where W_1, v_1 are water level and velocity at station 1, this velocity being taken as uniform over the whole cross-section, and $E_2 = gW_2 + \frac{1}{2}v_2^2$

therefore $gW_2 + \frac{1}{2}v_2^2 = gW_1 + \frac{1}{2}v_1^2 +$ energy loss between 1 and 2.

If we write $(v^2/2g) = hv$, the velocity head and let $(1/g) \times$ (energy loss between 1 and 2) $= hf_{1,2} + hb_{1,2} + ht_{1,2}$ where ghf is the energy loss due to friction, ghb is the energy loss due to change in alignment or bending and ght is the energy loss due to expansion or turbulence, then

$$W_2 = W_1 + hv_1 - hv_2 + hf_{1,2} + hb_{1,2} + ht_{1,2} \quad \ldots(1)$$

The expressions for the head losses due to friction, bending and turbulence are found from empirical equations. They are :

$$hb_{1,2} = \frac{B}{2}(hv_2 + hv_1) \quad \ldots(2)$$

where B is a head loss coefficient which is tabulated as a function of the total deflection of a given bend, and is found to vary between 0 and 0.34,

$$ht_{1,2} = \text{const.}\,(hv_2 - hv_1) \text{ when } hv_2 > hv_1 \quad \ldots(3)$$
$$= 0 \text{ when } hv_2 \leq hv_1$$

and for the work reported here the constant has been taken as 0.5,

$$hf_{1,2} = \frac{L}{2}\left(\frac{Q_1^2}{K_1^2} + \frac{Q_2^2}{K_2^2}\right) \quad \ldots(4)$$

where L is the reach length, Q is the discharge, and

and $$K = \frac{1.486}{n} AR^{2/3}$$

A = cross sectional area,
n = a roughness coefficient, known for the type of channel,
R = hydraulic radius $= A/(b + d)$,
b = river surface width
d = mean depth $= A/b$.

Noting that $Q = vA$ equation (1) becomes

Three Island Network

Fig. 1. Plan

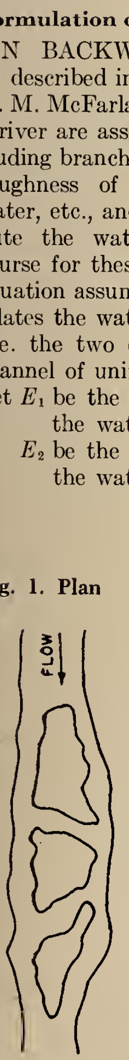

Fig. 2. Flow distribution

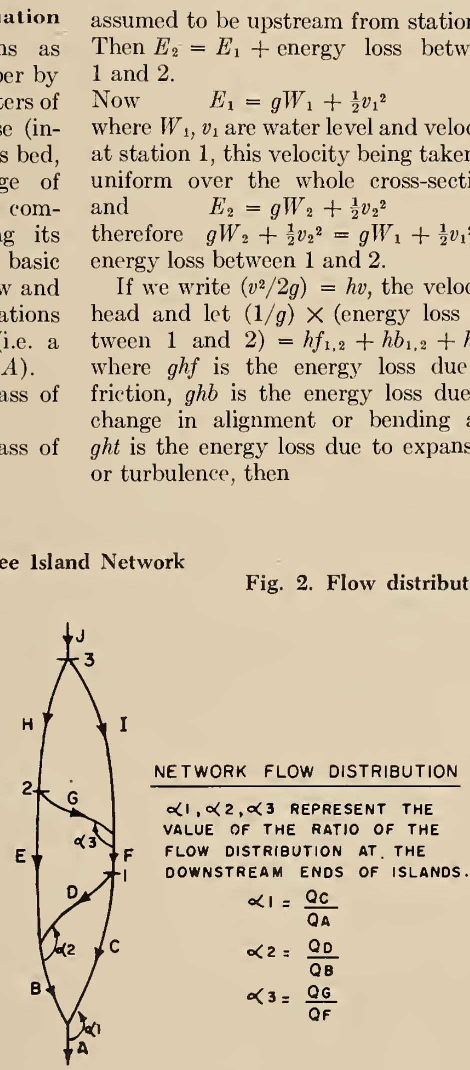


$$W_2 = W_1 + \frac{Q_1^2}{2gA_1^2} - \frac{Q_2^2}{2gA_2^2} + \frac{L}{2}\left(\frac{Q_1^2}{K_1^2} + \frac{Q_2^2}{K_2^2}\right) + \frac{B}{2}\left(\frac{Q_2^2}{2gA_2^2} + \frac{Q_1^2}{2gA_1^2}\right) + \delta\left(\frac{Q_2^2}{2gA_2^2} - \frac{Q_1^2}{2gA_1^2}\right)$$

where $\delta = 0$ if $hv_2 \leq hv_1$ and $\delta = \frac{1}{2}$ if $hv_2 > hv_1$ or

$$W_2 = W_1 + \frac{Q_1^2}{2gA_1^2}\left(\frac{gLA_1^2}{K_1^2} + \frac{B}{2} + \Gamma\right) + \frac{Q_2^2}{4gA_1^2}\left(\frac{gLA_2^2}{K_2^2} + \frac{B}{2} - \Gamma\right) \quad \ldots.(5)$$

with $\Gamma = 1 - \delta$.

Equation (5) is used to calculate W_2 from W_1. Since A and K depend on W_2 it is convenient to set up an iteration whereby $W_2{}^n$, defined as W_2 at iteration n, is assumed to be known and is used to determine the quantities appearing in the R. H. S. of (5) from which $W_2{}^{n+1}$ is found. This is continued as long as necessary, producing $W_2{}^{n+2}$, $W_2{}^{n+3}\ldots$ until convergence is reached. In practice only two or three iterations are required. The process is started by taking $W_2{}^0 = W_1$, at the end of the reach, i.e. by assuming that there is no change in level across the reach. An iteration of this kind is very well suited to an electronic computer which was used to carry out the calculation.

Island Nets

The calculations become considerably more complicated when there are islands in the river, causing the flow to divide. In discussing this, it is convenient to introduce a number of terms as follows:

Link—a reach or series of reaches having a common discharge or a single reach having different discharges at its ends;

Branch—a sequence of links having consecutive station numbers;

Net—the region including one or more islands between the two closest stations having full river discharge;

Section—a larger unit which may include several branches or nets but which must terminate with stations having full river discharge.

The method which was developed for handling nets will be illustrated by means of the example shown in Fig. 1 where there are three islands. The link representation of this net is shown in Fig. 2. If the correct flow were known for each branch then the calculation of the water levels could proceed by the straightforward application of equation (5). However, the flows are not known and therefore we introduce three parameters:

$\alpha_1 = (Q_C/Q_A)$ where Q_C = flow in branch C

Q_A = flow in reach A = total discharge and similarly

$$\alpha_2 = \frac{Q_D}{Q_B} \quad \text{and} \quad \alpha_3 = \frac{Q_G}{Q_F}$$

The flow in each branch is easily found in terms of these parameters and Q_A.

For example

$$Q_E = Q_A(1 - \alpha_1)(1 - \alpha_2)$$

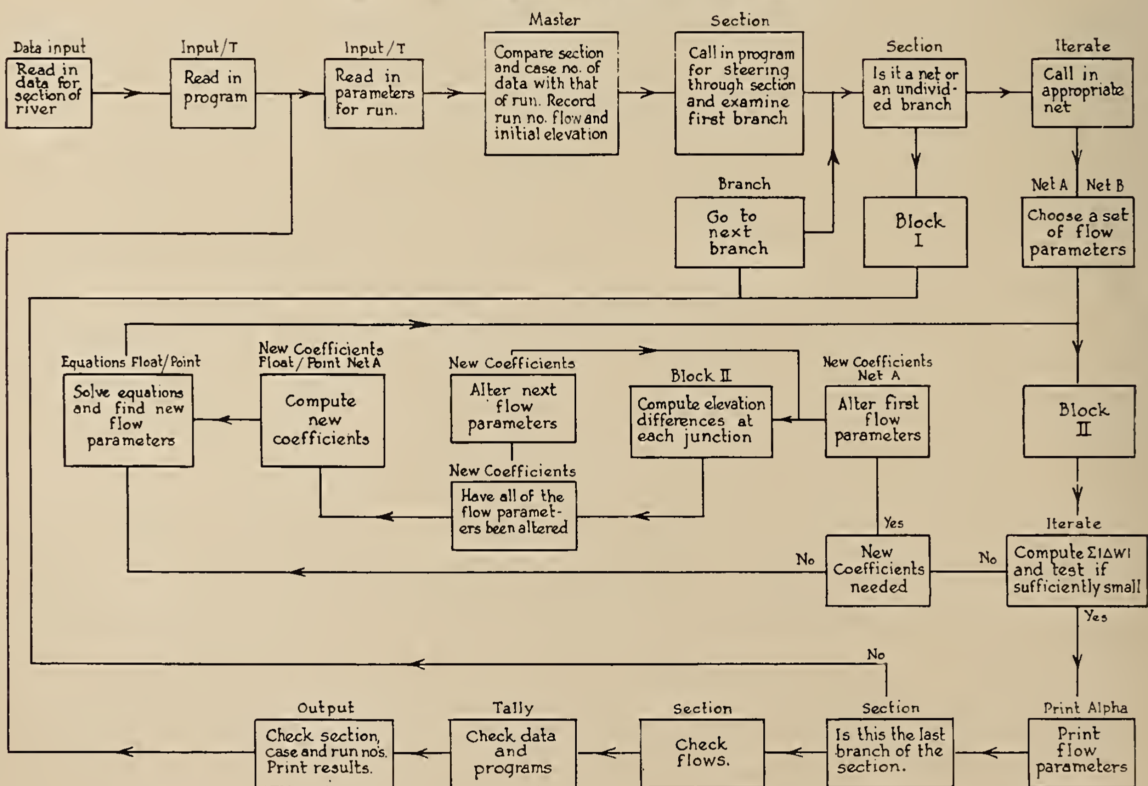
and $Q_G = Q_A\alpha_3(\alpha_1 + \alpha_2 - \alpha_1\alpha_2)$

If arbitrary values of α_1, α_2 and α_3 are chosen then the conditions of flow will not be satisfied as will be seen from the fact that W_1, the water-level at the junction of branches B, C, D, will be different as found by going up the branch C, than that found by going up the branches D and B. Similarly at confluences 2 and 3 (Fig. 2), the other places where branching parameters were not defined, the water levels W_2 and W_3 will depend on the route taken to reach the junction. The problem then, is to choose α_1, α_2 and α_3 so that

W_1 via link C − W_1 via links B, D = 0

W_2 via links B, E − W_2 via links $C, F, G,$ = 0

Fig. 3. Flow diagram for backwater calculations



W_3 via links $B, E - W$ via links $C, F, I, = 0$ ....(6)

Let $\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3$ be the true values which will satisfy the equations (6) and let $\alpha_1, \alpha_2, \alpha_3$ be approximate solutions. When $\alpha_1, \alpha_2, \alpha_3$ are substituted into the L.H.S. of the equations we will get not zero but ΔW_1, ΔW_2, and ΔW_3 and we may write:

$$\Delta W_1 = f_1(\alpha_1, \alpha_2, \alpha_3)$$
$$\Delta W_2 = f_2(\alpha_1, \alpha_2, \alpha_3)$$
$$\Delta W_3 = f_3(\alpha_1, \alpha_2, \alpha_3)$$

The functions f_1, f_2, f_3 may be expanded in Taylor's series about the point $\alpha_1, \alpha_2, \alpha_3$, and ignoring derivatives higher than the first we have:

$$\Delta W_1 = f_1(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) + (\alpha_1 - \bar{\alpha}_1)\left(\frac{\partial f_1}{\partial \alpha_1}\right)_0 + (\alpha_2 - \bar{\alpha}_2)\left(\frac{\partial f_1}{\partial \alpha_2}\right)_0 + (\alpha_3 - \bar{\alpha}_3)\left(\frac{\partial f_1}{\partial \alpha_3}\right)_0 + \ldots$$

$$\Delta W_2 = f_2(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) + (\alpha_1 - \bar{\alpha}_1)\left(\frac{\partial f_2}{\partial \alpha_1}\right)_0 + (\alpha_2 - \bar{\alpha}_2)\left(\frac{\partial f_2}{\partial \alpha_2}\right)_0 + (\alpha_3 - \bar{\alpha}_3)\left(\frac{\partial f_2}{\partial \alpha_3}\right)_0 + \ldots$$

$$\Delta W_3 = f_3(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) + (\alpha_1 - \bar{\alpha}_1)\left(\frac{\partial f_3}{\partial \alpha_1}\right)_0 + (\alpha_2 - \bar{\alpha}_2)\left(\frac{\partial f_3}{\partial \alpha_2}\right)_0 + (\alpha_3 - \bar{\alpha}_3)\left(\frac{\partial f_3}{\partial \alpha_3}\right)_0 + \ldots \quad \ldots(7)$$

where the subscript 0 indicates that the partial derivatives are to be evaluated at the points $\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3$. We also note that

$$f_1(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) = f_2(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) = f_3(\bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3) = 0.$$

For a given set of approximate values $\alpha_1, \alpha_2, \alpha_3$ the left hand sides of equation (7), $\Delta W_1, \Delta W_2, \Delta W_3$ can be calculated by applying the basic reach equation along each branch, and if the values of the partial derivatives were known it would then be possible to solve for $\bar{\alpha}_1 - \alpha_1, \bar{\alpha}_2 - \alpha_2$ and $\bar{\alpha}_3 - \alpha_3$, i.e. the corrections to the α's which will make the solution better. These partial derivatives can be found numerically by introducing slight changes in the α's and noting the corresponding changes in the ΔW's. Thus suppose a slight displacement k, is introduced systematically into the α's, and the W's found according to the following table.

Branching Parameters			*Corresponding level differences* W_1	W_2	W_3
α_1	α_2	α_3	$\Delta W_{0,1}$	$\Delta W_{0,2}$	$\Delta W_{0,3}$
$\alpha_1 + k$	α_2	α_3	$\Delta W_{1,1}$	$\Delta W_{1,2}$	$\Delta W_{1,3}$
$\alpha_1 + k$	$\alpha_2 + k$	α_3	$\Delta W_{2,1}$	$\Delta W_{2,2}$	$\Delta W_{2,3}$
$\alpha_1 + k$	$\alpha_2 + k$	$\alpha_3 + k$	$\Delta W_{3,1}$	$\Delta W_{3,2}$	$\Delta W_{3,3}$

Then we have at once that:

$$\frac{\partial W_1}{\partial \alpha_1} = \frac{\Delta W_{11} - \Delta W_{01}}{k}, \quad \frac{\partial W_2}{\partial \alpha_1} = \frac{\Delta W_{12} - \Delta W_{02}}{k}, \quad \frac{\partial W_3}{\partial \alpha_1} = \frac{\Delta W_{13} - \Delta W_{03}}{k}$$

and similarly for the other derivatives.

It should be noted that these derivatives have been found in the neighbourhood of the approximate solution rather than the neighbourhood of the true solutions where they are required. The corrections to the α's can then be found by solving the set of linear equations (7), and the results used as the beginning of a new iteration. It is not always necessary to redetermine the partial derivatives for later cycles. The sum of the absolute values of the errors ΔW can be used as a criterion for stopping the iteration.

There is no guarantee that the iteration used to solve for the flows will always converge, but in practice it was found that convergence was reached in a few cycles except in one circumstance. Suppose it turns out that the flow in a cross channel such as G in Fig. 2 is very small. On the next cycle it could happen that the flow in G would be reversed, and on still another cycle the flow might come back to the original direction. Such oscillatory solutions did in fact arise on the computer but it was possible to recognize their occurrence and take care of this case by setting the flow in G to be zero (taking $\alpha_3 = 0$) which is equivalent to setting up a wall in channel G.

The Computer Program

After some preliminary trials using desk calculation, an analog machine and conventional punched card equipment, the back-water computations were put on *Ferut**, the Ferranti electronic digital computer which had just been installed at the University of Toronto. *Ferut* has been described elsewhere[1] and therefore only its vital statistics will be given here. It is a serial binary computer, having two levels of store, one electrostatic with 512, 40 bit words, the other a magnetic drum with 256, 64 word tracks. The machine has 7 B registers, a versatile instruction code and addition and multiplication times of about 1 and 2 ms., respectively. At the time of installation input was by means of a photo-electric paper tape reader (200 characters/sec) and output could be punched on tape (18 characters/sec) or printed on an electric typewriter (12 characters/sec). A great deal of special preparation has to be done before a large problem can be run on a computer and this work for the back-water problem will now be described briefly.

Scaling

A machine such as *Ferut* regards all numbers as if they had a fixed decimal point e.g. on the extreme left in which case numbers are all fractions in the range $+\frac{1}{2}$ to $-\frac{1}{2}$, or on the extreme right in which case numbers are regarded as integers. This means that constants, parameters and variables have to be adjusted by scale factors which ensure that numbers always re-

*FERUT was operated at the University of Toronto from June 1952 to May 1958, after which it was moved to the Division of Mechanical Engineering, National Research Council where it is at present operating.

$$W = 2^{-21}W \qquad \beta = \tfrac{1}{2}$$
$$q = 2^{-40}Q^2/4g \qquad \gamma = 10^{-4}\Gamma = 10^{-4} \text{ if } x_2q_2 \le x_1q_1$$
$$\lambda = 10^{-4}L \qquad = \tfrac{1}{2} \times 10^{-4} \text{ if } x_2q_2 > x_1q_1$$
$$x = 10^4/A^2$$
$$y = (10A/K)^2 \qquad \bar{g} = g/100$$

With these substitutions, the working form of equation (5) becomes:

$$w_2 = w_1 + 2^{20}q_1x_1(\bar{g}\lambda y_1 + \beta + \gamma) + 2^{20}q_2x_2(\bar{g}\lambda y_2 + \beta - \gamma) \quad \ldots(8)$$

main within the proper bounds. The scaling for the quantities of the previous two sections is shown in equation (8) :

Routines

A computer calculation is divided into a number of connected segments or routines, and where the high speed store is of limited capacity, as is the case with *Ferut*, different routines and the data required for them, come down onto the high speed store and carry out their function in turn. The routines written for the back-water program are as follows :

Data Input—This reads the data of a reach into the machine, and converts the decimally punched information into the binary form used in the computer. Included in the data are identification number, reach length, bend loss coefficient, and area and K factor as a function of elevation. The drum was not adequate to store the data on the whole river and therefore the river was divided into four sections and the water levels calculated over a range of the parameters for each section in turn.

Inverse Data Input—This routine prints out the data on the river in the form of the original sheets used to prepare the data, providing a check that no error had been made by human transcription or machine input.

Master—Checks that the correct data has been used for the run being calculated, and enters the volume of flow and initial elevation into the proper locations.

Reach—Performs the basic iteration of equation (8).

Link, Branch—These routines guide the program to calculate the stations in the proper sequence.

Net A, Net B—These routines define the particular nets. They are different for each net and it is these routines, along with *section* and some constants in *Link* which have to be rewritten for each part of the river.

Section—This routine steers the program from one net to the next. It also plays an important part in the checking of results. On completion of the calculations for all the branches and nets in a section, *Section* causes the entire computation to be repeated using the computed levels as the first approximation in the reach level. A record is kept of the number of times the reach iteration is performed, less the number of reaches in the section. This count is printed out on completion of the check calculation and should be zero if the computed water levels satisfy the conditions required of them.

Iterate—This routine guides control through the various routines used to determine the flows in a net. It calls upon *Net A* to compute the level differences for a given set of flow parameters α, then calls upon

Print E to print the sum of the error terms for the operator's information. If necessary *Iterate* then reads down.

New Coefficients which in conjunction with *Net A* produces a set of partial derivatives which are the coefficients of the equations (7).

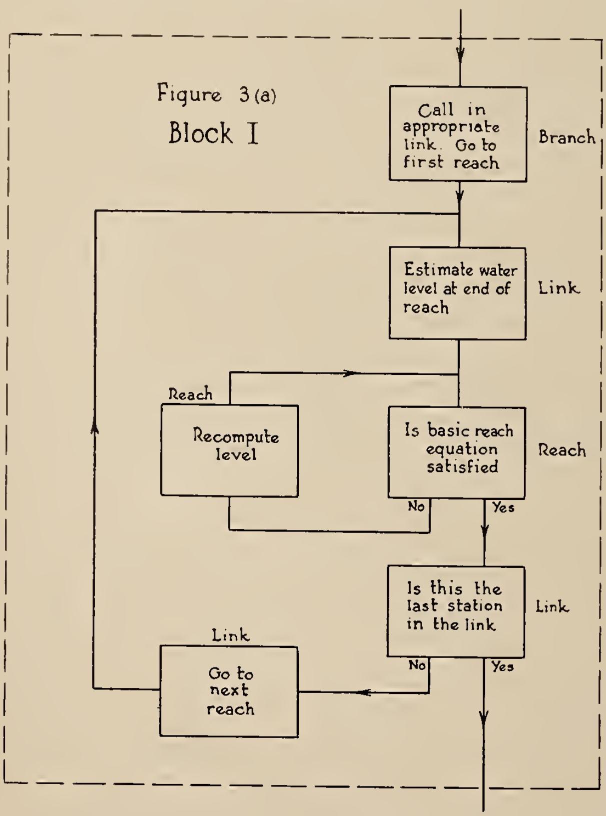
Equation—Solves the system of equations. In the form of the program as used, networks of only six islands or less could be treated automatically, although a net of seven islands could be handled with operator manipulation.

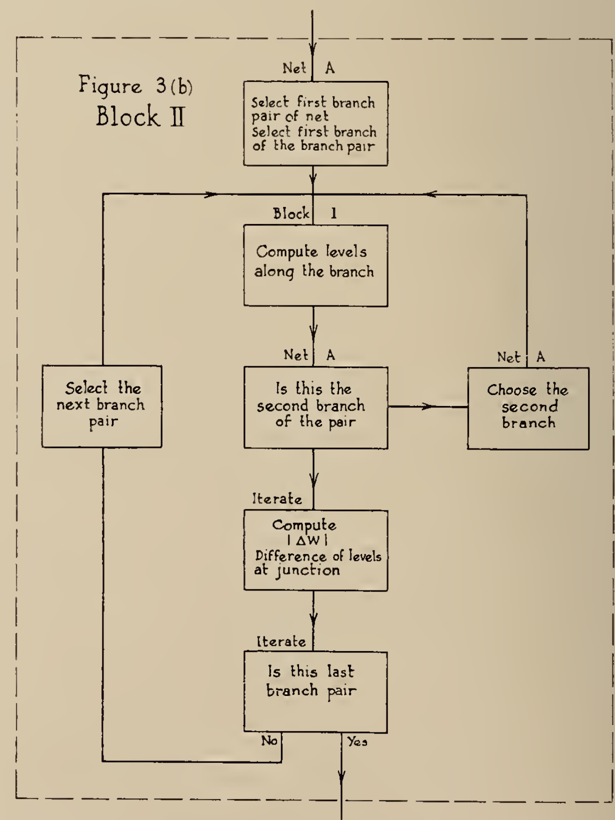
Float Point—This is a standard library routine for dealing with numbers in floating binary notation (i.e. with a power of two scale factor which is automatically adjusted) since the division operation used in the solution of equations will give rise to numbers outside the range of $\frac{1}{2}$ to $-\frac{1}{2}$.

Print Alpha—Prints the flow parameters in decimal form.

Tally—Is a final checking routine which sums all the data and program tracks, compares the sum with known check sums and prints a list of discrepancies if there are any. In this way it is known that no changes have crept in during a machine run.

Output—Prints the identifying data and water levels for the run.





Input/T is a standard library program for reading in the parameters necessary for a different case with the same basic data.

Flow Diagram

Fig. 3 shows a flow diagram for the program, i.e. the sequence of steps necessary to carry out the calculations. It indicates how the steps have been grouped into routines and how the routines follow one another.

Checking Procedures

Not only was *Ferut* one of the first large computers in operation but the back-water calculations were the first extensive computations undertaken with *Ferut*, and much was learned about techniques, now become standard, for doing such computations. Since the reliability of the machine in its early days was relatively low and would not be considered acceptable now, to achieve results which would be used with confidence it was necessary to include numerous checks in the program. Some of these have already been pointed out but the more important checks will be summarized here:

Table I. Input Reach Information

Elevation	*Area (sq. ft.)*	*Conveyance Factor K (millions)*
233	230,600	093.03
234	234,500	095.46
236	242,500	100.80
238	252,500	106.26
240	258,250	111.66
242	266,000	117.37
244	274,000	123.20
246	281,000	129.14
248	289,750	135.23
250	297,600	141.37

1. Checksums were attached to data and programs tapes and these could verify that no errors had been introduced during reading, or during the course of a run;

2. After each run the computed levels were substituted back into the basic reach equation and it was verified that no further iterations were necessary;

3. The solution of the linear equations, obtained by elimination, was substituted back to make sure the equations were satisfied;

4. Frequent restart points were incorporated into the program so that when the machine made a mistake some of the results of the run could still be used;

5. A great many hand calculations were carried out. For example the flow divisions and water elevations in networks were checked for consistency. At selected stations the velocity as calculated by the machine was compared with the value obtained on dividing Q by A. One complete run was computed on a desk calculator, using initial elevations at each reach which were close to, but not exactly the same as those found on the machines. The results for the various runs were compared for consistency and smoothness. At no time was a result which had been accepted from the machine rejected because of failure to satisfy the hand calculated checks;

It was also necessary to take special precautions against human error and the following are some of the checks adopted:

6. The names of all the routines were printed as they were read into the machine to make sure that none had been omitted;

7. The sets of input data were given identification numbers according to the parameters associated with them and the machine checked that the correct set was used for each run;

8. Operating procedures and instructions were carefully written out since only one or two of the people who operated the computer during production were familiar with all the details of the program.

Table II. Form of Computer Results

Run no—012 *Station No.*	Section 1 *Elevation*	Case 0 *Velocity*	*Flow*

46	35.4564	01.06	097,535

Data and Results

The following parameters were required to specify a machine run:

(1) Section number — Because the store was not adequate to contain the description of the whole river, the St. Lawrence was divided into four sections, labelled 0, 1, 2, 3. Altogether in the four sections there were 267 stations;

(2) Case number. Calculations were carried out for both natural and improved channels under both open water and ice-covered conditions;

Case No.	Channel Description
0	unimproved channels, open water
1	unimproved channels, ice cover
2	all Canadian Navigation, improved channel, open water
3	all Canadian Navigation, improved channel, ice cover
4	joint navigation, improved channel, open water
5	joint navigation, improved channel, ice cover

(3) The run number, comprising

(i) Roughness coefficient

Identifying Digit	*n-Natural*	*n-Improved*
0	0.020	0.020
1	0.0275	0.020
2	0.0275	0.0275
3	0.035	0.020
4	0.035	0.0275
5	0.035	0.035
6	0.050	0.035
7	0.050	0.050

(ii) Initial water surface elevation (at Barnhart Island Power House)

Identifying Digit	*Initial Elevation—ft. above sea level*	*Identifying Digit*	*Initial Elevation*
0	233.00	5	240.0
1	235.0	6	241.0
2	236.0	7	242.0
3	237.8	8	243.0
4	238.0	9	245.0

(iii) Discharge — This is the total flow, in c.f.s., leaving the section

Identifying Digit	*Flow—c.f.s.*
0	180,000
1	220,000
2	240,000
3	260,000
4	310,000

Every combination of these parameters was not run, there being 99 runs in all In addition two special dewatering cases describing the conditions of the temporary channel set up while the power-house was being constructed were also run. Table I. shows the input information for a typical reach. This information is preceded by the section, case and run numbers and by *L* the reach length in ft. and *B*, the bend loss coefficient.

Table II. shows the results for a run on one of the four sections. To save time on the relatively slow printer the headings were not actually printed.

The whole calculation required about 500 machine hours spread over a period of some eight months. From the one complete case which was computed by hand it is estimated that 20 man-years would have been required to do the work on desk computers.

Acknowledgements

Each of us (C. C. G. at the University of Toronto, and H. M. M. at the Ontario Hydro) was only one member of a team which helped to set up the backwater problem, carry out the calculations, and interpret the results. At the University particular mention should be made of Christopher Strachey, on loan from N.D.R.C. in the United Kingdom, who did much of the programming and computer organization. Dr. J. H. Chung, of the Computation Centre, and Cecily Popplewell, on leave of absence from Manchester University, also contributed heavily. T. J. Hogg, responsible for liaison between the two groups, worked most effectively on all phases of the problem and he was ably assisted on this by G. V. D. Crombie.

• BACKWATER COMPUTATIONS PART A

(Continued from page 60)

curves very extensively. Preliminary designs for the water passages in the power dam, the Long Sault Dam and the Iroquois Dam all were based on water levels determined by means of the backwater curves. Plans for rehabilitation of the population in the flooded forebay also were based on the range of levels in the headpond.

One of the major features designed by Ontario Hydro was the plan of channel enlargements between Morrisburg and Chimney Point. To assist in this work two large hydraulic models were constructed, and were used over a period of three years to develop satisfactory designs. In all, a total of eleven hydraulic models were used to develop or prove hydraulic designs or to determine a satisfactory sequence of operations for field construction. Starting or limiting conditions for these model tests were obtained in many instances by means of the backwater curves.

Use of the backwater curves, however, has not been limited to engineers at Ontario Hydro. As was anticipated at the outset, the Seaway entities have based the designs for their navigation locks and canals in the Power Project area on water levels provided by means of the backwater curves. In addition, various other government agencies in Canada and the United States have referred to them frequently.

Many manhours of painstaking effort went into the preparation of the backwater curves. However, their widespread use, and the confidence which was implicit in this use, amply repaid those who were engaged in this work.

Acknowledgement

The decision to make use of the Ferranti computer to perform the backwater computations was a wise one. In less than one year's time, all 99 backwater profiles had been computed, and it is estimated that approximately 20 man-years would have been required to perform the same work manually. This tremendous saving in time was due not only to the performance of the computer, but also to the skill and perseverance of the staff at the Computation Centre under Dr. C. C. Gotlieb's direction, in pressing this difficult problem to completion.

Of those on the Ontario Hydro engineering staff engaged in preparing the backwater slopes, T. J. Hogg and G. V. D. Crombie deserve special mention for their effective liaison work with the Computation Centre. P. S. Quan provided invaluable assistance in the development of the interpolation equations, and also a method for the manual solution of a channel network. Overall supervision of the engineers and technicians engaged in the backwater studies was very capably handled by J. B. Bryce, Hydraulic Engineer, and his assistant, D. G. Harkness.

THE ST. LAWRENCE POWER PROJECT
REHABILITATION
A Review of Major Features

J. H. Jackson, M.E.I.C. *Construction Manager of Otter Rapids Project*
Hydro-Electric Power Commission of Ontario.

Presented at the 73rd Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, Ont., June 1959.

THE CONSTRUCTION of the power development phases of the combined St. Lawrence Power and Seaway Projects forced the dislocation of some 6500 St. Lawrence River Valley residents and the flooding of approximately 20,000 acres of riverfront land on the Canadian side, including seven communities and part of an eighth.

The creation of two completely new communities, Ingleside and Long Sault, and the relocation of Iroquois and part of Morrisburg, were the main features of the rehabilitation program undertaken by Ontario Hydro as one of its responsibilities as joint developer of the St. Lawrence Power Project with its American counterpart, the Power Authority of the State of New York. The task of relocating complete communities, some of which had been in existence for over a century, was a formidable one.

The physical creation of new townsites with roads, sidewalks, waterworks, sewage treatment plants, etc., was a simple matter and one which is being carried out daily in the expansion of towns and cities across the country. The unique features of these townsites were that the residents were being moved from homes and communities in which they had spent a lifetime and relocated in new surroundings with new or moved homes, new churches, schools, shopping centres and recreational facilities. These residents, many of them direct descendants of the United Empire Loyalists who originally settled the area, were required not only to give up their homes, churches, etc., but even a way of life to permit construction of the long awaited St. Lawrence Power Project. The attitude of the residents was one of cautious skepticism, particularly as the Powei Project had been rumoured for over 40 years but had never developed.

Fig. 1 Water Pumping Station at Ingleside.

Hydro's attitude with respect to the St. Lawrence was expressed as far back as 1921 during the chairmanship of the late Sir Adam Beck:

"The lands bordering the north shore of the St. Lawrence River between Cornwall and Prescott were, to a large extent, originally settled by United Empire Loyalists. The best lands in this territory, and consequently the most thickly settled, lie close along the shore of the river. They are among the earliest settled lands in the Province, and the homesteads, churches and public institutions have existed and functioned for several generations. It seems evident, therefore, that if any scheme of development on the St. Lawrence River necessitates the injury, destruction or elimination of these interests and institutions, a sentimental factor is introduced which cannot be appraised as a definite cost item, but to which, nevertheless, due respect must be accorded." *

From the beginning the co-operation of the municipal representatives in the area was sought to solve the problems mutually which would be created in such a program.

The purpose of this paper is to review some of the major features in-

*From Joint Statement by Robert H. Saunders, Chairman, Ontario Hydro, and William K. Warrender, Minister of Planning & Development, Province of Ontario, contained in Proposals for The Rehabilitation of Communities Affected by Construction of the St. Lawrence Power Project, August 17, 1954.

volved in the rehabilitation program. A description of the areas to be flooded is followed by a review of the planning involved and the construction schedule. The actual field program is discussed under the following headings:

1. Municipal services, 2. House moving, 3. Relocation of schools and churches, 4. Shopping facilities, 5. Rental housing, 6. Cemeteries, 7. Cottages, 8. Shoreline improvements, 9. Highway relocation, 10. Railway relocation.

Fig. 2 Aerial view of New Iroquois with Canadian Seaway Locks and Iroquois Dam in background.

Flooded area

The area affected by the new headpond to be formed on completion of the joint Canadian and American powerhouse and the Long Sault dam, extended roughly from the city of Cornwall to the village of Iroquois, a distance of 35 miles. The headpond elevation was established by the International Joint Commission to be 238 ft. above sea level for a period of 10 years or less. Experiments conducted during this period would determine the advisability of operating at an elevation in excess of 238'. Based on these elevations and allowing for seiche conditions, it was decided that virtually all land below the 250 contour would be purchased and the residents relocated.

Communities affected by the flooding and plans for their relocation are as follows:

The Village of Iroquois; This village, situated at the extreme western limit of the flooded area, had a population in 1954 of approximately 1,100. The one major industry in the area, a linen mill, was located at the western limit of the village in the Township of Matilda. This industry was subsequently relocated within the village limits. The built-up section of the village was to be entirely flooded. However, sufficient area remained above the new flood line within the corporate limits of the village to locate the new community.

Matilda Township; Between Iroquois and Morrisburg, a distance of approximately 10 miles, a number of farms and residences situated along the river bank and along No. 2 Highway would be flooded. Some of these residences would have to be purchased outright while others could be relocated on higher ground within their own property limits.

Morrisburg; Located 10 miles downstream from Iroquois with a population of approximately 2000; this community was sustained by three small industries and an active business section which serviced the farming communities surrounding it. The locks of the old St. Lawrence canal in Morrisburg as well as several resorts on the outskirts were an attractive spot for tourists. The flooding here wipes out most of the riverfront homes as well as all of the business section and the locations of the three industries. However, here again, there was sufficient land within the corporate limits of the village to locate a new subdivision and also to relocate the industrial and business sections.

Fig. 3 Moving historic church on house moving trailer. Note extra "dollies" at rear to distribute load. This church was moved approximately 15 miles.

Williamsburg Township; Extending roughly between Morrisburg and Aultsville for a distance of 7½ miles, this was a predominately farming area but also included a large number of cottages situated on the river bank. This is probably the most historic portion of the Valley, being the location of the Battle of Crysler's Farm in 1812. It was also the location decided upon by the Ontario St. Lawrence Development Commission for the reestablishment of a park and memorial to the Crysler battle. Although many of the farmers in this area preferred to move elsewhere to look for new farms, many of those affected took locations in a new subdivision to be created within the township for residences and including sufficient land to operate small garden plots. This new community known as Riverside Heights is situated along the new No. 2 Highway approximately three miles east of Morrisburg.

Osnabruck Township; This township

stretched for approximately 9½ miles along the river and included the hamlets of Aultsville, Farran's Point, Dickinson's Landing and Wales, all of which had to be completely relocated. This too was largely a farming community with the small hamlets which served them. These were all to be combined in one new community at first known as New Town No. 1, but later named Ingleside by its Council. The new community was located roughly in the middle of the township and on the new No. 2 Highway. It is also serviced by the relocated C.N.R. and had access provided to No. 401 Highway.

Cornwall Township; This township stretches for approximately 11 miles along the river and completely surrounded the city of Cornwall. During the life of the Project a large portion of this township was amalgamated into the city of Cornwall. The two hamlets here affected by the flooding were Mille Roches and Moulinette. These two communities were to be combined in one new community known as New Town No. 2, and later named Long Sault, situated on a height of land north and west of Moulinette. This new community overlooks one of the finest bays to be found on the new lake.

In addition to these communities which were affected by the flooding, also the two major transportation routes in the area were affected to a major degree. No. 2 Highway which wound its way along the riverbank between Iroquois and Cornwall was almost completely flooded but a short section between Iroquois and Morrisburg could be re-used as a service road. Also the Canadian National Railways main line between Toronto and Montreal had to be diverted at Cardinal for a distance of approximately 39 miles around the flooded area. A portion of the old railroad bed was used to relocate No. 2 Highway.

Fig. 4 Brick home in Morrisburg being moved by Hartshorne mover.

Planning

It was realized at an early date that any new plan for the rehabilitation of the towns would have to have the co-operation of the municipal councils affected. This co-operation was sought early by Hydro and as a result a close working relationship was established with the six councils affected which did much to ensure the success of the rehabilitation programme. The councils were consulted on all phases of the operation and as such became key members of the planning team.

Frequent meetings were held with councils and public bodies as early as 1953. The first broad plan for the relocation of the townsites was presented to the communities at meetings in August of 1954. This plan was prepared jointly by Ontario Hydro and the Ontario Department of Planning and Development. This was the first of many meetings held with the municipal representatives to create new towns which would be a credit to all concerned. The municipalities were encouraged to retain their own town planning consultants to ensure that their interests were represented and protected. These consultants would be retained at Hydro's expense. By the summer of 1955 general agreement had been reached on the plans and locations for the new townsites and had developed to a point where actual construction could commence.

The design of municipal water and sewage systems was carried out by firms of consulting engineers retained by Hydro for each townsite. These consulting engineers worked closely with the consultants retained by the municipalities to further protect their interests.

Fig. 5 Aerial view of Morrisburg after flooding. Note new shoreline and beach area.

For the Ontario Hydro, the responsibility for all phases of the St. Lawrence Power Project was vested in the Commission's Chief Engineer, Dr. Otto Holden. He was represented in the field by Mr. Gordon Mitchell, Project Director, and Mr. Harry Hustler, Director of Property. Mr. Ken H. Candy, Commission Architect, was responsible for all planning and design features of the rehabilitation program. Prof. Kent Barker was retained as Town Planning Consultant. The author as Rehabilitation Engineer was responsible for field engineering and construction, and co-ordination of the field efforts of other groups.

Co-ordination of the many groups

and agencies involved was a key factor in completing the project on schedule. The rehabilitation schedule had to be closely co-ordinated with other phases of the Power and Seaway Projects. For example, the complete village of Iroquois had to be demolished and cleared to permit disposal of earth excavated from channel improvement projects on Iroquois Point. Similarly cemeteries had to be relocated to permit excavation work to proceed for canal diversions and shoreline improvements. Also close liaison was maintained with the Village Councils, Planning Boards, and church, school and cemetery boards as well as outside agencies such as C. N. Railway, Ontario Department of Highways, the Ontario St. Lawrence Development Commission, Bell Telephone, etc. It is to the credit of these groups that such a complicated program could be completed on time. Despite many differences of opinion there was a general desire to co-operate to bring the Project to a successful conclusion.

Schedule

The actual rehabilitation program began in June, 1955, with the award of the first major contract for construction of municipal services in the Village of Iroquois. By July 1, 1958, the flooding date, the main rehabilitation program was complete.

The following are the main items involved:

1. Development of 3 new townsites and an addition to the fourth including the construction of all water and sewage facilities, power distribution, street paving, etc., for approximately 1150 serviced lots plus serviced lands for industry;
2. Moving and rehabilitation of 531 homes as well as barns, garages and auxiliary buildings;
3. Construction of 9 new schools with a total of 51 classrooms;
4. Construction of 14 new churches and 10 parsonages;
5. Construction of 4 new shopping centres with a total of 90 stores;
6. Construction of replacement buildings for town halls, curling club, skating arena and recreational facilities such as wading pools, golf course, tennis courts, etc.;
7. Construction of 3 new cemeteries and raising two others to relocate 18 cemeteries affected by flooding.

With the exception of final landscaping of park areas, this program was largely completed by the end of 1957, allowing the last 6 months previous to flooding for final clean-up of the flooded area and completion of demolition work.

Municipal services

Some of the major benefits accruing to the new communities were the provision of modern water and sewage facilities, paved roads, new sidewalks and completely new electrical distribution and telephone systems. Two of the communities (Iroquois and Morrisburg), had municipal water systems in their original locations. The remaining communities had no municipal water systems and therefore welcomed this provision in the new townsites. Some of the main features of these services will be discussed here.

1. *Water Supply* — The source of water supply in each case was the St. Lawrence River. Due to the fact that the new pumping stations would have to operate before the water was raised, special care had to be taken to provide interim supplies of water. At Iroquois the permanent intake was installed to allow for operation of the plant under minimum pre-flooding water elevations. At Ingleside and Long Sault temporary intakes had to be constructed to provide water during the period between the time families were moved to the new towns and the headpond was flooded. In Morrisburg a deep shaft was sunk on the shoreline and an intake tunnel driven under the old St. Lawrence canal to connect to the river, presenting one of the more difficult construction problems encountered. A typical pumping station is that constructed at Ingleside and shown in Fig. 1. Equipment installed included one 300 U.S.G.M. and one 600 U.S.G.M. electrically driven vertical turbine pumps and one 600 U.S.G.M. vertical turbine diesel driven pump as a standby unit. These pumping stations were designed for normal expansion of the communities and in some cases were made large enough for additional pumping capacity to be installed. As part of the water supply system in each community, a 208,000 gal. elevated storage tank was erected. Automatic controls were installed to eliminate the full time operation of the pumping stations by an operator.

2. *Sewage Pumping Stations* — In three of the four communities sewage pumping stations were required for all or part of the sanitary sewage flow. In Ingleside the sewage pumping station was required to lift the entire sanitary flow to a gravity line leading to the sewage treatment plant. In Long Sault and Iroquois only a portion of the flow was pumped.

3. *Sewage Treatment Plants* — In the original communities, there were no sewage treatment plants and where sewers existed (Iroquois and Morrisburg) they were generally combined with storm drains. As part of the rehabilitation program and in line with Ontario Department of Health regulations, each new community was provided with a sewage treatment plant. At Morrisburg, Iroquois and Ingleside, only primary treatment was required. However, at Long Sault, secondary treatment was required due to its proximity to Cornwall. A typical sewage treatment plant is that constructed at Ingleside.

4. *Roads and Sidewalks* — Approximately 4½ miles of paved roads

Fig. 6 Trinity Anglican Church, Riverside, before dismantling.

were constructed in each townsite. Paved width was generally 24 ft. but on some main arteries was extended to 28 ft. Surface drainage ditches were constructed on each side, which led to underground storm trunk sewers at several locations. Sidewalks were of concrete and were constructed on both sides of the street.

5. *Power Supply and Telephone*—New power distribution and telephone lines were constructed on the "back-lot" principle. This feature not only improved the appearance of the streets by the elimination of overhead wires, but also aided materially in the moving of houses. Adequate street lighting was provided on concrete poles with underground service wires to the power supply. The Bell Telephone Company took this opportunity to install completely automatic dial telephones in the new communities, providing yet another modern feature.

Fig. 7 Trinity Church as it was rebuilt using salvaged material. Note even the stone and iron fence has been relocated.

House moving

Probably one of the most publicized features of the rehabilitation program was the house moving operation.

In total, some 531 homes were moved in addition to 15 historic buildings moved to the Crysler Memorial Park. The breakdown of the moves is as follows:

Iroquois	151
Matilda Township	28
Morrisburg	93
Williamsburg Township	21
Ingleside	108
Long Sault	130

The above totals do not include auxiliary buildings such as garages, barns, etc., which also had to be relocated.

When an owner was approached by Hydro Property officers, he was given a choice, in the case of a residence, to either:

1) Have it purchased outright by Hydro;
2) Have it moved.

Before approaching the owner, the Property Dept. were advised by the Rehabilitation Dept. as to whether or not the house was suitable for moving. This was based on a survey and inspection of the house to determine its structural qualities, general appearance and suitability for relocation in the new townsite. If this report was favourable and the owner was agreeable to the proposed move, an application was submitted to a house relocation committee for approval. This committee was formed for each townsite and consisted of the reeve and one or two members of Council, representatives of the Town Planning Board, Town Planning Consultant, and members of Hydro's Rehabilitation and Property departments. The purpose of this committee was to prevent unsuitable houses being relocated in the new towns, and also to reconcile all the various problems connected with relocating the families. This group not only approved the move of the house but also its location. Plans were prepared showing suggested house types for each lot. Houses with similar characteristics were grouped together and owners were encouraged to choose a lot designated for their house type, e.g., bungalow, 1½ storey or 2 storey.

An owner proposing to have his house moved to the new town was advised several weeks in advance of the probable date of the move. He was also advised that with the exception of preserves no packing of furniture, dishes or food was necessary. The house would be moved with the furniture intact. Several days before the actual move, moving crews would remove all material stored in the basement to a storage building. This was to allow the foundation walls to be opened for insertion of supporting beams. On the day of the move, the owner and his family were taken to a "stop-over" home which was provided for their convenience. They would occupy this home for a period of one day to two weeks, depending on the amount of work required on their house and also depending on weather conditions. "Stop-over" facilities were required for longer periods in winter to allow for installation of the heating unit. In the summer months, however, many owners returned to their homes the same day. In the case of elderly folk, arrangements were made to board them with friends or relatives to reduce the shock involved in the move.

Despite all the precautions taken, most owners suffered some inconvenience as a result of the move. To meet schedules, many of the homes were moved in winter and landscaping and grading could not be completed until spring. Under these circumstances the co-operation of the residents was remarkable.

The original equipment engaged in the house moving operation consisted of the two Hartshorne house moving machines, winch trucks and extra conventional house moving dollies. Houses up to 150 tons in weight were handled by the larger of the two machines.

The house moving operation in Iroquois, using the above equipment, was as follows:

Each machine operated independently, picking up a house in the old town, moving it to the new location and placing it over the foundation. Due to the width of these machines, this required construction of wide (45 ft. - 50 ft.) access roads between the two locations. In the case of Iroquois this amounted to less than a half of a mile and therefore was not a serious problem. However, as plans were being developed to move to the extreme east end of the Project and commence house moving operations from Mille Roches and Moulinette, the problem of access roads was all-important. In view of this, a different technique in house moving was developed.

A house moving trailer was designed and fabricated which would carry a 100 ton house and which could travel on conventional roads.

This trailer was fitted with a removable goose-neck and had the rear tires and axle units spaced to 21 ft. widths to make full use of the existing roads and at the same time stabilize the load. Using this trailer, one house moving machine was stationed in the old town and one in the new. One machine lifted the house from its foundation and placed it on the trailer for transportation to the new town, and the second machine removed the house from the trailer and placed it on the new foundation. During the summer of 1956 an average of almost two houses a day was maintained by this method. The house moving trailer is shown in Fig. 3 and the Hartshorne mover in Fig. 4.

The house moving operation, although criticized severely at the outset, became accepted more and more as the program advanced. Many owners who had originally decided to sell and build new homes changed their minds and asked to have their homes moved. In virtually every case, the home owner was considerably better off in his rehabilitated house in the new community than he had been before. Provision of a full dry basement, central heating and general repairs including exterior painting, increased the value of his home. More particularly, the shock of disturbance for elderly folk was considerably lessened by being able to return to their own homes after a few days.

Special moves

In addition to the house moving operation, a number of other buildings and structures were moved as part of the rehabilitation program. As mentioned above, 15 buildings of historic interest were moved to the pioneer village being established by the Ontario St. Lawrence Development Commission. The Christ Church from Moulinette was moved intact a distance of approximately 15 miles to the pioneer village. This church was moved on the house moving trailer using additional sets of dollies to distribute the load.

A complete bulk oil storage plant near Morrisburg was moved approximately ½ mile to a new site on the relocated No. 2 Highway. Two 520,000 gal. tanks were moved intact and set on prepared foundations. A gridwork of steel beams was set up inside each tank. The base of the tank was supported by rods suspended from the grid to preserve its shape. The tanks were then raised by jacking at the perimeter at reinforced locations and moved by conventional means.

Fig. 8 Typical view of moved homes on street in New Iroquois.

Schools and churches

One of the first decisions that had to be made was in respect to schools and churches in the flooded area. Many of these could have been moved to the new townsites, while others would have been either too expensive or structurally unsound. Also, it was possible in all cases except Iroquois to combine a number of one-room or two-room school houses situated in the villages into one 8 or 10 room modern school in the new community. Similarly for instance, churches of similar denominations located in such villages as Aultsville, Farran's Point and Wales could be combined into one new church at Ingleside.

For this reason, it was decided to provide new churches and schools to replace those affected. The procedures adopted for churches and schools were roughly identical. The matter of location was in most cases decided by the town planners and agreed to by the Boards concerned during the preliminary stages of planning. When a new church or school was to be built, Hydro first asked the group to form a building committee with whom it could carry on negotiations. This done, Hydro officials met with the building committee and advised them of the procedure to be followed in obtaining the new building. In the case of the schools, the policy was to replace classroom for classroom, keeping in mind modern requirements. The Board was then advised that they could retain an architect of their choice to prepare designs and plans for the building, and to supervise construction. Plans were to be submitted to Hydro for approval before working drawings were started, and working drawings were submitted before tenders were called. The purpose of this was to maintain some uniformity in the quality of construction between the various architects involved.

When the schools were approximately 50% complete the Boards received a furniture allowance to provide new furniture for each classroom. This allowance was approved by the Ontario Department of Education, and was generally accepted as being adequate.

Similarly for churches, the Boards were advised that the churches would be replaced on a per sitting basis and that the architectural treatment would be similar to the existing church; for instance, a brick church would be replaced by a brick church and a frame church for a frame church etc. Within this general framework, the plans of each church were reviewed, revised and approved, and then advertised for tender. Cash allowances were provided for the purchase of new church furniture. The Trinity Anglican Church at Riverside was demolished and the material salvaged and rebuilt in the new community of Riverside Heights. Photographs of the church in its original and new location are shown in Figs. 6 and 7.

Shopping facilities

In the communities to be flooded, the existing shopping facilities were in two categories. First, in Iroquois and Morrisburg, they consisted of a wide variety of stores and shops lining both sides of the main street which in most cases was part of No. 2 Highway. They were generally two or three storey buildings with flats and apartments over the stores. Very little new building had taken place in the shopping area in the past 20 or 30 years, and also little or no modernizing of existing buildings. For these merchants the move to the new shopping centres would not be too upsetting.

They would still retain their old customers and would be able to do business in a modern shopping centre, with adequate parking facilities and located on the new No. 2 Highway. Secondly, in the communities of Osnabruck and Cornwall townships, the shopping facilities consisted of general stores in each of the communities affected, each serving the village in which it was located and part of the surrounding farmland. When these communities were merged into one new community in each township, Hydro was faced with the problem of creating a shopping centre which would include five general stores. Merchants in the communities were encouraged by Hydro to change their line of business to create a more balanced shopping centre. Some switched from general stores to hardware stores and others to appliance stores, and still others into modern supermarket groceterias. With the inclusion of banking facilities, post offices, barber shops, beauty shops, etc., they presented a well rounded business section.

To deeide on the type of building and layout of the new centres, many meetings were held with the merchants and their Councils and also with shopping centre consultants. Merchants were, in many cases, reluctant to accept a single storey building with no living accommodations or apartments overhead as was proposed. However, they finally realized that modern community planning called for separation of residential and business sections, and eventually agreed to the single storey building.

The shopping centres were designed on a very flexible basis to accommodate various types of businesses in self contained shops, each having its own plumbing, heating, and electrical facilities. The buildings are 80 ft. in depth on one floor and are constructed with a steel frame on a module of 20 ft. with a clear span of 40 ft., allowing the installation of various widths and depths of shops.

The exterior walls are of masonry construction insulated and the roof is a steel deck. The shop fronts are of aluminum and glass constructed to the edge of the sidewalk to give the maximum floor area and a uniformity of appearance from the exterior. The sidewalks are covered with continuous metal canopies for the convenience of shoppers. Illuminated signs were provided for each shop which, as well as contributing to the aesthetics, provide light for pedestrians at night. The rear of the shops is divided from the selling space to provide a workshop or storage area with access to a service entrance or for the delivery of merchandise.

Surrounding the shopping centres are parking areas of ample size with small landscaped areas provided on the perimeter and in the mall to complete the aesthetics and encourage transient business.

Most of the owners quickly became adapted to doing business in their new surroundings. Many of them took this opportunity to completely modernize their operations and invested considerable amounts of their own money to bring their stores and fixtures up to the same standard as the new buildings.

Service facilities

In addition to the business men who could be relocated in the shopping centres there were service facilities which had to be relocated. Plumbing and heating shops, service stations and farm equipment dealers were located in areas zoned for this purpose. Probably the most difficult problem was that of deciding on locations for the service stations. In Morrisburg, for instance, there were six stations to be relocated and all were insisting on locations on the new No. 2 Highway. Highway regulations re siting of service stations are much more stringent now than when these stations were originally located. After considerable negotiations between service station operators and the Department of Highway officials, suitable locations were found. Similar problems existed in all four townsites.

Rental housing

As well as the problem of rehabilitating those who owned their own homes in the area to be flooded, there was the problem of providing accommodations for tenants. In nearly all cases encountered, the owner of a rented house did not with to retain ownership in the new community. This meant that he took a cash settlement for his house and Hydro was left with the responsibility of relocating the tenant. Also, there were a large number of tenants living in the apartments and flats over the business sections in both Iroquois and Morrisburg. In Morrisburg this tenant group represented approximately 40% of the people affected. The same situation was true to a lesser degree in the other two communities. This problem of relocating tenants was solved as follows:

In Iroquois a large number of the homes purchased by Hydro were acceptable for moves into the new town. Even though the owners had decided to purchase or build new homes, Hydro arranged to move their old home into the new community and to use it for rental purposes. There were also a number of large homes which could be readily converted into two or three apartments. This helped to provide accommodation for smaller families. When this accommodation had been exhausted, 12 units of row housing were built to accommodate the remainder. However, in Morrisburg there were not sufficient older homes that could be moved economically and used as rental accommodation. Therefore, a program of row housing was undertaken which provided 84 units. These were two storey buildings with 4 or 6 units per build-

(Continued on page 77)

A PROFESSIONAL OUTLOOK

Mervyn Woods, B.A., LL.B. (Sask.), LL.M. (N.Y.), Q.C.
Professor of Law at the University of Saskatchewan.

LIVING at a time of extreme pressures, most of us simply have more things to look after than time permits. We are hard put to keep up with developments in our own professional field, let alone spend our time in learning about others. But if we are ultimately to play an effective part in any overall plan, there must, somewhere along the line, be a blending or a meeting of direction and scope of our activities. What is the nature of the particular outlook that a professionally qualified person should bring to life and its problems? What is the difference between a person who has a professional outlook and one who has not? In other words, what is the difference between an engineer and a professional engineer?

In Webster's New International Dictionary, Second Edition, we find the word "professional" defined as follows: "Of, or pertaining to, a profession, especially a learned or skilled profession; characteristic of or conforming to the technical or ethical standards of a profession or an occupation regarded as such". There are further definitions but we will deal with these for the moment. Let us look then at the first portion of this.

"Of or pertaining to a profession": This is a type of classification that a great many people use. That is, we often think of a profession as being related to a particular classification of work. We think of law, of medicine, of theology, as being professions. In recent years engineering, accountancy, nursing, and still more recently dietetics and social service, have come to be regarded as professions. We think of engineering work, of legal work, of medical work as professional work. In other words we can and often do recognize occupations as professions by the type of work which is done by those who engage in that particular profession. It will be readily seen, of course, that this yardstick does not get us very far. As a matter of fact logically it takes us in circles, but it is a yardstick which is readily applied and it is perhaps used so often because of its readiness in application. To simply say that a profession is any one of a number of types of work is a much too shallow basis to use as a definition.

Let us look then at the next definition which is "characteristic of or conforming to the technical . . . standards of a profession". Here we see another approach. Here — see the profession as a form of activity for which specialized training is required. Law, medicine, and theology were the traditional so-called "learned professions" and around these three avenues of study the traditional University training was centred. However, engineering, accounting, nursing, household science, and other fields of activity are now included in such specialized training and we think of people in these fields as being professional because they are highly trained, having pursued extensive study above the high school level. This we will see is also a very handy yardstick and one that is easy of application. But again it is somewhat superficial to say that a professional man is simply one who knows more about some particular field of endeavour than do others. This is not to place him upon the plane to which he should aspire. This element is of course usually present in a professional man, but to adopt it as the basis for distinguishing him from other people is simply to adopt a part for the whole.

Looking then at the next definition which is "characteristic of or conforming to the ethical standards of a profession", we find ourselves on a higher plane and members of a profession would be the last to minimize the importance of ethical standards. But a professional man needs more than ethical standards, important as these are.

The problem presents scope for further analysis: we find, of course, in defining the word "professional" the same type of problem met in defining most other words. A term that is used in such a general way to cover such a wide range of activities must always present us with something of a problem in semantics. A suggested definition is as follows: "A profession is a self disciplined group of individuals who hold themselves out to the public as possessing a special skill derived from training or education and who are prepared to exercise their skill primarily in the interest of others".

Here several elements will be noted. A profession initially is a group—you do not have a profession consisting of one person. It is also self disciplined. This indicates a considered determination of its aims as well as of its rules of conduct. Thirdly, those comprising it hold themselves out to the public as possessing special skills. That is, they purport to have special qualifications and the public should be able to rely upon this representation. Lastly, but perhaps most important, a profession exists for the purpose of serving others. In other words, a profession is not organized for its own advancement. The purpose of the lawyer is to make the law work. The purpose of the medical profession is to see to the health of the community. The purpose of the accountant is to help people keep their affairs in order. The purpose of the teacher is to bring out the knowledge of those entrusted to his guidance. The purpose of the engineer is to see to the efficient use of our resources in the furtherance of our social destiny. But whatever the profession, it is suggested that its primary purpose should not be private gain. It is to be distinguished from a trade or from ordinary business activities in that it exists or should exist for service to others. This is the mark of a true profession and should be contained in the outlook of a professional person.

From this it may be inferred that a proper attitude of mind is perhaps the most important characteristic of a person with a professional outlook. This attitude of mind should distinguish those in a profession from those without. You can have several people doing the same type of work with a difference in attitude and it will make a great deal of difference in the result of that work. It is said that when Sir Christopher Wren was supervising the construction of St. Paul's Cathedral he came upon three workmen dressing the same stone. He asked the first man what he was doing. The reply given was that he was dressing the stone. He asked the second what he was doing and the reply was that he was supporting his family. He asked the third man what he was doing and he replied, "I am helping you, sir, to build this Cathedral". Each of these men had a proper motive and the third man was not necessarily engaging in a profession. But he certainly had the professional outlook because he saw more clearly than did his fellow workmen the purpose and objective of the work he was doing. He viewed it in its wider aspects and other things being equal, no doubt such a man would do a better job of dressing a stone and would go farther in his chosen occupation than the other two would.

It will be apparent that a professional person has three groups of people with whom he should concern himself. The first of these is those whom he serves, the lawyer his client, the doctor his patient, the teacher his pupil, and the engineer whoever engages his services. Secondly there is a relationship with others in his profession. In other words, a relationship with his colleagues or other people with similar qualifications doing similar work and endeavouring to achieve similar objectives. Thirdly, of course, there is his relationship with society because after all, a professional man is still a citizen and he should be among our very best.

Let us now turn our attention to these three relationships of the professional man in turn. First there is his relationship with those whom he directly serves. This, of course, is most important because after all here the professional man is dealing with a person who is paying him. It is obvious that the professional man must be adequately trained to give the necessary service. But training itself is not enough. He should be adapted to the particular type of calling in which he is engaged. But assuming that he is adequately trained, he must also be industrious and toil diligently in the interest of his client, or his patient, or by whatever other term he may refer to the person who is retaining his services. Our concern for the professions may take another direction. Our Universities and other training institutions are aware in this age of sputniks of the necessity of keeping pace with the times. The challenge of present day developments is tremendous, not only in the field of technology but also in the field of social organization. There are so many fields of research and of social and technical development that training facilities are taxed to the limit. Yet I do feel that our authorities are, by and large, fully aware of the necessity of expanding and looking after this formal part of professional training.

A great many of our professional people engage in what might be called competitive fields and here I have not so much fear for lack of competence. If the lawyer, the doctor, the accountant or the engineer is not competent he just will not get his share of the business. Any man who wishes to succeed in any such competitive field will find that he will have to work and work very hard. As a matter of fact the pressure of this work will be one of his greatest problems. There are some professions which are not competitive in the same sense and there is perhaps here more need of awareness on the part of the profession that industry, diligence and proper training are at all times essential. Taking the teaching profession as an example, it is perhaps somewhat easier for a teacher to lower his standards and still hold his job than for some other people. A teacher in a large institution with a well organized profession behind him can get along on a minimum of work. The same is true of almost any professional man working, for example, in the civil service. Fortunately, however, this seems to be the exception. But it takes a real professional attitude and a sense of responsibility for one who is secure in his appointment to keep himself constantly on his mettle. If he has a professional outlook he will do it.

We are speaking of the responsibility of the professional man to those he serves. This relationship must, of course, be closely watched. A lawyer, for example, should perhaps have no dealings whatever with his client that are not purely professional, and the same is probably true of an engineer. It is bad business for a professional man to borrow and lend with a client. The professional man who makes a business deal with his client, in which he has a personal interest, departs from the straight professional course, courting embarrassment and perhaps even disaster for the obvious reason that he cannot deal with his client on equal terms. He has the advantage and if the business arrangement does not work out satisfactorily, the professional man stands to suffer in reputation. This is certainly true in law. Law, it has been said, is a jealous mistress and the professional canons of all professions rightly impose definite moral restrictions on those who enjoy the benefits that come from membership in that profession. A lawyer should not confuse his professional duties with his own business interests and in a greater or less degree this applies to all other professions.

The professional person, of course, in dealing with those whom he serves must keep his independence. An engineer should never be the mere tool of his employer. The lawyer should not be the mere mouthpiece of his client. In each case the engineer and the lawyer should be the adviser. So should the doctor; so should the accountant; and so should any other person giving professional advice. No professional man should put forward an unreasonable proposition based on the fact that he has been told by his client or his employer that this is the desired course of action. All professional people should be required to do only that which is professionally proper and not that which an employer or client proposes. A professional man is not merely an agent of the party who hires him. All professional people must have standards and they must set these standards themselves. They cannot let the people who buy their services buy the right to set their standards.

A professional person should, of

course, keep confidential his relations with those he serves. This applies almost without exception to people in positions of professional responsibility. Certainly it is true with the doctor, with the lawyer, and with the accountant and presumably it is equally true with the engineer. A professional man must regard his client's, his patient's or his employer's problems as of great interest to himself as a professional man. He must view them as his immediate and direct concern but he must never lose sight of the fact that the problem is still not his problem but is rather the problem of the one he serves. Anyone who places his trust in a professional man is entitled to have that trust, whatever it is, kept in the utmost confidence.

Professional confidence can go very much farther than some people take it. The responsibility of the professional man to his client or his patient, or whoever he may be serving, is both onerous and demanding. But no less important is the relationship to his colleagues. It goes without saying that it is the responsibility of every professional man to have both a sense of loyalty and a sense of responsibility toward others in his profession. This does not mean that he should condone failure to measure up to the standards of his profession, but among professional people there should be no cut-throat competition. He should see that it is to his interest as well as to that of others to keep the standards of the profession high. He should take an active interest in his colleagues, particularly the younger practitioners. He should give assistance to bring them along so that they may develop in the proper way. When time then comes for these younger members to assume control they will have a background both from precept and example which will enable them to further enhance the standards of the profession. In other words, a professional man should be far-sighted with his professional interests in view. He should be just as jealous of the respect and prestige that his profession will enjoy twenty years from now as he is of the present.

While the professional man's relationship with his client and with those whom he serves will play the larger part in his professional life, a great deal of the enjoyment of his profession, as well as a great deal of his success, will depend on his relations with his fellow practitioners. It is, I am sure, more important for a lawyer, for example, to enjoy the good opinion of the profession than of the public, important as this latter may be. A lawyer can succumb to ambition to please people, to please juries, to get his name in the paper, to become a subject of conversation amongst spectators, yes and among loungers of the court room. Things which may pass for eloquence with the masses may really be not only ineffective but even undesirable. However, if his ambition is to please his fellow practitioners, he can never be misled. As Lord Sharswood has said, "Their good graces are only to be gained by real learning, by the strictest integrity and honour and by attention, accuracy, and punctuality in the transaction of business". It is very pleasant to have public acclaim but probably the truest test in a profession is the estimation in which one is held by colleagues. This is not always the case. In all professions, of course, jealousy and other unprofessional attitudes may creep in but by and large an engineer who is respected and admired by other engineers has earned that respect the hard way. A lawyer who is known as a "lawyer's lawyer" is paid the highest compliment that can be given to him. A physician who is regarded by other physicians as being outstanding and capable will in almost every instance be found to be worthy in every sense of that accolade. A professional man who is well regarded by his colleagues is in a happy position and is well on the way to not only a successful but a most enjoyable career.

The third and final relationship, but by no means the least important, is the relationship of the professional man with society at large. Those of us who are privileged to be in professions enjoy an importance in the eyes of society out of proportion to our numbers. Now this influence is something of a trust and it must be carefully exerted. There is a heavy responsibility on every professional group both individually and collectively to see that the contribution which it makes to society is both adequate and proper.

Members of professional groups are given special concessions by society and we must appreciate that these are given in trust. Physicians have a monopoly on the practice of medicine. Lawyers have a monopoly on the practice of law. Engineers have a monopoly on some phases of our industrial and economic life. Chartered accountants have a monopoly on some aspects of our businesses. Now these are special concessions. They are given by society to the professions in trust and they must not only be carefully guarded and watched, but members of professions should realize that they owe this debt to society. In addition to special concessions, of course, all professional people naturally cost the country money. It costs the country millions of dollars a year to train people to professional competence, and while we often attribute our own accomplishments to our own efforts, we should not be forgetful of the circumstances which made it possible for us through our own efforts to arrive where we are. Our opportunity was made available through the united efforts of those who comprise our society. If any groups in the nation should have a sense of social responsibility it should be professional groups.

It is not suggested that every engineer should go into civic politics, or that every professional person should feel obligated to become the member of a political executive or a school board, but what we should do is to avoid allowing our affairs to become so ordered, or so disordered that we have no time for anything else. Any professional person who becomes so immersed in his own work or his own advancement that he has no time for the important things that are going on round about him is courting disaster not only for himself, but for others. We are not all interested in the same things. We do not all have ability along the same lines. But there is a place in this complex society of ours for the efforts of everyone and there is particularly a place for the highly trained competence that comes from membership in a professional society. This nation has been kind to our professional people. In spite of the fact that we must work for what we get, the opportunity to work at our present level constitutes a social debt of which every professional man should be acutely conscious.

Anyone purporting to have a professional outlook must be prepared to accept heavy responsibilities. The professional man should be self disciplined. He must work hard to further his skill in his own particular calling. But above all he must be prepared to faithfully serve those who need his services. Anyone whose primary interest is in private gain should never enter a profession because few professional men die wealthy and those who do usually do not acquire their wealth from fees.

But if a young man picks a suitable profession he has indeed made a happy choice. Professional life is filled with variety and interest. It is filled with constant challenge. It is filled with the opportunity to really help people with their problems, to help them to realize their dreams, and often to give them help that is available from no other quarter. There is no reason why a professional man should not look forward eagerly to each day. If he does the type of work in which he is interested; if he brings average intelligence to bear upon problems and handles them with industry, he will do a good job. And if he gives good service people will come to him and his income will be adequate. Any good professional man, of course, can expect a modest competence. Some make a great deal of money. But to anyone who is professionally minded, this is not the chief reward. A professional outlook sees far past this. To the man who is true to his profession the horizon must be much wider.

THE ST. LAWRENCE POWER PROJECT

REHABILITATION

(Continued from page 73)

ing, each unit self-contained and including 3 bedrooms. In addition, to accommodate some of the older tenants and also for those with smaller families, 12 semi-detached units were built of similar design but including only two bedrooms. In the two communities at the eastern end of the Project, there were sufficient moved houses to accommodate all the tenants involved.

Cemeteries — In the area affected by the flooding were some 18 cemeteries. Two of these, one in Iroquois and one in Morrisburg, could be raised and remain in their original location. Three new cemeteries were created to replace the remainder. One of these, now known as the St. Lawrence Valley Union Cemetery, combined 13 of the cemeteries located in Cornwall, Osnabruck and Williamsburg townships. A site was chosen near the original hamlet of Wales, situated between the new shoreline and the relocated No. 2 highway. Sections of the new cemetery were allocated to the four religious denominations involved with sufficient lots provided for future interments.

Cottages — Scattered along the shoreline from Iroquois to Cornwall and also on Sheik Island near Mille Roches were some 250 cottages. To provide for relocation of these cottages Hydro allocated one whole and part of another island to be developed as cottage sites.

Highway relocation

The relocation of No. 2 Highway which connected seven of the eight communities affected was carried out by the Department of Highways of Ontario, Ottawa District. Close liaison was maintained between Highway engineers and Hydro as to location and scheduling as it was necessary that the schedule be closely related to the power phases of the Project. Despite some particularly poor construction weather in 1956, co-operation of all concerned kept this phase of the program on schedule.

Railway relocation

Similarly the C.N.R. main line connecting these communities had to be relocated. Diverted at Cardinal, a new double track line was built for approximately 39 miles re-connecting at Cornwall. Design of all features connected with the railway relocation including track location, five railway stations, switches, sidings, communications and signal equipment was carried out by the Canadian National Railways, but the field engineering and contract supervision was the responsibility of Ontario Hydro. Here again, close liaison was necessary as large sections of the original track had to be removed to allow construction of major features of the project at Mille Roches and Iroquois.

Conclusion

It would be extremely difficult to measure the effect of the program described above on the future of the communities affected. In a physical sense, everything is in their favour for an era of expansion and growth. New municipal services, schools, churches, civic buildings, shopping centres, and modern transportation facilities via highway, railway and water are attractive features for industries both large and small. The development of the extensive park land along the shore of the new headpond will within a few years make this area extremely attractive to tourists. The economic possibility of deep water harbours will also encourage industrial expansion.

Equally important is the new spirit and enthusiasm which has developed among the residents and their elected Councils. This if continued, should bring a new wave of prosperity to the area.

DISCUSSION

CONTROL OF MOVING ICE IN THE U.S.S.R.

John A. Kerr, *Research Engineer,*
Public Health Engineering Division,
Department of National Health & Welfare,
Edmonton, Alberta.

The recently published textbook by Professor A. M. Estifeev[1] is a valuable addition to the list of references on frazil ice given by G. P. Williams[2] and covers a broader field as it deals with all types of moving ice. The contents of this article are based upon material in this textbook except where otherwise noted.

Ice Processes

The four major factors affecting ice processes are:

1. Water velocity (low velocities, v, and high velocities, V);
2. Heat content change (continuous cooling, s_c, and periodic cooling, s_p);
3. Morphological conditions (M);
4. Wind velocity (w).

The four basic combinations of water velocity and heat content change are (v,s_c), (V,s_c), (v,s_v), and (V,s_v).

The first process involves a progressive growth of ice and the establishment of a rigid ice cover on channels with velocities of up to 0.5 metres per second and with air temperatures of -10° C. and cloudy skies.

The second process gives rise to prolonged and intense shooga (conglomerations of frazil ice, small ice chunks, etc.) formation.

The third process involves temperature fluctuations (due to waves of cold and heat) which prevent the rapid formation of a surface ice cover, even when velocities are low. Polinias (unfrozen patches) act as sources of supercooling and shooga formation, causing zazhor (shooga) jams downstream. Warm spells cause thin ice to break up and hence zator (surface ice) jams, the displacement of shooga masses and hence zazhor jams, the floating up of anchor ice, and zator-zazhor jams.

The fourth process is similar to the second but is less severe (as it only occurs periodically) except when a shooga cover is formed in the second case.

An important effect of ice processes is the steepening of the surface profiles of channels.

Wind effects and morphological conditions (forms of cross sections, presence of natural and artifical reservoirs, bends, islands, channel constrictions, lake outlets, etc.) are analyzed in a systematic manner in conjunction with the study of any one (or different combinations) of the above processes.

The following nine components are summed to give the resultant heat content change:

- $^s1$—Evaporation (emission);
- $^s2$—Convection (emission);
- $^s3$—Radiation (emission);
- $^s4$—Direct solar radiation (absorption);
- $^s5$—Diffused solar radiation (absorption);
- $^s6$—Heat exchange between the bed and the water;
- $^s7$—Internal friction (absorption);
- $^s8$—Atmospheric precepitation;
- $^s9$—Inflowing exterior water.

Rational universal quantitative easily-applied mathematical formulae for each of the above components are listed by Professor Estifeev. The apparent complexity caused by the large number of variables and components is reduced by the fact that $^s8$ and $^s9$ can usually be neglected and that certain of the other seven components have relatively insignificant values in most practical cases. The values of all components must be determined in each specific case, however, as a component neglected in one region and in one case may be important in another.

In the case of shooga-bearing channels in Central Asia, an example is cited to show that $^s1$, $^s6$ and $^s7$ are small in comparison with $^s2$, $^s3$ and $^s4$, and $^s5$ is only a small percentage of $^s4$ at noon on a clear day in November and for specific meteorological and hydraulic conditions.

An increase in w leads to an increase in both $^s1$ and $^s2$. For the conditions cited in the above example, for instance, a fivefold increase in w (from 2 to 10 meters per second) causes $^s1$ to triple and $^s2$ to double; $^s1$ is still only a small fraction of $^s2$, however, even at the higher velocity.

Under conditions similar to those in the above example, s is a measure of the total heat emission from the water surface. Plotting air temperature versus s for a specific time of day and specific sky conditions shows that s equals zero at a specific temperature which is known as the critical temperature. The critical temperature is fixed by the combination of meteorological factors in the basin. In many cases forecasting can be based upon this temperature alone as it is an indirect measure of all the principal components of heat emission and can be determined theoretically for a given region. Experience on Central Asian rivers demonstrates the complete applicability of these assumptions and good agreement between calculations and observations.

Controlled Regimes

The importance of controlled regimes is emphasized. Storage, transport and bypass regimes are analyzed and rigorous mathematical analyses are presented.

A shooga carpet is completely preserved when velocities are less than 0.7 metres per second and commences to disintegrate when velocities are equal to or greater than 1.3 metres per second; complete mixing of the shooga in the flow occurs when velocities are equal to or greater than 2.0 metres per second.

Shooga discharge can be computed or determined experimentally. Intricate physical and mathematical analyses are presented. Measuring devices based on the calorimetric principle (change in volume of mixture after shooga is melted, electrical energy required to liquify and heat sample, water temperature at end of tube after shooga passing through it has been liquified and heated) are recommended in preference to devices measuring the volume of shooga after water has been drained off. Measuring procedures are given.

Local Measures

Modern methods of *heating screens* and bypassing shooga through unique *vortical funnels* around turbines described by Professor Estifeev are of special interest to hydropower engineers.

Unique types of inexpensive *dams* are of more general interest and will be described briefly.

Debris dams are created by blasting steep slopes into river valleys. In Uzbekistan, for instance, approximately 250,000 cubic metres were displaced by blasting to create a dam with a body of 40,000 cubic metres, thus saving 4,000 man-months. Conditions required for this type of construction include a large vertical distance between the center of gravity of the displaced mass and the river bed; impermeable base and walls for the dam, erosion-resistant rock, general slope of rock strata such as to impede infiltration, easily-displayed rock in the upper section of the valley, and favourable topographical conditions (U-shaped or V-shaped gorge with steep walls to a considerable height).

Large ice flows are passed over inexpensive *rockfill overflow weirs*.[3]

Structural element dams are unique in that the entire river flow can be passed through the structural elements without overtopping them. One series of tests[4] with structural elements on a stone base and with stone protection showed that when the head is 4 metres a discharge of 4 cubic metres per second can be passed through a dam composed of elements weighing 1,700 kilograms (7 cubic metres of concrete per linear metre).

Stone, stone-brushwood and teepee dams and combinations of these three types of structures are recommended as shooga-retaining works for the foothill reaches of Central Asian rivers. Three logs, lashed together at the top, are used for each teepee, and stones and brushwood are piled around its base. Larger teepees are held in place by anchors formed from gabions (screens filled with stones). Angle iron members used as cross-beams aid in the rapid settling out of frazil ice and hence in a more rapid accumulation of shooga.

Cable dams are arranged in several rows at a distance of from 800 to 1,000 metres from each other. The use of two or three rows is desirable. The upper ends of the cable network are attached to pontoons placed at intervals of from 12 to 15 metres across the channel and the lower ends are held down on the river bottom by anchors. Calculations are based on the assumption that the dynamic force on the network is equally distributed between the cable and the anchors and that the entire river channel is choked with shooga.

Metal hedgehogs consist of iron rods hung from a cable stretched across an open channel; star-shaped units of small rods are attached to each main rod. The metal rods aid in the rapid settling out of frazil ice and hence in the formation of ice jams.

Timber booms parallel to the flow are used to guide ice while timber booms perpendicular to the flow are used to retain ice.

Certain of the above structures are built at river bends where the width is large and the depth small, and where part of the ice thrust can be transmitted to the river bank.

BUSINESS TRAINING FOR PROFESSIONAL ENGINEERS

R. J. Bedard, *Former Editor of "Genie Construction". The Engineering Journal, November, 1959, p. 75.*

Author's Reply

In reply to Prof. B. M. M. Carpendale, to Prof. P. B. Hughes and to Prof. V. Jolivet.

To what extent can engineering schools give their students effective business instruction at the undergraduate level is a question to which at present I have no answer. Therefore, I cannot comment on the decision of Varsity to suppress Course IV and to create another undergraduate course in Industrial Engineering.

This however, does not contribute much to the solution of the problems faced by the engineer turned — or about to turn — manager.

The change at the U. of T. does not much affect my argument since the focal point of my paper was the creation of opportunities for *graduate and post-graduate* studies in administration by Canadian engineering colleges.

My reasons for thinking that graduate education in administration is a function of engineering schools are three. They are rooted in what I consider to be the responsibilities of colleges of technology:

1 — to the engineer as an individual;

2 — to engineering as a profession;

3 — to society as a whole.

Full discussion of these points would take more space than *The Engineering Journal* can supply for this comment. Therefore I will limit myself to a brief outline.

Responsibility to the engineer as an individual

If I am not mistaken, the aims of engineering education — and for that matter, of all university education — are: a) to impart knowledge; b) to strengthen intellectual powers; c) to develop attitudes. These objectives are simultaneous. The order of presentation is by no means an order of importance. Further, I find myself in agreement with Prof. Carpendale's remarks about the personal factors in teaching.

a) Knowledge. Canadian engineering schools are generally doing a good job in transmitting technical information. However, technology is not all there is in heaven and earth. Man, for instance, is certainly as worthy of an engineer's attention as any other phenomenon.

Now, in the transmission of knowledge, engineering colleges may say little or nothing about man, and leave the students under the impression that man is just another thing. The previous generation did that. Engineers went and applied to the handling of men, knowledge and methods effective in the handling of things. The result? Technologists went to the College of Hard Knocks. There, they have experienced enough trouble to become wiser.

The automobile industry, for in-

AUTOMATION AND CONTROL ENGINEERING IN CANADA

Instrument Installation in a Modern Chemical Plant

R. E. Bark, *Engineering Department, Du Pont of Canada Ltd.*

WITH THE INCREASING quantity and complexity of process controls in modern chemical plants, it is imperative that adequate consideration be given to the methods used in their installation. In a multimillion dollar plant, with its growing use of such sophisticated equipment as continuous stream analyzers and computer controls, it is not unusual for the installed instrument cost to exceed 10% of the total value of the plant. This is a heavy investment and the days when the instruments were hung on the process as appendages, and treated as necessary evils, have long since passed. If sufficient thought is not given to installation, then maintenance and trouble-shooting become difficult, resulting in serious losses in production while the source of the trouble is bieng located.

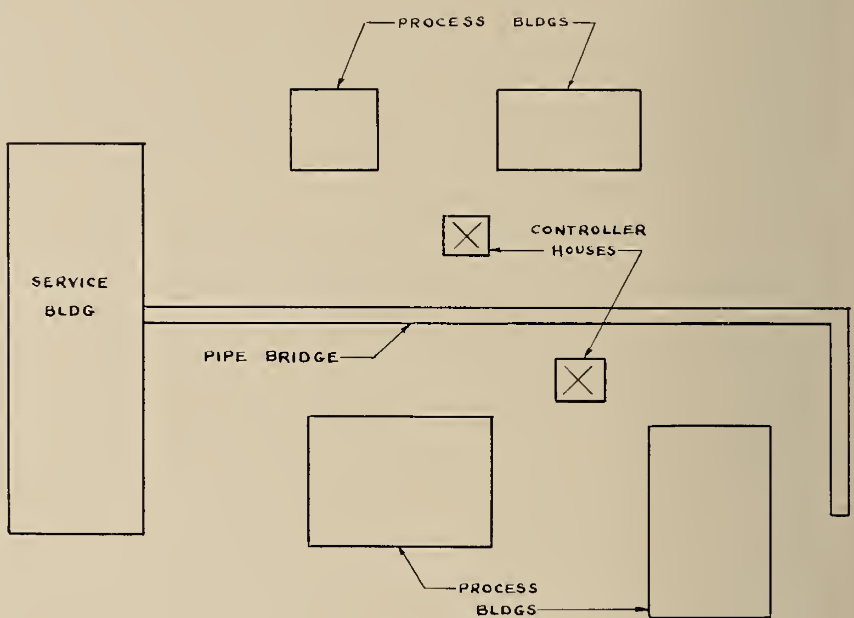

Fig. 1. Plot plan.

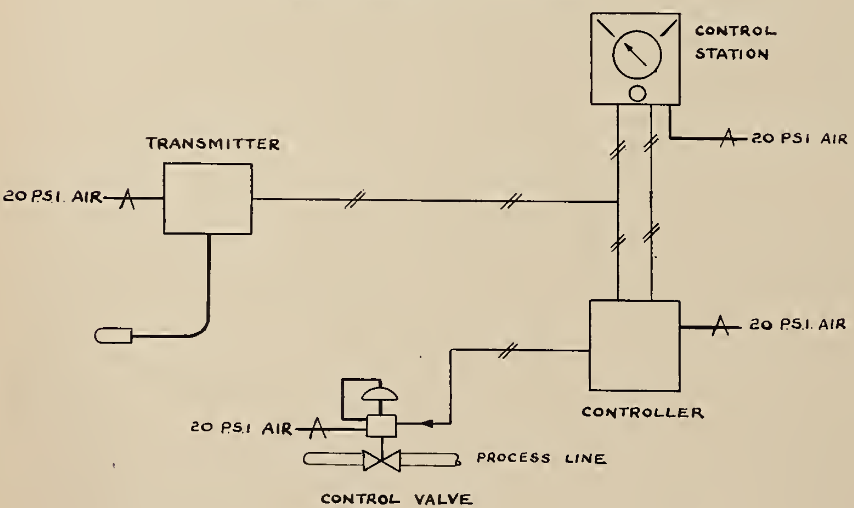
In the petro-chemical industry we are faced with some recurring problems in the design of most new plants. Many of the materials which are handled are toxic or of an inflammable nature. This is one of the reasons why we construct open buildings, which reduce or eliminate the problem of fume removal. Several other difficulties, however, are introduced, among which are weather-proofing and steam tracing. In addition, since there are no walls, other suitable means must be found for installing and supporting piping, tubing and the instruments. The following description of some of the design considerations for a plant, using open buildings and handling hazardous materials, could be applied to several of the facilities which we have designed and built in the past few years.

Fig. 2. Simplified control loop.



One of the questions which must be answered very early in the design stage, is the location of the central control room which contains the main operating panel. As will be seen from the plot plan (Fig. 1) this is located in the service building which is some 300 to 500 ft. away from the process block. This building houses the control room and shops. There is usually considerable debate between the operating personnel, the process engineers and the instrument engineers before the final location is determined. From the operating standpoint it is highly desirable to have the control room in a location which provides easy access to production and technical supervision. Since the process may be handling hazardous materials, it is also desirable to have the control room removed from the process block so that an orderly and safe shutdown can be effected in case of fire.

The instrument engineer, while appreciating these points, must of necessity attach much more importance to the performance of the instruments which he is going to install. To provide a little information for those not familiar with the elements of a modern control system the main parts are shown in Fig. 2. The transmitter measures and delivers a pneumatic or electrical signal proportional to that value. It follows, then, that the transmitter must be located at the point of measurement in the process. This is also true of the control valve, where the final regulation takes place. Of the other two elements the control station must be located on the main control panel. This is the unit on which the operator can see the indication on record of the process variable, and where he can vary the control point, or by means of a knob can by-pass the controller and adjust the control valve manually. The controller is a separate unit which can be connected directly to the control station or remotely mounted in the field, close to the control valve. In general it can be stated that the closer the controller is to the control valve the better it will respond to upsets in the process and take corrective action. The instrument engineers know that many of the loops will not provide proper control if the transmission lag resulting from a 500 ft. separation

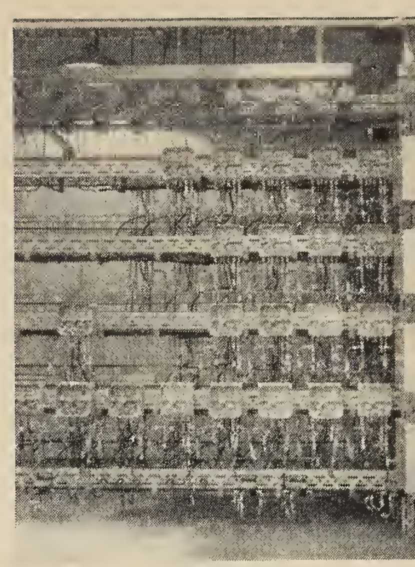


Fig. 3.

were introduced into the circuit. This means that a number of the controllers

Fig. 4. Expansion Loop Assembly.

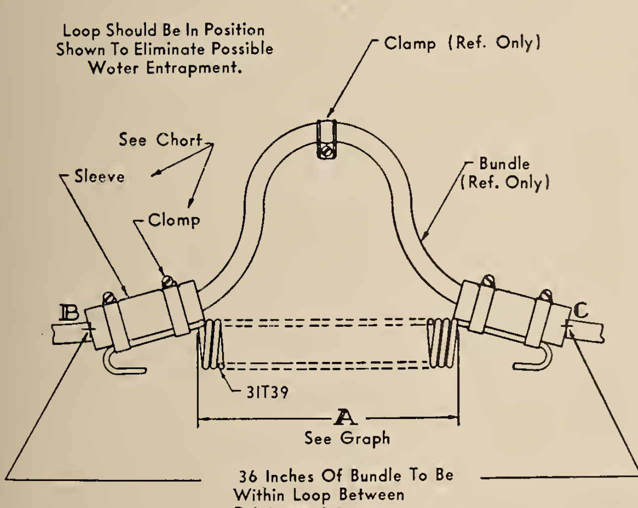
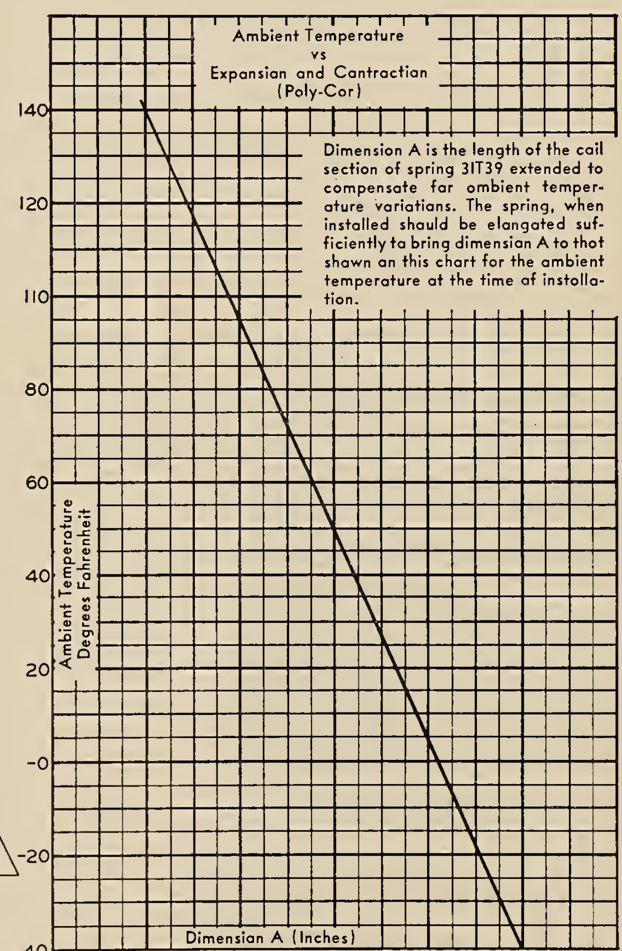
11T35-P8	3/8-7 Line	31T40-P8	31T6
11T35-P9	3/8-10 Line	31T40-P9	31T41



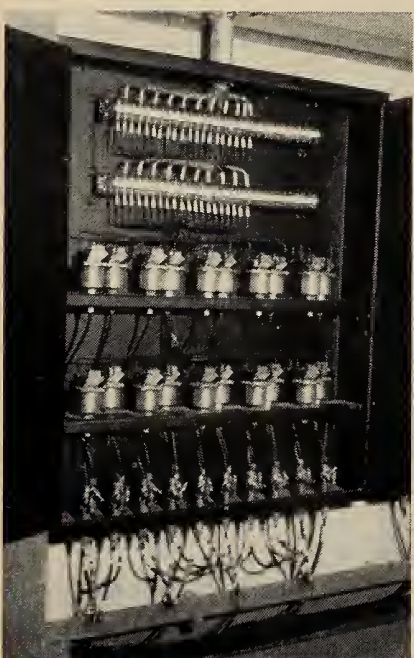


must of necessity be located in the area. The process engineer comes into the picture at this point because he has to ensure that there is sufficient space in each of the buildings to hold these instruments, as well as provide access to them for servicing.

In one case the following satisfactory compromise was reached. Two separate small buildings were provided for housing all the controllers, thereby providing complete protection from the weather and making maintenance a very simple matter. These were neatly mounted in racks inside the buildings as shown in Fig. 3. We also foresaw another major advantage in the use of separate buildings. Due to the nature of our operation all the process buildings were classified as hazardous which meant that explosion proofing must be provided for electrical apparatus. Our electrical interlock and shutdown system necessitated the use of many solenoid valves. However, by locating them in the controller house and providing adequate air purging it was possible to use standard construction. This meant a saving in first cost as well as making maintenance and installation much easier.

For several years now it has been our practice to use bundles of polyethylene tubing for the quarter-inch pneumatic transmission lines. These can be made in bundles of up to nineteen tubes, 1000 ft. in length. A typical plant might contain some forty or fifty of these nineteen-tube bundles on the pipe bridge between the control room and the production area. Each bundle of tubing is purchased with built-in telephone wires. This greatly facilitates checking loops between the control room and process area, by using portable telephone sets. One of the difficulties encountered with this tubing is its considerable expansion and contraction with temperature changes. In order to overcome this problem, expansion loops must be provided at various intervals. One supplier has a design of expansion loop which makes use of special spring assemblies as shown in Fig. 4. From his tables it is a simple matter to calculate the amount of tension required in the spring for the particular temperature at the time of installation. On the pipe bridge in particular it is necessary to protect the polyethylene bundles from welding sparks during the construction period. For this reason the uppermost layer of piping on the bridge is reserved for instrumentation tubing, so that it can be installed at the same time as the process piping without having to worry about the tubes being melted.

Fig. 6.



With the hundreds of pneumatic tubes which require proper installation and connection it is mandatory that a system of numbering and identification be adopted. We have developed a system, now in use on all new projects, which has proven most successful. Tubes which run directly from the control room to the process area use the number system 1-1000. There are also those lines which run entirely within the production area. An example of these might be a local control loop, including a transmitter, valve and recorder controller, the latter possibly mounted on a small panel close to the equipment it is controlling. Such tubes are numbered from 2000-3000. A third set of numbers, 3000-4000, is assigned to those tubes which provide interconnection between units in the control room only. This might be a branch line which connects the measured variable signal to an alarm device, such as a pressure switch. We have found that the contractor's personnel, who are not always familiar with instrumentation, have made fewer errors in installation when using this system, as it requires very little explanation.

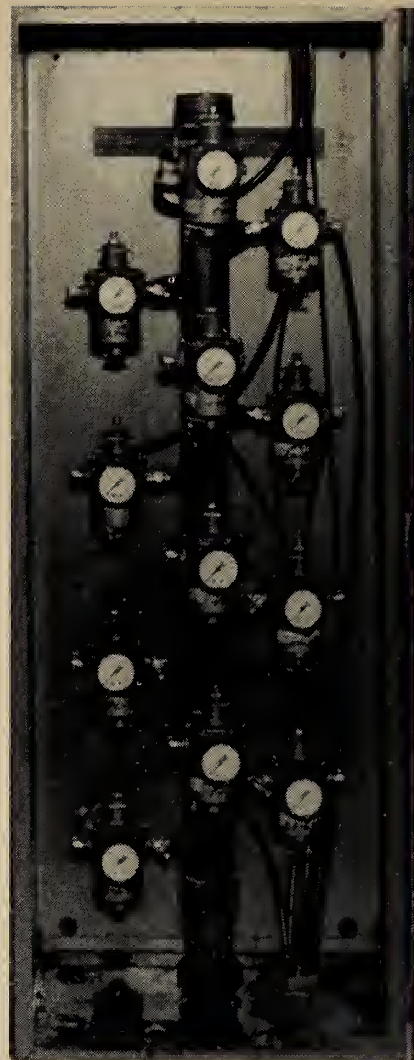


Fig. 5.

It should be pointed out that each transmitter, controller and control valve with positioner requires an air supply as well as a transmission tube. Air is usually provided by a separate compressor and dryer at 100 p.s.i.g. and reduced to 20-25 p.s.i. for each instrument air user. This, then, requires a distribution system similar to that used for the transmission tubing.

Since the plastic tubes in each building are run in conduit it is necessary that a systematic approach be used in order to keep to a minimum the number of small conduits running throughout the building. We therefore provide main junction boxes at strategic locations around the periphery of each building. Another cabinet adjacent to the main junction boxes contains a "hedge-hog" of air supply regulators. Each of these regulators is tagged with the item number of the instrument it is servicing. It now becomes possible to pick up the proper transmission tube and an air supply tube, and run them together in a ½ in. conduit to the proper instrument, (see Fig. 5).

Let us now take a look at some of the considerations necessary in the design of the central control room. Here, apart from the main operating panel, are located many auxiliary controls such as interlock relays, annunciator relay cabinets and pressure switches used for shutdown and alarm purposes. To mount all these units on the control panels themselves presents quite a problem, as the amount of space they take up would make access to the other instruments on the panel rather difficult. Rather than use a standard enclosed pressure switch we purchase a skeleton type, and twenty or thirty of these can be conveniently mounted in a standard electrical box (see Fig. 6). Conventional annunciator relay cabinets can also be installed on the wall adjacent to the pressure switch cabinets thereby making the interconnection between these sets of units very simple.

During the design stage of the plant, the subject of fire protection receives a great deal of study. There is usually some concern that a flash fire might melt the plastic tubing before orderly shutdown could be achieved. This certainly is a problem with bare polyethylene tubing, but can be overcome in several ways. Information is available from the suppliers of the bundled tubing, indicating the length of time the tubes will stand up if subjected to direct flame. This rating depends to some extent on the material used for the protective sheath. The most fire-resistant type, consisting of polyethylene tubes covered with a vinyl sheath, on top of which is a layer of asbestos, followed by a second vinyl sheath, will last approximately five minutes in a fire of 2000°. Compared to other forms of construction, this type of bundle lasts:

- 10 times longer than bare copper tubes.
- 6 1/3 times longer than plastic tubes in a plastic sheath.
- 3 1/2 times longer than copper tubes in a flexible metal wrap.

It is realized that installing this highly-protected material is very costly. Furthermore, nobody can predict with accuracy where this protection will ultimately be required. As a result the following scheme has been adopted in several plants:

Due to their height above ground the main tubing bundles on the pipe bridge are fairly remote from a source of fire, and we therefore use standard polyethylene tubes with a polyethylene sheath. The take-offs from the bridge to the buildings are put in insulated trough. This precaution is taken due to the concentration of tubes at these points. The plastic bundles in buildings are run in conduit, hung in such a manner that insulation can be provided at a later date, if required. At a point close to the instrument the conduit ends in a small 4 in. x 4 in. junction box, and a transition is made to copper tubing so that no bare plastic tubing exists. There are also certain emergency pneumatic valves which are operated directly from the panel. For these valves we install armoured copper bundles from the control room to the buildings. At the entrance to the buildings a transition is made to steel tubing, which runs to the shutdown valves.

The subject of protection of instruments from freezing, using steam tracing and insulation, is worthy of mention. In many plants this is one item which is too often left until the end of the design, and is installed in a rather haphazard fashion. We have tried several protective schemes in the past, such as steel boxes with glass wool lining, various types of blankets and other methods. None of these has been entirely successful. If the insulating material proves too difficult to remove and re-install, after a period of time the maintenance people may not replace it as thoroughly as necessary, and freeze-ups are bound to follow. We have therefore developed several types of insulated boxes using bonded compressed asbestos sheets of half inch and one inch thickness. The sheets are cut to shape in the shop, dipped in water-proofing lacquer, and assembled on an angle iron frame with wing nuts, so that any side of the box can be removed quite easily. On flow transmitter installations the boxes are made large enough for the by-pass manifold to be included in the box. A typical box is shown in Fig. 7.

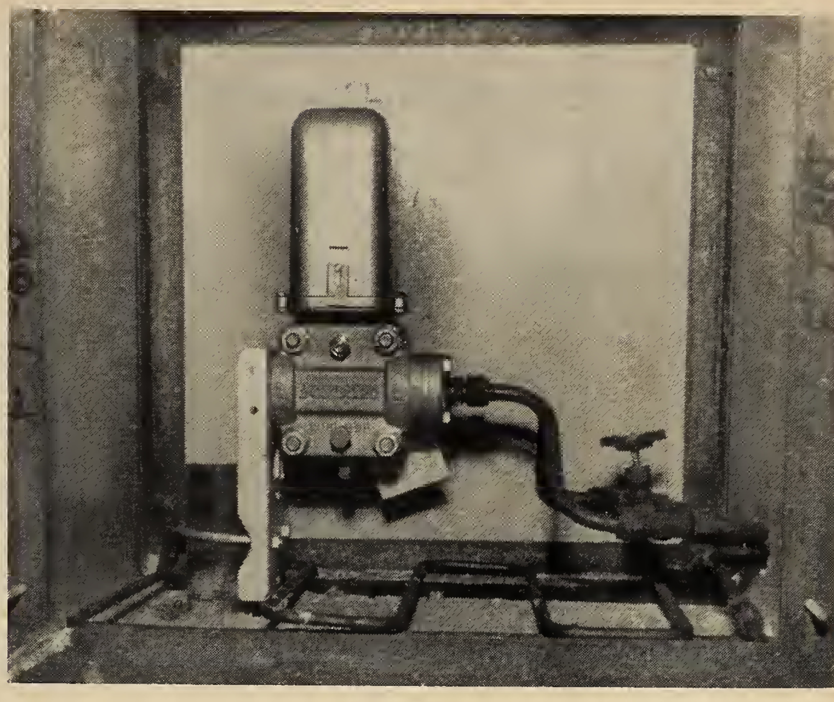

Fig. 7.

In conclusion it should be pointed out that the methods described in the preceding pages are the result of a continuing effort to reduce labour and material costs, as well as to provide a neat installation which is easy to service.

They are far superior to those used five years ago, but will doubtless themselves be modified considerably as new materials and ideas become available and are proven to be economically feasible.

Canadian Developments

In a recent four-way telephone interview set up by the Toronto Daily Star two of Canada's more eminent space scientists, Dr. D. C. Rose, chairman of the Canadian National Committee on Space Research and Dr. Phillip Lapp, chairman of the Canadian Astronautical Society, suggested that Canada's geographical location could be the reason for her playing an important role in the space explorations of the next decade.

Dr. Rose pointed out that Canada's work would be concentrated on the fringes quite close to the earth. Canadian scientists, he said, have already made extensive studies of the Aurora and cosmic rays. Dr. Lapp elaborated on the possibility of Canada's overcoming the obstacle of the Van Allen radiation belt.

Although the nature of this radiation layer is still very little understood, scientists now think that both the inner and outer layers of the Van Allen belt blend into the cosmic ray spectrum. Earlier in this interview Dr. Rose explained that there are bursts of some kind of radiation from the sun which look like low energy cosmic rays, but they occur very irregularly. Dr. Lapp pointed out that scientists are interested in so-called holes in the Van Allen belt. If space vehicles were able to slip through the belt at one of these holes, using a minimum of time and incurring a minimum amount of radiation, this might be the solution to one of the most perplexing problems facing space technologists.

Space Ships and Canadian Industry

Speaking on a panel recently at the University of Toronto's Institute of Aerophysics, on the subject of "Canada's Technical Role in the Space Age", Dr. Lapp expressed the view that Canada would get only a small share of space-age business. He stated that "It has been made fairly clear that within the next decade or more, Canada cannot afford to undertake any large astronautic mission," Dr. Lapp indicated that the natural alternative – industry's looking beyond her national borders for contracts – was more or less ruled out because it was unlikely that another country would want to let such a contract go into foreign hands. "As a result," Dr. Lapp contended, "Canadian industry must be content to play a secondary role in the specialized support field." This would include providing highly specialized novel components for space vehicles.

According to Dr. Lapp, Canadian industry must enlarge its research facilities considerably. Dr. J. J. Green, chief superintendent of the Canadian Armaments Research and Development Establishment at Valcartier, Quebec, also speaking on the panel, said that research work directed specifically toward the region of near space, to a height of about one third the Earth's diameter, would be a sound objective for Canada. Some of the fields which he suggested include: the earth's magnetic field, the nature of the upper atmosphere, nature of the ionosphere, cosmic rays and their origin, and phenomena connected with re-entry into the atmosphere. He also suggested that Canadian research scientists could profitably coordinate their efforts with those in the U.S.

Shock-Resistant Transmitter

A miniature radio transmitter which will work even after colliding with the Moon has been designed by a group of Canadian scientists and successfully tested at the Canadian Armaments Research and Development Establishment at Valcartier, Que. It comprises nine electronic components fitted into a cylinder. To test the mechanism, the transmitter was placed in a projectile and fired off at a speed of 6,000 ft. per second from a smooth-bore gas gun. Though the transmitter batteries were broken off, when new batteries were put in the transmitter was still intact. Dr. G. V. Bull, superintendent of the aerophysics wing of CARDE, concluded that the transmitter could be subjected to up to 100,000 g's upon landing on the Moon and still withstand the shock.

Astronautical Society of Canada Lectures

A series of talks on subjects related to space exploration have been in progress under the aegis of the Astronautical Society of Canada, Montreal, this Fall and Winter. Among them have been discussions of geology and space travel by Professor Vincent Saul of McGill and the possibility of life on other planets by Dr. J. M. Berrill, also of McGill. Professor Saul pointed out that exploration of the Moon and the planets holds great interest for the biologist because of the possibility of life in space, but that for the geologist the prospect of probing other masses represents not *the chance* of discovering mineral and rock formations but *the certainty*. The challenge for the geologist is to be able to discover a variety of geological phenomena that will enable him to better understand the Earth. He anticipates

(Continued on page 86)

• CANADIAN DEVELOPMENTS

(Continued from page 84)

that his methods of exploration and analysis will not be very different from those used on Earth.

Henri T. P. Binet of Montreal presented a paper entitled "Toward Solving the Space Sovereignty Problem" at the Second Colloquium on "The Law of Outer Space" sponsored by the 10th Congress of the International Astronautical Federation in London during September, 1959. Reviewing the history of air law, Mr. Binet pointed out that the provisions of the 1944 Chicago Conference were concerned with flight within the Earth's atmosphere.

In 1958 the General Assembly of the United Nations determined to form an *ad hoc* committee on the peaceful uses of outer space. When the committee met in the summer of 1959, it pointed out that the nations appeared to have accepted the principle of space being freely available for exploration and use by all. They had sent out space vehicles without regard to what particular territory they passed over in their flight through space. The committee agreed that an international agreement on the limits of air space and outer space would be premature at that time.

Since then many people have suggested the establishment of a special United Nations Agency to supervise administration of the new convention to be framed which would be much like the International Civil Aviation Organization set up to administer the 1944 agreement. Others have suggested that ICAO should take on administration of the new space convention. The U.S.S.R. does not belong to ICAO but could be made a member. There is much to recommend combining the administration of laws concerning air space and outer space because there are numerous situations in which space craft operate for a time in their flight as conventional aircraft.

Current Events

Canadian Economy Review for 1959

Canada's gross national product increased by 7% in 1959, while prices rose on the average by 2%. Total national output for the year was up approximately 5%, according to figures recently released by Mr. Gordon Churchill, Minister of Trade and Commerce. Agricultural production was affected by below average harvests of grains and various other crops, but most industries gained substantially and the year's industrial production represents an 8% increase.

Capital spending, public and private, rose slightly in 1959, with commercial, institutional and public investments playing a proportionately larger part than in the previous year. Capital spending in manufacturing amounted to $1.1 billion; housebuilding maintained a high level, though a little lower than in 1958. Housing starts for 1959 were estimated at 140,000 compared to 1958's 165,000.

Recovery in material-producing industries was led mainly by iron and steel which experienced the dual stimulus of rising consumption and restricted American production. Canadian iron and steel output rose two-fifths in 1959. Iron ore output and export have risen 40%. The uranium industry will have a levelling-off period after a very high year in 1959. Within the fuel group, petroleum production and refining increased slightly with rising domestic consumption and higher export volume.

Ontario

Ontario Hydro's Richard L. Hearn plant on the Toronto waterfront, the largest thermal-electric station in Canada, boosted its generating capacity by one-third in January. A 200,000 kw. steam turbo-generator is now feeding power into Ontario Hydro's Southern Ontario System, raising the station's capacity to 800,000 kw. By the end of 1960 the station's output will be at 1,200,000 kw.

Prince Edward Island

According to recent word from Ottawa, considerable progress has been made in the complicated study of a proposal to construct a crossing for the Northumberland Strait between New Brunswick and Prince Edward Island. Nowhere before has a crossing of such length (nine miles) even been contemplated. David J. Walker, Federal Minister of Public Works, has outlined some of the difficulties under study at the present time.

The construction of a causeway would bring about an increase in the range of tides of up to 3 ft. throughout the whole Northumberland Strait. In addition, water levels in the Strait would vary up to 3½ ft. This would result in a differential between opposite sides of the causeway of 7 ft. at mean tides and as much as 10 ft. at high tides.

A full causeway would also result in ice movement being caused only by wind since the currents in the Strait would be stopped. The construction of bridge piers would present a problem because of the velocity of water passing through carrying large ice formations.

Saskatchewan

Construction of the 1959 natural gas program has been completed in Saskatchewan according to J. E. Mollard, chief gas engineer for the Saskatchewan Power Corporation. The last major project of the year was a 40-mile 6-inch transmission line between Alida and Nottingham. The line will transport natural gas from the gasoline plant mid-way between the two communities. This plant and the recovering facilities are now complete and have begun to produce gas. Total production from this source will be between six and seven million cu. ft. per day.

Manitoba

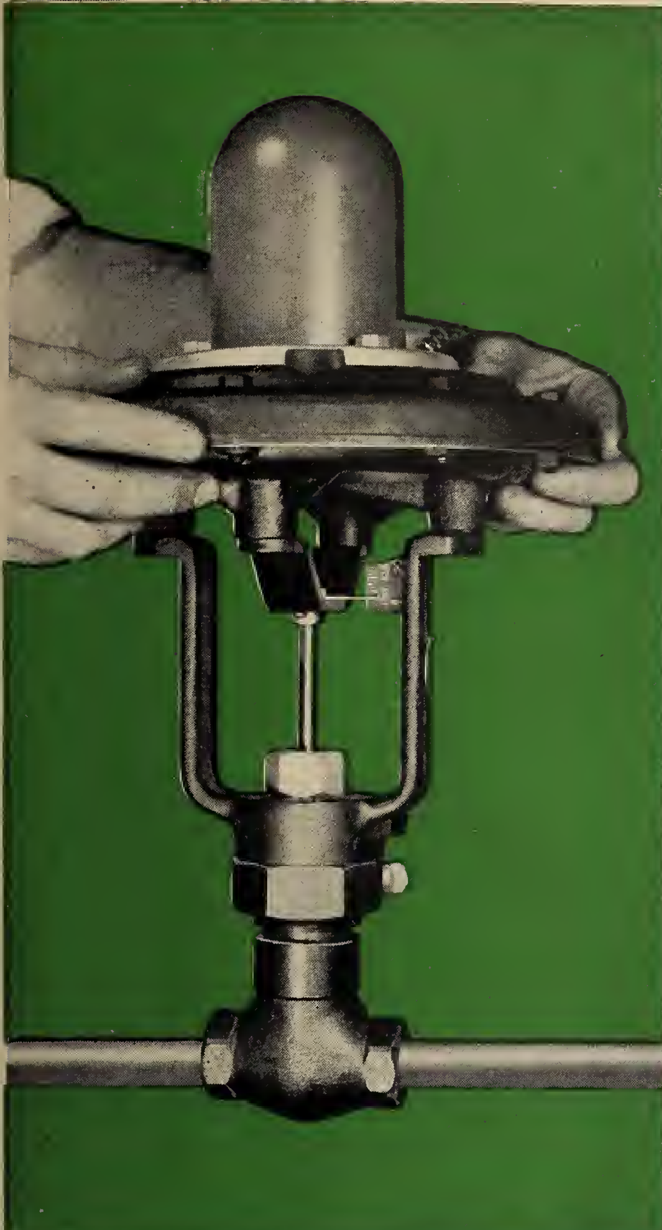
The December issue of the Manitoba Industry and Commerce Bulletin had this to say about an expanded market for Canadian products in the U.K.:

"Generally there is an acknowledged preference on the part of Britons for Canadian food items and consumer products. Some of the products compete succesfully simply by a price or quality advantage. Others are superior to competitive lines in styling, finish, method of packaging, or because a complete range of sizes is readily available. Many items enjoy a tariff preference over foreign competition. The following are some commodities and categories added to those which have been recently freed from import controls: machinery, electrical equipment and apparatus including valves, glass fibre and manufactures, and scientific industrial and optical instruments.

Alberta

Calgary has for a long time been

(Continued on page 88)



LOOK HOW EASY IT IS TO REVERSE THE ACTION OF A FOXBORO CONTROL VALVE!

air-to-open ... air-to-close — one valve for the job of two

Unbolt the motor casing and rotate it 90°; rebolt and shift air connections — that's all you do to reverse the operation of a Foxboro control valve. Takes just a few minutes — without touching valve body or process piping — without employing special tools or skills.

Foxboro reversible motors are especially suited for needle valves, Saunders-type valves, and other control valves having non-reversible bodies. They're also used with Foxboro Stabilflo Valves — the original valves with equal percentage flow characteristics and wide 50 to 1 rangeability.

Foxboro control valves with their quick-reversible valve motor, are an exclusive Foxboro development. They're perfect for pilot plant operations and other processes frequently "juggled." Types and materials to meet any process requirement.

Write for detailed bulletins today. **The Foxboro Company, Limited, 707 Dollard Ave., LaSalle, Quebec.**

• CANADIAN DEVELOPMENTS

(Continued from page 86)

trying to find an answer to serious frost heave problems. Recently city engineers and workmen laid down an "air mattress" sidewalk on 7th Street SW between 8th and 9th Avenues. They used cardboard "egg crate" forms beneath the concrete to create a cushion of air which would absorb the pressure from frost heave. Each of the crates measures 4 ft. x 2 ft. x 6 in. The concrete was reinforced with steel, but the conventional gravel base was eliminated.

Prior to this Calgary engineers had tried installing wire mesh in a section of sidewalk but, whereas serious cracking was eliminated, the frost heaves persisted. To completely eliminate frost heave it would be necessary to lay a gravel base of greatly increased thickness and the cost of such an operation would be prohibitive.

C.C.A. Construction Equipment Report

Construction equipment will rise in cost during 1960 as a result of a rise in the price of steel and wage increases in the manufacturing industry. Continuing research by equipment manufacturers has resulted in new models and machines designed to increase efficiency. Faster obsolescence of present equipment is inevitable.

Canada's Economy

According to the recent report issued by Gordon Churchill, Minister of Trade and Commerce, the last decade has been one of substantial growth and the period ends, as it began, on a strong expansionary trend. However, the prevailing conditions are quite different from ten years ago. In 1950 and the immediately ensuing years, the key stimulus to growth came from defence preparations and related demands emerging from the Korean crisis and the N.A.T.O. defence effort. At that time, shortages and fears of shortages were prevalent, excessive demand pressures created strains in some segments of the economy and prices rose sharply. By contrast the current expansion is anchored to the more solid foundations of constructive peace time pursuits.

The growing needs of the Canadian people, whether for public facilities or for goods and services, have given the dominant push to the present upward surge of productive activity. During the past year, as the economy continued to move out of the 1957-58 recession, operating levels in most industries have moved closer to capacity and the productive resources of the economy generally have been more fully employed. At the same time, in no area of production has demand become excessive, price changes have been moderate and the general level of prices has increased only slightly.

Production and Employment

Canada's Gross National Product in 1959 has increased by 7 per cent from the level of the preceding year. Prices have risen on the average by 2 per cent. This means that total national output, in physical volume terms, is up by about 5 per cent. Agricultural production in 1959 has been affected by below-average harvests of grains and some oher crops, but most other industries have experienced substantial gains. Industrial production has increased by 8 per cent.

INTERNATIONAL NEWS

Much has been said in the press about the military significance of space flight. Something has been said of its importance in developing communications, weather-forecasting methods, and navigation systems. But Dr. Arthur Kantrowitz, director of the Avco-Everett space laboratory, Cambridge, Mass., has said: "It seems to me that learning to live in space is really the exciting prospect. I regard as the next great landmark in our efforts in space the establishment of manned laboratories in a low orbit near the earth".

Dr. Kantrowitz has also made the point that although the scientific probes being carried on can have either military or civilian application, the essential findings remain the same. We find Dr. Krantrowitz, who has said that the greatest challenge in the space probe is to establish life beyond the earth, devoting himself to magnetohydrodynamics and, most specifically, the problem of re-entry heating of nose cones.

This work began in 1954 when Dr. Kantrowitz, then a professor of gas dynamics and engineering physics at Cornell University, suggested that a shock tube could be set up in the laboratory to simulate re-entry conditions. Not long afterward he was asked to set up Avco's new research laboratory at Everett, Mass. In six months he had substantial data on stagnation point heating under re-entry conditions from a special shock tube over 100 ft. long which he had built. Gas, fired through the tube, simulated flight speeds up to 18,000 m.p.h. Later an arc wind tunnel, using electric arcs to heat air to very high temperatures, replaced the shock tube.

In late 1956 Dr. Kantrowitz and his team made two important discoveries: At speeds up to 18,000 m.p.h. up to 10 kw. per sq. cm. heat would be transferred to an object during re-entry; the best resistance to these conditions could be had from ablating materials.

At present Dr. Kantrowitz is working on high- and low-temperature magnetohydrodynamics. The high temperature studies are concerned with fusion reactor applications, the nature of the Van Allen radiation belt, and propulsion of space vehicles using nuclear and solar energy. The low temperature work is on the possibility of generating electric power from gases less than 10,000° K. which have been heated by uranium fission.

British Design Shock Tube

The British have recently announced that scientists at the National Physical Laboratory are constructing a hypersonic shock tube to simulate the conditions of missile flight at speeds up to 18,000 m.p.h. Like the Kantrowitz tube, it is based on the principle of the sudden release of pressurized gas. The required aerodynamic performance of the shock tube calls for high "driver" pressure in the chamber of the shock tunnel. About one cu. ft. of hydrogen, at a pressure a thousand times greater than the atmosphere, is released by rupturing the diaphragm into the working section of the tube. A dump tank, fitted downstream of the working section, ensures that the final equalization pressure in the apparatus does not exceed five atmospheres.

ASME Talks on Space Flight

The American Society of Mechanical Engineers, meeting in Atlantic City, New Jersey in early December considered a number of space flight problems. Ezra S. Krendel, head of the engineering psychology branch of the Franklin Institute, Philadelphia suggested that rocket ship pilots may find themselves cranking and pedalling — rather than pushing buttons. A human passenger in a space ship may have to supply some of his own power in order to save the weight and space needed for other power sources such as batteries, according to Mr. Krendel. At the same meeting a number of papers were presented on the physiological effects of space flight. The U.S. Navy's Aviation Medical Laboratory at Johnsville, Penn., reported a series of experiments indicating that the ability of men to resist acceleration decreases as the temperature goes up. A paper written by a physician, however, pointed out that properly designed space suits could cut the effect on humans of the high temperatures produced as the space ship leaves and re-enters the atmosphere.

Cornell University Space Study Center

Cornell University has announced plans to set up the first large university-sponsored center for radiophysics and space research. Professor Thomas Gold, internationally recognized British cosmologist, will direct the new center and Professor Henry G. Booker, known for his theoretical research of electromagnetism and radio propagation, will serve as associate director. The Cornell University Center for Radiophysics and Space Research will have the world's largest and most powerful radar at its disposal, according to an official report from the university. The giant radar, composed of a 1,000 ft. wide dish and 600 ft. high tripod supporting the feed antenna, will send signals at a power peak of 2.5 million watts and a frequency near 420 megacycles. Located in Puerto Rico, the radar should permit staff members of the center to study the under-surface of the planet Jupiter, about 400,000,000 miles away when closest to the Earth.

(Continued on page 91)

8,000 bbl. sphere, 44 3" diameter, 50

• INTERNATIONAL NEWS

(Continued from page 89)

The record distance for a radar beam reaching out into space and being recorded on earth is credited to Jodrell Bank, England, where a signal has been bounced off Venus.

In addition to the radar colossus which the Department of Defense is financing for the Cornell space research unit, two other new installations will permit extensive research —a radio astronomy receiving apparatus to be built south of Ithaca, New York and a transmitting station, on University property.

Plastics in Space Ships

Plastics have come to play a large part in rocket design research. Reinforced plastics offer a number of attractive characteristics including a good strength-to-weight ratio, thermal and electronic insulating qualities and usefulness from the logistics point of view. They have also been found good as ablating insulations for rocket nozzles and aerodynamic surfaces where flame temperatures exceed the service temperature of any available metals and refractories.

W. E. Zisch, vice president and general manager of the Aerojet General Corporation, recently pointed out that whereas 4% of his company's expenditures this year were for plastics activities, he expected that five years from now the figure would be closer to 20%. He emphasized than increased efforts in education on plastics is essential to their emergence as an important material in rocket and missile construction. Centres on quality control and an industry-wide standardization of materials will also be necessary, if plastics are to have any future in the space field.

Fibreglass for Atlas

The combustion chamber of the U.S.'s Atlas is now being wrapped with fibreglass threads rather than the conventional steel restraining bands. This innovation represents a cost saving of 25% and approximately a 25% weight reduction on the Atlas engines.

Space Paint

A paint which will resist the extreme heat of re-entry into the Earth's atmosphere has been developed by a Missouri company It works by a process of bulimation, the transition of a solid into vapour without an intervening liquid stage.

Midget Camera for Missiles

At Woomera, Australia, scientists have developed a camera hardly bigger than a spool of cotton to be mounted in British missiles for recording details of target interceptions at test firings. "Wreciss" (Weapons Research Establishment camera interception single shot) is virtually indestructible.

Swedes Design H-Power Tube

A new apparatus designed to study the behavior of hydrogen plasma when accelerated in a magnetic field is being tested at the Physical Institute of Upsala University, Stockholm. It is hoped that this may be a step towards hydrogen-power propelled

space rockets. It has been possible to attain ion speeds in the experimental unit which, converted into thermal movement, correspond to one million degrees C. The apparatus consists of a 60 cm. tube with an inner diameter of 12 cm. The heavy electric impulse fed into one end of the tube causes the induction of a counter-current in the hydrogen plasma. The two currents, repelling each other, cause the plasma to rush through the tube, in the shape of a ring, at a speed of about 60 miles per second. According to experts a similar unit, considerably enlarged, might be used for rockets of the future. The exhaust speed of the plasma is 30 to 40 times greater than that of any known chemical rocket fuel. Scientists must still discover a means of energizing on board the rocket the heavy electric impulses required for accelerating the plasma.

U.S. develops H-power

A hydrogen pump which makes possible hydrogen-fueled space engines with up to 500,000 lbs. thrust has been designed by Aerojet. James H. Madden, head of the Engine Reliability Department at Aerojet's Liquid Rocket Plant, has stated that with a cluster of from seven to ten liquid fueled rocket engines, each with a thrust of from 100,000 to 200,000 lbs., the best immediate booster propulsion system for manned space vehicles could be made available. Authorities at Aerojet consider this new hydrogen pump the key to production of powerplants with up to 10,000,000 lbs. thrust.

The output of each engine in the cluster, as Madden described it, would be such as to compensate for one or even two engines if they were to give out in flight. The remaining engines in emergency would increase their thrust level to a point where the total thrust was the same as that provided when all engines were operating.

U.S. Reactor for Space Ships

A 220 lb. nuclear reactor has been designed by the Atomic Energy Commission to supply electrical power for advanced space vehicles. It is unquestionably the smallest reactor to be built this side of the Iron Curtain and may be the smallest in the world. It will generate 3 kw. of power for long periods of time.

British Satellite

By 1961 British scientists hope to have their own space satellite circling the earth 300 miles up. A radio transmitter and 150 lbs. of equipment should be housed in the satellite. It is expected that an American three-stage rocket using solid fuel will put the station in orbit and that the launching will take place in either Virginia or California. Cost of research and equipment for the satellite is estimated at $1,200,000 to $2,400,000.

French Missile Plans

An intermediate range ballistic missile developed with U.S. technical aid and armed with a French warhead will be the mainstay of the French striking force. The I.R.B.M., according to present plans, will be in the 1,500 to 2,500 mile range and will run on solid fuel. Responsibility for developing France's I.R.B.M. will rest with the Societe pour les Etudes et Realisation des Engines Ballistiques (S.E.R.E.B.), a new combine set up several months ago. It comprises most of the French aircraft companies and several government agencies.

Japanese receive Sidewinders

Fourteen Sidewinder air-to-air missiles were delivered by the U.S. to the Japanese experimental unit at Gifu in December. Ninety more are en route. These were ordered by Japan's Air Self Defence Force.

The Japanese Maritime Self-Defence Force has set up a three-year program for building a missile destroyer of 2500 tons displacement.

Soviet Missile Bases Out-Number NATO's

The Institute of Strategic Studies, London, reports that Soviet missile bases outnumber NATO's 100 to 7. The Soviet missile base network is commanded by a single Engineer-General who controls the production of rockets, guided missiles and nuclear weapons. He is also in charge of testing.

U.S. Fellowships for Space Study

Daniel and Florence Guggenheim Fellowships for 1960-61 graduate study in space flight, rockets, jet propulsion and flight structures will allow up to 18 American and Canadian students to study at the Daniel and Florence Guggenheim Jet Propulsion Centers at Princeton University, California Institute of Technology and the Florence Guggenheim Institute of Flight Structures at Columbia University, New York. The fellowships provide tuition and a stipend of $1,500 to $2,000 depending on the stage of advancement of the student.

Fellowships are open to qualified science and engineering students resident in either the U.S. or Canada who intend to make a career in rockets, jet propulsion, flight structures or astronautics. Applications are due by March 1, 1960.

IXth International Astronautical Congress

Proceedings have been published from the IXth International Astronautical Congress held in Amsterdam in 1958. They may be obtained through the American Astronautical Society, 516 Fifth Avenue, New York 36, N.Y. Sessions included: Upper Atmosphere Research; Physics of Space Flight; Astronautical Engineering; Propulsion; Artificial Satellites; and Space Biology and Medicine.

Current Events

Finland Requests Uranium

The Finnish government has requested the International Atomic Energy Agency to supply enriched uranium for its Triga Mark II reactor. This is the first formal request for fissionable materials which the International Agency has received.

The Finnish reactor, to be completed before the end of 1960, will require uranium enriched up to 20% in the isotope U-235. An estimated 2.6 kg. of the isotope will be required. Finland has also requested assistance in fabricating the enriched uranium into fuel elements for the Triga reactor which needs 60 elements for one complete loading. Approximately ten spare fuel items are also called for, consisting of an alloy of enriched uranium and sirconium hydride clad with aluminum.

Big Wheels in the BLOCK BUSINESS

TIMBERLAND

Rollalloy BLOCKS

The line grooves of Timberland wire rope blocks are flame-hardened. Wire rope does not mark these grooves . . . groove retains its surface and shape—greatly extending wire rope life. All Timberland Rollalloy blocks are mounted on roller bearings. Housings cup around the sheaves and prevent cable fouling. Require only seasonal lubrication.

Buy the Block That Pays For Itself

Remember—these quality features not only ensure maximum safety and long life but return real dividends through savings in wire rope costs. Whatever your requirements, a Timberland engineer can help you get the proper blocks for the job.

Saskatchewan:	J. C. Traynor		Prof. John B. Mantle
Yukon:		E. W. King	

Education Committee: Dean H. G. Conn, Kingston, *Chairman;* Vice-Dean L. P. Bonneau, Dean H. Gaudefroy, Dean P. Gendron, Dean G. W. Govier, J. Hoogstraten, Dean R. R. McLaughlin, Dean A. Porter, Dean D. M. Myers, E. V. Buchanan, Commodore H. G. Burchell, J. L. Feeney, P. W. Gooch, R. L. Hearn, W. D. Hurst, G. N. Martin, M. J. J. McAuliffe, K. F. Tupper.

Policy Committee: V. A. McKillop, London, *Chairman.*

Prairie Water Problems Committee: G. A. Gaherty, Montreal, *Chairman;* C. S. Glendenning, G. L. MacKenzie, H. J. McLean, B. Russell, P. M. Sauder, T. D. Stanley, J. M. Wardle.

Professional Development Programs Committee: E. T. W. Bailey, Hamilton, *Chairman;* E. S. Bell, K. R. Crean, W. A. H. Filer, W. J. O'Reilly.

(There are also corresponding members throughout the country)

Professional Interests Committee: J. S. Waddington, Brockville, *Chairman;* H. L. Branchaud, W. E. Brown, G. J. Currie, G. A. Gaherty, R. W. Losie, N. Metcalf, W. G. Swan, I. R. Tait.

Property Committee: F. G. Rutley, Montreal, *Chairman;* A. Deschamps, Vernon B. King, C. N. Murray, R. C. Pybus, L. Austin Wright.

Student Policy Committee: C. G. Southmayd, Montreal, *Chairman;* J. Dubuc, H. P. Gatin, R. E. Jamieson, E. J. Muszinski, A. Pakalnins, D. A. Young.

Canadian IAESTE Committee: *(Operating under the auspices of the E.I.C.)* H. Gaudefroy, Montreal, *Chairman;* J. M. Cape, C. A. Colpitts, L. A. Duchastel, W. G. H. Holt, A. Leclerc, G. A. Wallace, T. H. G. Michael, C. Gerow, D. L. Morrell, D. Jones, B. Howarth. *Ex-Officio*—Garnet T. Page, E. C. Luke.

Harry F. Bennett Fund: Dr. Otto Holden, Toronto, *Chairman;* James F. MacLaren, Toronto, Eric T. Smith, Montreal.

REPRESENTATIVES

American Society of Mechanical Engineers:
Council: A. G. Christie.

ASME-EIC International Council: H. G. Conn, *Chairman;* P. W. Gooch, L. C. Sentance, J. A. Thomas.

Air Pollution Control Committee: E. A. Allcut.

Canadian Chamber of Commerce: F. G. Rutley.

Canadian Conference on Education: K. R. Swinton.

Canadian Science Fair Council: K. R. Swinton.

Canadian Standards Association:

Canadian National Committee of International Electro-Technical Commission: E. D. Gray-Donald.

Committee on Structural Timber: C. R. Cornish.

National Joint Committee on Wintertime Construction: W. B. Pennock.

Civil Defence Engineering Advisory Board:
Liaison Officer: R. E. Hayes.

Column Research Council: D. T. Wright.

Engineers' Council for Professional Development:
Council: W. S. Wilson, G. R. Henderson.

Education and Accreditation: C. H. R. Campling.

Ethics: George Demers.

Guidance: Representative awaited.

Information: Garnet T. Page

Recognition: J. C. H. Dessaulles, Guy Savard.

Student Development: E. J. Muszinski.

Training: K. R. Crean, W. E. Lardner, W. J. O'Reilly.

International Heat Transfer Conference (1961): J. W. Stachiewicz.

Nuclear Congress, 1960: I. N. McKay.

Union Panamericana de Asociaciones de Ingenieros (UPADI)

Board of Directors: James A. Vance, C. R. Vegh Garzon.

UPADI Fund Incorporated: James A. Vance.

The General Secretary represents the Institute on the following where the work is mainly of an administrative nature:

Montreal Board of Trade
Canadian Association for Adult Education
Canadian Conference on Education
Canadian Science Fairs Council
C.S.A. Technical Council
Column Research Council
Council of Engineering Society Secretaries
Institute of Association Executives
World Power Conference

OFFICERS OF THE BRANCHES

AMHERST
Chairman, H. L. Steel; *Vice-Chairman,* G. C. L. McEnery; *Executive,* J. R. MacQuarrie, L. L. Spurr, O. M. Sweetser.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU
Chairman, E. Bodmer; *Treasurer,* T. G. Rust; *Executive,* G. W. Scott, P. Suttie, J. M. Pope, G. Laboissiere.
Secretary, Louis Tellier, Manoir Comeau, Baie Comeau, Quebec.

BELLEVILLE
Chairman, W. C. Benger; *Vice-Chairman,* H. T. Floyd; *Executive,* T. J. Mcquaid, W. J. N. Throop, D. A. Law, E. T. Hilbig, W. L. Canniff, W. L. Lewis.
Sec.-Treas., F. E. Moore, 71 Golfdale Boulevard, Belleville, Ont.

BORDER CITIES
Chairman, J. E. Dykeman; *Vice-Chairman,* J. M. Reid; *Treas.,* F. P. Mascarin; *Executive,* L. Kennedy, A. Barker, W. Macdonald.
Secretary, R. H. Darke, 3281 Everets Ave., Windsor, Ont.

BROCKVILLE
Chairman, D. C. Turner; *Vice-Chairman,* J. R. Eastwood; *Executive,* H. A. Gilchrist, J. B. Moriarty, W. W. Ashworth, T. W. Reade, D. B. Ashenden, R. F. Mucklestone.
Sec.-Treas., W. E. Currie, 41 Bramshot Ave., Brockville, Ont.

CALGARY
Chairman, J. S. Neill; *Executive,* Neil Carr, J. A. Swift, J. A. Warke, B. L. Moreau; *Treasurer,* R. G. Price.
Secretary, A. F. D. Short, c/o Royalite Oil Company, 615 2nd St. S.W., Calgary, Alta.

CAPE BRETON
Chairman, W. L. Dodson; *Vice-Chairman,* C. A. Campbell; *Treasurer,* H. C. Maitland; *Executive,* R. A. Bradley, L. R. Boutilier, J. Laffin, R. Bezanson, P. R. Terry, J. S. Stevens.
Secretary, H. M. Aspinall, P.O. Box 485, Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, M. J. Shelley; *Vice-Chairman,* H. A. Price; *Executive,* R. C. Wannup, B. S. Harvey, E. R. Gayfer, J. W. Nelson.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Ave. West, Penticton, B.C.

CHALK RIVER
Chairman, C. E. L. Hunt; *Executive,* G. Fanjoy, A. Wilson, J. S. Flavelle, C. A. Crawford.
Sec.-Treas., W. O. Findlay, Box 661, Deep River, Ont.

CORNER BROOK
Chairman, Kevin St. George.
Sec., E. R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL
Chairman, L. H. Snelgrove.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Chairman, J. C. Davidson.
Sec.-Treas., H. A. MacLean, Moulton Hill Road, Lennoxville, Que.

EDMONTON
Chairman, S. R. Sinclair; *Vice-Chairman,* J. Longworth; *Executive,* C. R. McFadyen, B. A. Ellis, D. B. Smith, A. W. Peterson, I. G. Finlay, J. C. Moon, G. A. McNeill, A. Sandilands.
Sec.-Treas., G. Hodge, 10615-146th St., Sub. 7, Edmonton, Alta.

FREDERICTON
Chairman, W. L. Barrett; *Vice-Chairman,* H. E. Marshall; *Treasurer,* J. C. Bliss; *Executive,* G. R. W. Bliss, John Burrows, G. F. A. McLaughlin.
Sec., Eric C. Garland, 806 Hanson St., Fredericton, N.B.

HALIFAX
Chairman, H. A. Marshall; *Vice-Chairman,* J. G. Belliveau; *Executive,* H. F. Peters, J. B. Ternan, W. T. Windeler, R. F. Hirtle, C. G. Lindsay.
Sec.-Treas., John H. Boyce, 8 Old Ferry Road, Dartmouth, N.S.

HAMILTON
Chairman, R. H. Stevenson; *Executive,* K. R. Crean, W. H. Hohn, P. J. McNally, M. M. Kennedy.
Sec.-Treas., J. L. Harbell, 230 Edgewood Ave., Hamilton, Ont.

HURONIA
Chairman, S. R. Walkinshaw; *Vice-Chairman,* A. H. Pangman; *Executive,* F. Alport, E. L. Cavana, R. MacKay, D. M. Harris, W. A. Plant, C. A. Fry.
Sec.-Treas., Louis Morgante, 36 Borland St. West, Orillia, Ont.

KINGSTON
Chairman, W. M. Campbell.
Sec.-Treas., D. I. Ourom, c/o Aluminum Company of Canada Ltd., Kingston, Ont.

KITCHENER
Chairman, A. H. Austin; *Vice-Chairman,* W. Bobbie; *Executive,* A. E. LeFeuvre, W. L. Bulmer, Murray H. Schmitt, R. Dahmer.
Sec.-Treas., C. G. E. Downing, 25 MacDonald Ave., Guelph, Ont.

KOOTENAY
Chairman, R. F. Bailey; *Vice-Chairman,* L. S. Piper; *Treasurer,* E. Rohatynski; *Executive,* C. G. Rogers, J. N. Carbert, L. Williams, J. I. McClelland, E. B. Broadhurst, A. Lauriente.
Sec.-Treas., I. Waterlow, Supt., Maintenance Refinery, Consolidated Mining & Smelting, Trail, B.C.

LAKEHEAD
Chairman, Curtis M. Cotton; *Executive,* H. Marshall, G. Hanson, J. Brown, E. Ashton, W. Cheney.
Sec.-Treas., P. W. Pinn, 630 Dawson St., Port Arthur, Ont.

LETHBRIDGE
Chairman, R. L. Francis; *Vice-Chairman,* G. S. Brown; *Executive,* J. Fisher, R. J. D. Gardner, H. Bower.
Sec.-Treas., R. F. Smith, c/o City Hall, Lethbridge, Alta.

LONDON
Chairman, C. H. Osborne; *Vice-Chairman,* G. O. Hayman; *Executive,* L. Scott Murray, G. E. Wilson, H. E. Martin, G. W. Chorley, W. C. Sinkins, Professor L. S. Lauchland.
Sec.-Treas., G. T. Fenwick, c/o Unifin Tube Company, P.O. Box 7, Clarke Sideroad, London, Ont.

LOWER ST. LAWRENCE
Chairman, L. P. Dancose; *Vice-Chairman,* A. Michaud; *Executive,* A. Leroux, Jean Menard, A. Albert, F. Roy.
Sec.-Treas., Gerard Fournier, c/o Lower St. Lawrence Power Company, 6 St. Jean Street, Rimouski, Que.

MONCTON
Chairman, W. M. Steeves; *Vice-Chairman,* H. S. McCleave; *Executive,* L. F. Clifton, R. G. Cowan, D. A. Foster, R. L. Parsons, L. R. Wadlyn, R. F. Weir.
Sec.-Treas., V. C. Blackett, 97 MacBeath Ave., Moncton, N.B.

MONTREAL
Chairman, R. A. Phillips; *Vice-Chairman,* J. Benoit; *Executive,* J. Hahn, O. R. Brumell, L. Scharry.
Sec.-Treas., G. M. Boissonneault, c/o The Shawinigan Water & Power Company, P.O. Box 6072, Room 809, Montreal, Que.

OFFICERS OF THE BRANCHES

NEWFOUNDLAND
Chairman, R. F. Martin.
Sec., A. E. O'Reilly, c/o Newfoundland Light & Power Company Limited, P.O. Box 976, St. John's, Nfld.

NIAGARA PENINSULA
Chairman, D. O. D. Ramsdale; *Vice-Chairman,* E. D. Denham; *Executive,* R. T. Bailey, W. D. Tanner, H. S. Lundy, H. Jones, W. J. O'Reilly, O. J. Smith, A. Zahavich.
Sec., Arthur Alexander, c/o English Electric Company of Canada Limited, George Street, St. Catharines, Ont.

NIPISSING AND UPPER OTTAWA
Chairman, J. M. Roseborough; *Vice-Chairman,* T. H. Chapman· *Executive,* C. A. Hellstrom, D. Cullingham, P. Rebin, H. Staniforth, D. W. Briden, G. M. Goodreid.
Sec.-Treas., William A. Adams, White Oaks Inn, Temiskaming, Que.

NORTH EASTERN ONTARIO
Chairman, I. M. Foster.
Sec., J. W. Shipman, 65 Dominion Ave., Box 1364, Kapuskasing, Ont.

NORTHERN NEW BRUNSWICK
Chairman, P. J. Delicaet; *Vice-Chairman,* V. G. MacWilliam; *Executive,* G. A. Bird, K. A. W. MacDonald, P. E. Desserud, R. E. Haines, R. A. Cameron, F. B. Ervine.
Sec.-Treas., P. J. Dallien, 390 Main St., Bathurst, N.B.

NORTH NOVA SCOTIA
Chairman, J. E. Clarke.
Sec.-Treas., R. S. Morrow, 151 Almont St., New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE
Chairman, R. W. Kirkland; *Vice-Chairman,* R. B. Hamel; *Executive,* M. Michaud, R. Hebert, M. Storier, D. Marston, V. M. Wallingford, S. Luciano.
Sec.-Treas., Lawrence E. Fischer, Iron Ore Company of Canada, Dock Terminal, Seven Islands, Que.

OTTAWA
Chairman, John S. Watt; *Vice-Chairman,* H. C. Brown; *Executive,* A. B. Connelly, K. R. Meyer, D. R. Grimes, G. W. Shorter, H. P. Stockwell, H. A. MacKenzie.
Sec.-Treas., W. V. Morris, Water Resources Branch, Department of Northern Affairs and National Resources, Ottawa, Ont.

PETERBOROUGH
Chairman, Howard Powell.
Sec.-Treas., Brian G. Ahern, 259 Bellevue Street, Peterborough, Ont.

PORT HOPE
Chairman, John A. Pollock; *Vice-Chairman,* J. Sylvester; *Executive,* D. Williamson, J. Coopman.
Sec.-Treas., D. A. Runciman, 49 Chapel Street, Coburg, Ont.

PRINCE EDWARD ISLAND
Chairman, Robert D. Donnelly; *Executive,* A. D. Cameron, J. L. Boomhower, C. H. Stewart.
Sec.-Treas., E. S. Chandler, 242 North River Road, R.R. No. 2, Charlottetown, P.E.I.

QUEBEC
Chairman, Pierre A. Duchastel; *Vice-Chairman,* P. Bousquet.
Sec.-Treas., Marc Bergeron, Concrete Repairs & Waterproofing Company, 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY
Chairman, D. W. Stairs; *Vice-Chairman,* D. L. Aker.
Sec.-Treas., J. R. Eason, 533 Normandie St., Arvida, Que.

SAINT JOHN
Chairman, J. W. G. Scott.
Sec.-Treas., J. P. Mooney, 50 Princess Street, Saint John, N.B.

ST. MAURICE VALLEY
Chairman, Wm. A. Pangborn; *1st Vice-Chairman,* J. I. Butcher; *2nd Vice-Chairman,* L. Orbane; *Treasurer,* M. C. Caron; *Executive,* M. C. Caron, L. Orbane, J. P. Gignane, F. C. Bertrand, W. G. Low, T. W. Ross, W. B. Scott, C. G. Bickerdike, J. W. Gathercole.
Sec., W. George Low, 1970 Lajoie, Apt. 3, Three Rivers, Que.

SARNIA
Chairman, A. W. Wirth; *Treasurer,* C. M. Stewart; *Executive,* M. A. Waghorne, P. Donato, L. F. Marwood, J. Allen.
Sec., Harold V. Page, c/o Dow Chemical of Canada Limited, Vidal Street, Sarnia, Ont.

SASKATCHEWAN
Chairman, J. B. Mantle; *Vice-Chairman,* L. T. Holmes; *Executive,* J. T. Cawley, R. E. Ludwig, L. R. McLeod, J. C. Traynor.
Sec.-Treas., Reginald Bing-Wo, 2043 Cameron Street, Regina, Sask.

SAULT STE. MARIE
Chairman, N. A. Paolini.
Sec.-Treas., R. L. Wimperis, c/o General Delivery, Sault Ste. Marie, Ont.

SUDBURY
Chairman, E. M. Powell; *Vice-Chairman,* R. P. Crawford; *Executive,* F. Burchell, D. Dingwall, L. Gill, G. Green.
Sec.-Treas., C. A. MacMillan, 1237 Woodbine Ave., Sudbury, Ont.

TORONTO
Chairman, Professor A. C. Davidson; *Vice-Chairman,* A. M. Toye.
Sec.-Treas., C. L. Thompson, c/o Honeywell Controls Limited, Vanderhoof Ave., Leaside Toronto 17, Ont. *Asst. Sec.-Treas.,* C. A. Clements, c/o H.E.P.C. of Ontario, 620 University Ave., Room 514, Construction Division, Toronto, Ontario.

VANCOUVER
Chairman, C. P. Jones; *Vice-Chairman,* J. H. Swerdfeger; *Executive,* C. H. White, J. F. Muir, G. A. Antenbring, E. S. Rhodes, H. Lillie, W. E. Stone, C. H. Maartman; *Treasurer,* R. H. Carswell.
Secretary, R. Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND
Chairman, L. C. Johnson; *Vice-Chairman,* E. T. Quirk; *Executive,* N. W. Life, J. A. Cowlin, A. Ker, G. W. Moule.
Sec.-Treas., R. W. Lockie, 314 Cadillac Ave., Victoria, B.C.

WINNIPEG
Chairman, W. L. Wardrop; *Vice-Chairman,* J. B. Striowski; *Executive,* L. A. Bateman, R. N. Sharpe, R. T. Harland, N. S. Bubbis, R. E. Chant.
Sec.-Treas., C. S. Landon, Room 418, 265 Portage Ave., Winnipeg 2, Man.

YUKON
Chairman, G. B. Starr.
Sec., K. J. Baker, P.O. Box 2077, Whitehorse, Y.T.

ONTARIO DIVISION
Chairman, H. R. Sills; *Vice-Chairman,* H. G. Conn; *Treasurer,* G. R. Turner.
Sec., John G. Hall, 92 Heddington Ave., Toronto. Ont.

Elections and Transfers, for February, 1959, are listed on page 98 of this issue.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on September 12, 1959.

Member: P. W. Ainley, Morrisburg; L. Allen, British Guiana; J. Baby, Montreal; R. A. Barnett, Brownsburg; A. P. Bernhart, Toronto; K. W. Button, Welland; E. K. Capstick, North Bay; K. C. Comyns, Toronto; W. V. Coventry, Vancouver; H. L. Dowd, Brownsburg; B. D. Edgar, Pit Siding; H. Q. Golder, Toronto; P. G. Hardie-Bick, Montreal; D. D. Harwood, Montreal; T. D. Hayes, Toronto; A. A. Kay, Vancouver; E. Kelemen, Montreal; D. J. Kerr, Sarnia; J. A. J. Knox, Toronto; E. Kuiper, Winnipeg; F. J. Kumchy, Sarnia; M. D. Lester, Montreal; P. R. Marvin, New York; B. J. McKenna, Montreal; D. M. Myers, Australia; A. J. Naughton, Kapuskasing; C. F. Staargaard, Three Rivers; F. J. Travers, Niagara Falls; G. L. Way, Montreal.

Junior: R. H. B. Hebbert, Kingston; D. C. Stephenson, Niagara Falls; R. B. White, Montreal.

Affiliate: M. L. Smith, Hamilton.

Junior to Member: I. J. Billington, Toronto; R. A. Butts, Montreal; C. M. Cotton, Fort William; A. Curran, Montreal; R. A. DeBou, Vancouver; L. L. Denoncourt, Montreal; J. S. Flavelle, Pembroke; R. F. Frank, Montreal; E. A. Gauthier, Montreal; H. R. W. Marsh, England; L. D. McKenna, Ottawa; H. R. Pelle, Burlington; R. R. Schieck, Thorold; R. F. Shapcotte, Vancouver; J. Sidler, Montreal; G. S. Sugiyama, Winnipeg; C. L. Wild, England; D. T. Wright, Waterloo.

Student to Member: W. A. Scholz, Montreal.

Student to Junior: R. S. Butler, St. John's; E. B. Smythe, Toronto.

STUDENTS ADMITTED

Ecole Polytechnique: R. Aquin, R. Aubin, R. Bibeau, A. Brasseur, K. Chounramany, G. Corbeil, G. Daigneault, A. Desjardins, J. F. Desmarais, G. Dubuc, A. Dugal, C. Durand, M. Fournier, A. Gagnon, E. Gervais, D. Gill, P. Giroux, J. J. J. Gravel, N. Hebert, A. Hennico, H. Hudon, F. Jerabek, E. L. Juneau, G. Lacroix, J. C. Lalancette, M. D. Lalanne, J. Lamarche, M. Langlois, J. G. Latremouille, P. Lavallee, A. Lavoie, G. Lecours, C. Leduc, J. Lemelin, J. J. Leveille, M. Limoges, E. G. Longpre, J. G. Lorrain, M. Maccaferri, P. Marchand, C. Murray, N. Payette, G. Piche, A. Pilon, J. Rivet, H. Sanith, J. G. Sicotte, K. Tainglim, G. Turcotte.

McGill University: J. E. Michalski, R. A. F. Montoute, I. Spinner, D. P. Temponeras, B. Ziegler.

University of Toronto: C. Lischkoff, K. Lum, D. B. Munro, M. D. V. Williams.

Ontario Agricultural College: J. L. Barlow, J. E. Kudlac.

University of Alberta: D. R. Shepherd.

Nova Scotia Technical College: J. L. Coughlan.

Mount Allison University: G. D. Spencer.

B. G. Porter, B.A.Sc. (Civ.), University of Toronto 1959; F. Williamson, B.Sc. (Mining Engrg.), University of Alberta 1959; R. K. Wood, B.Eng. (Chem.), University of Saskatchewan 1958; J. G. Simoneau, Student, Corporation of Professional Engineers of Quebec; D. M. P. Scott, G., I.M.E., 1958.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Student to Junior: A. Willumsen.

SASKATCHEWAN

Members: J. Ferrara, G. F. Fleming, R. J. McIntyre, B. W. Mickleborough, J. Nikolaychuk; **Juniors:** W. A. Derry, A. D. Newsham, G. M. Parker, C. A. Pegg; **Student:** A. J. Gallinger; **Junior to Member:** T. E. Huta; **Student to Member:** M. Gumprich; **Student to Junior:** M. Feldman, D. A. Smith, A. F. Lukey.

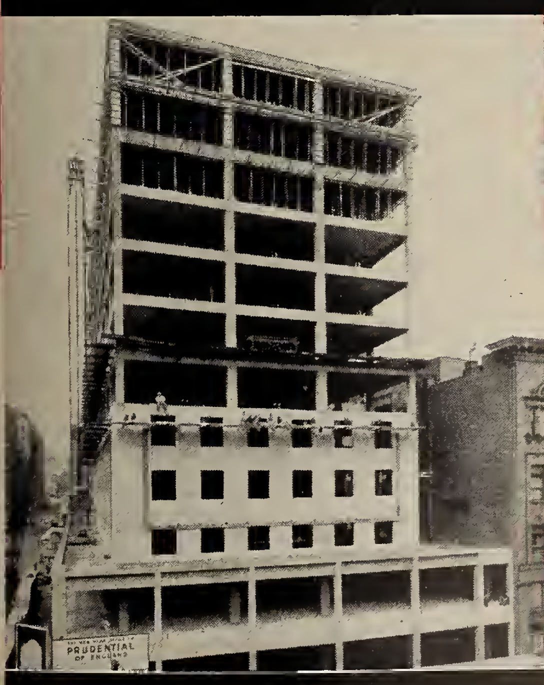
NOVA SCOTIA

Junior to Member: F. J. Abbass, C. J. De Lory, J. A. Waugh.

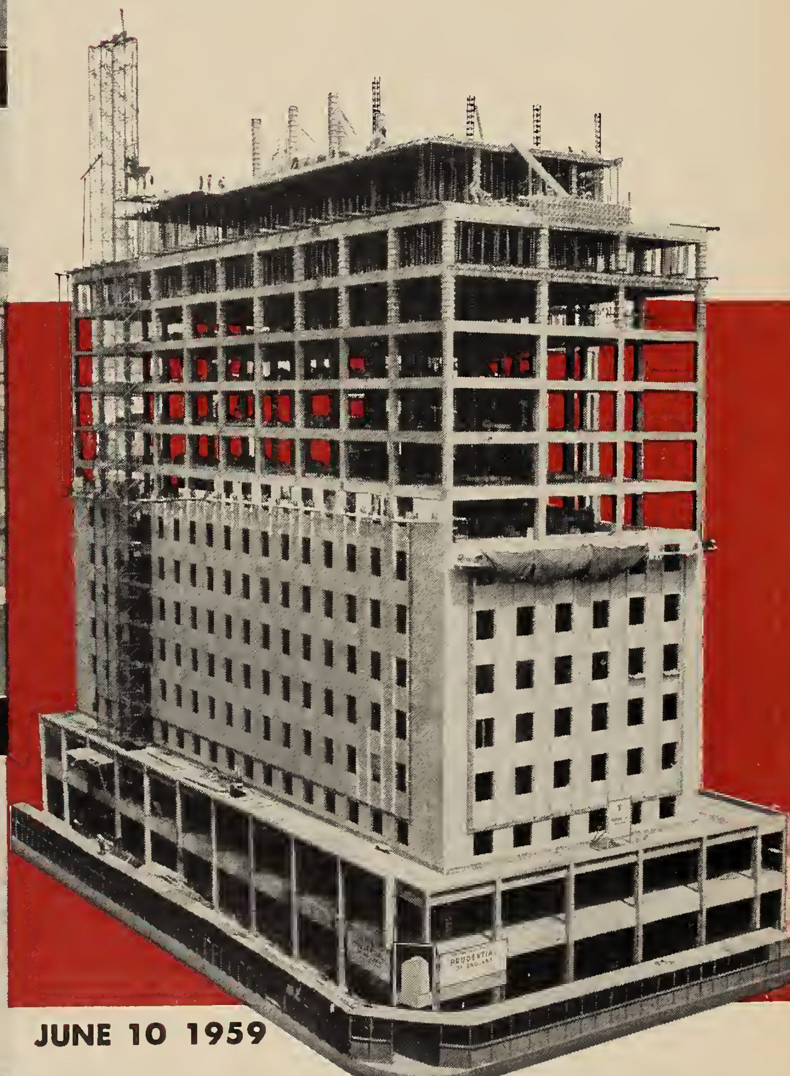
FEBRUARY 9 1959

MARCH 10 1959

APRIL 9 1959



MAY 11 1959



JUNE 10 1959

Personals

Gerald B. Williams, M.E.I.C. (Manitoba '35), chief engineer of the Department of Public Works' Development Engineering Branch (Ottawa), has been appointed assistant deputy minister (technical) for the Department.

G. B. Williams, M.E.I.C.

F. L. Peckover, M.E.I.C.

F. Lionel Peckover, M.E.I.C. (Toronto '44), in charge of the soil engineering section, St. Lawrence Seaway Authority until May, 1959, is now employed by the Canadian National Railways as engineer of soils and foundations, Montreal.

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

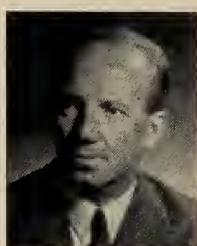
Address all information to: *The Engineering Journal*, Editorial, 2050 Mansfield Street, Montreal, Que.

Morley G. Taylor, M.E.I.C., (Nova Scotia Technical '27) has been made president and chief operations officer of International Power Company Limited. He succeeds Frederick Krug, M.E.I.C., who becomes chairman of the board and continues as chief executive of the company.

Dwight S. Simmons, M.E.I.C., (Queen's '32), general manager of manufacturing for Imperial Oil, is the new president of the Association of Professional Engineers of Ontario.

F. T. Gale, M.E.I.C., (Alberta '35) has been appointed assistant general manager of Calgary Power Ltd. He will continue in his present capacity as vice-president of Farm Electric Services Ltd., as well.

R. L. Raikes, M.E.I.C. (London University, England '32) has been appointed a director of Lewis, Lane and Company Ltd., Consulting Civil Engineers, Sudbury.



R. L. Raikes, M.E.I.C.

G. C. Widdup, M.E.I.C.

G. C. Widdup, M.E.I.C. Manchester '43) has been made chief engineer of Canadian Schenley Ltd. with headquarters in Valleyfield, Que.

Lawrence C. Sentance, M.E.I.C. (Saskatchewan '35), manager of the defence apparatus division and atomic energy division, Canadian Westinghouse Company, has been elected first vice-president of the APEO.

E. H. Brooke, M.E.I.C. (Alberta '42), chief engineer of Texaco Canada Limited, has been appointed to direct the company's new central Executive Offices Engineering Department in Montreal.

G. H. Crase Jr., M.E.I.C. (Toronto '42) has been appointed Ontario District Sales Manager of Horton Steel Works Limited, Toronto.

R. R. Jackson, M.E.I.C. (Alberta '44) has been appointed vice-president and general manager of Ontario operations of Mussens Canada Ltd., Toronto.

Allison F. Mosher, M.E.I.C. (British Columbia '44) has been appointed to establish the Ontario branch of Philip French Sales Ltd. He will be located in Toronto.

Michael Shayna, M.E.I.C. (Saskatchewan '51) has recently taken up the post of assistant plant superintendent of Western Clay Products Limited and is in charge of their research and development.

W. J. Smith, JR.E.I.C. (Manitoba '51) has been appointed chairman of the County Engineers' Advisory Committee. He is also the 1960 president of the County Engineer's Association of Ontario.

T. R. Marien, M.E.I.C. (McGill '52) has been named a director of the Pentagon Construction (1959) Co. Ltd.

Allan G. Moffatt, M.E.I.C. (Toronto '44) was recently elected director of Haddin, Davis & Brown (Manitoba) Ltd.

A. G. Moffatt, M.E.I.C.

A. A. Albert, JR.E.I.C.

Auguste A. Albert, JR.E.I.C. (New Brunswick '50) is the new secretary and engineering director of Dimock Construction Inc., New Richmond, Que. with a branch office at Rimouski.

W. J. Mann, JR.E.I.C. (Manitoba '54) has been made general manager of Canadian Curtiss-Wright Ltd.

William J. Carson, JR.E.I.C. (Nova Scotia Technical '56) has been made executive assistant of Hewitt Equipment Ltd., Montreal. He was formerly general sales manager.

NEWS OF THE BRANCHES

Brockville

J. R. Eastwood, M.E.I.C., *Correspondent*

Dean Mordell of McGill University addressed the December 7 meeting on the importance of engineering to food, energy, shelter and transportation. Scientific achievements would not be possible without the assistance of engineers, he pointed out, hence the betterment of living conditions is dependent on the profession. Engineering has played a large part of recent years in projects in underdeveloped countries only a few of which have been irrigation, conversion of salt water into fresh, and the development of new sources of energy such as the sun and sea tides.

Calgary

Herbert Bailey, M.E.I.C., *Correspondent*

Calgary E.I.C. members heard Mr. Israel Switzer, computer applications analyst with the McBee Company, discuss the importance of electronic computers to engineering on December 1. He stated that engineers were slower than some other groups in adopting computers. Research teams working on ballistics and space vehicles, he pointed out, have adopted computers quite universally for their work. Mr. Switzer strongly recommended that professional societies and university extension departments make an effort to train engineers in the use of computers.

Cape Breton

H. M. Aspinall, M.E.I.C., *Correspondent*

On December 9 the Cape Breton Branch held their Annual Business Meeting in the Officers' Mess, Victoria Park, Sydney. The meeting was presided over by W. L. Dodson, branch chairman. The secretary, treasurer, program convenor and student guidance convenor presented their reports on the year's activities and new officers were elected.

Edmonton

George Hodge, M.E.I.C., *Correspondent*

Dr. R. M. Hardy, a member of the Borden energy commission, addressed branch members on Nevember 27, stating that a pipeline to carry Alberta's crude oil to Montreal would be advantageous to the Canadian economy. In order to make the proposed pipeline feasible, Dr. Hardy, former dean of engineering at the University of Alberta, pointed out that the federal government would have to impose restrictions on the import of foreign crude now being processed in the Montreal refining area.

Fredericton

John Burrows, JR.E.I.C., *Correspondent*

A panel discussion, "Are engineers professional or technical advisers?", was held at The Lord Beaverbrook Hotel on December 14. Mr. R. D. Neill of the N.B.E.P.C. acted as moderator and Mr. J. L. Feeney, commissioner of the N.B.E.P.C., and Mr Stanley B. Cassidy, electrical contractor, were panel members.

In support of the professional status of the engineer, the members of the panel remarked that engineering in general promotes works which are to the benefit of mankind. They pointed out that those active in this field pursue an occupation requiring a varied and lengthy technical education as well as much practical experience. They are responsible for, and much concerned with, the performance of engineering structures which they design.

It was felt that ideally engineers should be freely engaged in individual activity. Although this is not possible for all engineers, those on salary should make an effort to retain their identity by gaining recognition in their field of specialization and accepting responsibility. Industrial engineers were cited as those frequently included in labour organizations of a type not usually beneficial to professional status.

Halifax

W. J. Phillips, M.E.I.C., *Correspondent*

"The Digital Computer—An Engineering Tool" was the subject of a talk by Messrs D. G. Brown and K. F. Duggan on November 24. More than 70 members were in attendance. The men reviewed the development of both analog and digital computers and discussed the problems of programming with particular reference to a demonstrator computer lent by Saint Mary's University.

Kootenay

I. Waterlow, JR.E.I.C., *Correspondent*

Mr. Gordon Turner, research engineer with Consolidated Mining and Smelting, gave a talk on semi-conductors December 8. He discussed their formation and electrical properties in relation to temperature and current available.

Niagara

E. C. Little, M.E.I.C., *Correspondent*

Some 45 members met at the Lenord Hotel, St. Catharines, for the December meeting. Mr. E. W. Haack, applied science representative for IBM, described the analog computer and showed how it could be used as an engineering tool in the design of power houses, transmission lines, transformers and generators.

Ottawa

Philip Ristow, JR.E.I.C., *Correspondent*

On November 5, Mr. N. B. Hutcheon, assistant research director of the Division of Building Research, National Research Council, spoke to members on problems of development in India. He recently returned from a three-month technical mission to assist India's building research department. He pointed out that the low cost of labour discouraged the adoption of modern mechanisms and that the quality of products in India was highly variable.

Peterborough

R. M. Allemang, M.E.I.C., *Correspondent*

Dr. Philip A. Lapp, president of the Canadian Astronautical Society and senior project engineer with DeHavilland Aircraft, spoke at a dinner meeting in December on "Space Vehicle Engineering". Dr. Lapp concentrated on the guidance and control functions in missiles and outlined the limitations and possibilities of the various propulsion methods. He concluded with a description of the major problems yet unsolved in space vehicle design.

Sault Ste. Marie

R. L. Wimperis, JR.E.I.C., *Correspondent*

Mr. A. Joynson, of Proctor & Redfern Consulting Engineers, was guest speaker at the November 27 meeting. He stated that government action has brought about the purification of water. Both municipalities and industries are guilty of water contamination and will need to take a responsible role in getting rid of it, he stated. Mr. Joynson discussed plans for the sewage disposal system for Sault Ste. Marie and the surrounding area.

Sudbury

Archie B. Platt, JR.E.I.C., *Correspondent*

Over 30 members and guests attended the December meeting held in the Granite Club. Dr. T. Hugill of Canadian Liquid Air spoke on tonnage oxygen plants, covering the ferrous and non-ferrous industries. Of particular interest was his description of the low pressure air separation plant at Copper Cliff, Ont. Mr. Hugill also described the units used in petroleum refineries to produce ammonia from refinery "off" gases and the double cycle air separation units mainly used in the steel industry for oxygen process steel furnaces.

News of Other Societies

American Astronautical Society

The Sixth Annual Meeting of the A.A.S., held in New York City, January 18-21, included sessions on Space Communications, Propulsion, Guidance and Control, Space Medicine and Astrobiology, Space Flight Mechanics, Space Vehicle Design, Applications of Astronautical Systems, and Space Physics. The guest lecture in the Astronautical Sciences was delivered by George P. Sutton, chief scientist, Advanced Research Projects Agency.

The Society of the Plastics Industry

Over 1,000 persons attended the Fifteenth Annual Reinforced Plastics Division Conference of The Society of the Plastics Industry in Chicago, February 2-4. Under discussion were: radomes, missiles, decorative laminates, structural panels, submarine superstructures, underwater weapons, preimpregnated fabrics, joints on concrete pipe, and reinforced plastic pipe.

The Plastic Bottle & Tube Manufacturers' Institute will be held in New Orleans, La. February 16 and 17, while the Seventeenth Annual SPI Western Section Conference will take place on April 7 and 8 in Palm Springs, Calif.

Soil Mechanics and Foundations Division, American Society of Civil Engineers

A Research Conference on Shear Strength of Cohesive Soils is to be held at the University of Colorado, Boulder, June 13-17. Engineers interested in attending the conference or obtaining a copy of the proceedings should contact Dr. J. W. Hilf, Secretary, Task Committee on Shear Strength of Soils, ASCE, Bureau of Reclamation, Building 53, Denver Federal Center, Denver 25, Colo.

Instrument Society of America

The Sixth Annual Symposium on Instrumental Methods of Analysis is to be sponsored by the Montreal Section of I.S.A. in co-operation with the Chemical Engineering Section of the Chemical Institute of Canada. It will be held at the Queen Elizabeth Hotel, Montreal, June 1-3. Papers are required in the following fields of analysis instrumentation: Medical, Pulp and Paper, Food and Tobacco, Petrochemical, and Metallurgical. Intent to present papers must be mailed by February 28, 1960, to Mr. J. J. Gravel, Technical Publicity Chairman, Pulp and Paper Research Institute, 3420 University Street, Montreal 2.

Coming Events

The Chemical Institute of Canada

February 18—Protective Coatings Division Conference, Toronto.
February 19—Protective Coatings Division Conference, Montreal.

McGill University, Faculty of Engineering

Symposium on Flight—January 21 to March 10.
February 18—"Polar and Mid-Latitude Navigation", K. R. Greenway, R.C.A.F.
February 25—"Flight Propulsion", D. L. Mordell, McGill
March 3 —"The Evolution of Aircraft Structures", A. R. Edis, McGill
March 10 —"Flight into Space", W. F. Campbell, National Aeronautical Establishment.

Toronto Quality Control Society

March 5 —Seventh All-Day Forum, University of Toronto
May 24-26 —14th Annual Convention and Exhibition of American Society of Quality Control, San Francisco.

University of Florida, Mechanical Engineering Department

March 7- 8—Heat Transfer Symposium

Institute of the Aeronautical Sciences

March 10-11—Flight Propulsion Meeting (classified), Cleveland.
April 20-22 —Manned Space Stations Symposium, Los Angeles.

Instrument Society of America

April 3- 8 —6th Nuclear Conference, New York
April 5- 7 —3rd National ISA Chemical and Petroleum Instrumentation Symposium, Rochester, N.Y.

"Expomat" Exhibitions

March 17-27—International Construction Exhibition, Paris
May 19-29 —International Public Works and Building Equipment Exhibition, Paris, France.

American Management Association

June 13-15 —Workshops on Research and Engineering Administration, Toronto.

E. I. C.

ANNUAL MEETING

WINNIPEG

MAY 24-27

NEWS OF THE

Associations and Corporation

Ontario Professional Engineers Hear Panel on Enlightened Administration of Engineering Staff

A NUMBER OF IDEAS concerning the relationship between engineer manager and technical engineer were introduced by panel members at the annual meeting of the Association of Professional Engineers of Ontario, in Toronto, January 23. On the panel were: L. R. Campbell, Bell Telephone; Henry S. Dawson, Canadian General Electric; R. G. Teasdale, Atlas Steel; R. W. Dunlop, M.E.I.C., Imperial Oil, all in management.

Mr. Campbell described the most important element in the implementation of management philosophy as recognition of individual contribution.

Mr. Dawson felt that business factors and professional productivity were most important in proper administration of engineering staff.

Mr. Teasdale stressed the need for development of the individual. He supported a program founded on the belief that it must help the participant to learn to use himself.

Mr. Dunlop expressed the relationship between people in an organization as most important in carrying out effective programs.

The second panel of Association members contributed to the discussion by interjecting some of the thinking of professional engineers who see the problem from a different vantage point as essentially non-management engineers. It included: C. E. Rickards, Northern Electric; D. T. Bath, M.E.I.C., Canadian General Electric; K. B. Shirazee, Canadian National Telegraphs; and R. M. Sachs, Orenda Engines.

R. W. Diamond, Hon. M.E.I.C. (left) is presented with an engraved replica of the Honorary Life Membership certificate which he was awarded by the Association of Professional Engineers of B.C. last year. Making the presentation is Past-President R. E. Wilkins, M.E.I.C. (right), while the new president, H. P. J. Moorehead, looks on.

Mr. Rickards advanced several points which might bring about better relations between management and engineers: the termination of automatic progression salary payments and the adjustment of the professional engineer's salary to his own individual effort; institution by industry of a trial period of employment for professional engineers; the surrender on the part of professional engineers of protection under formal bargaining agreements and a willingness to depend upon their own abilities for guarantee of working conditions and remuneration.

Mr. Bath felt that better communication between employee and employer was the key to a better relationship. He said professional engineers feel a need for mutual confidence with the employer.

Mr. Shirazee said the professional engineer wants social approval of his work, and self-respect results. He also wants to be used to his highest capacity.

Mr. Sachs pointed out that there was a division in the engineering profession with the two groups formed—one group which became managers and the other which concerned itself with purely technical engineering. "The manager group doesn't often understand the technical group and vice versa," he stated.

Theoretical Courses Gaining in Number

A greater emphasis on advanced theoretical courses and mathematics is the current trend in engineering education, Prof. V. G. Smith, of the University of Toronto, told the Association of Professional Engineers of Ontario at their annual meeting.

Professor Smith, who is on the university's electrical engineering faculty, said the trend is to eliminate some of the practical courses from engineering curricula in favour of more advanced theoretical courses and mathematics. He said this trend is reflected by a new syllabus of examinations, approved by the Canadian Council of Professional Engineers, which is being brought into use.

(Continued on page 126)

Now Allis-Chalmers brings its 85 years of pump experience to the short-coupled vertical turbine-type field. This addition not only rounds out industry's most complete single source for pump installations, it offers many advantages wherever liquids are to be pumped. Standard sizes for heads up to 400 ft or more, and capacities ranging from 20 to 8000 gpm.

Pressures can be increased by simply adding a stage to the existing pump without increasing space requirements. Equipment and installation costs are low. Motor and discharge nozzle are supported by a single, small foundation. There's no need for suction pipe, interlock controls or priming equipment. Allis-Chalmers hollow-shaft motors remove the danger of open couplings.

Many advantages — Self-priming • eliminate suction piping costs • save space, motor support and discharge nozzle are integral • low first cost • increase pressure easily • operate quietly • low maintenance with one stuffing box • no motor flooding.

Many applications — Water systems, irrigation, condenser systems, bilge and sump service, dry docks, fire equipment, filter washing, recirculation, transfer pumping, process pumping, cooling condensers and diesel engine jackets, air conditioning, caisson and mine dewatering, general-purpose pumping.

Allis-Chalmers pump experts will be happy to tell you about this new addition to an outstanding line. For complete information, contact your nearest CA-C Sales Office or write direct to Canadian Allis-Chalmers Limited, P.O. Box 37, Montreal, Quebec.

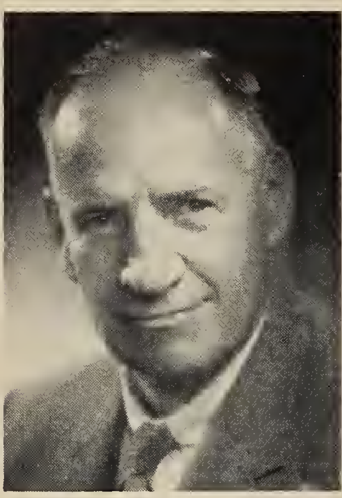
CANADIAN ALLIS-CHALMERS

59-P-8

Dr. Convey Addresses B.C. Meeting

One of the highlights of the annual meeting of the Association of Professional Engineers of British Columbia in December was an address by Dr. John Convey, Director of Mines and Technical Surveys in Ottawa.

Dr. Convey explained that the international ban on nuclear experiments stands in the way of applying atomic energy to the extraction of oil from the Athabasca tar sands. Many other methods have been tried without success, he said, but there is evidence that the shock and heat of nuclear explosives can separate the oil from sand and allow it to be pumped to the surface. Nine separate expcriments in the U.S. have proved that nuclear explosives can be safely discharged underground, and the dangerous radioactive elements contained in a great underground slage bubble, Dr. Convey reported.



Dwight S. Simmons, M.E.I.C.

Dwight S. Simmons President of Ontario Association

The Association of Professional Engineers of Ontario has elected Dwight S. Simmons, M.E.I.C., of Toronto, as its 1960 president. He succeeds A. W. F. McQueen, of Niagara Falls.

Mr. Simmons is general manager of manufacturing for Imperial Oil. A native of Sarnia, Ontario, he graduated from Queen's in mechanical engineering in 1932 and has been with Imperial Oil since then. He has served on the A.P.E.O.'s Executive Council for five years and last year was the Association vice-president.

Elected 1st vice-president for 1960 is Lawrence C. Sentance, M.E.I.C., of Hamilton. The 2nd vice-president is Robert L. Hicks, M.E.I.C., Toronto.

A.P.E.O. Awards Gold Medal

The A.P.E.O. Gold Medal Award, presented annually to the two engineering students who have graduated with the highest standing from the University of Toronto and Queen's University, has been given to John R. Luke, of Toronto, a graduate in mechanical engineering from the U. of T., and Raymond J. Buhr, of Coburg, who graduated from Queen's in engineering physics. The awards include a $50 cheque to be used by the recipients in the purchase of text books.

The Association also provides $250 scholarships which are awarded annually in the first three years at the University of Toronto and Queen's. Each award is made to the student who, taking honours in engineering, obtains the highest standing in his work in the academic year.

OBITUARIES

John Hammersley-Heenan, M.E.I.C., a life member of the Institute, died at North Hollywood, California on January 17, 1960. He was 80.

Born in New London, South Africa and graduated from Central Technical College in London, England, Mr. Hammersley-Heenan became assistant engineer to the admiralty in charge of construction of Admiralty Harbour, Dover, in 1900.

In 1902 Mr. Hammersley-Heenan was made engineer in charge of design and construction at the Port of Durban, Natal, South Africa. He visited Canada in 1910 and established what is now known as the Dominion Engineering and Inspection Company. He practiced as a consulting engineer in Montreal until the outbreak of World War I at which time he took over the supervision of supplies and inspection of materials purchased by the Union of South Africa in Canada and the U.S.

After the war Mr. Hammersley-Heenan settled in the U.S. and worked as an engineer with the Pan Pacific Piling and Construction Company in Wilmington, California. During World War II he did construction work in that city for the Navy. From the end of the war to the time of his retirement, Mr. Hammersley-Heenan did survey and subdivisioning work in and around Los Angeles and San Diego.

Word has been received of the recent passing of **Norman T. Smith** in Phoenix, Arizona. General manager of Nova Scotia Light and Power from 1949 through 1957, Mr. Smith had lived in Arizona since his retirement.

Francis Darrell Gifford, M.E.I.C., died in Colborne, Que. on January 8, 1960. Earlier this month he had been granted a life membership in the Institute.

Mr. Gifford was for many years resident engineer for the Huntsville division of the Department of Highways, Ontario. In 1950 he was appointed inspecting engineer of the Department of Resources and Development, Special Projects Branch, Trans-Canada Highways Division.

A Major in the Royal Canadian Army in World War II, Mr. Gifford was awarded the Military Cross.

J. W. H. Ford, M.E.I.C., a life member of the Institute and an authority on hydraulic development, died at Preville, Que. on January 24, 1960. He was 70.

A graduate of the University of Toronto in 1915, Mr. Ford went to work with the W. I. Bishop Company on construction of paper mills at Ste. Anne de Beaupre, Que. and Grand Falls, Nfld. He later was employed as superintendent for Shawinigan Engineering at LaTuque and Rapide Blanc power developments. For a time he was on loan to the Aluminum Company of Canada as superintendent of the Shipshaw power development.

Upon retirement in 1956 Mr. Ford joined the St. Lawrence Seaway Authority as assistant to the chief engineer of construction.

William Albert Bickell, M.E.I.C., of Vancouver, B.C. died on August 30, 1959. A member of the Institute since 1944, Mr. Bickell worked at the Directorate of Works and Construction in Ottawa until his retirement in 1946.

From Ottawa Mr. Bickell went to Vancouver and was engaged in the contracting business.

Charles John Chaplin, M.E.I.C., a member of the Institute since 1904, died in August, 1959. For more than twenty years Mr. Chaplin was timber mechanics officer in Forest Products Research (Department of Scientific and Industrial Research), England.

In 1945 Mr. Chaplin left his post and returned to Canada. He was living in Almonte, Ontario at the time of his death. Mr. Chaplin was given life membership in the Institute in 1947.

Bary James Ferries, JR.E.I.C., was the victim of a recent boiler explosion at the Portage La Prairie, Manitoba works of the Inter City Gas Company. He had been chief engineer there for three years.

Mr. Ferries graduated from the University of Manitoba in 1955 with a degree in mechanical engineering. He was a member of the Association of Professional Engineers of the Province of Manitoba and a past chief engineer of the Winnipeg Chapter of the Sigma Phi Delta fraternity.

Victor Anthony Harvey, JR.E.I.C., died as the result of an automobile accident on April 10, 1959.

A graduate of the University of Toronto in civil engineering, 1953, Mr. Harvey was employed in the design department of the Ontario Hydro-Electric Power Commission, Toronto.

Gerhard Herrman Heyn, M.E.I.C. died on August 29, 1959. Mr. Heyn established a private practice as a consulting engineer in 1951 in Toronto.

In 1952, in a private capacity as project engineer representing E. & B. Cowan, Consulting Engineers, Montreal, he worked on the St. Lawrence Corporation's expansion program at Red Rock, Ontario.

Thomas Lees, M.E.I.C. died on August 24, 1959, after a long and interesting career with the Canadian Pacific Railway Company.

Mr. Lees went to work with the company in 1905 and in 1923 was made district engineer at Calgary. In 1941 Mr. Lees was transferred to Vancouver to assume the duties of district engineer there.

Upon retirement Mr. Lees came East. He resided in Saint John's, Newfoundland until his death.

Norman Wagner, M.E.I.C., died on November 25, 1959. He had been a consulting structural engineer in Hamilton, Ontario for many years.

A graduate in civil engineering from the University of Toronto in 1910, Mr. Wagner was a partner of Wagner and Oliver in Hamilton before going into private practice.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

***CYROGENIC ENGINEERING**

Although the practical aspects of cyrogenic processes and equipment are emphasized, an effort is made to include the theoretical fundamentals required for understanding the subject. The major problems encountered in the development and application of low temperature techniques are described, including the liquefaction and separation of gases, cooling by adiabatic demagnetization, measuring low temperatures, low temperature insulation, and the storage and transfer of liquified gases. Two concluding chapters provide handbook type information on the properties of very cold fluids and solids. The material given treats of the most recent developments and is organized with a view to indicating the feasibility of any new project, as well as the difficulties which may be encountered. (R. B. Scott. Toronto, Van Nostrand, 1959. 368p., $6.00.)

***INTRODUCTION TO THE THEORY OF COMPRESSIBLE FLOW**

The fundamentals of compressible flow are described, ranging from basic assumptions and formulation of theory to various methods of solving the problems involved. The physical properties of gases are reviewed and followed by a detailed discussion of the theory of compressible flow of inviscid fluids in relation to both steady and non-steady flow. In addition such advanced topics as transonic flow, hypersonic flow and rotational flow are thoroughly examined. In the last three chapters the author provides a detailed analysis of a viscous compressible fluid including the effect of chemical reaction and electromagnetic forces. (Shih-I Pai. Toronto, Van Nostrand, 1959. 385 p., $10.50.)

***THE SCIENTIFIC REVOLUTION**

A long term assessment of the challenge created by the scientific revolution which the satellite launchings symbolized. The authors open with a discussion of this scientific revolution and its implications for the United States, move on to an appraisal of the problems faced in developing a science program adequate to the nation's needs, and then evaluate the role of science in society and the effect of a lack of public understanding upon science and the scientist. The concluding sections examine the adequacy of the educational system in providing the human resources needed. (Ed. by G. W. Elbers and Paul Duncan. Washington, Public Affairs Press, 1959. 280p., $6.00.)

LUBRICATION SCIENCE AND TECHNOLOGY

Papers on the theoretical and practical aspects of lubrication. Among the topics considered are the lubrication of bearings, the lubrication of slider blocks, fretting of hardened steel in oil, wear and frictional characteristics of some nickel base alloys, studies of wear in relation to lubrication problems, ceramic cutting tools, synthetic sapphire as a bearing material, etc. These papers form volume 1 number 2 of the Transactions of the American Society of Lubrication Engineers, and are a complement to their periodical Lubrication Engineering. (Ed. by John Boyd. New York, Permagon, 1958. 114 p., $10.00.)

WORK MEASUREMENT IN THE OFFICE

It has been estimated that the productivity of the average office worker could be increased by 20 to 60 percent. This volume is a guide to the use of work measurement to increase production.

The authors explain how to organize a work measurement programme, and make a pilot study. The various techniques used for gathering information are described, compared and evaluated. Finally the authors discuss ways of adjusting work standards, of their use in measuring performance, and in office incentive plans.

All those interested in increased office efficiency will find many useful ideas in this book. (E. V. Grillo and C. J. Berg, Jr. Toronto, McGraw-Hill, 1959. 186 p., $6.65.)

WAGE ADMINISTRATION

Intended primarily to give the reader the basic information needed for successful wage administration, this volume analyzes the tools used, and shows how others have applied them to the problem.

After an introductory section, the author discusses the determination of the relative worth of jobs, by the use of job evaluation and analysis, job ranking and classification, etc. The next sections are concerned with the determination of the going wage, wage surveys, payment plans, incentives, etc. Two chapters deal with personnel rating, and the control of the wage administration programme. A final chapter contains problems. (C. W. Brennan. Homewood, Ill., Irwin, 1959. 439 p., $8.10.)

PRACTICAL DREDGING

The author has had much practical experience of dredging in both South Africa and the United Kingdom, and has written this book for those actually engaged in dredging operations. He discuses the various types of dredger now available, their functions, and their management and operation. Also covered are preliminary surveys, borings, currents, dredging gear, buckets, moorings, reclamation work, overhauling gear, etc. There are many illustrations of the different types of dredgers and gear, adding to the value of this useful practical text. (H. R. Cooper. Glasgow, Brown, Son and Ferguson, 1958. 270 p., 65/-.)

PRINCIPLES AND PRACTICE OF FLOW METER ENGINEERING, 8TH. ED.

This eighth edition has been enlarged, and includes new primary devices, different tap locations, and the use of electronic computers.

All aspects of flow measurement and metering are covered, including an introductory section on general flow measurement and meters, and liquid, steam and gas flow measurement. Much of the information is presented in graphs and tables, and there is a useful bibliography. (L. K. Spink. Montreal, Foxboro, 1958. 549 p., $15.00.)

SCIENTIFIC RUSSIAN

Already known for his guides to scientific French and German, the author has now written a text for those wishing to read scientific Russian. All the major grammatical constructions are covered, and the emphasis throughout is on reading passages taken from Russian texts. The explanations given are clear, and this will be a useful manual either for beginners or for those wishing to refresh their memory on some point. (G. E. Condoyannis. New York, Wiley, 1959. 225 p., $3.50.)

ELEMENTS OF SOLID STATE THEORY

Intended for graduate and other advanced students, this volume presents a brief outline of the theory of solid state physics. The subjects covered are: geometry of the crystalline state; diffraction of radiation by crystals; dynamics of lattice vibrations; co-operative phenomena in solids; one-electron theory of solids, metals; semi-conductors; friction in electron dynamics; Ohm's law; solid cohesion and chemical bonding. Problems and an extensive bibliography are included in each chapter. (G. H. Wannier. Toronto, Macmillan, 1959. 270 p., $6.00.)

JIGS, TOOLS AND FIXTURES, 5TH. ED.

In this fifth edition, a new chapter has been added on indexing mechanisms, the chapter on press tools has been enlarged to include information on die construction, crop feeding and die layout for delicate pressings.

The author describes the drawing and design of all types of equipment used with machine tools: jigs, chucks, cutters, gauges, cans, jig bushes, materials. A useful practical book. (Philip Gates. Toronto, General Publishing, 1959. 215 p., $6.00.)

SIXTH REPORT OF THE CORROSION COMMITTEE

The fifth report of this Committee of the Iron and Steel Institute was presented in 1938. This report includes a review of progress in the last twenty years, and of the work of the Committee in the fields of atmospheric, marine and soil corrosion, corrosion by industrial waters, protective coatings, corrosion test procedures, and research. More detailed information is given on tests conducted on the atmospheric corrosion of iron and steel, corrosion and protection up to 300°C and marine corrosion. (J. C. Hudson, comp. London, Iron and Steel Institute, 1959. 217 p., £3.3.0.)

THE UNCOMMON MAN

Du Pont's tenth president presents his philosophy of business management in this volume, which is based on a series of lectures given at the Graduate School of Business Administration at Columbia University. His thesis is that organizations, nations, societies and civilizations will prosper only to the extent that they can encourage common men to perform uncommon deeds. In this way emerges the Uncommon Man.

Mr. Greenwalt gives his ideas on executive training and evaluation; political science; social organization; taxation. His thoughts will be intensely interesting to all those interested in modern society. (C. H. Greenwalt. Toronto, McGraw-Hill, 1959. 142 p., $4.60.)

L'INDUSTRIE ATOMIQUE EN FRANCE ET DANS LE MONDE

The book is divided into three parts—technical data, economic factors and programs of nuclear development in the U.S.S.R., the U.S.A., Great Britain, and France. Within these subdivisions, the author discusses nuclear fission, use of radioactivity, raw materials, national nuclear programs and the international work being done in this field. The history of energy, its potentials and uses are considered in detail. (C. Benoit. Paris, Dunod, 1959. 159 p.)

BASICS OF MISSILE GUIDANCE AND SPACE TECHNIQUES, VOLS. 1 & 2

This two volume "picture book" explains in elementary terms the fundamentals of the important areas of electronics that will contribute to the conquest of space. The books are divided into two broad parts. Volume 1 covers the principles of control and guidance and gives extensive coverage to such topics as radio and radar command links, computer applications and celestial navigation. Volume 2 emphasizes telemetering, space exploration by optics and electronics, satellite theory and practice, satellite monitoring and tracking as well as applications of earth satellites. Anyone with an interest in guided missiles can profit from these books (M. Hobbs. New York, Rider, 1959. 2 Vols., $3.90 each.)

TECHNIQUES OF PLANT MAINTENANCE AND ENGINEERING, 1959.

This comprehensive 10th volume in the series covers the proceedings of the conference held in January 1959. The numerous papers presented apply to all types of industries in general, whereas the round table discussions are concerned specifically with nuclear industry, abrasive products, chemical, electrical manufacturing, and metal working and metal fabricating plants as well as research and development laboratories, foundries, pulp and paper mills, and petroleum refineries. The variety of maintenance topics covered are of particular value to maintenance engineers in small and large plants. (New York, Clapp & Poliak, 1959. 266 p., $10.00.)

(Continued on page 134)

● LIBRARY NOTES

THE MANAGEMENT OF TIME

The author, a Montrealer, believes that the man who is always terribly busy, may be merely inefficient. He shows how time may be managed so that a man of originality, given reasonable conditions, can find time to do his work, and develop his mind also. The author also shows how management can speed up the origination of new ideas, by encouraging the "idea" man, rather than the team.

This volume should be read by all those who feel they could be getting more out of their day. (J. T. McCay. Englewood Cliffs, Prentice-Hall, 1959. 178 p., $3.50.)

NAUTILUS 90 NORTH

These three words announced the completion of the Nautilus's journey under the Arctic ice pack from Pacific to Atlantic. This account is written by her Captain. He relates all the planning which went into the successful voyage, and the previous one when the Nautilus turned back 180 miles from the Pole. He describes the secrecy in which preparations were carried out, and re-creates the atmosphere on the submarine during the historic voyage. This is a gripping story. (W. R. Anderson and C. Blair, Jr. Toronto, Nelson, Foster and Scott, 1959. 251p., $4.75.)

PHOTOGRAMMETRY

Intended primarily as a college text, this volume covers the basic principles of photogrammetry, and their application.

The greater part of the volume is devoted to aerial photography, and the topics covered include: aerial cameras; geometry of the aerial photograph; flight planning; ground control; radial-line plotting and planimetric mapping; stereoscopy and parallax; mosaics; instruments; oblique photography. The last chapter is concerned with terrestrial photogrammetry.

There are many illustrations, and long bibliographies at the end of each chapter. (F. H. Moffitt. Scranton, International Textbook, 1959. 455p., $12.00.)

HEATING AND VENTILATING, REV. ED.

The introduction to the subject, giving a broad general survey of principles and practices. The topics covered include heat losses, fuels, radiators and other heat emission appliances, boilers, heat conveyance, hot water supply, piping systems, ventilation principles and apparatus, and an example of the design of both a heating and a ventilating system. New techniques mentioned include underfloor, baseboard and radiant metal ceiling heating systems, the high pressure system of ventilation, and nuclear energy as a source of heat. This volume has been revised by L. N. Doe, a member of the original author's firm. (Oscar Faber. London, Spon, 1959. 189p., 30/-.)

(Continued on page 136)

• LIBRARY NOTES

(Continued from page 134)

*THE DIESEL ENGINE

Based on the practical experience of the authors, this volume provides a survey of diesel engine operation and design. It begins with a discussion of petroleum and refining methods and of diesel fuel combustion. This is followed by the effect of the forces released by combustion on the moving parts of the engine and on the static or restraining parts of the engines. There is then a treatment of "parasitic engine parts" and a concluding section on economics, including power application. A feature of the volume is the introduction, at appropriate points, of a "basic design problem" which illustrates the theory with which it is associated. (L. V. Armstrong and J. B. Hartman. Toronto, Brett-MacMillan, 1959. 360p. $8.75.

*MATHEMATICS FOR TELECOMMUNICATION ENGINEERS

Written for the practicing engineer and the advanced student, this text covers the various phases of mathematics useful in electronics. It includes such topics as Laplace transformation and probability, complex functions, differentiation, integration, Taylor's series, and trigonometrical functions. Numerous examples help to relate the theoretical and practical aspects of the subject. (S. J. Cotton. Toronto, Ryerson, 1959. 245p. $7.50.)

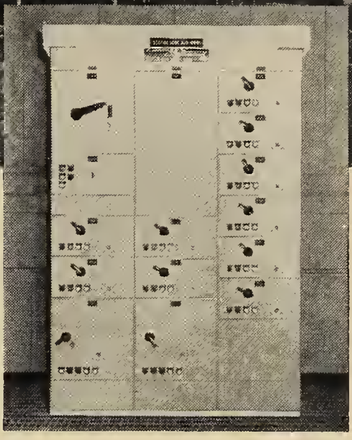
*SAFETY IN PETROLEUM REFINING AND RELATED INDUSTRIES, 2ND. ED.

The five basic causes of accidents are discussed: misoperation or improper practice; equipment failure; repair of equipment while operating; lightning, windstorms, and the other effects of the elements; improper equipment and miscellaneous causes. In addition, information is given on the provision of special equipment for accident prevention and the protection of facilities, as well as special treatment of detonative combustion, control of oil spills, tank explosion and collapse, and brittle fracture and fatigue of metals. Requirements for the safest practical equipment location and spacing are indicated. (George Armistead, Jr. New York, Simmonds, 1959. 484p., $12.50.)

*ELECTRONIC FUNDAMENTALS AND APPLICATIONS, 2ND. ED.

This edition reflects the belief that the transistor and other semiconductor devices have fully proved themselves. Accordingly the fundamental phenomena underlying vacuum tubes and semiconductor devices have been consolidated into a joint treatment and points of parallelism have been emphasized. In addition the introduction of the transistor has been used as an opportunity to correlate electronics and basis network theory, and to emphasize the standard methods once an electronic circuit is reduced to a linear active circuit. Other revisions include new information on single-side-band modula-

(Continued on page 138)



The new Boundary Dam Generating Station at Estevan, Saskatchewan . . . a steam plant designed and engineered for the Saskatchewan Power Corporation by Ewbank and Partners.

by a few talented fingers

To control many of the complex operations at this station all that's needed is a few talented fingers.

More than 90 sections of Motor Control Centres supplied by Canadian Controllers are 24 hour-a-day servants . . . ready to start, maintain or stop operations with the pushing of a button or the turning of a switch.

That's what we mean by "Canadian Controlled".

This is just another instance when the concentrated know-how of Canadian Controllers has been brought to bear on a weighty problem.

This Canadian company has an enviable reputation as designers and manufacturers of control equipment. With sales and service facilities across Canada—and with application experience coast to coast—Canadian Controllers are well prepared to lick *your* control problem.

• LIBRARY NOTES

(Continued from page 136)

tion, diode theory, transistor parameters and circuit analysis, direct-coupled and operational amplifiers, and voltage regulators (J. D. Ryder. New York, Prentice-Hall, 1959. 721p., $13.35.)

*INTRODUCTION TO ELECTRONIC ANALOG COMPUTERS

The basic elements of the analog and digital computer are covered with regard to differences and similarities as well as their applications. The author then reviews differential equations, classifies engineering problems, and indicates how they can be solved by electronic means. This is followed by sections on time and amplitude scaling, simulation of physical systems, problems of stability and sensitivity, generation techniques, and methods of checking analog computer results. The topological aspects of analog computers are stressed through the use of signal flow graphs. (J. N. Warfield. New York, Prentice-Hall, 1959. 175p., $6.00.)

*HOT ORGANIC COATINGS

The constitution, applications, and properties of such hot organic materials as asphalt, coal tar pitch, petroleum waxes, and cellulose derivatives are presented. Specific information on formulations of proprietary products is included. Hot melt applications without solvent such as peel coatings, protective linings, flame spraying and the fluidized bed process are then discussed, and a special chapter is devoted to hot applied coal tar pitch base coatings. Hot spray techniques and their advantages are also covered. (R. B. Seymour. New York, Reinhold, 1959. 233p., $7.50.)

*AUTOMATION AND SOCIETY

Various aspects of automation are reviewed in this collection of papers which examine the present and potential impact of automation on society. Topics presented include the evolution of automation, its application to critical industries in the American economy, the challenges of automation, and the problems it raises in the areas of education, leisure, politics, and business and public administration. The final paper by two Russian authors gives a picture of automation in the Soviet Union. A glossary of automation terms and thirty-seven short case histories are also included. (Ed. H. B. Jacobson and J. S. Roucek. New York, Philosophical, 1959. 553p., $10.00.)

*MATERIALS AND PROCESSES OF ELECTRON DEVICES

A practical manual for the physicist or engineer concerned with designing and building electron devices such as high-vacuum tubes, gas- or vapor-filled rectifiers, thyratrons, X-ray or luminescent tubes, flow or incandescent lamps, Geiger or ionization counters, vacuum photocells, photoconductive cells, diodes, and transistors. Extensive information is provided on the preparation and working of materials used in these devices; the finishing methods for vacuum tubes, particularly degassing, pumping, and getter procedures; and the production of solid state devices. A valuable feature is the approximately 2300 references given. (Max Knoll. Berlin, Springer-Verlag, 1959. 484p., 66 DM.)

*MATHEMATICAL THEORY OF COMPRESSIBLE FLUID FLOW

The book is divided into five parts: introductory materials, general theorems, one-dimensional flow, plane steady potential flow, and integration theory and shocks. The general theory of characteristics with its applications is given detailed treatment as is the theory of shocks as asymtotic phenomena. The latter theory is set within the context of rational mechanics. A thorough presentation of the hodograph method is included. This is volume 3 of Johns Hopkins Applied Physics Laboratory series "Applied Mathematics and Mechanics." (Richard von Mises. New York, Academic Press, 1958. 514p., $15.00.)

*HYPERSONIC FLOW THEORY

Concerned with the problems of determining the details of the flow field about a body placed in a high velocity gas stream. Following a general consideration of the subject, the authors continue with a discussion of the small disturbance theory, the Newtonian theory, constant-density solutions, the theory of thin shock layers, methods for solving blunt-body and locally supersonic flows, viscous flows and interactions, and free molecule and rarefied gas flows. (W. D. Hayes and R. F. Probstein. New York, Academic Press, 1959. 464p., $11.50.)

*HOCHSPANNUNGSTECHNIK

V. 1, pt. 1 Gasentladungen.
V. 1, pt. 2 Hochspannungamessungen; Hochspannungamessungens-Laboratorien.
V. 2, Isolatoren und Isolierungen.

A German translation of a comprehensive Russian work on high-voltage technology. The three books deal respectively with the following aspects:

V. 1, Part 1: Gas discharges — covering ionization phenomena, discharges in vari us electrical fields, channel discharge, duration, break-down voltage, lightning, and corona phenomena.

V. 1, Part 2: High-voltage measurements of all kinds, including surge voltages.

V. 2: Insulators and insulation for high-voltage cables, condensors, transformers, and other electrical equipment, including the pre-testing of insulation. (L. I. Sirotinski. Berlin, VEB Verlag Technik, 1955-1958. V. 1, pt. 1, 298p., 17 DM; v. 1, pt. 2, 259p., 20 DM; v. 2, 384p., 25.80 DM.)

*FLOW MEASUREMENT AND CONTROL

Emphasizes practical measurement and control of flow rather than theoretical

(Continued on page 142)

• LIBRARY NOTES

(Continued from page 138)

concepts. Beginning with a classification of fluid meters and with tables of capacities, a discussion of differential head meters is given which includes the derivation of working formulas and explains the use of Reynolds numbers. The book then continues with primary elements for measuring differential pressures, the installation of pressure difference devices, a detailed consideration of weirs of different cross-sections and of flumes, and a survey of typical instruments used in the measurement of fluid control. It concludes with automatic control, control of continuous processes, and miscellaneous control installations. (W. F. Coxon. Galt, Brett-Macmillan, 1959. 312 p., $11.00.)

*TUNNEL ENGINEERING

A comprehensive survey of tunneling methods and recent developments that have affected tunneling practice. Following a brief history of tunneling, the book covers lining methods with practical examples, shield tunneling, and subaqueous tunneling. It continues with a chapter on rock tunneling which covers shaft sinking problems, drilling, blasting, rock falls, and shattering. Concluding sections deal with tunneling through difficult ground, and such problems associated with long tunnels as temperature control. (Rolt Hammond. Galt, Brett-Macmillan, 1959. 332p., $11.00.)

*THE THEORY OF THIN SHELLS

This translation from the Russian presents an analysis of stresses and deformation in shells, treated as a linear problem with displacements assumed to be small in comparison with the thickness of the shell and strains not to exceed the limit of proportionality. The four chapters treat the general theory of thin shells, the membrane theory, analysis of cylindrical shells, and shells of revolution, giving a unified point of view based on a wide utilization of complex transformations. (V. V. Novoshilov. Groningen, The Netherlands, P. Noordhoff, 1959. 376p., $9.50.)

*THE TECHNOLOGY OF PRINTED CIRCUITS

Beginning with an account of the invention and development of printed circuits techniques, the author provides a detailed explanation of printed circuit production which includes such aspects as a typical production line, suitable printing methods, plating and foil techniques, protective coatings, flow and dip soldering, and potting. In addition details are provided for the design of printed circuits, the insertion of conventional components into the printed circuit, and the detection and tracing of faults. Recent developments examined encompass automatic assembly, miniaturization, printed components, and microwave printed circuits. (Paul Ersler. New York, Academic, 1959. 405p., $12.00.)

*HYDRAULISCHE PRESSEN, VOLUME III

This third volume of a German treatise on hydraulic presses and installations deals with extrusion presses for the manufacture of metal tubes and cables. It reviews the design, working elements, and operation of such presses, as well as the recent processes based on modern practice. There are special chapters on presses for the production of lead tubes and cables, presses for the production of lead and aluminum cable sheath, and on practical construction details. (Ernst Muller. Berlin, Springer-Verlag, 1959. 265p., 43.50 DM.)

*HYDROLOGY, 2ND. ED.

This volume covers stream flow, its fluctuations and their causes, and includes the presentation of a method using the unit hydrograph principle for determing the magnitude of floods that may be expected to occur with specified rare frequencies on any given stream. In this second edition two new chapters on the hydrology of semi-arid basins and the effect of snow on the hydrology of an area have been added. Runoff, precipitation, soil moisture, water losses, ground water, floods, and stream flow records are dealt with; and field problems concerning methods of flood reduction, the evaluation of potential water power on a river, water conservation practice and determination of spillway and bridge discharge capacities are also presented. (C. O. Wisler and E. F. Brator. New York, Wiley, 1959. 408p., $9.25.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Aeronautical engineering

Approximate method for determining the potential flow about an arbitrary aerofoil section in a two-dimensional finite stream with particular reference to large stream deflections, by D. G. Gould. Ottawa, National Aeronautical Establishment, 1959. (Laboratory Report 260).

An experimental study of rotating stall in a two-stage axial compressor, by R. F. Meyer. Ottawa, National Aeronautical Establishment, 1959. (Laboratory Report 259.)

Bridges. Design

Design of highway bridges in prestressed concrete. Chicago, Portland Cement Association, 1959.

A record of history and evolution of early American bridges, by L. N. Edwards. Orono, Maine, University Press, 1959. $5.00.

Canada

Ceramic plants in Canada. Ottawa, Dept. of Mines and Technical Surveys, Mineral Resources Division, 1959. 25c.

Selected bibliography of Canadian geography with imprint 1957. Ottawa, Dept. of Mines and Technical Surveys, Geographical Branch, 1959. (Bibliographical series no. 23). 50c.

Staffing the universities and colleges of Canada; a study by the Research and Information Service of the Canadian Universities Foundation, dir. by E. F. Sheffield. Ottawa, Canadian Universities Foundation, 1959.

Working and living conditions in Canada. 8th ed. Ottawa, Dept. of Labour, 1959. 25c.

Coal. Combustion

Combustion of eastern Canadian coal in thin fires on a spreader-fired air-cooled oscillating grate, by E. R. Mitchell and others. Ottawa, Dept. of Mines and Technical Surveys, Mines Branch, 1959. (Technical bulletin 1.) 25c.

Computers

The solution of an eigenvalue problem (rate of evaporation and decomposition of a droplet of an ozone-oxygen mixture) by means of analogue and digital computers, by R. Sandri. Ottawa, N.R.C., 1959. (Mechanical engineering report 15.)

Concrete construction. Prestressing

Ultimate flexural strength of bonded prestressed concrete. Chicago, Portland Cement Association, 1959.

Electrical engineering

Electrical Research Association reports:— CL/T1: Summary of proceedings at international symposium on electricity in the tropics: 1. Climatic conditions and equipment, by M. E. Thompson. 30s.0d. F/T 194: Heating of cables: transient temperature rise due to a line source in a semi-infinite medium with a radiation boundary condition, by H. Goldenberg. 7s.6d. G/XT 161: Circuit interruption in vacuum, by M. P. Reece. 7s.6d. L/T 388: The I.E.C. tracking test; design of an automatic tracking comparator, by N. Parkman. 7s.6d. L/T 357: The impulse breakdown of uniform-field gaps in air; interim report, by R. Galloway. 12s.6d. O/T 17A: The prevention of internal decay in creosoted Baltic redwood poles. 6s.0d.

O/T 20: The protection of 11 kV and 33 kV bushings from damage by arcs in still air and in a wind, by A. E. Guile and S. F. Mehta. 12s.0d.

age 25/30 having a minimum of three years industrial experience in work measurement and related areas of industrial engineering. Attractive compensation range. Applications should provide full particulars and will be held in strict confidence. File No. 6915-V.

SALES ENGINEER — Excellent opportunity for aggressive graduate Mechanical or Chemical engineer, 25-35 years of age who is interested in selling engineered equipment to Pulp & Paper Industry. Some experience in Pulp & Paper Industry desirable. Reply in confidence to File No. 6921-V.

SALES ENGINEERS, two recent graduates, Mechanical or Electrical required by progressive manufacturer of ventilating, air conditioning and related engineered products. Some experience preferred, but not essential. Following completion of company training course successful candidates will be assigned to Hamilton and Montreal Branch Sales Offices. Wide range of employee benefits and attractive starting salary. Send complete resume and salary requirements. File No. 6923-V.

PUBLIC HEALTH ENGINEER for administrative work in engineering problems associated with non-municipal water supplies and sewage disposal, mild and other food processing plants, swimming pools, new subdivision proposals and general sanitation. Liaison with local health agencies and municipalities with some travelling involved. Engineering graduate with not less than 3 years post-graduate experience in municipal or related public health work. Send summary of education, qualifications and experience to Director, Environmental Sanitation Division, Ontario Department of Health, Room 519, Annex, 67 College Street, Toronto 2, Ontario. File No. 6927-V.

MECHANICAL OR AERONAUTICAL ENGINEERS are required for employment with major airline at Winnipeg. Must be graduates with extensive experience in aircraft structures and power-plant engineering. Full complement of employee benefits and opportunity for advancement. Replies must include details of personal history, professional training and experience. File No. 6933-V.

Business and Industrial Briefs

Year-Round Service as a supply, buoy, search and rescue vessel is ahead of the C.G.S. "Tupper", recently launched at Marine Industries Limited, Sorel, P.Q. Fairbanks-Morse and Canadian Westinghouse supplied propulsion machinery for the ship, commissioned by the Department of Transport for duties in Maritime and Gulf of St. Lawrence waters.

Wrinkling, Shrinkage and moisture transmission are resisted by KST "Cellophane" cellulose film, which Du Pont of Canada produces at its Shawinigan plant. Originally developed as a direct-wrap material, KST has now come through tests that prove it equally useful in the carton overwrap field.

Walworth Industrial Valves will be manufactured and sold in Canada by Canada Iron Foundries Limited, Montreal, under an exclusive licensing arrangement with The Walworth Company, New York. Bronze, iron, steel, plastic and lubricated plug valves are included in the Walworth line.

More Power For Less Air, through a patented valve system — an attractive feature of Atlas Copco's E 20 paving breaker — is true also of the E 40, a new heavy-duty breaker which the company says has a higher output than any other of its size on the market. The new model also offers the advantages of low recoil, simpler lubrication and easier dismantling.

Insulating Group Piping and straight runs of large pipes from 0°F. to 1200°F. is a job for which Spunrock pipe insulation is especially suited. Spun Rock Wools Limited of Thorold, Ont. produce this material, which is recommended for stainless steel piping as it is chemically inert. Spunrock has an extremely low heat transfer coefficient, is resilient, and does not crumble or dissolve in water. It can be shipped flat, saving space in warehouse and truck.

Stiff Competition from the U.S.A., Germany and Japan was overcome by L'Air Liquide, manufacturing affiliate of Canadian Liquid Air Company, Montreal, to secure a $1,600,000 contract from the Yugoslav Government for a low temperature gas separation plant. The Development Loan Fund in Washington is financing the project, and the plant will be shipped sometime this year. It will produce in twelve months 100,000 tons of oxygen and 120,000 tons of ammonia synthesis gas, with a quantity of the rare gas argon as a by-product.

Brighter and More Uniform illumination is given to any plastic facing or cap colour used in front of a neon glow lamp with a round end produced by Canadian General Electric's Lamp Department. The radically different design allows placing of the electrodes closer to the end of the lamp, which helps also when wide-angle viewing of the bare lamp, indicator unit, or panel is necessary.

Only Three Sizes of rotating parts are required for the complete new line of "Canadian Buffalo" Paper Stock Pumps announced by Canada Pumps Ltd. of Kitchener. The new line offers considerable savings in maintenance time, spare parts inventory, and replacement costs.

The Biggest Blast ever fired in Venezuela detonated 88 tons of CIL "Nitrone" at the Caroni River Hydro-Electric Project recently.

Air Conditioning Boomed last year, and despite record shipments every month since June, the Trane Company of Canada still has the largest backlog of orders in its 35-year history. A plant extension will add 55,900 square feet to factory and office space by May.

Picket-Size Hook-On volt ammeters for testing a-c voltages have been introduced by General Electric.

Error Correction For Radio Teletype communications has been explained to Department of Transport personnel in the first formal course conducted by Siemens and Halske, manufacturers of equipment which recognizes errors as they occur and refuse to print them.

Dofasco's Pig Iron Capacity will increase approximately 50% with the opening of a new blast furnace expected late this year. The company will also extend bay front facilities at its Hamilton headquarters, and plans to spend some $20 million on improvements in 1960.

Unnecessary Steps and lost time prompted Canadian Westinghouse to introduce a continuous chain dragline system which travels throughout the warehouse at York Mills, the company's Ontario distribution centre. Moving under the floor, the system pulls four-wheel carts which can be unhooked from the dragline and moved into the stock areas for loading or unloading. A warehouseman, who under most systems must make at least some regular journeys without a load, will work strictly in his assigned area. Each of several such areas is serviced with stock and orders by the underfloor conveyor system.

India's Steel Output is being increased from 1.3 million tons in 1955-56 to six million tons in 1960-61. On December 29 last the new steelworks at Durgapur was opened. This plant is an undertaking of 13 United Kingdom firms, a consortium formed especially for this project and called the Indian Steelworks Construction Company Ltd. (ISCON). Completion is expected by August, 1961, and initial annual output will be based on the production of one million tons of ingots.

Hearing Loss is measured by the M-S-A Noise Integrator, recently introduced by Mine Safety Appliances Company of Canada Limited. By integrating signals collected during five-second cycles, the instrument provides data from which it is possible to predict the degree of hearing loss that would normally result from a five-year exposure to a particular noise level.

Canadian Manufacture of Ellicott dredges and dredging machinery is the object of an association between Timberland Machines Limited, of Woodstock, Ont. and the Ellicott Machine Corporation of Baltimore. A new company, known as Timberland-Ellicott Limited, will manufacture not only for the Canadian market but for the sterling area and other established overseas markets for Canadian products.

(Continued on page 152)

• BRIEFS

(Continued from page 150)

Film For Fighting forest fires is a new technique permitted by the development of a durable polyethylene film in the laboratories of Union Carbide Canada Limited. Small artificial ponds are provided in forested areas through the use of 8 mil. black polyethylene liners fabricated by Northwest Polyrama Limited of Edmonton. The film eliminates loss of water that would normally seep through the soil.

Takeover by Orenda Industrial Limited of the Canadian sales and servicing of Standard-Triumph products is announced in a joint statement. Orenda Industrial will market, service and provide engineering support for the complete range of Standard-Triumph's diesel, gasoline and natural gas engines covering the agricultural, marine and general industrial fields.

No Moving Parts and no radio tubes are to be found in power controllers of a new type offered by Polytronics Company, 582 Bathurst St., Toronto. The power controllers can be used for such purposes as dimming lights, controlling temperature, and various chemical processes, and are manufactured in Canada.

Canadian Curtiss-Wright Limited has developed a new electric furnace for homes. Operating directly from standard wiring for 100-ampere service, the Thermapac Series B furnace is attached to ceiling joists and forms part of the heating ductwork in a hot-air heated home.

B. F. Goodrich have compiled a hose chart to assist users of rubber hose in a wide variety of specialized fields. This guide describes hundreds of uses for precision engineered industrial hoses.

Premium Iron Ores Limited intends to build a steel plant in the Fort William-Port Arthur area, at a cost of $10,000,000. It will use the HyL process engineered by Canadian Kellogg Company.

Canadian General Electric Company Limited have available an illustrated eight-page bulletin entitled "G-E Silicone Antifoams". Write to Chemical Materials Section, Canadian General Electric Company Limited, 940 Lansdowne Avenue, Toronto 4 for Bulletin CDS-204.

Canadian Kodak Company Limited provides a new set of high-speed autopositive papers to meet the printing industry's need for a quick, easy way to obtain proofs of paste-ups.

Furlong Plastics Company's Toronto plant is turning out in quantity such parts as swivel corners for tilting storm windows, window latches, rubbing blocks for windows, and wheel-and-frame assemblies for patio-type sliding doors. Small runs of nylon parts are produced economically using "Zytel" nylon resin manufactured by Du Pont of Canada at Kingston, Ont.

Canadian Westinghouse Company Limited are doing research in their new nuclear-metallurgical laboratory that could reduce the capital cost of nuclear power reactors. Investigations into the properties of beryllium under stress at high temperatures have been undertaken for Atomic Energy of Canada Ltd.

The McBee Company Limited has released a six-page brochure describing a new complete highway design program now available for the McBee LGP-30 electronic computer. Copies may be obtained by writing for S-519 to The McBee Company Limited, 179 Bartley Drive, Toronto 16.

B. F. Goodrich, chemical Division has developed a unique polyurethane material with resistance to abrasion wear. The product 'Estane' will have tremendous market potential in the automotive, electrical, footwear, textile and other industries, it is claimed.

(Continued on page 154)

• BRIEFS

(Continued from page 152)

Goodyear Tire and Rubber Company of Canada Limited have a Belt Splice and Repair Manual available. In addition to this authorative guide to belt maintenance the Company offers to train men and to rent vulcanizers.

American Air Filter of Canada Limited, 400 Stinson Blvd., Montreal, have available upon request a 28-page manual of Exhaust Hood Designs for the Foundry Industry.

Canadian SKF Company Limited sent its vice-president, Engineering, to attend as Canadian delegate, the International Organization for Standardization in Berlin recently.

Dresser Manufacturing Division are shipping what they claim are the largest solid ring pipe couplings ever built — 16 feet in diameter — by a devious route to avoid tunnels, low overpasses and bridges on special flat cars. Each of is designed for operating pressures exceeding 288 psi.

Time Sharing is the secret of the Orion data-processing system announced in Britain by Ferranti (Ferranti Packard Electric Ltd., Industry St., Mt. Dennis, Toronto 15). The keyboards can be operated continuously, even though the computer itself is doing other data-processing work.

Preparing Purchase Orders by copying the original requisition directly onto Verifax Copy Paper preprinted with the purchase order heading is one of the procedures described in a four page leaflet on the versatile Canadian Kodak Verifax system.

The World's Largest blender has been introduced by The Patterson-Kelley Co., Inc., using its patented Twin Shell design. Two cylinders cut at right angles and joined to form a V-shaped design can uniformly blend at one time enough plastic powder to fill two railroad hopper cars.

When Hulls Were Deformed but not ruptured by nearby explosions of mines and torpedoes, and tough alloys were sometimes found shaped around softer metals, U.S. naval scientists thought the information well worth publishing. Commercial application of this phenomenon is the objective of experimental studies at the new CIL explosives research laboratory, McMasterville, Que. Although some metal forming is accomplished in a gaseous medium, the bulk of the work is done with the dies, blank and explosive charge submerged in water, which transmits the shock pressure more effectively. The versatile new technique for metal working employs two methods. In free forming, the parts are formed with open-ended dies. Closed die forming requires a machined die sealed off from the water and evacuated. Explosives have already been employed in the manufacture of fuel tanks, booster cases for rockets and sound suppressor tubes for jet engines.

THE THOMPSON MINE of International Nickel, which starts operations this year and will come into full scale production in 1961, will be the largest nickel producing operation in the world next to Sudbury. The Manitoba project is being financed entirely from Company funds, and INCO's capital investment will approximate $115,000,000.

SUPER SEAL MOTORS are particularly emphasized in the appointment of Canmark Services Limited as national distributor of electric motors and control for Canadian Allis-Chalmers. Formed last year by twelve companies as associate members, Canmark provides nationwide engineering sales and services, warehousing, installation and service, and now consists of an affiliation of more than twenty separate distributing companies.

NARROW AISLE HANDLING is facilitated by use of the Raymond Corporation's new heavy duty electric truck. Development of a single wheel drive with offset caster enables the Company to sell the new model at a lower price while retaining most of the features of the original dual drive unit.

GROUT FAILURE is chiefly caused by shrinkage. The Master Builders Company, Ltd., Toronto 15, has produced a 16 page booklet which explains how to avoid this shrinkage with Embeco non-shrink grout and illustrates varied applications of cold and hot weather grouting.

THE WIRE TIRE, commercially available since 1957, was one of many developments surveyed in a paper presented to the American Society of Mechanical Engineers by Leora E. Straka, research librarian for Goodyear. The new tire contains no rubber and no fabric, and needs no inflation. In addition to its advantages for directional and braking control, it can withstand temperatures from 1000°F. to 2000°F. that might be encountered by a space craft re-entering the earth's atmosphere.

MECHANICAL PROPERTIES OF SILICONE FLUIDS are of interest to engineers designing equipment for use in high temperatures and other extreme conditions. Bakelite Company, division of Union Carbide Canada Limited, 40 St. Clair Avenue East, Toronto 7, has assembled a handy design file with charts, that can be obtained by design engineers and others. Some of the graphs are on 17" by 11" sheets, so that the designer can work right on them.

THE SPRING DESIGN permits the small envelope and light weight of a high pressure reducer for air or nitrogen which weighs only 8 ounces. Gas at 3,000 psi can be reduced to 300 psi, or to any pressure between 300 and 1800 psi by selecting the proper spring for the assembly. Excellent control of the downstream pressure is assured by the balanced design of this reducer, manufactured by Walter Kidde & Company, Inc., Aviation Division, Belleville 9, N.J.

SINGLE-LEVER REMOTE CONTROL for outboard motor boats has been made possible through the use of moulded nylon parts. The unit, known as the "Whitney Automatic" outboard control, is intended to replace customary two-lever controls, and its inventor C. W. Buddo, president of Lake Controls Limited, Toronto, has also adapted it to a steering wheel control for outboards. The nylon moulding operation is done by Midland Plastics, Midland, Ont.

EVERY FOUR YEARS the Machine Tool Trades Association of the United Kingdom organizes in London's Olympia exhibition halls the International Machine Tool Exhibition. At Olympia from 25th June to 8th July 1960 it will be possible to see under a single roof, machine tools from practically every country in the world.

EASY DISPERSION and a smoother texture with no loss of brightness are characteristics imparted to aluminum paints by an unusually versatile new leafing pigment designated as Alpaste 101. Samples of the new pigment can be obtained from the Chemicals Division, Aluminum Company of Canada, Ltd., 1700 Sun Life Building, Montreal.

ELECTRO-PRECIPITATION both for preventing atmosphere pollution and for recovering valuable materials is one of the many activities of Simon-Carves, the British engineering group which had its beginnings some eighty years ago and has opened offices in Toronto. Simon-Carves also have over fifty years' experience in mine engineering, covering the design, supply and construction of large installations from reception of mined material at pit bottom to despatch of cleaned products from rail sidings.

AN ALKALI-CHLORINE plant that will cost $2,600,000 is being built by Cominco at Trail, B.C. This venture in heavy chemical manufacture stems from a sales agreement with Celgar, Limited. Cominco will supply the liquid chlorine and caustic soda required for Celgar's $50,000,000 kraft pulp mill, and will also produce potassium hydroxide for its own processes at Trail.

A GAS TURBINE is now at work in the Canadian petrochemical industry. Ruston and Hornsby supplied the turbine which has recently been installed at the Edmonton polythene plant of Canadian Industries Ltd. It is coupled to a package Carrier freon unit as part of a low temperature ethane recovery plant.

• DISCUSSION

(Continued from page 79)

stance, has experienced bitter industrial warfare as long as its management (mostly engineers) has not understood the fundamental difference there is between a punch press and the operator behind it.

Engineers of the present generation know better. Those especially who have shouldered administrative responsibilities know that non-technical knowledge integrated with technological know-how is as important as technical knowledge itself.

The important thing is the integration of the two. I contend that no other institution in our society is better qualified than engineering schools for the *simultaneous process* of transmitting non-technical information and integrating it with the body of traditional engineering education.

Imparting knowledge is an important aspect of professional education, but it is not the only one.

b) Intellectual powers. Engineering curricula are designed to develop to a high degree analytical abilities and, to a lesser extent, to improve synthetical and creative powers.

These abilities are the lifeblood of engineering practice; they are also most valuable in management. Yet, the engineer must be conscious that the mode of application of analysis, synthesis, creation, is radically different whether he deals with things or with men or with both.

c) Attitudes. They are called self-confidence, openness to experience, willingness to take risk, desire to understand the other fellow's point of view, etc., etc., etc.

The development of attitudes has long been an "unconscious" objective of higher education. However, as of this day, attitudes have not yet been clearly defined nor identified. This reflects the lag of the science of man behind technology.

But what about their importance? Educators generally agree that proper attitudes are as important as knowledge for an effective personal life and professional career. Our colleges of applied science have been successful in helping their students develop some of the right attitudes for engineering practice. This is good, but not enough. Under the present circumstances, engineering schools have the further responsibility of creating for their people opportunities to develop the attitudes expected in high-grade private and public administrators.

Responsibility to engineering as a profession

Ministry to the people: this, I believe, is the idea of a profession. Historically, engineers have done a grand job in harnessing the forces of nature in the service of mankind. The prestige of the profession has grown accordingly.

Today, engineers continue to serve their fellow men in this way, but one half of the profession is called on to give society what it is badly in want of — leadership.

Engineering schools have always aimed to supply the profession with men of the right ability, character and motives. In the second half of the twentieth century, the engineering profession is expected to deliver both: outstanding technical performance and leadership of the highest possible order. The profession, I believe, really has nowhere else to go but to its professional schools for help in these most demanding tasks.

Our institutes of technology have made clear they will do all they can to enable their people to cope with higher and higher standards of technical performance. On the other hand, I am at a loss to understand why educators of the standing of Prof. Carpendale and of Prof. Hughes are hostile to the idea of leadership studies within engineering school, which after all, are as important to the profession as technological instruction. Here is a responsibility to the engineering profession our colleges of technology can hardly evade — nor can they "pass the buck" to anybody else.

Responsibility to society as a whole

By giving young men the right education and training for a fuller personal and more effective professional life, by supplying the profession with people who spend their career in the service of their fellow men, engineering schools perform a most valuable function in society.

The other major social responsibility of professional schools is to broaden and deepen knowledge. Over the years ahead the pursuit of knowledge in technical fields will grow in importance. More important still will be the adaptation of technology to what Carrel called "la nature profonde de l'homme". This blending of the science of things with the science of man will require hard thinking, and hard thinking is the purpose of graduate and post-graduate studies.

As I wrote earlier, the demand on the engineer today is for *applied technical science — engineering — and for applied human science — administration —*. How well will the engineer measure up to this challenge? The reply, for a large part, lies in what engineering schools will do (or not do) in the next few years.

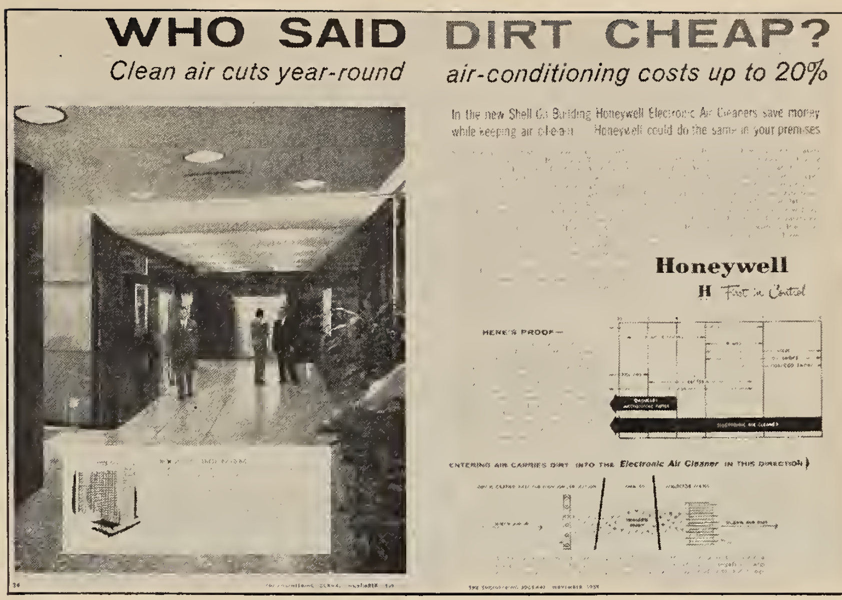
By creating opportunities for engineers to graduate and post-graduate studies in administration, our institutes of technology would serve the engineer, the profession and society. They would do a much-needed task, a task nobody else could perform effectively.

Honeywell Controls Limited are the winners of the E.I.C. Certificate of Advertising Merit for the "best" advertisement in the November 1959 issue.

This is the second time in 12 months that this organization has won a certificate. The advertisement which is headed: "WHO SAID DIRT CHEAP?" appears on pages 14 and 15 of the issue. It explains how Honeywell Electronic Air Cleaners save money, while keeping the air clean, in the new Shell Building in Toronto, Ontario.

The left hand page of the advertisement consists of a large illustration and inset is a brief description of the building and the air-conditioning equipment and gives further details on the new $6,000,000 Shell Building. The copy on the right hand page explains the operation and offers a brief description of the Honeywell Electronic Air Cleaners installed in the building.

Fifty readers of *The Engineering Journal* were asked to evaluate the advertisements in the November issue from the viewpoints of ACCURACY—INFORMATION and ATTRACTION. Certificates, certifying as to the decision of the fifty man jury will be awarded to Mr. K. K. Warne, Merchandising Manager of Honeywell Controls Limited and to Mr. A. D. Black of Cockfield, Brown & Co. Ltd., Toronto, the advertiser's advertising agents.



E.I.C. CERTIFICATE OF ADVERTISING MERIT

WINNING ADVERTISEMENT

The two page black and white advertisement reproduced above was judged the "best" from the viewpoints of ACCURACY—INFORMATION and ATTRACTION by fifty readers of *The Engineering Journal.* Each month the Institute asks fifty readers to evaluate the advertisements in the various issues from these three viewpoints. This is the second time the company has won the award during a 12 month period.

Plan now to attend

THE KINGSTON REGIONAL TECHNICAL CONFERENCE

Time: May 7, 1960

Place: Kingston, Ontario

Topic: Various aspects of automation and control of interest to Civil, Mechanical, Chemical, Electrical and Military Engineers.

Papers: Six papers will be given (two at a time).

General: A dinner will be held in the evening. A separate program is being arranged for the ladies.

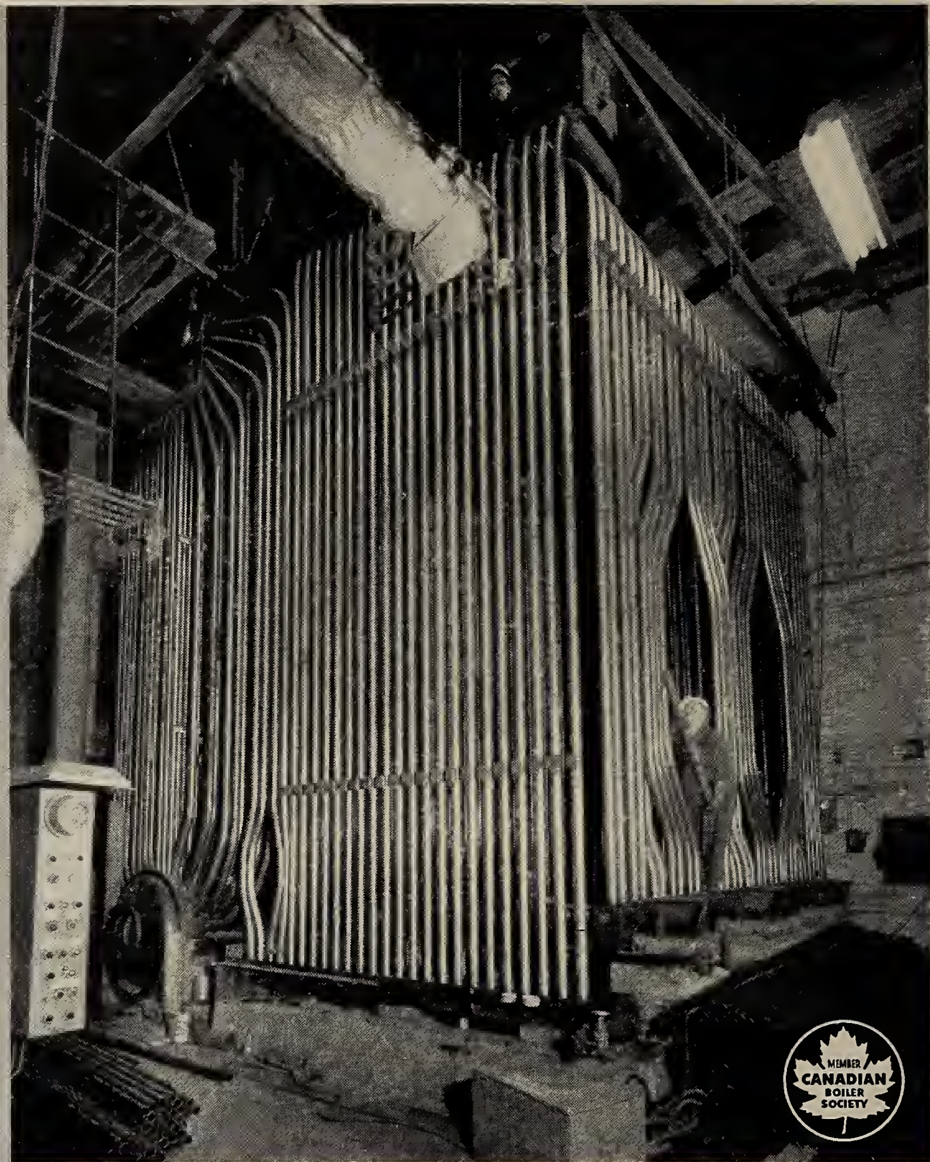
McGILL UNIVERSITY INSTALLS A THIRD DB BOILER



For the past 15 years, two Dominion Bridge steam generators, each having a capacity of 35,000 pph. have supplied most of the steam requirements at McGill University, Montreal. New buildings have been added requiring additional steam capacity and another Dominion Bridge steam generator is being installed to fill this need.

The "D" type boiler, shown here during construction, is designed for an output of 100,000 pph. and a pressure of 250 psig. The steam atomizing burners use No. 6 fuel oil and provision has been made for conversion to gas. Induced draft fan and high stack are unnecessary as the unit is designed for pressurized firing. Heat recovery equipment, in the form of a tubular air preheater is not shown in the picture.

MEET THE AUTHORS

B. E. Ohlson, B.Sc. '26 (Stockholm), Vice-President, Electrolux (Canada) Limited, Montreal, *(Industrial Design in Canada).*

After a brief period with the Bell Telephone Laboratories, Mr. Ohlson joined the development and sales engineering staff at The Tinius Olsen Testing Machine Company and specialized in dynamic balancing machines. He was appointed to his present position with Electrolux in 1936. He is a member of the Canadian Standards Association, the Canadian Manufacturers Association and over the past years has participated in the National Conventions of the American Society of Tool Engineers. Mr. Ohlson is also the holder of a number of patents.

R. D. Page, M.E.I.C., D.L.C., A.F.R.Ac.S., Nuclear Fuel Engineer, Fuel Development Branch, Atomic Energy of Canada Ltd., Chalk River. *(The Test Rigs and Facilities at Orenda Engines Limited, Nobel Test Establishment).*

After graduation Mr. Page joined the Bristol Aircraft Company, Engine Division in Gloucester, England. He came to Canada in 1954 as an aerodynamics test engineer at Orenda Engines' Nobel Test Establishment.

T. A. J. Leach, M.E.I.C., B.Sc. '38 (Sask.), Chief, Hydraulic Investigation Division, Water Rights Branch, B.C. Department of Lands and Forests *(Engineering Studies of the Fraser River Basin).*

Following an initial appointment with the Prairie Farm Rehabilitation Authority, Mr. Leach served overseas with the R.C.E. and later joined the Saskatchewan Department of Highways as a Resident Engineer. He has been with the B.C. Water Rights Branch for the past 12 years.

Robert A. Campbell, M.E.I.C., B.A. (Loyola), B.Eng. (McGill), Manager, Development Division, Transportation of Aluminum Company of Canada Limited, and Director of The Roberval and Saguenay Railway *(Aluminum in Rolling Stock; Hopper Cars on the Roberval and Saguenay Railway).*

Mr. Campbell has had wide experience across Canada in the Alcan Sales Department. He is a member of the American Society of Mechanical Engineers, the Corporation of Professional Engineers of Quebec, and of several transportation groups. Mr. Campbell has presented papers to the Nova Scotia Mining Society, the ASME (Railroad Division), and the Newfoundland Branch of the Canadian Institute of Mining and Metallurgy.

W. F. Campbell, M.E.I.C., Manager, The Roberval and Saguenay Railway Company, Arvida, Quebec *(Aluminum in Rolling Stock; Hopper Cars on the Roberval and Saguenay Railway.)*

Mr. Campbell's engineering career has included association with the Reid Newfoundland Company; the International Paper Company; the consulting firm of Lee & Nash, Brantford, Ont.; and the Aluminum Company of Canada. He is a member of the American Concrete Institute, the American Railway Engineering Association, and the Association of Professional Engineers of Ontario.

D. G. Breckon, B.A.Sc. (Tor.), Superintendent, NRX Reactor Branch, Engineering and Operations Division, Atomic Energy of Canada Ltd., Chalk River *(Nuclear Research Reactor Operations).*

Mr. Breckon has been directly associated with the operation of the nuclear research reactor, NRX, at the Chalk River Project since he graduated in 1946.

G. W. Govier, M.E.I.C., B.A.Sc. (UBC), M.Sc. (Alta.), Sc.D. (Michigan), Dean of Faculty of Engineering, University of Alberta *(Interpretation of Rheological Data for Engineering Use).*

Dr. Govier has been on the staff of the University of Alberta since 1940. Prior to his present post he was the Head of the Department of Chemical and Petroleum Engineering. He is the author of some 25 technical and scientific papers on problems related to the natural gas industry. Deputy Chairman of the Alberta Oil and Gas Conservation Board, Dr. Govier is also a member of the Chemical Institute of Canada, the Canadian Institute of Mining and Metallurgy, the American Institute of Chemical Engineers, and a past president of the Association of Professional Engineers of Alberta.

R. L. Raikes, M.E.I.C., (London University '32) Director, Lewis, Lane and Company Ltd., Consulting Civil Engineers, Sudbury, Ont. *(A Note on Rainfall Data Analysis in Ceylon).*

Mr. Raikes worked in the U.K. prior to 1951. For the next seven years he was concerned entirely with water resources development in Africa and Asia for the government of the Sudan and for the Food and Agriculture Organization of the U.N. He joined Hunting Technical and Exploration Services Ltd. as water resources engineer in 1957 and later became a Water Resources Consultant in Toronto. He is a member of the Institution of Civil Engineers and the Association of Professional Engineers of Ontario.

R. L. Walker, M.E.I.C., B.A.Sc. '50 (UBC), Chief Water Resources Engineer, Hunting Survey Corporation Limited, Toronto, *(A Note on Rainfall Data Analysis in Ceylon).*

Mr. Walker was assistant engineer, Drainage and Irrigation Department of Malaya before joining the Fraser River Board in 1953. He was later in Ceylon on a Columbo Plan project as water Resources Engineer and Field Survey Chief, Photographic Survey Corporation Limited.

C. H. R. Campling, M.E.I.C., B.Sc. '44 (Queen's), S.M. '48 (M.I.T.), Associate Professor, Department of Engineering, Queen's University *(Accreditation for Canadian Engineering Curricula?).*

Following his degree from M.I.T. Professor Campling engaged in research at the National Research Council and subsequently taught at the Royal Military College until he joined Queen's in 1955. He is a past president and councillor of the Kingston Branch of the E.I.C., a member of the Association of Professional Engineers of Ontario, the Institute of Radio Engineers and the American Institute of Electrical Engineers.

R. A. Frigon, M.E.I.C., B.A.Sc. '40 (Ecole Poly.), M.Sc. '41 (M.I.T.), Chief, Engineering and Equipment Division, Foreign Trade Service, Department of Trade and Commerce, Ottawa *(Engineering for Export).*

Mr. Frigon has been Scientific Attaché at the Canadian Embassy in Washington, D.C.; on the staff of the United Nations Technical Assistance Administration in New York; with the National Research Council, and with the Harbours and Rivers Branch of the Department of Public Works.

COVER PICTURE

Leonardo Da Vinci possessed what was possibly the greatest diversification of talents of any man in history. Besides being an artist, he was also an engineer and inventor. Reproduced here are original Da Vinci sketches for a winch with ratchet control.

DIVERSIFICATION

Diversity, together with versatility and ingenuity, are among Canadian Vickers' most valued assets . . . and in building fine mining equipment, like the massive jaw crusher illustrated below, Canadian Vickers again displays the range and diversification of its engineering skills.

Equipment and machines, large and small, for every imaginable industrial need, are designed and manufactured in Canadian Vickers' shops, thus fulfilling their pledge: "If Industry Needs It . . . Canadian Vickers Builds It . . . Better."

Hydraulic Machinery • Industrial Boilers • Chemical Process Equipment • Special Machinery Equipment • Ships • Pulp and Paper Equipment • Mining Equipment • Marine Equipment

INDUSTRIAL DESIGN IN CANADA

B. Erik Ohlson

Vice-President, Electrolux (Canada) Limited, Montreal.

An address delivered before a joint meeting of the Montreal Branch of the Engineering Institute of Canada, and Montreal Chapter of the American Society of Tool Engineers on January 20th, 1959.

AT THE OUTSET, it might be useful to analyse the title of this paper and its true meaning. It would therefore not be surprising to find that either the term **Industrial Design** is not clearly defined or else it is given different interpretations even by those who are directly active as Industrial Designers. In the layman's mind, the Industrial Designer is one who is primarily interested in creating or planning the external shape and form of an object, without giving much thought to the design of its functional part. This meaning of Industrial Design seems to agree with the definitions applied by the Ilsley Royal Commission on Patents, Copyrights and Industrial Designs. The report of this Royal Commission recommends that patents for industrial design should only be granted for new and in themselves useless shapes, or for patterns applied to industrial objects. If an original-appearing design or pattern should happen to combine with some useful function, it would be disqualified from design patent protection under the proposed new act. An almost opposite definition appears in a recent issue of a trade journal 'Product Design and Materials' October 1958 issue, in which the following appears: "Industrial Design concerns itself primarily with the design of products for large quantity manufacturing and is involved with the functional problems as they relate to performance, the materials, manufacturing processes and merchandising techniques." The professional industrial designers of Ontario have a more comprehensive definition. In their charter, the statement of Aims reads as follows:— "The term **Industrial Designer** is defined to include professional practitioners of industrial design engaged in designing, with regard to consumer acceptance, convenience, fitness to purpose, appearance and safety, diversity of product for machine and mass production, and in applying similar design thinking to the relation of appearance, function, and structure in packages, and other physical manifestations of business enterprise." It seems reasonable to conclude that Industrial Design relates primarily to pleasing form or appearance, external arrangement of functionl parts, ease of use, colour, etc., and that Industrial Design must go hand in hand with Engineering Design which is mostly concerned with the design and arrangement of the functional parts with particular consideration to service, life, quality, selection of materials and ease of manufacture and method of manufacture. A member of a large industrial design consulting association in Toronto described these functions very well. He said: "The Industrial Designer works from the outside-in, whereas the Engineering Designer works from the inside — out". The combination of Industrial Design and Engineering Design could possibly be termed Product Design-Engineering.

The profession of the Industrial Designer gained prominence in the United States in the early 1930s. Some of the more successful designers became very well known, and the association of their name with a product had a great influence on the merchandising success, much as the signature of a famous artist creates particular value in a painting or sculpture. There was probably very little or no industrial design activity in Canada at that time, and it was only after the last war, when the expanded Canadian Industrial capacity had to be converted to production of peace time goods, that the interest in and need for Canadian Industrial Designers became apparent. For this reason, the Canadian Government sponsored the organization of the National Industrial Design Council (N.I.D.C.) which was established in 1948 for the purpose of stimulating the Canadian manufacturers' interest in developing Canadian industrial designers to create products for manufacture in Canada. The Council has since been supported by the Canadian Government by means of a yearly grant and it embraces members from across Canada representing manufacturers, retailers, research officials, educationists, designers and consumers. N.I.D.C. has been very successful in stimulating and promoting the use of Canadian designing talent for all types of manufactured goods. This has been done through exhibitions of Canadian designed products throughout Canada, through films dealing with industrial design, and through competition for N.I.D.C. design awards. It is believed that the N.I.D.C. design awards have done more than anything else to create general interest in Canadian designed products inasmuch as these awards are granted for outstanding design in consumer goods of Canadian manufacture. It should be noted, however, that they are not limited to articles of Canadian design. Designs awards are divided into three main categories of goods, based on usage:

1) PERSONAL Such as luggage, musical instruments, sporting goods, photographic supplies, equipment, toys, etc.;

2) HOUSEHOLD Including appliances, such as radio and television sets, housewares, vacuum cleaners, polishers, cooking utensils, furniture, lamps, lighting fixtures, etc.;

3) OFFICE and INSTITUTIONAL Such as business machines, of-

fice equipment and fixtures, etc.

To enter this competition for Design Awards, manufacturers submit an entry form to the N.I.D.C. committee, with photographs or drawings, explaining the function, colour scheme; or a production sample of the article might be forwarded with the entry. These entries are sent to N.I.D.C.'s headquarters in the Design Centre, Ottawa where they are first screened by the N.I.D.C. Index Committee, and the articles selected by this Committee are passed for final judgment in each category by a jury of four or five qualified and outstanding Canadians, on the basic principle that an article of good design is easy to look at, easy to sell and easy to use. Design Award rating is based on Form—pleasing appearance and good taste. Function—suitability for purpose. Originality—basic improvement on designs. Good value — simplicity, usefulness and price. The winning designs receive from N.I.D.C. a certificate for excellence in design and are given wide publicity. In cases where the designer of an award winning product resides and practises in Canada, he also receives a special Award Certificate which he may use for personal publicity. All winners are illustrated in a Design Awards booklet. All entries which are accepted for consideration but do not win an award are listed and published in the Canadian Design Index. The first Design Award Certificates were awarded in 1953, and the results of last year's competition were announced in May 1958. It might be interesting to compare the number of entries and awards in these two years. In 1953, there were about 300 entries. In that year, 46 Canadian manufactured products received awards, and of these 46, 37 or about 80% were designed in Canada by Canadians. In 1958, there were nearly 600 entries by 140 manufacturers, and 67 products received design awards. Of these 67, 63 or 94% were designed by Canadian designers. The healthy increase in Design Awards, as well as in Certificates to Canadian designers, is a tribute to the good work done by the N.I.D.C. and all its supporting organizations, such as the Association of Canadian Industrial Designers, the Canadian Manufacturers Association, Canadian Retail Federation, the Engineering Institute of Canada, Primary Textiles Institute, the Royal Architectural Institute of Canada, and many others.

Generally speaking, there were no professional Industrial designers in Canada at the end of the last World War. There probably were many

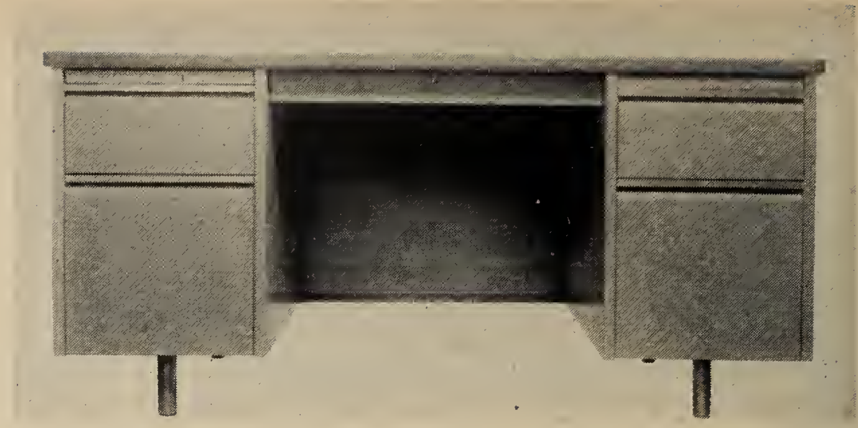

Fig. 1 One of a new line of steel desks, designed in Canada, known as "Strata" furniture.

Canadian-designed products at that time, but these were mostly created by production men or staff personnel who had no formal training in Industrial Design. This does not imply that it is not possible to create a good new design without formal training. In any profession, it is not unusual to find someone gifted with natural talent who is exceptionally successful in new undertakings. But the majority of these early Canadian designers were not very original in their creations and they were relying on adaptations of other successful designs, mostly of U.S. origin. The professional industrial designer found a receptive field in which to work when the war-born Canadian manufacturing plants had to convert their manufacturing capacity into production of consumer goods, and the number of people in the profession increased quickly. A nucleus of designers formed the Association of Canadian Industrial Designers (A.C.I.D.) in 1948. Membership in this Association is based on strict qualifications and limited to resident practicing designers. Membership is open to any creative designer of mass produced products. Prerequisites for election to membership are:

1. Five years' practical design experience;
2. Accomplishment of designs for a minimum of three substantial products which have been reproduced in quantity (500 or more) by industrial processes;
3. Standards of design to conform with those set by the A.C.I.D.;
4. Graduates of a school of design recognized by the A.C.I.D. will require only two years of practical design experience, and two products as above;
5. Two years' continuous residence in Canada.

Application must be made to—The Membership Committee, Association of Canadian Industrial Designers. The initials A.C.I.D. after a Canadian designer's name indicate that he has fulfilled these requirements and is fully competent to act as a consultant or staff designer in the creation of new products for commerce and industry. At the present time, there are about 50 members in the A.C.I.D., of whom 35 are staff designers and 15 consultants; most of these consultants own or operate their own firms very successfully. Many of the A.C.I.D. members have been very active in furthering the status of the industrial designer in Canada, partly through their cooperation in the work carried on by the N.I.D.C. The A.C.I.D. recently celebrated its tenth anniversary, and in this short period of ten years many of these Industrial Designers have become famous for their design work —not only in Canada, for they have also won respect and recognition internationally. Many have won awards for their designs at exhibitions in Milan, Brussels, Paris, London, etc. One off-shoot of A.C.I.D. is a recently organized association of Professional Industrial Designers of Ontario. A similar association is under consideration for the Province of Quebec. From the foregoing it is quite evident that Industrial Design by Canadians for Canadians, as well as for export trade, has been very successful. Activity in this field has grown more or less in step with the growth of Canada as an industrial nation.

The big impetus came, as already mentioned, with the sudden growth of the industrial plants during the war period. The end of the war left this industrial capacity with sudden cancellation of war contracts and with very little preparation for switching to production of consumer goods. The shortage of goods in general and the pent-up demand made it rather easy to satisfy the public requirements in design. Imitation of any saleable line was quite acceptable. There was very little competition from imported goods as all countries had a similar shortage and demand for consumer goods. As the demand gradually lessened, the Canadian manufacturer found foreign competition particularly from the United States, taking a great deal of the Canadian business. This developed into a shortage of U.S. dollars in Canada, and import restrictions became a necessity. In turn the Canadian manufacturer had the chance to develop his own line of products, and Canadian Industrial Designers thus became a necessity. Canadian manufacturers and retailers discovered that there was a need for products designed to meet Canadian conditions, Canadian tastes and Canadian production facilities.

The buying public is probably more educated or aware of good design today than it was ten years ago. Canadian designers appear to be of divided opinion on what constitutes the main difference in design requirements in Canada as compared with the United States, or in what respect the Canadian buyer differs from the U.S. buyer. Similarly opinion appears to be divided as to what influence the ethnological background and culture of the French-Canadian and the English-Canadian population has had on taste or preference in styling. It is generally agreed among Canadian designers that the Canadian buyer is more conscious of better quality and good service than the U.S. buyer. This could be because the average income of a Canadian is considerably lower than that of the American when measured as hours of work required to purchase a product. Consequently, a Canadian will be more cautious in his selection of goods, and quality is of more importance than appearance. The product must give excellent service for a longer period of time. He cannot afford to replace the article for a new model or design as frequently as his friends south of the border. There is less agreement between Canadian designers concerning the Canadian's taste in style or appearance. Some designers hold that the Canadian's taste leans a little more towards simplicity in design and less towards the flashy decor that American designs usually offer. One designer of T.V. and radio sets, who has considerable experience in designing for Canadians, is of the opinion that the Canadian product needs more glitter than the U.S. styles, but this requirement is limited to sets in the lower price ranges. There is also divided opinion among designers regarding the influence of the various social cultures in Canada on the styling and design of a product. There is probably a qualified difference in taste between these social groups which is influenced not only by ethnological and language factors but possibly to a greater extent by geographical distribution of population and traditions. The geographic difference is more distinguishable in the furniture market, according to one designer in the Montreal area who is very active in the design of this product. He compares the development of customers' style preference with the ladies' dress and garment business. Here, the new styles are mostly created by the big couturier houses in Paris. Copying of new styles is very common as there is little or no possibility of design protection in this field. New York manufacturers follow the style trends by studying and copying the Paris creations. The Montreal manufacturers follow the trends in New York and smaller cities around Montreal follow the styles adopted by the Montreal manufacturers. The new styles are first offered and accepted in the biggest population concentrations and gradually spread to the smaller communities. For this reason the big city dweller seems more sophisticated and advanced in his taste than the farm population, who would be the farthest link in the transmission of the new styles. There does not seem to be much disagreement amongst Canadian Designers that the Canadian buying public is greatly influenced by American design trends. Practically all American magazines with their colourful advertisements of American products are read in Canadian homes. Similarly, their radio programs and T.V. shows with all the powerful selling messages are seen and heard in Canadian homes. Many of the Canadian manufacturing plants are owned and controlled by Americans or American parent companies with a reported 40% of Canadian business thus controlled. It would seem only natural that such companies, having access to ready-made American product designs, should take advantage of this fact instead of developing special Canadian designs. Fortunately, this policy is not generally adopted by American controlled industries in Canada. As a matter of fact, there seems to be a tendency for the Canadian subsidiaries to 'go it' on their own, and many large companies have industrial design departments of appreciable size which have developed very successful Canadian designs, produced not only in Canada, but frequently also adopted for production in the United States. Nevertheless, the close economic ties with the U.S. are bound to have a great influence on the Canadian product designs, as the successful Canadian designer needs to be quite aware. They are too strong to be overcome by the virtues of Canadian designers' own ideas of what constitutes good design.

Fig. 3 Dresser of Canadian design and make.

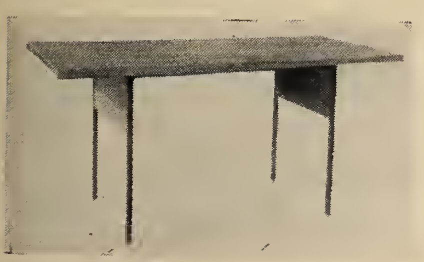

Fig. 2 Working Table designed and made in Montreal.

To what extent is the consumer's preference related to the design of a product? Does the designer create to an established taste or does he create and influence consumers' preferences through his designs? It might be unrealistic to talk about the consumer's preference in styling a product. It seems clear that the style preference does not originate with the consumer, but rather this preference has been developed and conditioned in the consumer through advertising and selling slogans, etc. The consumer at large is more apt to buy an article because it is like the Jones's, because it gives him prestige and superior standing in the community, or because it has "sex appeal", than because of his own considered judgment. The Industrial Designer must keep this in mind and his own educated taste for beautiful lines or appealing form can only be applied to new product designs at a very gradual pace. If the design concept is too far ahead of public acceptance, there is danger that the product will be an unsaleable failure. Many prospective buyers would hesitate to choose a product which is drastically different from the conventional because they are afraid of unfavourable judgment of their own taste by their friends or neighbours. The design of an article can be a little more drastic in styling when it is intended for the luxury buyer. The most expensive models can be sold to a more sophisticated clientèle. The styling of these expensive models can serve as fore-runners or pace-setters for future designs of the mass market models. A design created by a famous industrial designer can also deviate a little more from the accepted, inasmuch as the fear of being considered a 'goof' when buying his creations is much reduced by the generally expected acceptance of his work. This fear of making a mistake in choosing a product design extends to the manufacturer, who often will commission the famous designer to create his new products in the belief that this will eliminate or greatly reduce the chance for a 'dud'. It has been said that of all new products on the American market, about four out of five are commercial failures. It is also interesting to note that about 70% of new products are originated by small companies. Could it be that the small company does not have the means of publicising these new products as effectively as the big company and promoting the new ideas involved to the extent that public acceptance is accomplished. Or, on the other hand, is it possible that the small company does not have the qualified staff designers or does not avail itself of the services of design consultants, so that the new designs it creates are not approved by the buying public because they suffer from inadequacy in styling or performance. The major changes in styling trends are more successfully launched by the bigger corporations on account of their established prestige and their more powerful and widespread sales promotion. A good example of such style change is the new trend in refrigerator styling and other home appliances. The squared box effect or the "sheer" look was sold by a large U.S. manufacturer through extensive T.V. advertising in which the "sheer look" was demonstrated by the angled hands and arms of a beautiful girl. The smaller companies' new designs would probably have a greater chance for success if their designs were carefully planned to agree with current style trends. The technique of "Motivation Research" attempts to probe the depths of the consumer's mind in order to determine the reasons—conscious or sub-conscious, which make a consumer buy or not buy a product. The industrial design behind a product in particular as it relates to appearance, is important, not necessarily because the styling is in good taste from the Industrial Designer's own point of view, but because it appeals to the consumer's sometime sub-conscious desire to satisfy some basic emotional requirements. The human being does not always confess to vanity or egotistical traits. An individual who is asked what he would like to get in a product, for instance, quality and service as opposed to fancy styling, will often say that he prefers quality and service. When it comes down to buying, however, the consumer often buys the goods for appearance's sake. It is possible that the continued educational effort of the National Industrial Design Council will eventually have the desired effect of influencing the buyer to give more consideration to quality and simplified and refined styling.

In this connection, it is interesting to consider the automobile designs. For years the styling has been streamlining. The car is getting lower, longer and in all respects, is built to indicate speed—the speed of the airplane, where streamlining is of definite and practical importance. Lately, the styling of automobiles has tried to simulate speed by adding fins—here obviously capitalizing on today's preoccupation with supersonic speeds and rockets. It is doubtful whether streamlining or fins has any practical influence on the performance of the automobile, but it sells the car just the same—it satisfies some human desire for more and more speed. There has been much talk about the consumer's requirement for a smaller, more economical and efficient automobile: smaller for easier manoeuvring in city traffic and parking, less powerful engines for better mileage economy, and a more practical exterior for less costly repairs, etc. The small car is produced in Europe and is available in Canada and the United States at relatively low cost. It is interesting to observe that the percentage of small cars purchased in Canada is almost twice that in the United States. The larger American automobile companies are very dubious that a small car can compete with the flashier big ones. The fact that the small car has greater acceptance in Canada would tend to support the claim that the Canadian buyer is more conscious of value than the U.S. buyer, and it indicates the difference in economy prevailing in the two countries. The streamlining of automobiles has been carried over into the design of other articles where streamlining has no possible functional value. This sort of style transfer has been very much in vogue. Consumers have appeared completely satisfied that style and ostentation are of greater importance than fundamental design, sound engineering and reliable performance. They have been more conscious of fashion than of solid workmanship and sound quality. There is much discussion in the U.S. about the merits or demerits of the teachings in the so-called theory of "planned obsolescence". This doctrine attempts to increase the turn-over of goods by purposely making the product inferior so that it will have to be replaced after a short period of use. Frequently, the maintenance is so difficult and expensive

Fig. 4 Canadian designed coffee table.

that it is easier to replace the product completely. Planned obsolescence is also the policy of bringing out re-styled products every year in order to make last year's model old-fashioned, out of date and obsolete. Some American designers consider that planned obsolescence is good for the economy of the country, whereas others think that the public is beginning to tire of poorly designed and engineered products and is refusing to buy them. There is an indication that this trend to gadgetry in U.S. design is on the wane and that the consumer is revolting against poor quality goods by refusing to buy. The Canadian buyer who always has been interested in more value is probably ahead in this trend. Although Canadians are greatly influenced by American trends in design, do Canadians use better judgment in the selection of automobiles, appliances or furniture? Do Canadians have better taste for the sounder designs or stylings? Are the emotional requirements, which motivate their choice, any different from those of the American? Is there any real difference in product requirements in Canada which can be better interpreted and defined by a Canadian Industrial Designer? There are some very fundamental differences but these are not too obvious if we think of Industrial Design only in terms of styling and appearance. In one case a Canadian furniture manufacturer commissioned a famous U.S. industrial designer to develop for him new furniture stylings. The designs were obtained at a considerable expense, and they were probably very good, but they were never put into production. They were too expensive to produce in the quantities which a Canadian manufacturer can expect to sell. It is likely that an experienced Canadian Designer would have understood this and designed to suit the more limited market. The Canadian Manufacturers' Association has worked very diligently to promote a preference for Canadian products through a "Buy Canadian" publicity program. This is a very sound and deserving effort which should be supported by all Canadians as much as possible. The choice of a Canadian product will be natural when the product has special customer appeal, and the "Buy Canadian" habit can be greatly furthered by Canadian Product Designs that can be efficiently and economically produced in small quantities and still be very competitive with imported products. Appreciation of the value of our own products and confidence in the Canadian Designers' creative qualifications would stimulate the development of new Canadian products that would be preferred on their own merit. "Buy Canadian" would then become a natural consequence because of special value, and less of a patriotic gesture.

Fig. 5 Executive Desk.

The Canadian Designer should understand the production capabilities and limitations of Canadian plant in order to design for economic small quantity production. This is where co-operation and agreement between the Designer-Stylist and the Design Engineer is of great importance. The stylist may sometimes propose constructions which are too difficult to produce, but usually there is a solution or compromise to make possible economic manufacture, and to this end co-operation with the Design Engineer must be developed. When production volume is limited, as it must be in Canada, it is most necessary to design products which can be produced at reasonable cost despite low volume. This takes greater ingenuity, experience and effort, if the Designer must cope with these limitations than if he does not have to worry too greatly about the need of special equipment or involved tooling. It is in this area that the Industrial Designers' work becomes wider in scope to include all or most phases of product engineering, or product planning. The Canadian Designer through this wider application should be better suited to create new designs well suited for Canadian manufacture than one unfamiliar with local conditions. What kind of consumer products are best suited for design and manufacture by Canadians? There are naturally certain conditions in Canada which have an influence on the kind of product that should be produced and sold here. First, of course, there are articles which through climatic conditions, customs, or living conditions, have a sizeable market in Canada but meet little demand elsewhere. One such article, for instance, is the electric tea kettle. This appliance has won a wide acceptance and achieved good sales volume in Canada, whereas the demand is relatively limited in the United States. The reason must be that tea is a beverage widely used in Canada, whereas Americans prefer coffee. Another factor which should be borne in mind by the Canadian Designer is, of course, the extent to which the product should offer superior quality. As the Canadian average income is lower than that of the United States, it is to be expected that the Canadian buyer will look for better value. The philosophy of design for obsolescence should not be applied in Canada but rather an effort to combine durability and quality with appealing appearance. How should the Canadian Designer go about creating a new product and what factors must be considered? First, it must be understood that business is organized and companies are formed for the one ultimate purpose of making a profit on invested capital. Without profit, it is impossible for a business establishment to exist. Therefore the most important aim behind the planning of a new product is to create something that can be economically produced and will be attractive and useful to the consumer. This will sell in large enough quantities to permit the return of the investment in a reasonably short period of time. Profit cannot be realized before all investments and costs have been absorbed. The time during which these costs should be absorbed depends greatly on the nature of the goods and on competitive practices. In some cases all investments must be absorbed in one year, in other cases maybe five or ten years can be allowed. Thus the manufacturer who wishes to stay in business must have a reasonable assurance that the new product will be a market success at a price that will assure his distributors a profit margin as well as a reasonable return on the investment. The evaluation of the degree of consumer acceptance can be obtained from the selling force—from Sales Manager to Dealer—and also directly from the prospective customer, through various methods of market analysis or market research. "Motivation Research" is sometimes part of this investigation.

What is the role of the Industrial Designer in the total span from the creative effort to the final product? The first step in new product planning is of course the collection of ideas for new products. The ideas can come from many unsuspected sources; the need for new things sometimes is first voiced by the customer, or by the dealer or the sales manager, but it can also come from entirely different and unassociated directions—for instance, your toolmaker, serviceman, or any other source, for that matter. So the designer of new products should dip freely into the inexhaustible pool of ideas that occur to everybody at one time or another. The methods of collecting new ideas may vary greatly, but the important thing is that the flow of ideas be constantly stimulated and further developed. Many of the ideas submitted may seem too fantastic, impractical, or ahead of their times. These are many pitfalls in the process of screening the ideas. One of the more dangerous attitudes is to discard ideas because at first they seem too expensive or costly to manufacture. After careful study, it is often found that the production engineers will evolve new methods or tools in order to produce at the desired cost level. An idea for a new product that has interesting possibilities should be carefully studied, first on the merchandising side and secondly on the manufacturing side. It is surprising how often manufacturing difficulties can be overcome by the application of ingenuity and effort, making it possible to reduce cost of the final product and allow an acceptable selling price. After an idea has been approved, it should be further developed and some preliminary models made. A three-dimensional model is much more effective in generating ideas for improvement than a sketch or drawing. This first model could be purely functional, and little time should be given to styling at this point. The worth of the product and its possibilities in the market should again be considered by the sales experts and higher management members, and if it is still approved it should be properly designed for both good appearance and easier manufacturing. Revised models or prototypes are made as the development progresses and the improvements occur. There is some disagreement as to whether the styling designer should set the pace by making the design of the external appearance and arrangement, or whether the design engineer should make the arrangement of the working parts and then let the stylist try to house this arrangement in an appealing external form. The styling specialist who has less direct interest in the processes of manufacturing might be best suited to initiate the design effort because he will not be inhibited by knowledge of what "can't be done". He might make the design engineer's task more difficult, but he provides a challenge which often leads to the development of better techniques and improved materials and manufacturing methods, and tools which in turn tend to result in a better product. The happiest arrangement is when both stylist and engineer work together, allowing for some flexibility and permitting modifications of styling to simplify manufacture or improve performance. At the first stages of the design, it would be well to make a small quantity of the product for testing consumer response and for further consideration by the merchandising experts. This sampling of the customer's response and salesmen's enthusiasm for the product is quite important, as it can rule out unprofitable or unsuitable products, which if put into production on a greater scale could mean sizeable losses for the manufacturer, both in money and prestige. This test might bring out the necessity for further styling or design changes, and suggestions obtained should never be taken lightly. When finally a satisfactory design has been created, both from a functional and aesthetic point of view, the design and production engineers must prepare the necessary specifications for materials and parts involved and determine plans for the best manufacturing processes. Even at this stage there might be conflict, and some flexibility in the design specification should exist. Again, it is a matter of co-operation and some give and take. A very slight change in design might often result in considerable savings in manufacturing costs. Very often, too, the manufacturing engineer can see possibilities for combination of parts, such as integrating several parts into one casting instead of using separate components which might have to be riveted, welded or otherwise assembled. The production specialist or tool engineer is an invaluable adjunct to successful product design. And this is particularly true in Canada, where cost of tools per item produced is all-important.

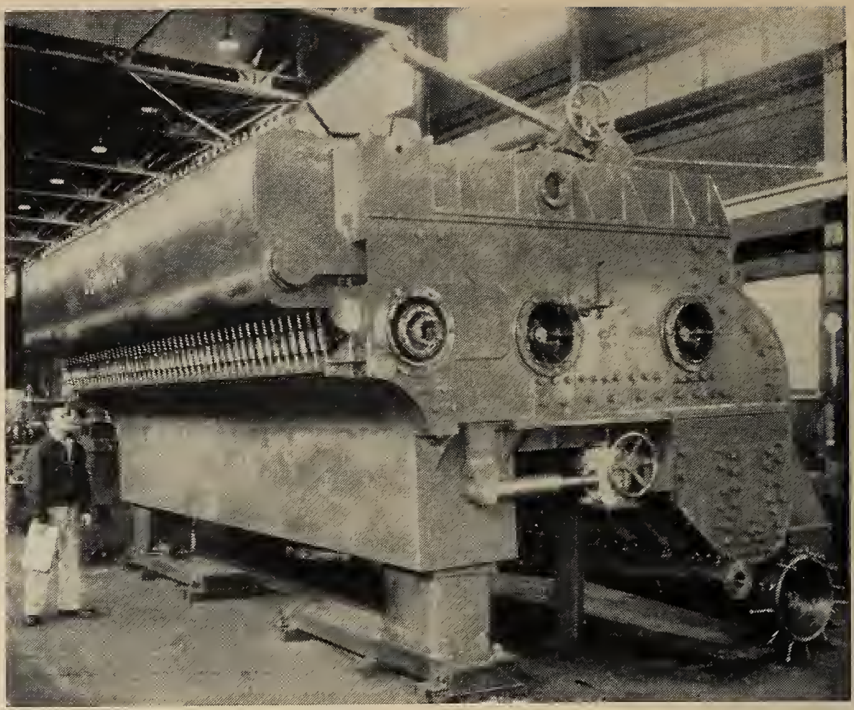

Fig. 6 The original concept of this type of pressure head box was Canadian.

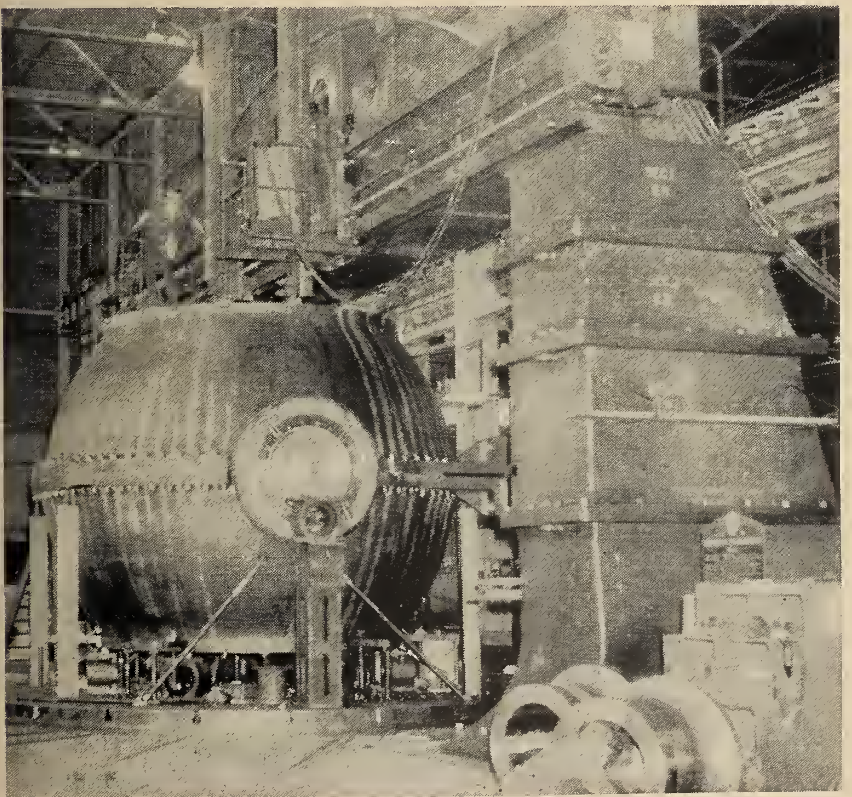
At this point, it is emphasized that the Canadian Tool Engineer has won recognition for his high standard of efficiency and ability. It has been said that "Necessity is the Mother of Invention". This might be particularly true in Canada where tools must do a job as efficiently and economically as those used for mass production in the United States, but production methods must be evolved which require tools costing considerably less. There are innumerable examples of the ingenuity displayed by the Canadian Tool Engineer. Special tools have been made in Canada which perform better and cost less than the tools used for the same job in the United States. An automatic painting machine for painting masked areas was made in Canada for less than $2,000. The corresponding machine for the same job in the United States cost $20,000 and did not work as well. A special coil winding machine which would cost $15,000 to import from the United States was made in Canada for less than $6,000, and it was actually an improvement over the American machine. There are countless examples of what can be accomplished in the simplification of tools when necessity calls for it. A drilling machine was constructed in Canada with air-operated drill feed units at a cost of $7,000., that drills up to 7 holes simultaneously in a casting: the corresponding American made equipment would have cost at least three times as much. During the war years, there was an adaptation made of a drill press that produced a striker for hand grenades as efficiently as an automatic screw machine, which would have cost at least $4,000. as compared to $250.00 for the drill including an automatic chuck and cutting tools. An example of cost reduction that reduced material cost, is the successful development by a Canadian firm of die casting aluminum in 1/16 in. wall thickness. This previously was not considered possible, but the engineers of this Canadian company made it a practical success, thereby saving about one-third of the aluminum content and reducing the weight of the product which also was a distinct advantage to the consumer. This did not in any way impair the required strength of the components involved. Magnesium die castings were considered for the purpose of weight reduction but the success of die casting in aluminum in 1/16 in. wall thickness made this more expensive material choice unnecessary. It is certainly not unreasonable to say that the Canadian Tool Engineer has done more toward economic manufacturing in Canada for successful competition with imports, than any other group of engineers. He has been instrumental in reducing production cost not only in the way of low cost tooling but also through reduced costs derived from design simplification; both conditions dictated by typically Canadian needs. As Canada's per capita dollar value of imports is about five times the corresponding value in any other country and about ten times what it is in the United States, it is evident that the Tool Engineer's contribution towards reducing this value by making manufacture in Canada economically possible, is of the greatest importance to Canada's future.

A prominent Canadian industrialist recently said: "The natural market for Canadian products is the 17 million Canadians in this country — and I say this, without in any way decrying the importance of foreign markets to the Canadian economy. Because we are all consumers, the most telling blow any one of us can deliver against the menace of unemployment is to spend our Canadian dollars on Canadian products". The creation of well designed Canadian products at competitive prices is the best possible means to induce the Canadian consumer to "Buy Canadian". For this reason, it is very important that the Industrial Designer, the Product Designer and the Manufacturing Engineers work in harmony and co-operation instead of taking opposing or even antagonistic attitudes towards each other as sometimes is the case. In the course of the design of a new product which recently appeared on the Canadian market, a rather interesting technique of *Brain Storming* was used. *Brain Storming* is a term applied to a method of creating ideas by free and unhampered discussions in a group of men of varying activities and interests. It is surprising how often a man "cannot see the forest for the trees". With the specialization that is so common today, one is prone to get in a rut and develop mental blocks which subconsciously inhibit one's thoughts and direct them only into certain limited channels. Someone who is not specialized in one particular field of endeavour is likely to take a fresher and more unfettered viewpoint when he is brought to think about the problems related to that particular field. This particular design effort was accomplished by a team consisting of a product engineer, an artistically-minded design engineer, a tool designer and a tool engineer, a service manager, a purchasing agent, a production manager, and a stores manager. The group was led by a co-ordinator who tried to bring about constructive criticism and ideas that related to the product. This active group worked as a team through the various phases of design from the first idea, the prototype stages, the design and material specifications and the manufacturing methods and tool design. At regular intervals the group would be joined by a management sales authority, who would criticise,

Fig. 7 11 ft. spherical valve, among the largest of its kind in the world, designed and built in Canada.



approve or discard the design so far developed, and sometimes other employees who had no direct connection with the development would submit their suggestions. Opinions were also gathered from salesmen and prospective customers. In this way it was possible to arrive at a design that found immediate and enthusiastic consumer approval. It was a top quality product which had many new features, and still was produced at a cost less than the product it replaced. The method closely resembles the concept of "Comprehensive Design Research". This method of Product Planning rightfully assumes that all functions of a business organization must participate and be responsible for the development of new products. This is a very sound approach since all functions have some vital part in the final accomplishments by contributing, factually or physically, to the product during its development stage. To come back to the Industrial Designer's role, it is evident that the profession as such, cannot be entirely limited to styling or external appearances. It must be a part, and perhaps the leading part, of the team that is engaged in planning and developing new products. In Canada, the organization for product planning will probably be informal and involve fewer people than in other countries. There is evidence that the closer cooperation and more intimate personal relations of a smaller group can perform at a faster and more efficient pace than a more formal and involved organization.

The foregoing has been directed mostly to the Canadian design and production of consumer goods. It would be unfair not to mention the outstanding achievements of the manufacturers of industrial goods. We have here in Canada engineering firms which enjoy world-wide recognition for their development and production of hydraulic turbines and associated equipment. One of these companies has research and development laboratories that have improved the efficiency of hydraulic turbines and associated equipment and originated such items as the spherical hydraulic valve. The undeserved lack of confidence in Canadian developments can be noted even in this type of industry. One firm originated and patented the pressure type head box in 1936, to improve the quality of paper and increase the speed of paper making machines. The Canadian paper industry was not then in a position to adopt and experiment with this advanced design of equipment. Subsequently an American firm designed the pressure type head box, but had to make an agreement to pool their designs with the existing patents. Today, almost all paper machines are equipped with pressure head boxes, and old head boxes are being replaced. This again shows the need for more confidence in the soundness of Canadian engineering undertakings. Many Canadian-built machine tools have proven themselves as efficient and well built as any of the imported ones. The papers have given attention to outstanding developments in the aeronautical field: Canadian designed turbo jet engines, landing gears and aircraft. There is lively discussion now as to whether or not the results of one of these aircraft developments should be produced in Canada. Whatever the decision regarding manufacture of this aircraft, the fact remains that its design and development is an outstanding example of Canadian engineering achievement. There are so many industrial goods produced in Canada that it is impossible to name them all here, but the mention of a few seemed appropriate.

The National Industrial Design Council does not give awards for excellence in design of industrial goods. This is probably only because the judging of industrial goods, if entered in a contest, would be too difficult. It would present quite a problem to send a locomotive, or even a crane or a shovel, to the N.I.D.C., and it would be too expensive to send the judges to the location where such industrial machines might be seen and evaluated. Nevertheless, there is great need for "Industrial Designing" in its limited interpretation of styling, even in this field. Even a tractor is easier to sell if its exterior suggests power and stamina and ease of operation through graceful and appealing lines and form, and through the selection of attractive yet practical colours. The use of *Colour Dynamics* in the creation of appealing designs is a very important factor, *Colour Dynamics*, (the science of utilizing colours to influence an individual) is of great importance in the machine tool industry. The working areas of a machine tool are painted in one colour whereas the nonfunctional parts are painted in another. These colour combinations will have the effect of making the worker's task more pleasant and efficient. It has been proven that the selection of colour does have a definite influence on the way the individual feels and responds to his surroundings. The use of pleasing colour combinations is just as important a consideration when designing industrial goods as it is in the design of consumer goods. The application of the qualified designer's training in what constitutes good taste in both form and colour styling, as well as his knowledge of the consumer's ultimate preference, has a great influence on the article's commercial success.

The smaller industries which do not have personnel capable of doing their own product development, would be well advised to get in touch with one of the highly trained and well qualified Design Consultants in Canada. The Canadian manufacturer should have confidence in their proven ability to create new products of excellent design and it is equally necessary that the Canadian consumer display a little more confidence in the Canadian product. By educating ourselves to "Buy Canadian" whenever there is a choice, we would eliminate, to a very great extent, our national problem of unused industrial capacity and unemployment.

If one can be allowed the liberty to stray from the limitations of the given title of *Industrial Design in Canada*, and to cover the broader field of Product Design and Development, certain predictions as to the future of Industrial Design in Canada can be made. In the foregoing, the Industrial Designer has been given the role of the Stylist, Artist and Dreamer, and the Engineering Specialist has been given the responsibility for the functional part of design. Probably this is the part that most Industrial Designers have taken in the past. In the future however, the scope of responsibility and activity of the Industrial Designer will widen. He will be a general practitioner in the field of styling, merchandising, market research, motivation research, product planning, engineering design, tool design and production and finance. He will not necessarily be an expert in all these fields but he will be able to coordinate, lead and inspire the various specialists who must play their part in the successful creation of new products. Such versatile talent already is available in Canada: the growth in the Industrial Designer's status should parallel the promising future and progress of Canadian industry.

Acknowledgments

THE TEST RIGS AND FACILITIES AT ORENDA ENGINES LIMITED NOBEL TEST ESTABLISHMENT

R. D. Page, M.E.I.C.,

Nuclear Fuel Engineer,
Atomic Energy of Canada, Chalk River, Ont.
formerly of Orenda Engines Ltd., Malton, Ont.

Lecture Presented on February 18, 1959 to The Deep River Branch of The Engineering Institute of Canada

Introduction

SINCE THE OVERALL efficiency or a gas turbine varies as the product of its component efficiencies, it is obvious that the individual component efficiencies must be developed to a high level.

It is impracticable to carry out performance development of the components solely by testing on a complete engine, as it is not possible to instrument an engine as fully or as accurately as is necessary. Further, mis-matching of components is not readily apparent on engine testing, as the operation of the components is interdependent, and only one curve on the characteristic family of curves of each component can be explored. Finally, the performance development of an engine is the result of a large number of minor modifications and the effect of each would be largely obscured by other variables on a full engine test.

It is necessary therefore to evaluate these modifications on a test rig permitting analysis of the component in question independently of uncontrolled variables.

The small mechanical components did not pose a major problem, but the compressor for an engine of the required specification would absorb some 12,000 h.p. under ground level intake conditions at full speed, and even under throttled intake, simulated altitude test conditions, it would require a prime mover of at least 4,000 h.p. for rig testing. Further, in order to test a single combustion chamber under ground level conditions an air supply of roughly 15 lb. per sec. and 60 p.s.i. is required.

Fig. 1. Aerial Photograph of the Nobel Test Establishment.

Historical

To design and construct an establishment adequate for testing of this order would obviously take several years and be very costly. Accordingly, several plants available through the War Assets Corporation were inspected. The power plant of the Defence Industries Limited explosive factory at Nobel proved to be the most suitable. (Fig. 1)

This plant was set up in 1940 for the manufacture of wartime explosives. It covered an area of about 2 sq. miles, and at its peak employed more than 4,000 employees. The plant was Crown-owned, built entirely for wartime use, and hence was available with all facilities through the War Assets Corporation.

The power house contained a turbo-alternator of 4,700 h.p. nominal rating; four air compressors each delivering about 3 lb. per sec. of air at a pressure of up to 110 p.s.i., and foundations and connections for a fifth machine; and twelve boilers, eight with a working pressure of 135 p.s.i. and four with a working pressure of 250 p.s.i., each capable of being over-rated to 25,000 lb. per hr. of steam output.

Electric power and water were adequately available. The machine shop was fairly well equipped and of good size. There was space suitable for offices and laboratories.

Housing was available in Nobel Village.

Accordingly application was made to have this plant made available, and in November, 1946, the central facilities, located on some 17 acres of land, were formally turned over to the company.

Description of Basic Facilities

The Nobel Test Establishment is located some 120 air miles and some 173 road miles north of Malton, Ontario, resulting in a driving time of 3½ hr. between these points. The Canadian Pacific Railway transcontinental line and the new Trans-Canada highway both pass through Nobel (See Fig. 2). The Trans-Canada highway is still under construction in some important sections and when completed will reduce the distance from Malton by road to 130 miles. Continuous teletype communication is maintained with the engineering office at Malton.

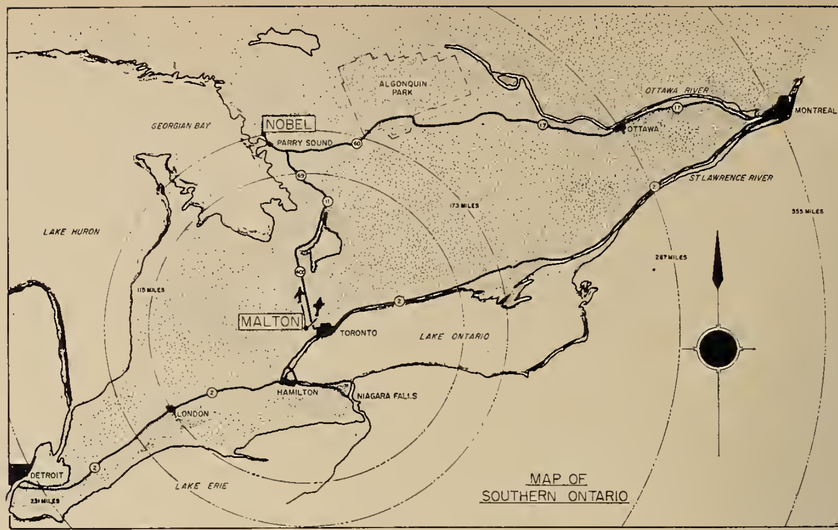

Fig. 2. Map of Southern Ontario.

The plant is about 7 miles north of Parry Sound, and roughly 1 mile from Nobel Village. Its immediate industrial neighbour, ½ mile to the west across No. 69 Highway, is a plant of the Canadian Industries Limited Explosives Division (See Fig. 3).

The Test Establishment covers an area of some 17 acres. This area is substantially level, and the granite bed rock is generally only a few feet below the surface. This is occasionally inconvenient, but on heavy structures foundation costs are minimized.

The plant comprises the power house, new test cells, machine shop, new office, old office, fire hall, assorted smaller buildings, and five buildings retained since the last war for storage purposes by Canadian Arsenals Limited (See Figs. 1 and 4).

Services

Steam: The boiler room contains six boilers each rated at 394 h.p. and 12,800 lb. per hr. of steam. They can, however, be over-rated to 25,000 lb. per hr. of steam.

The four high pressure boilers have a working pressure of 250 p.s.i. and deliver steam to No. 1 compressor test rig, No. 2 compressor test rig, or the ejector of the sector altitude com- boilers operate at 135 p.s.i. and deliver steam to the ejector of the Orenda altitude combustion test rig, the turbine drive of the blower, various auxiliaries, and the plant heating system.

These boilers were designed for a steady industrial steam load; however, test operation demands a rapidly fluctuating load and frequent overload. This necessary abuse naturally tends to shorten boiler life, and is bustion test rig. The two low pressure reflected in an accelerated maintenance schedule.

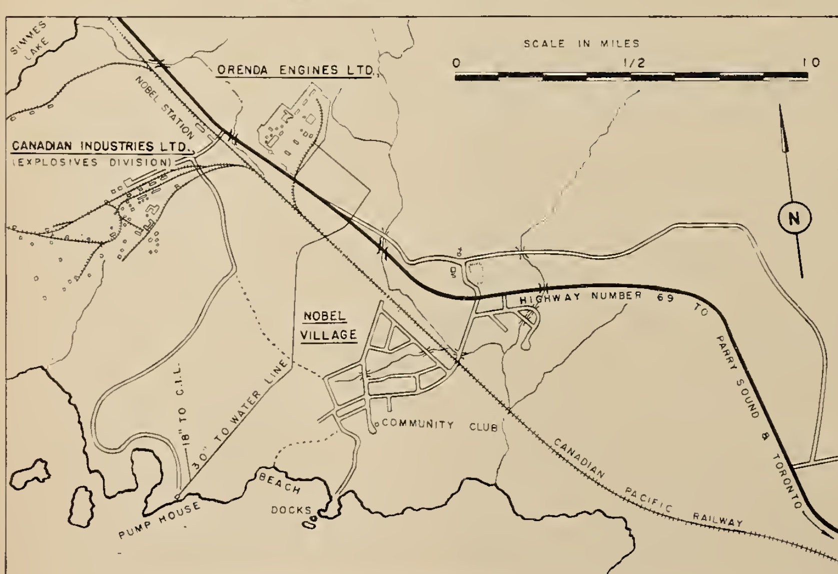
All the boilers have been converted to oil firing in the interest of operational flexibility and economy. The present storage tank capacity for Bunker "C" oil is 60,000 gal. and, as this is sufficient for only four days of heavy testing, the plant is somewhat dependent on rail service for the continuity of its operation.

Air: Compressed air is delivered from a bank of five 500 h.p. compressors making available a total of 15 lb. per sec. at up to 110 p.s.i. pressure. This air may be delivered directly to the test rigs at compressor delivery temperature, or any portion of it passed through an aftercooler.

Air for the Orenda atmospheric and altitude combustion test rigs is supplied by a blower which delivers 3.5 lb. per sec. of air at up to 3.0 p.s.i.g. This blower is driven by a 180 h.p. steam turbine and can be over-rated to deliver up to 5.5 lb. per sec. of air.

Water: The plant is provided with water delivered through a 30 in. water line from a pumphouse located on the shore of Georgian Bay (See Fig. 3). The pumping plant consists of four 2300 g.p.m. 231 ft. head centrifugal pumps each driven by a 200 h.p. induction motor, and a 1000 g.p.m. stand-by pump driven by a gasoline engine. Two of the main pumps are Crown Capital equipment assigned to Orenda Engines Limited, while the remaining equipment and building are owned by Canadian Industries Limited, who maintain and operate the pumphouse.

Fig. 3. Area Map Of Nobel.



Water up to a maximum of 6500 g.p.m. is normally available to the test establishment.

Two water storage tanks, each of 100,000 U.S. gal. capacity, are normally kept filled to cope with fire or other emergency. One is a gravity tank about 119 ft. high, which would supply water for fire-fighting purposes for a substantial period in the event of a power failure. The standby steam turbine-driven fire pump could, in this interval, be brought into service and draw on the further reserves in the 100,000 U.S. gal. stave tank. The gasoline motor-driven stand-by pump in the Georgian Bay pumphouse is, of course, the ultimate reserve.

Hydro: The main switchboard is located on the second floor level of the power house. One 44000/2200 v. 3-phase, 60 cycle transformer of 3000 K.v.a. capacity is located immediately outside the power house at this point.

The present hydro contract permits the use of two of the compressors between the hours of 7 a.m. and 7 p.m., and provides for adequate power between these hours for full operation of the Georgian Bay pumps and all other normal services and auxiliaries. The additional three compressors can be operated only between the hours of 7 p.m. and 7 a.m.

Fuel: The test fuel tank farm (See Fig. 4) has a total of nine storage tanks, four 30,000, one 10,000, one 5000 and three 1500 gal. size, giving a total capacity of 139,500 gal. The new afterburner rig uses JP 4 (wide range distillate), but all other combustion rigs normally use JP 1 (aviation kerosene) in the interests of safety.

Nobel Village

Built on land owned by Canadian Industries Limited, Nobel Village was founded in 1913 as a company town to house the supervisory personnel of their local explosives plant.

In 1940, to accommodate additional personnel of the war-time Defence Industries Plant, the village site was extended and additional houses and apartments erected. All but 66 of these units were removed to other government projects, such as Deep River, and of this number 44 (largely of the 2-bedroom type) are now occupied by Orenda personnel.

Description of Test Rigs

No. 1 Compressor Test Rig: The No. 1 compressor test rig was designed for the testing of multi-stage axial flow compressors in closed circuit operation. The closed circuit rig configuration, with provision for controlled evacuation of the circuit, simulates — for compressors currently on test — altitudes between roughly 70,000 ft. and 28,000 ft. The available drive horsepower defines the lower altitude limit.

In the closed circuit, the hot air leaving the compressor is turned downward in a vertical leg where it is throttled by a pintle valve which controls the compressor pressure ratio.

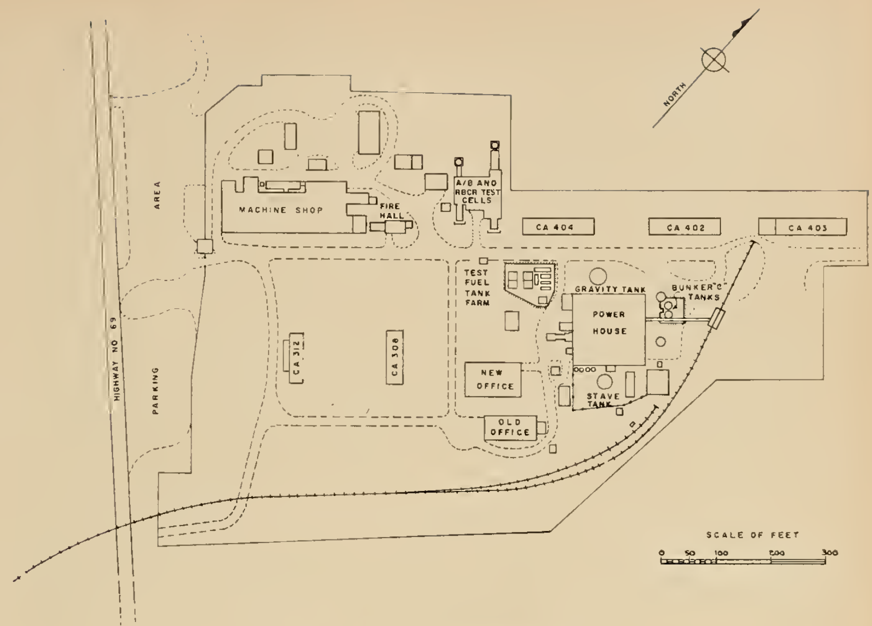


Fig. 4. Plan of Plant Area.

It is then turned horizontally and drawn through the air cooler. The airflow is measured in one of three interchangeable venturi meters, depending on the compressor under test, before turning upwards in a vertical leg and finally turning horizontal again where it passes through a long duct and screen section before re-entering the compressor.

The multi-stage condensing extraction type steam turbine can produce a maximum of 6500 h.p. at 3600 r.p.m. (its nominal rating is 4700 h.p.) with a steam consumption of 80,000 lb. per hr. The compressor r.p.m. is increased through the gearbox, normally by a ratio of 2.196 to 1, or optionally by rebuild of the gearbox, by a ratio of 2.976 to 1.

Air extraction from the circuit is from the highest pressure point of the rig — between the compressor and pintle valve — by a steam ejector which can reduce the air pressure in the rig to less than one p.s.i.a. at compressor inlet.

The air cooler operates with a coolant flow, normally 2500 g.p.m., of water pumped directly from Georgian Bay and discharged from the cooler to waste. The compressor inlet air temperature approaches the cooling water temperature under normal operating conditions; a minimum of 4°C is attained during winter. By reducing the water flow in the cooler, inlet compressor air temperatures of up to 100°C are obtainable.

Iroquois and Orenda compressors are tested on the rig to determine the characteristics of the configuration with new or modified blading.

On a normal test, some 75,000 separate readings are recorded and processed in determining the overall stage and rotating stall characteristics, surge line definition and strain gauge and vibration phenomena. This information is essential in the development of compressors to give higher mass flows for more thrust, improved or higher surge lines for better engine acceleration characteristics, and improved blade vibration characteristics for longer blade life.

No. 2 Compressor Test Rig: (Fig. 5) To investigate in detail the performance of a rotating blade row, it is simpler to investigate a single stage by itself rather than as one stage of a number on a multi-stage compressor test unit. The purpose, therefore, of a single stage unit is to allow the detailed examination of a single characteristic without the complication and interference of the multiple stages. No. 2 compressor test rig is used for single stage testing of advanced designs of compressor blading.

The rig consists basically of an inlet duct, compressor unit, outlet duct and exit throttle, drive turbine and condensor. The air is drawn through a filter house into an inlet venturi which measures the mass flow. The air then diffuses into a large diameter intake section and thence into the test unit proper.

In order to simulate actual compressor conditions, the test unit may have upstream of the blade stage under test—which comprises one rotor blade row and one stator blade row—several "tailoring" blade arrangements.

From the compressor unit the air is ducted to atmosphere via the corner turning vanes and a vertical leg of outlet ducting in which is situated a large electrically operated butterfly throttle valve for compressor pressure ratio control.

The compressor is fully instrumented with pressure and temperature instrumentation. Provision is made so that probes can be traversed simultaneously, both radially and circumferentially at entry and exit from each blade row. The probe traverse arrangement is such that mean values are obtained from three or four blade pitches for total head pressure, static pressure and yaw angle.

The drive turbine was a small reworked Chinook unit, which has been replaced with a two-stage Orenda II turbine capable of producing 2,600 h.p. at 8,500 r.p.m. The exhaust steam discharges into a jet condenser capable of handling 45,000 lb. per hr. of steam flow. The rig is capable of testing compressors which pass up to 150 lb. per sec. at pressure ratios of up to 1.3 to 1.

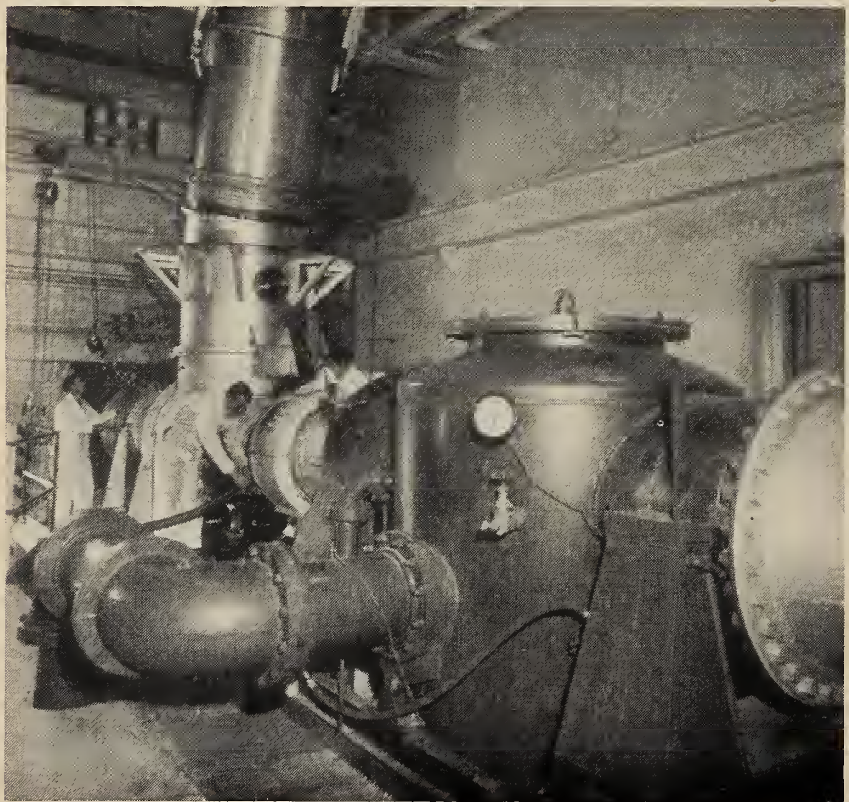
Cascade Test Rig: (Fig. 6 and 7) The cascade test rig, or variable incidence cascade wind tunnel, to use its full name, has been in use for nearly nine years, and has produced perhaps the largest quantity of useful results of any rig at Nobel. The rig has been in operation almost continuously and it has had only a few minor modifications since its initial installation. However, it has not reached the end of its usefulness, as there is still much to be covered in determining blade characteristics. It is through these tests that our basic knowledge of gas turbine blading for use in compressor and turbine design is obtained.

A cascade is made up of a number of constant section blades representing only one of many combinations of pitch/chord ratio, thickness/chord ratio, stagger angle and camber angle. In addition to these variables, there are also changes in basic profile, non-standard blade forms and special blades to be tested. A cascade is usually tested at various incidences and over a range of inlet Mach numbers to determine the positive and negative incidence stall point and the highest loss limiting Mach number at each incidence. The total pressure loss, static pressure rise, air deflection and deviation angles are found and in this way the working range of a blade is established, as well as its optimum operating conditions. Over 500 different cascade configurations of compressor turbine and inlet guide vane blades have been tested to date.

The rig is supplied with up to 15 lb. per sec. of air from the compressors through a 10 in. diameter pipe. From this pipe the air passes through a converging duct which changes the cross-section to a smaller rectangular shape (area ratio 1.7 to 1.0). The air then enters a tunnel which has parallel top and bottom plates but where a further reduction in area (approximately 1.8 to 1.0) is achieved due to the profile of the sliding side walls; this area depends upon the angle to which the tunnel is set. The cascade can be rotated to give air inlet angles from zero degrees to 67° as required to cover the cascade incidence angle range. The air then passes through the cascade of blades and out to atmospheric pressure in the test cell and is directed through the cell wall by outlet guide vanes. Injection of high pressure air into the boundary layer — parallel to the gas stream — straightens out the gas stream at the inlet to the cascade.

Pitot and yaw traversing is conducted downstream of three blades of the cascade. An automatic recorder system in conjunction with a photocell manometer and a yaw capsule amplifier system gives a permanent record of each test as well as carrying out an integration and averaging of flow conditions downstream of the cascade.

Fig. 5. No. 2 Compressor Test Rig.



Probe Rig: (Fig. 8) The calibration and evaluation of various aerodynamic and thermodynamic probes under known and controlled conditions in the probe rig is required in order to properly evaluate the results obtained when these probes are later used in engine and aerodynamic test units. In addition, this rig plays a major role in the research and development of probes.

The general aim in aerodynamic work is to obtain the necessary accurate data from the test unit with the least interference from the sensing devices. Hence, a demand always exists for smaller and stronger probes which will sense total pressure, static pressure, yaw and total temperature either in the form of a single or combined probe. Other factors which affect both probe design and performance are wall effect, Reynolds number, pressure gradients, turbulence and response. As the operating velocities of the various test units and engines increase, so the effect of compressibility and shock waves will become more prominent and require different probes and techniques.

The probe rig consists of a 17 in. diameter total head tank which is supplied with air from the compressors through a 10 in. diameter pipe, a diffuser and screens. Situated on the end of the total head tank is an aluminum 4.5 in. diameter quarter elliptical nozzle. The probe is held in the nozzle jet by a traverse micrometer with remote yaw control. The micrometer is mounted on a tilting bridge, which can be moved along the axis of the nozzle jet, spanning the nozzle stream.

The true total head pressure and temperature are obtained in the total head tank where the air velocities are very low and the values can be sensed accurately. These readings are compared with those obtained from the probe under calibration at various Mach numbers, over the operating range of the probe. The static pressure of the nozzle jet is assumed to be ambient and the static pressure of the probe is compared with the barometer at the time of test. The probe is normally evaluated under various conditions of tilt and yaw to obtain a general idea of its performance under non-axial flow conditions. The general operating range of the Probe Rig is from 0.1 to 0.65 Mach number which can be obtained from the air flow available during the day.

It is possible to choke the nozzle with the full output from the compressors but the nozzle is not generally suited to transonic and supersonic work. The limiting Mach number is approximately 0.80.

The probe rig is also used to provide air for other miscellaneous airflow rigs.

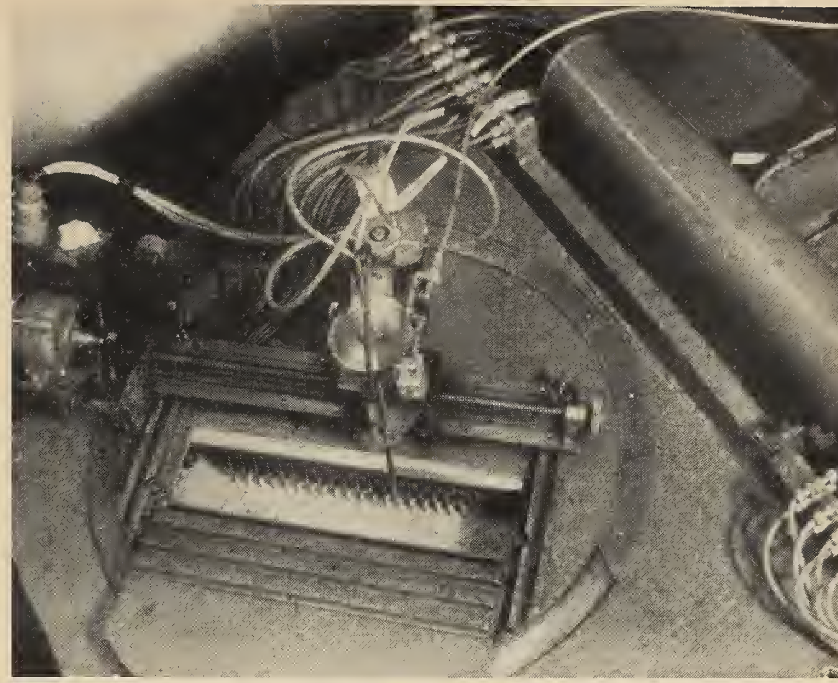


Fig. 6. Cascade Test Rig.

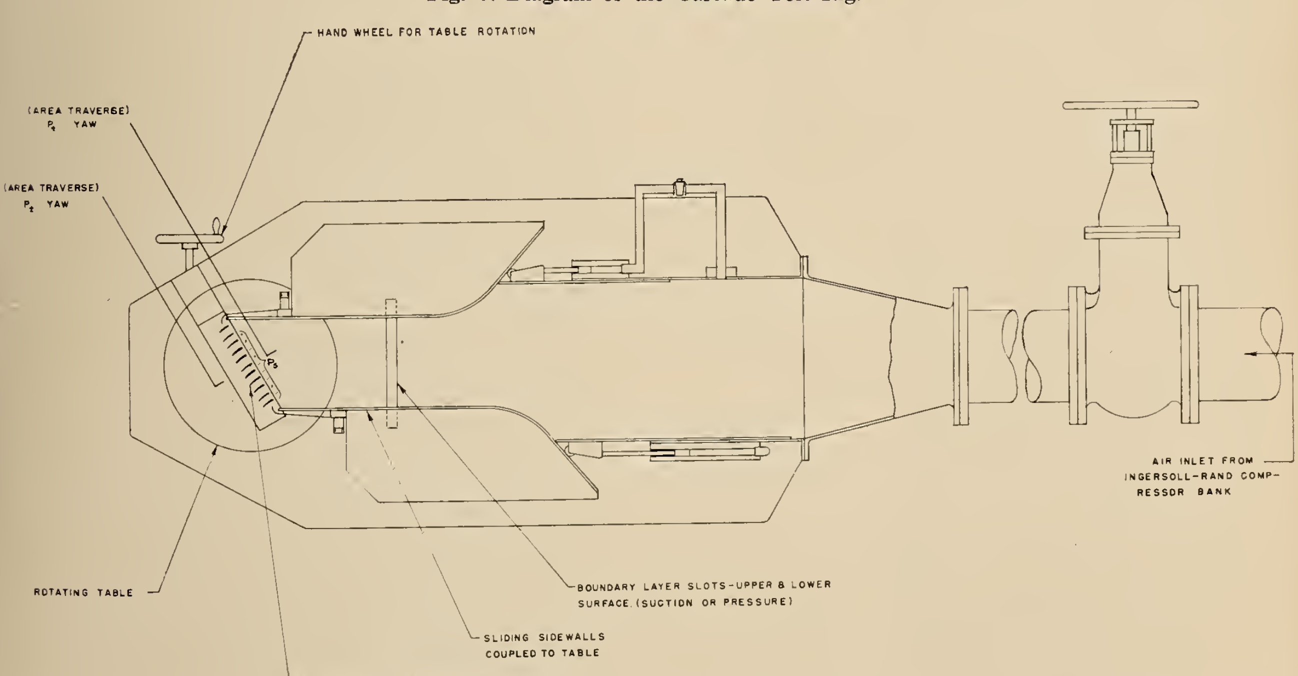
Cooling Air Ejector Test Rig: (Fig. 9 and 10) After-burning in the modern jet engine for high speed flight has developed to the stage where it is imperative to cool the external surface of the jet engine and the afterburner fuel supply as a protection against the heat generated during after burner fuel operation.

This is done by ducting air from the engine air intake around the engine in two passages. The inner or secondary cooling air is ducted concentrically around the jet pipe, while the tertiary air ventilates the fuel manifold and turb-pump area to prevent contact of combustible vapours with hot engine parts. An adequate flow of air is maintained at all times by a double ejector in which the jet efflux from the engine final nozzle is used as the driving medium. The secondary and tertiary ejector nozzles are concentric with the engine final nozzle.

It has been found that the thrust of the primary nozzle can be increased or decreased by the addition of ejectors and that careful ejector nozzle design is necessary if full advantage is to be taken of its effects. The cooling air ejector test rig was designed to investigate the performance of small scale models of the ejector assembly.

The rig is entirely supported by flexible straps attached to the ceiling and is isolated from the inlet duct by an air breathing or seal which facilitates the measurement of the thrust of the ejector configuration. The main air supply is ducted through the air bearing arrangement into a plenum chamber whence it is ducted to the three nozzles of the ejector

Fig. 7. Diagram of the Cascade Test Rig.



through flow tubes, venturis, and valves to the annular ducts in the header assembly, on to which the test nozzle specimens are attached. To enable constant flow ratios to be maintained between the cooling and primary airflow, the secondary and tertiary flow tubes are connected to a common source in which is situated a choked orifice.

The general characteristic of the ejector is obtained over a range of primary, secondary and tertiary pressure ratio during which the following measurements are taken: primary, secondary and tertiary total pressure; primary, secondary and tertiary mass flow, and overall thrust of the ejector configuration.

The maximum pressure ratio across the primary nozzle is limited by the air supply of 15 lb. per sec. from the compressors. This has to serve the primary, secondary and tertiary flow paths but of these the largest proportion passes through the primary nozzle and limits the pressure across it to slightly less than 7.0 to 1.

In addition to air ejector testing, this rig has been adaptable to jet deflection tests and to other work such as evaluation of the exhaust ejector for the engine altitude test facilities.

Slip Ring Test Rig: For engine development work, a slip ring is necessary to convey strain gauge, thermocouple, or any other low level signal, from the engine rotor assembly to the engine frame and thence to instruments for analysis. The development of a suitable slip ring unit for the modern engine poses a particularly difficult problem since, due to space limitations, the contact brushes must operate at rubbing speeds of the order of 500 ft. per sec. Since signals of less than 100 microvolts are often invesitgated, considerable refinement of design is required to ensure that the required signal is not masked by surface contact interference.

The slip ring test rig was designed to reproduce the operating environment of the slip ring unit on an engine. It encloses the unit in a case which can be flushed with air at up to 200° C at various pressures. Drive is from a 15 h.p. electric motor through a variable speed transmission which permits operating speeds from 1500 to 9000 r.p.m.

In addition to evaluating various basic designs for slip ring units, this rig can be used for comparing and analysing such variables as ring material, ring surface finish, brush material, and brush design.

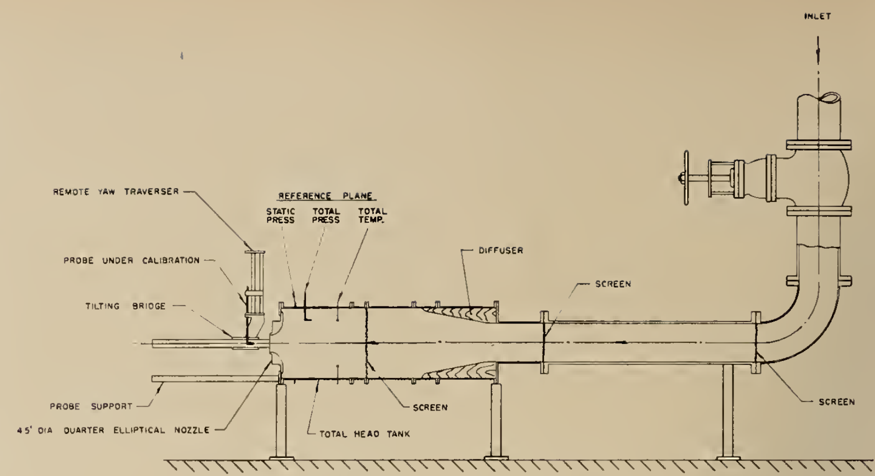


Fig. 8. Diagram of the Probe Test Rig.

Static Blade Cooling Rig: To improve the performance and output of a gas turbine engine it is desirable to increase the combustion temperature and hence the temperature at the turbine inlet. If higher temperatures are to be tolerated, either improved turbine blade materials or cooled turbine blades are required. The static blade cooling rig was designed to carry out preliminary testing on various cooling blade configurations. The more promising blade configurations are then tried in the rotating blade cooling rig. The test blades have cooling passages of three basic types, chordwise, radial or helical. The type of construction of the blade is either load carrying shell, load carrying strut, hollow shell without baffles, or integral construction. Blades made up of different combinations of the above are tested in the static blade cooling rig.

The airflow to the rig is supplied by two compressors giving six lb. per sec. This airflow is augmented by an air injector which draws an additional 1.5 lb. per sec. The air is brought to the rig through a 10 inch diameter pipe. Then it goes to the air injector after which it passes on to a preheater, basically an Orenda combustion chamber, and thence to a mixing chamber where the combustion gas flow is evened out. From the chamber it goes through a transformation duct conducting the flow from a circular passage to a rectangular passage. Here it enters the hot cascade box in which are mounted one centrally located cooled blade specimen with two dummy blades on either side, making a cascade of five blades. After passing from the hot cascade box, the gases are spray cooled with water and exhausted to atmosphere through a stack.

Blade cooling air and root cooling air are tapped off the air supply line upstream of the air injector. The root cooling air flow is fixed and does not change throughout the test. It is heated by two heaters, then fed into the hot cascade box from the bottom. Here it enters the root cooling air chamber in the bottom of the liner where it cools the root of the blade and exhausts into the main gas stream. Both the blade cooling air and the root cooling air can be controlled for mass flow and temperature. The cooling flow is usually varied from 1% to 4% of the total flow past each blade. Thermocouples are located at the root, mid-section and tip of the blade. The testing is carried out then to determine the effective cooling, the blade temperature distribution and the pressure loss in the blade passages at various flow and temperature conditions.

Rotating Blade Cooling Rig: The rotating blade cooling rig is essentially a turbine test rig but is specifically designed to develop various types of cooled turbine blades both as to mechanical reliability and performance. Evaluated on this rig are the more promising blade designs as determined by testing on the static blade cooling rig.

Preheated air is supplied by an upstream slave unit consisting of a rig compressor which pumps air through a rig combustion system and modified combustor in series. The air so delivered to the turbine simulates a high altitude flight condition. After expanding through the turbine the gases are cooled with a water spray and passed through an outlet silencer.

The rig is driven by the test turbine, but to allow for mismatching of this turbine with the rig compressor excess power is absorbed by an eddy current dynamometer (formerly used on the turbine test rig in the power house) which is capable of absorbing 6000 h.p. at speeds between 5000 and 9000 r.p.m. The rig is protected by special speed trips.

Blade cooling and root cooling air is drawn from the ducting downstream of the rig compressor and raised to the required delivery temperature in the combustion preheater. It is then reintroduced to the rig through radial tubes in the duct upstream of the modified combustor, and thence fed through an axial passage to the blade cooling and root cooling system.

The turbine test unit is heavily instrumented for the recording of blade temperature and vibration stresses by thermocouples and strain gauges which produce signals which are transmitted through a water-cooled slip ring unit in the tailcone to the recording instruments.

The turbine test unit is designed to duplicate closely the design of the rotating components so that gas loads, speed, and vibratory forces are the same as on an engine. Provision is made for visual examination of the test blades and for removal and replacement of the first row of blades.

Afterburner Rig: (Fig. 11) This rig, completed during the first week of September, 1956, is intended for use in evaluating the burning characteristics, stability range and mechanical properties of various full scale afterburner systems.

The rig consists basically of a slave engine with reheat exhausting into an injector. The augmented gas flow passes through a mixing duct, then through an annular measuring duct into a test rear frame and jet pipe in which afterburner test specimens are mounted. The exhaust gases are cooled in the exhaust duct and pass through a silencer to atmosphere.

By means of adjusting the slave engine reheat fuel flow and engine speed it is possible to vary the primary and augmented gas flow. Thus, it is possible to vary the test unit inlet Mach number and gas temperature.

The pumping capacity of the present rig configuration is 160 lb. per sec. of gas flow up to 750° C at 5 psig.

Sector Afterburner Rig: The sector afterburner rig is intended for use in evaluating the stability range and burning characteristics of segments of various afterburner systems.

Air from five compressors is preheated in a rig combustion chamber and passes through a mixing duct into the sector afterburner where the test specimens are mounted. Exhaust gases are water cooled and passed through a silencer to atmosphere.

A sector unit of this type cannot duplicate various types of screech instability sometimes found on annular afterburners, but to minimize temperature gradients and other end wall effects, the radial walls of the sector are ceramic which is allowed to heat up to the full gas stream temperature. The test unit is fitted with observation windows.

The upstream airflow is adjusted by means of an air operated valve, and the afterburner inlet temperature is varied by altering the preheater fuel flow. The maximum air flow obtainable is 15 lb. per sec.

Sector Altitude Combustion Rig: The sector altitude combustion rig is used for combustion development work on altitude ignition, stability limits and performance.

Air is drawn from atmosphere through one of three interchangeable flat plate orifices, is throttled by a remote-operated butterfly valve, is smoothed by two screens, and passes through a transition duct into the combustor inlet. The combustion unit is ceramic lined on the radial walls to minimize end wall effects and has viewing windows for observation of the combustion process. Downstream of the combustor a 60 degree sweep traverser is used to obtain gas samples and temperature and pressure profiles. The gases are then ducted to the steam ejector which exhausts through a silencer to atmosphere.

The ejector consumes 100,000 lb. per hr. of steam at 205 psi and provides, for a typical combustion unit, cold air inlet conditions between 4.6 in. of mercury absolute at a mass flow of 3.0 lb. per sec. and 24.0 in. of mercury absolute at a mass flow of 18 lb. per sec.

It is planned in the future to use this test rig for altitude afterburner work and to install a preheater so that realistic operating conditions can be set up for performance tests.

Orenda Altitude Combustion Rig:

Fig. 9. Cooling Air Ejector Test Rig.

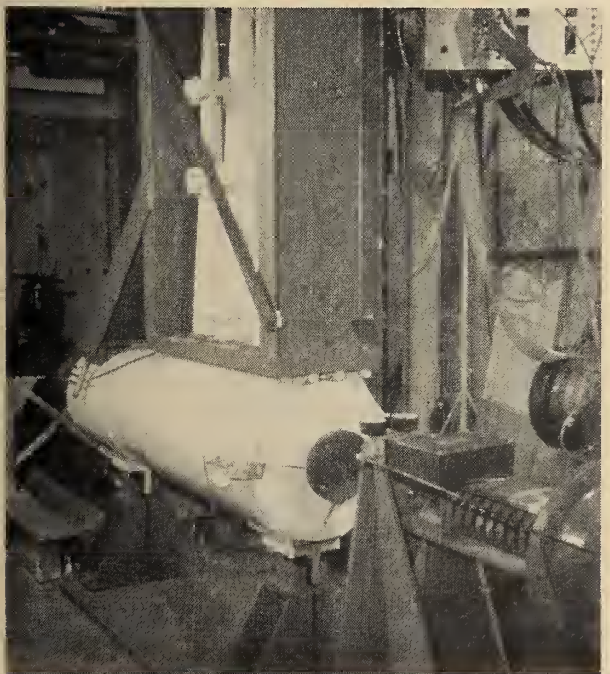

Fig. 10. Diagram of the Cooling Air Ejector Test Rig.

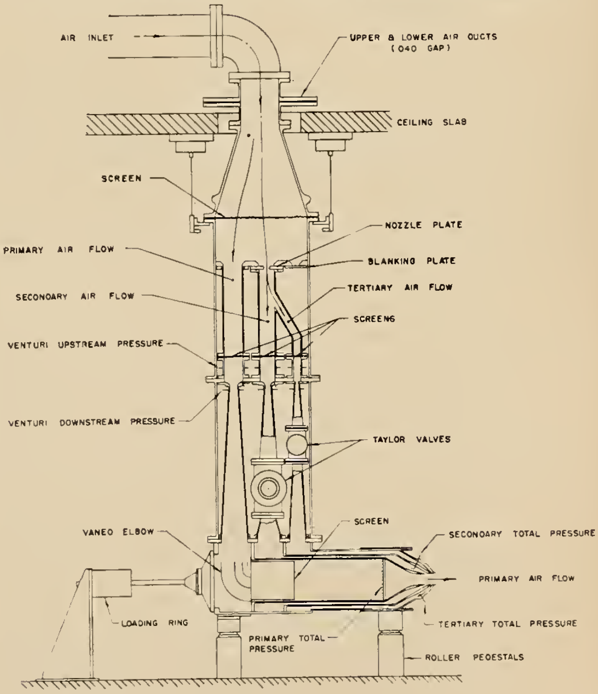

The Orenda altitude combustion rig is used for determining ignition and stability characteristics of various combustion chamber configurations under altitude conditions.

Air is drawn from the cell through one of a series of inter-changeable orifice plates, or alternatively for higher mass flows, through an electric preheater which may or may not be used, and a low-loss venturi meter. The air from either source is throttled by a remote operated butterfly valve and flows to a total head tank from which the two dimensional primary zone box is supplied. This box is fitted with viewing windows.

The combustion gases are drawn from the test unit by an ejector which uses 30,000 lb. per hr. of steam at 125 psi. The characteristic curve of this ejector permits testing at a lower pressure in the test specimen than is attainable on the sector altitude combustion rig.

Orenda Atmospheric Combustion Rig: This test rig was originally designed to test Orenda combustion chambers of various configurations at roughly sea level atmospheric pressure, which simulates altitude operation of the combustor in a complete engine. The rig is now inactive for Orenda work, and is used for airflow studies, and with the addition of a combustion preheater and a special downstream duct, for thermocouple response tests.

The air supply for the rig is obtained from a blower which is rated to deliver 3.5 lb. per sec. of air at 3.0 psig. A 450 Kw electrical air preheater equipped with a temperature controller is installed in the air line downstream of the blower. An alternative air supply may be drawn from the compressors by means of a four inch diameter crossover line entering the rig supply line downstream of the preheater. The preheater must be isolated when this supply is used. Air flow to the rig is measured by a venturi meter.

Orenda High Pressure Combustion Rig: This test rig has been used for the testing of Orenda type combustion chambers under conditions approaching sea level flight. The 15 lb. per sec. of air available from the compressors duplicates the mass flow in one Orenda type chamber under low altitude conditions, but permits set-up of correct air velocities and air fuel ratios for sea level investigations.

Outlet temperature distribution, metal temperature, pressure loss, and combustion efficiency determinations and "slam throttle" deceleration simulations typify the work done on this rig.

Air from the compressors passes through an Orenda type combustion preheater to a total head tank and thence to the test combustor. A water-jacketed traversing section downstream of the combustor is used for determining temperature and pressure profile. The outlet gases are cooled with a water spray upstream of a remote operated butterfly valve which establishes the combustor outlet pressure.

Turbo Pump Rig: The turbo pump rig is used to evaluate and calibrate air turbine driven fuel pumps of various designs.

Air is supplied to the turbine after passing through a metering orifice, steam and electric preheaters (for low flows), and a combustion preheater (for high flows). Air from the turbine may be exhausted to atmosphere, or drawn through piping to the Foster-Wheeler steam ejector for altitude work. Air requirements at turbine inlet may vary from four pounds per second at 100 psia. and 300° C, to one pound per second at seven psia. On a typical test, measurements are made of the turbine air flows and pressures required to give desired fuel flows and pressures. Speed indication is by an inductive pick-up which imposes no restraint on shaft rotation.

A closed circuit fuel system provides up to 65,000 lb. per hr. of fuel at the test pump inlet at 15 psig. pressure after passing from the boost pumps through a filter, a cooler and a flowrator. Fuel discharge is throttled and then returned to the supply tank. The discharge system is designed to withstand up to 1500 psig.

Waterflow Analogue Rig: The rig is used for visualization of flow patterns in main combustion chambers and in afterburners to determine, for example, reasons for flame tube hot spots, and optimum position for igniter plugs.

The test section of the rig is a plate glass tank which will hold a model, generally constructed of plexiglass, up to 15 x 15 x 48 in. The rig is in the form of a closed circuit, using water as the flow medium with a pump which will deliver 2000 gpm, although for normal running much less than this is used.

The analogy follows the Reynolds' principle that different fluids can be made to have similar flow patterns if the Reynolds' number is made the same. It has been found by other waterflow rig operators that combustor flow pattern is sensibly independent of Reynolds' number so long as the flow is in the turbulent regime. This allows the rig to be run at velocities of the order of 10 ft. per sec. which are low enough for convenient viewing and also low enough that the model is not overstressed.

In operation, air bubbles entrained in the circulating water reflect the light from a special slit-beam light source which can be adjusted to give the flow pattern in any desired plane. These patterns may be examined visually, photographed using flashbulb slit illumination, or filmed with a motion picture camera.

ENGINEERING STUDIES OF THE FRASER RIVER BASIN

T. A. J. Leach, M.E.I.C.,

Chief, Hydraulic Investigation Division,
Water Rights Branch
B.C. Department of Lands and Forests
Victoria, B.C.

Presented at the Western Technical Conference of the Engineering Institute of Canada October 2 and 3, 1959, Banff, Alberta

Adequate control of the Fraser River against a "design flood" greater in magnitude and volume than any known discharge could be realized through a system of power and storage dams located throughout the main river and its tributaries. Such a system would not only keep the freshet flows in the Lower Fraser Valley within the capacity of the existing dyke system, but would also be economically self supporting through the sale of electrical energy. However, the three suggested systems each with over 5 million k.w. of firm power do not include fish facilities, which were omitted primarily because of lack of pertinent information on all factors involved.

This led the Fraser River Board to a study of partial developments of the three main systems which, while having a minimum adverse effect on the fishery resource, would be part of an overall system in which flood control would still be realized, while the total cost would still be borne by the sale of electrical energy. The preliminary investigations carried out in support of these conclusions revealed a lack of representative meteorological data, which has been partially corrected through the introduction of a snow survey program. Similar lack of hydrometric data or only short term records necessitated correlations with older stations to obtain 20 yr. of continuous discharges.

General Scope

WHILE the title of this paper is rather broad in its implications, the intention is to describe the water resources of the Fraser River Basin, the tentative planning for its use and some of the problems encountered in carrying out the preliminary investigations.

Much of the material that follows, including the illustrations, has been taken from the *Preliminary Report on Flood Control and Hydro-electric Power in the Fraser River Basin* which was completed by the Fraser River Board in 1958. The paper is limited, therefore, to the early stages of water resource investigation in a relatively undeveloped river.

Comparative Size

In recent months much publicity has been given in the press, not only to the Fraser, but also to the Columbia and Peace River systems. All three have their headwaters in British Columbia and it is interesting to note that, because of their geographic positions, each watershed presents certain unique characteristics or conditions. Thus the Columbia is an international stream, the Peace an interprovincial stream, while the Fraser might be termed the "Ole Man River" of British Columbia for, with the exception of one small southern tributary, its watershed is wholly contained within the Province.

In terms of average annual runoff the Fraser at Vancouver with 80 million acre feet* exceeds the Columbia at the international border and is over three times the Peace discharge as measured at Hudson Hope.

Internationally the average annual discharge of the Fraser at Hope of nearly 68 million acre feet* is about equal to that of the Nile River at the famous Aswan damsite.

Salient Features

Physical Features: A great trough from one to three miles wide, known as the Rocky Mountain Trench, extends northwesterly through the eastern portion of the Province separating the Columbia Mountains to the west from the Rocky Mountains to the east. Within this trench, proceeding from the international border northwesterly, can be found the headwaters of the Columbia, Fraser, Peace and Liard Rivers.

The Fraser itself originates near Beacon Peak about 30 miles south west of Jasper and in its first 70 miles drops some 4,000 ft. meeting the Rocky Mountain Trench at Tete Jaune at an elevation of 2,400. For the next 250 miles it pursues a meandering course within the trench, emerging from it and turning southward near Prince George. This portion of the river is a rather sluggish stream with average gradients between 1/5000 to 1/10,000.

In its course southward through the rising Interior Plateau country the river valley deepens from a few hundred feet at Prince George to about 5,000 ft. near Lytton. In the next 70 miles the Fraser River cuts through the Coast Range Mountains, emerges at Hope and turns westward to flow through the alluvial valley of the Lower Mainland. It finally discharges at Vancouver into the Pacific Ocean.

From its source to its mouth the total length of the river is 850 miles. Its drainage basin comprises some 84,600 sq. miles or almost one quarter of the total area of the Province. This does not include the Aluminum Company of Canada's Upper Nechako Watershed of 5,400 sq. miles since most of its inflow is now diverted westward through the Coast Range to the Kemano power house.

Other main tributaries of the Fraser from the west include the lower Nechako, Chilcotin, Bridge and

* Annual discharge does not include 4.5 million acre feet of Upper Nechako River Basin inflow, a large portion of which is now diverted westward through the Aluminum Company of Canada plant at Kemano.

Lillooet Rivers. While the Upper Fraser dominates the drainage from the eastern mountains, its inflow is also augmented by the Quesnel and Thompson Rivers.

Climate: It is not surprising that such an extensive watershed contains no fewer than 5 distinct climatic regions* varying from alpine sub-arctic in the north to alpine maritime in the south. The precipitation and the temperatures which occur in these various regions are the most pertinent factors to be considered in a study of hydrology of the watershed, and climatic considerations will be limited to these two items.

Precipitation: The moist air of the Pacific Ocean in passing eastward over the Coast Range Mountains into the Fraser River watershed is subject to varying temperature and pressure conditions. The greatest precipitation occurs in the south west portion of the basin, where small drainage areas adjacent to the Lower Fraser Valley may receive over 100 in. per year. Further north much of the moisture falls on the west side of the Coast Mountains but nevertheless the head-waters of the Nechako, Chilcotin and Bridge receive precipitation averaging over 60 in. per year.

At the same time the Coast Mountains do create an effective rain shadow over the Interior Plateau, and in this central region around Ashcroft and Kamloops an extremely low precipitation of only 7 to 9 in. is experienced.

In contrast, the precipitation to the east rises from 40 to 60 in. along the Easterly Mountain slopes. It is from this region, which includes the Upper Fraser and Thompson River systems, that a major portion of the runoff occurs.

It is of great significance that about two thirds of the precipitation occurs as snow which accumulates at the higher elevations during the winter months.

Temperature: Spring temperatures particularly in the main snowfields located at elevations of 4,000 to 7,000 ft. play a very predominant role in the hydrology of the basin. Generally during the winter months temperatures well below freezing are experienced throughout the interior watershed.

Under normal conditions the spring thaw begins in the south and moves northward and upward into the main snow regions. However, the change from winter to summer can be very rapid as was noted in the record

* Climatic areas listed in descending order of magnitude are Dry Continental, Humid Continental, Alpine Humid Continental, Alpine Maritime, and Alpine Subarctic.

Fig. 1. Potential sites included in System 3.

flood year of 1948 when warm moist air from the Pacific Ocean invaded and occupied the snow fields for many days, thus producing a high and sustained period of melting.

Hydrology

The hydrology of the Fraser River watershed is typical of a predominantly snow-fed basin which experiences one main flood each year. In early spring the valley snow (generally below the 3,000 ft. elevation) melts and runs off. This may cause minor local flooding, but the discharge at Hope does not show any appreciable increase until above freezing temperatures occur at the 5,000 ft. elevation. In fact, continuous warm weather during the latter part of May and the first few weeks of June can produce a rapid rise of about 1 ft. a day on the Mission gauge some 60 miles downstream from Hope.

It has been found that 85% of the annual runoff occurs in the seven month period of March through to September, and on many of the tributary watersheds melting snow supplies this discharge entirely.

Historic Floods: Although accurate hydrometric information on the Fraser at Hope only goes back to 1912, it has been established from old water level records that the 1894 freshet was the greatest known flood. In those early days the Lower Fraser Valley was very thinly populated and damage was not too extensive. However, as more and more people occupied the flood plain of the river they were forced to protect themselves from the high water by the construction of dykes. At first these improvements were by individual effort only, but eventually private dykes were joined up and incorporated into districts. Today there are 31 dyking districts along the river between Agassiz and Vancouver in which a total of 223 miles of dykes protect some 160,000 acres from the river and in some instances the sea.

Flood of 1948: In some respects the spring of 1948 was similar to the record high water year of 1894. Barkerville in the north central portion of the watershed at elevation 4,180 (about 400 ft. above the mean watershed elevation) was experiencing mean daily temperatures about 5° above freezing during the first week of May. By the 10th of the month the temperature had started to rise and by the 29th reached a peak of 65° F. and remained very near this maximum for about 3 weeks. This rapid invasion of the snowfield by warm air produced a steadily increasing runoff which funnelled past Hope causing a rise of about one foot a day on the Mission gauge.

In most years during this critical period there are lapses in the temperature, which reduces the snow melt rate. This in turn is reflected through falling discharges at Hope several days later. However, the 1948 flood was the exception to the usual condition for it never cooled off.

The maximum daily temperature of 65° at Barkerville was followed two days later by a peak discharge of 536,000 c.f.s. at Hope. However, for the next 10 days the water levels on the downstream Mission gauge remained almost constant and in fact rose to a maximum height of 24.73 ft. on June 10, 1948.

Other regions along the Fraser and its tributaries including Kamploops, Prince George, and Quesnel had also suffered and in fact throughout the Province the rivers had gone on the rampage. Nevertheless by far the greatest damage had been wrought in the lower Fraser Valley where 55,000 acres, or almost ⅓ of the dyked area, had been flooded. In fact, out of a total of some $20 million expended by the Federal and Provincial Governments throughout the Province, $17.5 million was used in the lower Fraser Valley with about one half of this amount going to dyke reconstruction.

The latter work was carried out by the Fraser Valley Dyking Board, made up of Federal and Provincial agencies. Their all-out effort in reconstructing over 200 miles of dykes by early 1950 was a tremendous undertaking and it was fortunate indeed that this work was completed in time to withstand the 1950 spring freshet which rose within half a foot of the record 1948 level at Mission.

Multipurpose Investigations

While the immediate remedy of limited dyke protection was going ahead the two governments were beginning to realize the need for a comprehensive water resource plan of the whole watershed.

By the end of 1948 the Dominion-Provincial Board, Fraser River Basin had been formed with representation from nine government agencies. Its terms of reference were broad, but essentially it was charged with preparing a plan of multiple purpose development of the whole watershed with emphasis on flood control. In its early days the Board concentrated on collecting basic data and mapping many miles of river valley.

New terms of reference in April 1955 reduced the Board to a membership of six and changed its name to the Fraser River Board. The new Board picked up the work of its predecessor and a year later produced an interim report on flood control.

In March 1956 its membership was further reduced to four, but through working groups and additional Board staff its efforts were intensified and a second publication entitled *Preliminary Report on Flood Control and Hydro-electric Power in the Fraser River Basin* was presented to the two Governments. Much of the information already quoted and some of that which follows has been taken from this report.

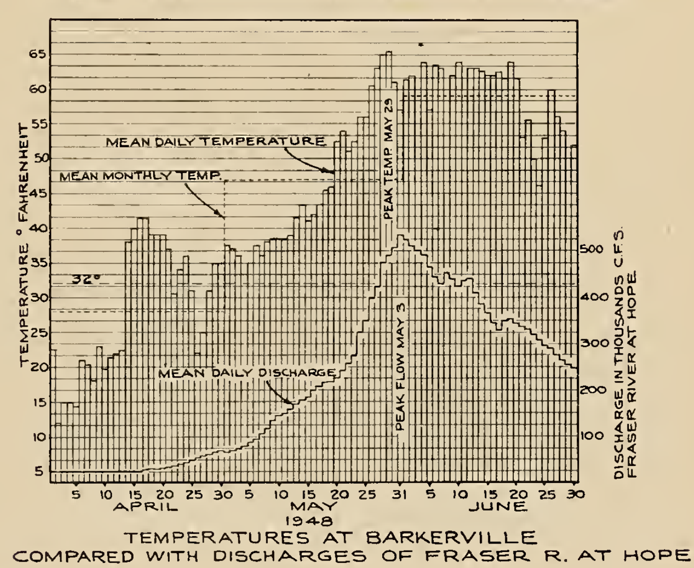
Flood Control: Early attention was given by the Board to the determination of the design flood and the best method of protecting the lower mainland from discharges of this nature.

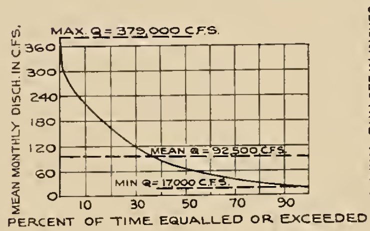
The basis for this study was the hydrometric records at Hope, available from 1912, and downstream river levels at Mission which are partially effected by tides. Finally, with the design flood hydrograph determined, upstream discharges were computed to show the expected contribution from each portion of the watershed.

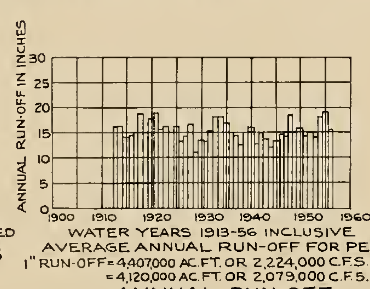
Prior to arriving at the design flood a simplified plot was made of the annual spring hydrographs at Hope for discharges above 250,000 c.f.s. This base flow, equivalent to about 19 ft. at Mission, was chosen because it is approximately bankful capacity and it is at this discharge that the dykes start to take effect.

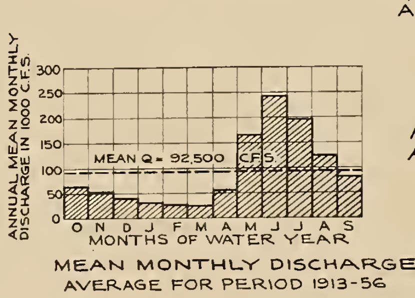
In examining the various hydrographs, the 1948 curve, with its peak discharge of 536,000 c.f.s. and its total volume above the base flow of 5.4 million c.f.s.-days (for May, June and July) was found to be the greatest recorded flood both in magnitude and volume. However, from old historic high water marks it was evident that 1894 crest had exceeded

Fig. 2. Barkerville Temperatures and Hope Discharges









From Fraser River Board Preliminary Report 1958.

this record and probably reached a maximum discharge of 600,000 c.f.s. although little was known about its volume.

Essentially, then, in arriving at the design flood hydrograph an enveloping curve simplified to the form of a triangle was constructed in which the altitude was made equal to 600,000 c.f.s. The rising stage was made somewhat steeper than the 1948 hydrograph and, while the falling stage did not enclose the less critical and long drawn out 1920 and 1933 flood hydrographs, it presents a somewhat flatter gradient than either the record 1948 or 1950 freshets.

The Alcan diversion of some 5,400 sq. miles of the Upper Nechako watershed runoff resulted in the reduction of 24,000 c.f.s. in the peak discharge, so that the final design flood hydrograph parallels the higher curve reaching a maximum discharge of 576,000 c.f.s. The volume contained within this modified design flood hydrograph is 7.86 million c.f.s.-days above 250,000 c.f.s. extending over a base period of 48 days.

Part of this flood could, of course, be contained within the existing dyking system, and a maximum safe discharge curve which reached a peak of 375,000 c.f.s. equivalent to 23 ft. at Mission was superimposed on the flood hydrograph. The problem, then, was to control some 5.22 million c.f.s.-days of surplus water, the difference between the design flood hydrograph and the discharge the dykes could safely contain.

The Fraser River Board investigated a number of flood control methods and reported that an improved dyking system in combination with upstream flood retention reservoirs looked like a promising solution. Under this system, storage reservoirs located throughout the watershed would be drawn down during the fall and winter months in readiness for the spring flood. The river would then be so regulated that it did not exceed the maximum safe discharge capacity of the lower river channel.

Flood Control and Hydro-electric Power: It was immediately evident that flood control through improved dykes and upstream flood retention reservoirs would be an expensive undertaking, roughly estimated in the neighborhood of $150 million. However, the obvious answer in part was to use the stored water for the production of electrical energy.

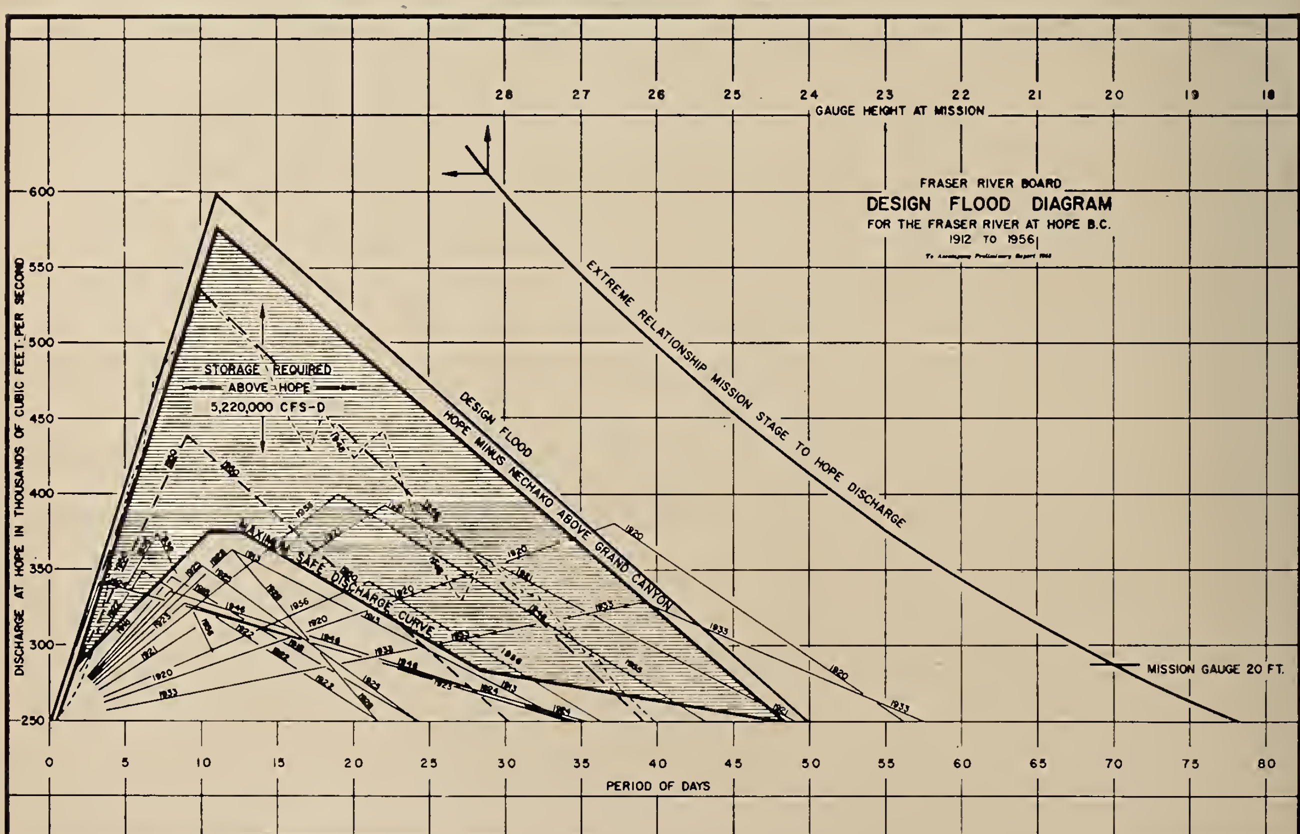
Thus flood control and hydro-electric power were the basis of the Board's preliminary report completed in 1958. It offers a choice between systems any one of which would, in combination with flood control, provide 5 million k.w. of firm capacity, or about double the existing Provincial hydro-electric facilities. On the basis of the value of the electrical energy alone and not including flood control benefits such a system would pay for itself. Very roughly the cost of any of the three systems would amount to $2 billion from which an annual wholesale return of $300 million might be realized from the sale of electrical energy.

Effects on Fisheries: However, the preliminary report points out that such a system of storage and power dams on the main Fraser and such tributaries as the Thompson and Quesnel could destroy a large portion of the salmon fishery resource which has become famous throughout the world for both its quality and quantity.

The 1957 wholesale value of the Fraser River salmon industry has been placed at $34.5 million of which $21 million was collected by Canadian fishermen while the remaining $13.5 million went to their American counterparts.

Much has been said about the possibilities of passing the migrating fish upstream over dams or the fingerlings downstream without damage or delay; but even where fairly elaborate facilities do exist in other parts of the world they are in many instances of limited capacity and often of doubtful value. In the case of the Fraser at the proposed Moran damsite it is estimated that maximum upstream migration could reach 750,000 fish per day. This mass of fish or a large portion of it would have to be lifted several hundred feet depending upon

Fig. 3. Design Flood Diagram.



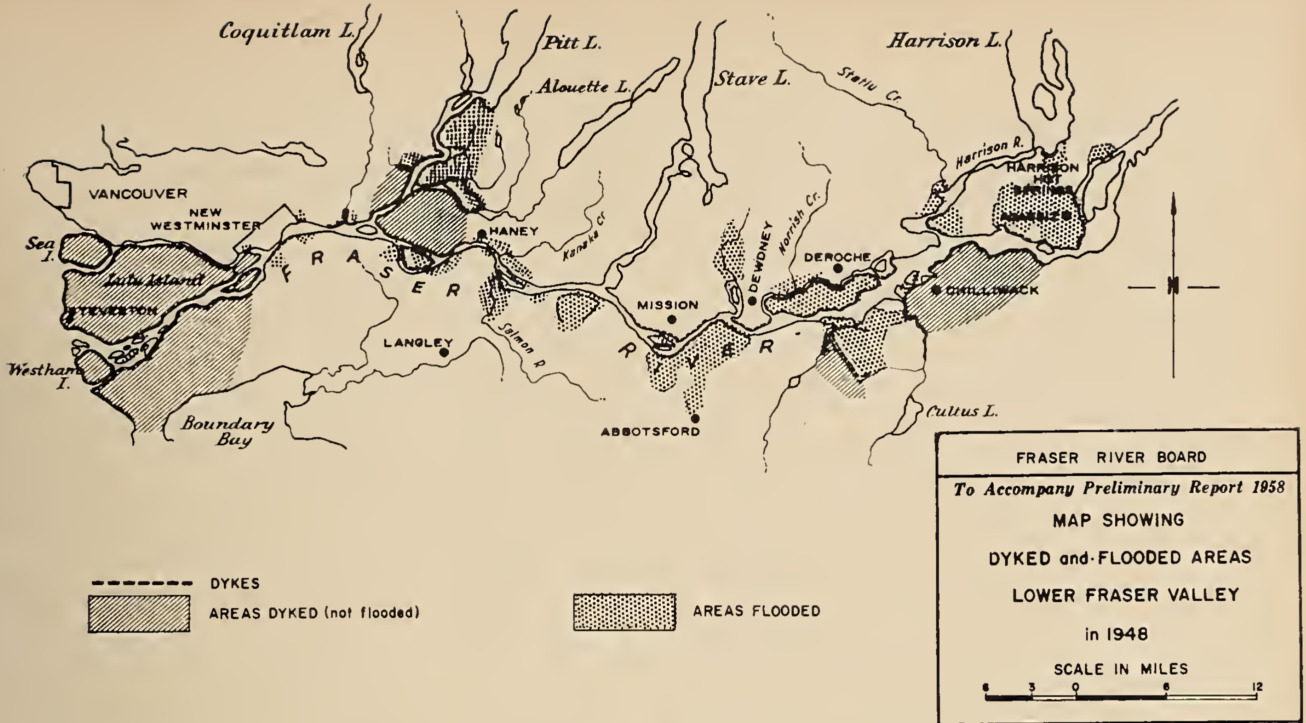


Fig. 4. Dyked and Flooded Areas Lower Fraser Valley.

the height of dam chosen.

At present there is no fish structure approaching this magnitude or capacity in operation. Other factors present themselves such as changing water temperatures, flooded spawning beds, etc. which are detrimental to fish propagation. These conditions and a number of others which would result from flood control and hydro-electric operations are receiving the attention of the fishery experts today both in the field and in the research laboratory.

Partial Development: The Board in recognition of this major problem and also the need for an early solution to flooding came up with three partial developments of the major systems which would:—

1. provide flood control to non-damaging levels in the Lower Fraser Valley;
2. form an integral part of a comprehensive plan for the basin in which all economical power sites would be fully developed;
3. be compatible with maintaining anadromous fish runs; and
4. be economically self-supporting through power production.

System A which is a partial development of System 3 probably approaches most closely the four objectives. Very briefly, it consists of five dams on the Clearwater, three on the Cariboo, one on the McGregor, one on the Upper Fraser east of Prince George and one on Stuart Lake. These in themselves would generate only about 1/7th of the total energy that would be realized from the full development of System 3. Nevertheless it would be an appreciable addition to the installed hydro-electric capacity within the Province. The return from the energy sales would about balance the carrying charges plus operating costs based on a capital cost of $521 million. Again, the benefit-to-cost ratio improves when such advantages as flood control are considered.

A modification of System A would require that the dykes be brought up to the original standards that existed at the time of their completion in 1950, thus eliminating the need for the Stuart Lake dam. The estimated cost of this improvement has been placed at $4.5 million.

Thus out of the Fraser River Board's preliminary report of 1958 has come a tentative plan for flood control in combination with the production of hydro-electric energy, with returns from the latter providing sufficient funds to cover the annual charges and operating costs.

It should be emphasized at this point that foundation conditions at the various damsites are for the most part unknown, and no doubt subsequent field explorations which are now under way will modify or change completely the preliminary plans that have been prepared.

Preliminary Investigation Problems

Within the limits of the interim and preliminary reports already outlined it might be instructive to describe briefly some of the problems met in investigating the Fraser River Basin to date.

Actually, in terms of multiple water use, only those dealing with flood control and hydro-electric power and their effects on the fishery industry have received detailed attention. This points up the difficulty of attempting to cover the broad field of water resource use in relatively undeveloped watersheds such as the Fraser.

For this reason the approach has been to plan on the basis of one or two of the more critical uses and then to modify the system as other considerations are introduced. In this respect, the interim report dealing with flood control through upstream retention reservoirs was modified by the introduction of hydro-electric power facilities. Economic analysis in turn pointed up the most efficient grouping and from this, particular developments were selected which provided the four main objectives.

The continuing broadening scope of the investigations brought with them demands for more and better information on a variety of subjects some of which are described briefly in the following pages.

The lack of basic data in meteorology, hydrology and topography and other physical phenomena is probably the most common complaint of engineers concerned with water resource investigations and the Fraser River Basin is no exception.

While the physical conditions such as topography and geology can be obtained as rapidly as funds will permit, it is not possible to suddenly acquire some 10 to 15 years of climatic and hydrologic data in areas where such observations have not been made.

Generally in a river basin at least 10 yr. of continuous temperature, precipitation and stream flow records are considered desirable for water resource studies. For this reason an early appreciation of the meteorological and hydrological requirements of a basin should be carried out followed by the establishment of stations in critical areas where such information is lacking.

Usually it is not posible to wait until all the hydrological and meteorological stations have "come of age" before preparing any reports and probably such a procedure would not be desirable. In fact, the early interpretation of existing data into report form will, in itself, stimulate group thinking and possibly point up errors or gaps in the existing program.

Meteorolgy: Ideally, meteorological data within the Fraser River Basin should reflect weather conditions as they occur in the various sub-drainage areas. Moreover, this representation in any particular region should provide climatic information at various altitudes extending from the valley bottoms up to the higher elevation snow fields.

However, such information can only be collected where there are observers to record it or at least to service self-recording instruments at frequent intervals. For the most part the settled areas of the Fraser are within the valleys below the 3,000 ft. elevation. It is not surprising therefore to find that only 16% of the meterological stations are above this altitude. In fact Barkerville, one of the key points in temperature studies, is the highest station in the watershed and at altitude 4,180 is only 400 ft. above the mean watershed elevation.

An indication of the lack of representative precipitation data is evident when the mean runoff at Hope of 16.2 in. is compared to an average precipitation of 31.5 in. obtained from an isohyet map. Obviously the latter should be much higher to produce the recorded runoff.

The lack of precipitation data for higher altitudes exists within all the main watersheds of British Columbia as well as the mountainous regions of the northwest States. It was one of the reasons for the establishment of snow survey courses first in the Columbia River Basin on the American side and eventually in 1935 in the Canadian portion of the same watershed.

The introduction of snow survey courses into the Fraser Basin was somewhat later, although today there are 25 snow courses ranging in elevation from 2,250 ft. at Blue River north of Kamloops to 6,300 ft. at Alberta Mountain near the headwaters of the North Thompson.

Near the end of each winter month starting in January, core samples are taken at marked points using aluminum tubes, and the snow moisture content is obtained. It has been found that as winter progresses the snow moisture content increases from the usual 10% figure up to 40 to 45% by the end of March which is generally considered the end of the snow accumulation period. On or about this date all main snow courses are sampled.

For predominantly snow fed rivers such as the Columbia and Fraser it has been found that the moisture content of the higher elevation snow fields about the end of March can be correlated with the total volume runoff which occurs during April to July or April to August, inclusive. Thus, where 10 or more years of snow moisture records are available to-

Fig. 5. Location of Sites under System A.

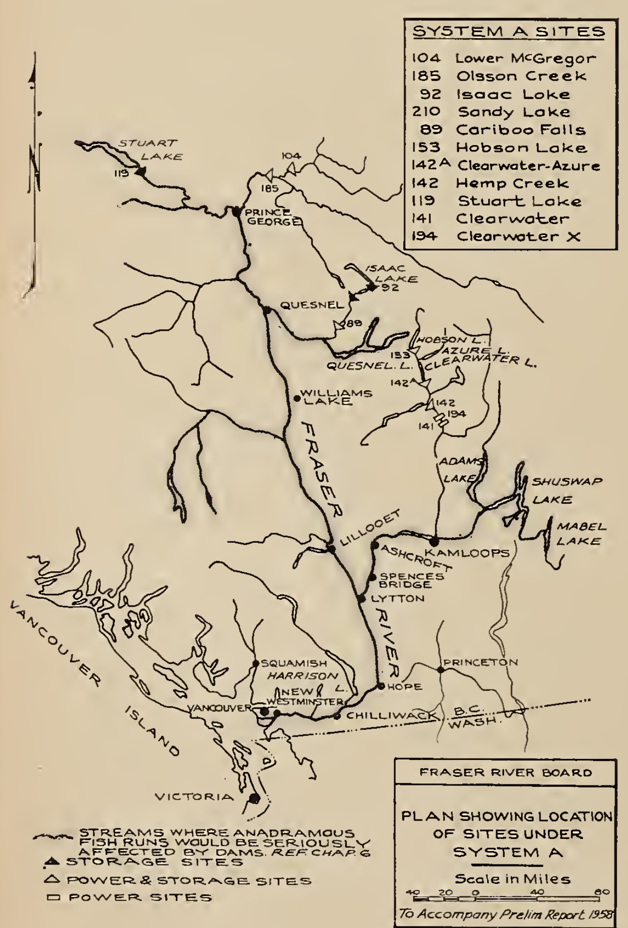

Fig. 6. Profile of Fraser River Tributaries Showing Potential Sites Included in System III.

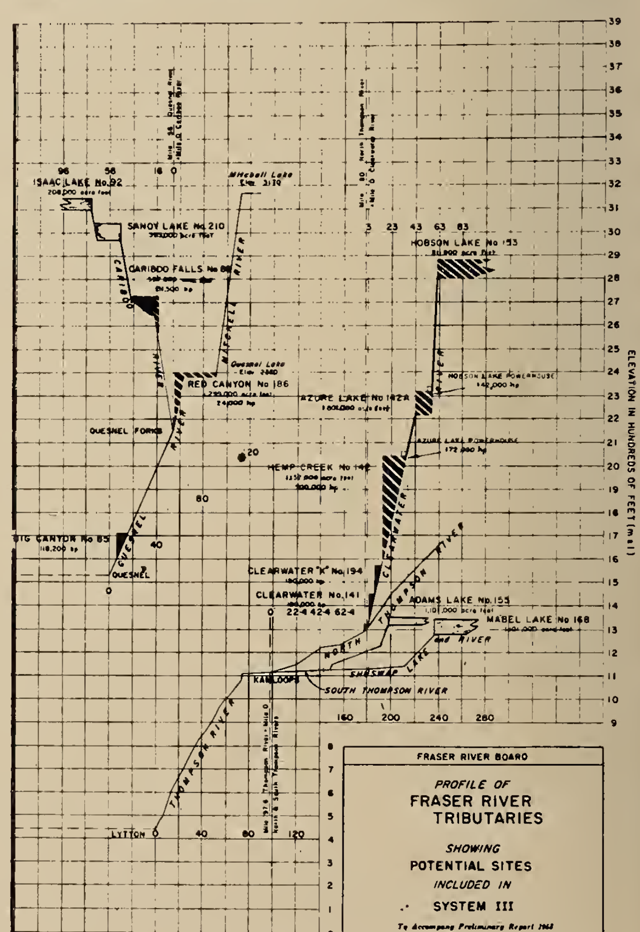

gether with the corresponding summer volume discharges of the watershed, it is possible from snow sampling to predict the following 4 or 5 months of runoff. However, while this procedure provides the probable volume of the summer hydrograph, no reliable method has yet been found to predict the peak flow.

Only 3 of the 25 snow courses within the Fraser River Basin have been sampled for more than 10 years, the desirable minimum period. Tentative correlations, therefore, exist until further records become available. Nevertheless, from some 20 or more years of Columbia River records in the Canadian portion of the watershed volume runoff predictions have proven extremely reliable.

The ultimate in flood forecasting would, of course, be the prediction of the peak flow and its probable time of occurrence. In other words, the shape of the flood hydrograph at various points throughout the watershed would be anticipated a number of days in advance.

This is actually done to a very limited extent now through the observations of rising stages upstream which are flood routed downstream allowing a prediction of the river levels a few days in advance.

However, a complete flood warning system would go beyond this by actually providing the expected inflow into the various upstream tributaries several days in advance.

While such a program would be desirable under existing conditions, it would become almost imperative if a system of flood control and power dams were built on the Fraser River.

Snow melt runoff computations require up-to-date information on a number of factors, the main ones being snow moisture content and existing and expected maximum and minimum temperatures in the various snow fields betwen elevations 4,000 and 7,000 ft. The relationship between degree-days above freezing and runoff would be the basis for the inflow calculations, probably modified by such factors as soil moisture conditions.

Unfortunately, daily snow field temperatures are not available because of the lack of higher meteorological stations in the watershed. It is possible that remote control stations may, in the future, transmit continuous temperature readings from snow courses and the meteorologist in turn will be able to make detailed forecasts of expected maximum and minimum temperatures at those higher elevations. This, together with similar information on snow moisture content, should provide the hydrologist with a basis for inflow predictions.

In the meantime, the most representative data available of the Fraser watershed snow field temperatures are those taken daily at Barkerville. Another promising source may be the free air temperature obtained at approximately 5,000 ft. by the Department of Transport radiosonde equipment at such stations as Prince George airport. It is possible that there may be a good correlation between these free air temperatures and those in nearby snow fields at about the same elevation although to date very little research has been done on this.

Hydrometric Data: Hydrometric stations which provide stream discharges and river and lake levels do not present as many problems in their location as do meteorological stations. However, in the sparsely settled northern portion of the watershed there are difficulties in obtaining observers.

Some of the key stations along the old railway belt such as the Fraser at Hope and the Thompson at Kamloops were established back in 1912, whereas the Upper Fraser stations, where one third of the 1948 flood originated, have only been operating since 1950. In fact, out of a total of 63 continuous gauging stations on the Fraser River today, about ⅓ have less than 10 years of record.

In many instances correlations had to be resorted to between newly established and long term stations in order that the watershed could be studied over a continuous 20 yr. period from September 1928 to August 1948.

Also in a number of the tributary watersheds, lake systems made up a substantial portion of the watershed and while outflows from these natural reservoirs had been recorded for a number of years no daily lake level readings were available to compute inflows.

Again, at many of the proposed damsites stage-discharge relationships had to be established to provide tail water curves for power analysis.

In one important study to check the 1894 peak discharge a correlation was carried out with the Columbia River at The Dalles where records were available back to 1858. It is interesting to note that the peaks of the two rivers frequently occur within a few days of each other, and, since the two watersheds have somewhat similar characteristics and both are predominantly snow fed streams, it might be expected that they would reflect parallel conditions.

The coefficient of correlation for the peak flows was found to be 0.72 and from the regression equation established, it was found that the 1894 flood of 1,240,000 c.f.s. recorded at The Dalles on the Columbia on June 6 was equivalent to 502,000 c.f.s. on the Fraser at Hope with possible extreme values varying between 389,000 c.f.s. and 615,000 c.f.s. Obviously the 600,000 actually chosen is very liberal according to this analysis.

Another difficulty arises in attempting to determine the probable frequency of the design flood. Its three variables, magnitude, volume and duration above 250,000 c.f.s. can be assigned re-occurrence intervals but the frequency of such a combination occurring is hard to establish.

Topographic Data: Early in the Board's history it was recognized that a major portion of the watershed was not adequately mapped and from 1949 onward an almost continuous program of air photo mapping was carried out. Today there are topographic map sheets available of all the reservoirs at scales varying between 1/6000 to 1/12000 on which either 20 or 40 ft. contours have been shown. In the case of damsite surveys the plotting scale was increased to 1/1200 to 1/2400 on which 10 ft. contours were drawn. Also through all navigable portions of the river including a number of canyon sites bathometric surveys have been carried out.

Mapping for preliminary investigation work requires early agreement by all interested parties as to the details needed for it is from this, particularly the contour interval, that the scale is determined.

It can be argued that topography which defines reservoir volumes need not be any more accurate than the hydrometric data available. On the other hand, where the mapping is used for the determination of flood damage, the re-location of communication lines, and benefit cost studies, much more detailed and accurate information may be desirable.

Erosion and Silting: In a Province such as British Columbia where the major portion of the population and lines of communication are within the valley bottoms, the people are very conscious of erosion and silting.

From a flood control and hydroelectric point of view it is also important, for heavy silt laden waters can reduce storage capacities within the reservoirs. Again fluctuating high water levels behind dams can cause silt banks to fail. Even today, with no artificial obstructions, slides do occur along the Fraser particularly in the interior plateau country. It is this sloughing during the flood period which creates what appears to be a

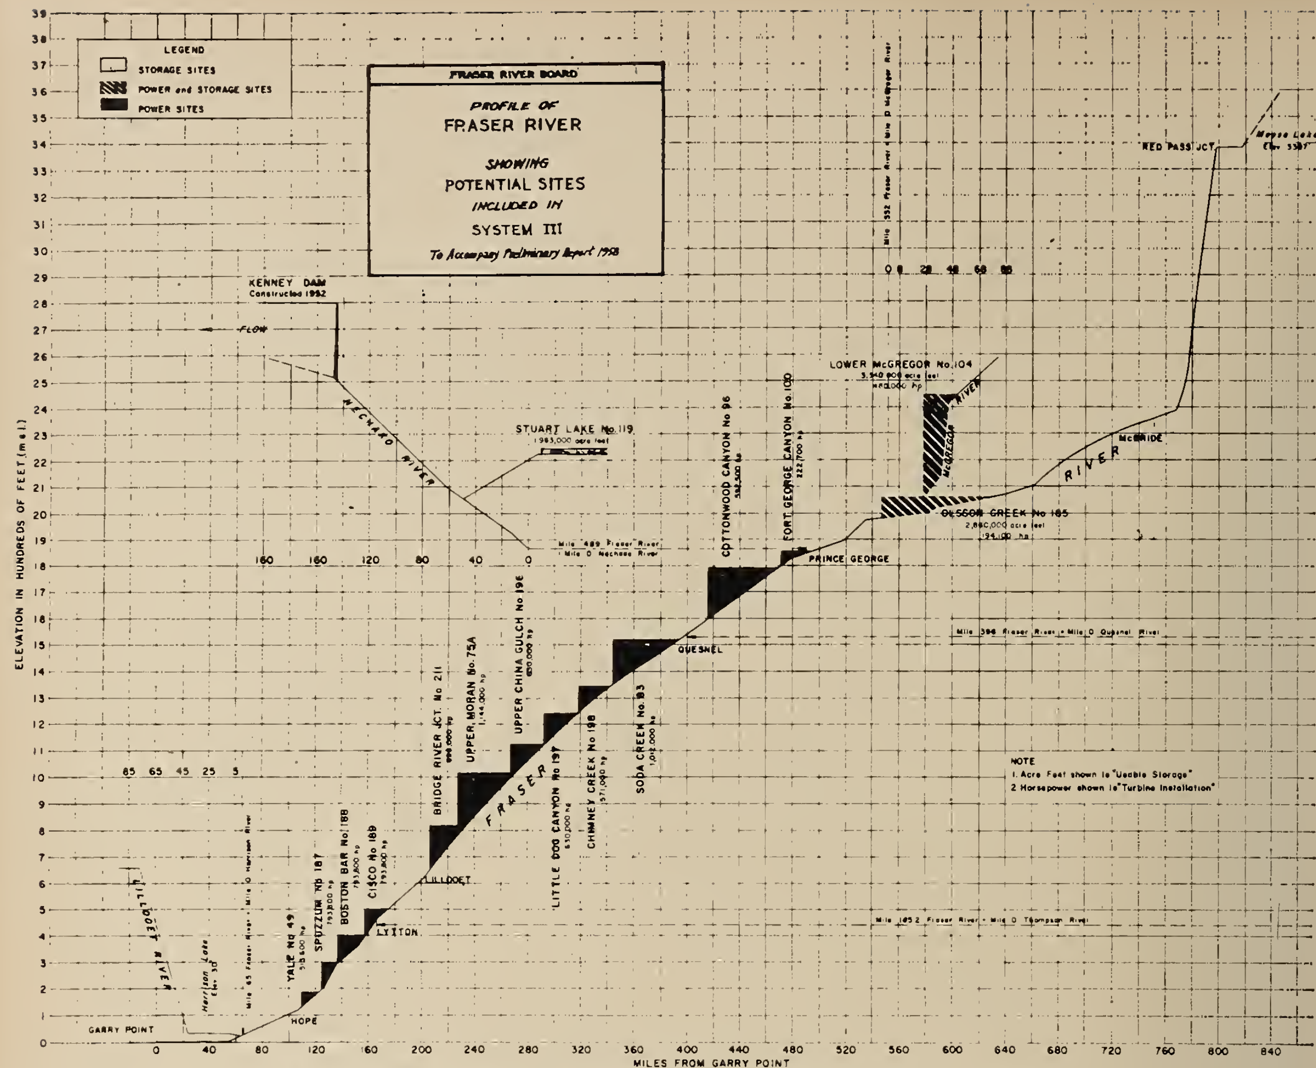

Fig. 7. Profile of Fraser River Showing Potential Sites Included in System III.

very silt laden water.

In order to arrive at a measure of load transported by the river a suspended sediment sampling program was carried out along the main stem of the Fraser during the period 1949 to 1952 using a P-46 point integrating sampler.

For the three years of record from 1950 to 1952, inclusive, it was found that a large proportion of the suspended sediment discharge at Hope occurs during the high flow months of May, June and July reaching a maximum value of 500 to 800 p.p.m. just before the peak occurs and dropping to a low of 20 to 50 p.p.m. during the fall and winter.

In terms of volume the annual average suspended sediment discharge at Hope for the three years of record is 10,600 acre ft. or 12.4 acre ft. per 100 sq. miles of drainage area. For comparison, the Colorado watershed carries about 10 times this load per sq. mile.

The suspended sediment concentration of the Thompson River on the other hand is only about 1/10 that of the Fraser due to the settling effects of Shuswap and Kamloops Lakes.

No attempt to date has been made to measure the bed load of the river although from regular soundings below Hope its movement shows up in the form of sand waves which appear to progress downstream with each freshet.

With this limited information it is rather difficult to predict just what effect a series of storage reservoirs upstream of Hope might have on the regime of the lower Fraser. No doubt the higher fall and winter flows would assist navigation. On the other hand it is at these medium flows that some of the greatest erosion occurs particularly along some of the dyked areas.

Dyking and Drainage: So far the problems discussed dealt with the natural physical conditions within the Fraser River watershed. However, as noted early in this paper, the lower valley is protected from flooding by a system of dykes.

These dykes afford protection to the heavily populated areas and while they were designed to retain the greatest known flood, this protection has been appreciably reduced due to aging and lack of maintenance.

Tributary drainage through the main dykes is handled by gravity flow through culverts equipped with flap gates while at highwater the inflow is pumped over the dykes.

While the spring flood can create critical conditions in the lowlands behind the dykes, a further and sometimes more serious threat can occur in the fall and winter when heavy rainstorms penetrate the lower valley resulting in as much as 12 in. of precipitation in a 3 to 4 day period. Generally pumping facilities to handle such inflows are not sufficient and local flooding occurs.

This condition would be further aggravated if increased channel capacity were realized through the raising of the dykes and this in itself is an argument for upstream storage. Thus, it would be better to stop the waters near their source rather than to attempt to control them in the Lower Fraser Valley.

E. G. Dunlop,
Chief Engineer–Rail Products, Canadian Car Company, Limited, Montreal.

Canada has led the world in many developments in aluminum in railway rolling stock; a significant one has been the world's first all-welded aluminum open hoppers brought about by the combined efforts of Canadian Car Company, Limited, Aluminium Laboratories Limited and The Roberval and Saguenay Railway Company. Thirty of these cars went into service in May 1957 at Arvida, Quebec and were an addition to 118 open hopper cars with aluminum bodies already in service. Although aluminum hopper cars have been used since 1931, these thirty resulted from many technical achievements in prototype building and testing car design, car shop techniques, alloy developments, welding developments and techniques, extensive shake-out tests and impact tests at collision speeds.

Introduction

THE WORLD'S FIRST welded all-aluminum open hopper cars went into service in May 1957 at Port Alfred, P.Q., carrying bauxite on the 20-mile haul to the Aluminum Company of Canada, Limited smelter at Arvida. Built for The Roberval and Saguenay Railway Company (R.&S.) by Canadian Car Company, Limited, Montreal, the 2300 cu. ft. capacity cars offer several technical advances in design and construction. They are eight tons lighter than steel cars and have a payload to deadload ratio of 5.5 to 1. Delivery of the thirty cars in the latest order (May 1957) brings to 148 the number of aluminum hopper cars being operated by the R. & S.

The R. & S. Fleet

The Roberval and Saguenay Railway Company own and operate 213 open hopper cars which can be separated into five categories:

a) Forty-six of the cars have been in service for over 25 years. They are steel cars of 50-ton capacity with 30° slope sheets and a light weight of 39,000 lb;

b) Ninety cars with aluminum bodies and steel underframes. These cars are of riveted construction with 30° slopes and a light weight of 36,000 lb. They were built between 1948 and 1951 and are a direct conversion from existing steel designs;

c) Nineteen of the cars were built in steel by the R.&S. since 1947. They have 40° slopes, have a capacity of 70 tons and a light weight of 48,000 lb. They are a new concept of car design and led to;

d) The R.&S. 1300 Series with a light weight of 36,600 lb. There are twenty-eight cars in this series with welded aluminum bodies, 40° slopes and steel underframes. They were the first welded aluminum open hopper cars ever built. These were the forerunners of;

e) The R.&S. 1400 Series with a light weight of 32,400 lb. There are thirty of these cars. They are all-aluminum with 40° slopes and are the first welded aluminum open hopper cars ever built with a welded aluminum underframe.

History

Early Riveted Designs — Hopper cars have been made with aluminum bodies since 1931, when the Aluminum Ore Company put ten into service in the United States. In the succeeding years several U.S. roads followed suit. By 1945 Pennsylvania, Texas & New Orleans and Baltimore & Ohio each had one car in service. In 1944 Burlington put an aluminum-sheathed hopper car into service, followed by Missouri Pacific with twenty-five aluminum-bodied cars and Montana with one aluminum body and underframe car. Later, Illinois Central and Chesapeake & Ohio each built five aluminum body cars, and Southern undertook a rebuilding program using aluminum. (See Table I).

Aluminum hopper cars made their first appearance in Canada in 1948 when The Eastern Car Company, Limited of Trenton, Nova Scotia, built thirty cars for The Roberval and Saguenay Railway Company. These hopper cars, numbered R.&S. 932 to 961, were a direct conversion from the steel A.A.R. Class HT 70-ton triple hopper car of 2775 cu. ft. capacity with 6 in. x 11 in. journal. (See Fig. 1). These open-bodied cars were made from Alcan 65S-T6 plate and extrusions joined with Alcan 55S-T6A rivets. The sides were 3/16 in. thick sheet and the slopes and hoppers were ¼ in. thick plate. In joining the side sheets, slope sheets and shapes, ⅜ in. diameter rivets were used. The centre sill, body bolsters and crossbearers were steel. The weight saved per car was 12,000 lb., compared to a standard steel car. This was obtained by employing 6500 lb of aluminum, resulting in a light weight of 36,000 lb and a load limit of 174,000 lb. To make these light cars suitable for interchange, they were equipped with Westinghouse "ABLC" brakes.

Fifty cars of the same type were purchased in May 1949 and were numbered R.&S. 1200 to 1249. In view of trouble caused by the "ABLC" brake mechanism becoming fouled with bauxite dust, these cars were equipped with straight "AB" brakes.

During the open season of navigation these and the above thirty cars are loaded and unloaded as much as three times every two days under a Hewitt-Robins Car Shake-Out. To resist the effect of the vibration, to carry the load of the shaker and to generally strengthen the side plate, additional 6 in. x 6 in. x ⅝ in. angles were riveted to the top of the cars directly over the diagonal braces at the cross ridges. With this modification the cars are to date performing satisfactorily.

In August 1951 ten more cars, numbered R.&S. 1250 to 1259, were placed in service. Except for minor modifications, these cars were similar to the previous cars. Early in 1952 the Canadian National Railways purchased five cars of this construction.

The New Concept—A new concept of car construction and a design especially suited to hauling and unloading bauxite was initiated by Mr. R. Cabana of The Roberval and Saguenay Railway Company. In 1947, using trucks and centre sills from cars whose bodies had been scrapped, two prototype steel cars were built. These triple hopper cars are 70-ton capacity with 6 in. x 11 in. journals. There are no side posts except for the bracing at the cross ridges, and a 40° slope rather than 30° was used on the slope sheets and hoppers. The bodies were built using 3/16 in. steel side and ¼ in. thick steel slope sheets. The side plates are about twice as strong as those used on a standard 70-ton steel triple hopper car and great care was taken to apply the side sheets in such a way as to give continuity from end to end of car.

With 40° slopes and no inside posts, the bauxite flows much faster from these cars than from 30° slope cars. At 2000 cu. ft. capacity, the cars are ideally suited to carrying bauxite which requires 1800 cu. ft. for a full axle loading of 210,000 lb, with a car weight of 48,000 lb. The density of bauxite is 90 lb per cubic foot.

By 1954 the R.&S. had built and operated sixteen such cars and were satisfied that the prototype cars were entirely satisfactory for their operations.

More cars were required and the car companies were requested to quote on steel and aluminum cars of this new design.

The Aluminum Company of Canada, Limited undertook to study this new design concept as it applied to aluminum. The latest known developments in aluminum alloys, design of shapes and economical fabricating practices were reviewed. A stress analysis was made and the studies indicated that this concept could be applied to construct a welded aluminum hopper car designed from first principles.

Welded Hopper Cars—In July 1955 the Canadian Car Company delivered to the R.&S. the first welded open-bodied aluminum hopper cars ever produced. The cars are known as the R.&S. 1300 Series. They are triple hopper cars of 2200 cu. ft. capacity with 6 in. x 11 in. journal. They are equipped with Westinghouse "7⅞ in. x 12 in. Empty and Load Fully Automatic Brakes". The weight saved was 11,400 lb, giving a light weight of 36,600 lb. Although 8000 lb of aluminum was used, which was more than in the previous ninety cars, the total dollar value of the aluminum was less. Thicker plate was used, but it was confined to one gauge. The only pressings were the hopper doors. Only five different shapes were used in the car, of these four were standard

TYPES: (a) Aluminum Sheathed
(b) Aluminum Body
(c) Aluminum Body and Underframe

Fig. 1. Inside View of 70-ton Open Hopper Car with Aluminum Body. 30 cars of this type were built in 1948, 50 in 1949 and 10 in 1951 for the R.&S.

shapes and only one, the extra heavy side plate (see Fig. 2), was especially designed for the car.

These cars proved very satisfactory in service, requiring no body maintenance. Extensive shake-out fatigue and impact tests at collision speeds revealed a minor weakness in the diagonal side braces which may never fail in service.

During the latter part of 1956 impact tests showed that a welded aluminum centre sill, under dynamic loads, meets the proposed design requirements of the Association of American Railroads (A.A.R.). The carbuilders then felt free to use a welded aluminum centre sill for new construction.

In April 1957 the Canadian Car Company delivered thirty of the first all-welded, all-aluminum open hopper cars with welded aluminum centre sills to the R.&S. These triple hopper cars, known as the R.&S. 1400 Series, are 2300 cu. ft. capacity with 6 in. x 11 in. journals. The bodies, with the exception of an increased cubic capacity and a modified diagonal side brace, are the same as the previous twenty-eight cars. The centre sill, body bolsters and crossbearers are of welded aluminum construction. The weight saved per car is 16,000 lb, giving a light weight of 32,400 lb and a load limit of 177,600 lb, or nearly 89 tons. 11,000 lb of aluminum was used per car.

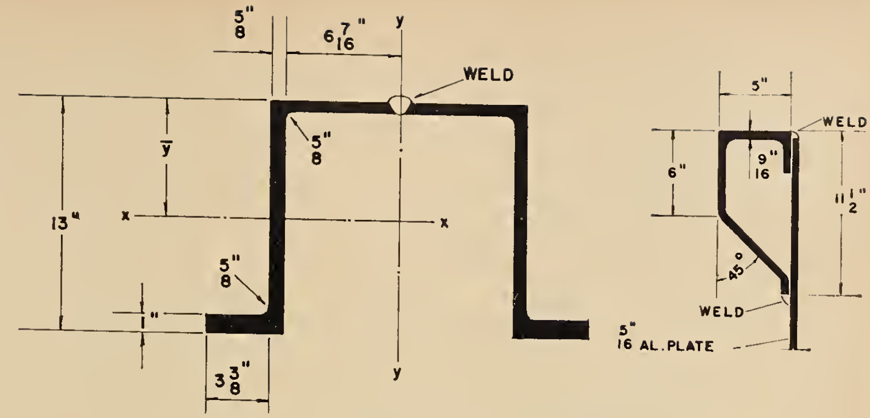

Fig. 2. Centre Sill and Side Plate Extrusion

A.A.R. Proposed Requirements (DV 400) For End Loading

Ultimate Load	1,000,000 lb.
Yield Load	500,000 lb.
Design Load	250,000 lb.

Mechanical Properties — Guaranteed Minimum

Tensile Strength	38,000 psi
Yield Strength	35,000 psi
Elongation	10 %

Properties of Sill Section

$A = 29.8$ in^2 $\quad Ix = 734$ in^4
$\bar{y} = 6.51$ in $\quad Iy = 1368$ in^4
weight = 34.9 lb./ft.

Side Plate Section
$A = 10.3$ in^2
Weight = 12.36 lb./ft.

Design Considerations

In designing the R.&S. 1400 Series of aluminum welded hopper cars, the following factors were given consideration:

(1) *Weight Distributions* — The estimated weight of the car was 32,500 lb (16.25 tons) with a load limit of 177,500 lb (88.75 tons). It was estimated that these weights would be distributed with half the load carried by the centre sill and the other half by the sides. The centre sill is supported by the two trucks and the two crossbearers. The crossbearers, by supporting the centre sill, transfer about 20% of the total load from the centre sill to the car sides. This increases the load carried by the car sides to about 70%, which load is transferred through the body bolsters to the trucks. The remaining 30% is transferred directly from the centre sill to the trucks.

(2) *Design of Car Sides* — The angle of repose for bauxite is 35° and its density is 90 lb per cu. ft. The horizontal pressure was calculated by the Rankine formula. The resulting horizontal pressure is distributed by membrane action to the surrounding framework.

The shearing force in the sides is distributed by means of diagonal tension to the top and bottom chords. As the car is frequently unloaded under a car shake-out, the two vertical stiffeners were reduced to the minimum to make the car more elastic than conventional cars. Several stiffeners would make the sides rigid and create several stress concentrations. With only two vertical stiffeners, the load carried by the top chord (side plate) and bottom chord (side sill) is much greater than the load carried by these members in conventional cars with vertical stiffeners at about 3 ft. 6 in. intervals.

The bottom chord is a 5 in. x 3½ in. aluminum angle. The top chord is a specially designed box section. (See Fig. 2).

(3) *Buffing Load*—The A.A.R. proposes that buffing loads of 1000, 500 and 250 kips shall be taken by the centre sill based on its ultimate, yield and working stresses. An aluminum centre sill was designed to this requirement. This sill, like the A.A.R. steel centre sill, is made by welding two Z sections. (See Fig. 2). In designing the centre sill, the eccentricity of the load was taken into account. The welded area, as well as the heat affected zone of the centre sill, was not included in the effective net area.

(4) *Shifting of the Lading Due to Buffing Load*—The shifting of lading, which invariably takes place with materials such as bauxite, imparts stresses to the body, the underframe and the connections between them. A flexible type of construction was adopted to absorb these stresses.

(5) *Unloading*—To unload the car efficiently with a shake-out machine, it was necessary to permit the components of the car to vibrate to a maximum amplitude without causing undue strain on the connections. The high amplitude, combined with 40° slope sheets, reduces the shake-out time and the car damage.

Materials

Corrosion Resistance—The successful performance of aluminum alloys in open hopper cars has been demonstrated on both practical and experimental grounds. From a practical point of view, there is ample proof of corrosion and abrasion resistance in the excellent performance of the 148 open aluminum hopper cars (Alcan 65S and Alcan B54S) now being used at Arvida by the R.&S. mainly to carry bauxite, but also in coal, coke and fluorspar service. Supplementing this is the experience of the Dominion Steel and Coal Corporation, which has been using aluminum in mine cars (Alcan 65S) in their coal mines since 1947; over 1200 aluminum mine cars are now being operated without corrosion problems. From an experimental point of view, convincing proof of aluminum's ability to withstand the ravages of corrosion has been standing in an Aluminum Company of America test yard near Pittsburgh since 1932. The proof is in the form of an aluminum hopper car body, which is still in good condition after having been standing in the weather, loaded with different grades of sulphur-bearing coal over all these years.

Aluminum Alloys—The aluminum alloys used on the ninety riveted hopper cars were Alcan 65S-T6 sheet and plate and Alcan 55S-T6A rivets. Alcan 65S-T6 sheet and plate have a typical yield strength of 40,000 psi. These alloys are suitable for riveted structures but as such cannot be fabricated as cheaply as steel.

A significant advance has been the development of Alcan B54S, in the fabrication of which new high-speed welding techniques can be employed. Furthermore, high-speed production jigs formerly used for steel production can be used in welding the new aluminum alloys simply by changing the welding units.

Tables II and III show the properties that are prevalent in the R.&S. 1300 Series.

TABLE II

Mechanical Properties of representative Samples of the 5/16 in. B54S-H11 Plate Used in R. and S. 1300 Series.

Sample No.	*Weight of Plate Represented by Sample*	*Tensile psi*	*Yield psi*	*Elongation % in 2"*

2	40,950	40,800	32,900	21.5
3	45,360	40,000	28,350	22.5
4	7,560	41,100	28,600	23.0

Fabricating Advances

Riveting—A great deal of valuable experience has been gained since 1931 in fabricating aluminum for open hopper cars and other rolling stock applications. Many deficiencies in fabricating techniques were realized and overcome. One of the greater difficulties has been the necessity to cold drive aluminum rivets in order that satisfactory strengths might be developed in the riveted joints. The rivets used in Canada are Alcan 55S-T6A, for which the minimum guaranteed shear strength prior to driving is 20,000 psi and the ultimate tensile strength is 30,000 psi. On a high-speed production line, which exists in freight car manufacturing shops, the cold driving of Alcan 55S-T6A rivets by hand is a burdensome task and results in slowing down the production line. Unfortunately, it is impractical to heat the rivets because controls of the required accuracy are too costly to install and operate in a car shop. Heating with equipment usually available causes the rivets to become annealed, with resultant loss of properties to 7,500 psi yield strength and 17,000 psi ultimate tensile strength, or brings about an embrittling effect due to incipient fusion which also gives properties greatly inferior to those in the annealed condition.

Fig. 3. A mammoth jig which, with automatic welding equipment, is used to weld the aluminum side sheets to the aluminum side plate and side sills.

This problem has been overcome by the introduction of welding or by using a combined welding and riveting procedure.

Aluminum to aluminum structural joints are usually fabricated by welding. In those cases where a riveted joint is absolutely necessary, aluminum rivets up to ⅝ in. diameter are driven cold by hand using a low pan driven point, or if rivet diameter is above ⅝ in. they are usually driven by machine using cone points. If rivets above ⅝ in. diameter must be driven by hand, then hot driven steel rivets are used and these are later suitably primed and painted.

Aluminum to steel riveted joints are fabricated with hot driven steel rivets. The aluminum faying surfaces are primed with zinc chromate, the steel surface with a non-lead bearing primer and the joint insulated with a layer of car cement. The steel rivets are not treated prior to driving but are primed and painted after fabrication.

Other fabricating practices such as punching, shearing and drilling, are carried out according to well established practices and have not presented any difficulties.

Welding — Automatic aluminum welding was used for the first time in car construction when the R.&S. 1300 Series of open hopper cars were built. It was accomplished by a thorough study of aluminum, its weldability, modern welding equipment and existing jigs.

The car sides were designed to permit a maximum use of this high-speed technique. One Model "C" Aircomatic Head mounted on an Airco Welding Head Positioner and a Lincoln 600 amp D.C. Welder were fitted on the jigs. The side sheets made up of eight separate pieces were welded on one jig. The top and bottom structural members were welded to the sides on another jig. (See Fig. 3).

Other jigs and fixtures were built for manual welding using eight Sigma Welders SWM-2 Series 5 and eight A. O. Smith D.C. Rectifiers 400 amp.

The result was an entirely satisfactory car economically manufactured with the best carbuilding practices.

Building the R. & S. 1400 Series

The same equipment and techniques used in welding the R.&S. 1300 Series were used for the R.&S. 1400 Series. The structure was divided into the following sub-assemblies: (See Fig. 4.)

1. Centre sills
2. Body bolsters
3. Slope sheets
4. Hoppers
5. Sides
6. Crossbearers and transverse apex sheets
7. End framing

These sub-assemblies were fitted together by riveting and the joints completed by IMA welding.

1. *Centre Sills*—To weld the sill, an hydraulic jig used to weld steel centre sills automatically was equipped with Aircomatic automatic welding equipment. Alcan 56S electrode wire of 3/32 in. diameter was used. Two 400 amp Westinghouse rectifiers were used in parallel as the power source.

The following procedure was used:

1st pass—450 amp, arc travel speed 34 in. per min.

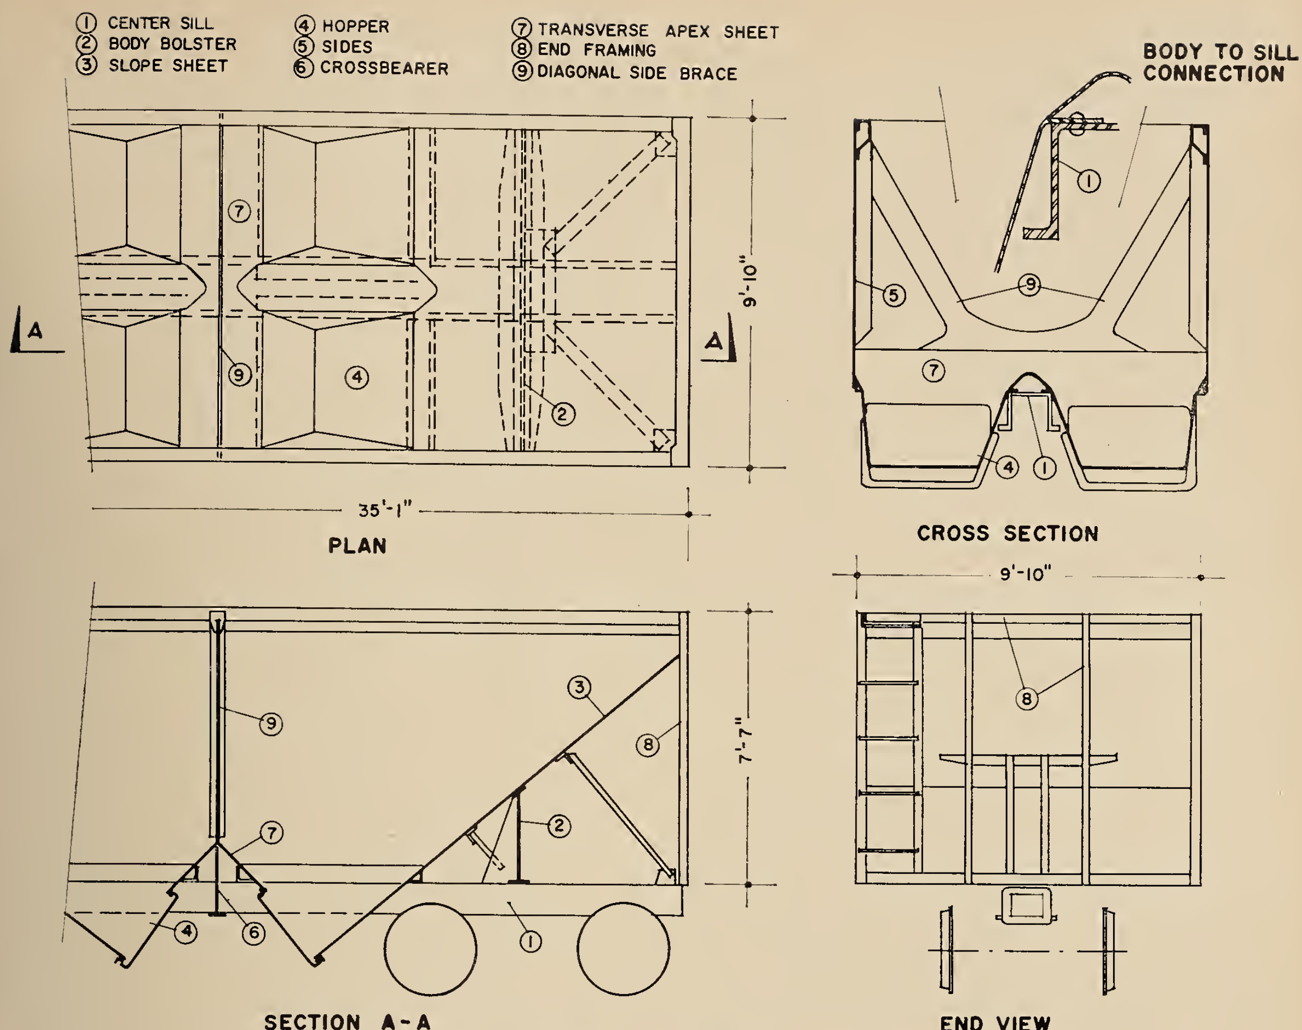

Fig. 4. R & S 1400 Series Hopper Car — General Arrangement

2nd pass—420 amp, arc travel speed 34 in. per min.

2. *Body Bolsters*—The body bolsters and crossbearers which included the transverse apex sheets were designed with vertical side flange plates butt welded to the webs so as to provide a riveted connection to the side sheet which would be independent of the variation in location between these members and the side posts. The material used in these members consisted of flat rectangular aluminum plates, some having a single V-die bend, IMA hand welded into a unit in a simple jig fixture.

3. *Slope Sheets*—Slope sheets consisted of large flat rectangular aluminum plates automatically butt welded into a unit, extending from the hoppers to the end plate. The connection between the slope sheets and the side sheets consisted of a simple T-butt welded erection joint, thus affording a large margin of variation with no additional difficulty in fitting and erection.

4. *Hoppers* — The hoppers were designed to match a standard cast steel Wine door frame, and to provide a 40° slope on the hopper bottom sheet. The flat aluminum hopper bottom sheet was butt-welded to the hopper side sheets in a small jig fixture. The hopper sub-assembly was completed by riveting the door frame to the weldment. The hopper side sheets consisted of triangular plates bent outwards to form a top flange for riveting to the centre and side sills. This provided adequate shear attachment of the hoppers to resist impact loads, without imposing a local high bending moment on the centre sill.

5. *Sides*—The side sheets consisting of eight 5/16 in. Alcan B54S-H11 rectangular aluminum plates was automatically welded together to form a continuous skin. A square butt

B54S-H11	38,000	19,000	12	43,000-42,000	31,000-25,000	20-23	40,000	20,000	16	10,000	10,000

(i) All welds in Alcan 65S-T6 in this hopper car are especially designed so that the full working stress of 17,500 psi can be used.

joint with 1/16 in. gap was employed. Welds were made automatically using 1/16 in. diam Alcan 56S welding wire. The eight plates were joined on one side, then turned over and welded from the other side for complete penetration. The current used was 300 amp, the voltage 30 and the welding speed was 35 in. per min.

The side sheet was in turn jig clamped to the side plate and the side sill for automatic welding. (See Fig. 3). The current used was 350 amp, the voltage 32 and the welding speed 36 in. per min.

The two side posts were welded by hand to the side sheet and side plate, however at the bottom these posts tapered away and were terminated at a point approximately 2 in. above the intersection of the crossbearer web. From this point downward to the side sill the side sheet was reinforced by welding a 7/16 in. triangular flat plate. This feature made it unnecessary to have an exact alignment between the side posts and the crossbearers during erection. It also eliminated the usual rigid connection between these members.

The crossbearer assemblies were jigged and welded by hand, as were the apex sheets and end framing.

Final Assembly—The erection of the car body was performed in the following sequence. The centre sill was clamped in position on a simple underframe jig and the body bolsters, crossbearers, end frames and other cross members were located in position on the sill and riveted thereto. This was followed by the application of the assembled slope sheets, which were riveted to the body bolsters and to a bottom cross member and clamped and welded to the top of the end frames. This arrangement provided the necessary flexibility, since a variation in distance between the cross members would only result in a slight change in the angle of the slope sheet. The structure was then ready for application of the hoppers, which were riveted in place to the centre sill, bottom of slope sheets and transverse apex sheets and then IMA hand-welded to complete the connection. On the final major assembly, the sides were hoisted into position by cranes and then bolted and riveted to the ends of the cross members. This was followed by clamping the side sheets, so as to bear tight against the edges of the slope sheets and then proceed to weld the full length of the side connection.

Testing

The R.&S. 1300 Series of cars was the first attempt at designing and building welded aluminum hopper car bodies with steel underframes. After these cars were produced, an aluminum centre sill, designed to meet the published requirements of the A.A.R., was produced. (See Fig. 2). Sixteen welded aluminum covered hopper cars for alumina service in Jamaica were built in early 1956 using this welded aluminum centre sill.

To prove the soundness of the design of the R.&S. 1300 Series and of the welded aluminum centre sill, a series of shake-out and impact tests was carried out. As a result, the R.&S. cars of the 1400 Series are equipped with essentially the same bodies as the R.&S. cars of the 1300 Series and have welded aluminum underframes.

Shake-Out Fatigue Tests — R.&S. car No. 1304 was taken out of service for shake-out fatigue testing.

A 6-ton Hewitt-Robbins car shake-out was operated at full capacity on the empty aluminum car body weighing 4 tons (excluding the steel bolsters, crossbearers and centre sill, the weight of which was 4 tons). In practice the aluminum welded cars are loaded to about 100 tons on rail and are unloaded using a similar shaker of lower capacity.

The Hewitt-Robbins car shake-out supplied an oscillating force of 3600 lb at a frequency of 24 cycles per second. Thirty-six SR-4 strain gauges were affixed to those locations on the car at which it was thought major stresses would occur. The strain indications were recorded using a Brush oscillograph.

The car shake-out was operated on the empty car for 20 sec. periods for the first 8 min., then at periods varying from 10 sec. to 10 min. for the remainder of the test. After each period the car was thoroughly inspected for damage.

The maximum alternating stress measured was about 8000 psi, it occurred both at the centre of the panel immediately under the car shake-out, and at the juncture of the top member where it joined the car sides, which was also immediately under the car shake-out. The large number of strain gauge readings provided sufficient information to give a relatively clear picture of the distribution of stresses and their frequencies throughout the car sides. Figs. 5 and 6 show the peak stresses that were recorded and their location.

A comparison of the performance of this aluminum car with that of welded steel hopper cars, tested under similar conditions, showed that aluminum performed as well or better than steel. As a result of these tests, the R.&S. 1400 Series was built with a heavier weld at the side sheet to side plate joints and with diagonal side braces designed to eliminate stress raisers.

Impact Tests—Seventy-five impact tests, forty-seven of which involved forces of 500,000 to 947,000 lb and speeds of 5 to 15.4 mph, showed that welded aluminum railway cars can be designed to stand up as well as steel cars under dynamic loading.

These tests were planned collisions between R.&S. car No. 1304 with a welded aluminum body and steel underframe and an all-aluminum covered hopper car with an A.A.R. type of welded aluminum centre sill.

The cars were loaded and during the tests the "on the rail" weight of the aluminum open hopper car was 200,000 lb and of the covered hopper car, 168,000 lb.

Electrical resistance SR-4 strain gauges, Type A5-1, were located on the covered hopper car to determine the stresses at various locations along the centre sill and in the body-to-sill connections, as well as to determine the distribution of force from the centre sill to car body. The impact force was determined by a dynamometer which replaced the coupling on the covered hopper car. The dynamometer was calibrated statically in compression in a Universal testing machine to determine the sensitivity. Deflection measurements were taken after each impact test to determine the amount of residual deformation in the cars. Piano wires were used as reference lines and deflections were obtained by measuring the distance between the wire and the car body, or centre sill.

The body of the car R.&S. 1304 suffered no significant damage throughout the seventy-five tests. At the conclusion of the tests there was visible deflection on the side sheets caused by the sand being forced into the front end of the car by the impacts, which were all in the same direction. When the sand was removed the deflection disappeared, which proved that it was elastic and not significant.

Two of the four diagonal side braces joining the car sides to the hopper peaks failed because of the shifting of the load during the tests. Two tie rods were used to counterbalance the forces exerted by the timber after the diagonal side braces had failed.

The tests were stopped after a force of 947,000 lb was reached because of the failure of the draft gears and steel draft lugs in the covered hopper car.

The data obtained have shown that the welded aluminum centre sill under dynamic loading meets the suggested requirements of the Association of American Railroads. Also, that the body and the body to centre sill connections on R.&S. car No. 1304 were adequate.

Economic Considerations—Operations of the R. & S.

In an attempt to evaluate the savings directly attributable to the use of aluminum cars, a careful analysis of its operating conditions has been made by the R.&S.

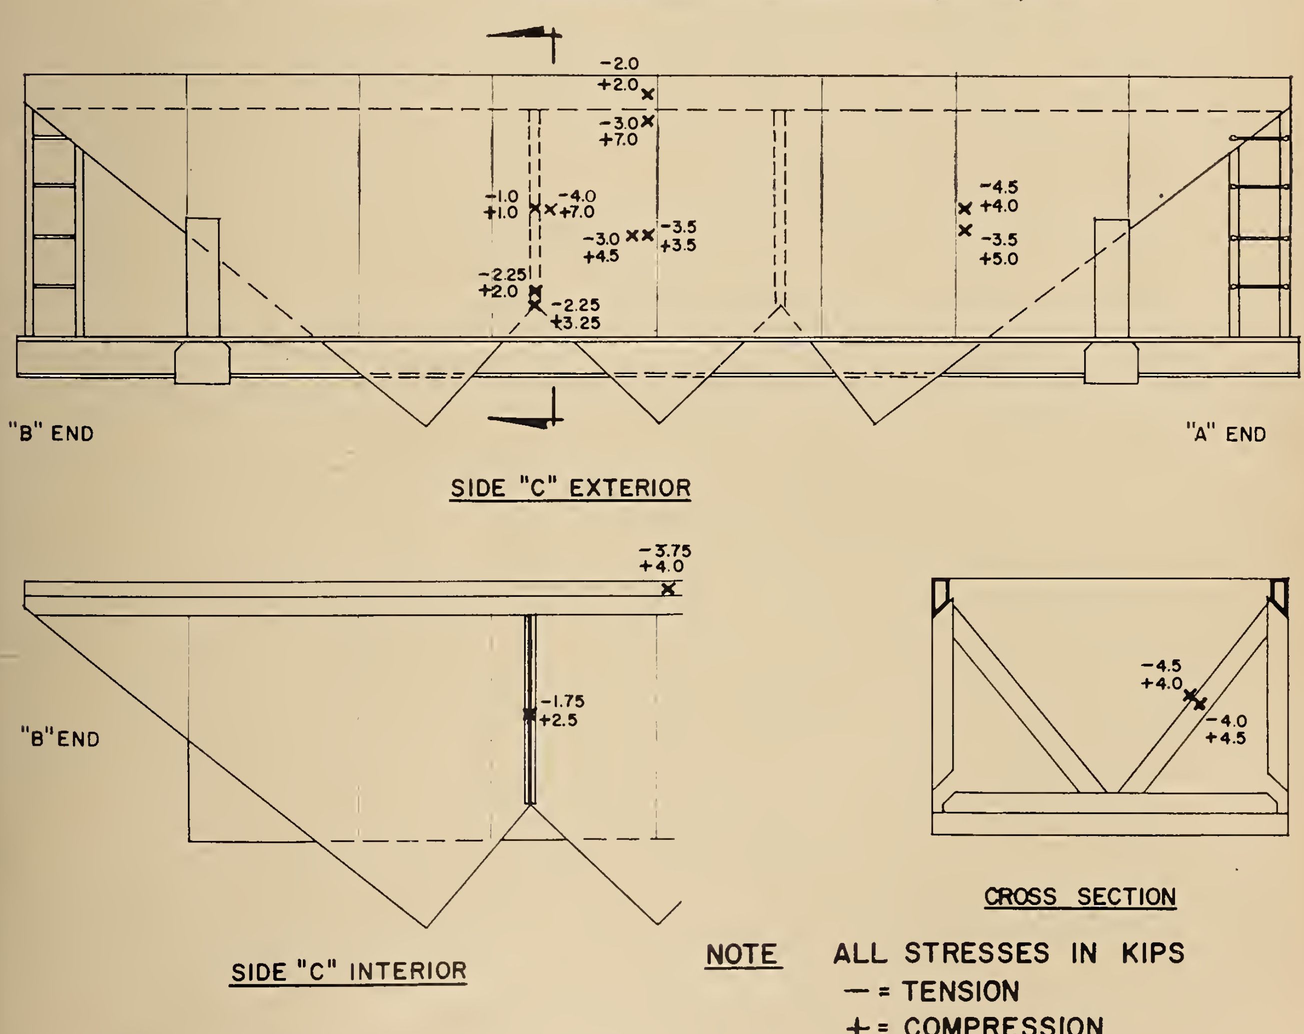
About 50% of the overall R.&S. operations and 90% of the open hopper car movement consist in moving bauxite from Port Alfred, P.Q., to the plant of the Aluminum Company of Canada, Limited at Arvida, P.Q.; the balance comprises carrying paper, coal and other commodities. In this operation, 213 open hopper cars are used, 148 of which are aluminum cars with 70-ton nominal capacity. Among the balance, which are steel cars, 19 are 70-ton cars with a light weight of 48,000 lb and 46 are 50-ton steel cars with a light weight of 39,000 lb.

The tonnage of bauxite moved on the R.&S. is in the order of 2 million tons per year. The bauxite is mined from large deposits in British Guiana and French West Africa, shipped to Port Alfred and unloaded at the dock either into R.&S. open hopper cars or large storage sheds.

During the navigation season, the R.&S. hopper cars are operated for 200 days with the average quantity of bauxite moved per day about 9000 tons, although on peak days it may go over 18,000 tons. During this period the cars may be loaded directly from the ship or from the warehouses. On the days of heavy traffic the cars are loaded and unloaded three times every two days. In the closed season of navigation, the cars are operated for about 100 days and carry about 4000 tons per day. The 40° slope cars are used and supplemented when necessary by the 30° slope aluminum cars.

Port Alfred is at sea level and the elevation at Arvida is 400 ft. above sea level. This change in elevation takes place within the first seven miles out of Port Alfred in the twenty miles of rail line. The ruling grade of 1.3% is continuous for this seven miles. The power used to make this haul is provided by 1600 hp diesel electric units operated singly or in multiple according to traffic conditions, with each unit capable of hauling about 1100 trailing tons up the grade. The average load in aluminum cars is about 80 tons, in 70-ton capacity steel cars about 70 tons and in 50-ton capacity steel cars about 50 tons. The 1100 trailing tons can be made up using mixed cars or with steel cars or aluminum cars loaded with bauxite. It is possible to haul eleven 70-ton capacity steel cars with about 1034 tons total trailing load, of which 770 tons are payload. Alternatively, it is possible to haul eleven

Fig. 5. R & S Hopper Car No. 1304. Peak Stresses During Shake-out Fatigue Test, Side "D"



aluminum cars which will give about 1056 tons trailing load, of which 880 tons are payload. Both operations are carried out with the same power, crew time and fuel consumption.

On the basis of its 2 million-ton operation, the R.&S. requires 28,570 carloads if the bauxite is carried in standard steel cars, or the proportionately reduced figure of 25,000 carloads if carried in aluminum cars, i.e., 2600 train loads in steel cars, or 2270 train loads in aluminum cars. Thus, if all trains consist of aluminum cars, a saving of 330 train loads is effected in moving 2 million tons.

The running time from Port Alfred to Arvida with a loaded train is about one hour, two hours are required to switch the empty and loaded cars and make up and dispose of the train, and another hour is needed to run from Arvida to Port Alfred to complete the cycle.

Saving In Time

The saving in time, if only aluminum 40° slope cars were used, would amount to about 1320 hr. of locomotive and crew time per year. A further saving in time is realized from increased efficiency in unloading aluminum cars with optimum slope. In unloading at Arvida a Hewitt-Robins Shaker is used in conjunction with compressed air jets. A thorough check of unloading operations disclosed that two 40° slope cars could be unloaded during the time required for one car with 30° slope sheets. The aluminum cars with 40° slopes discharge 80 tons during the time steel cars with 40° slopes discharge 70 tons. The 40° slope aluminum cars actually discharge bauxite under favourable conditions in one-eighth to one-tenth less time than that required for 30° slope cars.

Saving In Number

The saving in number of cars by 13 to 14% is reflected in labor costs for maintenance. Since the superior resistance of aluminum to corrosion has been amply demonstrated, the aluminum cars have never been painted. To date there has been no maintenance of any kind on the bodies of the 40° slope aluminum cars built in 1955 or of those built in 1957. Yet another saving of some proportions is in trackage for sidings; the decrease in the number of cars has brought about a decrease in the total length of yard tracks.

Conclusions

The experience with hopper cars on The Roberval and Saguenay Railway has established many interesting features:

1. The design of hopper car bodies can be simplified with a reduction in the number of shapes required;

2. The new concept in car design has simplified car shop practices in the construction of hopper cars;

3. Aluminum hopper cars provide a high degree of corrosion resistance and a high payload to deadload ratio;

4. The development of aluminum alloys and high-speed welding overcame many of the advantages that steel construction had over aluminum in car shop practices;

5. Extensive tests demonstrated that welded aluminum structures can be designed to stand up as well as steel under dynamic loading;

6. Special cars for specific jobs can result in marked economies, particularly if the cars are operated in a closed circuit;

7. Light weight cars when used in ore service reduce the number of train loads moved per year.

NUCLEAR RESEARCH REACTOR OPERATIONS

D. G. Breckon,

Superintendent, NRX Reactor Branch,
Engineering & Operations Division,
Atomic Energy of Canada Limited,
Chalk River, Ontario.

BEFORE REFERRING TO problems associated with the operation of nuclear research reactors and illustrating the engineering uses to which these reactors are put at Chalk River, it is perhaps advisable to review briefly how a nuclear reactor works.

A nuclear reactor is basically a device which enables a fission chain reaction to proceed at a controlled rate with a means provided for removing the heat generated in the reaction. The fission process is initiated by a small particle called a neutron. Atoms of nearly all the elements contain neutrons in their nucleii. However, only a very few of the heavy elements, such as uranium, are fissile (capable of undergoing fission). Natural uranium contains 0.7% of uranium 235, the fissile isotope. When a neutron strikes a uranium 235 atom it can cause this atom to break into two fission fragments. Simultaneously, two or more neutrons are liberated and a large amount of energy is released. The energy appears in the form of heat. The neutrons produced are travelling quite fast. They must be slowed down before they will initiate fission in other uranium 235 atoms. The material used to slow down the fast neutrons is called a moderator. Graphite and heavy water are the most common moderators. Of the two, heavy water is by far the most effective. Once slowed down, the two neutrons liberated during fission will cause other uranium 235 atoms to split or fission. This, in turn, results in the production of four neutrons and the cycle is repeated for each of these. This is how the fission chain reaction is propagated.

In a reactor the fuel containing the fissile uranium, and the moderator are so arranged that more neutrons are produced than are lost to the structure. To ensure neutron economy the reacting core is usually surrounded with a reflector to divert escaping neutrons back into the chain reaction. Control of the reaction is usually achieved by insertion of strong neutron absorbers, such as boron or cadmium rods, into the core. The reactor power may also be controlled by varying the moderator level in the reactor vessel if heavy water is used as the moderator. This method of control adjusts the quantity of fuel in the reacting mass. In many reactors both methods are used to control the reaction. If the number of neutrons absorbed in the core exceeds those produced, the reactor is said to be sub-critical. When these two quantities are equal the reactor is just critical. The condition when more neutrons are produced than lost is termed over-critical. This latter state is required to achieve a self-sustaining chain reaction. If the reaction were left unchecked, the reactor structure would eventually melt due to the heat produced. Thus a coolant must be provided to remove the heat generated in the fuel. In research reactors the heat removed is generally put to no useful purpose, whereas in power reactors it is used to produce steam which in turn operates a turbine to produce electricity. The prime purpose of a research reactor is to produce an abundant supply of neutrons for experimental purposes.

There are five research reactors at the Chalk River Project operated by Atomic Energy of Canada Limited. Four are in operation and one is under construction. The two principal reactors are NRX which has been in operation since 1947 and NRU which was commissioned in 1957. Both of these reactors are natural uranium fuelled and heavy water moderated. I will now briefly outline the main features of these reactors.

A photograph of the NRX reactor model is shown in fig. 1. The reacting vessel is fabricated of aluminum and is essentially a tank 10 ft. in diameter by 10 ft. high. The tank is penetrated with approximately 200 tubes into which the natural uranium fuel rods are inserted. Heat is removed from the fuel by means of water from the Ottawa River which enters at the top and leaves at the bottom. The effluent coolant is passed through delay tanks prior to discharge to the river. The heavy water moderator system is totally enclosed in stainless steel pipe and storage tanks vented with helium gas. Provision is made for introducing moderator to the reactor vessel and for cooling it in heat exchangers to remove the heat generated in the reaction. Water cooled steel and aluminum thermal shields are located above and below the vessel to remove the heat created by the intense gamma radiation. An air-cooled graphite reflector surrounds the vessel to divert back into the reacting core neutrons that would otherwise be lost to the reaction. The maximum reactor power is 40,000 KW. Fuel changes must be made with the reactor shut down. Following withdrawal of the spent fuel into a flask shielded with 10 in. of lead, the fuel is discharged to a water-filled trench or canal for storage.

A photograph of the NRU reactor model is shown in fig. 2. The reacting vessel is made of aluminum and stainless steel. Unlike NRX there are no tubes in this vessel. The fuel elements are inserted directly into the moderator in the tank. Provision is made for 227 fuel rods. The natural uranium fuel in this case is cooled by the heavy water system. The combined moderator-coolant is contained in a closed stainless steel piping system and is circulated continuously through heat exchangers to remove the heat produced in the fuel. The present reactor power is 200,000 KW, five times that of NRX, and the fuel may be changed with the reactor operating. Fuel removal is accomplished in a manner somewhat similar to that employed in NRX, except that the removal flask also provides heavy water cooling.

Although both reactors are fuelled with natural uranium, the geometrical arrangement of the two fuel elements is quite different. This is primarily due to the higher power of the NRU reactor. The fuel in the NRX reactor takes the shape of solid uranium cylinders clad with aluminum. This clad prevents corrosion of the fuel by the coolant and serves to contain the fission products. Fig. 3 indicates a schematic diagram of the NRX fuel element. The clad uranium bar is inserted into an aluminum can to provide a channel for coolant flow. This passage is made quite small in the interests of neutron economy to reduce the number of neutrons captured by the coolant.

The NRU fuel element is shown in fig. 4. Owing to the high power of NRU, more heat must be removed from each fuel element than in NRX. The heat transfer rate in the NRU fuel may be as high as 600,000 BTU/hr./sq.ft./°F. One shape that satisfies this condition comprises five uranium flats clad with aluminum. The flats are placed inside an aluminum can which acts as a flow director for the moderator coolant. From a nuclear standpoint this fuel element achieves better neutron economy than that in NRX, as the heavy water coolant does not absorb as many neutrons as ordinary water.

Now that we have seen how we make nuclear reactors work and have a general idea of the construction of the NRX and NRU research reactors at Chalk River, I would like to discuss one of the major problems encountered in reactor operation. This is concerned with the continuous removal of heat generated in the fission chain reaction. The heart of a nuclear reactor is the region containing the fuel. It is here that the heat is initially generated and transferred to the coolant. Specifically, I will refer to heat removal from the reactor fuel, although there are many other auxiliary cooling circuits in a reactor system to which many of the remarks to follow also apply.

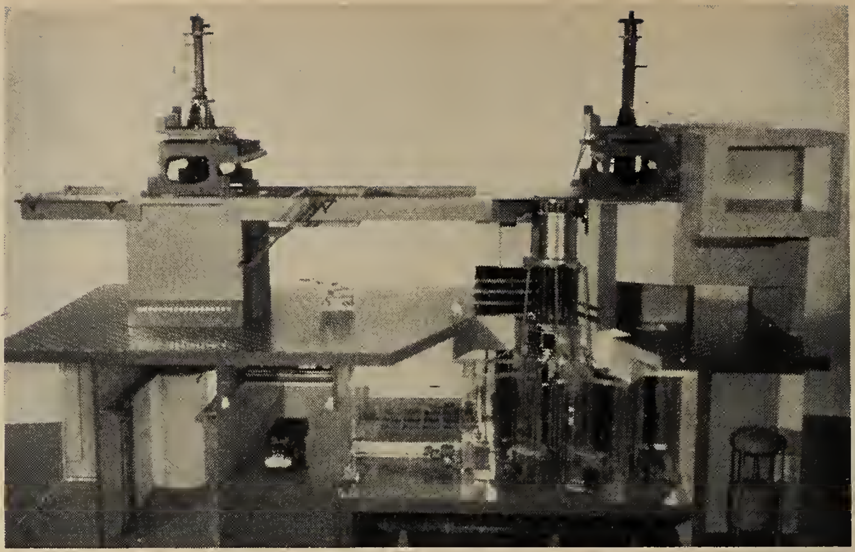

Fig. 2. Model of the N.R.U. Reactor

The NRX fuel element is cooled with Ottawa River water. The coolant passage is made as small as possible consistent with adequate heat transfer for reasons mentioned previously. Uranium metal tends to distort after it has been in the reactor for a while. This usually results in an overall length change together with expansion of the diameter. This may lead to partial blockage of the coolant channel and in some cases complete blockage. The effluent coolant stream is so instrumented that a reactor shutdown is called for when the coolant on an individual element is not adequate. Complete and rapid shutdown is mandatory in this condition. Otherwise the fuel would overheat, culminating in a meltdown of the element with possible damage to the reactor vessel tube. In addition, radioactive fission products might enter the water coolant, the air coolant in the annulus between the vessel tube and the fuel element, and the moderator. For fission products to escape from the fuel, it is assumed that one or all of the following components will have ruptured: the fuel clad, the coolant containment can, and the vessel tube.

Fig. 1. Model of the N.R.X. Reactor

A review of operating experience with the NRX reactor shows that incidents of this nature have in fact occurred. For example, in 1952 a power surge occurred during an experiment to determine reactor behaviour. This resulted in severe damage to several fuel elements and the reactor vessel. The coolant flows on several fuel rods were reduced for the experiment. The coolant boiled out of these rods as the reactor power increased and this loss of coolant resulted in a further power rise. The fuel temperature increased until it melted and the fuel cladding, the coolant can and the vessel tubes in these positions ruptured. The coolant mixed with the heavy water moderator. Fission products were released to the water coolant leaking from the damaged rods and also to the air coolant exhaust. Owing to a combination of errors the reactor control system did not stop the reaction before this damage was done. If personnel and equipment had functioned normally this accident might never have happened. Fourteen months elapsed before repairs were completed and the reactor was back in operation.

Following the accident the control system came under close scrutiny with a view to improving the reliability. This event showed clearly that the prime shutdown devices viz. the boron carbide neutron absorbers, called shut-off rods, were not reliable. These devices were normally held out of the reactor during operation. However, they are poised above the core, ready to drive into the reactor and stop the chain reaction when a condition hazardous to continued operation develops. In 1952 these rods were pneumatically operated in travelling in and out of the reactor core. Their performance had not been without failure due to the close tolerances required for air operation. In 1955, this air driven shut-off rod was replaced with a type using a motor driven cable hoist. This new type of shut-off rod has performed very well. To date these rods have never failed to shut down the reactor when required. In addition, the shutdown capacity of the control system has been augmented by the requirement of a moderator dump from the reactor vessel on every shutdown.

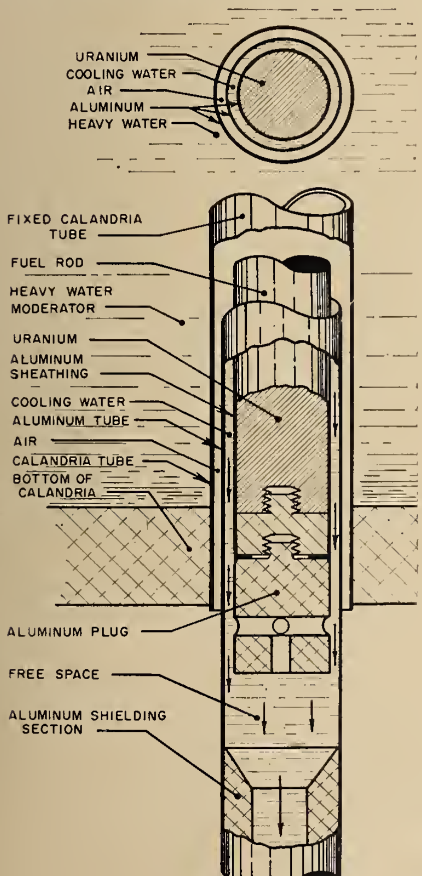

Fig. 3. Schematic Diagram of NRX Fuel Rod in Calandria Tube

Operating experience indicates that we now have a very reliable shutdown system in NRX that will function properly when required e.g. when coolant flow to a fuel element is not adequate.

The instrumentation used to monitor the fuel coolant flow was triplicated recently to improve its reliability. The electrical circuits used to shut down the reactor are so arranged that two of the three instruments must see the unsafe condition to initiate an automatic reactor shutdown. The latter is referred to as a reactor trip and the associated electrical circuits are termed trip circuits. This type of system has practically eliminated transient trips due to instrument failure. This is reflected in increased reactor operating efficiency. The triplicated system also permits testing of individual trip circuits and instruments with the reactor operating, as one circuit out of operation does not call for a reactor trip. The fuel rod coolant monitoring system has been used as an example of how multiplication of instrumentation will provide safer, more reliable protection. Triplication of instrumentation has been applied to all important systems used to detect unsafe reactor conditions.

If natural uranium fuel could be so fabricated that it did not distort under irradiation then the coolant flow would remain unchanged throughout the lifetime of the rod in the reactor. It does not appear practical to make such a fuel rod. However, continued efforts are being made to fabricate fuel that will exhibit a minimum distortion when irradiated in a reactor.

In summation then, with regard to the heat removal problem, it is essential that reliable instrumentation be provided to sense the unsafe coolant condition and that reactor shutdown be initiated immediately by reliable shutdown devices on a signal from these instruments.

Many of the problems encountered in reactor operation are due to the presence of radioactivity. A nuclear reactor generates various types of radiation which are biologically dangerous. Shielding must be provided to reduce the radiation to safe working levels for personnel. In addition, all personnel working at a reactor site are provided with film badges and pencil dosimeters to measure their radiation exposure. Records of individual exposure must be carefully maintained to ensure that no one exceeds the permissible amount of radiation on a weekly, quarterly, and yearly basis.

If we consider the reactor structure, we see that many feet of concrete

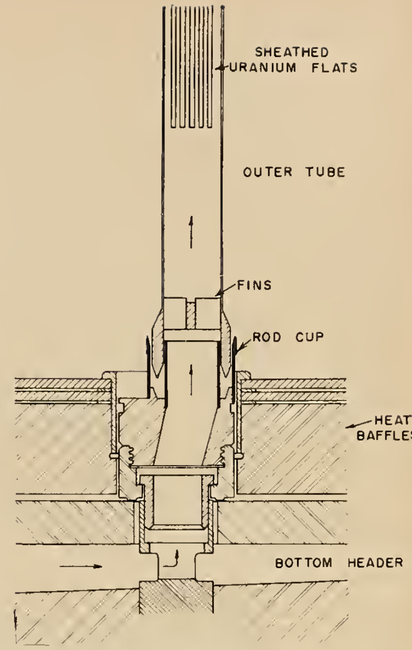

Fig. 4. NRU Fuel Rod and Cup Assembly

shielding have been provided to protect personnel from irradiation. No one could work around the face of the reactor if this shield were not present. This protection is, of course, augmented by routine radiation surveys taken around the reactor. Particular attention is given to horizontal penetrations in the biological (concrete) shielding used for experimental purposes.

It is also readily apparent that any material removed from the reactor core will be highly radioactive. This requires the use of shielded removal containers and special operating procedures. Let us consider the case of removal of a ruptured fuel element from the NRX reactor. This assumes that the aluminum clad has ruptured and fission products are present in the coolant stream. A flask shielded with 10 inches of lead is used to contain the fuel as it is withdrawn from the reactor. Temporary cooling must be applied to the rod during its extraction due to the residual heat contained therein. Water spilled during changing of coolant connections will be radioactive due to the fission products it contains. This may give rise to airborne contamination in the reactor building. If this should occur, personnel working on the fuel removal will be required to wear respirators or perhaps fresh air masks. These will provide protection against internal contamination. Also to control the spread of contamination, an area local to the fuel removal operations is generally isolated from the rest of the building. This avoids contamination spreading on the feet of the workers. Personnel monitoring stations located in these areas must be used before leaving them. Fuel removal requires men to work in a room below the reactor to disconnect the coolant connections. These workers are provided with a complete change of clothing including a plastic suit, hood, and fresh air mask. Communication is provided by a microphone installed in the mask connected to a public address system. In addition, warning of high radiation levels in operating areas is provided by instruments which sound a distinctive signal.

Once the fuel is removed it is transferred in the shielded flask to a canal system. Here, radiation protection is provided by a shield of 12 ft. of water. This permits workers to cut and handle the irradiated fuel with special tools where they can see what they are doing.

The presence of radioactivity can make even the simplest maintenance job a complicated operation. When maintenance of equipment is required, radiation surveys and protective clothing are provided much in the same manner as described for fuel removal. On some occasions when the radiation level is high, temporary shielding must be installed to reduce the radiation to safe working levels. In situations where the radiation level may change abruptly, a radiation surveyor is constantly in attendance to monitor the health hazard. Accessibility of equipment in reactor systems is essential if reasonably fast, effective maintenance is to be carried out. Equipment that is essential to the continued operation of the reactor is generally provided in duplicate. One of the units acts as standby in the event of failure of the other. This means that maintenance of the failed unit can be deferred to a scheduled shutdown and reactor operation can continue with only a minor interruption.

Waste disposal is another problem created by the dangerous radiation generated within a reactor. Liquid wastes having low radiation levels are pumped to large disposal pits located within the confines of the project. Here the liquid seeps through the sandy soil which retains the radioactivity. Movement of this activity in the soil is carefully surveyed on a continuing basis. High radiation liquid wastes are concentrated and stored in stainless steel tanks underground. Solid wastes are buried in the ground in a specially designated disposal area. Some material is buried directly in the soil; some is placed in steel and concrete containers installed in the ground. These containers are sealed with asphalt when filled.

The air coolant from the reactors is passed through absolute filters to remove active particulate material before it is discharged to the atmosphere through a 200 ft. stack. The single pass of water used to cool the NRX fuel is directed through two tanks in series to delay it before it is ultimately discharged to the Ottawa River. In the tank the radiation contained in the coolant decays to levels well below permissible drinking water tolerance.

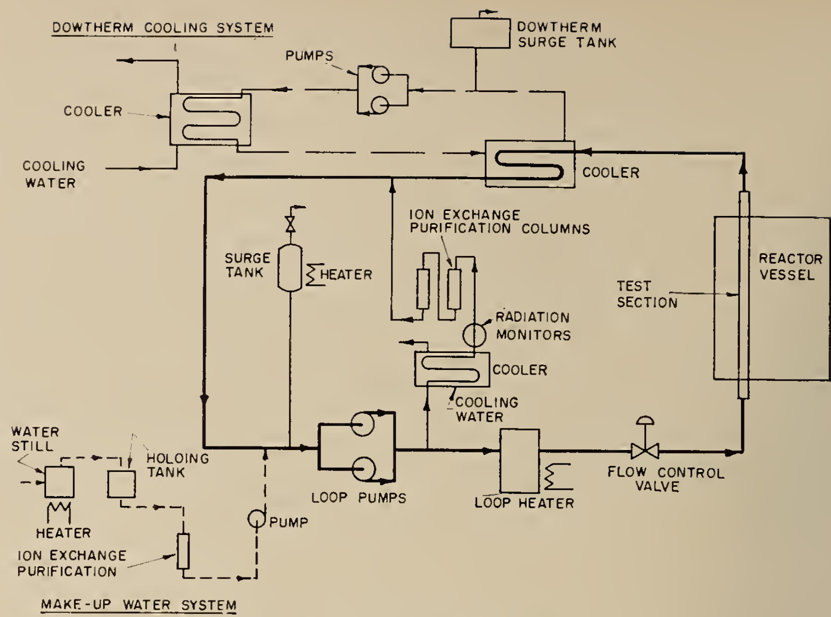

Fig. 5. Loop Schematic Diagram

The reactors at Chalk River are used for a great variety of experiments. The most important engineering use to which the reactors are put concerns the testing of prototype fuel elements and materials for use in power reactors. Facilities are installed in the reactors which provide the sort of environment to be found in nuclear power reactors. A typical facility is shown schematically in fig. 5. This comprises a closed piping loop which allows the circulation of water at a pressure of 2,000 p.s.i. and a temperature of 600°F. Fuel elements are inserted in the pressure tubes which are located in the reactor core. Cooling is provided by the pressurized water. Six of these so called "loops" are in operation in NRX and two in NRU. Uranium oxide fuel is undergoing rigorous tests in these facilities as this is the type planned for the NPD-2 reactor, Canada's first power demonstration project, and also for the CANDU reactor, the 200 MW power station now being designed. The cladding material being tested for use with the oxide fuel is an alloy of zirconium metal called Zircaloy-2. The latter has mechanical properties which permit its use under power reactor conditions. Further, it is suitable from a nuclear standpoint in that it has a low affinity for neutrons.

The pressure tubes for these loops are installed in the reactor vessel tubes replacing standard fuel elements. The operation of the loops is of necessity closely integrated with that of the reactor. Instrumentation on the loops is used to sense conditions which are hazardous for the operation of the experiment as well as for reactor operation. In the latter case a trip signal is sent to the reactor control room to initiate automatic shutdown.

The NRX reactor has proved to be a most valuable and versatile research machine during its 12 years of operation. It is indeed a credit to the original designers. Much information has already been provided to the power reactor designer through data obtained in NRX experiments. More data will be forthcoming from experiments now in progress. The NRX reactor has kept pace with the times. The latest developments are incorporated in its control and safety systems. Fuel element designs for the NRU reactor and for submarine propulsion reactors were tested in its core. Fuel designs for Canada's first nuclear power reactors are now being tested in NRX. Now that NRU has been successfully operated for about two years, this reactor is sharing the experimental load with NRX. Designed as a plutonium producer as well as for engineering testing, the NRU reactor has already produced outstanding experimental work. The operation of these two reactors has contributed to a very large extent to the advancement of nuclear reactor technology and will, I am sure, continue to do so in the future.

INTERPRETATION OF RHEOLOGICAL DATA FOR ENGINEERING USE

G. W. Govier, M.E.I.C.,
Professor of Chemical Engineering, Dean of the Faculty of Engineering, University of Alberta

Increasing applications of the flow of complex mixtures such as solid-liquid suspensions, high pour point crude oil and other non-Newtonian materials require of the engineer some appreciation of the elements of rheology and the interpretation of laboratory measurements of consistency.

The basic rheological classifications are defined and reviewed. The versatile rotational viscometer is described and its calibration and use for the testing of non-Newtonians is outlined. A method of data interpretation for engineering use is presented. The method permits a ready visualization and assessment of the extent and kind of non-Newtonian behaviour over a wide range of shear rate.

Introduction

THERE IS INCREASING interest in the flow and related behaviour of complex mixtures and especially of solid-liquid suspensions. Recent developments and full scale application of the pipeline transport of suspended solids have called for a knowledge of the consistency or "viscosity" of such mixtures. Applications of "heavy media" to mineral ore processing and of suspended solids systems as heat transfer media also require an appreciation of the effect of concentration and other variables upon consistency. The so-called "high pour point" crude oils are non-Newtonian and exhibit unusual flow behaviour at moderately low temperatures. The engineer who is not a specialist in rheology generally considers the property of viscosity to be the one and only measure of consistency and often is at a loss to interpret basic rheological data obtained in the laboratory. Yet such a knowledge is vital to an understanding of the flow behaviour of these mixtures and plays an important role in their heat and mass transfer characteristics. This review is written to acquaint the non-rheologist with a few of the basic concepts of rheology, with the calibration and use of the versatile rotational viscometer and with a method of data interpretation which the author has found useful in engineering application of rheological data.

Rheological Classification of Fluids

Many discussions of the rheological classification of fluids have appeared in the recent literature. The following brief discussion is taken from a previous paper.[2]

Fluids are classified into several rheological types in accordance with their behaviour when subjected to shearing forces of such a magnitude as to cause laminar or non-turbulent motion of the fluid. Conventionally, the unit shearing stress, (dF/dA), is compared with the rate of shear or the velocity gradient developed normal to the applied stress, (dV/dX). Typical shearing stress—rate of shear curves appear in Fig. 1 (arithmetic coordinates) and Fig. 2 (logarithmic coordinates). These figures have been prepared for fluids behaving similarly at one rate of shear and illustrate their different behaviour at other rates of shear.

In the case of most liquids and all gases the rate of shear developed is found to be directly proportional to the unit shearing stress applied. This may be stated by the simple relationship

$$\frac{dF}{dA} = \frac{\mu}{g_c}\frac{dV}{dX} \qquad (1)$$

where

(dF/dA) is the unit shearing stress, or the shearing force per unit area,

(dV/dX) is the velocity gradient normal to the applied shear, or the rate of shear,

μ is the constant of proportionality known as the viscosity,

g_c dimensional conversion factor.

A fluid whose rheological behaviour is described by equation (1) is known as a Newtonian fluid, and a single quantity, the viscosity, serves to give a complete description of its rheological behaviour. This relationship for a typical Newtonian fluid is shown by the line so labelled in Figs. 1 and 2. Inasmuch as viscosity itself is defined by equation (1) it is clear that only a fluid which behaves in accordance with this equation can be considered to exhibit the property of viscosity. Interpretation of the Newtonian line on Fig. 1 indicates that the viscosity of a Newtonian fluid is the slope of the line when the unit shearing stress is plotted against the rate of shear on arithmetic coordinates. Since for Newtonian fluids this line is necessarily a straight line through the origin, the slope is constant and the viscosity is independent of the rate of shear. On logarithmic coordinates the Newtonian fluid exhibits a straight line of slope equal to one—see Fig. 2.

Certain fluids, notably those of complex compositions or those which are really physical mixtures, do not exhibit this simple relationship when the unit shearing stress is plotted against the rate of shear. These fluids are called non-Newtonian. Some such systems yield a complex shearing stress—rate of shear curve which cannot simply be described. Among the simpler cases, however, are the Bingham plastic and the pseudo-plastic. The Bingham plastic is defined as a material for which a finite shearing stress is required to initiate shear and for which there is a linear relationship between all greater unit shearing stresses and rate of shear. The Bingham plastic is defined mathematically by equation (2):

$$\frac{dF}{dA} - \tau_y = \frac{\eta}{g_c}\frac{dV}{dX} \qquad (2)$$

where

τ_y is the yield of the material corresponding to the unit shearing stress

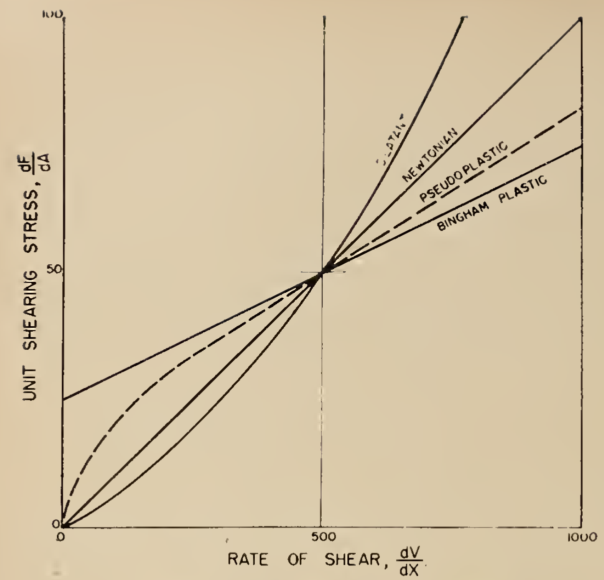

Fig. 1. Unit Shearing Stress—Rate of Shear Relationships (Arithmetic Plot).

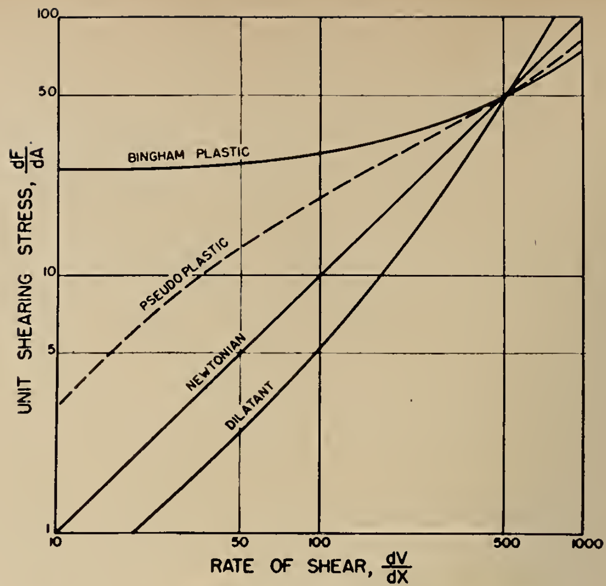

Fig. 2. Unit Shearing Stress—Rate of Shear Relationships (Logarithmic Plot).

required to initiate motion

η is the coefficient of rigidity.

The relationship between unit shearing stress and rate of shear for a Bingham plastic is indicated by the line so labelled in Figs. 1 and 2. The intercept on the unit shearing stress axis on Fig. 1 corresponds with the yield value, τ_y, and the slope of the straight line is the coefficient of rigidity, η. On logarithmic coordinates (Fig. 2) the Bingham plastic exhibits a curve convex to the rate of shear axis approaching zero slope at low shear rates and a slope of one at high shear rates. Relatively few materials have been found to exhibit true Bingham plastic behaviour and this rheological type is important chiefly in that it serves as a limiting case for the pseudo-plastic type.

A pseudo-plastic material may best be defined by reference to the line labelled pseudo-plastic in Fig. 1. On arithmetic coordinates the line relating the unit shearing stress to the rate of shear passes through the origin and is curved convex to the shearing stress axis up to a certain shearing stress, but is approximately linear with rate of shear beyond that point. On logarithmic coordinates (Fig. 2) the pseudo-plastic yields a relationship similar to that of the Bingham except at low rates of shear. It will be apparent that at high rates of shear pseudo-plastics behave much like Bingham plastics in that there is a near linear relationship between the shearing stress and the rate of shear. Because of this, pseudo-plastics are occasionally characterized, at high rates of shear, by an "apparent coefficient of rigidity" and an "apparent yield value". The apparent coefficient of rigidity is equal to the slope of the near linear part of the curve on the arithmetic coordinates and the apparent yield value is equal to the intercept formed by linear extrapolation of the line to zero rate of shear.

Among several other types of non-Newtonians is the dilatant fluid whose characteristics are indicated by the line labelled dilatant in Figs. 1 and 2. This type of fluid is less commonly encountered.

The widespread use of the term "viscosity" as a measure of consistency has led to its incorrect use in the case of Bingham plastics, pseudo-plastics, dilatant fluids, and other rheological types. Since the viscosity of a Newtonian fluid is proportional to the ratio between the unit shearing stress and the rate of shear, the term viscosity has been applied to this same ratio in the case of non-Newtonians. It is clear from Fig. 1, however, that the ratio between unit shearing stress and the rate of shear for Bingham plastics, pseudo-plastics, etc., varies at different rates of shear indicating different consistencies. These different consistencies should not be referred to as viscosities, but may usefully and accurately be called "apparent viscosities".

Thus while the Newtonian fluid is rheologically characterized by a single quantity, the viscosity, which is independent of the rate of shear; the Bingham plastic and other rheological types are sufficiently complex to require more than one quantity to define the shear stress-rate of shear curve and to describe their rheological behaviour. Alternately, the rheological properties of these latter materials may be described by a series of apparent viscosities spanning the range of rates of shear of interest. This latter method has found favor among engineers because of the similarity of meaning and the identity of units and dimensions of apparent viscosity and viscosity.

Rotational Viscometer and Calibration

Many different types of viscometers have been developed for the testing of both Newtonian and non-Newtonian fluids. These are discussed in detail elsewhere[6]. Of all the types the concentric cylinder instrument is probably the simplest of the designs really useful for the study of non-Newtonians. This instrument, of which there are many varieties on the market, consists essentially of an inner and an outer cylinder so arranged that, with the fluid to be tested in the annular space between the cylinders, one of the cylinders may be rotated while the torque transmitted through the fluid to the other stationary cylinder is measured in some way. A popular semi-precision commercial viscometer of this type is the Model 35 manufactured by the Fann Instrument Corporation, Houston, Texas. The Fann instrument combines simplicity of operation with good accuracy and permits sustained testing at each of several rates of shear.

For use with a Newtonian liquid the relationship between the rate of shear at the stator wall and the rotor speed for such a rotational viscometer may be determined mathematically from the Reiner-Riwlin[8] equation which is

$$\frac{dV}{dX_r} = \frac{4\pi R_1^2 R_2^2}{r^2(R_2^2 - R_1^2)} N \qquad (3)$$

where

(dV/dX) = rate of shear, sec^{-1} at the stator wall

R_1 = inner radius of the annulus

R_2 = outer radius of the annulus

s = ratio of the outer to the inner radius of the annulus = (R_2/R_1)

r = radial position at which

shear rate is given when $R_1 < r < R_2$

N = rotor speed, rev. per sec.

If the outer cylinder is rotated and the torque on the inner cylinder is measured it is the rate of shear at the wall of the inner cylinder that is of interest.

Substituting R_1 for r,

$$\frac{dV}{dX_{R_1}} = \frac{4\pi}{1 - 1/s^2} N \qquad (4)$$

Conversely if the inner cylinder is rotated and the torque on the outer cylinder is measured the rate of shear at the wall of the outer cylinder is of interest and

$$\frac{dV}{dX_{R_2}} = \frac{4\pi}{s^2 - 1} N \qquad (5)$$

For the remainder of this discussion it will be assumed that, as in the Fann viscometer, the torque on the inner cylinder is measured. Accordingly equation (4) relates the rate of shear of interest to the system geometry and the rotational speed.

The relationship between the deflection of the spiral spring, or other torque measuring device, and the unit shearing force at the stator wall is best determined by calibration. This may be done readily by obtaining speed-deflection data for a true Newtonian liquid of accurately known viscosity. A linear relationship between deflection and unit shear stress may be assumed, viz.

$$\frac{dF}{dA_{R_1}} = K\theta \qquad (6)$$

where

$\frac{dF}{dA_{R_1}}$ = unit shear force in the liquid at the wall of the inner cylinder (stator), dynes per sq. cm.

θ = deflection of torque measuring device, degrees or divisions

K = factor of proportionality.

With measured values of N and θ, and the viscosity of the calibrating liquid, simple solution of equations (1), (4) and (6) will yield values of K. A well designed instrument will yield the same value of K for any Newtonian liquid at any operating speed, N, so long as laminar flow conditions prevail in the annulus. Maintenance of laminar flow may be checked by the modified Reynold's criterion of Barr[1]. As quoted by Merrill[5], this criterion indicates that stable laminar flow maintains to a value of the dimensionless quantity

$2\pi R_2(R_2 - R_1)\rho/\mu$ equal to 500.

In this expression ρ is the density of the fluid in the annulus.

Data Processing

Equations (4) or (5) and (6) or its counterpart for the outer cylinder constitute the calibration equations for a rotational viscometer for use with any Newtonian liquid. The Reiner-Riwlin equation (3), upon which equations (4) and (5) are based, is however strictly applicable only when the annular fluid is Newtonian. The more general Krieger-Maron[4] equation expresses the rate of shear at the stator wall for a non-Newtonian. This equation applied to the wall of the inner cylinder is

$$\frac{dV}{dX_{R_1}} = \frac{4\pi}{1 - 1/s^2} NF \qquad (7)$$

where

F = Krieger-Maron correction factor for non-Newtonian annular fluid

$$= 1 + k_1\left(\frac{1}{n''} - 1\right) + k_2\left[\left(\frac{1}{n''} - 1\right)^2 + \frac{d(1/n'' - 1)}{d \ln v}\right]$$

and

$$k_1 = \frac{s^2 - 1}{2s^2}\left(1 + \tfrac{2}{3} \ln s\right)$$

$$k_2 = \frac{s^2 - 1}{6s^2} \ln s$$

n' = slope of log-log plot of θ vs N.

Often the final term in the Krieger-Maron correction factor is relatively small and may be neglected.

Thus for use with a non-Newtonian fluid the basic equations for interpretation of data are equation (6) with the value of K determined with the aid of equation (1) from a Newtonian calibration, and equation (7) with the value of F determined from a log-log plot of θ versus N. Much data in the literature has been calculated using equation (4) instead of the recently developed equation (7). Fortunately in most cases the F factor is not too much greater than unity and the error is relatively small.

For ordinary applications in a thorough investigation of the rheological characteristics of a fluid, θ values should be determined over a wide range of rotor speeds corresponding to rates of shear from below 10 to about 1000 sec^{-1}. Determinations should be made at controlled temperature and must be made under laminar flow conditions. The raw $\theta - N$ data are conveniently plotted on multicycle log paper for preliminary smoothing and Krieger-Maron processing. Derived (dF/dA) and (dV/dX) data are also conveniently plotted on multicycle log paper from which the extent and kind of non-Newtonian behaviour is clearly apparent.

Data Interpretation

A technique found by the author to be extremely useful is to plot the final results as $(dF/dA) + 0.1$ versus $(dV/dX) + 0.1$ on 5 or more cycle logarithmic paper. The addition of the small constants permits the 0.1, 0.1 co-ordinates to serve as the origin of co-ordinates with respect to (dF/dA) and

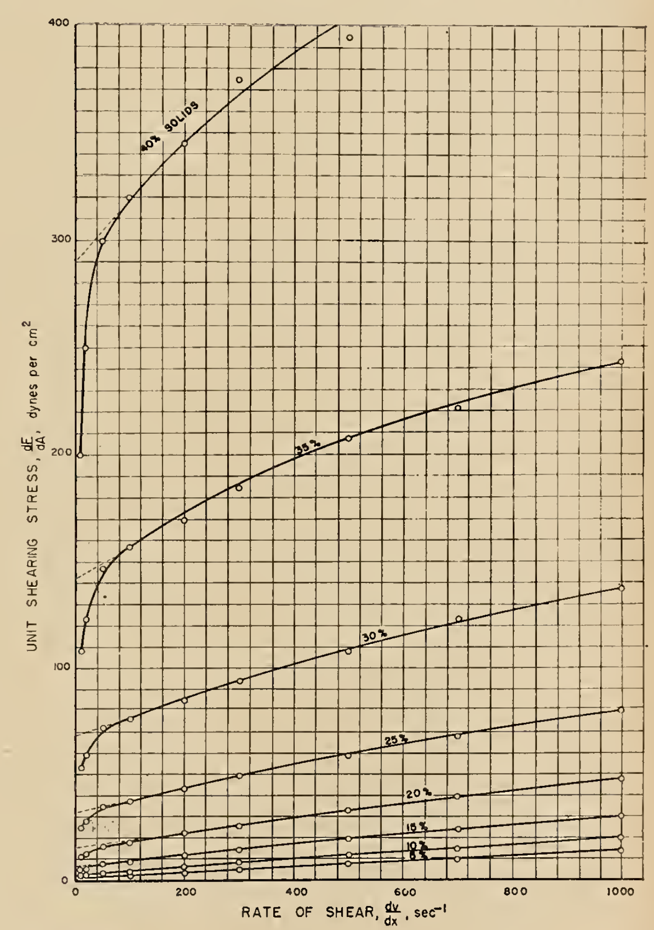

Fig. 3. Typical Unit Shearing Stress—Rate of Shear Data (Arithmetic Plot).

(dV/dX) themselves. In this way data may be extrapolated to the origin in the many cases where pseudoplastic behaviour is encountered. The utility of the plot is further enhanced by drawing in the lines corresponding with Newtonian fluids of 1, 10, 100, 1000 and 10,000 centpoise. Beyond the first two cycles of both coordinates these lines appear as straight lines of 45° slope and serve as a third scale from which one may read directly the viscosity, apparent viscosity, coefficient of rigidity or apparent coefficient of rigidity for a system for which test data are plotted.

If on such a plot the data form a curve which asymptotically approaches a horizontal line at low rates of shear and a 45° line at high rates of shear, Bingham plastic behaviour is indicated. The yield value, τ_y, may be read directly from the ordinate scale by extrapolating the horizontal portion of the curve and the coefficient of rigidity may be read directly from the position of the 45° line with respect to the "third scale". Moreover apparent viscosities at any rate of shear may be read directly from the intersection of the data point curve with the third scale lines of constant apparent viscosity.

More commonly the data for systems of engineering interest will form a curve indicating pseudo-plastic behaviour. Assuming such behaviour, one can extrapolate the curve to zero rate of shear using as a general guide the curves of the Newtonians. If necessary the data may also be extended to higher rates of shear by trending the curve asymptotically to a 45° straight line. From such an extended curve apparent viscosities may be read directly for any rates of shear of interest.

Frequently it is convenient to represent pseudo-plastics in an approximate manner by treating them as though they were Bingham plastics and assigning apparent yield values and apparent coefficients of rigidity to them. Such a procedure is often justifiable when the flow behaviour at relatively high rates of shear is of major interest. There are a variety of ways of obtaining these apparent properties. One way is from an arithmetic plot of the (dF/dA) – (dV/dX) data. Here the apparent yield value is obtained by linear extrapolation to zero rate of shear of the near-linear portion of the curve. The apparent coefficient of rigidity is obtained from the slope of the near-linear portion of the curve. Another method of obtaining the apparent coefficient of rigidity is to plot the ratio of (dF/dA) to (dV/dX) (which is the apparent viscosity) versus (dX/dV) and to extrapolate to zero (dX/dV) or infinite (dV/dX). This method is recommended by Weltmann.[9] A third way of obtaining the apparent properties is from a logarithmic plot either of (dF/dA) versus (dV/dX) or of

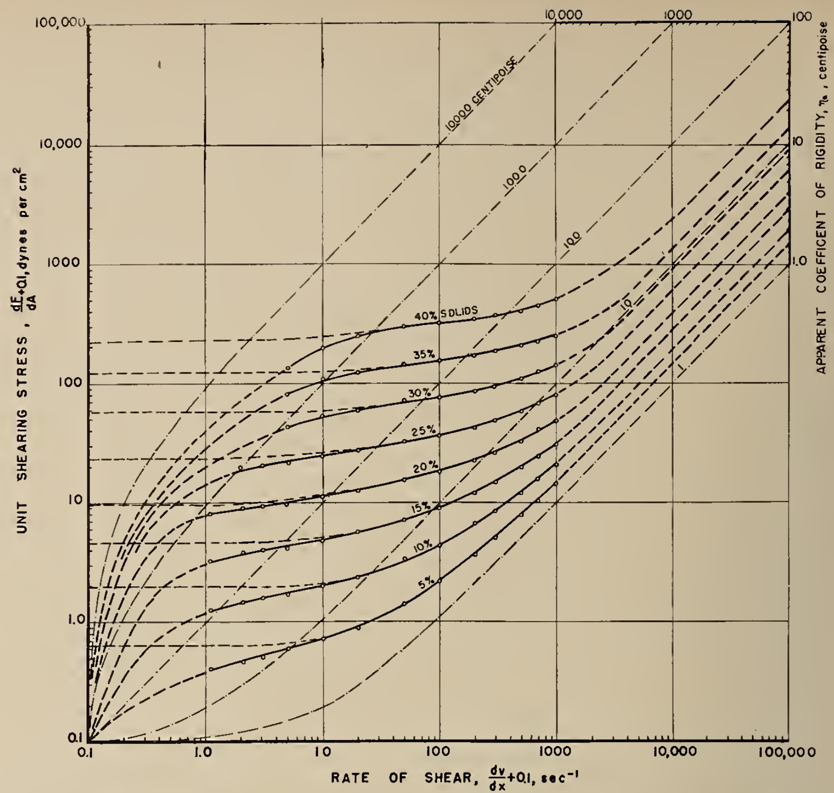

Fig. 4. Typical Unit Shearing Stress—Rate of Shear Data (Modified Logarithmic Plot).

$(dF/dA) + 0.1$ versus $(dV/dX) + 0.1$. In this case the apparent yield value is obtained by horizontal extrapolation of the experimental curve from the convex to concave inflection point. The apparent coefficient of rigidity is obtained by extrapolation of the high rate of shear portion of the curve asymptotically to the limiting 45° straight line.

None of these methods has any fundamental advantage over the others because the apparent properties have little fundamental significance in any case. The author uses all methods but rather favours the last mentioned especially when dealing with a family of curves for related mixtures.

To illustrate the methods of data interpretation, typical (dF/dA) and (dV/dX) data for a series of clay-water suspensions are given in Figs. 3 and 4, Fig. 3 is the conventional arithmetic plot of the data while Fig. 4 represents the same information on the modified logarithmic plot. Both figures indicate that all of the suspensions behave as pseudo-plastics but that at rates of shear above about 10 reciprocal seconds their behaviour approaches that of Bingham plastics. Fig. 4 permits ready extrapolation of the data to zero and to high rates of sheer. Thus the heavy curves through the data points and the heavy broken line extensions give a good representation of the rheological behaviour of the suspensions over a wide range of rate of shear.

Apparent yield values and coefficients of rigidity may be obtained from either figure by the methods described. The apparent coefficients of rigidity may also be determined by the reciprocal extrapolation method. A comparison of the apparent properties as determined by the various methods appears in Figs. 5 and 6. It will be noted that there is some difference in the results. This is due to differences in interpretation and is a measure of the inaccuracies inherent in all methods. Since the suspensions are not really Bingham plastics none of the interpretations is really correct. Each however represents the data about equally well.

Returning to Fig. 4 it is seen that from data spanning a shear rate range of 5 to 1000 sec^{-1} the rheological performance may be estimated over substantially all rates of shear. Real or apparent yield values and coefficients or rigidity may be read directly from such a plot. Apparent viscosities may be read at any shear rate merely by observing where the data line at that shear rate cuts the "third scale".

A real appreciation of the rheological nature of a system may be obtained from a fully extended curve on Fig. 4.

Consider for example, the line for the 10% clay-water suspension. Compare it with the 1 centipoise or 0% clay-water line. The nature of the system precludes the existence of a true yield value and the data line is extended to zero shear rate—as for water itself. At shear rates of 1—10 sec^{-1}, unit shearing stresses about 10 times as great as for water are required for the clay-water system. The shear stress increases with increasing shear rate but more slowly than for water and at 100 and 1000 sec^{-1} the comparative shear stresses are respectively about 4.5 and 2.3 times those for water. The extension of the data line to the right indicates an asymptote of 1.9 centipoise. This is the apparent coefficient of rigidity of the suspension or its apparent viscosity at high rates of shear. Extending the convex portion of the data lines to the left indicates an apparent yield value of some 1.8 dynes per sq. cm. In other words, if one wished to approximate the behaviour of the suspension by the two Bingham constant these valves would be appropriate and the actual rheological behaviour would be fairly closely represented for all shear rates above 10 sec^{-1}.

In terms of apparent viscosities one may observe directly that the apparent viscosity of the 10% suspensions is over 100 centipoises at extremely low rates of shear; it decreases to 10 centipoises at a rate of shear of 25 sec^{-1}, to 5.5 centipoise at 100 sec^{-1}, to 2.2 centipoises at 1000 sec^{-1} and to a limiting value of 1.9 centipoise at very high shear rates.

Application of Data

While it is not the intent in this review to discuss design methods in which rheological data are used some reference to the application of such data seems appropriate. Rheological data are required for the design of systems for the pumping, transportation, mixing, and heating of non-Newtonian fluids, for the settling of particles in them and in all cases where the consistency of the fluid is important.

The commonest application is to pipeline transportation and to the calculation of pressure drop—flow rate relationships as function of line size and fluid properties. For Newtonian fluids the procedures are now well established both for laminar and turbulent flow conditions. Much less is known for non-Newtonian fluids although in the simpler cases methods have been developed.

For a true Bingham plastic in laminar motion the Buckingham equation has both theoretical and experimental backing. The equation is

$$\frac{8V}{D} = \frac{g_c}{\eta}\left[\frac{D\Delta P}{4L} - \frac{4}{3}\tau_y + \frac{1}{3}\frac{\tau_y^4}{(D\Delta P/4L)^3}\right]$$

where

V = average velocity, per ft. per sec.
D = pipe diam., ft.
η = coefficient of rigidity, lb_m per ft. sec.
g_c = 32.2 lb_m ft. per lb_f sec^2
L = length of pipe, ft.
τ_y = yield value, lb_f per $ft.^2$
ΔP = pressure drop, lb_f per $ft.^2$.

This equation may be rearranged in several ways. Govier and Winning[2] demonstrated by dimensional analysis that, for Bingham plastics, the friction factor, f, could be expressed as a function of $(DV\rho)/\eta$, a modified Reynolds number and, $(D\tau_y g_c)/V\eta$, a "yield number". In terms of these groups the Buckingham equation becomes

$$\frac{1}{R_m} = \frac{f}{16} - \frac{Y}{6R_m} + \frac{Y^4}{3f^3R_m^4}$$

where $f = \dfrac{g_c D\Delta P}{2V^2L}$, the friction factor

$$R_m = \frac{DV\rho}{\eta},$$

the modified Reynolds number

$$Y = \frac{D\tau_y g_c}{V\eta}, \text{ the yield number}$$

Perkins and Glick[7] have rearranged the Buckingham equation to the form

$$\frac{1}{R_m} = \frac{f}{16} - \frac{H}{6R_m^2} + \frac{H^4}{3f^3R_m^8}$$

where

$$H = YR_m = \frac{\tau_y D^2 \rho g_c}{\eta^2},$$

a dimensionless ratio suggested by Hedstrom[3] who has also prepared a graphical representation of the Buckingham equation in the form of f versus R_m with H as a parameter.

It is of interest to compare these rearranged forms of the Buckingham equation with that for Newtonians.

$$\frac{1}{R} = \frac{f}{16} \quad \text{where} \quad R = \frac{DV\rho}{\mu}$$

Under fully developed turbulent motion the Newtonian methods may be used for a Bingham with the substitution of the coefficient of rigidity for the Newtonian viscosity in the Reynolds number. One remaining difficulty is in connection with the transition zone. There is conclusive evidence to the effect that the transition from laminar to turbulent motion depends not only upon the (modified) Reynolds number but also upon diameter, yield value, velocity and coefficient of rigidity. Moreover the transition range is known to be very wide. The best present guide seems to be the observation that strict laminar flow extends only to a friction factor value of about 0.008.

In the case of pseudo plastics the situation is less clear. One procedure, satisfactory at reasonably high rates of shear, is to treat the pseudo plastic as an equivalent Bingham employing apparent values of the yield value and the coefficient of rigidity. Another procedure, proposed by Metzner[6] involves the use of the conventional (Newtonian) friction factor—Reynolds number correlation with a modified Reynolds number defined as

$$\frac{D^{n'}V^{2-n'}\rho}{\gamma}$$

where n' is a flow behaviour index approximated by the slope on logarithmic co-ordinates of the (dF/dA) – (dV/dX) relationship ; and

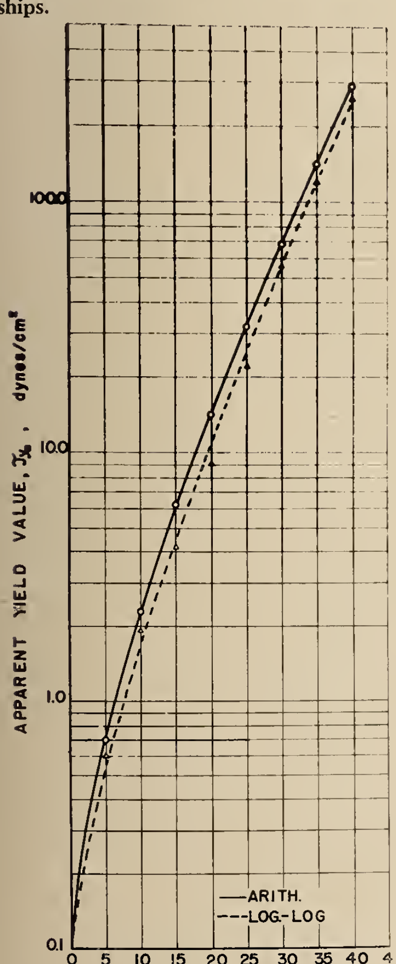
$$\gamma = g_c K' 8^{n'-1} \quad \text{where}$$

$$K' = K\frac{(3n'+1)^{n'}}{4n'} \quad \text{and}$$

$$K = \frac{dF/dA}{(dV/dX)}$$

Engineers are tempted to simplify the problem by trying to use a single apparent viscosity and to treat the fluid as though it were a Newtonian. This is satisfactory sometimes but it is also dangerous. The difficulty centres in the

Fig. 5. Apparent Yield Value Relationships.



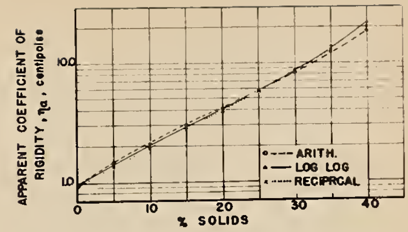


Fig. 6. Apparent Coefficient of Rigidity Relationships.

choice of the apparent viscosity. At what shear rate should it be taken? In turbulent motion the effective rate of shear is high and an apparent viscosity taken at 1000 or more reciprocal seconds appears appropriate. Such a value however is little different from the coefficient of rigidity or the apparent coefficient of rigidity so the procedure reduces to that described above. In laminar motion the rates of shear are much less and vary more over the flow section. The use of an apparent viscosity here is definitely not recommended and the Buckingham equation or some modification of it is to be preferred.

Generally speaking and in all applications the use of an apparent viscosity should be restricted to cases of reasonably constant rate of shear and the apparent viscosity should be evaluated at the rate of shear of interest.

Acknowledgement

Acknowledgement is made to Mr. W. G. G. Lindley who obtained the rheological data on the clay-water suspensions and who, with the assistance of Mr. J. Hahn, carried out the processing of the data.

ENGINEERING STUDIES OF THE FRASER RIVER BASIN

(Continued from page 66)

Benefit Cost Studies: Mention has been made of benefit cost studies in connection with the Board's flood control and power investigations. In this case the application was rather a severe one in that the only benefit evaluated was that accruing from the production of electrical energy while the benefits of flood control and other water uses were not evaluated. On the other hand, due primarily to lack of adequate information, no attempt was made to include fish facility costs on the debit side. This rather arbitrary position will likely require further modification as more information on fishery and other water resource use becomes available.

One of the recommendations of the preliminary report is that a benefit cost study be carried out for the Lower Fraser Valley in which the cost of various degrees of flood protection might be compared with the benefits derived. While this would appear to be a very realistic approach, it is fraught with considerable complexity if applied too rigidly.

It is possible, theoretically, to study a valley and determine from different flood levels the value of the land and property damage resulting. However, while this may account for direct physical damage, it tends to ignore the fact that the valley is an economic unit in which the indirect effects of floods such as the disruption of communication lines may be more serious than local inundation. Even moderate flooding in such a case may disrupt the economic activities nearly as much as the more severe freshets.

Flood Plain Restrictions: It has been advocated by some that a river should, within certain limits, be allowed its flood plain or right of way and within this portion of the valley improvements would be limited to agricultural works which would not be damaged by flooding.

In the very early settlement of a valley it might be possible to introduce such restrictions. However, in frontier areas, governments are hesitant to impose limitations on newly developing regions. Hydrometric data is also usually scanty or non-existent so that it is difficult to define the proper channelway.

Some authorities also claim that restrictions within a river valley by government might imply a responsibility for damages should a record flood be experienced which invades the so-called safe area.

Conclusions

The foregoing has been an attempt to summarize some of the problems facing the Fraser River Board throughout its 12 yr. of investigational work and the expenditure of $1,440,000. This effort can be roughly divided into three distinct phases.

The first phase ran from 1948 to 1955 and included an intensive program of mapping and the collection of hydrometric and meteorological data.

The interpretation of this raw material with respect to flood control could be called the second phase and this terminated with the completion of the Interim Report in 1956.

The approach was then broadened to encompass both flood control and hydro-electric power under what is known as the Preliminary Report of 1958.

The Fraser River Board within the last month has started on a new four-year program which will include exploration of a number of the proposed damsites. While this drilling program is proceeding, fishery research and certain flood investigations in the Lower Fraser Valley will be carried out.

Generally, the very broad picture of how flood control and hydro-electric power may be realized has been painted. It remains now to start filling some blank spaces which, no doubt, will lead to a continuing broadening outlook of the use of the water resources of the Fraser River watershed.

A NOTE ON RAINFALL DATA ANALYSIS IN CEYLON

R. L. Raikes, M.E.I.C.,
formerly Water Resources Consultant,
Hunting Technical and Explorations Services Limited, Toronto

R. L. Walker, M.E.I.C.,
Chief Water Resources Engineer,
Hunting Survey Corporation Ltd., Toronto

THE OBJECT of this brief paper is to point out certain of the precautions that have to be observed when using in one country hydrological techniques developed in another. The particular techniques with which it is concerned are those for (a) the filling out of the record of a raingauge station where its length is less than the period considered minimum for the particular study in question, and where the length of the record at other stations in the area is of the requisite length; and (b) the examination of all the data both actual and either interpolated or extrapolated under (a) for inconsistencies or changes and the making of the necessary adjustment of the data.

Objective (a) is achieved by calculating for the whole period and from a group of nearby stations the average rainfall for each month or season or year as the case may be and by obtaining from this and from the actual corresponding rainfall for any station during the period of record of that station a correlation ratio for each month or season, etc. The correlation ratio for the station and period, applied to the averages for those years for which there was no record, gives an acceptable approximation to the monthly, seasonal or annual values that are missing.

Objective (b) can be achieved by double mass plotting, that is plotting the accumulated station period (month, season or year) totals against the corresponding accumulated averages over the period under review.

These techniques have been found extremely useful in North Africa where they were developed. Here it is considered reasonable to base the average on a group of stations which do not all necessarily have a complete record for the period under review. Obviously there must be some minimum number of stations within the group having a complete record: it is for the hydrologist to judge from the quality and nature of the record what this minimum should be.

The object of the investigation referred to in this paper, of which the analysis of existing rainfall data formed a part, was to determine for a major river basin in Ceylon the rainfall-runoff relationship. The ultimate object of the whole investigation was to determine for this river basin the availability and monthly distribution of water for irrigation and hydro-electric power generation at various points in it. As only a few runoff recording stations have been in operation for a relatively short time, it was necessary to compute synthetic flow data. This entailed correlating runoff and rainfall for each month of each year of record and using the coefficients derived in this way for extrapolation of existing records and the preparation of computed flow data for other points in the basin.

Ceylon is fortunate, compared with many countries in a similar state of development, in having a very extensive and dense network of daily depth raingauge stations, the records of the earliest of which go back to about 1870. As in the case of more developed countries records are in many cases incomplete, gauge locations have been changed with or without a change of name and, more significant to the analysis, the density of the network has increased irregularly as and when funds have become available.

Raingauges fall into three categories in Ceylon: (i) the first class stations operated by the Meteorological Service directly, which are comparatively few in number, (ii) second class stations operated for the Meteorological Service by other government agencies (e.g. at police stations and hospitals), and (iii) co-operating stations, varying from first class to dubious: these are generally at tea and rubber estates; they maintain records in the form prescribed by the Meteorological Service and send the results to the latter. The observers employed vary from technical and subtechnical staff of the Meterological Service, through clerical staff of estates, to semi-literate or illiterate persons.

It was decided that a 50-year period of rainfall should be the basis of establishing means; and that, because of seasonal variations in the probable use of water for irrigation or hydro-electric power generation and the high monthly variability of rainfall, the data should be analysed monthly. 50 years of data are considered by most hydrologists as a reasonable compromise between what is desirable and what is practicable for the determination of most of the variation of rainfall and runoff that affect the design of dams and reservoirs. Furthermore the economic life of most major dams and structures is generally taken as 50 years and it is unusual to cater for events outside this scope except where risk to life or property justifies a greater degree of protection.

In the particular basin under review many of the raingauge stations had records for less than 50 years, which comprised the period 1907 through 1956.

For determination of the total onfall of rain on the various catchment and sub-catchment areas it was decided to use the Thiessen polygon method of weighting the rainfall records. The first step therefore was the double one of selecting from the total of available stations those having more than a certain minimum number of years of record and, from among these, those that gave the best geographical network for the Thiessen polygons. In the first attempt, and mainly in order to improve the Thiessen polygon network, a minimum of 10 years was considered acceptable.

In North American practice a 10-year record is considered by most authorities as sufficient for good correlation. This practice is satisfactory in North America mainly because of the generally high standard of reliability of records. When this project was set up there was no reason to suppose that the standard of reliability would not be at least reasonable. Indeed the large number of stations and the length of the majority of the records led one to expect a high standard and it was not until the analysis was well under way that evidence to the contrary began to emerge from the analysis itself.

In order to have comparable records it was decided to fill out the records of incomplete stations by extrapolation. The system used was that described in the opening paragraph, i.e to determine for each month for each station a correlation ratio relating the rainfall for that month to an average for the whole area for that month. Following generally the lines laid down in the *Hydrology Handbook* of the American Society of Civil Engineers, it was decided that the average for the month should be that for the whole basin including stations with incomplete records. This involved the assumption that over a long period and a sufficient number of stations, errors are self-compensating. Extrapolated data was calculated from the correlation ratios.

The next step was to check the results to determine whether the records had been affected by changes of exposure of the gauges or by changes in observing technique, etc. For this purpose double mass plotting of accumulated station monthly totals against the accumulated all-station monthly means, was resorted to. In theory this should have revealed, by changes in the slope of the plot, any non-climatic factors and the years in which they occurred: adjustment of the whole record for any particular station month could then be made on the basis of slope ratios.

All this work, involving a considerable mass of data, would have taken a very long time and larger numbers of appropriate local technicians than were in fact available in Ceylon. The greater part of the work was therefore performed, first in Canada and then in the United States, by electronic computer (the IBM 650) and the plotting by an automatic line plotter which had, fed to it, the data from the IBM 650.

When the first batch of double mass plots arrived — there were close to 2,000 altogether — it immediately became obvious that slope determination was going to be difficult if not impossible owing to the enormous number of short period slope changes. On consideration it was decided that it would materially help in identifying dates of significant changes to have annual double mass plots prepared: clearly if the rainfall record for any station had been affected by a change of exposure, etc. this should show up on the annual plot which would then be used as a guide to the identification of dates. Monthly totals were considered to be more liable to fortuitous variations due to the observer being careless or ill or on holiday. Experience elsewhere led one to believe that absence of the observer due to illness or holiday could sometimes mean that the record had been filled in by not very enlightened guesswork!

Very few stations on the annual plots showed identifiable changes of slope but where they were identifiable the dates so determined were used in attempting to fit slopes to the monthly plots.

This still left a majority of the station monthly plots indeterminable as to slope changes except by guessing. Obviously this would not do. A careful check of the plots showed that in many cases, in addition to what appeared to be fortuitous slope changes, there was a distinct (sometimes very great) change in slope between the extrapolated segment and the factual data segment. This pointed to the method of calculation of the correlation ratios being at fault. When the dates of slope changes were first determined it was noted that very often they occurred around the years 1947, 1938, 1923, 1918, and 1914. Eventually the explanation came from examination of a graphical representation of the lengths of actual and extrapolated record. At or around each of the dates above there was a significant increase in the number of raingauges.

At this point it is necessary to digress. Ceylon lies in the monsoon belt and its weather is basically dependent on the annual movement north and south of the intertropical front. This in simplified terms is the line of demarcation between the northeast 'trade winds' of the Northern Hemisphere and the equatorial westerlies and between the two air masses concerned. The actual zone of contact is the zone known to sailors as the doldrums, characterized by intense local instability, variable winds, violent thunderstorms, etc. The movement of the intertropical front is not exactly predictable at present as regards its date of arrival at any particular latitude. The combination of this basic climatological background and the topography of the Island is responsible for the enormously varying rainfall experienced. In terms of depth the variation is from around 40 in. annually to around 250 in.: in terms of season one part of the island derives much of its rain from the northeast monsoon in the months October through January, while another derives much from the southwest monsoon from May through October. Yet another part appears to be under the influence of both monsoons and a fourth zone—along the southwest coast—appears to be under the influence of orographic effects on the doldrum phase.

In most years the periods March/April and September/October are those in which the actual intertropical front moves north and south respectively over the island — this is what has just been referred to as the doldrum phase. Rainfall in September and October, occurring as it does immediately before or after one or other of the monsoons, can be considered as belonging to one or the other according to circumstances.

Reverting to the study of rainfall data it became clear on reconsideration that the assumption that 'over a long period and a sufficient number of stations errors are self-compensating' was not valid. This is because the errors in this case are not true errors of observation or siting, but are systematically inherent in the weather system. If new stations had been brought into the record each time in numbers proportional to the numbers originally existing in different weather areas, the assumption would have been valid. As it was, the introduction of varying numbers from areas having, in some cases, exactly opposed monthly rainfall distribution introduced errors in the calculation of correlation ratios and falsified the accumulated total of mean monthly rainfalls — the abscissa values of the double mass plot.

Once identified, the trouble could fairly quickly be put right. Scrutiny of the rainfall records and of the monthly means for all stations published by the Colombo Observatory (admittedly including inaccuracies but reliable enough for indications of the stations' monthly distribution of rain-

Accreditation for Canadian Engineering Curricula?

C. H. R. Campling
Associate Professor
Department of Electrical Engineering
Queen's University, Kingston, Ontario

"But on every subject on which difference of opinion is possible, the truth depends on a balance to be struck between two sets of conflicting reasons."

John Stuart Mill
On Liberty

ARE THE FACULTIES of Engineering and Applied Science in Canadian Universities doing work of the calibre that is required in engineering education? Are our engineering graduates the sort of men who can contribute greatly to the development of Canadian industry? There is evidence that some of our graduates have the engineering ability, the bold imagination, and the enterprise to do more than help to operate a satellite economy. But are we educating our engineering graduates in a way which will ensure that a significant proportion of them have the technical competence, the depth of understanding and the breadth of view necessary to assure the engineering future of Canada?

One hears a great deal about the loss of our best brains to the United States, and we must admit that there is a significant migration of talent to the south. Whether this migration of talent is a loss to the nation is a good question for debate of course, because if we imagine ourselves without the benefits of American technology—to which these "lost brains" make their contribution—we can see that it is not necessarily all loss. The very fact that some of our best engineering talent finds its way across the border and in many cases does well in an atmosphere of keen competition is some assurance that all is not wrong with our system of engineering education. Some would argue that this fact is proof that we are doing very well and that no improvement need be contemplated. Some indeed would probably hold that our engineering graduates are superior in all respects to their American counterparts, will inevitably dominate them in any competitive situation, and need no improvement.

To argue this way is to blind oneself to the excellence of a large segment of American engineering education. The attachment of undue weight to the success of some of our own engineering graduates in the United States should also be treated with caution. Men who have inherent qualities of intelligence, ability, energy and ambition will do well in the world regardless of the educational system to which they are exposed in a university for four or five years. Indeed many will do well without such exposure. So it is pertinent to ask whether our best engineering graduates do well at home or abroad because of the quality of our engineering education, in spite of it, or whether their success is unrelated to their education.

There is real doubt about whether this question can be answered. The effects of any educational system are difficult to measure in a quantitative way. Furthermore changes take place slowly and the effects of great changes may not be felt for many years. If the changes are for the worse they may not be recognized as such for a long time. The present concern in the United States over the effects of the educational philosophy of John Dewey upon high school education is a good example. It is not enough however to say that we ought not to contemplate change because things at present are good and any change is likely to make them worse. Thus, while it may be impossible to answer specifically the questions which have just been raised, it is well worth while and indeed almost imperative that they be considered, and that the results of their thoughtful consideration be used as a guide in appraising our present methods of educating engineers.

Accreditation—Pro and Con

What are the merits and drawbacks of a system of inspection and accreditation in relation to our present arrangements for educating engineers? There are those who feel that such a system is a practical way of insuring the maintenance of high standards of professional education among engineers, and of fostering the development of stronger faculties of engineering and applied science. On the other hand there is a strong feeling in other quarters that this procedure would serve no useful purpose and would be detrimental to the best interests of university education. This view seems to be held quite generally by the universities themselves.

The number of engineering faculties in this country has never been very large, and for a long time there was no change in the number of institutions offering degrees in engineering. The past ten years however have seen a marked increase in the number of institutions involved in engineering education. Not all of these institutions have embarked upon the presentation of engineering curricula of the traditional type. This new activity has helped to stimulate interest in accreditation procedures, and in some cases the provincial associations of professional engineers have seen fit to institute inspection and accreditation procedures of a rudimentary sort.

The situation has in it the seeds of a conflict of interests. Traditionally the engineering profession in Canada has left the maintenance of standards of education leading to admission to the profession almost entirely to the universities. It has been argued that the universities have been our benefactors in this matter, and that the recognition which our profession receives is due in no small measure to the fact that our members increasingly have come from the universities. This is the point of view expressed so ably a few years ago by Dr. Claude Bissell,[1] then Vice-President, now President of the University of Toronto, when, holding up the medical profession as an example, he said, "The practice of medicine was ennobled by its marriage to liberal education and the medical profession thus attained its status as a learned and respected group." Yet it should be added that what Dr. Bissell failed to say was that in Canada now the medical profession has considerable influence through external accreditation and examination requirements upon the teaching of medical undergraduates in the universities.

Dr. Bissell made these remarks and others, none of which was favorable to the concept of accreditation, to an assembly in Toronto of the Engineers' Council for Professional Development. This body originated in the United States in 1932 a system of inspecting and accrediting engineering curricula. Since that time it has carried out this program with increasing influence until now it is one of the dominating features of engineering education in the United States. In effect Dr. Bissell told this assembly of American engineers and engineering educators dedicated to the accreditation program that Canadian universities wanted to have nothing to do with it. It is by no means certain that all presidents and deans in American universities were unsympathetic to his remarks.

Dr. Bissell's objections went right to the core of the matter. He said, "It would be a pity if the centre of educational thought were to shift from the universities themselves to any outside body, no matter how reputable and wise that body might be." This is what the accreditation system is doing for a great many of the engineering schools in the United States. Those within ECPD who dominate the thought and action of its Education and Accreditation Committee are without exception engineering educators. However, the great influence which they exert upon almost all American engineering schools and faculties is that of an external group. And while the inspection which may lead to accreditation must be requested and paid for by the institution, the prestige of ECPD accreditation and the pressure to conform is such that few institutions ignore the accrediting program.

But there is another side to the coin. Few who are informed would deny that in Canada we have engineering faculties where the curricula are backward, where the human and physical resources needed to effect improvement are lacking, and even where realistic, sympathetic and active consideration of the needs of the engineering education process is absent, inadequate or belated. We have engineering professional schools within our universities, but necessarily and probably rightly they are not considered to be the prime business of the universities. We do not have the sort of leadership for our engineering faculties which is provided in the United States by the great institutes of technology, except insofar as we look to those in the United States for leadership. Julius A. Stratton, eleventh president of the Massachusetts Institute of Technology, has said, "There rests upon such institutions as ours a heavy responsibility to provide standards of excellence, to set new patterns, to give leadership, and to lift the sights of all."[2] Lacking this sort of national influence, the strength which can come from a few institutions of high calibre which devote their prime efforts to science and engineering, we may well consider whether the profession in Canada is not justified in concerning itself directly with the education of its members in the universities.

Some may claim that nowhere but in a university can a young man gain the broad education which will fit him for professional life. But we should not make the mistake of assuming that the institute of technology is merely a trainer of technicians. These institutions have come to regard themselves as *universities polarized around science*. With some justification they might claim that they do a better job of educating their engineering undergraduates in the broad sense than do our own universities. There may be wisdom in the waggish saying that the universities *humanize the scientists* while the institutes of technology merely *Simoniz the humanists*. Nevertheless, when we think of the lack of interest in and indeed respect for the humanities which is evident among many of our engineering undergraduates and even in some of the products of our engineering courses, we should not lightly claim that all is well.

Consider also this statement (in context it was not made as an argument in favour of an accreditation system, but it can be taken as such): "We need only recall the retrogression of American colleges in the first decades of the last century when the rapid multiplication of institutions over-ran the support available and a widespread mediocrity enveloped them. In the longer past we might recall the lethargy of the European universities in the sixteenth, seventeenth, and eighteenth centuries. Cultural, social, and financial forces have from time to time diminished the vigour of universities; in the light of the past we cannot take for granted that our present-day system is immune to deterioration or that it does not require alert and vigorous efforts to keep it strong."[3] One might argue that as far as the engineering profession is concerned a systematic inspection and accreditation procedure would be a contribution to such "alert and vigorous efforts".

ECPD Accreditation

In considering the merits and demerits of an inspection and accreditation system it will be useful to consider in some detail the practices which have evolved in the United States over the past twenty-seven years. We may not like them, we may not want them, but at least we ought to examine the system for it involves a good deal more than a cursory inspection and it is no automatic rubber-stamp routine. We ought also to examine what we do in Canada in this direction, for even now there are embryonic forms of accreditation in this country.

Accreditation of engineering curricula in the United States is carried out by the Engineers' Council for Professional Development through its Education and Accreditation Committee.[4] This committee comprises a chairman and two representatives from each of seven geographical regions. These two are designated regional chairman and vice-chairman. In addition the immediate past-chairman sits on the committee as does a representative from the Engineering Institute of Canada.

The accreditation procedure used by the ECPD is based upon well-defined general policies.[5] The procedure is initiated only at the request of the institution. This policy applies when initial accreditation is involved and also when extension of an existing accreditation is sought. Accreditation is never granted for longer than a five year period. Shorter periods are often authorized for special reasons although accreditation for less than a three year period is not usual. ECPD accredits curricula and not institutions. It would be quite possible for an institution to have an accredited curriculum in civil engineering and a nonaccredited curriculum in electrical engineering.

Accreditation procedure involves the submission of written data by the institution to ECPD and subsequent inspection on the spot by a visiting team whose business it is to evaluate qualitative aspects of the institution and the curricula under consideration. The recommendations of the visiting committee are reviewed by the Council's Education and Accreditation Committee and later by the Council itself before it arrives at a decision.

There are other policies which are important to the maintenance of high standards in the accreditation program. No form of accreditation is employed at present for graduate curricula. Even for undergraduate curricula the ECPD aims to ensure "the avoidance of rigid standards as a basis for accrediting, in order to prevent standardization and ossification of engineering education and to encourage well-planned experimentation."[5] Further, the ECPD publishes "a list of accredited curricula only, with no information available to any person (other than proper officials of the institution concerned) as to whether any curriculum or institution not on the accredited list has been under consideration by ECPD".

Curriculum Inspection

Consider now the mechanics of a curriculum inspection. When a request is received from an institution for consideration of one or more curricula with a view to accreditation a questionnaire[6] is sent to the institution. This questionnaire covers all the important aspects of the institution's operations insofar as they relate to the curricula under consideration. It provides the inspectors with information which makes possible the efficient use of their time during the inspection process. The bare documents total about twenty pages and inquire searchingly into the characteristics of the institution as a whole including its type of control and its financing; the features of the engineering unit; its finances both in total and as they are distributed among the various departments; policies toward faculty including salary ranges and averages; physical facilities including buildings, laboratory equipment and libraries; enrolment statistics; admission requirements; graduation requirements; courses taught in the curricula for which accreditation is sought; the objectives of the institution insofar as they relate to these curricula; and finally the background of all staff members whose work affects these curricula. Copies of the completed questionnaire are supplied to the chairman of the ECPD Education and Accreditation Committee, to the regional chairman and vice-chairman concerned, and to the members of the team of inspectors which is to visit the institution.

Members of inspecting teams are chosen from the ranks of engineers of high repute in industry, private practice, and education. The great majority of them however are engineering educators. For each curriculum which is to be inspected the visiting team will have at least one member whose field of engineering corresponds to that curriculum. Customarily the regional chairman or the vice-chairman also is a member of every visiting team within the region. Thus, when the report of an inspection team comes to the Accreditation Committee there is a member present who has first-hand knowledge of the case. Those who are appointed to positions as regional representatives on the Committee are men with extensive experience and proven ability in the techniques of inspection.

An inspection is carried out over a two-day period. The chairman of the visiting team is expected to familiarize himself beforehand with the reports and actions on previous inspections if any. He is also responsible for the selection of a balanced team. The team meets for a preparatory session the evening before the inspection is scheduled to begin. On the following morning the visitors assemble with the dean or chief administrative officer of the engineering programme in the institution. After this meeting they may meet the president. The team then splits up and the members proceed with their individual inspection assignments. In the evening they meet again to discuss and correlate their findings, and to see whether such weaknesses as may have been discovered are general or peculiar only to certain departments. The morning of the second day is allotted to completion of the inspection and such cross-checking of the findings of the first day as may be necessary.

In the afternoon of the second day the team meets to reach agreement upon the points which the members feel should be included in the written report, and to decide what recommendation should be made to the ECPD Education and Accreditation Committee. The committee then meets once more with the dean and possibly the president to review its findings. The committee reports only upon facts and observations at this point, and ascertains whether the officials of the institution agree with the findings. No intimation is given as to whether the curricula inspected will be recommended for accreditation or not. After this meeting the visit to the institution is complete.

The formulation of a written report is the responsibility of the chairman of the visiting committee. To assist him in this task each team member is expected to prepare a report covering the assignments which he has carried out. The consolidated committee report has two distinct portions. One of these is confidential and for perusal only by the responsible officials of the ECPD and its Education and Accreditation Committee. It contains the statements of observations, facts, and opinions relating to the curricula under consideration as well as to the departments and facilities directly related to the support of these curricula. This portion of the report also contains the visiting committee's recommendations to the Education and Accreditation Committee for accrediting action if any.

The second portion of the report comprises a statement of less confidential nature which can be transmitted to the institution concerned. The objective is not merely to indicate to the institution the basis for the accrediting action, but to assist in improving its educational standards where such improvement is believed to be necessary or desirable, and also to point out the strong points. Great emphasis is placed upon the tactful wording of the portion of the report which is sent to the institution, since it is intended to instil a desire for action and not resentment. The ECPD aims to effect general improvement in the level of engineering education and not merely to provide minimum standards. Those institutions which are accredited, even the best of them, have in these reports means for evaluating their shortcomings. The report may also provide some of the stimulus required to encourage improvement.

The reports of the team members and the chairman's consolidated report together form a rather voluminous document. The Education and Accreditation Committee meets twice a year, in June and October, to consider many of these reports. After thorough consideration it frames its recommendations to Council. These recommendations are carried by the Committee chairman to the Council which considers and acts upon them once a year at the annual meeting of ECPD in October. No word is transmitted to the institution until action has been taken by the Council. The visiting committee's comments are then despatched along with the Council's decision on accreditation.

Accreditation Criteria

More important than the mechanics of accreditation is a consideration of what the ECPD looks for and expects in an accreditable curriculum. Under the Rules of Procedure of the ECPD the Education and Accreditation Committee is charged to "develop, and modify when necessary, criteria for colleges of engineering which will ensure to their graduates a sound educational foundation for the practice of engineering".

The basic criteria for accreditation purposes were set forth in a statement approved by the ECPD in 1933. While these criteria have not been modified in the intervening years they have been supplemented with additional criteria. The original criteria laid emphasis upon both the qualitative and quantitative aspects of the curricculum. The qualitative aspects include the extent to which the curriculum develops the ability to design — this being regarded as one of the chief distinguishing characteristics of the engineer; the "qualifications, experience, intellectual interests, attainments, and professional productivity of members of faculty"; the "standards and quality of instruction" both in the engineering departments involved in the curriculum and in the scientific and non-scientific departments contributing to it; the relationship of scientific training in the early years to engineering teaching in the later years; the "scholastic work of students," the records established by graduates of the curriculum — both in graduate schools and in practice; and finally the "attitude and policy of administration toward its engineering division and toward teaching, research, and scholarly production."

While the qualitative features of a curriculum are most readily evaluated by the visiting committee while at the institution the quantitative aspects are readily communicated in print. Substantially the quantitative criteria used by the ECPD are those which have already been presented as the subject matter of the questionnaire.

With the passage of time and intensification of the work and influence of the ECPD Education and Accreditation Committee there arose a need and demand for more precise statement of what the committee and ECPD regarded as adequate organization and content for a curriculum. In 1955 the Council adopted a set of *additional criteria* which set out in some detail the minimum requirements for work covered in basic sciences, engineering sciences, engineering analysis and design, and the humanities. Because it was found that these additional criteria were being interpreted often in too narrow a sense the statement of them has been revised subsequently. This revision, which first appeared in the ECPD Annual Report for 1958, emphasizes the Council's basic policy of avoiding rigid standards which might discourage new developments and experimentation.

An approvable curriculum contains "at least the equivalent of one academic year of basic sciences, about half of which is mathematics beyond trigonometry."[5] Basic science is understood to include mathematics, physics, chemistry and geology, with emphasis upon the teaching of fundamental natural principles and their quantitative expression. Engineering science on the other hand is understood to mean the organized body of knowledge within the scope of the word science which forms a *bridge between basic science and engineering*. While this distinction may be difficult to interpret, particularly when there are institutions within the acquaintance of most in which basic science is taught within engineering departments and others in which engineering science is taught by basic science departments, it is a meaningful one. The criteria of 1955 specified mechanics of solids; fluid mechanics; thermodynamics; transfer and rate mechanisms; electrical fields, circuits and electronics; and the nature and properties of materials as engineering sciences. It was specified also that at least the equivalent of one academic year should be devoted to these sciences. The more recent statement however is less specific. It recognizes a "merging of boundaries between the basic and engineering sciences," expresses more concern with the breadth and depth of coverage in both, and lays less emphasis upon the division of time between the two. This change reflects the tendency in the United States to expand the scientific content of engineering curricula.

The additional criteria also call for at least the equivalent of one-half of an academic year devoted to engineering analysis, design and engineering systems. A further requirement is that one-half to a full year be devoted to studies in the *humanistic-social* area. To emphasize that more than lip service is to be paid to the latter, and to ensure that the subjects are chosen for their cultural value and not merely for their utility, it is specified that at least one-half year should comprise study of such subjects as history, economics, government, literature, sociology, philosophy, psychology, or fine arts, and should not include such courses as accounting, industrial management, finance, personnel administration, or military studies. It is understood that the whole degree programme must require a period of study of not less than four full academic years.

Canadian Activity

Such is the accrediting system sponsored in the United States by the ECPD. What equivalent if any have we in Canada at the present time? Certainly we have no widely known system. We have no regularly maintained and publicized list of accredited curricula. No national engineering body attempts to speak publicly for the profession in Canada on this subject. The Engineering Institute of Canada and the provincial associations are however not inactive in the matter.

The EIC interests itself in educational standards by virtue of its stated aim "to develop and maintain high standards in the engineering profession." This aim is the basis for EIC membership in the ECPD, and it is the reason for ECPD activity in the accreditation field in the United States. The ECPD, like the EIC, is not concerned with the licensing of engineers to practise, even though the licensing bodies have a direct interest in the ECPD. The National Council of State Boards of Engineering Examiners is one of the eight constituent bodies.

The measure of the extent of EIC participation in the accrediting field is the publication of a list of Canadian Universities with the engineering courses which they offer[5] along with the ECPD list of *Accredited Curricula Leading to First Degrees in the United States*. For each course there is a statement to indicate whether graduation from it is considered formally to fulfil the academic requirements for membership in or registration with the Chemical Institute of Canada, the Engineering Institute of Canada, the Canadian Institute of Mining and Metallurgy, and the various provincial associations (Corporation in Quebec) of professional engineers. The specific statement is made that publication of the list "does not imply accreditation by

ECPD or by any Canadian Organization." In the absence of initiative from those universities which have only recently begun to grant engineering degrees in Canada none of their names or the courses which they offer appear on the list in the Annual Report of ECPD for 1958.

Some of the provincial associations have become involved in the accreditation of curricula, notably in Ontario where in the past few years several universities have embarked upon new programmes leading to engineering degrees. The Ontario Association[7] set up in April, 1957, an accreditation committee. It operates through ad hoc visiting subcommittees. When an application is received for accreditation of a course one of these subcommittees visits the university in question and reports upon the staff, laboratory facilities, class room accommodation, and degree proposed. Final action is the responsibility of the Council of the Association. These arrangements are patterned very closely upon those used by ECPD, although the objective in a sense is different.

In other provinces in Canada[8] the associations of professional engineers usually accept the standard set by the provincial university as a measure of the academic requirement for registration. The standards of other institutions within or outside of the province are judged by comparison with the provincial institution.

Appraisal

Canadian practices differ in several ways from those used in the United States. Many of these are apparent from the foregoing account. Accreditation in Canada, where it exists, does so because of its relation to registration. In the United States a licensing body may see fit to accept graduation from an ECPD accredited curriculum as a prerequisite or at least a qualification for registration, but ECPD has no registration authority. There is another important difference. Accreditation by ECPD is for a limited period only. In Canada there is no form of accreditation which carries with it a specified time limit.

Taking into account the inertia to which both professional associations and universities are subject, one can see that without periodic review a course of studies or curriculum in a particular institution could deteriorate to a low standard and remain there for a long time before action was taken. Nor is inertia the only reason for such a state of affairs. There are a host of possible reasons including lack of funds. Responsible outside authority can be a potent influence, perhaps even one which the institution might welcome in such cases, for the improvement of standards. Deterioration is not something which can occur only in small and obscure universities. It can occur in specific departments in the best or the largest or the wealthiest of institutions. The main argument for a professional organization taking a direct interest in such situations is that the professional group can claim a duty to protect itself and the public. The public may be involved in two ways. It may be adversely affected by the incompetence of those who have followed inferior courses of study. It may also be affected in the sense that young men may be led to register in courses of study which they may judge to be excellent because of the high reputation of the university as a whole, but which in fact may be quite inferior among professional courses in the selected field.

The practice in some provinces of setting the provincial university up as the standard is only a very informal sort of accrediting, and of course it leaves the provincial university free to regulate its own standards. There is nothing in these arrangements to promote a national standard either of minimum requirements or of excellence. It is easy at this point to slip into a discussion of provincial and national responsibilities in the field of education and professional registration. These matters are under provincial control and few seriously question the desirability or feasibility of attempting to make any change. There is however nothing illegal or even necessarily undesirable about attempting to influence for better on a national scale the standards of education for a profession, there being nothing to bind any institution legally to accept such influence. We already have in education for the medical profession strong influences of this sort which cross not only provincial but national boundaries.

Summary

An attempt has been made here to present arguments both for and against the institution of some form of nation-wide accrediting of engineering courses. A description has been given of the accrediting systems already in use for engineering curricula in the United States and Canada. If greater space has been given to the case for accreditation, it is not necessarily because the author is firmly convinced that such a system would be a definite asset to our country and profession, but rather to stimulate thought and even provoke argument about a subject which we are likely to treat with too much complacency.

So often when enquiry has been made as to why we do not have a more active accreditation scheme in this country the answer is altogether vague, or perhaps to the effect that our engineering schools have been long with us and are generally agreed to be excellent — after all we graduated from them so they must be. Then again it has been said that our universities or our faculties of engineering and applied science have been asked whether they would like to see a system of accreditation instituted, and they have replied with one voice, "No." The profession seems to accept this "No" without question. What does not seem to be realized is that our universities look upon this as interference and naturally they do not want to be interfered with. Their position is sound; the universities must be free if they are to maintain their respect as universities; they do not want to receive "letters to college presidents"[9] from representatives of a profession telling them how to improve their engineering faculties—no matter how ably, diplomatically, and sympathetically the comments may be written.

But the position of the profession is equally sound if it wishes to exert efforts to better the educational background of its members for the benefit of both profession and public, and if it can see that there are cases where an educational program attaches secondary importance to engineering or where there is lack of sympathetic or informed understanding of the needs, objectives, and requirements of a program in engineering education. Reference has already been made to the opinions expressed by Dr. Bissell of the University of Toronto. His remarks should be supplemented with a reading of the discussion of them by Dean Hardy[10] of the University of Alberta. Dean Hardy contends that "The engineering profession in Canada relies completely upon the universities for the standard of engineering education, but the universities have no inherent right to the responsibility."

What is needed of course is effective cooperation between the universities and the profession, and the real question is whether a system of accreditation would foster such cooperation in greater measure. There should be no basis for concern that matters relating to accreditation would be placed by the profession in the hands of engineers of great competence in their own fields but with little understanding of or sympathy for the aims and essential characteristics of a university. Experience has shown that in both the United States and Canada these matters have been left almost entirely in the hands of professional engineering educators, many of them university deans of eminence. We ought, however, seriously to ask ourselves whether the stimulus of such formal cooperation between the profession and the universities is needed as a supplement to the stimuli which our engineering faculties now receive. They are at present subject to the interplay of a host of forces as well as to subtle and informal influences some of which relate to competition and some to cooperation. The success of an accreditation system involves many complex human factors, but the potential rewards may be worth seeking. The question is not simple, nor is there likely to be a simple answer; but it is important, and our profession ought to give it serious consideration.

ACCREDITATION FOR CANADIAN ENGINEERING CURRICULA?

(Continued from page 86)

fall) indicated that the stations in the basin could be assigned to one or other of three groupings in each of which the distribution followed a reasonably regular pattern. At the same time it was considered that enough variation within the groups still existed to make long period extrapolation risky so that all stations were rejected in which extrapolation exceeding two-thirds of the actual length of record would be required to produce a 50-yr. record.

Within each group of stations which, for convenience, were called the Northeast Monsoon, Mixed Monsoon, and Southwest Monsoon groups, averages were determined for that group from those stations within it having the full 50 yr. of record; correlation ratios were determined and extrapolated monthly rainfall totals calculated.

The reason why these techniques did not work out as originally used lies entirely in the different climatic conditions obtaining in North America and in Ceylon. In North America and within the area of any particular catchment under study there is little variation in type of weather. Raingauge stations may, due to differences of altitude, general topography, aspect, etc. show wide variations in daily, monthly, seasonal and annual depths but, within such catchments the periods of relatively higher and lower precipitation will be substantially the same all over the catchment. Really wide variations obviously exist within North America, but at such geographical distances apart as to make them of no practical signficance in relation to any individual catchment area. The same could, in practice, be said to apply to the whole of the temperate zones: the same can indeed be said to apply to some areas of Africa and Asia.

Where, as in Ceylon, the weather system is not homogeneous over the whole of the very small island, the technique can still be applied but with modifications. These modifications can be generalized so as to apply to the areas where conditions are not homogeneous. They can be summarised as follows:

1. Where evidence exists of lack of homogeneity of the weather type over the area being studied it is advisable to limit wherever possible the extent of extrapolation of data. This is because of the difficulty of identifying the boundaries of weather types: along the boundaries there is much shading due to stations being sometimes more under the influence of one type and sometimes more under the influence of another. Extrapolation of two-thirds of the length of the actual record is considered the maximum permissible until further information is available. However the setting of such a limit is best left to the experience of the hydrologist undertaking the study.

2. It is essential to identfy and map as accurately as possible areas within which the seasonal or monthly distribution of rainfall is fairly homogeneous and to sort the raingauge station records into corresponding groups. Even if the basis of study is annual, the same applies, for the rainfall in one part of the area in one season may spring (as in Ceylon) from causes totally distinct from those causing the rainfall in another part of the area.

3. Having sorted the raingauge stations into appropriate categories the only further modification indicated is to calculate the monthly, seasonal, or annual averages for the group from **only** those stations within the group having a complete record for the period under study. It is easy to imagine areas where the literal observance of this modification would leave too small a group for the establishment of averages and in such a case the hydrologist must rely on his experience: often such areas have such a thin network of raingauges that it is not possible to adhere to these recommendations. The same may be said to apply to some parts of Canada, but with the reservation that in general North American techniques can be applied without modifications.

Even in North America where the techniques used originated, double mass analysis of hydrological data has not been widely used. This is partly because before the advent of the digital computer such as the IBM 650 it was generally impracticable or uneconomic to deal with the mass of data involved: and partly because often the quality of data is good enough for the method to be dispensed with.

And so the kind of problem with which this paper deals is at present comparatively rare. If any general recommendation can be made, apart from the specific recommendations made above in respect of areas where lack of homogeneity is known to exist, it is that each new rainfall study must be assumed to be distinct and unrelated to other studies until reliable evidence to the contrary is available. In the study described, parallels with other studies were assumed until evidence to the contrary was available.

Underdevelopment is very often due to inadequacy or uneven seasonal distribution, or even to excess of rainfall with its attendant problems of damaging floods and denudation. Development in the physical sense will most often take the form of irrigation and/or hydroelectric power generation and both these require at least seasonal, and often monthly, analysis of hydrological data. It is essential therefore that in such countries a general picture of the rainfall distribution should be obtained as a first step and that the hydrologist should consciously try to identify different weather types and map them.

ENGINEERING FOR EXPORT

R. A. Frigon, M.E.I.C.

Chief, Engineering and Equipment Division,
Foreign Trade Service,
Department of Trade and Commerce, Ottawa

Paper Presented at the Annual General Meeting of the Engineering Institute of Canada, held at Toronto, June 8 to 10, 1959

MORE THAN at any time in the past, engineers are playing a vital role in the development of international trade. On the site of great works abroad, in the design office, on the production line, as consultants, as leaders of industry, engineers are making an increased contribution to trade between nations. In this, the modern engineer is following in the footsteps of his immediate predecessors of the Industrial Revolution and the days of colonial expansion. He may even be emulating those earliest engineers, the men who developed the very beginnings of technology. For the stimulus that drives men to trade with other nations is as old as man himself. Pressures of population, struggle with environment, harnessing of nature, migrations of technological invention, the mere struggle for survival have combined with the irrepressible will of man to seek new and fresher fields.

The contrast of today with the past lies in the vastly accelerated pace of development as communications have improved and scientific discoveries have come to add a measure of orderliness to the cruder efforts of earlier days. Today, engineering participates in trade against a background of intricate technology and complex international organization. The range of engineering products traded between nations includes the very simplest apparatus as well as such highly developed products as electronic components, chemical processing plant and large scale engineering works involving coordinated construction procedures. Such international organizations as the United Nations, NATO, World Bank and Colombo Plan and technical assistance programmes all play a part in spreading trade in technological commodities.

The movement of engineering products and services between nations is taking place under the impetus of such influences as money seeking investment fields, entrepreneurs venturing into new endeavours, industrial expansion and the vast programmes for development. These are associated with the determination of the newer nations of the world to secure for themselves the benefits of an improved material standard of living. In this last respect, the newer nations of Asia, Africa, Latin America, The West Indies, the Middle East are not only engaged in their own efforts. They are being assisted through vast international and bilateral programmes which include basic resources development as well as progressive industrialization in all sectors. The requirements of these economically underdeveloped countries pose at once an opportunity and a challenge to those countries that have developed engineering equipment and services of a type that are needed to bolster economies in need of development. In this respect, Canadian engineers and Canada's engineering industry are meeting the challenge and will undoubtedly continue to do so at a greater rate, as it is increasingly realized that Canada's stage of development is remarkably close to the type of development that many of the newer nations now need and will continue to need for some years to come.

Fig. 1. Model of a pulp and fine paper mill now being built near Cairo, Egypt. A Canadian firm acted as consultants, made the layout, and are supervising the engineering.

Most of us are, of course, implicitly aware of the situation as it stands today but few of us have the opportunity to participate in the whole and to observe the overall scene and its many interconnections. The Foreign Trade Service not only furnishes assistance to industry as required, but provides a vantage point from which useful observations can be made.

We in the Foreign Trade Service are in touch with the engineering industry in all its phases. We have come to know the consulting engineer and the pride he so correctly takes in the engineering code of professional ethics, the manufacturer and his almost traditional but wise caution, the contractor and his daring and spirit of risk-taking. We have sensed in all an almost wistful wish that one might borrow from the other a little of that which makes for the other's strength. The consulting engineer would like to be a little more flexible in his arangements with a client, and wonders if he might not correctly do so in other lands. The manufacturer, who is accustomed to selling on his reputation or to filling orders at home but always concerned that a proper return is made on heavy capital investment, wonders if he might not reconsider his method of pricing, manufacturing procedures and standards, taking a risk on closer pricing for export. The contractor, a risk taker and entrepreneur at heart, yearns for more stability. At times, all three decide that it is to their best interest, as well as to that of the client, to join in a marriage of convenience as a consortium, bringing to bear a blended mixture of all three approaches. All three, of course, realize that the domestic market in the long run is seldom if ever a sufficient outlet for the kind of special services and products that engineering firms are wont to provide. Whether alone or together, they have a common interest in exporting.

Whatever their guiding philosophy, whether they be consultants, manufacturers or contractors, most firms as can be imagined have some very practical questions which they would like to have answered. First and foremost, of course, is the question: What are the advantages of foreign markets for engineering services and equipment? Next come the questions: What conditions or obstacles are we likely to encounter abroad; what are the methods of coping with these conditions; what are the opportunities; what are Canadians now doing in this field?

Let us now discuss some possible answers to these questions.

What Are The Advantages

The export market offers a useful or even essential adjunct to a limited domestic market. Specially-made equipment, and specialized services, are in limited demand in any one country and at any one time. Even in those countries where requirements for years ahead are enormous, there is a limit to the number of engineering firms that can be effectively supported by the home market. The pace at which industrial development can effectively progress is limited and uncertain and in turn determines the maximum industry that can be supported. The great fluctuations in demand can in part be met by overseas requirements. Such fluctuations often result in the disbanding of technical staff carefully assembled, with consequent loss of valuable experience, not to mention loss of employment. Foreign contracts not only offer the opportunity of retaining such staff intact in some measure, but provide challenging engineering assignments. There is no need to tell members of this Engineering Institute that engineers need the challenge of difficult assignments in order to flourish professionally. Canadian engineers have had more than a full share of difficult tasks within their own country, and have performed remarkable engineering feats that have attracted world wide attention. But such opportunities are limited even in a vast country like Canada, and furthermore must be shared with a growing number of competitors.

A nation like Canada, in full force of development, builds up an inventory of skills and knowledge which in due course leads to pressures for their full utilization. Overseas work can utilize these pressures and insure use of engineering developments that might otherwise go unused.

Although the advantages to the country as a whole are, of course, obvious, the contribution made by each segment of the industry may be briefly mentioned. The consulting engineer* is receiving increased recognition for his important role as an ambassador for his country. He can do much to influence within the limits of his professional status and the economics of the situation, the choice of equipment and materials. He is naturally most familiar with the performance and characteristics of products from his own country. All other factors being equal he will tend to favour a product of which he has knowledge. The contractor who submits an all inclusive bid will, of course, want to remain competitive and will not necessarily select home equipment, but he will nevertheless tend to favour the home supplier whose products he knows well. The manufacturer can well regard his exported equipment as standing evidence to local populations abroad of his country's ability to supply equipment of quality, not to mention the benefit he himself can expect from possible re-orders, as is so often the practice of satisfied users of special equipment.

What Are The Obstacles

One of the major obstacles to the development of foreign opportunities is the need to spend considerable time and money on travel and investigations, in search of assignments. There are ways of dealing with this problem, as discussed below, but there is no minimizing the difficulty for the small firm. Nevertheless, some have found that once an assignment has been secured, other assignments are more easily obtained. Of course, the difficulty will vary with the type of firm. Consulting engineers need to do more on-the-spot investigating than do manufacturers. Contractors are faced with substantially the same problems as the consultant, but a contracting firm may have more extensive resources and a larger stake than the consultant.

Other difficulties include a lack of familiarity with local business methods, taxation legislation and the absence of reliable data upon which to base cost estimates. Payment conditions may require the extension of short or long term credit, acceptance of local currencies or of commodities on a barter basis. There are additional risks that arise from political instability. These difficulties are not without solution, as explained further on, but they do add to the complexity of foreign dealings and entail expenditure of time and money, often with no immediate returns in sight.

Other difficulties arise from within the exporting country. Some of these are intangible but very real. For instance, some manufacturers conclude *a priori* that their prices will not meet foreign competition, forgetting that price may not be the main competitive factor or that the foreign standards may permit the utilization of lighter construction. Some consulting engineers continue to quote terms that are unrealistic in the light of local business practices. Prospective exporters need to examine their own views before reaching conclusions as to their ability to compete abroad.

Let us take the situation in Canada for example. The matter of high Canadian costs needs to be examined in the light of hard realities. High wages tend to lead to higher cost products and services and Canadian exporters are at times priced out of the market. However, our tenders can be encouragingly competitive when the trouble is taken to "sharpen pencils", to use a term of the trade. Many Canadian exporters of engineering products and services are displaying ingenuity in finding solutions. These solutions are based on such devices as the use of alternative materials that foreign competition is not using, combinations of equipment from various countries ensuring that at least a portion of the contract will go to Canadian suppliers, and the establishment of foreign partnerships

* The role of the consulting engineer in foreign trade was the object of a special study in France. The report published in L'Usine Nouvelle for January 1958 contains an interesting analysis of engineering as an export commodity. (See bibliography)

leading to joint submissions. Many of these tenders are based on the realization that price is not always the main factor in competition. Ability to deliver at a given time and to keep delivery promises, technical superiority, availability of spare parts and service, are all factors that the buyer takes into account when making a choice. These are almost self-evident truths, but it is remarkable how often prospective exporters will let stand in the way, obstacles that can be overcome.

Solutions To Overseas Problems

While there are many ways of dealing with export problems, there is an approach which holds so much promise that it is singled out for special mention. This involves a group effort by several firms cooperating in all phases of the operation from the initial steps towards finding work to the final execution of a contract. The group effort, as exemplified by the consortium, offers the advantage of pooled resources and should be an attractive proposition for both large and small firms. For the latter, it may provide the only effective means of prospecting for foreign work, as many small firms do not have the financial resources to engage in foreign travel that at times is so necessary to negotiate contracts involving highly developed products or services. Larger firms will also benefit, especially when large projects are involved. A large-scale project is normally beyond the abilities of a single firm and requires a variety of services and products. The cooperative effort offers the attractive possibility of liaison with foreign groups located either in the importing country or supplier countries, on the principle that half a loaf is better than none at all.

The Consortium

The consortium is typical of the cooperative effort. Consortia are either *ad hoc*—set up for the occasion, or a permanent arrangement between firms. The consortium has for origin the demand for contractors to undertake schemes beyond the technical and financial capabilities of a single firm.

The objective of the *ad hoc* organization is usually to tender or negotiate a specific project and to undertake that project if the tender or negotiations are successful. The objective of the more permanent type of organization is to provide a common service to its member firms to explore contract possibilities, or to put it in other terms, to market its joint services and products. There are, of course, variations. Among the consortium type organizations there are associations whose purpose is mainly the marketing of equipment and, if required, arranging for group combinations to supply products and services.

An outstanding example of the consortium set up for a specific purpose is ISCON, the Indian Steel Works Construction Company Limited, which came into being in 1955 as a consortium of thirteen British manufacturing, electrical, structural and civil engineering firms to deliver in India in a package deal a 1¼ million ingot-tons per year steel plant. ISCON was set up mainly through the activities of MEECO, the Metallurgical Equipment Export Company Limited, a permanent-type consortium formed in 1945 and composed of six firms. Among more recent groups are the nuclear power consortia established in the United Kingdom in connection with the construction of reactors, and other nuclear plant. Another example of the ad hoc consortium is RUSTYFIA a group of British companies formed to build a tire factory at Dnepropetrovsk in the USSR.

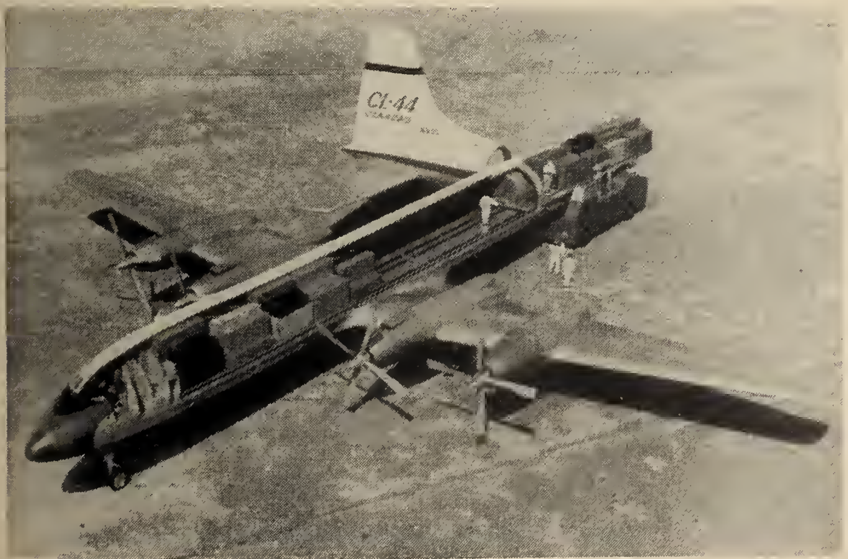
For examples of the permanent type consortium one need not go further than right here in Canada. A purely Canadian firm is Canadian Overseas Projects Limited, which constructed the Maple Leaf Cement plant in Pakistan under the auspices of the Colombo Plan. BEPCO, British Electrical Plant Company (Canada), formed in 1933 for the sale and servicing of equipment imported into Canada from the United Kingdom, is engaged in manufacturing activities of its own in Canada.

Group One Limited, a British organization which includes some foreign firms, is a typical permanent organization that might well serve as an example for Canadian firms to follow. Group One's purpose is to bring large scale engineering projects to the attention of its members and to arrange where required the formation of consortia. The work is carried out by the consortia and the administration normally remains with Group One. The work is mainly confined to member firms, but there is some flexibility as the Group always attempts to bring in a local firm. This is often a requirement in some countries today and is very desirable from a practical point of view for the prestige that it can bring.

Consortia are to be found in all countries of the world interested in overseas work. In France, France-Technique is an association of eleven French companies established for the purpose of developing contracts for member-firms. It arranges for the formation of consortia of French firms, members or not, either alone or in partnership with non-French firms. This group furnishes another excellent example that could be followed. ICOFRANCE, a French group is not strictly a consortium but rather an association of French consulting engineers interested in overseas projects. In Italy, ITALCONSULT, Societe Generale per Progettazioni Consulenze e Pertecipazioni, was organized to undertake consulting engineering assignments as well as to take on the responsibility for the actual carrying out of works. Associated companies comprise IMPRESIT—Imprese Italiane allo Estere and ELECTRO-CONSULT which carry out respectively construction works and electrical installations.

Netherlands Engineering Consultants, NEDECO, is another cooperative unit that pools the efforts of con-

Fig. 2. A four engine, jet-prop long range transport plane, built in Canada, already has a market in the United States.



sulting engineering bureaux with the assistance of other experts and technical or scientific organizations in the Netherlands.

If the cooperative effort has been treated at length, it is to stress the potential of such an approach in providing a solution to some of the problems that confront exporters of engineering equipment and services. In Canada especially, where firms on the whole are comparatively small, but have so much to offer countries in process of development, the formation of consortia or associations especially aimed at engineering exports, would appear to offer attractive possibilities.

Fig. 3. Log bundles being hoisted from the river at the Khulna, East Pakistan pulp and paper mill, designed and constructed by Canadian firms.

Consortia and Consultants

Before leaving the subject of consortia, it seems appropriate to consider the part the consulting engineer may play in such associations. As consortia by their very nature, at least in their original form, are likely to be involved in turn-key projects, the consulting engineer associated with a consortium may find himself in an untenable position, from the professional point of view. There are, however, ways that the consulting engineer can deal with this situation. He may be engaged as consultant to the contractor on a fee basis and not as a participant in profits. Another solution that holds some promise and seems to be gaining in favour is the consultant acting as an adviser to the project sponsor and "vetting" the designs submitted by the consortium members. Such an arrangement has apparently met with some success in the case of the ISCON contract with the Indian Government's steel mill. A Canadian consulting engineering firm has recently had this type of assignment for an industrial project in the Middle East.

On a broader plane, an arrangement of some interest is the agreement between the Export Group for the Constructional Industries and the Association of Consulting Engineers in the United Kingdom. A consulting engineer can work for a contractor or group of contractors in preparing designs for the works and giving technical advice. This can be considered a significant development, as the Association of Consulting Engineers in the United Kingdom, as is our own, is well known for the high professional standards of its members. This and other developments would seem to indicate that the professional engineering groups recognize that practical steps must be taken to allow the professional engineer to take an increasingly effective part in the highly competitive international scene. There has even been the suggestion in the United Kingdom that the consulting engineers would view with favour the formation of a government-supported British equivalent to the Continental organizations backed by finance houses and in some instances governments. Selected group members proceed to the site, make a project report and then offer consulting services for the scheme.

The Foreign Trade Service

It seems appropriate at this juncture to discuss the services available from the Department of Trade and Commerce. The facilities in Ottawa and abroad provide an example of a cooperative effort maintained by Canadian companies, as taxpayers. The Foreign Trade Service is in fact, a listening post for all types of engineering opportunities abroad. It is a clearing house and assists Canadian firms find solutions to export problems. The Engineering and Equipment Division assists consulting engineering firms, equipment manufacturers and contractors in obtaining a share of foreign contracts and orders. Information can be obtained from the department on the services available from this and other divisions. It may be useful, however, to point out here that Canada maintains trade commissioners in over fifty trading centres throughout the world whose services are available on request. Direct communication with our posts abroad makes for an efficiency for which our Trade Commissioner Service is well known. This procedure is not found in many other countries. Personnel at headquarters offices, maintain a close personal relationship with firms interested in exporting. This makes for a most useful triangular arrangement involving exporters, trade officers overseas and headquarters.

The Department utilizes several devices for export trade promotion. One of these is the fortnightly publication "Foreign Trade", which has of late devoted increasing attention to subjects of interest to engineering firms. A recent issue features nuclear engineering in export trade and contains an account of the Canadian trade exhibit sponsored by the Department at the AtomFair in Cleveland last April. Trade exhibits are used by the department for promoting trade. A Canadian display featuring the products and services of thirty firms for engineering designers was part of the Design Engineering Show held in May in Philadelphia. Through this means it is hoped to gain increased recognition for Canadian engineering products in the United States and other countries.

The difficulty in keeping in touch with developments abroad and interpreting local conditions can be partly met by the appointment of a local representative, or by a partnership arrangement. The selection of the agent is naturally most important. The trade commissioner can readily assist in this direction, and give advice on local business practices, taxation, etc. In many countries it may not be possible to find suitably qualified persons, especially if highly technical products or services are involved. In such instances, it will likely be necessary to travel to the country in question to look into matters at first hand. A local partnership arrangement or joint venture is effective, when sufficiently competent partners can be found. A knowledge of local conditions is obtained that might otherwise be difficult to secure, and valuable introductions to locally prominent persons come without too much difficulty, to say nothing of the local good relations such an association can bring.

Conditions of Contract

Because practices differ in different countries, there is sometimes some difficulty in drawing up a satisfactory contract especially for the larger type of project involving extensive works and where the call for tenders is on an international basis. To cope with this condition a model contract document was issued last year, entitled "International Conditions of Contract for Civil Engineering Works". It is the result of many years joint effort by the Federation Internationale des Ingenieurs Conseils (FIDIC) and the Federation Internationale du Batiment et des Travaux Publics (FIBTP). It has the endorsement of member organizations in twenty-six countries includi:ng Canada (Canadian Construction Association). The relationship between client, consulting engineer and contractor is defined in precise terms. "The Engineer" is held responsible for supervision of the work and for adjudicating on claims. A clause provides for arbitration by the Board of Arbitration of the International Chamber of Commerce, in the event of dispute.

Financing

Many foreign purchasers of engineering services and equipment insist on credit terms varying from a few years to five, seven or more. Some obtain such terms and, in addition, no payments on principal for a number of years and at low rates of interest. Such terms are often made possible through the backing of financial houses who have an ownership interest in the suppliers, or credit may have been advanced by a government supported development lending institution.

In Canada, it has been possible for a number of firms to secure chartered bank loans running into millions of dollars through their own credit standing, in combination with an insurance policy issued by the Export Credits Insurance Corporation (ECIC) covering the foreign risk. ECIC is a Crown agency, which will consider issuing an insurance policy covering foreign risks of non-payment for eighty-five per cent of the amount of the contract for periods amounting to several years for assisting the financing of substantial contracts. ECIC is a member of the Union des Assureurs de Credit Internationaux de Berne (Berne Union), an organization that provides a forum for export credit insurers from eighteen nations. Changes in the legislation affecting export credits insurance to provide additional facilities for assisting the financing of large contracts were indicated in Parliament in the Throne Speech.[1] Export credit insurance is available for exporters of services, including consulting engineers and contractors.

A private bill is before Parliament for the establishment of a company to be called Export Finance Corporation of Canada Limited.[2] It is understood that this private Corporation is designed to make available loans to exporters or foreign buyers.

When dollars are not available, it may be necessary for a firm to consider accepting commodities or currency other than dollars. Barter dealing or negotiating currencies is not a substantial part of the experience of Canadian engineering firms, though some are known to have accepted sugar, oranges, and other commodities. A consortium with its vaster possibilities, especially if it has foreign connections, may be in a position to consider barter deals and accept soft currencies. Bartering is the oldest form of trade and in the mind of some exporters of engineering commodities offers the possibility of doing business that would otherwise be impossible.

Though long term financing and soft currencies present problems, there are a number of interesting projects for which financing and dollars are already provided. These are the projects financed by the International Bank, International Finance Corporation, U.S. Development Loan Fund and U.S. International Cooperation Administration and other organizations that provide financing for approved projects in countries requiring economic assistance.

The investor often determines the source of supply for services and equipment. Close association with initiators of projects abroad will provide an engineering firm with a greater share of export markets. It is well known that the engineering for projects tends to come from the country of origin of the project initiator or investor. An example of an effort in this direction in Canada is to be found in the Indian-Canadian Corporation proposed by a prominent Canadian consulting engineer. The proposed Corporation would involve Indian investment for local costs and Canadian investment in equipment and engineering services for basic industries in India.

While price, delivery and financing are important factors, it should not be lost sight of that competitive advantage in many cases depends upon technological excellence. Highly developed products or complex works are dependent upon ideas and know-how developed through years of experience and systematic research. To remain ahead in foreign engineering markets, firms need constantly to develop products and services leading to new lines. These can be introduced at the right time to meet competing products as they catch up.

What Are The Opportunities

Almost everyone is aware of the extensive programmes for economic development throughout the world, especially in countries seeking higher levels of economic development. These programmes offer opportunities to consulting engineers, contractors and manufacturers. At the initial stages, surveys and services of all kinds are required, including feasibility studies, resources surveys, aerial surveys, exploration drilling and helicopter services. At later stages, actual design studies and construction supervision, construction of works, installation and supply of equipment and in some instances the start-up of operations. Projects include docks, harbours, railways, bridges, roads, airports, dams, irrigation schemes, pipelines, oil refineries, chemical plants, as well as factory buildings, housing, hospitals, hotels and universities.

Projects financed or proposed to be financed by the International Bank require consulting engineers for engineering and economic feasibility studies. The consulting engineer is selected and retained by the borrower, but must meet with the approval of the Bank. It is, therefore, important that consultants interested in international work be known to the Bank. This can be done by depositing with the Bank a description of past work done and professional qualifications of staff. In the case of Canadian firms, this can be facilitated through the Minister (Commercial) of the Canadian Embassy in Washington, D.C.

It is of interest to note that, at the end of 1958, the International Bank had made two hundred and nineteen loans in the twelve years of its existence totaling some $4 billion. In the same period, imports from Canada by borrowing countries with the proceeds of the Bank loans amounted to about $121 million of approximately $2.4 billion spent abroad, or just about 5%.

1) Legislation eventually enacted in 1959 provides for export credit guarantees to be made directly to lenders thus providing a broader source for funds.
2) Export Finance Corporation was established in 1959 as a private company by Act of Parliament. The authorized capitalization is $50 million, with lending power of $500 million.

There are large scale projects under the NATO Infrastructure Programme for the construction of airports, pipelines, telecommunication systems, for which tenders have been called internationally by host countries. Some of these projects have proved to be of interest to Canadian suppliers, while others have been of such nature as to be of interest only to the host country or at least to close-by European countries.

Though perhaps not of as direct interest to Canadian suppliers, mention should be made of the activities of the Commonwealth Development Finance Company, a public United Kingdom company established in 1953 following the Commonwealth Economic Conference in 1952 whose share capital is subscribed by private interests and the Bank of England. The main objects of CDFC are to provide or procure financial facilities for the development of the natural and other resources of any part of the Commonwealth, particularly those which may benefit the balance of payments of the sterling area. According to circumstances it may make a direct loan, take up debenture stock or subscribe to equity capital. CDFC cooperated with the International Bank in making an investment of £3 million in the Kariba Hydroelectric project in Rhodesia. It helped finance for the Tasman Pulp and Paper Company, a pulp and paper plant in New Zealand in the amount of £3 million. It also has a financial commitment in Algom Uranium Mines Limited for development of a uranium mine in the Blind River area of Northern Ontario at £1,350,000.

The International Cooperation Administration (ICA) and the Development Loan Fund are two United States international activities that are of interest as many of the tenders are on a world wide basis. ICA was created in 1955 as the United States agency responsible for the administration of economic aid given by the United States to other countries. ICA aid may be in the nature of either a grant or a loan. Where the aid is a grant, purchasing is done by the recipient country or procured by ICA by public tender generally on an international basis. Consultants are selected from a list of United States firms in Washington. When the aid is a loan the calls for tender are generally made by the recipient country.

The Development Loan Fund was established by the United States in 1957 as a means of providing for long term development. Loans are made either to governments or to private firms in recipient countries for long terms (up to forty years) and a period may be allowed before repayment commences, interest only being due in the meantime. They are for use primarily to purchase industrial plant and capital goods and pay for highly skilled labour and technical advice on installation. It would appear that, in general, calls for tender in connection with projects financed by the Development Loan Fund are on a world wide basis.*

Canadian Engineering Abroad

It may well be asked whether Canadian engineering firms are fully participating in overseas projects. As a net importer of engineering services and equipment, Canada has not generally been regarded as a major supplier but in the last several years there has been a noticeable upward trend in interest and in actual participation. This has been due no doubt to the high activity that has prevailed at home. Firms were kept so occupied that they were relatively uninterested in overseas work until the recent pause in the economy aroused new interest. Firms were not only driven by the need to find new outlets but they found themselves equipped with extensive inventories of skills and know-how of a kind that is needed in many developing countries.

Canadian firms are today to be found in Asia, Africa, Latin America and the Middle East involved in exporting such engineering commodities as aerial surveying, consulting engineering, construction contracting, telecommunications networks, equipment of various types including turbines, generators, aircraft, special vehicles and nuclear products. This is in addition to the exports under the Colombo Plan of large scale dam engineering, cement plants, fish plants, which provide valuable foreign experience and may lead firms to seek work under the conditions of competitive trade.

Canadians are naturally finding that they are most wanted for services and products which they know well, such as aerial surveying, hydroelectric engineering and pulp and paper consulting engineering. Aerial survey firms find that not only are they able to provide services equal in quality to any offered anywhere, but are able to do so at competitive prices. The warmer climates in which many underdeveloped countries are located offer an opportunity to use equipment that would otherwise not be used because of Canada's winter weather. Canadian aerial survey firms are to be found everywhere in the world.

Our pulp and paper consultants are active in Spain, Portugal, Brazil, Mexico, Pakistan, Norway, Sweden, Finland, Tunisia and Egypt. Foreign projects offer these firms the opportunity not only of making available highly developed knowledge, but the demand comes at a time when Canadian programmes in the paper industry are somewhat curtailed.

Canadian equipment is enjoying some favour abroad. Hydroelectric turbines have had substantial markets for many years. Aircraft are being exported in increasing quantities as their quality and special characteristics become better known. Especially built machine tools and accessories are being sold in the United States under highly competitive conditions. All-terrain vehicles developed in Canada are to be found in many countries of the world.

If a general conclusion can be drawn, it is that many of the difficulties encountered by engineering firms wishing to export are by no means insurmountable, if the right approach is taken. The rewards can be great — to the engineer in his professional capacity and to the firm as a business enterprise.

* Policy changes effected late in 1959 limit procurement normally to United States sources.

The Seventy-Fourth Annual General Meeting of the Engineering Institute of Canada will be held on Wednesday, May 25, 1960, at the Royal Alexandra Hotel, Winnipeg, Manitoba, between the hours of 10:00 a.m. and Noon. This meeting will receive the report of the official auditors, the Annual Report of Council, Committees, Representatives, and Branches, and such other business as may come before the meeting.

Garnet T. Page, M.E.I.C.
General Secretary

DISCUSSION

of Technical Papers and Other Articles

RIVER CONTROL IN THE INTERNATIONAL SECTION ST. LAWRENCE POWER PROJECT

Mr. K. A. Henry, Jr.E.I.C.
River Control Engineer,
The Hydro-Electric Power Commission of Ontario.
The Engineering Journal, 1960, January, p. 63

Discussion by Mr. Geo. H. Kohl, M.E.I.C.

Mr. Henry is to be commended for the presentation of his paper which describes clearly and concisely an important and delicate operation carried out over a 4 yr. period.

The paper describes the procedure so adequately that very little comment is required and these remarks will be confined to two items, one concerning the conditions for river control set up by the Government authorities and the other referring briefly to negative seiches recorded in the past.

The Order of Approval covering construction and operation of the power works issued in 1952 by the International Joint Commission stated that "the works shall be so planned, located, constructed, maintained and operated as not to conflict with or restrain use of the waters . . . for domestic and sanitary purposes, and . . . navigation" and also "in such manner as to safeguard the rights . . . of others engaged or to be engaged in the development of power below the International Rapids Section". The latter, of course, refers to existing development of Quebec Hydro at Beauharnois and the possible future development of Lachine Rapids by the same entity.

Two Boards were also set up. One, The St. Lawrence River Joint Board of Engineers reporting to the Government through the Minister of Transport is an approval and supervisory Board to act during construction, and the other The International St. Lawrence River Board of Control reporting to the International Joint Commission and charged with responsibility of overseeing and reporting on River Control operation when the present control "as in nature" is changed to an artificial method of regulation following a method already recommended to the two Governments by the International Joint Commission. During the construction period these two Boards work in close co-operation with regard to all matters affecting levels and flows.

The Joint Board at an early date gave general approval to a plan of control prepared by the two Power Entities, Ontario Hydro in Canada and the Power Authority of the State of New York in the United States, stipulating, however, that the River Control Engineer must have ample, direct authority in order to permit him to carry out his heavy responsibilities. It also directed that the control must be so carried out as to maintain natural river discharges at all times, with minor variations under certain critical conditions which would enable him to control seiches in the most expeditious manner and to provide for filling of the power pool. Under these conditions of discharge there could be no hurt to downstream power entities and no change in the natural levels of Lake Ontario, Lake St. Louis and Montreal Harbour.

The Power Entities were also directed to maintain river levels necessary for navigation in the International Rapids Section particularly at the entrances to the Iroquois, Morrisburg, Farran's Point and Cornwall Canals. Minimum levels required 14'9" on lock sills and maximum levels should not be such as to overtop the canal gates or endanger the embankments. This latter directive required very careful scheduling as the channels were excavated and as the cofferdams were placed and removed. Above the Iroquois Dam, the old canal embankment had to be raised and riprapped prior to the opening of the Galop Cut. At Lock 21 opposite the big cut at Long Sault Island, the river discharge at the time of the diversion was such that the river level could be raised 3 ft. above the natural level without interfering with lock operation eliminating considerable remedial work which otherwise would have been necessary.

During filling of the power pool in the early part of July 1958, the conditions in Montreal Harbour were such that the downstream flow could safely be reduced below the natural discharge. Advantage was taken of this situation to speed up the filling of the pool and so reduce the delay to navigation involved in transferring shipping from the old 14 ft. canals on the Canadian side to the new locks at Massena and Iroquois, but this was only possible by the wholehearted co-operation of Quebec Hydro.

In spite of, and possibly because of these rigid requirements, the control of the river has been maintained substantially in the state of nature with no interruption to 14 ft. navigation due to changes of water levels. Mr. Henry and his associates have performed their arduous task with complete satisfaction.

With regard to the sudden changes in river levels caused by combined wind and barometric pressure, that is a seiche, a study was made early in 1955 to determine what allowance

(Continued on page 126)

ABSTRACTS

OF 1960 ANNUAL GENERAL MEETING PAPERS

Design and Erection of Structural Steel for the Thompson Project
W. H. Bender

The process and type of equipment used in construction of the auxiliary buildings, concentrator, headframe, smelter and refinery at International Nickel's far northern Moak Lake, Mystery Lake development demonstrate the close connection between plant and structure in an industrial project of this nature. Design procedures were in large part determined by two rules — simplicity and standardization. Anti-corrosion treatment was used in construction of the refinery. Discussion of: various aspects of steel erection — target tonnages, equipment, manpower and weather difficulties; erection of the hoist house steel atop a 220 ft. headframe; erection of two 60-ton heavy duty cranes; placing of four rotary converters in the smelter. Concludes with comments on advanced planning for this large-scale project.

The Dunvegan Suspension Bridge
T. Lamb, M.E.I.C., and *R. N. McManus*, M.E.I.C.

Conditions of local topography, existing approach roads and other factors led to the choice of a skew crossing just upstream from the present ferry crossing on the Peace River near Dunvegan, Alberta. Investigations showed that the proposed site was underlain by a glaciated shale 25 to 65 ft. below water level, which in turn was covered with a layer of river-deposited gravel of from 10 ft. on the south shore to 70 ft. on the north. Recommended that all pier bases be carried at least 80 ft. below high water and through all river-deposited material. A suspension bridge was selected which could be supported by two piers, only one of which would have to go through the deep gravel. Final design of the foundation for the north pier was a three-cell reinforced concrete open caisson. The south pier required only a conventional cofferdam. Superstructure design followed A.A.S.H.O. specifications as far as possible. Towers were hinged at the base and tapered both ways from a point of maximum size

A New Canadian Structural Test Installation
W. R. Schriever and *W. G. Plewes*, JR.E.I.C.

An installation for structural tests was recently constructed in the main laboratory of NRC's Division of Building Research in Ottawa to provide a convenient and standard facility for loading tests on a variety of structural components. Three main parts: a strong reinforced concrete test floor, a set of steel frames to be assembled around the test object and anchored to the floor, and portable hydraulic jacks for application of loads. Test floor is constructed to resist upward forces, using weight of underlying bedrock through special pretensioned rock anchors. Structural steel reaction frames, connected to the slab and to each other by torqued high-strength steel bolts, provide maximum rigidity. Portable jacks, varying in capacity from 2½ to 50 tons, are suitable for both static and dynamic testing. Design and construction of the installation are described with reference to similar projects in other countries.

The Structural Behaviour of Highway Bridge Decks
S. D. Lash, M.E.I.C., and *B. B. Hope*

Theoretical studies included the problems of composite action, load distribution and research questions. From full-scale tests on three bridges information is recorded on ultimate strength, loads transmitted longitudinally by floors, composite action on timber floor and concrete floor, load distribution, deflections, effects of concentrated loads applied between stringers, and a comparison of timber and concrete floors. Conclusions concern safe capacity of bridge floors under static loads and methods of straightening existing bridges.

Construction of the Warsak Hydro-Electric and Irrigation Project, West Pakistan, A Canadian Colombo Plan Undertaking
C. C. Kingsmill, M.E.I.C.

The project aims to produce power and irrigation and to train Pakistani workers in modern construction methods. Costs have been divided between Canada and Pakistan. The paper describes geography, climate and regimen of the river as well as availability of construction materials, power and food facilities. Construction schedule and job cost estimate made with scant knowledge of conditions and unknown requirement of experienced personnel from Canada. Special problems: religion, language and culture, methods of local recruitment and labour turnover. Efforts made toward standardization and repair facilities provided. Difficulty in bringing skilled labour from other parts of country. Concentration of work on dam where narrow gorge limited working area. Cofferdam construction to stand overtopping during floods. Tunnels included diversion, power, penstock and irrigation.

Engineering Computation in the Chemical Industry Using Digital and Analog Computers
V. J. Bakanowski and *R. N. Boyd*

Electronic analog and digital computers produce better and more economic answers through the use of more analytical methods of solution. This paper describes the application of both types of computers to engineering problems in the chemical industry. Reasons for a shift from empirical to analytical technology. Discussion of: basic characteristics of the computers; history of development; criteria for determining the types of problems best solved on either computer. Case studies of computer application: IBM type 650 used to analyse the stresses in fixed head shell and tube heat exchanges from thermal and pressure loading; 120 amplifier Pace analog computer used to simulate part of a chemical process for analysis of the dynamic response of the system of process vessels, connecting piping and instruments.

The Principles of Automatic Control
Arthur Porter

Control system technology has undergone a profound change during the past two decades due to application of analog and digital computers, increased reliability and efficiency of electronic components, evolution of a comprehensive theory of linear systems, and the recognition that certain classes of non-linear control systems can be designed scientifically. Control problems now formulated on the basis of system optimization. Re-evaluation of the basic principles of automatic control. System optimization is optimum utilization of information. It necessitates feedback processes. First-order feedback loops are usually inadequate to optimize complex processes, thus second-order and a hierarchy of control loops are perhaps required. Coding is a prerequisite for information classification and leads to the concept of pattern recognition. Discussion of: associated problems of decision-making and logical goal-seeking; requirements of automatic controls based on the principle of self-organization.

Process Control

PROCESS CONTROL is a term that is rather loosely applied nowadays. This article will consider the control of vapour-phase and liquid-phase continuous processes such as are commonly in use in the petroleum and chemical industries.

Why are these processes controlled? How? What future developments are likely? These are some of the questions to which answers will be attempted, though they must necessarily be brief. A few examples of advanced techniques now in use may serve as a link between current general practice and some conjecture about the ultimate goals of the processing industries in the field of control.

Why are Petroleum and Chemical Processes Controlled?

It may seem rather elementary to ask an engineer why control is necessary in the process industries. Not too long ago the answer might also have been fairly elementary, but now it is becoming ever more complex.

In the petroleum industry, for example, the refining of crude oil was originally largely a simple distillation operation. Little attempt was made to get more than a few useful fractions until the demand for gasolines as motor fuel became widespread. Control was manual, and consisted mainly of operating the furnace at the correct rate. Even recording instruments were few, and there must be many who can remember the convenient, though not too accurate,, method of determining temperature by spitting on a hot line.

From simple distillation the refining of petroleum has developed to include many physical and chemical processes operated over a wide range of temperatures, pressures, rates of flow, and other variable conditions. Often, these processes are carried out continuously in a series of interconnected process units, the aim being to convert the crude oil or other raw material into certain desired end-products. In between the start and end points several process streams divide, undergo individual treatment under various conditions, may be further divided or recombined at different stages, recycled, extracted, and so on. All these procedures take place simultaneously, and departure from correct conditions in any one process will affect all the others, possibly to the extent of causing a complete shut-down of the installation.

The unplanned shut-down of a refinery or chemical plant is a very expensive and undesirable event. A complete shutdown is also more likely with the present trend to integration of entire plant operations and the elimination of intermediate product shortage facilities, which were necessary when process units within a plant operated independently or in small groups. Then, if one unit went out of control and had to be shut down, the other units could continue to operate and either send their products to, or draw their feedstock from, intermediate storage.

To compete economically, the process industries must reduce their installation and operation costs. There are too many factors involved for a discussion here of how this can be done, but control and automation of processes are among the leading methods for achieving greater efficiency. Obviously a completely integrated plant can be more efficient and less costly to build and operate than one that requires extra intermediate product storage and handling facilities, and also involves additional energy needs for reheating and recirculating these intermediates. To achieve this complete integration, and to keep individual units and hence the whole plant working most efficiently, reliable control of process variables is essential.

What is Controlled, and How?

In the process industries considered here, the factors most commonly measured and controlled are temperature, pressure, and flow-rates of process streams, and liquid levels. Advanced control also considers the composition of process streams, the activity of catalysts, and so on by continuous analytical methods.

Temperature. Process temperatures may be measured by thermocouples, resistance-bulbs or bimetallic dial thermometers. Remote indicators and controllers may use filled-bulb force-balance pneumatic transmitters, up to about 800°F., or electronic null-balance instruments. Electric-pneumatic transducers are used for high-temperature control points above the limit for pneumatic transmitters. For control work, transmitters may have rate action to overcome measurement and transmission lags.

Pressure. The main instruments used to measure pressure are bourdon tubes, bellows, and diaphragms. For control applications, force-balance transmitters are used with bellows or diaphragm.

Flow and Level. Differential pressure manometers, area-meters, and positive-displacement meters are used to measure flow. Level measurement, also frequently necessary in the processing industries, is usually by gauge-glass, float and tape, float-actuated, and differential pressure. The first two are used for local level indication, though float-and-tape indication (e.g., in large storage tanks) may be used with a transmitter for remote indication or recording. Ball float instruments are used for narrow-range level control or level alarm switches, displacer instruments are used in more critical applications. Differential-pressure instruments may be used for local control (deflection bellows type manometers with integral pneumatic control) or for remote indication and control (transmission from force-balance and diaphragm-type manometers).

Transmitters and Receivers. Pneumatic or electric transmission is used between measuring and control instruments and, for example, a control centre. Force-balance pneumatic transmitters are largely used; indicator or recorder types of receiver may be round-dial, miniature, or large-case multipoint recorders, according to the application required. Electronic transmitters use a measuring element to produce an electronic signal proportional to the process variable; the electronic receiver is often a miniature control station mounted on a control board, separate indication being provided by a dial voltmeter or ammeter.

Controllers. Pneumatic control is widely used and economical and convenient, though it has certain limitations. Controllers may be mounted in the field (e.g., valve-mounted for flow-control) or on the control board, depending to some extent on the distances involved. The all-electronic control loop is used when transmission distance exceeds a useful limit for pneumatic control (of the order of 500 feet between, say, control valve and controller). The great advantage of electronic control is the reduction of control time lag compared with pneumatic systems, and the great flexibility of system design possible, particularly when considering advanced control involving computer applications.

Process-stream Data

The foregoing outline deals with some of the methods used to get data about process variables, which may be used for record or control. The instruments involved and the principles used are now well-tried and generally familiar to many engineers. A more detailed description of particular instruments and applications is not possible here.

The continuing advancement of the efficiency of processing industries, as far as it can be achieved by control methods, depends on the production of improved instruments and the extension of the information these instruments can provide. The optimum control, within specified limits, of the variables dealt with above (temperature, pressure, flow, and level) is no longer considered the ultimate goal of the processer.

Not only the physical variables, but also certain chemical factors are critical in the maintenance of optimum conditions in a processing plant. Many chemical reactions and equilibria are involved in an integrated series of processes, and in order to know what is happening it is necessary to keep track of key constituents of the process streams. The traditional method of periodic laboratory analysis only confirmed that the physical controls were resulting in a suitable product—or indicated too late that something was amiss.

For optimum control, the processer must know of any departures from ideal stream conditions, and he must know this as soon as possible so that the necessary corrections can be applied before conditions deteriorate beyond acceptable limits. Continuous-stream monitors are now available, and are being further developed, to give the operator essential product data such as end point, initial boiling point, viscosity, vapour pressure, flash point, colour. Gas chromatography enables continuous analyses of stream samples to be made.

At present, the data from such monitor installations are largely being used for manual adjustments to operting conditions, but the ultimate use of monitors will be in a control loop to reset control points on standard controllers.

Control by Computer

Assuming that the ideal process dynamics are known a given plant can be kept operating continuously at optimum efficiency only if measuring instruments can provide sufficient data practically instantaneously. A computer system is then necessary to digest all the information provided and to apply necessary corrections before appreciable changes can occur.

Several computer-control applications are already operating, and a wide development in this field may be expected. Initially, the most activity will probably be found in the application of analog units to individual sections or units of processes.

In the petroleum industries, analog computers are now being used in several ways. One system controls reflux in a fractionating tower to maintain capacity vapour rate; annual savings of some $5000 are estimated from an installation that costs less than $10,000. Another analog computer maintains internal reflux of a fractionator at a constant value. An oil company that has set up a process control research centre will use small portable units as process controllers to determine data on which a permanent installation can be designed; the portable unit can then be used in another application.

Computer systems have been developed for 'optimizing' process conditions. One example is a computer with analog input and output, containing comparison and memory, logic, and output sections, plus checking and indicating sections and various operational controls. The system continually experiments with the process, much as a human operator might, but more quickly and accurately, to determine and then to hold the optimum performance level. Such a unit has been in operation since mid-1958 to control a pilot plant that makes styrene by dehydrogenation of ethyl benzene.

Once all the necessary factors are known, and optimum control of individual processes has been achieved, the next step towards complete automatic control is control of entire processing units by digital computer. The first such fully automated process in the United States has been operating in a Texas refinery since March 1959. A digital computer completely controls a polymer unit which handles some 15-million cu. ft. a day of feed gas, in which significant variations in composition can occur. The digital unit takes information from 110 different sources, including temperatures, pressures, and flow rates on 16 different streams. From the measurements, settings are determined for feed to the unit, recycle and water flow rate, reactor pressure, and catalyst bed outlet temperature. The computer resets the plant control pattern every five minutes, records what it is doing, and gives warning if the operation limits are exceeded. Considerable increase in efficiency of the unit and savings in catalyst used are expected.

A recent survey indicated eight digital computers already available for process control, and three more on the way. The ultimate goal of the completely automated refinery or chemical plant is a vision of the future. Even if it can be achieved, much work remains to be done to consider all the economic factors involved. Much work will be done in the next decade on the development of better measuring instruments and the determination of optimum conditions for individual processes. Then, perhaps, the completely automated processing plant may become a reality.

1951 Graduates - Please Note

According to amended Institute regulations covering Junior membership, 1951 graduates must apply for transfer (by written application form) to the grade of Member during 1960, if they wish to avoid payment of a transfer fee.

The applicable sections are as follows:—

"——— he shall not remain in the class of Junior beyond the end of the tenth year after graduation.

A Junior may be transferred to Member without payment of a transfer fee providing he makes application before the end of the ninth year after graduation ———"

Canadian Developments

The Columbia River International Joint Commission has published its recommendations for determining and apportioning benefits from cooperative use of the river. Although there is much negotiation still ahead, this is considered a significant step toward the $1 billion hydro-electric development which one day is expected to produce 145 billion kilowatts. The following is the report in its entirety:

"The Governments of the United States and Canada, as a part of their continuing discussions, have agreed to request the International Joint Commission to report specially to the Governments at an early date its recommendations concerning the principles to be applied in determining:

"(a) the benefits which will result from the cooperative use of storage of waters and electrical interconnection within the Columbia River System; and

"(b) the apportionment between the two countries of such benefits more particularly in regard to electrical generation and flood control."

In the preparation of this special report, the Commission utilized as background data all the information available to it on the water resources development needs and possibilities in the Columbia River area. This included the reports of the International Columbia River Engineering Board under the Columbia River Reference, as well as studies of other agencies in both the United States and Canada. A special work group was established to prepare summaries of the available data that would provide a background and orientation and thus facilitate mutual understanding of the situation and conditions under which principles for benefit determination and apportionment would be applied. Also, the Commission aproached the problem of formulating principles within the context and intent of the Boundary Waters Treaty of 1909.

The studies of the International Columbia River Engineering Board, as well as other available information, indicate clearly that there are possibilities for cooperative development in the Columbia Basin that could be of mutual advantage to the two countries.

Accordingly, the Commission was able to approach the problem of formulating principles for benefit determination and apportionment with information on specific projects for cooperative development which would offer advantages to both countries. The Commission was guided by the basic concept that the principles recommended herein should result in an equitable sharing of the benefits attributable to their cooperative undertakings and that these should result in an advantage to each country as compared with alternatives available to that country. The Commission gave consideration to the practical problems that will be encountered in applying the principles to cooperative arrangements between the two countries on specific projects in the Columbia River Basin. This was done to ensure that the principles would be workable but no attempt was made to spell out in the principles the detailed procedures that will necessarily be delineated when cooperative arrangements are entered into. The Commission recognizes that several administrative and legislative actions in each country may be necessary before these details can be worked out.

The principal benefits in the downstream country from cooperative use of storage of waters within the Columbia River System are improvements in hydroelectric power production and prevention of flood damage.

Although other benefits would also be realized from such cooperative use, the outlook at this time is that their value would be so small in comparison to the power and flood control values that formulation of principles for their determination and apportionment would not be warranted. This is not intended to preclude consideration by the two Governments of any benefits, tangible or intangible, which may prove to be significant in the selection of projects or formulation of agreements thereon.

The prospective downstream power benefits are transportable and within reasonable transmission distances of the boundary. With adequate electrical interconnection, it would therefore be feasible to share these benefits in kind, that is, share the power itself rather than its value in money.

The flood control benefits, however, accrue in specific localities and are not transportable. Co-operative use of storage designed to produce such benefits therefore requires recompense in money or by other means. In addition to providing a means for the return to the upstream country of its share of downstream power benefits, electrical interconnection between the power systems in the upstream and downstream countries opens the possibility of significant economies and advantages in the operation of the interconnected systems in both countries through the co-operative use of generation and transmission facilities.

In view of the foregoing, the Commission's recommendations on principles for benefit determination and apportionment are presented herein in three sections, namely, general principles, power principles and flood control principles.

GENERAL PRINCIPLES

SELECTION OF PROJECTS

A necessary step in the development of cooperative arrangements involving sharing of downstream benefits is the selection of the projects to which such arrangements would apply.

In selecting individual projects from among the available alternatives in both countries for comprehensive development of the Columbia River Basin, it would be consistent with customary practice to give first consideration to those projects that are most attractive economically as reflected in the ratio of benefits to costs. It is suggested that this widely accepted principle be followed in international cooperative development of the Columbia River Basin to the extent that it may prove practicable and feasible to do so. If projects are developed successively to meet the growing needs for power production and to provide flood protection, the most efficient projects for those purposes should generally be developed first in order to maximize the net benefits to each country. It is recognized, however, that the results to be obtained from possible cooperative projects in the Columbia River Basin will constitute only a part of the total requirements for water resource development and use in the affected regions in both countries.

Therefore application of the principle will necessarily be subject to the sovereign responsibilities in each country with respect to many vital and important national interests which must be taken into account in utilizing the water resources in each country.

The Commission therefore recommends the following general principles:

GENERAL PRINCIPLE NO. 1

Cooperative development of the water resources of the Columbia River Basin, designed to provide optimum benefits to each country, requires that the storage facilities and downstream power production facilities proposed by the respective countries will, to the extent it is practicable and feasible to do so, be added in the order of the most favorable benefit-cost ratio, with due consideration of factors not reflected in the ratio.

DISCUSSION OF GENERAL PRINCIPLE NO. 1

It is intended in the application of this principle that benefits and costs of the projects given consideration in either country would be determined on the basis of the same or comparable evaluation standards, including such factors as the nature and extent of the benefits to be considered, the evaluation of such benefits, the determination of the initial investment and the computation of the annual costs.

The phrase "to the extent that it is practicable and feasible to do so" is included in recognition of the fact that it will not always be possible to adopt a project wholly on the basis of its benefit-cost ratio as compared to other projects in the river basin.

There may be important non-monetary factors, not reflected in the benefit-cost ratio, which may require consideration and which may be of compelling influence in choosing projects for construction.

Such factors include the disruption of community and regional economies, scenic, historic or aesthetic considerations, the preservation of fish and wildlife, and similar considerations, which cannot be adequately evaluated in monetary terms. Other practical considerations that might preclude the theoretically desirable order of construction of projects would include the following:

(a) the availability of funds, whether from public or private sources, may be an important consideration in the scheduling of projects within each country in an extensive basin-wide plan. This factor alone may require selection of a small project providing urgently needed benefits even though the small project may have a lower benefit-cost ratio than a larger project requiring more funds than are available. On the other hand, it is important to recognize that a small project undertaken for such an immediate consideration might jeopardize an eventual development of far-reaching beneficial consequences.

(b) an urgent need to provide for such purposes as local or regional flood control, navigation, irrigation, or exceptional increases in power requirements may determine the order of project construction rather than the ratio of benefits to costs.

(c) the attitude of affected interests on the flooding of lands and improvements or to the effect of a project on other uses of the water resource may require postponement or abandonment of construction of projects that are the most attractive when viewed solely from the standpoint of their benefit-cost ratio.

GENERAL PRINCIPLE NO. 2

Cooperative development of the water resources of the Columbia River Basin should result in advantages in power supply, flood control, or other benefits, or savings in costs to each country as compared with alternatives available to that country.

DISCUSSION OF GENERAL PRINCIPLE NO. 2

This principle was used as a basic concept by the Commission in the preparation of the more specific principles recommended herein, and is recorded for future guidance in the application of those principles.

TRANS-BOUNDARY PROJECTS

Projects which could produce downstream benefits to be shared between the two countries may be located entirely in the upstream country, or may be trans-boundary projects in which the benefit-producing potentials of storage and head are partly in each country.

Such projects affect the level of water above the boundary and in consequence are subject to Article IV of the Boundary Waters Treaty of 1909. The principles presented elsewhere in this report are applicable directly to storage projects situated entirely in the upstream country and relate to the effects produced in the other.

To apply these principles to a trans-boundary project, it is first necessary to assign to each country an "entitlement" to the storage.

This entitlement or share of the benefit-producing potential of the storage would then form the basis for determination and apportionment of downstream benefits between the two countries in accordance with the principles recommended herein. In addition, an entitlement to at-site power generation should be determined based on the benefit-producing potential of the head and flow involved. Also, the respective entitlements to share in any other benefit-producing potentials should be determined if significant.

As a basis for determining the "entitlement" of each country to the benefit-producing potentials of storage and head at trans-boundary projects, the Commission recommends the following general principle:

GENERAL PRINCIPLE NO. 3

With respect to trans-boundary projects in the Columbia Basin, which are subject to the provisions of Article IV of the Boundary Waters Treaty of 1909, the entitlement of each country to participate in the development and to share in the downstream benefits resulting from storage, and in power generated at site, should be determined by crediting to each country such portion of the storage capacity and head potential of the project as may be mutually agreed.

DISCUSSION OF GENERAL PRINCIPLE NO. 3

The "entitlements" determined in accordance with this principle provide a basis for establishing benefit credits. The principle is designed to provide flexibility in the arrangements between the two countries for cooperation on trans-boundary projects. The entitlement of a country computed in accordance with this principle would be the basis for determining the share of downstream benefits due to that country in accordance with the other principles presented in this report for projects wholly in one country.

POWER PRINCIPLES

The setting in which principles for determining and sharing power benefits from the cooperative use of upstream storage in the Columbia River system would be applied is one in which significant changes are likely to occur within the life of projects that might be considered for development at this time.

At present the power loads in the United States portion of the Columbia Basin and adjacent areas of the Pacific Northwest are supplied almost entirely from hydro-electric plants. The downstream generating plants in the United States are now in a position to benefit materially from storage regulation upstream primarily through improvement of the dependable capacity and useable energy of the downstream plants. As the more economically attractive hydro plants are developed progressivly, it will become necessary and advantageous to add thermal plants to the system until ultimately the Pacific Northwest power system in the United States will become predominantly thermal.

In the course of this change, the character of the benefits to downstream hydro-electric plants in the United States from storage will change to benefits in the form of peaking capacity and thermal replacement energy and may change in value.

In Canada, the hydro-electric power potential has not yet been developed to a comparable extent. For this reason, the type of change envisioned in the United States is unlikely to occur in the Canadian portion of the Columbia River Basin and adjoining areas until a considerable period of time has elapsed.

In the light of the foregoing, the Commission has found it necessary in its formulation of principles for determination and sharing of power benefits to allow for changing conditions during the specified period that a cooperative development agreement or any extension thereof would be effective. The principles recommended below for the determination and apportionment of power benefits to be sufficiently flexible to provide for equitable arrangements to permit taking into due account the changing conditions expected.

Application of the power principles to conditions in the Columbia basin would require electrical interconnection between the power systems of the two countries to make possible delivery of the upstream country's share of the power produced in the downstream country from the use of stored waters.

Although such delivery could be accomplished initially with a somewhat limited degree of interconnection, the Commission is of the opinion that provision should be made for the eventual development of a broader, long-range plan for cooperative operation of the interconnected power systems of the two countries. Accordingly, the power principles include in addition to those governing cooperative use of stored waters, a principle providing for interconnection and coordination of the major power systems in the Columbia basin and adjoining areas in both countries so as to permit the power utilities of the two countries to gain the advantages of cooperative arrangements in power system operations.

POWER PRINCIPLE NO. 1

Downstream power benefits in one country should be determined on the basis of an assured plan of operation of the storage in the other country.

DISCUSSION OF POWER PRINCIPLE NO. 1

This principle is basic to a determination of the dependable capacity and usable energy that can properly be credited to operation of upstream storage for the benefit of hydro-electric power generation downstream. Emphasis is placed particularly on the concept of an assured plan of operation of the storage with the expectation that the downstream system will be developed and operated so as to make optimum use of the stream flow regulation provided.

It is a generally accepted engineering principle in the electric power field that any power supply which is classified as "firm" or "dependable" must be deliverable on such a schedule or plan as to assure availability of the power at the times when it is needed to serve the load, particularly during peak load periods.

It is, therefore, highly important that river-flow regulation be provided under an agreed operating plan or rule curve that will assure the dispatch of water by the owner of storage facilities to the owners of downstream hydro plants in such a manner as to meet the needs of the latter for delivery of firm power to their customers. Such a plan of operation will provide the maximum downstream power benefit consistent with the degree of coordination agreed upon.

It is expected that a general plan of operation of the upstream storage project will be estimated for the entire period of the agreement with the understanding that mutually satisfactory adjustments in the long-range plan of operaion can be made from time to time as necessary. This general provision for adjustment is additional to the flexibility for changes by either country which may be specifically provided for in the agreement. Factors that may bring about the need for adjustments in the operating plan are covered in the discussion of Power Principle No. 2.

POWER PRINCIPLE NO. 2

The power benefits attributable to an upstream storage project should be estimated in advance to the extent possible to the mutual satisfaction of the upstream and downstream countries. These estimates of power benefits should be subject to review in accordance with the agreed principles every five years, or more often as may be agreed, to take into account in subsequent estimates any change in previously assumed conditions and to insure optimum utilization of the storage and accurate determination of future benefits.

DISCUSSION OF POWER PRINCIPLE NO. 2

This principle is intended to provide in advance of construction of upstream storage reservoirs a long-range estimate of the expected benefits of the international cooperative undertaking. The estimate of benefits, expressed in power, or in monetary terms if necessary, would be determined on the basis of the current assured plan of operation as described under Power Principle No. 1 and in accordance with Power Principle No. 3.

It is contemplated that the appropriate agencies in each country will collaborate in the preparation of the estimate and that it will cover the entire period of the international agreement. Any extension of the agreement would also require similar estimates. It should be based on the relevant conditions of load and power supply expected to prevail during the period of the agreement. The assumed power supply should include the projects, both hydro-electric and steam-electric, considered most likely to be constructed to meet the long-range needs of the power systems concerned.

In estimating the long range power benefits attributable to upstream storage and in the periodic reviews provided for in this principle, due recognition should be given to the adjustments in storage operation that are likely to be required to meet power loads and other water use needs in either country.

Factors in either country which could change and thus alter the role of storage include: the magnitude and characteristics of the power loads to be served, installed generating capacity available in the hydro-electric plants on the affected systems, the amount of thermal generating capacity available and the requirements of other water uses. The time and effect of such changes should be anticipated by the appropriate Canadian and

United States agencies as far in advance as possible and taken into account either by provision in the assured plan of operation or by agreement on mutually satisfactory adjustment as a result of the periodic review of the plan of operation and long-range estimate as provided for in this principle.

In addition to the primary purpose of furnishing a long-range estimate of the benefits of the international cooperative undertaking the advance estimate and periodic reviews are expected to serve several other purposes. The agencies affected will be afforded a basis for anticipating the probable long-range use or role of the storage in the respective countries so that other developments on the affected power systems can be planned well in advance and timely provision made for their construction as required by each country. Assurance as to use of the storage would facilitiate advance planning of the transmission systems required to coordinate the storage operation with generating plants on the interconnected power systems. Information provided from the estimates would also aid the two countries in determining the timing and value of other projects of international scope in which they may be jointly interested.

POWER PRINCIPLE NO. 3

The amount of power benefits considered to result in the downstream country from regulation of flow by storage in the upstream country should be determined in advance by computing the difference between the amount of power that would be produced at the downstream plants with the storage regulation and the amount that would be produced without such regulation. This determination would be made on the assumption that upstream storage is added at an agreed-upon level or condition of storage and power supply. The storage credit position of the upstream storage thus established should be preserved throughout the period of the agreement.

DISCUSSION OF POWER PRINCIPLE NO. 3

Application of the with and without principle involves several significant determinations and procedures to insure that the upstream storage receives proper credit for its contribution toward meeting the load. Because of the fact that successive units of storage capacity added to a system of projects result in decreasing amounts of regulatory effect per unit, the time at which a project is considered as added to the system in relation to the time at which other storages are added affects the amount of regulatory effect and accompanying firm power benefit with which a particular storage project may be credited. Thus the conditions under which a project is considered as added determines its "credit position".

Under this principle, it is intended that the storage credit position of an upstream storage reservoir be determined on the assumption that it is added at an agreed-upon level of condition of storage and power supply. This "level" or "condition" might be defined by relating it to a "base system". The "base system" would be comprised of all developments existing at the time of negotiation of an agreement together with developments actually under construction at that time.

Since many estimates and computations have already been made on the basis of data available during the Commission's consideration of these principles, it is suggested that negotiations undertaken in the near future utilize as a base system the developments existing and under construction on January 29, 1959, the date of the two Governments' request for this report. The pertinent storage developments in the current base system are:

Project	Useable storage
Kootenay Lake	673,000 acre-feet
Hungry Horse	2,982,000
Flathead Lake	1,217,000
Albeni Falls	1,153,000
Coeur d'Alene Lake	225,000
Grand Coulee	5,072,000
Chelan	676,000
Brownlee	1,034,000
	13,032,000 acre-feet

If negotiations are undertaken or continued at a time when major changes have occurred, a revised base system should be agreed upon. Conditions of International Joint Commission Orders of Approval affecting any of these developments would continue to be applicable.

It is contemplated that the representatives of the two governments who negotiate arrangements under these principles would agree on the order in which the storages they have under consideration would be considered as added to the base system so that a credit position for each such storage could be established. It is intended under this principle to provide that the credit positions of the storages thus established will not be adversely affected by the addition of subsequent storage and that the storage credit of such agreed upon storages may increase or decrease only as the role of storage generally in the system changes.

POWER PRINCIPLE NO. 4

The amount of power benefits determined to result in the downstream country from regulation of flow by storage in the upstream country would normally be expressed as the increase in dependable hydroelectric capacity in kilowatts under an agreed upon critical stream flow condition, and the increase in average annual useable hydroelectric energy output in kilowatt-hours on the basis of an agreed upon period of stream flow record. Since this procedure requires relating the increased power production to the loads to be met in the downstream country and adjustment of the upstream country's entitlement to conform more nearly to its load requirements, consideration might be given in the negotiations to the adoption of arrangements that would be less de-

(Continued on page 108)

• CANADIAN DEVELOPMENTS

(*Continued from page 106*)

pendent upon consideration of the load patterns in each country.

DISCUSSION OF POWER PRINCIPLE NO. 4

In determining the increase in dependable hydro capacity and in useable energy output at downstream plants resulting from upstream regulation, the estimates should be based on the ability of those plants, enlarged as necessary, to serve the coordinated system loads in the downstream country expected to be realized during the periods under consideration.

The critical flow period used to determine hydro plant outputs available for supporting dependable capacity on the downstream load would be that corresponding with the agreed-upon level or condition of storage and power supply as contemplated in Power Principle No. 3.

Estimates of increase in average annual useable energy output at the affected downstream plants should be based on an agreed upon period of stream flow record which is expected to give results representative of long term condtions.

It is expected that both dependable capacity and energy benefits will result during the early and intermediate stages of the storage operation, but during the later stages the power benefit may consist only of increased useable energy.

Whether the objectives are to produce the maximum firm power, peaking capacity or thermal replacement energy, the power useable on the downstream load is the basis for determining the monetary value of the power resulting from the cooperative arrangements.

Such value as defined later in Power Principle No. 5 would serve as the basis for adjusting the upstream country's entitlement as between capacity and energy, to amounts of equivalent total value, which conform more nearly to the requirements of the upstream country's load.

POWER PRINCIPLE NO. 5

Whenever it is necessary to place a monetary value on downstream power benefits arising in one country from storage operation in the other country, the value should be the estimated cost to the downstream country of obtaining equivalent power from the most economical alternative source available except where the appropriate Canadian and United States agencies specifically agree on some other basis of evaluation.

DISCUSSION OF POWER PRINCIPLE NO. 5

This principle is intended to provide a basis for the evaluation, in monetary terms, of downstream capacity and energy benefits attributable to upstream storages for whatever purposes such monetary evaluation may be required; but is intended to have application only in those cases where appropriate monetary values for specific purposes are not otherwise agreed upon by the appropriate United States and Canadian agencies. It is further intended that where such monetary values are agreed upon by the agencies, for any period during the life of the covering agreement, the value so agreed upon shall over-ride the provisions of this principle.

The alternative source used as a basis for the evaluation should be the most likely source available to furnish an amount of power equivalent to the power being evaluated and might be hydro-electric, thermal or some combination thereof.

POWER PRINCIPLE NO. 6

The power benefits determined to result in the downstream country from regulation of flow by storage in the upstream country should be shared on a basis such that the benefit, in power, to each country will be substantially equal, provided that such sharing would result in an advantage to each country as compared with alternatives available to that country, as contemplated in General Principle No. 2. Each country should assume responsibility for providing that part of the facilities needed for the cooperative development that is located within its own territory. Where such sharing would not result in an advantage to each country as contemplated in General Principle No. 2, there should be negotiated and agreed upon such other division of benefits or other adjustments as would be equitable to both countries and would make the cooperative development feasible.

DISCUSSION OF POWER PRINCIPLE NO. 6

It is assumed that each country would bear all capital and operating costs for facilities it would provide in its own territory to carry out the cooperative development. The upstream country's share of the power would be transmitted to the boundary by the downstream country at such points as may be most economical to the downstream country. Other points could be selected upon request of the upstream country provided that any excess costs to the downstream country are paid by the upstream country. Losses in transmission of the power to the international boundary from the points of generation would be borne by the upstream country. The voltage at which power would be delivered to the upstream country would be mutually agreed upon but such voltage should be a level that is in common use on the downstream power system through which the transfers of power are to be made.

The load factor at which the upstream country's share of power is delivered should also be agreed upon in advance. Basically, the downstream country should not be required to provide more facili-

(*Continued on page 112*)

• CANADIAN DEVELOPMENTS

(Continued from page 108)

ties for generation and transmission to furnish the upstream country its entitlement of power than would be required if the power were to be used in the downstream country at the load factor generally applicable to its affected hydro plants.

POWER PRINCIPLE NO. 7

In addition to benefits from cooperative use of stored water, interconnection and coordination of the electric power systems to the extent that they are practicable and desirable, would also provide many mutual benefits which should be shared. Coordination being a continuing function would require specific arrangements on the part of the operating agencies as the need arises.

DISCUSSION OF POWER PRINCIPLE NO. 7

The first six power principles recommended in this report are directed to determination and apportionment of benefits which would result from international cooperation in the use of stored waters. These are basically hydraulic benefits which can be realized by storing flood flows during the spring and summer months and releasing the stored waters during the fall and winter months when they can be put to use for the production of firm power at the storage site and downstream. Electrical interconnection between the power systems of the two countries would be required to make possible delivery of the upstream country's share of the power produced in the downstream country from the use of stored waters, but the interconnection capacity provided for this purpose would be only that needed to accomplish such delivery. This limited degree of interconnection would not, however, make possible the greater benefits that would accrue to the two countries from a comprehensive plan of interconnection and coordination.

Such coordination should be recognized in the development of the agreed upon plan of upstream storage operation and in the computation of system power benefits. Separate arrangements may be required for sharing coordination benefits because the electrical coordination envisaged could extend geographically beyond the service areas of the generating plants or power systems directly benefitted by the release of stored waters from storage projects constructed by the upstream country.

It is recognized that the power systems in British Columbia are not now developed to the same extent as in the United States portion of the Columbia River basin, but it is the intention of this principle to provide for long-range international cooperation between the systems of the two countries as they continue to develop in the future.

Under arrangements for coordination, it would be expected that all participating power systems would retain their local autonomy but would necessarily operate their generation and transmission facilities under the terms of appropriate agreements with a view to maximizing mutual benefits. The arrangements should set forth the broad operating principles to be observed and should be written in sufficient detail to describe the specific purposes and objectives.

FLOOD CONTROL PRINCIPLES

Among the sections in the United States to which principles for flood control benefit determination and sharing would be applicable are the Kootenai River downstream from Bonners Ferry, Idaho, and the lower main stem of the Columbia River. These areas now have partial protection against flooding and there are plans for utilization of storage in the United States to be developed primarily for power purposes in such a way that ultimately a high degree of protection against major floods would be obtained.

As successive blocks of storage for flood control purposes are added to the system, the amount of flood damage that can be prevented per unit of flood control storage decreases. Accordingly, the value that can be assigned to upstream storage for flood control purposes is greater for projects to be constructed in the near future than for those to be built later.

Also, in the Columbia Basin the hydrologic and hydraulic characteristics are such that storage can be operated in the interests of flood control to a considerable extent with little, if any, interference with the operation of the same storage project in the interests of power generation.

These factors, as well as other information available to the Commission, have been taken into account in formulating the following principles for determination and sharing of flood control benefits which may result from cooperative development of storage in the Columbia River Basin.

FLOOD CONTROL PRINCIPLE NO. 1

Flood control benefits should be determined on the basis of an assured plan of operation and flood control regulations agreed to in advance.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 1

The assured plan of operation for flood control would not be a separate plan of operation but rather a joint or composite plan of operation of a given storage project in the interests of flood control as well as for other purposes, principally power. The plan of operation for any reservoir included in the flood control plan, therefore, should be worked out initially so as to obtain the best combination of benefits for all purposes. In the Pacific Northwest meteorological and hydrological conditions and the requirements for storage operations in the interest of power and flood control are such that little, if any, loss of ability to maximize power benefits is required to accommodate flood control. In any event, the plan of operation worked out in accordance with these principles would be the basis for determination of the flood control and power benefits to be shared.

Once the plan of operation is agreed to, normal operations for both power and flood control would be in accordance with the plan.

It is to be expected that both the upstream storage interests and the downstream power and flood control interests may wish from time to time to request or suggest deviations from the plan.

If such deviations would involve an adverse effect on the other party at interest it would be expected that a basis for compensating for the adverse effect would also be proposed. Such deviations would then be made possible if the deviations and any required compensation were mutually acceptable to both parties. If the upstream country wished to have the option of using alternative storage to provide equivalent downstream flood control effects as contemplated in the plan of operation, such option should be provided for in the agreement.

It is assumed that acts of God, emergencies, and other events over which neither party has control, would be interpreted and handled in the manner usually contemplated in a "force majeure" clause in an agreement.

FLOOD CONTROL PRINCIPLE NO. 2

The downstream flood control benefit of the upstream storage to be operated in accordance with an agreed-upon flood control plan should be estimated in advance on the basis of the effectiveness of such storage in meeting the flood control objectives applicable in the downstream country at the time the upstream storage is provided.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 2

This principle places prospective Canadian storage to be operated in accordance with an agreed-upon flood control plan in exactly the same position that any concurrently prospective United States storage for flood control purposes would have. The effectiveness of all flood control storage is measured in terms of the flood control objectives applicable at the time the storage is to be provided and the effectiveness determined at that time is applicable for the entire life of the project in question or for the period of agreement in the case of Canadian storage.

In the United States the current primary flood control objective is to obtain storage sufficient to control a flood of the magnitude of that of 1894 at The Dalles to 800,000 cfs.

All additional storage in the United States or Canada necessary to achieve this objective (approximately 7½ million acre feet of storage usable for flood control) would, if included in the flood control plan, be given equal credit on the basis of the effectiveness of each acre foot of such storage in controlling floods at The Dalles. Storage either in the United States or Canada added after the necessary amount has been reached to control the 1894 flood to 800,000 cfs would, if included in the flood control plan, be evaluated at a lesser rate based on the average value of all additional storage needed to control the 1894 flood at The Dalles to 600,000 cfs.

Local flood control objectives have also been identified in other parts of the basin especially on the Kootenai River downstream from Bonners Ferry where control of the 1894 flood to a maximum of 600,000 cfs is desirable. Storage either in the United States or Canada should be entitled to credit on the basis of satisfying such local objectives.

FLOOD CONTROL PRINCIPLE NO. 3

The monetary value of the flood control benefit to be assigned to the upstream storage should be the estimated average annual value of the flood damage prevented by such storage.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 3

The average annual value of flood damage prevented by upstream storage can be computed by conventional methods using stage-frequency and damage-frequency relationships. The methods are described and their application illustrated in the most recent report of the Corps of Engineers on the Columbia River Basin recently submitted by the Division Engineer, US Army Engineer Division, North Pacific, to the Chief of Engineers under the title "Water Resources Development, Columbia River Basin" dated June 1958.

FLOOD CONTROL PRINCIPLE NO. 4

The upstream country should be paid one-half of the benefits as measured in Flood Control Principle No. 3, i..e, one-half of the value of the damages prevented.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 4

In the event that application of this principle should indicate a payment to the upstream country greater than the estimated cost of alternative means of obtaining equivalent flood control in the United States the requirement of General Principle No. 2 that there should be an advantage as compared with available alternatives would not be satisfied and consideration should be given to this circumstance in the negotiations.

FLOOD CONTROL PRINCIPLE NO. 5

The amount due to the upstream country under the foregoing principles should be determined in advance of construction of each storage project. Payments to cover the entire period that the arrangements are to be effective should be made in cash as a lump sum or as periodic amounts as may be agreed upon

INTERNATIONAL NEWS

The Colombo Plan is not a partnership of ideologies or doctrines, "but it is a partnership which has as its sole objective the welfare and prosperity of the member countries of the organization," stated Dr. R. Subandrio, Minister of Foreign Affairs, Republic of Indonesia, at the eleventh meeting of the Consultative Committee of the Colombo Plan, held in Jogjakarta, in November. Similarly, both Prime Minister Diefenbaker and the late Dr. Sidney Smith, Minister of External Affairs, have expressed the view that, participating in The Colombo Plan, countries recognize the importance to the world at large of careful development of both natural and human resources in the countries of South and Southeast Asia.

Canada has played a significant part in the Colombo Plan since its inception in 1950. At that time the Commonwealth foreign ministers, meeting in Colombo, set up a plan for cooperative economic development of South and South-East Asia for six years ending June, 1957. In 1955, the Plan was extended till June 1961 and at the November 1959 meeting it was extended another five years from 1961. Whereas the membership in 1950 included only Commonwealth countries—Australia, Canada, Ceylon, India, New Zealand, Pakistan, and the U.K.—it has been extended to all countries of South and South-East Asia, Japan and the U.S.

During the year 1958-59 Canada contributed $35 million to Colombo Plan projects, bringing her total as of March 31, 1959, to more than $231 million. Beyond this, Canada has made special grants of wheat and flour to India, Pakistan and Ceylon with a total value of $70 million. She has sent 134 experts in public health, agriculture, fisheries, mining, engineering and aerial survey to South and South-East Asian countries and has received 1035 trainees in Canada from Colombo Plan countries.

Hydro-electricity and Irrigation

The Warsak Project on the Kabul River about 19 miles northwest of the city of Peshawar, Pakistan, is one of five irrigation and power development projects which Canada has contributed to in Pakistan. Into the Warsak Project alone she has put $33.5 million.

The total drainage area to the project site is approximately 26,000 square miles, for the river rises in Afghanistan about 60 miles north of the capital city, Kabul. When the Warsak Dam is completed it will supply 160,000 kw. of electric power to northwest Pakistan and the surrounding districts. Power will be able to be transmitted to the growing industrial areas to the south where there is a shortage of power as the output of the Warsak Project is increased.

The main dam is a concrete gravity overflow structure approximately 700 ft. long, rising 220 ft. above the lowest level of the river bed. Downstream of the dam is a power house which at present houses four units but has space for an additional two. Both the Warsak Dam and the power house have been designed by Canadian firms and the generators and electrical equipment, manufactured in Canada. In January 1959, 157 Canadians and 10,673 Pakistanis were employed in various phases of the project. While the project manager is a Canadian, both Pakistani and Canadian engineers are at work there.

The Thal Irrigation and Colonization Project on the River Indus in Pakistan has been carried out with capital and technical aid from Canada, the U.K., Australia and New Zealand. The project

Canadian Assistance Under The Colombo Plan
To March 31, 1959

Country	*No. of Experts Sent*	*No. of Students Trained*	*Expenditures on Technical Assistance*	*Allocations of Capital Assistance*	*Total of Expenditures on Technical Assistance and Allocation of Capital Assistance*
Burma	10	77	494,931	399,563	894,494
Cambodia	4	16	113,192	64,634	177,826
Ceylon	42	77	1,321,075	13,309,917	14,630,992
India	20	295	1,510,583	122,241,019	123,751,600

	6 (1)	—	42,507 (2)	—	42,507 (2)
	134	1,035	6,617,657	211,644,090	218,261,747

(1) Two or more countries. (2) Contributions to Technical Co-operation Bureau.

includes the settling of over 50,000 family units in 700 new villages with modern sanitation, markets and electricity. The area, which less than a decade ago was shifting sands, is now a fertile belt of more than 500,000 acres of cotton, sugar cane, maize, fodders and wheat.

The Shadiwal Hydel Scheme, a major irrigation project for East Pakistan, will produce 12,000 kw. of firm power from a fall on the Upper Jhelum Canal. The generating sets and some of the construction machinery are being given by Canada.

The Karnaphuli Hydro-Electric Station is in process of being connected with the **Steam Station At Siddhirganj** (Dacca) by means of a 132 kv. transmission line for which Canada is in large part responsible. State ipment for a steam station at Khulná and much of the plant and equipment at Goalpara have been made possible by Canadian contributions through the Colombo Plan.

The Gal Oya Valley Development in Ceylon, based upon the impounding of the waters of the 62-mile long Gal Oya River in a giant reservoir, is a multipurpose project for flood prevention, irrigation and hydro-electric power. Though the project has been financed principally by national funds, Canada has helped by providing the power transmission extension system and power-driven lift irrigation equipment for experimental purposes.

Other Projects

"Canada Dam" on the Mayurakshi River in West Bengal is but one of the hydro-electric power and irrigation projects in India contributed to by Canada. **The Kundah Project**, one of the largest power installations in Madras, and **The Shadiwal Project** in West Pakistan have also been the concern of Canadian engineers under the Colombo Plan. **The Mekong River Scheme**, which is an international project to benefit four Colombo Plan countries, Laos, Thailand, Cambodia and Viet-Nam, is to be studied by a Canadian expert to determine feasibility, costs, and problems involved in making an aerial survey along the Mekong.

Although 40% of all Canada's financial and technical aid through the Colombo Plan has been devoted to water power and irrigation projects, Canada has also contributed to the development of fisheries in Ceylon; the first atomic reactor in India; transportation and communications facilities in India, Ceylon and Indonesia; and the equipping of a Technical school in Singapore. Canada ranks third of the Colombo Plan countries in number of training places provided for Colombo Plan students from South and South-East Asia.

Month to Month

Commonwealth Scholarship and Fellowship Plan

The first Commonwealth Education Conference held in Oxford, England, July 15-28, 1959, laid the foundations for a Commonwealth Scholarship and Fellowship Plan for interchange of students within the Commonwealth countries. The plan includes all phases of high education — humanities, sciences, and vocational courses. The first awards—will be made to students who already hold a first degree and wish to do advanced work. A limited number of Commonwealth Visiting Fellowships will also be available for senior scholars of established reputation. Most scholarships will be offered by the country receiving the scholar, after having made its own selection of Scholars and Visiting Fellows. Candidates will apply on their own initiative.

Dean Gaudrefroy, of Ecole Polytechnique, Montreal. was a member of the Canadian delegation to the planning conference.

French Government Scholarships for Canadian Engineers and Technicians

The French Government has established a *Service de Cooperation Technique* to organize and coordinate foreign students' work in France, both in formal courses and in training positions in industry. They offer a grant of 75,000 francs a month (considerably more in purchasing value than $200 a month in Canada), free return trip from France to Canada, free travel relating to work while in France, and comprehensive medical coverage.

Candidates must hold an engineering degree from a university of high standing; must have had some field experience for at least one year; must have a sufficient knowledge of French; and must present good references and a proposed plan of study. Letters of application, listing date and place of birth, academic training, practical experience, references, knowledge of French, and proposed duration of stay and plan of study should be sent *immediately* to: Mr. Raymond Treuil, Chairman of the Comité France-Technique, c/o French Embassy, 464 Wilbrod Street, Ottawa, Ont. Professional engineers and university professors who wish to supplement their knowledge in their particular field are particularly eligible for such scholarships.

Education Conference in Toronto, 1962

The Second Canadian Conference on Education will take place in the Royal York Hotel, Toronto, during the week of February 19, 1962. A group of Canada's outstanding educators and lay thinkers is in process of determining the program for this convention. The National Committee met in Montreal recently, with Kurt Swinton and Dr. Robert Gauthier as co-chairmen, and drew a record attendance.

University Appointments

Dr. Claude Bissell, president of the University of Toronto, has announced the appointment of two new department heads. Prof. J. G. LeRoy will take over the department of chemistry, and Prof. J. B. Breckenridge, the department of chemical engineering and applied chemistry. Both appointments take effect July 1.

The appointment of new faculty members in electrical engineering at McMaster University is announced by Dr. J. W. Hodgins, dean of engineering. Dr. C. A. Edward Uhlig is appointed associate professor of electrical engineering and G. J. Hoolboom, assistant professor in the department.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on October 17, 1959.

Member: J. L. Baardman, Montreal; J. Beattie, Ottawa; S. M. Blair, Toronto; J. N. Clinton, Toronto; P. H. Davies, Fort William; S. B. Ford, Montreal; N. S. Hammond, Kitimat; S. F. Hunt, Winnipeg; W. J. Lenson, London; A. P. MacGrath, Ottawa; I. C. MacLean, Toronto; M. J. Palmer, Hamilton; J. M. Philip, Montreal; A. Rutka, Toronto; J. J. Schoustra, Toronto; H. Stephens, Kitchener; C. Szollosy, Schefferville; B. L. Vass, Montreal; C. G. Woof, Toronto.

Junior: R. Collins, Toronto; Y. I. Fellman, St. John's, Nfld; J. J. Grieco, Shawinigan Falls; T. T. Morrison, Montreal; I. Nabi, South Bend, Ind; A. R. Rowcroft, Montreal; M. T. Vickers, Montreal.

Junior to Member: C. L. Bessette, Iberville; L. J. Bandiera, Kitimat; M. J. Kitchen, North Bay; J. K. Park, Toronto; H. A. C. Stokes, New Westminster; W. J. N. Throop, Belleville.

STUDENTS ADMITTED

University of Toronto: G. R. Biggs; Yiu-Cho Li, Yiu-Chung Li, D. L. Meyers, L. G. Richings, H. Shifman, Cho-Yuk Sin, J. Timusk, A. Tunner, C. Warchol.

Sir George Williams College: B. Christiansen, R. E. Doyle, B. D. Emery, P. P. Jurgutis, J. Labreche, C. Maletskas, M. Rosenbloom, D. K. Schroder.

McGill University: S. R. Allen, A. S. Hill, R. G. Knystautas.

University of Manitoba: B. M. M. Long.

Dalhousie University: P. W. H. Willcock.

St. Joseph University: C. Losier.

Northwestern University: G. T. Jorgenson.

University of Toronto: R. E. Anderson, B.A.Sc., (Mech.) 1959; C. T. David, B.A.Sc., (Engrg. Physics) 1959.

Imperial College (University of London): G. F. Dorling, B.Sc. (Chem.) 1959.

University of British Columbia: D. C. Baynes, B.A.Sc., (Civ.) 1959.

Application through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Members: R. A. Cimolino, G. A. McCreary; **Junior:** M. J. Burgess, G. H. Palmer; **Junior to Member:** N. G. Brown.

SASKATCHEWAN

Members: I. Brand, R. L. Cheesman, D. D. Davison, N. F. Gordon, D. M. Kilgour, J. J. Kovach, B. H. Lacey, M. L. Olynyk, F. D. Patton; **Juniors:** D. Hortensius, D. D. McLean, J. S. Tulooch; **Junior to Member:** D. L. Fuller, H. G. Wiber.

NOVA SCOTIA

Members: G. W. Baker, F. R. Fraser.

PRINCE EDWARD ISLAND

Junior to Member: L. A. Coles.

KINGSTON REGIONAL TECHNICAL CONFERENCE

Automation and Control

Saturday May 7, 1960

10 a.m. **REGISTRATION:** By special form as mailed to each member or with L. C. Miller, 277 Mack St., Kingston, or at the conference.

11 a.m. **OPENING ADDRESS AND TECHNICAL PAPERS:** Ellis Hall, Queen's University.

12.30 p.m. **LUNCHEON:** In the Students' Union, Queen's University. Ladies are welcome.

PROGRAM OF TECHNICAL PAPERS

11 a.m. DR. ARTHUR PORTER, *Dean of Engineering—University of Saskatchewan.*
Growth of Automata

2 p.m. MR. P. HERTZL, *Sperry Gyroscope*
A Numerically Controlled Positioning System

MR. J. D. LEE, *J. D. Lee & Co. Ltd.*
The Application of a Small Digital Computer to Some Civil Engineering Problems

3 p.m. MR. A. DUGUID, *Computing Devices of Canada*
Dead Reckoning Airborne Navigation Systems

MR. G. A. LOCKE AND MR. R. H. ANDRES, *Canadian Industries Ltd.*
Instrumentation Problems in Hydrogen Gas Generation

4 p.m. A paper delivered by a Service Officer on a Military Application of Automation.

A paper delivered by a Student Member on a subject associated with Automation and Control. This paper is being selected on a competitive basis from those submitted by a number of educational institutions.

LADIES' PROGRAM: Ladies are welcome to attend any of the technical papers. A tour of Fort Henry and tea have been arranged.

6.30 p.m. **RECEPTION:** Burgundy Room, La Salle Hotel.

7.30 p.m. **DINNER-DANCE:** In the La Salle Hotel, dress informal.

Accommodation will be arranged as requested on the registration forms.

Plan Now to Attend

THE KINGSTON REGIONAL TECHNICAL CONFERENCE

George McKinstry Dick

PRESIDENT

THE ENGINEERING INSTITUTE OF CANADA

1960 — 1961

GEORGE McKINSTRY DICK, M.E.I.C., was born in Scotland and attended public schools over there, prior to coming to Canada. After a short sojourn in the Canadian West, he took up residence in Sherbrooke, Quebec, and entered the employment of Canadian Ingersoll-Rand Company as an apprentice. During World War I, he was employed in the design of machinery for the manufacture of munitions. He was a student at Bishops University in Lennoxville in 1920 and later attended McGill University, Montreal, where he graduated with the degree of Bachelor of Science, Honours in Mechanical Engineering, in 1924. He was British Association Medallist at graduation and was holder of the Babcock & Wilcox Scholarship. His summer essay took prizes in The Canadian Pulp & Paper Association and also The Engineering Institute of Canada.

Eager for a diversified career, Mr. Dick gained extensive knowledge in the pulp and paper field by being associated with The Brompton Pulp & Paper Company at East Angus, Quebec, as well as experience in the design of boilers and stockers by working for Babcock-Wilcox & Goldie-McCullough Limited at Galt, Ontario. He eventually re-entered the employment of Canadian Ingersoll-Rand Company where his activities have brought him in contact with a wide range of engineering interests. For many years he was Chief Hoist Engineer, and, as such, pioneered the design of a considerable volume of the mine hoists used in Canada today.

During World War II, Mr. Dick was Chief Engineer of The Sherbrooke Pneumatic Tool Company, a subsidiary of Canadian Ingersoll-Rand, and was responsible for the design of much of the shell manufacturing equipment used by this company.

His interests, however, were not confined to engineering, and he later became Technical Assistant to the Works Manager of Canadian Ingersoll-Rand Company Limited, a position he held until 1945 when he was appointed Manager of Engineering with dutics which embraced management of all phases of his company's engineering and technical activities. These duties were later broadened to include complete control of the company's purchasing program, and he became Manager of Engineering and Purchasing. Since 1952, Mr. Dick has been Chief Engineer and has since then devoted his time principally to the development of new products, materials and processes.

Mr. Dick is a Past Vice-President of The Engineering Institute of Canada, a member of the American Society of Mechanical Engineers, The Technical Association of Pulp & Paper Industry of the U.S.A., The Corporation of Professional Engineers of Quebec, The Canadian Institute of Mining and Metallurgy, The Canadian Pulp & Paper Association, and The British Association for the Advancement of Science.

With the late Dr. Armand Crepeau, he founded the Eastern Townships Branch of The Engineering Institute of Canada. He was a charter member and the Branch's first chairman. Mr. Dick was for several years Regional Representative for the Eastern Townships on the Council of the Corporation of Professional Engineers of Quebec. He was a member of The Engineering Institute of Canada's Committee on Confederation, and is now a member of the Corporation of Professional Engineers of Quebec's Committee on Confederation.

When the Engineers Confederation Commission was set up jointly by The Engineering Institute of Canada and The Canadian Council of Professional Engineers, Mr. Dick was appointed its Vice-Chairman.

Mr. Dick is a member of the St. George's Club, Sherbrooke, and a Past-President and member of Sherbrooke Y.M.C.A. He is a Past-President, Past Honorary President, and member of the Sherbrooke Snow Shoe Club, and a member of Sherbrooke Curling Club. He is a member of the Session of St. Andrews Presbyterian Church, Sherbrooke, and a Governor of the Sherbrooke Hospital.

Keenly interested in Education, Mr. Dick is a member of the Advisory Committee of the Faculty of Science of the University of Sherbrooke and has also assisted in giving lecture courses.

Mr. Dick is married and has one son, James, who is a graduate in science of Bishops University, Lennoxville, and a graduate in engineering of McGill University.

During almost half a century, Mr. Dick has taken a leading part in the engineering development of this country. He has travelled extensively both on this continent and in Europe and in this way has kept himself well abreast of important engineering trends.

Personals

D. A. Barnum, M.E.I.C. (Michigan '29) has been appointed vice-president and general manager, Transmission Tower Division of Beamer & Lathrop Limited, Welland, Ont. Mr. Barnum resigned in November from Provincial Engineering, Ltd., Niagara Falls, Ont., where he was manager of the tower division.

D. A. Barnum, M.E.I.C.

J. T. Dyment, M.E.I.C.

J. T. Dyment, M.E.I.C. (Toronto '29), chief engineer of Trans-Canada Air Lines, has been appointed to represent air transportation on the Engineering Activity Board of the Society of Automotive Engineers.

E. A. Allcut, M.E.I.C. (Birmingham '09), Professor Emeritus of Mechanical Engineering at the University of Toronto, has been appointed commissioner of the Ontario Fuel Board by the Ontario Government.

S. Bonser, M.E.I.C. has been named works manager of Anthes Steel Products, Toronto. This company was formerly Standard Iron and Steel Works Ltd.

Clarence MacLeod Pitts, M.E.I.C. (McGill '14) has been appointed a director of British Oxygen Canada Limited, Toronto. Mr. Pitts is president of the People's Gas Supply Company, Ottawa.

Casimir C. Flis, S.E.I.C. (McGill) has been made town engineer of Newmarket, Ont.

H. W. Short, M.E.I.C., recently retired sales manager of Dominion Bridge, Toronto, has been appointed director of public relations and sales representative of the Sault Ste. Marie Branch of Dominion Bridge.

Robert Ford, M.E.I.C. (McGill '22) has retired as director of engineering at the Dominion Rubber Company, Montreal, and is residing in Ottawa.

H. G. Welsford, M.E.I.C., president and a director of the Dominion Bridge Company, and president and managing director of the Dominion Engineering Works, has been elected to the board of directors of The Royal Bank of Canada.

J. B. Mawdsley, M.E.I.C. (Princeton '24) has been appointed director of the new Institute for Northern Studies established by the University of Saskatchewan on its campus. Dr. Mawdsley will retain his present position as professor and head of the department of Geology at the university.

C. Ritchie Timm, M.E.I.C. (McGill '30) is the new director of engineering for the Dominion Rubber Company, Montreal.

C. R. Timm, M.E.I.C.

P. W. Barchard, M.E.I.C.

Philip W. Barchard, M.E.I.C. (British Columbia '40) has been named general manager of B.C. Electric's gas division.

Ralph R. Willis, M.E.I.C. (New Brunswick '31) is the new vice president and general manager of Ross Engineering of Canada.

James E. Neilson, M.E.I.C. (Queen's '28) is the new president and chief executive officer of Foster Wheeler, St. Catharines, Ont.

W. A. Cairns, M.E.I.C. (Alberta '36) has been appointed superintendent of Cominco's new Caustic Chlorine Department in Trail, B.C.

Patrick J. Kelly, M.E.I.C. (Manitoba '38), president of A. M. Kelly & Sons, Winnipeg, has been elected president of the Prairie Road Builders' Association.

T. G. Quance, M.E.I.C. (Toronto '38) has been made president of CLM Industries (formerly Canadian Line Materials Limited).

W. H. Powell, M.E.I.C. (Toronto '39), general manager of the Peterborough Utilities Commission, has been elected president of the Peterborough Chamber of Commerce.

A. F. Mosher, M.E.I.C. (University of B.C. '44), formerly vice-president, sales, with Croname (Canada), has been appointed to establish the Ontario Branch of Philip French Sales, Montreal. Headquarters will be in Toronto.

W. W. Robertson, M.E.I.C. (Saskatchewan '45) has been transferred by his firm, the Aluminum Company of Canada, to Switzerland where he will attend the Centre d'Etudes Industrielles.

J. W. Brison, M.E.I.C. (Queen's '48) has been appointed vice-president and manager of Windsor operations of Giffels & Vallet of Canada, Ltd., consulting engineers, Windsor, Ont.

Gregory R. Williams, M.E.I.C. (Toronto '48) has left C. D. Carruthers & Wallace Consultants Ltd. to establish his own practice of structural consulting engineering.

L. A. Parker, M.E.I.C. (McGill '51) has left John B. Parkin Associates and Giffels and Vallet of Canada with whom he was an electrical project engineer to form his own electrical consulting firm in Port Hope, Ont. under the name of L. A. Parker and Associates Limited.

L. A. Parker, M.E.I.C.

Capt. D. H. Curling, JR.E.I.C.

Capt. David H. Curling, JR.E.I.C. (McGill '52), who has been attending the Royal Military College of Science, Shrivenham, England, has taken up the position of test officer, experimental and test wing, Army Development Establishment, Ottawa.

J. E. Wainwright,
M.E.I.C.

Word has been received by the Institute of the passing of **Arthur Healy Dargie**, M.E.I.C., on September 8, 1958, at the age of 42. Mr. Dargie was for seventeen years connected with the Department of Highways & Public Works, Halifax, N.S.

Roland Kenneth Kilborn, M.E.I.C. died December 22, 1959, in Atlanta, Georgia. He was 56.

Mr. Kilborn was born in China under British registry. He was educated at North Toronto Collegiate Institute and at Queen's University. In 1947 Mr. Kilborn formed a consulting company specializing in the design of mining and milling plants, water supply and sewage treatment plants.

Mr. Kilborn was president of Kilborn Engineering Limited, Toronto. A Member of the Institute since 1945, he also belonged to the Canadian Institute of Mining and Metallurgy; the Ontario and Quebec Professional Engineers Associations, and the Canadian Institute on Sewage and Sanitation.

Harold Victor Serson, M.E.I.C., died suddenly in Orlando, Florida, on January 8, 1960. He was 77.

After graduation from the University of Toronto in 1905, Mr. Serson's first professional experience was on the construction of the Hudson River Tunnels in New York City. He continued in construction work in the United States until 1914, when he began a private practice in Arnprior, Ontario. During World War I, he served for three years in France with the Canadian Engineers.

For the next 32 years, Mr. Serson worked on construction projects across Canada, including hydro-electric developments at Island Falls, Ont.; Ottawa; Calgary; Dalhousie, N.B.; Masson, Shipshaw and Valleyfield, Que.; and Campbell River, B.C. He was connected with the Foundation Company for 16 years, and at the time of his retirement in 1951 was with the General Construction Company of Vancouver.

Mr. Serson joined the Institute as Associate in 1909, became a Member in 1940, and was made Life Member in 1947.

John Reed, M.E.I.C., a former councillor of the Institute representing the Saint John Branch, died suddenly in hospital at East Riverside, N.B., December 22, 1959. He was 63.

Mr. Reed was born at Trinity Bay, Nfld. and educated in Montreal. Graduating from McGill, he went to work as a draughtsman for the Phoenix Bridge Company, Montreal, until 1923 when he joined Canadian Vickers Limited as chief draughtsman. During World War I he served with the Ambulance Corps and with the Engineers of the Royal Canadian Army.

In 1928 Mr. Reed left his position as assistant chief engineer of Canadian Vickers' structural steel department to become chief engineer with the Saint John Dry Dock Company, Saint John. He retired from the post in 1958 and since that time had been doing consulting work for the company.

A former vice-president for New Brunswick and Prince Edward Island of the Canadian Institute of Steel Construction, Mr. Reed had also been a chairman of the Saint John Branch of the Institute and a member of the Association of Professional Engineers in New Brunswick.

Kenneth K. Pearce, M.E.I.C., died at Dewittville, Que., on August 8, 1959. For many years a resident of Montreal, Mr. Pearce retained his membership in the Montreal Branch of the Institute though he moved to Dewittville in July, 1959.

A graduate of the University of Toronto, Mr. Pearce started work in Montreal at the Dominion Bridge Company and was with that company for many years. Subsequently he was with Monsarret & Pratley, Consulting Engineers, and during depression years he was in the office of Noranda Gold Mines. Mr. Pearce was also employed at Canadian Vickers for a number of years.

Since 1950 Mr. Pearce had been with Brian Perry, Consulting Engineers, Montreal. He was granted a Life Membership in the Institute in January, 1957.

James George Radenhurst Wainwright, M.E.I.C. chief engineer of the Toronto Harbour Commission from 1929 to 1936, died December 10, 1959 at the age of 89.

A graduate of McGill, Mr. Wainwright began his work with the Commission in 1911 and had a major part in developing the present port facilities.

Mr. Wainwright's affiliation with the Institute began in 1890 when he applied for Student Membership. He was granted Life Membership in 1941.

Until his retirement in 1941, Mr. Wainwright acted as a consultant to the Toronto Harbour Commission.

Harold William B. Swabey, M.E.I.C., chief inspector of steel for the Department of Militia and Defence during World War I, died on January 30, 1960, at the age of 80.

Mr. Swabey was born in Bedfordshire, England and educated at the Crystal Palace School of Practical Engineering in London. He came to Canada in 1907. Prior to World War I, he was engaged in railroad construction. Mr. Swabey was supervising engineer on the construction of the Quebec and Saguenay Railway and he served the Canadian Pacific Railway Company as resident engineer on construction of the Campbellford-Lake Ontario and Western Railway.

For several years Mr. Swabey worked as construction engineer with Lockwood Greene and Company of Canada and in 1922 established the Service Engineering Company in Montreal. In 1926 he joined J. T. Donald & Company, Montreal and Toronto, general consulting engineers, and later became managing-director of that company.

During World War II Mr. Swabey worked with the Defence Purchasing Board and in 1946 he was named Assistant Steel Controller of the Department of Reconstruction and Supply. Retiring from active government service in 1950, he took up the position of town engineer in Pointe Claire.

A Life Membership in The Institute was bestowed upon him in 1947, after 37 years of membership.

News of Other Societies

IAEA Conferences on Isotopes and Reactors

Two major scientific conferences and eleven symposia are included in the provisional schedule of meetings to be organized by the International Atomic Energy Agency in 1960. One large conference will deal with radioisotopes in the physical sciences and industry; the other will concern itself with problems of medium and small-size reactors. The tentative list of symposia, for which invitations will be extended to all Agency member states, includes:

Fuel element fabrication
Vienna, May 3-6.
Radiation dosimetry
Vienna, June 7-13.
Inelastic scattering of neutrons in solids and liquids
Vienna, October 11-14.
Neutron pile (reactor) research
Vienna, October 17-21.
Nuclear ship propulsion
mid-November.
Experimental and test reactors
Vienna, November 28-December 2.
Education and nuclear energy
Argentina, end of year.

Electrical Engineers' Exhibition (London)

The Ninth Electrical Engineers' Exhibition, a display by the leading manufacturers of Britain's Electrical Industry, will be held at Earls Court, London, April 5 to 9. Nearly 450 manufacturers will show their products, covering every aspect of the generation, distribution and utilization of electricity.

Society for Experimental Stress Analysis

"Stress Analysis of Propulsion Systems" is the theme chosen for the 1960 Spring Meeting of the Society for Experimental Stress Analysis to be held in Indianapolis, Indiana, May 18-20. Further information about the meeting can be obtained from: Society for Experimental Analysis, Post Office Box 168, Cambridge 39, Mass.

World Power Conference

The Madrid Sectional Meeting of the World Power Conference will be held in Madrid, Spain, June 5-9, 1960. The five technical sessions will cover the following subjects: methods of investigation of energy sources and requirements; efficiency of production and utilization of energy; technical developments in transportation; establishment of nuclear reactors on an industrial scale; and functional interrelation between conventional and nuclear production of energy.

Machine Tool Exhibition

Sponsored by The Machine Tool Trades Association of Great Britain, the International Machine Tool Exhibition will be held in London June 25 to July 8, 1960.

Conference on Medical Electronics

The Third International Conference on Medical Electronics will take place in London, July 21-27. The Electronics and Communications Section of the Institution of Electrical Engineers (U.K.) is responsible for the organization of the conference.

Utility Management Workshop

The Ninth Annual Utility Management Workshop will be held at Columbia University, Harriman, New York, July 24-August 5. The objectives: "to enable a group of Utility executives to study the job of top management in the Utility Industry and to develop . . . workable solutions to the executive training problems in their own companies."

Proposed Conference on Electrical Engineering Education

September 1960 will see 100 persons, 75 of them Americans and 25 non-Americans, convene at Syracuse University, New York, for an International Conference on Electrical Engineering Education.

1960 National Die Casting (U.S.) Exposition

The First National Die Casting Exposition and Congress will be held in the Detroit Artillery Armory, November 8-11, 1960. Sponsored by the Society of Die Casting Engineers, the exposition will concentrate on the rapidly expanding die casting field.

Institute of Radio Engineers

The Fifth Institute of Radio Engineers' Canadian Convention and Exposition will take place in Toronto, in October 1961. An expanded technical program and increased industrial participation will be allowed by postponing the exposition for a year.

Petroleum Geologists (U.S.)

The American Association of Petroleum Geologists has elected Dr. Ben H. Parker, president of the Colorado School of Mines Board of Trustees, to its presidency.

Consulting Engineers of Canada

The Association of Consulting Engineers of Canada recently elected the following to office: R. R. Duquette, Montreal, president; John H. Rose, Toronto, vice president; James A. Kearns, Montreal, secretary-treasurer; and J. Murray Muir, executive secretary.

American Meteorological Society

The American Meteorological Society, Boston, Mass. recently celebrated its 40th anniversary. Dr. Thomas F. Malone, director of research for The Travellers Insurance Companies, Hartford, Conn., was elected president of the society for the two-year term 1960-61. Honorary Memberships were bestowed upon Sir Edward Appleton, University of Edinburgh; Prof. Andrei N. Kolmogorov, Moscow State University; and Dr. Theodore von Karman, NATO, Paris.

Astronautical Society

The Astronautical Society of Canada, Montreal, heard Professor Hubert Reeves, astrophysicist, University of Montreal, speak on "Spatial Erosion, Comets and Meteorites" on January 13.

Canadian Electrical Council

Canada's Electrical Day was celebrated in Winnipeg February 11 with meetings of the Canadian Electrical Council and the Electrical Bureau of Canada; a luncheon addressed by Mr. I. F. McRae, chairman of the board of Canadian General Electric; and conducted tours of the electrical displays at the Hudson's Bay Company. The Canadian Electrical Council, the Manitoba Electrical Association and the Electric Service League of Manitoba were joint sponsors.

Toronto Quality Control

The Toronto Quality Control Society (Toronto Section of the American Society for Quality Control) held its Seventh Annual All-Day Forum at the University of Toronto March 5. Sessions included a basic training course in statistical quality control, a series of lectures and a panel discussion on quality control applications in industry.

Canadian Electrical Association

All sections of the three Canadian Electrical Association divisions, Western Zone, will hold meetings at the MacDonald Hotel, Edmonton, March 21-23.

to the mutuol sotisfoction of the upstreom ond downstreom countries.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 5

The payment of a lump sum or periodic amount as may be agreed upon would, of course, be subject to the authorization of such payment by the Congress of the United States. Request for such authorization could be presented to the Congress for consideration as soon as a definite arrangement between the two countries became available as a basis for the request.

FLOOD CONTROL PRINCIPLE NO. 6

In the event of the downstreom country requesting speciol operotion for flood control of storoge included in the ossured plon of operotion, beyond the type of operotion provided for in such ossured plon, the upstreom country should be compensoted for ony loss of power which moy result therefrom. In the event of the downstreom country requesting the operotion, for flood control, of storoge not included in the ossured plon, the upstreom country should similiorly be compensoted for ony loss of power which moy be sustoined by the upstreom country ond in oddition should be poid on the bosis of holf the domoges prevented by the operotion of the storoge in question.

DISCUSSION OF FLOOD CONTROL PRINCIPLE NO. 6

This principle is included to provide for emergency operations to meet unusual flood producing conditions not covered in the assured plan of operation discussed under Principle No. 1. As long as operations for flood control remain in conformity with the assured plan of operation, there would be no compensation beyond that provided for in the other power and flood control principles.

If, however, unusual flood producing conditions should occur and, at the request of the downstream country, the upstream country should draw down its storages included in the assured plan to a greater extent or at a different time or in any manner not provided for in the assured plan of operation, the downstream country should compensate the upstream country for the loss of power sustained in providing the additional flood protection. That is, if such action caused a loss of power as compared with the results that would have been possible by adhering to the assured plan of operation, then the upstream country would be reimbursed for the loss of power at its plants and for the decrease in its share of power in the downstream country's plants.

The reimbursement could be either in cash or in power as might be mutually agreed upon.

In any event, the downstream country should give assurances that it would furnish sufficient power to meet minimum load requirements of the upstream country if the loss of power were so great as to adversely affect the upstream country's ability to meet the loads from its own resources.

The foregoing arrangements will apply also to upstream storage not in the flood control plan but which is operated in response to the request of the downstream country to give emergency relief. In this case, however, the downstream country should, in addition to the compensation to the upstream country for power loss, make a payment to the upstream country on the basis of half the damages prevented.

Signed at Washington this twenty-ninth day of December 1959.

NRC Conference on Muskeg

A Muskeg Research Conference, organized by the Associate Committee on Soil and Snow Mechanics of the National Research Council's Division of Building Research, will be held on April 20-21 in Calgary. The over-all theme will be "Muskeg in Relation to Northern Development".

1960 Nuclear Congress (N.Y.C.)

The 1960 Nuclear Congress is to be held at New York City's Coliseum, April 4-7. A total of 57 technical papers will be presented during the four-day session, concerning Reactor Problems, Environment Problems, Materials and Components, Nuclear Standards, Isotopes and Radiation Processing. The Sixth International Atomic Exposition will be held in conjunction with the congress at the Coliseum.

Chemical Institute—AECL Symposium

A Nuclear and Radio-Chemistry Symposium will be held at the Chalk River laboratories of Atomic Energy of Canada September 6-8 under the joint auspices of the Inorganic Chemistry Division of The Chemical Institute of Canada and AECL. Participants are asked to submit abstracts of up to 11,000 words by June 15.

• DISCUSSION

(Continued from page 99)

must be made in the navigation channels to provide the full 27-foot depth at all times. Channel grades were based primarily on a profile showing the minimum water surface levels along the river for the critical monthly mean Lake Ontario levels and outflows under a method of regulation and the extra depth to provide for negative seiches was estimated from past records. Table I indicates as percentage of occurrences the degree of deviation at three locations during the navigation season. It also indicates the cumulative effect of a seiche as it progresses downstream from Lake Ontario.

With the dams completed at Iroquois, Long Sault and Barnhart Island, the seiches would be reduced owing to the increased area of the river surface. Based on studies made primarily by the St. Lawrence Seaway Authority it was finally agreed that an allowance of 2 ft. above Iroquois Dam and 1 ft. for those channels below Iroquois Dam would probably be sufficient. Experience to date indicates that this allowance is reasonably accurate.

Discussion by D. M. Ripley

The problem of river control during construction of the St. Lawrence Power Project was undoubtedly made more exacting, if not more difficult, by the knowledge that riparian interests around Lake Ontario have been extremely sensitive to adverse lake stages. This fact was well demonstrated by the objections raised by shore property owners during the high water level period of 1952. The approval of the International Joint Commission for the project was given in October of that year and the St. Lawrence River Joint Board of Engineers, appointed by the government of Canada and the United States pursuant to the Order of Approval, was keenly aware of the need for maintenance of pre-project conditions within close limits during construction. Their concern over a unified control of river works, as pointed out by Mr. Henry, is, therefore understandable. No less important during the construction period was the safeguarding of downstream navigation and power interests, which are more quickly affected by changes in river flow than the Lake Ontario interests. For example, a change in river flow of 20,000 cfs results in a change in the level of Montreal Harbour of about 1 ft., whereas this change in flow would have to be sustained for a period of four months to change the level of Lake Ontario by that amount.

The choice of Mr. Henry as River Control Engineer was a fortuitous one —the record speaks for itself.

Construction of the St. Lawrence Power Project is virtually complete but the control of the levels and outflows from Lake Ontario must be continued. For the time being the regulation "rule" is the maintenance of pre-project conditions. In the near future, a more appropriate plan of regulation will be instituted which will decrease the range of stage on Lake Ontario to the benefit of shore property owners, modify the outflows to increase the dependable power output at St. Lawrence River generating stations and safeguard downstream interests, including those of navigation. When such a plan of regulation is put into operation the experience gained on river control during construction will point the way to the most effective means for observance of the criteria of regulation.

NEWS OF THE BRANCHES

Assumption University

William Pulleyblank, S.E.I.C.,
Correspondent

The Border Cities Branch of E.I.C. invited the Student Members to their dinner meeting on January 20. A very friendly relationship was established between the Members and Students.

On January 28, 29, 30 and 31, the third year Student Members travelled to Hamilton and Toronto to visit Proctor & Gamble, Stelco, Westinghouse and the University of Toronto. This field trip will undoubtedly turn out to be the highlight of this year's activities.

Baie Comeau

G. W. Scott, M.E.I.C.,
Correspondent

The Annual General Meeting of the Baie Comeau Branch was held on November 6, 1959, at the Manoir Comeau and the following officers were elected for the coming year: chairman, G. W. Scott; secretary, Louis Tellier; treasurer, John O. Down; executive committee, P. Suttie, M. Pope, A. H. C. Carson; Labrieville representative, G. Labossiere; member emeritus, E. Bodmer.

Before relinquishing office, Mr. Bodmer, retiring chairman, gave a review of the past year's activities which included two field visits and five papers by distinguished visiting speakers. Overall branch membership stood at 71, including 25 branch affiliates. The past year has been a most successful one and Mr. Bodmer paid special tribute to the work done by the Branch Secretary, Louis Tellier, Jr.E.I.C.

Belleville

Wilburt Canniff, JR.E.I.C.,
Correspondent

Mr. H. R. Chipman, new product development manager at the Dominion Rubber Company, Kitchener, was the speaker at the branch meeting February 8. His topic: Engineering Applications of Re-inforced Plastics. He explained that although the first re-inforced plastics were produced about ten years ago, adequate design data was sparse. Mr. Chipman discussed the various re-inforcing materials and the properties of the resins used. The major resin in this field, polyester, is fabricated by hand lay-up, pressure bag molding, vacuum draw molding and matched metal molding.

Mr. J. J. Hanna, president of the E.I.C., was guest speaker at a stag dinner held in his honour at the Belleville Shrine Club, Monday, January 25. Approximately 50 Quinte District E.I.C. and A.P.E.O. members were there to hear Mr. Hanna, who recently retired as manager of the Calgary Oil Refinery, speak on the need to use but not abuse Canada's natural resources. He impressed upon the members the need for developing new processes and labour-saving equipment to keep our export prices down.

The president also announced that, starting with the February issue, The Engineering Journal was extending its circulation to all Professional Engineers.

Border Cities

W. A. Macdonald, JR.E.I.C.,
Correspondent

The Border Cities Branch Auxiliary has successfully completed its eighth year. Four interest groups are in action—mixed bowling, an afternoon bridge, and two evening bridge groups. The Annual Meeting, a dinner meeting, was held at Mario's February 3, 1959, and Mrs. St. Aubin spoke to the membership on "Ceramics". On March 17 a social evening and membership drive were held, resulting in a total membership of 82. Other events of the year included a family picnic, June 20; a luncheon at the Lakewood Golf Club, September 15; and a party given by the executive for Mrs. Lilian Robertson, secretary, Toronto office, November 17.

The executive for 1960, installed at a dinner meeting in the Palm Room at Mario's, February 2, 1960, is as follows: president, Mrs. H. J. Chapman; first vice-president, Mrs. J. W. Brison; second vice-president, Mrs. G. G. Henderson; recording secretary, Mrs. H. Bily; corresponding secretary, Mrs. E. T. Rivington; treasurer, Mrs. A. McCaw; publicity convener, Mrs. D. Servage; groups convener, Mrs. D. Osmun; councillors, Mrs. C. M. Armstrong, Mrs. J. Reid, and Mrs. E. Dykeman.

Participants in the Montreal Branch, Junior Section, Students' Night: *Back Row* (l. to r.): Messrs. Gantsheff, Philips, Benoit, Walker, Barcelow, and Kane. *Front Row* (l. to r.): K. Soosar, McGill; R. Lalencette, Ecole Polytechnique; M. Gagnon, Sherbrooke; and G. Desrosiers, Laval.

Calgary

Herbert Bailey, M.E.I.C.,
Correspondent

Mr. A. G. Martin, city planner for Calgary, discussed "Planning in a Changing Environment" at the Calgary Branch meeting January 21. He outlined the various universal and local forces that have been and are molding our present environment and pointed out that the last decade was not the only boom in Calgary. In fact, the sewers and water mains which were installed during the early boom of 1911-13 accommodated the city's expansion until 1953. At the legislative level, a completely new planning act gives the city wide authority in the enactment of zoning by-laws, development schemes, and planning boards. Mr. Martin suggested that the development of self-supporting urban centres which are closely linked but separated geographically from the main city will have to be seriously considered, and that this form of development was being tried in England. Mr. Martin closed in saying we should beware of the sceptic who says "It can't be done."

Cape Breton

Lloyd R. Boutilier, M.E.I.C.,
Correspondent

Members of the Cape Breton Branch at the January 28 meeting heard Mr. George Kirkpatrick of the exploration division of Imperial Oil talk on exploration and how and why geologists choose a prospective sight for oil drilling. Mr. Kirkpatrick, an expert in oil drilling who has been engaged in exploration work across Canada for 25 years, showed a film entitled "Search Unending" and displayed drill bits and small equipment. The meeting was quite informal, the better part of it an open discussion period relating to drilling procedures, findings and results in the Cape Breton area. The speaker was introduced by Mr. Brian Hansen of Imperial Oil and the vote of thanks was given by Mr. Rod Bradley, Dominion Steel and Coal.

Central B.C.

A. F. Joplin, M.E.I.C.,
Correspondent

On January 22, Mr. Edward Rohatynski, M.E.I.C., an engineer with the Consolidated Mining & Smelting Co., Kimberly, presented a paper to members entitled "Model Studies Leading to Modification of Waneta Dam", which he had given at the Western Technical Conference in Banff in October. At this first meeting of 1960 the year's program was discussed and field trips were proposed to see Cominco at Trail, B. C. and the power development at Cranberry Creek, Revelstoke.

Hamilton

Charles A. McCurdy, JR.E.I.C.,
Correspondent

The first meeting of the Civils Group of the Hamilton Branch, January 14, took the form of a panel discussion and a film on winter construction. Mr. Paul Goyette, Central Manufacturing & Housing, spoke on "Need for Winter Construction"; Mr. Hugh Connor, M.E.I.C., C. C. Parker & Associates, "Technical Aspects of Winter Construction"; Mr. Pat McNally, M.E.I.C., S. McNally & Sons, "Practical Solution to Winter Construction". Mr. W. A. Filer, Wagner, McCarger, Filer, was the moderator.

Kitchener

A. R. LeFeuvre, M.E.I.C.,
Correspondent

Mr. D. B. Redfern, senior partner, Proctor & Redfern, Consulting Engineers, Toronto, addressed the Kitchener Branch meeting on January 28. Speaking on pollution and sewage treatment in the Grand Valley, Mr. Redfern outlined the historical background of the pollution problem. He gave credit to the Water Resources Commission of Ontario for the vast improvement in facilities for sewage treatment in the last few years. Specific reference was made to the new or extended facilities at Elora, Waterloo, Kitchener, Preston, Galt and Brantford.

The new executive for 1960 was introduced as follows: councillor, L. J. R. Saunders; past chairman, W. J. Horner; chairman, A. H. Austin; vice-chairman, W. Bobbie; sec.-treas., C. G. E. Downing; directors, R. Dahmer, A. R. LeFeuvre, W. L. Bulmer, and M. H. Schmitt.

Fredericton

John M. Burrows, JR.E.I.C.,
Correspondent

Dr. G. V. Bull and Wing Commander E. A. Smith of the R.C.A.F. detachment at C.A.R.D.E. were guests of the Fredericton Branch January 25. Dr. Bull, who is superintendent of the aerophysics division at the Canadian Armament Research & Development Establishment, Valcartier, Que.. spoke on "Zero Physical Research Activities at C.A.R.D.E." He discussed the in-flight behaviours of various guided missiles, the temperature problems encountered with the various materials used, and the reaction of missile components under controlled, simulated flight conditions at C.A.R.D.E.

Wing Cmdr. Smith addressed the gathering on Project Look Out, where the R.C.A.F. at Ascension Island inspect re-entering missiles fired from Cape Canaverall, Fla., in cooperation with the U.S.A.F.

A formal presentation of the E.I.C. Prize to Ralph Francis for academic standing in his fourth year of civil engineering at U.N.B. was made by the

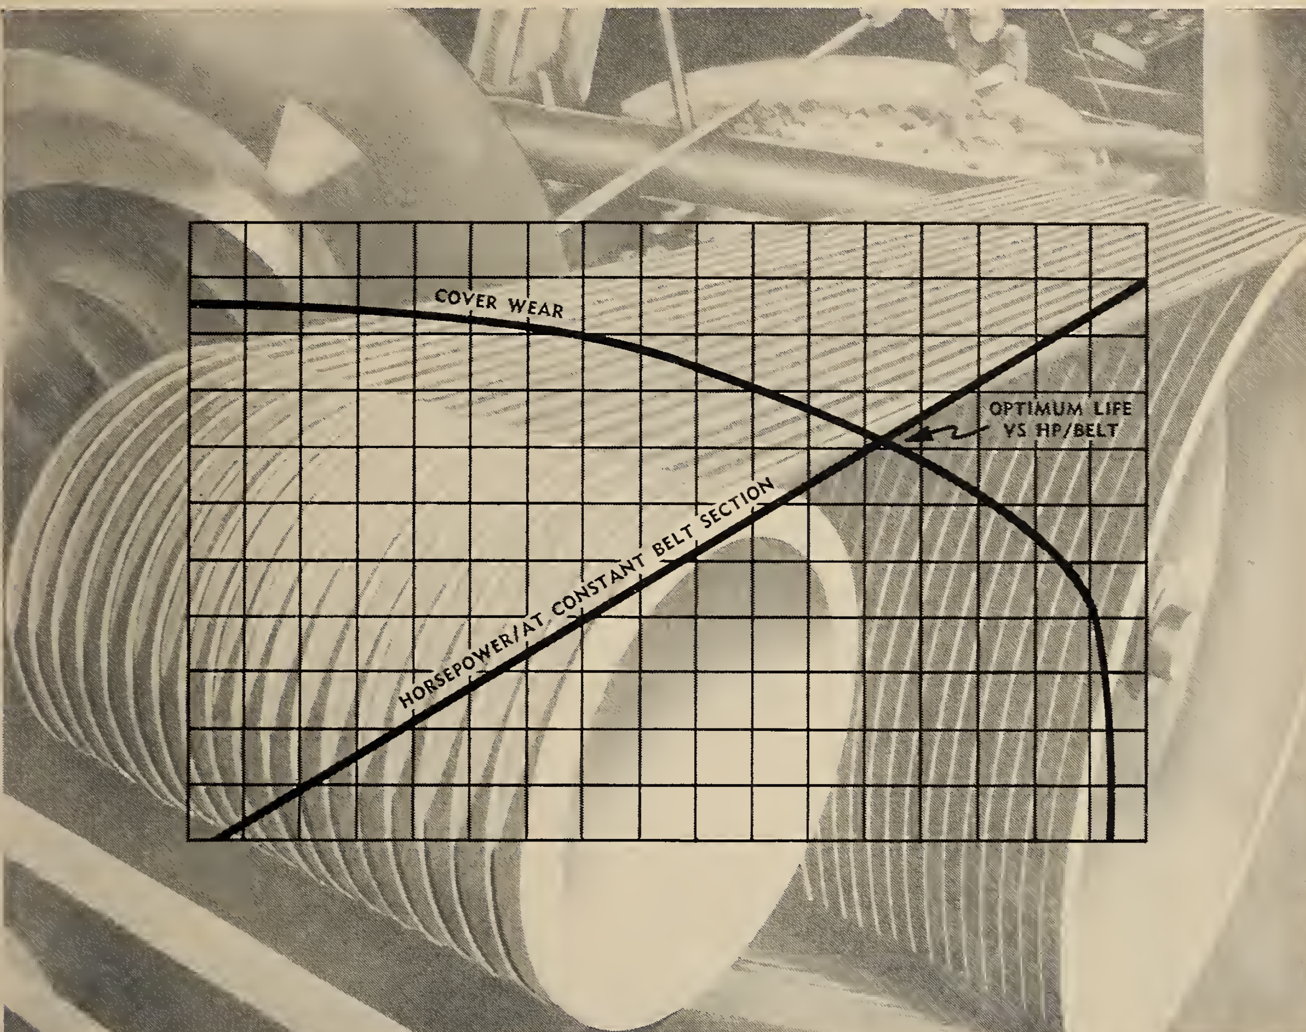
ALLIS-CHALMERS



Texrope drives are engineered to L-A-S-T

to cope adequately with this critical wear/h.p. factor

This chart illustrates something you know very well: the more horsepower you expect each individual belt to deliver, the greater the wear on the cover. You *can* increase transmitted power by tightening the belt . . . but this *accelerates* wear. It makes more sense to cope with more power the TEXROPE way—by seeing that each drive is equipped with tough, standard belts, engineered in each case to give optimum efficiency.

Think about this chart the next time you buy drives, and select for low maintenance. Remember, repeated belt replacements can cost more than the original drive. TEXROPE V-belts are engineered for strength. In good supply at CA-C distributors across Canada or write CA-C, Box 37, Montreal.

60TR-2

The TEXROPE Grommet Belt was developed as a result of cooperative research of Allis-Chalmers and a leading rubber company. It represents the only basic advance in V-belt design in years. For the complete story ask for Bulletin CAC6046A.

Correspondent

Mr. R. J. B. McNally, plant engineer with the North-West Nitro Chemical Plant, Medicine Hat, Alta., gave a talk to Lethbridge members on construction and operation of the nitro-chemical plant on January 16. The plant, completed in 1956, produces primarily the chemical fertilizers ammonium phosphate and ammonium nitrate. It uses about 400 tons of phosphate rock (obtained from Montana) per day, about 135 tons of sulphur (Pincer Creek, Alta.), and approximately 12 million cubic feet of gas from the Medicine Hat area of Alberta. Air and water also go into the fertilizer production, and the water is brought from the South Saskatchewan River by 16-in. line directly to the company's own water treatment plant.

Dr. Arthur Kantrowitz, director, Avco-Everett Research Labs, Boston, reviewed the field of space flight using unmanned equipment and discussed the challenges which this expanding field offers the different branches of engineering at a meeting of the Toronto Branch January 14.

Reports were received from the Electrical and Power Sections of the branch and the Joint Area Committee (Civil). The meeting was turned over to the 1960 chairman, Mr. A. M. Toye. Dr. R. R. McLaughlin, dean of the University of Toronto's engineering faculty, is the new branch vice-president.

The Toronto Branch Student Activities Committee, chaired by Mr. Les Hutchinson, recently arranged a tour of the Ford Motor Company of Canada, which was attended by 115 students. Host for the tour was Mr. Jim Ronson, manager of Ford's Oakville Operations. Following the tour there was a film on the Dearborn Research Center and a question-and-answer session.

The Joint Area Committee (Civil) held an extremely interesting panel discussion entitled "Economy or Good Construction" on January 21. Moderator of the panel was Professor E. A. Allcut and members included Mr. Harry B. Kohl, architect, and Messrs. Harvey Self, C. D. Carruthers, and C. E. Potter, all engineers, but respectively representing the viewpoints of owner, consultant and contractor.

On January 27, sixty members of the Power Section heard a paper by H. A. Smith, assistant general manager, Engineering, H.E.P.C. of Ont., and W. F. Allen, Jr., mechanical engineer, Stone and Webster Canada, entitled "Concept and Salient Design Features of Two Modern Thermal Power Stations". The two stations discussed were the R. L. Hearn Generating Station Extension and the Lakeview Generating Station.

Vancouver

C. H. White, S.E.I.C.,
Correspondent

The Vancouver Branch of E.I.C. has published its Professional Development Program for 1960, following the theme "Beyond the Engineering Horizon—the Arts". The sessions include: "The Utopias", Feb. 3; "Greek Archeology", Feb. 10; "What do we know about Shakespeare?", Feb. 17; "Music—A Reflection of the Times", Feb. 24; "Philosophy", March 2; "B.C.—The Writing of its History", March 9; "Geometry Yesterday and Today", March 16; and "Russian Culture", March 23.

Vancouver Island

W. N. Tivy, M.E.I.C.,
Correspondent

Mr. R. R. McLeod, senior petroleum engineer, petroleum and natural gas branch of the Department of Mines, B.C., was the guest speaker at the January 20 meeting. His subject: "Oil and Gas Development in B.C.". Mr. McLeod dealt with the geography and general history of the development of the northeastern portion of the province.

On January 23 members visited the Victoria Machinery Depot to inspect the new B.C. government ferry, M. U. Sidney. The ferry will commence operation between Sidney (about 18 miles north of Victoria) and a point south of Deas Island Tunnel on the mainland this year.

Brig. A. B. Connelly, C.B.E., C.D., chief of the engineering division, Northern Administration Branch, Department of Northern Affairs and Natural Resources, addresed the membership on January 28 on the subject of "Northern Construction". Brigadier Connelly discussed various unique aspects of construction in the Far North and dealt with roads, bridges, airstrips, docks, reservoirs, water supply, sewerage, power houses, utility ducts, but put main emphasis on buildings and foundations and permafrost problems. The talk was supplemented by 150 colour slides. The speaker was introduced by Lt. Col. H. D. Berry, Command Engineer, Prairie Command, and thanked by Prof. W. F. Riddell of the University of Manitoba.

This was the Annual Meeting of the branch and the slate of officers was announced: chairman, W. L. Wardrop; vice-chairman, R. E. Chant; members of the executive, J. B. Striowski, C. S. Landon, L. A. Bateman, D. Chappell, and T. E. Weber; councillors, S. Barkwell, N. M. Hall; E.I.C. nominating committee, W. D. Hurst; general papers chairman, G. C. Marsh; E.I.C. university representative, J. P. C. McMath; membership chairman, L. E. Poyser; electrical section representative, A. S. Williams; civil section representative, I. B. Henderson; student section representative, D. N. Brown; branch reporter, P. M. Abel; vice president, zone A, C. V. Antenbring.

Montreal

(Junior Section)

R. D. Hatfield, S.E.I.C.,
Correspondent

On February 5, the Montreal Branch sponsored its annual students' night involving all four of Quebec's major engineering schools, Laval, Sherbrooke, Ecole Polytechnique and McGill. The meeting was chaired by Mr. Roger Miller, of Ecole Polytechnique, and organized by Mr. R. D. Hatfield, of McGill. The four contestants were Mr. K. Skooner, "Rolling Lift Bridges", first prize, $50; Mr. R. Lalancette, Ecole Polytechnique, "Ice Formation", second prize, $35; Mr. M. Gagnon, Sherbroke, "Tidal Generating Stations", third, $20; and Mr. G. Desrosiers, Laval, "Hydraulics", fourth, $10.

Two of the papers were in French; the other two, in English. Judges were Mr. Gantsheff, Ecole Polytechnique; Mr. Philips, past chairman, Montreal Branch; Mr. Barcelon, C.P.E.Q., and Mr. Kane, Dominion Bridge.

Mr. Hance Legere, director of technical services for E.I.C., addressed the meeting after the judging.

Kootenay

I. Waterlow, JR.E.I.C.,
Correspondent

"Trends in Fertilizer and Chemical Industries" was the subject of a talk given by Mr. E. A. Colls, manager, fertilizer division, Cominco, to the Kootenay Branch on January 18. Mr. Colls indicated that the fertilizer and heavy chemical industry had grown in relation to population growth and discussed the changes in types of fertilizers required.

Sarnia

Paul Donato, M.E.I.C.,
Correspondent

Mr. V. J. Bakanowski, principal project engineer, and Mr. R. N. Boyd, supervising engineer, both of Dupont of Canada, Montreal, gave a joint talk, "Technical Uses of Computers in the Chemical Industry", at the January 20 meeting.

Dr. H. F. Waldron of the Defence Research Board was guest speaker on February 23 on the subject of missiles.

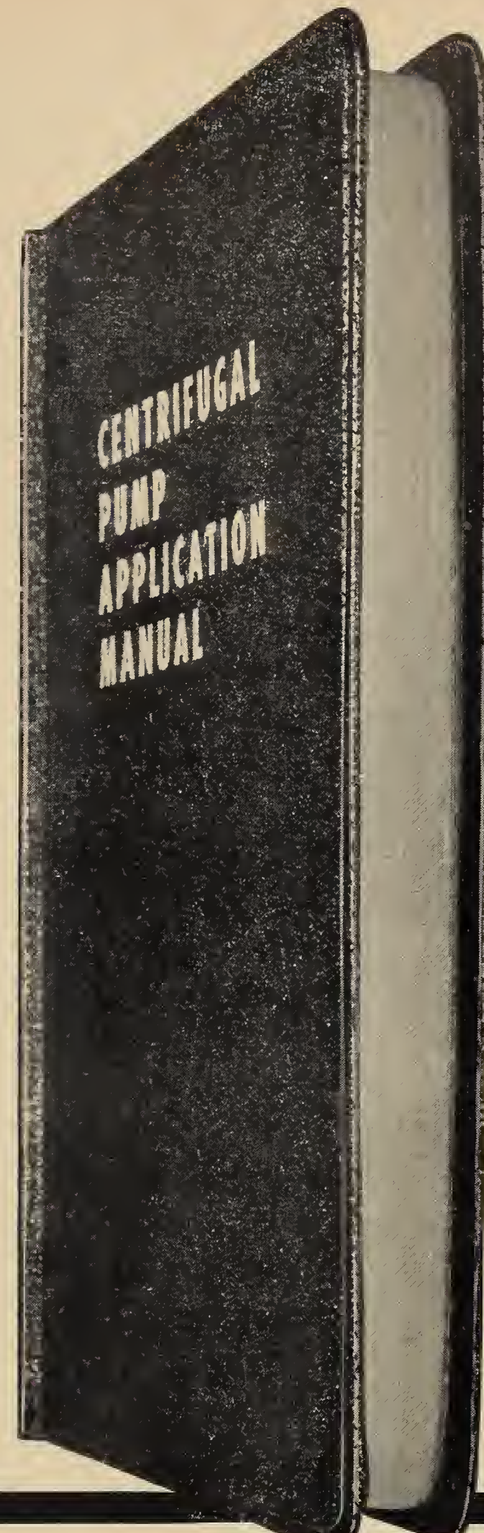
CENTRIFUGAL PUMP APPLICATION MANUAL

by CANADA PUMPS ENGINEERS



A "MUST" FOR EVERY PUMP ENGINEER

Here in concise useable form are complete facts on centrifugal pumps and their application. Quick, ready reference is provided by subject sections tabulated at the front. A wealth of illustrations and diagrams amplifies the subject matter.

The purpose of this Engineers' Handbook is to cover the various uses of Centrifugal Pumps, the different types designed to meet specific needs, their operation and the solution of pump problems. Also included are general data and Standards of the Hydraulic Institute.

The pocket-size Manual contains 277 pages of fact-filled information of vital importance to every user of pumps. It will prove an invaluable tool and reference to every Pump Engineer.

Use Handy Coupon to Order Your Personal Copy Now!

There's a BUFFALO Centrifugal Pump for Your Job!

- Single- and multi-stage pumps for general and special industrial service.
- Wide range of pump designs, sizes, materials and capacities.
- Special pumps for moving paper stocks, corrosive and high temperature liquids and slurries.

You can rely on your nearby Buffalo Representative for expert help. Remember, he helped write the "book".

NEWS OF THE

Associations and Corporation

C.P.E.Q. President Says Young Engineers Must Specialize in New Branches

The field for engineers in Canada will be wide open at least to the end of this century, W. J. Riley, M.E.I.C., president of the Corporation of Professional Engineers of Quebec, stated at a press conference in Montreal February 17. The exodus of Canadian engineers to the U.S.A., he pointed out, suggests only that these young engineers have not specialized adequately to find employment in the newer, and increasingly important, fields of engineering. The approximate $1000 difference in salary, he stated, is a constant discrepancy in engineering salaries regardless of position, so that the senior engineer is not greatly tempted by financial benefits to emigrate.

Increased university enrolments do not mean that employment in Canada will be more difficult to find, stated the president. It only means that students will have to think early about what industry is demanding and specialize accordingly. Electronics, electro-mechanics, and nuclear engineering are the fields which Mr. Riley sees as the key fields to engineering's future expansion.

Mr. Riley also stressed the importance of the engineer's professional status. As the great majority of engineers become employee-engineers it is necessary for them to establish their professional status so that, in a business, they are treated in the same light as the company doctor or company lawyer.

B.C. Association Holds Annual Honours and Awards Luncheon

The Association's annual Honours and Awards Luncheon honoured five Life Members of the Association: A. E. Carter, Sutton, Quebec; W. C. Douglass, Seattle, Washington; Stanley Gary, Vancouver; H. K. Qually, New Westminster; and J. Sinclair, Vancouver. At the same time Retiring President R. E. Wilkins, M.E.I.C., announced the winners of special awards.

The Letson Memorial Prize for the best report or thesis on mechanical engineering submitted in support of an application for registration was awarded to Paul Koeller. K. Teng and H. Arndt, both students in the Faculty of Applied Science, University of B.C., won this year's Ingledow Prizes.

A.P.E.O. Makes Secondary School Science Teaching Award

Harold L. Eubank, vice-principal of Etobicoke Collegiate Institute in Metro Toronto has been chosen Ontario's outstanding mathematics and science teacher of the year by the Association of Professional Engineers of Ontario.

The award, established last year, recognizes the contribution made to the engineering profession by the secondary school teacher in mathematics and science. The Ontario Secondary School Teachers Federation is responsible for the selection of the award winner.

Mr. Eubank is a former president of the Science Teachers Association of Ontario and is co-author of two school text books, *Basic Physics for Secondary Schools* (used in Grade 11 of the Ontario schools) and *Physics for Secondary Schools* (authorized for use in Alberta).

A.P.E.O.'s Retiring President Predicts Bright Decade for Engineering

In his address to over 1,000 professional engineers attending the recent annual meeting of the Association of Professional Engineers of Ontario A. W. F. McQueen, retiring president of the association, stated that there was every reason to expect a greater pattern of technological progress during the 1960's.

Calling upon the engineering profession to prepare itself to meet the future's "grave responsibilities", Mr. McQueen referred to a statement made recently by Dean J. W. Hodgins of McMaster University, Hamilton, that "whether we like it or not, many of the decisions which most affect our lives in the next decades are likely to be made by scientists or engineers". Mr. McQueen also pointed to the co-operation being offered by the Association to the universities in advancing engineering education.

"In this matter of engineering education, the universities and the Association need each other's help," he said, adding that he believed this was the A.E.P.O.'s biggest task. He noted that 115 engineers had participated in the new correspondence courses instituted last year by the University of Toronto for registered professional engineers. These courses included English Composition, English Literature, Economics and Business Organization. Next year more subjects are to be added to the correspondence course program.

The retiring president called upon the membership of A.P.E.O. to support the recently established Professional Engineers' Foundation for Education which provides direct financial assistance for both undergraduate and graduate students in engineering.

Manitoba Association Elects Officers

W. L. Wardrop was re-elected president of the Association of Professional Engineers of Manitoba at their Annual General Meeting, January 23, in Winnipeg. Prof. R. E. Chant was elected vice-president; Dr. C. S. Landon, secretary and registrar. Others elected to the Council of the Association are Prof. O. Marantz, B. Chappekk, and T. E. Weber.

Closer Co-operation for Engineers and Architects

Senior officers of the Royal Architectural Institute of Canada and the Canadian Council of Professional Engineers met in Ottawa recently to study ways and means of improving the quality and efficiency of architectural and engineering services through closer cooperation between the two professions.

It was agreed to establish a joint committee of both bodies at the national level to: develop better understanding between members of the two professions; assist in maintaining and developing proper relations between Architects and Engineers in the best interest of the public they serve; to provide a means of co-operation on problems which are of interest to both groups and national in scope.

LIBRARY NOTES

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

BASIC AUDIO

Another of Rider's easily understood "picture book" courses, requiring only a basic knowledge of electricity for its comprehension. It explains the part played by each component in an audio system, and the electronics and circuit theory needed to assemble or operate a hi-fi or audio reproducing system.

The topics covered include: sound and acoustics; microphones; loudspeakers; impedance matching; resonance; audio response curves; transistors; frequency response; phase-splitting circuits; feedback; power supply; shielding; etc. (N. H. Crowhurst. New York, Rider, 1959. 3 vols. $2.90 each. $8.70 set.)

SURFACE DEFECTS IN INGOTS AND THEIR PRODUCTS, 2nd. ed.

Recommended definitions for defects occurring in ingots and certain semi-finished and finished products, compiled in an attempt to standardize the terms used. The definitions, which are clearly illustrated, are divided into three sections: surface defects in the ingot; defects in finished products arising from ingot defects; processing defects. (Ingot Surface Defects Sub-Committee of the British Iron and Steel Assoc. London, Iron and Steel Institute, 1958. 58 p., 25/-.)

*HANDBOOK OF INDUSTRIAL RESEARCH MANAGEMENT

This volume provides a guide for the organization, evaluation, and control of industrial research. For those in top management the book can be a yardstick and a guide to controlling and evaluating this costly operation; for directors of research, administrative problems are dealt with; for their executive directors, the day-to-day details and responsibilities are presented; and for financial executives there are papers on accounting and budget control of the research function. The final chapter discusses government contracts. (Ed. by Carl Heyel. New York, Reinhold, 1959. 513 p., $12.00)

*SPACE TECHNOLOGY

A thorough exposition is given of the fundamental physical principles of very long-range ballistic vehicles, stressing the quantitative relations that are most useful for space flight. In addition to a particularly thorough discussion of ballistics and flight dynamics, coverage is given to propulsion, communications and guidance, man in space, and the scientific uses of space. The five hundred selected references given provide a guide to the significant literature in this field. (Ed. by H. S. Seifert. New York, Wiley, 1959. Various pagings. $22.50.)

*NUCLEAR FUEL ELEMENTS

Papers presented by U.S. and European scientists at the First International Symposium on Nuclear Fuel Elements (January 1959) form the basic part of this book on the development, design and fabrication of nuclear fuel elements. Topics covered include element standardisation and fabrication cost-analysis, as well as the physical and operational characteristics of elements. Appendices offer typical specifications and an extensive bibliography. (Ed. by H. H. Hausner and J. F. Schumar. New York, Reinhold, 1959. 409 p., $12.50)

*FOUNDRY ENGINEERING

A comprehensive approach to the engineering principles and methods of foundry operation is presented. Up-to-date coverage is given for such topics as refractories, casting processes, sand reclamation and control, welding, and heat treatment. A feature of the book is the treatment of solidification and structure of cast metals, and of correct gating and risering of castings. Numerous three dimensional drawings help to clarify the text. (H. F. Taylor, and others. New York, Wiley, 1959. 407 p., $9.75.)

*CHEMICAL PROCESS PRINCIPLES: PART II, THERMODYNAMICS, 2nd. ed.

The fundamental principles of thermodynamics are presented with particular attention to generalized methods. In this volume the material contained has been revised to reflect recent technological advances dealing with such aspects as improved generalized tables of state and thermodynamic properties, thermodynamics of fluid flow including the cases of compressible fluids at sub- and supersonic velocities, detailed cycle analysis of modern vapor turbine power units, and cycle analyses of modern internal combustion engines including free-piston gas turbines, turbojet, ramjet, and rocket engines. (O. A. Hougen and others. New York, Wiley, 1959. 1072 p., $9.75.)

*HANDBOOK OF AUTOMATION, COMPUTATION, AND CONTROL, VOLUME 2

The second of three volumes, this volume provides a comprehensive coverage of the design and use of analog and digital computers and data processors. Some of the features of this handbook are chapters which deal with computer terminology, magnetic core and transistor circuits, advanced programming, and unusual computer systems involving operational digital techniques, combined analog-digital computer systems, and turing type computers. (Ed. by Eugene M. Grabbe and others. New York, Wiley, 1959. Various pagings. $17.50.)

*NOMOGRAPHY, 2nd. ed.

A text that provides a working knowledge of the basic theory and construction of charts involving straight line scales, curved scales, and combinations of the two. In this edition new chapters are presented on circular nomograms, projective transformations, and the relationship between concurrency and alignment nomograms. In addition there is a considerable expansion of the material included in the previous edition and a number of new problems and examples are introduced. An appendix includes 58 nomograms from various scientific fields. (A. S. Levens. New York, Wiley, 1959. 296 p., $8.50.)

*SYMPOSIUM ON PARTICLE SIZE MEASUREMENT

Representing current thinking in the field of particle size measurement, many aspects of this type of measurement are discussed, including sieves, mechanical methods of separation, electronic methods of measuring, and photo-electric procedures. (Philadelphia, American Society for Testing Materials, 1959. 310 p., $6.25 S.T.P. 234.)

*CALCUL A LA RUPTURE ET PLASTICITE DES CONSTRUCTIONS

This translation from the Russian deals with the calculation of the breaking points of structures based on the theory of plasticity. The elastic limits of both statically determinate and indeterminate structures are defined, as are the laws of linear and non-linear deformation under different types of stress. Essential theory is given for calculating the plastic limits of beams, plates, etc.; and the book concludes with the general principles for determining tolerances and safety coefficients in construction work. (A. R. Rjanitsyn. Paris, Eyrolles, 1959. 284 p., 4400 fr.)

*AMENAGEMENTS HYDROELECTRIQUES

Following a discussion of hydroelectric equipment within its historical and geographical framework, the author examines the fundamental principles of hydroelectric structures, the various types of dams, related structures (spillways, gates, conduits, intakes), and turbines and pumps. An appendix discusses the use of scale models in the determination of experimental values and the factors that influence the magnitude of these values. (R. Ginocchio. Paris, Eyrolles, 1959. 480 p., 3500 fr.)

*BARRAGES MOBILES ET PRISES D'EAU EN RIVIERES

A study of movable dams and water-intake systems in rivers, covering such aspects as rate of water flow, water level, drift of alluvial deposits, and flow through sluices. The construction of sluice gates, coffer dams, water- tapping devices, and sand and gravel filtering equipment is also discussed. (M. Bouvard. Paris, Eyrolles, 1958. 238 p., 2600 fr.)

*THE CATHODE-RAY TUBE AND ITS APPLICATIONS, 3rd. ed.

The use of the cathode ray tube in oscillography is stressed in this volume which provides a guide to the operation and use of the tube as a versatile measuring instrument. Among the topics considered are power supplies, amplifiers, time and frequency bases, photographic recording, and transducers. Also considered are mechanical, electrical, and nuclear applications. While the sections dealing with applications and associated circuits have been considerably expanded in this edition, only a superficial coverage is given to the theory and design of the electron gun. (G. Parr and O. H. Davie. Toronto, Ryerson, 1959. 433 p., $10.00.)

*THERMODYNAMIC AND TRANSPORT PROPERTIES OF GASES, LIQUIDS, AND SOLIDS

In addition to reviewing and evaluating the subject as a whole, the forty-two papers included report a large amount of new data as well as recent techniques. The papers discuss transport properties from the standpoint of theory and experiment, the thermodynamic properties of liquids and gases, PVT data and equation of state, thermodynamic properties of boron compounds, high temperature transport properties of metals and ceramics, and high temperature thermodynamic properties of gases. These papers were presented at the Symposium on Thermal Properties held in February 1959. (New York, American Society of Mechanical Engineers, 1959. 472 p., $12.50.)

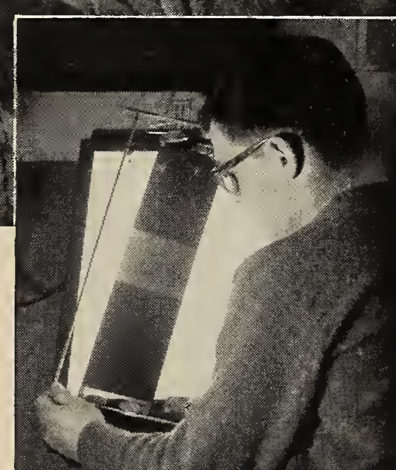
*SEMICONDUCTORS

A comprehensive account of the physics of semi-conductors is given along with a brief review of their applications. The author discusses energy levels in crystalline solids; impurities and imperfections in crystals; carrier concentrations in thermal equilibrium; electron transport phenomena; thermal, optical, and high-frequency effects in semi-conductors; diffusion of electrons and positive holes; measurement of semiconductor properties; and the properties of the various types of semiconductors known. The treatment is based on the "effective mass" concept, and only a brief and elementary account is given of the quantum theory underlying the motion of electrons through a crystal. (R. A. Smith. Toronto, Macmillan, 1959. 494 p., $11.25.)

*EXTRACTIVE METALLURGY

Essentially a revision and enlargement of the second part of the author's "Introduction to Metallurgy", this volume surveys the entire field of extractive metallurgy. As a means of emphasizing the basic principles of the subject, the unit process method is used rather than a presentation of the subject on a metal-by-metal basis. In addition to the material normally covered in such a text,

X
X



(Continued from page 142)

topics from physical metallurgy have been included, such as metal crystals, equilibrium diagrams, and Gibbs' phase rule. (Joseph Newton. New York, Wiley, 1959. 532 p., $9.75.)

*APPLIED SOLAR ENERGY RESEARCH, 2nd. ed.

The work of laboratories and of individuals engaged in solar energy research is described, and a bibliographical survey is made of the field. Arrangement of the bibliography is by broad subject divisions which include such aspects as solar radiation and its effects, and the use of solar energy as heat-low temperature conversion, as heat-high temperature conversion, and as light. (Phoenix, Association for Applied Solar Energy Research, 1959. 275 p., $7.50.)

METAL FATIGUE

A symposium of lectures presented at a week-long course at Nottingham University, designed to present to practising engineering designers the known facts about metal fatigue and its effects on design. Each chapter, or lecture, is by an expert in the field, and the volume is divided into three sections. The first of these deals with the fundamentals of fatigue, including the theory of fatigue failure, stress concentration factors, residual stesses, corrosion fatigue, temperature effect.

The second section is concerned with the fatigue properties of engineering materials and components, including high-temperature alloys, aluminum alloys, cast iron, brass, aircraft, joints and welds. The last section discusses the fatigue testing of engineering components, including bearings, welded structures, and aircraft structures, and the reproducibility of results in fatigue testing. References for further reading are included. (Ed. by J. A. Pope. Toronto, Ryerson, 1959. 381 p., $12.50.)

*EXAMPLES OF THE DESIGN OF REINFORCED CONCRETE BUILDINGS

In the first section of the book the author gives design calculations of bending-moment factors and structural parts, based on British Standard Codes and data for design. The second part deals with details in the design of a typical multiple-story building which has been planned to incorporate as many of the matters treated in the code as is practicable. New material includes revised bending-moment factors; the load-factor method applied to the design of structural parts subject to bending; concentrated loads on slabs spinning in one or two directions, and flat-slab floors as parts of a frame. (C. E. Reynolds, London, Concrete Publications, 1959. 265 p. $3.00.)

*RADIO STATIONS: INSTALLATION, DESIGN AND PRACTICE

A highly practical approach to the subject for the planning or station design engineer and the field installation technician. Based on up-to-date practice, each aspect is discussed, ranging from general planning, site selection, and ground systems to detailed station layouts, equipment rooms, message distribution systems and wiring systems. Although largely devoted to small station design, much of the material included is also applicable to large stations. (G. A. Chappel. New York, Pergamon, 1959. 248 p., $7.50.)

*NATURE AND PROPERTIES OF ENGINEERING MATERIALS

Here is information on basic materials for specific engineering applications. A consideration of the basic concepts of interatomic and intermolecular forces and their relationship to the structural characteristics of crystalline and amorphous materials forms the basis of the discussion of the phenomena of diffusion, crystallization, phase transformation and phase equilibria. Then follows a more specific development of the characteristic physical properties of metals and ceramics, electrical and magnetic properties of materials, corrosion, friction and lubrication, concrete, and protective coatings. (Z. D. Jastrzebski. New York, Wiley, 1959. 571 p., $11.00.)

*FOUNDATIONS OF AERODYNAMICS, 2nd. ed.

The fundamentals of perfect, compressible, and viscous flows is presented. In general, specific technical applications are not treated except as illustrations of the underlying principles. In this edition, the chapter on energy relations has been rewritten, and the treatment of one-dimensional compressible flows has now been expanded to include sections on heat addition. The material on wings in compressible flow is now presented from the viewpoint of lifting surface theory, while the material on viscous flow includes an expanded discussion of compressibility in both laminar and turbulent flow. (A. M. Kuethe and J. D. Schetzer. New York, Wiley, 1959. 446 p., $11.75.)

*MIDWESTERN CONFERENCE ON SOLID MECHANICS, PROCEEDINGS, 1959

Papers in this volume indicate the directions of analytical research and fundamental experiments in the field of solid mechanics. General areas covered include shell theory and shell deformation, buckling, thermal stresses, wave mechanics, vibration, and strain. The twenty-nine papers included range from basic topics such as the impact of cylinders of different areas and the collapse load of a spherical cap to specialized treatments of spin dynamics of a thrusting rocket in a vacuum and bending waves in free-free beams. (Austin, University of Texas, 1959. 530 p., $12.50.)

*MIDWESTERN CONFERENCE ON FLUID MECHANICS, PROCEEDINGS, 1959

Aerodynamics, heat transfer, characteristics of hypersonic and tangent flow, shock waves, boundary layer conditions, lubrication, and wave motions are the general areas covered by the thirty papers in this volume. Specifically, papers deal with such topics as secondary flow in straight open channels, theoretical and experimental study of heat transfer magnetic fields, an extended Reynolds analogy, and scale effects in turbulent shock wave boundary layer interactions. (Austin, University of Texas, 1959. 465 p., $12.50.)

*INTERNATIONAL SYMPOSIUM ON PLASTICS TESTING AND STANDARDIZATION

A collection of papers, divided into four sections, dealing with the achievement of national standards. The engineering properties of plastics, the thermal properties of plastics, and molecular characterization. (Philadelphia, American Society for Testing Materials, 1959. 276 p., $6.00 S.t.p. 247.)

(Continued on page 146)

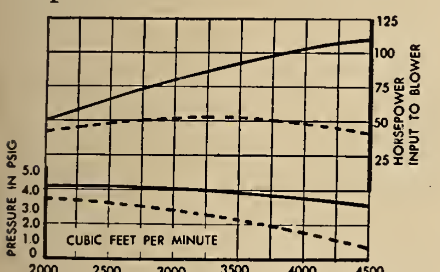
The Use Of Air Offers Great Prospects For Increasing Industry's Productive Capacity

—Thomas Alva Edison

Today, when much is being written on the necessity of reducing overhead, it is significant that custom engineered air equipment is leading the way to increased plant efficiency and lower operating costs. For example, in delivering clean, dry air or gas continuously at constant pressure, Hoffman Multistage Centrifugal Blowers and Exhausters and Hoffman Positive Displacement Cycloblowers are at work handling a wide variety of products. These range from the crating of fragile eggs to the rugged service demands of Pneumatic Conveying.

Efficiency and Adaptability

Hoffman Centrifugal Blowers and Exhausters furnish pressures up to ten pounds per square inch or vacuums up to 12 inches of mercury with volumes to 20,000 cfm. By varying the number of stages and utilizing different types of impellers, various ratings and operating characteristics can be obtained. Centrifugal Units are furnished with radial or backward curved impellers or combinations of these types to satisfy individual process requirements. The performance characteristics of these impellers are illustrated in Graph "A".

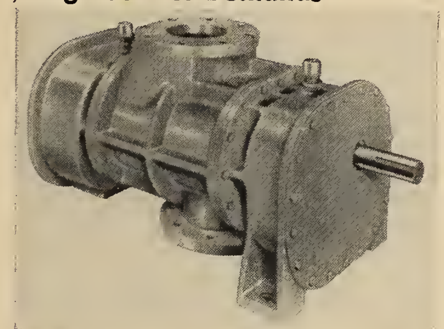


Graph A

The radial impeller has a relatively flat pressure characteristic throughout its volume range. A backward curved impeller differs from the radial impeller in that it falls off in pressure as volume increases. The graph shows that the horsepower requirement of the backward curved impeller reaches a maximum and then falls off to provide a non-overloading characteristic. Economy of operation is assured since power is consumed only in proportion to the actual air or gas volume handled. The absence of any internal wearing surfaces and the lubrication of bearings in outboard mounted housings makes it impossible to contaminate the air or gas handled.

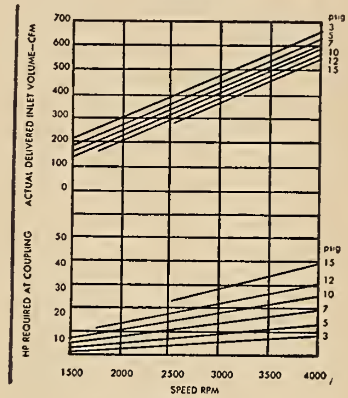
Send for Bulletin AB-104.

Cycloblower Meets Tough Service Demands



Designed for similar tough service demands, the Hoffman Cycloblower is a compact axial flow, Positive Displacement Blower/Exhauster incorporating perfectly symmetrical rotor forms. Interruption of the continuity of rotor seals without sacrifice of the advantages of such forms allows increased water rates for wet compression and vacuum service. Shock, temperature and loading due to build up of pressure is effectively eliminated. The Cycloblower has a normal operating range up to 15 lbs. per square inch and 15 inches of mercury with dry compression. With water injection, vacuums of 22 inches of mercury and pressures of 30 lbs. per square inch can be obtained. Volume capacities range from 80 cfm to 3500 cfm.

A Positive Displacement Unit is a constant volume machine, whereas a Centrifugal is a variable volume machine. In Graph "B" it will be noted that at a constant RPM, the Positive Displacement Blower/Exhauster can deliver pressures from 3 to 15 lbs. If a unit is selected to operate at 500 cfm and 3 psig, it will have to operate at approximately 3050 RPM and require 8 HP. Should changes in the process



Graph B

require more pressure, the Positive Displacement Unit will automatically build up to the required pressure while still maintaining constant volume. It will, of course, require the additional horsepower as indicated in the graph. A pre-set relief valve acts as a built-in safety device. It limits the amount of pressure which can be built up when the requirements of the system exceed the capabilities of the equipment. Lubrication within the compression chamber is unnecessary since the rotors do not touch. The possibility of oil contamination is thus avoided in the same manner as it is in the Hoffman Centrifugal Units.

Send for Bulletin CB-157.

Wide Performance Range

Centrifugal and Positive Displacement Units have an overlapping range of performances. Without cost or obligation Hoffman engineers will recommend the most efficient units for your particular requirement. Whatever your problem, feel free to call on Hoffman's quarter of a century of engineering experience and background to meet your special needs. Send now for these free helpful booklets.

*A.S.T.M. MANUAL FOR RATING DIESEL FUELS BY THE CETANE METHOD

This manual has the two-fold purpose of revising and bringing up to date the ASTM Cetane Method D613, and of serving users of ASTM ignition quality rating engines by providing detailed information and data on the operation and maintenance of the rating equipment. (Philadelphia. American Society for Testing Materials, 1959. 132 p., $8.50.)

TECHNICAL BULLETINS

Airports

Airports for jets, by J. E. Peterson. Chic., American Society of Planning Officials, 1959. $2.50.

Amplifiers

Low-frequency amplifier systems, ed. by A. Schure. N.Y., Rider, 1959. $1.80. R-F amplifiers, ed. by A. Schure. N.Y., Rider, 1959. $2.40.

Annual reports

Annual report of the Board of Regents of the Smithsonian Institution for the year ended June 30, 1958. Wash., U.S. Gov't Printing Off., 1959. $3.75.

CABMA Register

CABMA register of British industrial products for Canada, 1959-1960. London, Iliffe, 1959.

Canada. Dept. of Mines and Technical Surveys

Markets for iron and steel products in western Canada, by T. H. Janes. 1959. 25c. (Mineral Resources Division Bulletin MR33) A survey of the uranium industry in Canada, by J. W. Griffith. 1959. 50c. (Mineral Resources Division Bulletin MR 34.) A survey of the petroleum industry in Canada, 1957 and 1958, by R. A. Simpson and R. L. Borden. 1959. 50c. (Mineral Resources Division Bulletin MR 35.)
Flotation of uranium ores from the Elliot Lake area, Ontario, by W. R. Honeywell. 1959. 25c. (Mines Branch Technical Bulletin TB 2.)
Heavy media separation in aggregate beneficiation, by V. A. Haw. 1959. 25c. (Mines Branch Technical Bulletin TB 5.)
Relationship of various factors to the quality of coked briquets made from mixtures of coking coals and inert material, by E. Swartzman. 1959. 25c (Mines Branch Technical Bulletin TB 6.)
Helicopter operations of the Geological Survey of Canada, by Officers of the Geological Survey of Canada. 1959. 75c. (Geological Survey of Canada Bulletin 54.)

Canada. National Research Council

Flight tests of an experimental helicopter rotor blade electrical de-icer, by J. R. Stallabrass. 1959. (Aeronautical report LR 263.)
A probability analysis of coincident gust and manoeuvre loads in low-flying aircraft, by S. D. Baxter and others. 1959. (Aeronautical report LR 264.)
Comparison of some experimental and theoretical data on damping-in-roll of a delta-wing body configuration at supersonic speeds, by L. T. Conlin and K. J. Orlik-Ruckermann. 1959. (Aeronautical report LR 266.) Half-model measurements of longitudinal force and moment characteristics of AGARD model "B" at subsonic and supersonic speeds, by J. G. Laberge. 1959. (Aeronautical report LR 267.)
The corrosion behaviour of the major architectural and structural metals in Canadian atmospheres; summary of two year results. Ottawa, Associate Committee on Corrosion Research and Prevention, 1959.
An annotated bibliography on laboratory buildings, comp. by A. Brass. 1959. (Bibliography No. 16.)
Direct measurement of power spectra by an analog computer, by T. H. Wonnacott. 1959. (Mechanical engineering report MK-5.)
Combined analog-digital simulation of engineering problems, by F. W. Pruden. 1959. (Mechanical engineering report MK 6.) Requirements for a hybrid analog-digital computer, by D. C. Baxter and J. H. Milsum. 1959. (Mechanical engineering report MK 7.) Recent failures point out importance of snow loads on roofs, by H. J. Thornton and W. R. Schriever. (Reprinted from National Builder, vol. 8, no. 5, May 1959, p. 18.) 10c. What frost action did to a cold storage plant, by J. J. Hamilton and others. (Reprinted from the ASHRAE Journal, vol. 1, no. 4, April 1959, p. 54-58.) 10c.
Insulation in northern building, by R. E. Platts. 1959. (Div. of Bldg. Res. Technical paper no. 75.) 25c.
The compacted snow road. 11. Climatic considerations, by B. H:son Ager and tr. by D. A. Sinclair. 1959. (Technical translation 816.)
Snow as road-building material, by K. Putkisto and tr. by E. Perem. 1959. (Technical translation 822.)

Electron tubes

Phototubes, ed. by A. Schure. N.Y., Rider, 1959. $1.80.

Highway engineering

Concrete pavement: subbase and joint construction. Wash., Highway Research Bd., 1959. (Bulletin 229.) $1.00.
Highways and economic development. Wash., Highway Research Bd., 1959. (Bulletin 227.) $1.60.
Highway pavement design in frost areas, a symposium: part 1: Basic considerations. Wash., Highway Research Bd., 1959. (Bulletin 225.) $2.60.

Isotopes. Radioactive

Use of radioactive isotopes for measurement of cutting tool wear, by G. Engstrand. Stockholm, Royal Institute of Technology, 1959. (Transactions 143.)

Mathematics

Algebraic theories, by L. E. Dickson. N.Y., Dover, 1926. $1.85. (Reprint).
An elementary treatise on Fourier's series and spherical, cylindrical, and ellipsoidal harmonics, with applications to problems in mathematical physics, by W. E. Byerly. N.Y., Dover, 1893. $1.95. (Reprint).
The theory of numbers and diophantine analysis, by R. D. Carmichael. N.Y., Dover, 1914. $1.50. (Reprint).
A treatise on algebraic plane curves, by J. L. Coolidge. N.Y., Dover, 1959. $2.70. (Reprint).

Photogrammetry

Photogrammetry: developments and applications, 1959. Wash., Highway Research Bd., 1959. (Bulletin 228.) $1.20.

Tobermorite

The surface energy of tobermorite, by S. Brunauer, D. L. Kantro and C. H. Weise. Skokie, Ill., Portland Cement Association, Research and Development Labs., 1959. (Bulletin 105.)

Wage payment plans

A guide to systematic wage and salary administration, by R. D. Gray. Pasadena, Calif., Calif. Institute of Technology, Industrial Relations Section, 1959. (Bulletin 29.) $1.00.

Water analysis. Copper.

Copper in domestic water systems (a review), by J. Ungar. Ottawa, Dept. of Mines and Technical Surveys, Mines Branch, 1959. (Information circular 107.) 25c.

Water supply. Cold climates.

Water supply and sewage disposal in permafrost areas of Northern Canada, by H. B. Dickens. (The polar record, vol. 9, no. 62, May 1959, p. 421-32.)

Education

Education of the academically talented; summary of a discussion by the Trustees of the Carnegie Foundation for the Advancement of Teaching. (Reprinted from the 1958-1959 annual report.)
A survey of the practical training for students at the German technical universities, comp. by H. Winter and H. Hirrich. Brunswick, Germany, Technical University, 1958.

Electrical engineering

Basic electronics, by Van Valkenburgh, Nooger & Neville, Inc. vol. 6. N.Y., Rider, 1959. 136 p. $2.90.
Master receiving-picture tube substitution guide book, by H. A. Middleton. N.Y., Rider, 1959. $7.45.
Principles of transistor circuits; introduction to the design of amplifiers, receivers and other circuits, by S. W. Amos. N.Y., Rider, 1959. $3.90.
R-L-C components handbook, by D. Mark. N.Y., Rider, 1959. $3.50.
Repartition du potentiel et du courant dans les electrolytes, by R. H. Rousselot. Paris, Dunod, 1959. 980 Fr.

Engineering universities. U.S.A.

Engineering college research review, 1959, ed. by R. Contini and P. T. Bryant. 9th ed. Urbana, Ill., Engineering College Research Council of the American Society for Engineering Education, 1959. $2.00.

(Continued on page 171)

buildings. Applicant must have at least 8 years' experience in these fields and be able to take complete responsibility. Administrative and personal qualities will be considered as well as professional. Excellent salary to start, plus eligibility for profit sharing. Please apply with full particulars to: Izumi Arnott and Sugiyama, Architects and Engineers, 2151 Albert Street, Regina, Saskatchewan. File No. 6959-V.

MECHANICAL ENGINEER required for engineering department of an expanding Maritime Province pulp and paper mill. Applicant should have 2 to 5 years' engineering experience. State age and complete history of experience and education. Reply to File No. 6963-V.

MECHANICAL ENGINEER. Challenging opening for a Mechanical Engineer at a large experimental establishment near Quebec City concerned in part with rocket testing for upper atmosphere investigations. Some past experience in dealing with high pressure fluid or gas systems is desirable. The work involves the experimental ground firing of rocket components together with the design, modification, and calibration of relevant test equipment. The mechanical project engineer will be responsible for test programmes and for a team of test technicians, etc. Ingenuity, imagination and drive are required as nearly all the work is of a novel character and none is routine. File No. 6967-V.

MECHANICAL ENGINEER. Required by a heavy industry in the Eastern Townships, with four to six years' experience in machine design, plant and building lay-out, also a recent graduate Mechanical Engineer for maintenance engineering. Permanent positions with good starting salary. Wide range of employee benefits. Excellent recreational and educational facilities in a modern community. File No. 6968-V.

MISCELLANEOUS

ENGINEERS FOR SALES, project, design, research, development, control and management. Graduates of all types and ages required by clients of The Technical Service Council, a non-profit industry, sponsored placement service. Write 2 Homewood Avenue, Toronto 5, Ontario, for an application. There is no charge for work done on your behalf. File No. 6648-V.

TECHNICAL SALES & SERVICE ENGINEER. Recent graduate to manage sales territory. Montreal area marketing petroleum products to industry. File No. 6914-V.

SALES ENGINEER — Excellent opportunity for aggressive graduate, Mechanical or Chemical engineer, 25-35 years of age who is interested in selling engineered equipment to Pulp & Paper Industry. Some experience in Pulp & Paper Industry desirable. Reply in confidence to File No. 6921-V.

SALES ENGINEERS, two recent graduates, Mechanical or Electrical required by progressive manufacturer of ventilating, air conditioning and related engineered products. Some experience preferred, but not essential. Following completion of company training course successful candidates will be assigned to Hamilton and Montreal Branch Sales Offices. Wide range of employee benefits and attractive starting salary. Send complete resume and salary requirements. File No. 6923-V.

UNUSUAL OPPORTUNITIES. Continued growth of nationally known Toronto manufacturer of consumer products has created some very attractive openings for alert, aggressive personnel interested in advancement based on initiative and performance. PRODUCT ENGINEERS. To develop, design, test and specify new products and improvements to existing lines. PROCESS ENGINEERS. To plan and provide efficient mass production processes and equipment. INDUSTRIAL ENGINEERS. To establish methods, time standards, plant layouts, material handling, systems etc. Engineers with 5 years of applicable experience should apply in strict confidence, supplying complete resume of education, experience, present earnings and a recent photograph. File No. 6945-V.

FIRE PROTECTION ENGINEER. Montreal office of well known Canadian firm of Insurance Brokers servicing large industrial clientele requires engineer experienced in fire inspection work and familiar with underwriters' fire protection standards. Good opportunity for the right man. Salary according to experience and ability. Pension plan and insurance benefits. Please apply, giving full particulars, to File No. 6957-V.

ENGINEERING PARTNER. Engineer establishing practice in Northern Ontario desires engineering partner or association with consultant. Financial investment required. File No. 6960-V.

APPLICATIONS for several faculty appointments for July 1, 1960 are now being considered. Applicants with teaching experience in Civil, Electrical and Mechanical Engineering courses at the senior level should write to The Director, School of Engineering, Carleton University, Ottawa, Ontario. File No. 6961-V.

UNIVERSITY OF ALBERTA Invites applications for Academic Appointments in the Faculty of Engineering. **Chemical Engineering.** Assistant Professor — Ph.D. preferably with background in Fluid Mechanics and Reaction Kinetics. **Civil Engineering.** Two Assistant Professors — Ph.D. or M.Sc. with background in Structural Analysis and Design. Assistant Professor — Ph.D. or M.Sc. with background in Strength of Materials and Structural Analysis. Assistant Professor — Ph.D. or M.Sc. with background in Sanitary Engineering. **Electrical Engineering.** Professor — Ph.D. with substantial experience in Teaching and/or Research and with special background in Microwaves or Transistor Circuitry. Appointment to be made June 1, 1960. Assistant Professor — Ph.D. or M.Sc. with background in electronics preferably in Transistor Circuitry or Microwaves. **Mechanical Engineering.** Assistant Professor — Ph.D. or M.Sc. with background in Thermodynamics. Assistant Professor — Ph.D. or M.Sc. with special background in Fluid Mechanics and Heat Transfer. **Petroleum Engineering.** Assistant Professor — Ph.D. or M.Sc. preferably with background and interest in Drilling Methods and Reservoir Engineering. Applications will be considered only from persons having first class academic records and with proven ability, or strong recommendations as to their potential, in Teaching and Research. Some industrial experience is desirable but not essential. Appointees will be expected to participate in both undergraduate and graduate teaching and to initiate and direct graduate research programs. Considerable freedom to engage in consulting work may be expected. Promotion prospects for the right people are excellent. The salary schedule for the 1960-61 academic year is: Assistant Professor — $6,000 to $8,200; Associate Professor — $8,500 to $10,700; Professor — $11,000 minimum. Except where otherwise noted appointments will commence September 1, 1960. Fully documented applications including recent photograph; personal statistics; transcripts of all academic records; resume of teaching, research, and industrial experience; list and reprints of publications, and list of references may be sent to. **Dean, Faculty of Engineering, University of Alberta, Edmonton, Alberta. File No. 6956-V.**

PERSONALS

(Continued from page 118)

Robert T. Bailey, M.E.I.C. (Queen's '48) has become the city engineer of Windsor, Ont.

John G. Frost, M.E.I.C., a partner in the firm of Wiggs, Walford, Frost and Lindsay, consulting engineers, Montreal, was recently elected to the council of the American Institute of Consulting Engineers.

N. S. Trouth, M.E.I.C. (Alberta '49), manager of the Kelwood Corporation, was recently re-elected president of the Urban Development Institute of Alberta. V. S. G. Lewis, M.E.I.C., general manager of land development, Engineered Buildings Limited, is the new vice-president.

Glynne J. Evans, JR.E.I.C. (Alberta '50), formerly of the Texaco Exploration Company, Edmonton, has been elected vice-president and general manager of the Montreal-Hamilton product pipe line of the Trans-Northern Pipe Line Company.

William N. Isberg, JR.E.I.C. (Queen's '55) has been appointed sales engineer for special projects at Bristol Aero-Industries, Winnipeg Division.

W. N. Isberg
JR.E.I.C.

R. C. T. Stewart, M.E.I.C. (McGill '49) has been appointed executive vice-president of Cameron Contracting Limited.

D. K. Teasdale, M.E.I.C. (Nova Scotia Technical '49) has been appointed senior civil and hydraulic engineer of the Nova Scotia Light and Power Company and subsidiary companies.

E. R. Skanes, JR.E.I.C. (Nova Scotia Technical '51) has accepted a position with the Department of Public Works of Newfoundland in St. John's. He was formerly with Bowaters Nfld. Pulp & Paper Mills, Corner Brook.

G. Douglas Zimmerman, M.E.I.C. (Toronto '52) has been elected executive vice-president and director of Canadian Curtiss-Wright Ltd., Montreal. He has also been named managing director of the Canadian operation.

Howard S. Rothman, JR.E.I.C. (McGill '58) has been appointed a director of the Secant Construction Company Montreal.

Business and Industrial Briefs

Appointments and Transfers

KENNETH C. BRUMLEY has been appointed Advertising and Publicity Supervisor of the Plywood Manufacturers Association of British Columbia. The announcement was made in December by Colin J. Hempsall, Advertising and Publicity Manager for PMABC. Mr. Brumley returned recently to the west coast after serving for two years with the public relations division of the Aluminium Limited group of companies.

E.C.C. Canada Limited announce the appointment of **MR. V. SOUTHON**, Assoc. I.E.E., to the position of Chief Inside Sales Engineer and Office Manager of their Toronto Office. Mr. Southon was recently Secretary-Treasurer of Electrical Maintenance and Repairs Co. and was formerly with the Hydro-Electric Power Commission of Ontario and Senior Assistant Commercial Officer with the Eastern Electricity Board in England.

Three key appointments in the management of the Aeronautical Group are announced by A. V. Roe Canada Limited. They are: **KENNETH W. BROWN**, as Vice-President and General Manager of Avro Aircraft Limited; **JOHN L. PLANT**, as Vice-President and General Manager of Canadian Applied Research Limited; and **BURTON A. AVERY** as Vice-President and Assistant General Manager, Orenda Engines Limited. **HARVEY R. SMITH** remains Chairman and President of the three Companies, all of which are located in the Toronto area.

Canadian Westinghouse executive **EDWARD R. NARY** who has been director of the company's headquarters manufacturing department since 1956, retired in December after 45 years service with the Westinghouse organization in Canada, the United States and Europe.

The Lamp Department of Canadian General Electric Company Limited announces the appointment of **KEITH S. WOOD** as Manager — Eastern Sales Region. He has his headquarters in the Company's office at 280 Faillon St. W., Montreal.

Business News

QUICK-MAKE, QUICK-BREAK load interruption is offered by a new switch announced by Canadian Westinghouse. The switch designated "Type LCB" is essentially a design improvement over the previous "LCB" switch and is CSA approved. The device will close without hazard to the operator against a 40,000 ampere fault.

DESILICIZER is a new process now commercially available. Introduced by the Cochrane Corporation, Philadelphia 32, Pa., it reduces Silica and eliminates HCO_3 and CO_3 alkalinity in boiler feedwater. It is claimed to be particularly suitable for medium pressure boilers (450 to 1100 psig) and can be added to existing Zeolite Softener Systems.

THE WORLD'S FIRST airborne gravity gradiometer, a Canadian development, has been unveiled to leading scientists from all over the world. Dr. Hans Lundberg has demonstrated the device to the first international symposium of Arctic geology sponsored by the Alberta Association of Petroleum Geologists. Scientists say the gradiometer will be extremely valuable in the Canadian Arctic. By providing fundamental gravity data revealing geological structure, it will aid in the search for essential oil, gas and minerals. It is also expected to help in determining the true shape of this planet as an aid in navigating nuclear submarines, ICB's, rockets and space ships.

TRANSISTORIZED POCKET RECEIVERS of a new type can now be had for use with the Multitone "Personal Call" Staff Location System. Known as the Series Eight, the receivers are for use in low to medium ambient noise levels and are capable of receiving a spoken message as well as a selective call signal. Improvements include greatly increased impact resistance of the case and increased sensitivity. Weight, complete with mercury batteries, is only 5¾ ounces.

AIR CONDITIONING BY NATURAL GAS is foreshadowed in arrangements recently announced by Robertshaw-Fulton Controls (Canada) Limited. A machine of a new type, called a Free Piston Refrigerant Compressor, will be manufactured and marketed by Robertshaw-Fulton under exclusive license. The piston is called free because there are no mechanical links from it to the use of power. Combustion of gas takes place at one end of the cylinder, and compression of the refrigerant such as freon at the other. From this point cooling action is the same as in the conventional air conditioning unit.

A LIQUID LOCK for metal parts, to prevent costly breakdowns due to loose nuts and bolts, is offered by Loctite Sealant, a product of American Sealants Company, Hartford, Conn. Loctite is a thin liquid plastic that hardens between closely fitting metal parts, forming a tough bond that resists heat and oil.

A CANADIAN AUTOMATIC DATA LOGGER has been ordered by Quebec Hydro for its Charland Substation. Either fully automatic (at stated intervals) or manually started logging is possible with the logger, which prints data on a paper roll together with a code number to indicate the point logged and a time reading in hours, minutes, seconds and thousandths of a second from a 24 hour digital clock. Central Dynamics Ltd., whose manufacturing facility is at Pointe Claire, Quebec, is the first Canadian company to design and completely manufacture this type of equipment in Canada.

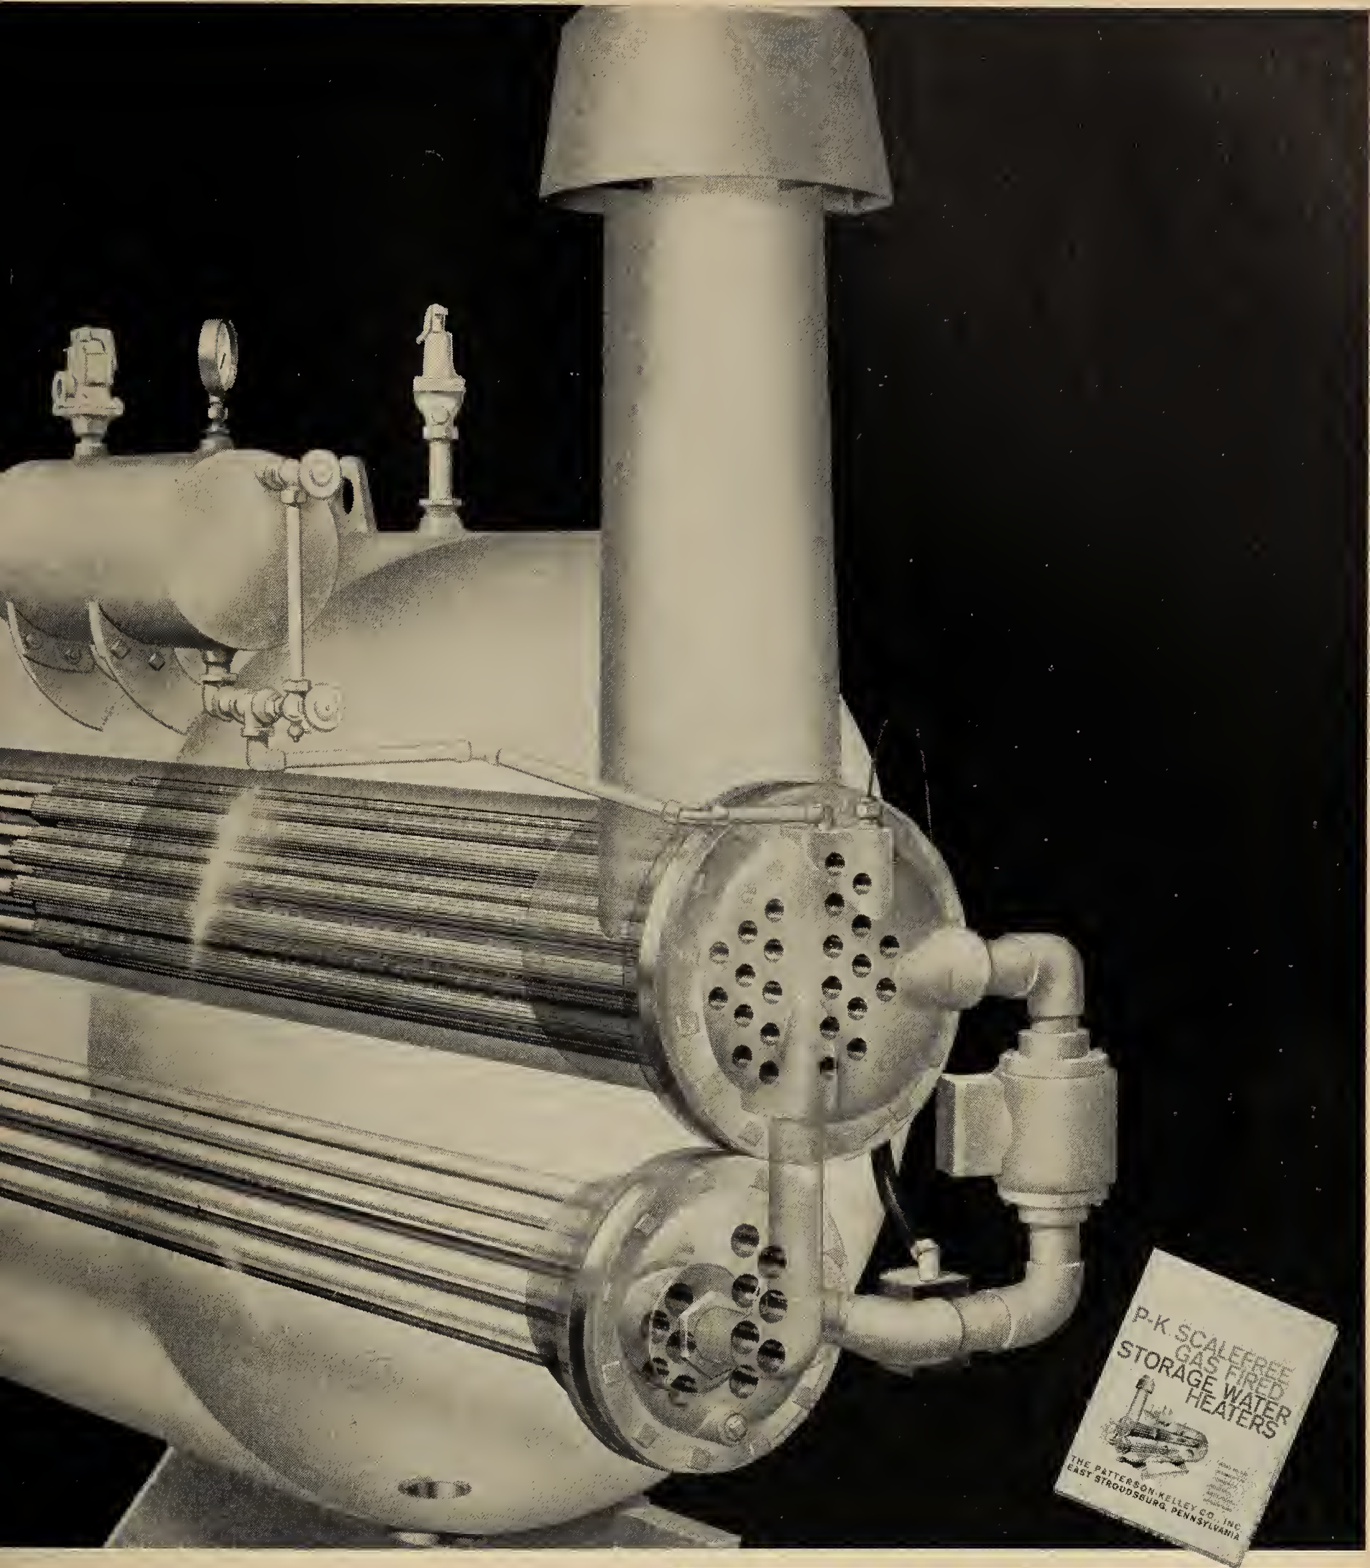
UNION CARBIDE TRADE MARK

"Hastelloy", "Heliarc", "Linde" and "Multimet" are trade marks.



No foundation is necessary. A rugged skid-in type base is supplied. It is easily accessible for inspection. Tube bundles are removable.

SCALEFREE 230 is completely safe. It has a fail-safe chain of built-in protective devices. It is available in more than 100 storage and recovery combinations. Storage capacities range from 250 to 4000 gallons. Recovery sections range from 390,000 to 2,215,000 Btu. Send the coupon for complete information.

*Patent pending

SARCO CANADA LTD.
611 Gerrard St., E. Toronto 8, Ontario

☐ Please send complete technical data on SCALEFREE 230
☐ Please have a P-K Sales Engineer call to discuss design and operational features.

(Continued from page 154)

THROUGH MILES OF TUNNELS, with installation and upkeep costs far lower than for less efficient methods of ventilation, "Fabron" P.V.C. Brattice Cloth provides air proof protection for the miner. England's National Coal Board approved the use of "Fabron" in their mines, but it is suitable for all types of underground mining. "Fabron" does not support combustion and is self extinguishing. Because of its colour, carbon black imparts maximum ageing properties to the material.

THE COMPLETE LINE of Link-Belt car spotters, car pullers and 33 accessories is described in a new 20 page book "Haulage Machines". The book, number 2892, also provides engineering and selection data.

MANGJET, A NEW ELECTRODE, is announced by the Lincoln Electric Company of Canada Limited, Leaside, Ontario. Intended for easier and cheaper welding of 12-14% manganese steels, the new electrode is suitable for building up manganese steel hard surfacing deposits on either manganese or carbon steels, and also for making sound joints between two manganese steel parts or between manganese and carbon steel parts. Mangjet is a low hydrogen, iron powder electrode with high deposit rates, smooth beads and a steady arc. It is used with both AC and DC welding machines.

FASTER, MORE FLEXIBLE application in measuring gases, vapours and liquids in industrial process streams and atmospheres is permitted by a completely new and portable infra-red analyzer that Mine Safety Appliances Company has developed. The MSA Model 300 LIRA analyzer weighs only 30 pounds and is housed in a case measuring only 8 inches in height and width, and 19 inches in length. Compactness and light weight permit rapid transfer and facilitate use of the analyzer where moderately priced instrumentation is required.

COSTLY PIPING alterations at compressor stations along natural gas pipe lines is reduced by a unique electronic machine which the Worthington Corporation has developed. This machine allows Worthington engineers to create electrical circuit analogies which accurately predict machine and system performance before design and construction are finalized. They can anticipate vibration patterns that cut efficiency and cause maintenance problems. At the compressor stations multiple compressors repressurize natural gas being piped to market areas and discharge it back into the main line pipe. Pulsations cause the vibration and wear.

HORIZONTAL CONTROL for location of highways, pipelines, transmission lines and other construction projects is the purpose of the Tellurometer system of distance measurement. A completely redesigned model of the original system is now announced by Highway Information Services of Washington, D.C. The new "micro-distancer" permits interchangeability of units—either unit may be used as the master or the remote, permitting readings to be taken from either end of a line. Equipment is produced by Tellurometer Inc. of Washington.

HUMAN JUDGMENT VARIABLES are eliminated and the operator can start or stop the Clark packaged compressor engine, by means of automatic control panels recently introduced, consisting of a complete pneumatic starting and stopping system which operates at 75 psi air or gas pressure. The control is furnished as an integral part of the compressor package.

DRILLING SMALL HOLES in stone, concrete, brick and other building materials is the job of the Wasp, a new plug hole drill announced by Atlas Copco. With an aluminum handle, casing and front head, the unit weighs only 6.6 lbs. and is claimed to be the lightest air-operated, self-rotating plug hole drill on the market.

AS AN IMPELLER "Delrin" does not absorb moisture and is lighter in weight than metals but stronger than most other plastics. As a motor component it is in use in a power saw as a carburetor insulator to prevent vapour locks. In both cases the new moulded plastic part eliminates other costs, such as machining required for metal parts. This acetal resin was developed after 10 years' research and an expenditure of $42,000,000, says Du Pont.

CENTRALIZED TRAFFIC CONTROL is going into operation on the C.N.R. mainline between Hawthorne, Ont, and Coteau, Que., a distance of some 70 miles. This will place all trains between Montreal and Ottawa under automatic signalling. C.T.C. is a modern signalling system by which the operation of traffic can be governed by a despatcher seated in front of a panel. It replaces the working timetable and eliminates the transmission of train orders between despatcher and train crews. In addition, the new system will allow train movements to be constantly monitored.

THROWING AND STORING grain, sand or other granular small lump bulk materials to heights of 20 feet over a radius of 50 feet is possible with the wheel mount Swivel-Piler developed by Stephens-Adamson of Aurora, Ill. Easily moved and operated by one man, the Stephens-Adamson swivel-piler is designed for ground storage of bulk materials, and is especially suited to piling, original filling, turning or aerating grain in storage buildings.

ENGINEERING DRAWINGS can be "retrievably miniaturized" by means of the new Revolute continuous reducing printer and processor announced by the Paragon-Revolute Division of Charles Bruning Company. Retrievable miniaturization combines advantages of miniaturization with visual communication of reliable information. Invariably a print cannot be a reliable copy unless it clearly reproduces all information from the original drawing. The new process reduces drawings to a size which will be sufficiently readable in the ultimate copy prints. It is a fast, economical method of reducing the cost of making, handling and storing prints without disposing of existing facilities or making drastic changes in current drafting standards or print-making systems.

ENGINEERING PRODUCTS represented 41.9% of the U.K.'s total manufacturing output in 1958, according to the U.K. Information Services. This compares with 29.2% in 1935.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

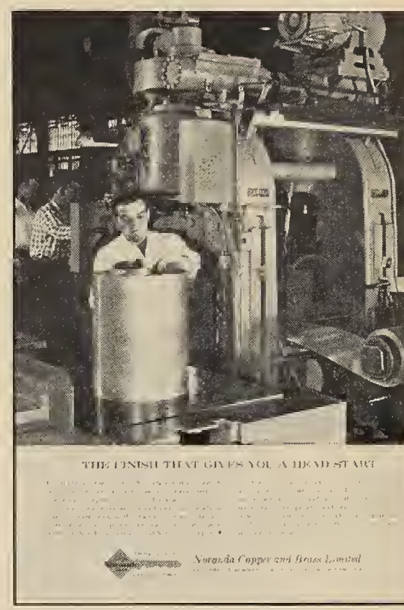
A one page, 4 colour insert placed by Noranda Copper & Brass Ltd., was judged the "best", by a fifty reader jury, in the December 1959 issue, from the viewpoints of ACCURACY—INFORMATION—and ATTRACTION.

The advertisement appeared on page 33. It is headed: "THE FINISH THAT GIVES YOU A HEAD START". The illustration shows an employee handling a coil of brass strip just off the production line. The copy emphasizes that brass strip produced by Noranda Copper & Brass Ltd. is ready for use by a manufacturer as it comes off the line. It continues by emphasizing the scientific control which is carried on through all the mining and manufacturing operations of the company.

This is the second time Noranda Copper & Brass Ltd. have won the Certificate during a 12-month period. The company's insert in the September issue was their previous "winner".

Advertising Manager of the company is Mr. R. C. DeVilliers.

Each month fifty readers are asked to evaluate the advertisements from the viewpoints of ACCURACY—INFORMATION and ATTRACTION and this opportunity is taken to thank all those who have assisted by their co-operative effort.



NORANDA COPPER & BRASS LTD. WINNING INSERT

The above illustration shows, on a reduced scale, the 4-colour insert which was judged the "best" from the viewpoints of ACCURACY—INFORMATION and ATTRACTION in the December 1959 issue. The advertisement appeared on page 33.

Index to Advertisers

The revenue derived from the sale of advertising space assists the Institute in publishing THE ENGINEERING JOURNAL on a regular monthly basis. Listed below are the names of the Companies and Individuals whose advertisements appear in this issue.

Specify the right valve

— FOR THE JOB!

Whether it's for water, steam, air, oil, nuclear power or corrosive substances, wherever fluids are conveyed, McAvity has the right valve for the job— or will *design* it for the job.

McAvity valves are a tradition in the pulp and paper industry throughout the world. They play a vital role in municipal water systems and in all kinds of steam fitting. There are nearly a thousand types and sizes of McAvity valves, each the *right* valve for the job. Your McAvity representative can offer specialized services for your installation.

SUPPLIERS OF TOP QUALITY VALVES TO CANADIAN INDUSTRY FOR 126 YEARS

Meet the Authors

F. W. Buckley, M.E.I.C., B.Sc., Elec. (N.S.T.C. '38), chief engineer, Bathurst Power and Paper Company, Ltd., Bathurst, N.B. *(Bathurst's New 1250 p.s.i.g. Kraft Chemical Recovery Boiler and Back Pressure Turbine).*

After graduation Mr. Buckley joined the Nova Scotia Power Commission as a field engineer and later became design engineer on steam and hydro plant design. He has been associated with the Bathurst Power and Paper Company for the past 13 years. Mr. Buckley is a registered professional engineer in the Province of New Brunswick.

J. W. MacLaren, M.E.I.C., B.A.Sc., (Tor. '46), M.A. (M.I.T. '47), principal, James F. MacLaren Associates, Consulting Engineers, Toronto, Ontario. *(Supervisory and Automatic Control System for Winnipeg Unattended Pumping Station).*

Mr. MacLaren was with the firm of Gore and Storrie for three years as a junior project engineer on municipal and sanitary engineering works. He then joined his present firm, specializing in sanitary engineering.

D. J. Moon, M.E.I.C., A. Mem. A.I.E.E., senior electrical engineer, James F. MacLaren Associates, Consulting Engineers, Toronto, Ont. *(Supervisory and Automatic Control System for Winnipeg Unattended Pumping Station).*

Mr. Moon graduated in Electrical Engineering from the University of London, England, in 1950. After settling in Canada in 1945, he worked for the Department of National Defence and the Department of Transport where he was electrical engineer on the Welland Ship Canal. With his present firm he specializes in the electrical control requirements associated with sanitary engineering.

W. D. Hurst, M.E.I.C., B.Sc. (Manitoba '30), C. E. (Virginia Polytechnic Inst. '31), city engineer and chairman of commissioners, Greater Winnipeg Water District, Winnipeg, Man. *(Supervisory and Automatic Control System for Winnipeg Unattended Pumping Station).*

Mr. Hurst has been associated with the City of Winnipeg Engineering Department as resident engineer, office engineer, engineer of water works, assistant city engineer and city engineer. He has also been with the Winnipeg Sanitary District and the Winnipeg-St. Boniface Harbour Commission. Mr. Hurst has held executive positions in the Association of Professional Engineers of Manitoba, The American Water Works Association, The American Public Works Association and is a member of numerous other professional associations.

F. G. Denson, M.E.I.C., B.Sc., Civil (Manitoba '50), Engineer of waterworks and sewage, City of Winnipeg Engineering Department, Winnipeg, Man. *(Supervisory and Automatic Control System for Winnipeg Unattended Pumping Station).*

Prior to obtaining his degree Mr. Denson was with the Winnipeg Electric Company for seven years and was stationed in England with the R.C.A.F. as a pilot during the war. He joined the Winnipeg Waterworks Department as Distribution Engineer in 1950. He is a member of the Association of Professional Engineers of Manitoba, the American Water Works Association and the Canadian Institute on Sewage and Sanitation.

R. A. Forrester, B.A.Sc., Civil (U. of T. '40), Project Engineer, The Hydro-Electric Power Commission of Ontario, Toronto, Ontario, *(Silver Falls Project).*

Mr. Forrester began his professional career with the Department of National Defence as field engineer on airport construction. During the war he served overseas with the Royal Canadian Engineers. Employed by H.E.P.C. since 1945, he has been project engineer for several hydraulic generating stations.

C. W. Hodgson, M.E.I.C., A.M., I.M.E., Director and Chief Engineer, Ewbank & Partners (Canada) Ltd., Toronto, Ont. *(Salient Mechanical Design Aspects of the Selkirk Generating Station).*

Before the Second World War Mr. Hodgson was with Merz & McLennan, Consulting Engineers. He served as an engineer officer in the Royal Navy during the War. He then joined the Central Electricity Authority at Nottingham, England, and was later appointed a generation engineer (construction). Mr. Hodgson is a member of the Institution of Mechanical Engineers.

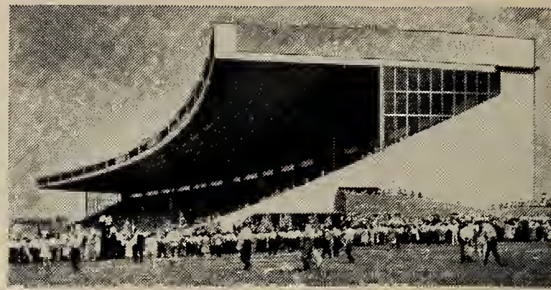
R. W. Wilson, M.E.I.C., B.Sc. (Dalhousie '50), radio systems engineer, Maritime Telegraph and Telephone Company Ltd., Halifax, N.S. *(Application of Microwave Radio Links).*

Mr. Wilson has been with his present company for the past ten years and is in charge of design layout and application of all company radio facilities in Nova Scotia and those of the Island Telephone Company in P.E.I. He is a member of the Association of Professional Engineers of Nova Scotia and the Institute of Radio Engineers.

STRUCTURAL STEEL and TOWERS for the NATION SINCE 1900

it's our **60***th*

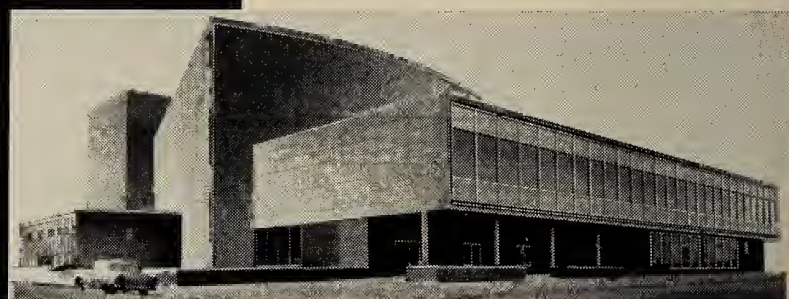
ANNIVERSARY YEAR



The Grandstand at the Canadian National Exhibition

The Princess Margaret Bridge at Fredericton, N.B.

Since 1900 the Canadian Bridge Works has been a major industry in Canada. Our engineers and skilled craftsmen design and fabricate structural steel for bridges, towers, grandstands and modern buildings for erection across the country, and in other parts of the world . . . Noted for its highly specialized services and facilities the Canadian Bridge Works ranks as a leader in the structural steel industry.



The Cleary Civic Auditorium on the Waterfront, Windsor.

THE FOLLOWING SUMMARIES OF ENGINEERING ACHIEVEMENT IN CANADA DURING 1959 ARE BASED ON INFORMATION RECEIVED IN THE ANNUAL REPORTS OF CHAIRMEN OF THE EIGHT DIVISIONS OF THE INSTITUTE'S COMMITTEE ON TECHNICAL OPERATIONS

ENGINEERING PROGRESS

1959

Mining Engineering

THE mineral industry continued to grow in volume and value during 1959. Preliminary estimates by the Dominion Bureau of Statistics indicate a value of production of nearly $2,390-million and a new high D.B.S. index (1949 = 100) of physical volume of production at 252.0; a 10% gain over 1958.

The total figure of value includes metals ($1,359-million), non-metallics ($176-million), structural materials ($314-million), and coal ($73-million); petroleum production of some 184,593,000 barrels, and natural gas output of 427,800-million cubic feet (an increase of over 26% over 1958), were valued at about $467-million.

Gains were shown among all the important minerals except gold, lead, and coal. Largest increases in value were recorded by nickel ($63-million), copper ($59MM), iron ore ($60MM), and uranium ($49MM). The largest percentage increase was shown by iron ore (55.6% in volume, 47.6% in value).

The future of uranium is clouded with uncertainty. The original contracts were to expire in 1962 and early 1963. The United States government has announced its decision not to take up the options on production after that time, but there has been a stretch-out in the delivery time. Contracts to supply uranium oxide may now be transferred and a company acquiring an uncompleted contract may proceed to fill that contract until 1967. This stretch-out has rescued some of the mines that had contracts which formerly were not transferrable and that did not have the ore enabling them to meet the contract.

The physical output of iron ore may be down nearly 6 million tons because part of the U.S. market was closed off by the strikes in the steel industry. The opening of the St. Lawrence Seaway may have far-reaching effetcs on the iron ore industry. The outlook is that there will be an annual production of 20 to 30 million tons of ore tributary to the north shore of the St. Lawrence. Whether this will move to the mid-continent via the Seaway or overland from Contrecoeur below Montreal or from Philadelphia, will depend on the relative cost of each method of shipping. 1959 was not a good year to judge the impact of the Seaway on the iron ore trade and vice versa because of U.S. steel strikes. Canada will not benefit to the fullest possible extent from Seaway trade unless shipping is provided that can work the Seaway routes during the open season and ocean traffic during the closed months.

The status of the industry in the different provinces varied widely, and here are considered only some of the outstanding events in provinces where there was a marked change.

Newfoundland

The Atlantic Coast Copper Company is developing old reserves at the old Little Bay Copper Mine in the Notre Dame Bay area. The results are encouraging.

A test mill was installed during the year on the Asbestos property near Baie Verte in the Cape St. John area. This should become an important source of asbestos.

The American Smelting and Refining Company, Buchans Unit, continued production at a reduced rate because of the over-supply of zinc in the world markets. The MacLean shaft designed for 4,000 feet was nearing completion at the year's end.

Iron Ore. The first increase in the iron ore production in Newfoundland-Labrador will come from the Iron Ore Company installation at the Carol Lake Project which will probably attain 6 million tons of concentrate production per year. The Wabush Ore Company was preparing to go into the pilot plant stage preparatory to putting in a plant to produce about 5 million tons of concentrate per year. The two companies combined to build a railroad into the Wabush Lake area about 40 miles from Mile 227 of the Quebec, North Shore and Labrador Railway and it was under construction during the year. Power is expected from the Grand Falls on the Hamilton River. Capital expenditure in the area will be close to $300 million.

Nova Scotia

The coal industry in Nova Scotia continued to be in difficulty. The mines are remote from coal-consuming centres and the markets of the Maritimes are too thin to encourage large-scale manufacture.

A new salt mine with a capacity of 3,000 tons per 8 hours was opened at Pugwash by the Malagash Salt Limited.

Other minerals of importance to Nova Scotia are barytes, used mainly in drilling muds by the petroleum industry, and gypsum, of which the province's production represents about 80% of total Canadian output.

Over 1200 prospecting licences were issued during 1959, more than half of these to major Canadian companies.

New Brunswick

There was no remarkable advance in mining activity in New Brunswick during 1959, though there was a considerable improvement in conditions over 1958. Total value for the year was about 13% above 1958, with coal showing a 20% improvement in volume to about one million tons.

General prospecting and exploration increased more than 50%, a developing interest being shown in base metals.

Quebec

A large part of the increase in Canadian iron ore production will come from Quebec. During 1959 the Quebec-Cartier Mining Company was building a 193 mile railway to Lac Jeannine. It was installing harbour facilities at Shelter Bay and building two towns which will have a population of about 6,000 people.

The second mine in Chibougamau, the Copper Rand, was nearly ready for production at the year's end. Prospecting and exploration continued in the Mattagami area northwest of the Chibougamau area. Eventually this area will be a large producer of zinc. There was renewed and successful prospecting in the Noranda and Val d'Or areas.

Ontario

Mineral production in Ontario, in 1959, reached a record peak estimated at over $962-million with an increase over 1958 of $161.5 million. Metallic minerals showed the greatest gain.

A new iron producer, the Lowphos Ore Company, started its beneficiation plant near Capreol, Ontario, in May.

A salt mine was opened at Goderich by the Sifto Salt Limited. This mine has a capacity of 4,400 tons per shift.

The strike of the International Nickel Company's employees was settled early in the year and production was resumed. Reserve stocks of nickel had been lowered, and that, with the political upset in Cuba, completely changed the near-term outlook for nickel demand.

Manitoba

The outstanding mineral operation in Manitoba continued to be the Thompson development of the International Nickel Company. The town of Thompson now covers a 3000 acre site on the Burntwood River. The mining project will be the second largest nickel producing operation in the world, after the Inco plant at Sudbury, Ont.

Saskatchewan

Potash is the main item of interest in Saskatchewan's mineral industry. First Canadian production of potash came from the Patience Lake operation of Potash Company of America in 1958. This company has spent over $20-million on its mine and surface plant, and hopes to produce some 600,000 tons of finished product a year.

International Minerals and Chemical Corporation (Canada) Limited started to sink a shaft to potash deposits near Esterhazy, northeast of Regina, during the year. Other companies are testing leased areas.

It is estimated that, of 17,700-million tons of potash in the province, about 6,400-million tons are recoverable.

Alberta

Petroleum and natural gas are by far the most important contributors to the mineral industry of Alberta, in which coal, sulphur, salt, and structural materials also play a part. Increased production of petroleum, natural gas, and coal helped to raise the value of mineral production in Alberta to an estimated $378.1 million.

The potential production of petroleum and natural gas is much higher than present figures, but is restricted by various controls. Many verbal battles raged during 1959 over the export of natural gas from Alberta, and it was not until the beginning of 1960 that prospects brightened when the National Energy Board approved several applications to export gas.

Sulphur production continued at much the same level in 1959 as in 1958 ($1.8-million), but is almost certain to increase, since it is derived from the processing of sour natural gas. Recoverable sulphur from natural gas reserves in Alberta has been estimated at 82,000,000 long tons.

British Columbia

Though the mainstays of the B.C. mineral industry, lead and zinc, showed a combined increase in value of only about 1% (1959 over 1958), the industry showed an overall increase in value of over 5%. This was partly due to greater diversification in operations and to an increase in the petroleum industry which more than offset a decline in coal.

Iron ore output was about 855,000 tons, the bulk of which was exported to Japan. During the year, the Consolidated Mining and Smelting Co. of Canada Limited started construction of a $22.5-million smelter at the Sullivan Mine, Kimberley. The first phase is scheduled for completion in 1961; annual capacity from this is to be 100,000 tons of steel and 36,500 tons of pig iron from sulphide concentrate. Sulphur from the operation will continue to be used in Cominco's fertilizer plants.

Value of sulphur from smelter gas continued at nearly the same figure as in 1958 ($1.65-million), but the value of sulphur from petroleum sources rose remarkably from less than 2% of this figure to about 47%, at over $776,000.

Yukon and Northwest Territories

Great interest was shown in the Yukon and Northwest Territories during 1959, particularly concerning petroleum. Though actual drilling activity was considerably less than in other post-war years, 1959 saw the second well to be drilled in the Yukon. This well proved to be successful.

Considerable exploration activity continued by petroleum and other mining interests. Both government and private interests were engaged in various surveys, including mapping and other investigations of the continental shelf and Arctic islands.

The Canadian chemical Industry

in 1959 continued to show progress, but fell far behind its past record. Although production showed a small increase, employment decreased slightly which may be attributable to capital investments for effecting improvements in processing. Chemical prices in 1958 increased about 3.2% except for fertilizer and coal tar products which changed only slightly. Thus the value of the chemicals and allied products industry increased 3% to $1,300 million.

The chemical industry is highly competitive within itself and imports of chemicals have been increasing with the result that total exports decreased in 1958.

The Canadian chemical market expanded about 4% during 1958 and manufacturers' shipments showed an average growth as was forecast for 1959.

Major industrial expansion in the Canadian Chemical Industry is given in the accompanying tabulation.

Petroleum and petrochemicals. In addition to the chemical industry, the petroleum, natural gas, and petrochemical industries are also of concern to the chemical engineering field.

Petroleum refinery capacity in Canada increased nearly 6% in 1959 over 1958 to about 878,000 barrels a day.

New Brunswick

Work progressed on the new 40,000 barrel/day (b/d) refinery of Irving Refining Limited at St. John. This will include a hydrogen plant, the hydrogen to be used for desulphurizing processes.

Quebec

Texaco Canada Limited added a hydro-treater at their Montreal East refinery to remove sulphur from middle distillates. The unit has a capacity of 350,000 gal. of oil a day, from which 2 to 15 tons of sulphur are recovered daily.

Canadian Industries Limited started construction at Beloeil of a plant (the first in Canada) to manufacture pentaerythritol tetranitrate (P.E.T.N.) used in various blasting explosives.

Carbide Chemicals Company, Division of Union Carbide Canada Limited, initiated the third major expansion of polyethylene production at its Montreal East plant, to be completed early in 1960. The Visking Division started construction of a polyethylene film plant at Cowansville.

Shell Oil Company of Canada Limited introduced production of an odourless solvent from their petrochemical plant at Montreal East.

Construction proceeded on a new complete refinery for BP Canada Limited at Ville d'Anjou, east of Montreal. This plant will have a capacity, initially, of 25,000 b/d and is due to go on stream about April 1960.

Also in the Montreal East area, a gas concentration unit was commissioned at the Canadian Petrofina refinery in mid-1959.

Ontario

Rio Tinto Dow Limited started operation at Elliot Lake of a $1-million plant for the recovery of thorium from waste solutions resulting from uranium recovery.

Hercules Powder Company (Canada) Limited began construction of the first plant for the fractional distillation of crude tall oil. The plant will produce resin and fatty acids.

There were several developments in the Sarnia area. The Canadian Oil Companies Limited refinery added a new 20,000 b/d crude unit, hydrogen-desulphurizing unit, and other facilities in a major expansion program. At the nearby plant of Ethyl Corporation of Canada Limited a new plant was under construction for production of ethyl chloride and ethylene dichloride. Dow Chemical of Canada Limited were working on a new plant to produce high density polyethylene.

Du Pont of Canada Limited were also interested in polyethylene with their new plant under construction at Corunna, near Sarnia. As in the case of the Dow plant, technical data were closely guarded. Du Pont started production of polyethylene film from a new plant at Whitby, and opened a new nylon tire yarn plant at Kingston, accompanied by expansion of nylon intermediates capacity at Maitland, at a cost of $7.5-million.

Canadian Industries Limited started construction of a $500,000 plant at Cornwall for production of caustic potash which will be used in the manufacture of soaps and detergents, liquid fertilizer, and in oil refining.

Hardifoam Products Limited, of Toronto, is a new firm entering into the manufacture of polyurethane foam with an initial capacity of 5-million pounds a year.

Manitoba

The major development during the year was the start of construction of the Thompson nickel refinery by the International Nickel Company. Part of a great mining and refining operation which will be the second largest nickel producer in the world when completed, the refinery will cost some $25-million and have a capacity of up to 75-million pounds a year.

In the petroleum refining field, a $2,600,000 HF alkylation plant was completed at the Winnipeg refinery of Imperial Oil Limited.

Alberta

Sulphur production from natural gas was on the increase during 1959. Texas Gulf Sulphur Company started operations at a plant at Okotoks, under agreement with Shell Oil of Canada Limited and Devon-Palmer Oils Limited. Plant capacity is 100,000 tons a year. British American Oil Company Limited was also at work expanding its sulphur-producing facilities at Pincher Creek and Nevis. California Standard, Home Oil, and others built a $3-million gas processing plant near Red Deer, at which sulphur will be produced.

Imperial Oil Limited opened its virtually completely rebuilt oil refinery at Calgary and was working on a new HF alkylation plant at the Edmonton refinery. Other refinery expansion took place at plants of British American Oil, Calgary, and Texaco Canada Limited. A start was made on a new plant for Canadian Oil Companies near Red Deer, to process mainly gas condensate.

The Red Deer area of Alberta has been in the news several times as a possible major centre for petrochemical operations. Polymer Corporation Limited may soon have a butadiene plant in the area with a capacity of 25,000-30,000 tons a year.

British Columbia

Celgar Limited, a subsidiary of Canadian Chemical and Cellulose Company, constructed a 500-ton/day pulp mill which will be supplied with chlorine and caustic from the Cominco plant at Trail, some 28 miles away.

Production of sulphur from natural gas increased considerably during 1959. At the gas processing and oil refining plant of Phillips Petroleum Company, at Taylor, work started on a new crude unit, catalytic cracker, and alkylation unit, for completion in 1960.

New Industrial Process

A new industrial process, developed by Dr. Wm. Gauvin of the Pulp and Paper Research Institute of Canada, for the treatment of wastes from pulp mills has been found to be successful in the treatment of sewage. The process is called the Atomized Suspension Technique or AST. Basically AST involves the atomizing and spraying of material in fluid form into the top of a tower. Waste can be destroyed and valuable components separated from wastes.

The AST sewage installation at Beaconsfield, near Montreal, has been pronounced a success and all Canadian governments, municipal, provincial and federal may use the process royalty-free.

Uranium Industry

The Canadian uranium industry, which comprises 21 working mines and 16 ore processing plants, finds itself in a critical position due to the uncertainty of U.S. intentions of contract renewal after 1962-63.

Canadian uranium oxide production is about 16,000 tons per year, while world civilian power requirements will not likely exceed 5,000 tons in 1962 and could reach 9,000 tons by 1965. This market must be shared by Canada, United States, S. Africa, and to a lesser extent the Belgian Congo, Australian, and French interests. However, the long-term picture is encouraging as civilian requirements are estimated at 35,000 tons by 1975.

Future of the Chemical Industry

The provinces of Ontario, Quebec and Alberta continue to expand their chemical interests. Manitoba has engaged the consulting firm of Arthur D. Little (Cambridge, Mass.) during the past four years to conduct feasibility studies for certain chemical

MANUFACTURERS' SHIPMENTS BY CHEMICAL GROUP

industries. At present local markets are small and large volume outlets are sufficiently distant to make transport costs a restraining factor.

The capital outlay for expansion of the chemical industry as planned for 1960, which will take in some instances till 1962 to complete, is about $440 million.

There are few plans for the production of chemicals not previously made in Canada. Exceptions are caustic potash, refined tall oil, and maleic anhydride. The absence of new products is due to a limited market, foreign competition, and unfavourable duty rates that have to be faced.

Electrical Engineering

In the electrical engineering field automation and automatic control have been undergoing intensive study.

Pioneer work is being done in the field of extra high voltage power transmission lines. Another Canadian development has been the provision of an aluminum prefabricated substation.

Improvements in rotating electrical machinery continue to be made, and greater use of automatic control of facilities is in evidence in public utilities.

Economics plays an important role in the planning and operation of hydro-electric systems. An exhaustive study in Manitoba may be of interest to other provinces (E.I.C. annual meeting paper).

The development of epoxy insulating resins promises to make changes and improvements in the design and manufacture of electrical equipment just as it has done in the case of electrical components. The application of printed wiring continues to expand.

Several papers on electrical engineering subjects will be given at the E.I.C. annual meeting, including: two papers on automatic control; one on extra high voltage transmission, featuring the use of aluminum towers; evolution in the field of rotating electrical machinery; automatic control at a major waterworks; electronic control via communication networks; application of microwave links; and the economic study in Manitoba.

Extra High Voltage Transmission

Transmission line voltages have risen quite rapidly since the inception of the electrical power industry. In the 1930's a level of 220-kv. was familiar; at present there are lines operating in North America up to 362-kv. In Europe, even higher voltages are in operation, up to the Russian line of 525-kv., which may soon be exceeded if current Russian plans for very long distance transmission are carried out.

Both in Russia and North America, engineers have considered transmission over a grid that would cover more than one time zone. Briefly, this could enable peak loads in one area to be supplied by plants in another time zone, in which there was an off-peak operation. Of more immediate interest is the possibility of making economical use or large amounts of power from relatively remote sources, such as might be done across Ontario or from the Peace River, in B.C., and the Hamilton Falls site, in Labrador, rather than building thermal stations close to load centres.

Ontario Hydro has started extra-high-voltage tests at Coldwater, some 80 miles north of Toronto, to determine the economics of building and operating a line at 460-kv. for transmission of large amounts of power from remote sources.

Communications

The TD-2 radio relay system used on the Trans Canada microwave network operates in the 4000 Mc. band and carries 3000 telephone circuits or five two-way TV network channels over distances of 4000 miles. However, a system is being investigated that operates in the 6000 Mc. band and could carry up to 13,320 telephone circuits or six two-way TV channels over similar distances. Equipment operating in the 50,000 Mc. band would provide about 133,000 telephone circuits, though the signal could not readily be transmitted through the atmosphere. Experiments are being done in the Bell Telephone Laboratories to determine if signals of this frequency can be transmitted via a suitable waveguide.

Work proceeded in Canada during 1959 towards the extension to Montreal and elsewhere (in March 1960) of direct distance dialling, by which an individual caller can dial a normally long-distance call without the help of an operator. A multi-frequency pulsing system is used, instead of the d.c. loop used between instrument and telephone office in normal local dialling. Long-range plans envisage the replacement of the mechanical dial by electronic type dial switching systems, making extensive use of transistors.

Communication in northern areas is complicated by conditions such as the aurora. The troposphere scatter technique is widely used for defence communications and in the Quebec-Labrador system (*The Engineering Journal*, April 1959).

Hydro-Electric Engineering

THE development of the hydro-electric generating industry in Canada during 1959 was surveyed in some detail in the October 1959 issue of *The Engineering Journal*. The present report is necessarily a rather brief review of the major developments during 1959. Several papers to be presented at the 1960 annual meeting of E.I.C., in May, will discuss certain aspects of the industry in greater detail.

British Columbia

Work continued during the year on the B.C. Electric Co. Bridge River No. 2 plant of four units each of 82,000 h.p. The second stage involves the completion, in the spring, of Mission Dam, a 3-million cu. yd. earthfill structure extending 1200 ft. across the Bridge River Valley. Total capacity of Bridge River area plants will be 680,000 h.p.

Major hydro-electric development during 1959 for B.C. Hydro was completion of the Ash River unit of 35,000 h.p. Plans were made for future developments, and studies showed that more than one-million h.p. would be available from the Clearwater River system, north of Kamloops.

One of the most controversial subjects for some time has been the development of the Columbia River. B.C. Hydro has been designated by the provincial government to develop the Columbia in Canada, and reserves have been granted on crown lands at the High Arrow damsite of Lower Arrow Lake and on Duncan Lake damsite at the head of Kootenay Lake.

Perhaps no less controversial is the subject of the Peace River development, with which the name of Wenner-Gren has been closely associated. The largely British- and Canadian-backed Peace River Power Development Company Limited continued with various studies during 1959 to complete a report called for under an agreement made with the B.C. government in 1957. This report was filed with the Comptroller of Water Rights at the end of 1959, as required. The plan proposes two dams: the main one, Portage Mountain Dam, would impound 88-million acre-feet of water (or five to six times the total hydro-electric storage in B.C., Washington, and Oregon). The second dam, Site No. 1 Dam, would be near the foot of the Canyon. Combined potential from the two sites would be over four-million h.p., and another one-million h.p. would be available from other sites on the Peace River between Site No. 1 and the Alberta border. Transmission would be by a 500-kv. line between the Peace River and the B.C. Electric system at Lillooet.

If the report is approved, and other formalities completed, the Peace River Company might start driving the pilot tunnel by midsummer of 1960, and could expect to produce 750,000 h.p. by 1968.

Alberta

It is estimated that there is a potential of five-million h.p. on the Peace River in Alberta, though no studies have been made of actual development sites. The advance in high-voltage transmission techniques could make power available from the somewhat remote Peace River at economical rates.

Saskatchewan

During the year, a seventh unit was added to the Island Falls development on the Churchill. This added 19,000 h.p. to the existing 106,500 h.p. The plant is operated by the Churchill River Power Company.

The Squaw River development on the Saskatchewan River is an assured project, but is only at the stage of clearing and camp construction. Plans call for the installation of six 46,000-h.p. Francis turbines operating under a head of 105 ft. The estimated energy production is 1-billion kwh., and the cost about $45 million.

The proposed South Saskatchewan River Dam is to be built jointly by the Prairie Farm Rehabilitation Administration and the province. Plans call for three hydro-electric units of 85,000 h.p. each operating under a normal head of 180 feet.

Manitoba

During 1959 construction started on the Kelsey power plant on the Nelson River. The construction difficulties associated with this project were out of the ordinary, especially the foundation conditions at the rock fill dam and the sand dykes. (The plant is the subject of a paper at the E.I.C. annual meeting in May.)

The Grand Rapids development on the Saskatchewan River calls for a 378 Mw. station of four units with a normal head of 120 feet. The estimated cost is $112,000,000, apart from transmission costs of about $30 million.

Ontario

The Silver Falls station on the Kaministikwia River, 30 miles northwest of Port Arthur, was completed during 1959. This is a single unit of 35,000 kw. operated by remote control from the lakehead. It features a two-mile tunnel through granite, concrete-lined to a finished inside diameter of 14 ft. 6 in., as well as a surge tank of stand-pipe type, 180 ft. high and 38 ft. outside diameter. The cost is said to have been $16,500,000. (Papers on the station and tunnel are to be given at the E.I.C. annual meeting.)

In 1959, nine additional units were installed at the Robert H. Saunders station of the St. Lawrence development, to complete the station. There are sixteen units in all at the station, each of 72,500 h.p., with an operating head of 81 feet.

The Red Rock Falls station was under construction on the Mississagi River in northern Ontario. This is a station of two units of 26,000 h.p. each operating under a head of 93 feet. The two units are due to go into service late in 1960.

Construction also started on the Otter Rapids station on the Abitibi River. This consists of four units of 66,000 h.p. each. Two units are scheduled for 1961, two for 1963. Normal operating head is 107 feet.

Quebec

The Shawinigan Water and Power Company's Beaumont project was operating during 1959. Six units of 55,000 h.p. each operate under a head of 124 feet. This is now the eighth plant in active service on the St. Maurice River.

During the year, construction started at the Carillon plant on the Ottawa River. This plant of twelve 60,000-h.p. Kaplan units will operate under a 60-ft. head.

Work continued on the Hydro-Québec Bersimis II development, where three 171,000 h.p. units were completed; two more are to be completed in 1960.

First power was produced from the Chute-des-Passes project of the Aluminum Company of Canada. (This project is discussed in some detail in *The Engineering Journal*, January 1960, p. 39.)

New Brunswick

The third unit at the N.B. Electric Power Commission plant at Beechwood is to be started. During the year the N.B.E.P.C. took over the Grand Falls plant of Gatineau Power Limited, thereby adding four units of 20,000 h.p. each to the system; normal operating head is 125 feet.

The revival of interest in the Passamaquoddy Tidal Project, and hence in Rankin Rapids, caused the N.B. Electric Power Commission to concentrate on their studies of the optimum development of the St. John River. The engineering staff are more than ever convinced that integration of hydro-electric with thermal power, as they advocate, is the proper procedure to get the highest potential and maximum overall energy.

Nova Scotia

In 1959 the Nova Scotia Power Commission started construction of both the Sissiboo Falls and Weymouth developments which they plan to bring on line in 1960. These are both single unit plants, the former of 6,000 h.p., the latter of 9,000 h.p.

Civil Engineering

CIVIL engineering design and construction continued at a high level of activity during 1959.

Highway construction continued as a major element in engineering activity in all parts of Canada. Incidental to this, extensive new highway bridge construction was also continued.

Work progressed on runways at Inuvik, at the mouth of the Mackenzie River, at Prince Rupert, and at Edmonton, and on terminal facilities at Montreal and Edmonton, all among the larger of such projects.

Institutional building continued on a substantial scale, with perhaps the major expansion in this type of activity being in the field of University buildings in all parts of Canada.

Construction in far northern areas was largely confined to several big projects and involved considerable specialized design.

Municipal engineering was highlighted principally by the installation of new sanitary facilities in small communities, and by the completion of two or three advanced designs for far northern conditions.

In the field of earth dam construction, activities were marked by a number of extraordinarily large dams, with unusually difficult design conditions, particularly in western Canada. The most spectacular event in this field was the start of construction on the South Saskatchewan project, but designs were also brought close to completion on the Squaw Rapids development in Saskatchewan and the Brazeau project dam in Alberta.

In the field of mining construction, major activities continued in northern Quebec, at the International Nickel development in Manitoba, and at the Caland Ore project at Steep Rock Lake, in western Ontario.

The year also witnessed the formal openings of the highly publicized and monumental projects, the St. Lawrence Seaway and the Deas Island tunnel in Vancouver.

Highway Engineering

Petroleum and natural gas developments in the north have already led to the construction of a road in the Yukon to serve the Eagle Plains development; this will be Canada's most northerly road for a while. A road linking Alberta centres with the Arctic Ocean has been predicted. Heavy expenditures are foreseen for Yukon and Northwest Territories during the next few years.

Both the Canadian Good Roads Association and the Canadian Construction Association play a large part in promoting the development of an adequate roads system in Canada, but both agree that there is a great need for improvement.

The CGRA, as the co-ordinating agency for road research in Canada, has published a list of all road research projects in Canada. About $1 million were spent on research in 1958. However, the CGRA finds that Canada lags well behind the United States highway industry and other private industries in its rate of investment in road research.

Work continued on the Trans-Canada highway, and it is expected that most of the project will be completed by the time the present agreements between the provincial and federal governments expire at the end of 1960.

Railways

The railways have been very active in constructing new facilities. Canadian National Railways were working on 4 major hump yards, in Montreal (costing $28.5-million), Moncton ($15-million), Winnipeg ($24-million), and in Toronto. The Montreal yard is electronically controlled and will be the largest of its kind in North America. Many extensions to rail lines were continued, and considerable work was involved in constructing new facilities for traffic in the St. Lawrence Seaway area around Montreal. Canadian Pacific Railway also were engaged in construction of yard facilities at Lancaster, N.B., Agincourt, Ont. Construction of 'piggy-back' terminals was carried out at various centres.

St. Lawrence Seaway

Much has been published about the construction of the St. Lawrence Seaway.

There was a marked increase in traffic during the 1959 season, despite the fact that cargo tonnage through the Montreal to Lake Ontario section was actually down 23.8% in April compared with the 1958 season, and down again in December. These are months of relatively minor traffic, and the net increase for 1959 over 1958 was 73%, with a total of 20.35-million cargo tons. This increase was also reflected at the Welland canal, which showed a gain of 27.6%, with 27.16-million tons of toll traffic in 1959.

Public Works

The Federal Department of Public Works is one of the largest spenders on construction work in the country. Construction of highways, bridges, other highway structures, harbours and navigation facilities are among their projects.

About $53-million was paid to provincial governments during the calendar year 1959 towards the Trans-Canada Highway; grading was completed on 564 miles, paving on 269 miles, and 70 structures of various types were built. Direct expenditures on the Trans-Canada Highway through the National Parks were some $12-million, and on other roads in the parks another $10-million. Work in the Northwest Territories and Yukon amounted to a further $7.3-million.

A major undertaking started in 1959 was the modernization of the harbour at St. John's, Newfoundland. New wharves, transit sheds, and berthing facilities for large ships will be built, as well as new access roads. Another large harbour development is that at the Lakehead, at a site between Port Arthur and Fort William. Three berths are being built at first, though there is room for ten in future. One of the berths has been designed for handling deep-sea ships.

Another proposed harbour development, in which federal participation may be expected, is that at Moosonee, on James Bay, in northern Ontario. Preliminary work has already been carried out by the Ontario government and Ontario Northland Railway, which has a rail link between Moosonee and Cochrane, and which is expected to spend some $20 to $30 million on development.

A new harbour, to be known as Port Cartier, is being carved out of rock on the North Shore of the St. Lawrence as part of Quebec Cartier Mining Company's iron ore development in northern Quebec.

Water Resources

The South Saskatchewan River project will have the largest rolled-earth fill dam in Canada, and one of the largest of its kind in the world. It will rise 210 ft. above the present river floor, and extend laterally for almost 3 miles. Five 20-ft. diameter tunnels, averaging 4050 ft. long, will be used for diversion of water during main fill construction, and will subsequently be converted to supply water for hydro-electric power development and for regulating river flow.

Several flood-control projects were under consideration in Manitoba. These were a 26-mile long Greater Winnipeg floodway, a dam on the Assiniboine River near Russell and another near Holland, and a diversion from the river near Portage la Prairie to Lake Manitoba. These projects would eliminate flood damage in the Red and Assiniboine river valleys.

In Ontario, the Water Resources Commission has been active in developing and controlling resources since its formation in 1956. Of great importance is the work of the Commission in controlling pollution of waters by municipalities and industries. Ontario has a particular problem arising from the existence of international boundaries with the United States in the middle of narrow waterways (for example, Niagara, Windsor, Sault Ste. Marie, Sarnia). In protecting these waters, the Ontario Commission works closely with the International Joint Commission.

Defence Construction

Under an agreement between Canada and the United States, refuelling bases are being built at Frobisher Bay and Churchill, Man., and at Namao and Cold Lake, Alta. Work proceeded towards the construction of bases in northern Ontario and Quebec for the Bomarc guided missile.

Bridge and Structural Engineering

THERE was much activity in construction of bridges and other engineering structures during 1959. Included among major bridge projects were the Second Narrows Bridge in Vancouver, the Peace River highway bridge in northern British Columbia, and the Dunvegan suspension bridge across the Peace River in northern Alberta. Construction was also started on the Port Mann bridge across the lower Fraser River in the Vancouver area.

Average monthly shipments by the steel fabricating industry in 1959 were 47,000 tons, representing an increase of 15% over the 1958 rate. About three-quarters of these shipments is for structural applications.

Bridge Developments

The Port Mann bridge will carry the Trans-Canada Highway across the Fraser River about 15 miles east of Vancouver. To cost about $25-million, the bridge will be 6900 ft. long with a centre span of 1200 ft., side spans of 360 ft., and a vertical clearance of 145 ft. above high water. A particular feature is an orthotropic deck of steel plate only ½ in. thick, with stiffeners and cross girders to form an integral structure saving considerable weight.

A smaller, but interesting, development also in the Vancouver area is the Capilano Canyon bridge, over the Capilano River. The 615-ft. long structure will incorporate the longest concrete fixed arch span in the Commonwealth (345 ft.).

In Ontario, a contract was let in 1959 for construction of the $3.7-million vertical lift bridge at Burlington, on the Queen Elizabeth highway. The largest and longest of its type in Canada, the bridge will be 370 ft. long, 51 ft. wide, and have suspension towers over 200 ft. high. Also in Ontario, a start was made on a high-level bridge on the Q.E. Highway to cross the Welland Canal at St. Catharines. Yet another project in the province is the $18-million international bridge to link the two towns of Sault Ste. Marie, in Ontario and Michigan.

The provinces of Quebec and New Brunswick, and the federal government, are helping to finance a bridge across an arm of the Baie des Chaleurs between Campbellton, N.B., and Pointe à la Croix, Quebec. There will be an 800-ft. clear span in the centre to allow passage of log booms from the Restigouche River.

Among projects in the north, a $2-million contract was awarded in 1959 for construction of bridges over the Pelly and Stewart Rivers, in the Yukon, and improvement of the Yukon River bridge at Carmacks. The first two bridges are on the Whitehorse-Mayo highway, 160 and 220 miles north of Whitehorse, respectively.

Large Buildings

Heavy investment in new buildings was noted during 1959. Montreal and Toronto were to the fore, though much work was done in other centres. A few large office projects in Montreal represent over $200-million in capital investment. The Place Ville Marie development accounts for $75-million, and a further $42-million will be spent on the Windsor Plaza development of the Canadian Bank of Commerce which will be the tallest building in the Commonwealth. The Canadian National Railways are building a 17-storey structure for new office accommodation, and other large projects include the 31-storey C-I-L House of Canadian Industries Limited. The centre of the Place Ville Marie project is a 42-storey cruciform office building.

Also in the Dorchester Street area of Montreal, Hydro-Quebec's new sub-station and headquarters building was excavated for and some 8-000 tons of steelwork were erected.

In Ontario, contracts for new hospitals and similar institutional buildings let in 1959 amounted to about $40-million. The federal government has several large projects under way for government buildings in Ottawa and in other centres, buildings include new airport terminals.

At Dorval airport, near Montreal, Trans-Canada Airlines has been at work on its new $20-million aircraft maintenance facilities. The main hangar incorporates what is said to be the largest single-cantilever roof in North America. The roof is 835 ft. long, 50 ft. above ground level, and extends 175 ft. out from the main columns. It consists of 28 conventional trusses spaced at 30-ft. centres, supported from above by diagonally-placed suspension bars pin-connected to the top chord and to the tops of the main columns, which also carry the inner ends of the trusses. The columns are 110 ft. tall; they provide a clearance of 50 ft. below the trusses. Loads on the overhanging roof are balanced behind the main column by tying into the building structure which contains two floors of workshop and offices. The hangar will accommodate 5 Douglas DC8 aircraft side by side.

Housing

1959 housing construction was slightly less than in 1958: main figures were (1958 in parentheses), starts: 141,345 (164,632); completions: 145,671 (146,686); under construction at year-end: 81,905 (88,-162).

Wider use of new materials is indicated; such as aluminum, plastics, laminated wood. Prefabrication has been used to a greater extent for some aspects of housing construction.

Management

EFFICIENT management may make the difference between success and failure in a great variety of enterprises, large and small, in industry and commerce. Correct management is as important to engineering undertakings as to any other field.

Aware of the importance of management, the Management Division, Committee for Technical Operations, of the Engineering Institute of Canada was formed in April 1959. Among the aims of the Division is the establishment of a body of members who have a proven interest and ability in management, chosen from all parts of the country.

Co-operation with other organizations interested in management is necessary. The Division works closely with the Canadian Management Council (CMC), of which the E.I.C. was a founder member. CMC represents Canada on the International Organization for Scientific Management (CIOS), which has a membership of 29 countries.

The Canadian chapter of the American Society for Quality Control will also co-operate with the Division, and are to contribute a paper "Statistical Quality Control as a Management Tool" at the annual meeting of E.I.C. at Winnipeg, in May.

The Management Division of the American Society of Mechanical Engineers (ASME) has also expressed interest in the E.I.C. Division.

Management Training

Diploma courses in management are available for engineers at McGill and University of Toronto. The advantage of combining additional business training, in economics, business administration, and so on, with a conventional sound training in engineering should be apparent.

There has been an emergence, in recent years, of responsible business consultants operating on engineering and scientific principles.

Industrial engineering has also become a valuable practice for infusing new life into industrial operations, perhaps basically by instilling the principles of sound management. This may be done with the help of industrial engineering consultants, maintained by industrial engineering departments permanently incorporated into an industrial organization, or by individuals trained in the principles of good engineering and good management. Regarding this latter case, the need can be seen in many small companies, at a certain stage of their development, for men with such dual training.

Mechanical Engineering

THE progress of Canadian life and industry depends to such a large extent on technical developments in the field of mechanical engineering that it is not easy even to outline the major developments. However, in considering Canada's great size and huge natural resources, it is relatively simple to realize the need for transportation equipment, by air, land, and waterway; equipment to handle and produce the natural resources in the mines and forests; and the machinery and equipment throughout general industry that make the whole operation possible.

Aeronautical Engineering

The progress of aeronautical engineering in Canada from 1909 to 1959 is dealt with in the February 1959 issue of *The Engineering Journal*. During 1959 many *Beaver* and *Otter* aircraft, though products of an earlier stage in the Canadian aircraft industry, continued to give valuable service in remote and difficult areas. The *Caribou* transport was a relative newcomer, having first flown in July 1958. Production of the CL-44, the largest aircraft built in Canada, continued.

Automotive Industry

The automobile, truck, and bus industries involve little original Canadian design, but do require much mechanical engineering effort in planning and tooling for new models. A considerable alteration to equipment and procedures was necessitated by the introduction of the 'compact' cars.

Pulp and Paper

The pulp and paper industry in Canada has expanded its capacity considerably. During 1959 the industry was operated at not much more than 80% of capacity, and competition was severe. Much effort was made to combat difficulties and rising costs by improving the efficiency of cutting and handling pulpwood and of manufacturing processes in the mills.

The benefits of earlier work on the extension of wire life on paper-making machines was felt during the year. Some more recent research work showed the feasibility of moving wood chips in water through a pipeline over long distances.

The Canadian Pulp and Paper Association has been concerned with the cost of material handling within the industry. One project is the development of a special rail car for the shipment of pulpwood. Instead of conventional box cars, which have to be unloaded manually, an end-packed flat car could be loaded and unloaded by mechanical handling equipment. An investigation has shown reported estimated savings of 40% to 75% would be possible by using the proposed method over the present techniques.

Mining

The mineral industries have expanded at a very high rate in Canada during the post-war years. Though there was some reduction in this rate of expansion in 1959, the amount spent on capital and repair work in the mining and smelting industries is estimated at $549-million (compared with $570-million in 1958 and $681-million in 1957). The 1959 figure includes an estimated $106-million capital expenditure on machinery and equipment, and $112-million (approx.) repair expenditure.

As in the case of the pulp and paper industry, the year 1959 saw considerable activity towards the reduction of costs and improvements of efficiency.

There was a continuing trend, particularly in uranium mining, from trackless mining to slusher scraping in stopes and track haulage. On the other hand trackless mining was adopted by producers of rock salt and potash.

The largest capacity man cage in the uranium field was installed at Milliken Lake during 1959. This is a three-deck unit that can carry 86 men at one time. It is powered by one 1500-h.p. motor, is suspended by a 1¾ in. steel rope, and operates at a speed of 1800 f.p.m.

There has been a trend to new friction type hoist installations in Canadian mines. Canadian-designed disc air brakes have been introduced, which are said to give definite advantages over the old conventional parallel motion shoe types.

Attention has been paid to the efficient operation of heating and ventilating plants, with resultant savings in fuel and power costs.

One example of improvement in efficiency of above-ground haulage is seen in the use of two 40-ton payload road trucks for dry ore haulage. These trucks have aluminum-magnesium bodies which receive 40 tons of ore from a hopper and are discharged through air-operated gates.

Remote control of conveying systems, and automatic sampling of materials are further fields in which progress has been made.

Seaway and Power Projects

The many mechanical features of the various locks, dams, and other structures of the St. Lawrence Seaway — many of them designed specifically in Canada for the job — were tested thoroughly during the first season of operation. The St. Lawrence Power project was also in full operation.

Work continued on the expansion of the Richard L. Hearn steam plant in Toronto, to increase capacity from 400,000 to 1,200,000 kw., involving very large boiler and auxiliary installations. Also in the Toronto area is the new Lakeview station, which is to be among the largest thermal-electric plants in the world. A third thermal plant in Ontario is that at Thunder Bay, by Fort William, on which work progressed.

In addition to these and other thermal plants, the heavy fabricating industry was kept busy on water-power equipment for the many developments in the hydro-electric power field, of which some further details will be found in the separate report on that subject.

Projects posing some new problems to the engineer were the nuclear energy developments scheduled to be operating in the next few years. The two plants of immediate concern are the NPD (Nuclear Power Demonstration) unit of 20,000 kw. capacity on the Ottawa River, and the projected 200,000 kw. CANDU operational plant.

Special Vehicles

Much work has been done on the properties of muskeg, one of the major difficulties involved; and engineers have also been busy designing suitable vehicles for use on other types of rough terrain.

The Canadian-designed equipment ranges from six-passenger tracked personnel carriers, powered by a Volkswagen 30-h.p. industrial engine, to articulated tracked load carriers nearly 50 feet long, capable of carrying a 20-ton payload.

Industrial Developments

The transmission and distribution of petroleum and its products involves the use of a lot of mechanical equipment. Major pipelines operating in 1959 exceeded 20,000 miles in length, and Canada had the longest crude oil line and longest natural gas line in the world (respectively that of Interprovincial Pipe Line Co., 1930 miles, and of Trans-Canada Pipe Lines Limited, 2290 miles). These lines require large pumping or compressor capacity for their operation. Additions included 5000 h.p. on the Interprovincial system (in Canada) and 17,000 h.p. in four compressor stations of the Trans-Canada system.

Considerable interest was shown in the production of steel pipe for oil and gas lines, including the larger sizes (30 inches plus) formerly obtainable only from the U.S. or Europe. The major pipe manufacturers already established in Canada carried out programs of expansion, and two new manufacturing organizations had plants in course of construction during 1959 in western Canada.

A $12-million plant was opened in the summer in Montreal for the manufacture of steel wheels for railway use by a British-licensed process. The plant incorporates automatic control of many operating cycles and handling methods. The forging and rolling shop can produce 60 wrought steel wheels an hour, under controlled and recorded conditions, with the supervision of only seven operators.

Capacity for handling heavy machining operations was also increased during the year by the opening of a new machine shop at Trois Rivières, Quebec, by a major organization in the heavy fabricating field.

Bathurst's New 1250 P.S.I.G. Kraft Chemical Recovery Boiler and Back Pressure Turbine

F. W. Buckley, M.E.I.C.,
Chief Engineer,
Bathurst Power & Paper Co. Ltd.,
Bathurst, N.B.

This paper will be presented at the Annual General Meeting of the Engineering Institute of Canada, Winnipeg, May 1960.

When Bathurst Power & Paper Company Limited of Bathurst, N.B. ordered their new kraft chemical recovery boiler to operate at 1250 p.s.i.g. and 850°F, there were none in existence operating at over 975 p.s.i.g. and 850°F. The 8750 kva Ljungstrom back pressure turbine which operates with this boiler was the first turbo-generator of this type over 1,000 kva ever installed in North America. This plant, which burns black liquor to recover the chemical from the kraft cooking process, has emphasis on the production of the most possible high pressure steam to produce cheap by-product power. The use of oil as a supplementary fuel has been used to allow more flexibility in burning liquor and also to keep the turbine operating at full load and best efficiency.

The Ljungstrom turbine, widely used in many parts of the world, has two complete sets of blading. One set, normally the fixed blading in other types of turbines, has a generator directly connected to it and rotates at a velocity equal in magnitude but opposite in direction to the other set which also is mechanically connected to a generator. The generators are electrically connected but mechanically free.

A PAPER MILL, of all industrial plants, probably has the best opportunity to produce cheap thermal power. This is due to the use of large quantities of process steam, which makes possible the production of a large block of what is commonly called by-product power or power made on back pressure turbines. This back pressure power is made by skimming off the top heat from the steam for conversion to power before going to process. The cost of this power for any steam condition, considering fuel cost only, is about 2 mills per kwh. Turbine efficiency, of course, is very high in this operation since the only losses are those from bearing friction and radiation, friction heat in the blading being passed on to process. About 3800 B.t.u are required to produce a kwh. Since the cost of most thermal power in the Maritimes for fuel only will be more than three times this amount, one can see the importance of making as much of this type of power as possible.

Uses of Steam

The Bathurst Power & Paper Company Limited mill at Bathurst, N.B. produces mostly chemical pulp. The plant contains a Groundwood mill which produces pulp by mechanical grinding of the wood but most of the pulp production is chemical, that is, cooking wood chips in digesters. These digesters, besides using chemicals, consume large quantities of steam at pressures of from 100 to 150 p.s.i.g. Hardwood is cooked by a semi-chemical process—a short cook and then mechanical defibration; softwood in an acid cook known as sulphite pulp, but the main use of softwood is to produce pulp in an alkali cook. This pulp is known as sulphate or kraft pulp. After the pulp is made, it is washed in vacuum washers, screened and refined. It then goes to the paper machines where the water it contains is first drained by gravity, then squeezed by presses, and finally dried by passing over steam cylinders which use large quantities of steam.

Recovery

In the sulphate process for the production of kraft pulp, large quantities of chemical are required. In order to make this process economical, the chemical must be recovered for use over again. After the chips are cooked the residual liquor, called black liquor, is drained off in the pulp washing process, while the pulp stock goes to the paper machine. The liquor is now ready to go through a process to reclaim the chemicals which it contains. Also, in this liquor are the wastes or wood fractions which are subject to solution under the cooking conditions. The heat value of this material is about 6300 B.t.u. per pound of dry solids. The first stage in the reclaiming process is to concentrate the liquor to about 50% dry solids in high vacuum evaporators. After further concentration in direct contact evaporators, it is then suitable for firing in a furnace where the wastes are burned off. The chemical is melted and runs out at the bottom of the furnace in the form of a red hot slag into a dissolving tank.

Early kraft mill recovery plants were designed chiefly as smelters to recover the chemical, the heat generated in burning the wastes being partly saved, sometimes by heating water. The first steam generating recovery boilers were also designed primarily for recovering the chemical. The quantity of steam generated was not as important as chemical recovery efficiency and operation. Modern recovery boilers are now being built to efficiently recover the chemical and at the same time efficiently use the available heat to produce high pressure steam for power generation.

New Recovery Boiler

In 1956 a decision was made to install a new recovery boiler to take the place of the old overloaded unit which generated about 35,000 lb. of steam per hr. at 175 p.s.i.g. At that time the steam generating plant consisted of two pulverized coal burning boilers operating at 625 p.s.i.g. and 715°F producing 110,000 and 175,000 lb. of steam per hr. and a bank of 175 p.s.i.g. boilers producing about

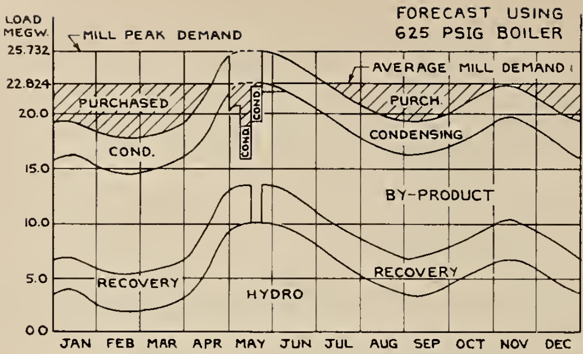

Fig. 1. Power productions forecast curves for 625 p.s.i.g. recovery boiler and turbine.

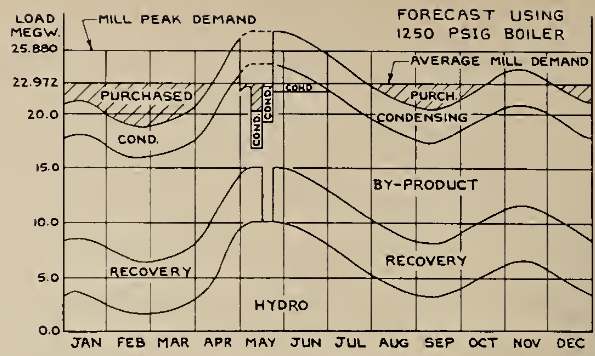

Fig. 2. Power productions forecast curves for 1250 p.s.i.g. recovery boiler and turbine.

80,000 lb. of steam per hr. with coal on underfed stokers. An old bank of Wicks boilers which produced 175 p.s.i.g. steam at about 60,000 lb. per hr. were to be removed to make room for the new recovery boiler installation. The above with the old recovery unit made up a total production of about 400,000 lb. of steam per hr.

The mill power requirements of about 22,000 kw. are met by three sources: thermal power from turbo-generators, with a total capacity of 23,000 kw., 11,000 kw. from the company's hydro plant which has no storage, and a 10,000 kw. transformer tying the plant to the New Brunswick Electric Power Commission network.

The paper machine dryers and all low temperature process work use steam from the 48 p.s.i.g. header which is supplied by back pressure and bleed turbo-generators. Steam at 165 p.s.i.g. is used for the cooking of chips in the digesters and also to run the steam engines driving the paper machines. These engines exhaust into the paper machine dryers at about 36 p.s.i.g. Some of the 165 p.s.i.g. steam is produced on the low pressure boilers but most is exhaust or bleed from turbo-generators.

When the order was placed for the new recovery boiler to operate at 1250 p.s.i.g. and 850°F, there was nobody in America operating a unit burning this fuel above 800 p.s.i.g. and 750°F. In Finland a unit was operating at 975 p.s.i.g. and 850°F. The decision to use these conditions came after making a thorough investigation of the various pressures and temperatures up to 1500 lb. and 900°F. The simplest installation would have been 625 p.s.i.g. and 715°F since it would have tied in directly with the other high pressure boilers. There was no reason why a recovery boiler could not be constructed to operate at high pressures similar to boilers burning other fuels but there was a limit on temperature. There would be quite an advantage in operating at the usual temperature for this pressure of 1000°F but due to the danger and trouble caused by chemical attack and slag adhesion on the superheater tubes, 900°F was considered the limit. At this temperature the whole superheater would have to be stainless steel.

Economy studies were made in which the yield from the additional power available from the higher pressures was balanced against the increased capital cost. The total annual saving from this boiler and turbine is produced from two sources: first, by the saving in coal by producing a greater quantity of steam from the black liquor burned, and second, by the additional quantity of cheap power produced. The old recovery boiler was greatly overloaded and was working more as a smelter. It was working at very low efficiency and producing about half as much steam as should be available from the black liquor. Also, this boiler did not produce by-product power, being one of the first steam generating recovery units in the industry, built by Babcock-Wilcox & Goldie-McCulloch Limited and installed in 1939 to produce 175 p.s.i.g. steam for process. The saving from by-product power produced on the new boiler and turbine is about equal to the saving from burning liquor instead of coal. Thus, one can appreciate the importance now attached to the production of power on this recovery boiler. This boiler then has three important jobs to do: first, recover chemical for the kraft cooking process, second, produce steam from the heat available in the liquor and save coal fuel and third, produce steam at conditions which will allow the greatest return from the production of by-product power.

To make a study, future mill electrical loads had to be estimated and since power produced depends largely on the amount of process steam used, the demand for steam at the various pressures also had to be closely studied and estimated for the future. Many electrical and steam load balances had to be made since the generation would be on three back pressure units which share the load differently, depending on the electrical and steam demands. An example of one of these steam and load balances is shown in Fig. 3. Curves shown in Fig. 1 and 2 are a sample of those used to anticipate the purchased power saved by the increased generation from the new back pressure turbine. The bottom curve shows the average power from the hydro plant. The next block of power is that available from the new recovery boiler and back pressure turbine. Next to this is the block of power from the 625 lb. steam turbines as by-product power. On top of this is a block of power made by one turbine by steam exhausting into a condenser. The level line is the mill load and the block of power between the top curve and the load line is the amount of power required to be purchased from the New Brunswick Electric Power Commission. The savings available from the increase in production by higher pressure steam is the difference between the low cost by-product power and the power purchased from the New Brunswick Electric Power Commission.

The mill power contract with the Commission is one in which either party will help the other when power is available and there is no firm contract. Although this arrangement has worked exceptionally well, it is an advantage to make more power so as to be as independent as possible. The difference in power production between the steam conditions of 625/715 and 1250/850 worked out to be 1500 kw. at the estimated operating conditions.

The percentage yield from the total savings from fuel and power for a 625 lb. installation is about the same as for a 1250/850 installation but the additional yield from the higher pressure gave a very good return on the additional capital cost. With 850°F steam about half the superheater had to be stainless steel and a change to 900°F required additional stainless steel at a cost of about $50,000. The yield from the additional superheater was only about $6,000 so that this would not be an economical choice.

Increasing the pressure to 1500 p.s.i.g. at 850°F decreased the steam volume to such an extent that the turbine blading became too short in the high pressure stages and efficiency was reduced so that only about half the extra available heat would be available in power. To get good turbine efficiency at 1500 p.s.i.g. the temperature would have to be increased to at least 900°F. The yield by increasing from 1250/850 to 1500/900 was only about 5% after paying taxes. Considering the low return and the fact that there was a good possibility of excessive superheater maintenance at this temperature, there was no difficulty in deciding against these conditions.

The design, investigation, and specifications on this job, as on all of our projects, was done by our Engineering Department. The boiler was purchased without auxiliaries such as fans, pumps, instrumentation, heaters, water treatment, etc. Actually, the whole boiler was not purchased from the boiler manufacturer as it was also purchased without the supporting steel.

Method of Firing

The kraft liquor comes from the evaporators at a temperature of about 180°F and contains about 50% solids and 50% water. It looks similar to tar although at this temperature it is similar to water in viscosity. Before going to the furnace it is passed through a direct contact evaporator in the boiler flue gas after it leaves the air heater where the water is reduced to 36% and the solids raised to 64%. The liquor is then pumped to a saltcake mixing tank where the chemical make-up is added to the system. Some of the sodium chemical which is used to cook the chips is lost in washing the chemical from the pulp and also in the form of dust up the stack. To make up for the losses, saltcake is added to the liquor before firing. From the mixing tank the liquor is pumped directly to the burner which is a spray type oscillating nozzle mounted on the front wall of the furnace. The furnace is similar to that used for oil or pulverized coal only it is considerably larger. The liquor is sprayed back and forth and dries on the furnace wall, then falls to the bottom of the furnace where a pile of dried solids forms and burns. The resulting smelt runs out of two spouts at the low side of the sloping bottom into a tank where it is dissolved in weak wash to be pumped to the caustic plant for processing.

For starting, temporary oil burners may be inserted in the secondary air ports that are located on the furnace periphery about seven feet above the bottom of the furnace. Five burners may be used for this purpose and one or more of these may be required to heat up the furnace until ignition of the wet fuel will take place.

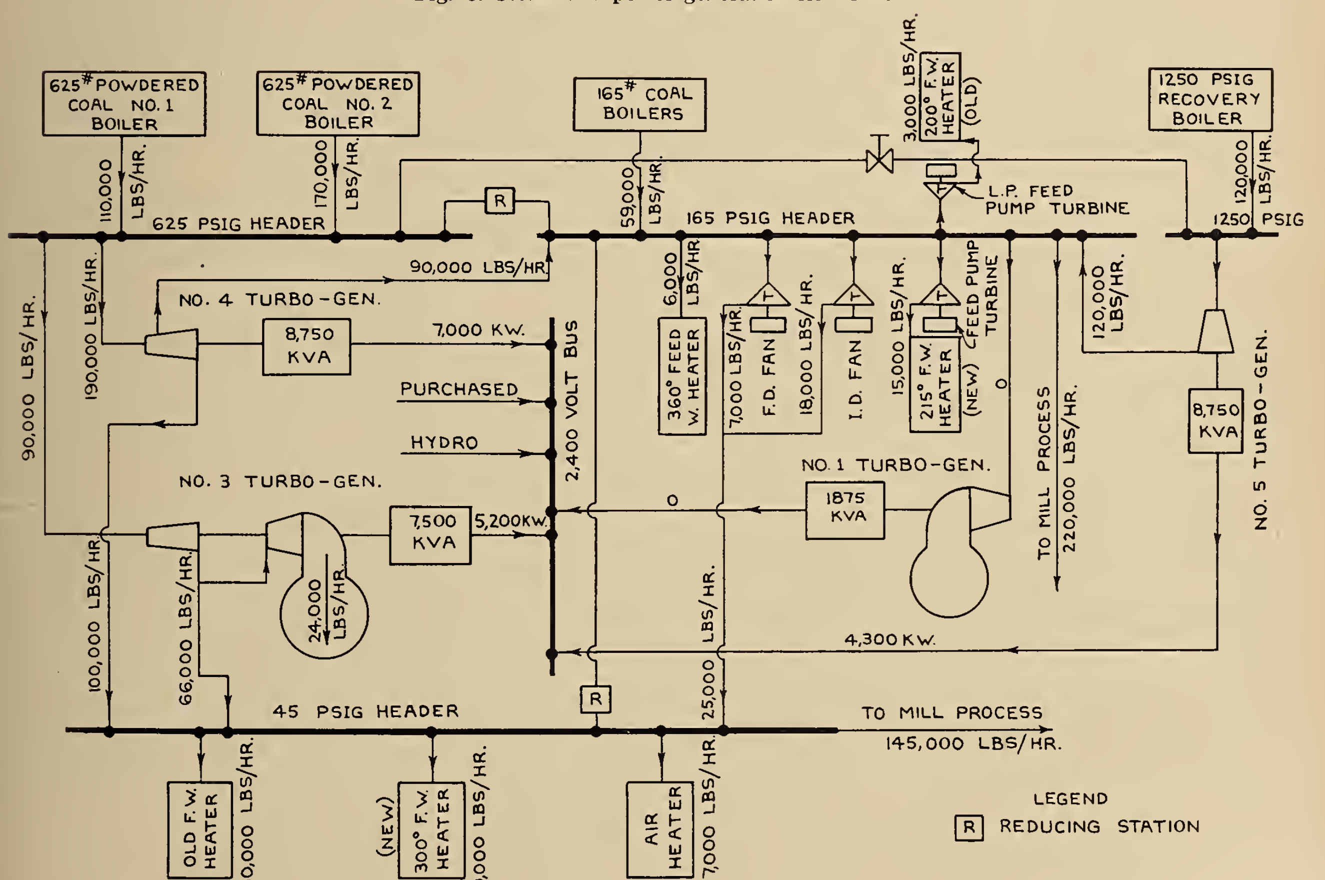
Chemical Recovery for Flue Gas

During the combustion process considerable chemical is carried up the stack and, in a plant of this size, the annual loss can be well over $100,000. There are two methods of recovering this chemical.

One method which has been quite common on recovery boilers is to pass the flue gas through a cascade evaporator, a tank with paddle wheels revolving in liquor so that the liquor is carried up on the paddles and is exposed to the hot gases, then passing the gas through electrostatic precipitators. The gas is kept above 300°F leaving the evaporator so as to keep the gas dry and above the dew point of sulphuric acid in the precipitators.

The other method, and the one

Fig. 3. Steam and power generation flow sheet.



which was selected, is to pass the gas through a venturi evaporator scrubber and a cyclone separator. This is a system developed by Babcock-Wilcox & Goldie-McCulloch Limited for use on their recovery boilers. Bathurst had installed the second venturi scrubber in existence on the old recovery boiler in 1948. This system consists of a venturi section in the boiler outlet duct through which the gases travel at about 250 f.p.s. with a pressure drop of 25 in.-35 in. of water. At the point of highest velocity black liquor is sprayed in through several nozzles. The very high velocity breaks down the liquor into a very fine mist wetting down the chemical dust particles. The gas is then passed tangently into a cyclone tank where the liquor containing the chemical dust is separated, the gas passing out the top to the induced draft fan and the liquor running down the walls of the tank. A pump circulates the liquor from this tank back to the venturi and also to a group of showers at the top of the tank that are used to continuously wash down the tank walls. As the liquor circulates around from the venturi to the tank in the hot gases, water is evaporated until the liquor is at the desired consistency for burning. Liquor for burning is bled off from the circulating pump to the saltcake tank and then to the furnace. This system will average about 90% efficiency in removing the chemical from the flue gases.

The total draft loss through this system is 30 in.-40 in. and the power consumed by the induced draft fans is considerably more than for the first method, but the lower stack gas temperature of about 180°F to 200°F gives an additional 6300 lb. of steam per hr. from the boiler at full capacity. The value of this additional steam and its by-product power is more than enough to pay for the cost of the greater power use by the fans. Although the peak efficiency of the precipitator is slightly higher than the venturi scrubber, for this investigation we estimated the average annual efficiency to be equal. We also estimated the cost of the precipitator installation to be over $100,000 more than the scrubber and the maintenance to be higher also. Even at the high power cost in this area the study showed the venturi to have a considerable saving over the precipitator.

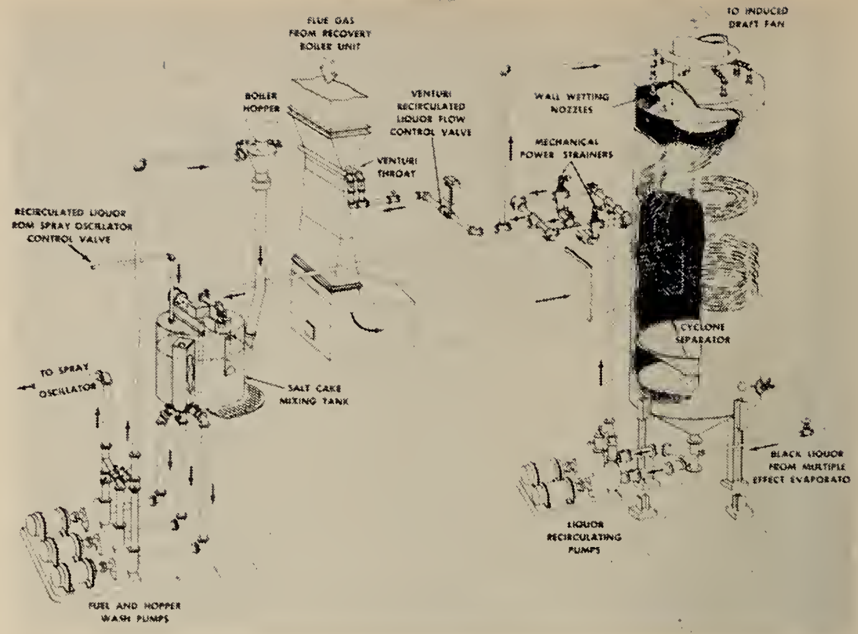


Fig. 4. Venturi scrubber evaporator and cyclone separator.

Boiler Capacity and Supplementary Fuel

It has been the usual practice to rate a kraft recovery boiler in tons, meaning that it is capable of handling the black liquor resulting from so many tons per day of kraft pulp production. This rating actually does not tell much since the amount of heat available from different kraft processes is not the same for all mills. It is generally considered that a ton of production gives 3,000 lb. of solids for burning, but Bathurst's process yields considerably less per ton of kraft production.

Sizing a recovery boiler is perhaps not as simple as sizing a power boiler. First, it is necessary to decide what capacity is required to look after the Kraft mill without adding another unit until this one is worn out, or for at least another 25 years. Normally, a recovery boiler capacity is not very flexible. Due to the wet fuel, ignition will fail unless the furnace is working at about 60% of designed capacity and good operation can be expected up to 20% overload. At normal full load, efficiency is about 64% (based on dry fuel).

For 10% under rating, efficiency is about the same with a drop to about 62% at 20% under rating. At 15% overload, efficiency will drop to about 63% and at 20% overload it is down to 62%. Over 20% overload efficiency falls off rapidly and plugging between the tubes can give a lot of trouble although some boilers have been operated at very high overloads.

Thus, in using one unit, if the above conditions are to be satisfied, it is important to know what the kraft production will be in the future. Many things can change the kraft production; changes in the types of paper board may change the demand or the type of cook required may change the amount of solids available per ton of pulp.

Since the boiler was also to be operated as a power boiler, making cheap by-product power on its own turbine, it would be important to operate it within rather narrow limits in order to get the best efficiency and make it easier to size the turbine. This is believed to be the first recovery boiler in existence operating its own turbine. Other recovery boilers supply steam for power production through a common header with other coal or oil burning boilers.

Although recovery boilers had not been used to burn other fuel with the liquor except for start-up, the solution to most of the above problems in sizing could be solved by burning oil as a supplementary fuel. Burning oil with liquor was considered possible and practical within limits. Furnace temperatures would be increased but this was not expected to cause any trouble as long as the quantity of steam from oil was not much over an estimated 30% of the boiler rating.

With a supplementary fuel there would be no concern with the boiler being slightly large for periods of low production. The oil fire would eliminate the danger of fire failure at low loads. The boiler was therefore sized for our estimated greatest future requirements when running at 20% overload. At full load, designed capacity is 30,625 lb. of black liquor per hr. to produce 123,800 lb. of steam per hr. Two oil burners with a maximum capacity of 40,000 lb. of steam per hr. were installed above the liquor burners to operate only when insufficient liquor is available for full load. Continuous use of the lower start-up burners is not recommended due to their location close to the ash bed and the bottom of the furnace.

In sizing the turbine to take the steam from this boiler, it is quite important, especially with a reaction type turbine, to run it at rated capacity, which is also peak efficiency. Since the quantity of steam produced from liquor may vary considerably the turbine would operate much of the time at reduced efficiency. With a supplementary fuel the turbine could be designed to operate at 120,000 lb. of steam per hr. and run continuously at this load. Liquor might produce only 90,000 lb. of steam per hr. but the oil burners could automatically keep the steam flow at 120,000 lb. per hr.

In sizing the unit, it was necessary to decide on the advantages of one new large unit as against using the old low pressure boiler, which was only 17 years old, and a smaller high pressure unit. The advantages of the large unit were quite obvious and the study showed the one large unit to give an annual saving of about $250,000 over the two units.

Although the cost of oil at present prices (bought in tank cars) is higher than coal, the extra steam made by oil gives a good yield because of the larger amount of by-product power available from the 1225 p.s.i.g. turbine.

Maximum Amount of 1225 p.s.i.g. Steam

Due to the fact that cheap power from hydro is not available in the Maritimes, it is very important to produce as much by-product power as possible. For this reason, every effort has been made to produce the maximum amount of steam from this 1250 lb. unit. The other high pressure boilers use feed water at 295°F but in this one the temperature was increased to 360°F by heating in a closed heater with 165 p.s.i.g. steam. Air enters the air heater at 250°F after being heated with 45 p.s.i.g. steam in a steam coil air heater and enters the combustion chamber at 370°F. This, of course, does not increase the mill steam supply but it does make more by-product power by circulating more heat through the turbine and back to the boiler. The boiler was originally quoted on a design using liquor at 57% solids but greater heating surface was added to the economizer and air heater so that liquor could be fired at 64% solids. It is much more efficient to evaporate water in high vacuum evaporators where several pounds of water can be evaporateed with one pound of steam than to evaporate in the furnace at atmospheric pressure. With the changes made in this unit it now produces more heat in the form of steam from a pound of black liquor solids than any other unit in existence.

Drives for Auxiliaries

There is perhaps a tendency sometimes to overlook some of the advantages in using turbine rather than electric drives for auxiliaries. If a plant is purchasing high cost power such as is produced by a condensing plant and is using low pressure process steam, then the small turbine drives offer an opportunity to make some cheap by-product power for pumps or fans. The fact that pumps and fans can be run slower to effect control with a considerable power saving than to waste power in throttle valves or dampers is very generally accepted. There is another good reason for using turbines on auxiliaries in power plants or mills where the exhaust steam can be used for process, and this also applies to plants generating their own by-product electric power. Every electric motor has to be backed up with a turbo-generator which costs about four times the cost of the motor per horsepower. The capital tied up in a 500 hp. motor drive may be about $50,000. The same size turbine will cost about $5,000 and when piping is added the motor installation is still probably five times as much. The large turbine will have a slightly better efficiency than the small one, but with the motor drive we have the electric losses in both the motor and the generator which are more than enough to make up for the difference in the turbine efficiencies.

The main turbo-generators exhaust into the 165 p.s.i.g. and 48 p.s.i.g. headers. By installing two open heaters, one to operate at 2 p.s.i.g. and one at 45 p.s.i.g., an opportunity is provided to exhaust one 500 hp. turbine at 2 p.s.i.g. and thereby gain a little more by-product power.

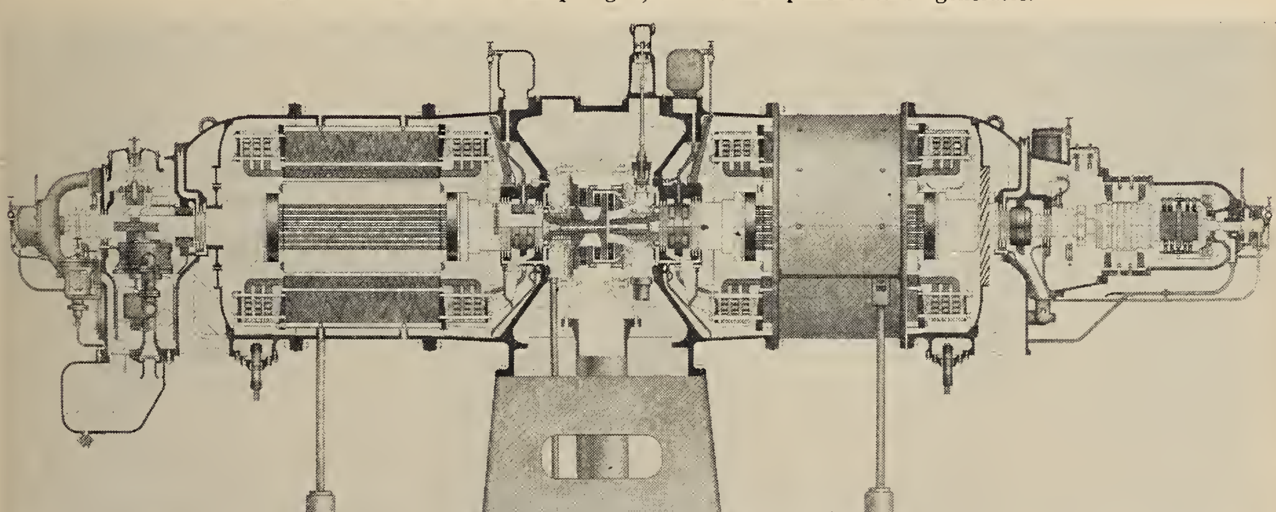
Boiler

The two drum 16 ft. 9 in. wide boiler has a height of 95 ft. and a furnace volume of 14,020 cu. ft. Heating surfaces are 4.070 sq. ft. in the furnace, 16,357 for the boiler, 10,280 in the economizer and 10,600 for the gas air heater. The superheater is a pendant two stage type with a heating surface of 7,928 sq. ft. and having about half of the tubes made of stainless steel. This boiler is comparable in size to that of a boiler operating on coal with a steam capacity of about 300,000 lb. per hr.

Boiler Cleaning

The main body of the boiler is cleaned by 13 retractable automatic

Fig. 5. Sectional view of 1225 p.s.i.g. 7,500 kw. back pressure turbo-generator.



sequential soot blowers operating with up to 300 p.s.i.g. steam from the 625 lb. system. The economizer and air heater are cleaned by a shot cleaning system in which a batch of steel shot, ¼" x ¼" punchings, is carried by air to the top and falls down through the units. The system is automatic and the intervals of operation can be set at the control panel. The system is run by compressed air at 150 p.s.i. but to cut down on the size of compressor and storage the air is compressed to 300 p.s.i.g.

Feed Water Heaters

Feed water is supplied from the water treatment plant to the 2 p.s.i.g. open heater which has a storage of about ten minutes at full capacity. Steam is supplied from the boiler feed pump drive turbine exhaust and a reducing valve from the 48 p.s.i.g. header.

Deaerating of feed water is done in the 48 p.s.i.g. heater which raises the water temperature to 295°F before entering the feed pump. This heater has a storage of about two minutes at full capacity.

The closed heater is located in the feed pump line and operates at 165 p.s.i.g. steam pressure to deliver 360°F water to the economizers. Economizer outlet temperature is 475°F.

Boiler Feed Pumps

Two single casing, 12 stage, centrifugal boiler feed pumps, rated at 180,000 lb. of water per hr. at 3800 ft. head or 1,525 p.s.i.g. running at 3600 r.p.m. are used. One, driven by a 535 hp. steam turbine, will be used normally and one with an induction motor is used as a spare. The turbine takes steam at 160 p.s.i.g. and exhausts at 2 p.s.i.g. When the turbine is used, the feed water level control adjusts the turbine speed to keep the pressure across the feed water control valve at 75 p.s.i.g. Feed water is automatically bled back to the heater if the feed water flow goes below 50 g.p.m.

There has been a definite swing to double casing boiler feed pumps today. This is certainly justified when the boiler operating pressures get above 1500 or 1800 p.s.i.g. but, in the writer's opinion, for the 900 to 1400 p.s.i.g. plants it is a waste of money to use these pumps. Not only is the cost of the pump double, but when the pump has to be worked on, the maintenance cost is much higher also. Apparently some of the manufacturers discontinued this line of boiler feed single casing pumps for 1200 to 1800 p.s.i.g. rating after they started making the double casing pumps and are now recommending double casing pumps for all plants above 1000 p.s.i.g. This is especially bad for the smaller installations where the cost of feed pumps is a rather large part of the cost.

Fans

The forced draft fan has a capacity of 55,000 c.f.m. at 15 in. H_2O and is driven by a 175 hp. turbine with a 4500/1245 r.p.m. reduction gear. Turbine speed is controlled automatically by the air requirements of the boiler. This turbine is designed to take steam at 160 p.s.i.g. and exhaust at 45 p.s.i.g. but the exhaust is also piped to go to the 2 p.s.i.g. heater, if desired.

The induced draft fan requirements on a recovery boiler equipped with a venturi scrubber are unusually high compared to most boilers. Two fans running at 1170 r.p.m. with a combined capacity of 91,000 c.f.m. at 48.1 in. of water operating at 200°F are connected in series. One is driven by a 470 hp. turbine with a 4500/1150 r.p.m. reduction gear taking steam at 160 p.s.i.g. and exhausting at 45 p.s.i.g. and the other by a 500 hp. induction motor. This electric motor driven fan is operated with a slight amount of throttling and the draft is controlled by first opening or closing the damper for quick response and then changing the speed of the turbine. This is done automatically by the combustion controls.

For simplicity and economy a single fan arrangement was at first much preferred. There was considerable resistance to this on the part of some of the fan manufacturers due to the high peripheral speed of about 31,000 f.p.m. for the fan wheel. The fan wheel was specified to be type 316 stainless steel in order to combat corrosion. This material does not stand up well under fatigue and the manufacturers were afraid of failure due to a calculated periphery stress of 23,000 p.s.i. Some of the manufacturers did agree to build a single large fan, but on further study it was decided that because of the high stress and also because there was a spare 400 hp. motor from the old venturi fan available, the double installation was selected. The boiler can be run at part load with one fan. Due to the high cost of stainless steel in the large fan casings, only the wheels and the entrance cones to the wheels were made of stainless steel. The remainder of the fans was made of ½ in. thick cor-ten steel.

Stack

From the first, it was planned to use a steel stack supported on the roof and the building steel was designed to carry a 75 ft. high, 5 ft. dia. stack made of ½ in. mild steel. As the job progressed and more thought was given to the stack and its erection, it was found that a light weight stainless steel stack would save considerably in erection cost and then there would be no concern about corrosion. The height was needed to carry the wet chemical fumes away from a brick stack which was close to the new stack. Finally, since the brick stack would be taken down in a few years and 25 ft. would have to be taken off the top immediately, it was decided to reduce the height of the stainless steel stack to 40 ft. A stainless steel stack, with the bottom half of 3/16 in. and top half of ⅛ in. material, was purchased. It was erected by clamping a mild steel frame to the bottom of the stack and connecting it to the portion through the roof with a pin hinge. Chain blocks were fastened to the top of the steel frame and the frame pulled down so as to tip the stack up into place. The hinge and framework were then removed.

Piping

All plant piping was designed by the company's Engineering Department including the main 8 in. steam line to the turbine. The main steam pipe and header were fabricated in Montreal and shipped to Bathurst in large sections. Erection of this pipe was contracted to an outside firm since the company did not have the necessary stress relieving equipment nor welders experienced in welding this material.

Liquor Pumps

Probably the only difficult pumping job of special interest is the pump taking the heavy liquor from the cyclone evaporator tank and pumping to the venturi scrubber and showers. This pump has a capacity of 1550 U.S.G.P.M. at 124 ft. head with liquor at 65% solids and is driven by a 200 hp. motor.

The heavy liquor gives difficult suction conditions and on similar installations in the past it was considered that only a 1200 r.p.m. pump could be used. It was found that of the pumps available, a more efficient selection could be made with a 1750 r.p.m. pump. Seeing that with the proper suction conditions there was no reason why the higher speed pump would not perform just as well, it was selected for continuous use and a slow speed pump, as recommended by the boiler manufacturers, was selected for a spare. Since starting up, the high speed pump has been preferred by the operators.

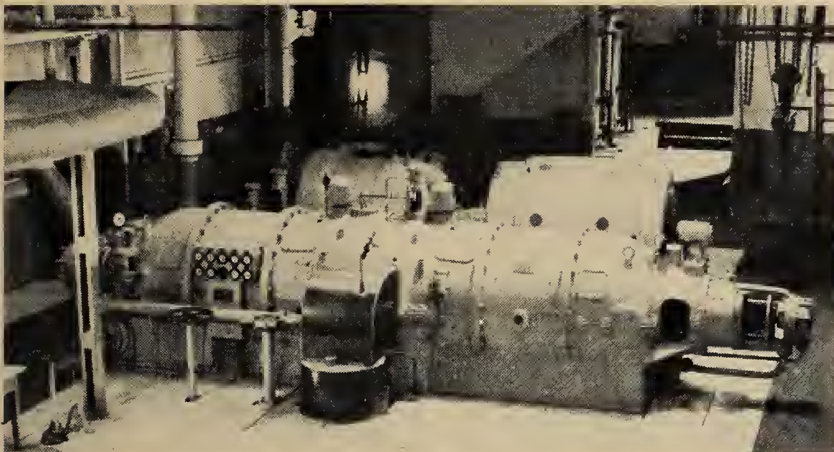


Fig. 6. New 1225 p.s.i.g. 7,500 kw. back pressure turbo-generator installed in turbine room.

Instrumentation

The instrumentation on this boiler is probably more extensive than is usual for boilers of this type. As a result, the boiler can normally run on automatic control with only occasional adjustments being made by the operators. Also, the normal complement of four operators has been cut to two. Further, the precise control afforded by a properly designed instrumentation program allows the boiler operators to more closely approach the efficiency inherent in the recovery plant.

Some of the control features include:

(a) Three-element drum level control which also controls feed water flow;
(b) Feed water pressure and pH control;
(c) Steam pressure and temperature control;
(d) Oil and black liquor flow control;
(e) Air fuel ratio control;
(f) Excess air control;
(g) Fuel temperature control;
(h) Black liquor density control;
(i) Draft control;
(j) Strategic furnace gas differential indication;
(k) Strategic water, steam, gas and air temperature indicators. Some of the more important are recorded and/or tied to an alarm system;
(l) Tank level control and indication;
(m) Integration of water, steam and black liquor flow;
(n) Remote controls allowing the operator to completely control the boiler from the control panel.

Water Treatment

Since so much of the steam is used in process for cooking and direct heating, approximately 50% raw water make-up is required for the boilers. With this large amount of make-up, the present internal boiler water treatment on the 625 lb. boilers was not considered satisfactory and some improvement was preferred if additional high pressure boilers were to be added.

With the 1250 p.s.i.g. boiler it is essential that pure water is provided and this required the installation of a raw water clarifier, filters, and a complete demineralizing system. Effluent contains less than 1 p.p.m. dissolved solids and less than 0.02 p.p.m. dissolved silica.

Some of the condensate returns would be clean but there was a chance that some pollution could occur. It was therefore decided to return all condensate to the 625 p.s.i.g. boilers and to install a mineral exchange plant to use all raw treated water for the new boiler. This water plant was installed with an initial capacity of 300 U.S.G.P.M. but it was designed so that its capacity can be inexpensively doubled.

Semi-automatic equipment was installed to control flow, chemical feed and demineralizer regeneration. Chemicals used are alum, sodium aluminate, sulphuric acid and caustic soda.

Economizer on Dissolving Tank

There is a considerable amount of heat liberated in the dissolving tank from the chemical smelt. Also, steam showers are used to break up the streams of smelt to reduce the noise caused by the smelt entering the water. This tank is normally vented to atmosphere through the roof. To save a large part of this heat, an economizer system was installed to use this waste heat to heat air for the furnace from zero in winter up to 150°F before entering the steam coil air heater.

Oil Supply

For the present, oil is purchased by rail in tank cars and only a small storage tank of about 40,000 gal. is used. Winter harbour facilities are not available due to ice, so purchasing cheaper oil by tankers would require large storage facilities. These will be considered at a later date if considered economical.

625 lb. Operations

The recovery boiler, as part of the kraft pulp process, must run when the pulp mill runs. Normally, the 1250 p.s.i.g. steam is reduced to process 165 p.s.i.g. steam through the turbine. If anything should happen to the turbine or if it were down for overhaul, the liquor must be burned and the boiler kept operating with a method of using the process steam.

Instead of installing a reducing station between the 1250 lb. and 625 lb. heaters, only a stop valve was installed. The boiler has been designed with additional circulating rises to operate properly at both 1250 and 625 lb. and if the turbine is down, the boiler will be operated with the steam going into the 625 lb. header. Actually, the boiler is started up by feeding steam to this header. After the turbine has been started on 625 lb. steam, the stop valve is closed and the pressure then is raised to 1250 lb.

Turbine

For some time we had been interested in the radial flow, double rotation type of turbine. This turbine was invented in 1912 by Birger and Fredrik Ljungstrom of Sweden. It has not been too well known in North America but has had considerable success in all other countries of the world.

The design is a radical departure from the conventional turbine in that it has no stationary blading. It is a reaction turbine with the blading mounted on two wheels turning in opposite directions. Steam enters at the center of the wheels around the shaft and expands radially through the blades towards the circumference. Small size is possible due to the high relative velocity of the blading travelling in opposite directions, and narrow blades of the small unit tend to give somewhat better efficiency.

The turbine in the Bathurst unit is especially small due to the high inlet and exhaust pressure. The water rate on this unit is 7% lower than that of the nearest competitor from which quotations had been obtained. This small turbine, having a blading assembly measuring only 15 in. long and 20 in. diameter, can develop 12,000 hp. and is probably the most powerful engine in existence for its size.

W. D. Hurst, M.E.I.C., *City Engineer and Chairman of Commissioners, Greater Winnipeg Water District.*

F. Gordon Denson, M.E.I.C., *Engineer of Waterworks, Engineering Department, City of Winnipeg.*

This paper will be presented at the Annual General Meeting of the Engineering Institute of Canada, Winnipeg, May 1960.

THE CITIES of Winnipeg and St. Boniface and the suburban municipalities by the incorporation of the Greater Winnipeg Water District in 1913, commenced the development of a permanent water supply system with construction of an aqueduct to bring a supply of clear, pure, medium-soft water from an arm of the Lake of the Woods known as Shoal Lake, 97 miles east of the metropolitan area.

Shoal Lake is some 290 ft. higher than prairie elevation at Winnipeg, and advantage was taken of this fact to deliver water under open flow conditions through a horseshoe shaped conduit of plain concrete varying in dimension from 10 ft. 9 in. x 9 ft. 0 in. to 6 ft. 4¾ in. x 5 ft. 4¾ in. for some 80 miles. From the west end of the horseshoe section there is a depressed section of reinforced concrete pressure pipe 8 ft. in diam., 4 miles long to a reservoir site at Deacon (Mile 13).

From Deacon (Mile 13) to St. Boniface (Mile 5) a 5 ft. 6 in. diam. reinforced concrete pressure pipe carries the water to a surge tank on the eastern bank of the Red River. The water then passes into a 5 ft. diam. cast iron pipe in tunnel under the Red River, and thence through a 4 ft. diam. reinforced concrete pipe through the streets of Winnipeg to an 18 million gal. covered concrete reservoir (McPhillips Street Reservoir) in the north-western part of the City (Mile 0). The 5 ft. 6 in. reinforced concrete pipe was provided with 36 in. off takes at Transcona and St. Boniface where these cities maintain pumping equipment to pump directly from the aqueduct into their respective distribution systems.

When the supply came into service in March, 1919, St. Boniface was required to pump water to the Municipality of St. Vital and to supply itself while Winnipeg was required to undertake the supply of all the other municipalities except the Town of Transcona.

The maximum capacity of the aqueduct between Shoal Lake and Deacon was 85 million imperial gallons per day, but the capacity of the pressure section between Deacon and the McPhillips Street Reservoir was only about 35 million imperial gallons per day when the demand to both Transcona and St. Boniface was high.

In 1929-1931 the City of Winnipeg constructed a 50 m.i.g.d. pumping station (since increased to 67 m.i.g.d.) and a 40 m.i.g. reservoir of the open concrete lined earth embankment type at McPhillips Street immediately adjacent to the 18 m.i.g. existing covered concrete reservoir. Fears were expressed at the time as to the wisdom of operating an open reservoir in the City considering the possibility of pollution, the development of algal growths, and damage to the reservoir itself by soil action and prolonged periods of sub-zero temperatures. These fears have proven to be groundless except for one period of severe algal growth and resultant taste and odour troubles (since overcome by the continuous feeding of copper sulphate during the summer season at the intake and the use of breakpoint chlorination).

The system described above remained from 1919-1950 almost without change but in 1949, owing to the substantial post war growth of the Winnipeg area, it became difficult to deliver sufficient water to the McPhillips Street Reservoir by gravity.

The Greater Winnipeg Water District, in 1950, built a 40 m.i.g.d. booster pumping station in St. Boniface which pumped water from the surge tank across the Red River to McPhillips Street thus making available at the McPhillips Street reservoir a supply of 38 m.i.g.d. using 2—20 m.i.g.d pumps or 42 m.i.g.d. using 3—20 m.i.g.d. pumps. With the installation of this station the District could fully develop the capacity of the 5 ft. 6 in. line to 50 m.i.g.d.

Major Improvement Programme

It soon became apparent, however, that this was a stop-gap measure and therefore the City of Winnipeg and the Greater Winnipeg Water District became jointly engaged in the first major expansion of their water works facilities in the past 40 years.

The engineering staffs of the Greater Winnipeg Water District and the City's engineering department, in 1952, made a joint study of the problem and as a result the City Engineer recommended to the City Council that—

1. New pumping and storage facilities be established near the south-western boundary of the City;
2. A 36 in. diam. tie feeder main be constructed to join the McPhillips Street Pumping Station on the north-western edge of the City with the new reservoir and pumping station to be established near the south-western boundary;
3. A 5 yr. programme of distribution main improvements be undertaken;
4. The proposed programme be undertaken on the condition that when the new reservoir and pumping station is constructed by the City the Water District provide the second branch aqueduct line to feed the new facilities.

The joint committee believed that the new reservoir, pumping station and branch aqueduct would be required some time between 1960 and 1965 and that the reservoir should have a capacity of 80 million gal. to provide a two day supply of water in the event of a failure occurring on the aqueduct east of Deacon.

The recommendations of the City Engineer were accepted and the City commenced the programme by construction of enlarged distribution mains.

In 1956, it became apparent, because of rapid population growth, that the cross-town tie feedermain would have to be commenced immediately to be followed by the construction of the new 80 million gal. reservoir, pumping station and branch aqueduct. The Greater Winnipeg Water District then undertook the preparation of plans for a 66 in. pressure pipe line from Deacon (Mile 13) to the proposed Wilkes Avenue reservoir in south-west Winnipeg. In addition the District came to the conclusion that it would have to take measures to ensure that 85 m.i.g.d. could be introduced into the aqueduct at the intake under any possible low lake levels. Studies were undertaken to determine whether this might best be accomplished by the construction of a dam at the entrance to Shoal Lake, or by the construction of a pumping station at the intake. The Districts' engineers ultimately recommended construction of the low life pumping station at the intake.

Construction of New Works

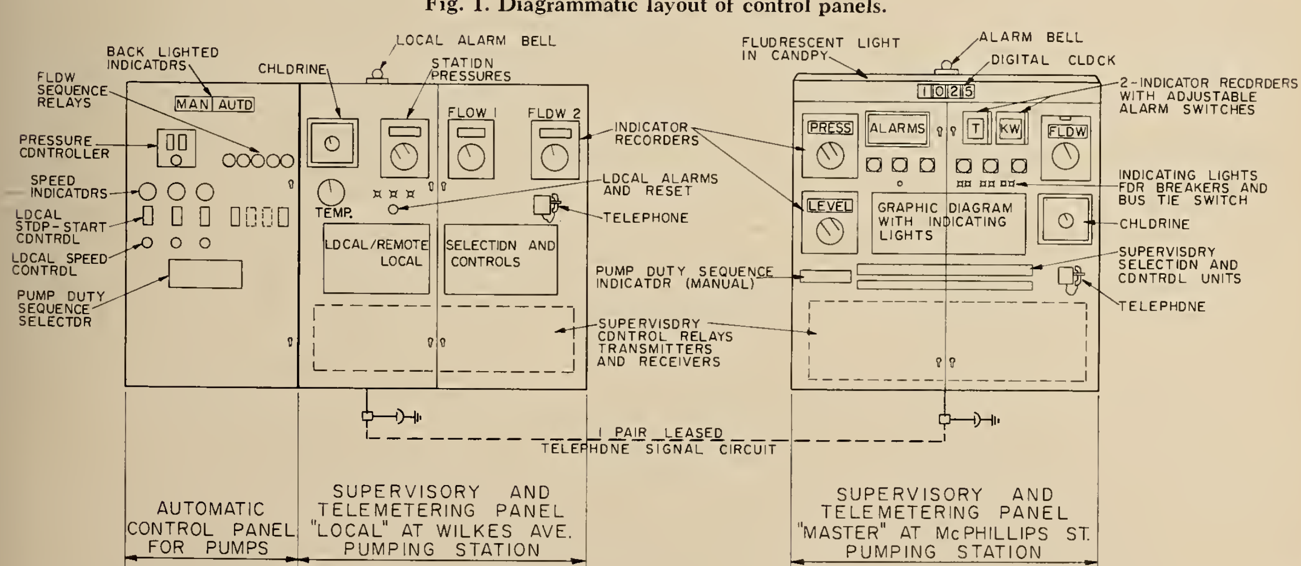
Construction began in 1956 with the installation of the 36 in. cross-town feeder main. In 1959 construction commenced on the branch aqueduct line, the low lift station and intake at Shoal Lake and the new reservoir and pumping station in south-west Winnipeg.

The details of the work carried out by the City of Winnipeg follow:

(a) *Balancing (or tie) Main:* The 36 in. balancing main (fully constructed) will act primarily as a feeder main in the Winnipeg distribution system, but is designed so that in an emergency, it can be isolated and used as an alternate aqueduct to feed either reservoir, if a branch of the aqueduct is ever out of service. This complete main will consist of some 22,000 ft. of prestressed concrete cylinder pipe with a short 24 in. pipe connection to the new reservoirs, and includes a watermain bridge crossing over the Assiniboine River.

(b) *Wilkes Avenue Reservoir:* The new reservoir is currently under construction and with all piping and valves will cost about $1,475,000. It is situated near the corner of Waverley Street and Wilkes Avenue in South Winnipeg. This reservoir will be of the open, earth embankment type, with a 6 in. thick plain concrete lining on the bottom and a 6 in. reinforced concrete lining on the sides. It will consist of two separate basins with piping and valves so arranged that each basin can be operated independently to facilitate cleaning and maintenance. Each basin will have a capacity of 40 million gal. and it is estimated that the additional 80 million gal. will provide Winnipeg with adequate storage facilities up until approximately 1980. This reservoir has been laid out to utilize only one half of the total reservoir site, and hence the total ultimate storage which can be

Fig. 1. Diagrammatic layout of control panels.



provided at this site is 160 million imperial gallons.

The side slopes of the reservoir embankment are 3:1 on the water side and 2:1 on the outside. The floor of each basin is to be graded so that it will drain by gravity into three drainage structures located near one end of each basin. This drainage will then be carried by a 24 in. diam. sewer to a lift station, where it will be lifted into the City's combined sewer on the adjacent street.

The concrete lining was poured in panels. The floor panels are non-reinforced concrete poured in 15 ft. strips, highway fashion with dummy contraction joints every 15 ft.

The wall panels are reinforced with bar mats and are approximately 20 ft. square with the lowest row of panels being approximately 20 ft. by 40 ft. No expansion joints are used except around rigid structures, all of the joints between wall panels are of the butt type, contraction joints with dowel bars, and 6 in. Polyvinyl-chloride waterstops are installed along all of the joints in the wall slab.

All of the inflow, outflow and inter-connecting piping at the reservoir is prestressed concrete cylinder pipe, and was manufactured at a temporary plant set up primarily for the 66 in. diam. pipe for the Greater Winnipeg Water District aqueduct.

All of the valves at the reservoir, with the exception of the two inlet valves, are to be rubber-seated butterfly valves.

The 54 in. diam. and 48 in. diam. inlet valves will control the flow from the aqueduct into the reservoir and are to be square bottom throttle construction horizontal gate valves. These will be automatically controlled according to Reservoir Levels.

Wilkes Avenue Pumping Station

The Wilkes Avenue Pumping Station now under construction is located immediately adjacent to the reservoirs. A 54 in. diam. suction header within the station is supplied from the reservoirs at both ends through 54 in. butterfly valves and it is sectionalized by a similar valve at mid point. The 48 in. diam. station discharge header with dual discharge arrangement is similarly valved and a venturi tube is located on each discharge outside the station, each rated 3 to 30 m.i.g.d.

The initial installed pumping capacity of the station is 60 m.i.g.d. consisting of two electrically driven pumping units and three dual driven pumping units. Provision has been allowed for the future installation of two 20 m.i.g.d. electrically driven

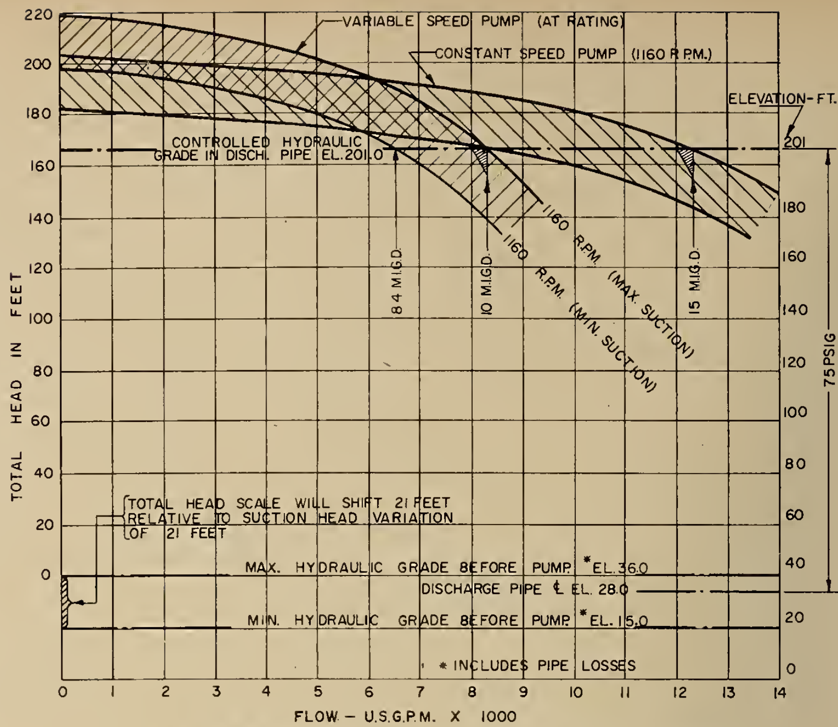


Fig. 2. Characteristic curves for 10 and 15 m.i.g.d. pumps.

pumping units to provide an ultimate installed capacity of 100 m.i.g.d.

The present pumping equipment is as follows—

Three Variable Speed Pumping Units:

Each unit is dual driven with a 450 hp. 1180 r.p.m. constant speed squirrel cage induction motor in line with a scoop-controlled fluid coupling on one side and a variable speed gas engine in line with a centrifugal clutch on the other.

(a) Pumps: Type: Double Suction, horizontal, centrifugal. Size: 16 in. suction x 14 in. discharge. Rating: 10 m.i.g.d. at 165 ft., 400 hp. at 1160 r.p.m.

(b) Gas Engine: Type: 4 stroke spark ignition V-12. Fuel: Natural Gas. Rating: 450 b.hp. at 1200 r.p.m. Governor: Pneumatic-hydraulic 0.5% accuracy 3-15 p.s.i.g. air input, 1025 to 1160 r.p.m. speed range.

Two Constant Speed Pumping Units:

Each unit is single driven with a 600 hp. 1180 r.p.m. constant speed squirrel cage induction motor. Type: Double Suction, horizontal, centrifugal. Size: 16/20 DH 20 in. suction x 16 in. discharge. Rating: 15 m.i.g.d. at 165 ft., 580 hp. at 1160 r.p.m.

Control Systems for Wilkes Avenue Pumping Station

The application of supervisory control and telemetering equipment to operate a large waterworks pumping system from a central operating and/or data logging station, is not by any means new and the systems described in this paper are of a conventional type.

Similarly, instrumentation has been employed for many years to provide a signal proportional to pressure, flow or any other variable in order to control automatically the operation of pumps and other equipment. Again, the combined "pressure-flow" system described in this paper is based on conventional practice.

However to the best of the authors' knowledge, there is no other major utility system where supervisory and automatic control have been previously combined to control constant speed (electric) pumps and variable speed, dual driven (electric-gas) pumps discharging into a closed distribution system having no elevated system storage; and where such a closely regulated discharge pressure is required under all extremes of flow demand including power failure conditions and peak load operation.

It is proposed to consider the supervisory and automatic control systems separately so as to obtain a better understanding of the basic functions of each. Although both systems have to be carefully co-ordinated and interlocked, they operate separately and either may be used to control the pumping units. Thus the satisfactory operation of the pumping station is not solely dependent upon possible weak links or operational failures of either system.

Supervisory Control System

In order to accomplish the required remote manual control of the present and future pumping units together with the telemetering and alarm requirements, it was necessary to provide for the transmission of approximately 80 functions between the existing McPhillips Street Pumping Station (referred to hereafter as the Master Station) and Wilkes Avenue Pumping Station (referred to hereafter as the Local Station). These comprise the following:—

For each variable speed pumping unit:

Stop-start and indication of the electric motor.

Increase-decrease speed control of the fluid coupling.

Stop-start and indication of the gas engine.

Increase-decrease speed control of the gas engine.

For each constant speed pumping unit:

Stop-start and indication of the electric motor.

It should be noted that these supervisory controls may only be operated when the system is selected to operate on remote manual control in preference to the normal automatic control system. This selection may be made over the supervisory control system from the Master Station or manually at the Local Station. Red and green lights however will indicate the operating state of each unit irrespective of which system is in control.

In addition, when under manual control, the units may either be controlled over the supervisory system by an operator at the Master Station or by an operator at the Local Station, as determined by the position of local/remote selector switches at the Local Station. These switches will normally be set in 'remote' to provide control over the supervisory channels, but if selected to 'local' they will block the supervisory control, and warn the Master Station operator that he no longer has control.

Controls are also provided for the 6 butterfly valves in the suction and discharge headers and for the standby generator unit.

Telemetering: The actual pump speed will be continuously telemetered and indicated at the Master Station.

The flow from the discharge header through each Venturi will be separately indicated, totalized and recorded at the Local Station and will be summated to provide total station flow which will be continuously telemetered, indicated and recorded at the Master Station.

The Master Station will also be provided with a continuous indication and for certain functions a record of the following:

Suction and Discharge header pressures

Reservoir Levels

Station Power (kw), Voltages and Temperatures

Residual chlorine dosage of the pumped water, following its automatic chemical treatment prior to pumping.

These readings will enable the operator at the Master Station either to check on the correct functioning of the pumping units if the system is under automatic control or alternately to select pumping units and control their speed to meet discharge pressure requirements for any system flow conditions if the system is under manual control.

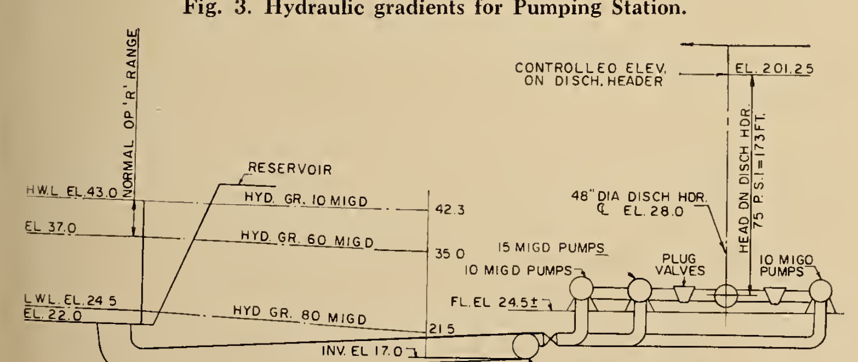
The control panel at the Master Station will be provided with a graphic diagram of the pumps and valves at the Local Station to facilitate manual control.

A diagrammatic layout of the control panels at both stations is shown in Fig. 1.

Safety Provisions and Alarms: Apart from normal overload protection, each motor and pump is provided with thermal switches in each hearing or other critical location, which, in the event of high temperature, are arranged to shut down the unit in question and initiate a common audible alarm at the Master Station. The appropriately engraved section of an annunciator panel is simultaneously lighted providing visual indication of the trouble until the condition is corrected.

Each gas engine is equipped with the normal protective devices incorporated with its automatic starting panel, which shut down the engine in the event of alarm conditions. Actuation of any of these devices also initiates at the Master Station a general alarm for the specific engine in the manner described previously for the motors.

Fig. 3. Hydraulic gradients for Pumping Station.



Alarms operated from the telemetered signals are provided to warn the Master Station operator of high or low pressure conditions, high or low reservoir levels or if the station temperature exceeds desired limits.

Alarms are also provided for general protection of the station and these comprise: gas leakage; carbon dioxide fire protection release; chlorine leakage; burglary; station flooding.

It may be noted, that, if the latter alarm reaches a preset level, valves in the ends of the suction and discharge headers close automatically to isolate the station from the system and reservoirs; and the pumping units are shut down.

Types of System: The Supervisory system was designed to operate over a single pair telephone circuit to be leased from the Manitoba Telephone System and the equipment was specified to operate within the normal communication circuit limitations, namely — Maximum impressed AC voltage, 120 v.; Maximum current, 350 ma.; Maximum signal level across a 600 ohm balanced impedance, 8 db.m. at any frequency.

All signals will be in the audio frequency range from 400 to 3400 cycles per sec. and it will be possible to provide telephone voice communication over the same channel without undue interference by the use of a low pass filter having a cut-off frequency in the order of 2000 cycles per sec.

Actually eighteen separate tone channels will be supplied. These will be utilized as follows:

Channel 1—Station check, point selection and control signals from Master Station to Local Station.

Channel 2—Confirmation signals from Local to Master Station.

Channel 3—Alarm signals from Local to Master Station.

Chanel 4 to Channel 17—Continuous telemetering signals.

Channel 18—As called for telemetering signals.

The system has an ultimate capacity to handle many additional control functions because it will use a 3 digit code for selection and control using rotary stepping switches to produce the pulses.

Selection of a point at the Master Station will set up the corresponding digital code and pressing the 'operate' button will cause the correct train of pulses to be transmitted via a tone generator to the Local Station. Here a tone receiver will supply a code translation circuit which will operate only the required relays through telephone type crossbar switches.

Within the scope of this paper it is only possible to outline briefly the type of operation and state that each code will be carefully checked to prevent false operation and that the time taken to select, check, operate and receive confirmation of a control function will not exceed 3 seconds.

The equipment generally will be designed for long life, minimum maintenance and utmost flexibility. Relays and switches will be telephone type, enclosed in dust proof cases and designed for at least 10 million operations. The audiotone equipment will be transistorized and plug-in units will be utilized where possible.

The power supplies were originally intended to be provided by a station battery of the nickel-cadmium type, but in view of the necessity of providing an alternating current power supply at 120 v. 60 cycle for the time-impulse telemetering equipment (transmitters and recorders), a standby gas engined alternator will be installed to provide all standby power. This has the added advantage that the normal ventilation fans, sump pumps and similar equipment may be maintained in operation during a Hydro System power outage.

Automatic Control System

The original concept of controlling this unattended pumping station by a completely automatic system developed partly due to economic considerations and partly to provide a more accurate control of system pressure capable of faster response to operating requirements.

Due to the physical arrangement of the pumping equipment and its control the operator at the Master Station is normally fully occupied in controlling that station manually. Until such time as the pumping equipment there is modernized to provide for panelboard control (similar to the supervisory system) additional operators on a four shift basis would be required to control Wilkes Avenue on a manual basis over the supervisory system from the Master Station. In view of such requirement and considering the present rates paid to operating personnel, an expenditure of as much as $100,000 for an automatic control system can be justified. In fact, the cost of the automatic system will not exceed 20% of that figure.

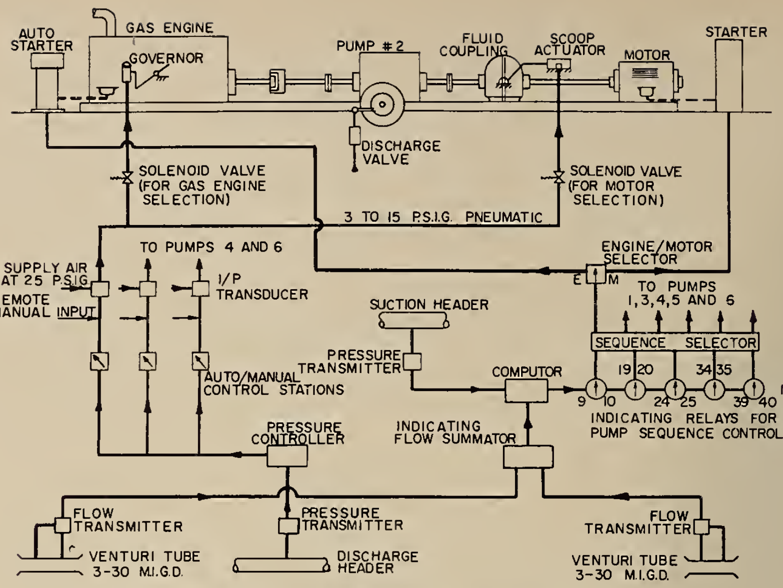


Fig. 4. Schematic arrangement of automatic control system.

Experience with the present system of manual control indicates that an experienced operator can normally maintain the system pressure on McPhillips Street discharge header within plus or minus 5 p.s.i.g. of the required 75 p.s.i.g. He does this manually by observing the system pressure and adjusting the speed of wound rotor induction motor driven pumps accordingly, or by starting or stopping additional variable speed or constant speed pumps to meet flow variations. However, at times of power failure or major system flow disturbances, pressures drop to very low values for brief periods.

Thus, the objects of the automatic control system as designed for the Wilkes Avenue pumping station may be summarized:—

(1) To sequence the starting and stopping of the various pumps as necessary to provide for variations of flow demand, while maintaining discharge pressure as closely as possible to 75 p.s.i.g.

(2) To control the discharge flow of the 10 m.i.g.d. pumps by speed variation in order to maintain discharge pressure within ± 2½ p.s.i.g. of the 75 p.s.i.g. set point.

(3) To allow for instantaneous starting and provide control for the gas engine-driven pumps in the event of power failure.

(4) To allow for selection and control of gas engine-driven pumps in the normal sequence of operation thus limiting the power demands on the Hydro system at times of peak water requirements, and reducing the overall power costs.

Type of Control: Up to the present time insufficient information has been available to permit an accurate analysis of the pressure surge conditions that may be produced in the system when the new station is completed and in operation. However, approximate calculations indicated that no excessive pressures would result due to rapid closure (20 sec.) of the pump discharge valves at Wilkes Avenue. These valves are automatically controlled with the operation of motors or gas engines to perform a check valve service as explained later.

Nevertheless, it was felt that the upsetting effect of pressure surges caused by a closed water distribution system and by manual operation of pumps at the remote McPhillips Street station on a control system sensitive only to pressure might well result in control instabilities and unwanted transient effects. Accordingly, the basic philosophy of the control system was to sequence the operation of all pumping units by the flow variable and to vary the discharge of variable speed pumping units only by the pressure variable in order to maintain the 75 p.s.i.g. set point.

The design sequencing control was based on electric switches actuated by the flow signal, which would sequence the starting and stopping of all pumps according to a pre-selected duty established by the interaction of system demand and pump characteristic curves. Speed control was based on a pressure control loop designed to provide a signal proportional to pressure deviation for control of either the scoop lever at the fluid coupling or the governor on the gas engines. Originally, preference was expressed for an all electric control scheme but because it was necessary that the gas engine hydraulic governor have a pneumatic control and because a pneumatic operator seemed most advantageous for the fluid coupling control, the overall scheme was open in the tendering stage to permit either electric or pneumatic systems to be offered. With the exception of the actual operators the scheme to be provided will be all electric.

Suction Pressure Compensation: Reference to Fig. 2. will show the pump characteristic curves having a total head of 165 ft. at discharge rates of 10 and 15 m.i.g.d. for the variable and fixed speed units respectively. Fig. 3. shows the hydraulic gradient for the station suction header and indicates that under extreme conditions when the reservoir level varies between top water and low water elevations, a suction head shift of 21 feet results.

Thus, to ensure correct functioning of the automatic control system it was essential to provide the necessary compensation for this varying level condition in the reservoir. Two methods were considered, one to continuously modify the pressure set point according to suction pressure, which would drop the controlled discharge pressure to as low as 66 p.s.i.g. (for minimum suction pressure) but still maintain rated delivery of the station. The other method and the one which will be provided, was to artificially modify the flow signal relative to suction head shift and thereby sequence additional pumps on the system at lower flows when required. This has the advantage of maintaining set point pressure at 75 p.s.i.g. but drops the rated delivery of the station by approximately 15%.

Instrumentation: Two Venturi tubes were provided, one in each end of the discharge headers together with transmitting, summating and recording instruments for measuring station flow. Similar transmitting and recording instruments were provided for station pressure and reservoir levels. In order to provide undivided responsibility for satisfactory operation of the automatic control system and also to provide additional flexibility should one system fail, it was decided to provide for separate flow and pressure transmitters and instruments for use with the automatic control equipment.

The arrangement is shown schematically in Fig. 4. for a typical variable speed pumping unit. The flow in each venturi will be determined by a flow transmitter having a lineal output signal directly proportional to flow. The outputs being linear, will be summated to give a total flow signal which will be one input to a simple computer. The other input to this computer will be supplied from a suction pressure transmitter having a reversed output of 15-0 ma. for a suction head change from 14 to 35 ft. to provide the required flow signal compensation.

Thus, the output from the flow computor will be directly proportional to flow modified by suction pressure and this will be fed in series through 5 current sensitive relays each with different settings calibrated in terms of flow. These initiating contacts will have a 1 m.i.g.d. differential spread between on-off settings and will be set selectively at increasing flows of 10, 20, 25, 35 and 40 m.i.g.d. (based on zero compensation signal). The setting and differential of these contacts may be independently adjusted in the field to suit the operating conditions.

A pressure transmitter will provide a signal proportional to discharge pressure which will be fed into a process controller giving 3 mode control i.e.

(a) Proportional (proportional to error)

(b) Integral or reset (proportional to magnitude of error)

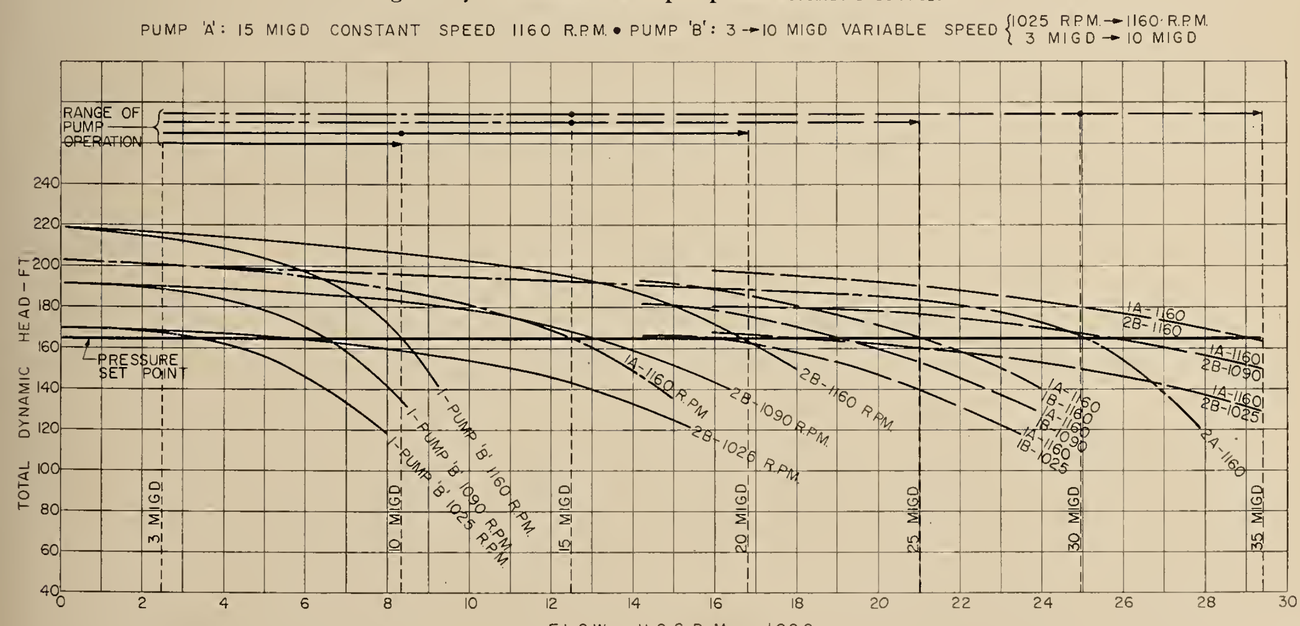
(c) Derivative or rate (proportional to rate of change of error)

The output signal from this controller will be directed through the auto side of an automatic-manual selector into 3 current/pressure transducers to provide a pneumatic signal which will operate any or all the speed regulating operators, as selected. Under manual control either locally or remotely over the supervisory system a manually actuated potentiometric signal will be fed into the current/pressure transducers instead of the automatic signal from the pressure controller. Provision will be made so that the manual signals can be matched to the controller output signal in order to effect a 'bumpless transfer' when changing from manual to automatic control.

Pump Discharge Valve Control: Associated with each pump is a rotating plug valve automatically controlled to serve both as shut-off valve and check valve. The valve has an hydraulic actuator operated by a four way solenoid valve, the control of which is interlocked with the motor and gas engine starters so that a pump always starts and stops against a closed valve. On valve opening this is accomplished by a pressure switch which initiates the opening solenoid after satisfactory upstream conditions have been attained. On valve closing, the 'stop' signal first of all energizes the 'closing' solenoid and, when the valve has fully closed a limit switch then shuts down either the motor or gas engine.

The normal or closing time will be between 2 and 3 min. but when used

Fig. 5. System demand and pump characteristic curves.



as a check valve for either power failure or other emergency shut down conditions, the fast-closure solenoid will provide an accelerated closure time of 10 to 20 sec. and, in any case, will be set to the fastest time consistent with acceptable pressure surges.

These valve operating times provided some complication to the automatic control scheme and consideration had to be given at pump changeover points to allow for the effect of gradually decreasing flow from the pump to be stopped and/or that of gradually increasing flow from the pump being started, and yet at the same time allow the pressure controller signal to maintain the necessary degree of speed control to suit the pressure conditions arising as a result of this changeover.

Safety Provisions: Limit switches on the valve in conjunction with a time delay relay will be used to detect a fault condition so that if either the pump fails to start or the valve fails to open, an alarm will be sent over the supervisory system and a similar pump pre-selected to standby duty will be started up.

Mechanical failures such as a broken shaft or faulty fluid coupling could result in reverse flow through the pump which would give rise to excessive speeds and cause damage. To provide for this condition, reverse flow protection was specified for each pump and this will be obtained from the DC tachometer generators, which are provided for telemetering each pump speed. In the event of reverse flow a negative signal will be used to operate a relay which will close the discharge valve, shut down the driving unit and send an alarm.

Operation of Pumping Units: Fig. 6 shows the pumping curves related to the system demand from 3 to 35 m.i.g.d. and the normal sequence of operation will be as follows:—

(a) Increasing Flows — Normal Hydro Power:

Flow mi.g.d. (based on Reservoir top water level)

0—Start one pump manually and switch to auto.

3 to 10—1st duty 10 m.i.g.d. variable speed pump electric motor operating and speed control signal acting on fluid coupling.

10—Start 2nd duty m.i.g.d. variable speed pump at the speed set by the control signal.

10 to 20—1st and 2nd duty variable speed pump electric motors operating and both respond equally to control signal and share the load.

20—Start 3rd duty 15 m.i.g.d. constant speed electric motor.

—Initiate shut-down of 2nd duty pump by closing plug valve.

20 to 25—3rd duty constant speed pump supplying base load of 15 m.i.g.d. and 1st duty variable speed pump responds to speed set by control signal.

25—Restart 2nd duty pump, either electric motor or gas engine as selected, at control signal speed.

25 to 35—3rd duty constant speed pump supplying base load of 15 m.i.g.d. and 1st and 2nd duty variable speed pumps respond together to control signal and share the balance of the load.

For increasing flows up to the ultimate station capacity the sequence will be very similar using the constant speed pumps as the base load with one and/or two variable speed pumps providing the balance according to the pressure controller signal.

(b) Decreasing Flows:

Flow m.i.g.d.

24—Initiate shut-down of 2nd duty 10 m.i.g.d. variable speed pump, i.e. close plug valve and block speed control signal to maintain low speed.

—1st duty 10 m.i.g.d. variable speed pump will increase speed to compensate for above.

19—Restart 2nd duty pump at controlled speed.

—Initiate shut-down of 3rd duty 15 m.i.g.d. constant speed pump.

9—Initiate shut-down of 2nd duty pump, i.e. close plug valve and block speed control signal.

(c) Power Failure and Restoration:

—All electric driven pumps shut down and all discharge valves will close rapidly.

—Standby generator will start up and provide power for the supervisory and automatic control system and the discharge valve operating controls.

—All gas engines selected for duty start and the normal sequence selector is by-passed.

—The appropriate discharge valves open and the gas engines together respond to the speed control signal.

—Upon power restoration, all gas engines remain operating and discharge valves remain open.

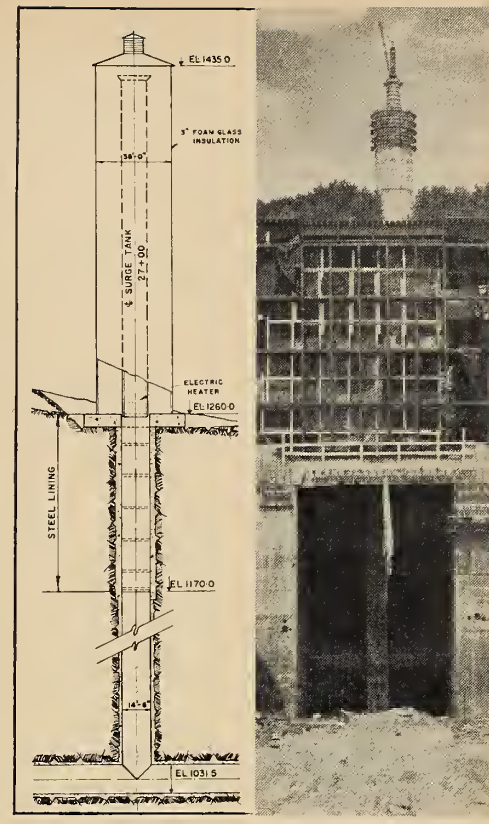
—When the operator at the Master Station is ready to resume normal operation, the control may be set to 'manual', the gas engines shut down and the electrically driven units started in the correct sequence to suit the necessary flow demand. The control may then revert to 'auto'.

It may be noted that for economic reasons it was not practicable to provide for selecting the desired pump duty sequence over the supervisory system. This will probably be changed not more than once per week and a manual plug and jack type selector has been included in the Local Station control panel. An indicator only has been provided at the Master Station, and this must be manually set to agree with the sequence selected at the Local Station.

All pumps have an elapsed time meter which will record the number of hours the pump has been in use and this will operate from the (electric motor driven only) starter circuit.

Silver Falls Project

R. A. Forrester,
Project Engineer,
The Hydro-Electric Power Commission of Ontario, Toronto.



This paper will be presented at the Annual General Meeting of the Engineering Institute of Canada, Winnipeg, May 1960.

Silver Falls Generating Station was built in response to the continuous demand for more electrical power in Northwestern Ontario. The powersite is located approximately 30 miles northwest of Port Arthur and is on the Kaministikwia River. It is readily accessible by road and rail, being about 12 miles north of Highway 17 at Kaministikwia. During its construction, it became a main construction attraction for the Lakehead and its surrounding area.

The station has an installed capacity of 45,000 kw. designed for both base and peak loading and for remote control operation. The essential features consist of an intake structure, a 300 ft. intake shaft, a 2 mile tunnel, a surge shaft and surge tank, and a single unit powerhouse.

Hydraulic power is derived from the 350 ft. head between Dog Lake and Little Dog Lake on the Kaministikwia River. Dog Lake is the storage reservoir for Silver Falls and is also the headwaters of the Kaministikwia River which falls some 775 ft. in its 50 mile course to Lake Superior. Part of this head, 194 ft., is utilized by Kakabeka Falls Generating Station, developing 34,000 hp. Kakabeka is quite an old plant, having been in operation since 1906.

History and Preliminary Work

SILVER FALLS, under flow in its natural state, is quite a pretty sight, and consists of a series of falls and rapids nestling in the upper valley of the Kaministikwia River, with a predominance of silver birch in the surrounding bush.

In the early days, access routes to western Canada passed through this area, either up the Kaministikwia River, with portages around the various falls to Dog Lake, or overland by the Dawson trail to Dog Lake. The old landing on Dog Lake was located about 100 yd. west of the intake.

Its history as a power development is the story of the search over half a century for a practical and economic diversion route for its water; the main problem being to provide a secure hydraulic conduit. The Kaministikwia Power Company made site surveys in 1906. Various studies and proposals have been made since then, including tunnel diversions and surface canals, single-stage developments and multiple low-head developments ranging from 13,000 to 40,000 hp. However, it was not until 1945, when Ontario Hydro acquired power rights on the Kaministikwia River, that a detailed survey was made.

The results of these investigations indicated no apparent problem with low-head multiple-stage schemes but there were major geological problems associated with the more attractive single-stage schemes: too low bedrock elevation adjacent to the intake; a tunnel horizon which was too deep for economic construction; also, soil and ground water conditions were not favourable for excavation of open-cut canals. This all pointed to the need for still further investigations.

So, in 1955, as power demands increased, more intensive field investigations and further surface mapping were resumed and in 1956, by means of a seismic survey the whole diversion area was delineated between Dog Lake and the Kaministikwia River Valley. This investigation, in spite of the irregularity of the bedrock, finally disclosed an area having sufficiently high bedrock in which to locate a diversion tunnel, intake and powerhouse. Following this, late in 1957 and throughout the winter, an accelerated program of investigation was carried out to finalize site locations. This included further seismic work, intensive drilling of intake and powerhouse areas; deep borings of up to 450 ft. through overburden along the tunnel line, to check the seismic report and determine rock conditions at the tunnel horizon. Deposits of granular materials were identified, and the location of the intake channel on Dog Lake and the nature of the tailrace channel improvements in the Kaministikwia River were determined.

On February 3, 1957, Commission approval was finally obtained for the construction of a 45,000 kw. station to be completed by September 1, 1959.

Geology

The general topography of the area

is hummocky uplands with elevations ranging from 1,000 to 1,500 ft. above sea level. Bedrock outcrops occur along the Kaministikwia Valley and along the shore of Dog Lake, reaching Elevation 1,400 ft. in places. Except for these scattered outcrops, most of the bedrock in the area is overlain by layers of glacial and post glacial sediments having an accumulated depth of as much as 800 ft. This material consists of glacial moraine and shallow-water deposits. The Kaministikwia River has cut its way through this material and so eroded the bedrock that a series of falls and rapids exists in the river valley.

As a result of seismic surveys, a ridge of bedrock was found in the area of the proposed project, running roughly parallel to the Kaministikwia Valley. This ridge falls off steeply on the east side into the old glacial valley and on the west to the present-day Kaministikwia Valley. A profile of this ridge indicated a relatively flat bedrock surface with a deep depression near Dog Lake and a rock knob on the lake shore.

As seismic results are only accurate to within 10 to 20% of the depth range, intensive diamond drilling was carried out along the ridge in the area of this depression to find the lowest point of the depression so that the tunnel could be located in an adequate thickness of rock.

Diamond drilling was done every 1,000 ft. along the tunnel line with concentrations in the locations of proposed structures. The drill cores revealed generally competent rock, consisting of massive paragneiss and granite throughout. However, a faulted zone about 500 ft. long was found in the depression area, and another in the location of the intake shaft, both being potential sources of water loss.

As a safety precaution, the intake shaft area was grouted prior to excavation, and as the tunnel approached the depression area, diamond drill holes probed up to 300 ft. ahead and angled up to 30° to check the condition of the rock and the amount of rock cover.

A seepage problem also existed, as the water table was found to be high above the tunnel line throughout its length. This resulted in leakage through joints and fissures while the tunnel was being drilled.

Hydrology and Turbine Selection

Dog Lake is a perennial storage reservoir for Silver Falls Generating Station. Storage capacity is 578,000 acre feet for a 16 ft. range between elevations 1367 - 1383. Dog Lake watershed covers 1,340 sq. miles and extends from a line due north of Fort William northwest to the headwater of the Seine River near Muskeg Lake. Average yearly inflow is 1,100 c.f.s. With a net head of 330 ft., this indicated a unit capacity of 40,000 hp. for base load.

However, a 60,000 h.p. unit using 1,800 c.f.s. was installed as the peaking power obtained was cheaper than thermal power. Also, the 1,800 c.f.s. required for 60,000 hp. would be utilized by the Kakabeka plant in the future, when the very old units there are replaced by a larger installation. Further, the extra capacity would provide a 35 mw. or 6.6% reserve in the 536 mw. system by December, 1960. Also,, this reserve would augment the loss of peak from Hydro's Winnipeg and English River plants during June (a high load month) as a result of high tailwater.

Fig. 1.

Originally the N.T.W.L. was 1025. With a N.H.W.L. of 1375, this gave 350 ft. gross head. Tunnel losses were estimated at 20 ft., leaving a net head of 330 ft. Subsequent channel improvements amounting to a gain of 6 ft. lowered the N.T.W.L. to 1019, with a range 1016 to 1022. This increases turbine output to about 61,000 hp. Actual maximum full gate output is about 3% in excess of the nominal rating of 60,000 hp.

A synchronous speed of 240 r.p.m. was proposed by the manufacturer and adopted for design. The corresponding specific speed of 42 resulted from the latest improvements in blading, and indicates continuing development of higher speed hydraulic turbines in an effort to reduce weight and costs of prime-mover equipment.

The turbine is a modern high speed Francis turbine which, by comparison with designs available ten years ago, represents a 25% increase in synchronous speed. This in turn allows proportionate savings in unit costs and certain other fringe benefits.

A hydraulic feature of this turbine is the deep setting of the runner. To meet the specified performance and cavitation standards with this high specific speed, the manufacturer requested that the centre line of the distributor be set 6 ft. below the minimum tailwater. During periods of high tailwater, this meant a submergence of as much as 15 ft. to the bottom of the runner blades.

To allow synchronous - condenser operation of the generator, a tailwater depression system is provided for the turbine, to minimize the quantity of motoring power.

Structural Features

Intake: The intake structure is a conventional headblock type which, in combination with the transition section behind it, was designed to be stable without assistance from backfill. It was constructed behind a natural earth barrier of somewhat limited durability. However, on completion of the intake structure and installation of the service gates, this structure provided an effective bulkhead against Dog Lake during construction of the intake shaft.

Two air vents are built into the structure: a small one in the structure designed to deflect any back surge of

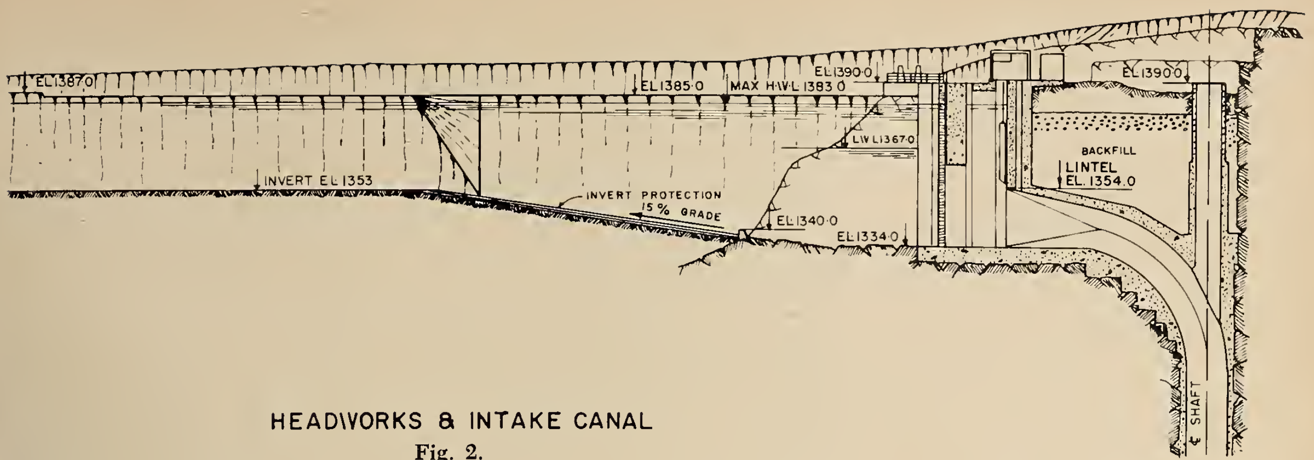


Fig. 2.

water into the intake bay, but allowing air movement through deck gratings and hoist house louvres; the larger vent is a 9 ft. diam. shaft located directly over the intake shaft and extending to the surface. This vent relieves whatever trapped air accumulates in the tunnel during filling operations; also this vent shaft provides a future access for tunnel repairs.

Although standard trash racks and service gates are stored outside, there is no permanent gantry, since the infrequent lifting operations can be done by a mobile crane.

Tunnel: Economic studies of lined and unlined tunnels indicated a lined tunnel would be cheaper to maintain and more secure against the possibility of loose rock blocking the tunnel in the future, which would necessitate major repairs. A nominal lining thickness of 18 in. was selected because the arch action of such a thickness provides sufficient strength to withstand the external water pressure; also 18 in. was recommended for construction. A thickness tolerance down to 13 in. was allowed in isolated local spots caused by tights when drilling the tunnel.

The tunnel diameter of 14 ft. 6 in. was selected entirely on the basis of economic studies, weighing the cost of constructing a certain size of tunnel against the power loss in friction through it.

The concrete lining is designed to withstand an external water pressure to ground water level, which in places is higher than Dog Lake.

The tunnel invert was set horizontal at elevation 1030. This level was high enough to prevent any tunnel flooding from Little Dog Lake during construction, and low enough to provide a reasonable rock cover when tunnelling through the rock depression area. It also enables the tunnel to be drained, either for inspection or if the penstock valve ever failed.

Powerhouse: Two locations for the powerhouse were considered feasible: a site on Silver Lake, shortly up-river from Little Dog Lake, and the chosen site on Little Dog Lake. The latter was considered somewhat more economical: a greater head was available, there being a rapids between the two sites; there was the prospect of a lowering of Little Dog Lake by excavation activities, which would not have led to any power improvements at the former site; a larger surge tank would have been necessary at the former site; the present tunnel line is the more advantageous of the two, geologically. An underground powerhouse was considered rather more expensive than a surface structure.

The powerhouse substructure is set in rock as high as the generator floor. Plastic waterstops and water-proofing are used throughout the substructure to withstand tailrace flooding also as high as the generator floor.

The penstock and the substructure concrete are mutually isolated by means of a special caulking material, so as to avoid spalling the concrete wall around the penstock during movement of the latter. This also eliminates stresses in the penstock end caused by the rigidity of this wall. The penstock itself is embedded in a concrete envelope for anchorage purposes; a gravel fill is placed on top of this to absorb the impact of rock falls.

The superstructure houses the whole powerhouse floor area. The erection bay is located on the downstream deck, permitting the overhead powerhouse crane to handle the draft tube service gates, thereby eliminating a trailrace gantry. Floor hatches permit removal of the penstock valve, the generator and shaft, and provide access to the transformer service bay on the turbine floor. The generator floor is designed for a loading of 1,000 p.s.f. between crane columns and at least 300 p.s.f. elsewhere. The superstructure steelwork bents are a rigid frame type, and these are covered by insulated wall and roof cladding which features aluminum on the outside.

Surge Tank: Since a two-mile pressure tunnel was to be the main feature of the system, a surge tank was required to disperse the water-hammer pressure resulting from any sudden flow stoppage when rejecting the unit load. In addition, in cases of sudden power demand, the surge tank provides a source of high-head water which helps to accelerate water in the tunnel.

It is desirable to locate a surge tank as close to a powerhouse as possible. In this case, the location was fixed at a position 885 ft. upstream of the unit, after weighing up economic considerations like height of tank, rock and soil profiles along the tunnel line, accessibility and cost of the shaft; it was more expensive to locate the tank anywhere nearer the powerhouse.

Both elevated and standpipe types of tank were considered permissible and the decision to use the latter resulted from a comparison of tenders. Studies showed that the differential tank would be 38 ft. diam. and stand 180 ft. above a base at elevation 1260; the internal riser being 12½ ft. diam. and 170 ft. above the base. The surge shaft is steel lined for 90 ft. below the base. The differential action occurs through ports totalling 25% of the conduit area.

Although the most rapid unit closure time is 8 seconds, design was based on a 4 sec. closure. The performance of the surge tank under all conditions of headwater level and load rejection was evaluated, using a computing machine.

Field tests since installation have proved satisfactory, and further tests will decide the final port area.

Block Dams: Along with the program of constructing a generating station, it was decided to carry out repairs and replacement work on four of the five existing block dams which had deteriorated.

Sonic tests were performed on the concrete cores of three of these dams; they proved to be in poor condition.

As it would have required a major dewatering program to renovate them, it was decided to build new dams of compacted earth, located downstream from the originals.

The best local core material was found to be a compacted silt. For compaction, this material had a very limited range of moisture content, the optimum being 14%. This necessitated dry weather conditions during handling and compaction, along with close control of moisture content.

Filter and riprap material was placed on top of the silt, and the final shape consisted of a 17 ft. wide flat top, upstream and downstream slopes of 2½:1 and 2:1 respectively, and a maximum depth around 30 ft.

Repairs to a sluice control dam consisted mainly of concrete renovations and gate replacement.

Intake Channel Design: It was necessary to ensure that in winter a continuous sheet of ice formed in the forebay, so as to avoid clogging the intake during periodic breakups. Hence, an unusually large and deep channel was necessary. In the section designed, surface velocity is kept to less than 2 f.p.s. The maximum and minimum depths are 30 and 12 ft. respectively, and the ice cover is not less than 2 ft. thick.

Tailrace Channel Design: Between Little Dog Lake and Crooked Rapids, a 2 mile stretch, the river level drops by about 15 ft. Economic studies showed that 15,000 cu. yd. of rock and 100,000 cu. yd. of silt material had to be removed to eliminate 6 ft. of that head. The rock excavation was carried out, but only 30,000 cu. yd. of the tougher clay was removed, at strategic points, as it was believed that the remaining 70,000 cu. yd. would be eroded in time by the higher velocities created.

Research: In addition to the continuous job of concrete control, research work was performed in the following fields: Petrographic examination of rock to ascertain drilling conditions prior to tunnelling; checking of blasting methods and detonating circuits for reasons of safety; installation of circuits and strain gauges on the penstock walls, and in tunnel and shaft linings, for future measurement of stresses in the concrete and steel; installation of electric pressure cells to determine head and friction losses in the tunnel, and also in the surge tank, for comparison with results obtained by using manometers; sonic testing of concrete quality in the original block dams; testing and control of moisture content of the core material used in the new earth dams; in-service testing of the turbine, generator and surge tank.

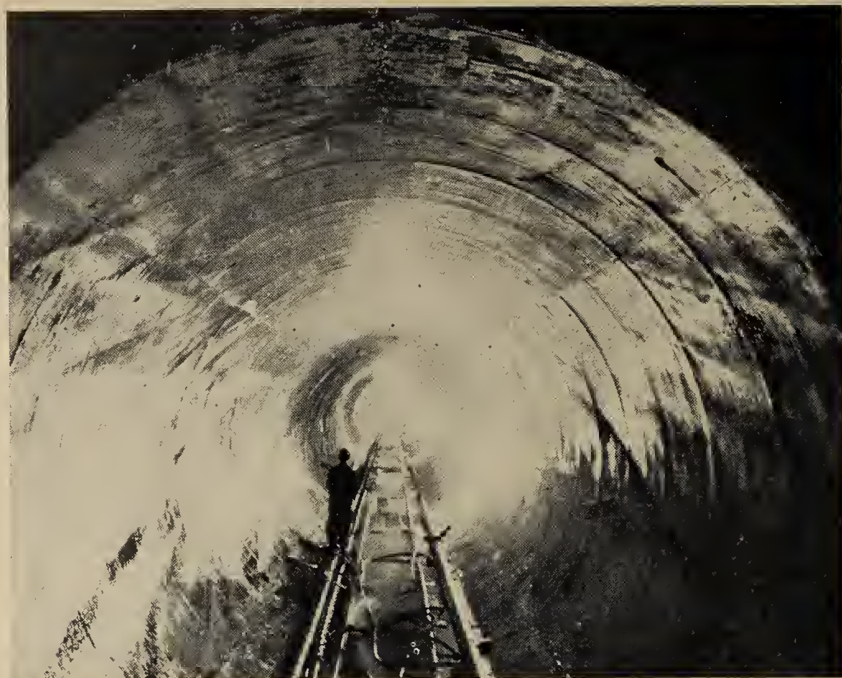

Fig. 3. Fogging operations in the tunnel to maintain humidity during concrete curing.

Mechanical Features

Headgate: Intake is controlled by a single headgate operated by a hoist located on the headworks deck and enclosed by a housing which is removable for maintenance purposes.

The gate covers a clear opening 18 ft. wide and 20 ft. deep. It weighs 55,000 lb. and is designed for a 44 ft. head on the sill. The gate is a face-roller type, has downstream sealing, and a pointed edge on the sill. It is also provided with aeration holes to reduce downpull on the hoist.

The hoist is designed for a hoisting speed of 5½ f.p.m. and a lowering speed of 12 f.p.m.; it is powered by a 15 hp: squirrel-cage induction motor. The gate is lowered without power and braking is effected by an overloading type fan brake. A solenoid-operated holding brake is fitted to the motor shaft, the coil being energized to release it.

Inlet Valve: The inlet valve is located immediately upstream of the spiral scroll-case. It is a straight-flow type, having a bore of 9 ft. It is able to close in an emergency under the maximum turbine flow of 2,100 c.f.s. and a differential pressure of 240 p.s.i. Both opening and closure time is one minute.

The valve body is spherically shaped and consists of an upstream and a downstream portion fabricated from formed plates, heavily ribbed and flanged for bolted connection. The upstream portion is provided with two bearings which support the hemispherical door. The downstream portion carries the internal extension pipe.

The hemispherical door, fabricated from 4 in. formed plates, transmits its load to the valve body through two cast steel trunnions welded to the dome structure.

Sealing of the valve is effected by a pressurized moulded rubber, carried on the upstream end of the internal extension pipe, and seating against a stainless steel annulus provided on the downstream side of the door. Seal pressure is taken from the penstock upstream of the valve through an interlocked control, which prevents the valve door from opening before the seal has been withdrawn. The valve is operated by a servomotor, using penstock water pressure: the opening pressure from the downstream side of the valve, and the closing pressure from the upstream side. Before opening, the downstream side of the valve is primed through a manually operated by-pass.

The valve is connected to the scroll casing by a Dresser coupling which allows small horizontal movement. The valve is supported on heavy footings which can make a small horizontal movement on bronze thrust plates. The valve weighs 90 tons.

Turbine: The 60,000 hp. Francis turbine has a cast steel runner and a throat diameter of 100 in. A stainless steel overlay was applied to the back of the blades in areas of heavy pitting, as determined from model tests.

The speed ring consists of cast steel top and bottom rings, welded to steel plate vanes. The scroll case has an inlet diameter of 9 ft., and is fabricated from rolled plate varying from ⅝ in. to 1-⅜ in. thick. For purposes of field erection, it was made in two parts which were bolted together in the field. The casing is designed to withstand 235 p.s.i., which includes a 64% pressure rise resulting from a rejection of full load in 4 sec., while operating under the rated head of 330 ft.

The turbine shaft, 26 in. nominal diameter, is provided with a self-pumping bearing immersed in an oil bath. This bearing is supported on the headcover which is of fabricated plate construction.

The speed of rotation is controlled automatically by a governor mechanism, which is sensitive to changes of load demand, and which actuates the wicket gates through two servomotors.

Crane: The major equipment located in the powerhouse is serviced by an overhead electric crane travelling on rails spaced 39 ft. 10 in. apart. It is provided with a main and an auxiliary hoist; the main hoist having a capacity of 175 tons when operating at a speed of 5 f.p.m.; the auxiliary hoist having a capacity of 25 tons when operating at a speed of 40 f.p.m. Each hoist is driven by a 75 hp. wound-rotor motor, through a gear reduction, and is provided with both a mechanical load brake and an electric holding brake.

Auxiliary Mechanical Systems

Compressed Air: Compressed air for the generator brakes and the station service air system is supplied by a single compressor rated at 100 c.f.m. and 100 p.s.i., with one air receiver.

Compresed air for the draft tube water depression depresses the water level in the draft tube to 4 ft. below the runner when the unit is operating as a synchronous condenser. The equipment consists of a single air compressor identical to the station air compressor and two air receivers of 300 cu. ft. vol.; it is operated by an electrodetype level control.

Compressed air for the governor and switchgear is supplied by two compressors, each rated at 37 cu. ft. and 350 p.s.i.

Cooling Water: Water for the generator air coolers, turbine guide bearing, generator thrust bearing, air compressors and turbine runner bands is supplied from the tailrace by a deep-well pump rated at 1,400 US gal. per min. 75 ft. head. Alternate supply can be obtained from the penstock fire header.

Generator Damper Control: Four intake and four discharge louvres on the generator are operated by pneumatic air motors, so that warm air is circulated inside the powerhouse during winter.

Oil System: Lubricating oil for the generator thrust bearing, the turbine guide bearing and the wicket gate servomotors is supplied by 40 Imperial gal. per min. filter press and pump, and three handling tanks of 1,200 Imperial gal. each.

Transformer oil for power and station service transformers is also supplied by a 40 Imperial gal. per min. filter press and pump, plus a 125 Imperial gal. per min. booster pump and three tanks having a total capacity of 6,200 gal.

Fire Protection: General fire protection consists of 9 hose stands, each equipped with 75 ft. of hose, and a combination fog and stream nozzle. Water is supplied from the penstock fire header at 150 p.s.i. This fire header also supplies the generator sprinkler rings and the transformer deluge system.

Power and station service transformers are protected by deluge systems which are actuated automatically by temperature control devices.

A CO2 system protects both the generator and the oil room; it is fired either by thermostats or manually. Equipment consists of one in-service and one reserve bank of thirty-two 50 lb. cylinders.

Both local and remote warning devices are used in conjunction with the fire protection systems.

Dewatering: Accumulated drainage water in the sump is emptied by one deep-well pump rated at 450 US gal. per min. at 47 ft. head. The draft tube is dewatered by one deep-well pump rated at 2,500 US gal. per min. at 20 ft. head. Both pumps have automatic level controls.

Water for both domestic use and the turbine carbon seal is supplied from the tailrace by a deep-well pump rated at 30 US gal. per min. at 145 ft. head or from the penstock fire header. The domestic water is chlorinated.

Electrical Features

The Silver Falls generator is a 13,800 v. 3 phase, 60 cycle, 240 r.p.m. unit equipped to operate either as a generator rated 50,000 kva. at 90% power factor or as a synchronous condenser rated 30,000 kva. re-active at zero power factor. Class B insulation is used by the manufacturer and the generator is designed to deliver its rated output continuously with a maximum temperature rise in the rotor and stator windings of 60°C over an assumed ambient of 40°C. In addition, the unit is capable of operating at 115% of its rating with a maximum temperature rise of 80°C above the ambient.

The generator is cooled by a closed air system with air-to-water heat exchangers. Four air ducts connected to openings in the generator frame provide hot air for heating the powerhouse. Dampers in each of the hot air ducts close automatically when the generator CO2 fire protection system operates. The generator air system is separated from the turbine but by a steel plate membrane between the bracket openings.

Three triple unit current transformers on the stator neutral leads are used for metering and relaying purposes and are located in a cutout in the generator pedestal. A 13,800-230/115 v. grounding transformer in a single-cell cubicle assembly is connected between the star point and ground. Primary balanced type split phase current transformers are located on the main stator leads in the air housing. An automatic high speed continuously-acting voltage regulator and a motor-operated voltage adjusting rheostat are provided with the unit.

The 13.8 kv. switching is contained in a single metalclad structure and consists of one 2,500 amp. airblast generator breaker with isolating switches and two pneumatically-operated 600 amp. load interrupter switches for primary switching of the station service transformers.

Two 600 kva., 3 phase, 13,800-600 v. station service transformers with on-load tap changers are provided, with switching so arranged that one transformer is normally loaded and the other standby. In the event of a failure on the normally loaded transformer, the load is automatically transferred to the standby unit. Power for the intake structure is supplied from the 600 v. station service panel in the powerhouse, stepped up to 12 kv. for transmission along a 5.5 mile wood pole line, then stepped down to 600 v. at the intake. This pole line parallels the access road to Big Dog Lake for ease of maintenance and was erected early in the project to provide construction power at the intake structure. Transformation consists of a bank of three 25 kva., distribution-type units located on a wood pole structure at each end of the 12 kv. line.

Three 17,333 kva., single-phase, 60 cycle, 13.2-69.86 kv. oil-immersed forced-air-cooled power transformers, connected delta-wye, step up the generator voltage to a nominal transmission line voltage of 121,000. A spare power transformer has been provided.

A single circuit, 115 kv., steel-tower transmission line 8.8 miles long, links Silver Falls Generating Station with the Commission's existing 115 kv. line from Moose Lake Transformer Station to Port Arthur Transformer Station No. 1. The connection is made at Conmee Junction, 20 miles from Port Arthur.

Supervisory control equipment operating via power line carrier channels is used for remote operation of the plant from Port Arthur Transformer Station No. 1. Twenty operations including starting and stopping the generator are remote controlled. Supervision of the generating station equipment is maintained by visual indicators and alarms which will indicate such occurrences as relay operations, over-temperatures, low oil levels, etc.. Telemetering provides continuous indication at the controlling station of generator vars and wicket gate positions; nine other electrical and mechanical quantities such as generator watts, gate limit position, headwater level, etc., are telemetered on an "as called for" basis. A six-pair No. 19 Alpeth-type aerial cable strung on wood poles along the tunnel right-of-way provides a voice circuit and a metallic extension of the supervisory and telemetering system from the powerhouse to the intake structure.

Construction Camp and Plant

Camp facilities adequate for 350 construction personnel were installed; additional labour commuted each day from the Lakehead.

Aggregate crushing was done by a portable crusher, which turned out 40,000 cu. yd. of 1½ in. and 40,000 yd. of ¾ in. aggregate from the tunnel rock. Finer material was readily available for screening and some 40,000 tons of sand was stockpiled.

100 lb. compressed air was supplied by 3 large compressors. Power was supplied from Kaministiquia, 10 miles away, through an 8,000 v. construction line directly to the site. Steam was supplied by three 100 hp. portable boilers at 100 p.s.i. Water supply was taken from a 10,000 gal. wood-stave tank erected on a Bailey tower, the tank being topped up by a 400 gal. per min. pump.

The concrete mixing plant featured a 75 cu. yd. mixing-bin capacity, a semi-automatic batcher and two 2 cu. yd. mixers having an output of 85 cu. yd. of concrete per hr. Aggregate was fed into the gravel hoppers from stockpiles by a front-end loader, and thence by conveyor belt to the mixing plant. Cement was transported from the Lakehead in bulk-cement trailers of 400 bag capacity and stored in an 11,000 bag steel silo. From there, it could be distributed either to the mixing-plant hopper or direct to the batching bin, by means of a screw conveyor or a bucket elevator.

Construction

In March, 1957, construction began on the access road located along the east bank of the river from Kaministikwia to the powerhouse, and another to the intake and control dams. This work included 8 miles of realignment and improvement of the existing township road from Kaministikwia to Little Dog Lake, 2 miles of new road to the powerhouse site at the north end of Little Dog Lake, 5 miles of new road from Little Dog Lake to the intake area on Dog Lake and 2 miles of new road from the intake to the dam area.

No major problems occurred during road construction, materials being quite plentiful. The maximum grade was 10%.

A temporary camp was set up from March, 1957 to November, 1957, at which time the permanent camp was completed and located near the powerhouse. Some of the features of the final camp included extensive dormitory housing for the employees, a large cafeteria, a recreation hall, games rooms, guest and staff houses, offices, workshops, service shops, changing sheds for the miners, a trailer park and full services for the whole camp.

Excavation of the approach to the powerhouse and portal area began in July, 1957 and consisted of removing a deep overburden of silt and boulders totalling 110,000 cu. yd.; this was completed down to tunnel invert by October 1, 1957. Tunnel railway track was laid in a rock cut around the west side of the powerhouse, extending across the tailrace cofferdam to the disposal area in Little Dog Lake.

The rock surrounding the portal was generally in good condition, although some rock bolting of the face was done. A portal shed was constructed over the tunnel entrance, for protection against rock falls.

Tunnelling progress began slowly due to proving-up of both the organization and equipment. By mid-November, a speed of 27 ft. per day was reached, 640 ft. being done at this rate. By mid-January, 1958, a steady advancement rate of 42 ft. per day was developed, and this was maintained for the rest of the 10,000 ft. Tunnelling was completed by August 15, 1958. Bonus incentive had a marked effect on progress. A rate of 60 ft. per day could have been made, but was considered unwise for safety reasons. The main restraint on advancement was the policy of allowing a maximum length of drill steel of 16 ft.

Generally, rock was good in the tunnel. Steel arch supports were used in only one area, although extensive rock bolting of the roof was done as a precautionary measure. Some 120 men were employed in three shifts covering drilling, mucking, rock disposal, track laying,, installation of services and maintenance of equipment. Equipment used included a drilling jumbo of 7 drills, a 130 hp. electric mucking machine, 3 diesel locomotives with exhaust filters and a train of 5 cu. yd. side dump cars. Track consisted of 30 lb. rail at a 3 ft. gauge. Compressed air, water and drain pipes were hung along one wall, and power and lighting circuits were fastened to the other. Ventilation was obtained by using a 30 in. fresh air pipe in conjunction with axial-flow blowers; the air was heated by a 1,250,000 B.t.u. oil-fired furnace, operating near the portal.

The average number of blasting holes was 70 per round, 5 lb. of powder being used per cu. yd. of rock. This blasting arrangement produced fairly small broken rock, thus simplifying mucking operations. The average overbreak was 8 in. on the nominal radius.

Wet conditions were encountered in two areas: one approaching the depression area and the other about 2,000 ft. in from the portal. On approaching the rock depression area, a diamond drill probed forward and up at an angle of about 30° for 100 ft., to reconnoiter any dangerous rock or water conditions; this also being an added check on the rock cover. In this region, a 30 ft. drill hole was used to probe directly ahead, prior to each blasting round, as well.

To guide the drilling crew, the tunnel face was spray-painted along both vertical and horizontal centre lines and around the perimeter before each round of drilling. A full cycle of excavation was completed during every eight-hour shift.

Work on the surge shaft began about mid-January, 1958. This was done by the so-called Swedish method. In this, a churn-drill sank a 9 in. hole from the surface to the tunnel; a hoist cable was threaded through the hole. A 6 ft. diam. pilot shaft was raised from the tunnel by work done from an access cage, which itself was hoisted up and down on the cable. Blasted rock was collected in timber bins at the bottom of the shaft and fed into the mucking cars automatically. The full sized 17 ft. 6 in. diam. shaft was subsequently slashed out by blasting from the top downwards.

Work on the intake shaft began about August 20, 1958 by the same method as for the surge shaft, except that the cable hole was obtained by using a 4 in. diamond drill. Fouling of the hoist cable was found to be a difficulty with the smaller-sized hole. The vertical alignment of the cable hole was about 2 feet off-centre. About 3 lb. of powder per cu. yd. of rock was used in the shaft work.

The intake shaft area was drilled and grouted from the surface prior to excavation, so as to ensure a water-tight work face.

Immediately on completion of rock excavation, tunnel cleanup was commenced, this being finished by November 15th. The work involved the removal of the ventilation pipe and the other services; the blasting down of tights, and the washing down and cleanup of the invert.

Tunnel Concreting

The concrete lining was placed in three separate stages: first the twin curbs, then the invert and finally the arch. Invert pouring required the use of a long train of equipment and this made progress at the rate of 500 ft. per day. Arch pouring also required an assembly of special equipment to place the concrete by the continuous advancing-slope method. In this system, concrete is pumped through a pipe up behind steel arch forms. The space fills up and the concete, which slumps along the walls to an angle of about 30°, advances in the opposite direction to the pumping motion. The pipe is steadily withdrawn throughout. In this method, concrete is placed about 3 times as fast as in the standard bulkhead system, but is likely to produce a somewhat less dense concrete.

In general, a 6 bag mix was used, as the concrete was required to have a strength of 200 p.s.i. after 12 hr., at which time the forms were removed; also, a liquid type of air-entraining agent was used. To minimize cracking, a continuous water-spraying and fogging operation was used.

Curb pouring commenced about the end of June, 1958 and was completed by November 1st. Invert pouring commenced November 15th and was completed by December 6th, except for a 600 ft. section in the depression area. Arch pouring commenced December 15th, beginning at the intake shaft. A speed of 275 ft. per day was quickly attained and the first 1,400 ft. to the depression area was completed by Christmas.

On pouring the 600 ft. reinforced concrete section in the rock depression zone, progress was quickly slowed down, as it was found that the concrete was not getting up behind the reinforcing bars at the crown and the shoulders. This reinforcing varied in density from 6 in. to 18 in. centres with a clearance between the top of the pipe and the bars of as little as 3 in. in places. Various adjustments were made to the concrete mix, such as using finer stone and a wetter mix, but with little success. Finally, two slick pipes were installed, roughly at 11 o'clock and 1 o'clock on the circle. This proved successful and concrete placement recommenced, the two slick pipes being retained for the remainder of the tunnel. The average rate of progress was 300 ft. per day.

Test drilling in the reinforced section revealed large voids and honeycomb concrete. A large section in this region was subsequently cut down and repoured.

Thirty days after placing, low-pressure grouting was commenced, followed by high-pressure grouting 90 days later. A third and fourth grouting pass was found necessary in the zones of water leakage. Approximately 1 cu. ft. of grout per foot of tunnel was used. A pressure of 50 p.s.i. was used for low-pressure grouting and up to 200 p.s.i. for high-pressure grouting.

Bulkhead forms were used at the intake elbow and at the T-section at the surge shaft, as both these sections were heavily reinforced.

Concreting around that section of penstock extending into the tunnel was done by pouring bulkhead lengths of 80 ft. at a time. Threaded holes were left in the steel plate for grout pipe attachments. Only pressures of up to 35 p.s.i. were used, so as to avoid buckling the liner.

Fig. 4. Placing of one-half of the steel scroll case.

Surge Tank and Penstock

Design of the differential surge tank indicated a 38 ft. diam. outer tank with the top at elevation 1435 and a 12½ ft. inner riser to elevation 1430, with an external 14½ ft. diam. steel liner extending to elevation 1170 in the surge shaft. Location studies indicated a base at elevation 1260, 885 ft. upstream from the unit. Plate thickness of the shell varies from 1-7/16 to ⅜ in.

Erection of the surge tank began about July 1, 1958. The general scheme of erection consisted of welding the shaft liner in 16 ft. sections, lowering them down the shaft and concreting around them subsequently. The internal riser was shipped to the site in complete rings 8 ft. deep. Riser erection was done by using a stiff-legged derrick for the lower rings, and by a jumper pole and jib derrick, attached to the riser, for the upper rings.

The outer shell was formed from semi-circular steel plates, 8 ft. deep, these being welded together in place. Hoisting of these curved plates was done by means of a short mast attached to the top of the inner riser, the latter being previously guyed to the ground.

All welds, both in the shop and in the field, were stress-relieved by the Linde water-spraying method, and were subsequently x-rayed to check their quality. All vertical welds were an x-shaped, double-vee type. Horizontal welds were a k-shaped, double-bevelled variety, these, however, being subsequently ground flush. Low hydrogen rods were used throughout. The shaft liner was completed by mid-August, 1958, at which time the concrete tank base was poured. Work then proceeded on the internal riser, and this was completed by October 1st. Shortly before completion, some local deformation was noted in the lower rings where a bracket footing was attached. This distortion may have been caused by welding. However, as a safety measure against ring buckling, eight 12 ft. vertical stiffener beams were welded inside the riser, one opposite each bracket.

Tank-bottom plates were welded in place and dry packing was done beneath them. Erection of the outer shell was now started and this went on until December 12th, when operations had to stop because of cold weather; by this time, 11 of the 22 rings had been placed.

Steel erection work now commenced on the penstock, beginning with the erection of a stiff-legged derrick on one side of the penstock. Penstock sections were delivered to the site in prefabricated circular pieces about 8 ft. long. All welding consisted of the above-mentioned x-shaped, double-vee type. Those sections immediately adjacent to the powerhouse wall were placed first, and after this, a concrete envelope was poured around them. Penstock work was then suspended for about 5 weeks to permit the removal of tunnel services and track, and final cleanout. About March 20, 1959, a 70 ft. long erection platform was constructed immediately outside the tunnel portal. On this platform, rings for the tunnel section of the penstock were welded into 80 ft. lengths, and thence rolled into the tunnel, positioned carefully and concreted in place. The penstock was finally completed and the surrounding concrete envelope poured by July 1st.

Work on the surge tank shell was resumed about June 1st, this being completed by August 15th, in time for the in-service testing.

Insulation of the surge tank commenced on September 1st. It consists of 3 in. of foam glass in 12 x 18 in. blocks, glued onto the outer shell by an insulmastic vapour seal and supported by a network of vertical rods and horizontal bands welded to the steel shell. This, in turn, is covered by two layers of asphalt glass fabric alternating with a coat of vapour seal for each layer, the whole thing being finally finished off with aluminium paint. The work was completed by winter, apart from the final paint.

Powerhouse

Excavation of the powerhouse site, consisting of 34,000 cu. yd. of rock was begun about April 1, 1958 and completed by October 1st. Line drilling of the penstock cut and the powerhouse outline was done, to confine the overbreak and wall fracturing during blasting operations. A combined tailrace plug and access road was left in place, this being also used for the tunnel railway. Excavated material was disposed of in Little Dog Lake.

A Bailey construction bridge was built across the rear bay of the powerhouse for general hoisting purposes and for concrete pouring operations.

Concreting of the draft-tube began October 1, 1958. The steel draft-tube liner was set in position by December 20th. Shortly after the New Year, the steel scroll case was set in place. It came in two halves, the larger weighing 35 tons. Placing was done by using two 35 ton mobile cranes located on the Bailey bridge; these lifted each scroll section from a float, and set them down on pedestals in the turbine pit. Both halves were temporarily bolted together until final riveting was done. After alignment of the embedded parts, the scroll case was concreted in. By May 1st, work had begun on assembling the turbine parts.

Generator erection began about May 10th, the first process being the stacking of the rotor. Both the superstructure steel and the 175 ton powerhouse crane had been previously erected by about May 1st. The generator stator was made in two halves, each 40 tons. Field poles were attached and keyed to the rotor by June 20th. The stator itself was placed by July 1st, and by July 25th, the shaft, bearing assembly and rotor were in position. By August 10th, the turbine governor piping had been completed and a rotational check on the unit was made.

Tunnel filling, which had to be done quite slowly, was begun on August 22nd. The first rotational check and dryout run were completed by August 26th, and on September 1st, the generator was placed in-service. An excessive runout of 18 mills in the generator shaft was found, when the unit was on load. This was attributed to the floating iron-rim design of the rotor. This was overcome by welding in shims, which eliminated the floating action until an over-speed of 340 r.p.m. was reached.

Intake

Following completion of the intake road, intake excavation commenced October 1, 1957. It consisted of removing 45,000 cu. yd. of earth and 12,000 cu. yd. of rock; this was taken out in the dry behind a natural earth cofferdam, made up of granular glacial material. The excavation invert was 50 ft. below lake level. Rock excavation began about December 1st; a slot, 60 ft. deep, 40 ft. wide and 100 ft. long was cut into a rock hillside. Line drilling was done to limit fracturing of the rock walls when blasting. A certain amount of lake water percolated through the natural cofferdam during this operation, but the volume was well within the pump capacity. Excavation of the elbow behind the intake began May 1, 1958. At the same time, the shaft area was drilled and grouted, since exploratory drilling had shown considerable faulting and doubtful watertightness. Intake concreting began July 1st, and by October, 1958, service gates had been installed in the upstream checks, after which pumping of the cofferdam leakage water was discontinued.

The cable hole for the intake shaft was begun August 1st, by using a 4 in. diamond drill; a previous attempt with an air-track was not successful. Shaft excavation was completed by October 1st and the concreting was done by December 1st.

Intake channel excavation consisted of completing as much dry excavation and surface protection as possible before removing the cofferdam plug. This was followed by wet excavation, using a 10 in. suction dredge. As the material contained a fair number of boulders and was somewhat compacted, difficulty was encountered, and dredging was stopped; the remainder was removed by a 1½ cu. yd. clam, operating from a barge in some 25 ft. of water.

NOTICE

The Seventy-Fourth Annual General Meeting of The Engineering Institute of Canada will be held on Wednesday, May 25, 1960, at the Royal Alexandra Hotel, Winnipeg, Manitoba, between the hours of 10.00 a.m. and Noon. This meeting will receive the report of the official auditors, the Annual Report of Council, Committees, Representatives, and Branches, and such other business as may come before the meeting.

Garnet T. Page, M.E.I.C.
General Secretary

Salient Mechanical Design Aspects of the Selkirk Generating Station

A. C. Blue, M.E.I.C..
Chief, Mechanical Section,
Engineering & Construction Division,
Manitoba Hydro-Electric Board, Winnipeg.

C. W. Hodgson, M.E.I.C.,
Director & Chief Engineer,
Ewbank & Partners (Canada) Limited, Toronto.

This paper will be presented at the Annual General Meeting of the Engineering Institute of Canada, Winnipeg, May 1960.

The Selkirk Generating Station is a new thermal plant required by The Manitoba Hydro-Electric Board to meet the steady increase in power demand in the Province. Two 66,000 kw. units are at present being installed and these are programmed to commence commercial operation this year.

This paper deals with mechanical equipment. The civil design aspects of the Station are mentioned only where they affect the layout of mechanical equipment. No reference has been made to the electrical equipment.

The Station site is located approximately 20 miles north of Winnipeg on the east bank of the Red River, opposite the town of Selkirk.

Selection of Site

THE FUNDAMENTAL requirements which have to be met when selecting a site for a coal burning thermal generating station are:

1. Ample water supplies for condensing;
2. Rail and road access facilities;
3. Right of way for transmission lines;
4. Adequate area for coal storage;
5. Means of ash disposal within the general vicinity of the site;
6. Soil conditions suitable for foundations designed to take column loadings of up to 1,000 tons or more;
7. Even terrain, where possible.

The site seleeted for Selkirk Generating Station satisfied all these conditions. Its boundaries are the C.N.R. Pine Falls line to the south-east, Cook's Creek to the east and the Red River to the north and west. The river in fact forms almost half of the site perimeter.

The area of the site is 450 acres thus imposing no restrictions on rail, coal or ashing facilities and allowing ideal planning conditions for development. The average altitude of the site is 738.00 ft. elevation and the normal high water level of the Red River locally is 717 ft. elevation with a normal low of 710 ft.

Planning the Site Layout

From inspection of the site itself and detailed examination of surveys and aerial photographs it became apparent that this site could be a valuable asset to the Board for future developments and offered excellent potential for expansion up to about 1,000 mw. This conclusion formed the basis of the broad aspects of planning, and the locations of the main building, cooling water pumphouse, transmission lines, coal storage area, ash lagoons and water treatment building were established to allow maximum expansion.

Although the present stage of Station development embraces the installation of only 132 mw. of generating capacity, the more detailed planning was based on a plant capacity of 400 mw. A portion of the capital outlay has been made with this in mind and additional plant up to 400 mw. capacity can be installed more economically and the benefits of forward planning realized.

It was considered undesirable to arrange for the cooling water outfall to be discharged directly into the Red River in the vicinity, due to the risk of recirculating warm water during low flow conditions in during the summer months. This possibility has been eliminated by using Cook's Creek as the outfall. Even when the plant is extended to its ultimate capacity the long route of the Creek will provide the necessary cooling effect.

The location of the main building to house the present generating units and any future units which may be installed, together with the location of areas for coal storage and switchyard, etc., are shown on Fig. 1. This key plan indicates the way in which the various components of the generating plant would be allowed to grow. The shape of the coal pile was to some degree influenced by the location of the main building, but the foremost thought in mind was to provide rail facilities which could be developed to handle 250 seventy ton cars per 8 hr. day when the Station reaches its ultimate capacity. The trackage was laid out on the basis that the coal stockpile would be contained within a loop, thus providing for the maximum length of track with the minimum of turnouts in order to simplify car movements. Sufficient length of straight track has been installed prior to the car dumper house to allow the installation of thaw sheds should they be found necessary for winter operation.

The relative locations of the main building, cooling water pumphouse and cooling water outfall are such that the cooling water inlet pipework and discharge tunnel follow the shortest possible routes. The cooling water outfall enters Cook's Creek tangentially at a point where the Creek bends, thus minimising the risk of bank erosion.

Determination of Basement Elevation in Main Building

The boiler house basement is at 740 ft. elevation and the turbine house basement is at 725 ft.

The decision to have a stepped basement which results in differing operating floor levels followed a great deal of investigation. The principal factors which had to be considered before reaching this decision were the cost of building and equipment foundation work and the cost of pumping cooling water through the condensers. The savings which will be realized by the reduced pumping costs with this arrangement more than offset the amount spent on the more complex foundations in the turbine house area.

Main Building Foundations

The conclusion drawn from a report prepared by Professor A. Baracos on the soil conditions was that bearing capacities of 1,500 psf. could be employed in the grey-brown clay 8 ft. and more below grade. This figure gives a factor of safety of about three and is determined from the unconfined compression strengths.

The clays above the 20 ft. depth would undergo large volume changes accompanying soil moisture changes, thus it was considered inadvisable to support structural floors upon the ground. It was recommended that heavy loads should be carried to the hard silt, sand, rock flour, gravel and boulder mixture at approximately 37 ft. below grade level.

To achieve this requirement the foundations are supported on augered cast-in-place "caissons". The minimum diameter of caisson employed was 3 ft. to permit manual excavation of the base to ensure bearing upon the "hardpan". Where exceptionally heavy loads occur the caissons were "belled out" to twice their top diameter to provide additional bearing area. A maximum net safe bearing value of 15,000 p.s.f. was used in the design.

Fig. 2. shows a section through a diamond drill hole which was bored in the turbine house area.

When it was established that the prevailing soil conditions necessitated an air space between the underside of the basement floors and the excavation it was decided to make full use of this for piping and cabling. By routing the piping and the power and control cables associated with the equipment located at the boiler house and turbine house basement levels in the air space, the complex system of floor trenches normally required in a large thermal electric plant was eliminated. This arrangement also enabled cabling and piping installation to be commenced in the subbasement whilst equipment erection was still in progress above. Furthermore, the basement floors were designed, and construction commenced, before all the equipment details were available, thus reducing the time between design and actual construction.

The 54 in. diam. steel pipes conveying the cooling water to the condensers are hung in the air space beneath the building.

To keep the distance between machines to a minimum the cooling water pipes in the turbine room area are contained in a cellular space in the base of the turbo-generator foundations.

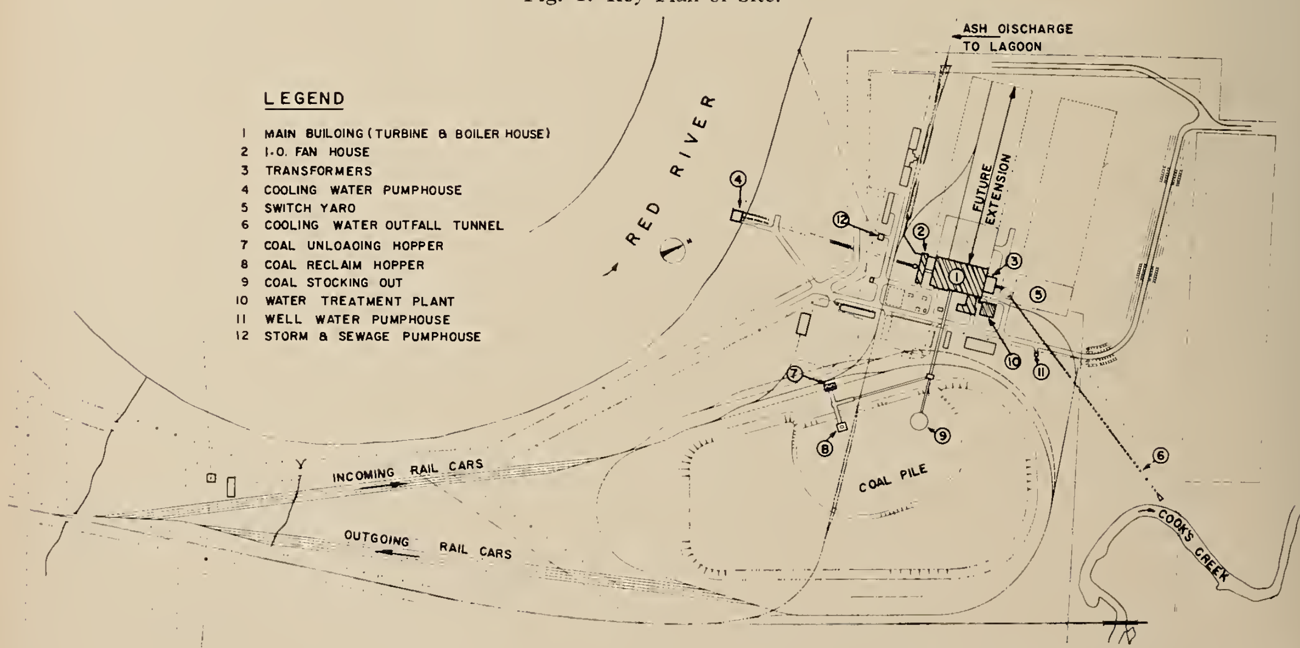
Description of the Cooling Water System

Water from the Red River is admitted to each cooling water pump chamber via a fixed coarse bar screen and a ⅜ in. mesh travelling band screen. The band screens are 10 ft. wide and at 38 ft. centres. A sluice gate is arranged between the fixed and travelling screens to allow isolation of a pump chamber.

The cooling water system is on a unit basis with one set of screens and one pump for each turbo-generator. No provision is made for cross connections.

The level of the intake is at 699.5 ft. elevation, thus providing the screens with a minimum wetted depth of 10 ft. 6 in.

Fig. 1. Key Plan of Site.



The cooling water pumps at present installed are single stage, vertical, mixed flow, propeller type and are each capable of pumping 72,700 US gal. per min. against a head of 36.6 ft.

The winter requirements for the condenser and auxiliary heat exchangers are approximately 36,000 US gal. per min. and to minimize pumping costs the pumps are driven by two-speed (354/237 r.p.m., 900/250 hp.) 4,000 v. vertical squirrel cage induction motors. Each motor has separate high and low speed windings, each winding having its own circuit breaker. The pumps may be run at low speed when the cooling water inlet temperature is less than approximately 45° F.

The discharge from the pumps is below the floor. Each pump has a 54 in. hydraulically operated discharge butterfly valve.

Each pump discharges into a 54 in. steel pipe approximately 1,200 ft. long. The bottoms of the pipes are about 16 ft. below grade level.

An interesting feature of the cooling water system is that the 54 in. pipes pass underneath the chimney foundations. This was done to avoid diverting the route of the pipes as they enter the main building area and thus avoid interference with future extension work. The concrete base slab of the chimney is supported on caissons, and, if necessary, access to the pipes can be had by digging beneath the chimney base without disturbing the chimney foundations.

Each 54 in. pipe terminates in two 42 in. branches, one branch to each half of a condenser. These condenser inlet branches are each fitted with a hand operated butterfly valve. The 36 in. condenser outlet branches are each fitted with electrically operated butterfly valves.

There are rubber expansion bellows between the valves and the condenser on both the inlet and outlet pipes to permit expansion of the condenser, which is supported on helical springs.

The 36 in. outlet branches connect into a 54 in. outfall pipe which terminates in a concrete syphon sealing chamber 150 ft. away from the condensers.

One outfall pipe is provided for each unit. The bell mouth outlet is always sealed by a minimum of 5 ft. of water due to the installation of a weir in the chamber at 715 ft. elevation.

The water flows from the sealing chamber to Cook's Creek via a 7 ft. 6 in. diameter concrete tunnel.

A section through the sealing chamber is shown in Fig. 3.

To ensure release of air from the pipes when the system is being primed, both automatic and manually operated air release valves are installed at the high points.

Due to the height of the syphon in this system and the low temperature of the Red River in winter, it was considered desirable to install vacuum pumps to remove the air coming out of solution at the high points in the system which are above the hydraulic gradient. The high points in the system are piped to a vacuum sealing tank from which the pumps exhaust the air.

There are two vacuum pumps installed to serve Nos. 1 and 2 Units. Each pump is capable of evacuating 240 c.f.m. at 25 in. Hg.

To avoid water hammer in the system which could occur if a pump is tripped out, or fails, anti-vacuum valves of a special design have been installed on the condenser outlet pipes. Thus, if the water column separates at the point of low pressure, air is admitted in sufficient quantity to prevent rejoining of the columns.

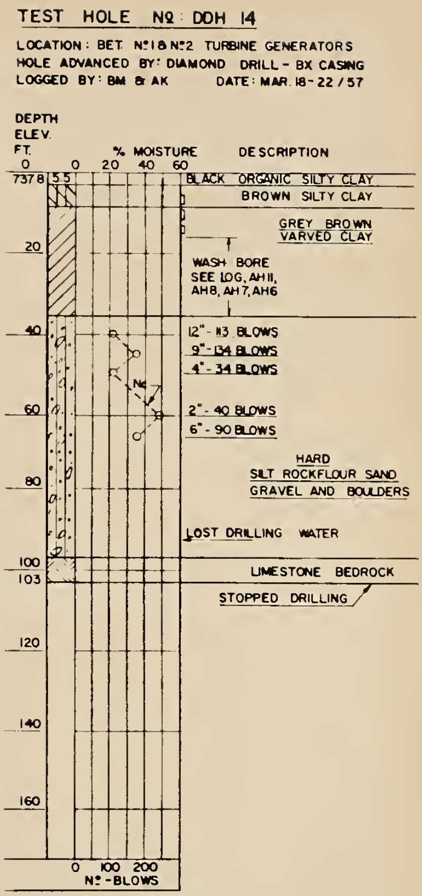


Fig. 2. Typical Soil Boring in Vicinity of Main Building.

Coal Handling Equipment

South Souris lignite coal, unscreened and crushed to minus 2 in., is delivered to the Station in 70 ton nominal capacity, gondola type, railroad cars and discharged to an underground coal dump pocket to enter the coal handling system.

The flow of railway traffic is shown on Fig. 1. This arrangement provides an efficient flow pattern for incoming loaded cars and after discharge at the dumper house cars continue round the loop to be finally marshalled on the outgoing siding.

Unloading of cars while the Station capacity remains at 132 mw. will be assisted by a coal car shakeout. The rate of coaling during this period will not exceed 400 tons per hr. At a future date, however, should the Station be extended, the shakeout will be replaced by a rotary car dumper. Provision has been made in the design of the dump pocket so that a rotary dumper of any existing type can be fitted with the minimum of inconvenience. To match this increased unloading rate, all conveyor equipment can be boosted to handle 800 tons per hr. by the substitution of larger motors and drive couplings and by changing chain drive sprockets on the conveyors.

The system of conveyors is such that coal emptied into the car unloading hopper can be taken to the coal bunkers in the main building after passing through the coal crushers in the crusher house, or delivered to the Station stockpile. When withdrawing coal from stock it must be dumped into the reclaim hopper by scraper or bulldozer where it enters the conveyor system for crushing and transfer to the Station coal bunkers.

The car unloading hopper and the reclaim hopper are fitted with reciprocating feeders and vibrating feeders respectively to ensure an even flow of coal on to the conveyor belts.

Upon commencement of a coaling operation the conveyors, feeders and crushers are started in sequence and tripping of any item will shut down all preceding equipment in sequence. A pushbutton local to all major equipment must be depressed by a roving operator before the system can be started from the coal plant control panel. A personnel protection system in the form of a fail safe emergency trip cable is furnished alongside all conveyors. All equipment is stopped and an alarm is initiated if this cable is pulled. Control circuits must be key reset before equipment can be restarted.

An outstanding feature of the Selkirk Station is the design of the coal bunkers. Each of the four bunkers is an independent container, comprising a 31 ft. diam. and 39 ft. high vertical cylindrical section mounted above twin discharge cones each feeding a pulverising mill. Each bunker when fully charged will hold 725 tons of coal and with all bunkers full the two units could operate at maximum rating for 24 hrs. with the coal plant out of service.

It is considered that there are certain distinct advantages to be gained by adopting the silo type of bunker arrangement in preference to the more conventional rectangular design. The foremost of these is that due to the absence of corners, flow characteristics are improved. There is also a saving in the quantity of steel involved to give the same storage capacity. The silo type of bunker can more readily be sealed against dust and air leakage. These advantages are to some extent offset by additional field steel erection costs.

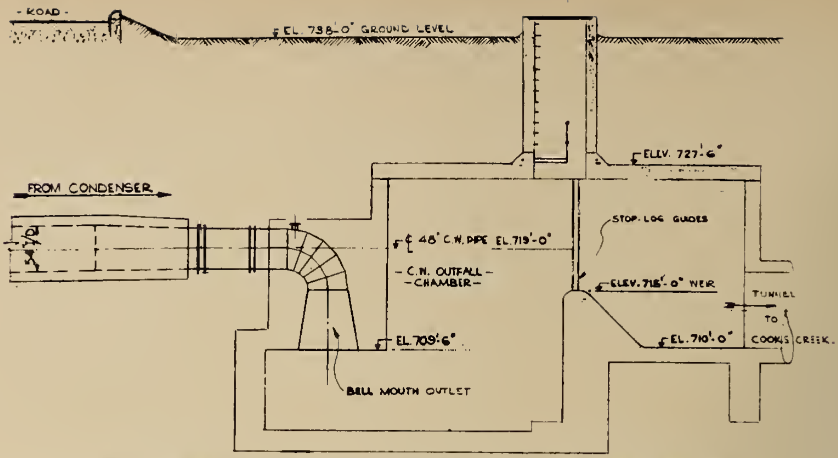

Fig. 3. Section through Cooling Water System Sealing Chamber.

Water Supplies and Methods of Treatment

Considerable quantities of water are required in the operation of a thermal generating station. For many of the varied services for which water is used quality is a prime consideration.

As in the preliminary studies for all generating stations, considerable research time was spent before deciding on the source of water and method of treatment for each system at Selkirk. The choice open for source of water in this case was limited to the Red River or subterranean waters beneath the Station site.

Analyses were available of the Red River water and study of these, in conjunction with samples taken during the investigation period, indicated that this water would require a high degree of clarification before it could be processed by either deionisation or evaporation. Efforts were then concentrated on obtaining the maximum information available on the aquifer.

Local well owners were approached and data obtained on quality and drawdown indicated that tests on the Site would be justified. The outcome of these tests is that there are now two wells sunk to a depth of 140 ft. from which two 5-stage bowl pumps can each deliver 500 US gal. per min. to cater for boiler feed, general service and domestic water requirements.

All water discharged from the deep wells is injected with 2 p.p.m. of chlorine for the purpose of killing any trace of bacteria. It is then piped to the water treatment building (See Fig. 5) where it is passed through a coke tray aerator to oxidise any soluble iron present. The water is then divided into two streams, one of these being destined for boiler feed make-up, the other for general water services and domestic supplies.

The boiler feed make-up which can be processed at a rate of 60 US gal. per min. passes through three separate stages of treatment before reaching the desired standard of purity. The first of these stages consists of partial softening with lime in an 11 ft. diam. reactor. This treatment reduces the alkinity, hardness and dissolved solids content and simultaneously coagulates and removes any organic matter present. Water from the reactor is passed to a clearwell from which it is pumped as required through two anthracite filters. This is followed by a second filtration through a carbon filter to remove chlorine and any remaining traces of organic matter that may have escaped coagulation.

Effluent from the filters is piped to the demineralisation units where silica and dissolved solids are almost completely removed.

The demineralising plant consists of two separate banks, each bank having one 3 ft. 6 in. diam. cation unit, one 3 ft. 6 in. diam. anion unit and one 3 ft. diam. mixed bed unit. In service, each bank is regenerated alternately, using common regerant pumping and storage facilities. The regeneration proceeds automatically after unit selection and initiation by the operator.

Chemical effluent from the demineraliser units during the regeneration cycle is directed to a collecting tank located in the basement of the water treatment building. This lined mild steel tank which will hold the waste products from one complete regeneration cycle, or a quantity in excess of 11,000 US. gal. plus approximately 1,000 gal. of lime slurry blown down from the reactor, is equipped with a slow speed agitator to retain solids in suspension. These wastes are pumped by one of two stainless steel pumps via an asbestos-cement pipeline to the ash disposal lagoon.

All feed make-up water leaving the demineralisers is fed directly to the condensers. Due to the corrosive nature of this ultra pure water, polyethylene piping is used for this service. The water is introduced into the top of each condenser via a stainless steel spray nozzle so that it can be broken down into small particles and its dissolved oxygen content effectively reduced by the condenser air ejectors.

The second stream leaving the aerator, that for general services and domestic requirements, is far greater than that for feed water make-up and is of the order of 350 US gal. per min. By pumps taking their suction from the aerator clearwell the water is passed through three 6 ft. diam. sand and gravel filters which remove iron precipitates from the water. The filters discharge to a concrete reservoir built into the foundations of the water treatment building. The maximum capacity of this reservoir is 44,000 US. gal. and it acts as an extension to the water storage facilities in the main station building. Pumps controlled by level switches in a high level general service water tank located centrally in the main building take their suction from this reservoir and deliver water to the high level tank for distribution to the many items of equipment in the Station requiring cooling water.

Water for drinking purposes and

other domestic uses is tapped off the main supply line to the high level general service tank and further processed before entering a 1,500 US. gal. storage tank. The treatment given to this water comprises a minimum of one hour's retention in a small tank while being dosed with a 1% solution of sodium hypochlorite. It is drawn from this tank by a booster pump to be passed through a carbon filter to remove all traces of odour and taste picked up in the preceding treatment and then through a base exchange softener before finally reaching storage.

Water Storage Facilities

Reference has already been made to some of the provisions for the storage of water, therefore this section will deal briefly with another aspect of the water storage problem in a power station.

Great care has to be exercised in the proper selection of lining materials for tanks and pipework. As in the selection of all materials and equipment, economics play an important role in the choice of linings; whereas if cost were of no consideration, most of the pipework and tanks would be given a liberal lining of rubber, some less experience substitute has to be found in most instances.

In the case of the feed water storage vessels, this substitute takes the form of vinyl plastic. This material will have no harmful effects on the demineralised water in storage and is expected to maintain complete separation between the water and the steel tank, without maintenance, for well over five years. The vinyl plastic is sprayed on to a thickness of 25 mils after the tank interior has been sandblasted and forms a cocoon over all steel parts.

The collecting tank for water treatment wastes is also lined with a sprayed-on vinyl cocoon and in this case the lining material has to protect the tank from attack by a mixture of dilute sulphuric acid, dilute caustic soda and lime slurry. Again no maintenance is anticipated during the first 5 years of operation.

The domestic water tank and the general service water tank are treated internally with special paints. After the internal surfaces have been prepared by wire brushing a coat of metal primer is applied, followed by two final coats of a gilsonite base preparation. Length of life and ability to prevent odour and taste being imparted to the water are essental properties of this coating.

Vessels receiving high temperature drains and boiler blowdown receive no internal treatment.

Steam Generators and Ancillary Equipment

The two boilers are each designed for a continuous capacity of 600,000 lb. per hr. of steam and a 4 hr. peak load of 625,000 lb. per hr. The steam condition at the superheater outlet at these ratings is 875 p.s.i.g. and 915° F.

The single pass furnace of the boiler units is completely water-cooled and employs natural circulation. There are two drums per unit, one 72 in. diam. and the other 48 in. diam. The steam drum, which is the larger of the two, is equipped with cyclone steam separators with a collecting manifold and steam scrubber baffles.

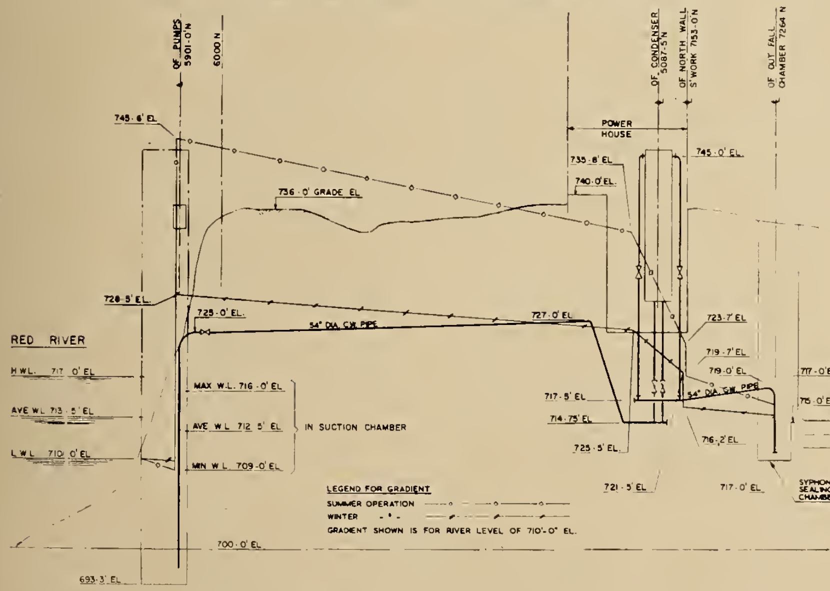

Fig. 4. Hydraulic Gradient for Cooling Water System.

The superheaters are of the radiant type arranged to be fully drainable. Between the primary and secondary sections of the superheaters a submerged surface-type attemperator is located to give fine control on steam temperature. The desired superheater temperature can be automatically maintained over a load range of 90,000 to 625,000 lb. per hr. of steam.

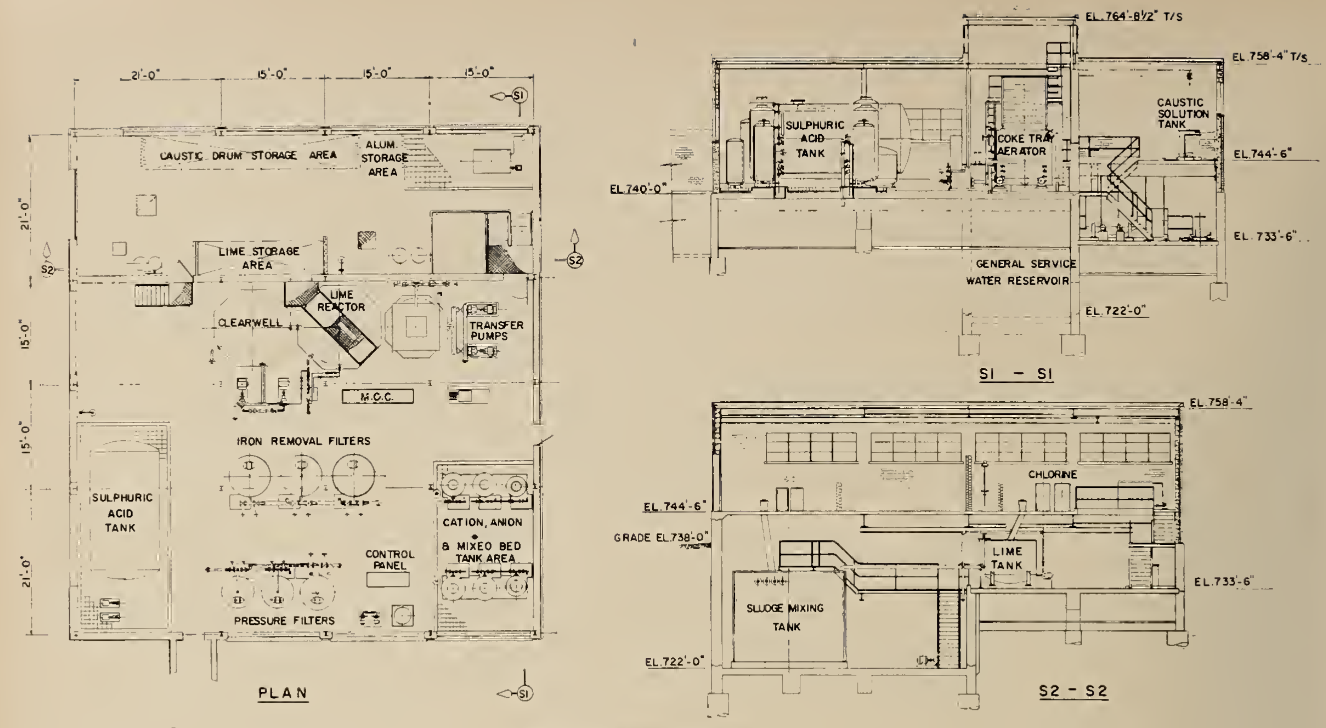
The boiler bank and superheater tubes are furnished with electrically operated retractable type steam sootblowers arranged for automatic sequential control from the plant control room.

The four pulverisers per unit each serve three circular coal burners distributed across the front wall of the furnace in 4 rows of three. An automatic electrically-operated igniter operating on No. 2 fuel oil is provided for each burner. The burner lighters are of the mechanical atomising type and twelve of them are capable of maintaining a steaming rate of more than 90,000 lb. per hr. The burner impellers, air registers, igniters and coal/air valves are all power operated and controlled from the plant control room.

The two forced draft fans and the two induced draft fans per unit are driven through hydraulic couplings. The forced draft fans are fitted with variable inlet vanes and the induced draft fans with adjustable multi-leaf inlet dampers.

At very low loads air flow through the forced draft fans and gas flow through the induced draft fans is controlled by remotely positioning the inlet vanes and dampers respectively. Upon increase in load the inlet vanes and dampers will be fully opened and flows will be varied by means of the hydraulic couplings.

There are two regenerative type air heaters per unit. Each air heater is fitted with a cleaning device for steam or air blowing. The cleaning operation can be controlled manually, or automatically, in sequence with the main furnace sootblowers, from the sootblower panel in the plant control room. Air or steam can be selected as the blowing medium by a switch on the sootblower panel. Air will be used when steam is not available during start-up. A high pressure off-load, water washing system is also provided for each air heater. During the washing operation the air heater rotor speed has to be reduced. This is achieved by means of an air driven motor which can be engaged to the rotor drive speed reducer by manually operating a clutch lever. During the washing operation the water after passing



WATER TREATMENT PLANT

Fig. 5.

through the air heater elements is collected in a hopper below the discharge gas duct and drained to waste.

Two tubular type dust collectors with an anticipated collection efficiency of 89.1% remove suspended solids from the gas stream.

Ash and Dust Equipment

Furnace ash is collected in a wet hopper located below the boiler. It is discharged as a water-ash mixture through a clinker crusher and passed to the ash lagoon with the assistance of a venturi type jet propulsion pump. The 9 in. diam. pipework between the main building and the ash lagoon is approximately 1,300 ft. in length and is of cast alloy material. It is arranged so that it can be turned periodically to allow an even amount of wear to take place on the pipe wall.

During operation of both steam generator units it will take about 35 min. to empty their two ash hoppers. After all bottom ash has been manually discharged, fly ash is automatically withdrawn from the collection points of both units. This is done in sequence, from first one unit and then the other at a rate of 20 tons per hr. The fly ash system will operate for approximately 12¾ hrs. in every 24 hr. to remove the dust accumulation from two units operating continuously at MCR. Fly ash accumulated in the mechanical dust collector hoppers, air heater hoppers, high level hoppers in the gas ductwork, furnace rear pass hoppers, stack hoppers and the vacuum cleaning plant dust storage bin is withdrawn in a dry state through a water jet exhauster where it is mixed with water. It then passes through an air separator, which vents entrained air to atmosphere, and the mixture of dust and water then flows by gravity through the ash discharge pipework to the lagoon.

Turbo-Generators

Each turbo-generator unit is capable of a continuous maximum rating of 66,000 kw. The turbine is of the impulse reaction type consisting of 2 cylinders on a single shaft directly coupled to a hydrogen-cooled alternator.

Bleed points from the turbine supply steam to 5 stages of feed water heating. The third stage heater takes the form of a high level deaerator.

Each machine has its own independent motor driven exciter set.

Turbine House Crane

The turbine house is equipped with a loading bay and a 150 ton overhead crane. This crane is sized to lift the heaviest piece of equipment of a 100/120 mw. machine and will, therefore, save installing of a further crane if a machine up to this size is called for in the future.

Plant Control

Both boiler-turbine units are controlled from a central plant control room. This room is located at the boiler operating floor level and overlooks the operating floor of the turbine room.

It is anticipated that 3 control room operators and 2 roving external operators will be required each shift. The roving operators will carry out specific local operations during start-up and shut-down of the machines and will maintain contact with the control room operators by means of a PAX and voice paging system.

Although boiler light-off and loading will be carried out from the control room, the control room operator will rely on the external operator for assessment of flame conditions.

Automatic means are provided to maintain constant steam temperature, to control feedwater flow to the boiler and to control the fuel/air supply to the furnace.

Steam after leaving the drum passes through a 2-stage superheater. To provide a means of controlling final steam temperature, a three-way valve in the primary superheater outlet can be positioned to control the amount of steam delivered to a drum type attemperator. The cooled steam is then mixed with the main supply before entering the secondary superheater.

A resistance type sensing device measures steam temperature leaving the secondary superheater. The output from an electronic controller is converted to a pneumatic signal to operate the air cylinder positioner on the three-way valve. To improve system response, steam flow is utilised to produce an anticipating signal.

Feedwater flow to the boiler drum is controlled by changing the feed pump speed. There are two 100% boiler feed pumps and each is driven by an electric motor through a hydraulic coupling. There is no feedwater regulating valve.

Boiler drum level acts as the final feed flow control element but signals from the steam and feedwater flow transmitters are utilized to give a 3-element control system.

A steam pressure-steam flow two-element control system (steam pressure being the master) automatically controls fuel and air into the boiler to maintain steam pressure constant at the superheater outlet.

The amount of fuel delivered by the pulveriser is varied by controlling the amount of primary air passed through the mill by the associated P.A. Fan. This is done by pneumatically positioning the P.A. fan discharge damper. A 2 speed coal feeder motor automatically adjusts the amount of coal fed to the pulveriser and maintains coal bed thickness in proper relation to primary air flow.

Combustion Air and Station Heating Systems

The ventilation and combustion air supply system is designed on a unit basis. There is one boiler house plenum chamber and one turbine house plenum chamber for each generating unit, each with its own air intakes, coil face and bypass dampers, heating coils, fans and discharge ducts.

The boiler house plenum fans draw outside air through the heating coils and discharge into the boiler house area near the forced draft fan suctions. The face and bypass dampers in the plenum chamber are arranged to modulate so as to maintain a selected air temperature in the discharge duct to the boiler house. Control of dampers is carried out by means of duct mounted thermostats.

The turbine house plenum fans deliver air to the turbine house via distribution ducts located in the roof trusses. This air ultimately passes through louvres provided in the partition wall between boiler house and turbine house. Upon entering the boiler house a portion of the air is taken by the forced draft fans for combustion purposes. The remainder passes upwards, providing a means of ventilation, and is eventually drawn off and recirculated by the turbine house plenum fans. The air used for combustion is replaced by drawing outside air through the face and bypass dampers and the heating coils. The dampers in the turbine house plenum chamber are arranged to modulate to maintain a selected air temperature in the discharge duct to the turbine house.

Coil heating in the plenum chambers and space heating in the main building and water treatment building is accomplished by 100 p.s.i.g. steam. Steam from the same system but reduced to 15 p.s.i.g. is used for heating purposes in the administration wing.

The method of distributing heat in the general working areas is by use of finned radiation and unit heaters. Fin strip radiators are located around the main building walls in roughly two tiers. The upper tier is controlled at various points by thermostats actuating on-off control valves so that these heaters are brought into service as demanded by temperature level. The lower tier can be controlled by hand as desired. Unit heaters are located at all outside doors and at other selected points throughout the Station. Operation of these unit heaters is by means of local thermostats providing on-off control of the fan motors. Thermostatically controlled unit heaters are the sole means of maintaining temperature in the water treatment building and induced draft fan house. The administration wing offices are served by finned radiation and the workshop area by unit heaters.

Steam for all heating services is available from three sources. A package type water tube boiler arranged to fire No. 2 fuel oil and to produce 20,000 lb. of saturated steam per hour at 100 p.s.i.g. is the basic source of supply. This boiler will be used to provide heating steam during off-load periods in the Station and also for combustion air heating during initial start-up of the main station generator units.

The other means of providing heating steam is from the two main steam generator units via pressure reducing and de-superheating equipment. When sufficient steam is available from either or both of these sources, the auxiliary boiler will be shut down.

All condensate from the heating system is led back to the reserve feed water tanks. The arrangement of this system is such that condensate is returned to the tank associated with the unit from which the steam was taken. During operation of the auxiliary boiler, feed water is drawn from either feed water tank and condensate is returned to the same tank.

Outlying buildings at the site are equipped with their own heating systems. The cooling water pumphouse is heated by an oil fired hot air space heater coupled to a system of distribution ducts. Besides heating the general pumphouse area, the hot air is also discharged into the cooling water screen chambers for de-icing purposes. The coal crusher house is heated and ventilated by a hot air ducted system, utilizing return air plus a portion of filtered outside air. Heating is carried out by electrical coils. This system pressurizes the crusher house areas containing electrical and control equipment and also the locker room and shower stall, thus preventing the ingress of coal dust.

The plant control room and telecommunications room are served by a 12 ton package type air conditioning unit, using fresh and return air delivered through a duct distribution system located in the ceiling of these rooms. The unit incorporates a steam heating coil for air tempering purposes.

Exhaust fans are provided in the main building, induced draft fan house and water treatment building for use during the summer months.

Piping Materials and Construction

In selecting materials to be used for the main steam and feed pipework, temperature is the main criterion. Since the superheater outlet steam temperature at Selkirk will be 915° F., a 1¼% chrome, ½% molybdenum alloy was selected for the main steam pipework. If a plain carbon or even a carbon-molybdenum steel were used for this service, there would be a distinct risk of graphitisation taking place. The presence of chromium in the piping material tends to have a stabilising effect and inhibits the formation of graphite at elevated temperatures. The use of this material extends to auxiliary steam pipework and to all fittings and valves which will be subject to main steam temperature.

The final feedwater temperature of 400° F. is well inside the limit for use of carbon steel materials, and apart from the necessity for heavy wall piping on the discharge side of the boiler feed pumps, the feed pipework is to ASTM A.53 specification.

Butt welded joints are employed practically throughout the various piping systems and all shop and field joints in the steam mains are made by an inert gas welding process.

Application of Microwave Radio Links

R. W. Wilson, M.E.I.C.,
Radio Systems Engineer,
Maritime Telegraph & Telephone Co., Ltd.

This paper will be presented at the Annual General Meeting of the Engineering Institute of Canada, Winnipeg, May 1960.

Microwave radio-relay systems have played an increasingly important role in recent years in the provision of large quantities of high-grade communication circuits. Systems can be categorized as "heavy route" or "light route" depending on circuit requirements and distances involved between terminal points. Careful route layout is required in order to use the minimum number of repeaters necessary to provide the desired performance and reliability.

The requirement for a system is created by the demand for more circuits or the improvement of existing circuits. Once a requirement has been established, the most suitable route must be determined. If the end points of the system are widely separated and intermediate requirements are not of major proportions, considerable savings can accrue with wise routing. An actual case will be used to demonstrate this approach to routing. Sometimes special cases create the demand for a microwave system. A case will be described in detail where a complete toll line was replaced by a microwave system without circuit additions.

For a proposed system, the required performance must be established with consideration for the ultimate capacity of the route. The system must then be engineered to these requirements. Cost and propagation studies must be made and the technical and service features of available equipment must be investigated to determine the best means of meeting the requirements. This paper details the calculation and considerations for performance and reliability necessary to engineer a light route system for a typical case. Performance figures based on actual results are presented. Systems using both frequency and space diversity to maintain propagation reliability are described.

THIS IS an age when good communication with our fellow man is of more concern than ever before. It is a continuing search for the goal of perfect communication that has led to vast networks all over the world for the sole purpose of passing information immediately from one person or machine at one location to another over vast distances.

Possibly the greatest single contributor to this and future realizations is the application of the microwave spectrum and associated technique to serve as the carrier of information. During the past decade, the use of microwave systems has become the means of transmitting large numbers of high-quality voice circuits as well as television pictures and data information over distances of thousands of miles. Microwave is also coming into wider use for short-haul facilities over distances of the order of 100 miles or so. It is the intention of this paper to outline considerations for the use of microwave in the short-haul field, from the point of view and the experience of an operating common carrier which has been using microwave for just this application for some thirteen years.

The use of microwave has developed to a high degree because of necessity. A bandwidth of several megacycles is required for the transmission of television pictures and large groups of voice circuits. The microwave spectrum is the only source of bandwidth capable of satisfying the requirements. Thus the state of the microwave art has developed to the degree that systems can be engineered with reliability and performance characteristics equal to or better than those of other facilities. The width of the baseband which carries the information on a microwave system is only a small percentage of the operating frequency. Because of the nature of microwave frequencies, the energy from a transmitter can be maintained within a prescribed area, so that the same frequencies can be used in adjacent areas without interference. There is, of course, a practical limit to the spectrum space available for efficient usage, but this limit is expanding day by day in research laboratories and field installations.

The manufacturers of microwave equipment are continually improving their product so that there is suitable equipment to do a given communication job, be it thousands of circuits over thousands of miles in one extreme, or dozens of circuits over hundreds of miles or less in the other extreme. Reliability of materials used has improved, and more is known about system behaviour. The use of the microwave spectrum has become so wide that regulatory bodies find an increasing problem in their administration of the spectrum.

Frequency assignments must be made on a coordinated basis for maximum efficiency in use of the spectrum, and the greatest benefit to all users. Even though the energy from a microwave transmitter can be maintained within a certain area, this is only in degree, and each case must be considered on its own. This applies stringent requirements on the user to ensure that a proposed system will not interfere with another system or that some other system will not interfere with his. The ultimate capacity of a route within a given frequency band, the type of antenna, the transmitter power and output spectrum, receiver sensitivity and selectivity as well as geographical proximity are factors involved in interference considerations. Users must comply with the Radio Act. In Canada it is the Minister of Transport who administers this act. Those who contemplate the use of microwave equipment must have approval of the Department of Transport before such a system may be placed in service.

A need must be established before a microwave system is planned. Since it may be possible to provide facilities by some other means, such as cable or open wire, these facilities must also be investigated. This is particularly true in the case of light route systems. The basic requirements are established by demand for new or additional facilities, or replacement of old facilities. Sometimes this requirement may come about as the result of natural growth, or it may arise for other reasons such as storm damage, rapid unexpected economic growth in an area or for defence requirements. The number and quality of the circuits required is a major consideration since the ultimate choice of equipment to be used will depend to a large extent on this. There is no point in establishing a high-capacity system, using equipment capable of long-haul circuits. Cost studies considering capital investment and annual carrying charges must be carried out.

The location of the terminals will be determined by requirement for facilities, but the location of repeaters between terminals will be determined by factors which have no direct relationship to the requirement for facilities. If there are requirements at other locations between the end terminals, this will, of course, influence the route. In general, a repeater will be required on an average of every 25-30 miles between terminals. The repeater must be self-contained and capable of operating continuously for weeks or even months without being revisited. This means that standby power equipment must be provided as part of the repeater which must be capable of carrying the station load. The site should be accessible from travelled highways and should be as close to a maintenance centre as practical. In systems in use today in most applications, interruptions of a few milliseconds cannot be tolerated, thus it is necessary to provide a protection channel and a source of power which will not be interrupted for even an instant.

The actual location of a repeater station is usually proposed as the result of map studies. Following this the site must be visited to ascertain actual conditions and a propagation survey is usually carried out to confirm intermediate elevations, calculated clearances and required antenna heights. Features of the paths between repeaters which require special consideration are usually obvious from maps and profiles drawn from maps. These features may be such things as large bodies of water or flat land which may or may not require special treatment

On average paths sufficient clearance of the direct ray over intervening obstacles must be provided. The necessary clearance over a given obstruction is a function of the wave length of the frequency used, the length of the path and distance of the obstruction from the ends of the path. The radius of the fresnel zone at the point of obstruction must be determined and the amount of clearance in percentage of fresnel zone can be specified. The first fresnel zone radius is calculated in accordance with the following formula:—

$$R_1^2 = \frac{\lambda d_1 d_2}{d}$$

Where all quantities are expressed in the same units.

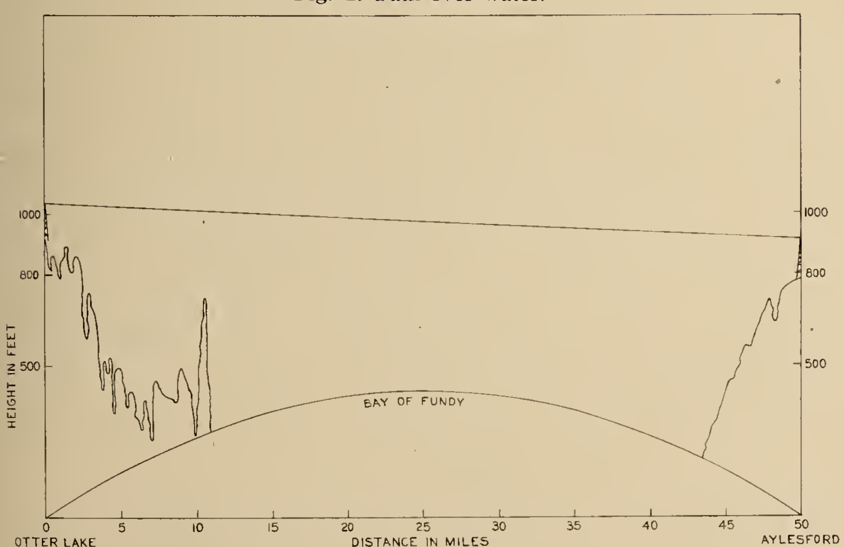
In simplified form

$$R_1 = 72\left[\frac{d_1 \times d_2}{d \times F}\right]^{1/2}$$

Where $d_1 + d_2 = d$ and F is the frequency in thousands of m.c.s. If a profile of the proposed path is drawn on true earth profile paper, 0.6 of first fresnel zone clearance should be provided. This has been found to provide sufficient margin on average paths over rough terrain.

In the case of a path over water such as shown in Fig. 1 special treatment is necessary. Paths of this type are particularly susceptible to fading due to interference of the direct and reflected rays. This is known as fresnel type fading and is severe when the point of reflection falls on a good reflecting surface with a phase shift of 180° on reflection. If natural obstructions can be used to block the reflected ray, the effect of fresnel type fading can be reduced. Such a path is shown in Fig. 2. If however, blocking of the reflected rays cannot be achieved, a form of diversity reception must be used. This may take the form of vertical space diversity or frequency diversity. Paths using both types at different frequencies are described in this presentation. Fig. 3 shows the relative performance to be expected with Rayleigh distribution fading on non-diversity circuits and those using frequency diversity.

Fig. 1. Path over water.



Tests have been conducted on over water paths which showed that fresnel type fading of the order of 40-45 db. was common and that coefficients of reflection were as high as 90%. Fades can be overcome by the use of extremely high power transmitters, but this is generally not economical nor is the predictable improvement sufficient to warrant the high cost. Vertical space diversity has been used with a great deal of success. Space diversity will generally maintain the circuit within limits but it is maintained by others that it will not completely eliminate fresnel type fades, since the lobe size varies during the fading period and correlation of fading does not exist at the antennae. Normal dual diversity is used but in severe cases triple space diversity will fill in most of the gaps left by dual space diversity.

By placing the third antenna ½ Svd above or below the other two antennae complementary diversity is secured over a range of ½ to 1½ times Svd. (Where Svd is the calculated vertical spacing for fully complementary diversity.) Svd can be determined in the following manner:

The spacing should provide approximately a $\lambda/2$ variation between the geometrical path difference in the two cases. The spacing in feet for d in miles, h in feet and λ in centimetres and f in megacycles is given by

$$\text{spacing} = 43.4\lambda d/h$$

Where h is the height of the transmitting antenna above a plane drawn tangent to the point of reflection.

Frequency diversity provides the most reliable protection against fresnel type fading since transmitters and receivers usually use common antenna and the protection equipment is diplexed with the regular equipment so that exact correlation is maintained at both frequencies. Using this method the amount of signal received by one receiver when the other receiver is in fade can be predicted as a function of the path and frequency difference. Tests by others have shown that frequencies

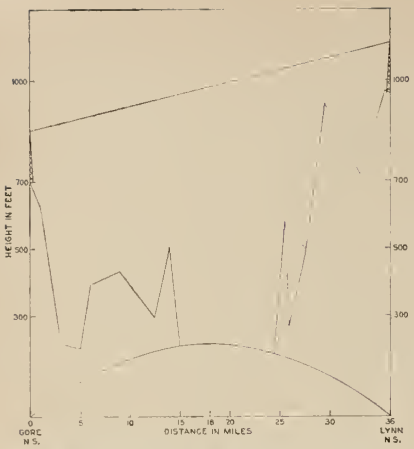


Fig. 2. Fresnel type fading reduced by blocking of the reflected rays.

differing by 4 to 8% are required for frequency diversity. Thus it seems that at microwave frequencies, frequency diversity is perhaps the most reliable means of maintaining propagation reliability and since higher microwave frequencies become easier to control as to where they go, the use of additional frequencies for this purpose would not be so likely to limit other systems in the same area as would more likely be the case with high power transmitters. A further major argument for the use of frequency diversity is that a highly reliable form of protection is provided for the regular channel and one channel is available for maintenance and routines which are absolutely necessary to the provision of highest reliability.

Once the paths of a system have been established as satisfactory and antenna heights have been determined for the frequency band to be used, the performance requirements must be considered. If frequency diversity is to be used, the diversity equipment will also perform the function of equipment protection in case of component failure. Hot standby equipment on the same frequency may be used, but even on light routes this is not too good a method since an interruption can occur on switchover. Thus even for equipment protection, a frequency diversity system with diversity combiners or microsecond switches offers the best solution.

The degree of reliability is represented by the ability of the system to provide uninterrupted service. Reliability is thought of in terms of propagation reliability and equipment reliability. In well designed systems, the degree of reliability can be in excess of 99.99% which is relatively few minutes outage in a year.

The performance of a microwave system is measured by its ability to maintain a good ratio of signal to noise over a long period. Noise includes crosstalk, which arises as the result of intermodulation in non-linear elements of the system and will appear as babble on circuits operating over the system. The receiver noise figure, path losses between transmitter and receiver, the transmitter modulation characteristics and the type of antenna and transmission lines are the most important factors in determining noise performance of a system. The effect of these factors is either known or can be calculated for a specific case so that the performance to be expected of a system is predictable. In calculating the performance characteristics of a system, care must be taken that sufficient margin is provided to care for variations in path loss due to fading, and that a maintenance margin is provided. No piece of electronic equipment in the field will maintain its peak performance indefinitely. Components and vacuum tubes are bound to deteriorate. These variations in performance show up as a deterioration in system performance, and therefore must be carefully considered in the system design.

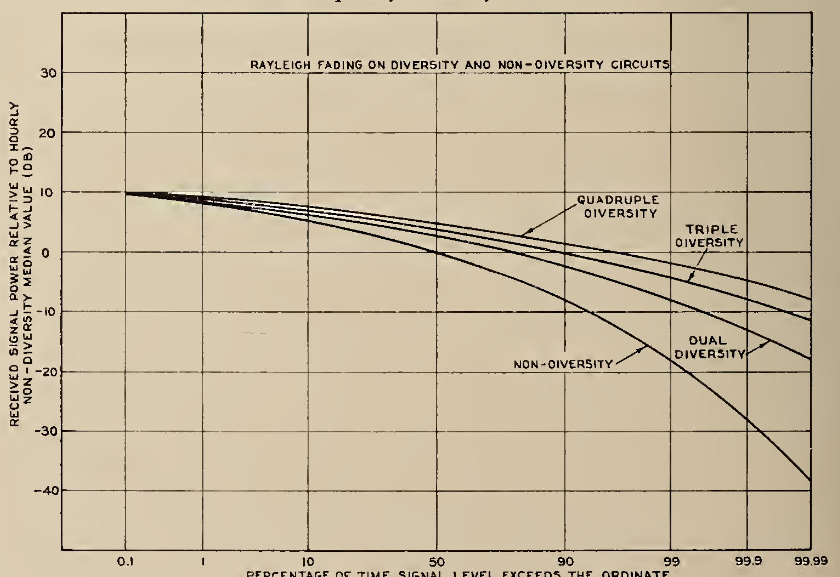
The mechanics of measuring the actual performance of broad band microwave systems has been somewhat simplified recently by the introduction of white noise tests sets. These sets can be used to load a broad band facility at the transmitting end with noise which represents the full complement of circuits. The equivalent space of one circuit is not occupied at the transmitting end, and the amount of noise received at the far end in the corresponding unoccupied space provides a rapid means of checking intermodulation performance.

Maintenance considerations are of prime importance in the establishment of a microwave system. The mechanical layout of the equipment, similarity to other equipment familiar to the user, and the quality of components used in circuitry, all affect the maintenance of the system. A maintenance margin as mentioned above should be provided. The quality of instruction books provided with a given equipment is one of the largest single factors in determining the quality of maintenance, since equipment failures, mainly vacuum tubes, are the source of most outages in a well engineered system. Good maintenance may be taken for granted, but in the end it is the maintenance man on a system, whose efficiency will determine the system performance and reliability once it is installed, and he must have the right information and tools for the job.

In choosing the equipment for a system, there are many sources of satisfactory equipment, and it is up to the system design engineer to determine which equipment is best suited for a particular job. All available information should be reviewed and if at all possible, working systems of the same type equipment should be visited for first-hand information.

A good alarm system is an important part of any microwave system. Since repeater stations are normally unattended, it is essential that information be passed to an attended location, as to whether or not abnormal conditions exist at a repeater. The scope of an alarm system might range all the way from a simple station alarm which indicates yes or no, to a complex system which can check many conditions and give a qualita-

Fig. 3. Relative performance with Rayleigh distribution fading on non-diversity and frequency diversity circuits.



tive report. Part of the alarm system should contain control functions so that the switches may be controlled remotely for such functions as exercising the emergency power equipment. The importance of a reliable alarm system cannot be over-emphasized, and the provision of a reliable alarm system either over the microwave system itself or over other facilities warrants major consideration in system design.

The major items to be considered in the establishment of a repeater on a microwave system once the sites have been determined are:—

- Building
- Radio Equipment
- Emergency Power Equipment
- Tower
- Antenna
- R. F. Transmission Lines
- Test Equipment

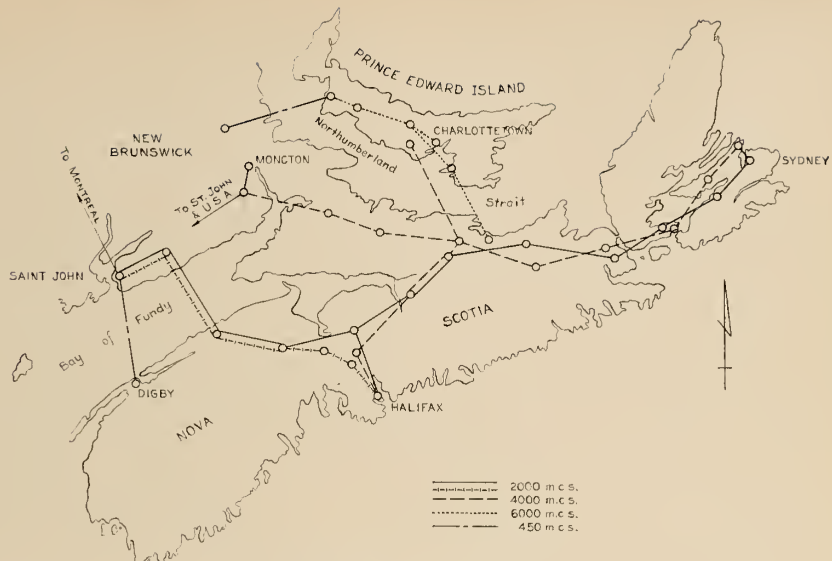
If each of these is thoroughly investigated and properly installed, operating problems will be a minimum.

The process from ordering of the various equipments to the establishment of a reliable system with the desired performance characteristics should be a smooth coordinated flow of accomplishment with realistic target dates.

Before a system is cut over for service, the user should ensure that each piece of equipment meets its own performance requirements and that the system as a whole is satisfactorily integrated. Following cutover to service, a long-term analysis should be conducted to ascertain that the system lives up to the calculated reliability and performance characteristics.

Despite the low population densities, the geography of the Maritime Provinces has brought about a high concentration of microwave equipment in that area and even further expansion is already in progress, with more in the planning stage. As shown in Fig. 4, the Northumberland Strait separates Prince Edward Island from Nova Scotia and New Brunswick, and the Bay of Fundy reaches inland across a direct route between the larger centres of population at Halifax and Saint John.

In 1947 one of the earliest commercial applications of microwave on this continent was placed in operation between Nova Scotia and Prince Edward Island. This system operated in the 2000 m.c.s. band, over 47 miles of open water. It was subject to severe outages due to inverse bending, but after the installation of a mid point repeater, it provided a satisfactory service until it was replaced in 1957 with a 6000 m.c.s. system over a slightly different route, using space diversity on a 37 mile over-water hop. In 1951 another 2000 m.c.s. system was established between Halifax, N.S., and Saint John, New Brunswick. One of the paths on this system is a 50 mile over-water hop, using triple vertical space diversity. In 1955 a 4000 m.c.s. path was established between Nova Scotia and Prince Edward Island, using frequency diversity. In the same year a 4000 m.c.s. system was established from Sydney Mines, N.S., through Saint John, N.B., to the U.S.A., with a connection to Halifax. A 2000 m.c.s. system is now being installed from Sydney, N.S., following roughly the same route as the 4000 m.c.s. Sydney Mines system to the center of Nova Scotia, and thence over the route of the 2000 m.c.s. system across the Bay of Fundy to Saint John, N.B., with a spur to Halifax as it passes through Nova Scotia. Portable 6000 m.c.s. equipment is used in the area and numerous operations have been successfully conducted over 35 and 45 mile over-water paths, with and without diversity. Numerous V.H.F. facilities are also provided in Nova Scotia for communication purposes. The apparent affinity for radio in the Maritime Provinces had its beginning in 1941, when a 40 m.c.s. system was established between Digby, N.S., and Saint John, N.B., and of course, even that was on a 43 mile over-water path. That particular system has since been replaced with a 450 m.c.s. system over a slightly different over-water path. A 450 m.c.s. system also connects Prince Edward Island and New Brunswick via a 43 mile over-water path.



MICROWAVE SYSTEMS IN NOVA SCOTIA

Fig. 4.

Previous to the establishment of the Halifax-Saint John 2000 m.c.s. system in 1951, difficulty was anticipated on the 50 mile over-water path. Thus prolonged propagation tests were conducted across the Bay of Fundy. Initial tests, using space diversity, showed that although individual fades were in excess of 40db., the best signal did not fall more than 10db. below the mean for 95% of the time. For the remaining 5% of the time, fades as deep as 25db. were experienced. Based on these test results, it was anticipated that the signal to noise ratio on a derived channel using FlA weighting would not be worse than 46db. for .02% of the time. This was the limit set by the user as a considered outage. The signal to noise ratio was expected to be not worse than 58db. for 0.2% of the time. Theoretical space diversity was used, and a third antenna was located half the calculated spacing below the bottom antenna. This was warranted, since it subsequently appeared that the fog layer, sometimes prevalent over the Bay of Fundy, was not sufficiently high to affect the direct ray, but did cause severe refraction to the reflected ray, while the direct ray experienced only normal refraction. This, along with the 50 ft. tides in the Bay of Fundy, could upset the diversity spacing. This system eventually consisted of 2, two-way paths, each carrying 23 toll quality circuits with 1, two-way protection path which was switched manually at the ends, solely for equipment protection. Records over the past 9 years on this system, show that reliability and performance figures were maintained within limits, but that maintenance costs based on capital expenditure were higher than for other types of system. This system is an example of the use of microwave on a light-route basis. The distance between Halifax and Saint John via land line, is some 300 miles, whereas the radio distance with five repeaters is 135 miles. The radio system was provided for a fraction of what it would have cost to provide the same facilities on open wire, and while maintenance costs were 5.95% on an annual basis; this is still some 2% higher than other microwave systems in the same area.

In 1956, a severe ice storm inflicted extensive damage to outside plant installations in Prince Edward Island. In a matter of a few hours, $300,000 worth of plant was entirely wiped out. This led to an extensive study which resulted in the replacement of the entire main toll lead through Prince Edward Island, with a 6000 m.c.s. radio system at a cost less than that inflicted by the storm. This system includes a 37 mile over-water path, with vertical space diversity and partial blocking of the reflected ray. The reliability of this system is in excess of 99.9%, and the performance of the system is maintained within limits with maintenance costs representing 3.5% of the capital investment on an annual basis. The system will carry some 60 long distance circuits and 3 high quality program circuits. It is essentially a 120 channel system, but the extra loading introduced by the program circuits reduces the traffic capacity.

A sample calculation to determine the noise performance of a specific path will be shown. Once the C/N ratio is known at the input to the radio receiver, the channel noise performance can be established, based on characteristics of the multiplex equipment used.

N_r Receiver Noise Level
P_t Transmitter Output
G_t Transmitting Antenna Gain
G_r Receiving Antenna Gain
L_{rt} Miscellaneous Filter and Transmission Line Losses
A Path Loss

These calculations are based on a receiver with a 14 m.c.s. bandwidth to the −3db. points, and a receiver noise figure of 14 db.

1. $N_r = NP(\text{Thermal Noise}) + N_f(\text{Receiver Noise Figure})$

$$NP(\text{dbm}) = -174 + 10 \log BW \text{ (cycles I.F.)}$$

$$NP(\text{dbm}) = -174 + 10 \log 14{,}000{,}000 \text{ c.p.s.}$$
$$= -174 + 71$$
$$= -103 \text{ dbm}$$
$$N_r = -103 + 14$$
$$= -89 \text{ dbm}$$

2. P_r (Received Carrier Power) $= P_t + G_t + G_r - L_{rt} - A$

3. $C/N_{rf} = P_r - N_r$

The 6000 m.c.s. path between Fraser Mountain, Nova Scotia and Mount Buchanan, Prince Edward Island is 37 miles long. The following values have been used to determine Pr.

P_t	+20 dbm
G_t	40 db
G_r	40 db
A	140 db
L_{rt}	6 db
N_r	−89 dbm

$$P_r = 20 + 40 + 40 - 6 - 140$$
$$= -46 \text{ dbm}$$
$$C/N_{rf} = -46 + 89$$
$$= 43 \text{ db}$$

Most equipments will maintain a sufficient signal to noise ratio on a derived circuit down to a C/N_{rf} of 10 db. Thus on this basis, in the case at hand, there is a 33 db. margin on this path.

It has been an established fact for some years that microwave systems can provide excellent communication facilities. Until the past few years the emphasis has been on long haul systems. The same techniques apply for short haul facilities with the possible exception that in some cases the requirements may not be quite so severe. Each case must be investigated on its own merits and planned accordingly. Fig. 4 shows various applications of light route and heavy route microwave equipments as applied to specific communication problems in Nova Scotia and Prince Edward Island in particular and their connections with the neighboring Province of New Brunswick. In the more sparsely populated areas there is an important part to be played by light route microwave systems. If the area eventually grows to the point where heavy route equipment is required, the provision of interim light route facilities is usually justified on a cost basis.

It is the obligation of the system design engineer to provide a communication system with the best reliability and performance consistent with the economics of a given application. The field of light route microwave offers great possibilities in sparsely populated areas and in the case of a potential user whose requirements are for not more than a few hundred circuits.

BATHURST'S NEW 1250 p.s.i.g. KRAFT CHEMICAL RECOVERY BOILER AND BACK PRESSURE TURBINE

(Continued from page 75)

A conventional alternator is connected to each turbine wheel making a double ended unit supported in the middle by the turbine casing. The alternators are connected electrically so that they are always synchronized as long as the field current is on.

A sectional view of this turbine is shown in Fig. 5, and Fig. 6 shows a picture of the turbine installed in the turbine room.

The turbine was purchased to operate most efficiently at 120,000 lb. of steam per hr. with inlet steam at 1225 p.s.i.g. and 850°F with exhaust pressure at 165 p.s.i.g. The turbine was designed to take 900°F steam if at a later date another boiler operating at higher temperatures might feed some steam to its header. At the above steam flow, the unit was guaranteed to deliver 5,650 kw. The maximum capacity with the overload valve open is 150,000 lb. per hr. and 6.540 kw. A change in blading can be made easily for other capacities up to a maximum efficient flow of 150,000 lb. per hr. and 7,250 kw. or an overload condition of 184,000 lb. per hr. and 8,300 kw. A new set of blading can be purchased for about $35,000 for a high load condition if another 1250 lb. boiler is installed in the future. The change is quite simple and can be made in a short down period of about a week. The generators are rated at 8,750 kw. so that they are ample for future higher turbine capacity.

The turbine normally operates with the throttle valve wide open with no governor. Speed is controlled by the generators being synchronized with the other machines and load is determined by the amount of steam made by the boiler. The overload valve has been disconnected. If the boiler flow happens to go a little above normal full load, the pressure at the turbine will go a little above normal until this additional steam is pushed through. A pressure actuated governor controls the throttle if the boiler pressure drops due to low fire or a sudden loss of fire, so as to hold the boiler at 1250 p.s.i.g.

The boiler and turbine were ordered in July 1956 and went into operation early in September 1958. Equipment throughout the plant performed as expected after a very successful start up. In general, there has not yet been any reason to regret any of the major design decisions and engineering applications involved in this project.

Discussion

OIL TANK SITES PRELOADED BY WELL POINT SYSTEM

Ronald F. Scott, M.E.I.C.
Formerly Divisional Soil Engineer,
Racey McCallum & Associates Ltd., Toronto
The Engineering Journal, August 1959, p. 79.

Author's Reply

It is very kind of Mr. Kenney to appraise my paper so generously. As Mr. Kenney surmises, my intention was merely to present a description of the method and technique of preloading the tank sites and only enough soil information was given in the paper to make the discussion clear. I am preparing a much more detailed and technical paper for publication elsewhere, to incorporate the measurements made since the writing of the paper under discussion and to include more soil information.

However, it is possible, I think, to give enough data at present to answer most of Mr. Kenney's questions, which I will deal with under the headings he has used.

1-Classification and Shear Strength

(a) The sediments at the site generally varied in color from light to dark grey, but under a part of the area the soil had a reddish brown color. In this case closer inspection showed that the varves were alternately grey and red, the red material being clay, the grey, silt or clayey silt. At this site no attempt was made as part of the investigation to obtain moisture contents, limits, or grain size analyses for the different soils in the varves. It is difficult to say how distinct the layers were, but they could easily be seen on fresh samples before any drying out took place even on the all-grey soils. The varves did not appear generally to grade into each other, but of course the soil varied greatly from depth to depth and place to place.

The thickness of individual varves also differed from sample to sample. I think I can say fairly that the varves were generally thin, of a thickness of ⅛ to ½ in., but I have a note of one sample in which the clay layers were about ¾ inch thick, separated from each other by ⅛ in. thick silt or clayey silt zones. In many of the samples from shallow depths (20-30 ft.) the thicker varves seemed to predominate while at greater depths (40-50 ft.) the varves were generally thinner. Variations in thickness occurred at all depths, however. We did not make notes on the manner in which the relative thickness (of silt to clay layers) varied with depth.

(b) The original calculations were based on the results obtained from samples from five boreholes which were supplemented by two additional holes as checks in the areas of the tanks before construction. In the clay layers, 2 in. diameter Shelby tube samples were obtained at 5 ft. intervals in the first set of holes, 3 in. diameter Shelby samples in the two supplementary holes.

In the "varved clay" of Fig. 2 of the article, the average moisture content is given as 60%; it actually varied from about 50-55% at the top of the layer to about 65-70% at the bottom, based on mixed samples. No moisture content determinations in the individual varves were made. The top and bottom boundaries of this layer varied from hole to hole and were not easy to distinguish except on the basis of water contents and sensitivities.

In the "varved silty clay" of Fig. 2, the moisture content of mixed samples did generally decrease from about 35% at the top to about 25%, but in two individual holes it remained constant, close to 30%, with depth.

The nautral moisture contents in both layers varied from the liquid limit to 3 or 4% higher than the limit. That is say, the liquid limit in the upper clay layer increased from about 50% at the top to about 60 to 65% at the bottom, while in the underlying layer ("varved silty clay") the liquid limit decreased from about 30% at the top to about 25% at the bottom of the layer. As far as can be indicated from the data, straight line variation between these boundary values can be assumed.

The plastic limit of the upper clay layer appeared to diminish slightly with depth, from about 30% at the top of the layer to about 25% at the bottom. The plastic limit of the lower silty clay was relatively constant with depth at a value of about 20%.

(c) The field vane shear strength increased very nearly linearly with depth through clay layers from average values of 500 p.s.f. at the (approximately) 24 ft. depth in Fig. 2 to about 1500-2000 p.s.f. at 70 to 75 ft. depth. The ratio of shear strength to calculated intergranular stress, c/p, had an average value of about 0.30 to 0.35 in the upper clay layer, but about 0.41 in the lower layer.

In the upper clay sensitivity based on the vane test varied from 2.5 to 3.5; in the lower layer from 1.5 to 2.5. No particular variation with depth was observed. Laboratory unconfined compression tests on 2 in. diameter, 4 in. high samples as usual gave a

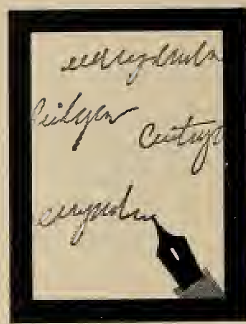
Abstracts



The Greater Winnipeg Water District's Second Branch Aqueduct and Low Lift Pumping Station
N. S. Bubbis, M.E.I.C.

Organized in 1913 to bring water from Lake of the Woods into Greater Winnipeg, the Greater Winnipeg Water District is currently undergoing construction of additions and extensions. Discussion of: history; design considerations; method of guaranteeing the required flow coefficient; problems, methods, and plant used in manufacture and installation of 66 in. embedded cylinder prestressed concrete pressure pipe. Comparison of bridge, riverbed and rock tunnel crossings. Comparison of two methods, a dam at Ash Rapids in Shoal Lake vs. a low lift pumping station. Description of: selection of pumps, design, safety measures to protect aqueduct when pumping, and construction methods.

Sault Ste. Marie International Bridge
C. H. Gronquist

The crossing of the St. Mary's River to connect the two "Soos" by a vehicular bridge has long been considered essential to the growth and development of the area. The bridge, financed in large part by the International Bridge Authority, will have a 28 ft. concrete asphalt surfaced roadway. Statistics: 11,684 ft. long including plazas; maximum bridge grades of 3¾% on U.S. side and 4% on Canadian; 430 ft. Main Span continuous trusses of arch form. Substructure: two-legged concrete bents for truss spans; single shaft hammerhead type piers for beam spans.

Joints in Precast Concrete Building Frames
E. M. Rensaa, M.E.I.C.

Structural efficiency and the economy of precast reinforced concrete building frames depend largely on methods of joining. Since little saving of material results from precasting beams and columns, savings must come in the form of work and labour. A chief advantage of cast-in-place frames is continuity. Study of possibility of obtaining continuity in precast frames. Results obtained in developing suitable joints for precast concrete beams and columns. Jointing under winter conditions.

The Work of the Column Research Council
D. T. Wright, M.E.I.C.

A description of the Column Research Council with special reference to the forthcoming major work "Guide to Column Design Specifications". Focus on problems of design involving instability of metal structures and structural elements and contributions made by Council. The guide establishes new precepts—among them that design is a complicated task. Some of the limitations of the Council's work and areas not yet treated.

The Measurement of Industrial Water Pollution
T. W. Beak

A definition of pollution related to the beneficial use of waters. Methods of measuring pollution by measurement of effects of pollution rather than by direct measurement of the causitive agent. Description of the biochemical oxygen demand test. Oxygen sag curves and their relation to B.O.D. Toxicity and methods of measuring it. Biological surveys to measure pollution. Two recently developed applications of this method.

Benefit Cost Analysis of Greater Winnipeg Floodway
Carson H. Templeton, M.E.I.C.

Methods for reducing flood damage in the Winnipeg area including dams, river diversions and floodways or bypasses around Winnipeg. An outline of the projects, including the Greater Winnipeg Floodway with its 100 million yd. of excavation. Methods used in estimating damages of floods of various magnitudes and frequencies and of comparing benefits and costs. Study of final report recommending the use of a combination of three projects at an estimated $73 million. Method of making Benefit-Cost studies.

Hydrological Investigations for the South Saskatchewan River Project
E. F. Durrant, M.E.I.C.

Flood potential at the damsite and water supply for the project. Study of basic relationships between runoff and precipitation on the Eastern slopes of the Rocky Mountains, storm studies and flood routing problems for estimation of a probable maximum flood and selection of the design flood. Determination of water supply, considering existing and future projects.

An Approximate Analytical Method for the Determination of Foundation Natural Frequencies
George Ford, M.E.I.C.

The approximate procedures outlined in this paper are based on Rayleigh's Principle and may be used to find the natural frequencies for all six degrees of freedom of rigid foundations. Application of the method to vertical and horizontal vibration. Values obtained for vertical natural frequencies of foundations agree closely with those in the empirical plot of Tschebotarioff.

Uranium City Water and Sewerage System
H. P. Klassen, M.E.I.C.

A short history leading up to National Research Council work. Description of unusual factors affecting design such as temperatures, soil conditions and rocky terrain. Methods of looping the areas with pipe for recirculation. Flows and heat requirements, with consideration of domestic and fire demands. Protection for house service connections. Flows, temperatures and fuel consumptions during the first years of operation.

Automation in Thermal Power Plants
A. R. Scott

A thermal generating station serves as a valuable example of a complex industrial process to which digital computers have been applied to the functions of data logging and alarm supervision, calculation and performance, and control. Means for measuring and converting quantities into a language the computer understands. Importance of adequate sensors for measuring pressures, temperatures, flows and electrical quantities. Application of digital control to a steam plant. Provision can be made for start up and shut down of a unit and its auxiliaries as well as control under varying load conditions. Comparison of computer control with conventional boiler, turbine and generator controls.

Design and Construction of Chute-des-Passes 345 kv. Transmission Line
H. B. White
The first unit of Chute-des-Passes generating station was completed in October and the entire five units of 200,000 hp. each are scheduled for completion in early 1960. A 345 kv. transmission system of two 345 kv. single circuit bundled conductor lines transmits the output of this station 91.2 miles for interconnection at Isle Maligne with the 2,600,000 hp. of the Saguenay hydro-electric system. Studies to establish transmission line parameters. Construction of the lines with emphasis on techniques and special equipment for string and sag of bundled conductors. Testing of full-scale guyed mast tower fabricated of aluminum structural alloys near Arvida, Que. Tests carried out on the tower and its components.

The Evolution of Large Synchronous and Induction Motors in Canada
G. W. Herzog, M.E.I.C. and *K. Z. Lukaszewicz*
The evolution of large synchronous and induction motors in Canada. Early types, applications and construction are compared with modern units produced by one manufacturer. Comparison of induction and synchronous motors with emphasis on their proper application. Motor application considerations, including the effect of environmental conditions on motor construction and size. Changes in construction types, materials and processes in relation to changing applications and increased technology. Design process for an A.C. motor.

Standard Aluminum Sub Station Design
J. R. McMullan and *Howard Meyers*
Early designs of aluminum sub stations followed closely their counterparts in steel in which standard shapes were employed and all parts bolted or riveted. A structure weighing 50-75% that of the steel resulted which cost two to three times more. Welding was impractical because heat softened the tempered alloys reducing their strength. Advent of the Alrectic system, utilizing specially extruded shapes designed to minimize the heat affected zone. A large mass of metal at the weld zone reduces annealing and permits working stresses comparable to steel. With welding columns and girders can be made in a fraction of the time required for a bolted structure. Erection is made easier by light weight. Standardization developed. Simplification of design, fabrication and erection.

Long Range Planning for the Manitoba Hydro-Electric Board
L. A. Bateman, M.E.I.C.
A discussion of factors influencing the growth of Manitoba's electrical system and proposals concerning development of the hydro-electric potential. Economic factors associated with interconnection of neighboring provinces. Availability of possible short-time markets to the South. Manitoba is one of the few areas of the world to possess natural water storage in excess of six million acres under the sole jurisdiction of the local power producers. Long-range planning. Economic factors affecting development of any combined system of hydro-electric and thermal-electric generation.

Load and Frequency Control System of the Manitoba Hydro-Electric Board
K. H. Williamson, JR.E.I.C.
Interconnection of power systems, through greater flexibility and diversity, results in increased economy and reliability for the member systems. The Winnipeg Central Load Dispatch Office is equipped to control the operation of two major interconnecting lines, the 138 kv. transmission line between the systems of the Manitoba Hydro-Electric Board and those of the Northwestern Region of the Hydro-Electric Power Commission of Ontario, and the 138 kv. tie line between the Saskatchewan Power Corporation system and Manitoba's. Provision for future interconnections. Dispatcher's equipment can be operated on either flat tie line, flat frequency or tie line bias mode of operation. High speed telemetering of tie line flows and control information recorded by frequency type telemeters. Master controller interprets the signals and causes the unit governors to respond by raising and lowering the machine outputs.

Microwave Radio Application to an Electric Utility Load Dispatch System
E. M. Scott, M.E.I.C.
In 1959 the Manitoba Hydro-Electric Board began a development program to interconnect four hydro-electric generating stations on the Winnipeg with Ontario and Saskatchewan systems. Construction of a thermal electric generating station at Brandon, Manitoba, and another at Selkirk, Man. Interconnection with the City of Winnipeg Hydro-Electric System. Considerations in establishing the new systems. Location and function of the load dispatch office in Winnipeg. Instrumentation and telemetering. Choice of particular microwave radio system. Siting of the repeater station. Usage of cold standby equipment and emergency power supplies. Integration with neighbouring utilities.

Silver Falls Tunnel and Surge Tank Design Considerations
L. A. Leeyus, M.E.I.C.
Design of the relatively high head pressure tunnel and surge tank at the Silver Falls development presented some unusual problems. Design assumptions and methods. Tunnel: concrete lined conduit, 14 ft. x 6 in., extending horizontally from bottom of vertical intake shaft at Dog Lake to the powerhouse at Little Dog Lake. Surge shaft intersects near downstream end. Tunnel and shaft linings designed for internal and external pressure. Surrounding rock structure provides resistance to internal pressure. Where rock is inadequate, loop reinforcing steel and welded steel liners used. Welding in penstock and surge tank. Selection of standpipe tank. Economic, hydraulic and construction considerations.

Concrete Lining of the Tunnel at Silver Falls G.S.
J. H. Jackson, M.E.I.C. and *C. T. Bath*
Methods used in concreting operations of the tunnel at Silver Falls G.S. A 10,000 ft. tunnel built between Little Dog Lake and Big Dog Lake to by-pass a series of rapids and take advantage of about 350 ft. difference in elevation to operate a 62,000 hp. turbine generator at Little Dog Lake. Mainly unreinforced concrete lining. Total of 760 lineal feet reinforced concrete lining, in three sections, especially at the depression area with low rock cover. Low and high pressure grouting. Concreting of the intake and surge shaft.

Whitehorse Rapids Power Development
L. A. Carey
Earthfill dam and concrete spillway were built across the upper end of the Whitehorse Rapids Gorge in the Yukon, one of the river obstacles on the trail of '98 to Dawson City. All river diversions done in the gorge with timber crib cofferdam built in below-zero temperatures. Quicksand encountered in powerhouse excavation. Canal founded on mainly pervious gravels. Earthfill structures made from local materials.

The Warsak Hydro-Electric Project (A Colombo Plan Undertaking in West Pakistan)
J. H. Ings, M.E.I.C.
Project for the generation of electricity and irrigation of some 100,000 sq. miles of land. First power will be produced in 1960. Complex organization has necessitated the work of six Canadian and eight Pakistani government

bodies. Storage development in the watershed limited by the fact that 20,000 of the 26,000 sq. miles of drainage area are in Afghanistan and the remaining 6,000 sq. miles are topographically difficult. Headpond extends to Afghan border but is in a gorge. The dam will develop 20,000 acre feet of live storage. The scheme: 250 ft. high gravity dam, a 39 ft. diam. concrete-lined power tunnel, manifold, steel-lined penstocks and a surface powerhouse, spillway section with crest gates, a stilling basin to dissipate energy of large flow within gorge, four Francis turbines of 55,000 hp. and two more to be added.

Optimum Adjustment of Governors at the Hydro Generating Stations of the Manitoba Hydro-Electric Board
L. M. Hovey, M.E.I.C.

Elementary theory of speed governing. Simple differential equation of governing shows why it is necessary to provide for speed droop in order to stabilize the prime mover. Normalized or per unit system represents speed, torque, power, etc. and the inertia effects and time delays are represented by their equivalent values in seconds. In deriving the equations of an hydraulic turbine governor, certain simplifying assumptions are made to obtain differential equations of linear form comparatively easy to solve on an analog computer. Assumed that the equation closely approximates the performance at or around the point of maximum turbine efficiency. Since all generating stations on the Winnipeg are joined by a stiff tie line near the stations, in determining optimum governor settings all machines in these plants have been treated as a single equivalent machine. Methods for measuring temporary droop and dashpot time constant. Adjustment of each to selected value.

Moran Dam and the Fraser River
Russell E. Potter, M.E.I.C.

Although the Fraser River is the greatest potential hydro power source in British Columbia, it is disqualified by its valuable salmon runs. If power were developed, only part of the runs would be affected. Every river in B.C. which enters the ocean has the same problem to some degree. The people of B.C. will have to decide whether the sockeye, the only seriously affected salmon, are to be saved or the power developed.

Design and Construction of Kelsey Generating Station Dam and Dykes
R. A. Pillman, JR.E.I.C., *D. H. MacDonald*, M.E.I.C., and *H. R. Hopper*, M.E.I.C.

Economic and schedule considerations dictated the building of a rock-fill dam on bedrock for the Kelsey Generating Station. Dykes constructed on unfrozen and permanently frozen foundations. Laboratory testing of highly plastic core materials to determine properties for design. Construction of the core in freezing weather within heated enclosures placed upon the dam. Dykes built of sand on frozen ground. As foundations thaw, due to heat from reservoir, sand drains in the foundations facilitate drainage and accelerate consolidation. Design, without precedent, based upon theoretical heat transfer and consolidation considerations. Sensitive temperature and settlement measurement devices installed in foundations give warning of trouble and provide information for future structures.

Braking of Hydro-Electric Generators
H. O. Wilson, M.E.I.C.

Present practices used in the braking of hydraulic turbine driven generators. Results of tests on medium size Francis turbine driven generators. Theories and problems concerning braking encountered in generator design work. Operating philosophies on automatic braking and associated problems. Recommendation for a method of automatic braking for unattended generating stations.

Management—Horse Trading or Trusteeship?
Lyndall F. Urwick

Management has been defined in the Concise Oxford Dictionary as "trickery, deceitful contrivance". The word is derived from the French for "stable" and has, in interpretation, been associated with horse trading. However, owners and managers in a free, competitive economy must act as trustees for the interests of their consumers. Need for leadership in managers. Individualistic *laissez-faire* economy is replaced by social consciousness.

Statistical Quality Control as a Management Tool
B. H. Lloyd

Statistical quality control was initially intended to assist management in gaining a better understanding of the manufacturing process. Lag in accepting and applying statistical quality control. Importance of risk concept in applying sampling methods. Dramatic history illustrates the value of statistical method in solving problems where more conventional methods have failed. Communication between scientist and management facilitated if management is equipped to meet the scientist halfway.

An Exercise in Operations Research—RCAF Aircraft Maintenance
W/C A. B. Howell

A development of expressions for aircraft group response to change. Relating these expressions to work output equations provides means of analysis for better guidance of aircraft maintenance and flying management. Expressions for rates of becoming unserviceable and for manpower ability to recover a serviceable state. Practical Tests. Demonstration of Analysis methods. Model and analytical methods made possible by it are fitted to RCAF usage and requirements but promise application to other forms of aircraft operational management.

Recent Advances in Experimental Stress Analysis
J. B. Mantle, M.E.I.C.

Review of recent advances in experimental stress analysis techniques with examples of their application. Discussion of photoelastic stress analysis, including the new photostress technique, the photostress gauge, and some of the newer materials for three-dimensional stress analysis work, such as Hysol 6000 OP and photoelastic casting resin EPA. Electrical resistance strain gauges: the new forl gauges. Experiences with dynamic stress analysis in the microsecond range using standard gauges.

Liquid Petroleum Gases As Fuels for Automotive Engines
Henry A. Spencer, M.E.I.C.

Seasonal surpluses of butane and propane require a new market. Research directed to automotive uses, particularly in farm vehicles. Equipment available not satisfactory. Examination of commercial conversion equipment to find reasons for lean mixture tendencies. Methods of overcoming the basic problems. Utilization of butane for automotive engines in cold weather. Burning of propane with diesel in an automotive diesel engine. Control for variable speed engines and indications of greater horsepower.

The Application of High Powered Epicyclic Gearing for Marine and Industrial Uses
H. N. G. Allen, and *T. P. Jones*

Rapid progress during the last fifteen years in the application of epicyclic gearing to high speed, high torque and high powered conditions. This gearing is suitable for speed reducing and speed increasing applications. Developments for speed change, reverse reduction or de-clutchable applications. Use of combined co-axial and parallel axis gearing. Ability to deal with high speeds and torques without exceeding recognized maximum tooth speeds and stresses. Unusual form of hardening tooth components; comparison of results with the more usual carburising method. Illustration of many types of installation and application.

Design of Industrial Gears
R. D. Mutch, M.E.I.C.

Investigation for a new kind of gear began with the difficulty of relating face width to pitch in the existing gears. Attempt to establish method for calculating the face width necessary for varying loads, speeds and materials to use this value to determine the size of tooth required. Comparison of helical gears with spur gears. Description of test set, results and conclusions.

Automation and Control Engineering in Canada

Control of Steel Plate and Strip Mills

THIS article outlines the methods of producing plate and strip in the steel industry, and indicates some of the ways in which automatic control can improve and maintain the quality of the end-product. The general principles involved apply equally to operations on other metals.

Steel slabs and heavy plate are generally made from hot ingots (as cast after production in the steel furnace) in a reversible rolling mill; that is, the ingot or slab passes one way along the mill table, through the rolls which reduce the slab thickness, and along the table at the opposite side until clear of the rolls. The slab is then stopped, the roll opening reduced to a predetermined size, and the mill reversed to pass the slab back through the rolls; and so on, until the required slab thickness is reached. Actually, rolling is continued until the original size is reduced by 10% or more, and the slab is then rotated 90° and rolling completed in the new direction, for metallurgical reasons.

Considerable reduction in size can be attained on reversible mills, but relatively thin strip is often made on hot or cold strip mills, which are operated in one direction only. Whereas reversing mills are of the single-stand type (i.e., have only one set or stand of rolls), strip mills may have several stands of rolls in tandem. Hot strip mills are more difficult to control automatically than cold reduction types because of the added factor of temperature variations.

The slab or strip is passed between two motor-driven work rolls, each of which is supported by one or more back-up rolls. The gap between the rolls is adjusted mechanically by means of a screw-down motor.

Reversing Mills

When a standard thickness of plate is produced from regular ingots on a hot reversing mill, the operation can be automated by a punched-card system, for example, that can store the sequence of roll screw-down settings required. A set of instructions can be acquired for each type of plate or slab produced. A recent development in this field, the first of its type in the United States steel industry, is the use of a magnetic drum to store a whole library of rolling schedules; this should be more satisfactory than punched cards, which need more careful handling in an environment such as a steel mill.

Control by computer is a favourite topic these days, and it crops up again in connection with hot plate mills. Several installations are in existence, one example of which is a transistorized digital computer used to control a slabbing mill that is used for production of special orders, rather than long runs of standard sizes. The operator feeds in the initial roll opening, succeeding drafts to be taken after each pass, and the end limits of thickness. The computer applies the setting reference signals directly to the roll screwdown system and automatically controls all the mill passes necessary to bring a piece to required thickness limits; it calculates the intermediate roll settings needed. A load cell on the rolls senses when the metal leaves the rolls, to stop the rolls and mill table when the pass is complete, and to start the screw-down to the next setting. An infra-red scanning device gauges the length of the metal as it leaves one end of the mill.

Automatic Gauging Control

Steel strip is produced in many gauges within certain limits of thickness; these tolerances become ever closer as demand for improved quality increases. Several methods are in use for automatic control of gauge during rolling operations.

In practice, the actual reduction in thickness of a strip during rolling can be achieved in more than one way. When squeezed between rolls the strip flows plastically to a certain resultant thickness; however, if tension is applied to the strip at either the entry to or exit from the rolls, the roll pressure decreases and the rolls tend to move closer together, so producing a thinner strip under the new equilibrium conditions of the work system. The net result is that the strip can be reduced by the increasing roll pressure alone (usually the case in making plate or heavier gauges of strip), by increasing tensions, or by a combination of the two. In practice there is a limit beyond which increasing roll pressure alone may not continue to decrease emergent thickness of strip, because of flattening effects on the rolls.

There are three methods of measuring thickness of metal in a rolling mill: contact gauges, non-contact gauges, and the mill stand itself. Contact gauges use small rolls in contact with the strip; the separation of these rolls is measured mechanically and converted to an electrical indication of thickness. The non-contact gauges are the familiar x-ray or gamma-ray absorption type used in several industries. Both these types have the disadvantage that the sensing device must be some distance from the work rolls, thus introducing an element of delay in controlling thickness variations.

The third method of measuring thickness gives instantaneous reading of changes in dimension. It uses the principle that the mill stand and rolls act as a large spring; from the relation between roll-separation before and after metal enters the rolls, a measure of thickness can be obtained. The roll separating force is measured by load cells mounted behind the back-up roll chocks; when this force is divided by the spring constant of the mill and the result added to the unstressed roll separation, a value of the stressed roll separation (and hence the strip thickness) is obtained. The calculation is done electrically and the resultant instantaneous indication of thickness can be used in closed-loop gauge control with an advantage over other methods of thickness measurement that involve transport delay.

Certain inaccuracies must be guarded in this method of thickness measurement, which does not take into account changes in roll diameter. Where diameter changes slowly (e.g., due to thermal expansion of wear), compensation can be made manually or automatically by recalibration from, say, an x-ray or gamma-ray gauge which feeds back a true thickness signal that can be compared with the signal from the mill stand meter. Rapid variations in diameter may result from eccentricity of back-up rolls; this may be small enough, compared with accuracy required on the finished product, to be ignored, but precautions may be necessary, particularly on cold mills, to counter eccentricity. If sufficiently serious, the mill stand gauge may become less accurate than the non-contact type of gauge for control purposes.

Single Stand Mills

A single stand reversing cold mill may use screw pressure to control thickness of heavy gauges, back tension to control thickness in lighter gauges, or a combination of methods. Several automatic gauge controls have been applied to this type of mill; for example, systems using radiation thickness gauges on either side of the rolls with control being effected by screw-down. Because there is a time lag between mill roll bite and the gauge, such controls are of the sampling type.

One Canadian installation uses the mill stand meter principle, as described above, to indicate deviation of strip thickness. The particular installation can vary both screw setting and back tension. Rolling speeds are usually fairly slow, and operators have achieved good control down to thread speed. The advantage of the mill stand method here over the radiation gauge is particularly marked because of the slow speeds which tend to lengthen the transport time lag in the latter case. In this installation radiation gauges are used on either side of the rolls to keep the mill stand meter in calibration, as discussed above.

Tandem Multi-stand Mills

There are many more variables that could be controlled to limit thickness of strip from a multi-stand tandem mill. Considering a cold-rolling operation, to avoid further complication, it is possible to vary thickness at each stand by altering roll pressure or tension at entry or exit. Thus, in a five-stand mill, five screwdowns and six tensions could be varied. In theory, all of these could be controlled, but in practice it is possible to attain desired manufacturing limits with control of only one or two variables.

One development from manual control practice with this type of mill has been the regulation of fairly constant thickness from the first stand by monitoring an x-ray gauge after the stand and thence regulating the screw-down on the stand, on a sampling basis. 'Fine' control is then obtained by a regulator that continuously monitors a gauge after the final stand and controls the speed of the motor on the last stand. In many cases it is possible to control thickness within commercial limits by using the first-stand or 'coarse' control alone.

Hot Strip Mill Control

The control of thickness on multi-stand hot strip mills is much more complex than on a cold mill. The temperature of the incoming material may vary because of water cooled skids in the reheat furnace and general cooling on the approach tables. The result of varying temperatures in preceding mills may be a variation in thickness of the incoming material. In addition, the gauge of the first and last hundred feet or so of a strip may be heavy because these ends have to be rolled without the assistance of tension.

It is found in practice that the tension between stands of a hot strip mill must be kept fairly constant, within quite close limits. Too-low tension causes poor tracking; too-high tension tends to neck down the strip width and significantly increase tail end thickness. Hence, most gauge control on this type of mill should be by screw-down, with some slight tolerance of tension variation.

One system used on a six-stand hot mill has mill stand meters on stands 2, 3, 4, and 5 to control screw-down, as described above for the case of a single-stand mill. Such a system avoids much change in inter-stand tensions and so does not affect strip width. A radiation gauge after the last stand is used to monitor the system and record final strip thickness.

Some progress is being made to satisfactory operation from less complicated, and therefore less expensive, control systems. Thus, the number of meter/screw-down controls has been reduced to two (on stands 2 and 3), with a meter/tension control on stand 5. Finally, the system may be reduced to screw-down control on stand 2 only plus tension control on stand 5. Where close control of tension is needed, it is found necessary to provide speed regulators in the system.

In fact, speed regulators at each stand would maintain pre-set speeds and eliminate variations due to impact loading or other conditions that could have an adverse effect on metal gauge.

Towards Full Integration

Some particular aspects of control of steel rolling operations have been discussed. The industry is working towards complete integration of such operations (not to mention fully-integrated blast-furnace and open-hearth operations).

Perhaps one of the main difficulties is the lack of practical experience, but this is being overcome by observations on the existing types of control installation and the analysis of the problems involved on digital and analog computers.

When these problems have been worked out and the production of the necessary equipment is economically feasible, then it will be possible to describe the fully-integrated steel mill.

Canadian Developments

If the predictions made recently by the British Columbia Power Corporation's president, A. E. Graur, concerning Canadian economic prospects for the coming year are an indication of the general prospects for 1960, the year will be a more productive one than 1959. Business and government capital investment should reach a peak totalling $8.8 billion, a 4% increase. The Corporation's purchase of the coal deposits at Hat Creek, B.C., which may have a power generating capacity equal to the full development of the Peace River or the Upper Columbia, is thus a sign of the times.

C.C.A. Makes Submission to the Federal Government

Following their 42nd Annual General Meeting in Calgary, the Canadian Construction Association submitted a brief to the Federal Government concerning C.C.A. policies which pertain to Federal Government activities. The introduction of this submission points out that the construction industry is Canada's largest, its annual value $7.3 billion and its on-the-site employment over 600,000. The following recommendations have been made by the C.A.A.:

National Highway Policy: (1) Establishment of a National Highway Policy and Organization to coordinate on a continuing basis the long-term planning, financing and construction of roads of national importance (1952). (2) Federal investment in roads under provincial jurisdiction on an equitable basis for the improvement of Canada's main highway system and in accordance with regional needs for access roads, international connections and grade separations (1947, 1953).

Housing: (1) Allocation of funds to Central Mortgage and Housing Corporation for National Housing Act investment activities. (2) Amendment of the N.H.A. provisions for rental projects so as to be more attractive to investors (1958).

Wintertime Construction: (1) Continuation of the Federal Government's efforts designed to increase the volume of wintertime construction and employment (1956). (2) Increased research activity by NRC in the field of wintertime construction (1960).

Canadian Nuclear Association in Planning Stages

The first step toward the formation of a Canadian Nuclear Association was taken at the recent First Canadian Conference on Uranium and Atomic Energy in Toronto. Chairman of the ad hoc steering committee is J. L. Olsen, Jr. E.I.C., of Peterborough, and the following will be represented on it: A.M.F. Atomics (Canada) Ltd., Canadian Bechtel Ltd., Canadian General Electric Co., Canadian Westinghouse Co., Foundation Co. of Canada, Orenda Engines Ltd., Rio Tinto Mining Co. of Canada, and the University of Toronto.

B.C. Harbours Projects

The National Harbours Board plans to spend $1,257,000 during 1960 on capital expenditures in the Port of Vancouver, according to plans tabled in Ottawa. In comparison, $16,868,450 is to be spent on the port of Montreal. The money for Vancouver works will go mainly toward completing the new Centennial Pier, where storage sheds need to be built and movable cranes installed.

Winnipeg To Have New Air Terminal Building

A $10 million air terminal building for the Winnipeg International Airport has been announced by Transport Minister George Hees. The Winnipeg International Airport is the main central terminal airport in the Canadian system and, because of its central location, is the major distributing centre for the Prairies, Western Ontario and Northern Canada.

The new terminal building should be completed in 1964 and will consist of two units, an administration building for the operational services of the Department of Transport and the terminal building proper to accommodate airlines and public.

New Brunswick Base Metals Mining

J. Roger Pichette, Minister of Industry and Development, recently announced a new financial and sales manoeuvre between the Brunswick Mining & Smelting Company and Sogemine's Ltd. which may mark the beginning of a substantial development in the base metal producing area near Bathurst, N.B. Predictions have been made that in three years' time a smelter could be put into operation in Bathurst and subsequently plants might be built to produce sulphuric acid, iron, fertilizers, and all the various by-products of a fully-integrated mining operation like Trail, B.C.

Gas and Oil in Northern Territories

The sale of oil and gas exploration permits has reached $10 million in the past two years and another million acres has been opened up to search. All but one of the 17 parcels of land most recently bid on were in the Fort Simpson area of the Northwest Territories about 150 miles north of the B.C. boundary. To maintain their permits over the next nine years (three three-year terms) companies are required to spend a combined total of $2½ million.

South Saskatchewan River Project

The winter work program on the South Saskatchewan River Project has kept development on schedule. From October to March the program involved heaping granular material on the downstream section of the dam and raising the perimeter dyke around the river section of the west embankment. Four hundred people were employed at moving these materials which have to be compacted, an operation unique in Western Canada.

Through the same period work on the superstructure of the construction bridge continued, with the supply of 1,700 tons of structural steel to the damsite, 1,500 tons of which has now been erected. Some 55 tons of reinforcing steel was also placed during this period and the bridge superstructure, four 200 foot spans and approach girders, is now nearly completed.

Use of Test Buildings in Building Research

G. O. Handegord, M.E.I.C., *N. B. Hutcheon,* M.E.I.C.

Recognizing that test buildings are not always a valid approach to research into building problems, the authors outline the kinds of building research studies for which test buildings are useful. Description of test buildings in use at NRC's Division of Building Research. Their potential contribution to the solution of particular problems.

The Formation of Continuous Chips in Metal Cutting

W. B. Rice, M.E.I.C.

An experimental investigation of the formation of continuous chips in metal cutting. Description of a mechanism different from those assumed in classical analyses observed during orthogonal cutting. Mechanism used to explain chip-curl and cratering wear. Observation by high speed photography of the formation of continuous chips.

(More Abstracts Page 196)

How To Obtain Preprints

Preprints of the following Annual General Meeting Technical Papers may be obtained by forwarding a suitable remittance to:

The Librarian, 2050 Mansfield St., Montreal, Que.

The nominal charge of $0.50 per paper for members and $1.00 per paper for non-members has been fixed to cover handling expenses.

Liquid Petroleum Gases as Fuels for Automotive Engines.
H. A. Spencer, M.E.I.C.

Construction of the Warsak Hydro-Electric and Irrigation Project.
C. G. Kingsmill, M.E.I.C.

Economic Aspects of Industrial Power Plants.
H. R. Wright, M.E.I.C.

The Structural Behaviour of Highway Bridge Decks.
S. D. Lash, M.E.I.C., B. B. Hope.

Long Range Planning for the Manitoba Hydro-Electric Board.
L. A. Bateman, M.E.I.C.

The Evolution of Large Synchronous and Induction Motors in Canada.
G. W. Herzog, M.E.I.C., K. Z. Lukaszewicz.

Design and Construction of Chute-des-Passes 345 KV Transmission Line.
H. B. White, M.E.I.C.

Automation in Thermal Power Plants.
A. R. Scott.

The Principles of Automatic Control.
A. Porter, M.E.I.C.

Optimum Adjustment of Governors at the Hydro Generating Station of the Manitoba Hydro-Electric Board.
L. M. Hovey, M.E.I.C.

The Warsak Hydro-Electric Project.
J. H. Ings, M.E.I.C.

The Application of High Powered Epicyclic Gears for Marine and Industrial Use.
H. N. G. Allen, T. P. Jones.

White Horse Rapids Power Development.
L. A. Carey.

Engineering Computation in the Chemical Industry using Digital and Analog Computers.
V. J. Bakanowski, M.E.I.C., R. N. Boyd, M.E.I.C.

Standard Aluminum Sub-station Design.
J. R. McMullan, Howard Meyers.

An Approximate Analytical Method for the Determination of Foundation Natural Frequencies.
George Ford, M.E.I.C., J. B. Haddow.

Uranium City Water and Sewage System.
H. P. Klassen, M.E.I.C.

Moran Dam and the Fraser River.
R. E. Potter, M.E.I.C.

Management — Horsetrading or Trusteeship?
Lyndall F. Urwick.

Statistical Quality Control as a Management Tool.
B. H. Lloyd.

Soil Problems Encountered in Mining on the Canadian Shield.
R. F. Legget, M.E.I.C., W. J. Eden, r.E.I.C.

Concrete Lining of the Tunnel at Silver Falls Generating Station.
J. H. Jackson, M.E.I.C., C. T. Bath.

Preprints of the following papers have been delayed but it is expected that they will be available at Winnipeg, where copies may be obtained at the Library Exhibit.

Design and Construction of Kelsey Generating Station Dam and Dykes.
R. A. Pillman, Jr.E.I.C., D. H. MacDonald, M.E.I.C., H. R. Hopper, Jr.E.I.C.

Design of Industrial Gears.
R. D. Mutch.

The Dunvegan Suspension Bridge.
T. Lamb, M.E.I.C., R. N. McManus, M.E.I.C.

Design and Erection of Structural Steel for The International Nickel Company's Thompson Project.
W. H. Bender.

Sault Ste. Marie International Bridge.
C. H. Gronquist.

The Greater Winnipeg Water District's Second Branch Aqueduct and Low Lift Pumping Station.
N. S. Bubbis, M.E.I.C., R. C. Sommerville, Jr.E.I.C.

A New Canadian Structural Test Installation.
W. R. Schriever, W. G. Plewes, Jr.E.I.C.

The Measurement of Industrial Water Pollution.
T. W. Beak.

Benefit Cost Analysis of Greater Winnipeg Floodway.
C. H. Templeton, M.E.I.C.

Manned Space Flight.
Orest Cochkinoff.

Hydrological Investigations for the South Saskatchewan River Project.
E. F. Durrant, M.E.I.C.

The Work of the Column Research Council.
D. T. Wright, M.E.I.C.

The Economics of an Industrial Gas Turbine Installation.
D. Panar, M.E.I.C.

Development of Western and Northern Canada's Mineral Resources.
John Convey.

Silver Falls Tunnel and Surge Tank Design Considerations.
L. A. Leeyus, M.E.I.C.

The Khulna Newsprint Project.
D. P. Wyness.

Microwave Radio Application to an Electric Utility Load Dispatch System.
E. M. Scott, M.E.I.C.

Braking of Hydro-Electric Generators.
H. O. Wilson, M.E.I.C.

Future of Western Canadian Potash.
W. J. Pearson.

Recent Advances in Experimental Stress Analysis.
J. B. Mantle, M.E.I.C.

Load and Frequency Control System of the Manitoba Hydro-Electric Board.
K. H. Williamson, Jr.E.I.C.

Joints in Precast Concrete Building Frames.
E. M. Rensaa, M.E.I.C.

The Formation of Continuous Chips in Metal Cutting.
W. B. Rice, M.E.I.C.

The Use of Test Buildings in Building Research.
N. B. Hutcheon, M.E.I.C., G. O. Handegord, M.E.I.C.

The Potential in the Free-Piston Engine Principle.
Anton Braun.

An Exercise in Operations Research — RCAF Aircraft Maintenance.
A. B. Howell.

The following papers were preprinted in the April issue of The Engineering Journal. Members wishing to refer to these papers at the Annual General Meeting should bring this issue with them.

Supervisory and Automatic Control for Winnipeg Unattended Pumping Station.
J. W. MacLaren, M.E.I.C., D. J. Moon, M.E.I.C., W. D. Hurst, M.E.I.C., F. G. Denson, M.E.I.C.

Silver Falls Project.
R. A. Forrester, M.E.I.C.

A High-Pressure Steam Plant for a Modern Paper Factory.
F. W. Buckley, M.E.I.C.

Application of Microwave Radio Links.
R. W. Wilson, M.E.I.C.

Salient Mechanical Design Aspects of Selkirk Generating Station.
C. W. Hodgson, M.E.I.C., A. C. Blue, M.E.I.C.

International News

Negotiations between India and Pakistan toward an Indus Waters settlement appear to have been given a considerable boost recently and a Water Treaty will likely be forthcoming in the next few months. Six countries have promised funds, through the World Bank, for the billion-dollar development which would include irrigation, hydro-electric projects, soil reclamation, drainage and flood protection for India and Pakistan.

The Indus Waters Treaty would be based on a division of the Indus Waters proposed by the Bank to the two governments in 1954. It calls for allocation of the three Eastern Rivers of the Indus system to India's use, and of the three Western Rivers to Pakistan. The division would necessitate construction of works to transfer supplies from the Western Rivers to meet irrigation needs in those areas of Pakistan which have hitherto been supplied by the Eastern Rivers. India would, of course, contribute to the cost of these works.

Canada has pledged $22.1 million over the next ten years toward development of the Indus Waters, as part of her increased Colombo Plan contribution. All pledges are subject to ratification of a water treaty between India and Pakistan. Also participating in the development plan are: Australia, Germany, New Zealand, the U.S., and U.K.

French Special Freight Cars

The Compagnie Industrielle de Materiel de Transport (C.I.M.T.) and Ateliers de Forest have designed and built two new freight cars, one with sliding roof and the other with sliding sides. They provide free access to all parts of the car and greatly speed up loading and unloading. The sliding-sides freight car is particularly designed for merchandise stocked on platforms, while the sliding-roof model facilitates loading heavy pieces by crane.

New Swedish Power Line Tower

The Swedish State Power Commission anticipates saving approximately $3,800,000, or 30% of costs, in the installation of 620-mile long 380 kv. transmission lines between Messaure and Hjalta and Kilforsen and Orevo. They are using a new lighter type of tower, the product of four years' development. Fifty pairs of such towers have been erected between the recently inaugurated Stornorrfors power plant and the Harrsele distribution centre, and light weight has been found to decrease mounting time and simplify transportation considerations.

Japanese Expressway

Japan has been granted a loan by the World Bank for construction of a 45-mile expressway between Amagasaki and Ritto, linking the Osaka metropolitan area with that of Kyoto. This is one of the more heavily industrialized areas of Japan. The development of transport facilities has seriously lagged behind other sectors of the Japanese economy, and only 10% of the 93,000 mile road network is paved. Japan now intends to invest about $2.8 billion during the period 1958-63 in a program to improve and reconstruct existing roads and build expressways.

International Atomic Energy

The Spanish government has offered 140 tons of uranium for sale to the International Atomic Energy Agency and its member states in 1960-62. The countries which have already agreed to make nuclear materials available for sale to members through the Agency are Belgium, Canada, Czechoslovakia, Portugal, and South Africa. The U.S., U.S.S.R. and U.K. have agreed to make enriched uranium available to the Agency.

A symposium on The Chemical Effects of Nuclear Transformations is to be held in Prague, Czechoslovakia, October 24-27, 1960. The director general of the Agency has invited member governments and interested international organizations to nominate participants.

English Channel Crossing

The Channel Tunnel Company is due to report this Spring on its plan for constructing an access route between England and the European continent. They have contemplated a railway tunnel with passenger trains and rail flat cars which could take 400 cars an hour. It would cost approximately $450 million. A road tunnel of 36 miles, 22 of them under sea, would over-strain drivers and be difficult to ventilate, but a four-lane steel and concrete bridge is under consideration. Such a bridge would cost about $240 million. It would be ten times as long as the record two-mile-long Zambesi River bridge in Central Africa.

Iron Ore Deposits in the Islamic Republic of Mauritania

Sixty-six million dollars have been loaned to the Islamic Republic of Mauritania in Northwest Africa by the World Bank for the development of high-grade iron ore deposits. The loan will be devoted to purchase of equipment and services to mine ore, construction of a 415-mile railway to transport the ore to port, and development of port and other facilities.

Swedish Arresting Net for Jet Aircraft

An arrester net designed to stop jet aircraft which have overrun the paved runway has been designed by the Swedish Air Board and is being adopted by the R.A.F. in Britain and NATO bases throughout Europe. A wide-mesh net catches the aircraft's wings. The four main components of the gear are the arresting net, arrangement for supporting, raising and lowering the net, lamella friction brakes with winding drums and braking wires, and anchorages.

PROVINCE OF MANITOBA
OFFICE OF THE PREMIER
WINNIPEG

April 5th, 1960.

Mr. J. H. Hanna, M.E.I.C.,
President,
Engineering Institute of Canada,
2050 Mansfield Street,
Montreal 2, Quebec.

Dear Mr. Hanna:

We in Manitoba consider it an honor to be the host Province for the 74th Annual Meeting of the Engineering Institute of Canada, from May 24th to May 27th.

With the heavy undertakings now proceeding in Manitoba, we have a special affection for the professional engineers in the Province and for those who consult with them, and so we are pleased to extend a warm welcome to them and to their colleagues.

Few people, I think, stop to realize the major role that engineers have played in the physical development of our nation, the Seaway notwithstanding. Every road, rail line, mine, factory, public service installation, utility and major building -- indeed almost every visual evidence of our progress -- bear the stamp of the man with the slide-rule.

It is, then, with considerable pleasure that we look forward to having members of the Engineering Institute of Canada and their wives amongst us.

I wish you a successful Convention and one of many enjoyable stays in our Province.

Yours sincerely,

Premier of Manitoba

STEPHEN JUBA
MAYOR

Winnipeg, 2, Man.,

April 6th, 1960.

The Members and their Ladies,
The Engineering Institute of Canada,
c/o Mr. J. H. Hanna, M. E. I. C.
President,
Engineering Institute of Canada,
2050 Mansfield St.,
Montreal, 2, Que.

Dear Ladies and Gentlemen:-

Winnipeg welcomes you! The Council and citizens of the City are delighted by the fact that the Engineering Institute of Canada will hold its seventy-fourth Annual Meeting in Winnipeg, May 25th, 26th and 27th, 1960.

Your Winnipeg Branch Annual Meeting Committee has worked hard and long in planning a program which should be of the greatest interest to all who attend the meeting, or read the papers to be presented in the Engineering Journal.

You will have opportunities to see how the City has grown and is growing, and how the work of the engineer is being used for the benefit of all.

I have been invited to be with you at your meeting and at that time I shall take the opportunity to repeat the welcome this letter contains.

The City of Winnipeg will be proud to be your hosts and we shall all do our best to make you sense our pride in having you with us.

Yours very truly,

MAYOR.

Month to Month

The Engineers Confederation Commission

The Co-ordinating Committee of the Engineers' Confederation Commission held its first meeting in Toronto on March 6, 1960 with Mr. J. H. Fox, Chairman of the Commission, in the Chair.

All committees of the Commission were represented by their respective Chairman and/or Vice-Chairman and submitted reports of their activities to date.

The main purpose of this meeting was to give an opportunity to committee Chairmen to discuss the work of their own committee with representatives of other committees and to ascertain that all committees are reasonably in agreement on major issues.

It is reported that the progress made since the first meeting of the Commission in October 1959 is very substantial and that the work assigned to the various committees is being carried out on schedule. There remains however a considerable amount of detail work to be done before any part of the final plan can be published.

The following were present at the meeting: Mr. J. H. Fox, Chairman; Mr. G. M. Dick, Vice-Chairman; Messrs. J. G. Dale, Chairman of the committee on Charter; E. D. Gray-Donald, Chairman of the committee of Finance; H. Gaudefroy, Chairman of the committee on By-Laws; W. K. Gwyer, Chairman of the committee on Branches; H. Smith, Chairman of the committee on other Societies; J. B. Mantle, Chairman of the committee on Services; T. Foulkes, Chairman of the committee on Administration; F. Bennett, Vice-Chairman of the committee on Relationship with Provincial Associations; N. S. Bubbis, Vice-Chairman of the committee on Branches; C. T. Carson, member of the committees on By-Laws and Finance; D. D. Whitson, member of the committee on Administration; L. M. Nadeau and G. T. Page, Joint Secretaries.

Cooperation with Commonwealth Engineering Societies

During the past several years the Institute has been increasingly aware of the relatively large number of members of sister Commonwealth engineering institutions who have come to live and work in Canada. Motivated by the desire to provide a "technical home" in Canada for these engineers, and to assist them in every way within the philosophy of close co-operation already existing between the Institute and its sister societies throughout the Commonwealth, in 1959 the Council appointed a special committee to investigate and recommend a suitable course of action by which the E.I.C. might best fulfil the above general objectives.

At its meeting in Montreal on February 20, the Council received a detailed and constructive report from its committee and the useful suggestions contained therein are now being considered jointly by appropriate officials of the sister societies, and the Institute has a basis for negotiating the best possible methods for providing acceptable services to members of Commonwealth engineering societies resident in Canada.

Council Appoints Committee to Study Civic Affairs and Public Relations

At the February 20, 1960 meeting, Council adopted the report of the E.I.C. Civic Affairs and Public Relations Committee regarding possible branch activity in these fields. The report reads as follows:

Recommendations:

a) It is suggested that each branch of the Institute designate one or more members of their executive committee to keep in touch with civic affairs and public relations on a local basis. In certain branches only one member of the executive may be needed. Larger branches, particularly those serving a number of communities, more than one representative may be required.

b) Such branch executive representatives should closely co-operate with any similar committee of the provincial associations or corporation.

c) No public action of any kind should be taken by these representatives until approval is given by the branch executive.

d) To indicate the field that could be covered by Civic Affairs and Public Relations representatives of the branches the following limitations are set out.

What Cannot Be Done

1) Express opinions on a national level.

2) Offer services direct to a government body.

3) Express an opinion except through the engineer on the job.

4) Publicly defend an engineer or engineering firm.

5) Make a general practice of providing free service to engineers or others.

6) Take any action that will endanger public sympathy for engineers.

What Can Be Done

1) Advise municipal and other public authorities to use the services of engineers, preferably Canadian.

2) Educate the public to leave engineering decisions to engineers.

3) Ask for more engineers at various levels of government.

4) Encourage engineers to run for public office or to serve on committees and help them get elected where possible.

5) Give support to urban transit and commuter service in the larger centers as being the most economical way of overcoming or preventing traffic congestion.

(Continued on page 134)

74th ANNUAL GENERAL AND PROFESSIONAL MEETING of

THE ENGINEERING INSTITUTE OF CANADA

May 25, 26, 27, 1960 Royal Alexandra Hotel, Winnipeg, Manitoba

Registration

Advance registration through E.I.C. Headquarters closes May 18.
Registration opens 12 noon May 24 and continues at 9 a.m. May 25 and May 26.

Accommodation

The Royal Alexandra Hotel is headquarters, with more than 200 rooms reserved for E.I.C. members and guests. Accommodation has also been set aside at other hotels and motels in the area.

Technical Program

The technical program is listed on the following 2 pages.

Ladies Program

Early plans for this include the following:

3 p.m. Wednesday, Reception at Government House.
12.30 p.m. Thursday, Luncheon and Fashion Show at the "Town and Country".
10 a.m. Friday, Engineers' wives meeting.

Winnipeg Diary

Events for all 4 days at the Royal Alexandra Hotel are listed on the back of this program.

Committee

Chairman
Mr. J. R. Rettie

Vice Chairmen
Mr. C. V. Antenbring
Mr. W. A. Devereaux

Representative & Chairman Branch Management Committee
Mr. W. L. Wardrop

Secretary
Mr. G. C. March

Publicity
Mr. N. S. Bubbis

Budget and Finance
Mr. D. C. Bryden

Technical Papers
Mr. R. E. Chant

Hotel Arrangements
Mr. F. G. Denson

Registration
Mr. W. A. Devereaux

Reception and Information
Mr. C. L. Fisher

Ladies
Mr. G. Flavell

Plant Visits & Transportation
Mr. J. MacDonald

Communications & Projection
Mr. G. A. Muir

Muriel's Room & Entertainment
Mr. R. Noonan

Annual Dinner and Dance
Mr. T. Weber

Ladies Program:
Convener Mrs. C. V. Antenbring, Co-Convener Mrs. D. Stratton

TECHNICAL PROGRAM

Wednesday, Thursday, Frid

Wednesday, May 25

Design and Construction of Kelsey Generating Station Dam and Dykes.
R. A. Pillman, JR.E.I.C., D. H. MacDonald, M.E.I.C., H. R. Hopper, JR.E.I.C.

Design of Industrial Gears.
R. D. Mutch.

The Dunvegan Suspension Bridge.
T. Lamb, M.E.I.C., R. N. McManus, M.E.I.C.

Supervisory and Automatic Control for Winnipeg Unattended Pumping Station.
J. W. MacLaren, M.E.I.C., D. J. Moon, M.E.I.C., W. D. Hurst, M.E.I.C., F. G. Denson, M.E.I.C.

The Warsak Hydro-Electric Project.
J. H. Ings, M.E.I.C.

The Application of High Powered Epicyclic Gears for Marine and Industrial Use.
H. N. G. Allen, T. P. Jones.

Design and Erection of Structural Steel for The International Nickel Company's Thompson Project.
W. H. Bender.

EIC *Annual Meeting, 1960*

Automation in Thermal Power Plants.
A. R. Scott.

Construction of the Warsak Hydro-Electric and Irrigation Project.
C. G. Kingsmill, M.E.I.C.

Sault Ste. Marie International Bridge.
C. H. Gronquist.

The Principles of Automatic Control.
A. Porter, M.E.I.C.

Thursday, May 26

Engineering Computation in the Chemical Industry Using Digital and Analog Computers.
V. J. Bakanowski, M.E.I.C., R. N. Boyd, M.E.I.C.

The Greater Winnipeg Water District's Second Branch Aqueduct and Low Lift Pumping Station.

ANNUAL MEETING

Tuesday, May 24

9.30 a.m.	E.I.C. Committee on Education. Branch Officers' Conference.
10.00 a.m	Council Meeting.
12.30 p.m.	Joint luncheon, all conferences.
2.00 p.m.	Committee on Technical Operations. Continuation of meetings.
4.30 p.m.	Press conference.
8.30 p.m.	Reception — Muriel's Room.

Wednesday, May 25

7.45 a.m.	Authors' breakfast.
10.00 a.m.	Annual General Meeting.
12.00 noon	Muriel's Room.
12.30 p.m.	Opening Luncheon.
2.00 p.m.	Students' Conference.
6.30 p.m.	Muriel's Room.
7.00 p.m.	Dinner.
9.00 p.m.	Social evening.

Thursday, May 26

7.45 a.m.	Authors' breakfast.
9.00 a.m.	Professional Development Committee. Consulting Engineers — Directors' meeting.
10.00 a.m.	New Council Meeting.
12.00 noon	Muriel's Room.
12.30 p.m.	Honours and awards luncheon.
2.30 p.m.	Consulting Engineers' Annual Meeting. Professional Development Forum. Continuation of Students' Conference.
7.00 p.m.	Consulting Engineers' Annual Dinner.
9.15 p.m.	Muriel's Room.
10.00 p.m.	Entertainment.

Friday, May 27

7.45 a.m.	Authors' breakfast.
9.00 a.m.	Joint ASME – EIC International Council.
2.00 p.m.	Field Trips. Students' Conference — Final session.
6.30 p.m.	Muriel's Room.
7.30 p.m.	Annual Banquet.
10.00 p.m.	Annual Dance.

the Engineering Institute of Canada

NEWLY ELECTED OFFICERS OF THE INSTITUTE

At the Annual Meeting, three vice-presidents and twenty-four councillors will take office and will serve with others whose terms of office continue. The complete list of Council members will appear in the June issue.

E. A. Cross, M.E.I.C.

Paul G. A. Brault, M.E.I.C.

J. S. Watt, M.E.I.C.

Edgar A. Cross, M.E.I.C., elected vice-president of the Institute representing the Province of Ontario, has been in private practice as a consulting engineer in Toronto since 1930.

Born in England in 1889, Mr. Cross is a graduate in civil engineering of Birmingham University. His carrer has been: assistant engineer, Birmingham Canal Navigations, 1909-15; chemical warfare branch of the British Army in France, 1915-17, research department, Royal Arsenal, Woolwich, 1917-19; chief assistant engineer, Birmingham Canal Navigations, 1919-20; superintendent on construction for W. L. Stoddart, Architect, N.Y.C., 1920-22; designing structural engineer for Albert Kahn, Architect, Detroit, 1922-27, and for Chapman & Oxley, Architects, Toronto, 1927-30.

Mr. Cross is a Member of the Association of Professional Engineers of Ontario and the American Society of Civil Engineers; a Past Councillor for the Institution of Civil Engineers, Great Britain; and a Past President of the Association of Consulting Engineers of Canada.

Charles Miller, M.E.I.C., has been elected vice-president of the Institute representing the Province of Quebec. Mr. Miller is general manager of the Manicouagan Power Company.

Graduating from Queen's University in 1930 in civil engineering, Mr. Miller joined the staff of the Saguenay Power Company at Arvida, Quebec, as draftsman. He became hydraulic engineer and, in 1940, resident engineer. In 1944 Mr. Miller was appointed chief engineer of the Aluminum Power Company. From 1945-47 he was with the Beauharnois Light, Heat and Power Company as general superintendent; from 1947-49 he was chief hydraulic engineer, Ontario Paper Company; from 1949-53, manager of construction for the Manicouagan Power Company's development at the First Falls of the Manicouagan River; from 1953-56, consulting engineer; and from 1957-59, project manager, Canadian British Aluminium Company, Baie Comeau, Quebec. He was appointed general manager of the Manicouagan Power Company in 1959.

Mr. Miller was chairman of the Saguenay Branch of the Institute in 1939.

T. C. Higginson, M.E.I.C., president of Eastward Industries Ltd., Saint John, N.B., has been elected to Council as vice-president of The Institute, representing the Atlantic Provinces.

Mr. Higginson is also Maritime manager of the Automatic Sprinkler Company of Canada, Limited; vice-president and managing director of Country Club Heights Ltd.; and president of the Saint John Board of Trade.

He was born and educated in Montreal. Mr. Higginson joined the Automatic Sprinkler Company of Canada in 1928 and became manager of their interests in the Maritimes in 1946. At the same time he formed Eastward Industries Ltd., and in 1952 he entered the housing and development field.

P. G. A. Brault, M.E.I.C., chief engineer of the Dominion Bridge Company, Ltd., is the Councillor-elect for the Montreal Branch.

A graduate of McGill University in 1921 with a B.Sc. degree, Mr. Brault joined the structural design division of the Dominion Bridge Company in 1926. Loaned to United Shipyards with responsibility for the design of cargo vessel launching arrangements in 1942, Mr. Brault returned to Dominion Bridge in 1945 as assistant to the design engineer. In 1951 he was appointed design engineer; in 1958, assistant chief engineer, Eastern division; and in 1959, chief engineer, structural division, Montreal. In recent years Mr. Brault has been associated with construction of the Halifax-Dartmouth Bridge, the Queen Elizabeth Hotel and St. Lawrence Seaway bridge alterations in the Montreal area.

Mr. Brault has served on the Montreal Branch executive of the Institute and on various committees.

Roy A. Phillips, M.E.I.C., has been elected a Councillor of the Institute representing the Montreal Branch. He is manager of the marketing, appliance and television receiver department, Canadian General Electric Company, Ltd., Montreal.

Mr. Phillips was born in Vancouver and received his B.A.Sc. degree from the University of British Columbia in 1939. Joining Canadian General Electric on their test course immediately upon graduation, Mr. Phillips was an engineer in the switchgear department from 1940-49. He then became works' engineer, Montreal works, and in 1952 was appointed manager, product planning and marketing research, major appliance department. When the major appliance department became the appliance and television receiver department in 1955, Mr. Phillips was appointed manager, product planning and marketing research, of the reconstituted department. He was named to his present position in 1958.

Active in the Canadian Electrical Manufacturers Association and an elected officer of the Corporation of Professional Engineers from 1952-56, Mr. Phillips has served the Institute in several elected offices and is currently chairman of the Montreal Branch.

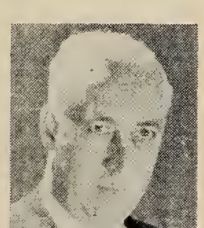
John S. Watt, M.E.I.C., has been elected to represent the Ottawa Branch of the Institute on Council. He is on the staff of the headquarters engineering department, National Harbours Board, Ottawa.

A graduate of the University of New Brunswick in 1943, with a B.Sc. degree in civil engineering, Mr. Watt began his engineering practice on foreign contract to the Bahrein Petroleum Company where he worked on refinery construction in the research and development department. Returning to Canada, he worked in the engineering department of Imperial Oil, Montreal East refinery. Since 1947 he has been employed by the National Harbours Board, working on design of marine structures with the headquarters engineering staff in Ottawa.

A past chairman of the Ottawa Junior Section of the Institute and member of the Ottawa Branch executive, Mr. Watt was chairman of the Ottawa Branch in 1959.

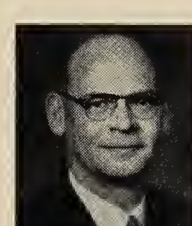
A. C. Davidson, M.E.I.C., is the Councillor-elect from the Toronto Branch of the Institute. Mr. Davidson is an assistant professor in the department of civil engineering at the University of Toronto and the Past Chairman of the Toronto Branch of the Institute.

He graduated from the University of

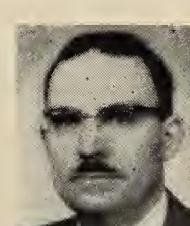


C. Miller, M.E.I.C.

T. C. Higginson, M.E.I.C.



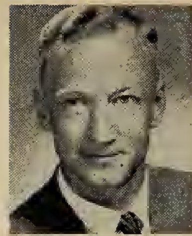
R. A. Phillips, M.E.I.C.



A. C. Davidson, M.E.I.C.

Manitoba with two degrees, one in civil engineering and one in electrical engineering, and received his Master of Applied Science from the University of Toronto. During the last war Mr. Davidson served with the Royal Canadian Engineers at National Defence Headquarters in Ottawa, directing the purchase of equipment and supervising research projects. His civilian experience includes: work with Dominion Bridge on design and erection of steel structures; design of steel frames for large power houses, Hydro Electric Power Commission of Ontario and Brazilian Service Limited; design of concrete structures for Yonge St. subway, Toronto Transit Commission; buildings, housing and municipal services, Defense Construction and Central Mortgage and Housing Corporation; and work on the microwave relay line across Newfoundland, Canadian National Telegraphs.

W. G. Heslop, M.E.I.C.



S. R. Sinclair, M.E.I.C.

R. D. Livingstone, M.E.I.C.

W. G. Heslop, M.E.I.C., has been elected to represent the Vancouver Branch of the Institute on Council. Mr. Heslop has been associated with the University of British Columbia since 1945 and is at present an associate professor of civil engineering. He is also employed by Morrin & Knutson Construction Engineering at Kenamo, B. C.

After graduation from the University of Toronto in 1930, civil engineering with hydraulic option, Mr. Heslop worked in the transmission department of Ontario Hydro and the Department of Highways of Ontario doing location and construction work. From 1935-40 he was employed by Hollinger Consolidated Gold Mines on underground ventilation and silicosis prevention. During the war, 1940-45, he served in the Royal Canadian Air Force supervising navigation training under the Empire Air Training Plan in Canada.

Since joining the University of B.C. faculty in 1945, Mr. Heslop has worked with H. G. Acres & Co., 1946; the Fraser River Dyking Board, 1948; B.C. International Engineering, 1949; and Morrin & Knutson, since 1951.

Mr. Heslop is an Associate Member of the Canadian Institute of Mining and Metallurgy.

Stewart R. Sinclair, M.E.I.C., of Edmonton, professor and head of the civil engineering department, University of Alberta, has been elected to serve as Councillor for the Institute, representing the Edmonton Branch. He is the Immediate Past Chairman of the Branch.

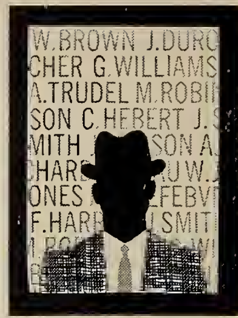
Mr. Sinclair is a graduate in civil engineering from the University of Alberta, B.Sc. 1944, M.Sc. 1947. He joined the staff of the University of Alberta in 1947 and took over his present position in 1959. He also serves as a consultant in the fields of soil mechanics, highways and foundations.

R. D. Livingstone, M.E.I.C., general manager of Lethbridge Collieries, Ltd., has been elected to the Council of the Institute as representative from the Lethbridge Branch.

Graduating with a B.Sc. in mining engineering in 1939 from the University of Alberta, Mr. Livingstone worked underground for the next two years to gain his Mine Manager's and Surveyor's papers under the Alberta Mines Act. From 1941-45 he served with the Royal Canadian Engineers and was twice decorated. After the war Mr. Livingstone returned to Lethbridge and was employed as mining engineer and manager until 1956 when he was promoted to

(Continued on page 125)

Personals



A. O. Dufresne, M.E.I.C. (Ecole Polytechnique '11), Deputy Minister of Mines for the Province of Quebec, retired April 1, after 45 years' association with that department.

James M. Wardle, M.E.I.C. (Queen's '12) is a member of the National Capital Commission, Ottawa.

W. E. Stone, M.E.I.C. has been transferred to Toronto to open up an office there for Western Reinforcing Steel Services Ltd. as manager of the Company's Ontario division.

A. W. Manby, M.E.I.C. (Michigan '21) has retired from the post of general manager of the Ontario Hydro-Electric Power Commission.

John W. Hackney, M.E.I.C. (Carnegie Institute of Technology '34) has been appointed vice-president of Beaco Limited's process plant divisions across the country.

W. P. Nesbitt, M.E.I.C. (Queen's '35) has been appointed general manager of the pulp and paper division of Howard Smith Paper Mills Ltd.

William H. Stuart, M.E.I.C. has been in the United States for the past year as Manager of the New York Office of A. D. Margison and Associates, Consulting Engineers, for Canada on matters relating to certain aspects of U.S.-Canada Joint Defence.

John Terry, M.E.I.C. (Calcutta '48) has been appointed assistant mechanical engineer of Dosco's coal operations.

Roy F. E. Bunston, M.E.I.C. (Queen's '42) has been appointed vice-president and general manager of M & M Line Construction Co. Ltd.

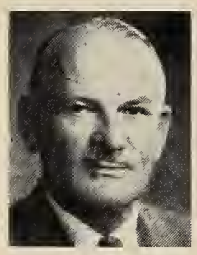
Philip M. Meis, M.E.I.C. (Manitoba '43) has been made western region manager for Honeywell Controls Ltd. The post is newly created.

H. A. Marshall, M.E.I.C. (Nova Scotia Technical '43) is the chairman of the Halifax Branch of the Institute. He is manager of consumer sales for Imperial Oil Ltd.

Stanley W. Pappius, M.E.I.C. (Royal Naval Engineering College, U.K. '45) has been appointed sales manager of the mechanical division of Dominion Bridge Company, Ltd. He was formerly associated with Canadian Vickers, Ltd.

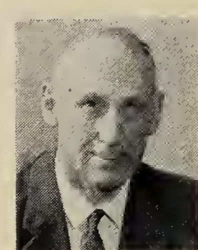
W. Lloyd Sharpe, M.E.I.C. (Saskatchewan '47), city engineer of Weyburn, Sask., is the new president of the Western Canada Water and Sewage Conference.

R. F. Harris, M.E.I.C. (Toronto '49) has been elected president of the Builders' Exchange of the City of London, Ontario for the year 1960. He is district manager of The Foundation Company of Ontario's London office.



A. W. Manby, M.E.I.C.

H. J. A. Chambers, M.E.I.C.



R. Hobner, M.E.I.C.

F. L. West, M.E.I.C. (McGill '16) has been granted a life membership in the American Society of Civil Engineers. Mr. West is vice-president of Mount Allison University, Sackville, N.B.

H. C. M. Gordon, M.E.I.C. (McGill '23) has been appointed vice-president of The Dominion Steel and Coal Corporation's mining operations. He is also vice-president and general manager of Dosco's Dominion Coal Company.

Roland R. Duquette, M.E.I.C. (Ecole Polytechnique '32) was recently elected president of the Association of Consulting Engineers of Canada.

Georges Demers, M.E.I.C. (Ecole Polytechnique '35), consulting engineer at Quebec City, has been elected president of the Association of Graduates of Ecole Polytechnique.

Harold J. A. Chambers, M.E.I.C. (Toronto '24) has been appointed president of Fluid Power Ltd., Toronto, a newly incorporated company.

R. E. Grout, M.E.I.C. (Alberta '36) has been appointed a vice-president of The Shawinigan Engineering Company Ltd. He was formerly chief engineer, electrical division.

Robert H. Hobner, M.E.I.C. (Manitoba '35) is project engineer with the Northern Construction Division of the Department of Public Works' building construction branch.

Nelson S. Hepburn, M.E.I.C. (British Columbia '50) has been appointed a director of A. B. Sanderson and Company Ltd. He is Chief Engineer of the firm and manager of the Vancouver office.

H. W. Percival JR.E.I.C. (McGill '50) has accepted a position as project engineer with the Aluminum Company of Canada, Arvida, Quebec.

J. C. J. Heroux, JR.E.I.C. (McGill '52) formerly employed by the Public Works Department of Canada, in Montreal (harbours and rivers branch) is now town engineer for Shawinigan South, Quebec.

Donald R. Evans, JR.E.I.C. (Toronto '53) has been appointed city engineer of Sault Ste. Marie, Ont. He was formerly a project engineer with Marshall Macklin Monoghan Ltd., Don Mills, Ont.

N. B. Breen, JR.E.I.C. (Saskatchewan '49) has left the Canadian Locomotive Company and is now associated with Aluminium Laboratories Ltd. in Kingston, Ont., as service welding engineer.

N. R. Breen, JR.E.I.C.

W. Strok, M.E.I.C.

W. Strok, M.E.I.C. (Durham '55) has become a Professional Engineer of the Province of British Columbia.

I. Waterlow, M.E.I.C. (McGill '51) recently took over the position of superintendent of Maintenance Yards and Services for Cominco at Trail, B.C.

R. Donald Emmett, JR.E.I.C. (Toronto '51) has opened an electrical consulting practice in the Toronto area. He has been in architectural and industrial electrical design and supervision work.

R. D. Emmett, JR.E.I.C.

S. R. Mester, JR.E.I.C.

S. R. Mester, JR.E.I.C. (McGill '57) has been appointed sales manager for Needco Cooling Semiconductors Ltd., Montreal, a new Canadian company.

Melvin J. Shelley, M.E.I.C. (British Columbia '55), former city engineer of the City of Vernon, has accepted a position as city engineer of Moose Jaw, Sask. He leaves his post as chairman of the Central B.C. Branch of the Institute.

O. M. Hodgkins, S.E.I.C. (Toronto '59) has accepted a position as construction engineering officer in the RCAF at Lac St. Denis.

● OFFICERS

(Continued from page 120)

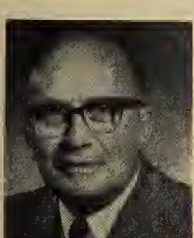
his present position. He served on the council of the Association of Professional Engineers of Alberta from 1953-56 and has been a member of the joint finance, discipline and investigations, meeting, and membership and enforcement committees.

Mr. Livingstone is a past chairman of the Lethbridge Branch of the Institute. In 1952 he served as national chairman of the coal division, Canadian Institute of Mining and Metallurgy. He is also a member of the Institute of Mining Engineers of Great Britain and the American Institute of Mining Engineers. Continuing to be active in the Royal Canadian Engineers' Militia, Mr. Livingstone is the Commanding Officer of the 8th Field Engineer Regiment, with the rank of Lieutenant Colonel.

W. G. Sharp, M.E.I.C., is the Councillor-elect for the Calgary Branch of the Institute. He has been on the executive of the Calgary Branch and served as its chairman in 1954-55.

Since graduation from the University of Alberta in 1933, with a B.Sc. in electrical engineering, Mr. Sharp has been engaged in the theatre supply business. In the early years Mr. Sharp's interest was mainly in installation and servicing of motion picture projection and sound equipment and in the latter years it has been in the administration and operation of his own business, Sharp's Theatre Supplies, Ltd.

Mr. Sharp is a member of the Association of Professional Engineers of Alberta.



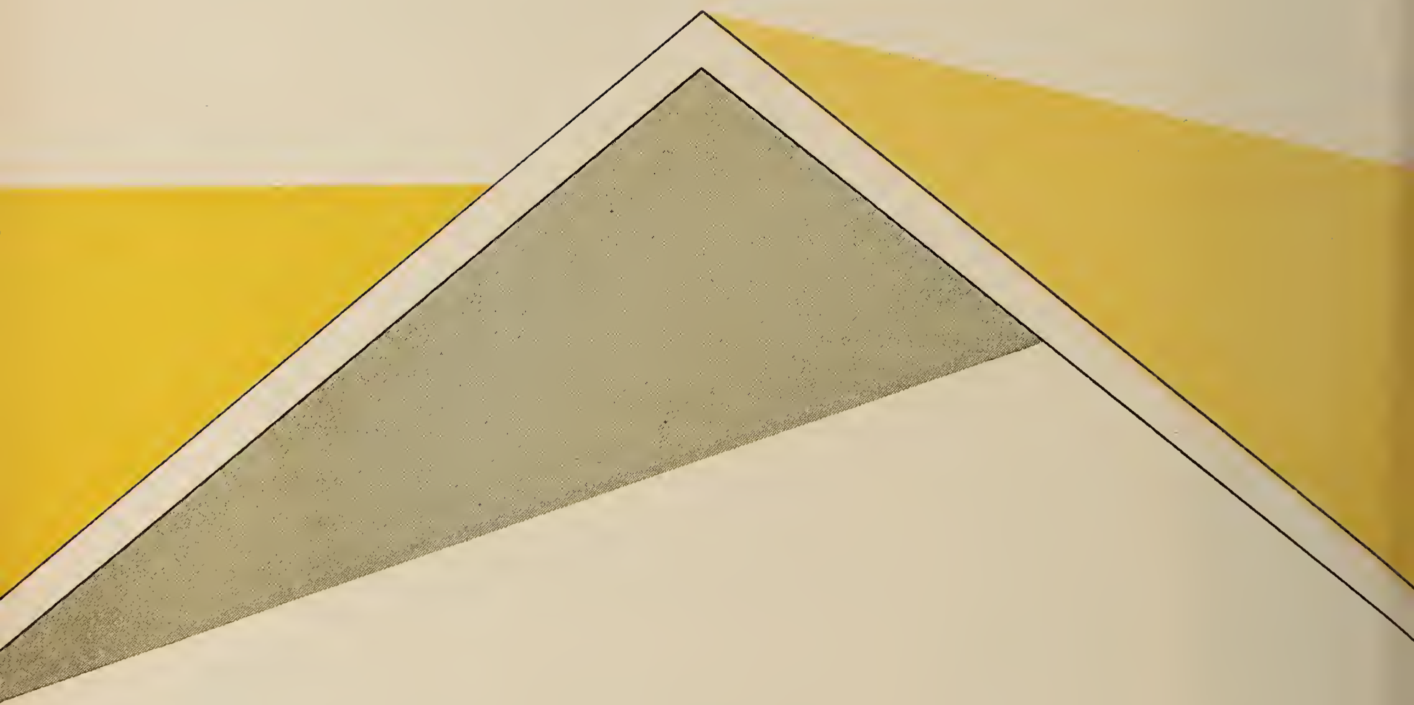
W. G. Sharp, M.E.I.C.

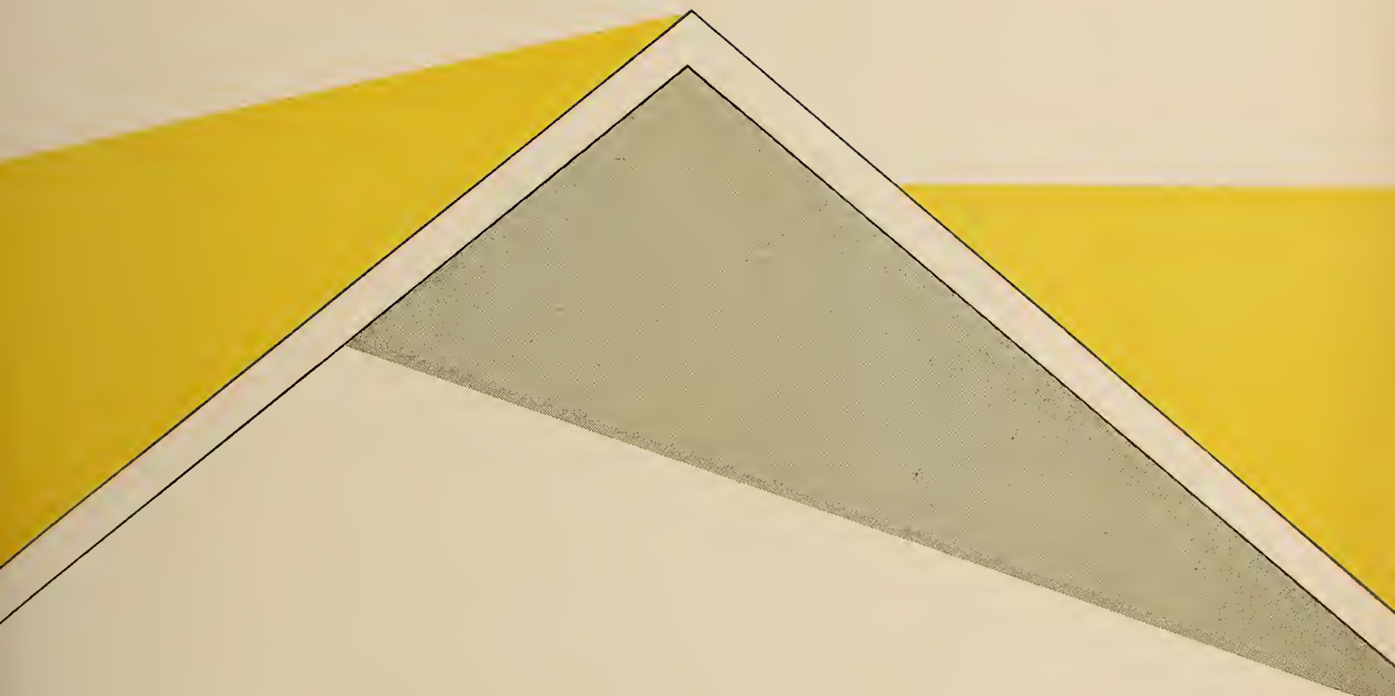
J. L. Thompson, M.E.I.C.

J. L. Thompson, M.E.I.C., has been elected to Council to represent the Saskatchewan Branch of the Institute. He is head of the agricultural engineering section, Canada Department of Agriculture, research branch, experimental farm, at Swift Current, Saskatchewan.

Holding degrees from the University of Saskatchewan (B.E. in agricultural engineering, 1938) and Iowa State College (M.Sc. in agricultural engineering, 1948), Mr. Thompson worked from 1938-47 as irrigation supervisor for Canada Department of Agriculture at Swift Current, preparing agricultural lands for irrigation on new projects being developed by P.F.R.A. In 1948 he transferred to the research field doing power and tillage studies on agricultural equipment with the Experimental Farm. Mr. Thompson accepted his present position in 1950.

(Continued on page 128)





• OFFICERS

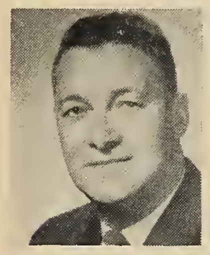
(Continued from page 125)

N. S. Bubbis, M.E.I.C.

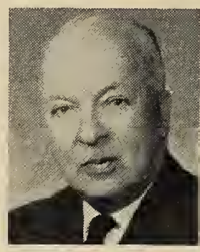
N. S. Bubbis, M.E.I.C., has been elected Councillor for the Winnipeg Branch of the Institute. He is general manager and chief engineer for the Greater Winnipeg Water and Sanitary Districts.

A graduate in civil engineering from the University of Manitoba, 1934, Mr. Bubbis started work with the City of Winnipeg as a pipe plant inspector. He transferred to the drafting and designing branch, where he was later promoted to engineer in charge. In 1944 he was promoted to engineer of water works and sewerage and held that position until 1949 when he became general manager and chief engineer.

Mr. Bubbis is a past president of the Association of Professional Engineers of the Province of Manitoba, of the Canadian Institute on Sewage & Sanitation, of the Western Canada Water & Sewage Conference and of the Minnesota Section of the American Water Works Association. He is a diplomate of the American Society of Civil Engineers, a member of the American Water Works Association, the Federation of Sewage & Industrial Wastes Association, the American Public Works Association and the American Academy of Sanitary Engineers.



W. M. Hogg, M.E.I.C.



F. Alport, M.E.I.C.

W. A. Dawson, M.E.I.C.

William MacDougall Hogg, M.E.I.C., president and director of Great Lakes Power Corporation Ltd., and Great Lakes Power Company, Ltd., has been elected to the Council of the Institute to represent the Sault Ste. Marie Branch.

Mr. Hogg received his B.A.Sc. from the University of Toronto in 1939. Prior to graduation he was with Ontario Hydro as surveyor and engineer on survey and construction work throughout Ontario. In 1939 he became a design engineer with Ontario Hydro and in 1946, project engineer. In 1949 he was senior resident engineer, Des Joachims Power Development; 1951, field project engineer, Sir Adam Beck Power Development and 1954, St. Lawrence Power Development. In 1957 Mr. Hogg joined Great Lakes Power Corporation, Ltd., as vice-president and chief engineer. At present he is its president and director and is also director of The Lake Superior Power Company.

He is a member of the Association of Professional Engineers of Ontario and of the executive of the American Society for Metals. Mr. Hogg is also vice-president and director of the Sault Ste. Marie Chamber of Commerce and a member of the Sault Ste. Marie Industrial Committee.

Frederic Alport, M.E.I.C., has been elected to represent the Huronia Branch of the Institute on Council. Mr. Alport is a consulting engineer at Orillia, Ontario.

A graduate of Orillia Collegiate Institute and the University of Toronto, Mr. Alport received his B.Sc. in 1913. During the summers 1903-06 he worked with the C.P.R. on railroad location and construction on the Prairies and in B.C. In 1906 he transferred to the National Transcontinental Railway, District F, on preliminary and location surveys and construction. He completed Dominion and Manitoba examinations as land surveyor. From 1914-19 Mr. Alport was with the Canadian Corps in France and in 1918 he joined the staff of the 4th Brigade Engineers. In the years 1920-21 he worked with Holbrook, Cabot and Rollins Corporation in Detroit on construction, and in 1924 began a twelve-year term with Patrick McGovern Inc. as contractor. In 1934 Mr. Alport took the position of superintendent on road construction with Curren & Briggs, Ontario, and in 1935 he began work with the Department of Public Works of Canada in Toronto, transferring to the Halifax office in 1938. Working on design of docks for the Canadian Navy from 1939 on, Mr. Alport was transferred to Naval Headquarters in Ottawa as consulting engineer, Naval Service, in 1943. He was awarded the O.B.E.

Mr. Alport returned to the Department of Public Works in Canada, Ottawa, in 1945, and resigned in 1957 to open a consulting office in Orillia.

Jack Edward Harris, M.E.I.C., is the Councillor-elect from the Sarnia Branch. Mr. Harris, is district manager of A. Cope & Sons Ltd., general contractors.

J. E. Harris, M.E.I.C.

D. A. Lamont, M.E.I.C.

A graduate of the University of British Columbia, Mr. Harris received his B.A.Sc. in chemical engineering in 1938 and his M.A.Sc. in 1942. From 1942-55 he worked for Dow Chemical of Canada Ltd. as instrument engineer, maintenance superintendent, works engineer, construction manager and engineering manager. Since 1955 he has been district manager of A. Cope & Sons Ltd., general contractors, specializing in roads, sewers and watermains.

Mr. Harris is a member of the Association of Professional Engineers of Ontario.

W. A. Dawson, M.E.I.C., assistant sales manager of The Brown Boggs Foundry and Machine Company Ltd., Hamilton, Ont., has been elected to represent the Hamilton Branch of the Institute on Council.

Mr. Dawson graduated from Queen's University in 1923 with a degree in mechanical engineering. For twelve years he was associated with the Ford Motor Company of Canada in Windsor, advancing from mechanical draftsman to chief tool engineer. Upon leaving Ford he held successive positions with Algoma Steel Corporation, Sault Ste. Marie, as superintendent of shops and foundries; Chrysler Corporation of Canada Limited, Windsor, as plant engineer of their new motor works; E. Long Ltd., Orillia, as plant manager; Otis Elevator Company Ltd., Ordnance Division, Hamilton, as chief planner and chief inspector of Bofors Gun manufacture. Immediately following World War II, Mr. Dawson was associated with the F. F. Barber Machinery Company, division of Massey-Harris Company, Ltd., Toronto, and opened up a sales office at Hamilton. In 1958 he took up his present position.

Mr. Dawson graduated from Queen's University in 1923 with a degree in an active member of the Association of Professional Engineers of Ontario and a past director and national secretary of The American Society of Tool Engineers. He was the charter chairman of their Hamilton Branch in 1941-42. In 1955 he was elected president of the Queen's University Alumni Association and chairman of its board of directors.

D. A. Lamont, M.E.I.C., manager of systems applications engineering in the apparatus department of Canadian General Electric Company, Peterborough, has been elected to represent the Peterborough Branch of the Institute on Council.

A graduate of Queen's University in electrical engineering, 1945, Mr. Lamont joined the Canadian General Electric Co. on their test course in Peterborough and Toronto immediately upon graduation. Leaving the test course, he joined the engineering department in Peterborough and has spent the majority of his time there in the systems application engineering section.

Obituaries

William Edward Wakefield, M.E.I.C., chief of the division of timber mechanics of the Forest Products Laboratories, Department of Northern Affairs and Resources, until his retirement in 1954, died January 13, 1960. He was 67.

Mr. Wakefield was born at Long Eaton, Derbyshire, England, and graduated in mechanical and electrical engineering from the Derbyshire Institute of Technology in 1914. He joined the Midland Railway as testing engineer upon graduation, but at the outbreak of World War I joined the Sherwood Foresters, later transferring to the Royal Engineers.

Mr. Wakefield came to Canada in 1920 and started a farming venture with his brother near Prince Albert, Saskatchewan. In 1926 he joined the Forest Products Laboratories. During World War II he served as chief of Ottawa's Air Raid Precaution police. He was a member of the NRC sub-committee on wooden aircraft; the associate committee an aeronautical research; and the joint Canada-U.S. mission to the U.K. to study wooden aircraft production methods.

Mr. Wakefield was for a number of years a director of the Professional Institute of Public Service of Canada. He was also active on a number of technical committees of the American Society for Testing Materials.

William Manton Treadgold, M.E.I.C., head of the University of Toronto's civil engineering, surveying and geodesy department for 22 years, died in Toronto on February 17, 1960.

Born in Brampton, Ont., Professor Treadgold received his diploma in civil engineering from the University of Toronto in 1905. He joined the staff of the School of Practical Science the following year as a lecturer in surveying; was appointed assistant professor in 1913; associate professor in 1919; and professor in 1930. In 1931 he became head of the department of civil engineering and held this post until his retirement in 1953 when he was appointed professor emeritus in civil engineering.

During his undergraduate years and for some time after graduation, Professor Treadgold was employed on railway surveys in British Columbia and with the Geodetic Survey of Canada. During the years 1917-19 he was granted leave-of-absence to serve with the Steel Inspection Department of the Ministry of Munitions. Professor Treadgold was active in the consulting engineering and contracting fields throughout his teaching career. For some years he was consultant to the Town of Brampton, and he was director of John Patterson Construction Company Limited and of Patterson Fuel and Supply Limited, both of Brampton. After his retirement,, Professor Treadgold rendered important service on the three-man Engineering Board of Review which advised the Ontario Department of Highways on contractor's claims.

Professor Treadgold was a member of the Association of Professional Engineers of Ontario.

William L. Fraser, M.E.I.C., 65, director of the Ontario Hydro-Electric Power Commission's St. Lawrence Power Project, died in Cornwall on February 19, 1960.

Mr. Fraser was born in Thorburn, N.S., and received his education at Dalhousie and McGill Universities. He served as a lieutenant in the First World War with the Royal Canadian Engineers, and returned to join the staff of C. D. Howe and Company, consulting engineers, at Port Arthur, Ontario.

In the course of his career Mr. Fraser worked as a resident engineer on highway construction in Nova Scotia; a design engineer for the Shawinigan Water and Power Company; a resident engineer for the Nova Scotia Power Commission during the building of the Cowie Falls development; and assistant chief engineer for the Nova Scotia Department of Highways and Public Works.

He joined Ontario Hydro in 1947 as project manager of the Chenaux Development on the Ottawa River and later was appointed project manager of the Sir Adam Beck Niagara Generating Station No. 2 at Queenston, Ont. He was named assistant director of the St. Lawrence project in 1957 and director in 1959.

Mr. Fraser was a member of the Association of Professional Engineers of Ontario.

Wills Maclachlan, M.E.I.C., known for his widely published research work concerning the effect of electric shock on human beings, died February 29, 1960. He was 74.

Before his retirement five years ago, Mr. Maclachlan was head of the Ontario Hydro-Electric Power Commission's employee relations department; a member of the executive staff of the Toronto Hydro Electric System, and secretary-treasurer and engineer of the Electrical Employers Association of Ontario. Mr. Maclachlan was a Life Member of the Institute.

A graduate of the School of Practical Science, University of Toronto, in electrical engineering, 1907, Mr. Maclachlan published a most valuable index of literature on electric shock, international in scope, after his retirement.

Mr. Maclachlan served as general chairman of the American Society of Safety Engineers and the National Safety

• OBITUARIES

Council. He was chairman of the medal awards committee and a member of the accident prevention committee of the Edison Electric Institute, New York; vice-chairman of industrial relations, E.I.C.; and president of the Royal Canadian Institute.

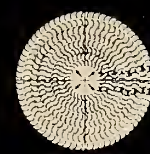
Francis Stuart Lazier, M.E.I.C., consulting engineer of Toronto, died February 23, 1960, at the age of 74.

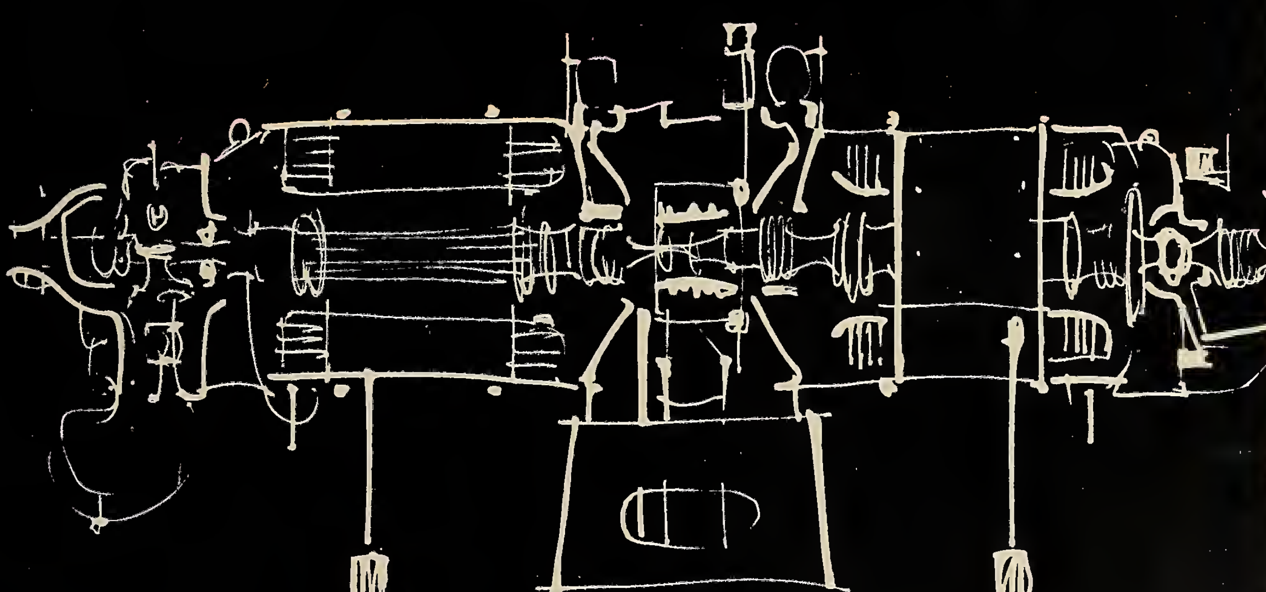
A Life Member of the Institute, Mr. Lazier's career began with railway construction on the Central Ontario, Norfolk & Western, and National Transcontinental Railways. In subsequent years he supervised design and construction of the Trent and Welland Canals. He later was in charge of a power survey of the Madawaska River for Smith, Kerry and Chase, consulting engineers, and was chief engineer and assistant to the president of J. P. Porter & Sons, St. Catharines, Ontario on railway, canal, dredging and harbour projects from the Niagara district to Halifax. As inspecting engineer for the Department of Railways and Canals, Mr. Lazier worked on the Beauharnois Power Development, and later with the National Harbours Board he supervised and reported on construction projects in Quebec and Vancouver harbours.

Born in Charlottesville, Va., Mr. Lazier graduated from Queen's University in civil engineering in 1907. During World War II he became resident engineer for the Allied War Supplies Corporation on construction of explosive and chemical plants at Valleyfield, Que., and of a shell plant at Ajax. Involved in private consulting practice after 1944, Mr. Lazier was Canadian chairman of the International Committee on Yukon River Navigation in 1950 and a member of the Claims Committee for the Department of Highways of Ontario from 1955 to his death.

Hs was a Member of the Association of Professional Engineers of Ontario and The Corporation of Professional Engineers of Quebec.

We regret that our notice of the death of T. M. Lees, M.E.I.C. of Corner Brook, Nfld. made erroneous references to Thomas Lees of Vancouver. Our sincere apologies are offered to Mr. Lees, his relatives and friends for any anxiety this may have caused.





• OFFICERS

(Continued from page 128)

Mr. Lamont has served on the executive of the Peterborough Branch of the Institute for several years and in 1956 acted as branch chairman. A member of the Association of Professional Engineers of Ontario, Mr. Lamont also belongs to the American Institute of Electrical Engineers and the Association of Iron & Steel Engineers.

Bert Thomson Yates, M.E.I.C., is the Councillor-elect from the Cornwall Branch of the Institute. Mr. Yates is a real estate broker in Cornwall.

B. T. Yates, M.E.I.C.

Upon receipt of a B.Sc. from Queen's University in 1917 in civil and chemical engineering, Mr. Yates worked as assistant to the late Dr. "Tilly" Stearn at the Nobel Division of Canadian Explosives Limited. In 1922 he joined the engineering staff of the Abitibi Power and Paper Company Ltd., Iroquois Falls, Ontario, and worked there until 1929, when he returned to Cornwall, Ontario, to run his father's retail business of H. Yates & Co. Ltd. Later he opened his present real estate and brokerage business.

Mr. Yates has served as alderman on the Cornwall City Council and has been a chairman of the Cornwall Branch of the Institute.

G. Demers, M.E.I.C.

F. W. Buckley, M.E.I.C.

Georges Demers, M.E.I.C., consulting engineer in Quebec City, has been elected to Council from the Quebec Branch.

Mr. Demers graduated from Ecole Polytechnique, University of Montreal, in civil engineering and studied subsequently at the Ecole Nationale des Ponts et Chaussees in Paris. In 1935 he became resident engineer, Road Department, Riviere du Loup, Quebec, and in 1936, division engineer for the Roads Department, Carleton, Quebec. In 1938 he was division engineer in the Roads Department, Sherbrooke, Quebec, and the following year was employed as senior design engineer by Z. Langlais, Quebec City. Since 1942 Mr. Demers has had his own consulting practice in Quebec City. He was a professor at Laval University in 1954. In 1955 Mr. Demers was a member of the Joint Commission of the Federal Government and Consulting Engineers on Maritime and Waterways Engineering.

Mr. Demers is a member of the Society of Industrial and Cost Accountants, the Corporation of Professional Engineers of Quebec, the Association of Consulting Engineers of Canada, the American Waterworks Association, the Canadian Institute of Sewage and Sanitation, the Association Internationale des Ponts et Charpents, the Sociéte des Ingenieurs Civils de France, the American Society of Civil Engineers, and the Federation Internationale de la Precontrainte.

Mr. Demers was president of the Corporation of Professional Engineers of Quebec in 1954 and president of the Dominion Council of Professional Engineers in 1955. He is at present on the council of the Association of Consulting Engineers of Canada.

Frederick William Buckley, M.E.I.C., is the Councillor-elect from the Northern New Brunswick Branch. Mr. Buckley is chief engineer at the Bathurst Power & Paper Company, Ltd.

A graduate in electrical engineering from Mount Allison University and Nova Scotia Technical College, Mr. Buckley joined the Nova Scotia Power Commission in 1938 as a field engineer on ransmission and distribution line location. In 1941 he became design engineer on steam and hydro plant design and in 1947 he joined the Bathurst Power & Paper Company Ltd. as design engineer, becoming chief engineer in 1950.

Mr. Buckley is a member of the Association of Professional Engineers of New Brunswick.

C. L. Trenholme, M.E.I.C.

C. L. Trenholm, M.E.I.C., district engineer in the Maritime and Newfoundland areas for Alchem Ltd., has been elected to Council to represent the Moncton Branch of the Institute.

Mr. Trenholm is a graduate of Nova Scotia Technical College, mechanical engineering, 1944. After serving with the Royal Canadian Electrical and Mechanical Engineers in World War II, he joined the New Brunswick International Paper Company. In 1947 Mr. Trenholm took a position with Alchem Limited, Burlington, Ontario, and has been with them since, acting now as district engineer with offices in Moncton.

He served as chairman of the Moncton Branch of the Institute in 1958-59.

C. V. Campbell, M.E.I.C.

J. D. Kline, M.E.I.C.

W. A. MacDonald, M.E.I.C.

P. E. Buss, M.E.I.C.

L. J. R. Sanders, M.E.I.C.

C. V. Campbell, M.E.I.C., has been elected to represent the North Nova Scotia Branch of the Institute on Council.

Mr. Campbell received his pre-engineering education at St. Francis Xavier University, Antigonish, Nova Scotia, and his bachelor of engineering from Nova Scotia Technical College.

He is vice-president of I. Matheson & Company, Limited, New Glasgow, N.S.

J. D. Kline, M.E.I.C., has been elected to represent the Halifax Branch of the Institute on Council. He is general manager of the Public Service Commission of the City of Halifax.

Educated at St. Mary's University and Nova Scotia Technical College, Mr. Kline received his B.Sc. in 1938 and a B.E. in civil engineering in 1940. Following graduation he was employed by Defence Industries Ltd., a Crown Corporation engaged in munitions production. During 1940-41 he worked as a draftsman in Montreal on structural and mechanical design of shell-filling plants. He was transferred to the Pickering Works in Ajax, Ontario, in 1941, as field engineer and in the next three years was successively assistant construction superintendent, project engineer and design engineer. Returning to Halifax in 1944, Mr. Kline took up the position of design engineer in the newly formed Public Service Commission. He became chief engineer in 1947, assistant manager in 1954, and general manager in 1958.

Mr. Kline has been active in the Association of Professional Engineers of Nova Scotia as secretary-treasurer-registrar from 1946-54, a member of council in 1957, and vice-president in 1958. He served as secretary-treasurer of the Halifax Branch of the Institute from 1946-48 and as chairman of the branch in 1958. He is currently the vice-chairman of the Canadian Section of the American Water Works Association.

W. A. MacDonald, M.E.I.C., manager of the Seaboard Power Corporation Ltd., is the Councillor-elect from the Cape Breton Branch of the Institute.

Mr. MacDonald graduated from Mount Allison University, with an engineering certificate, in 1927, and from Nova Scotia Technical College, with a degree in electrical engineering, in 1929. After five years of service with the Northern Electric Company, Montreal, and the Nova Scotia Department of Highways, Mr. MacDonald began working for the Dominion Steel and Coal Corporation in 1934, and, following a brief term at International Piers on special assignment, became a member of Dosco's electrical staff. In 1942 Mr. MacDonald was appointed field engineer and in 1956 he took over his present post.

He is a member of the Registered Professional Engineers Association of Nova Scotia and also of the Mining Society of Nova Scotia.

Paul E. Buss, M.E.I.C., has been elected to represent the Niagara Peninsula Branch on the Council of the Institute. Mr. Buss is president of Spun Rock Wools Limited, Thorold, Ontario. This will be Mr. Buss's eighth consecutive term on the council.

A graduate of the University of Michigan with a B.Sc. in electrical engineering, Mr. Buss joined the engineering staff of Provincial Paper Ltd. as a plant engineer, Thorold division, after overseas service with the United States Army Engineers in World War I. He was also associated with the Dominion Engineering Works. During 1932-33 Mr. Buss and his brothers experimented in a new process for producing wool by the spinning method. Soon afterward Mr. Buss set up the firm Spun Rock Wools Limited, at Thorold, of which he is president.

Mr. Buss was secretary-treasurer of the Niagara Peninsula Branch in 1931 and chairman in 1935. He recently retired from the Thorold Board of Trade after twenty years' service as secretary-manager.

L. J. R. Sanders, M.E.I.C., president and managing director of the L. J. R. Sanders Engineering Company, Galt, Ontario, has been elected to serve on the Council of the Institute as representative from the Kitchener Branch.

Mr. Sanders is a graduate of Loughborough College, England, 1923, with a degree in mechanical engineering. He began his engineering training with the Westinghouse Company in England. After post-graduate work at Cornell University, Mr. Sanders went to work with Tudhope Anderson in Orillia, Ont., as chief engineer, and later with Lake Shore Mines at Kirkland Lake, Ont. In 1929 he joined the Aluminum Company of Canada as divisional superintendent in Toronto. After a few years as a consultant in machine shop and foundry practice in the United States and Canada, he joined the Algoma Steel Corporation, Sault Ste. Marie as superintendent of shops. In 1940 he was one of those to go to England with a group from the Otis Elevator Company to study the Bofors gun. Mr. Sanders joined the Wartime Merchant Shipping in 1941 and was eventually made director of naval stores in Ottawa. At war's end Mr. Sanders purchased the C. H. Smith Machine Company in Galt and founded the organization which he now heads.

A charter member of the Kitchener Branch, Mr. Sanders was chairman of the branch in 1955.

● MONTH TO MONTH

(Continued from page 114)

6) Support measures for adequate water supplies, sewage disposal and conservation of natural resources.
7) Co-operate with Boards of Trade or similar public bodies interested in civic, provincial or federal planning.
8) Give greater publicity to engineering meetings, addresses by engineers, important engineering achievements, etc.
9) Encourage engineers to write letters to newspapers when they have a sound opinion to express.

M. P. Whelen, M.E.I.C.
P. F. Peele, M.E.I.C.
L. J. R. Sanders, M.E.I.C.

Athlone Fellowships

The British Government awards 38 Athlone Fellowships annually to enable Canadians who have earned an engineering degree in Canada to further their studies in the U.K. Twenty-eight fellowships are offered for graduates on completion of a bachelor's or higher degree; the other 10 fellowships are for engineers who have already spent some time in industry. Awarded for a two-year period, the Athlone Fellowships can be used for works training in one or more approved industrial organizations; for post-graduate studies in a U.K. university, college or research establishment; for a combination of these; or for research in a U.K. university toward the degrees of M.Sc. or Ph.D.

The Athlone Fellowships Scheme for the Practical Training in Industry of Canadian Engineering Graduates in Great Britain has been in operation since 1950. Its primary objective has been, and is, to familiarize Canadian engineering graduates with British industry, and thus the emphasis of the fellowship scheme is on the works program. Attention is given to geographical distribution in selection of candidates and the fellowships are apportioned to all Canadian universities having engineering faculties.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on December 18, 1959.

Member: G. H. Barrett, Montreal; T. L. Batke, Kitchener: R. B. Campbell, Ottawa; S. L. Carter, Calgary; K. A. Downie, Vancouver; H. Fennerty, Toronto; A. B. Fraser, Fort Smith; D. Gardner, Calgary; F. Green, Montreal; J. W. Hackney, Montreal; R. Hamelin, Montreal; J. C. Hanbury, Prince George; E. Henye, Montreal; L. G. W. Jarvis, Sudbury; K. R. Kettlewell, Edmonton; F. Lafranco, Sept Iles; R. I. MacDormand, Montreal; J. G. Macpherson, Niagara Falls; B. R. Myers, Waterloo, Ont.; A. G. Osborne, Sudbury; N. D. Pappas, Toronto; J. A. Rice, Vancouver; H. W. Sisson, Edmonton; E. J. Taylor, Montreal; W. H. Vermillion, Montreal; J. H. Wright, Vancouver; C. G. Zimmerman, Galt.
Junior: E. B. Davies, Halifax; M. F. C. Emmett, Brockville; J. Froggatt, Hamilton; W. Gibian, Montreal; W. W. J. McHugh, Montreal; B. J. Thorn, Kapuskasing.

Affiliate: J. T. Davis, Ottawa.

Junior to Member: A. H. Austin, Guelph; J. A. Cowlin, Victoria; G. N. Farantatos, Toronto; K. A. Henry, Cornwall; H. G. Marshall, Port Arthur; W. N. Meikle, Waterloo, Ont.; G. M. Severin, Toronto; D. M. Shook, Calgary; I. M. Squire, Montreal; R. S. Taylor, Richmond, B.C.; J. D. Tudor, Vancouver.

STUDENTS ADMITTED

University of British Columbia: M. Ambach, R. L. P. Applewhite, F. J. Arnold, B. E. Backler, K. J. Barlow, R. Bartel, D. K. Bell, J. P. Berdusco, S. P. Betts, D. E. Beynon, D. L. Bridsall, C. M. Blackburn, K. Blower, G. N. Booth, G. W. Brothers, D. J. Buckland, D. W. Burnham, B. M. Burns, R. E. Butler, R. W. Card, E. T. H. Cardey, G. A. B. Catherwood, T. L. P. Chan, V. L. Chong, W. T. Chu, F. S. Chute, W. A. Coles, B. J. Collins, W. S. Corless, B. S. Cowie, E. W. Craft, M. A. Cronie, M. A. Cross, R. F. Cross, R. R. Culbert, J. A. Davies, R. F. Davis, P. M. Dickie, G. E. Dirom, K. F. Dobell, N. A. R. Douglas, E. J. Dubberley, D. C. Duff, N. H. Dulson, N. J. Duncan, N. A. Eckstein, R. D. Effa, J. S. Elliott, J. G. Farstad, I. B. Foulks, P. R. N. Felker, A. E. J. Ferrie, J. D. Flynn, J. K. Foster, N. R. Fowler, B. F. Garrood, T. B. Gibson, T. M. Gordon, A. D. Gosman, F. A. Graham, B. Gregory, T. L. Guest, D. O. Gurel, T. W. Guthrie, R. W. J. Hahn, T. M. Hamaguchi, P. W. T. Hamilton, R. A. Hamson, W. H. R. Hellwig, E. D. Hetherington, J. G. F. Hoefl, R. D. Hyndman, A. D. Jablonsky, E. Joa, T. G. John, D. G. Johnson, D. H. Johnson, T. W. Johnson, A. S. Y. Jung, K. Kaila, B. Y. B. Kan, D. A. I. Kelly, G. M. Kennelly, S. Khanna, R. Kichler, E. H. Kozuki, W. B. Lange, M. R. Langford, G. J. Lastman, D. B. Lawson, K. Lee, W. W. Lissiman, P. Lo, D. I. Macpherson, B. H. Mansfield, R. C. Martin, L. Martinson, T. S. Mathieson, J. H. McAusland, R. P. McBean, J. D. McKay, D. C. McKechnie, L. P. McKenzie, C. W. McLachlan, G. W. Megaw, K. E. Meissner, T. L. Miletich, H. K. Mittal, R. C. Molina, L. M. Mottu, R. Y. Mukai, D. C. Mulder, H. E. Mulzet, G. Z. Nagy, H. J. Neumann, H. D. Ney, M. D. Olson, J. O'Rourke, N. E. Paget, R. Parker, F. L. Parkinson, M. H. W. Pau, R. L. Pettil, R. H. D. Philp, P. V. Picha, P. Piry, E. Plett, R. A. Ploc, W. W. Plotnikoff, M. Porkolab, I. C. Pratt, J. W. G. Quail, R. G. Ratzlaff, D. J. W. Reid, W. Rempel, J. L. Riddell, D. W. Roberts, J. D. R. Robinson, P. P. Roller, R. A. Rusch, E. T. Ryujin, G. A. T. Salama, D. L. Saxton, R. G. Schaad, G. D. Schildt, A. J. Schmidt, A. Scott-Moncrieff, T. G. Semadeni, H. Shimizu, R. W. Shindel, D. E. Snead, A. Sokol, E. K. Stanley, A. K. L. Strauss, M. J. Sullivan, R. A. Sutherland, D. Svetic, M. Swan, Y. Tanaka, G. W. Tappay, W. A. Trythall, R. Y. W. U., D. S. Ure, R. W. Volkmann, J. A. Vopicka, B. P. Walker, R. D. Warda, H. J. Webster, K. D. Welch, E. A. West, D. B. Wheatcroft, C. P. White, R. T. White, T. M. White, W. H. White, G. J. Whitten, H. Wiebe, F. W. Wiffen, E. C. Wiklund, H. K. Wong, J. A. Wood, F. H. Wyder, R. A. Yestadt, R. Y. J. Young, M. C. Yu.

University of Alberta: D. T. Alexander, H. M. Alton, N. P. Archer, J. Balko, G. T. Ballash, J. M. Baranyk, J. Batycky, T. Belke, H. M. Bender, G. A. Berdahl, H. A. Berg, O. Bergen, G. W. Bigg, B. R. St. Joseph's University: C. Albert, R. J. Albert, H. Allain, P. A J. Arsenault, R. E. Arseneault, J. P. Belliveau, L. M. Bilodeau, J. P. Bourgeois, E. Bourque, H. C. Bourque, C. E. Brison, R. A. Frechet, T. Langis, G. T. LeBlanc, R. T. LeBlanc, Y. G. LeBlanc, J. B. Leger, J. R. Levausseur, P. C. Nadeau, J. D. Saulnier, P. Savoie, Y. Vautour.

Loyola College: T. F. Lee, M. Zadarnowski.

Laval University: R. Dussault.

Mass. Institute of Technology: V. K. Chung.

D. B. Harrison, B.Sc.El. University of Alberta 1959.
P. G. Hodgson, Student, Institution of Electrical Engineers.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations the following elections and transfers have become effective:

ALBERTA

Members: J. E. Armstrong, R. F. Comstock, A. T. Iwasivk, J. P. Verschuren. Junior to Member: K. A. Millions.

SASKATCHEWAN

Members: S. S. Brkich, L. V. Johnson, L. P. Maier, D. H. Maier, D. H. Mode, G. R. Piros, O. Van Bockel, J. F. Wade, J. G. Wotherspoon; Juniors: D. J. Ferguson, L. D. Gerhardt, D. A. Sharp; Students: L. W. Arnst, L. L. Davidoff, J. E. Ellefson, E. J. Ellis, G. A. Martin, R. K. Radford, L. M. Robinson, E. S. Shayna; Junior to Member: W. D. Blue, T. J. Bradshaw, D. E. Cherry, D. L. Dow, E. B. Garrett, R. C. Miller, T. J. Mynihan, H. Pelech, J. R. S. Sadler; Student to Member: J. G. Trotter; Student to Junior: D. D. Baldwin, G. F. Hutch, J. E. McGuire.

NOVA SCOTIA

Members: J. C. S. Campbell, L. E. Powell, D. E. Yeadon; Junior to Member: E. S. Bengston, C. L. Fulton, M. R. McKay, K. C. Scott.

MANITOBA

Member: W. H. Milley, K. L. Philip.

How to get more service than you bargain for

Specify rubber maintenance products made of Du Pont neoprene or HYPALON . . . they often outlast ordinary rubber goods. For example:

Neoprene transmission belts withstand high-speed flexing, resist heat and oil, have outlasted other belts 3 to 1.

HYPALON coated nylon tarpaulins will not crack or dry out; highly resistant to abrasion and cutting, yet ⅓ the weight of conventional tarps.

Neoprene conveyor belting carried molten sand and metal fragments for 1 year; other belts last 90 days.

HYPALON hose has carried hypochlorite since May, 1954; ordinary hose broke down in a few months.

This means longer service per dollar, reduced replacement cost and savings in downtime.

Wherever you use maintenance goods of neoprene and HYPALON you are assured of durability, and excellent resistance to a wide range of deteriorating factors. Neoprene, a versatile synthetic rubber, offers good oil, weather and abrasion resistance. HYPALON is a special-purpose synthetic rubber, ozone-proof and impervious to most oxidizing chemicals.

Your local rubber goods distributor handles neoprene and HYPALON maintenance products and can recommend the right product to meet your needs. Take advantage of his knowledge and service by calling him soon. For additional information write for DU PONT ELASTOMERS IN INDUSTRY, Du Pont of Canada Limited, Room 400, 85 Eglinton Avenue East, Toronto, Ontario.

Rubber products of neoprene and HYPALON® last longer

DU PONT CANADA

● DISCUSSION

(Continued from page 103)

fairly large scatter, but showed shear strengths of about 1/2 to 2/3 those evidenced by the field vane. No other strength tests were carried out.

(d) No grain size distribution tests were run.

2. Consolidation Tests

(a) The original five boreholes were put down over an area of about 1000 ft. square, and the tests described above indicated very uniform subsoil conditions indeed. Thus, seven consolidation tests were very carefully carried out to supply results on which the preliminary calculations were based; four of these tests were on soil from the "varved clay" layer, the remainder from the less compressible "varved silty clay". For each test a sample was used which included several varves, in order to obtain average characteristics of the soil as far as possible. Remarkably similar results were obtained for all tests in each soil, and these test results are summarized in an average form in Fig. 3. The tests were carried out on samples obtained at 25 to 27 ft. and 45 to 51 ft. depths. No attempt was made to determine any variation of consolidation properties with depth.

(b) Fig. 3 gives averaged values obtained from consolidation tests at the depths indicated in 2(a) above and water contents and limits can be obtained from any reply to 1(b).

I realize that the number of consolidation tests is small in relation to the area and depth of sediments involved, but it should be borne in mind that the other tests had already indicated an extremely uniform soil profile over the area, that only preliminary estimates were at first required with a view to preloading the site, and that the site investigation was a commercial proposition, and not a laboratory investigation. Much more importance was to be placed on the results of preloading the site as a full-size test rather than on any number of tests carried out in the laboratory on soil disturbed to some degree.

3. Settlement Calculations

(a) The answers to these questions are too long for the limited space at our disposal and will be dealt with more thoroughly in a future paper. Briefly, it was necessary to compute immediate "elastic" and "plastic" settlements in each of the sandy silt, varved clay, and varved silty clay layers. In the first of these, the settlements were estimated from the applied stress and the relative density of the material, considering the tank to be a very wide footing. The results were checked by a search through our files for previously similar situations. Obviously such an estimation is only approximate.

For the varved clay layer, immediate settlements were calculated using Reference (1) and the stress-strain results of laboratory unconfined compression tests. Since the settlement computed this way would be too large owing to the disturbance of the samples and lack of confinement, it was considered that this settlement amount would take into account any deformation of the lower clay layer. Another computation was also carried out using the method of Reference (2) which gave similar results. In this case, the "elastic" moduli used were also taken directly from the unconfined compression since this would include both "elastic" and "plastic" yielding of the soil. As most of the settlement would take place in the upper layer of clay, an average value of modulus of 100,000 p.s.f. was taken for this layer. The value only changed appreciably with depth below a depth of about 50 to 60 ft. All the test samples were composed of many varves.

(b) All settlement calculations were based on results of tests carried out on samples with several varves; no attempt was made to estimate settlements resulting from each type of soil in a varve, as it would be impossible to estimate the total thickness of different soils. Different samples from different varves may also have had differing properties, although average properties remained the same.

For all settlement predictions for the water tests and completed tanks, the results of the preloading settlement measurements were of course used, rather than data from laboratory tests.

ENGINEERING FOR EXPORT

R. A. Frigon, M.E.I.C.
Chief, Engineering and Equipment Division, Foreign Trade Service, Department of Trade and Commerce, Ottawa.

The Engineering Journal, 1960, March, p. 93.

Author's Comment on Discussion:

One of the main objectives of my paper was to provoke discussion. I am gratified to note the response in the form of written discussion presented by several consulting engineers having experience in the export of engineering. These discussions come as a welcome supplement to the ideas expressed in my paper. They are proof that Canadian engineers are keenly interested in the subject. I have no other comment except to say that I have found the discussions both verbal and written most valuable and I am encouraged to continue my study of this field.

Discussion by Nicholas Fodor, M.E.I.C.

Mr. Frigon is certainly to be congratulated on his excellent coverage of this most important and very interesting subject. I personally am very much interested in every aspect of this subject 'Engineering for Export' and based on my experiences I am taking the liberty of making a few comments.

1. In my opinion (and I am sure every engineer who has the future and welfare of Canada in his heart will agree), nothing better could be done by us, in the interests and prestige of our country, than the selling of engineering abroad. It is, in effect, the selling of brain products, and what could be finer than that. England is perhaps the best example in this respect; I firmly believe that the greatness of the British Empire resulted to a great extent from just such a program.

2. The engineer who is exporting his brain products is doing it also in his own personal interests. Not only do we all hope for it to be a profitable venture on its own, but also it plays a considerable part on the position of the engineer within his own country's boundaries. Such work will increase immensely his own reputation inside Canada, as there can be no better promotion for any engineering firm than increasing the reputation from the publicity and experience coming from work being well done abroad.

I assume that everyone will agree on the importance of this type of export for all concerned. Therefore it probably follows for me to make some practical suggestions based on my own personal observations.

(a) Perhaps it is unfortunate in many ways, but from a practical point of view it is only being sensible to face the fact that only larger firms can do any effective engineering for export. Admittedly, the selling of engineering abroad involves very expensive trips in the promotional stage where the return is far from assured. Coupled with this fact, and equally important, is the length of absences required from the office.

(b) While I myself, and our firm, are strictly consulting engineers in its purest form, in engineering for export we admit that we have to face somewhat different circumstances. That is in practically all countries where I have had the opportunity in various ways to attempt to do engineering for export, it was obvious

Other Societies

American Institute of Industrial Engineers To Organize Montreal Chapter

A meeting was held on February 4, 1960, to organize a Montreal chapter of the A.I.I.E. A pro tem executive was elected and membership and constitution committees formed. The seven existing members of the A.I.I.E. met in Montreal on February 23 to discuss the aims and policies of a local chapter and expressed the feeling that such a chapter would best serve the industrial engineering community as a group which "could discuss problems and methods on a high technical level." It would complement rather than compete with other organizations in the area.

Toronto Quality Control Society

The Toronto Section of the American Society for Quality Control has scheduled meetings for May 4 and 18. The first is to be a lecture by Mary N. Torrey, Bell Telephone Laboratories, New York, on "Selection of Samples for a Purpose" and will be held in the electrical engineering building, University of Toronto, at 8 p.m. On May 18 members and guests are invited to tour the A. C. Wickman Company, 1425 Queensway, New Toronto, starting at 8 p.m.

Recently Published Reports

The European Convention of Chemical Engineering 1958, Frankfurt (Main), Germany. Lectures delivered at the second Congress of the European Federation of Chemical Engineering and the ACHEMA Congress have been published in seven volumes. They may be obtained free of charge on application to the DECHEMA, Frankfurt (Main) 7, Postfach.

The thirteen papers presented at the Symposium on "The Organisation of Chemical Engineering Projects", held in London in 1958 as the 17th meeting of the European Federation of Chemical Engineering, are now available in book form for approximately $5.50. Orders should be sent to: The Institution of Chemical Engineers, 16 Belgrave Square, London S.W.1.

The Transactions of the Sixth Congress on Large Dams, held in New York, September 1958, are being published in five volumes, the first two of which are ready now. The complete set will cost approximately $40 and should be ordered from: Mr. J. K. Sexton, vice-chairman CNC/ICOLD, c/o Canadian Electrical Association, Room 320, Tramways Building, 159 Craig Street West, Montreal 1.

The Associations and Corporation

The 41st Annual General Meeting of the Corporation of Professional Engineers of Quebec was held on March 19, in Montreal. The theme, "The Engineer in Public Life", was chosen to encourage a wider participation of Professional Engineers in the political and social life of the country. The special guests of honour were the four members of the Corporation who sit in Parliaments: Messrs. Yvon Tasse, Parliamentary secretary of the Federal Minister of Public Works; Maurice Bourget, of Levis, who held the same position under the liberal administration; C. E. Campeau, member for Montreal-St. Jacques, and F. J. Lafontaine, member for Labelle in the Quebec Legislature.

The Association of Professional Engineers of Ontario in the March issue of its publication *The Professional Engineer* has published the decision against Orenda Engines Ltd. handed down in court, at Toronto, February 11 and 12, 1960.

The dismissal of professional engineers upon the abandonment of contracts at the Avro and Orenda plants, with termination pay of one or two weeks, was considered inadequate by the A.P.E.O. Representations were made to the companies and to the Government, contending that the notice did not recognize the professional status of the engineers and that these specialists in question would be lost to Canada if they were not given reasonable time to relocate themselves. The Plaintiff in the Toronto court case, Gustaw Lazarowicz, was awarded "three months' wages in lieu of notice". Orenda Engines Ltd. is appealing the case.

This Month

April 12-27 —Milan International Trade Fair

April 20-21 —ASME and AIEE Railroad Conference, Pittsburgh, Penn.
Muskeg Research Conference (NRC) Calgary.

April 20 —Composite Design in Steel and Concrete Conference, Case Institute of Technology, Cleveland.

April 25-26 —National Maintenance and Plant Engineering Conference, St. Louis, Mo.

April 25-30 —National Industrial Health Conference, Rochester, N.Y.

April 25-29 —Metals Engineering Conference (ASME, AWS), Los Angeles, Calif.

April 28-29 —Canadian Industrial Trainers' Association Conference, Montreal

Future Meetings

May 2-3 —ISA Electrical Safety Instrumentation Symposium, Wilmington, Del.

May 2-4 —Canadian Highway Safety Council Conference, Vancouver.

May 17-20 —Symposium on Nuclear Reactor Containment Buildings and Pressure Vessels, Glasgow.

The Bersimis II Power Project was the subject of a talk by Mr. Clement Forest, assistant chief engineer, Quebec Hydro-Electric Commission, on March 3. Mr. Forest summarised the current position of hydro-electric development in the Province of Quebec, Canada's leading province in hydro power resources. He observed that as further developments take place the cost of generated power will go down until it is below that of Norway, the country with the lowest cost hydro power today.

Mr. Forest described in detail the engineering, construction and administration of the Bersimis II development and accompanied his talk with slides and colour films.

Correspondent

F. Rolf Morral, coordinator of cobalt research center, Battelle Institute, Columbus, Ohio, spoke on the transformation of cobalt and nickel-cobalt at the March 7 meeting. Mr. Morral indicated that the uses of cobalt range from metal alloys to biochemicals. It is vital to alloys which must be heat resistant, corrosion resistant and wear resistant — the sort which are used in turbines and have an expected life span of from a few minutes in a missile to 100,000 hours in a steam turbine. A new use for cobalt, he pointed out, is the addition of 0.5% to the gold plating bath for printed circuits.

University of B.C.

Bud Meckling, S.E.I.C.
Correspondent

This year's membership drive ended with 214 new members. The E.I.C. Professional Development Program is going well. Two field trips and a Spring dance will conclude the student activities for this year.

Mr. G. van Beck, director of Courtaulds (Canada) Ltd., Cornwall, spoke to members on February 1 on the subject of engineers and accounting methods. He defined the engineer as "someone who can design, build, or repair inanimate things properly at a lower cost than those not so trained," and went on to say that this definition applies particularly to engineers in private industry where the final result is measured by the profits on the balance sheet.

Calgary

Herbert Bailey, M.E.I.C.
Correspondent

Mr. J. Stevenson, of J. Stevenson & Associates, speaker at the February 1 meeting, stated that about 250 Institute members from Alberta are engaged in building construction. What is more, these engineers may be responsible for 80% of the design for a complex industrial building. More often, however, they would handle about 40% of the design under the coordinating hand of an architect. As and if the gulf between architecture and engineering widens in modern building, it is our responsibility, stated the speaker, to pay some heed to it.

Cape Breton

President J. J. Hanna met members of the Central B.C. Branch and their wives at a well-attended meeting in the Aquatic Club, Kelowna, B.C., March 9. After the Smorgasbord supper, Mr. E. C. Luke from headquarters, who accompanied Mr. Hanna, spoke on the organization of the Institute and the arrangements for administration. Mr. R. C. Wannop, M.E.I.C., outlined Mr. Hanna's career in the Institute, after which the president gave a State of the Union message on confederation, membership and services.

Mr. Hanna went on to describe three generations of engineers: those who were born prior to the turn of the century and carried a heavy load through the depression years, desiring to carry on the work of comrades lost in the War as well as their own work; a second group, born between 1900-25, involved in the depression and World War II, the present leaders in the profession; and the last, who have little or no knowledge of the depression and were too young to fight in the War. They have grown up in a period of easy credit and a booming economy. They may not always be in sympathy with their seniors.

The president's review of Canadian economy presented a somewhat pessimistic view of the present but suggested that it can be assumed that from now on the outlook is for a long period of stable, if somewhat unspectacular, development.

President Hanna Meets Ecole Polytechnique Students: (left to right) Pierre Lambert, vice-president of the Students' Society; Professor Julien Dubuc, JR.E.I.C., faculty representative; Jules Belanger, president of the Students' Society; Dean Henri Gaudfroy; E.I.C. On February 19, the Montreal Branch was honoured by a visit from President Hanna and the Branch Annual Dinner-Dance was held. The president addressed the students of Ecole Polytechnique in the morning and took advantage of the

Group of stainless-clad steel digesters

occasion to present an E.I.C. Canada Prize for 1959 to Claude Racine, S.E.I.C. That evening, at the banquet, he presented a second E.I.C. Canada Prize for 1959 to McGill student, Edward Higgins, S.E.I.C.

Some 17 members of the branch executive battered their way through drifting snows to attend the luncheon for the president. Guests of honour on this occasion were President J. J. Hanna; Mayor Sarto Fournier and Mrs. Fournier; Mr. J. Benoit, chairman of the Montreal Branch, and Mrs. Benoit; Mr. Garnet T. Page, general secretary of the Institute, and Mrs. Page; Mr. R. A. Phillips, past chairman of the branch, and Mrs. Phillips; Mr. F. L. Lawton, vice-president of the Institute, and Mrs. Lawton; Mr. Racey, representing the Corporation of Professional Engineers of Quebec, and Mrs. Racey; Dr. Henri Gaudefroy, dean of Ecole Polytechnique, and Mrs. Gaudefroy; Professor de Stein, representing the dean of engineering, McGill University, and Mrs. de Stein; Mr. R. B. Walker, chairman of the Junior Section of the Montreal Branch, and Mrs. Walker.

Newfoundland

Mr. J. Hoogstraten, president of Nova Scotia Technical College, gave his views on education for engineers and technicians at the March 3 meeting. He stressed the increasingly scientific approach to and content of engineering education. More pure science and mathematics are being included in the engineering curriculum, he stated. This trend can be traced in the qualifications of teachers in engineering schools. Whereas in the comparatively recent past schools looked for broad professional qualifications in their faculty, they now choose young instructors who have advanced degrees and are interested in research rather than outside professional activity.

Discussing the technician, Mr. Hoogstraten pointed out the need for a definition of his position. With the greater scientific content of engineering courses, it would be advantageous to have courses of rather narrower technical limits to train technicians.

Robert F. Legget, director of the Division of Building Research at NRC, spoke to members on February 18, discussing building research in Winnipeg and Western Canada. He discussed various aspects of construction design, foundation problems and insulation which are being experimented with in the prairie region, and gave a full account of heat control houses located on permafrost for studies of insulation. Following the address, Mr. Ken Smith showed a film entitled "Setting Fires for Science", which deals with the Department of Building Research's study of burning brick and frame houses under controlled conditions.

Civil Section
Arnold Bookbinder,
Correspondent

Mr. James O. Granum, deputy chief engineer, highways division, Automotive Safety Foundation, Washington, D.C., gave a talk on "Attacking Highway Problems in the U.S.A." on February 11.

The new executive of the Civil Section includes: I. B. Henderson, chairman; T. A. Crosier, past chairman; L. H. Macdonald, vice-chairman; F. G. Denson, secretary; D. Murray, papers chairman; J. P. Scaitex and G. R. Reshaur, executive members.

Engineers' Wives Associations

Belleville: Although there is no official organization in Belleville, Mrs. W. C. Benger, whose husband is chairman of the Belleville Branch, and the wives of the members of the executive invited wives of the branch members to a dessert party on March 23, at Mrs. Benger's home.

Border Cities: The 1960 executive is as follows: president, Mrs. H. J. Chapman; 1st vice-president, Mrs. J. W. Brison; 2nd vice-president, Mrs. G. G. Henderson; recording secretary, Mrs. H. Bily; corresponding secretary, Mrs. E. T. Rivington; treasurer, Mrs. A. McCaw; publicity convenor, Mrs. D. Servage; groups convenor, Mrs. D. Osmun; councillors, Mrs. C. M. Armstrong, Mrs. J. Reid, and Mrs. E. Dykeman.

Corner Brook: The first meeting of this new group was held at the home of Mrs. Thomas T. Rose on November 9, 1959, and it was decided that the group would meet every third Monday evening.

Kitchener: A constitution was adopted at the January meeting and the group was officially given the name "The Engineering Institute of Canada K.W.G.P. Wives Association" incorporating Kitchener, Waterloo, Galt, Guelph and Preston. Meetings are to be held in each city in turn.

Moncton: Seven new members were welcomed at a bridge party held at the home of Mrs. M. F. K. Leighton in February.

Niagara Peninsula: A luncheon was held at the Niagara Falls Club on March 5. The annual membership tea will be on April 28, again at the Niagara Falls Club.

Ottawa: The Annual Spring Luncheon will be held on May 4. The location is not yet settled.

Peterborough: The Auxiliary is planning to hold their first supper dance on April 12, with a Gay Nineties theme. Port Hope Branch members and wives will be invited.

Port Hope: A dinner dance will be held April 29.

Toronto: A Spring Luncheon was held March 1 at the Granite Club, with 100 members present. Mrs. C. P. Sturdee is the new president and Mrs. A. C. Davidson is vice-president.

• DISCUSSION

(Continued from page 143)

that only turnkey jobs could be expected to be successful. It is also only logical, because after all it is much easier for someone in a remote area to buy a fully finished project, instead of buying the brain work in advance of the actual project. It follows that while the beginning should be done by the consulting engineer, the execution of the project in nearly every instance would be done on a consortium basis. This has been very well described by Mr. Frigon and there is very little I could add to it in these remarks. In my opinion, I would say that it should include the consulting engineer, the manufacturer, or contractor, and possibly even the financing agency as well.

(c) The help of our trade commissioners is absolutely essential. The more conversant one becomes with the work they are doing, the more one realizes and appreciates the wonderful job being undertaken by them for the benefit of everyone concerned. The interest shown by Mr. Frigon in this field is well exemplified by the thoroughness and manner in which he has presented this paper. He is to be congratulated.

Discussion by Jasper H. Ings, M.E.I.C.

In opening my discussion on this excellent paper I would first of all like to pay tribute to our Canadian Foreign Trade Service and particularly to the various Trade Commissioners or Commercial Secretaries whom I have met in my travels. Without exception, all of the people whom I have encountered in the Foreign Trade Service have been extremely cooperative and very helpful.

I am sure that all of you will realize that when one disembarks from a plane in some foreign country where language, customs and even methods of thinking differ, it is a tremendous boon to the travelling individual to find someone who is ready, willing and able to give as much help as possible, to offer advice and to make appointments on one's behalf. Occasionally even to act as an interpreter at meetings. Quite frankly, I cannot speak too highly of our Canadian personnel who perform these services and I can assure you that our representatives stand far above those of most other countries in this regard. In my experience Trade Commissioners regard it as their first duty to help the Canadian abroad.

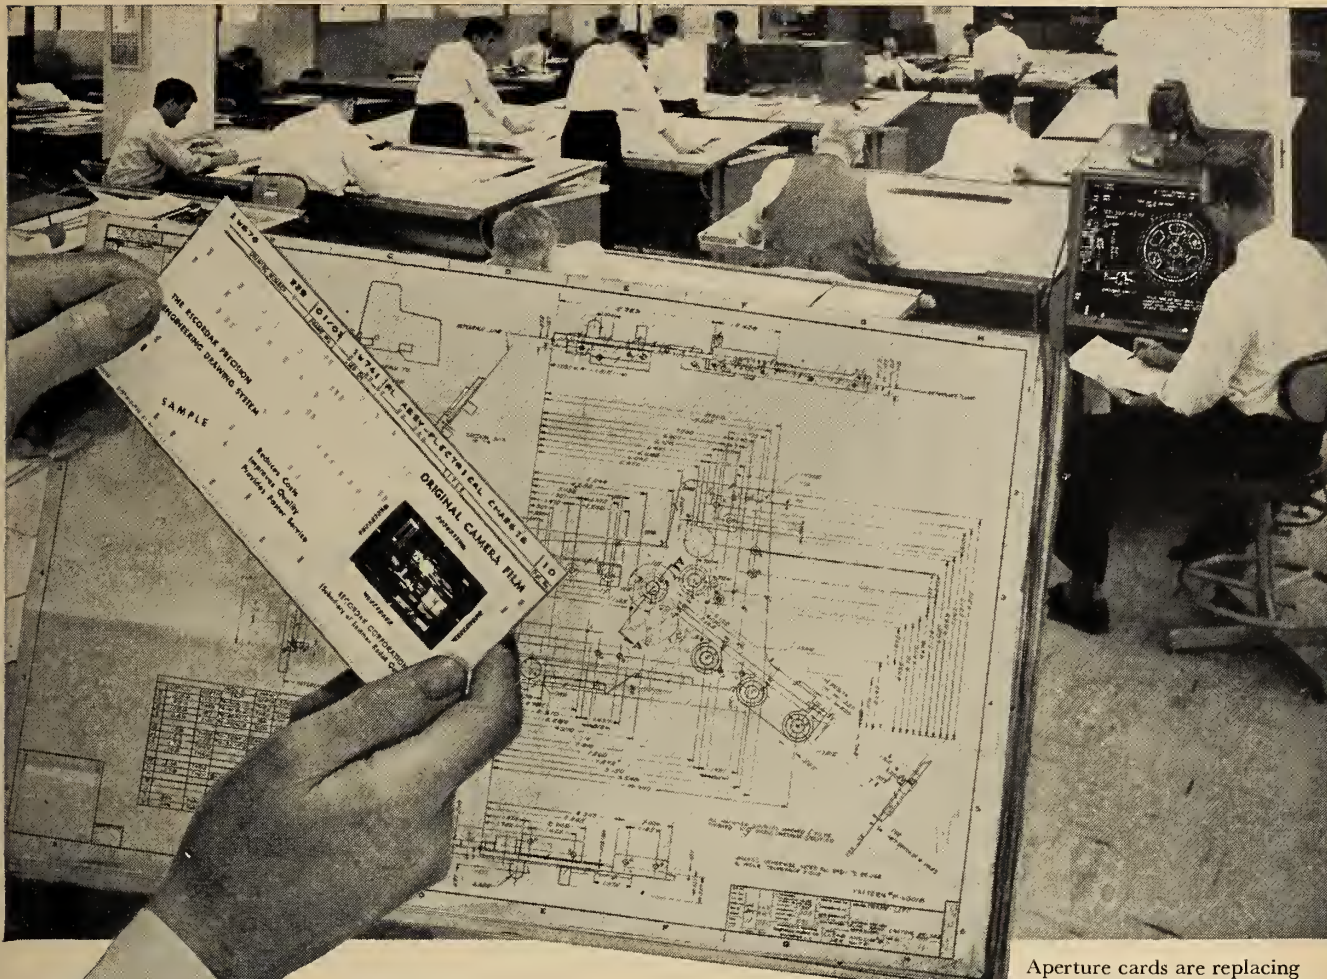
Something which, possibly, is not set out in Mr. Frigon's paper but which is of interest to the consultant are the gains to be obtained from foreign work and in this regard I am not thinking entirely of financial gains. Apart from one's normal profits foreign projects offer three definte attractions to the company participating in work abroad:

(a) The filling out of the home production work curve is a gain which frequently leads to stability of staff.

(b) Overseas work gives a great broadening of both technical and personal experience to the individuals concerned. One sees foreign methods of design and construction radically different from what one may be used to at home but achieving the same results. This sort of thing is in itself a great means of shaking the individual out of the rut.

(c) When participating in foreign work one often has to deal with governments and government departments, both our own and those of the clients overseas. This has a salutary influence on the individual in that he learns to develop patience as necessarily government methods by their very nature differ from those encountered when dealing with private enterprise.

To obtain consulting work abroad there is no better method than the personal contact. It is true that this calls for what are sometimes strenuous trips, but there is no question whatsoever that the personal call on individuals overseas carries the most weight and arouses interest to a far greater extent. It is one thing to read in the technical press that an individual or a consulting company has accomplished a certain job, but it is another thing entirely when a representative from that company walks in the door prepared to offer their services to the development of the country concerned.



Aperture cards are replacing bulky drawings in drafting rooms of every size

First step in automating your drawing file:

Sharp, legible pictures on low-cost 35mm Recordak Microfilm

When you automate your engineering drawings—when you turn these bulky records into trim decks of cards—you can count on: 1) Faster reference and communications; 2) Lower blueprint costs; 3) Savings in filing space and equipment; 4) Greater protection.

Your success with this new system depends, first, upon the quality of your microfilm reproductions. They must be completely legible when viewed in film readers; they must also produce accurate, easy-to-read paper prints when needed.

Using the Recordak Precision System, you are assured that your films easily pass the most rigid requirements. For Recordak pioneered the job of reproducing engineering drawings on low-cost 35mm microfilm. Developed controls and standards which assure that drawings and prints of all ages, sizes and colors, are reproduced with remarkable clarity and uniformity.

So step into "automation" with full confidence! Call your Recordak representative today for full details, or mail this coupon.

City ____________ Prov. ____________

Apart from making oneself known in any given country, sooner or later one sees the advisability, if not the necessity, of establishing a local agent or liaison officer. Such a person, particularly when it comes to working out a definite contract, can be of tremendous assistance due to his knowledge of local laws, customs, finances, taxes, legal pitfalls and so on. However, it is imperative that such a person be chosen carefully and there are three criteria which must be met:

(a) The agent must have personal stature in his own country.

(b) He must show an above-normal competence in his own work.

(c) Most important of all, his integrity and good character must be unquestioned.

The paper gives some comments on consortia formed to undertake overseas work. I would like to point out, however, that sometimes such groupings are not always the answer. From the consulting point of view, one can quite easily get into a difficult ethical position which could give the appearance of trying to work both sides of the street. In addition, in some areas there are definite legal bars which prevent a consultant from associating himself in any way with a contractor on the work to be undertaken. I may say that I have run into this particular bar in Ceylon. Nevertheless there are times and areas where consortia may be the answer and such groupings are more favourably regarded in South America. The future may see more and more of such joint ventures in Central America and South America.

Sometimes, however, there is another type of consortium which may work. That is a grouping of consultants in which each may undertake a given phase or specialty of an investigation or project. Here again though, care must be taken in the selection of one's partners in such a venture.

It is not intended in this discussion to enter into the detailed aspects of the financing of overseas work. I would like, however, to point out that in some respects Canadians are operating at a disadvantage compared to the nationals of other countries. I have heard of individuals abroad quite frankly saying that they would be coming to, say, Washington to go shopping for credits, aid and loans. As we are all aware the United States has been extremely generous in helping other countries and particularly the underdeveloped countries. This has resulted in building up a multiplicity of banking and lending institutions, helping agencies and so on. Canada, on the other hand, seems to have just one agency to assist the underdeveloped countries and that is our excellent Colombo Plan Administration, which, as you all know, is a joint Commonwealth venture. The Colombo Plan is operated efficiently and very helpfully and I can say from my own experience is generally appreciated abroad. Nevertheless, it is only one agency, and one which must operate with limited funds. Governments abroad, of course, know of all the various loaning and helping methods set up in other countries and quite naturally wish to take full advantage. After all, why work with one's own money under difficult foreign exchange conditions if somebody else will take that part of the burden off your shoulders? The result of this, therefore, to the individual Canadian is that he is at a distinct disadvantage in that his American, French, German or Italian competitor can mobilize loans, credits or even subsidies which may spread the financial load of the client over a period of some years. Offsetting this, it is sometimes possible for a Canadian firm to get in under some other country's loan or aid program through association in a joint venture with an affiliated company.

GEOLOGICAL FEATURES AND FOUNDATION TREATMENT AT THE BEECHWOOD DEVELOPMENT

I. D. MacKenzie, M.E.I.C., *Geologist*

E L. Brown, M.E.I.C., *Field Engineer, The Shawinigan Engineering Company Limited, Montreal, Que.*

The Engineering Journal, 1959, December, p. 54.

Discussion by Robert March, M.E.I.C.

The writers are to be complimented on producing such a complete coverage of the geological conditions at the Beechwood site and the work done to consolidate rock which otherwise was unsuitable for superimposing a dam and power house structure. At the time Beechwood was constructed Mr. Brown was on the Power Commission's field staff and was assigned the supervision of subterranean drilling and pressure grouting and the carrying out of directions from Mr. MacKenzie, geologist at Shawinigan Engineering's head office. Both men were accordingly well equipped to handle that phase of the Development which they have chosen as a subject.

Within the limits of that subject I find nothing to add and nothing to question. It may be of interest however to add a few remarks on some of the ways in which construction was affected by foundation conditions which were not apparent or suspected until uncovered.

One effect common to all discoveries of unfavourable conditions was the loss of time while decisions were made and plans were changed. The other common effect, of course, is the increase in cost to keep the structure sound against adverse conditions. You do not decide overnight how to proceed when you find a fault in the foundation rock which may increase costs by a quarter of a million dollars.

From my experience at Beechwood and at other river construction sites I would strongly urge engineers to insist with their clients on the importance of ascertaining information as completely as possible on the condition and quality of foundation rock. At Beechwood the information given to bidders for tendering looked to be thoroughly complete but it developed that there was all the difference in the world in the half of the river bed west of the fault and the half east of the fault.

The massive formation west of the fault had very few joints and the surface in many places was almost polished by sand and gravel carried by the stream. Concrete was poured on these surfaces without excavation for most of the piers and rollways. Toward the west bank an old channel worn about 30 feet deep in the rock and much wider than indicated by borings and filled with gravel was encountered. A test pit in the gravel revealed that water flowed freely through it but carried no silt. It was considered necessary to impregnate the gravel in this old channel where it crossed under the upstream cofferdam with a thick cement grout. Between 2000 and 3000 extra yards of concrete were required for the dam in crossing this old channel.

Heavy excavation of the vertically jointed and badly shattered shale in the power house area was accomplished mostly by horizontally drilled lifters at successively lower levels. The last lift was always shallow — about 5 ft. and shot much lighter. In spite of all precautions it was very difficult to scale and cleanup either vertical or horizontal surfaces suitable for pouring concrete. Light excavation as under the intake structure had to be done without using explosives. Bulldozers, compressed air jets and air tools were used. Overbreak under the intake was heavy and an extra concrete mat was placed on the rock and carried as a face wall down the step to draftube floor level. By drilling through the mat and face wall a low pressure grouting job was done to consolidate and seal the rock contiguous to the structure.

The artesian water encountered in a number of drill holes made tight grouting very nearly impossible. It was regretted toward the end of the job that an artesian well was not developed as a drinking water supply for power house use.

It has been said of the Saint John River that it is only consistent in the regularity of its inconsistencies. We found this to be as true of the river bed and the underlying rock as it is of river flows. This is no doubt true of many other streams.

I again repeat that preliminary boring information should be as complete as possible. Hind sight at these jobs should teach us that the drill cores should be carefully analyzed and studied by both the engineers and the contractors.

Discussion by Prof. A. L. McAllister

The very detailed treatment of the grouting procedure and location and spacing of grout holes and curtains should provide extremely valuable information to engineers engaged in similar projects elsewhere.

A zone of slates and blocky argillites such as is found at the Beechwood dam site, will almost invariably be cut by a number of small slip zones or minor faults and be characterized by seepage along these breaks as well as along cleavage planes and fracture zones. In any site underlain by such rocks a duplication of Beechwood conditions can be anticipated. The experience gained at Beechwood and so well described in this paper will be especially appreciated in New Brunswick, where a number of possible sites underlain by similar rock have been partially investigated.

In a slate environment, cut by a number of minor slips as at Beechwood, lost core and blocky zones are common problems in drilling. In areas where cleavage parallels the core recovery is particularly low. It is thus generally impossible to recognize significant fault zones from results from a single hole. It is particularly important that all drill results be immediately recorded on sections across the site so that correlation can be made from hole to hole. This is the only way that a comprehensive geological picture can be attained, and the additional cost over and above drilling is negligible. From a geologist's point of view one or two such geological sections across the Beechwood site would have done much to clarify the geological picture described in this paper.

Also from a geological point of view I would like to comment on the enclosed map showing the generalized geology of New Brunswick and Northern Maine. On this map the area is divided into areas underlain by rocks of different ages, Carboniferous, Devonian, mainly Silurian and mainly Precambrian. Without criticizing the validity of the generalization I would suggest that such a division, based solely on rock ages, conveys little information of significance in dam construction. For example, the area of Beechwood and most of the drainage basin north of it is described simply as being underlain by rocks of Silurian age. A better approach would be to describe the area as underlain by slates, shales and argillites, a fact which is of significance in future upstream construction and which has directly controlled the quality of the local gravel supply. Other areas southeast of Beechwood described as Devonian could also much better be simply described as being underlain by granite.

Discussion by
Prof. H. W. McFarlane, M.E.I.C.

Mr. MacKenzie and Mr. Brown are to be congratulated on their full coverage of the subject. It is interesting to note some of the effects the grouting program had on other aspects of the construction.

Since it was impossible to determine in advance the amount of grouting required and therefore the amount of time required for grouting, the time scheduling of the other operations became extremely difficult.

For instance, as late as the middle of May 1956 it was hoped that construction of the earth dam section could begin about the first of June. This would have allowed the earth compaction to take place during the longer days of June and July. The earth work however could not begin until the foundation was properly treated, and could not proceed far until the retaining wall was erected between the earth dam and the intake section. Construction of the retaining wall was in turn delayed by treatment of the foundation rock of the intake section where the situation had been aggravated by discovery of the fault described in the paper.

The starting date on the earth fill was delayed again and again until the first fill finally went in on August 6. The moisture content of the core material was excessively high and although a few days of dry weather would reduce the moisture content to acceptable values the "few days of dry weather" turned out to be rare. Rains that summer were not heavy but they were frequent. The days were getting shorter and the sun producing less drying power as time went on. It became more and more difficult to dry the fill by aeration. August and September passed, half of October passed. The fill was nowhere near complete and was proceeding very slowly.

Unless the earth dam reached a sufficiently high elevation before winter set in, work on the complete dam would be held up until after the spring freshet.

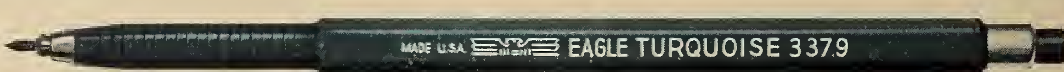
Many possibilities were discussed and finally it was decided to dry the impervious fill in an asphalt aggregate dryer. Once this artificial drying process was set up the fill progressed steadily. The impervious core reached the necessary elevation on November 21 and the other aspects of the job were able to go ahead on schedule.

The following spring the earth fill was brought up to design elevation quickly, and without difficulty.

Although other factors contributed, this chain of events was really started by the delay caused by the unpredictable amount of foundation grouting required.

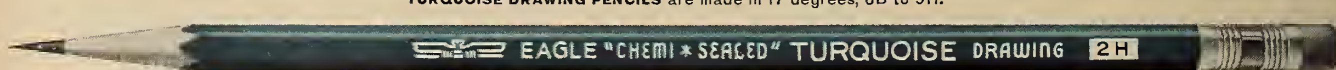
Use any reproduction process . . .

Your drawings reproduce sharper, clearer with Eagle Turquoise



TURQUOISE LEAD HOLDERS hold any TURQUOISE lead (5B to 9H).

TURQUOISE DRAWING PENCILS are made in 17 degrees, 6B to 9H.



TURQUOISE WITH ERASER, in grades 4B to 6H, is increasingly popular as a field tool.

Whatever the process, you'll get sharper, clearer prints if you use an Eagle TURQUOISE. Lines are more opaque and also blacker—because the graphite in TURQUOISE is finer-ground with denser-packed particles.

Get smoother, neater drafting, too! TURQUOISE glides effortlessly, evenly over paper, cloth, vellum, "Mylar"® And uniform grading means consistent peak performance.

So, no matter what you draw on, how you reproduce it, use Eagle TURQUOISE for superior results every time!

EAGLE

WANT A FREE SAMPLE? Write for a TURQUOISE pencil or lead, in the degree you'd like to test on your favourite drafting material. Eagle Pencil Company of Canada Ltd., 217 Bay St., Toronto 1.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*PRINCIPLES OF PAVEMENT DESIGN

The basic principles that apply to the design of airfield and highway pavements are presented, and data is provided for establishing the design criteria to fit the many conditions that may be encountered in practice. Both theoretical and practical aspects of the field are covered in sections dealing with the properties of pavement components, design tests, the design of flexible and rigid pavements and pavement evaluation and strengthening. Examples illustrate the various design methods described. (E. J. Yoder. New York, Wiley, 1959. 569 p.,

THE MANUFACTURE OF IRON AND STEEL: VOL. 2. STEEL PRODUCTION.

In this revised edition, new material has been added to bring the book up-to-date, and a chapter is included on the physical chemistry and thermodynamics of steelmaking. The volume surveys the basic principles underlying the modern processes of steel production, and the plant and equipment employed. Some of the topics covered include: the Bessemer process; open-hearth; acid open hearth; electric furnaces; special steels. (G. R. Bashforth. Toronto, Ryerson, 1959. 390 p., $8.00)

A SHORT HISTORY OF SCIENTIFIC IDEAS TO 1900.

The author's intention in writing this volume is to give some idea of how science came to occupy its distinctive position in modern life. He places basic scientific ideas in the framework of world history, and indicates particularly some of the less well-known factors, such as the influence of the Arabic-speaking world. The author covers his subject from the early days of Mesopotamia to 1900.

Mr. Singer is well-known as an editor of the five-volume "History of Technology," issued by the same publisher. (Charles Singer. Toronto, Oxford, 1959. 525 p.)

*ELECTRONIC ENGINEER'S REFERENCE BOOK.

This handbook, written from the point of view of British practice, covers the following areas: fundamental concepts; radiations, including infra-red and ultra-violet sources with their industrial and medical applications; electron tubes, including design of tubes and measurement by electronic instruments; materials, particularly those that are magnetic; vibrations; computers; automation. (Ed. by L. E. C. Hughes. Toronto, Macmillan, 1958. 1311 p., $18.00.)

DIESEL ENGINEERING HANDBOOK, 10th ed.

Now completely re-written, this tenth edition places increased emphasis on basic engineering principles, and the design and construction of present-day engines and their auxiliaries. The twenty-nine chapters cover such topics as fuels, combustion, fuel injection systems and pumps, pistons and rings, air systems, lubrication, speed governors, gas and dual-fuel engines, and engine drives. An appendix includes information on current makes and models and specifications for diesel, dual-fuel and natural gas engines. (K. W. Stinson. Stamford, Diesel Publications, 1959. 383 p., $10.00.)

ENGINEERING MECHANICS

An undergraduate text on engineering mechanics for all engineering students, written in an informal style. The authors have used the vector notation, and in the statics section the concept of a fixed vector. Problems are used to point out the applications of mechanics in a variety of classical and modern technological fields. Their solutions are found by the vector method. (D. F. Gunder and D. A. Stuart. New York, Wiley, 1959. 391 p., $7.75.)

INTRODUCTION TO PROBABILITY AND STATISTICS

An undergraduate text, intended to provide the student with a basic foundation. The first five chapters deal with probability models, and other chapters cover sampling, the presentation of data, testing statistical hypotheses, estimating and testing variability, etc. A final chapter provides a brief introduction to sequential analysis, analysis of variance, regression, and decision theory. References are included for further reading, and review problems, many of which are drawn from the engineering field. (B. W. Lindgren and G. W. McElrath. Galt, Brett-Macmillan, 1959. 277 p., $6.25.)

INDUSTRIAL ACCOUNTING, 2nd. ed.

The emphasis in this book is on learning to use, rather than to do, accounting. The first thirteen chapters provide a firm foundation in basic accounting principles and bookkeeping procedure. The next seven chapters cover the main features of sole proprietorship, partnership and corporation accounting. The final fifteen chapters deal with cost accounting theory and procedure. (S. W.-Specthrie. New York, Prentice-Hall, 1959. 583 p., $10.00.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 A.M. to 5 P.M.; All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

COLLECTIVE BARGAINING AS VIEWED BY UNORGANIZED ENGINEERS AND SCIENTISTS

This is a report of the opinions of 264 non-supervisory engineers and scientists on the subject of collective bargaining for professional employees. It analyses critically the reasons given for and against collective bargaining, and presents some of the ideas put forward on the causes of unionization among engineers and scientists. This is one of a series of reports on management's relations with engineers and scientists. (J. W. Riegel. Ann Arbor, University of Michigan, Bureau of Industrial Relations, 1959. 105 p., $4.00.)

SUCCESSFUL TECHNICAL WRITING

In his first chapter the author cites some of the advantages of writing technical articles, and suggests various markets available to writers. He next enumerates twelve types of technical articles, and the characteristics of each.

Chapter three is concerned with the problem of finding and developing suitable ideas for articles, and subsequent chapters cover actual methods of writing articles, technical papers, reports, manuals and catalogues. Three final chapters are devoted to writing the technical book.

This should be required reading for all engineers. (T. G. Hicks. Toronto, McGraw, 1959. 294 p., $6.35.)

MACHINES A CALCULER ELECTRONIQUES: ARITHMETIQUES ET ANALOGIQUES

One of the few volumes in French on the subject of electronic calculating machines, this commences with an introduction explaining the terms used, and the different types of machines available.

The first section covers analogue computers, and the second, and larger, digital computers. In both sections, information is given on the various types of machines available, the manner in which they work, and their applications. The author has had experience working with computers in the United States. (M. Pelegrin. Paris, Dunod, 1959. 395 p., 4,400 fr.)

LA MACHINE-OUTH, TOM 7 & 8.

The seventh volume of this series on machine tools is concerned with forging. The ten chapters, each by an expert, cover such topics as: creep and heat tests; forgeability of metals and alloys; deformation of metal during welding; heat required for forging; forging machines; stamping and stamping machines.

The eighth volume covers the machining of wood and plastic, the machinery used, methods of work, and finished products. There are also chapters on the application of electronics in the machine shop, and the use of hydraulic and electrical control systems. (Ed. by A. R. Metral. Paris, Dunod, 1959. V. 7, 452 p., 7,400 fr.; V. 8 222 p., 3,900 fr.)

LIANTS ROUTIERS ET ENROBES: MATERIAUX DE PROTECTION-PLATRE-AGGLOMERES-BOIS.

The first section of this volume deals with the so-called "black" binding materials, tar, asphalts, pitches and rubber asphalts. The second section covers hydrocarbonic concretes, and the third, terms used in highway engineering. Other sections deal with plasters; clays; ceramics; glass; waterproofing materials, rubber, paints and varnishes; plastics; and wood. In each case, information is given on the properties and uses of the materials, results of tests performed, specifications etc. (J. Arrambide and M. Duriez. Paris, Dunod, 1959. 553 p., 2,475 fr.

L'ENTREPRISE ET LA STATISTIQUE: TOME 2, STATISTIQUE ET GESTION DE L'ENTREPRISE, 2 ed.

This second, revised edition has been divided into two volumes, the first of which is concerned with statistical techniques and documentation. The second volume considers the practical application of statistics to the management of a business, including control of manufactures; operations research; market research; trade outlook; statistics and accounting. Also considered is the organization of a statistical section in a firm. References for additional reading are given. (R. Dumas. Paris, Dunod, 1959. 252 p., 2,800 fr.)

ELECTRONS, ATOMES, METAUX ET ALLIAGES

Translated from the English, this volume considers the mathematieal developments of wave mechanics, and their application in the structure and properties of metals and alloys. The first two sections of the book consider the nature of the atom, and the nature of metals. The third discusses the nature of alloys, whilst the last section examines the structure of the nucleus. The book is written in the form of a dialogue, mostly questions and answers. (W. Hume-Rothery. Paris, Dunod, 1959. 456 p., 3,900 fr.)

DICTIONNAIRE ANGLAISE-FRANCAIS: ELECTRONIQUE, PHYSIQUE NUCLEAIRE ET SCIENCES CONNEXES

The 24,000 terms in this dictionnary are those encountered by the author in his day-to-day work in the fields of electronics, nuclear physics and related sciences. Any differences between English and American usage have been clearly shown. A French-English volume is in preparation. (G. G. King. Paris, Dunod, 1959. 311 p., 2,600 fr.)

*CALCULATEURS NUMERIQUES, ELEMENTS ET CIRCUITS

A French translation of a 1957 U.S. publication, this basic text for the student or practising engineer emphasizes basic engineering approaches to digital techniques. A wide range of components and circuits of an experimental nature is covered, as well as logical functions and digital storage, basic operations to be performed by a digital computer, and the advantages and disadvantages of various approaches to design. Design concepts are stressed rather than specific details. (R. K. Richards. Paris, Dunod, 1959. 538 p., 6,400 fr.)

CALCUL A LA FLEXION DES COQUES CONIQUES

The authors' firm has been conducting studies for several years on shells. In this volume are published some of the studies on the deformation of conical shells, axisymmetrically loaded. The results are given in tabular form at the end of the volume, and permit the calculation of strains and deformation in "short" or "long" truncated cones. A bibliography of 31 references, more than half of which are in English, is included. (S. Casacci and J. Bosc. Paris, Dunod, 1959. 161 p., 1,800 fr.)

METHODES ET MODELES DE LA RECHERCHE OPERATIONNELLE

Another in a series on business economics, this volume outlines the applications of mathematics in industry in the field of operations research.

The book is divided into two parts, the first of which gives specific instances of its use, with actual case histories. In the second part, chapter by chapter, are given the mathematical methods used, worked examples, algorithms, etc. The topics covered include linear programming, queuing problems, inventory control, and the replacement and maintenance of equipment. Most of the references in the twelve-page bibliography are to U.S. publications. (A. Kaufmann. Paris, Dunod, 1959. 534 p., 6,800 fr.)

METALLURGIE DE LA SOUDURE

Already well-known for his books on welding, the author in this volume considers the metallurgy of welding, which has become of increasing importance as welding is used more and more in construction.

In the first part he deals with the metallurgical aspects of the welding of steels, the processes used, structure of the weld, arc-welding, absorption of gas by welds, cracking and pre-heating.

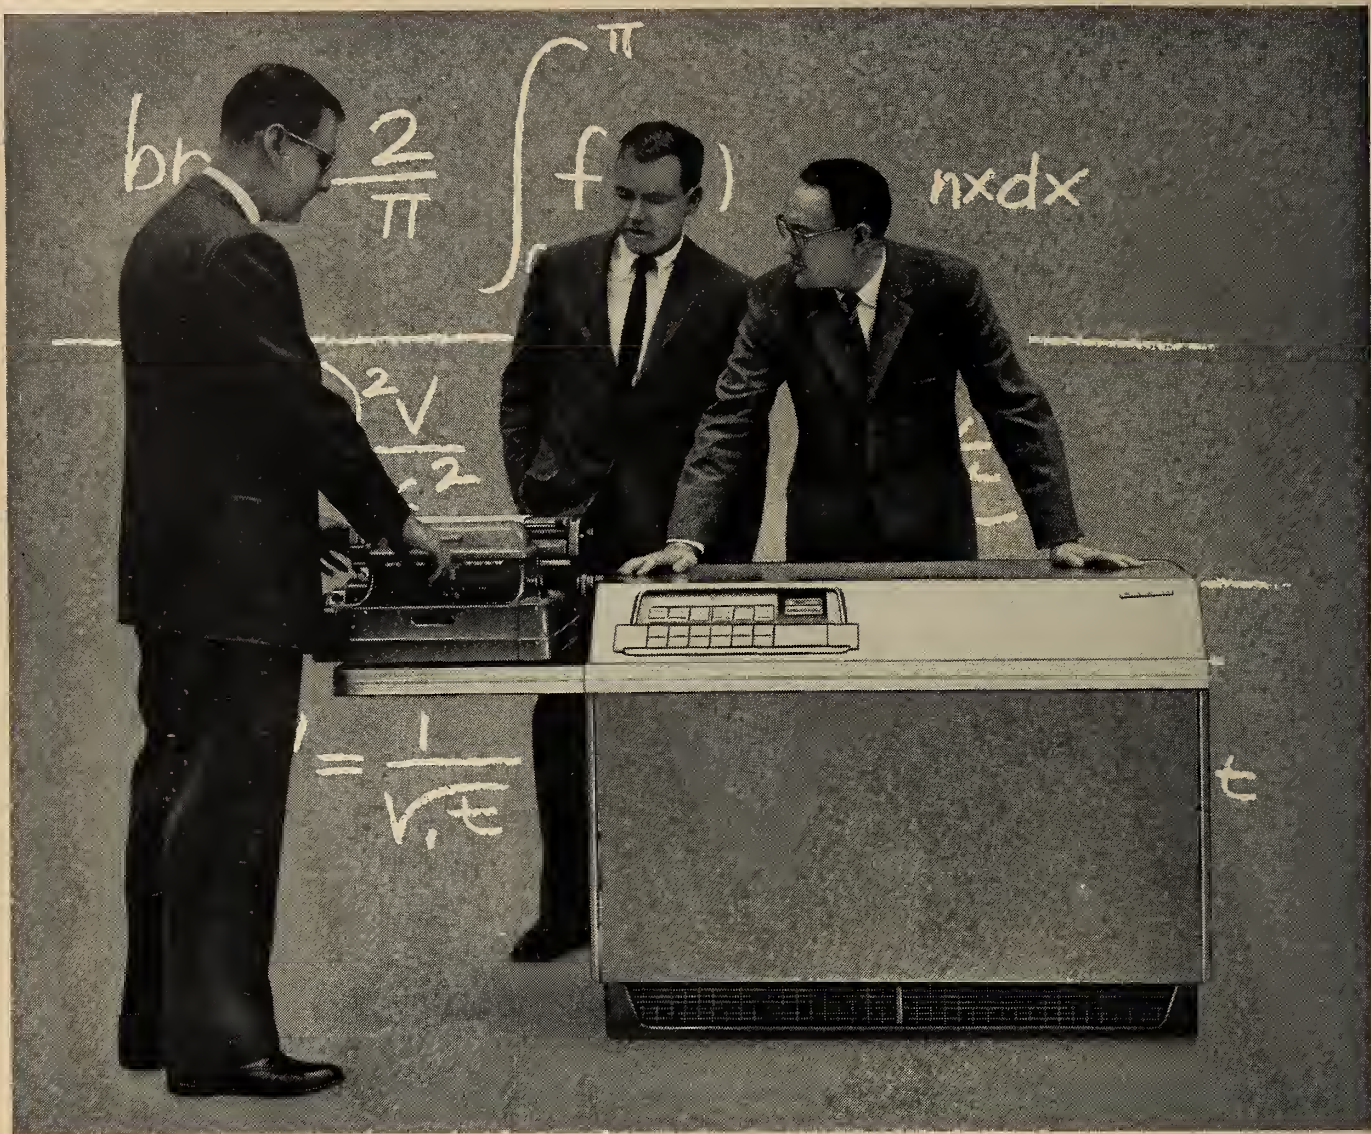
In the second section there is a discussion of the weldability of different types of steel, including carbon, austenite, nickel-chrome, boron and chrome-molybdenum and other semi-refractory steels used in the petroleum industry. (D. Seferian, Paris, Dunod, 1959. 393 p., 5,800 fr.)

LES MACHINES S'EN CHARGERONT

A translation from the English "Let ERMA Do It", this volume presents a brief history of automation, outlining its principles and applications in various fields—accounting, manufacturing, production control, etc. The author gives social and economic reasons for the use of automatic machines, and mentions examples of their use.

The second part of the book gives more details on the different machines and their uses, including ERMA, RESERVISOR, and SAGE. References are given for further reading, but there is un-

(Continued on page 173)



Speed routine calculations—increase creative time with this powerful electronic computer McBEE LGP-30

Large capacity . . . easily programmed and operated . . . mobile . . . low in cost

Compact, simple to use, McBEE LGP-30 will today bring high-speed computation *right to your desk* . . . thus relieve you of the tedium of standard hand calculations . . . increase available time for truly creative work . . . help you simulate optimum designs in a matter of minutes. And at the lowest cost ever for a complete computer system!

Unusual capacity. Operating from a standard wall outlet, performing an almost unlimited range of calculations, LGP-30 gives you the flexibility of stored-program operation combined with speed, memory (4096 words) and capacity equal to computers many times its size and cost. Completely mobile, LGP-30 is easily wheeled from room to room, building to building.

Simple to operate and program. LGP-30 controls have been so thoroughly simplified that it may be operated with only minimum computer experience. Direct print-out of answers—no deciphering required. Programming is easily learned—even by non-technical personnel. Library of sub-routines, plus programs for a wide variety of applications, is available.

Wide range of applications. In addition to general design and system optimization, LGP-30 is currently being used for the refinement of estimates; computation of design parameters; specification of new product properties and capabilities; calculation of such data as reactance, load saturation curves, time constants, harmonics, torque-speed and vee curves.

Exceptional value; complete service. Smallest initial investment ever for a complete computer system is combined with low operating and maintenance costs.

For further information and specifications, write Dept. 30.

McBEE FOR PRACTICAL OFFICE AUTOMATION

• LIBRARY NOTES

(Continued from page 167)

fortunately no index. (D. O. Woodbury, Paris, Dunod, 1959. 303 p., 1,480 fr.)

PROCESSUS ALEATOIRES ET SYSTEMES ASSERVIS

A translation of the McGraw-Hill publication "Random processes in automatic control", this volume provides both the practical engineer and the research scientist with the basic theory of random signals and noise, together with techniques used in the analysis and synthesis of linear control systems subjected to random inputs. It considers the basic concepts of probability and random time functions using them to develop analysis and design techniques for linear control systems containing both constant and time-varying components. (J. H. Laning and R. H. Battin. Paris, Dunod, 1959. 442 p., 6,600 fr.)

LES SEMICONDUCTEURS ELECTRONIQUES

An introduction to the physics of rectifiers and transistors, commencing with an explanation of the mechanism of conduction in semiconductors, network imperfections and impurities, and the functions of crystal rectifiers and amplifiers. In the chapters on the physics of semiconductors, the author considers the problem of the hydrogen molecule in quantum mechanics, Fermi statistics applied to the electrons of a crystal, reactions between centres of impurities, and the electrical properties of the surface of solids.

This is a translation from the German edition. (F. Spenke. Paris, Dunod, 1960. 349 p., 5,600 fr.)

TECHNIQUES DES ULTRASONS

The first two chapters of this text discuss the characteristics and measurement of ultrasonic waves, and the nature of cavitation. The next four chapters discuss generation, including piezoelectric and magnetostriction transducers, jet generators and electro-magnetic transducers.

The second half of the volume is concerned with the applications of ultrasonics in engineering, in such processes as precipitation and agglomeration, emulsification and dispersion, metal coating and cleaning. Also considered are their uses in the fields of chemistry, metallurgy, biology and medicine, and in control instruments. (A. E. Crawford. Paris, Dunod, 1959. 456 p., 4,800 fr.)

TRAITE D'EXPERTISE ET D'ESSAIS DES MATERIAUX ET DES CONSTRUCTIONS. METHODES GENERALES D'ESSAI ET DE CONTROLE EN LABORATOIRE: TOME I — MESURES GEOMETRIQUES ET MECANIQUES

The first volume of a new series to be published by the Institut Technique du Batiment et des Travaux Publics, on testing materials and structures. This volume is concerned with general methods of testing and control in the laboratory, and in particular with geometric and mechanical measurements.

The eight chapters cover: control and measurement, choice of test, laboratory organization; statistics applied to testing and control; measuring instruments and machines; geometric measurement; mechanical measurement; extensometry, the measurement of deformation and strain; equipment for mechanical testing.

There are long bibliographies included in each chapter. As one expects from Mr. l'Hermite and his colleagues, this is a detailed work, embodying their own experiences, and the series should prove of great value to all those concerned with materials testing. (R. l'Hermite and others. Paris, Eyrolles, 1959. 739 p., 9,965 fr.)

TRAITE DE MACHINES A COMBUSTION INTERNE: T. I., THERMODYNAMIQUE

The first of a series of five volumes to be published on the internal combustion engine, covering all aspects of the subject, and emphasizing particularly the different types of engine in use, their evolution and possibilities.

In this volume, the author analyzes the basic principles of thermodynamics, required for the study of any engine. He illustrates the application of thermodynamics to the internal combustion engine, and includes tables of thermodynamic constants of the principal chemical components of combustion, up to 5000° K. (M. Serruys. Paris, Dunod, 1959. 250 p., 3,800 fr.)

LES UTILISATIONS DU GAZ NATUREL

Natural gas has been used in the southwest section of France for the last ten years and the discovery of the reserves at Lacq, and the development of the Sahara fields, mean that natural gas will now be available to consumers in large areas of France.

Introductory chapters outline the physico-chemical and thermal characteristics of natural gas, and succeeding ones consider the use of natural gas in various fields. These include: steam production, the iron industry, glass-making, cement works, brick and tile making, and furnaces. The use of gas as a fuel in diesel engines, turbines, and compressors is considered, as are chemical applications, and domestic use. A final chapter discusses safety measures.

The book is translated from the Italian, and examples are given of both Italian and American applications. (M. Medici. Paris, Dunod, 1959. 241 p., 3,600 fr.)

STANDARDS RECEIVED

ASTM standards. American Society for Testing Materials, 1916 Race St., Phila. 3, Pa.

1959 compilation of ASTM standards on copper and copper alloys. 720p. $7.50.
ASTM standards on metallic coated iron and steel products. 176p. $3.50.
ASTM standards on methods of atmospheric sampling and analysis. 112p. $2.25.
1959 supplement to book of ASTM standards including tentatives. Part 1, Ferrous metals; Part 2, Non-ferrous metals; Part 3, Methods of testing metals; Part 4, Cement, concrete, mortars, road materials, waterproofing, soils; Part 5, Masonry products, ceramics, thermal insulation, acoustical materials, sandwich and building constructions, fire tests; Part 6, Wood, paper, shipping containers, adhesives, cellulose, leather, casein; Part 7, Petroleum products, lubricants, tank measurement, engine tests; Part 8, Paint, naval stores, aromatic hydrocarbons, gaseous fuels, engine antifreezes; Part 9, Plastics, electrical insulation, rubber, carbon black; Part 10,

Textiles, soap, water, atmospheric analysis, wax polishes.

CSA standards. Canadian Standards Association, 235 Montreal Rd., Ottawa 2.

0 112 series-1960: Specifications for wood adhesives.

0 115-1959: Specification for hardwood plywood. 2d ed. 75c.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Bridges, Highway

Highway bridge vibrations: Part 1. A review of previous studies, by D. T. Wright and R. Green. Kingston, Ont., Queen's University, 1959. (Report no. 4.)

Canada. Dept. of Mines and Technical Surveys

Bibliography of periodical literature on Canadian geography, 1930 to 1955; part 4, Prairie provinces. 1959. 50c. (Geographical Branch Bibliographical series no. 22.)
Metallurgical works in Canada; non-ferrous and precious metals. 1959. 25c. (Mineral Resources Division Operators list 1, part 2.)
A survey of the steel pipe and tube industry of Canada, by T. H. Janes. 1959, 50c. (Mineral Resources Division Bulletin MR 36.)
The Canadian gypsum industry, by R. K. Collings. 1959. 25c. (Mines Branch IC 114.)
Vacuum degassing of steel: Part 1: Literature survey, and preliminary work, by D. E. Parsons and W. A. Morgan. 1959. 25c, (Mines Branch Research Report R 47.)
Radioactive marking of steel balls for grinding tests, by G. G. Eichholz. 1959. 25c. (Mines Branch Technical Bulletin TB 12.)

Canada. National Research Council. Division of Building Research

Annotated bibliography on vane testing in soils, compiled by J. J. Hamilton. 1959. (Bibliography no. 17.)
Muskeg research: a Canadian approach, by I. C. MacFarlane. 1959. 25c. (Technical paper no. 83.)
An investigation into processes occurring in solifluction, by P. J. Williams. 1959. 25c. (Research paper no. 84.)
Evaluation of factory-sealed double-glazed window units, by A. G. Wilson and others. 1959. 25c. (Research paper no. 85.)
Snow load on buildings; translations of seven Russian papers, translated by D. E. Allen. 1959. (TT 830.)
A new waste disposal system, by E. Lindstrom and tr. by H. A. G. Nathan. 1959. (TT 838.)
Quick soils and flow movements in landslides by E. Ackermann and tr. by D. A. Sinclair. 1959. (TT 839.)

Canada. National Research Council. Division of Mechanical Engineering

Powerplants for VTOL aircraft: a proposed dual-operation system using wing-immersed fans for vertical thrust, by E. P. Cockshutt and N. Galitzine. 1959. (Aeronautical Report LR-265.)
On the transfer of heat from a river to an ice sheet, by W. D. Baines. 1959. (MH-93.)

Columns. Concrete.

Design of long reinforced concrete columns. N.Y., Reinforced Concrete Research Council of the Engineering Foundation, 1959. (Bulletin no. 11.)

Directories.

American Public Works Association Yearbook, 1959. Chicago, 1959. $5.00.
F.B.I. Register of British Manufacturers, 1960. 32nd ed. London, 1959. 42s.

Engineers

Criteria for professional employment of engineers. Montreal, Corporation of Professional Engineers of Quebec, 1959.

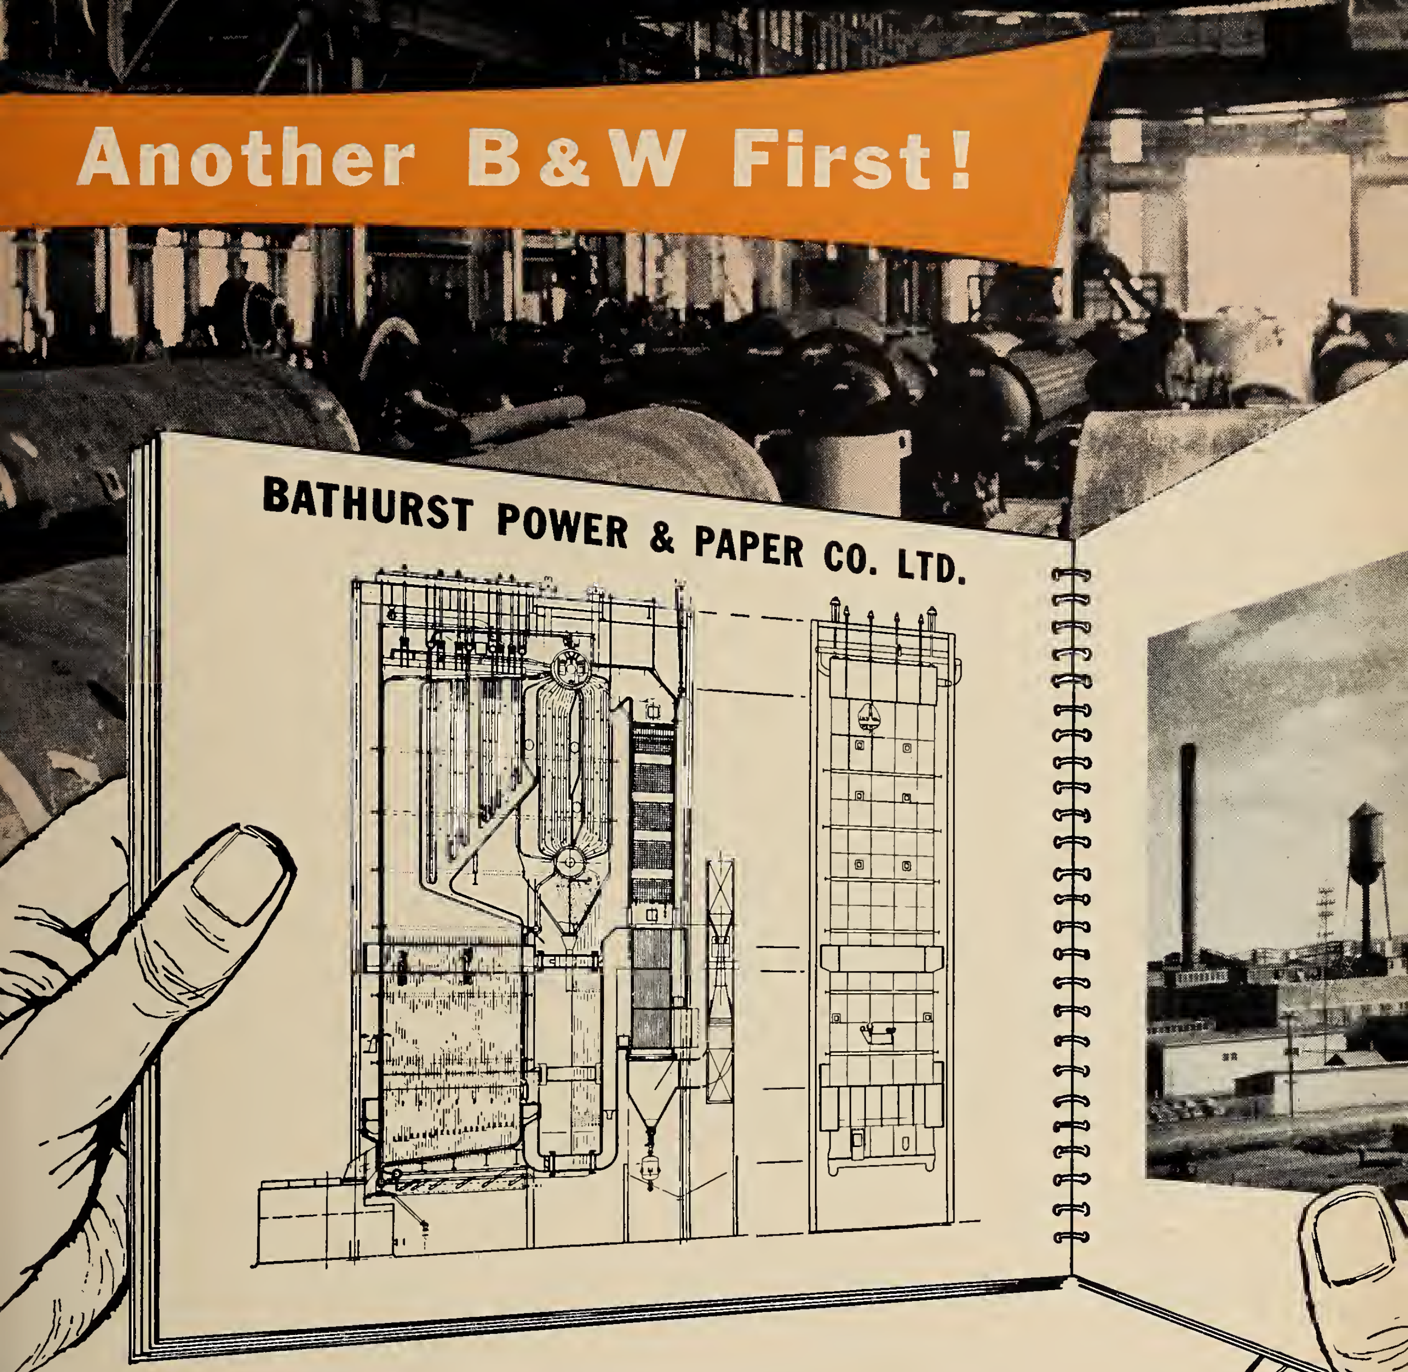
Fuel research

An investigation of the mechanism of the oxidation, decomposition, ignition and detonation of fuel vapors and gases, parts 1-30, 1947-1957, by R. O. King and others. Ottawa, Dept. of National Defence, Defence Research Board, 1959. (Reprints from the Canadian Journal of Research (1947-1950) and the Canadian Journal of Technology, (1951-1957.)

Industrial management

Systems and procedures responsibility, by P. H. Thurston. Boston, Harvard School of Business Administration, 1959. $2.50.

(Continued on page 195)



.....designed - manufactured and erected by B&W in Canada

These two Recovery Units are the highest pressure (1250 psi) Steam Generators of their kind in Canada. They have been in operation at the New Brunswick Mill of Bathurst Power & Paper Co. Ltd. since 1958.

These units incorporate many outstanding features including Venturi Evaporator-Scrubber, Cyclone Collector, Economizer and Airheater. This development represents another milestone in the B & W organization's research for the most economical and efficient means of obtaining power and steam from waste materials of the Canadian pulp and paper industry.

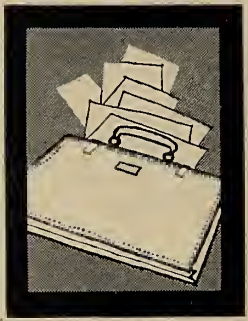
Business and International Briefs



Appointments and Transfers

The appointment of F. J. O'HARA and J. G. SUTHERLAND as Vice Presidents reflects the growing importance of the Technical Products and Tube Divisions in R.C.A. Victor's Operations.

Canadian Liquid Air announces three appointments. JAMES E. WILKIN becomes Secretary-Treasurer, M. V. BREBER is named Assistant Treasurer, and GORDON C. NAYLOR is now Manager of the Control Division.

STONE & WEBSTER announces the appointment of E. B. HYMMEN as Chief Engineer.

ROGER DUVAL has been appointed Manager, Municipal Sales, Quebec, for Canada Iron Foundries, Limited.

CANADIAN FAIRBANKS-MORSE announces the election of WILBUR WRIGHT as Vice President, Engine and Pump Division. He will be nationally responsible for the application, sales and service of the Company's full line of diesel engines and hydraulic equipment.

Canadian General Electric has appointed ARCHIE JOHNSTON as Manager, Quebec District, for the Wholesale Department.

K. C. CULHAM, President of Empire-Hanna Division, The M. A. Hanna Company, was elected President of the Bituminous Coal Institute of Canada at the recent Annual Meeting held in Windsor.

Canadian Westinghouse has been honoured by the election of ARTHUR A. RYAN as President of the Graphic Reproduction Association.

Business News

FOR FINDING LEAKS in enclosures that can be pressurized, with the aid of halogen leak detectors, Canadian General Electric has issued a six-page booklet: G.E.T.-2936. A portable electronic leak detector equipped with special probe is available from General Electric. Typical uses would be during the installation of large commercial and shipboard air conditioning systems, and any checking for refrigeration leaks in confined, unventilated devices such as vending machines.

STRICTLY NO GUN, but a hand tool, is the DX100L, latest addition to the Hilti range of methods for direct fastening into concrete, brick and steel. It operates with or without a cartridge. Although the cartridge strength is only half as much as the gun-tool cartridge, a pull of 2000 lbs. average is needed to extract the Hilti DX studs or pins, part of the equipment supplied by Crowther Ltd. of Westmount, P.Q.

TO SUSPEND CEILINGS in Shell's new 26-storey office building in London, England, "Chevron" slotted angle was chosen. Within the ceiling cavities are housed the air conditioning ducts and units, heating elements, electric conduits and cables, and these too are suspended by means of Chevron angles. Chevron's unique ability to fit together at any point and provide an infinite variety of bolting positions, no matter how joined or cut, derives from the constantly repeated chevron shaped slots in its design.

WORN SOCKETS are more quickly replaced when the compact 16 lb. portable tube tester introduced by Stark Electronic Sales is used. The tester checks filament voltages in 18 steps from U.6 to 117 volts, and the new socket design slips off easily, exposing an 11 pin socket.

A PUSH-BUTTON SWITCH for mass production has been produced by a British company. This type of precision switch has been the subject of American research and will be a unique addition to the wide range of multi-channel equipment now used in a wide variety of industries. Seton-Creaghe of London are designers and producers of the switch, which is especially suited to high-frequency applications and is designed to reduce maintenance and the likelihood of mechanical breakdown. The prototype is being tested to a life of one million operations.

THE LARGEST CAPACITY in Canada is claimed for the new British-American Oil gas processing plant which will soon appear on the Alberta prairie near Rimbey, 50 miles south of Edmonton. A group of 25 owner companies, all with production interests in the Dick Lake or Homeglen Rimbey fields, has designated British American Oil as plant operator, responsible for the construction, maintenance and continuing operation of the $12.5 million plant which will process up to 326 million cubic feet of gas daily.

PRESTRESSED AND PRECAST concrete uses and techniques were the subject of a recent tour sponsored by Supercrete of Winnipeg. A party of over 75 Canadian architects and engineers visited England, Italy, Belgium and France to see what is being done these days in this area of major construction.

SUPERSONIC SPEEDS and the aerodynamic shapes associated with them have brought the risk of skin friction causing spontaneous combustion of fuel and increased the similar risk from lightning. An explosion supression system developed by the British Oxygen Group used liquid nitrogen injected into the air bled from the engine compressor, which pressurizes the fuel tanks thus making the gaseous mixture in the tanks chemically inert. The system, which has the obvious advantage of being continually in operation, can be readily integrated with existing installations. It weighs only 12 lbs. for every thousand gallons of fuel carried.

A BULGE in the line is virtually all that is seen of a small rotary gas meter announced by Roots-Connersville, a division of Dresser Industries. Employing a new concept in rotary-type positive displacement gas meter design, and aimed at providing accurate metering at low cost, the 3M125 meter flange can be mounted directly in either a horizontal or vertical gas line without additional support, and provides straight-through gas flow.

DELIVERY IS LIMITED automatically to system demand at pre-selected adjustable pressures by Vickers Incorporated's new 6 gpm variable vane pump. Sharp cut-off characteristics enable the pump to deliver nearly full volume up the compensator setting even at low operating pressures. It is ideally suited as a fluid power source for varying volume demand circuits.

NUCLEAR PARTICLE detection research by R.C.A. Victor in its Montreal laboratories has resulted in the developing of a new semiconductor device which can detect the presence and measure the energy of alpha-particles emitted from radioactive materials. This work has previously been done by scintillation or Geiger counters, both of which require batteries or power supplies giving several hundred volts. Unlike these the semiconductor alpha-particle detector operates from a low voltage supply like a transistor and thus opens up a whole new set of interesting possibilities for miniature portable detection systems. It is extremely robust and relatively cheap, and can therefore be used where existing detectors are either too fragile or too expensive.

NICKEL TRANSDUCERS, which change alternating electrical energy into ultrasonic vibration, are being used for the ultrasonic cleaning of intricate assemblies including meters and guidance components for missiles, and are being employed in underwater sound devices for depth finding, detection and related purposes. A recently introduced nickel alloy containing 4% cobalt, which provides superior performance, is used extensively in this equipment.

A COMPACT TESTER announced by Canadian General Electric is designed for easier testing and servicing of 720 cycle carrier controllers used by electrical utilities for peak load control. This tester features 720 cycles for calibrating or timing the circuit, as well as the mixing of 720 cycle with 60 cycle for operational testing. The cathode ray tube gives visual indication for the adjustment of 720 cycles. The tester can be supplied with or without a test voltmeter.

ONTARIO sales and service of Dominion Power Cranes & Shovels have been taken over by the Construction Equipment Company, Limited. The Dominion plant at Montreal is one of the largest and most diversified of its type in North America.

YOUR BEST FRIEND FINANCIALLY

The Man from Investors can show you how to

Save Tax Dollars on your Retirement Plan

Investors Syndicate offers you three different types of tax-deductible Registered Retirement Plans: (1) fixed-interest; (2) equity; (3) combined fixed-interest and equity. Any one of these may be qualified as a Registered Retirement Plan for Income Tax purposes — with substantial saving of tax dollars for you.

HERE ARE 4 OTHER WAYS INVESTORS CAN HELP YOU IN MONEY MANAGEMENT

1. **How to Guarantee a Cash Reserve for Your Future.** Decide how much money you want and when you want it. Your Investors Syndicate Representative will show you how to reach your goal. More than 110,000 Canadians are using the Investors Syndicate Plan to make their savings grow.

2. **How to get More Money from Your Investments.** By investing as little as $1,000 in Investors Mutual, you can become part-owner of more than 100 "blue-chip" securities, representing Canada's major industries and enterprises.

3. **How to Benefit from Long-Term Capital Gain.** Get information on the new Investors Growth Fund. This Fund concentrates on common stocks — and enables you to share in the growing wealth of Canada.

4. **Low-Cost Group Pension Plans.** Investors Syndicate and Investors Trust Company have complete facilities for installing and managing low-cost Trusteed Group Pension Plans —tailored to the exact needs of any company.

For complete details of any of these services, contact your Investors' representative, "YOUR BEST FRIEND FINANCIALLY."

ISC Investors syndicate OF CANADA, LIMITED

HEAD OFFICE: WINNIPEG · OFFICES IN PRINCIPAL CITIES

EASY ADJUSTMENT to produce a not-yet-determined optimum feed size for autogenous grinding mills is a feature of the 60-89 inch gyratory machine being supplied to Iron Ore Company of Canada by Canadian Allis-Chalmers. Hydraulic adjustment of the crushing head is the feature which will provide this advantage in the primary crushing of iron ore at Wabush Lake.

GALLIUM ARSENIDE, a little known semiconductor material, has enabled General Electric to produce tiny electronic parts (tunnel diodes) which will work at frequencies above four billion cycles. Gallium Arsenide tunnel diodes have current densities of 5,000-10,000 amp. per sq. cm. By comparison, the current density of 12 gauge housewire is 7,000 amp. per sq. cm.

MONTREAL ARMATURE WORKS has been taken over by General Electric, and will come within the responsibility of the Apparatus Department.

A NEW LINE of electronic testing equipment, manufactured in Scotland by Allscott Electronics, is being introduced to the Canadian market by Ferranti-Packard Electric Limited. The line includes noise measuring equipment and a spectrum analyser.

BY 1970 there may be about 290 lb. of aluminum in every car, according to Dr. G. E. Willey, Vice-President of Electro Metallurgical, a division of Union Carbide. "The experimental stage for the incorporation of aluminum in the automobile is past; it is now only a question of time until its general applications will become standard." Electro Metallurgical has expanded facilities at its Beauharnois and Welland plants.

FOR INJECTION MOULDERS to receive the best possible service on products is the objective of the DuPont Plastics Division as preparations go forward for producing high-density polyethylene resin at St. Clair River works. Under this policy, Canada Colours and Chemicals Ltd. has been appointed as a distributor to compliment the services of the DuPont sales force.

TO INCREASE SAFETY and improve on-time performance, C.N.R. has introduced a two-way radio communications system from Vancouver and Prince George to Edmonton. The new system enables train crews and despatchers to obtain immediate information on track conditions and emergency situations.

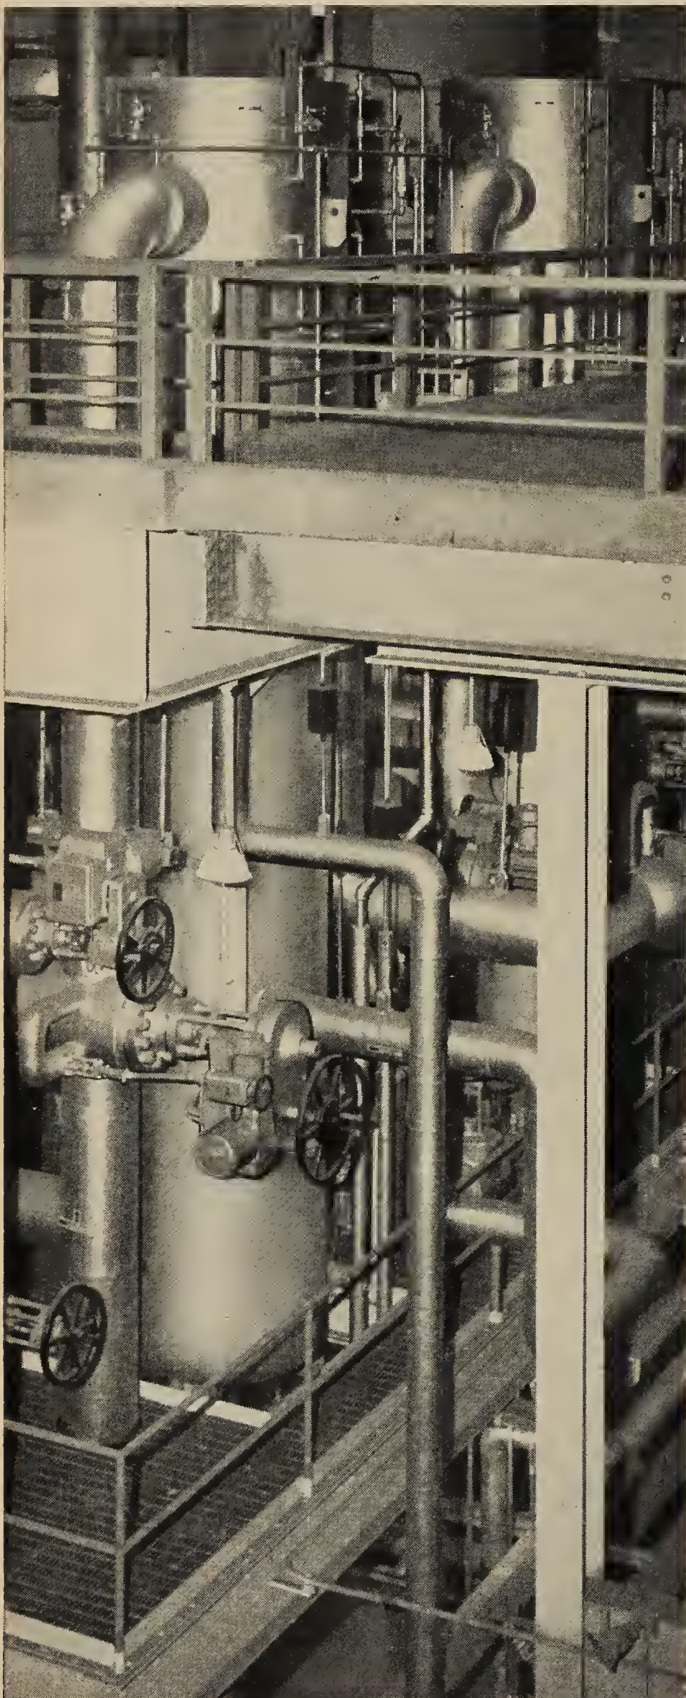
POLYDYNE DRIVES, an entirely new line of packaged adjustable speed drives has been announced by General Electric. The new series represents the first mechanical adjustable speed drives to be offered by the Company's Apparatus Department. Polydyne Drives, available in a wide range of outputs and speed ratios, operate on the principal of V-belt-connected adjustable pitch pulleys. Field trials have brought favourable reports on simplicity of belt changing and smooth operation of the stepless control mechanism.

THE LAST CONTRACT for major dredging at Cornwall on the St. Lawrence Power Development has been awarded to McNamara Construction of Toronto, Ontario Hydro announces. McNamara's bid of $3,666,470 was the lowest of five tenderers. The contract calls for excavation of an estimated 1,363,000 cu. yd. of material from an area extending downstream from the powerhouses for approximately 5000 ft. on both sides of the international boundary.

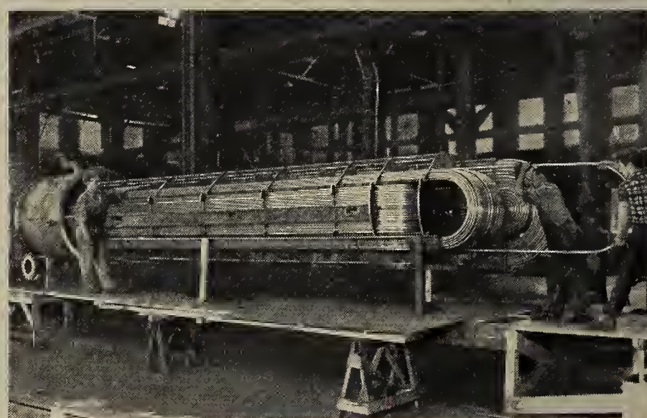
THE ALUMINUM INDUSTRY foresees a lively and widespread interest in the new Alcan aluminum guyed tower design for transmission line construction. Four years of design study followed by more than a year's intensive development and test work have produced an attractive structure of considerable versatility. Made up of components that can be erected in either of two arrangements to suit conditions of terrain and right-of-way, the Alcan aluminum guyed tower can be erected on a single base in the form of a V or on twin bases with parallel uprights.

FOR ECONOMICAL magnetic recording and monitoring in the field, Southwestern Industrial Electronics has introduced the MS-15A Magnetic Recording and Monitoring System, equipped with 24 broad-band, linear phase-shift seismic amplifier-FM modulator combination channels. Bridged-T hi-line filters are available, and the equipment is easily installed in a portable recording cab.

CANADA'S LARGEST FEEDWATER HEATERS ...BUILT BY M.L.W.



MLW Feedwater Heaters installed at Richard L. Hearn Power Station.



Shop assembly of MLW Feedwater Heater.

These are the largest feedwater heaters ever made in Canada. Designed for Canada's largest power station, these heaters were built by Montreal Locomotive Works.

Now installed at the Richard L. Hearn Generating Station of the Hydro-Electric Power Commission of Ontario, they incorporate the exclusive Alco High Pressure Closure. This exclusive Type "D" high-pressure closure means easier maintenance than ever before. It is simple, economical and highly effective. It can be dismantled and assembled with a minimum of small tools.

These units are typical of MLW's leadership in the manufacture of heat transfer equipment, and typical also of MLW's manufacturing scope in designing and building equipment for a wide variety of Canadian industries.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

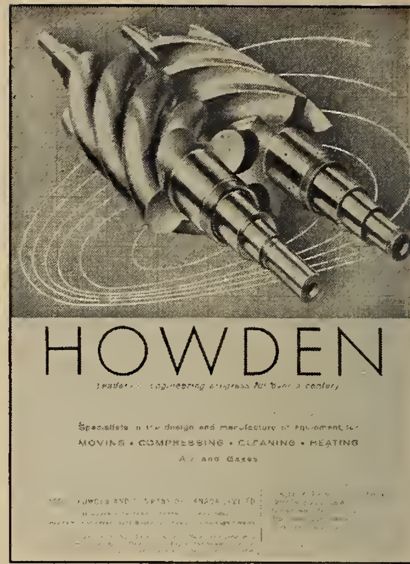
The James Howden & Company of Canada Limited 3-colour advertisement which appeared on the inside-back-cover of the January 1960 issue was judged the "best", in that issue, by a jury of fifty readers.

The illustration shows the rotors of a new screw compressor which pump at a compression ratio up to 5:1.

The advertisement has great "attention-getting" value as it combines excellent artwork with a dominating combination of red, yellow, grays and black.

James Howden & Company of Canada Limited have their head office and plant at 1510 Birchmount Road, Scarborough, Ontario and branches in Vancouver, Calgary, Toronto and Montreal. The Managing Director of the company is W. MacOwan. The advertising agency who prepared and placed the advertisement is Chris Yaneff Ltd. of Toronto.

Reproduced here, on a reduced scale, is the 3-colour advertisement which was judged the "best" in the January issue, from the viewpoints of ACCURACY — INFORMATION and ATTRACTION, by the fifty readers who were asked to evaluate the advertisements. The James Howden advertisement appeared on the inside-back-cover of the issue. It is printed in three colours — black, yellow and red.



JAMES HOWDEN AND COMPANY OF CANADA LIMITED WINS CERTIFICATE OF AD MERIT

• MORE ABSTRACTS

The Economics of An Industrial Gas Turbine Installation
D. Panar, M.E.I.C.

Economics of power generation, emphasizing variable costs and peak power costs. Utility interconnection, demand and stand-by charges. Feasibility of private interconnected generation with various types of prime movers. The particular properties of the gas turbine. Possibility of by-product energy. Analysis of the University of Alberta's problem and solution. Economical loading of the system, present operating experience and future trends.

Economic Aspect of Industrial Power Plants
Howard R. Wright, M.E.I.C.

It is difficult to predict whether the generation of power will be profitable in an industrial plant without detailed feasibility studies. Ratio of process steam to process power used as general guide. Bulk of capital and operating charges belong to production of process steam. Incremental cost for high pressure and temperature boiler design are chargeable to power generation. Charts give estimated costs. Typical total power cost calculations. Comments on recent wood/oil-fired installations for power production.

The Khulna Newsprint Project
D. P. Wyness

The first mill to produce newsprint and mechanical printing papers in Pakistan commenced production in July 1959. Experimentation with the tropical hardwood, gewa, as a pulpwood showed that the chemi-groundwood process was best suited to the project. The demand for newsprint by 1962 has been estimated at 23,000 and for printing papers, at 41,000 long tons. Sandwell and Company, Limited, Vancouver, completed construction of the mill in July 1959 and for 18 months managed its operations.

The Potential in the Free-Piston Engine Principle
Anton Braun

The unused potential in the free-piston engine principle can be compared to the potential remaining in conventional engine principles of today. Early models of free-piston engines represent conservatively designed units. Today's free-piston engines must be considered as in early development stages, whereas modern spark ignition and compression ignition engines are close to the limits of their respective principles.

Soil Problems in Mining on the Canadian Shield
R. F. Legget, M.E.I.C., and *W. J. Eden,* JR.E.I.C.

Soils found in mining operations on the Canadian Shield are almost all glacial in origin and range from well-drained sand and gravel deposits to silts and clays deposited in glacial lakes. Description of typical glacial clays and explanation of their unusually high moisture content. Successful handling of these materials; erection of mining structures upon them.

Western Canada Potash and Its Future Prospects
W. J. Pearson

Manitoba and Saskatchewan potash is of higher quality than that being mined in New Mexico and Europe. The first company to explore these deposits finished its shaft in 1958 and the first shipment was in March 1959. Excessive inflow of water into the shaft caused a shutdown in November. By January 1, 1960, 16 companies representing five national interests had holdings. Canada's potash prospects are good. Consumption throughout the world is on the increase and reserves elsewhere are being deplenished.

YOU CAN SEE IT'S SAFER!

Better visibility, more convenient control and less operator fatigue are principal features of this new Dominion Bridge crane cab. No longer is it necessary for the operator to stand and look over the side for close-to lifts—he can see the whole operation from his seat. This is more efficient and safer.

Other improved features include a completely enclosed access ladder to the bridge walkway from inside the cab; a non-slip floor; non-glare internal paintwork; a seat designed for greater comfort, and a control set-up conveniently grouped for easy operation. Heating and/or air conditioning can be supplied as optional extras. Open type cabs are also available.

The design of Dominion Bridge cranes is always under review and new improved features such as these are added as they are proven satisfactory. Dominion Bridge manufactures cranes of all types from the small ½-ton hoist to machines capable of lifting several hundred tons.

Meet the Authors

L. H. Chater, B.Sc., Civil (Saskatchewan '32), Chief Engineer, The Steel Company of Canada, Ltd., Hamilton. *(Some Major Problems in Steel Plant Engineering for Growth at Stelco).*

Mr. Chater joined a firm of consulting engineers London, England in 1936 and later came to Canada as a design engineer with Ontario Hydro. In 1947 he joined Stelco as design engineer, became Assistant Chief Engineer, then Chief Engineer, Hamilton, and was appointed chief engineer of all works of the company in 1957. He is a member of The Association of Professional Engineers of Ontario, The Association of Iron & Steel Engineers and the American Iron & Steel Institute.

G. L. MacKenzie, M.E.I.C., B.Sc., Civil (Queen's '19), Director, Prairie Farm Rehabilitation Branch, Canada Department of Agriculture, Regina, Sask. *(The South Saskatchewan River Dam).*

Mr. MacKenzie worked for consulting engineers in Saskatoon for 14 years before joining the Federal Department of Public Works. Chairman of the Prairie Provinces Water Board and Canadian Chairman of the International Engineering Board, he is also Chairman of the Federal Provincial South Saskatchewan River Development Board. He is a registered Professional Engineer of Saskatchewan.

A note on **J. W. MacLaren** appeared in the April 1960 issue of The Engineering Journal.

D. B. Clement, M.A. Mechanical (Cambridge '52), Project Engineer, James F. MacLaren Associates, Consulting Engineers, Toronto, Ontario.

N. D. Pappas, M.E.I.C., B.A. Sc. (Toronto '48), Associate, James F. MacLaren Associates, Consulting Engineers, Toronto, Ontario, (*A Deep Pumping Station for the Ottawa Sewage Treatment Plant*).

Upon graduation, Mr. Clement was employed by consulting engineers in London, England. In 1957, he came to Canada and joined the Montreal Engineering Co. Ltd. He is a member of the Corporation of Professional Engineers of Ontario and an associate member of the Institute of Civil Engineers, Great Britain.

Mr. Pappas was with the Welland Canal staff of the Department of Transport, St. Catharines, Ontario, and left his position as Assistant Superintending Engineer in 1956 to join his present firm. He is a member of the Corporation of Professional Engineers of Ontario.

T. Ingledow, M.E.I.C., B.Sc., (Glasgow), M.A., D.Sc., President, International Power and Engineering Consultants Limited, Vancouver, B.C. (*Some Features of the Port Mann Gas Turbine Generating Station*).

Dr. Ingledow served in various engineering executive capacities in Canada and the U.S. until 1940 when he joined the B.C. Electric Company Ltd., in Vancouver. In April, 1960, he retired to take up his present position.
A past member of the Defence Research Board of Canada, he has also served with B.C.'s Columbia River Basin Development Committee and the Governor's Power Policy Committee of the Northwest United States of America. He is a Past-President of the Canadian Electrical Association, the Association of Professional Engineers of B.C., and the Northwest Electric Light and Power Association, and a Fellow of the American Institute of Electrical Engineers.

W. S. Watson, B.Sc., Electrical (Manitoba '45), Electrical Engineer, The Shawinigan Engineering Company Ltd., Montreal.

V. Gabruss, Dipl. Ing., Electrical (Institute of Technology, Munich '47), Electrical Engineer, The Shawinigan Engineering Company Ltd., Montreal. *(Remote Control of Dufferin Falls Generating Station).*

Mr. Watson was with the English Electric Company of Canada Ltd. until 1949. A Member of the Corporation of Professional Engineers of Quebec, he is also an Associated Member of the American Institute of Electrical Engineers.

After graduation Mr. Gabruss worked with "AEG", Stuttgart, Germany until 1949 when he joined the H. G. Acres Company, Consulting Engineers, Niagara Falls. He is a Member fo the Association of Professional Engineers of the Province of Ontario and a Member of the Latvian Engineers Association.

J. C. Thomson, B.A.Sc. Mechanical (U.B.C. '48), Research Engineer, Production Research and Technical Service Laboratory, Imperial Oil Limited, Calgary, Alberta. (*Vehicles in Muskeg*).

Mr. Thomson was with the National Research Council for two years in the Division of Mechanical Engineering, Engine Laboratory. He spent six years with the Defence Research Board in charge of the Soil and Snow Mechanics Group and Vehicle Mobility.

R. F. Legget, M.E.I.C., M.Sc., Civil (Liverpool '25), Director, Division of Building Research, National Research Council, Ottawa. *(Engineering Astride the Border.)*

Mr. Legget came to Canada in 1929, joined the staff of Queen's University in 1936 and, in 1938, the University of Toronto. He later went to Ottawa to start the new Division of Building Research of the N.R.C. and has been Director since 1947. A Member of the Institution of Civil Engineers and the American Society of Civil Engineers he is also a Fellow of the Royal Society of Canada, the Geological Society of America, and an Honorary Fellow of the Royal Architectural Institute of Canada.

J. Zorzi, M.E.I.C., B.Sc., Civil '39, Consulting Engineer, St. Eustache Sur-le-Lac, Que. (*Cofferdam at Mile 6 Quebec Cartier Mining Railroad, Port Cartier, Quebec*).

Before starting out as a consultant in 1945, Mr. Zorzi had wide experience on structural design, soil mechanics, hydraulic developments, mining, heavy construction, welding and marine engineering, and is now studying nuclear engineering. He is a Member of the Corporation of Professional Engineers of Quebec.

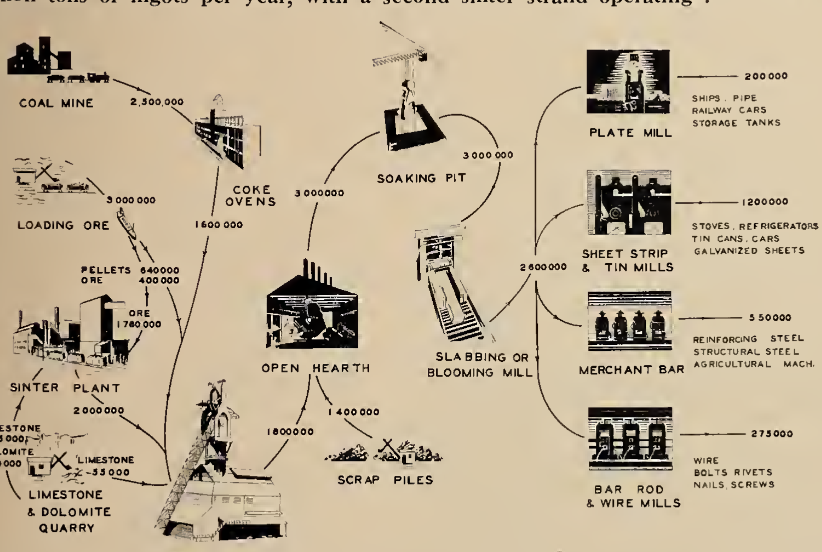
SOME MAJOR PROBLEMS IN STEEL PLANT ENGINEERING FOR GROWTH AT STELCO

L. H. Chater, *Chief Engineer, The Steel Company of Canada Limited, Hamilton*

Most people are under the impression that the steel industry's main job is to make and erect steel shapes for large buildings and bridges and to produce steel for cars. It is perhaps a natural misconception since these are the items which attract attention and therefore make an impression. Actually, no Canadian steel producer is in the fabricating and erecting business and only 25% of the total tonnage of steel produced in Canada goes into the above items. The largest proportion of steel is used to produce other items which are so much a part of our everyday life, such as tin cans, stoves, refrigerators, washing machines, pipe, wire, nails and screws, to mention a few. The Steel Company of Canada alone produces 300 finished lines, but the greater part of the semi-finished steel it produces is used by secondary industries.

FEW PEOPLE stop to think about what goes into the manufacture of steel and how it is produced. However, it is not the purpose of this paper to go into the intricate chemical reactions or the varied metallurgical aspects in the manufacture of steel, rather it will be principally confined to one of the most important aspects of the steel plant engineer's job — materials handling. But a brief knowledge of the various steps in the production of steel and their sequence is necessary to grasp the magnitude of the materials handling problems involved. Fig. 1 shows the flow of materials through the various steps in a typical integrated steel plant as well as some of the products manufactured by secondary industries from the various forms of semi-finished steel. An integrated plant is one which contains all the processes necessary to produce semi-finished steel, such as sheets and bars, from the basic raw materials iron ore, coal and limestone. The Hamilton Works of The Steel Company of Canada is typical. Individual steps may vary depending principally on raw material conditions [1], but most steel is made by the process sequence used by Stelco, as indicated in Fig. 1.

Fig. 1. Illustration of the steps required to produce steel in its various forms. The yearly flow of material between processes is shown for Hamilton Works producing 3 million tons of ingots per year, with a second sinter strand operating .



MATERIALS HANDLING

When the present expansion program at Hamilton Works is completed in 1960 steel ingot capacity will have grown from 1.25 million tons in 1951 to 3 million tons per year. Facilities at ore properties and Hamilton Works to produce this increase in steel ingots and the additional facilities required to treat and form the ingots into semi-finished steel forms will have involved a capital expenditure of about $230 million. The importance of materials handling in a steel plant can be realized when it is considered that a large proportion of this cost has gone directly and indirectly into materials handling. The importance of efficient handling looms even larger when it is considered that 40% of all production costs within a steel plant are taken up in the handling of materials. Since these costs add nothing to the value of the product the challenge to the plant engineer is obvious, especially when one realizes that it is the only major area remaining for substantial cost reduction.

There are certain basic considerations which the engineer must keep constantly in mind when planning and designing handling facilities in a steel plant.

1. Since steelmaking is a continuous 24 hr. daily operation and the various units in the process are interdependent, the flow of material must be reliable. The required amount of each item must be available at its destined location at the required time.

2. It follows that the prime consideration in laying out new units, or extending those already existing, is the dependability of getting materials to and away from those units.

3. Adequate surge reserves must be provided between those units in the process which, in the event of a breakdown, would otherwise shut down all subsequent operations.

4. Alternate handling methods must be available for vital links in the handling chain.

5. In general, within physical capabilities, the larger the pay load the smaller the unit handling cost.

6. Adequate provision must be made for future expansion and to take care of increasing loads as the various units grow in output.

7. So far as practical handling facilities must be flexible to take care of forseeable changes in the steelmaking process.

8. Capital costs must be balanced against operating costs to ensure the most economical facility.

With these points in mind let us follow the steelmaking sequence in looking at some of the handling problems involved in recent expansions at Stelco.

Ore & Coal Handling & Storage Facilities

To produce the iron required in the manufacture of 3 million tons per year of steel ingots the blast furnaces consume 3 million tons of iron ore, 2.5 million tons of coal in the form of coke, and 700,000 tons of limestone and dolomite. Since ore and coal are delivered in Great Lakes freighters they must all be brought in and unloaded during the shipping season (1st April to 15th November). In addition, adequate storage must be provided to keep the furnaces going during the winter when shipping cannot operate.

In 1951, to keep pace with the growing demand for steel in Canada, Stelco decided to increase its steel capacity. This meant providing not only open hearth furnaces, but a new blast furnace with sustaining coke ovens and raw materials handling and storage facilities. Unfortunately the only location for storage facilities which would meet the requirement of easy access to both the coke ovens and blast furnaces consisted of water lots, underlain with mud and very soft clays, to a depth varying from 60 ft. to 95 ft. On this site ship unloading bridges with supporting runways had to be built. These 675 ft. bridges span a stocking area which must sustain a unit loading of 4½ tons per sq. ft. The dock had to be capable of future progressive expansion without interference with everyday operation.

New Type of Dock

Estimates showed that the cost of the usual method of supporting this type of dock entirely on bearing piles capped with reinforced concrete was exorbitant. Stelco engineers in collaboration with eminent soils mechanics consultants conceived and built a radically new type of dock.[2] A trench was dredged along the face of the dock to firm clay, in places down to 95 ft. This trench was filled to above water level with the slag by-product of the blast furnaces. Sheet piling forming the dock bulkhead was then driven into the slag to a depth of 18 ft. below eventual channel level. The piling was then tied back to the reinforced concrete bridge runway adjacent to the dock face. This type of dock was built for 60% of the cost of the conventional bearing pile dock. The original 800 ft. dock has now been extended to 3000 ft. and will be further extended to its ultimate 4100 ft. length as required.

Since only one unloading bridge was to be installed in the first instance, it had to be reliable and carry as large a pay load as was practical. This was necessary to get rapid unloading of the ships to enable them to make as many trips as possible during the shipping season. The size of grab bucket was restricted by the width of the hatches of the Lake carriers. Even with this limitation the bridge can unload and stock 17 tons of ore per cycle, equivalent to a rate of 1100 tons an hr. For reliability it was variable voltage equipped throughout and all critical items were spared. In 1957 a second bridge was added after the dock was extended to 2500 ft. (Fig. 2 shows bridges and portion of dock.)

Fig. 2. View of two bridges unloading a boat and stocking. Construction of recent extension to bridge runway in the foreground. Sinter plant is at the left.

Conveyor System from Dock

In addition to unloading the boats the bridges must be capable of feeding ore or coal from the stockpile to conveying equipment for transfer to the blast furnaces and coke ovens respectively. As initially conceived, the new dock (No. 2) would start out by handling coal only, with all ore being handled through the old No. 1 Dock. Progressively, as the plant increased in size, ore would replace coal until all the ore would be carried on No. 2 Dock. Ex-stocking facilities had to be geared to this transition. Studies showed that when the new coke ovens, which were to be built to supply coke to the new blast furnace, came into operation in 1953 the old method of handling coal by railway cars from the stockpile to the coke oven storage bins would be inadequate. This was due principally to the difficulty in unloading the bottom dump hopper cars due to freezing in the winter. Various alternatives were studied with the cardinal points always in mind. These studies showed that from a reliability and handling cost standpoint a conveyor system from the new dock to the coke oven storage bins was the best arrangement. While the capital cost was high, it was more than offset by the reduced handling costs.

This system took the form of a collecting conveyor behind the landside bridge runway. The conveyor is fed by the bridges through a self-propelled hopper car, running on rails, and straddling the conveyor. Flexibility is provided since the belt can be loaded from the stockpile by conventional crawler derrick equipped with a grab bucket. This is necessary when the bridges are tied up for long periods unloading ships. A cross conveyor takes the discharge from the collecting belt to the coal blending storage bins. The collecting conveyor was designed so that it could be moved progressively as ore replaced coal on the dock. The conveying system was originally designed to carry 600 tons of coal per hr. to deliver a 24 hr. supply to the coke oven storage bins in a 16 hr. period. Provision was made for ultimately speeding up the system to carry 800 tons an hr. pending future construction of a new coal dock.

Fig. 3. View of new coal handling system just after completion. The travelling hopper is being loaded at the extreme right. Blending bins at right centre. Storage bin above coke ovens at left centre. Construction of new conveyor system to new oven bin at upper left.

Coke Ovens

The coal is converted to coke, which is suitable for the chemical reactions in the blast furnaces, in coke ovens. Once a coke oven is fired it must remain in continuous operation until it is dismantled. While a coke oven can be slowed down to a certain extent, it must never be allowed to cool because contraction would damage the fire-brick linings and a complete rebuild would be necessary. It is essential therefore, that the ovens be assured of a constant supply of coal. This is provided for in various ways. There are two sets of surge bins between the dock storage area and the ovens. The first set is located at the coke oven end of the main conveyor from the dock. In addition to providing storage these bins are used for blending the various grades of coal required to make good quality coke. The other storage bins are above the ovens themselves. They discharge by gravity into charging machines which feed the coal into the top of the ovens. These storage bin systems can maintain the ovens at full operation for 18 hrs. This surge ensures a steady flow to the ovens in the event of an interruption in the handling system, such as a conveyor breakdown.

Since 1947 one hundred and ninety-one new coke ovens have been built. Some of these replaced the original battery of ovens which operated continuously from 1918 to 1953. Fig. 3 shows the new coal handling system.

Sinter Plant

The sinter process deserves special mention since it has just come into its own in the last few years. Its impact has involved considerable changes to plant layout concepts and raw material handling systems. Briefly, sintering consists of placing a mixture of fine iron ores, flue dust, and coke fines for fuel, on a moving grate and igniting. Air is sucked through the moving bed until the mass fuses and becomes a porous clinker. Until recently the sinter plant was used as a scavenger, particularly as a means of utilizing the fine flue dust removed from the gas by-product of the blast furnaces. This dust contains as much as 45% iron. When mixed with fine ore and sintered it is in a form which is very palatable to the blast furnaces. Before the present trend to sinter and other ore benefication methods, ore as dug from the Mesabi range, coke and limestone lumps were fed into the top of the blast furnaces. The fines in the ore made the bed of materials in the shaft quite dense and iron production was limited due to the restricted amount of air that could be blown upwards through the bed, channelling of this air and poor contact of the ore, limestone flux and coke. Tests showed that as the percentage of sinter in the blast furnace burden was increased the more permeable the bed became and the less coke was required as a reducing agent. In addition it was easier to separate the pure iron from its oxides state in the sinter form compared with the iron ore form. Consequently for any given blast furnace the iron production increased as sinter replaced ore in the raw state.

However the benefits obtained from ordinary sinter have been far surpassed by the use of self-fluxing sinter which has been pioneered in Canada by Stelco, during the last two years. Self-fluxing sinter is made by adding limestone and dolomite fines to the ore and coke mix before it is fed to the sinter grate. This eliminates the necessity of adding the flux lumps at the top of the blast furnace. The fluxes are therefore intimately dispersed throughout the sinter and can do their job quicker and more thoroughly. Full scale tests on blast furnaces at Stelco have proven that iron production can be increased at least 60% by replacing all the raw iron ore in the charge with self-fluxing sinter.[3] At the same time the overall coke requirement per ton of iron produced decreases 20%. The impact on the industry can be seen when it is considered that this increase in iron production can be obtained at 65% of the cost of the equivalent blast furnace facilities utilizing raw ore.

Importance of Location

Now let us examine the effect of the sinter plant on the old concepts of material handling at Stelco. Before the advent of the sinter plant, ore was loaded from the dock stockpile by the unloading bridges into 60 ton bottom dump ore cars either at the front or the back of the dock; these cars were hauled up a grade to the top of the blast furnace storage bins. A multitude of bins had to be provided for the ultimate blending of the various ores. A better arrangement would have been to have the ore dock backing onto the blast furnace storage bins so the cars could be loaded directly at the high level. However, this was not possible at Stelco hence the long grade. Since the ores will now be diverted through the sinter plant it is now more important that the sinter strands be located adjacent to the ore storage facilities. A reliable facility for conveying the finished sinter to the blast furnaces is also a necessity. At present Stelco has only one sinter plant which went into operation in 1955. It supplies 30% of the iron bearing material to the blast furnaces. All ore to be sintered is at present hauled by truck from the No. 1 Dock and dumped into small capacity bins which feed the conveyor supplying the sinter plant. Flue dust, limestone and dolomite fines are handled in the same manner. Various types of ores used for blending in the sinter mix must be handled separately. In addition all the ores must be screened since only —⅜″ material is suitable for good sinter. Since the single belt feeding the sinter strand can only handle one type of material at any ore time, adequate storage bins are provided ahead of the sinter strand for each type of material. Proportioning rotating disc feeders at the bottom of each bin discharge onto a single collecting conveyor to provide the required mix. This is conveyed to the top of the sinter strand and fed onto the grate. Completed sinter drops from the end of the strand to a rising cooling conveyor. This discharges across streams and onto a conveyor which conveys the material to hopper cars. These cars are hauled to the blast furnace bins in a similar manner to the ore. Fig. 4 shows the sinter machine in operation.

Planning a 100% pre-prepared charge to the blast furnaces at Stelco is well underway. It is not proposed to go into this planning at this time. It should be pointed out, however, that sintering is becoming a vital link in the chain, so an assured sinter supply and adequate sinter handling and storage facilities must be provided to ensure continuous operation of the blast furnaces.

Fig. 4. View looking towards loading end of sinter strand. Conveyor elevating mixed material to head of strand at left.

Blast Furnaces

Stelco has 4 blast furnaces in a line, adjacent to, but at right angles to the ore dock and coke ovens. "D" Furnace, the latest and largest, was completed in December 1952 and is situated at the west end closest to the Coke Ovens and Ore Dock. While this location created critical construction problems it was felt that the ultimate ease of getting materials to this furnace would more than compensate. Blast furnaces are also operated continuously so a constant flow of materials to and from them must be assured.

Let us first consider the overall materials flow at the furnaces. Each furnace is provided with a number of elevated storage bins situated near its base. The number and size of bins depends first on the number of different materials to be charged to the furnaces, including separate bins for each type of ore required for different grades of iron; secondly on the amount of reserve capacity considered necessary to keep the furnaces in operation during any reasonable foreseeable disruption to the handling systems feeding the bins. Each material, with the exception of coke, is drawn from the bottom of the bins into a self-propelled weighing car which, in turn, dumps the load into one of two skip cars in the required proportions and sequence. The skip cars alternately hoist the material to the top of the furnace on a sharply inclined track ramp. They discharge into the top of the furnace through a revolving seal. The coke bins are located adjacent to and on either side of the skip pit so that they can discharge directly into the skips through their own weigh hoppers.

"D" furnace was built into this system while the other three furnaces were kept in operation. Since it was built between the existing three furnaces and their source and route of ore and coke it was no easy job. The various materials supplied to the existing furnace bins were delivered in bottom dump hopper cars. These operated on two tracks located on top of the bins and common to all furnaces. This elevated system commonly called the "highline" was fed by a single elevating track at either end. "D" furnace bins had to be built into this system immediately adjacent to an operating furnace without cutting off the supply of materials. In addition the top elevation of the bins was restricted to the level of the common over-running tracks. Since space limited the length and number of bins and also the width the only alternative was to make them deeper to provide sufficient storage. This meant that the scale car at the bottom of the bins had to be located in a trough considerably below the ground level on which the other scale cars operated. Extensive alterations had also to be carried out to the approach trestle used to carry the ore cars to the highline.

Run-Around Track

Fig. 5 showing "D" furnace under construction gives some idea of how the job was carried out. A third elevated track was built adjacent to the bins and outside the curve of the existing approach trestle. To assure stability during the subsequent excavations for the new bins and skip pit the portion paralleling the bins was seated on projecting piles driven 80 ft. into the ground to refusal. This run-around track was connected to the existing highline tracks well clear of the new construction. Admittedly there was a ramp access at the other end of the highline but this could not carry all the materials required for the other three furnaces for an extended period without disruption. Access to this east ramp was at the opposite end of the plant from the ore dock and involved a tortuous railway haul through the plant. Connections to the new runaround track at both ends were therefore made in short order working around the clock.

The supply of coke to the existing furnaces also had to be maintained. Coal is roasted for 16 hr. in the coke ovens and the red hot coke product is then pushed by a large ram into a self-propelled car. The car carries the coke under a quenching station where it is drenched and cooled with water. It is then side dumped onto a ramp where it is further air cooled and then fed onto a belt conveyor. When construction on "D" furnace started this single inclined conveyor discharged the coke into a screening station where the fines were removed. A further inclined conveyor carried the larger coke to a loading station above the highline from which the three operating furnaces were fed. Since this loading station was supported on a portion of the approach trestle which had to be removed it had to be temporarily supported by a bridge straddling the highline. This is shown to the left of Fig. 5. You can also see coke cars being loaded on the runaround trestle.

Studies showed that the existing coke handling system could not cope with the 65% increase represented by "D" furnace for the following reasons:

1. The single conveyor system would be overloaded and was a serious threat to operations at the blast furnaces;

2. The existing coke screening station would also be overloaded giving poor screening and susceptibility to frequent breakdowns;

3. Since coke is a lightweight bulky material, rail traffic on the highline would become so congested it would be almost impossible to maintain the required flow to all the storage bins.

Additions Necessitated

In view of the first point it was decided to put a second conveying system from the new coke ovens, then under construction, to the highline. The second point was dealt with by the installation of a second primary screening station. To obviate congestion on the highline it was decided to convey the oversize coke from either screening station directly to "D" furnace coke bins by conveyor. In an emergency, however, "D" furnace coke bins can be charged by rail cars from the new car loading station servicing the remaining furnaces, and located on the new approach trestle.

Limestone lumps are delivered by rail from the company's quarries in Beachville in bottom dump cars. Storage tracks adjacent to the east approach trestle provide a surge for emergency. Various ores and sinter are still delivered from the two storage docks and the sinter plant to the Blast Furnace bins over the access ramp from the docks.

In 1957 planning for a fifth furnace, "E", at the east end of the highline was well underway when the welcome advantages of self-fluxing sinter appeared on the scene. Studies had shown that deliveries of material by bottom dump hopper cars to the five furnaces would be impractical. The additional congestion on the highline would have meant delays due to the inability to get material to some of the bins before they were empty. Deepening the bins on the original three furnaces while physically possible would have been far too costly. In addition it would have meant protracted shutdowns of the furnaces with consequent loss of much needed iron production. It had therefore been decided that a new conveying system running the entire length of the highline to the new furnace from the new dock would have to be provided. As engineering for this elevated and costly conveying system was about to start the advantages of self-fluxing sinter began to make themselves felt. Engineering for the new furnace was held up and it soon became apparent that self-fluxing sinter from the existing sinter plant would increase iron production from the existing four furnaces an amount equal to half the anticipated production from the new large "E" furnace. This increase in production meant that "E" furnace could be delayed for a few years. It also indicated that a further increase in iron production could be obtained by the addition of a second sinter plant with a substantial capital saving over "E" furnace. At present planning for the second sinter strand is well underway.

Another apparent advantage of self-fluxing sinter is the simplification of materials handling to the blast furnaces, especially when the stage of 100% pre-prepared burden is reached. At that stage only one iron bearing material, sinter, need be delivered to the blast furnace bins, instead of the multitude of different grades of ore previously required for blending at the furnaces. In addition this sinter will also contain the limestone and dolomite flux material which previously also had to be delivered separately in lump form, to the highline. The amount of coke required at each furnace will, however, increase. Although the amount of coke required per ton of iron produced will substantially decrease, the increase in iron production will more than compensate. So we can look forward to only three materials being required for charging to the blast furnaces, sinter, iron concentrate pellets, and coke. Congestion will be further relieved due to the fact that the sinter can be dumped in any one of the bins which were previously designed for a specific grade of ore.

Consideration is being given to delivering all the sinter from the sinter plant to a loading station on the highline by belt conveyor. This would necessitate adequate cooling of the sinter after it was discharged from the sinter strand. Against this we must balance the possible saving in heat by delivering the sinter to the furnaces while it is still hot. This, of course, would mean delivery in insulated hopper cars and the blast furnace bins would also have to be protected.

The congestion problem unfortunately now moves from the furnaces back to the sinter plant. Large separate bins must be provided between the ore stockyard and the sinter strand for each grade of ore required for blending in the sinter mix. In addition, bins will have to be provided for limestone and dolomite fines, coke fuel fines and the iron scale which is a by-product of the rolling mills. But the lessons we have learned in materials handling to the blast furnaces are now standing us in good stead in planning for materials handling to the sinter plants.

Conveyance of Molten Iron and Slag

Now that the materials are flowing into the blast furnaces we must get the products of the furnaces to their destination. With the exception of the gas piped from the furnaces, these are two, molten iron and slag. Slag is made up of the flux materials and the impurities from the original ore charge. In a molten state it floats on top of the molten iron in the bottom of the furnace. It is drained off into pits adjacent to the furnace, frequently. There it is water cooled, loaded by electric shovel, into large dump trucks for transportation to its destination. Blast furnace slag has many practical uses and the greater part of it is delivered from Hamilton Works to an outside processing plant. Each furnace has two slag pits for continuity. While one is being filled, the other is being dug out. Originally slag was drained into pots which were transported over the same tracks as the hot metal and dumped along the shore. A comparative study proved the present system to be much cheaper to operate. In addition congestion was relieved on the important hot metal runs; an important consideration.

Iron is drained off at a level below that of the molten slag. It flows by gravity to fire brick lined rail containers which deliver it to the open hearths. Vessels carrying 70 tons provide this service from the two smaller furnaces and on their arrival at No. 2 Open Hearth shop the iron is poured into an 800 ton mixing storage ladle. Iron from "C" and "D" is conveyed in 200 ton torpedo shaped ladles which also act as storage capacity.

Any disruption of the flow of iron from the blast furnaces to the open hearths could seriously impair open hearth operation especially since very little surge, in the form of stored liquid iron, can be provided. To date rail haul is the only means of transportation. To meet materials handling requirements therefore it is essential that this main track system be reliable and that an alternative route be provided where possible. In addition the haulage of other materials over the main hot metal track should be kept to an absolute minimum to obviate interference. The installation of "D" blast furnace required a rearrangement of the main hot metal tracks and a much heavier 130 lb. rail to take care of the increased wheel loads imposed by the 200 ton ladles. These changes were carried out step by step without disruption of the hot metal flow from the existing three furnaces. It required a great deal of planning and layout work including a separate drawing for each step to avoid confusion.

Open Hearths

The next link in the process is the open hearth furnaces. While steel is made in batches in individual furnaces, the operation of a battery of furnaces (a shop) can be considered a continuous 24 hr. operation. The first step in steel-making is the melting of scrap by intense heat in a covered bath shaped vessel. Hot iron is then added. The proportion of these two main ingredients varies depending on a number of conditions but equal proportions is a good average figure for our purposes. Various other elements are added, principally lime and high quality ore or sinter for heat control and purification purposes. The impurities collect in the slag formed on top of the steel in a similar manner to the blast furnaces. High heat is maintained within the furnace during the process, which takes about eight hours. When refining is complete steel is drawn off through a tapping hole and flows by gravity into a brick lined ladle. Any slag not drawn off previously collects on the top of this ladle and overflows into a second slag ladle.

Construction of Stelco's No. 3 Open Hearth shop paralleled that of "D" Blast Furnace and it came into operation one day before that unit. It consists of four furnaces rated initially at 275 tons each but now producing 315 tons per heat. A fifth furnace is now being added with a nominal capacity of 400 tons but provision is being made in the handling equipment for potential 500 ton heats from this furnace.

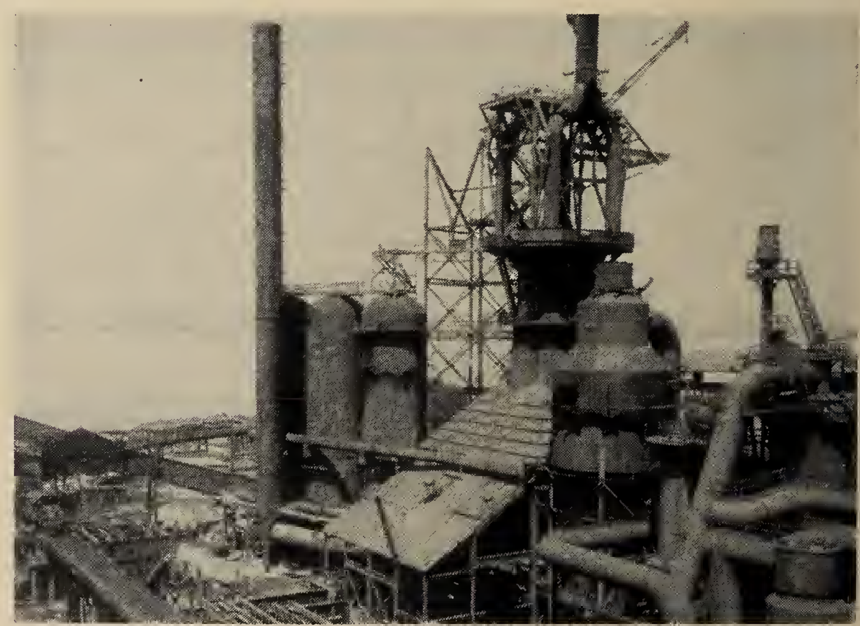
Non-interference of Flow To and From

Materials handling to and from No. 3 Shop dictated the layout. While the shop itself was located more or less on virgin ground the material flow had to be correlated with existing equipment. The first two principles of materials handling can be expanded to include a sub-rule stating that "the flow of materials to a unit should not interfere with the flow of materials away from that unit or with the material flow to and from any other unit". While this applies to all steps in the process it is particularly applicable to the open hearths. With this in mind No. 3 shop was arranged so that hot metal and scrap approach from the west while ingot and returning empty mould tracks extend to the east of the shop. In addition the hot metal track delivers to the ultimate centre of the shop, outside and to the south of the building, on ground level. Scrap is delivered into the south bay of the building but at an elevated level. The ingot and mould tracks are on the north side of the shop. Many layouts were studied before the ultimate one was adopted as the best from a materials handling standpoint. Figure 6 is a plan of the shop including the new furnace under construction. Figure 7 is a cross section. Reference to these two illustrations will aid in following the materials flow description.

Ladling Procedure

The 200 ton hot metal ladles are spotted on the south track at ground level. By rotation they pour into the ladles used to charge the furnaces. While these ladles are being filled they rest in a winch-driven transfer car situated below ground level on a weigh scale. It is essential that all

Fig. 5. "D" blast furnace under construction.



materials going into each batch of steel be accurately weighed both from a quality standpoint and a knowledge of the true weight of the batch of finished steel. The loaded ladle is then transferred to a point underneath the charging aisle. It is lifted through a hatch in the charging floor by 150 ton cranes which carry it and charge the iron into the scheduled furnace.

Scrap Boxes

Scrap handling and charging facilities are the chief bottleneck in restricting the output of Open Hearth furnaces. With this prior knowledge very careful consideration was given to scrap facilities in designing No. 3 shop. Scrap is charged into the furnaces in steel rectangular containers. These containers are delivered on flat buggies to a point immediately in front of the furnaces. An electric charging machine picks up each box in turn, on a ram, inserts it through a door into the furnace, then empties it by rotation. Naturally the larger the box the faster the furnace can be charged but the box size is restricted to the door opening and the lifting capacity of the charging machine.

When Stelco's older No. 2 shop was built it employed scrap handling facilities utilized throughout the industry at that time. This consisted of loading the buggies in a scrap yard at ground level and hauling them up a ramp to the charging floor level. Since the capacity of each buggy was limited a great deal of rail traffic was involved with frequent derailments of the small scrap cars principally due to scrap falling from the buggies. No. 3 shop was planned to cut down on the traffic and the frequency of derailments. For this shop, scrap is elevated by a highline ramp, in large capacity gondola cars, into a bay adjacent to the charging aisle. In this bay the boxes, resting on their buggies, are filled from the gondola cars by fast electric overhead magnet cranes. The scrap buggies therefore always operate at the charging floor level. As each train of buggies is loaded it is weighed and then located on storage tracks, from where it can be rapidly located in front of the furnace to be charged.

Efficiency Increase

Even in the short period from 1952 to the present the increase in operating efficiency has greatly reduced the time required to make a batch of steel. Even shorter times are anticipated in the very near future by the use of oxygen jetting through the roof. This means more material must be handled in a given time and it had a major influence in the planning for the new furnace. The footage of scrap loading and holding tracks per furnace has been substantially increased and the door left open for a further increase in the future.

The other large tonnage items used in the open hearths are ore, sinter, lump lime and dolomite. In other modern shops these materials are usually fed from ground hoppers, by inclined conveyors, to large storage bins above the scrap loading bay. It was felt that this was not satisfactory for our new shop for two reasons: first, it added to the congestion at the scrap loading level and secondly we anticipated that the gravity flow from these bins would be disrupted by freezing of the material in the bins. Accordingly it was decided to install a separate building for this material. This is indicated as the miscellaneous material building in Fig. 6 and 7. Material is fed into the open bins by bottom dump hopper cars operating on the high level track system. It is then transferred to the boxes on the charging buggies by means of an electric overhead crane equipped with a grab bucket. In addition, lime lumps can be delivered from our own lime kilns by large trucks which tip directly into the lime bin.

It should be mentioned that alloying and quality control elements in minor quantities are added throughout the open hearth process. While a great deal of care was required in planning the handling facilities of these materials, they will not be described in detail.

Handling of Slag

During the refining process slag is drawn off through the front charging doors and into a slag pot suspended on a transfer car below the furnace. This car moves the pot to the discharge side of the furnace (the pouring aisle). The slag pot is then transferred by the overhead cranes to a two pot slag car. The overflow slag from the steel ladle, mentioned above, is also transferred to the slag pot car. When the slag has set it is hauled by rail and tipped by specially adapted crawler derricks into a long slag pit. It is then water cooled, broken up, and magnetically processed to recover entrained steel.

Each completed batch of steel is tapped into a single ladle in the pouring bay. The loaded ladle is immediately lifted by heavy cranes for transfer to the pouring station. Cranes for the present four furnaces have a rated lifting capacity of 350 tons. A new crane to service the larger furnace will be capable of a 625 ton lift.

Design Problem

An interesting design problem was encountered in the large crane runway girders spanning the furnaces and sustaining the very heavy crane wheel loads. The span over the present furnaces is 112 ft. and the plate girders are nearly 12 ft. deep and weigh 125 tons. They were the largest plate girders ever manufactured and erected in Canada. The spans for the extension of the shop for the larger furnace are 130 ft. long and the new crane lift is much heavier. Since the crane runway rail level must be constant throughout the shop and the clearance over the furnaces is limited the new girders were restricted in depth. In addition it was desirable that the new crane be able to operate over the existing crane runway to service the older furnaces. The problem was solved by the use of low alloy high strength steels. The weight of the 130 ft. girders has been cut from a potential 300 tons with conventional structural steel to 200 tons. The wheel loadings of the new crane have been matched to those of the older cranes also by the use of high strength steels.

Steel is poured through a hole in the bottom of the ladle into a line of prepared ingot moulds sitting on flat ingot cars. This is done by the crane inching the ladle successively over each mould. A stopper mechanism actuated by a man on a platform shuts off the flow as the ladle is moved from above one mould to the next.

The next steps in handling the ingots are critical. The steel must have time to set in the ingot form but it is also important to get the stripped ingots into the reheating pits (soaking pits) as soon as possible to conserve heat. Steel men talking about "track time" are almost certainly referring to the time lapse between pouring the steel into molds at the open hearth and getting the ingots into the soaking pits. Any delay in this procedure over the minimum permits the ingots to set will materially affect their costs. The layout of the track system from the open hearth through the stripper building and to the soaking pits is very important. There must be no interference between the flow of ingots to the soaking pits and the return flow of empty ingot moulds to the mould preparation shop and subsequently back into the pouring aisle for recharging. At Stelco we not only had to consider that two open hearth shops would be discharging onto this track system, but allowances had to be made for an ultimate third shop. In addition, allowance had to be made for frequent surges due to furnaces pouring in rapid succession. To make matters worse, track changes to integrate No. 3 Shop into the system had to be carried out without interrupting the flow of ingots and empty moulds from, and to, No. 2 Shop.

A new mould stripper building was required with No. 3 Shop and provision also had to be made for an anticipated second ingot rolling mill with accompanying soaking pits. The problem was further complicated by track curvature restrictions and the difference in levels between No. 3 shop, No. 2 shop, the existing rolling mill and the planned second rolling mill. Various track layouts were made and studied by means of time flow charts. By this means the ultimate track layout slowly evolved. The smooth operation of the present track system justified all the comparative studies that were made.

New Stripper Building

In the stripper building the moulds are removed from the ingots or, in some cases, loosened for the subsequent removal of the moulds at the ingot soaking pits. This building must be conveniently located on the flow track between the open hearths and the soaking pits. Until No. 3 Open Hearth shop was built all stripping was done in a building located at the end of the soaking pits servicing No. 1 Bloom Mill. The original No. 1 mill and No. 2 Open Hearth Shop were located at right angles to each other. As the plant grew the two buildings were sucessively extended and converged at the base of an "L". This created a serious track bottleneck and it was apparent that no further extension of either building was possible.

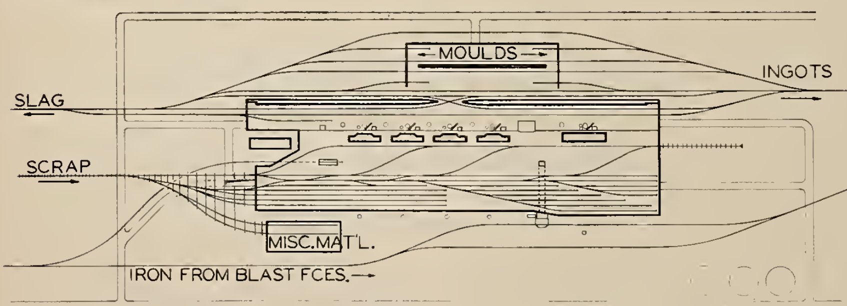
Second Blooming Mill

With the advent of No. 3 Open Hearth a larger stripper building was required. In addition a second blooming mill was in the offing since No. 1 mill was very near its maximum capacity and any serious breakdown could shut down all subsequent operations. A new stripper building was a necessity and its location to service the ultimate two blooming mills was extremely important. It was finally located on the extended line of No. 3 Open Hearth shop which forms the stem of a T between the two blooming mills. However, it was located far enough away from No. 3 shop to allow ample extension of that shop in the future. It was constructed straddling the new track system and equipped with a new 400 ton stripper crane. On completion the new track system was tied in to the old system and the new stripper building took over the full load. The 200 ton stripper crane from the original stripper building was modified and moved into the new building. The old stripper building was then dismantled permitting a better track arrangement at the former bottleneck. A stripper crane's capacity is rated by the pull it can exert on an ingot while holding down the mould; in other words the separating pull. Conversely it can hold down the ingot and pull up the mould. While the new crane is rated at 400 tons, it can momentarily exert a 1200 ton separating force. The location of the stripper building imposed additional restrictions on the track layout. Allowance had to be made for extension of the stripper building in the future and in addition the portion of the track straddled by the stripper and extending a reasonable distance from each end had to be level. This was necessary to prevent runaways of strings of ingot buggies.

Separation of Materials

We have now reached a point where our main stream of materials in process splits into two streams. One flows through the No. 1 blooming mill and secondary rolling mills, to be formed into bars and bar products. The other passes through the new bloom-slabbing mill, where it is rolled into slabs, and then through secondary mills where it is formed into flat rolled products.

Fig. 6. Plan of No. 3 open hearth shop showing larger fifth furnace now under construction. Note separation of track systems for different materials and extent of scrap tracks.



This paper has traced the handling of the main raw materials required to produce a finished steel ingot. However there are large amounts of secondary items without which a steel plant could not operate. The following figures will give some indication of what is involved in the use of these items at the present level of operations at Hamilton Works.

Water: 130,000 g.p.m. pumped from the bay and distributed throughout the plant. This is three times the quantity pumped by the City of Hamilton.

Blast Furnace Gas: 275,000 c.f.m. generated, by the blast furnaces, cleaned and distributed for use as fuel.

Coke Oven Gas: 30,000 c.f.m. generated by the coke ovens, purified and distributed for use as fuel.

Fuel Oil: 9,000 gal per hr. used in various furnaces throughout the plant. This would heat 20,000 homes.

Electricity: 1,300,000 kwh. per day is used throughout the plant.

FUTURE GROWTH PLANNING

One other important function of the steel plant engineer deserves special mention and that is his part in future planning. The words "his part in" were chosen specifically because future planning is a cooperative effort involving all divisions of the company. At Stelco it is the Engineering Department's job to correlate this planning under the guidance of top management.

The objective of future planning is to ensure a balanced logical company growth to meet the increasing steel demands of a growing Canada. It considers not only physical growth but financial. As a basis for planning some predictions of the future demand for steel must be made. The main factors influencing these predictions are:—

1. the trend of increasing population;

2. the greater use of steel per capita with the rising standard of living;

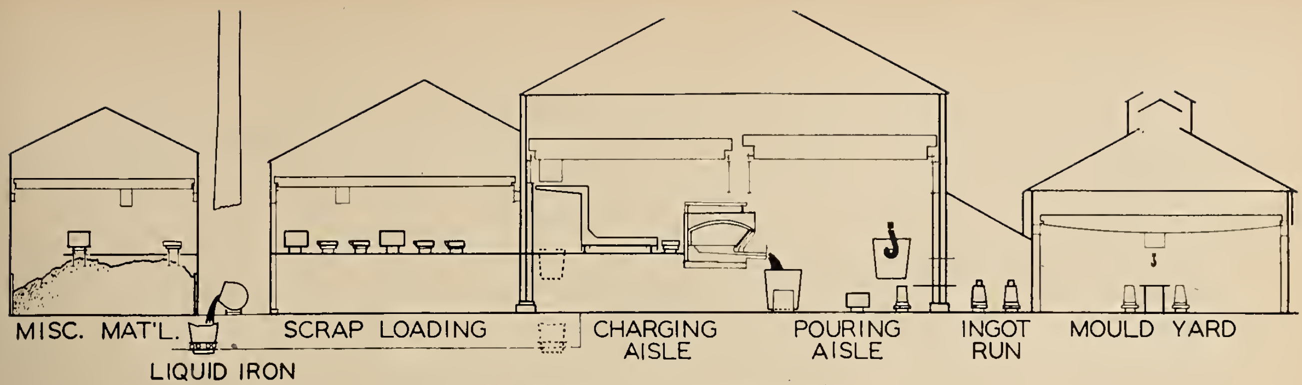


Fig. 7. Section through No. 3 open hearth shop.

3. the rapid industrialization of the country as Canada takes over the job of manufacturing more and more goods.

All these were considered in compiling Stelco's submission to the Gordon report and make a solid basis for future planning.

Planning Ahead

A logical question is "How far ahead do you plan?" Unfortunately there is no stock answer. A great many things will influence the decision, e.g. type of industry, frequency of radical changes in any particular industry and the magnitude and rapidity of trends in the country as a whole. Broad planning at Stelco covers about 20 years. In addition there is short term planning, which can be discussed in more detail.

Since the sales predictions take all the above factors into consideration they are the logical starting point for future planning. Through market research sales demand charts covering a twenty-year period are made up. Initially these cover broad categories for which steel must be provided, e.g. tin plate,, hot and cold rolled sheets and bars.

The Engineering Department, working with the operating division, then establishes what is required in the way of physical plant and when each unit is required to meet the sales demand forecasts. Starting with these forecasts, demands at each step in the process are traced right back to basic ore and coal. Curves are plotted showing yearly tonnage requirements for the future. On these, the timing of each unit can be indicated.

Flexibility of Plant Layout

The next step is plant layout incorporating the required units. In some cases alternative locations or processes, at different stages, require comparative economic studies. If these are not conclusive, due possibly to further development work being required, plant layout must be left flexible. Generally, however, once the individual units of physical plant are established layout can be advanced. While many factors influence the layout probably the most important are:

1. The size and shape of the property available for expansion of a given works;

2. A layout which reduces handling costs to a minimum by providing a smooth continuous flow from raw materials to the shipping of finished products. Materials handling will essentially govern the layout; and

3. The ultimate capacity of some of the major units as they affect the balanced production of other units, e.g. it may be possible to lay down a new slabbing mill which could produce 3 million tons of slabs per year but the huge capital investment involved would not be justified unless other units in the process could be extended to handle this additional tonnage.

Future Capital Requirement Schedule

When the physical layout has been established estimates of the cost of the new units are prepared. These are then incorporated into a future capital requirement schedule which is submitted for management's use.

The comparative economic studies mentioned above become more frequent in short range planning. They are usually correlated in the form of a report prepared by the engineering dept. but incorporating the work of many other departments. The metallurgical department studies the feasibility of comparative processes, particularly from a quality standpoint. The operating division work out unit capacities, surge requirements etc. to ensure that the new unit can be incorporated into their operations in the most efficient manner. Industrial engineering in collaboration with accounting estimate operating costs. Finally the accounting division combine operating costs, inventory costs, working capital and capital estimates to give a return on investment. This is generally the common denominator upon which management bases its decisions.

Importance of Review

In these days of rapid development and changing conditions it is necessary to review long term forecasts frequently. The main theme in planning is to have your course charted ahead so that when decisions have to be made there is a sound foundation on which to base them. At times a large portion of planning work may have to be discarded due to some unforeseen new development. This, however, does not mean that no benefit has accrued from the work. One of the principal benefits is the personal development of the engineer. He learns to look ahead and keep an open mind. His vision is widened and he develops a sense of proportion. Planning teaches him the value of teamwork and co-operation. It gives him an appreciation of the importance of the work of others in the overall pattern. He realizes that while his technical contribution is important, unless it is integrated with other functions there can be no assured progress.

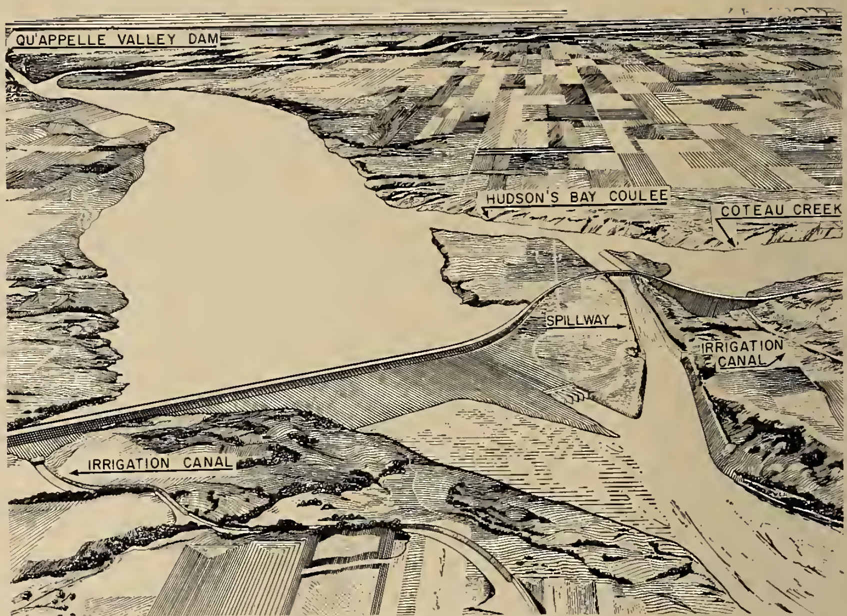
THE SOUTH SASKATCHEWAN RIVER DAM



G. L. MacKenzie, M.E.I.C.,
Director,
Prairie Farm Rehabilitation Branch,
Canada Department of Agriculture,
Regina.

Presented at the E.I.C. Western Technical Conference Banff, Alberta, October, 1959.

The South Saskatchewan River dam is the principal structure in a large multiple purpose project in central Saskatchewan. When completed the project will irrigate an area of approximately 500,000 acres in a region which has experienced severe losses from drought conditions and it will stabilize agriculture in an area several times as large. It will make possible the construction of a large hydroelectric power development in an area where hydro-electric power possibilities are otherwise very limited. It will furnish unlimited water supply for urban centres in Southern Saskatchewan which have no other visible source. It will provide flood control to all areas along a 400 mile reach of the South Saskatchewan River and create valuable recreational facilities within reasonable access for a larger portion of the population of Saskatchewan.

THE DREAM of damming the South Saskatchewan River has persisted in one form or another for 100 years. In 1857 the British Government sent an expedition under Captain Palliser to explore Western Canada. In 1858 the Government of Canada sent an expedition under Professor H. Y. Hind of Trinity College to explore the Assiniboine and Saskatchewan River valleys. Both of these explorers noted the close interrelationship existing between the valley of the South Saskatchewan and the Qu'Appelle lake and river system.

Palliser's observations concerning the interrelationship of the two valleys led him to suggest the feasibility of a water-communication system connecting the two. Hind went on to suggest the construction of a dam across the South Saskatchewan to divert its waters down the Qu'Appelle valley. He said that "the construction of a dam 85 ft. high and 800 yd. long would send the waters of the South Branch down the Qu'Appelle and Assiniboine into the Red River, thence past Fort Garry into Lake Winnipeg". He went on to say: "The time may yet arrive when the future population of Ruperts Land and the Dakotah territory will find it advantageous to construct these or similar works, even if they should be for the purposes of irrigation or inland navigation."

In 1919 the late Wm. Pearce, eminent engineer and land surveyor, pointed out the possibility of the diversion of water from the North Saskatchewan, the Clearwater and the Red Deer rivers to supply water for agricultural uses throughout the central plains of Alberta and Saskatchewan. This led to an extensive survey by the Reclamation Branch of the Department of Interior in 1920, which survey revealed two large tracts of land which could be irrigated from the sources suggested by Mr. Pearce, one in the Youngstown-Hanna area in Alberta and the other in the Rosetown-Outlook-Saskatoon area in Saskatchewan. The conclusion was that it was feasible. However, it would have been very costly. In 1930 the Federal Government, by agreement, transferred the natural resources to the Provinces and no further action was taken.

In 1939 the Prairie Farm Rehabilitation Administration of the Federal Department of Agriculture (P.F.R.A.) began detailed surveys of the William Pearce proposal. These were directed particularly towards the irrigation of areas in Alberta with possible extension into Western Saskatchewan. Some of the soils were found difficult to irrigate and the route into Saskatchewan presented major difficulties. A modification of the project, directed principally towards stockwatering, is now under active consideration.

In 1943, the P.F.R.A. began investigations of a modification of the Pearce proposal with the object of irrigating the lands in Saskatchewan by diversion of the South Saskatchewan River in Saskatchewan. The advantages seen were as follows:

(1) It would enable the Province of Saskatchewan to proceed with irrigation independently of another Province;

(2) It would bring the point of diversion closer to the irrigable lands in Saskatchewan, thus saving large water losses in transportation and maintenance costs on the long canals from Alberta;

(3) The dam required for diversion of water for irrigation on the South Saskatchewan would provide head for the development of hydroelectric power;

(4) The source of the water would be entirely within the basin of the South Saskatchewan and would not involve the diversion and use of water from the North Saskatchewan basin as would be required in the Wm. Pearce scheme.

The first alternative for a diversion in Saskatchewan involved a study of six possible damsites in the Cabri area north of Swift Current. There was some reason to believe that foundation conditions in this area would be better than was revealed by information on hand along other sections of the river where great depths of sand were indicated. Furthermore, it would be possible to divert water through a natural depression to the Elrose-Outlook-Saskatoon area by a dam about 130 ft. high. However, the borings in the Cabri area indicated that foundations were no better than elsewhere along the river and that the only feasible type of dam would be an earth embankment. Concurrent surveys indicated that a large area of good agricultural land would be flooded by the reservoir and that a large portion of the irrigable tract in the Rosetown-Elrose area contained heavy soils not suitable for and which did not require irrigation. It was also revealed that there were large areas of land suitable for irrigation on the east side of the river, north and east of Outlook, which could not easily be commanded from the Cabri diversion.

Attention was then directed to the Elbow-Outlook stretch of the river where a higher dam with a much larger reservoir would be possible and from which water could be delivered to the most desirable portions of the Rosetown-Outlook area as well as to the area east of Outlook. From it, also, water could be diverted down the Qu'Appelle River for irrigation in the Qu'Appelle valley and for the maintenance of lake levels, and for urban water supplies, including the cities of Regina and Moose Jaw. The potential power development would be greater than at the Cabri site and it would be closer to the load centre. The recreational facilities provided by the project would be within easy reach of the larger Saskatchewan cities.

Studies of several sites in the Elbow-Outlook area were carried out. The one finally selected is midway between Elbow and Outlook where Coteau Creek flows into the river from the west. Here the topography is ideal for the construction of the separate spillway required for an earth dam and there is an abundance of the various types of material required for a zoned earth fill. There is ample pervious material at hand as well as large quantities of concrete aggregate on the site. An engineering report on the feasibility of the dam was filed in 1947. The drainage basin and the sites referred to are shown on Fig. 1.

Agreement

This was the first multiple purpose project that had been proposed in Western Canada and so it was natural that extended negotiations between the governments were required before action, if any, could be taken that would lead to its realization. The negotiations were completed on July 25, 1958, when the Governments of Canada and Saskatchewan signed an agreement to proceed with the project and agreed to share in the cost.

The agreement provides that Canada will construct the reservoir by constructing the main dam on the South Saskatchewan River and a subsidiary dam in the Qu'Appelle valley and such related works as are necessary to complete the construction of the reservoir. It provides that Canada and Saskatchewan will share in the cost of constructing the reservoir, 75% thereof to be borne by Canada and 25% to be borne by Saskatchewan, provided that Saskatchewan's share of this cost shall not exceed $25 million. Upon completion, Canada is to transfer the reservoir and its related works to Saskatchewan but Canada is to maintain the works for a period of ten years and shall be responsible for the cost of such maintenance for a period of six years; during the remaining four years the cost is to be shared equally.

The agreement also provides that, if Saskatchewan proceeds with the construction of hydroelectric power facilities, the cost of these is to be borne by Saskatchewan provided that Canada will contribute 25% of the cost of constructing and installing such penstocks as may be necessary to produce, at minimum operating head, 200,000 hp.

The agreement also provides that Saskatchewan will assume full responsibility for and undertake the construction, operation and maintenance of all the irrigation works required for the conveyance and distribution of water to all lands to be irrigated by the reservoir.

The South Saskatchewan River

As a background to the understanding of factors which dictate features of the design and which will dictate construction procedure, a knowledge of the characteristics of the river is necessary. The South Saskatchewan River is a mountain-fed stream. Its source is its many tributaries rising on the eastern slopes of the Rocky Mountains. The principal tributaries are the St. Mary, the Belly and the Waterton Rivers which are international streams and which rise in the Glacier National Park in Montana, and the Old Man, the Bow and the Red Deer Rivers which rise in Alberta. The drainage basin is shown on Fig 1.

Being mountain-fed, the river has two normal high stages. The first occurs at the time of snow melt in the foothills and on the plains, normally about mid-April. The second stage, which is usually the larger, results from snow melt in the mountains and usually occurs about mid-June. Records of the flow have been kept since 1911. The flow at Saskatoon, where continuous records have been maintained, has ranged from a minimum of 502 c.f.s. on December 12, 1936, to a maximum of 147,500 c.f.s. on June 15, 1953. There is a similar wide variation in the total annual flow. It has varied from a low of 3,440,000 acre feet in 1947 to a maximum of 14,600,000 in 1916. The average is about 7 million acre feet. A typical annual hydrograph is shown in Fig. 2. It is this wide variation in flow which requires a reservoir of the maximum capacity available in order to make the greatest possible use of all the water available.

Fig. 3 shows the annual natural flows, during the period of record, of the South Saskatchewan River at Saskatoon and the Saskatchewan River at The Pas, Manitoba. It also shows the depletion of the flow to meet the ultimate demands of upstream uses and the requirements of the South Saskatchewan River Project.

The Reservoir

The dam will create a reservoir 185 ft. deep at the damsite and extending for a distance of 140 miles up the main valley of the South Saskatchewan River to a point northwest of Swift Current and eastward in the valley of the Qu'Appelle River about 12 miles. It will have a total area of 109,600 acres, of which only 5,700 acres is cultivated land. The total capacity of the reservoir will be 8 million acre feet and, assuming a 40 ft. usable range, the live storage capacity will be 2,750,000 acre feet.

The full supply level of the reservoir will be higher than the summit in the Qu'Appelle valley between the South Saskatchewan River and the Qu'Appelle River. Hence an earth dam 90 ft. high will be required across the Qu'Appelle valley to contain the reservoir and to control the flow down the Qu'Appelle River. This structure, known as the Qu'Appelle Valley dam, will be 9,000 ft. long on the crest and will contain approximately 7,500,000 cu. yd.

To determine the effect of river sediment on the life of the reservoir, a silt determination program was begun in 1947 and has been carried out almost continuously until the present time. Depth integrating silt samplers were used to obtain the samples and bottom withdrawal tubes were used for the laboratory analysis. The conclusion arrived at from this program is that silting will not affect the useful life of the reservoir.

The Canadian Pacific Railroad line between Moose Jaw and Macklin at present crosses the Qu'Appelle valley in the reservoir area. It is proposed to revise this line to cross the valley on the Qu'Appelle Valley dam.

Fig. 1. Drainage Basin of the South Saskatchewan River

The Canadian National Railway line between Central Butte and Dunblane presently crosses the South Saskatchewan River on a low level bridge near Elbow. This line will be inundated and have to be removed. Its relocation is under study and final location has not been determined.

Several provincial highways will have to be relocated and the provincial highway bridge over the South Saskatchewan River north of Swift Current will have to be raised.

The reservoir is shown on Fig. 4.

Irrigation

Based on completed topographic and soil surveys, it is estimated that approximately 500,000 acres can be irrigated from this reservoir. The area is shown on Fig. 4. Of this area, approximately 40% can be irrigated by gravity from the reservoir and the balance will require pumping. Of the area that can be served by pumping approximately one-half will have a lift of 30 ft. or less and the other half will have varying lifts of up to 120 ft.

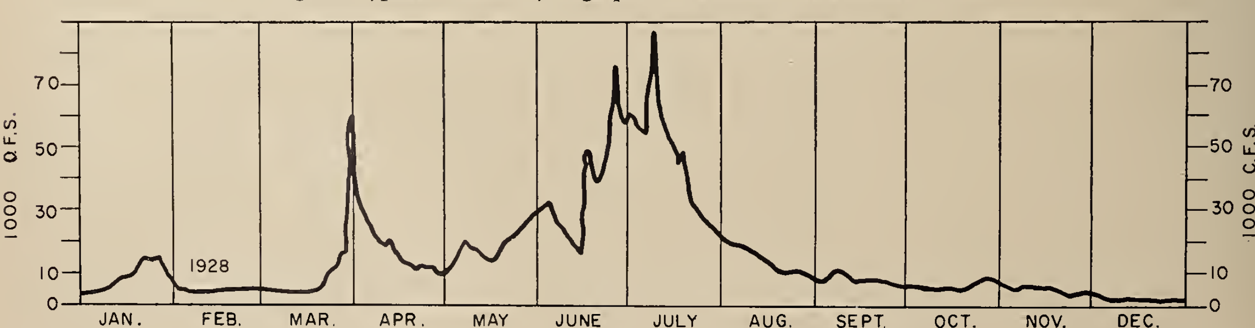
Power for pumping would be available from the generating station at the dam. Since the irrigation is the responsibility of the Province of Saskatchewan, the final area to be irrigated and the selection of the areas will also be its responsibility.

Power

The Province of Saskatchewan, through the Saskatchewan Power Corporation, will construct and operate the power facilities. At the present time the generating facilities of the Saskatchewan Power Corporation are composed almost entirely of thermal plants and there is no hydro plant in the system. Because there is no hydro plant in the system and because of the flow regulation available from the large reservoir, the hydro plant at this project will likely be used extensively for meeting peak demands. This will dictate the ultimate installed capacity.

After the river basin has been fully developed by upstream users for irrigation, domestic, industrial and power purposes, it is estimated that sufficient water will be available to produce 475 million kwh. annually.

Fig. 2. Typical Annual Hydrograph of the South Saskatchewan River



The wide variation of seasonal flow of this river has made power developments without large storage facilities impractical. The reservoir created by this project will provide almost complete regulation of the river flows and will increase the power potential of downstream sites, where storage cannot be provided at the plant.

Urban Water Supply

The creation of the reservoir will make it possible to provide a controlled flow of water down the Qu'Appelle valley. This will maintain lake levels in the Qu'Appelle valley and provide fresh flows down the Assiniboine River to Brandon and Winnipeg. The cities of Regina and Moose Jaw now pump water from one of these lakes and the project will guarantee and make possible the enlargement of this supply. The reservoir and associated canals will provide a water supply for towns and villages and for domestic and stock water supply throughout the area.

Description of Dam Site

The river valley at the site is about 225 ft. in depth and approximately 2,000 ft. in width at water level and nearly two miles wide at the top. During low flows the stream is much narrower and tends to meander between sand bars. The valley slopes are, in general, about 10:1; they vary from 6:1 to 14:1. Immediately downstream from the proposed fill, Coteau Creek flows into the river from the west. There is a low point between the river and Coteau Creek about two miles upstream from their junction. This is known as Hudson's Bay Coulee. Enclosed in a triangular area between Hudson's Bay Coulee, Coteau Creek and the River is a flat, plateau-like area. This makes it possible to utilize Hudson's Bay Coulee and Coteau Creek valley for location of a remote spillway and, at the same time, to locate the earth embankment in a two-mile stretch of river between Hudson's Bay Coulee and Coteau Creek.

The river bed at the site is underlain by up to 100 ft. of alluvial material consisting mainly of fine to medium sand located in a trough-like depression as shown on embankment centerline profile, Fig. 6. It is believed that at one time the river flowed at the bottom of this trough and has agraded to the present level. The sand is in a medium density state and pumping tests have indicated a permeability of 0.1 f.p.m. Undisturbed sand samples have shown some variations and stratification but, on the whole, the deposit is quite uniform.

The abutments are covered with a variable depth of overburden. Both the abutments and the river bed are underlain by bearpaw shale. This is a soft clay shale of Upper Cretaceous age. While from the geological point it is described as shale, from the engineering standpoint it is no more than hard clay. The material swells and softens in the presence of water and, therefore, the shale surface is softer than the underlying material. Arbitrary zones described as soft, medium and hard have been established to assist in studies. The soft shale is subject to slides and movements and one rather extensive slide area occurs immediately upstream of the site on the left abutment. Very extensive studies have been carried out to determine what slopes will be stable, both from the standpoint of short time construction slopes and long time permanent slopes. Generally, cut slopes in critical areas designed for long time stability are being made as flat as the existing natural stable slopes.

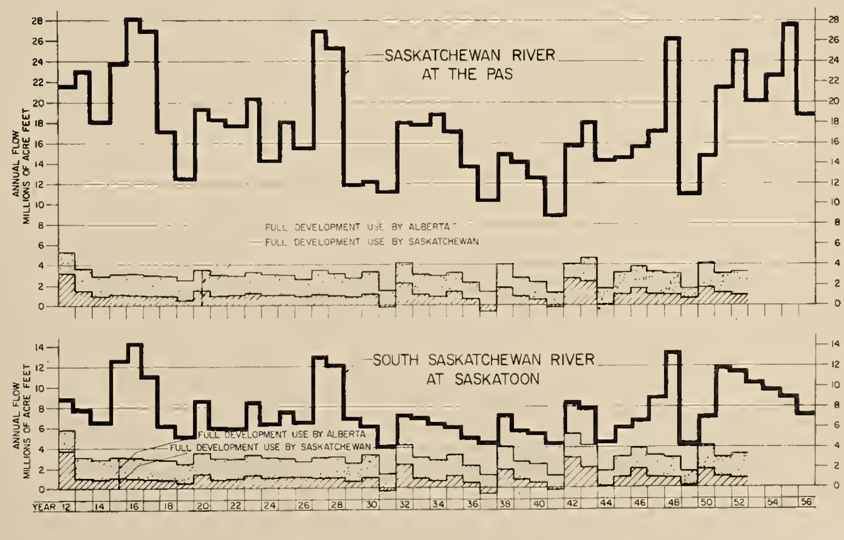
Ample quantities of suitable embankment materials are easily available at the site. The area on the east abutment contains predominantly medium plastic clays suitable for the impervious section of the fill, whereas the west abutment in the plateau area consists mainly of sand and gravel. The pit run sand and gravel is suitable for pervious fill but it requires washing and processing for the filter section and for concrete aggregate.

The Embankment

The embankment is 210 ft. in height and contains about 45 million cu. yd., made up of about one-half impervious and one-half pervious material. It will contain a random section to utilize the miscellaneous materials. The side slopes of the dam are relatively flat in the lower portion. They are about 8:1. These flat slopes are necessary for stability above the river sand in the stream-bed and on the abutments where the soft shale is encountered near the surface. The slopes increase to 2:1 at the crest. The top width is 60 ft. Other important features of the cross-section, which is shown in Fig. 5, are a 1200-ft. upstream impervious blanket, a downstream filter and relief wells. The upstream slope in the drawdown range will be protected by a 3 ft. layer of rock riprap.

The foundations in both stream-bed and on the abutments have been given careful study. Fig. 6 shows a centerline profile with typical test borings. One of the major problems was the type of cutoff through the river-bed sand. Steel sheet piling was first considered but laboratory tests and experience on similar projects have indicated that such a cutoff is relatively ineffective, particularly in a case such as this where boulders were encountered by drilling on the sand-bedrock contact. Consideration was given to a positive type cutoff through the river sand by backfilling a trench unwatered by well points. This was considered both difficult and costly, and probably unnecessary. A final decision was made in favour of a rather extensive upstream blanket. Studies showed that without a blanket the estimated quantity of seepage would be about 20 c.f.s. and that this would be reduced to 13 c.f.s. with a blanket.

Fig. 3. Annual Natural Flows



The steel sheet piling would have little effect on the quantity of seepage unless the interlocks became corroded or were rendered watertight by plugging with clay or silt. To control the seepage, a downstream filter will be utilized and, in addition, relief wells will be placed along the downstream toe. In view of the fact that there appears to be little, if any, sand in a loose condition, stability of the river sand will not be a problem with the very flat slopes on the dam and with seepage pressures controlled by the filter and relief wells.

Stability studies based on the shear strength of the soft surface shale indicate that flat slopes will be required in the shale and on the abutments where shale is exposed. The trim adjacent to the ends of the embankment in the natural shale slopes will be laid out so as not to steepen the existing slopes and, in some instances, flattening will be carried out. Where possible, slope flattening will be accomplished by addition of material in the toe area rather than by excavation of the upper portion of the slope.

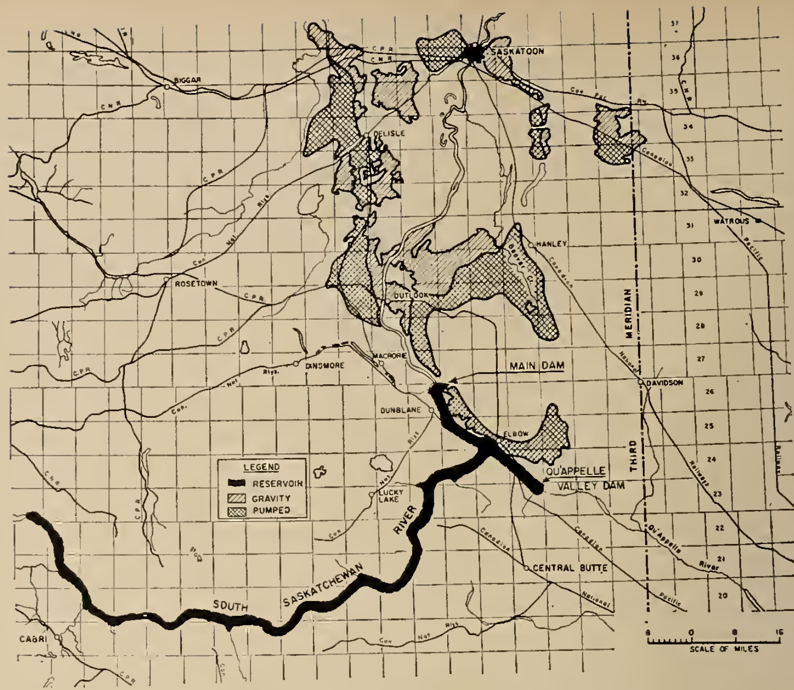


Fig. 4. Map of the Reservoir and the Irrigable Areas

Diversion Structures

In order to construct the closure section of the earth dam in the riverbed, it is necessary to divert the river around the construction area. Because of the large flow to be handled and other difficulties, this has proven to be one of the major site problems from the standpoint of design and cost. Tunnels through the abutments and conduits through the base of the fill have been studied in detail. A decision has now been made to use reinforced concrete-lined tunnels through the west abutment. Five tunnels, 20 ft. in finished diameter, are at present planned. The average length will be 4,050 ft. The tunnels will be located entirely in shale and, in order to have sufficient cover of hard shale above them, the main portion will be depressed about 30 ft. below river level. The profile of the tunnels is shown on Fig. 7. One of the major problems in connection with the diversion structures has been the stability of the cut slopes adjacent to the inlet and the outlet ends. While relatively steep construction slopes will be permitted, final permanent slopes will be no steeper than the present existing slopes in the area.

The tunnels may be used as penstocks for the power plant. In any case, they will probably be maintained as permanent structures and will be used either as penstocks for the power plant or for emergency use or for riparian water discharge. They will, therefore, be provided with a raised inlet and provision will be made to carry water from the river to the inlet through a temporary cut or through tempoary conduits or tunnels. The tunnels will be equipped with control gates located in a shaft near the axis of the dam.

Spillway

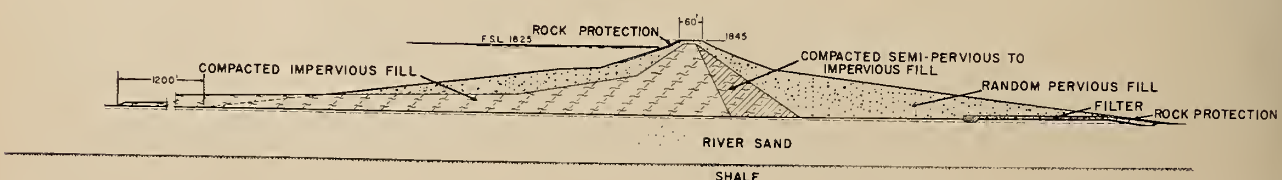
The spillway will be a reinforced concrete chute with a gated crest. it will be about one mile south west of the dam. The inlet channel will be through Hudson's Bay Coulee and the discharge channel will follow Coteau Creek.

The spillway will be designed to discharge a reservoir inflow flood of 400,000 c.f.s. and a total volume of 4 million acre ft. in 16 days, with a pool rise of 5 ft. above the full supply level of the reservoir. The discharge capacity required to meet this condition is 265,000 c. + s.

The spillway chute will be hourglass in shape, 3,000 ft. long, with a gross crest width of 528 ft. The crest will be gated, with 11 radial type gates, each 29 ft. high and 40 ft. long. The chute will terminate in a stilling basin designed to contain and control the hydraulic jump at all discharges.

The lower portion of the spillway will be excavated in the bear-paw shale. Exact final location has not been determined but it will require a deep excavation in the shale. It is planned to make this excavation early in the construction program so that most of the elastic rebound will occur

Fig. 5. Cross-section of the Dam



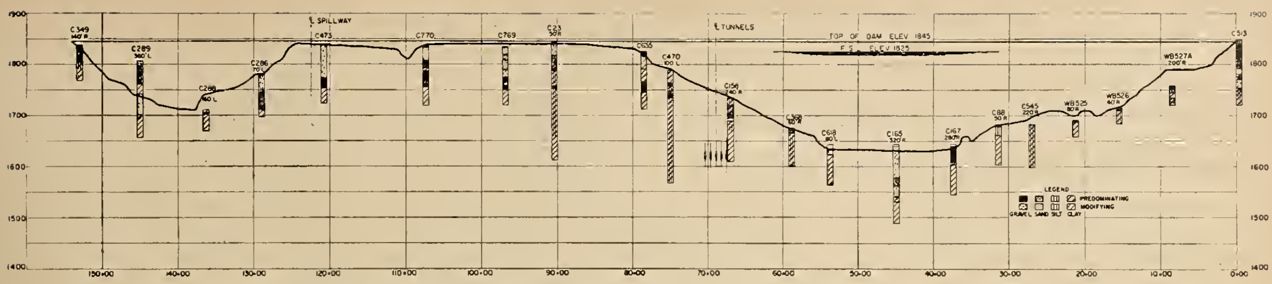


Fig. 6. Centreline Profile showing Typical Test Borings

before the stilling basin is constructed. The stilling basin and any portion of the chute which might be on shale will be securely anchored by concrete hold down piles.

Irrigation Outlets

The water for irrigation will be delivered to the irrigable area in two large canals, one on each side of the river. This will require gated outlets on each side, the design of which is not yet final.

Power-House

In the original planning it was assumed that the tunnels would be converted into penstocks and that the power-house would be located at or near the tunnel outlets, in which case the portion of the tunnels downstream of the gate controls would be lined with steel. More recently, consideration is being given by the Saskatchewan Power Corporation to locating the power-house further downstream and constructing a power canal to transmit the water to the downstream location. Final decision has not yet been made.

Construction

The work of constructing the dam and reservoir will be performed under several unit price contracts of varying magnitude depending on their nature and location. Already several contracts have been awarded for such items as access roads, administration headquarters, concrete aggregate preparation, a construction bridge and the first stages of the embankment construction.

Final river closure will be effected in the section spanned by the construction bridge and the bridge will be utilized for that purpose. River closure is expected in 1963.

It is anticipated that the construction will require seven full construction seasons and, therefore, completion is expected in 1965.

Administration

The agreement between Canada and Saskatchewan provides that Canada will be responsible for all administration and engineering services for the construction of the reservoir. The Prairie Farm Rehabilitation Administration of the Federal Department of Agriculture, with headquarters in Regina, Saskatchewan, has carried out all preliminary investigations and preliminary planning and has been given full responsibility for final design and construction for the Federal Government.

Mr. G. N. Munro, M.E.I.C., is Chief Engineer of the Prairie Farm Rehabilitation Administration and Mr. J. G. Watson, M.E.I.C., is Assistant Chief Engineer and is Project Engineer for the South Saskatchewan River dam. Mr. R. Peterson, M.E.I.C., Chief of the Soil Mechanics and Materials Division of the P.F.R.A., is responsible for all investigations and plans and specifications pertaining to design and specifications of the fill and the foundations. Original design was carried out under the direction of the late Mr. G. W. Parkinson, M.E.I.C., and Mr. W. M. Berry, M.E.I.C., is now in charge of the design of all structures. Mr. W. B. Thomson, M.E.I.C., is engineer in charge of construction.

Paper presented at the Regional Meeting of the Engineering Institute of Canada in Ottawa, October, 1959.

The council of the Corporation of the City of Ottawa early this year authorized the commencement of the design of the first stage of a pollutional control program for the City and surrounding area, including intercepting and sanitary trunk sewers, and a sewage treatment plant of the primary type with sludge treatment—a program estimated to cost approximately $21 million, of which the expenditure on the plant represents about 40% of this amount. The plant is designed to treat raw sewage at the rate of 40 million gal. per 24 hr., such flow deriving from an estimated population of 375,000 persons anticipated by 1975, but with provision for expansion to ultimately serve 590,000 persons, considered to be the eventual population resident within the green belt in the Greater Ottawa Area. Initially the plant will provide only primary treatment but will be designed to be extended at a later date to give complete treatment of the activated sludge type to all tributary flows.

This paper describes in general the sanitary engineering design of the plant and the detailed design of the first phase of the work—the main pumping station. The problems associated with the design of a 75 ft. deep main pumping station insofar as they relate to soil conditions, structural, mechanical and electrical treatment, are described and the actual designs employed to meet the conditions are outlined.

IN JANUARY of 1958 the Council of the Corporation of the City of Ottawa authorized our firm "to carry out the required services necessary to determine the volume of sewage now to be treated in the City of Ottawa, the solids and B..O.D. contents of the sewage, the estimated flow at present and ultimately, the supervision of borings and all other matters necessary to determine the design and estimated cost and to furnish a report accompanied by such preliminary plans as would enable the City to submit to various authorities applications for approval" with respect to the proposed Ottawa Sewage Treatment Plant. Similarly Council authorized others to prepare a report on the proposed Ottawa River Interceptor and Outfall Sewer.

The foregoing authorizations resulted from the insistence by the Ontario Water Resources Commission that the City take immediate action to control the discharge of sewage and industrial wastes from its sewerage system to the Ottawa River. Such decision was based on the pollutional survey of the River carried out by the Commission in 1955 and later referred to in this paper.

After six months study these reports were presented to the Council and in January of this year the design of the first stage of these works was authorized. The current authorization for the design of the sewage treatment plant applies to the main pumping station. It is to the design of this station that the greater part of this paper is devoted. For clarity, however, a complete description together with design factors of the sewage treatment plant as initially planned is presented.

Tributary Area and Population

The tributary area to be served by the Ottawa Sewage Treatment Plant can be best described as the inner limit of the "Green Belt" area proposed by the National Capital Commission. Although such limit at the time of making our report was only proposed, the Memorandum On Boundaries And The Use Of The "Green Belt" prepared by the previous Federal District Commission stated "that the limits of the Belt had been set so as to permit the extension of the Metropolitan Core to the practical economic limit of all municipal sewer and water services". Accordingly, it was only reasonable that it be used in defining the limits of the area to be ultimately tributary to the proposed sewage treatment plant.

Studies indicated that eventually the tributary area could be divided into fourteen separate tributary sections, as set out in Fig. 1. The boundaries of these sections are fixed by the actual layout of the sewers, where these were already in existence, and by general topography in areas which are not yet sewered. It includes a total of about 39,500 acres, including all of the City of Ottawa, the Town of Eastview and the Village of Rockcliffe Park and portions of the Townships of Nepean and Gloucester.

A study of the existing land use of the tributary area was made from up-to-date aerial photography, augmented by on-site surveys where necessary, and as a result it was determined that the area contained in 1958 a population of approximately 257,000 persons or about 43% of its estimated ultimate development. It was obvious that the greatest concentration of population lay within the old City Limits and in Rockcliffe Park and Eastview, and that future growth would be concentrated for the most part in the more recently annexed areas of the City and in the tributary sections of Gloucester and Nepean Townships.

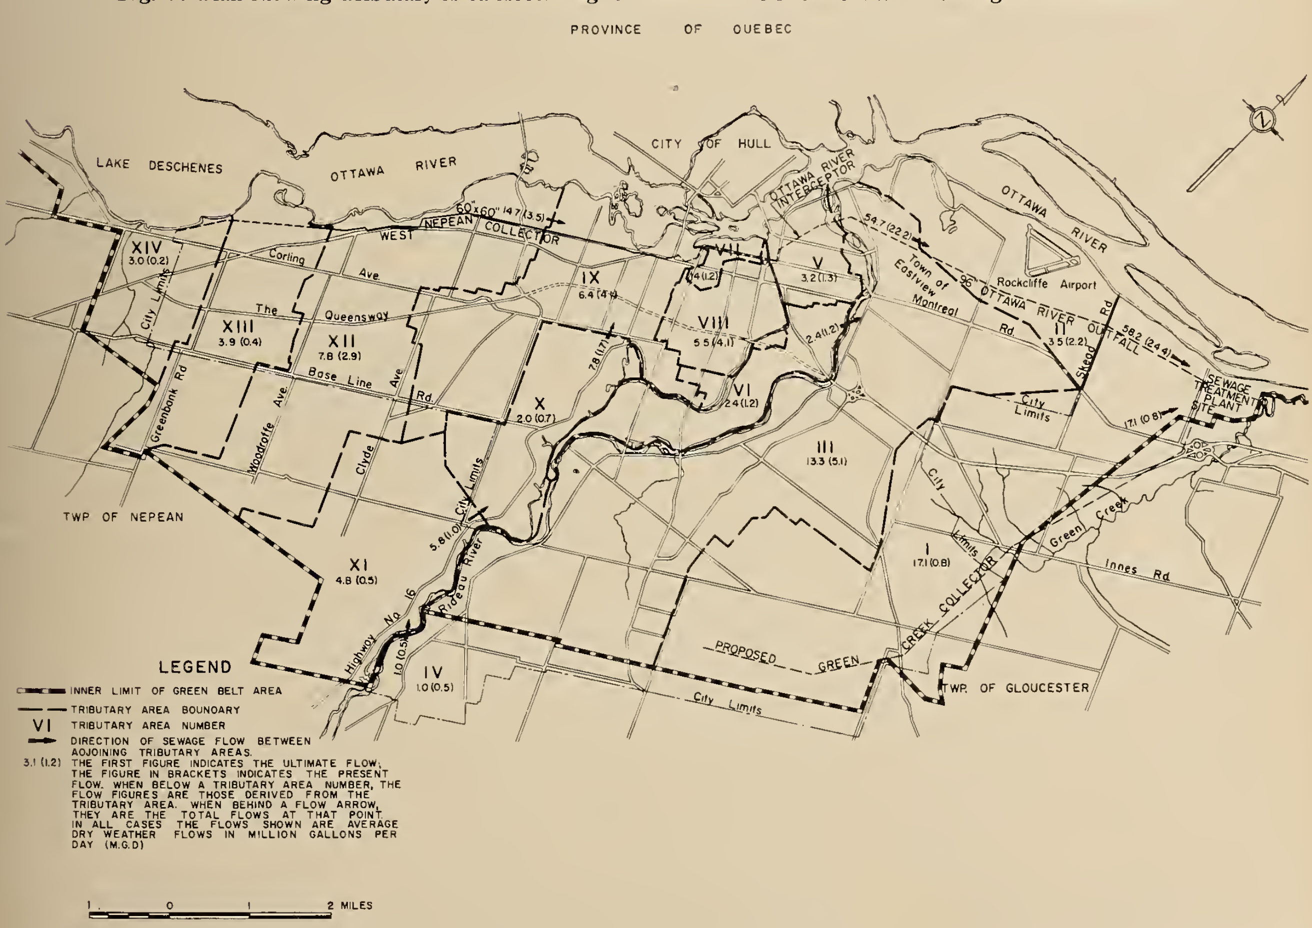
In order to properly assess ultimate sewage flows it was found necessary to compile an ultimate land use plan. Zoning by-laws prepared by the Planning Board of the City of Ottawa formed the basis of this analysis, together with information furnished by the National Capital Commission. From the foregoing, present and ultimate land use tables for the tributary area were prepared with division according to residential, commercial, industrial, park land, special use, institution, road, government buildings and vacant land acreages. From these land use studies and on the basis of previous studies in the area including works carried out by the City Assessment Department, the City Department of Planning and Works, and the National Capital Commission, a forecast of population growth for the tributary area was compiled. This indicated that a population of 375,000 might exist in the area under study by 1975 and that it was possible for an ultimate population of almost 600,000 people to be resident within the area, representing a gross density of approximately 15 persons per acre.

Design Flow and Sewage Strength

The land use divisions outlined above corresponded with records of the sale of metered water maintained by the City Water Department. It was also possible from the water meter records to determine the anticipated unit sewage flows on an area basis for each type of use, both now and in the future.

Then from the foregoing ultimate land use acreages and the acreage rates of sewage discharge for various pursuits, the sewage flows for present, near future and ultimate conditions were estimated. In an effort to obtain reliable infiltration allowances to use in establishing the estimates, to provide an approximate check on them, and to ascertain the approximate strength of the sewage to be treated, gauging and sampling were carried out in the Rideau Canal Sewer and the John Street Sewer, two main sewers in the City of Ottawa. The results proved most valuable and considerably strengthened the reliability of the estimates. On the basis of these studies it was apparent that if all developed sections of the tributary area were currently serviced an average sewage flow of 25 million gal. in 24 hr. would obtain approximately 97 gal. per capita per day. On the basis of ultimate development, however, a flow of 75 million gal. daily was indicated derived from a population of 590,000 persons and representing a daily per capita flow of 127 gal. indicating the anticipated increasing use of water and certain industrialization in the future Ottawa. Accordingly, in view of the existing and estimated ultimate populations of the area and the present and forecasted sewage flows, it was recommended that initially a plant capable of treating a daily average flow of

Fig. 1. Plan showing Tributary Area According to Sewer Districts to the Ottawa Sewage Treatment Plant.



40 million gal. of raw sewage derived from an estimated population of 375,000 persons be constructed.

On the basis of sewage analysis carried out and assuming future regulation under a municipal sewer ordinance of industrial waste discharges that might develop, it was recommended that the plant be capable of treating sewage having an average Biochemical Oxygen Demand (5-day) of 200 parts per million and an average suspended solids content of the same value. It was estimated that the tributary population would be in existence by 1975, and accordingly it was recommended that the plant be so laid out that it could be extended in two further stages to an ultimate capacity of 75 million gal. per day. Studies carried out indicated that such flows would reach the plant through the immediately proposed Ottawa River Outfall Sewer and the future Green Creek Collector and that on the basis of ultimate average flow 58 m.g.d. would be derived from the former and 17 m.g.d. from the latter.

Peak flows will vary for each since the Ottawa River Interceptor will intercept primarily the old combined sewerage area of the City while the Green Creek sewer will serve entirely a separate sewerage area.

The cost of works to provide for the treatment of large storm flows would be prohibitively expensive even if treatment of such large volumes of diluted sewage flows were scientifically feasible, and a study of the flow to be provided for in the combined sewerage area, having regard for this cost, indicated that a peak flow of 2.5 times average dry weather flow is the most feasible and practical. The amount of raw sewage escaping to the river under these conditions would be 2.2%.

On this basis and allowing a peak of 1.7 times average dry weather flow for the separate system an overall ratio of peak flow for treatment to average D.W.F. of 2.2 was derived.

Plant Site

The site of the sewage treatment plant had been previously discussed in a report rendered to the City some 11 years ago. This report noted that the logical site for a sewage treatment plant was the broad expanse of flat ground bordering the right bank of the Ottawa River between the proposed railroad and highway bridge over Duck Island on the west and Green Creek on the east. The site lies in the extreme north-east section of the urban area and is favourably located in respect to the latter. Also it offers a favourable point from which to dispose of treated sewage into the Ottawa River. The site is readily accessible and yet is well removed from all existing or probable populous areas.

Acting on the basis of that initial report the City made application some years ago to the Ontario Department of Health for permission to construct the proposed plant on a site of 320 acres in the indicated location in Gloucester Township.

Our review of that proposed site, which the City had previously purchased in part, indicated that only one alternative site could be considered at all feasible. This area which was to the west of the proposed site was however found to be impractical for development because of its location in line with Rockcliffe Airport runway, and the restriction imposed on the sludge, grit and screenings disposal by the adjacent residential development. Having in mind all aspects of the problem, even including soil conditions, the site currently owned by the City on the northwest bank of Green Creek adjacent to the Ottawa River was without question the most suitable in all respects for the establishment of the proposed sewage treatment Plant.

The Receiving Body—Ottawa River

A study of the hydraulic data on the Ottawa River furnished by the Federal Department of Northern Affairs and Natural Resources indicated that in the area of the proposed plant location an annual mean flow in the Ottawa River of 50,000 to 60,000 c.f.s. could be anticipated, with a mean low month flow of 30,000 c.f.s. generally obtaining. On the basis of such figures and the dilution offered to a plant effluent of the volume anticipated, it was obvious that at least initially, only a plant of the primary type for the treatment of municipal sewage comprising sedimentation and chlorination would be practicable, with complete treatment to be anticipated at some time in the future.

This was confirmed by studies carried out by the Ontario Water Resources Commission in 1955. In this study, bacterial counts as high as 100 times the maximum objective of 2400 coliform per hundred millilitre sample were recorded in the Ottawa River despite the heavy dilutional flow of the river. In addition, biochemical oxygen demand as high as 28 parts

TABLE I
BASIC DESIGN DATA

ESTIMATED FLOW (million gallons per 24 hours)

	Immediate	Initial Design	Ultimate Design
Population	258,000	375,000	590,000
Average Flow	25	40	75
Maximum Monthly Flow	31.3	50	93.8
Maximum Peak Hour	58.0	88.0	156.0
Minimum (for less than 1 hour)	15	24	45

ESTIMATED SEWAGE STRENGTH

	Raw Sewage ppm	Primary Percentage Removal	Treatment Settled Sewage–ppm
Suspended Solids	200	53	94
Biochemical Oxygen Demand	200	32	136
Grease (ether soluble)	60	50	30

SLUDGE DIGESTION

3 tanks each 110 ft. dia. x 24 S.W.D.
Total volume . . . . . 684,000 cu. ft.
Unit volume per capita . . . . . 1.83 cu. ft.
2 primary tanks, 1 secondary tank. All tanks have fixed covers. Separate spherical holder for gas. Gas recirculation on primary tanks.
Approximate detention at 375,000 persons . . . . . 40 days

PRIMARY SETTLING TANKS

6 units, 37 ft. wide, 10 ft. swd., 180 ft. long
Total volume . . . . . 400,000 cu. ft.
Retention at 40 mgd . . . . . 90 mins.
Surface loading at 40 mgd . . . . . 1000 gpd./sq. ft.
Weir overflow rate at 40 mgd . . . . . 21,200 gpd./lin. ft.

SLUDGE DISPOSAL

Complete lagooning of sludge.
30 month retention.
Initial depth of lagoon . . . . . 4 ft.
Approximate acreage for 375,000 persons 30

PRE-AERATION AND GRIT REMOVAL

2 units, single pass, each unit 180 ft. overall length, 15 ft. S.W.D., 30 ft. width
32 ft. of length for grit removal
148 ft. of length for pre-aeration
Total volume for pre-aeration . . . . . 66,600 cu. ft.
Retention time at 40 mgd . . . . . 30 mins.
Air supply at 40 mgd . . . 0.065 cu. ft./gal.

CHLORINATION

Prechlorination, Post chlorination, Sludge chlorination 4 units at 8000 lbs./day
1 unit at 2000 lbs./day . . . 34,000 lbs./day
Dosage at 40 mgd. at 20 ppm . . . . . 8,000 lbs./day
Detention in outlet at 88 mgd . . . . . 7 mins.
Detention in chlorination chamber 10 mins.

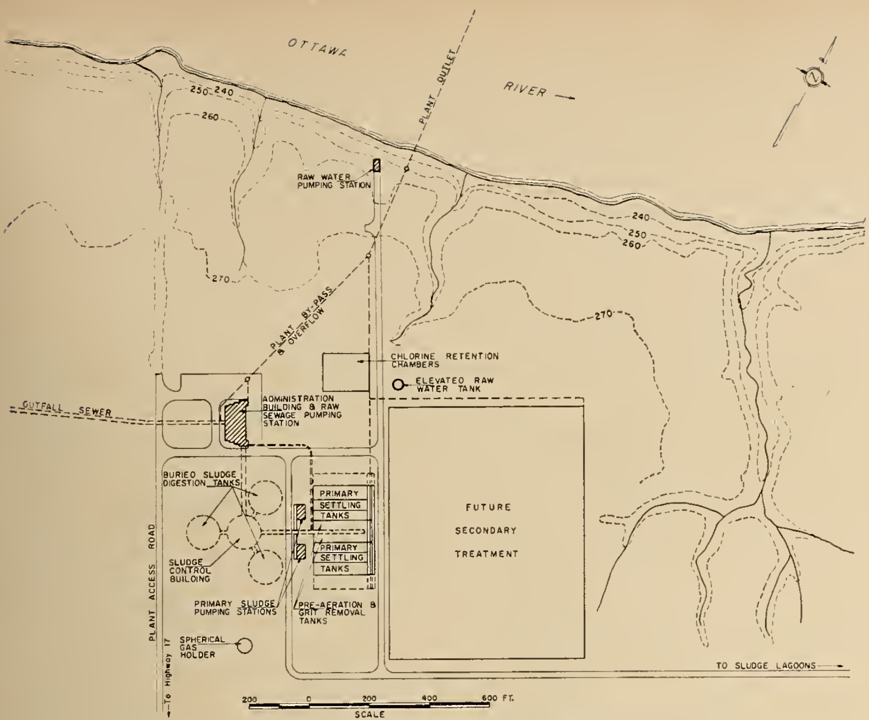


Fig. 2. Main layout of Ottawa Sewage Treatment Plant.

per million was encountered in the Ottawa area, representing a waste strength of almost 20% of normal domestic sewage, despite the dilutional effect of the flow. Indeed, the Ontario Water Resources Commission stated that taken altogether the results of the analysis conclusively indicated that the Ottawa River below Chaudiere Falls was quickly transformed into a heavily polluted river.

Further, the report indicated that the heavy discharges of untreated sewage and industrial wastes in this stretch of the river had rendered the water unsafe for use as a public water supply without complete treatment and hazardous for recreation and fish life. It is interesting to note however, that it did indicate that at least 80% of such pollution was due to the potential waste discharged by the pulp mills located on the Quebec side of the river in the Ottawa area.

The report of the Ontario Water Resources Commission recommended that remedial measures be undertaken in the Ottawa area without delay and that these measures must be sufficient to restore and protect the uses of these waters to which the people of both provinces were rightfully entitled. It further recommended, that treatment of municipal sewage by sedimentation and disinfection of the effluent be undertaken immediately to be followed by a biological process to complete the task at a later date.

Initial Plant

Accordingly, after a complete review of the data on hand and the conditions obtaining in the area our firm recommended that ultimately a complete treatment plant of the activated sludge type be installed by the City, but that for the present only the primary treatment portion of this plant including sedimentation and chlorination be built. Later, with the implementation of a pollutional control program on the Quebec side of the river thereby giving all waste discharges at least primary treatment prior to discharge, it would be possible to re-evaluate the condition of the river and determine when complete treatment had to be adopted by all concerned.

Ultimately the City Council acting on the recommendation of Board of Control decided that the plant should be built as a primary type as recommended with provision included for expansion to treat increased flows and to provide biological treatment through the use of the activated sludge process.

Basically, the Outfall Sewer was to parallel the Ottawa River picking up the main points of existing discharge from the City of Ottawa and carrying the flows to the plant site immediately west of Green Creek on the bank of the Ottawa River. As previously indicated this interceptor would carry an average of 58 m.g.d. or approximately 75% of the ultimate sewage flow to the plant.

It became obvious however that in order to carry sewage to this point and pick up all present and future discharges by gravity the sewer would terminate on the plant site at an elevation of approximately 108 (Geodetic Datum) as compared to a grade on the proposed site of the plant varying between elevation 160 and 170 and a variation in river level itself of elevation 130 to 140. In this situation, one of the major recommendations of the report was therefore the construction of a raw sewage pumping station on the proposed site which would include coarse and fine screening equipment and raw sewage pumps to lift the sewage to the treatment units. It was proposed that following this station pre-aeration with grit removal would be installed, the sewage flow passing on to primary sedimentation tanks equipped with grease collection and sludge removal equipment, the effluent to be eventually discharged to chlorine retention chambers where it would be chlorinated prior to discharge to the Ottawa River at depth through a plant outlet sewer. Sludge removed from the primary sedimentation tanks was proposed to be digested and lagooned in the large areas available at the site for ultimate disposal as a soil conditioner.

The disposal of the solids removed as sludge in the primary settling tanks of the Ottawa Sewage Treatment Plant represents a most costly portion of the project and that which might be termed the most difficult. Because of being highly putrescible, this sludge could be a serious nuisance to the successful operation of the plant unless properly disposed of.

The purpose, therefore, of processing and disposing of the sludge is to render it unobjectionable and to dispose of it sufficiently rapidly to prevent its excessive accumulation, by reasonably economical methods.

A common idea in the public mind is that fertilizer that can be produced from sludge through vacuum filtration and heat drying will sell on the market at a sufficiently high price to offset considerably the cost of sewage treatment. Nothing could be farther from the truth. An economic study indicated that the cost of filtration and heat drying of sludge for Ottawa would exceed $35 per ton of heat-dried sludge such price including capital and operating charges. At present the best price obtainable on the Ontario market for heat-dried primary sludge is $8 per ton and no fertilizer manufacturer has yet offered a contract based on accepting all plant production. Indeed, across the continent the price for heat-dried sludge has varied so radically and on the whole reduced so substantially in recent years that it is doubtful whether there is a single plant to-day that could not embark on a cheaper process. In such circumstances, the field has been attractive to proponents of the Zimmerman process, a wet oxidation process now being installed in Chicago, and the Atomized Suspension Technique now in operation in at least one municipality in Quebec. These methods represent sludge destruction processes on the whole and only the latter in our opinion shows merit for future application providing its operating costs can be maintained at the level now estimated by the manufacturers. In any case, the A.S.T. process would cost at least $32 per ton of dry solids treated to install and operate.

Accordingly, the digestion of raw sludge under controlled temperature conditions (90°F) thereby reducing, through the action of bacteria gaining their oxygen for their metabolism from the organic content of the sludge, the quantity of sludge from 50% to 60% of the original amount and liberating through this action sufficient gas (Methane primarily) to heat the plant is in our opinion the cheapest and most practicable sludge treatment to be followed in Ottawa. Digested sludge would be dewatered in sludge lagoons located on the plant site to a final moisture content of 40% and be finally disposed of to the parks boards and private homeowners as a soil conditioner. Disposal costs on such basis would be less than $22 per ton treated, including capital and operating costs, and the plant would still be able to adapt to one of the newer processes if and when its economy could be proven. Accordingly, our recommendations on sludge digestion and lagooning have been accepted.

It is not the purpose of this paper to deal in detail with all the various units and equipment that will be included in a plant of this size. As yet the work authorized embraces only the design of the raw sewage pumping station and accordingly, the remainder of the paper will deal in detail with this station. However, to clarify the matter of the design of the proposed plant, Table 1 indicates the design factors of the various phases of the plant as intended, and Fig. 2 outlines the main layout of the plant as proposed.

Soil Conditions

Prior to March, 1958, no extensive investigations had been made in the relatively level area east of Skead Road between Montreal Road and the Ottawa River;[1] consequently no information had been recorded which afforded assistance in establishing reliable criteria for the detailed design of the structures to be built in the first phase of construction of the Sewage Treatment Plant or indeed for the preliminary design of the remaining structures to be built in subsequent phases of construction of the Primary Treatment Plant and its extension as already described to provide additional facilities for complete treatment.

A study of the geological history of the area revealed that glacial ice had covered the entire region including the basic rock formation. As the ice receded it left behind a thin layer of till above the bed rock. Subsequently, the sea covered the area and deposited clays in the valleys over the glacial till. These preliminary studies emphasized the importance of a carefully planned and properly executed program of subsurface investigations.

The soil conditions at the plant site, as shown by the preliminary subsurface investigation carried out during March and April 1958, can be described in a general way. A thick deposit of blue clay known locally as 'Leda' clay overlies a thin layer of boulder till with bedrock beneath. It is probable that the ground water varies from the surface to a depth of 10 ft. below. The adjacent Ottawa River water level varies from about 25 ft. to 45 ft. below the ground surface elevation at the site of the deep sewage pumping station.

The 'Leda' clay is highly plastic, compressible although preconsolidated, generally stiff, very sensitive, with some organic layers. It loses almost all its strength or stability when disturbed, remoulded or reworked, indeed to the extent of becoming semi-liquid. Its thickness varies from 50 ft. to 100 ft., and its surface is most susceptible to gullying.

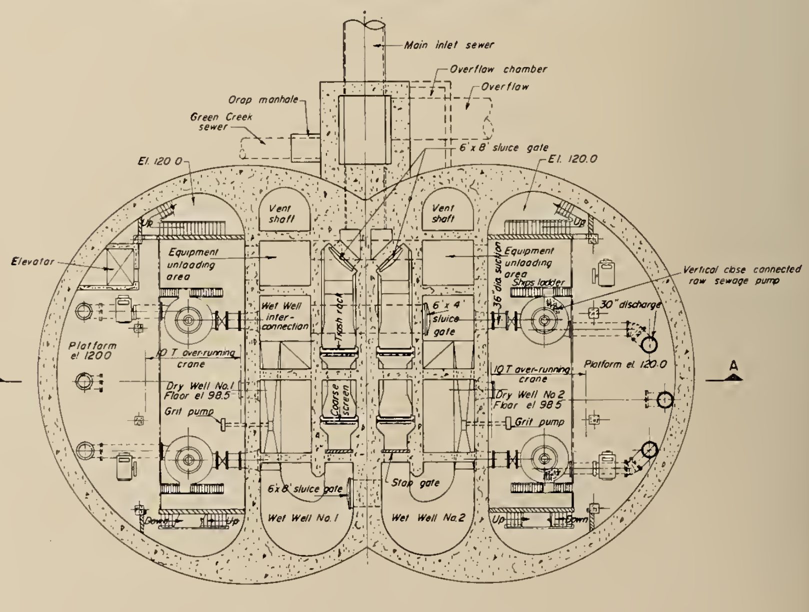
The underlying glacial boulder till is a mixture of silt, sand, gravel and boulders with densities varying from loose to very dense and may contain sand or gravel water bearing layers. The thickness of the till varies from a few feet to a maximum of 15 ft.

The bed rock is Dolomite of the Oxford formation which is generally massive with its top layers weathered. The rock surface is between 85 and 100 ft. below grade.

During construction the control of ground water will be a major consideration, especially in the excavation for the deep raw sewage pumping station. The possibility of small acquifiers in the clay cannot be overlooked. It is probable that the till and upper layers of the bed rock may be carrying water under a head which would lead to uplift and piping in the bottom of the 80 ft. deep excavation.

In the above noted deep excavation the problem of bottom heave will be met. This means that a condition exists whereby the clay has insufficient shear strength to resist the effect caused by the adjacent head of clay outside the sheeting imposing a load on the bottom of the excavation tending to heave it upward.

Fig. 3. Plans of Raw Sewage Pumping Station.



PLAN ABOVE ELEV. 120.0

Special consideration is required in the problem of placing backfill around structures.

Limitations are placed on methods available for piled foundation treatment when considering the type of till material through which piles are to be placed.

Because of the nature of the sensitive clay an accurate determination of its bearing capacity will be required for the construction in the future of the hydraulic structures not founded on rock. Total settlements, heaving and differential movements must be estimated to permit the design of these structures.

Due to the susceptibility of the soil to gullying, special precautions are being taken in the design of the surface drainage system for the entire site.

Following the preliminary soils investigation the locations of the various structures were accurately determined, and having regard for the unusual soil conditions, foundation elevations were set. When the field survey grid lines were laid out on the site, a detailed subsurface investigation program was planned. Owing to the importance of soil conditions at this site, it was decided to have a review made of the preliminary findings by an internationally renowned engineer specializing in the soil mechanics field, and to seek confirmation of the proposed detailed investigation. Accordingly, Dr. A. Casagrande of Cambridge, Massachusetts, was consulted in March, 1959, by the soil consultants and ourselves, and a basic detailed investigation was established embodying the use of piston type samplers, drilling mud and the obtaining of 3½ in. or 4 in. diam. clay samples. It is considered that the larger diameter should be used to obtain the best quality of samples in view of the sensitivity of the clay involved. Two large boreholes are to be put down at the site of the raw sewage pumping station to extend through clay, till and into the rock to investigate the thickness and character of the till soils and the elevations of the rock. In addition, a test well will be drilled into the rock and pumping tests performed, using adjacent holes as observation wells. This test will determine groundwater conditions and assist in evaluating the effectiveness of dewatering during construction by deep well pumps. The balance of the final investigation consists of the normal procedures of drilling, sampling and analysis of the soil conditions at the locations to be occupied by the sludge digestion tanks, the sedimentation tanks, the future aeration tanks, the raw water pumping station and the marine section of the plant outlet in the Ottawa River. This program is now well underway and the information obtained is being used as confirmation or revision to design criteria adopted as a result of the initial program findings.

Raw Sewage Pumping Station

General: As in the case of many of the larger sewage treatment plants, the raw sewage reaching the plant from the Ottawa River Outfall Sewer must be lifted from a considerable depth below ground to a sufficient height above ground level to permit the establishment of treatment units at an economical level.

The cost of the pumping station and the power costs for pumping are both functions of the depth of the station, and an increase in depth shows a corresponding increase in the costs of both of these items. On the other hand an economy can be effected in the cost of the incoming sewer by increasing its depth at entry to the station and thereby increasing its grade and reducing its diameter.

A study was carried out to determine the optimum depth of the pumping station, and it was established that an economical balance would be reached using an 8 ft. diam. sewer with an invert elevation of 108.0 and a wet well established 10 ft. below this point to maintain a low pump suction head under all conditions of operation.

The layout as shown in Fig. 3. and Fig. 4. is based on the use of divided wet wells so that the plant may continue in operation while one well or its screen chamber is shut down for cleaning. Facility will be provided for cleaning out all screen and wet well chambers with motor operated clam buckets carried on crane rail units. Also small independent sump pumps will be installed in the wet wells to permit the drainage of the lower levels of the pump sumps.

A vertical overflow shaft and conduit will be provided at the entrance to the screen chambers which will be capable of diverting excess flow over and above that which can be handled by the pumps and will further provide relief for any surge condition which might arise in the event of a sudden shut down of the pumps. This shaft has also been sized to facilitate the extraction of the tunnel shield which may be used in the construction of the incoming sewer.

A full stairway and elevator system will be constructed from the lowest point of the dry well to the highest floor. High capacity submersible sump pumps will protect the dry wells from flooding.

On the main floor level of the station will be located the entrance lobby, the chlorine storage room, and the plant personnel room. Administration and laboratory facilities and the control room will be located above the main floor level at one end of the building with the chlorine equipment room and potable water treatment unit at the other end.

Intermediate floors below ground level will contain the screening room, the electrical switchgear and transformer rooms, and the boiler and air conditioning rooms.

Structural: From the foregoing it is apparent that the station will extend to a depth of approximately 80 ft. below ground level.

In view of this considerable depth, the unusually sensitive nature of the Leda clay, and the high water table of the site, some careful thought was given to produce the particular structural pattern best suited to the environment. The design problems which these factors present could not be separated from the problems which might be met during construction.

The possibility of performing the excavation in opencut with stable side slopes was investigated and ruled out on the basis of economy—being extremely expensive because of the very flat slope of the Leda clay, and the unsuitability of the clay as a backfill material necessitating the use of large quantities of imported fill. It was therefore decided to base the design on a braced, sheeted excavation.

The problem of whether such a station can be more economically designed on a circular rather than a rectangular plan was examined. Recent designs at Pittsburgh and Philadelphia on similar projects have employed the circular design in order to avoid extensive cross bracing of the primary lining prior to concreting and to maintain wall thicknesses within reasonable limits.

In the Ottawa station the rectangular plan proved to be unsuited to the clear, unobstructed layout envisaged for the dry wells, since the wall thicknesses could only be kept reasonable by "compartmentalizing" the structure in an endeavour to reduce the unsupported spans.

The better layout afforded by the circular plan and the constructional advantages of circular sheet piling influenced the choice of the present layout of two intersecting circular cells.

The walls of the structure have been designed to resist earth pressures calculated with a coefficient of unity and a unit weight of 105 lb. per cu. ft., as these loadings closely approximate the maximum loading conditions of disturbed Leda clay. The wall thicknesses were so calculated that the line of thrust of the earth pressure passes through the middle third of the section. The central division wall separating the two wet wells is reinforced with structural steel to withstand the large unbalanced thrust at the common chord of the two cells.

Unfortunately, under all practical locations for the pumping station, it was not possible to base the floor of the station on rock. In its present location preliminary soil explorations reveal that the underside of the slab will rest on or near the till layer which extends approximately 15 ft. above the rock. Despite the varying densities of the till soils and the possible disturbances which may occur during construction, it is felt that these soils are suitable material for the support of the normal foundation loadings. However, taking into account the considerable concentrated loads which are carried down the main walls of the structure, causing high differential pressures on the base, the present intention is to take the wall loadings directly to rock by means of short bored concrete piles, and to allow the base slab to span between the main walls of the structure.

In view of the high ground water table the hydrostatic uplift on the structure constitutes a major problem. A method of anchoring the structure to the underlying rock by means of prestressed cables encased in bored concrete piles was thoroughly investigated. By this method it was intended to take the full weight of the structure on bored piles arranged around the perimeter and along the central division wall, while the uplift would be taken by the prestressed anchor piles located uniformly over the base of the structure. The cables of the prestressed anchorages would be grouted into the rock for approximately 30 ft. and would of course be protected from corrosion in the till by the concrete surround.

Despite the apparent suitability of the conditions for this application of stress anchoring, it was estimated that the most economical method in both time and money was to add positive weight to the structure by increasing the thickness of the base slab, which will also be capable of withstanding full hydrostatic uplift.

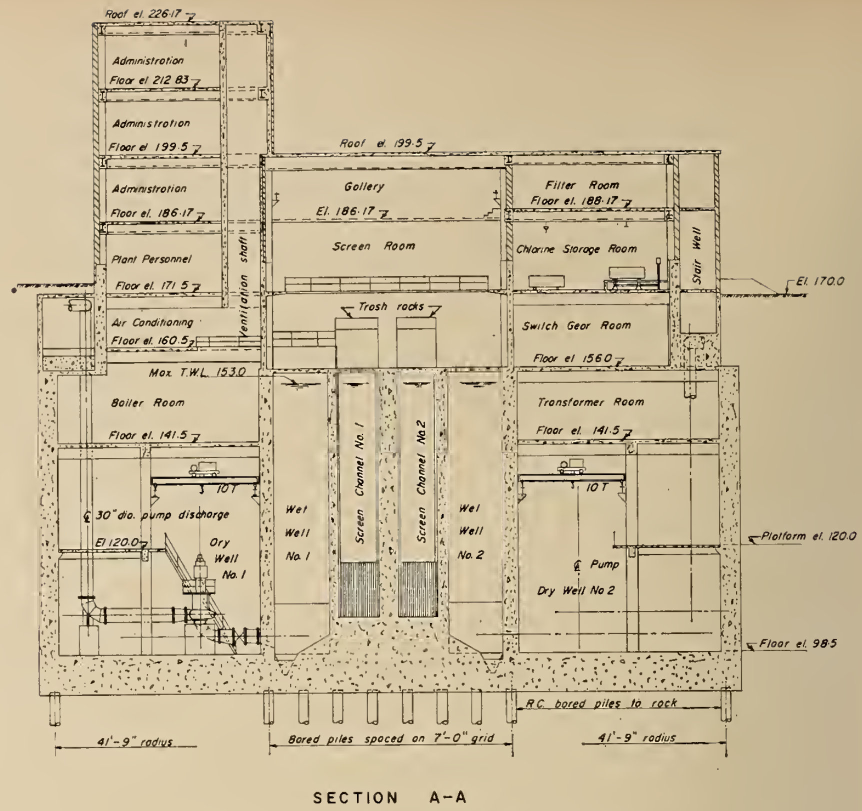


Fig. 4. Sections of Raw Sewage Pumping Station.

Mechanical: (i) *Pumping Units*—Present day practice in major sewage stations demands that the pumping rate be matched within reasonable limits to the sewage inflow in order to minimize the size of the wet well and to maintain a reasonable treatment efficiency. To accomplish this, a varying discharge from the wet well is necessary in order to hold the inflow level to the station as close as possible to the theoretical flow depth in the incoming sewer. Furthermore, facilities for recycling must be provided to ensure that when additional pumping units come into operation there is no sudden large increase in the rate of discharge.

In this instance, a preliminary study was carried out to ascertain whether a matched pumping rate could be maintained by means of pumping units with manually controlled constant speed drives, having regard for the storage capacity of the wet well and the incoming sewer. It was found, however, that flow conditions could not be satisfied and good velocities maintained at the same time without the use of an uneconomically large number of small pumping units.

Accordingly, it was decided to use close coupled vertical centrifugal pumping units employing any one of the three following methods of speed control to permit stepless variation in pump flow capacity within reasonable limits:—

(a) Wound rotor commutator motor, with Induction regulator speed control;

(b) Synchronous or Induction motor with magnetic drive coupling controller;

(c) Wound rotor motor with liquid slip resistance for speed control.

In order to facilitate the selection of one of these combinations, the supply of pumps and drives will be the subject of a separate contract, and the bids will be adjudged with due regard to the overall line to water efficiency as well as to capital cost.

The controllers on the variable speed drives will be actuated by wet well float controls on a recycle program in a similar fashion to that employed recently at Boston and New York.

(ii) *Piping, Valves* — Each pump unit will be equipped with a separate discharge main, and to prevent backflow to any unit out of service gooseneck siphon discharges are provided on each main. With this arrangement expensive check valves on the discharge mains will not be required. The pump discharge is extended above the level in the outlet conduit, then turned down and terminated below the minimum water surface in the discharge conduit.

During the pumping period the goose-neck acts as a true siphon and the static head is measured to the water surface in the discharge conduit. A solenoid operated gate valve is provided at the highest point of the goose-neck to automatically admit air and break the siphon when the pump is stopped.

When the pump has stopped there will be a tendency for the liquid remaining in the vertical limb of the discharge main to return through the pump to the wet well. The impulsive force caused by the sudden change in direction of flow might lead to serious damage to the impeller, and consequently the pumps will in this instance be equipped with a device to prevent reversal of the impeller.

(iii) *Screens and Grinders*: In each of the two screen chambers will be installed one coarse rack with 3 in. spacing followed by one bar screen with 1 in. spacing. Both trash rack and bar screen will be equipped with mechanical back cleaning equipment. Because of the great depth of the screen channels, the vertical type of screen must be used even though the inclined type would provide more efficient screening.

Under normal operation the screenings are collected at the head of each screen and fed by conveyor to a rotary shredder. All shredded screenings will be returned to the flow ahead of the screens.

As an alternative means of screenings disposal the screenings may be collected in tipping buckets located at the head of each screen, and removed by overhead crane to a main container which will be carried to the disposal point by a dump truck.

(iv) *Chlorination Equipment*: Chlorine will, in this first stage of the plant, be applied to the raw sewage immediately before the bifurcation point at the entrance to the wet well. This will also serve as a prechlorination point at a later stage when the primary treatment units of the plant are completed.

Five vacuum type solution-feed chlorinators will be installed in the chlorine equipment room, four rated at 6000 lb. per day per machine and one at 2000 lb. per day. The large machines will have an ultimate capacity of 8000 lb. per day and together with the small machine will be capable of providing for the present minimum and ultimate maximum flows. Three 8000 lb. per day evaporators will be provided to work in conjunction with the above equipment. All chlorinators will be completely manual in operation.

Chlorine cylinders in the storage room will be handled by means of a 2 ton monorail.

(v) *Heating, Ventilation and Cooling*: The plant heating system will be established in the boiler room of the pumping station and in this first stage two steam boilers will be installed. These will be suitable for gas or oil fuel and each will have a capacity of 10,000 lb. of steam per hr. Steam lines will radiate from this point to all heated areas and building heat will be through steam operated unit heaters.

The dry wells of the pumping station will be fitted with humidity control equipment for protection against corrosion through condensation of the main pumping equipment and ancillary fittings.

The whole of the pumping station will be ventilated by a forced draft system. The screenings room will be equipped with an automatic mechanical "sniffer" control and will receive a higher rate of ventilation than the rest of the building. Both air intake and exhaust in this room will be directly to the outside of the building.

Air conditioning will be incorporated in the main building for the administration section only.

Electrical System

In the process of sewage sludge digestion the production of sludge gas has established a practice of gas utilization as a source of power development as well as sewage treatment plant heating. Its use for the development of power can only be justified on the basis of cost comparison with the rates quoted by the applicable electrical utility.

The problem in the case of the Ottawa plant was to determine if the cost of the installation and operation of dual fuel diesel engine-generators could compare favourably with the cost of purchasing power from the Hydro-Electric Power Commission of Ontario, Eastern Region.

Three schemes were considered in order to make the necessary determination as follows:—

A—all power purchased;

B—purchased power for all plant requirements except pumps operating above minimum capacity which would be powered from dual fuel diesel engine-generator sets;

C—all power developed by dual fuel engine-generator sets.

On the foregoing basis the capital cost of engine generator sets rules out their application to the Ottawa problem. Accordingly, all power for plant use will be purchased from Hydro.

Discussions with officials of Ontario Hydro, Eastern Region resulted in an arrangement whereby a new transmission line will be built to deliver power at 12 kv. to the transformer vault in the Main Building.

At the Main Building transformer vault three sets of transformers will be provided to reduce voltage from 12,000 v. to 2400, 600 and 208/120 v. as required. The electrical system is single split bus radial system planned for power distribution at 600 v. to motor control centres located in the structures to be provided in future contracts. Power will be distributed underground at 2300 v. to future equipment required for secondary treatment.

All 600 v. motors will be started on full voltage by circuit breaker type combination starters. Exterior lighting will be mercury vapour on steel poles.

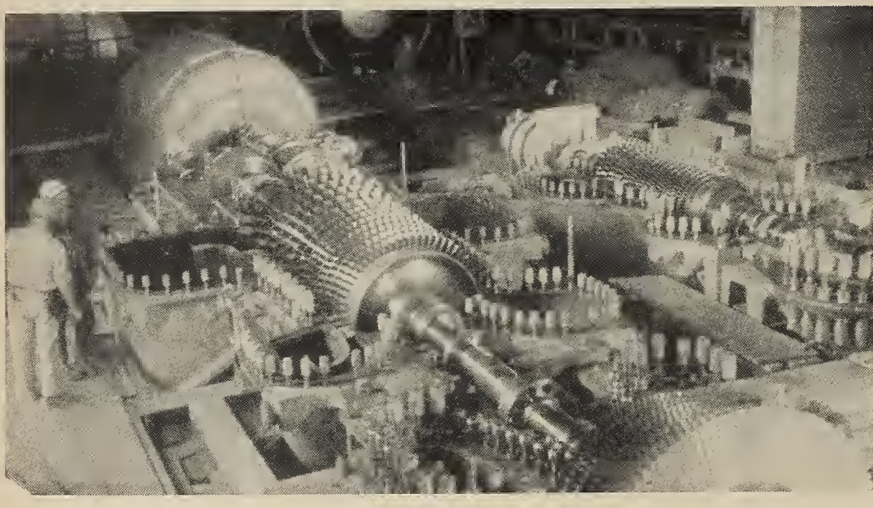
A central operating panel will be erected in the main control room on which all indicating, totalizing and recording units will be erected. Further, a diagrammatic panel indicating the operation of the plant in colour coding will contain miniature indicators showing total flow rates and key valve and gate positions. To further facilitate the control of operation of this plant, telephone communication will originate from this room to all key points of the plant.

The cost of the primary treatment plant as outlined here is estimated at $8,650,000 with the first phase, the raw sewage pumping station and ancillary works being estimated at $3,600,000. It is estimated that a total assigned personnel of 28 men will be required to operate the plant and that at design flow the annual plant operating cost will be about $400,000 per year.

Acknowledgment

The program is being carried out under the direction of Mr. F. E. Ayers, Director of Planning and Works for the City of Ottawa, through whose kind permission this paper is presented. Mr. W. L. Keay, Engineer in Charge of the Sewerage Branch of the Department of Planning and Works, is in immediate charge of work which is being designed by James F. MacLaren Associates, Toronto, with G. C. McRostie and Associates of Ottawa acting as soil consultants, Professor Arthur Casagrande of Cambridge, Massachusetts acting as soils adviser and with D. E. Kertland, Toronto, acting as associating architect.

SOME FEATURES OF THE PORT MANN GAS TURBINE GENERATING STATION



T. Ingledow, M.E.I.C.,
President,
International Power
and
Engineering Consultants Limited,
Vancouver.

In February this year, the first unit of the 100 mw. Port Mann gas turbine generating station came into service on the B.C. Electric Company's system. The station is fully automatic, unattended and controlled remotely from a control room in the Head Office some 15 miles away. The paper outlines some of the technical and economic features of the Port Mann gas turbine plant.

The prime function of the plant is to supplement hydro generation under adverse water conditions. Its secondary function is to provide standby for outages and peak loads of short duration. The Port Mann installation comprises four Brown Boveri 25,000 kw. two-shaft open cycle units with one stage of intercooling between high pressure and low pressure compressors. It is located approximately 3 miles East of New Westminster, in close proximity to an existing natural gas pipeline, an oil pipeline, a high voltage transmission line, rail and road facilities, and an adequate supply of coolng water from the Fraser River. The primary fuel is natural gas, supplied under an interruptible contract. On those occasions when the gas supply is cut off, the turbines will run on crude oil. A standby oil tank with a tap to the Trans Mountain Oil pipeline is provided for this purpose. Each gas turbine drives a 30,000 kva., 0.9 pf., 13.8 kv., 3,600 r.p.m. air-cooled turbogenerator. Power is fed from the single 13.8 kv. bus through two 50 mva., 3-phase transformers to an adjacent 230 kv. transmission line. The plant is controlled by signals from Head Office in Vancouver, which are transmitted by microwave to Ingledow substation, about 3 miles from the plant. Here signals are converted and continued by a single side band power line carrier system to the Port Mann plant.

THE INTEGRATION of a gas turbine plant into a predominantly hydro-electric system leads to substantial economic gains to the system as a whole.[1] The prime function of the plant is to stabilize the hydro system of the British Columbia Electric Company under adverse water conditions and merits further comment. The Company serves the southwestern area of the British Columbia Mainland and Vancouver Island including the cities of Vancouver and Victoria. The system has an installed hydroelectric capacity of 778,000 kw. Storage dams are filled during the summer months of low load and high run-off, and the winter loads are supplied mainly from storage. The hydroelectric energy available in a low water year may be as much as 350 million kwh. less than in an average year. If no other source of generation were available, the system would have to be engineered to provide reliability of service even in the most critical periods of water shortage. Thus at other times, excess water would be available which would either have to be split or used to generate secondary power saleable at very low rates. By "firming up" this secondary water power, a thermal plant can allow fuller utilization of the available water resources. It follows that during adverse water conditions, the plant will be operating at a high load factor, while at other times it will run at reduced output, or will be shut down altogether. Apart from firming up the hydro system, the plant also serves the following purposes:

1. To meet unforeseen peaks in the event of an unexpectedly high rate of load growth, and to serve as standby in case of forced or maintenance outage of any hydro or steam plant unit;
2. To serve as emergency source of power in the event of total system shutdown due to catastrophic outages of generating stations or transmission lines; to serve transportation, hospitals and other essential services under those conditions;
3. To provide power for starting up a future steam plant, now under construction.

Technical and Economic Advantages of a Gas Turbine Plant

For the functions described above, a gas turbine plant possesses a number of technical advantages over a conventional steam turbine plant. The units require only about 20 minutes from a cold start to full load as against 4 to 6 hours for the steam plant. Because of their basic simplicity, they lend themselves to automatic and remote control, obviating the need for operating labour. Gas turbines require a minimum of auxiliary equipment; they are compact and do not need heavy and elaborate foundations; they require considerably less cooling water than steam turbines, and the construction time is shorter.

These factors lead to generally lower capital and operating costs. The Port Mann gas turbine plant is estimated to cost 12.8 million or $128 per kw. exclusive of switchyard but including approximately $2.5 per kw. for remote and supervisory control. In contrast, a recent survey in the United States[2] indicates that steam turbine plant of the same 100 mw. capacity would have an average cost of $145 per kw. exclusive of switchyard, and automatic, unattended operation is not possible at present. It is estimated that operating and maintenance costs for an attended gas turbine plant will be 80% of those for a steam plant. For an unattended gas turbine plant this figure is reduced to 50% including the fixed charges for the additional investment in control equipment. Maintenance when required will be provided by mobile squads of servicemen.

The conventional re-heat steam turbine plant can be expected to give an overall thermal efficiency of about 30%, whereas the corresponding figure for a gas turbine plant is in the region of 22%. The resulting higher fuel costs are the main reason why gas turbine plants are not generally utilized for base load operation in a power system. However, when using thermal plants for stabilizing a hydro system a more favourable picture is presented. Such plants usually operate for only part of the year, and may be shut down altogether in some years. It follows that the long-term average load factor will be quite low, a figure of 15% being typical. On this basis, it has been estimated that gas turbines are more economical than steam turbines over a wide range of fuel costs ranging from 20c to 60c per million B.t.u.[3] since the higher fuel costs are more than offset by the lower capital charges, operating costs and maintenance costs.

Plant Location

The station is located at Port Mann on the south bank of the Fraser River approximately three miles east of the Pattulo Bridge. The site layout is shown in Fig.1.

The primary fuel is natural gas, supplied under an interruptible contract. On those occasions when the gas supply is cut off, the turbines will run on crude oil. The natural gas is supplied directly to the turbines through a 12 in. line fed from the 24 in. line immediately adjacent to the east property line. Crude oil is supplied via a 12 in. line from the Transmountain pipeline 1400 ft. west of the plant site to a dyked storage area enclosing a 100,000 barrel bulk storage tank, and a 24,000 gal. crude oil "day" tank. Within the storage area there is also a 24,000 gal. diesel oil tank for the stand-by generators which will be supplied by tank truck.

Cooling water is circulated from the river intake structure through two 42 in. steel pipes passing under the intervening Canadian National Railway marshalling yard. The switchyard is on the river side of the powerhouse and is connected by underground cables to the indoor switchgear. From the switchyard structure, transmission lines lead uphill, over the powerhouse, to the adjacent Horne Payne-Ingledow 230 kv. transmission line.

The outstanding advantages of the site from the viewpoint of accessibility

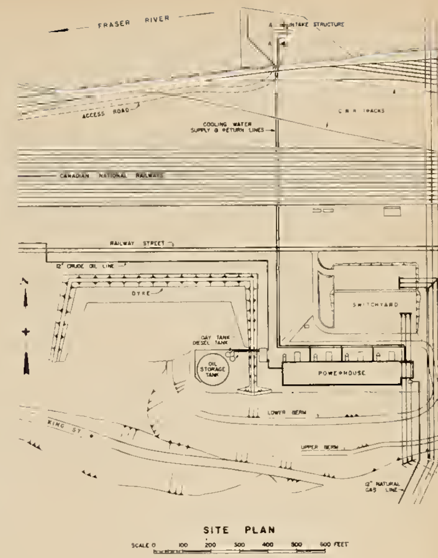


Fig. 1. Site plan

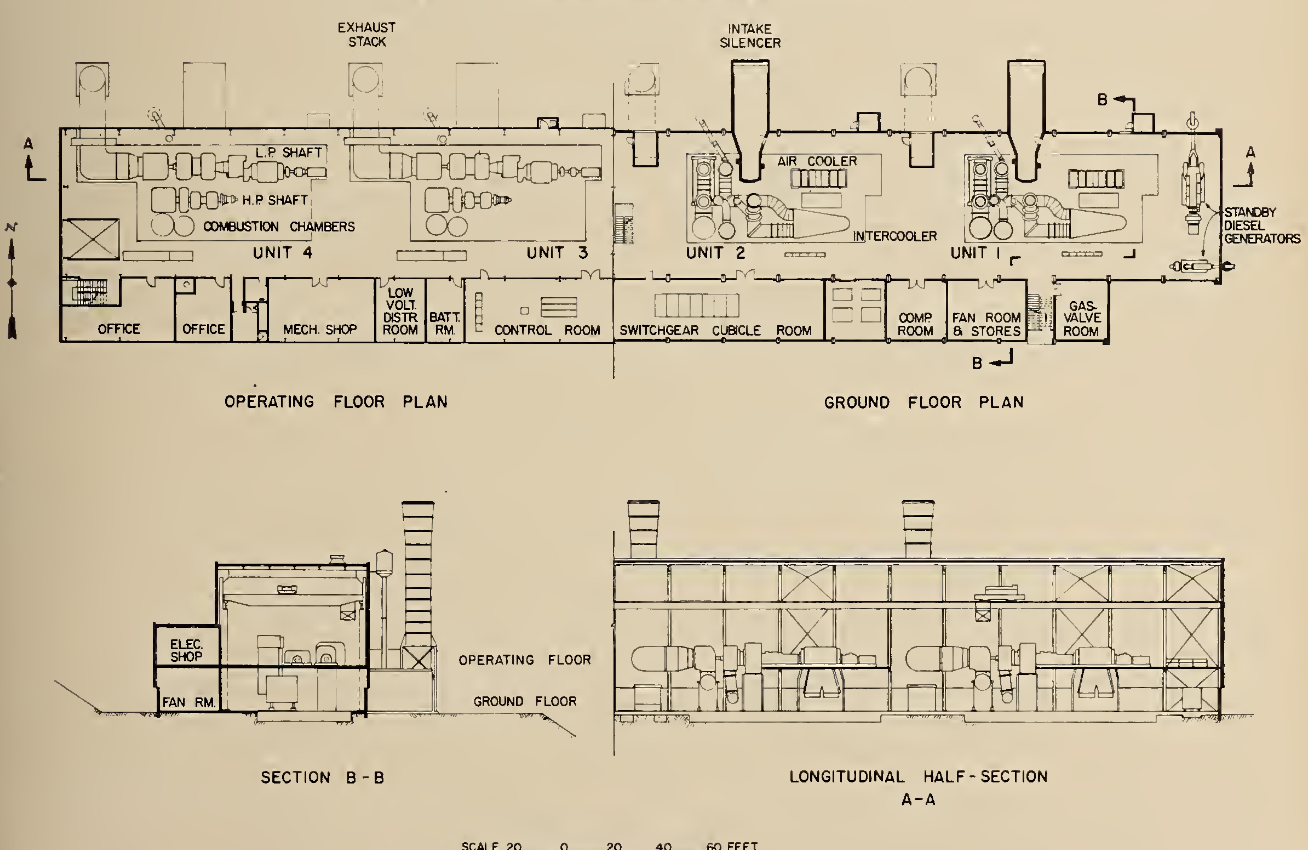
to fuel supply lines, cooling water and electrical transmission routes, outweighed the civil engineering problems introduced by the poor foundation condition.

Power House

The powerhouse is a steel framed structure of rigid bents. Considerable care has been taken in its design to ensure minimum sound transmissability by means of double skin cladding. The outer skin consists of

Fig. 2. Powerhouse general arrangement drawing



asbestos cement sheets on steel girts isolated for structural vibration by rubber insulators between girt and girt clips. The lathe and plaster inner skin is spring suspended to isolate air vibration.

As will be seen from the general arrangement drawing (Fig. 2.), the four gas turbine units are placed longitudinally in the power house to minimize the width of the structure and thus the excavation necessary to form the bench on which it is situated. Each unit is supported at operating floor level by an independent steel structure on independent foundation blocks. The operating floor around the unit is of reinforced concrete supported by a steel structure.

The Gas Turbine Units

All four machines are two stage, two shaft, reheat, intercooled, open cycle units, rated 25,000 kw. at 25° F air temperature and 21,600 kw. at 70°F. The greatly increased output at low ambient temperatures is particularly useful to meet the peak loads occuring during winter cold snaps. To utilize the increased output of the gas turbines under these conditions the 13.8 kv., 3,600 r.p.m. self ventilated turbo-generators are rated 30,000 kva. at 0.9 power factor.

It will be seen from the schematic diagram, (Fig. 3.) that the low pressure shaft comprises a turbine, compressor, generator, exciter and starting motor. The high pressure turbine, on the other hand, drives only a compressor and produces no electrical energy. For both high pressure and low pressure shafts, the air flow in the axial compressors and the gas flow in the turbines are in the same direction, and thus the end thrusts tend to compensate. Rigid couplings are provided between the compressors and the turbines, with flexible geared couplings between the other components. Fig. 4. shows one of the units in the course of erection.

The main air cycle can be followed on Fig. 3. Air is drawn in through sinusoidal silencers contained within the reinforced concrete air intake structure and enters the low pressure compressor. After partial compression it is re-cooled in the water intercooler, passes into the high pressure compressor and then into the high pressure combustion chamber where part of the total fuel charge is added. The hot gases are then expanded in the high pressure turbine and pass into the low pressure combustion chamber where more fuel is added. From the low pressure turbine the gasses are discharged through the exhaust stack to the atmosphere.

Each shaft is equipped with a gear-driven speed governor of the spring loaded centrifugal type. The governor of the low pressure shaft controls the load on the set. The speed of the high pressure shaft adjusts itself automatically to the load, and varies from about 3,600 r.p.m. at no-load to about 4,500 r.p.m. at full load.

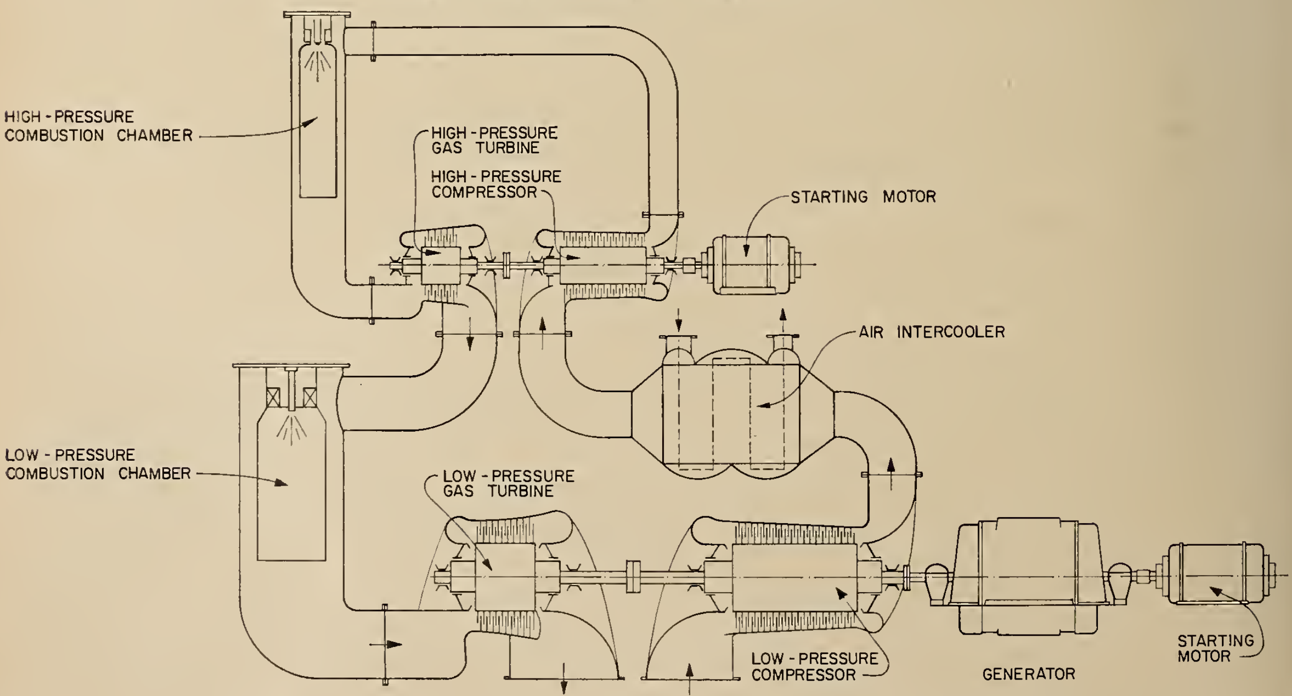
Cooling Water Supply

The plant requires 24,000 gal. of water per minute to cool the four gas turbine units. Considerable care was taken to ensure that no harm would be caused to the Fraser River salmon run by the use of this volume of water, and the intake and outlet structures were designed to comply with the requirements of the Department of Fisheries and the International Joint Salmon Commission in this regard.

Fig. 4. A gas turbine unit during erection

The final arrangement is shown in Fig. 5. The design provides for the installation of four 6,000 g.p.m. 200 h.p. vertical turbine pumps, mounted in four reinforced concrete cells submerged in the river, to supply water to the gas turbine plant through a 42 in. diam. steel pipe against a static head of 45.5 ft. The return line operat-

Fig. 3. Schematic diagram — gas turbine units



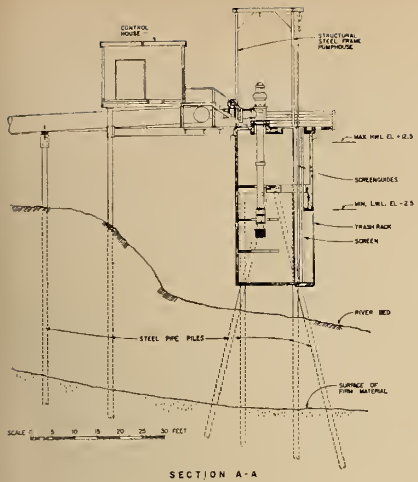


Fig. 5. Arrangement drawing of the cooling water intake structure

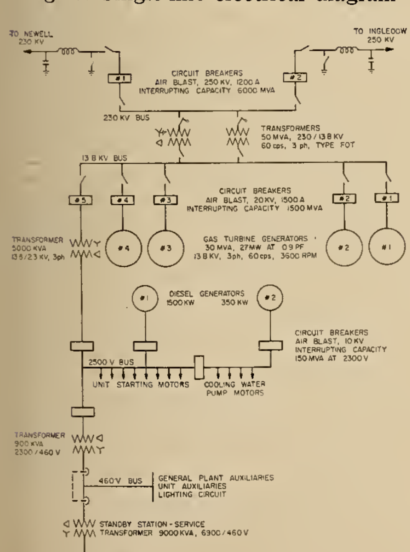
ing under gravity is of the same size as the supply line and returns the heated water into the river through a 48 in. diam. diffusing pipe 100 ft. downstream from the intakes.

Electric Features of the Plant

It will be seen from the single line electrical diagram (Fig. 6) that each generator connects through a 1500 mva. air blast circuit breaker to a single 13.8 kv. bus. Power is fed from this bus to the adjacent 230 kv. Horne Payne — Ingledow transmission line through two 50 mv. three phase type FOT step-up transformers and 1200 Amp., 6,000 mva. capacity air blast circuit breakers.

Station services are supplied by a 5,000 kva. 13,800/2,300 v. transformer with two diesel generating sets as standby. The provision of these diesel sets enables the plant to be started in case of a complete system shutdown, providing power for essential services, and for starting the new Burrard Thermal Generating Station now under construction. To maintain lighting and station services when the plant is shut down, power can also be fed to the 460 v. bus from a nearby 6900 v. distribution line.

Fig. 6. Single-line electrical diagram



Automatic Control

The plant is to be unattended, fully automatic, and will be controlled from the head office in Vancouver some 15 miles away. Signals from the Head Office are transmitted by microwave radio system to Ingledow Substation, 3 miles away. Here signals are converted and continue by a single side band power line carrier system to the Port Mann plant. Each unit can be completely controlled by the group of controls on the mimic diagram shown in Fig. 7.

To start the unit by remote control the turbine switch at the bottom of the mimic diagram is simply turned to the 'run' position. When this command is received by the supervisory equipment in Port Mann, it sends a signal back to the equipment in the Head Office. This causes the light in the centre of each switch to flash, indicating that the information has been received.

The impulse received at the station initiates all the operations required for starting the unit. The fuel and the cooling water valves are opened, the auxiliary motors are started, and the starting motors of the low pressure and high pressure shafts bring their stages to firing speed (approximately 30% synchronous speed) within about 4 minutes. Once the combustion chambers are fired, the gas turbine develops power and accelerates the set. Above firing speed, the power to the starting motors is cut off, but the starting motors continue to turn with their brushes lifted. When operating speed is reached the unit is automatically synchronized to the system, and the speed governor takes over. After execution of the command, another signal is sent back to the Head Office, and the light on the mimic diagram stops flashing, indicating that the required action has been completed.

Once the unit is on the line, load or voltage can be increased or decreased by pressing the appropriate 'raise' or 'lower' buttons alongside the mw. and mvar. meters. All the telemetering functions (mw., mvar. and kv.) are sampled on a cyclic basis and displayed continuously.

The plant is completely self-protecting. Although alarm indications are sent to the Head Office and are

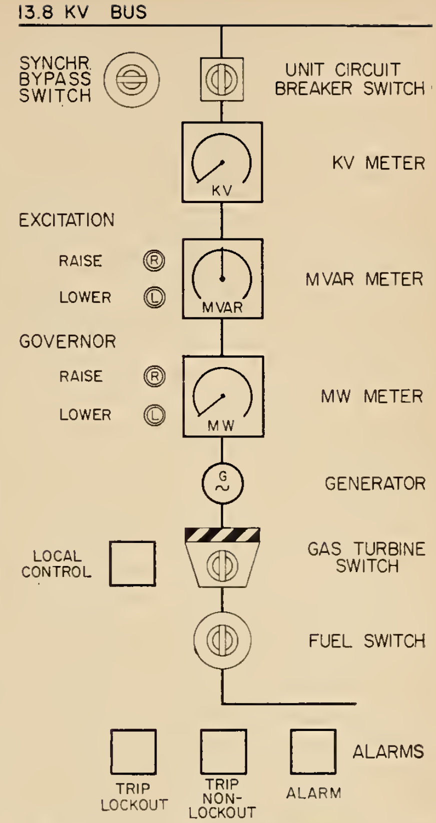


Fig. 7. Unit control panel mimic diagram

recorded by warning lamps on the control panel, the alarms are backed up by the necessary protective devices installed in the plant itself.

Conclusions

Gas turbine plants are now established as prime movers in the field of power generation. In an electric system such as that of the B.C. Electric Company, they can play a valuable part in improving the efficiency and economy of the system. Their relatively low capital cost and suitabiltiy for remote control makes them an attractive method of firming up the secondary power produced by a hydro-electric system, and they provide valuable standby capacity.

The Port Mann plan is of particular interest in that it is probably the largest gas turbine plant in the world, as well as the largest thermal power plant to be completely unattended and remotely operated.

REMOTE CONTROL OF DUFFERIN FALLS GENERATING STATION

W. S. Watson & V. Gabruss,
Electrical Engineers,
The Shawinigan Engineering Company Limited,
Montreal.

Presented at the Engineering Institute of Canada Ottawa Regional Technical Conference, October, 1959

Dufferin Falls Generating Station is situated on the Lievre River within the limits of the Town of Buckingham, Quebec, three miles north of Masson, which is the operating centre of the Maclaren-Quebec Power Company and the site of The James Maclaren Company Limited Paper Mill. This is the third generating station on the Maclaren-Quebec Power Company's system and consists of two 22.5 mva., 85% power factor, 163.6 r.p.m. generating units which produce power at 13.2 kv. at the generator terminals. The power is transformed to 115 kv. for transmission to the Electric Reduction Company in Buckingham and to the Masson switching station where it is fed into the paper mill and interconnected with the Hydro Electric Power Commission of Ontario and the Gatineau Power Company. By means of a third winding on the transformer some power is transformed to 6,900 volts for transmission to the Town of Buckingham and to the station service. This latter feed is stepped down to 575 volts for distribution throughout the powerhouse. The generating units are coupled to variable pitch propeller type turbines rated 25,000 hp. and operating under a net head of 62 ft.

CAREFUL consideration must be given to the advantages and disadvantages for each particular application of remote operation of generating stations. One of the greatest advantages of supervisory control systems is in the matter of operating costs. Supervisory systems will eliminate the use of a complete set of operators, usually six to eight men, with an estimated saving in the region of $20,000 to $30,000 a year. Since the equipment for Dufferin Falls cost approximately $50,000 not including engineering, installation and maintenance, it will be appreciated that after a very few years this equipment will have paid for itself. Even more of a saving would result if Dufferin Falls had not been located in the centre of a built-up area and housing for the operators had to be provided. However, there are other advantages to remote supervisory control. It affords the means of centralizing many of the operations of a system from one central point. The operator has before him a complete picture of the system, and should anything go wrong, he can take the necessary action to rectify the situation without the necessity of passing orders over communication facilities to local operators. In addition, remotely controlled stations contain more efficient and additional protective devices which lead to the detection of any fault at an early stage and prevent serious trouble and damage from occurring.

Therefore, when remote supervisory schemes are planned, extra protective devices are installed to make sure that the operation of the station is independent of the operator's skill and vigilance. Any attended station can have this same degree of supervision, but because it is planned to have operators in attendance the complex protective devices are not usually provided, although there is a trend to make all stations fully automatic whether attended or not. Even with the most competent personnel available accidents or negligence may not entirely be avoided.

The disadvantages of remote supervisory control lie in the slightly increased capital cost of the station, but this in itself is only a very small percentage of the total cost of the station. As has been pointed out, this can be written off very quickly due to the saving in operating expense.

Another disadvantage which should be considered is that the feel of the station no longer exists for the operator. He can no longer see smoke coming from a generator, or hear the change in pitch of a generating unit as it comes up to speed. He must have complete confidence in and rely entirely on his supervision and indication equipment.

In some stations the loss of generating capacity even for a period of one-half to an hour may be quite serious. It may take at least this time or even more to get to the unattended station when major trouble is reported.

New schedules of testing, inspection and maintenance must be set up. These schedules which include visual as well as electrical and operating inspections must be carried out by competent personnel who should also be capable of operating the station manually in emergencies.

Supervisory control was therefore decided upon here because it afforded a real reduction in the cost of operating this station over a manually operated station and because the complete loss of generating capacity, if this should occur, would not be serious, since the station is operated with one unit shut down a large part of the time. The station being in a built-up area, there was no need to build housing for operators, and should anything go wrong, entrance to the station could be made very easily.

The Supervisory and Equipment at Dufferin Falls and Masson

(i) *Definition of Supervisory:* Supervisory control, as this remote control equipment for generating and terminal stations is commonly called, is defined as a means of transferring the control and supervision of a number of apparatus units from one location to any other location to which a single telegraphic channel can be established. Any kind of apparatus which can be controlled electrically is adaptable to supervisory control.

(ii) *Desirable Features:* However, before discussing the supervisory apparatus which is used at Dufferin, it would be well to enumerate briefly certain desirable features which the equipment should possess in order to be acceptable for use in operating a plant remotely. These features are:

1. The equipment should be extremely reliable. If it is not reliable then there is no point in operating the plant remotely.

2. The equipment should be simple in construction and should occupy a minimum of space. Relays, switches, pushbuttons should be of standard design and easily available if required for replacement purposes.

3. It should be flexible in design so that it may be mounted as part of the dummy bus arrangement or in any other manner which will facilitate operations. Usually a dummy bus ar-

rangement makes for easier operation.

4. It should require minimum maintenance.

5. It should not be possible to perform false operations due to unusual conditions, such as an induced voltage or any other interference on the telegraphic link.

6. The telegraphic link should require a minimum number of line wires and if operated over a carrier channel, should require a minimum of frequency space.

7. Individual indication should be provided to show the position for each major piece of apparatus.

8. It should be possible to extend the range of the equipment to include more apparatus using the same line wires or carrier equipment.

9. It should be possible to obtain remote telemetering indications without the use of an additional telegraphic link.

10. It should be extremely flexible so that it is able to be operated over carrier, or microwave channels as well as line wires.

11. It should be able to store information during loss of channel.

12. Important functions should take precedence over relatively unimportant functions during abnormal conditions.

(iii) *Description of Equipment:* The supervisory system used here is a D.C. pulse code, whereby operation of the selection button for a particular point automatically sends out a code of pulses assigned to that point. These pulses are registered on a relay counting chain at both stations with the result that the selection relay in question is operated at the slave station. When selection takes place, an identical code is sent back to the controlling station to check the selection. The equipment is then operated by a further code common to all points which initiates the operation required, such as closing a breaker. This system requires a channel of two wires and can also be operated over carrier channels. In this connection the D.C. pulse keys an audio tone generator for transmission over the carrier link.

There are five general classes of points, four of which are used in this installation. Those used are:—

1. *Supervision only of 2 conditions* — This type of point is used to indicate the position of circuit breakers and disconnect switches, to supervise alarm indications such as over-temperatures, high water, low pressure, etc., or to supervise the status of any device which can be in either of two positions.

2. *Control and Supervision* — This type of point is used to control and indicate position, an example being closing and tripping a breaker and supervising its position by red and green indicating lamps, or to start and stop generators, pumps, etc., with indication of whether the machine is running or stopped.

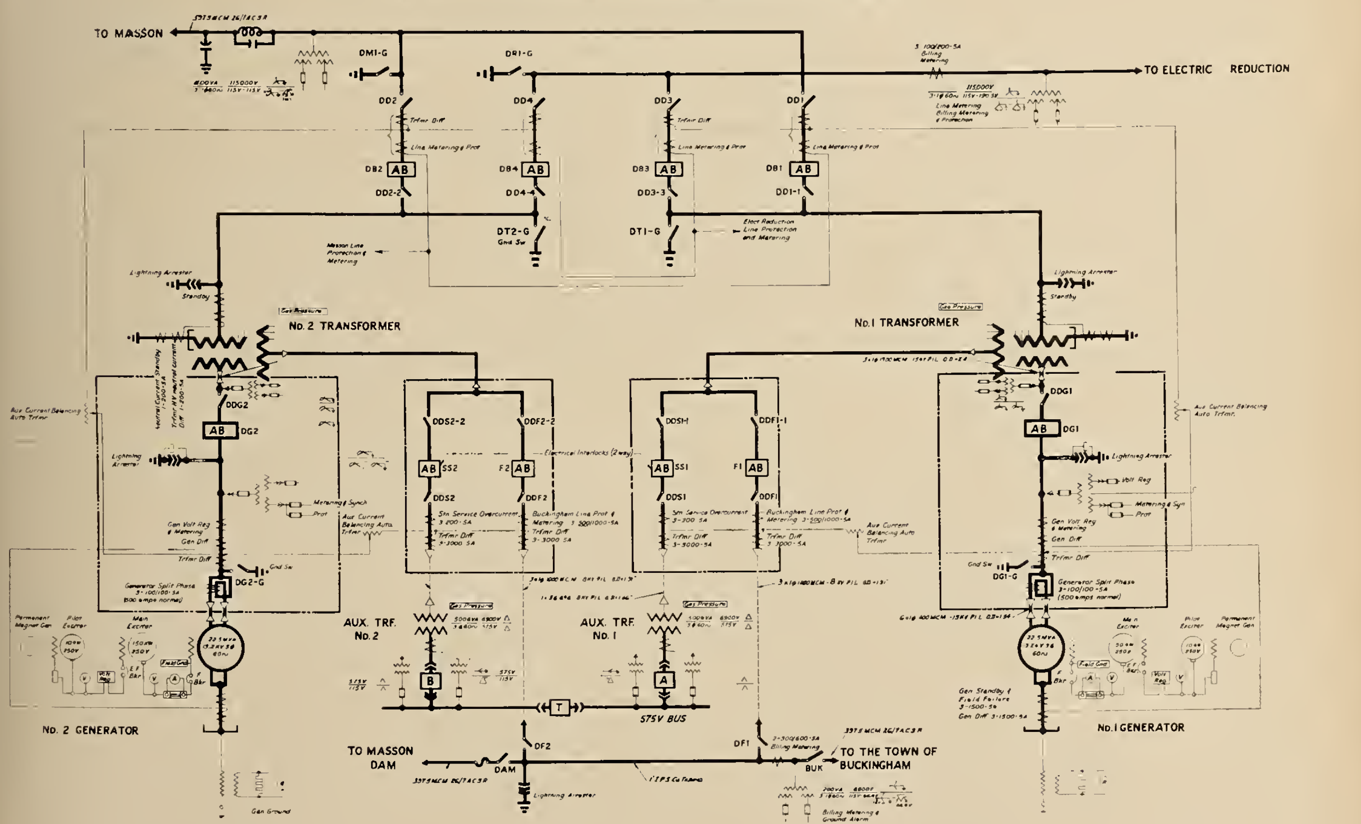
3. *Telemetering* — This type of point provides the means of obtaining a reading of a remote quantity on a telemetering receiver, for example, generator amperes.

4. *Control and Telemetering* — This type of point allows control of the quantity which is telemetered over that point, such as raising and lowering setting of tap changer with telemetering of tap position (or voltage), raising or lowering a gate with telemetering of gate position, raising and lowering the setting of a generator governor with telemetering of generator output, raising and lowering the setting of generator voltage regulator with telemetering of generator reactive loading.

The fifth type of point, which is control and supervision with telemetering, was not used in this installation. This is used to control, for instance, a circuit breaker, continuously indicate its position and also provide a telemetered quantity, such as current associated with the breaker.

In addition to these five points and their associated relays, there is common equipment at the master station, including an alarm bell and alarm lamp and a set of master control pushbuttons. These pushbuttons are common to all points and are

Fig. 1. Dufferin Falls Development Station Diagram.



operated after the point has been selected and have the following functions:—

(1) **Close** pushbutton key is used to operate the selected device to the close, start, or raise position as the case may be.

(ii) **Trip** pushbutton key is used to operate the selected device to the trip, stop, or lower position as the case may be.

((iii) **Check** pushbutton key is used to check the correctness of the lamp indications.

(iv) **Reset** pushbutton key is used to reset the control relays and restore the equipment to the normal at rest position at any time.

(v) **Alarm** pushbutton key is used to silence the alarm bell after an alarm indication has been received.

Other features which have been incorporated in the supervisory control are the scanning feature for the alarms and the master check. The scanning feature checks all alarm indications immediately after any alarm. The master-check checks the correctness of all lamp indications. This is particularly useful after restoration of lost battery power or lost channel facilities.

At Masson, which is the master station in the control of Dufferin Falls, a vertical cubicle is located in the control room on which is mounted a dummy bus arrangement of the Dufferin Falls Station. It is from here that all commands and intelligence to operate Dufferin Falls are made or received. Each piece of equipment at the remote station is controlled from an individual escutcheon plate containing indicating lamps and control selection buttons and mounted in the dummy buswork. The position of each piece of remote equipment is thereby indicated so that the operator at Masson knows at any given instant the condition at the slave station. The common equipment, as mentioned previously, and the alarm lamps and telemetering receivers are mounted above the dummy buswork. The control relays and wiring are mounted inside the cubicle.

At Dufferin Falls, the supervisory equipment consists of control relays, interposing relays and telemetering transmitters, which are mounted in a duplex switchboard similar to that supplied for the local automatic control and protection equipment.

Telemetering Equipment

Telemetering indication can be arranged to be received in conjunction with control points, or on separate points. An example of the former is the raising and lowering of turbine gate limit at the same time telemetering gate limit position. An example of the latter is telemetering generator reactive volt amperes. However, it must be pointed out that the type of telemetering transmitter used not only depends on the quantity being transmitted but also depends on the type of channel being used. Since a carrier is used at Dufferin, the impulse duration type of transmitter is used to provide the necessary keying. In the impulse duration system the measured quantity is proportional to the length of the pulse. The pulses are repeated at a constant rate.

Indications of all important metering quantities are obtained at the dispatcher's office. In most cases it is not necessary to have continuous indication of these quantities, so that each quantity is assigned a point of the supervisory and selected individually when required.

Mention might be made regarding the kilowatthour metering of the generators. These were placed on a selective point on the supervisory by the use of an impulse storage relay. The station kilowatthour meters are equipped with contact-making devices which provide a rate of impulse proportional to the kilowatthours. These impulses are then fed into a storage relay which stores the impulses until the operator selects the desired point. When the point is selected, the storage relay transmits all the stored impulses including any which are stored during this transmission. By proper selection of the contact device ratio, the number of impulses per kilowatthour can be chosen to suit the frequency of readings required by the operator.

Where continuous indication of a quantity is required, this quantity is telemetered over a separate channel so that it will not be interrupted by operation of the supervisory equipment. Continuous telemetering is provided for generator kilowatts and for Dufferin Falls headwater level.

The Transmitting and Receiving Equipment

In order to apply control to a generating station such as Dufferin Falls, such considerations as reliability, compactness of equipment, ease of operation and maintenance, etc., necessarily enter into any decision to choose a particular design. But more than that is required. The transmission and reception of commands and intelligence from one station to another must be considered. This equipment must not only be economical, but must also be compatible with the supervisory system being considered. Also the problem of voice communication and the type of line relay protection must be studied. This means considering all possibilities and combinations of possibilities before deciding on the complete system. Sometimes, it is possible to use one component from one manufacturer and some other components from another manufacturer to arrive at an economic and compatible scheme.

Types of Channel: There are three basic types of channel which could be used to provide the telegraphic link between the master station and the slave station. These are:—

(a) A pair of line wires. These can either be a pair or pairs of telephone line wires leased from a communication company or simply a multi-conductor cable installed and owned by the power company.

(b) Power line or telephone line carrier.

(c) Microwave.

The use of power line carrier: Power line carrier was decided as the telegraphic link between Masson and Dufferin Falls. The use of carrier resulted in an overall saving of approximately 15%, or $10,000, over a buried pilot wire cable. It may seem surprising that such a large saving was made using carrier. Most information on the subject suggests that in range of 3 to 5 miles it is a toss-up whether to use carrier or buried cable, and since the distance between Masson and Dufferin Falls is about 3½ miles, it would seem then that the two systems would be approximately the same cost. The reason for the difference lies in the fact that in this case, it would have been extremely costly to install the cable in the ground due to the rugged nature of the terrain between the two stations. It is suggested here that these rules-of-thumb be approached with extreme caution and should only be used as a guide and that all the factors of each situation be taken into account before a decision is made. Either type of channel was considered to be as reliable as the other, so the decision to use carrier was based purely on economic and technical factors.

Line Wires: The leasing of telephone circuits was not considered for three reasons, because of the number of channels required, because absolute reliability was required for at least two channels for protection purposes, and because it was felt better to have the transmission facilities under the control of the owners.

Microwave: Microwave was not considered too seriously because it was more expensive than carrier. The carrier equipment finally decided upon is a duplex, double side band, fixed frequency, amplitude modulated system with frequency shift.

The duplex feature is to provide communication facilities in both directions at the same time. The double side band section enables use of a full band width thereby eliminating the problem of crowding in the frequency range being used.

The carrier sends out a continuous fixed frequency which is modulated by means of audio tones keyed by the supervisory, telemetering, and relay protection equipment. Besides the transmitting and receiving equipment at each station, there are the capacitor coupling devices, wave traps, line tuning units and coaxial cable. This equipment connects the carrier sets to the H.V. transmission line at both stations, thereby completing the link for the reception and transmission of the communication, supervisory and telemetering signals to and from Masson and Dufferin Falls.

Each station is also provided with an emergency power supply for the carrier equipment in case of failure of the normal A.C. supply of the station. This supply is fed from an A.C. generator which is powered by a D.C. motor fed from the station battery. Condenser batteries are also supplied to maintain the plate voltages of the carrier equipment during switchover time from the normal to the emergency power supply.

The Remote Automatic Operation of the Generating Units

The basic station equipment used at Dufferin Falls is essentially the same as if it were being controlled manually with operators in attendance. There are, however, differences in the control equipment. Whereas in an attended station certain apparatus may be hand operated, these devices must all now be operated electrically and must be included as part of the control sequence. It is necessary to equip the station properly for automatic control in order to use as few supervisory points as possible and to prevent any serious damage from ever occurring to any piece of equipment.

Therefore, to do this, all the apparatus which must be operated automatically is equipped with control devices which can be electrically operated either directly through the supervisory or in response to some particular situation. These devices merely act as interlocks in the control circuit in the starting and stopping sequence of a generating unit. By this means each piece of apparatus is checked to see that it is in the correct position and in perfect running order. This meets our definition of an automatic generating unit which is one where the unit is started and synchronized automatically following a single impulse received from a control device. This impulse may be given by a local operator, by a remote operator through the supervisory control, or it may be initiated automatically.

There are other basic differences between attended and unattended stations. The problem is one of communication in the fullest meaning of the word. The operator at the remote station as we have explained before must rely entirely on the supervisory panel in front of him. His senses are useless to him. Therefore, in the design of such a station this must be kept in mind and everything done to help the operator overcome his position. For this reason the application of certain devices is different in unattended and attended stations.

At Dufferin Falls the protective features which shutdown the unit and lockout the unit are divided into two groups. In the first group the main field and main exciter field breakers and breakers of associated apparatus are opened immediately and the machine brought to a standstill as quickly as possible. In the second group the main field and main exciter field breakers are not tripped, but the generator breaker is tripped or opened when the unit passes through the speed-no-load position. The machine is then brought to a standstill as quickly as possible. The first group may be classed roughly as "electrical" faults, and the second group as "mechanical" faults. An example of the first group is generator differential protection. An example of the second group is generator overspeed (130%).

In considering the starting and stopping sequences at Dufferin Falls, it should be pointed out that these are typical of what is being done in most places in the automatic operation of generating units. Each installation should be studied on an individual basis however, because conditions vary from one plant to another.

In the starting up of the generators at Dufferin Falls from Masson over the supervisory, there are two distinct groups of equipment which must be in a definite position and working order before a unit can be synchronized on the line. The first group of equipment consists of the manually operated equipment such as hand reset relays, selector switches, hand operated breakers, etc. These devices must be set in position before leaving the unattended station. The second group of apparatus consists of equipment which must be running as a normal part of the everyday working equipment of a powerhouse. For example, the battery voltage must not be below a certain level, the air pressure for the generator brakes must be available, and cooling water must be circulating through the bearings. When these conditions are satisfied then it is possible, when the operator pushes the start button on the supervisory at Masson, to initiate the starting sequence of the generator. Pushing this button energizes the start-stop latching relay in the automatic equipment at Dufferin Falls, which in turn releases the brakes and energizes the master relay if all the interlocks are correctly set, and the auxiliary equipment is operating satisfactorily.

When the master relay is energized the governor solenoid is reset opening the turbine wicket gates and admitting water to the turbine. When the unit reaches 95% of rated speed, the voltage matcher and the auto-synchronizing equipment are connected. The voltage matcher matches the machine voltage to the line voltage, the auto-synchronizer adjusts the speed of the machine to match the system frequency. When the two voltages are matched and the two speeds are in synchronism, the generator breaker is closed. This connects the machine to the system. Once this is done the loading, excitation and gate limit can be adjusted as required.

Normal stopping of the generator is initiated by a stop impulse which de-energizes the master relay. This in turn energizes the governor shutdown solenoid, closing the turbine gates. When the gates approach the no-load position, the gate limit switch closes and trips the generator breakers. As the unit drops below a certain speed, a speed switch closes which initiates the application of brakes, first intermittently and then continuously. All devices will then return to the normal starting position.

It is evident from the above that the successful operation of an unattended station depends on the inclusion of extra control devices which limit the number of points on the supervisory control equipment, prevent the false operations, and detect early any faulty conditions. The starting and stopping of each generator at Dufferin Falls requires only one point on the supervisory.

Other Automatic Features

It is not enough to have the generating units operated remotely in an unattended location without considering the varied auxiliary equipment and its relation to the automatic operation of the Units. So it might be of interest to note some of the other features which were especially considered in view of the fact that this station is unattended.

(i) *The 575 Volt Auxiliaries:* There are two circuits to the 575 v. auxiliary equipment. Great flexibility is obtained as a result. These circuits are fed from the tertiary windings of the main transformers at 6900 v. to 500 kva. auxiliary transformers where the voltage is stepped down to 575 v.

If voltage should fail on one unit for any reason the equipment immediately detects this condition and will transfer over to the other source. This transfer contains a time delay feature, which had to be taken into account when supervision features were added to some of the auxiliaries. These had to be further time delayed to take care of the time delay of the transfer.

The time of the transfer from one feed to the other is in the order of two seconds. This is well above the time most authorities give as being necessary to make the transfer. If the transition time is too short, the residual voltage on the motors which can be 180° out of phase with the other source may cause excessive currents to flow in the motor windings when they are connected to the other source. No trouble was experienced from any motor equipment and especially the 50 hp. governor oil pump motor when a transfer was made. No attempt was made to determine the optimum time required for a transfer.

It was also necessary that each feeder breaker, which is the no-fuz type, be supplied with an auxiliary switch which would sound an alarm should it open under any abnormal condition, since equipment such as the governor oil pumps, transformer oil coolers, fire pump, compressors, etc., must be available for operating at all times.

(ii) *Fuses vs Circuit Breakers:* As well as the 575 volt auxiliaries operating at all times, it was necessary that there be no interruption in the D.C. control circuits. To prevent any loss of D.C., no-fuz circuit breakers were substituted for fuses as much as possible. Each circuit breaker has an auxiliary switch which sounds an alarm should the breaker open for any reason whatsoever.

(iii) *Governor Bypass Solenoid:* Due to the wide variation in the loads and the operating conditions experienced at Dufferin, it was necessary that the operation of the governor bypass solenoid on the units be automatic to meet these changing conditions.

(iv) *Braking:* The braking on the machines is so devised that on shutdown when the speed has dropped to 50% rated speed, and if the gates are closed, and the generator breaker has opened, a cycle of intermittent on-off braking will be applied to the machine, when the braking will be applied continuously. The circuit is devised so that the braking solenoid will be energized as long as the machine is shutdown. This is an operating policy. If anything should happen to the D.C. circuit, the creep detector will guard against any movement of the unit. A standby braking scheme is also applied to these units as back-up feature to the main braking. As has been mentioned, in the event of an electrical fault of any kind it is imperative that the machine be brought to rest in case fire has resulted, which would only be fanned if the machine is allowed to rotate. This standby braking is timed to operate a few seconds after the continuous application of the primary braking.

(v) *Creep Detection:* Damage to generator bearings will result if the unit is allowed to rotate at very low speeds for even a short time. This condition is likely to appear on shutdown if for some reason the brakes do not hold or do not stop the unit quickly enough when the low speed range of about 20 r.p.m. or below is reached. In order to guard against this, detectors are installed which will operate if the machine is not brought to rest within a certain time after the unit shutdown relay is deenergized. If the shutdown takes too long, then the operation of the creep detector will result in the machine starting up automatically and resynchronizing. If the shutdown is due to lockout, then the headgates are dropped.

(vi) *Shearpin Failure Alarm:* Shearpins in the gate mechanism of hydroelectric units from time to time fail because a stray log or foreign matter has lodged in the turbine wicket gates. This condition may prevent the shutdown of the generating units and may set up excessive vibrations in the powerhouse at certain loads. At Dufferin when the units were being installed the failure of a shearpin when the machine was running at 80% gate opening set up a very serious vibration which for all intents and purposes, vanished when the machine was brought down to speed-no-load. As a result of this situation, a shearpin failure alarm scheme is installed which automatically brings the machines down to speed-no-load and sounds an alarm at Masson. The scheme installed consists of tying all the gates together by means of a cable. Thus, if one gate is out of line a plug will pull open which operates the control features mentioned above.

(vii) *Alarm Panel:* The alarm panel at Dufferin Falls contains approximately ninety points and is divided into three groups, one for each unit and one for general station alarms. Not all the alarms brought to this panel are taken back to Masson. The whole matter of effective communication between the situation at Dufferin Falls and the operator at Masson centres around this alarm panel. It is not necessary for each alarm point to be taken back to Masson, but at the same time, it is necessary that the operator at Masson know whenever some faulty condition shows up. Therefore, alarms of a very serious nature are brought back on an individual basis. An example of this is the creep detector alarm.

Alarms of a less serious nature, such as turbine bearing temperature high, turbine oil level low, etc., are combined to form one alarm at Masson called the "unit miscellaneous alarm". For these alarms it is necessary for the operator at Masson to go immediately to the alarm panel at Dufferin Falls where he can identify the specific piece of apparatus involved. It will be seen here that the operator should be prepared for trouble on any of the equipment covered by this particular common alarm. Then there are alarms which are of a less serious nature still, such as battery low voltage, 575 v. bus ground, breaker no heat, etc., which are grouped together to form what is called "general station alarm." The seal-in features have been removed from some of these alarms in this group because they may come on regularly and the condition subsequently rectifies itself. The operator merely checks this group to see if it can be reset; if not he can wait for a convenient time before making a trip to Dufferin Falls station.

VEHICLES IN MUSKEG

J. G. Thomson,
Research Engineer, Imperial Oil Limited, Calgary

Muskeg is no longer an unknown material. An orderly classification of muskeg types has provided a basis for determining its physical and mechanical properties. In turn, these properties have been applied to the design of structures and vehicles suited to application in muskeg. It is now possible to treat muskeg as a known engineering material. The design and application of muskeg vehicles are used to illustrate the validity of the current muskeg technology.

TO DEVELOP northern Canada it is necessary to traverse muskeg. Many popular articles have been written which leave the reader with the impression that muskeg is a nebulous substance. It has even been endowed with the human ability to plot for the frustration of engineers and construction crews. The general result of such articles has been to rouse management reticence toward any field operations involving muskeg.

It is the intent of this paper, through the use of previously published data, to show that muskeg, far from being a mysterious, ever-changing substance, is in fact a well known engineering material. Muskeg has been defined and classified. Its physical properties have been listed and explained. A few measurements of some of the mechanical properties of muskeg have been made and applied. The known characteristics have served as the design basis for successful engineering structures founded on muskeg. They have also been applied to the design of successful vehicles for use in muskeg.

Vehicle design is used as the illustration of the status of the applicability of current muskeg technology.

TABLE I

Summary of Properties Designating Nine Pure Coverage Classes

Coverage Type (Class)	*Woodiness vs. Non-Woodiness*	*Stature (Approx. Height)*	*Texture (Where Req'd)*	*Growth Habit*	*Example*
A	Woody	15 ft. or over	—	Tree form	Spruce, larch
B	Woody	5 to 15 ft.	—	Young or dwarfed tree or bush	Spruce, larch, willow, birch
C	Non-woody	2 to 5 ft.	—	Tall grass-like	Grasses
D	Woody	2 to 5 ft.	—	Tall shrub or very dwarfed tree	Willow, birch, labrador tea
E	Woody	Up to 2 ft.	—	Low shrub	Blueberry, laurel
F	Non-woody	Up to 2 ft.	—	Mats, clumps or patches sometimes touching	Sedges, grasses
G	Non-woody	Up to 2 ft.	—	Singly or loose association	Orchid pitcher plant
H	Non-woody	Up to 4 in.	Leathery to crisp	Mostly continuous mats	Lichens
I	Non-woody	Up to 4 in.	Soft or velvety	Often continuous mats, sometimes in hummocks	Mosses

Classification and Occurrence of Muskeg

The word *Muskeg* is ascribed almost as many meanings as there are people using the term. The name has been applied to swamps, peat-beds, forest floors and tundra, to list a few. It is not properly applied to any of these, although some of the items listed are components of muskeg.

Briefly, the term muskeg designates organic terrain. The physical condition of organic terrain is governed and modified by the structure of the contained peat, the living surface vegetation, the mineral sublayer and topography. Radforth[1] has written convincingly that each of the four named condition factors are essential to any discussion or assessment of muskeg. Each must then be included in the definition. In addition to physical characteristics, muskeg has a dimensional property. Depending on the problem being investigated, it may be linear, areal, or cubic.

To a practical degree the class of living coverage describes the origin of the fossil material (peat) beneath it. Also, the coverage classification is a primary indication of the relative magnitude of the mechanical properties of a muskeg. For some purposes, noteably tracked vehicle operations, the implicit estimates of mechanical properties made from this classification suffice.

The nine pure coverage classes used by Radforth[2] to describe muskeg are shown in Table 1. Note that these classes require only observation of stature, degree of woodiness, and, in a few cases, texture. No knowledge of species is required or even desirable for engineering purposes. Only classes which represent 25% or more of the coverage are reported. Thus, a muskeg can be described by one, two or three letters referring to coverage classes. In practice, a fourth letter is never justified.

Topographic features listed by Radforth[2] are shown in Table 2. The 16 contour types have been consolidated into four major groups. This simplification is made on the basis of vehicle response to the contour types being roughly constant within any one of the coarser groups.

Subsurface constitution becomes important in some operations. Radforth's[3] 16-part classification of this muskeg feature is given in Table 3. Again, a simplified grouping, listed as "predominant characteristic" in this tabulation, suffices for vehicle purposes. Usually, only the degree of fibrosity which will be available to the vehicle after failure of the living mat will be of interest.

Figs. 1-5 inclusive, show some of the commonly occurring coverage classifications. All muskegs, even although only a few inches deep are impassable to wheeled vehicles. Of the types shown, only the muskeg of Fig. 1. could be traversed by a conventional tractor with a "bush" track. All of these can be crossed with special muskeg vehicles. Only the muskeg shown in Fig. 5. would require deviation from a straight line traverse to avoid weaker sections of mat.

Fig. 1. Type BDI Muskeg. The "B" element has been removed where the men are standing but may be seen in the background.

Fig. 2. Types FI, BFI and AI Muskeg. (a) FI. (b) BFI: "B" may be recently encouraged by action of the "swampy" ditch in foreground. (c) AI: This can be traversed by high ground pressure tracked vehicles except if it is underlain by wet, remouldable clay.

Mathematically, a very large number of combinations of the nine pure coverage classifications are possible. Of these, Radforth considers only 25 occur commonly. The five examples referred to above are typical of muskegs which had to be avoided in vehicle operations until quite recently. It does not follow that these are the only muskeg types resulting in mobility failures, nor that they are the most notorious causes.

Being able to classify muskeg, although essential, is strictly a passive art. The next and probably most important step is to decide what to do about the organic terrain in any given case. At this point the general and the specific extent of muskeg becomes important.

It is generally accepted that at least 320 million acres of Canada are muskeg covered. In this vast area, characterized by low bearing and shear strengths, engineering structures are rare and costly. Access has, until recently, been almost restricted to air and water travel. The few trails, roads and railroads which do traverse muskeg were extremely costly to construct. Except for a few very recent examples these ground access routes are very costly to maintain. Footings for buildings and machinery usually require total excavation of the peat. Temporary structures can be and are built on footings founded on shallow clay pads which in turn are floated on the muskeg mat. These floating pads are often successful under quite heavy structures. The economic advantages of the clay pad over deep excavations are obvious.

Economic Significance of Muskeg to One Industry

The Gordon Report to the Government of Canada noted that difficulty

Fig. 3. Type FHI Muskeg. The strips of "D" form less than 25% of coverage and so are not reported. However, an experienced driver would straddle the D coverage if proceeding in that direction.

Fig. 4. Type HFI Muskeg. Note "D" coverage in background and slight hummocking in foreground. The hummocks dictate a deep, soft vehicle suspension for early spring operations.

Fig. 5. Type FI Muskeg. Bare surface in the foreground is the result of mat damage by vehicles. Detailed route selection would be desirable over this muskeg.

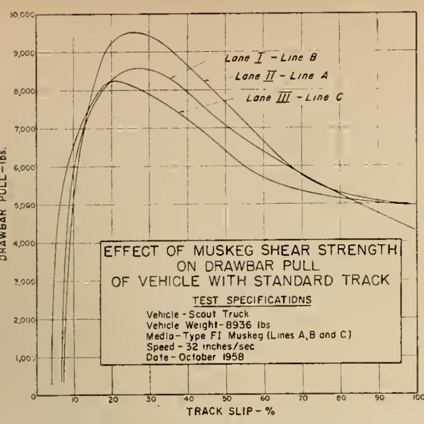

Fig. 6. Effect of Muskeg Sheer Strength on Drawbar Pull of Vehicle with Standard Track.

of access is hampering development of the northlands. Muskeg is the most prevalent single item contributing to the noted difficulty of access.

About 125 million acres of the 500 million acre Western Sedimentary Basin are muskeg covered. Therefore, the oil industry may ultimately conduct up to 25% of its exploration and development program in muskeg. Obviously then, this is one industry which must take the added cost of muskeg operations into all of its economic calculations. Further, it must substantially reduce the cost of one-quarter of its exploration and exploitation programs if crude oil from muskeg areas is to be competitive with that from other areas.

Since 1947, the industry has cut an estimated 180,000 miles of trails to facilitate exploration. Geophysical crews have continuously profiled over 250,000 miles on those trails at a probable cost of $150 million. After the geophysical work, a deep test well is often drilled. In muskeg areas these tests cost about two and one-half times as much as those of similar depth at plains locations. The transportation costs alone for a deep test hole in muskeg areas has reached $300,000 or about 30% of the total cost.

The Pembina oilfield, one of the largest in area in North America, has provided some interesting cost figures. Walsh[4] has stated that the capital investment in the Pembina field will be greater than in the St. Lawrence Seaway, excluding the power development. Hemstock[5] estimates the final exploitation cost in Pembina at $415,900,000. Of this amount, he attributes $25 to $30 million directly to muskeg.

From this rather cursory glance at the effect of muskeg on the economics of one industry, it is obvious that here is a field worthy of concerted engineering effort. Indeed, much of the development of northern Canada's natural resources is already hampered by lack of engineering data on muskeg. Activity in muskeg research and engineering is increasing and, happily, the problem is yielding in proportion to these efforts. There are many phases yet to be studied, however.

Transportation in Muskeg Areas

Transportation through muskeg is a frequently recurring problem of some notoriety. There are at least four major approaches to the solution of transportation problems over organic terrain. The method selected will depend on the particular problem and economics involved. The four systems are:

1. Build roads of a class suitable to the type and quantity of traffic to be carried;
2. Build temporary roads or tractor trails over frozen muskeg and restrict operations to the winter season;
3. Air or water-lift materials; or
4. Construct special tracked vehicles for operation in muskeg at all seasons without roads.

The first two of these methods have been the most common solutions attempted.

Various road building techniques are used and various results achieved. The cost is always high. The degree to which the technology of road building over muskeg has advanced is well illustrated in a recent paper by Brawner.[6] His paper details the application of the preconsolidation principle to a muskeg subgrade for a 4-lane highway. Obviously, this technique is only applicable to high density, long duration traffic. Short term access roads over muskeg are more simply constructed but may, in view of the limited tonnage to be transported, still be prohibitively costly.

The winter-cleared frozen muskeg trail is a crude form of road. Muskeg type and the construction effort expended will determine whether the trail is suitable for wheeled or tracked traffic. In the case of hummocked type "FI" muskeg, a smooth surface suitable for high speed wheeled vehicles is produced only at great cost. If the roots of type "A" trees must be removed construction costs will also be high. In both of these examples road-bed life will be short since sections of the road will be without a surface mat to protect the frozen peat and to help support the load. If a longer road life is required only minimum preparation of the trail should be undertaken. For example, trees should be cut rather than bulldozed and hummocks should not be cut off. Traffic will then be restricted to tracked vehicles operating at less than their already low maximum speed. Obviously, the winter trail system, although very common, is not entirely satisfactory. In one case, high speed traffic can be sustained for 2 to 3 months; in the other, tractor trains can be operated at 2 to 3 m.p.h. for 3 to 4 months. Even the longer of these periods is not adequate for economical exploitation of natural resources.

A winter tractor trail across type "FI" muskeg costs about $200 per mile. If, for example, a 600 ton oil drilling rig is transported in and out by truck the road charge is $1.20 per ton mile. If drilling is not finished in time to retrieve the rig before the spring breakup the road cost jumps to $2.40 per ton mile.

Air and water transportation are outside the scope of this paper. These two methods cannot, however, be ignored when choosing a transportation system for muskeg areas. In some cases it will be found that aircraft or boats will provide more economical transportation than vehicles. In only rare cases will either form eliminate the requirement for vehicles at both ends of the route.

With minor limitations, special purpose tracked vehicles permit access to muskeg areas in all seasons. With the few types available until recently, payloads were restricted to less than 5 tons per vehicle. Although in the last year the load capability of muskeg vehicles has increased to 20 tons, most development activity has been in the 1 to 10 ton class which meets the bulk carrier requirements of a

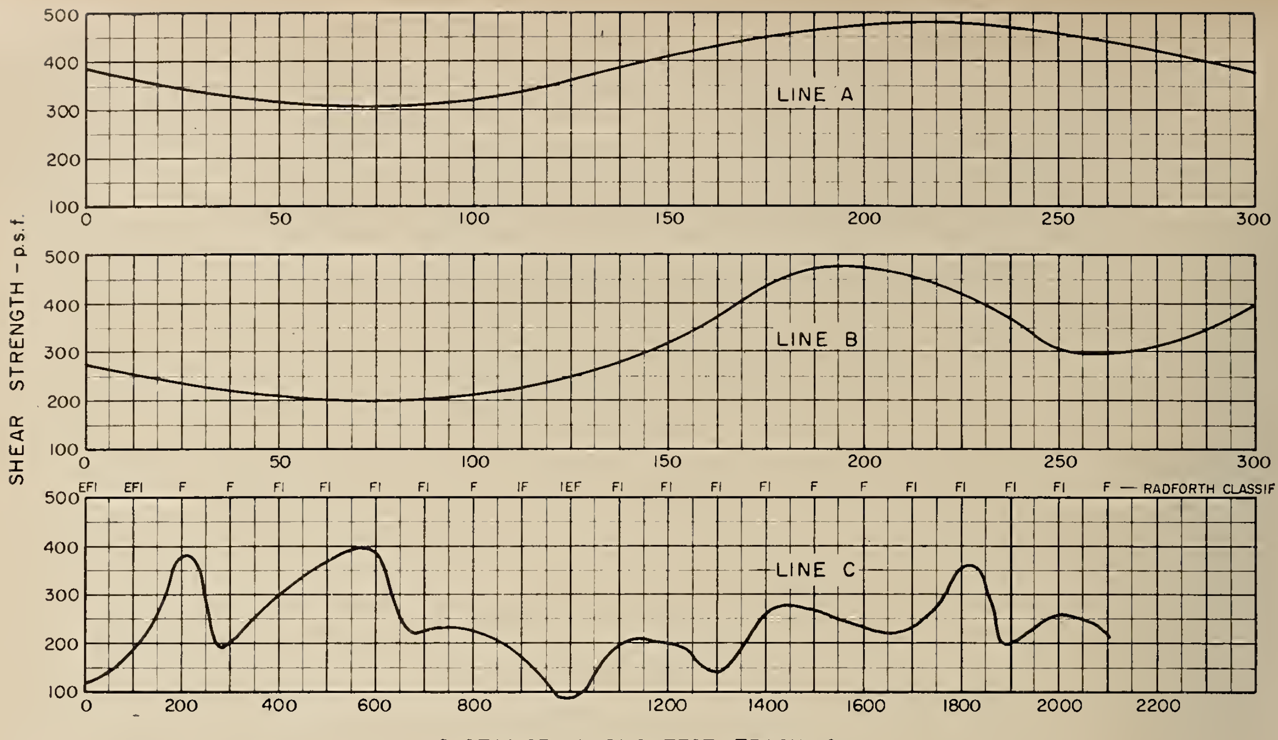

Fig. 8. Comparison of Undisturbed Shear Strength for Three Lines (Note: All data shown for 6 in. depth.)

broad spectrum of industries. A prototype 20 ton payload machine has recently been put into service to meet a special load requirement of the oil industry.

The economics of tracked vehicle operation in muskeg have not yet been well established. Development of the vehicles is being carried on while the machines are in field service. Thus it is difficult to separate the operating and development costs. However, at this time it is estimated that tracked transportation machines can be operated for $1 to $2 per ton mile. The high cost can be justified only when road construction costs can be avoided or when access at a particular time is worth a premium. For comparison, rail freight rates average 5c per ton mile and truck rates vary from 5c to 20c per ton mile on highways, and from 20c to 50c per ton mile exclusive of road costs on winter roads. A summer road over muskeg to a wildcat site will cost from $2,000 to $12,000 per mile and will be abandoned after 1200 tons have been moved over it. The road charge is then $1.60 to $10 per ton mile and the total cost $1.80 to $10.50 per ton mile.

Mechanical Properties of Muskeg

The progress made in the last 12 years in classifying muskeg is now being supplemented by investigations of mechanical properties. Fairly extensive work has been carried out in the fields of foundations and road construction in muskeg. In 1957, the determination of the mechanical properties of muskeg relative to vehicle performance[7] was started. This work was continued in 1958 and a correlation between muskeg shear strength and net vehicle performance was tentatively established.[8]

The test method used for the vehicle test programs in muskeg was adopted from vehicle tests in mineral soils and in snow. The method, known as the "Pull-Slip" test, has been described in detail in earlier publications. These tests are made with the test vehicle tracks rotating at constant velocity. The speed of the test vehicle, and therefore the slip rate of its tracks, is then varied in increments by changing the rate of advance of a dynamometer vehicle coupled behind. A strain gauged drawbar, included in the tow line between the test and dynamometer vehicle, measures the force required to maintain these imposed lower speeds of the test vehicle. Sprocket speed pick-ups on the test vehicle and a fifth wheel towed behind the dynamometer vehicle provide the data necessary to calculate track slippage. From these data, recorded on a common time base, a pull-slip curve is prepared.

Typical results of this type of test are illustrated in Fig. 6. The particular curves shown are from three lanes, Fig. 7, of varying shear strength, Fig. 8, as determined by a hand-operated shear vane. These three figures and Fig. 9 are treated in detail in a previous publication.[8]

Two separate results are presented in Fig. 9. It will be seen from the two dotted lines that a measureable decrease in performance results from progressive deterioration of the muskeg mat. Later checks revealed that some change, which cannot yet be quantitatively specified, occurred at depth in the muskeg. The correlation between experimental and calculated performance shown by the two solid lines is based on vane shear strength of the surface mat. The difference of numerical values between these two lines is satisfactorily accounted for by external motion resistance. This correlation is treated in detail in an earlier report.[8]

In summary, it has been shown from vehicle test programs[7, 8] that:

1. Vehicle performance is sensitive to the condition of the surface layers of the muskeg at the time of the test. Performance variations from this source were found to be as great as 12%. Repeated passes can result in 15% or more reduction in performance before rupture of the mat commences.

2. Vehicle geometry is the design feature which most affects mobility performance in muskeg. Such features as longitudinal location of the dynamic centre of gravity, belly width, track contact pressure, and grouser spacing can be mutually optimised. Optimum design will result in higher net traction on muskeg than

can be obtained from rubber tired all-wheel drive vehicles on dry concrete pavement.

3. The shear vane produces a strength profile which is compatible with the vehicle pull-slip curve. This instrument also shows that there is not an exclusive shear strength associated with a specific muskeg classification. The instrument could probably determine the range of shear strengths to be expected in various muskeg types. These data could be used, perhaps empirically, to specify which of a group of vehicles could negotiate a chosen route.

4. Generally, the results of the vehicle test programs support the contention that muskeg mechanics is within the realm of classical soil mechanics. For example, the vehicle performance curves are of the same shape obtained for tracked vehicles operating in sand, clay and snow. It has also been shown possible to predict the effect on a vehicle operating in muskeg of a design change based on experience gained with other vehicles in mineral soils.

Muskeg Vehicle Design

A valid system of muskeg classification was essential to the orderly determination of the mechanical properties of muskeg. In turn, the mechanical properties had to be established as a basis for vehicle tests. Data on the mechanical properties of muskeg and the vehicle response to variations in those properties are directly applicable to vehicle design. It is believed that some data meeting this requirement have been produced and are ready for broad application.

From the results of the test programs, it is obvious that important improvements can be made in current vehicles. Some of the modifications suggested by the test results are now being incorporated by both manufacturing and operating companies. Possibly the most important result obtained and applying to conventional tracked vehicles is that concerned with permissible ground pressure. It has been shown[7] that if the nominal ground pressure truly reflects the unit ground pressure over the entire track contact area the arbitrarily imposed 2 p.s.i. limit can be raised to between 3 and 5 p.s.i. in Type FI muskeg. Thus, a vehicle can be built stronger and with a little less attention to weight. The latter will usually reduce costs.

The results of the test programs have also indicated that there is a limit to the mobility which can be achieved with a practical, conventional tracked vehicle. For example, the test vehicles used and others in regular field use all trim nose high. This trim characteristic is most pronounced in short vehicles which are tail heavy. Increasing the track contact length and moving the centre of gravity forward reduce the trim angle and, as shown earlier,[7] substantially increase the drawbar coefficient. However, in a vehicle steered by any of the methods which impose a speed differential on the two tracks the ratio of length to tread must not be greater than 1.8/1 and preferably not greater than 1.6/1. Therefore contact length cannot be increased indiscriminately or trail, highway and railroad width limitations will be exceeded. The most effective way of advancing the longitudinal position of the centre of gravity is to move the engine and transmission forward.

TABLE II
Topographic Features

Simplified Grouping	*Contour Type*	*Feature*	*Description*
	A	Hummock	Includes tussock and nigger-head, has tufted top usually vertical sides, occurring in patches, several to numerous
I.	B	Mound	Rounded top, often elliptic or crescent-shaped in plane view
	C	Ridge	Similar to mound but extended, often irregular and numerous; vegetation often coarser on one side
	D	Rock gravel plain	Extensive exposed areas
	E	Gravel bar	Eskers and old beaches
II.	F	Rock enclosure	Grouped boulders overgrown with organic deposit
	G	Exposed boulder	Visible boulders interrupting organic deposit
	H	Hidden boulder	Single boulder overgrown with organic deposit
	I	Peat plateau (even)	Usually extensive and involving sudden elevation
	J	Peat plateau (irregular)	Often wooded, localized and much contorted
III.	O	Free polygon	Forming a rimmed depression
	P	Joined polygon	Formed by a system of banked clefts in the organic deposit
	K	Closed pond	Filled with organic debris, often with living coverage
	L	Open pond	Water rises above organic debris
IV.	M	Pond or lake margin (abrupt)	
	N	Pond or lake margin (sloped)	

TABLE III
Subsurface Constitution

Predominant Characteristic	*Category*	*Name*
	1.	Amorphous-granular peat
	2.	Non-woody, fine-fibrous peat
Amorphous-granular	3.	Amorphous-granular peat containing non-woody fine fibres
	4.	Amorphous-granular peat containing woody fine fibres
	5.	Peat, predominantly amorphous-granular, containing non-woody fine fibres, held in a woody, fine-fibrous framework
	6.	Peat, predominantly amorphous-granular containing woody fine fibres, held in a woody, coarse-fibrous framework
	7.	Alternate layering of non-woody, fine-fibrous peat and amorphous-granular peat containing non-woody fine fibres
Fine-fibrous	8.	Non-woody, fine-fibrous peat containing a mound of coarse fibres
	9.	Woody, fine-fibrous peat held in a woody, coarse-fibrous framework
	10.	Woody particles held in non-woody, fine-fibrous peat
	11.	Woody and non-woody particles held in fine-fibrous peat
Coarse-fibrous	12.	Woody, coarse-fibrous peat
	13.	Coarse fibres criss-crossing fine-fibrous peat
	14.	Non-woody and woody fine-fibrous peat held in a coarse-fibrous framework
	15.	Woody mesh of fibres and particles enclosing amorphous-granular peat containing fine fibres
	16.	Woody, coarse-fibrous peat containing scattered woody chunks

However, if the engine protrudes far ahead of the tracks the obstacle crossing ability of the vehicle will be impaired. To achieve the mobility increase known to be available from these two sources the morphology must be revised.

The desired increase in contact length and location of the centre of gravity can be achieved with articulated vehicles. The first vehicle in which joint-force-steered articulation was applied to muskeg, is simply two smaller vehicles hooked together with a steering joint. (Fig. 11) This unit was assembled to permit field assessment of the steering principle in muskeg. The vehicle was not intended as a prototype.

Application of the machine as an 8-ton transporter demonstrated the superior mobility available from the extremely long configuration. The suitability of the joint-force steering to oilfield use was confirmed. Also confirmed was that this method of steering causes only minor muskeg mat damage in comparison with the conventional, differential track steering.

Following the success with this vehicle, a version especially suited to geophysical work was constructed using a single engine. Power for the rear tracks is transmitted through the articulating joint. Mobility and manoeuvrability of this machine are exceptionally good.

The design principle has also been continued in the 'Musk-Ox', shown in Fig. 10. The vehicle, in service since April 1959, has carried 20 ton payloads through muskeg and soft clay. In one case the vehicle penetrated 45 in. into the muskeg while carrying a 19 ton payload. Even at this deep "sinkage" it was able to traverse a 3 mile stretch of muskeg without any indication of imminent mobility failure. Evaluation of this machine in field service is continuing. To date the machine has met all of the design requirements.

Review of the Present Position

Muskeg technology although far from complete is now fairly useable. An orderly classification has been devised and proven reliable. Some ranges of mechanical properties are known. Construction and access techniques have been developed and applied with predictable results. Vehicles capable of providing reliable, all-season transportation with payloads to 20 tons are available.

Sufficient facility with muskeg has been achieved to permit the conduct of more detailed engineering investigations of its mechanical properties. These further investigations must be carried out to improve both the reliability and the economics of engineering structures in muskeg. When muskeg can be handled as a routine engineering material it will no longer be a deterrent to the development of some of Canada's most valuable known resources.

ENGINEERING ASTRIDE

THE BORDER

R. F. Legget, M.E.I.C.,

Director, Division of Building Research, National Research Council, Ottawa.

From a talk given by the author at the Cleveland Convention of the American Society of Civil Engineers, May, 1959.

A few months ago, standing on the top of the great earth dyke which flanks the Canadian part of the immense new power house at Barnhart Island on the St. Lawrence, the writer had by his side a close friend, a distinguished scientist and engineer from a distant land. The Director of the St. Lawrence Project for the Hydro-Electric Power Commission of Ontario, standing there in the warm sunlight of that lovely summer day, told how this vast construction project had been carried out by two countries, working independently but side by side, without the slightest difficulty or real argument from the very start of the actual work. The foreign guest was amazed. "How can such things be?" he asked. "How can two great countries such as yours co-operate so closely? And if you can do it, why cannot other countries do the same? What is the secret?" These questions are worth considering, but without launching into the usual eulogy about the more than five thousand miles of undefended frontier.

IT IS doubtful if any of the popular speakers about the Seaway has reminded his audience, when talking about the frontier, that one of the great early American border forts was found to have been built in Canadian territory when surveys were checked. To be reminded of such an early piece of construction *really* astride the border may, however, provide a good starting point for a realistic look at the inter-relations of American and Canadian civil engineering, with special reference to works that are near the long border.

The St. Lawrence Seaway will assuredly stimulate greatly the commerce on the vast international waterways provided by the Great Lakes. Built with all the accustomed speed of modern construction, the Seaway and associated power works constitute a monumental project of civil engineering. When they were officially dedicated, there may have been some who remembered that it was almost exactly 27 years since (on July 18, 1932) a solemn treaty was signed covering the prosecution of this great undertaking. Unfortunately, the treaty failed to win the necessary two-thirds majority of the votes of the U.S. Senate and so it proved to be abortive. Canada had to wait. Even the imperative of war failed to win a simple majority of senatorial votes for the executive agreement prepared to authorize the start of construction in 1941.

These things are not said in any way critically. They are statements of historical fact that show that the answers to the simple questions cited at the outset are not clear-cut. The delay in the start of construction had many consequences, not the least of which was that the Province of Quebec, without the power that could be developed by a dam at the Lachine Rapids, one of the seaway works, had to go elsewhere for much needed power. Work was therefore started instead on the Bersimis project in northeastern Quebec, which will eventually develop 2 million hp.

For many reasons, therefore, Canadian patience was sorely tried, with the result that in 1951 the Prime Minister suggested to the President of the United States that if the International Joint Commission would agree to the generation of power jointly by New York and Ontario in the international section of the St. Lawrence, Canada would herself carry out all the associated seaway work. The Commission did so agree, on 29 October 1952, and Ontario and New York went ahead with the power works at Barnhart, now completed and in operation. Before Canada could get started on the Seaway construction, however, other factors had emerged which eventually led to the international agreement under which the job has been successfully carried through to completion—as a Canadian project on the Canadian part of the river from Montreal to Lake St. Francis, and as a joint project with the United States in the international section from there to Lake Ontario, all costs being shared. In this joint project the lift from the tail-water level at Barnhart is made by two locks on the U.S. side. At Iroquois, the lock to pass the Regulator Dam in in Canada. Later there may be locks at both places in both countries when the traffic so requires.

In 1952, however, it was said in some American engineering circles, statements even appearing in print, that Canada could not possibly carry out the Seaway project on her own, that her suggestion of doing so was just a political move, that she was just bluffing. That assertion, coming from fellow engineers, was not easy to take. Those who made this assertion had, apparently, never been to the eastern end of Lake Erie to see how ships both large and small manage to get to Lake Ontario, 326 feet below. This is done by way of the Welland Canal, one of the great canals of the world, which conveys the largest of upper lake freighters up and down the Niagara escarpment in just seven locks. It is entirely a Canadian achievement, just as were the five preceding, smaller

Welland Canals—in conception, design, construction and cost. Officially opened on 6 August 1932, more than a quarter of a century ago, the "new" Welland Canal cost $131,900,000. Replacement today is estimated to cost $350,000,000.

The sceptics could just as readily have gone to the western end of Lake Erie and into the St. Clair River, to have a look at the "chemical city" that has developed around Sarnia, and in particular at the installations of the largest and most successful of Canadian chemical plants. It makes synthetic rubber and was built at the height of war emergency, in 1942-43. Many will recall how critical a material rubber proved to be in the early war years and how it was decided that six synthetic rubber plants had to be built with the highest of all war priorities. Originally, it was planned that all six should be built in the U.S.A., on the grounds that even one such job was beyond the capacity of Canadian engineers and constructors.

Fortunately, the Minister in the Canadian Government responsible for war supplies knew well what the Canadian construction industry could do, for he was an engineer himself, the Rt. Hon C. D. Howe. He was able to have the original decision changed and so, after some delay, Canada was given the sixth and last plant to build. All equipment and process designs were shared between the several plants, a superb piece of American engineering, but plans for the Canadian plant site, its service structures and utilities were prepared by Canadian consultants, and the entire project built by Canadian contractors, using as many as 8,000 men on the square mile occupied by the plant. Last of the six to be started, it was said at the time that the Canadian plant was the first to be finished. Be that as it may, the fact remains that the first carload of styrene was shipped from this plant, to an unspecified destination in the United States, eleven months to the day after the first sod was turned.

Arvida

Moving a little away from the border, but still on St. Lawrence waters, many know the lovely sail up the Saguenay River, past Tadoussac, past Capes Trinity and Eternity, and finally into Ha-Ha Bay to the small port of Bagotville. Approaching the wharf there, late one fine evening in July 1942, a tourist was overheard explaining that on the other side of the tree-lined hills behind the little town there was "nothing but trees and rivers and lakes all the way to the Arctic Ocean." Little did she know that just the other side of the hills at which she was looking was the world's largest aluminum plant, at Arvida, then being expanded at breakneck speed, and that to serve it with vital power there was even then being completed possibly the greatest of all Canadian construction achievements, the building of the Shipshaw power plant. Developing 1,200,000 hp. this entire project involving five dams, large tunnels and a great power house, was "on the line" less than eighteen months from the start of active construction, eighteen months that included one of the most severe winters ever experienced in the Lake St. John country.

This recital of what Canadians can do will suggest the atmosphere of Texas—or should one now say Alaska, if the largest state is to produce the tallest tales? These are not tall tales, however, but matters which come to mind as one considers those pointed questions as to how two countries manage to work together so harmoniously in the carrying out of civil engineering works. This is surely done, despite the impediments that others may put in the way, because of mutual respect for what each can do when American and Canadian engineers work together and because of common high purpose. Canadian concrete experts may never persuade Americans that placing mass concrete in high lifts is good practice (thinking now of that same St. Lawrence power house). Canadians may never convince some Americans that winter concreting is an economical procedure, but both have learned much from the other; so may it always be.

And when Canadians and Americans do work together, with administrative and political hurdles removed, then the impossible becomes merely a challenge, the incredible merely a tale to be told. Think for example of the DEW Line, that great line of outposts for continental defence—much of it built in Canada, but with American money; designed by American engineers, but with some assistance regarding local conditions from Canadians; built in Canada by Canadian prime contractors but with invaluable assistance in the delivery of men and supplies from the American Navy and Air Force. There were some difficulties, naturally, but not at the joint working level. To stand on the Arctic Coast of Canada at a DEW Line installation and to be unable to distinguish Canadian workers from American is to see further vivid evidence of what can be done together.

Behind all such co-operation in the actual construction of civil engineering projects lies the much more difficult task of co-operation in the planning of these international ventures. For boundary water problems, this is done by the International Joint Commission, with equal membership from both countries, and under joint chairmanship. Another distinguished Canadian engineer, General A. G. L. McNaughton, has long served as the Canadian chairman of the International Joint Commission. This great venture in international engineering understanding has now a history of over half a century of splendid achievement. Great and difficult problems have been solved by this unique arrangement, with very few questions ever having had to be referred to higher authority or to the courts. Great problems are even now under consideration by the I.J.C. All civil engineers will hope that the Commission's work will continue to show what can be done by two nations, acting in concert, with a reciprocal sharing of responsibility, a reciprocal recognition of capabilities, a reciprocal interchange of skilled service.

Samuel Fortier

To speak of this co-operation as a reciprocal process may sound strange to some, especially to those who never think of Canada as very much more than the great white blank that appears north of the U.S. border on all too many American maps. It would be invidious to cite modern examples of the other side of the penny but if one turns back the pages of engineering history for a few moments, it is easy to illustrate what is meant. Samuel Fortier, for example, is a name now little known but a name still familiar to those few who know the history of irrigation in the western States as that of one of the great pioneer irrigation engineers of America. Fortier was, however, a true pioneer in the field of soil mechanics. Fifty years before the name *soil mechanics* had been coined, Fortier was experimenting with soil stabilization, soil compaction and other so-called modern techniques of soil engineering. And he was a Canadian, a native of Leeds, Quebec, trained at McGill University.

He graduated in 1885, but heard the call to the West soon after, for he was in Denver by 1890. His great work was done with the United States Department of Agriculture, where he became Associate Chief of the Division of Agricultural Engineering. He also served the Agricultural Colleges of Utah and Montana and was on the staff of the University of California for two periods. Fortier was not the only Canadian who helped with the start of irrigation in the West. The town of Ontario, in California, was so named by two young Canadians, the Chaffey brothers, who went out west from a small place near Ottawa in the 1830's. (Later, they also started irrigation in the Murray Valley of Australia where one may now see a memorial to them).

Turning to a different branch of civil engineering, the longest railway tunnel in North America, east of the Mississippi, is still the Hoosac Tunnel of the Boston and Maine Railroad. It is located in the heart of the mountains at the northwest corner of Massachusetts, near North Adams. Nearly five miles long, it is still in excellent condition and in regular service even though it was opened for use in 1877. How many know that it was finally built, after several false starts, by two Canadians? These were the Shanly brothers, Walter and Francis, two members of a quite remarkable group of young engineers who, by great good fortune, served Canada in the early days of her railway building and at the hey-day of canal construction. The Shanlys had gained such an enviable reputation as engineers and builders in Canada that the Commonwealth of Massachusetts invited them, in 1868, to submit a tender for the construction of the Hoosac Tunnel, after other contractors had failed. Their offer was accepted. They started work in 1869 and the tunnel was completed, on schedule, in 1874. The brothers introduced several new features into tunnel work, the most notable being the first use in North America of nitro-glycerine as an explosive; they paved the way for the great advance in tunnelling that followed in the next few decades.

T. C. Keefer

The only meeting that the American Society of Civil Engineers has ever held in Ottawa was in 1913. One of the highlights of the meeting was a garden party, held in the garden of one of Ottawa's lovely homes. In the centre of the garden was the host, then in his ninety-second year, still keen and active mentally but slowed down physically by the burden of his years. His name was Thomas Coltrin Keefer; he had been a friend of Walter and Francis Shanly. Far more than that, he was the acknowledged dean of Canadian engineers, the only man to serve twice as President of the Canadian Society of Civil Engineers (which became, in 1918, the Engineering Institute of Canada). His second term in the Canadian presidential chair coincided with his tenure of another office, for he was also the eighteenth President of the American Society, the only Canadian ever to hold this office. Small wonder, then, that he had a garden party at his home when the Society met in his own city; small wonder that those who were there regarded the event as so memorable an occasion. For Thomas Keefer was born in 1821, trained as an engineer on the early Erie and Welland Canals, steadily gaining such a high reputation that his practice at least touched almost every major Canadian civil engineering project of the nineteenth century.

Naturally, therefore, Keefer had much to do with the steady development of the St. Lawrence Canals, his work in this field continuing through most of his professional career and culminating in his membership of the International Deep Waterways Commission which conducted one of the first studies of the practicability of a deep ship canal between the Great Lakes and the sea. In this and many other ways, not least by his presidency of the A.S.C.E., he served the two countries well. At that garden party, the old gentleman could have shown a tangible link with the very first St. Lawrence Seaway which dates back to 1832, for Mrs. Keefer's father, Thomas McKay, was one of the builders of the Rideau Canal. So well did McKay execute his masonry work that, just before the Canal was opened, the Superintending Engineer, Lt.-Col. John By, presented to him a beautiful silver loving cup as token of his appreciation of work well done. The cup was bequeathed to Mrs. Keefer and is now in the possession of Thomas Keefer's grandson, another bearer of his distinguished name.

Reference to the Rideau Canal as the first St. Lawrence Seaway may be surprising to those who have never heard of the Rideau Waterway. It is the Canal that joins the cities of Ottawa and Kingston, formed by the canalization of two rivers and the linking of their headwater lakes. It is 127 miles long, includes 47 masonry locks and over 50 dams, large and small. And it was constructed by the Royal Engineers of Great Britain between 1826 and 1832, through what was then the virgin forest of Upper Canada. It was built as a military waterway, as a direct aftermath of the war of 1812, to provide an alternative route between Montreal and Kingston (by using the Ottawa and then the Canal), in case hostilities should break out again and the supply line up the rapids of the St. Lawrence be ambushed from the American side.

Fortunately, the Rideau Canal had never to be used for this warlike purpose. Today, it is used as never before for invasion purposes — the invasion of the lovely Rideau Lakes by hundreds of American holiday makers. But for over 20 years it served as the first St. Lawrence Seaway, a large fleet of small steamboats plying a busy trade on the "Triangular Route" from Montreal up the Ottawa River, then up to the Rideau Lakes and down again to Kingston, usually returning to Montreal down the rapids of the St. Lawrence. In 1855, the first St. Lawrence Canals were finished after the expenditure of over $20 million, a really vast sum for the those days which almost bankrupted Upper Canada, and which had appreciable influence upon Canadian history. The great activity on the Rideau was over. For the next 103 years, shipping was to sail up and down between the sea and the Great Lakes, using the St. Lawrence Canals which Canada built and rebuilt on her own. The Seaway of 1959 is no new thing, it should be recalled, but just a greatly enlarged version of what Canada herself has provided for international use for over a century, and without charge for these many years.

Thomas Keefer might well have told about all this, with a smile, had one been privileged to chat with him in his garden on that June day in 1913. He would certainly have told of one of his earliest boyhood memories—how, on a day in November 1829, he had seen the first two vessels to use the first Welland Canal, as they passed his home at Thorold, sailing side by side, one American and one Canadian, on their way up from Lake Ontario to the Welland River and so into Lake Erie. One hundred and thirty years later, two fleets of boats, gunboats but sailing on peaceful occasions, side by side in true naval comradeship, come up again from the sea, this time officially to participate in the opening of the greatest seaway link of all. As a part of the ceremonies on that day a stone was unveiled, granite set into the solid concrete of the great power house. One need go no further than this stone to find the answer to those early questions, for there engraved for all to see, for all time, are these words:

> *"This stone bears witness to the common purpose of two nations whose frontiers are the frontiers of friendship, whose ways are the ways of freedom, and whose works are the works of peace."*

COFFERDAM AT MILE 6 QUEBEC CARTIER MINING RAILROAD, PORT CARTIER, QUEBEC

J. Zorzi, M.E.I.C.,
Consulting Engineer, Montreal

One of the interesting problems encountered during the construction of the railroad from Port Cartier to Lac Jeaninne was the centre pier for the bridge over the Rochers River at Mile 6. The problem was not uncommon—about 13 ft. of water at low water, a river bed consisting of soft silty clay about 45 ft. deep, then a layer of sand overlying bedrock.

THE UNDERSIDE of the foundation is about 22 ft. below the low water surface and 9 ft. below the river bed. The reinforced concrete foundation for the pier is 24 ft. x 50 ft. x 6 ft. deep. It is supported on ninety 12 in. x 12 in. end bearing piles. All outside piles are driven on a batter of 1:4. Any standard steel sheet piling cofferdam would have had to be clear of the batter piles and driven into the sand below. Even if sheet piling long enough and strong enough had been available which it was not, and if there had been enough passive resistance in the few feet of sand overlying the bedrock to build a standard cofferdam, the cost would have been out of line. A two-wall jetty type, a cellular type and a crib cofferdam were also investigated and discarded for various reasons. It was finally decided to build the cofferdam as shown on Fig. 1. and 2.

New Type Driving Template

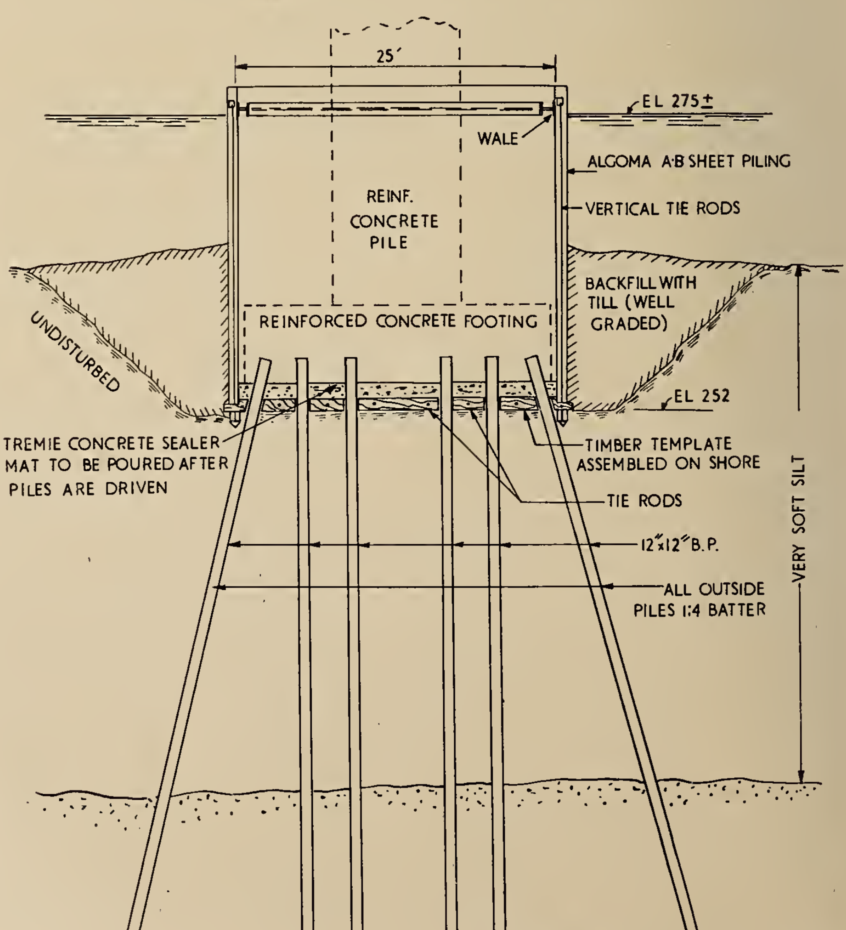
The idea was to excavate to somewhat below the underside of the footing, then to build a rigid and solid driving template slightly larger than the pier footing and strong enough to resist lateral pressure and distortion. The template was to have exactly-located guide holes for all the permanent bearing piles and a ledge around the perimeter on which a sheet piling wall could be set. This template or working platform was to be sunk onto the excavated river bottom with the centre lines in the exact position of the pier. Next the bearing piles were to be driven through the guide holes and a sheet piling wall was to be set on the ledge around the perimeter. The template was to act as bottom wale and brace and also support the sheet piling vertically. The setting up of the sheet piling wall could be done before or after the bearing piles were driven.

Good in Unstable Soils

If the soil was suitable, backfilling around the outside would hold back the water and the pumping out of the cofferdam could be done. If the soil was porous or susceptible to piping, a concrete seal could be poured under water on top of the template. After the concrete had hardened and bonded to the bearing piles the dewatering could be accomplished. In this case the concrete sealer mat would serve a two-fold purpose, first to seal the bottom against entry of water and reduce the buoyancy of the cofferdam by the weight of the concrete, and secondly to utilize the withdrawing resistance of the bearing piles against the uplift by bonding of the concrete to the piles. In either case the time required to construct the pier would be greatly reduced and the cofferdam would have to be only slightly larger than the pile cap in spite of the batter piles.

The owner engineers who had to approve of the method to be used in building the pier did see the advantage of the method outlined above and approved without hesitation.

Fig. 1. Cofferdam — Section A-A



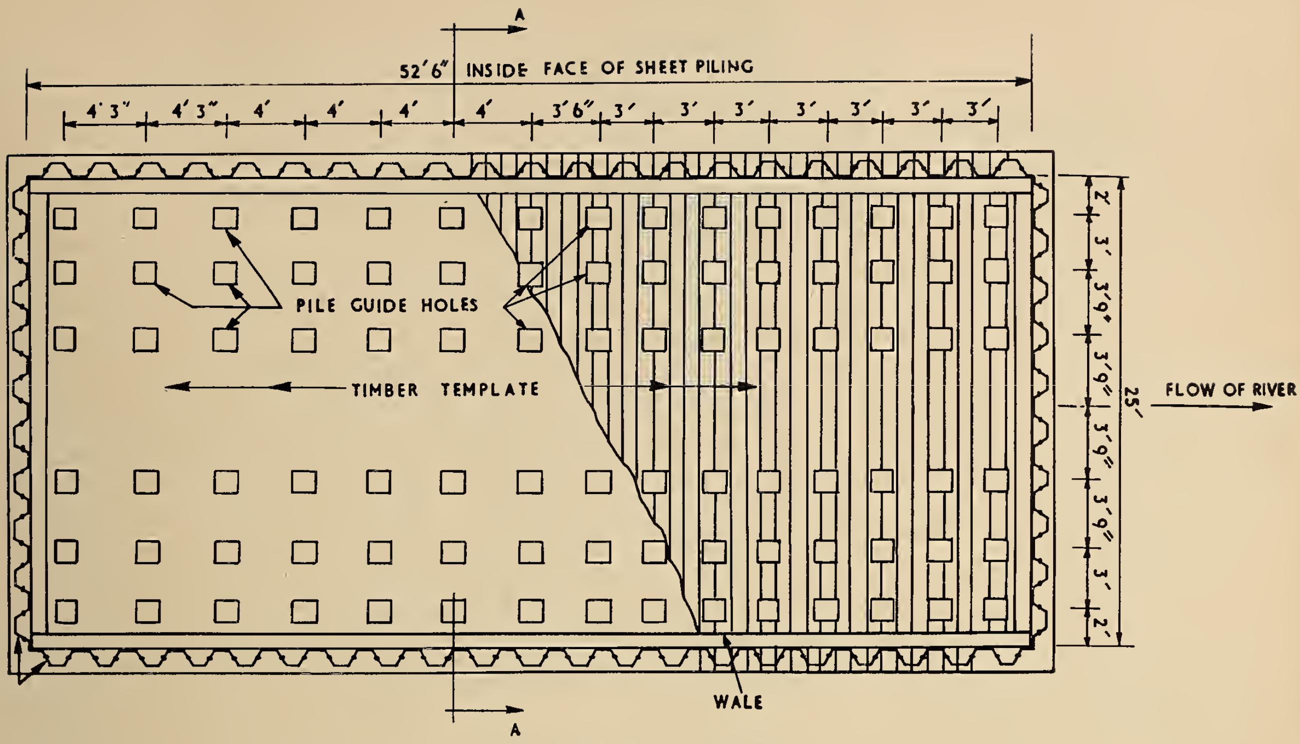


Fig. 2. Plan of Cofferdam

Construction Procedure

A standard timberpile approach to the pier side was constructed. The river bed was excavated with a clamshell as shown on the drawings. At the same time the laminated timber template was built on shore. The timbers were pre-drilled to a template and then slipped over the longitudinal tie rods. The overlapping rods were tightened as the work progressed. After all the timbers were attached to each other, the pile guide holes were located in their respective positions and then cut out with a power saw. The retaining wall shelf all around the outside of the template was then cut out. The longitudinal stringers were now bolted to the underside. The vertical tie rods were attached in their respective positions. The template was pulled across the ice to the open water over the excavation. After placing the platform in its exact position at water level, four guide piles were dropped plumb through the guide holes and partly driven. A predetermined number of steel piles (just a few tons in weight above the buoyancy of the timber) were loaded on the template. The crane let the platform sink slowly to the excavated river bottom, the guide piles assuring its exact location. A frame of 12 in. x 12 in. timber of the same overall dimensions as the shelf on the submerged template was positioned and allowed to freeze into the ice. Starting on an upstream corner, the sheet piling was now threaded onto the ledge of the template and tied to the 12 in. x 12 in. timber frame at water level. Backfilling with till to the level of existing river bottom was done. The backfill served two purposes. First, it was to hold the sheet piling on the shelf and secondly, it was to keep the water from piping through during the unwatering period at a later date. The bending stress in the secondhand steel sheet piling after backfilling and unwatering, was calculated to be about 13,800 p.s.i. This was considered well within the safe limits for this type of work and steel used.

Water Seal

The driving of the piles through the guide holes was now started. Some of the piles had to be cut under water by a diver at the required elevation. After all piles were driven, a tremie concrete sealer mat was poured on top of the template. When the concrete had hardened enough and bonded to the piles, the unwatering was carried out and the rest of the piles cut. The foundation was built in the dry and in the usual manner.

Possible Improvements

As in everything else that is new and untried, there were details that could have been and will be improved. The guide holes should have been a ½ in. larger each way. There should be about 2 ft. of clearance all around the foundation to accommodate the pumps. All vertical ties and cross bracing should be made of wire rope. The excavation should be levelled with gravel before the template is sunk into position. The shelf on the template should be higher and wider for easy threading of the sheet piling. There should be extra stringers under the template.

Human Factor

Before starting on this project the superintendents, foremen, and skilled labourers had to be won over to the new scheme. The work had to be explained in detail with answers to all questions. Most were eager, all were willing, but a few were skeptical to the day of unwatering. The idea found a different reception with the engineers who had any contact with the job. They were very keen, interested, encouraging and helpful in every way.

Discussion

A METHOD OF DETERMINING THE POWER POTENTIAL OF RIVERS WITH MANY RESERVOIRS AND POWER PLANTS

G. S. Cavadias, M.E.I.C.
Consulting Engineer, Montreal.
The Engineering Journal, October 1959, p. 103.

Discussion by R. Clinch

Mr. Cavadias is to be congratulated on having presented a paper dealing with one aspect of system planning, a subject which is assuming ever increasing importance at the present time. The primary object in system planning is to meet the demand for power and energy at the lowest possible cost. The methods employed in achieving this object will depend among other things on the nature of the demand, the cost of installation at the available power sites, and the cost of transmission from the individual sites to the load centre.

In determining the installed capacities at individual plants on a river, Mr. Cavadias has used a condition that the sum of the energies produced by the individual plants should be a maximum. This, in effect, resolves into a condition that secondary energy production should be a maximum. I suggest that in the majority of power systems, the cost of installation at available power sites and the cost of transmission are more important factors which should be taken into account.

The inclusion of these factors will, of course, complicate the problem considerably, and with all but the most simple of systems, a trial and error approach is desirable in determining the most economic installations at the various plants of the system. In this method, the cost of power and energy are compared for a number of possible installations at the various sites, taking into account installation costs, transmission costs and losses, drawdown at the storage reservoirs and power sites, voltage regulation and any other characteristics of the electrical transmission system which may impose limitations on system operation.

It is indeed fortunate that reliable high speed computers are now available for the solution of problems of this type, especially since the majority of power systems in Canada now include both hydro-electric and thermal-electric generation.

Discussion by K. Renger, M.E.I.C.

This paper is probably intended only for preliminary assessment of the power potentialities. I presume that the additional condition that the power production by each individual plant be as uniform as possible is meant to be of a secondary (maximum uniform total power production first) nature since it would increase the spillage in actual operation (especially without advance knowledge of the future run-offs) and reduce overall efficiency of the whole system if carried too far.

The assumption Item 2, "Power production as uniform as possible" (of all plants of the hydro system) is also not realistic if the hydro system is supplemented by thermal-electric plants as is already generally the case and will be increasingly so.

The method shown for determining the installation capacity at the individual plants is based on maximizing the energy output for a given total installation and assuming that the storage capacity is known. Actually both the total installation and the storage capacity are not known. On Page 10 the load factor was assumed (65%). To assume the load factor intelligently requires, among other information, estimate of the incremental hydro plant installation costs (including transmission) and of the installation and energy costs for alternative generation. The load factor to be assumed may range from say 30 to 90% depending on many factors (if it is certain that integration with a big power system is impossible then the range would be much narrower). Accepting that the load factor assumed has the proper value, it is still not certain that the suggested method represents the most economical planning because there are bound to be differences in incremental plant costs per Kw installed and also differences in incremental transmission costs.

Let us look at the example presented in the paper:

Plant P_1 has a head of 805 ft.
Plant P_2 has a head of 535 ft.

Knowing nothing else one would expect that the incremental installation costs for plant P_1 are less than for plant P_2. Assuming that everything else is equivalent at both plants, one could expect a higher load factor installation at plant P_2 than at plant P_1 for economic reasons. A look at Fig. 6 shows than plant P_1 would be a very high load factor installation whereas plant P_2 would have a much lower load factor. The incremental load factor for both plants is the same according to Fig. 6 (about 16%), but the plant with the lower incremental installation cost charge per annum could be developed to a lower incremental load factor than the plant with higher incremental charge, assuming equal return per kwh from increment energy. (See proceedings 81 (No. 697) of the A.S.C.E. "Selection of Installed Capacity at Hydro-Electric Power Plants" by L. S. Wing and R. H. Griffin, May 1955). Apparently the criterion for distribution of the capacity to the individual plants implies equal incremental installation costs (more exactly: incremental charges per annum) per Kw for both plants (including transmission). Depending on the situation the departures from this assumption may be large. The final criterion for the installed capacity should be greatest overall system economy (including the thermal-electric plants, if any) and not the greatest energy output for an assumed total hydro installation. Furthermore, the storage capacities of the two reservoirs were given at the outset. Frequently they will be unknown (Cedar Lake, Lake Winnipeg, for instance) and will have to be established through economic studies trying different regulation ranges in conjunction with different stages of development, not only downstream of the reservoir but of the whole system. However, as long as no installation and storage cost estimates are available yet, the method presented in the paper is very apt to give a preliminary answer.

Discussion by J. A. Thomas, M.E.I.C.

The author has presented a very interesting and timely paper. Power studies are often made using such approximate methods and in such general terms that the results are indicative only and do not permit power contracts for the best utilization of the potential. In many cases, the basic concepts have been found to be incorrect. It is only when one is faced with the problem of predicting the water use that the complexity of the problem and the number of variables involved is appreciated. Even so, the most detailed study is very likely an approximation to what will actually evolve through subsequent experience.

The author gives, in his paper, a generalized analytical treatment which permits an organized approach to the problem. It is precise within the limits of its assumptions.

If the rivers and their reservoirs under study are to be developed to supply power to an isolated system, this method should yield a result which closely predicts the actual regulation. However, if power is to feed into a network or into a system where the supply is partly thermal, the problem is somewhat more complicated. Under these conditions, the author's analytical method is very effective in determining the energy potential.

In order to evaluate the available capacity, however, it is usually necessary to re-regulate the reservoirs in such a way that the power output is far from constant.

In paragraph 4.1, the author assumes a load factor to determine the total installation. In the system mentioned above, the load factor must be determined from the analysis of capacity benefit.

In order to do this, power duration curves of the critical months during the regulating period may be drawn and on them, the existing and proposed installations fitted. Thermal capacity usually is placed in the lower part of the curve, i.e., it is base-loaded and hydro plants are fitted above with consideration of their respective storage and pondage. Finally, when the proposed developments have been located in proper relationship to existing plants on the duration curve, the load factors, or, precisely, the capacity factor and corresponding installation may be obtained.

The writer would like to question the author on a few details of the development of his method.

Firstly, in equation (10), the term $\triangle S_a$ represents a volume, which should be divided by a time factor to produce a flow in relation to power.

The definition for load factor is given by:

$$\text{L.F.} = \frac{\text{average load}}{\text{peak load}} \text{ for a specified period.}$$

The average load will include some secondary power.

When the peak load equals the installed capacity, as is usual, the load and capacity factors are equal and this equation can be written:

$$\text{L.F.} = \frac{\text{area under duration curve corresponding to the installation}}{\text{installed capacity x period of time}}$$

This equation is quite different in concept to that used by the author.

Finally, in equation (15), the author states that the differentials $dI_2 + \ldots + dI_n$ "are now independent". This is not apparent to the writer. However, the conclusions are correct and can be seen from the following alternate analysis:

Since $I_1 + \ldots + I_i + \ldots + I_n = I$ where I is the total installation and is therefore a constant, $dI_1 + \ldots + dI_i + \ldots + dI_n = 0$.

Since I_i must be positive and finite, dI_i must be equal to zero.

The net result of the mathematical analysis is to conclude that the total duration curve is the sum of its component duration curves, a fact that is rather obvious in the first instance.

Referring to Table 1, the columns headed "Power" should more correctly read "Energy" since the values are given in Mw. months.

The writer would like to commend the author on the clear presentation of his subject and his ability to express his concepts in mathematical form.

Discussion by E. Kuiper, M.E.I.C.

Mr. Cavadias applies in essence the following procedure: He determines the maximum dependable flow, and

Abstracts

These abstracts of Annual General Meeting papers were not available for publication in April. Most of the 1960 AGM paper abstracts appeared in the March and April issues.

The Contribution of the Mines Branch Services to the Development of Western Canadian Mineral Resources
John Convey

The known mineral resources of the area from the Canada-U.S. border to the Arctic and from Winnipeg to the Pacific, or about two-thirds of the Canadian continent, have at one time or another come under the scrutiny of the engineers and scientists at the Mines Branch, a unit of the Department of Mines and Technical Surveys at Ottawa. Deposits of metal ores, industrial minerals and fossil fuels have been examined and, where possible, have been processed into economic feed materials for Canadian industry. The more important processes of topical significance developed at the Mines Branch include those for uranium, coking coal, asbestos, light weight aggregate and the Athabasca Tar Sands.

Manned Space Flight
Orest Cochkinoff

The re-entry phase of manned space flight presents many new problems such as stability and control of the vehicle, heat shielding, communication and deceleration effects. Vehicles may be winged and allowed to glide in or may be of a high-drag type, following a ballistic trajectory. The aerodynamic heat that is generated may be dissipated by radiation, ablation or by some other form of shielding. Two research projects are underway to take man into space—the X-15 airplane and the Project Mercury ballistic vehicle, both sponsored by the U.S. National Aeronautics and Space Administration. The X-15, probably the most advanced aircraft yet built, is constructed largely from welded Inconel X and titanium and uses a 50,000 lb. thrust rocket engine, while the Project Mercury vehicle will be of the high drag type, placed in orbit by an Atlas booster and helped to land by parachute.

Automation and Control Engineering in Canada

Corrosion Problems in Chemical Plant Instrumentation

When designing instrumentation systems for chemical plants, the same types of problems occur time after time, even though the particular plants may differ considerably from one another. These problems arise because of the nature of many of the processes that are used in the industry. The materials handled are frequently either very corrosive, or very dirty, or present an explosion hazard, or, quite likely, all three at the same time. In many cases plant designers have difficulty in finding suitable vessels, pumps, piping, valves and so on, able to withstand these difficult operating conditions, in spite of the fact that they are dealing with heavy, rugged, equipment. The difficulty of making a measurement, possibly a very delicate measurement, under such conditions, and of being able to make it reliably twenty-four hours a day, is apparent. This article will consider ways in which the instrument engineer can overcome some of the difficulties which arise when measuring process variables such as pressure, liquid level, and chemical composition. The influence of corrosive plant conditions on the designer's choice of electrical control equipment will also be considered briefly.

Pressure Measurement

It may cost $20 to measure the pressure of a clean, non-corrosive gas or liquid stream, using a bourdon tube pressure gauge. The same measurement on a corrosive stream may cost over $200. This considerable difference points out that, in addition to the problem of finding something that will work, there are economic problems as well.

Bourdon tubes are available in phosphor bronze, beryllium copper, monel, and various alloy and stainless steels, but none of these materials may be suitable for use in contact with the corrosive agent involved. In

Fig. 1. Bourdon tube gauge fitted with a diaphragm protector.

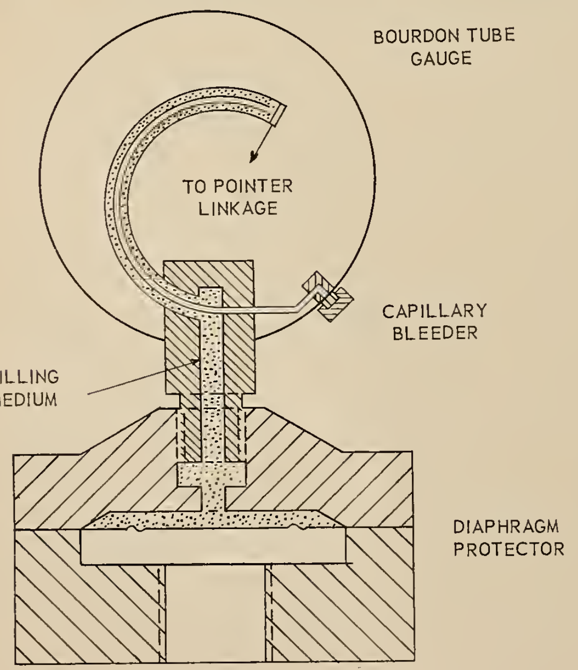

Fig. 2. Diaphragm gauge

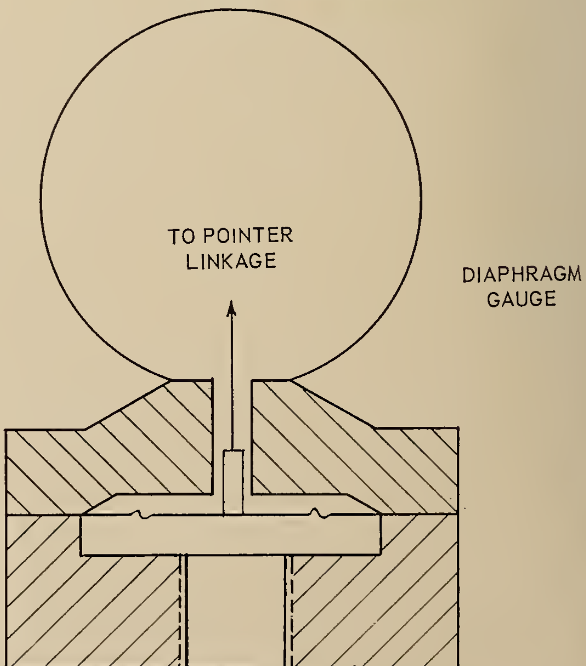

this case, the plant fluid must be kept out of the gauge by some kind of sealing arrangement. Two common methods are by the use of a bourdon tube gauge fitted with a diaphragm protector or "chemical gauge attachment", or by the use of a diaphragm gauge in which the diaphragm itself is the measuring element. The diaphragm gauge is likely to be the less expensive alternative when it can be used, that is, for vacuum and for pressure applications up to about 300 p.s.i. This type is widely used in Europe, but is less common in North America, where the diaphragm protector is normally used. A simplified sketch of a bourdon tube gauge fitted with a diaphragm protector is shown in Fig. 1. The diaphragm is enclosed in a housing, with the pressure to be measured admitted through a flanged or screwed connection to the underside of the diaphragm. The bourdon tube gauge is screwed into the top of the space above the diaphragm, including the bourdon tube, being filled with some inert oil or grease. A capillary bleeder is usually fitted as shown to ensure that all the air is removed from the bourdon tube during the filling operation, so that process pressures will be transmitted accurately through the diaphragm and filling medium. The diaphragm gauge is shown in Fig. 2. The process pressure or vacuum is applied to the underside of a stiff diaphragm, the other side of which is at atmospheric pressure. The small movements of the diaphragm which result from changes in the process pressure are geared up through a sector and pinion to drive the gauge pointer.

Neither of these gauges is as accurate as a straightforward bourdon tube gauge of the same quality. The diaphragm protector introduces errors because the diaphragm is not perfectly flexible and because of the effects of temperature changes on the filling medium. The diaphragm gauge is less accurate because the diaphragm is not such a good pressure measuring device as a bourdon tube. However, for corrosive applications, they both have the advantage that they can make use of a wider range of materials of construction for the "wetted parts" than can bourdon tube gauges. The diaphragms can be made of tantalum, or of corrosion-resistant alloys, or can be plastic-coated. The lower housings can be made of similar materials, or of plastic- or rubber-lined steel, or of polyvinyl chloride. Some of these materials are very expensive, and on applications where they have to be used it becomes very costly to measure a process pressure. There are many corrosive applications, however, working at up to 250 p.s.i. at 150°F, where a diaphragm housing made of inexpensive material such as p.v.c. is perfectly acceptable.

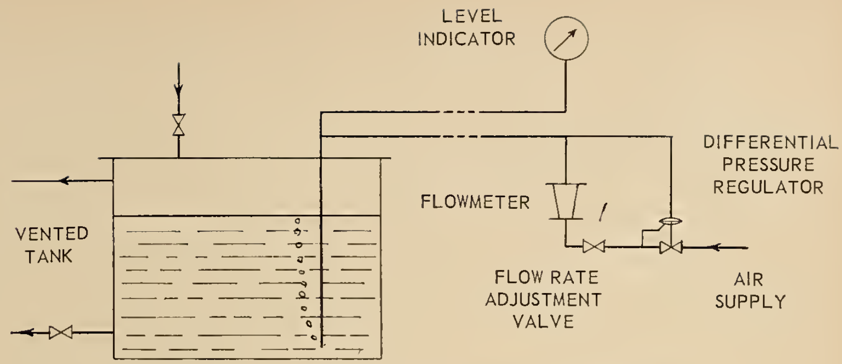

Fig. 3. "Bubbler" method of determining liquid level.

Liquid Level Measurement

Liquid level measurement on corrosive applications provides examples of two alternative approaches to the problem of keeping the corrosive agent out of the instrument, by the use of air purges and the use of sealing fluids. The obvious example of a purging system is the "bubbler" method of determining liquid level, shown in Fig. 3. Here a dip pipe, which may be made of glass, p.v.c., or other inexpensive corrosion resistant material, projects down into the liquid in the tank. A constant small flow of air is supplied to the dip pipe through a flow regulator and a flowmeter. The flow regulator maintains the pressure drop across a manually set valve constant, so that the purge flow will be constant whatever the liquid level and the resulting back pressure in the dip pipe. This back pressure can be indicated on a local or remote pressure gauge calibrated in feet of liquid or gallons, as required, or can be fed into a computing relay which will generate a standard 3 to 15 p.s.i. pneumatic signal proportional to the liquid head for transmission to a receiver type indicator or recorder controller.

When the tank is under pressure or vacuum, a differential pressure gauge or transmitter must be used, with a second air purge connected into the line from the tank vapour space to the low pressure side of the gauge. Difficulties can arise with this system when the tank pressure fluctuates rapidly over a wide range, because of the possibility that tank liquid will be blown into the connecting tubing and the gauge. There are other instances when a bubbler system cannot be used. One of these is when the tank liquid is a saturated solution. The dry air bubbling into the solution takes up moisture, resulting in the deposition of crystals at the bottom of the dip pipe, which rapidly causes a blockage. Another case is where the tank liquid is saturated with a gaseous product, the tank being vented to the header collecting this product. In these circumstances leakage of air into the system may have to be minimized, and even the low purging flow from a bubbler cannot be tolerated.

An example of the use of sealing fluids is the measurement of the level of a flashing corrosive liquid in a pressurized or evacuated vessel using a differential pressure transmitter. The problem here is not only corrosion but also condensation in connecting lines to the instrument. If an inert sealing liquid is used in these lines, the differential pressure measuring device must have negligible displacement as the applied differential varies, otherwise pumping will take place, making it impossible to keep the line full of sealing fluid, and resulting in errors in measurement. The pneumatic differential pressure transmitter, shown in a simplified form in Fig. 4, satisfies this requirement. The pressure differential is applied across a diaphragm, tending to move the diaphragm up, and the right hand side of the force beam down. The baffle approaches the fixed nozzle, so increasing the nozzle back pressure, which is applied to a pilot relay, increasing the relay output pressure. This increased pressure is applied to a follow-up bellows which tends to move the right hand side of the force beam upwards, resulting in a force balance method of operation. The relay output pressure is a measure of the differential pressure across the diaphragm, and the transmitter is so constructed that an output signal of 3 to 15 p.s.i. from the pilot relay results from a differential pressure input of zero to 100% of the nominal range. Over this range, the baffle-nozzle separation will change by only a very small amount, of the order of 0.001 in. Consequently, the diaphragm displacement will be negligible as the applied differential pressure varies, and the sealing fluid in the lines to the high and low pressure sides of the transmitter will not be pumped out.

In this type of level measurement, the choice of sealing fluid and of the method of installation must be made with some care. The seal and tank fluids must obviously be immiscible, and the difference in their specific gravities should be as large as possible. Heavy, inert liquids such as fluorinated hydrocarbons are useful sealing fluids, although they are rather costly. When the sealing fluid is heavier than the tank liquid, the transmitter would obviously be installed below the level of the connections to the tank.

Chemical Composition Measurement

Continuous process stream analyzers, such as infra-red absorption, ultra-violet absorption, and thermal conductivity analyzers, are widely used in the chemical industry for the continuous measurement of process stream composition. Many of these analyzers have been developed for plant operation from laboratory type instruments. Most of the operating troubles which are experienced with plant analyzer installations arise because of the dirty, contaminated nature of the streams being monitored. Gas streams, for instance, may be contaminated with solid and liquid corrosion products which must be kept out of the analyzer if reliable operation is to be achieved. A sampling system must be designed that will deliver a clean, representative sample, at a suitable pressure and temperature, to the analyzer cell.

As an example, consider the thermal conductivity analyzer shown in Fig. 5. This type of analyzer is used to measure the composition of binary gas mixtures when the thermal conductivity of one component is significantly different from that of the other component. The analyzer consists of a Wheatstone bridge, one arm of which is sealed in a reference cell, whilst another arm is enclosed in a sample cell containing a sample of the gas to be analyzed. The resistors in the sample and reference cells are heated by the current passing through them, and cooled by thermal conduction through the gas surrounding them. Their temperature, and therefore their electrical resistance, is then dependent on the thermal conductivity of the gas. Bridge unbalance can therefore be related to the composition of the gas being analyzed. The sample cell is so arranged that its resistor is not directly in the sample stream, otherwise the rate of cooling would be dependent on the sample flow rate. Gas from the sample stream can only diffuse slowly in and out of the sample cell, so that the cooling of the resistor is dependent only on conduction through the gas.

If the analyzer were measuring low concentrations of hydrogen in air, the reference cell would be filled with air. Hydrogen has a much higher thermal conductivity than air, and as the hydrogen concentration increased, the temperature of the sample resistor would decrease, resulting in a decreased electrical resistance and a change in bridge unbalance.

Thermal conductivity analyzers are available with glass-coated resistors enclosed in glass cells, with glass sample connections, so that corrosion does not normally present any problem. However, if the sample stream contains solid or liquid contaminants that can be deposited on the sample resistor, the analyzer output will rapidly become meaningless. Even a slight film on the resistor will have a considerable effect on the heat transfer to the gas. The problem then is to filter and scrub the gas sample very thoroughly so that only infrequent cleaning will be required. If the analyzer does go out of calibration, which in the hydrogen-air case would be shown by an inability to set the zero with 100% air in the sample cell, the cell must be washed out with a suitable solvent and then thoroughly dried before being returned to service.

A typical sampling system for such an analyzer is shown in Fig. 6. When long sample lines are involved, one problem is to cut down the time it takes the sample from the process line to reach the analyzer, so as to get a rapid analyzer response to changes in the process stream. Small bore sample lines are used, to give high velocities. However, the maximum flow through the analyzer, above which flow responsive effects appear, might be of the order of 2 c.f.h., which may be insufficient to give the required velocity. In such cases, a by-pass is installed around the analyzer, and sufficient flow is by-passed to give the required response time. On the low flow line to the analyzer, components such as the filter and the gas wash-

Fig. 4. Pneumatic differential pressure transmitter.

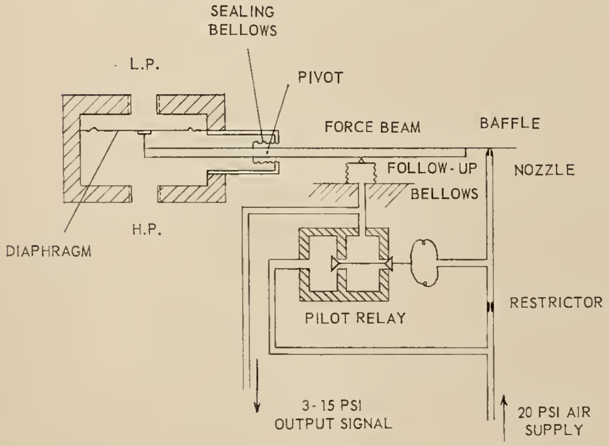

Fig. 5. Thermal conductivity analyzer.

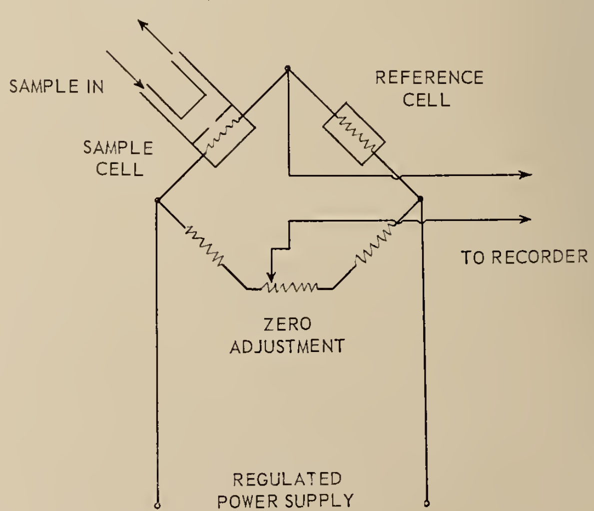

ing bottle should have the absolute minimum gas space volume. Ceramic and porous stainless steel filters are available which have been specially designed for this service. When the sample has to be dried before it can be passed through the analyzer, a drying agent such as concentrated sulphuric acid would be used in the wash bottle. If the moisture throughput in the sample is high, necessitating frequent replacement of the sulphuric acid, a different drying system with a larger acid capacity can be used. In this system, acid from a large reservoir is pumped continuously to the top of a packed glass column, down which it flows back into the reservoir. The sample flows up the column and into the analyzer. The acid can be circulated by an air lift type of pump.

Many process stream analyzers are enclosed in thermostatted cases, and it is sometimes necessary to heat or cool the sample flow in order to obtain satisfactory operation. This factor also has a bearing on the choice of a suitable location for the analyzer. With some types of analyzer it may be necessary to wait for a period of hours, after removing and replacing the cover, for conditions to become stable again. Now in warmer climates it may be possible to mount the instrument, on an outdoor plant, on a platform half way up a distillation column, but this is not possible in the Canadian climate. Aside from the discomfort of carrying out maintenance work on such an installation in winter, temperature effects would be very serious and lengthy whenever the case was opened. On the outdoor type of plant, analyzer huts are essential. A small, heated building can usually be located so that several analyzers can be installed in it without requiring excessively long sample lines. The analyzers would then transmit electrical signals to indicators or recorders located in the plant control room. The cost of an analyzer may be \$3000 to \$10,000 or more, so that the cost of the building required is small by comparison, considering that it will probably make the difference between a workable and an unworkable installation.

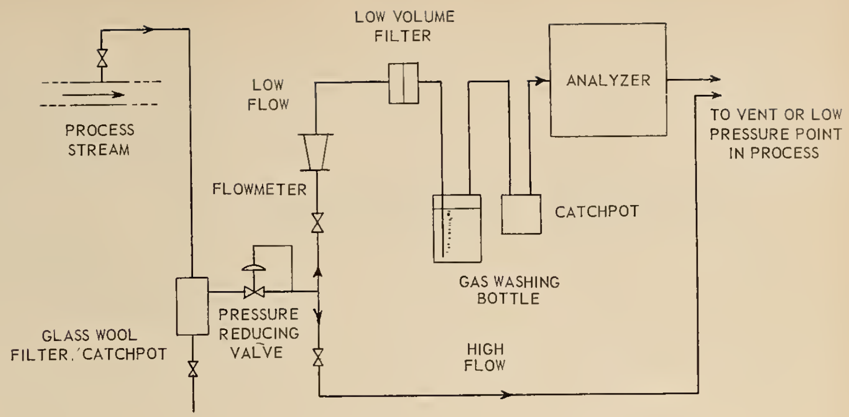

Fig. 6. Typical sampling system for a thermal conductivity analyzer.

Electrical Control Equipment

On plants where the atmosphere is corrosive or hazardous, pneumatic transmission and control systems have some advantage over their electronic counterparts. Air from pneumatic relay vent ports purges the cases and keeps out plant fumes, and they do not present any explosion hazard, whereas electronic equipment requires explosion-proof enclosures. There is one duty however for which electrical equipment is nearly always used. That is, for alarm annunciation, interlocking of equipment functions, and automatic shutdown of the plant when unsafe operating conditions arise. The necessary relaying is much easier to perform electrically than pneumatically. A typical small plant might have forty alarm conditions, such as high temperature, low pH, and so on, monitored on an alarm system, and in addition there may be twenty or so switches, actuated by process variables such as high pressure and low flow, that shut down the plant automatically when unsafe operating conditions arise. For the utmost reliability these switches will be actuated by a separate measuring system rather than by a pneumatic signal which may already have been generated for control or measurement purposes. Failure of pneumatic transmitters will then not interfere with the correct operation of the safety shut down system. Reliability considerations may also require that the shutdown system be operated on a d-c supply from a floating battery system.

Safety shutdown systems usually incorporate logical circuitry to ensure not only safe working but also safe start-up and safe shutdown. Pumps and compressors and so on must be started and shut down in the right sequence to give safe conditions at all times. Circuitry may also be required for a shutdown annunciator so that, when a shutdown switch operates, it lights an annunciator lamp and also locks out the lamp circuits associated with other switches. If this feature is not included it will probably be impossible for the operator to determine what caused the shutdown, because perhaps half the annunciator lamps will be lit seconds after the shutdown occurs.

Conventional relaying systems are usually employed for these systems, with the relays located in a non-hazardous location if possible. Even in this location, however, corrosive fumes are likely to give rise to relay contact troubles. If this is the case, hermetically sealed relays can be used. These relays are available in a plug-in form and also with solder-tag connections. Here the designer has to choose between the rapid replacement which can be made when plug-in relays are used, and the freedom from pin contact corrosion problems of the soldered connection type. Pressure switches and so on can make use of mercury tube switches, where the switch contacts are sealed inside a glass envelope.

In the future, it is likely that solid state switching systems will be used for this duty. Encapsulated logic elements will be unaffected by the plant atmosphere, and will be more reliable than electro-mechanical relays. If the system can at the same time be made intrinsically safe it will be a very worthwhile step. An intrinsically safe system would be so designed that, under normal working conditions, or under any possible fault conditions, it would be impossible to generate a spark, at the plant shutdown switch, with sufficient energy to cause an explosion. Non-explosion-proof components could then be used in the hazardous area. Such a system would be very valuable on modern plants which rely for safe operation on complex interlocking and safety shutdown systems.

Canadian Developments

New Plant for Testing Quebec Asbestos and Metals

The new pilot plant of the Quebec Department of Mines located in the St. Malo Industrial Centre is directed toward assessment and evaluation of the Province's metal and asbestos resources. Housed in a building constructed 40 years ago, the new plant comprises a sampling plant, a treatment plant and an asbestos plant on the ground floor and laboratories for mineral dressing, analytical control and asbestos treatment in the two longitudinal mezzanine sections.

The renovation and centralization of research and treatment facilities is in line with the remarkable upsurge in Quebec mining activity during the last decade. Since 1950 the annual value of the Province's mineral production has risen from roughly $200,000,000 to $460,000,000 and experts anticipate that this trend of acceleration will continue.

Professor J. U. MacEwen, head of the mechanical engineering department at McGill University, was chosen by Minister of Mines William M. Cottingham in 1958 to act as consulting engineer for the planning and installation of the new pilot plant. The 280 ft. long building has a central section 80 ft. wide and 32 ft. high and mezzanines to either side of this central section which are 20 ft. in width, 17 ft. in height. A CNR spur line extends 60 ft. into the building at the west end and a 25 ton crane, with an 80 ft. span, services this ore receiving section.

In the sampling plant the 6 in. feed material is crushed in a 9 in. x 16 in. jaw crusher operating at a reduction ratio of six to one. The 1 in. product then goes into a 30 in. cone crusher and is reduced to ¼ in. This crusher discharge drops onto a reversible conveyor belt and can be fed into either the sampling plant or the treatment plant.

A sampler retains 10% of the material in the sampling circuit and rejects the other 90%. The sample cut is crushed in a 12 in. crusher to −20 mesh and sent on by another conveyor belt to a second sampler which retains 20%. This time the selected material is crushed to −48 mesh. The process terminates with a third sample cut of 10%, rendering a final 4 lb. sample from each ton of mineral treated.

In the treatment plant the ¼ in. material discharging from the crusher goes to a screen in closed circuit with the crusher so that no oversized particles enter the grinding mills. There are two sections in this plant, one a 25 ton section, the other an 8 ton section. The flotation section is equipped with two batteries and four conditioners together with thickeners to handle both concentrates and tailings. Two drum filters, one disc filter and a portable dewatering classifier have also been installed.

In the asbestos treatment plant the 3 in. feed material is crushed first with a jaw, then two mills operating at different speeds. After each reduction, the product is screened on an oscillating screen to separate the freed fibre from the rock. The recovery of asbestos from its ores requires a very careful treatment to produce a maximum of long fibres. Collected in low pressure cyclones and a dust filter, the fibre is passed through a disintegrator for further separation and fiberization.

The laboratories are used for small-scale testing of ore concentration and for mill control through chemical analysis of samples. They include a crushing and sampling room, a flotation room and an asbestos section.

A sub-station at the entrance to the plant receives the electrical current needed for its operation. The incoming 4,000 volts is transformed to 550 volts and conveyed to five auxiliary panels in the plant and mezzanines.

Water Power Resources 1959

The annual report issued by the Water Resources Branch of the Department of Northern Affairs and National Resources underlines the vitality of hydro-electric development in 1959 and points to an increasingly prosperous decade ahead. The water is there — in bountiful quantity in almost every province of Canada — and the demand is there — particularly from the oil, pulp and paper and mineral industries. The legislation to make possible some of Canada's larger hydro-electric developments is in progress. The recent proposals concerning the Columbia River *(Engineering Journal,* Canadian Developments, March 1960) represent a sizeable accomplishment in this field.

Although Quebec and Ontario remain well in the lead in total hydro-electric installation, British Columbia, Manitoba and the Yukon are developing their potential rapidly. Calculations are not complete, and depend largely on what the power potential of major river diversions turns out to be, but it is clear that British Columbia and Quebec individually have at least twice the raw potential of any one of the other provinces, both having a little less than 20,000,000 hp. available continuous flow at 80% efficiency.

Because precipitation is unusually light in the two territories, the favourable sites are dependent upon large storage capacities. In order to encourage development of the resources of Northern Canada, the Federal Government in 1948 set up an agency now known as the Northern Canada Power Commission for the construction and management of public utility plants. The Deputy Minister of Northern Affairs and National Resources is the chairman of this Commission and the director of the Water Resources Branch is a member.

It is interesting to note how much coal would have been necessary in 1959 to operate thermal stations in place of hydro-electric plants and turn out the same kilowattage. Water power is distinctly important in the economy of power production. Water power generated 96,516,000,000 kwh. in 1959. It takes one pound of coal (12,000 BTU per pound) to produce one kilowatt-hour of electricity, so that it would have called for 48,250,000 tons of coal, in addition to the 24,000,000 tons burned in the existing thermal stations in 1959, to produce the total electric power of that year.

Canada is exceeded only by the U.S.A. in total water power installation and by Norway in per capita output. British Columbia has an outstandingly high ratio of power output to population. Prince Edward Island's is the lowest.

Developed Water Power in Relation to Population

Province or Territory	*Installed Capacity—hp. 31 Dec. 1959*	*Estimated Population 31 Dec. 1959*	*Installation per thousand population hp.*
British Columbia	3,509,460	1,592,000	2,204
Alberta	312,595	1,264,000	247
Saskatchewan	128,835	907,000	142
Manitoba	778,900	892,000	873
Ontario	7,982,151	6,029,000	1,324
Quebec	11,315,407	5,062,000	2,235
New Brunswick	254,875	595,000	428
Nova Scotia	183,168	719,000	255
Prince Edward Island	1,660	103,000	16
Newfoundland	370,135	453,000	817
Yukon & Northwest Territories	51,240	34,000	1,507
Canada	24,888,426	17,650,000	1,410

Water Power Resources of Canada Bulletin No. 2702.

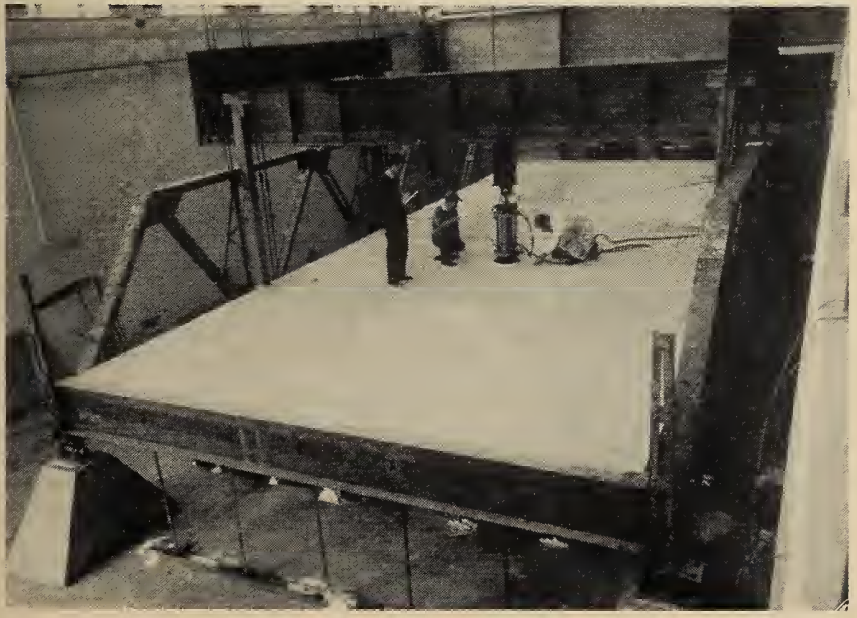
Available and Developed Water Power in Canada At End of the Year 1959

Province or Territory	*Available continuous power at 80% efficiency—hp.*		*Installed Turbine Capacity hp.*
	At Ordinary Min. Flow	*At Ordinary 6-Months Flow*	
1	2	3	4
British Columbia	18,200,000*	19,400,000*	3,509,460
Alberta	911,000	2,453,000	312,595
Saskatchewan	550,000	1,120,000	128,835
Manitoba	3,492,000	5,798,000	778,900
Ontario	5,496,000	7,701,000	7,982,151
Quebec	10,896,000**	20,445,000**	11,315,407
New Brunswick	123,000	334,000	254,875
Nova Scotia	30,500	177,000	183,168
Prince Edward Island	500	3,000	1,660
Newfoundland	1,608,000	3,264,000	370,135
Yukon Territory	4,678,000*	4,700,000*	38,190
Northwest Territories	374,000	808,000	13,050
Canada	46,359,000*	66,203,000*	24,888,426

* These figures reflect the effect of possible stream flow regulation based on known storage potentials.

** These figures undoubtedly will be revised substantially with the completion of the review of water power resources which the Quebec Department of Hydraulic Resources now has under way and in which the Water Resources Branch is co-operating.

This old bridge from Southeastern Ontario was dismantled last summer and re-erected in the structural laboratory at Queen's University, Kingston. Loads are being applied to the deck by means of a 40-ton hydraulic jack, the reaction being taken by the transverse girder above, which is anchored by the tie rods on either side of the bridge. Most of the measurements are taken on the under side of the deck.



CGRA Pavement Research

This summer the Canadian Good Roads Association will continue its pavement research and evaluation project begun a year ago, hoping that by next October they will be ready to report at the Toronto convention on phase 1. During the winter the vast amount of data collected during 1959, when several thousand miles of pavements were studied, was sorted and analyzed. Six to seven thousand more miles will be covered this summer. The papers to be presented in October will cover these subjects: the CGRA Benkelman beam procedure and its application in testing flexible pavements; rigid pavement tests; determination of spring load carrying capacity from Benkelman beam deflections; method of design for strengthening existing pavements; and the influence of shoulder types on flexible pavement strength.

Canada-USSR Trade Agreement

A three-year renewal of the Trade Agreement between Canada and the Union of Soviet Socialist Republics was

Space Vacuum Laboratory Opened at St. Cambridge, Mass.

The National Research Corporation in Cambridge, Mass., has recently established a space vacuum laboratory to provide ultra-high vacuum testing facilities for the nation's missile and space vehicle programs. Located in the headquarters of the Corporation, the laboratory makes it possible to test equipment for space flight at a minimal cost compared to that of actual space flight testing.
