AUTHORS

THE ENGINEERING INSTITUTE OF CANADA

The Roman numerals below refer to the Supplement in the April 1961 issue "Report of Council for 1960."

Beaver Bill says:

Did you realize Canada, with several sister nations of the Commonwealth of Nations, is singularly fortunate in its facilities for the education and professional development of engineers?

It is indeed unique, because Canada has a great Engineering University with 61 branches and sections and 12 student sections serving our country on a regional basis, from St. John's to Victoria, from Windsor to the Yukon. Of course, some of these branches are very large, some quite small, depending on the population served.

But each one of them has at its disposal the services of 10 faculties, covering every field of engineering. These faculties, or Engineering Divisions of the Committee on Technical Operations, are staffed with keen engineers anxious to provide you with the basis for a lifetime of improvement of your professional stature as an engineer, and your professional ability to serve Canada better.

This great Engineering University is the Engineering Institute of Canada, whose membership rolls proudly proclaim most of the great engineers who have played such a vital role in the development of Canada. Who are these men? Just a few—

Thomas Coltrin Keefer	*John Galbraith*
Sir Casimir Gzowski	*Col. R. W. Leonard*
Sir John Kennedy	*Julian C. Smith*
Henry J. Bovey	*George J. Desbarats*

This great Engineering University celebrates its Seventy-Fifth Anniversary in 1962.

Want to join? How much does it cost? Just 40 cents a week! The price of a package of cigarettes! But what a difference!

Sincerely,

W. R. Schriever, M.E.I.C. and **W. G. Plewes**, M.E.I.C. are ideally suited as authors of their paper, *A New Canadian Structural Test Installation.* This installation for large-scale structural loading tests was installed recently in the Division of Building Research of the National Research Council in Ottawa. Mr. Schriever was born in Weggis, Switzerland and graduated as a civil engineer at the Swiss Federal Institute of Technology (E.T.H.) in Zurich in 1944. Following laboratory work in Switzerland he obtained an M.Sc. from Harvard. In 1948 Mr. Schriever joined the NRC's Building Research Division and five years later was named Head of the Building Structures Section.

Mr. Plewes, a native of Russell, Man., obtained his B.Sc. in civil engineering at University of Manitoba in 1949, and a post-graduate degree in civil engineering from Queen's in 1954. He joined the NRC in 1954 and now is an Associate Research Officer in the Building Structures Section.

Their paper describes the test installation which provides universal facility for loading tests on a variety of structural components such as beams, slabs, columns, roofs and walls.

Recent Advances in Experimental Stress Analysis, by **Professor J. B. Mantle**, M.E.I.C. deals with some new techniques. Described are some examples of their application as carried out in the author's laboratory at University of Saskatchewan where he is Head of the Department of Mechanical Engineering. Experimental stress analysis has become an increasingly important tool for designers, particularly since the advent of the space age. Prof. Mantle was born in London, England, in 1919. His family moved to the Canadian West and he attended primary and high school in Paynton, Sask., and Saskatoon. He obtained a degree in Mechanical Engineering at University of Saskatchewan in 1941 and an M.Sc. in Theoretical and Applied Mechanics at University of Illinois in 1947.

Interest in *Frazil Ice and Flow Temperature Under Ice Covers* comes naturally to co-authors **Ernest Pariset**, M.E.I.C. and **Rene Hausser**, M.E.I.C. Mr. Pariset, Director of LaSalle Hydraulic Laboratory in Montreal, holds degrees from Grenoble University in both electrical and hydraulic engineering. Following research and consultant work in France and in Canada, Mr. Pariset assumed his present position. Mr. Hausser also holds degrees from Grenoble in electrical and hydraulic engineering. He worked with SOGREAH as a research engineer from 1950 until 1956 when he came to Montreal to take charge of the St. Lawrence Seaway models. Mr. Hausser now is an engineer with LaSalle Hydraulic Laboratory.

Their paper on frazil ice, undertaken for the Quebec Hydro-Electric Power Commission, outlines a general study on ice problems in rivers. Problems include the formation of ice covers, hanging dams, ice jams and the rate of ice formation. Purpose of the study was to determine the effectiveness of an ice cover in stopping frazil ice transportation, to protect a downstream power station.

Harold O. Wilson, M.E.I.C. had the advantage of 23 years of engineering experience to draw on for his paper, *Braking of Hydro-Electric Generators.* After obtaining his degree in electrical engineering from Queen's University in 1937, Mr. Wilson worked with Shawinigan Engineering Company Limited and the English Electric Company of Canada Limited before spending four years in the Canadian Navy as an Electrical officer. After the war he rejoined English Electric. In 1947 he returned to Shawinigan Engineering and in February, 1960, was appointed Chief Engineer, Electrical Division. Mr. Wilson's paper has a special significance due to the widespread adoption of automatic braking for use with automatic units and remotely controlled generating stations. The scope of the paper is limited to Francis or Kaplan turbine driven generators of medium size and moderate speeds.

David Cass-Beggs, M.E.I.C. author of the *Economic Feasibility of Trans-Canada Electrical Interconnection,* is responsible for the redesign of Saskatchewan's power production system. In less than a decade he has brought electricity within reach of almost the entire agricultural area of his province. In the same period, virtually all power facilities in Saskatchewan have been tied in an integrated system. In his paper Mr. Cass-Beggs outlines the practical value of inter-connecting generating stations into large integrated electrical systems. Apart from the obvious economies arising from the optimum use of low cost resources the time zones into which Canada is divided offer important opportunities for improvement of load factor, while integration could also reduce the reserve capacity required for a larger system. Mr. Cass-Beggs, General Manager of the Saskatchewan Power Corporation since 1952 and president of the Canadian Electrical Association, is a former professor of electrical engineering. He was born in Manchester, England, in 1905 and holds a degree of M.Sc. Tech. from Manchester University. Mr. Cass-Beggs taught at University of Toronto, did development work for the RCAF, and returned to teaching in Canada and in Wales before joining Saskatchewan Power Corporation.

Probably no author could have described *Montreal's Jet Age Airport* with the authority of **Harold J. Connolly**, M.E.I.C. A native of Toronto, Mr. Connolly entered University of Toronto in 1915, but service in the First World War interrupted his education and it was not until 1924 that he graduated with a B.A. Sc. degree. After working with a consulting engineering firm in the field of municipal engineering for 11 years he joined the Department of Transport. He now is Director in charge of the Construction Branch of the Department's Air Services. As such Mr. Connolly is responsible for airport construction. His treatment of Montreal's newly-opened airport includes its history, the difficult engineering problems which had to be solved, description of passenger facilities, and the sustaining services.

Beaver Bill appears this month on page 115. Stan **Cassidy** has a membership reminder on page 100.

CONCRETE ROOFS

MADE WITH

CANADA CEMENT

Spectacular!
New!
Functional!

Architects and engineers are freeing themselves from the limitations of conventional roof design. The results of this liberation are many: great beauty; wide spans over large, column-free areas; surprising economy; and, above all, a new challenge to the architect's and engineer's creative imagination. All this with one versatile material—Concrete.

With the introduction of the Third Dimension into concrete roof design many variations in shape and functional applications are now possible.

the 4 basic designs

1

BARREL SHELLS can often be precast and hoisted into place, with great savings in construction costs. Their functional efficiency is matched by the commanding yet graceful character they lend to any building (schools, public and commercial buildings) where they are used.

2

DOMES express lightness and symmetry. Their thin, ribless shells need only be supported at three points. The 275 ft. dia. dome roof of the new Maurice Richard Arena, an outstanding example of concrete domes is one of the largest inside column-free roofs of its kind on the Continent.

A New Canadian STRUCTURAL TEST INSTALLATION

W. R. Schriever, M.E.I.C.,
Head, Building Structures Section, Division of Building Research, National Research Council, Ottawa.

W. G. Plewes, M.E.I.C.,
Research Officer, Building Structures Section, Division of Building Research, National Research Council, Ottawa.

This installation provides universal facility for loading tests on such structural components as beams, slabs, columns, roofs and walls. It was installed in NRC's Division of Building Research.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

Summary

The three main parts of this installation are (i) a strong reinforced concrete test floor, (ii) a set of steel frames to be assembled around the test object and anchored to the floor and (iii) portable hydraulic jacks for the application of the loads. The test floor, with a maximum length of 54 ft. provides 42 regularly spaced anchorage points for the structural steel frames and has been designed to withstand vertical or horizontal forces of up to 50 tons at each of these points. In resisting upward forces, use is made of the weight of the underlying bedrock through special pretensioned rock anchors. The structural steel reaction frames are connected to the slab and to each other by torqued high-strength steel bolts to provide maximum rigidity. The portable jacks range in capacity from 2½ to 50 tons and are suitable both for static and dynamic testing, are of the lapped-piston type and provide an accuracy in load measurement comparable to that of a universal testing machine. The Paper describes the design and construction of this installation and makes reference to installations in other countries.

* * *

THE behaviour of structures under actual loading and the interaction between various components of a structure have of recent years become the subject of increased interest to structural engineers. In the past, structural design has usually been based on assumptions of (i) elastic behaviour, (ii) homogeneous materials and (iii) an assemblage of elements acting independently. Research has shown that these assumptions frequently do not lead to an accurate assessment of the actual strength of a structure because of complicated interaction of components or because the behaviour changes significantly as the range of true elastic behaviour is exceeded.

To investigate this interaction of components and the behaviour of various structures under actual loading it is often desirable to observe structures in the field or to conduct loading tests on full scale structures or assemblages of components in order to develop a more complete understanding of structural behaviour up to and including failure. Loading tests to failure are particularly important since it is frequently difficult to predict the true margin of safety of a structure from stress calculations in the elastic range.

The Division of Building Research of the National Research Council, and particularly its Building Structures Section which is concerned with the strength and deformation characteristics of structures and the loads acting upon them, has frequently encountered the need for such loading tests. In the past this called for special equipment, often designed or improvised for a single test. Tests had to be made on structures such as house components, roof trusses, beams, floors and walls. With improvised equipment it was often difficult to develop the large forces and reactions necessary to reach failure. Ordinary universal testing machines were found to be very limited in their application to such testing because they were not sufficiently adaptable to the variety of shapes and sizes that occurred.

Consequently, it was decided that the Division should develop and construct a testing installation which would allow a wide variety of loading tests on relatively large scale structures.

Basic Design Considerations

Other installations: Several structural testing laboratories in North America and Europe were visited and studied. It was found that although the installations varied considerably in detail the common basic parts were:

(a) a reinforced concrete slab with a system of regularly spaced anchorage points,

(b) a set of structural steel members which could be assembled and bolted together in a variety of ways around the test object and anchored to the slab, and

(c) a number of portable hydraulic jacks for the application of the loads, together with load measuring equipment.

The installations studied were those of:

(1) Fritz Engineering Laboratory, Lehigh University, Bethlehem, Pa., USA

(2) British Building Research Station in Watford near London, England

(3) The Cement and Concrete Association in Wexham Springs near London, England

(4) Association of the Industrials of Belgium (Grande Installation Mécanique Pour Essais de Durée, or briefly GIMED)

(5) University of Ghent, Belgium

(6) University of Liege, Belgium

(7) Division of Building Research of T.N.O. in Delft, Holland

(8) Materials Testing Laboratory of the Technical University of Munich, Germany

(9) National Civil Engineering La-

boratory at Lisbon, Portugal.

Some of these installations, particularly that of the GIMED in Belgium, are very elaborate and allow the application of very large forces. Some provide access to the underside of the test slab, allowing through-bolting of the test frames to the slab. The detail and spacing of anchorage points also varied considerably. In the Portuguese laboratory, prestressing was used to achieve a greater strength in the slab. Although the hydraulic loading equipment used in these laboratories varied it was found that the majority of the installations were equipped with Amsler jacks, pendulum dynamometers, and pulsators.

One of the most modern of these testing installations was found to be that of Lehigh University in Bethlehem, Pa. This installation incorporates some new ideas, one of which is the use of high strength bolts for rigid assembly of the reaction frames and of pretensioned bolts for anchoring the frames to the slab. This feature, particularly important in case of dynamic testing, eliminates slack in the reaction framework.

Anticipated Requirements: Some of the anticipated types of test were:

(a) vertical loading tests on beams, trusses, slabs, roofs and walls

(b) horizontal loading tests on walls and possibly columns

(c) combined vertical and horizontal loading tests on walls and entire building components

(d) miscellaneous tests including the application of loads in any desired direction.

This wide range of applications indicated a need for considerable flexibility in the arrangement of forces and reactions.

It was decided that the size of the installation should allow the testing of long members of lengths up to approximately 50 ft. and more or less square members such as slabs of the order of 20 ft. square. One of the main governing considerations in the choice of dimensions was the space available in the existing laboratory.

In making an estimate of the required loading capacity of the installation, it was thought that the application of a 100 ton load through two 50 ton jacks would be adequate and could be taken as a design criterion. In other words, each of the two columns of a portal frame was to be designed to resist a 50 ton force in an upward direction. A horizontal capacity of 50 tons was also considered desirable.

To produce the loading forces it was considered desirable to obtain a type of jack which would allow an accurate measurement of loads directly by the measurement of oil pressure, since this would eliminate the need for a separate load measuring system.

Available Space: The test installation had to be built within the confines of the existing structural testing laboratory of the Division of Building Research. This laboratory measures approximately 40 by 80 ft. in plan and extends to a height equivalent to three stories. It was realized that to arrive at the most economical type of test slab it would be better not to choose a rectangular type of slab but a combination of a long area for the testing of long members such as beams and an approximately square area for the testing of slabs, roofs, and similar items. Furthermore, it was desired to retain some of the existing floor, since it incorporates some light embedded I-beams for anchorage purposes which are useful for miscellaneous work in the Division. The test slab thus became T-shaped in plan, with the long area 54 by 8 ft. and the approximately square area 23 by 28 ft. (Fig. 1.)

Since the space between floor level and bedrock was rather shallow (3 to 4 ft.), it was soon realized that it would not be possible (without blast-

Fig. 1. Plan view of project laboratory.

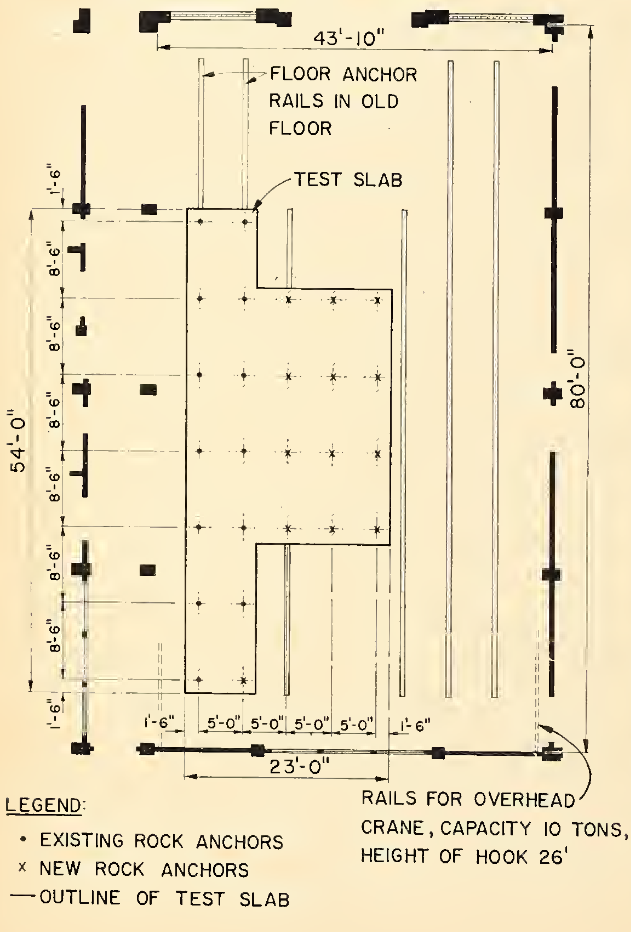

Fig. 2. Structural and reinforcing steel of test slab before concrete was placed.

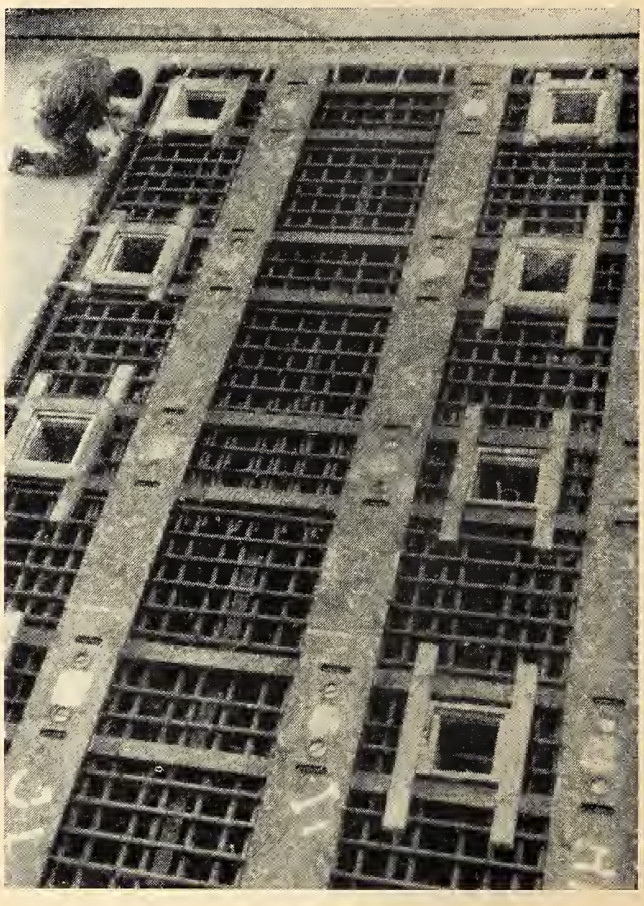


ing) to install a slab thick enough to provide the necessary flexural resistance for a loading test on a long and heavy beam, as was done in the Lehigh University installation where the slab is 6½ ft. thick. It was therefore decided to use the weight of the underlying rock, by means of rock anchors, to resist upward forces. Blasting operations inside the building would have been difficult and expensive, and rock anchors had already been installed in the old floor along the west side which it was hoped could be used in the new test slab.

Description of the Installation

Slab: Existing rock anchors in the old floor were available in two parallel lines 5 ft. apart along the west side of the laboratory with a longitudinal spacing of 8½ ft. (See Fig. 1.) It proved possible to continue this pattern for the rest of the new slab and to arrange the spacing of the column anchors in a pattern fitting in with that of the rock anchors. The column anchors were placed 5 ft. in an east-west direction and 4½ ft. in a north-south direction, making the ratio of column to rock anchors two to one. The slab can thus be regarded, in a way, simply as a means of disturbing the upward force introduced by the columns to the nearest group of rock anchors.

To achieve complete interchangeability of parts in the test installation it was realized from the start that high accuracy in the spacing of the column anchorage points and in the vertical level of the slab surface would have to be achieved. It was decided to aim at a tolerance in the spacing and elevation of column anchorage points of ± 1/16 in. It was therefore imperative to develop a construction method which would achieve this accuracy. With this in mind a step by step construction procedure was prepared which allowed the complete assembly and welding of all the steel going into the slab prior to the placing of concrete.

Fig. 3. shows typical cross-sections through the floor. Steel embedded in the slab consists mainly of three groups:

(a) reinforcing steel providing flexural and shear strength in the slab

(b) structural steel providing for resistance to horizontal forces developed during tests

(c) additional structural steel provided merely for accurate positioning and support of steel members (b).

Two-way reinforcing (a) was designed for the bending moments and shears, under the assumption that the slab acts in strips and distributes upward forces introduced at the column bases to the nearest group of rock anchors.

The embedded structural steel listed as (b) consists of "floor plates" flush with the floor and of pairs of longitudinal I-beams which run directly beneath the floor surface and are welded to the floor plates. These I-beams were designed to take the horizontal forces produced by the horizontal application of a 50 ton jack at a column base.

As stated earlier the additional structural steel (c) in the slab served to achieve the required accurate positioning of the floor plates with a tolerance of ± 1/16 in. during construction. This steel consisted of six transverse I-beams supported by short steel posts. The beams supported the longitudinal I-beams and floor plates and held them rigidly in place during placing of concrete.

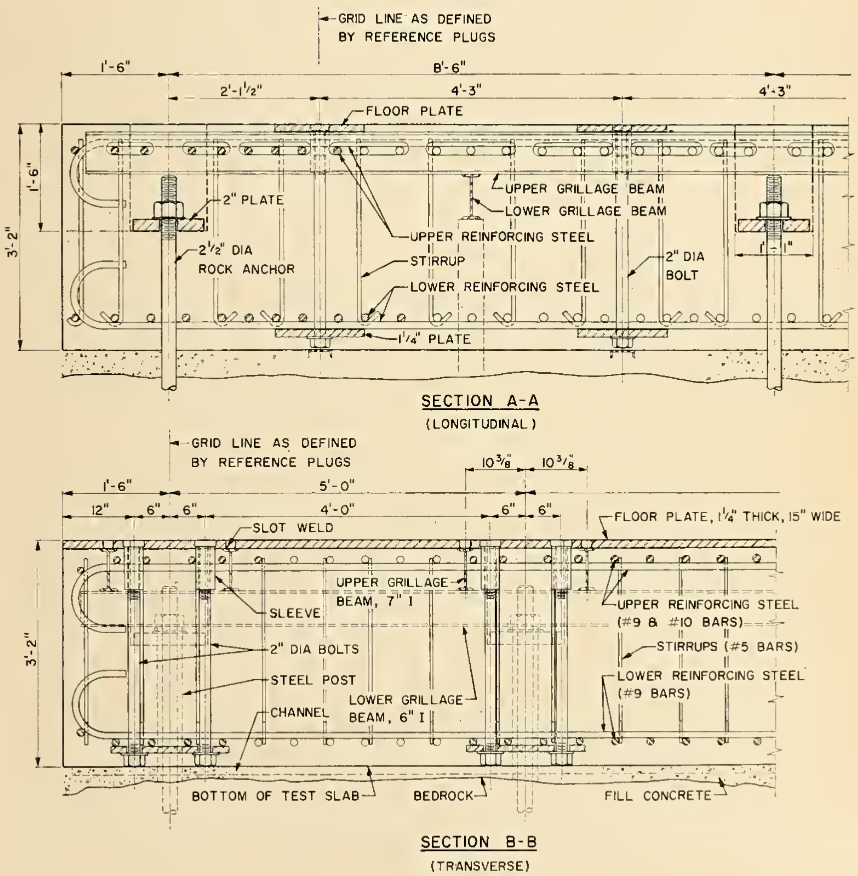
As assembly of the complete grillage progressed from bottom to top, more and more accurate positioning by shimming was possible, and after a complete check of dimensions the whole system was welded together into a strong unit capable of resisting all the pressures and vibrations resulting from placing and vibrating the concrete.

Rock Anchors: The test slab was "clamped" to the underlying bedrock by means of 26 pretensioned rock anchors. The rock anchors reached a depth of approximately 10 ft. below the floor surface, each anchor consisting of a 2½ in. diameter high strength steel rod designed to withstand an upward force of approximately 70 tons. It was not considered necessary to design the rock anchors to twice the capacity of the column anchors since it was unlikely that all rock anchors would be simultaneously loaded to capacity by the slab, which is intended to serve as a load sharing member.

The actual anchorage of the rods at the lower end was achieved by a system, devised for the purpose, which consisted of flaring the ends of the steel rods and grouting them into the bottom of the hole. This system was tested to a load of 100 tons in a rock outcrop in a nearby quarry. The flared end was produced by splitting the rock anchor rod crossways by two flame cuts and driving wedges from the bottom. The tops of the rods were threaded for pretensioning and bolting after completion of the slab.

Test Frames: The basic idea of test frames is to provide a system of reaction frames that can be assembled and bolted together in any desired manner around the test object and anchored to the slab. In some ways

Fig. 3. Sections through test slab.



these frames thus form a giant "meccano" set, to which the hydraulic jacks are bolted. A typical test set-up is shown in Fig. 4.

Since vertical downward loading is by far the most frequent requirement, particular attention was paid to the arrangement of the jacks to be used for this purpose. The combination of continuous adjustment in both directions in a horizontal plane makes it possible to position the jacks at any desired point over the structure, in spite of the fact that the frames themselves can only be positioned at discrete points. This can be achieved by sliding the jacks along the spreader to any desired point and sliding the spreader beam in the other direction under the cross beams joining the columns.

A main requirement of the test set-up is the provision of rigid joints in order to prevent slack, which would reduce the effective stroke of the jacks. This is achieved efficiently and inexpensively by the use of high tensile bolts rather than by accurate machining of parts as in some of the European installations. The anchorage of the frames to the slab is achieved by pairs of 2 in. diam. high-strength steel bolts which clamp the base plates of the columns to the floor. Details of a typical column anchorage are shown in Fig. 5. The system used provides a clear separation between the vertical and horizontal anchorage. Horizontal displacement of the column base plate, which would endanger the threaded anchor bolts, is prevented by two tightly fitting 3¼ in diam. collars which protrude through the column base plate into holes in the floor plates. Each column anchorage is designed to resist a static force of 50 tons in either upward or horizontal direction. After assembly of a column anchorage, the anchor bolts are pretensioned by means of a simple hydraulic jacking system (Fig. 6.) producing an upward force of approximately 30 tons while the nut on the bolt is tightened.

The test frames consist of ordinary structural steel members. As a first instalment intended to serve many of the anticipated ordinary needs, the following main members were acquired:

6 columns 12 WF 85, 16 ft. long;
2 cross beams, pairs of 18 ⌴ 58, 16 ft. long;
1 cross beam, pair of 18 ⌴ 58, 11 ft. long;
2 spreader beams, 12WF 106, 14 ft. 9 in. long;
5 supports for spreader beams or jacks;
4 diagonal struts, 10 WF 33 with stub columns.

These members are shown in Fig. 4, with the exception of the diagonal struts which serve to give horizontal support to the top of the columns when greater horizontal forces are involved.

Connections between the different members, with the exception of that between the spreader beam and the cross beam are made by 1 in. diam. high tensile bolts. This method offers the advantage of achieving complete joint rigidity without requiring accurately machined parts, ease of assembly and disassembly and better resistance to fatigue loading (in case such testing becomes necessary in the future). The bolts are tightened to the required 700 to 800 foot pounds by means of a special torque wrench or a pneumatic impact wrench.

The 1 3/16 in. diam. bolt holes are laid out in a 3 by 6 in. pattern on the members. One inch diameter high strength bolts are used in all ordinary work since the clamping force produced would eliminate any joint slippage up to working loads. Bolts 1⅛ in. diam. could, however, be used in case of exceptionally high loading where frame movement resulting from joint slippage might become a factor.

Load-Producing and Measuring Equipment: The hydraulic loading equipment consists essentially of portable hydraulic jacks fed from a pump in the pendulum dynamometer which serves to measure the load pressure applied with high accuracy. The loading equipment is made by a Swiss firm which has had extensive experience in the manufacture of this type of loading equipment.

The hydraulic compression jacks are of the lapped piston type in which the friction between the piston and the cylinder is reduced to a minimum so that the oil pressure can be used to indicate the load applied with considerable accuracy.

The hydraulic equipment available consists of the following main parts:

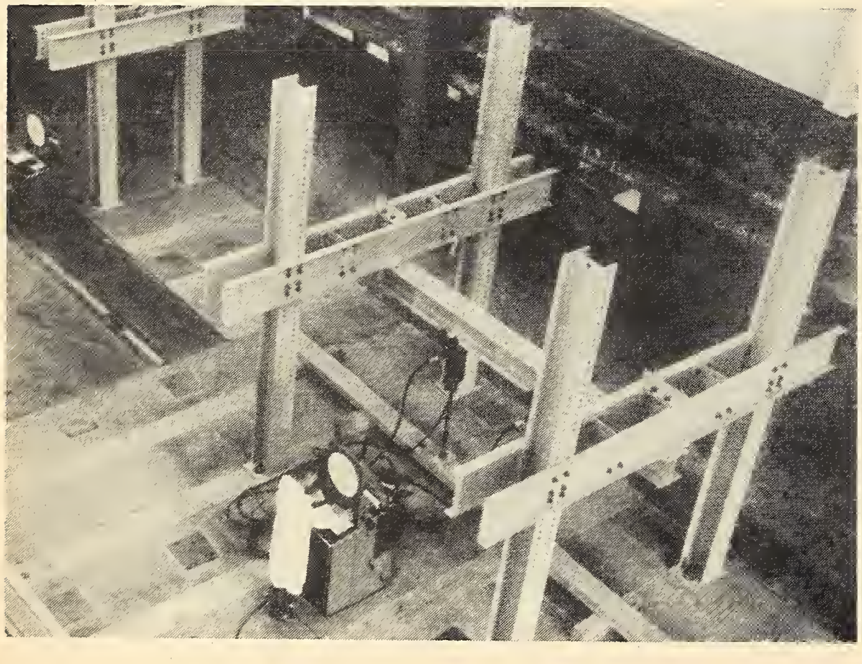
2 hydraulic jacks of 50 ton capacity;
2 hydraulic jacks of 10 ton capacity;
8 hydraulic jacks of 5 ton capacity;
4 hydraulic jacks of 2½ ton capacity;
2 pendulum dynamometers, both equipped with hydraulic load maintainers;
1 distributor used when necessary to distribute the oil from one pendulum dynamometer to a number of jacks;
Various high-pressure flexible hoses and miscellaneous accessories.

All jacks have a piston stroke of 5 in. The coil springs seen on the outside serve to compensate for the piston weight in the inverted position, and pull the piston back when unloading. Spherical seats are provided at both ends to ensure true axial loading through the jack. (Fig. 9.)

The same jacks can be used for dynamic or fatigue loading if fed from special pulsators which are made for this purpose. For the time being the installation is not equipped for dynamic testing.

The pendulum dynamometers have the double function of supplying oil pressure to the jacks and of measuring the load; this is done with the

Fig. 4. Over-all view of structural test installation.



same accuracy as in ordinary universal testing machines. The hydraulic pressure fed to the jacks acts on a measuring piston, which in turn pushes against the pendulum. A higher pressure on the piston is balanced by the higher swing of the pendulum, and the movement of the pendulum is transmitted to a large dial on the front of the cabinet. The measuring piston is constantly rotating about its own axis, thereby practically eliminating friction.

The pendulum dynamometer provides four load ranges for all jacks. The smallest gradation of the smallest jack in the smallest range is one pound. In contrast, the maximum capacity of the largest jack in the largest range is 112,000 lb. or 50 metric tons.

An automatic load maintainer allows application of constant loads over long periods of time, independent of the deformation of the structure. This feature is particularly valuable for creep tests on structures or when it is desired to maintain one load while varying another. The pendulum dynamometers can easily be moved and need not be bolted to the laboratory floor.

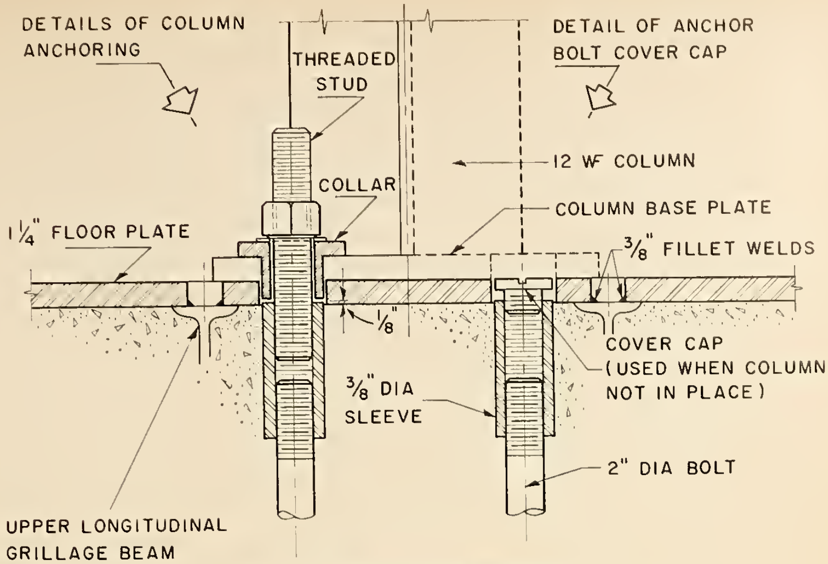


Fig. 5. Column anchorage detail.

Construction of Slab

It was realized at the outset that the complete interchangeability of component locations would require close control of dimensions during construction of the slab base. It was therefore decided to establish grid control points on brass plugs set in the floor along lines of a very accurate rectangular traverse established just outside the excavation area. Using precise triangulation and chaining methods along with careful scribing of the brass plugs, the grid control points were made sufficiently accurate to allow location of any point over the excavation area within ± 1/64 in. by means of a transit set up over the proper control points. The accuracy of the horizontal dimensional control system was therefore about twice that of the tolerance specified for drilling the anchor holes in the slab bed plates and four times that of the tolerance specified in the final location of the anchorage points.

The original laboratory floor was slightly sloped for drainage but it was decided to make the test slab surface as nearly horizontal as possible. The top elevation of the slab was set to be the same as the highest point of the surrounding floor adjacent to its perimeter. A rounded brass bench mark was set in concrete in a stable location for use in controlling the vertical location of the test slab.

As noted before, the plan of the slab was arranged to make use of some rock anchors already existing under the original laboratory floor. For convenience, the holes for additional new rock anchors were drilled through the existing floor down to the required level in the bedrock before any excavation for slab construction was started.

Construction of the new test slab was begun by sawing through the existing floor with a concrete saw on lines ½ in. outside the perimeter of the new slab location. The concrete removed was broken up with jack hammers and all material including crushed rock below the floor slab was excavated down to bare rock using a small backhoe and a conveyor for loading trucks.

The design depth of the test slab was 3 ft. 2 in. and the average depth of bedrock below the general laboratory floor proved to be 4 ft. 1 in. A layer of fill concrete was therefore cast over the whole floor of the excavation to bring the working level up to that assumed in the design and to provide a level working area.

Short steel posts were set vertically, with their lower ends embedded in the fill concrete and their top ends adjusted to an elevation slightly below that required to support six transverse I-beams, which in turn would carry the longitudinal I-beams and bed plates (Fig. 8). Small steel channels were also embedded in the top surface of the fill concrete to which the nuts and anchor plates for the column anchor bolts were later welded for accurate positioning.

Excavation of the slab area exposed the previously drilled rock anchor holes. Since the rock anchors were to be installed after the test slab was completed, short lengths of pipe were placed over the rock anchor holes to keep concrete from entering them and to enable the rock anchors to be lowered down through the slab at a later date (Fig. 8).

Following completion of the fill concrete, a low concrete block wall was built around the perimeter of the excavation beneath the exposed edges of the old floor slab to support them. To this low wall was nailed a layer of ½-in. asphalt-impregnated fibreboard which was placed to isolate the test slab from the general laboratory floor, so insulating it from the rest of the building. This was done in order to reduce vibrations in the rest of the building if and when the test installation was used for fatigue testing in the future.

The contractor then proceeded to place the transverse and longitudinal I-beams, the reinforcing steel, and the column anchor rods. The latter were greased and wrapped with tar paper to prevent bond with the concrete, so that when later pretensioning loads were applied they would be transmitted directly to the bottom anchor plates at the base of the slab. The rods were then screwed into the nuts below the plates, and after careful plumbing they were tack welded to the plates which in turn were tack welded to the small channels embedded in the fill concrete.

At this point the longitudinal I-beams were shimmed into proper position and the floor plates placed in approximate position. Members of the Division's staff then carefully set the plates for line and level and clamped them into position. The contractor proceeded to weld the several sections of the plates together and to weld the complete plates in turn to the longitudinal I-beams. Although a welding sequence was used that would minimize warping, it was necessary at this stage to check the levels of the plates constantly and to correct, by judicious shimming, changes in level caused by welding.

The final operation prior to concreting was to place small wooden forms over the top of the existing rock anchors and pipe openings left for new rock anchors. These were placed to form pits 15 by 15 in. by 1 ft. 6 in. in the test slab surface (Fig. 2). These extended down to a level just below the tops of the rock anchors, which were intended to have their tops about 8 in. below the slab surface.

Ready-mixed concrete with 4000 p.s.i. compressive strength at 28 days was specified for the main mass of the slab. The aggregates used were a local crushed rock aggregate and sand. Although the heavy slab reinforcement was rather closely spaced and the concrete mix rather stiff in consistency, the concrete was readily vibrated into place with very little segregation and, it is thought, very little if any honeycombing or voids. A 2 ± ½ in. slump was maintained by making tests of every truck load of concrete received and at least one compression test cylinder from every second load. After 28 days' standard curing the average strength of the test cylinders was 4080 p.s.i. with a minimum of 3810 p.s.i.

The top surface of the main body of the slab concrete was struck off about ¾ in. below the bottom of the steel base plates, and after 24 hr. members of the laboratory staff carefully dry-packed the space below the base plates with a dry mortar mix to make virtually certain that the plates would not be separated from the concrete by settlement of the slab but would have positive bearing. This was considered necessary as tests conducted before construction indicated that the 3 ft. depth of concrete could settle away from the plates by about 1/16 in. After this operation the contractor brought the slab concrete up to the level of the top of the base plates by placing a 2 in. layer of finish concrete containing ½ in. trap rock aggregate for hardness and abrasion resistance. Welded wire mesh was placed in the centre of the layer. A commercial curing compound was sprayed onto the concrete.

By careful checking and adjusting during all phases of construction a sensibly flat slab was achieved, so that with one minor exception, the deviation from the specified elevation of the anchor points was less than 1/16 in. Without this care the deviation would have been much greater owing to the natural variation of dimensions of all the slab components, workmanship errors, and the tendency for such grillage to warp when welded.

In the three years since construction, close inspection of the slab shows it to be in excellent condition and remarkably free of surface cracks. The latter is partly due to the fact that the finish concrete is divided into sections by the steel bed plates.

Installation and Tensioning of Rock Anchors

Three months after construction of the test slab, the flared end of an anchor rod was lowered through the pipe sleeves in the slab into bedrock. The lower end was about 7 ft. in the rock and the upper end approximately 8 in. below the slab surface and exposed in the small 15 by 15 in. access pit. A 20 ft. length of ½ in. O.D. copper tubing was lowered to the bottom of the rock anchor hole alongside the anchor rod. Clean, ⅜ in. traprock aggregate was dropped into the hole until a plug of stone 20 in. deep was formed around the flared end of the rod (extending about 12 inches above the top of the flare). Neat cement grout consisting of 5½ gal. of water per sack of high early strength cement plus 50 cc of Plastiment was then pumped through the copper tube until it completely filled the voids in the traprock plug. The amount of grout necessary was previously determined by calculation and experiment. In the grouting operation grout was poured into the copper tube through a funnel and pressure applied to it with a pump improvised from a caulking gun.

The rock anchors were pretensioned to about 65 tons, which was just below the yield point of the rods at the root of the threads. The prestressing operation was commenced four months after the rock anchors were installed. A 12 by 12 by 2 in. plate washer was placed over the top of each rock anchor and floated to even bearing on a bed of cement mortar at the bottom of the access pit (Fig. 3). When the bedding mortar had gained sufficient strength a nut was turned onto the rock anchor and tightened by hand against the plate washer. By means of a threaded sleeve, the lower end of an extension rod was then fastened to the top of the rock anchor and the upper end coupled to a 100

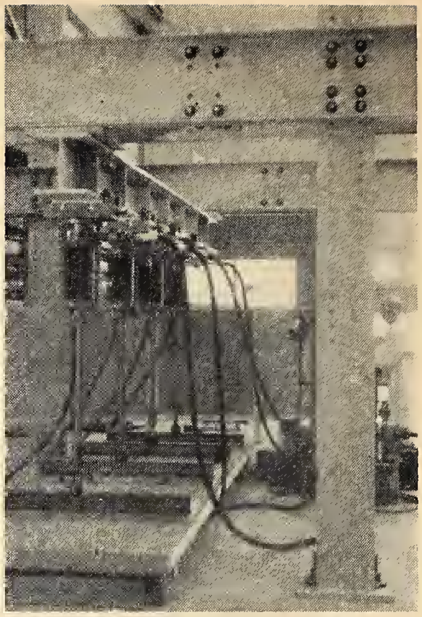

Fig. 7. Loading test on Arctic housing roof panel with four jacks.

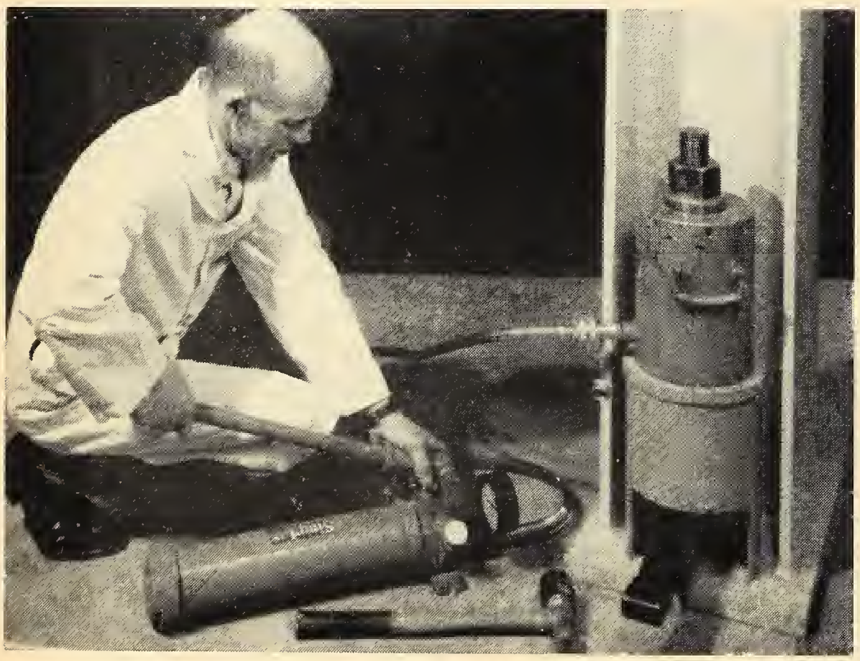
Fig. 6. Pretensioning column anchor with centre-hole jack.



ton centre-hole jack supported by a small reaction frame. A 65 ton load was then applied to the rock anchor, the nut at the bottom of the access pit tightened by special socket wrench and the jack pressures released, leaving the rock anchor pretensioned.

As a final step, 4½ in. un-reinforced concrete slabs were cast in place to provide semipermanent covers over each pit. From time to time one or more of these slab covers will be broken out to check prestress losses.

Handling of Testing Equipment

Considerable attention was given in the design of the installation to the convenience of assembling and dismantling the components of test frames and of the hydraulic loading equipment. The members of the frame were equipped with holes for easy lifting by means of the 10 ton laboratory crane. Thanks to the accuracy of column anchorage points, it has been found possible to leave entire bents assembled while moving them to different locations.

Since the hydraulic jacks are most frequently used in their "hanging" position, it was decided to store them also in this way. All except the heavy 50 ton jacks are kept on a storage rack from which they can be transferred by sliding them onto a dolly which is then wheeled under the desired point on the test frame. From there the jacks are hoisted by means of a crane and double sling and attached by special bolts and brackets to the underside of the spreader beam. A similar arrangement is used for the 50 ton jacks, but because of their 1400 lb. weight, they are kept permanently on the dolly and are not transferred to a storage rack. (Fig. 9).

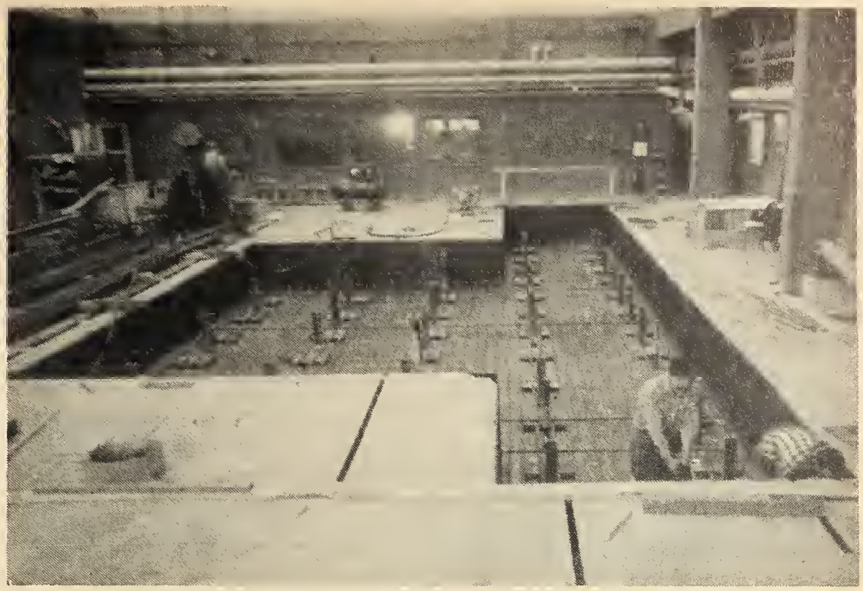


Fig. 8. Excavation for test slab after placing of steel posts, bottom plates for column anchorages and part of lower reinforcing steel.

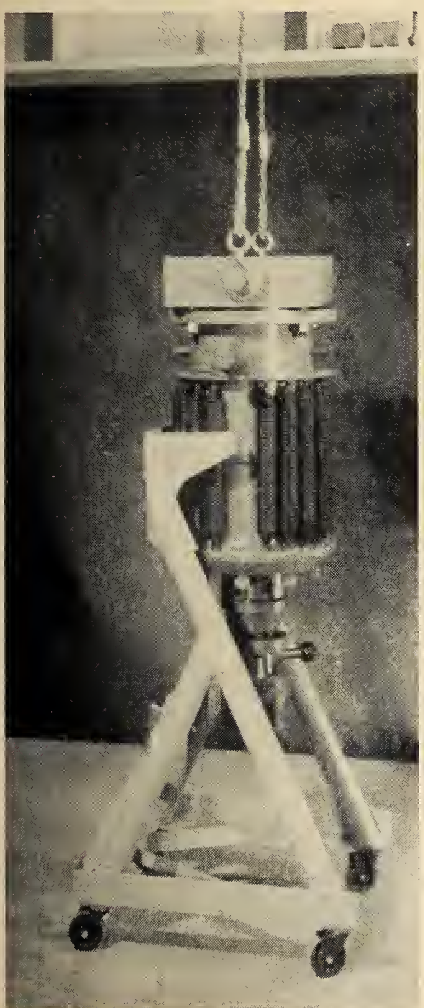
Fig. 9. Fifty-ton jack being lifted from dolly to test frame.



When the jacks are used under a single bent, as shown on the left on Fig. 4, a different attachment is used. The saddle support which normally carries the spreader beams is provided with a special hanger plate with holes at appropriate places to support the jack.

Use of Installation and Final Remarks

The installation has been used for loading tests on a variety of structural items including timber bridge planks (Fig. 4), prefabricated Arctic housing panels (Fig. 7), sections of wooden roof trusses, concrete and masonry walls subjected to combined vertical and lateral loading. It will shortly be used for loading tests on an entire house roof.

It may be noted that during the test of masonry walls both pendulum dynamometers were used simultaneously, one to provide quarter-point horizontal loads on the face of the wall, the other to keep, with the aid of the built-in load maintainer, a constant vertical load on the wall.

In conclusion it can be stated that the system of structural testing equipment adopted, consisting of an anchorage slab, reaction frames and portable hydraulic jacks, has provided the Division of Building Research with an extremely versatile structural testing installation, suitable for full-scale loading tests on a wide variety of structural elements. Experience to date with the installation has been entirely satisfactory. It is expected that, as the work of the Building Structures Section expands, the installation will be used more and more. Further parts will be added to the test frames and the hydraulic loading equipment as the need arises. It is believed that this new installation of the Building Research Centre will fill an important role in making available for service to the Canadian construction industry the best possible building research facilities.

Acknowledgements

The authors wish to express their appreciation to the many persons who generously contributed their services and experience to the successful development of the installation, particularly to members of staff of the laboratories listed at the beginning of the paper and especially to Dr. Bruno Thürlimann of Lehigh University, Bethlehem, Pa., for information leading to the general scheme of the installation. The authors are indebted to Dr. Sheldon Cherry for valuable assistance with the structural design of the slab and test frames. This paper is a contribution from the Division of Building Research of the National Research Council of Canada and is published with the approval of the Director of the Division.

Recent Advances in
Experimental Stress Analysis

J. B. Mantle, M.E.I.C.,
Professor and Head, Department of Mechanical Engineering,
University of Saskatchewan, Saskatoon

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

Space age demands for huge weight savings in missiles, rockets and satellites has resulted in growing interest in experimental stress analysis. This tool is of ever-increasing importance to designers. Particularly interesting are activities in three-dimensions.

A REVIEW is made here of recent advances in experimental stress analysis techniques with some examples of their application, as carried out in the author's laboratory being given. In respect of photoelastic stress analysis there is discussed the new Photostress technique, including the Photostress gauge, as well as some of the newer materials for three-dimensional work such as Hysol 6000 OP and photoelastic casting resin E.P.A. In the area of electrical resistance strain gauges the new metalfilm gauges are emphasized and in addition a description is given of some of the author's recent experiences with dynamic stress analysis in the milli-microsecond range using standard gauges.

With the advent of the space age experimental stress analysis has become an increasingly important tool for designers. All out weight saving is required for missiles, rockets, satellites and the like. This increased interest in experimental stress analysis has led to numerous developments that otherwise might not have occurred. In particular, three-dimensional work has moved into greater prominence. Three dimensional photoelastic stress analysis has received more attention with the result that materials having better properties have emerged. A teehnique has been evolved for attaching photoelastic materials directly to actual machines and structures and observing photoelastically strain variations when the loads are applied. Light weight electrical resistance strain gauges have been developed involving the printed circuit teehnique. With high energy transfer rates dynamic problems are increasingly facing the designer. Stress variations during time intervals of milliseconds and microseconds are now of vital importance. Refinements in recording and indicating equipment for dynamic applications are continually being announced.

At the University of Saskatchewan the author has attempted to keep abreast with these developments and has encouraged his students, both graduate and undergraduate, to do experimental work involving them. The purpose of this paper is to inform readers of the latest developments in experimental stress analysis and also to bring to their attention some of the projects that have been going on in the author's laboratory during the past year or two.

Fig. 1. Frozen Stress Patterns of Diametrically Loaded Discs after a Load-Thermal Cycle.

Three-Dimensional Stress Analysis by the Stress-Freezing Technique.

The most popular method of three-dimensional stress analysis is the stress-freezing procedure described in detail in several volumes.[1-2] In brief, the method involves preparing a model of the member from a sensitive plastic material, applying loads to it, heating to a critical temperature, soaking for a period and finally slowly cooling to room temperature. It will be found that a birefringent condition is locked into the model even with no load applied. The model may then be sliced and the stress condition in the slice examined quantitatively using a standard photoelastic polariscope. From the stress conditions found in the slices an overall evaluation of three-dimensional stresses may be made.

Photoelastic Material Properties: Several properties of photoelastic materials are of concern to those engaged in three-dimensional work. Especially, the photoelastician is interested in (a) critical temperature, (b) photoelastic sensitivity above critical temperature, (c) rigidity above critical temperature, (d) time-edge effect after the load-thermal cycle and (e) cost of material.

Critical temperatures vary from 170° to 320°F, depending on the material and batch. This value may be easily obtained by observing with polarized light a calibration member such as a diametrically loaded disc as it is being heated while under load. At the critical temperature one phase of the plastic softens and the remaining phase supporting the load is less rigid and much more photoelastically sensitive than formerly. Thus a certain amount of deformation occurs and a fringe pattern suddenly takes form. Upon cooling and removal of the load the new fringe pattern remains. Fig. 1 shows views of two discs originally carrying the same load; in one case cooling took place before the critical temperature was reached and in the other case the critical temperature was exceeded before cooling.

These same diametrically loaded discs make excellent members for calibration of the material, i.e. for determining its photoelastic sensitivity. Analytically it can be shown[3] that the relationship between fringe count at the centre of the disc (n), diameter (d-inches), load (P-pounds) and fringe value (f-pounds per inch per fringe-shear stress) is as follows:

$$f = \frac{4P}{\pi n d} \qquad (1)$$

For the disc shown on the right hand side of Fig. 1 the fringe count at the centre is 1.86 (fractional fringe order determined by Senarmont method[4]), the diameter is 0.750 in. and the load was 0.602 lb., so that one fringe is equivalent to a shear stress of 0.55 p.s.i. for material an inch thick (Absolute units: pounds per inch per fringe).

A small amount of distortion remaining after the load-thermal cycle can be tolerated but it must be remembered that the resulting distorted pattern is the one being analyzed and not the original shape. Rigidity (Young's modulus, E) may be evaluated by measuring the maximum deflection of a constant moment beam, after the load-thermal cycle, using the following relation which may be calculated from ordinary strength of materials:

$$E = \frac{Ml^2}{8I\Delta} \qquad (2)$$

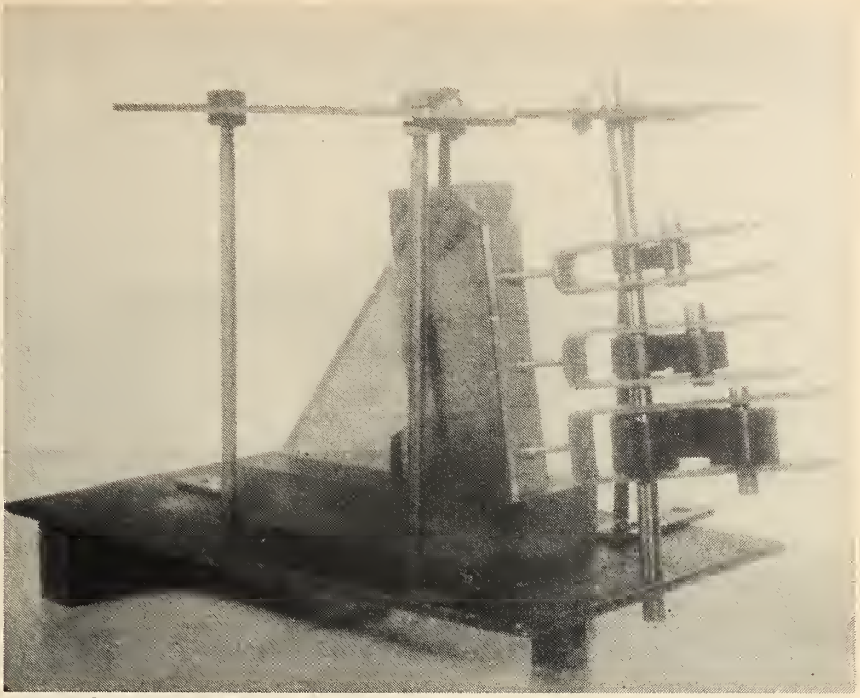


Fig. 2. Photoelastic Model of Diamond-Head Buttress Dam Mounted in Loading Rig and Having One Face Loaded.

where E = Young's Modulus—lb./in.^{2}
M = moment—lb. in.
l = length—in.
I = moment of inertia—in.^{4}
and Δ = maximum deflection—in.

Since the photoelastic worker is interested in maximum sensitivity with minimum distortion he uses a term "figure of merit"[5] for comparison purposes where:

$$\text{Figure of Merit} = \frac{E}{f} \qquad (3)$$

Time-edge effect is a constant threat to the accuracy of photoelastic results and must be avoided if at all possible. Freshly cut model edges tend to absorb moisture from the surrounding air resulting in swelling and in a matter of hours producing a stress system that will superpose on that due to external loads. There are a number of ways that may be employed to arrest this condition[6] but generally speaking each material has its own peculiarities in this regard. Quantitative measurements of the magnitude of time-edge stresses may be made by photoelastic observation of the edges of unloaded models.

Commercially Available Materials: Several materials are available commercially in the United States and Canada that are suitable for stress-freezing, each having its particular advantages and disadvantages in so far as their photoelastic properties are concerned. Catalin 61-893 is suitable but is not easily obtainable in sheets over one-quarter of an inch thick. Fosterite was used extensively during the past ten years but appears to be off the market now. Hysol 6000 OP having good characteristics is available in rods up to 5 in. in diameter and in sheets to 3 in. thick, but is expensive and delivery time is of the order of two months. The company formerly marketing Fosterite is supplying in its place a casting resin E.P.A. with hardener. This material has quite favourable properties but has been found by the author to be rather tricky to work with.

Table 1 shows comparative data for the above mentioned materials, the values having been obtained in the author's laboratory except where noted.

Some Experiences: The author has made use of Catalin 61-893, Hysol 6000 OP and E.P.A. photoelastic resin for various three-dimensional photoelastic investigations under his direc-

Table 1.
Photoelastic Properties of Some Three-Dimensional Materials.

Material	*Critical Temp. °F.*	*Fringe Value f lb./in./fringe shear stress*	*Figure of Merit Based on shear stress*	*Time-Edge Effect*	*Cost*
Catalin 61-893 ¼ in. sheet	240	1.65	668	Excessive	Approx. $15.00 per lb.
Fosterite (Fumeric)	250*	2.25*	1320*	Negligible*	Not Available
Hysol 6000 OP ½ in. sheet	220	0.55	1900	Negligible	$5.63 per lb.
Hysol 6000 OP 2 in. sheet	270	0.68	3540	Negligible	$5.43 per lb.
E.P.A. Casting Resin	320	1.04	2600	Excessive	$2.25 per lb.

tion in recent years.

One of the earliest was that using 61-893 to investigate the most efficient cross-sectional shape for a reinforcing ring to be placed around a circular hole in a plate under tension.[7] Here the reinforcing ring was attached to the main plate by means of a special adhesive. Following the load-thermal cycle the material in the plate adjacent to the hole was sliced in order to get an evaluation of stress gradients through the plate.

This was followed up lately by Toronchuck[8] using Hysol and E.P.A. resin. In this case the effect of various shaped reinforcements around a circular hole in a plate subjected to plane shear was investigated. The reinforcement was made integral with the plate by two different methods. In one the plate and reinforcement were machined as a unit from a half-inch thick plate of Hysol (Fig. 6 shows a typical frozen stress pattern of the plate with attached reinforcement prior to slicing). In the other the whole model including reinforcement was cast from E.P.A. resin using a steel mould. Time-edge stresses were a definite problem with the E.P.A. models but examination of the models several weeks after casting and stress-freezing revealed substantial reduction in time-edge stresses.

Catalin 61-893 was utilized by North in his studies of hydrostatically loaded conduits.[9] He was examining the stress distribution in conduits having circular internal loaded boundaries and external boundaries varying from square, to octagonal and finally to sixteen-sided. The stress-freezing technique was employed to evaluate the pressure variation through the model being imposed by the loading device.

A three-dimensional photoelastic stress analysis of diamond-head buttresses for an earth fill dam[10] is nearing completion in the author's laboratory. Initially it was hoped to cast the models using E.P.A. resin and plaster of paris moulds. The fact that it takes almost 48 hr. for the model material to gel led to considerable difficulties with leaking moulds. This was finally overcome but shrinkage cracking and other problems forced abandonment of attempts to cast the models. They were finally made by building them up from machined sections of Hysol; in one case using ½ in. slabs and in the other three large machined pieces. The parts were put together with a Hysol adhesive. After a period of cure of seven days a very satisfactory bond for the stress-freezing technique could be obtained. A diametrically loaded disc made up from laminations and having a stress pattern frozen into it is shown in Fig. 5. Loading of the models to simulate water and earth loads was accomplished by using fourteen Negator clamps supported in a framework as shown in Fig. 2.

Photostress and Photostress Gauge.

Recent innovations in photoelastic stress analysis are "photostress" and the related "photostress gauge". In the photostress method developed by Zandman[10,11] a layer of sensitive plastic is attached to the actual structure (steel, iron, concrete, etc.). After loading, the critical area is examined with the aid of polarized light reflected from the structure surface after passing through the plastic. The simplest instrument for examination is a piece of polaroid with integral quarter-wave plate. This, together with the plastic sheet, provides all the elements of a simple polariscope. The stressed area will show color bands from which quantitative stress measurement may be made by color matching. Greater accuracy of readings is possible with more refined instruments available from the manufacturer. Johnson[13] successfully analyzed gear teeth stresses at the University of Saskatchewan by attaching photostress sheet to the teeth and then examining the resulting stress pattern with a P Q/Z hand viewer.

The latest development in this area is the photostress gauge which is still more or less in the experimental stage although available commercially. These gauges are made from a strip of photoelastic material with a fringe pattern of colored bands frozen into it, with a piece of polarizing material over this and having a reflective surface at the bottom. Indeed, all the elements mentioned for photostress have here been combined into the gauge itself! A scale is incorporated along the edge of the gauge and with it the amount of movement of the fringes resulting from strains in the members is observed. This amount of movement is proportional to strain and may be used in its quantitative evaluation. They may be attached to any structure with the aid of a suitable adhesive. In Fig. 3 is shown a photostress gauge attached to a constant stress steel beam. This installation was used by Koch[14] to compare the accuracy of this gauge with that of the standard bonded wire resistance strain gauge, under both static and dynamic loads. Remarkable accuracy was obtained under these ideal conditions but one must be skilled at identifying colours. The gauges are inexpensive considering that no auxiliary equipment is required to aid in the measurement. Their disadvantages in the present stage of development are (a) very sensitive to heat, (b) principal stress direction must be known, (c) gauge length excessive,—one inch, and (d) correction factors are necessary when bending is present.

Electrical Resistance Strain Gauges.

The principle of measuring strain by observing resistance change to a grid of fine wires bonded to a structure has long been utilized in experi-

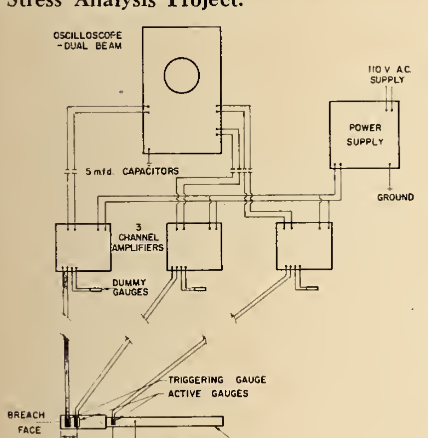
mental stress analysis work. These bonded resistance strain gauges have had many applications in the past for both static and dynamic work.[15,16] Lately advances have been made in light weight temperature-compensated gauges and also a high stage of perfection has been reached in measurement and recording equipment for dynamic stress analysis.

Metalfilm Strain Gauges: A notable achievement in electrical resistance strain gauges is the metalfilm gauge.[17] These gauges are formed by photo-etching on a special alloy foil. The foil may be made from materials that give automatic temperature compensation. The result is an extremely useful design — one that can give great accuracy on thin sections under bending conditions, can readily conform to curved surfaces, can be used immediately after attachment and can be used under high temperature conditions as well as under high values of acceleration without loosening. Burke and Ens[18] used this installation for studying vibration characteristics of a square bar under torsion.

Fig. 7. Schematic Diagram for Dynamic Stress Analysis Project.



Dynamic Stress Analysis Project: Recently George,[19] at the University of Saskatchewan, carried out some comparative tests of the power of various shot gun shells by circumferential strain measurements on the barrel and breach at the instant of firing. (Fig. 7.) A Sanborn 150 oscillographic recording system formed the basic apparatus element. However, the oscillographs did not have sufficient response so amplifiers were hooked in to a dual beam oscilloscope. Recording was accomplished by using one gauge as a trigger for the beams and photographing with a Polaroid camera. A photograph of one set of strain curves is shown in Fig. 4. The lower curve is that for the gauge on the breach itself and the upper one for the gauge placed six inches out along the barrel. The first peaks occur approximately one millisecond after firing.

Conclusion

New techniques have emerged recently and advances have been made in three-dimensional photoelastie stress analysis. Despite the lack of literature on the newly introduced light weight strain gauges, experimental work utilizing them is going ahead.

Frazil Ice and Flow Temperature Under Ice Covers

Ernest Pariset, M.E.I.C.
Director LaSalle Hydraulic Laboratory

René Hausser, M.E.I.C.
Engineer, LaSalle Hydraulic Laboratory

Frazil ice can present a serious clogging problem. This study is designed to probe the effectiveness of an ice cover in stopping the transportation of frazil ice, to protect a downstream power station.

FOLLOWING Mr. G. P. William's paper on frazil ice (Engineering Journal, November, 1959), we present here some new aspects of this subject. Our study on frazil ice was undertaken for the Quebec Hydro-Electric Power Commission and is part of a more general study on ice problems in rivers: formation of ice covers, hanging dams, ice jams, rate of ice formation. . . . This study, still in progress, has given interesting results, and probably will be published.

The fact that an ice cover will stop formation of frazil ice is well known, but sometimes it is not economically possible to have such a cover along the whole reach of a river. Therefore, a certain percentage of frazil ice generated upstream will be carried along under the ice cover to the power-station.

It was the aim of the study to determine this percentage, as a function of the flow characteristics and the length of the ice cover.

Frazil Ice Formation:

It is very probable that the formation of the frazil ice must be in close relation with the phenomenon of supercooling of water.

Classical theories assume that in running water at 0°C the heat loss of the exposed water surface generates localized masses of supercooled water which travel in the main flow until they meet some foreign particles in the water, or even existing frazil ice particles, which serve as nuclei for freezing of these masses of supercooled water. But we can also consider another possibility of frazil ice formation.

During cold weather, there is always a more or less thick layer of fog above the water. The convectional part of the water heat loss proceeds as usual by evaporating the water, which then forms the fog due to condensation of the vapor into very small droplets. These droplets are subject to cooling and supercooling and a certain percentage will drop back into the water.

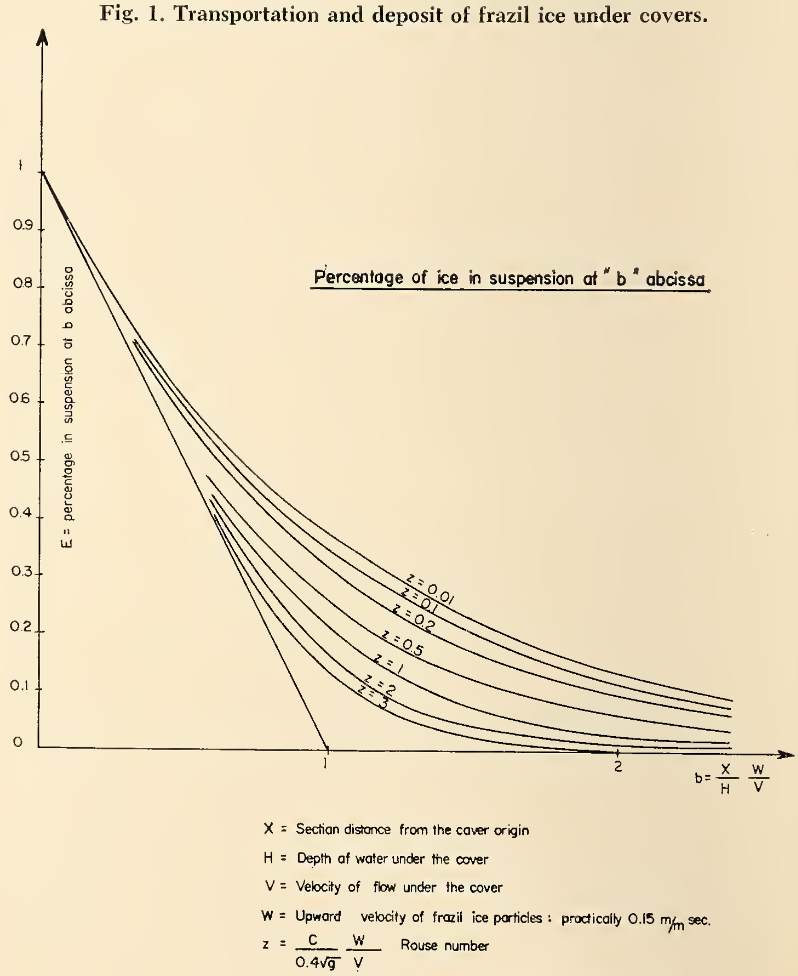
The supercooling of these droplets can be very extensive because of the pressure inside the droplets caused by surface tension (about 45 p.s.i. for droplets of a diameter of one micron). When these droplets fall back into the water, they flatten with a disk form. The release of surface tension forces will be sufficient to freeze them without the intervention of nucleating agents.

Transportation and Deposit of Frazil Ice

Frazil ice is, by definition, transported in suspension. Therefore turbulence phenomena play an important part and make its transportation study practically impossible on scale models. Thus we have tried to solve this problem by calculation, and have checked these results by field measurements on the deposit of frazil ice under ice covers.

Transportation under ice covers : Being less dense than water, frazil particles present an upward velocity similar to the settling velocity of the particles heavier than water. Then the problem of deposition of frazil ice under an ice cover is similar to that of a silting basin and we have solved it in the same manner. However, in order to simplify the study we assumed the following basic hypotheses :

Fig. 1. Transportation and deposit of frazil ice under covers.



1. The flow under the ice cover is uniform and influence of banks is negligible (this is practically true if the river is sufficiently wide);

2. At the front of the cover, all ice particles have the same upward velocity w and are uniformly distributed in the flow;

3. Deposited ice particles stick to the cover and cannot be removed by the flow;

4. We suppose also the mixture density is always close to unity, so that we can neglect density currents;

5. Finally, we suppose that the turbulence originating from the bed is smaller than that from the cover.

From the well-known mechanical equation of suspension (Dobbins)

$$\frac{\partial}{\partial Y}\left(\epsilon\frac{\partial c}{\partial Y}+wc\right) = V\frac{dc}{dX}$$

and by assuming that ϵ is given by:

$$\tau = \epsilon\rho\frac{\partial u}{\partial X}$$

(Rouse, experiment of Vanoni)

$$\frac{\partial u}{\partial Y} = \frac{1}{K}\cdot\frac{u*}{Y}$$

(Nikuradze, Von Karman)

We find:

$$\epsilon = \frac{Ku*}{H}Y(H-Y)$$

By taking into account the preceding physical hypotheses along, the integration of this equation gives:

$$E(b,z) = \sum_{n=0}^{\infty}\frac{(-1)^n(2z+2n+1)\Gamma(2z+n+1)}{(z+n)^2(z+n+1)^2\ n!_1\ (z)^2}\cdot e^{-(n+z)(n+z+1)(b/z)}$$

The general results of the integration are given on Fig. 1, but the direct application of the result is impossible because we do not know the upward velocity of frazil ice particles.

However, from the ice concentration variation and the ice discharge at the upstream edge of the cover, it is easy to calculate the shape of the ice deposit along the cover for various upward velocities. The comparison of the results so obtained with results of field measurements then will allow the determination of the upward velocity of frazil ice particles.

Application to the Beauharnois Canal: Application of this method of calculation to the Beauharnois Canal between 1953 and 1957 has furnished several interesting results.

(a) For the different years, ice particles appear to have constant upward velocity. The question is to know whether this constant velocity is independent of the site. If so, we would be in presence of a very particular ice which truly merits being called frazil ice. Future studies will probably provide verification of this point. From the velocity value and supposing ice particles as spheres of 0.92 density, we find that their mean diameter would be equal to 0.75 m/m. In fact ice particles are usually disk shaped.

(b) Theoretical and measured deposit profiles are reasonably close to each other (Figs. 2 and 3). This result constitutes an indirect verification of the theory.

The comparison of these profiles obviously shows some divergencies, especially at the beginning and at the end of the cover. However, we must point out that we have considered here only the action of frazil ice deposit and neglected all the other factors governing the thickness of the cover.

Some of the neglected factors, like erosion due to water flow or impact of ice floes can reduce the thickness of the upstream end of the cover. Others, like thrust of the cover tend to increase its thickness towards its downstream end.

Finally, we assumed that the initial ice cover was formed quickly with a uniform thickness. In fact this is not absolutely true, as there may be some frazil deposit during this formation. Also some growth in thickness can occur locally by ice crushing.

(c) Finally the study shows that in the Beauharnois Canal, even with an ice-cover of 60,000 ft. above the power-house, quantities of ice particles entering the turbines are of the order of three-quarters of the quantities produced by the ice free surface upstream of the cover. Therefore, it appears obvious that the use of covers to prevent frazil discharge through turbines is not very efficient.

In an effort to obtain a more precise verification of this theory, we have built and calibrated an electric probe to measure frazil ice concentration in rivers. This probe probably will be in operation this winter and we expect to do some measurements with it on frazil transportation in the city of Montreal water intake.

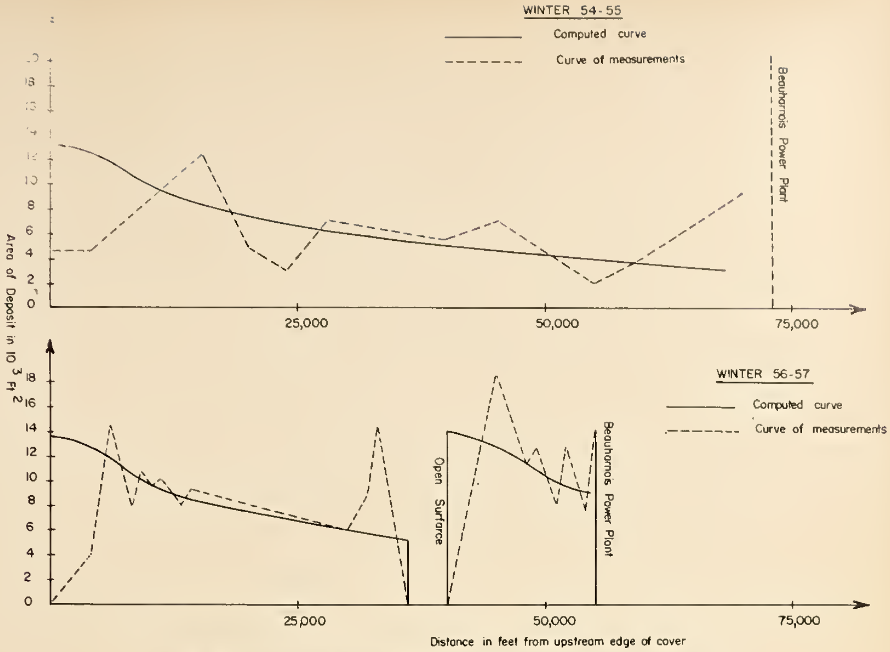


Fig. 2. Deposit of frazil ice under Beauharnois ice covers.

Frazil Ice Sticking

We have said that the use of ice covers to prevent frazil discharge through turbines does not seem very efficient. Otherwise the experiment has shown that ice covers in front of power-houses reduce greatly and sometimes even eliminate the troubles caused by frazil ice.

Consequently, these troubles do not seem due only to the presence of frazil, but rather to its sticking property. On this point, we think the adhesion of ice particles to objects in water probably depends greatly on the state of these crystals. The adhesion of these particles to the objects in water depends on whether they are growing or melting. On the other hand, studies have shown that the temperature of water tends to increase as it progresses under ice covers. We think, therefore, that after a sufficient journey under a cover, frazil ice is melting and cannot stick to objects, hence does not create troubles in power-house operation.

Water Temperature Variation Under River Ice Covers

We have said the temperature of water tends to increase as the flow progresses under an ice cover. This result can be determined by calculating heat balance between two sections.

If we consider a length of flow ΔX in meters under an ice cover and if discharge per unit width is q^{m^3}/sec/m and the energy line slope i, water temperature will increase or decrease by ΔT as a result of :

(a) a heat release or absorption by the water of :
$W_1 = \Delta T \cdot q \cdot 10^6$, in calories/sec.

(b) a heat release from head losses :
$W_2 = 2350 \cdot q \cdot i \cdot \Delta X$, in calories/sec.

(c) a heat transfer through the cover, since ice water boundary is always at 0°C :
$W_3 = hT \cdot \Delta X$, in calories/sec.
h being the coefficient of heat convexion.

(d) a heat release W_4 from the river bed to the water : this heat release is usually very small ($W_4 = 0.5$ to $I.$ 10^{-3}cal/m^2/sec. from some measurements) and negligible, except if springs or infiltration of warmer water occurs in the river bed.

Finally the heat balance between two sections distant ΔX is given by the equation :

$$+\Delta X \cdot h, T = -\Delta T \cdot q \cdot 10^6 + 2350 q \cdot i \cdot \Delta X$$

Whose the general integration shows that :

$$T°C = A e^{-(hx/10^6 q)} + \frac{2350}{h} iq$$

A being the constant of integration.

According to the conditions at the front of the cover, we may have the following cases :

(*a*) *Waters enters under the cover at 0°C :*

Mathematically we have at the front of the cover :

$$X = 0 \qquad T° = 0$$

then

$$A = -\frac{2350}{h} iq$$

and

$$T°C = \frac{2350}{h} iq(1 - e^{-(hx/10^6 q)})$$

In this case, the water temperature increases as the flow progresses under the ice-cover, up to the asymptotical value :

$$T°C = \frac{2350}{h} iq$$

practically reached a distance of :

$$X = 4.6 \frac{10^6}{h} q$$

(*b*) *Water enters under the ice cover temperature T_0 higher than 0°C :*

Following the general integration we have :

$$X = 0 \qquad T = T_0$$

and

$$A = T_0 - \frac{2350}{h} iq$$

In this case the water temperature X meters downstream of the ice cover edge is given by :

$$T = \frac{2350}{h} iq + \left(T_0 - \frac{2350}{h} iq\right) e^{-(hx/q10^6)}$$

Graph 4 shows the results of the different cases.

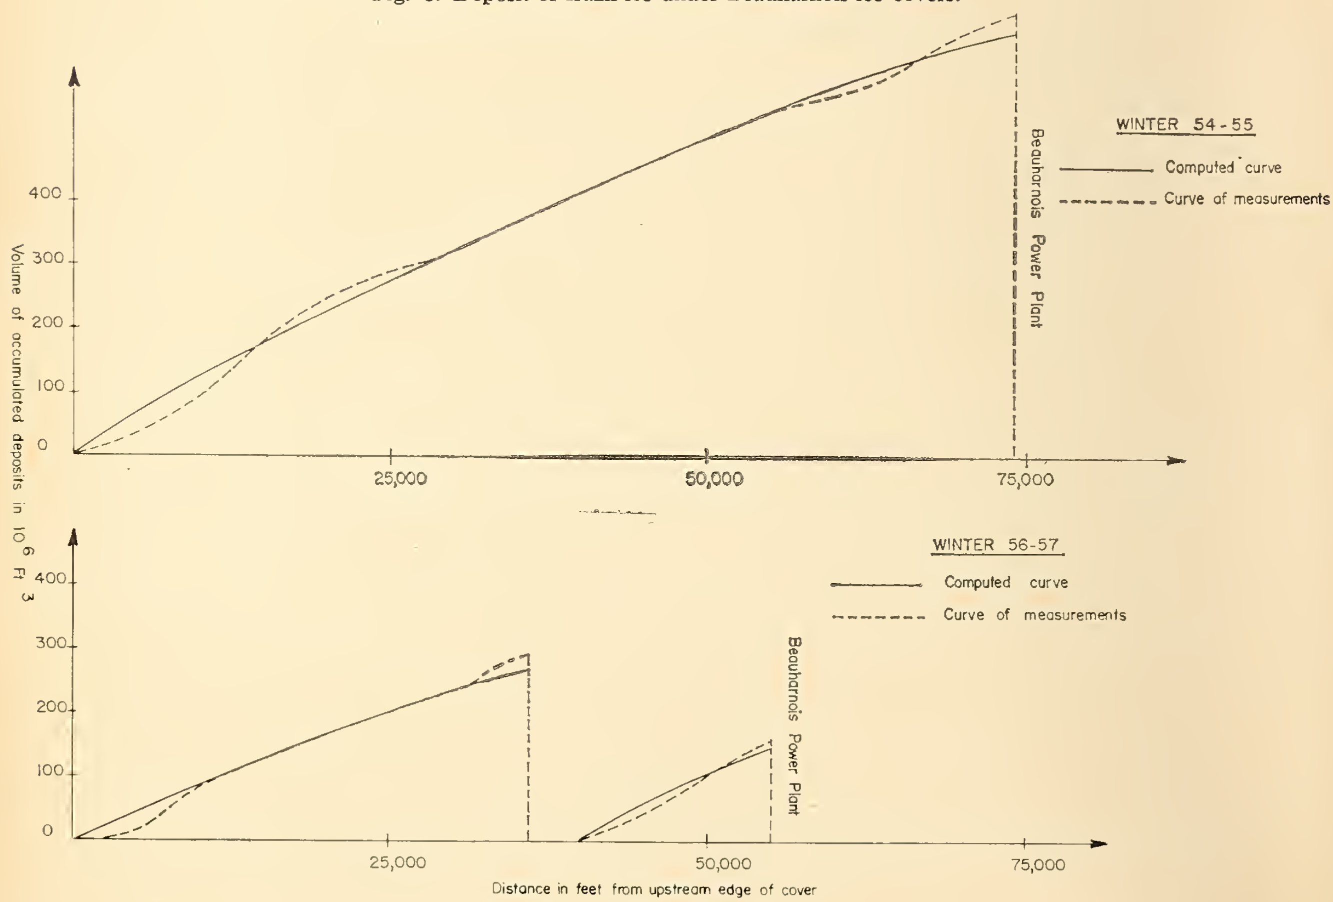
(*c*) *Water entering under the cover carrying ice particles in suspension :*

Part of these ice particles is deposited under the ice cover, another part is melted by the increase of heat of the flow during its travel under the cover, and a third part is carried downstream.

As long as the flow carries ice particles, its temperature remains at 0°C and there is no heat transfer through the cover. All heat produced by friction is hence used to melt ice particles so the quantity of ice melted per unit width is, in metric tons :

$$P = \frac{29.4}{10^6} i \cdot q \cdot X$$

Fig. 3. Deposit of frazil ice under Beauharnois ice covers.



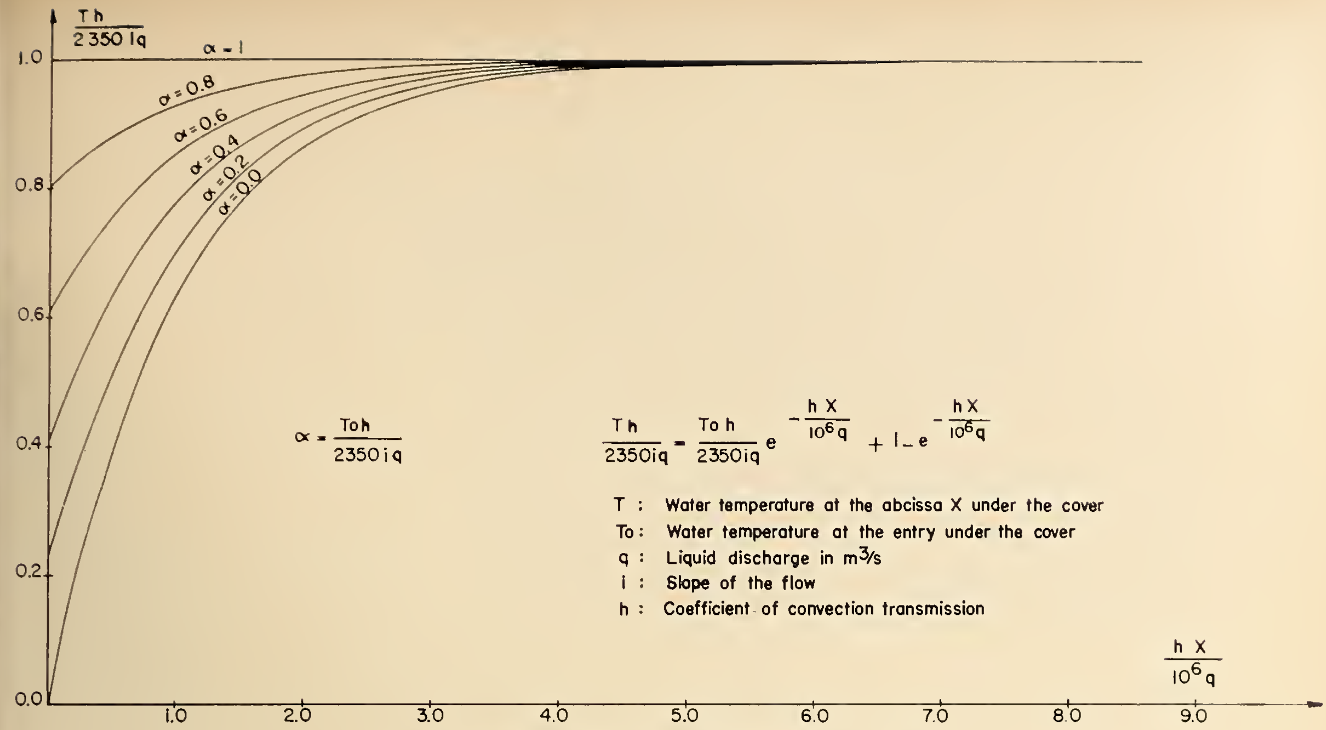


Fig. 4. Water temperature variation under an ice cover.

Application to Beauharnois Canal: The mean discharge is about 170,000 c.f.s. and the slope of the flow with an ice cover close to 0.6 10^{-4}. The width is about 4,000 ft. and the ice-cover reaches normally a mean length of 60,000 ft.

(a) Supporting that, near the front of the cover, water does not carry ice and its temperature is 0°C ; calculations show that, near the turbine intake the water temperature is :

$$+\frac{2.6}{1000}\ \text{C}$$

The rise of water temperature is hence very small and probably impossible to measure.

(b) Supposing that water enters under the cover with ice particles in suspension, we find by calculations that during its travel under this cover the flow can melt about 15,000 cubic yards of ice per day, and that independant of atmospheric conditions.

Atmospheric conditions will just govern the rate of melting or thickening of the ice cover ; the cover will thicken if the heat transfer from ice to atmosphere is higher than the heat transfer from water to ice cover ; it will melt in the opposite case.

Note the Coefficient h: The coefficient h may be written as :

$$h = k \cdot h_c$$

where : k is the correction index for the real surface of the ice cover in contact with the water ; it is therefore larger than one (1), and depends on the state of the bottom surface of the cover.

h_c is the convection transmission coefficient.

In the system we have chosen, it is approximately equal to :

$$h_c = 0.560(1 + 5V)\,\frac{\text{calories}}{m^2 \cdot {}^\circ\text{C} \cdot S}$$

where : V is the mean flow velocity in meters per second.

Finally,

$$h = k0.560(1 + 5V)$$

It is impossible to determine k without tests ; we know only that it is larger than unity, and may be taken as 1.57 if we consider the real surface as an agglomeration of hemispheres superimposed on the base of the ice cover.

Conclusion

Heat from losses of head is the main factor governing the temperature of flow under ice cover ;

If ice cover will stop local formation of frazil ice, it does not seem very effective in reducing the amount of frazil ice coming from upstream ; but it certainly is effective, by starting a certain melting of frazil ice and so greatly reducing its tendency to stick to trash screens and other equipment ;

Deposit of frazil ice under ice cover seems to follow closely the law governing settling basins, and field measurements check well enough theoretical calculations.

List of Symbols

Y, X	= coordinates.
H	= depth of water under the cover
ϵ	= coefficient of turbulent diffusion
w	= upward velocity of ice particles
C	= local concentration of frazil ice per volume
V	= velocity of water
E	= frazil ice concentration along the cover in relation to the ice concentration at the upstream edge of the cover
z	= the Rouse's number
Γ	= the gamma function
b	= the length from the upstream of the cover measured in units equal to the length that an ice particle coming from the bottom would travel to reach the cover in a non-turbulent flow
τ	= shearing strength
ρ	= specific weight of water
$K = 0.4$	= universal constant of Von Karman
$u*$	= shearing velocity
X	= distance in meters from the edge of the ice cover to the cross section considered
q	= discharge in m³/sec. per unit width
i	= the energy slope line
T°C	= temperature of water in degrees centigrade
W	= heat quantity in calories/second
h	= coefficient of heat convexion
P	= quantity of ice melted per unit width in metric tons

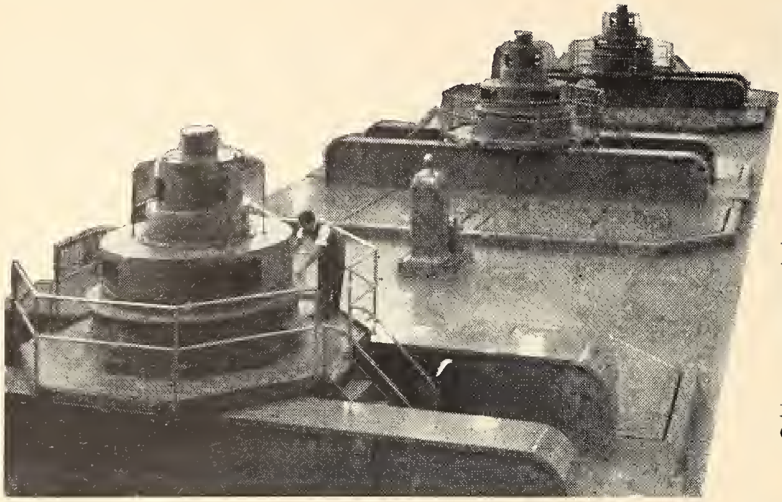
BRAKING OF HYDRO-ELECTRIC GENERATORS



H. O. Wilson, M.E.I.C.

Chief Engineer, Electrical Division, The Shawinigan Engineering Company Limited, Montreal

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May, 1960.

THE BRAKING of hydraulic turbine driven generators has assumed a new significance in recent years due to the widespread adoption of automatic braking for use with automatic units and remotely controlled generating stations. Also the increase in the number of units on the power systems has resulted in more braking operations being carried out than in the past.

The scope of the paper is limited to dealing with Francis or Kaplan turbine driven generators of medium size and moderate speeds.

Braking of a hydro-electric generator during a unit shutdown is required primarily to prevent slow deceleration of the unit in the critical period when the generator thrust bearing goes through the transition from the low friction of planing on an oil film through greased rubbing to static holding friction. If the bearing were left to linger in the rubbing friction area the babbit would heat up and eventually wipe.

Because bearing damage is to be avoided, a braking system supplied as part of the generator must be reliable, simple and easy to inspect and maintain.

Braking System

A generator braking system consists essentially of interconnected friction pad assemblies mounted on the lower bracket arms and a brake track attached to the under side of the rotor rim. To apply the brakes, air pressure is released through a solenoid-operated valve into the brake cylinders. The brake pistons, working against spring pressure, force the friction pads or brake shoes against the brake track.

To release the brakes, the solenoid of the air valve is de-energized, this shuts off the air supply and exhausts the air from the brake cylinders to atmosphere. The springs in the brake pad assemblies withdraw the shoes from the track.

A brake control switch, with *Hand-Auto* positions is usually located near the unit. For manual brake application the switch is turned to the *Hand* position and energizes the solenoid-operated valve. In the *Auto* position, the switch prepares the solenoid circuit for an automatic braking operation. The control switch is spring returned to neutral from the *Hand* position but is maintained in the *Auto* position.

The solenoid-operated valve is equipped usually with a hand lever for operating the valve mechanically to provide standby braking. A reliable source of air pressure, usually at 100 p.s i., can be obtained through a reducing valve from the air system supplying the governor accumulator tanks.

The braking system also serves as a means of jacking the rotor; a hand oil pump is used to apply relatively high oil pressure to the brake cylinders.

Design Considerations

The design of a braking system is determined by such items as:

Machine WR^2;

Peripheral speed of the brake track;

Turbine gate leakage torque;

Air pressure available;

Normal stopping time.

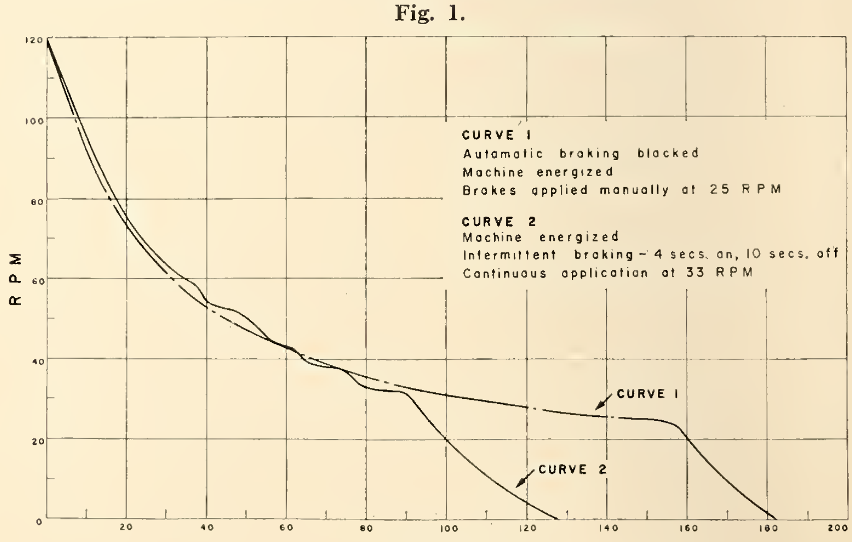
The torque of the unit which changes from a retarding torque initially on shutdown, to a driving torque as the speed decreases and the leakage torque becomes relatively more effective.

Governed by the above items, the designer must meet certain requirements such as:

Cracks in the track surface must not develop during normal braking;

Severe vibration of rotating and stationary members belonging to the brake assembly must be prevented in order to avoid fatigue in the highly stressed parts;

Fig. 1.



The pad lining material must not be allowed to score the track surface;

The brake pads must have a reasonable life and the replacement of worn pads must be a simple process.

The above requirements are met in general by:

Provision of the proper size and number of brake pads;

Specifying the speed at which normal braking should be initiated, thereby limiting the maximum rubbing velocity;

Designing the thickness of the brake plate to allow a temperature rise commensurate with the material used;

Erecting the track so as to eliminate waviness and obtain constant friction conditions;

Providing asbestos pad lining material without metallic particles or threads with the proper co-efficient of friction at a certain temperature and pressure.

Types of Braking and Shutdowns

Of the two classifications of braking, manual and automatic, only the latter will be discussed here in detail as it is considered that the methods used in automatic braking will apply as well to manual braking and can be incorporated into proper operating instructions.

Automatic braking is used with two types of unit shutdowns, normal and emergency. For this discussion a normal or planned shutdown is considered to be one in which the load is gradually dropped, the supply circuit breaker is opened and the unit brought to rest. An emergency shutdown is considered to be one in which the load is dumped by tripping the supply breaker, the generator field breaker is tripped and the unit brought to rest.

Emergency shutdowns are caused by either mechanical or electrical faults and usually result in a lockout of the unit involved. The unit cannot be started until the lockout relay is reset by hand.

Deceleration Curves

At this point it is of interest to examine the accompanying deceleration curves shown in Figs. 1, 2 and 3. These curves are the results of tests run on a modern 45 mva., 120 r.p.m. unit, the generator being driven by a Francis turbine.

Fig. 1:

Curves 1 and 2 illustrate the different characteristic deceleration curves of the machine for continuous and intermittent braking respectively. From a comparison of these curves it is evident that the intermittent application of the brakes produced very little effect on the rate of deceleration of the machine.

Fig. 2:

Fig. 2 illustrates the characteristic deceleration of the machine with and without the generator field energized. It can be seen that the deceleration is somewhat more rapid when the field is energized.

Fig. 3:

Fig. 3 compares the deceleration curves of a machine having gate leakage (Curve 5) and a machine having no gate leakage (Curve 7). (Incidentally, the gate leakage here was found to be due to a bent shear pin.) It should be noted that Curve 5 tends to flatten out at approximately 30 r.p.m. Curve 6 shows the result of applying the brakes continuously at 35 r.p.m. on the machine having gate leakage.

Observations

The following observations which can be made from a study of the deceleration curves are significant in the application of generator braking:

(a) In the intial stage of shutdown (i.e. above 60 r.p.m. or 50% speed) it makes little difference in the deceleration whether the field is energized or not (Curves 3 and 4).

(b) In the intial stage of shutdown it makes little difference whether or not the brakes are applied intermittently. (Curves 1 and 2).

(c) Gate leakage has little effect on the rate of deceleration in the initial stage of shutdown.

(d) The deceleration after the continuous application of the brakes below 40 r.p.m. or 33% speed is practically constant regardless of the actual speed at which the brakes are applied.

(e) Gate leakage could keep the machine in question running indefinitely at approximately 30 r.p.m. or 25% speed.

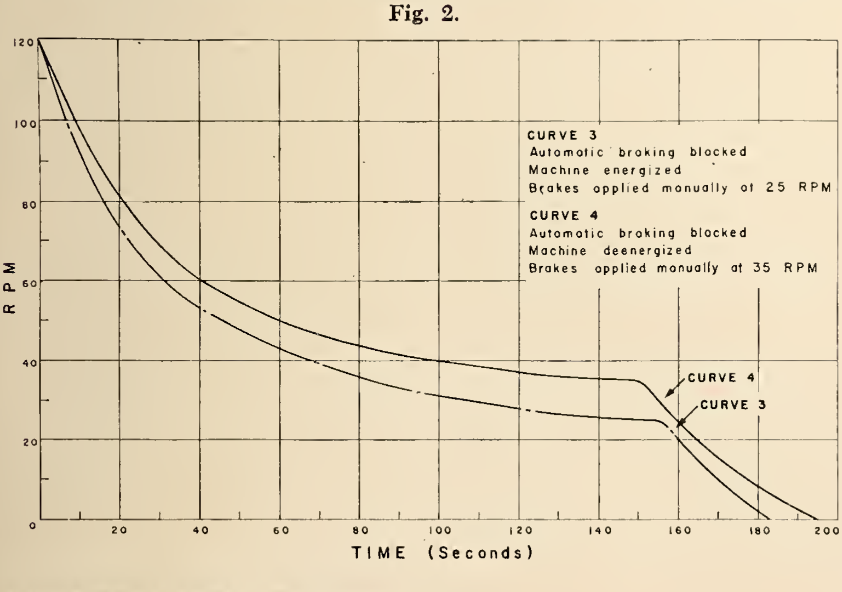
Proper Application of Brakes

From the above observations and in accordance with manufacturers' recommendations, the most suitable point on the deceleration curve for brake application is considered to be approximately at 40% of rated speed. Above this speed the turbine braking torque does an effective job of reducing the speed and, what is more important, brake application above this speed can cause destruction to the brake surfaces because of thermal fatigue caused by the high rate of heat generation.

Below 40% rated speed it is possible, due to gate leakage, to fall into the flat part of the unit's deceleration curve where the speed switch initiating brake application would not operate, and the machine would run indefinitely. While running at speeds just below 40% rated speed will not damage the generator bearing, this condition certainly will not shut down the unit.

Past braking practice in a great many cases has been to employ a braking timer which came into action at 50% rated speed and applied the brakes intermittently at first and then continuously and finally released the brakes a few minutes after the unit had come to rest. Present practice tends to eliminate intermittent braking and use continuous or maintained braking only. Intermittent braking is not considered advisable because the thermal cycles it produces cause more thermal fatigue in the brake surfaces than with continuous braking. In addition, intermittent braking accomplishes little or nothing in decelerating the unit. Also it is considered that with the elimination of a timer and its motor, simplicity is gained with maintained braking which could result in less maintenance. After the machine has stopped, oil oozes out from between the thrust bearing surfaces and in approximately four minutes the bearing static friction becomes greater

Fig. 2.



than the holding friction of the brakes and eventually overwhelms the brake friction. If the brakes are released too soon after shutdown and there is sufficient gate leakage there is a danger that the unit will start to creep, i.e. rotate very slowly, thus wiping the bearing, therefore it is considered safer to leave the brakes on continuously after shutdown. Monitor switches mounted on the brake pads and connected in series can be used to prevent a start-up of the unit until the brakes have been released.

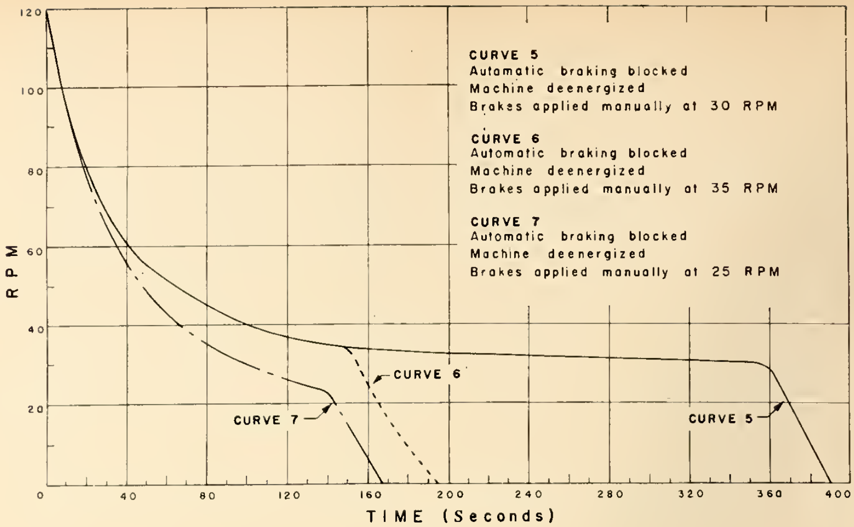


Fig. 3.

Braking in an Automatic Shutdown Sequence

For a normal or planned automatic shutdown, the "Unit Stop" switch or pushbutton is operated to set up a sequence such as follows:

1. The load is gradually removed from the unit;
2. The supply breaker is opened.
3. The wicket gates are closed by means of the governor shutdown solenoid;
4. A zero gate position switch closes when the gates are fully closed, thereby partially setting up a circuit to apply the brakes;
5. The unit decelerates due to the turbine braking torque;
6. At 40% rated speed a speed switch closes and completes the braking circuit to energize the solenoid-operated air valve and apply the brakes continuously;
7. The brakes remain on until the unit is required to start up again, when they are removed as part of the starting sequence.

For an emergency automatic shutdown the protective devices or the protection relays operate to trip the supply and field breakers and energize the governor shutdown solenoid. Thereafter the shutdown sequence would be similar to that shown above for a normal shutdown.

It is necessary for automatic shutdown to have the *Hand-Auto* brake switch in the *Auto* position so that the circuit is prepared for automatic braking. An alarm can be provided that will sound when this switch is not in the *Auto* position while the unit is running.

Various standby features can be added to the braking scheme depending upon circumstances and utility practice. Standby speed switches and standby solenoid-operated air valves have been used in some cases.

For larger machines it may be desirable to build up the brake pressure slowly as the unit decelerates so that the rate of heat generation will be approximately constant during the build up period.

It should always be kept in mind that an extra feature added in the interests of reliability should not be a source of hazard in itself.

Creep Indication

For units equipped for automatic braking it is suggested that a creep detector be provided to indicate rotation of the unit when there should be none.

There are different forms of creep detectors on the market but whichever type is chosen it is advisable that it should be capable of sounding a remote alarm and it should be used in such a way that false rotation alarms are avoided during the slow rotation periods that occur when starting or stopping a unit. Otherwise the value of a creep detector is lost.

A main cause of creeping could be the release of the brakes too soon after the unit has come to rest, when there is sufficient turning torque due to gate leakage to overcome the partially established bearing friction torque. Another cause could be the failure of a speed switch to initiate braking; under this circumstance when there is very little gate leakage the unit could slowly come to rest of its own accord.

Upon the occurrence of creeping, there are possibly two choices of action in the case of this with a normal shutdown. Another shutdown sequence may be initiated which will bring in the braking sequence again or a start up may be initiated which will bring the unit to speed-no-load and out of the dangerous low speed area. However, with an emergency shutdown the unit cannot be restarted due to the lockout feature of the shutdown relay.

Suggestions for a Braking System

In order to obtain a reliable braking system and make the best use of materials and facilities available:

The corresponding generator and turbine designers be requested to collaborate regarding the effects that the turbine torque can have on the unit braking;

The generator designer state the highest speed at which the brakes can be applied safely and the lowest speed at which the unit can be run without the danger of bearing damage;

A deceleration curve be obtained by actual test for each unit in order to determin the best speed during the shutdown at which to apply the brakes;

The brakes be applied at a speed below the highest safe speed given by the generator manufacturer and above the coasting speed that is due to gate leakage. Also it is suggested that allowance be made for an increase in gate leakage as the unit becomes older. A good average speed for brake application is considered to be 40% rated speed;

By means of a mechanical speed switch the brakes be applied continuously, not intermittently, and be left on until the unit is required to start up again;

The braking system be simple, easy to inspect and maintain. Careful consideration should be given to the addition of extra features or gadgets.

Conclusion

Reliable automatic braking systems can be and have been designed and it is considered that this factor has played an important part in the increasing use of automatic units and remote-control generating stations.

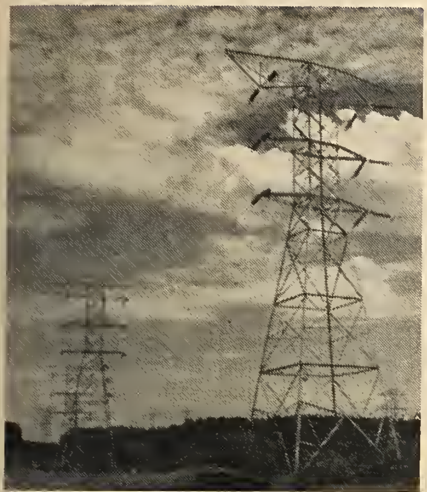
Economic Feasibility of TRANS-CANADA ELECTRICAL INTERCONNECTION



D. Cass-Beggs, M.E.I.C.,

General Manager, Saskatchewan Power Corporation

The possibility of a Trans-Canada interconnection of generating units is often discussed. Elsewhere such systems are common, but development here in Canada is principally on a provincial scale.

Paper presented to the E.I.C. Western Technical Conference, October 1959.

THE interconnection of generating units into large integrated systems is commonplace today. To a casual observer this process, in North America, might appear to have reached completion. It has been accompanied by the elimination of small and inefficient generating units, concentration of generation at plants with the lowest energy cost, and usually the transmission of relatively large blocks of power over the considerable distances that lie between low-cost resources and centres of population. Generally, Canadian development has been on a provincial scale, due largely to the fact that jurisdiction over the natural resources involved is vested in the governments of the provinces. While interconnections exist between adjacent provinces, notably between Ontario and Quebec where a common water resource forms the inter-provincial boundary, the concentration of load and the greatest capacity of the networks tend to be in the centre of the provinces. Facilities constructed towards the provincial boundaries are of little use for interconnection.

Connections presently contemplated between provincial systems such as the line under construction from Estevan, Sask., to Brandon, Man., are of limited capacity. They are generally for a specific purpose and cannot be considered to integrate the two systems.

The purpose of this paper is to examine the feasibility of a large-scale coast-to-coast interconnection. This interconnection would be such that a significant part of the power requirements of any province could be met from the facilities of others. Large amounts of energy would be moved from the region in which it naturally occurs, or not yet developed, to areas increasingly in need of new resources.

Obviously the studies involved in evaluating this question are both extensive and detailed. This paper does not attempt to do more than make a superficial examination of some of the factors in generalized terms and to indicate that it would appear that an a priori case for a trans-Canada electrical interconnection can be made.

Among necessary simplifications in a first study, attention should be drawn to the use of provincial systems as single units irrespective of the division of such units between separate utilities operating within the province. This is justified because separate utilities, whether they are private companies, municipal utilities or provincial commissions or corporations, are or will be largely interconnected within the particular province by 1965 and can be considered economically as single units. Further, Nova Scotia and New Brunswick have, for this purpose, been considered to be a single unit, and for geographical reasons, Prince Edward Island and Newfoundland have been omitted. Apologies are due to the individual utilities which have been arbitrarily merged or omitted, but some support for the action may be secured from the more readily available statistics on a provincial scale.

Other sweeping assumptions will be encountered as the argument proceeds. One of the first will be the allocation of a uniform price of $250 per kw. to new hydro developments, and $150 per kw. to new steam plants, wherever they may be.

For this analysis, 1965 loads have been estimated from trend curves indicated in Fig. 1. These are based on Dominion Bureau of Statistics figures with slight adjustments.

The economies that might be achieved by such an interconnection come from three main sources:

1. Reduction in the capacity that is held in reserve for contingencies, or that is constructed ahead of demand;

2. Reduction in peak demand due to increased diversity arising out of different consumption patterns in different regions, and particularly as a result of the displacement of peaks in the five time zones of Canada;

3. Savings due to the optimum use of minimum cost energy resources and the maximum use of available energy storage.

Reduction in Reserve Capacity

The reserve capacity maintained by utilities in Canada rarely has been that which they would consider most desirable. At times in the post-war period, reserves have been low due to war-time shortages combined with high post-war growth rates. At other times reserves have been individually high when new plants have been commissioned due to the justifiable decision to install very large units. However, a trend in the variation of reserves with the size of the system can be deduced by graphing the average reserve held by systems within certain size ranges.

The graph (Fig. 2) is based on average reserve capacity held by the nine provinces considered during a six-year period (1953-1958) as published in the Dominion Bureau of Statistics Annual Electric Power Survey of capability and load.

Points plotted represent the averages of systems which in any year fall within certain ranges of capacity, such as, 400 to 800, 800 to 1600 Mw. The smaller systems obviously have higher reserves compared with those in the region of 5000 Mw. (Ontario and Quebec). Some cases in the ranges between 1000 and 2000 appear to have abnormally high values which may be attributed to the effect of special isolated projects not integrated with the system. The points in question are for British Columbia.

Extrapolation of the graph to apply to single integrated systems of the order of 20,000 to 50,000 Mw. indicates that a reserve of 5% might reasonably be considered. For a fully integrated system of 20,000 Mw. (such as Canada by 1965) this would provide 1000 Mw. of reserve. The largest unit in operation might be 500 Mw. The simultaneous failure of two of these, or half a dozen or so units of smaller capacities would be covered. It should be noted too, that in a very large integrated system, indirect reserves in the form of overload capacities of steam units, interruptible loads, and the revision of despatching procedures to minimize losses rather than to minimize costs, would all be more easily mobilized.

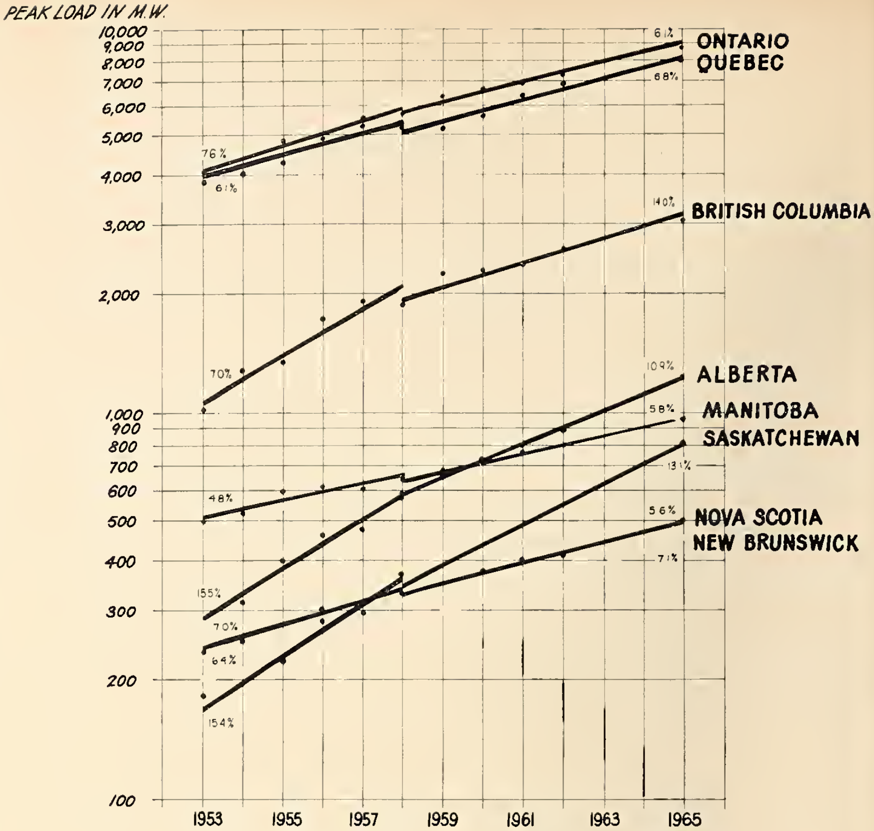


Fig. 1. Peak loads of Canadian Provinces 1953-65

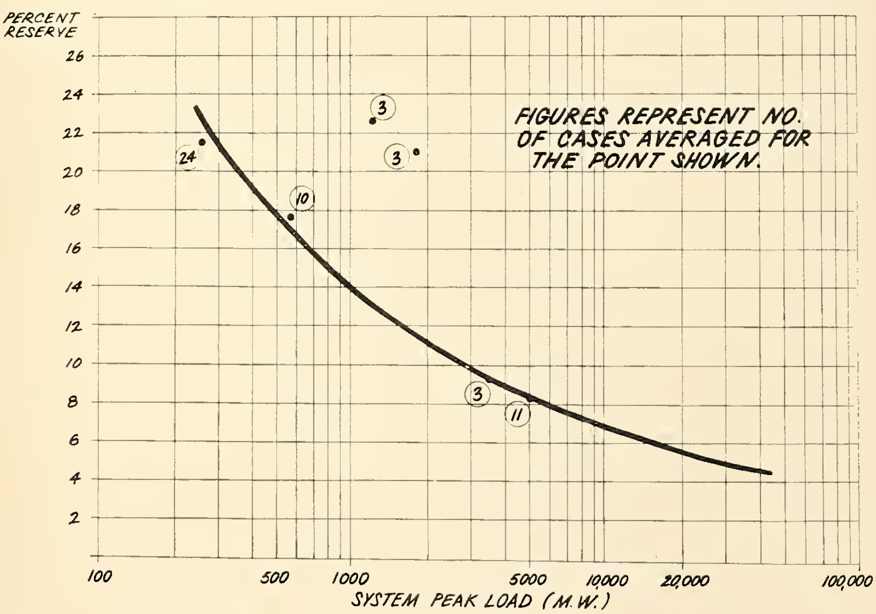
To estimate the saving in reserve capacity, the individual provincial peak loads have been projected to 1965, and a reserve factor according to scale has been applied from the graph (Fig. 2). This involves values ranging from 15.2% for Saskatchewan to 6.9% for Ontario. Considering (for this purpose) the peak load of the integrated system to be the sum of the separate peaks, a system of 22,000 Mw. would have required 5.4% reserve. Reduced to capacities this represents a saving in installed capacity of 715 Mw.

To find the investment involved in this reserve capacity it has been necessary to assign it arbitrarily to hydro and steam capacity in the proportion in which these resources are represented in the total. Valuing the hydro at $250 and the steam at $150 per kw., we find that the saving in investment due to the reduction in reserve capacity would be approximately $150 million.

Fig. 2. System peak load and percentage of reserve capacity (derived from 1953-58 data of provincial totals.)



Effect of Diversity

The savings to be secured from the diversity arising from the various time zones would be much more impressive if the provinces with the largest systems, Ontario and Quebec, were not in the same time zone. However, if it be conceded that other parts of Canada, particularly British Columbia and the Prairie Provinces, may expect relatively more rapid growth than the older established provinces, any estimate of savings calculated, for example for 1965, will be increased as time passes. Fig. 3 illustrates the distribution of provincial areas between time zones.

Daily load curves for a number of utilities have been obtained from which, with reasonable assumptions, composite load curves for the provinces have been constructed for

1965. These are shown individually in Fig. 4. Quite obviously Ontario and Quebec dominate the picture, but the other loads in aggregate are by no means insignificant and will be increasingly important.

These curves have been plotted to a base of Atlantic Standard Time. It is easy to see that the morning and evening peaks of British Columbia, Alberta and Saskatchewan, fit nicely on either side of the evening peaks of Ontario and Quebec.

A series of composite load curves has been developed starting from the Atlantic Zone and successively adding provincial loads until the total is reached with the inclusion of British Columbia. The top curve (in Fig. 5) represents the estimated total Canadian load for the peak day of 1965. It has been assumed that the peak day for the largest system would determine the peak day for the whole, and the corresponding day for other systems has been used. A more thorough compilation of load curves with more historical background would be desirable for this analysis, but it is felt that economies calculated on this basis are not likely to be over-stated.

The peak load thus calculated for Canada (with the omissions noted earlier) is estimated to be 20.7 million kw., while a summation of provincial peaks, irrespective of time of occurrence, gives 22.01 million kw. It is therefore argued that if integration can be achieved without loss of capacity, a saving of 1,500,000 kw. can be secured. This would represent capacity that need not be installed immediately after integration. According to whether this is hydro or steam capacity, it could represent an investment in the neighbourhood of $300 million.

In combining the savings due to both the effect of diversity and the reduction in reserve capacity, the following tabulation can be made:

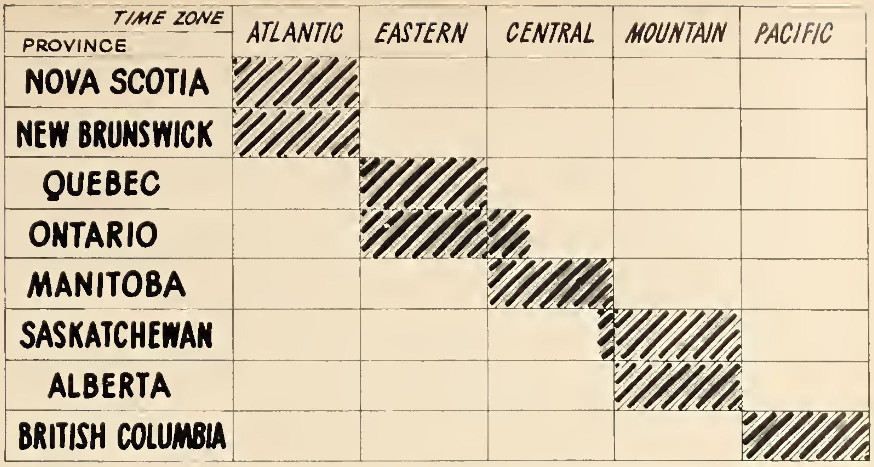


Fig. 3. Relationship between time zones and provinces in Canada

Necessary Capacity before Integration	
Sum of peak loads in each province:	22,007 Mw.
Sum of reserves separately required:	1,903
Total Capacity	23,910
Necessary Capacity after Integration	
Peak load for composite System	20,473
Reserve for composite system:	1,125
Total Capacity	21,598
Total Capacity Savings through Integration	2,132 Mw.

It is difficult to forecast what part of the capacity saved in this manner would be hydro and what part steam, or indeed nuclear energy at still greater capital cost. However, it is reasonable to assume it to be divided in the proportion for the presently planned increments of 36% hydro to 64% steam, which might apply between 1958 and 1965. Using the prices per kw. previously suggested for hydro ($250) and thermal generation ($150) the investment saved by a capacity saving of 2,312 Mw. is $430 million.

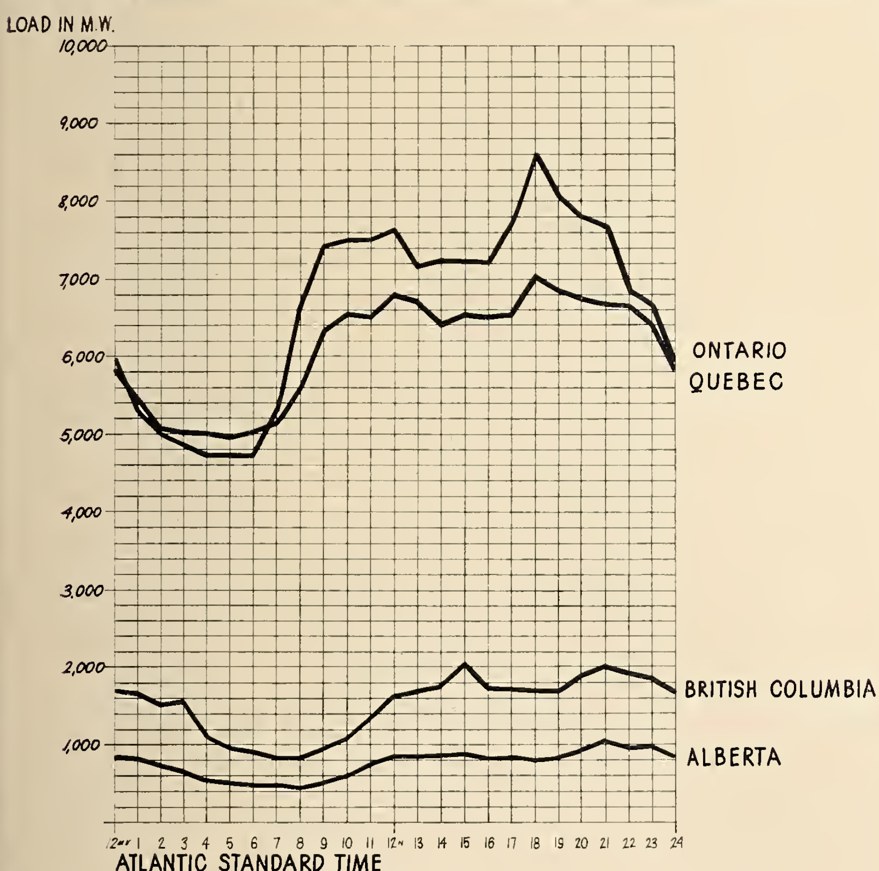
Optimum Use of Resources

The third possibility of significant savings, those arising from the optimum use of lowest-cost resources, is more obvious but still more difficult to evaluate.

The main resources capable of further development on a large scale (excluding nuclear energy) are coal in the Maritime Provinces, hydro in Labrador and Quebec and possibly in Northern Manitoba, coal in Saskatchewan and Alberta and hydro in British Columbia. Any development that would permit the flow of energy from east and west towards the centre of the country would be advantageous.

The analysis of the problem of matching resources to loads, and mak-

Fig. 4. Representative provincial load curves for peak day (estimated for 1965)



ing the most economical allocation within the limiting factors of availability and transmission capacity, is a task so large that it cannot be undertaken in this preliminary review. It is suited ideally to the techniques of operations research and with computing equipment is by no means insoluble. It would take into account the incremental cost of energy from various sources with plants of assumed efficiencies; the added cost of the losses involved in transmission; and the various limitations of capacity. It would produce ultimately a schedule for the loading of all major plants at all times, corresponding to all conditions of water supply and other variable factors. This could be done for an integrated system today, and indeed is a sine qua non of integration.

For the present purpose a skeleton-like sample of this analysis has been undertaken with greatly simplified assumptions.

Each province has been assumed to have two composite generating plants, one steam and one hydro. Composite costs based as far as possible on published information have been assigned to these plants. These incremental costs per kwh. have been increased as the power is assumed to move away from its source with a price assigned in each province. Thus British Columbia hydro priced at 1.5 mills in British Columbia increases to 1.62 in Alberta, 1.74 in Saskatchewan, 1.83 in Manitoba and 2.11 in Ontario. These increments are relatively large. They would cover more than the effect of transmission losses, but are not intended in this analysis to include the fixed costs of operating the transmission system. The relatively high incremental cost assumed for hydro (which excludes fixed charges) is intended to give a conservative approach to the savings involved.

The annual load in kwh. has been estimated for each province. The problem has been to assign this to local generation in the province, and to imports from adjacent or more distant provinces to secure maximum economy.

The methods of operations research have been applied to the problem and a logical and perhaps feasible solution developed for assumed conditions of 1965. The limitations of capacity of hydro and thermal installations and the degree of possible utilization, namely 100% for steam and 65% for hydro, were assumed for these dates.

The pattern that might be anticipated for 1965 is illustrated in Fig. 6. For example, Quebec would generate only with hydro, holding what steam capacity it might have in reserve. From its hydro it would meet all its own needs and export to Ontario, New Brunswick and a small amount to Nova Scotia. Ontario, on the other hand would use all its hydro and generate from coal for part of its own needs (with some of its steam capacity on stand-by), but would also import from Alberta, Saskatchewan and Manitoba as well as from Quebec. The middle portion of Fig. 6 shows the loads in the bus, which reach 1250 Mw. between Saskatchewan and Manitoba, and 1000 between Manitoba and Ontario. It should be noted that no new B.C. hydro power, such as the Columbia River, has been assumed to be available as soon as 1965. Consequently, British Columbia is importing power from Alberta in 1965.

The lowest diagram of Fig. 6 shows the energy and kw. fed into or taken from the bus, on an assumed load factor of 85%. The terminal equipment in Ontario must be capable of delivering 1500 Mw., while that in Alberta will handle an input to the bus of about 1000 Mw.

No claim is made that these tentative results are very reliable. An important assumption is that all steam plants in a province can be treated as a unit, with a weighted average incremental cost. In practice, consideration of individual plants would eliminate the higher cost units and increase the savings. The use of annual kwh. without reference to load factor is justifiable for 1965 in relation to the then existing excess of reserve capacity. At a later date, following integration, capacity would have been planned according to the optimum uses of resources, but allocation of energy would have to be related to daily load curves for the system.

The savings indicated by this analysis may be considered a minimum. Computing the savings for the hypothetical 1965 case, as compared with an extrapolated actual 1957 case, there appears to be a possible saving in annual operating costs of some $45 million. The saving in 1957 by a similar calculation would have been about $20 million.

Without looking further afield, these investments and operating savings are those that might be available to meet the initial and annual costs of a coast-to-coast interconnection.

It is preferable to reduce them all to an annual cost basis. For this purpose it will be assumed that the interest, depreciation and fixed part of operating cost for hydro is 8% of investment and for steam, 12%. These yield fixed costs per kilowatt of $20 and $18 respectively.

The annual saving due to the reduction in capacity secured by integration now appears to be:

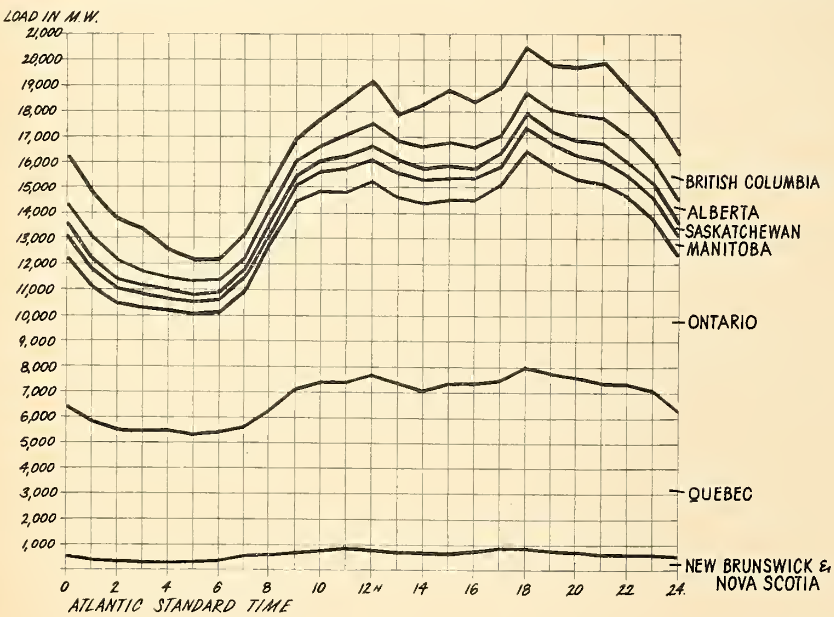
Hydro, $208 million at 8%	$16,640,000
Steam, $222 million at 12%	$26,640,000
Total	$43,280,000

Say $43 million per annum.

Adding the saving of $45 million through optimizing the use of resources, the total annual saving is some $88 million. The question remaining is whether this would pay for the facilities required.

It is hardly within the scope of

Fig. 5. Composition of daily load curve for peak day of integrated Canadian system (estimated for 1965)



this paper to propose the technical solution to the problem of interconnecting the major provincial systems in Canada. The proposal involves a transmission line or bus some 3000 miles long, capable of handling up to a million kw. at any point with taps connecting in each province with the locally integrated provincial system. The average distance between taps would be some 500 miles with the line starting in British Columbia, tapped in Alberta, Saskatchewan, Manitoba, Ontario and Quebec and terminating in New Brunswick. The location of the taps would be determined by the most suitable location in each provincial system. It would be anticipated that taps would be too expensive to allow more than one per province, although in particular cases, such as Ontario, a second tap might be justified, but will not be assumed for the present purpose.

The loading of the line will vary from point to point and it should be considered more as a bus than as a source to load transmission line.

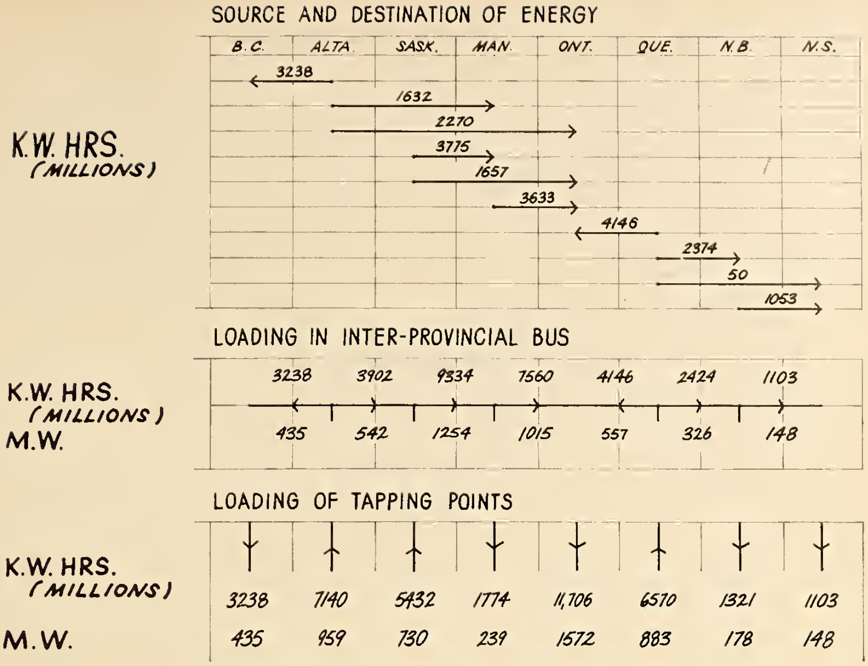


Fig. 6. Transfer of energy between provinces (1965 estimated)

Considerable discussion has taken place on the merits of DC transmission and the limits of AC transmission. There has been a tendency to argue that DC transmission is unlikely in the U.S.A. since the untapped distances are relatively small. It has been suggested that distances, of the order of 400 miles, and loads per circuit in excess of 750 Mw., are required for DC to prove the more economical. It would appear that this is precisely the case for the suggested trans Canada bus. A two-conductor circuit with lines operating at plus and minus 400 kv. DC could easily handle 1000 Mw. over the distances contemplated. Possibly lower voltages would be adequate. There would be no difficulty in arranging the end sections to operate on AC, if the loads at the ends were permanently lighter. There is probably no serious technical problem in the construction of such a system. Since the bus would interconnect large systems with considerable synchronous capacity, there is not likely to be much of a problem in providing the reactive kva. required for the operation of the inverters. However, costs quoted for terminal stations probably include the cost of static capacitors for this purpose. It is not suggested that an AC system might not be equally feasible but there appears to be sufficient justificiation for discussing the DC solution.

An outstanding advantage of DC for such interconnection is that it forms an asynchronous link between the systems, and provides a major measure of independence. The transfer of power to the bus, either into it, or out of it, at tapping points is easily secured by grid control or similar ignition control of the rectifiers or inverters. The entire control of loads into and out of the bus could be automatically handled in accordance with a schedule determined by suitable computers, which would continually take cognizance of the local loads and available resources.

The equipment required at a terminal station or tapping point, consisting of mercury vapour rectifiers, transformers and switchgear is expensive. There might be general agreement that for the large capacities involved an average cost of $30 per kw. would be adequate. There would be seven such taps with a total capacity of some 5 million kw.

The cost of the 800 kv. line (400 kv. to ground) would be somewhat less than the cost of an AC line of equivalent voltage class. An allowance of $50,000 per mile should be adequate for a first approximation.

The cost of the DC interconnection might thus be:

3,000 miles of line at $50,000 per mile	$150 million
7 taps totalling 5,000 Mw. at $30 per kw.	$150 million
Total	$300 million

It will be observed that this is considerably less than the investment saving estimated to be due to the reduction in plant capacity required, namely $430 million.

A better comparison may be secured in terms of annual cost. It is unlikely that the interest, depreciation and operating costs for the system would exceed the figure of 12% assumed for steam generating plants, and it might well be nearer 10%.

The total annual cost of the suggested trans-Canada interconnection may thus be of the order of $36 million compared with the estimated $88 million saving. If the net saving indicated was realized, it would amount to about a half a mill per kwh. throughout Canada.

Admittedly the estimates are crude but the margins appear sufficient to claim that an a priori case has been made, and to argue that further study is urgently required and fully justified.

It might be premature to discuss the administration of such a scheme. It is not difficult however to visualize an inter-provincial organization, co-operatively owned by the various utilities participating, which would own the facilities and buy and sell power from or to the utilities to secure their greatest advantage.

Alternatively, one can visualize the transmission line as a common carrier that would transmit, for a fee, the energy that would be bought and sold in deals between the utilities. A somewhat more orderly scheme might well be desired and would provide an interesting field for research in the organization on a national scale of the utilization of energy resources.

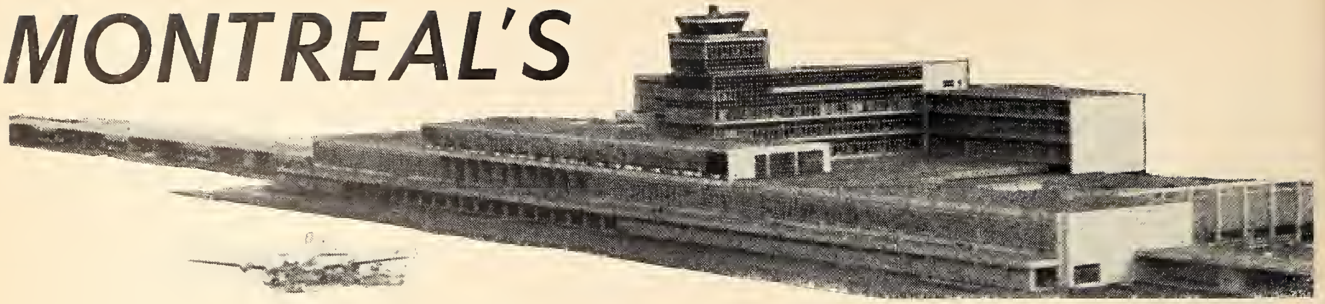
MONTREAL'S



JET AGE AIRPORT

Harold J. Connolly, M.E.I.C.,
Director, Air Services Construction Branch,
Department of Transport,
Ottawa

Montreal's Airport at Dorval was built hurriedly at the beginning of World War II. The massive rebuilding and rehabilitating job to accommodate the jet age started several years ago. The new airport was officially opened at ceremonies held in December.

THE entrance of Montreal's International Airport into the jet age is complete. After years of planning and frustration brought about by rapidly-changing needs and developments, the major new installations were opened late in 1960. These include a new terminal building, ancillary service buildings, runways and taxiways, navigational aids, refuelling systems, central heating plant, and runway and approach lighting systems.

The intent of this article is not to describe in detail, with technical data, the many aspects of the development. Rather, it is to give a broad description of what has been completed during the last five years at Dorval.

History

Before the Second World War the St. Hubert military airport was used by Trans-Canada Air Lines. TCA was incorporated in 1938 and when war was declared was operating about two flights a day with 12 passenger Lockheed aircraft. The state of war made essential a new site for civil operations, and the Montreal International Airport came into being.

Speed of construction was necessary and three runways, auxiliary taxiways and aprons complete with radio aids, runway and approach lights were built with the limited amount of engineering data available.

During this initial construction period Dorval was pressed into service as the base for the Royal Air Force Ferry Command. This shifted the emphasis from civil needs to military needs. One result was that the terminal building was inadequate despite many extensions and modifications.

Planning

Following the war the emphasis swung back to civil needs and the Department of Transport undertook a study to determine long-range needs. Included was a complete inventory of all Canadian airports to find what existing facilities could be used to meet the rapidly-increasing needs of commercial operations. Generally it was found that most facilities were obsolescent. Terminal buildings and runways were needed.

Budget considerations prompted a construction program to provide at least one heavy-duty runway at each major airport. When this phase was completed there began a phase of terminal building construction. As Montreal was one of the most important airports in Canada it was logical that runway construction should start there immediately.

Before 1939 pavement design as applied to airport construction in Canada generally paralled design methods then used by provincial Highways Departments. For aircraft with low tire pressures and which weighed less than 30,000 lb. the method was highly satisfactory. The development of heavier aircraft brought problems which could not be solved on the basis of existing information, and it was decided to seek further data.

In 1945, therefore, an intensive investigation of major airfields was undertaken by the Transport Department. The investigation, directed by Dr. N. W. McLeod, was planned to obtain data which would provide a design that would reflect more truly Canadian conditions than would the existing empirical systems.

Its primary objectives were: the making of a complete pedological soil survey including a study of the base course and subgrade materials beneath pavement structure; determination of load-carrying capacities of existing runways, taxiways and aircraft parking areas; the recommendation of a rational method for safe, economical pavement design following the evaluation of the numerous controversial designs criteria.

Thirteen airports were investigated during 1945-46. One of the fundamental conclusions indicated that the increase in load-carrying capacity provided by any given thickness of flexible base and surface varied directly with the load-supporting value of the subgrade and the pavement of the subgrade upon which it rested, provided both the bearing capacity of the subgrade and the pavement were measured at the same deflection by bearing plates of the same diameter.

This important conclusion has been approved mathematically for design purpose by the following empirical equation:

$$T. = K. \log \left(\frac{P}{S}\right)$$

In this formula, T. equals the total thickness of the pavement in inches; K. equals the base course constant; P. equals the applied load on a specific deflection; and S. equals the subgrade support at the same contact area and deflection as P.

Subsequent investigations conducted at more than 50 airports have verified the validity of this equation and have allowed constant expansion and refinements to the resultant design methods. Design and evaluation programs based on this initial research still are proceeding. This early design concept was the basis for runway construction at Dorval although increases in gross weight of aircraft and in tire pressures have been almost fivefold.

Runways

Fig. 1 shows runways already built and those proposed. The asphaltic concrete pavement now in use totals 156 acres and the portland cement concrete totals 203 acres. This is more than enough pavement to build a 24 ft. highway from Montreal to Ottawa. A storm drainage system was installed when the runways were built. This system consists of perforated pipe varying in size from 6 in. to 10 in. placed on each side of the runways and taxiways immediately below frost depth in graded granular material. Catch basins were placed at intervals of approximately 300 ft. These were connected by pipes up to 72 in. to four main drainage ditches which lead to Lake St. Louis. The amount of pipe in the system is approximately 166,000 ft.

Terminal Building

By 1955 all commercial airports in Canada had at least one runway capable of handling aircraft in use at that time, and the Transport Department turned its attention to a program of terminal building construction. The hope was that architects' plans would incorporate all known features and factors and that provision could be made for developments.

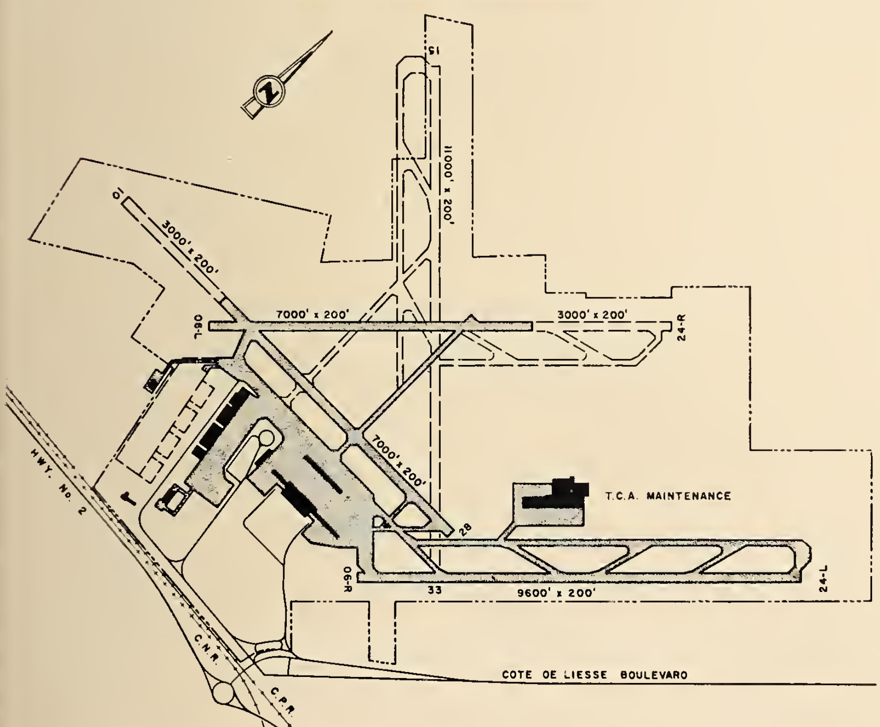
It was realized that auxiliary buildings and services would be required when the terminal building was finished. These includeed a central heating plant, power substation, control tower, navigational aids, refuelling system, water supply and sanitary sewerage lines.

Fig. 2 shows the perspective of the terminal building with the fingers and aeroquays.

The main terminal building is a rectangular, four-storey structure which rises to eight storeys in the control tower area. Two one-storey "fingers" project from each end of this main building. A one-storey aeroquay is located on the aircraft parking apron parallel to and some 600 feet from the main building to which it is connected by underground tunnels.

Total floor area exceeds 250,000 sq. ft. The principal dimensions in feet are: main building, 800 by 300; east finger, 850 by 55; west finger, 450 by 55; and aeroquay, 1160 by 55.

Fig. 1. Airport Development



All buildings have fully-developed basements. The main building encloses a large service court open from the ground floor up, and accessible to vehicular traffic by way of a tunnel through one of the end wings of the building. The main entrance is one floor up from the ground floor and is served by an elevated roadway along the face of the building.

Ice and snow will be kept from the ramp by a radiant heating system. A covered concourse runs the length of the building at ground floor level on the side bordering the aircraft parking apron.

Foundation

Soil investigations revealed a substrata of relatively level rock overlain by about 1 ft. of coarse gravel. Superimposed on this gravel is a tilted anticline of extremely hard boulder studded glacial till prevalent at the east end of the building site but running out on the gravel bed just west of the centre of the building. Laying against this glacial till at the west end of the site is a layer of marine clay. The entire area has an overlay of fine sand.

Because of these soil conditions a varied foundation design was selected. The easterly portion of the building was placed on poured concrete footings stepped in accordance with the glacial till. At the west end cast-in-place concrete piles were used for the interior columns. The outer walls were placed on poured concrete footing underlain by rock fill.

The Aeroquay and connecting tunnels were placed on "raft" foundations and the fingers varied between piling and "raft" foundation in accordance with the type of strata.

Shell and Services

The superstructure throughout is supported on steel framing. This framing follows a 20 ft. by 20 ft. modular grid in the main building and varies from these dimensions to meet the peculiar requirements of the fingers and aeroquay. More than 4000 tons of steel were used.

The outer walls are formed mainly with curtain walling sections relieved at suitable points by facings of brick, limestone and granite. All interior partitions are of fire-proof masonry except in the office areas where moveable steel partitions are used to permit maximum flexibility.

Most subflooring is of reinforced poured concrete. Exceptions are found in offices and other areas where extensive communications, telephone

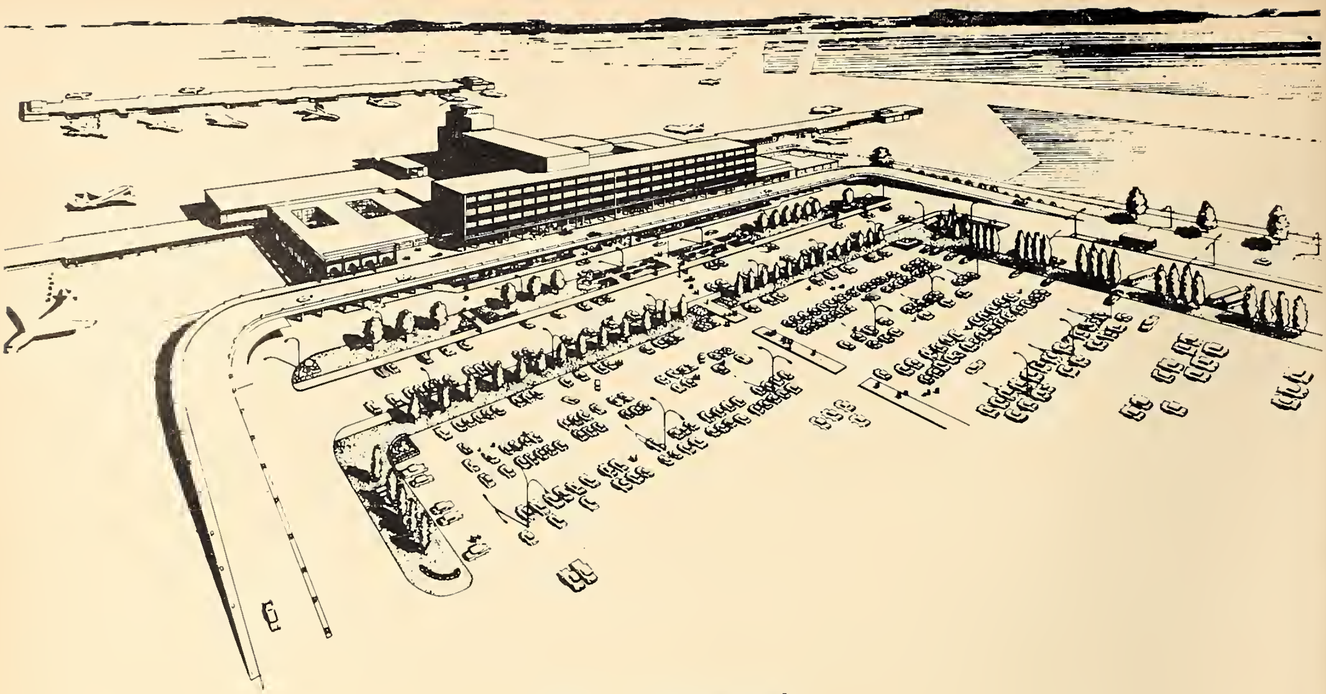


Fig. 2. Airport Terminal

and power cables are required. In these areas "Q flooring" has been used.

Pre-cast concrete is used for the main roof slab. Steel roof decking is used over office areas, aeroquay and fingers to facilitate grounding of antenna equipment. Suspended ceilings have been utilized extensively to provide concealment for ducting and to accommodate recessed lighting.

The general floor finish is terrazzo in a variety of patterns. A great variety of wall and ceiling finishes have been adopted appropriate to the use of individual sections. In the main public areas the emphasis is on the use of Italian marble.

The building is well equipped with escalator and elevator services. Special elevators are provided to accommodate wheel chairs and stretchers. Air conditioning is provided in all public areas and in all sectons where heat-producng equipment will be used. Further provision has been made for air conditioning units in rental areas, if required by the tenants.

Functions

Of necessity, the main building was designed, and construction started, before a decision had been made concerning the position of gates to serve individual aircraft. The need for a late decision was caused by rapid development in air travel.

Among the many alternates considered were long fingers projecting at right angles from each end of the main building.

The final decision, made in mid 1959, was based on established 1958 traffic of 1,077,500 inbound and outbound passengers, and an anticipated traffic density of 4 million persons in 1970. Influences were the desire to keep walking distances short while recognizing the noise factor involved in parking jet aircraft close to the main building.

The layout adopted provides a finger with seven gate positions for domestic traffic at the east end of the building. At the west end is a similar finger with four gate positions for trans-border traffic. This finger is convenient to customs inspection areas. There also is an island aeroquay with 12 gate positions for long distance foreign travel and for domestic jet flights. Each function is served by a separate passenger tunnel to the main building. The tunnel for foreign traffic leads directly to the inspection areas.

On a percentage basis, the functional space in the main building is distributed as follows: airlines ticketing, baggage handling, flight operation, 33; public areas, 35; health, immigration, and customs inspection facilities, 10; concessions, 8½; Department of Transport offices and equipment including weather, radar, radio and air traffic control facilities, 6½; rentable office space and storage, 7.

The basements of the buildings are used for mechanical, electrical and telephone equipment, and storage space. They also provide access to the basement-level tunnels connecting the aeroquay to the main building.

Primary functions of the ground floor are the complete accommodation of inbound passengers, and the handling of both inbound and outbound luggage. The first floor is designed for outbound passengers, and for the public.

The passenger accomodation on the ground floor is designed so an inbound passenger arriving from a foreign country can pass through the necessary inspection services without mingling with outbond passengers.

Of interest is the baggage pick-up system on this floor. Baggage from each flight is conveyed automatically to slowly-revolving 25 ft. turntables. The passenger claims his baggage as it moves past him and proceeds directly either to limousines parked beneath the elevated ramp which serves the floor above, or to the adjacent car parking area.

Also located on the ground floor are a well-equipped hospital, extensive cafeteria and commissary facilities for employees, and central food preparation areas to serve restaurants on the floors above and for in-flight catering.

The first floor provides the main entrance to the building from the elevated vehicular ramp served by the main entrance road. Along concourses leading to international departure points are ticket counters of more than a dozen airlines. Similarly grouped along the concourse leading to domestic departure points are the ticket counters of the various Canadian airlines.

Adjacent to these concourses are a variety of concessions including a barber shop with rentable showers, drug store, banks and flight insurance counters. Waiting rooms, a reading room and a quiet lounge extend the full length of the building overlooking the airport through a 16 ft. high wall of glass. Beyond this is an open deck for spectators.

A coffee shop, a lunch counter and a cocktail lounge also are on the first floor. Such pre-flight inspection services as necessary for international passengers are provided on this floor.

An in-transit waiting room for foreign passengers includes restaurant and refreshment facilities.

The second floor contains a spacious dining room, lounge and cocktail bar. An excellent view of the airport and the aircraft parking apron is provided through glazed walls. Extensive airlines offices are located on this floor. Succeeding floors are devoted to Departmental and rentable office space. The tower structure is designed to accomodate the Air Traffic Control functions and the complex equipment related to radio and radar.

Electric Power Supply

An electric power substation adjacent to the terminal building houses equipment for power distribution on the airport. Power requirements can be divied into three areas:

1. Normal supply of the most reliable type which can be offered by a commercial company.
2. Semi-essential supply for minimum operation and public comfort, usually achieved by manual switching operation in case of limited supply from the commercial source.
3. Emergency power for communications, air traffic control and air navigational aids during complete failure of the normal source of power. Usually this is achieved by a diesel generator unit which allows up to 25 seconds of power interruption.

The normal power supply to the terminal building is from two Quebec Hydro Electric Commission overhead transmission lines, with provision for a third line. Each is capable of delivering 8 mva. at 12 kv., 3 phase, 60 cycle. Two underground cable circuits take the power from the switching structure to the substation. For additional service reliability, each of the underground circuits is duplicated.

Each of the underground circuits terminates on a separate bus through a breaker. These two buses are interconnected through a tie breaker.

Power supply to the terminal building; is through four 3000 kva. 12 kv/575 v. transformers, to the main 600 v. secondary distribution board. This distribution board, consisting of two buses and a tie breaker between them, supplies 14 distribution centres at 575 v., located in the basement of the terminal building. Connected load for the terminal building is approximately 10 mva. with maximum demand estimated at 6 mva.

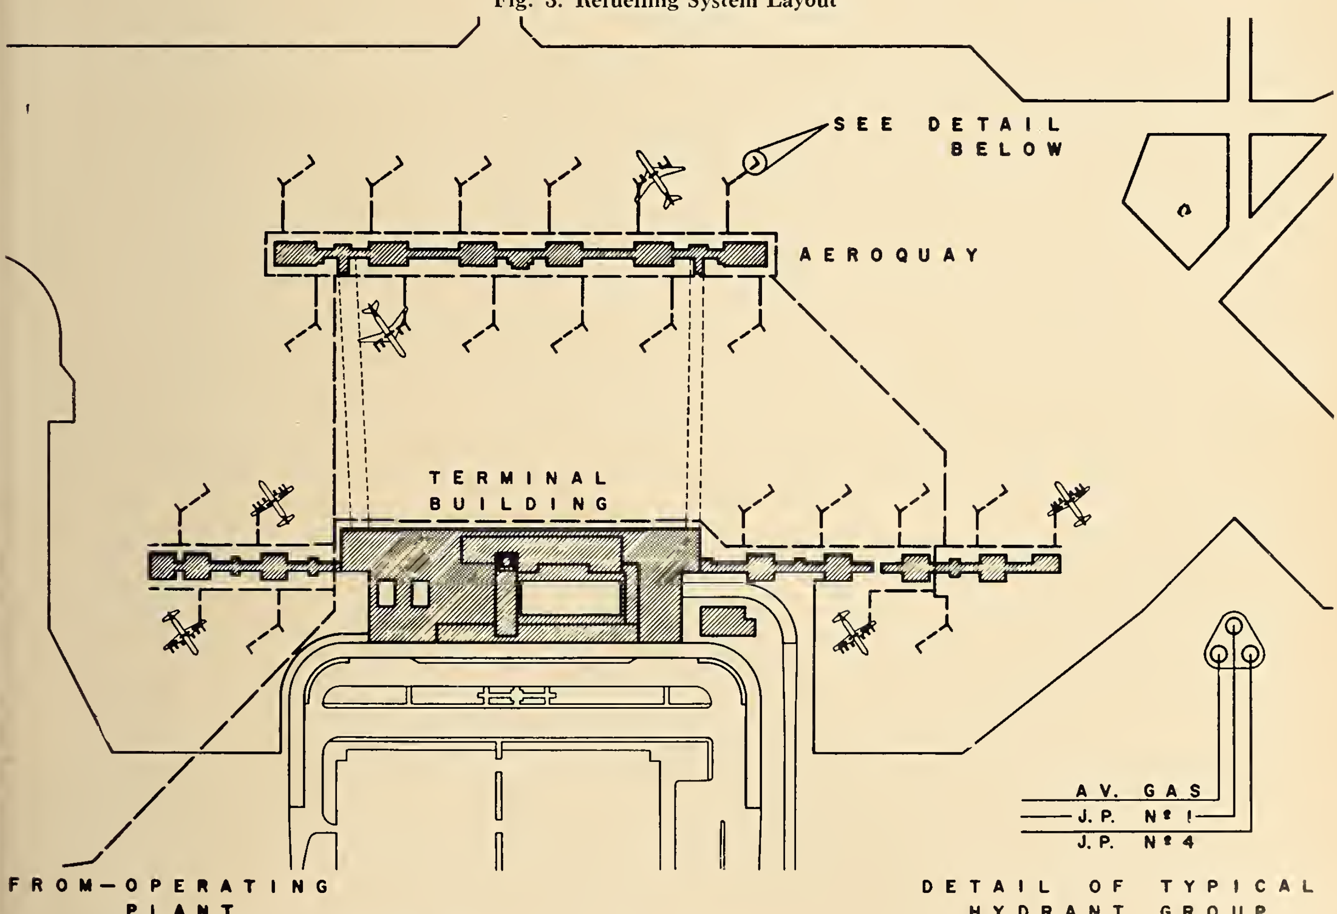
The substation is also designed to provide power to the other Department of Transport services in the area. For this purpose, two 4000 kva. 12 kv./4160 v. transformers have been provided. This circuit now provides service to the central heating plant, aeroquays and lighting for car parking area.

Power is supplied to the heating plant through two underground cable circuits at 2400/4160 v. and to two buses with an interconnecting tie breaker. A 1000 kva. distribution within the heating plant is 600 v. and 120/208 v. through various panels.

Each of the fingers and the aeroquay have a 1000 kva. substation. The substations are interconnected for alternate power supply. The distribution of power in the aeroquay and fingers is at 600 v. and 120/208 v.

The semi-essential power supply is from a separate 2000 kva. 12 Kv./575 v. transformer through a special distribution system. The cross-connec-

Fig. 3. Refuelling System Layout



tion between main secondary distribution board and this system allows power supply when commercial power supply is limited.

Emergency power supply is through a 500 kva. 12 kv./4160 v. transformer, an automatic transfer panel and a 500 kva. 4160 v./575 v. transformer to the emergency distribution system. Should the commercial power supply fail, the 500 kva. diesel-generator unit automatically would restore the power supply to emergency distribution system within 12 seconds. The cross-connection between main secondary distribution board and emergency distribution system allows the diesel-generator unit to be by-passed for maintenance on the emerbency plant and transformers. Provision is made for the establishment of a second unit.

A separate 300 kva. 600 v. diesel-generator unit installed in the heating plant allows partial supply of heat to the terminal building in case of commercial power supply failure. The switching operation and protection is from a remote control panel. All switchgear controls are operated by a 125 v. d.c. battery.

Design of the substation layout and electrical facilities was developed by the Construction Branch, Air Services, Department of Transport. (Fig. 7).

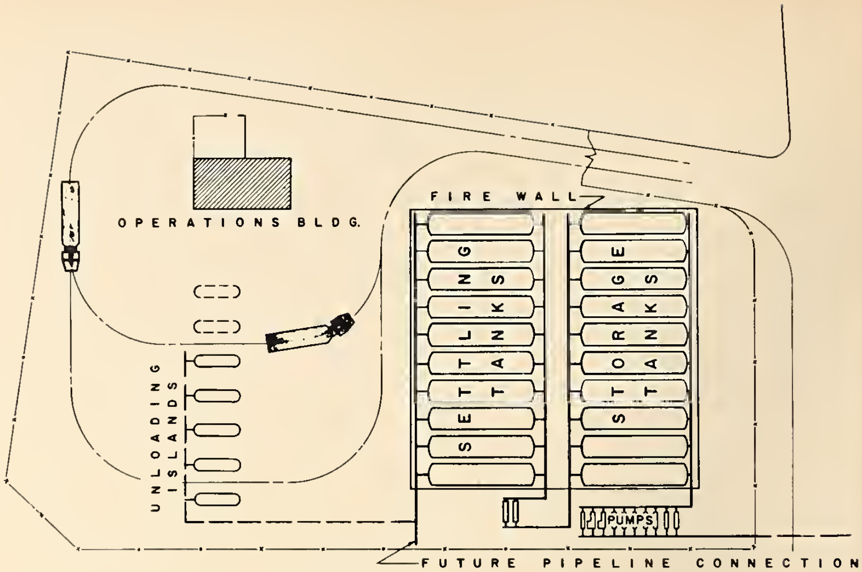


Fig. 4. Operating Plant

Heating Plant

It was decided that a central heating plant would best serve the terminal building and all other structures on the airport. The size of the plant, which is 3,808 ft. from the terminal building, was determined on the basis of ultimate development of the area.

The present summer load, which consists of heat for domestic hot water and for some kitchen services, is approximately 8 million B.t.u. per hour. The winter load is approximately 110 million B.t.u. per hour. The load for airports of this type grows at about 15% per year. A study of the available land and its probable ultimate use indicated that the final load should never exceed 300 million B.t.u. per hour.

On this basis it was decided the main heating units for the central heating plant should be two 40 million B.t.u. per hour boilers and two 70 million B.t.u. per hour boilers. Summer requirements can be accomodated by one 40 million B.t.u. boiler operating at 20% capacity. This equipment takes care of the needs for the next five years with at least 40 million B.t.u. per hour standby capacity available for emergencies. The plant can be extended to provide space for two 70 million B.t.u. per hour boilers for the ultimate load.

Studies indicated that for this installation, high temperature water would have owning and operating costs about 19% lower than a steam unit. The estimated capital cost of the steam system was approximately 17% higher than that of the high temperature water system.

The central heating plant is designed, therefore, to deliver water at 400°. Some existing heating plants could be abandoned and in these cases the equipment was replaced by steam vaporizers. These use high temperature water as the heating medium to generate the steam required. In some instances high temperature water was used in heat exchangers to heat domestic hot water on low temperature water heating systems. In the terminal building, high temperature water was used: in heating coils for air systems; in the heat exchangers for heating the anti-freeze for the snow-melting system; in heat exchangers for low temperature hot water heating systems; in heat exchangers for heating domestic hot water; and in the steam generators to provide steam at 75 p.s.i.g. where required for the kitchens and some air-conditioning services.

At 400° water will boil at a pressure of 233 p.s.i.g., and it is therefore necessary to keep the entire system pressurized above this point. At pump discharge points, pressures up to 350 p.s.i.g. are expected. This difference consists of the circulating pump heads, a margin due to elevation differences, plus the safety margin between the saturation pressure of 233 p.s.i.g. and a safe operating pressure. With the 350 p.s.i.g. maximum pressure and the 400° it is possible to use standard 300 p.s.i.g. class equipment.

The system is pressurized with a nitrogen cushion in a pressurizing tank. Nitrogen was chosen because of its non-corrosive properties. This tank has been sized to take the normal variations in water volume in the system from day to day. The larger variations found in the seasonal operation of the system are cared for by dumping the necessary volume of water into a secondary tank, and pumping back from that tank as more water is required. Therefore, the secondary tank can operate at lower pressures.

Tunnels run from the central heating plant to the new terminal building and along the road to a point near the old overseas terminal building. There are about 5,700 ft. of tunnels and approximately 2,300 ft. of buried conduit. More than 30,000 ft. of heating mains are included in the present installation.

Boilers in the central heating plant are of the gravity compensated forced circulation type. These are a variation of the forced circulation Lamont type which generally has been used on high temperature water systems. The boilers contain external downcomers from the upper headers which allow gravity circulation to take place. A much wider range of boiler capacity, without limitations in minimum flow, can be accomplished with this type of boiler.

The plant was designed to burn heavy oil and natural gas. The present competitive price of natural gas on an "interruptible rate" basis is such that gas probably will be burned for the next few years. The oil handling and storage system can use the heaviest residual oils with complete capability, but with an "interruptible gas" contract, lighter oils will be stored for use during gas interruptions. An allowance for future installation of an overhead coal bunker has been included in the design. Other provisions have been made to allow the plant to be converted, if necessary, to coal burning at some future date.

Boiler House Building

This is a structural steel frame building with corrugated insulated metal panels enclosing the upper walls. The front and sides, to a height of about 15 ft., are metal sash with opening sections, and are fully glazed. The opening sections are arranged to allow ventilation during summer. In the winter, the building is ventilated by heating units in the penthouse area. Air for combustion purposes, which also acts to ventilate the space, is introduced at high level and is drawn to the forced air fans and through the firing floor level.

The boilers are individually fitted with stub stacks which protrude to a minimum height above the roof of the building in conformity with good airport building design. A complete system of walkways and platforms provides access to all equipment above the firing floor level. All platforms are of the open grate type.

Central Heating Plant Features

a. Pumps — All water circulating, transfer, feed and booster pumps are of the vertical shaft type. They occupy less floor area and are suitable for more direct connection from the main headers located in the basement. These pumps are assembled in a row along the front of the boiler plant on a slightly depressed platform level. This allows a view from the exterior of the plant into the firing aisle, and easy observation of their operation from the firing floor level.

One of the main circulating pumps has been supplied with a variable speed motor with the speed controlled to maintain a constant differential head between the supply main and the return main at a remote point of the circulating system. This characteristic is required only during low load conditions where the reduced flow through the heating mains affects the available head at the remote points. The pressure loss through the mains is very small, thereby imposing, heavier duty on control valves at low loads to control the flow at the remote points. By reducing the available head at these remote points, the operation of the controls is improved. The speed control is electrically operated through a pneumatic electric servo mechanism.

b. Stand-By Diesel Electric Plant — A Stand-by diesel electric plant capable of operating the entire central heating plant under emergency conditions has been provided. This plant has a capacity of 300 kva.

c. Fuel Handling System — In the fuel oil handling system the oil burners are of a high pressure wide range mechanical atomizing type. In view of the high pressure required for this type of burner a two-stage oil pumping system is used to avoid excessive pressures in the oil heaters. On the oil heaters water pressure is higher than oil pressure. This avoids the serious consequences of oil leaks into the hot water system.

d. Combustion Controls and Safeguards — The burner control system consists of the normal combustion safeguards for the gas and oil firing systems. These are of the standard programming type with electronic flame detection equipment. The combustion control system on high temperature water installations differs somewhat from the orthodox "steam flow — air flow" system. In this installation the leaving water temperature controls the air flow to the burner with a correction being applied by the water flow through the boiler. The air flow, in turn, adjusts the fuel flow to the requirements of a characterized controller which has been provided with characterizing controls suitable for gas and for oil.

The entering water temperature is also measured and a B.t.u. calculating mechanism records and integrates the total heat delivered by each boiler. The water flow is also recorded on a chart which records B.t.u. flow. Other minor measurements indicated or recorded include draft conditions, exist gas temperature conditions, fuel flow and consumption, and fuel conditions.

e. Vacuum Cleaning System — The building is provided with a central vacuum cleaning system with outlets arranged for portable hoses for cleaning purposes.

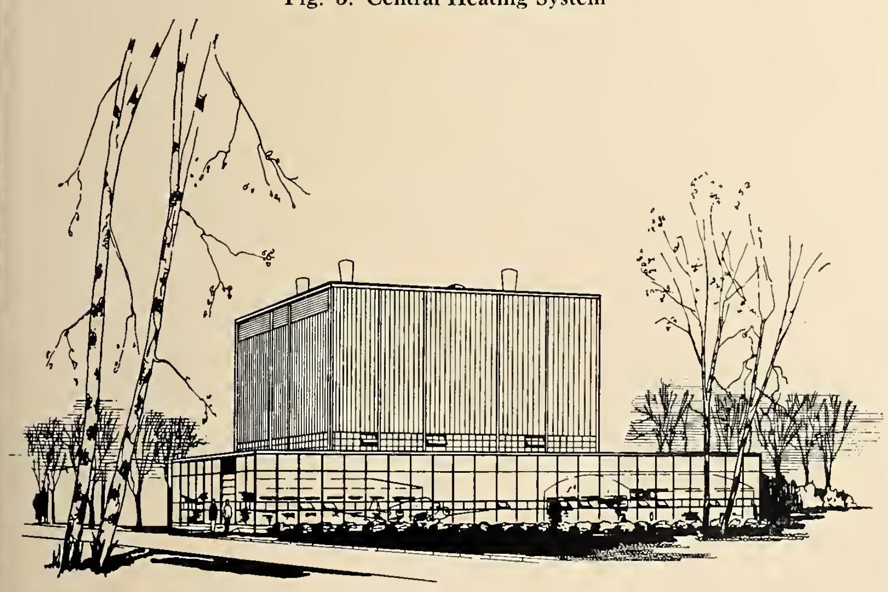
f. Workshops — A workshop has been included for maintenance and repairs of the building equipment, the distribution system and other heating equipment throughout the airport development. It includes a variety of power-operated tools and a well-stocked storeroom.

g. Water Treatment — While high temperature water plants require a minimum of water treatment, it is important that the original filling of the system and make-up to the system, which is very small, is treated properly. A water treatment plant included in the scheme provide water softeners and the equipment for the introduction of chemicals for control of oxygen and pH. The size of the plant is adequate to allow a minimum filling period, but onee the plant is in operation considerable spare capacity will be available.

Throughout the airport, high temperature water is used in many places. These include its use in vaporizers which generate steam at pressures suitable to replace the boilers which were removed. It also suits the steam requirements of new buildings. These steam systems require make-up water, and a water distribution system has been included to provide treated water to the vaporizers from the water treatment plant in the central heating plant.

h. Pipe Expansion Provisions — In the underground mains provision must be made for the normal expan-

Fig. 5. Central Heating System



sion and contraction of these lines through the range of temperatures which will exist. In the tunnels for heating mains it is normal practice to use either bellows type expansion joints or U-bends. However, it has been possible at Dorval to provide for the majority of thermal expansion in the elbows at changes in direction of the tunnel. The route of the tunnel to the new terminal building, for example, is parallel to building lines but diagonal from the location of the central heating plant to the terminal building. In this way, changes in direction of the tunnel have been co-ordinated with expansion requirements. Where this co-ordination has not been possible, and in underground conduits, U-bends have been used. An interesting feature of the tunnel piping is the support of the mains on insulated, integrally-lubricated metal plates. This allows free horizontal movement.

Hydrant Refuelling System

Modern jet airliners are voracious consumers of fuel. The modern intercontinental airliner of the DC8 or Boeing 707 class has a fuel capacity of about 20,000 imp. gal. compared with 1,900 imp. gal. for a Viscount. The large jet consumes fuel at the rate of approximately 50 gpm. at cruising speed. Refuellings for transatlantic flights average 14,000 to 16,000 imp. gal. The presence of such large quantities of fuel on the ramp in tankers is hazardous and an unnecessary obstruction to a long list of essential ground service equipment varying from baggage handling to aircraft sewage disposal wagons.

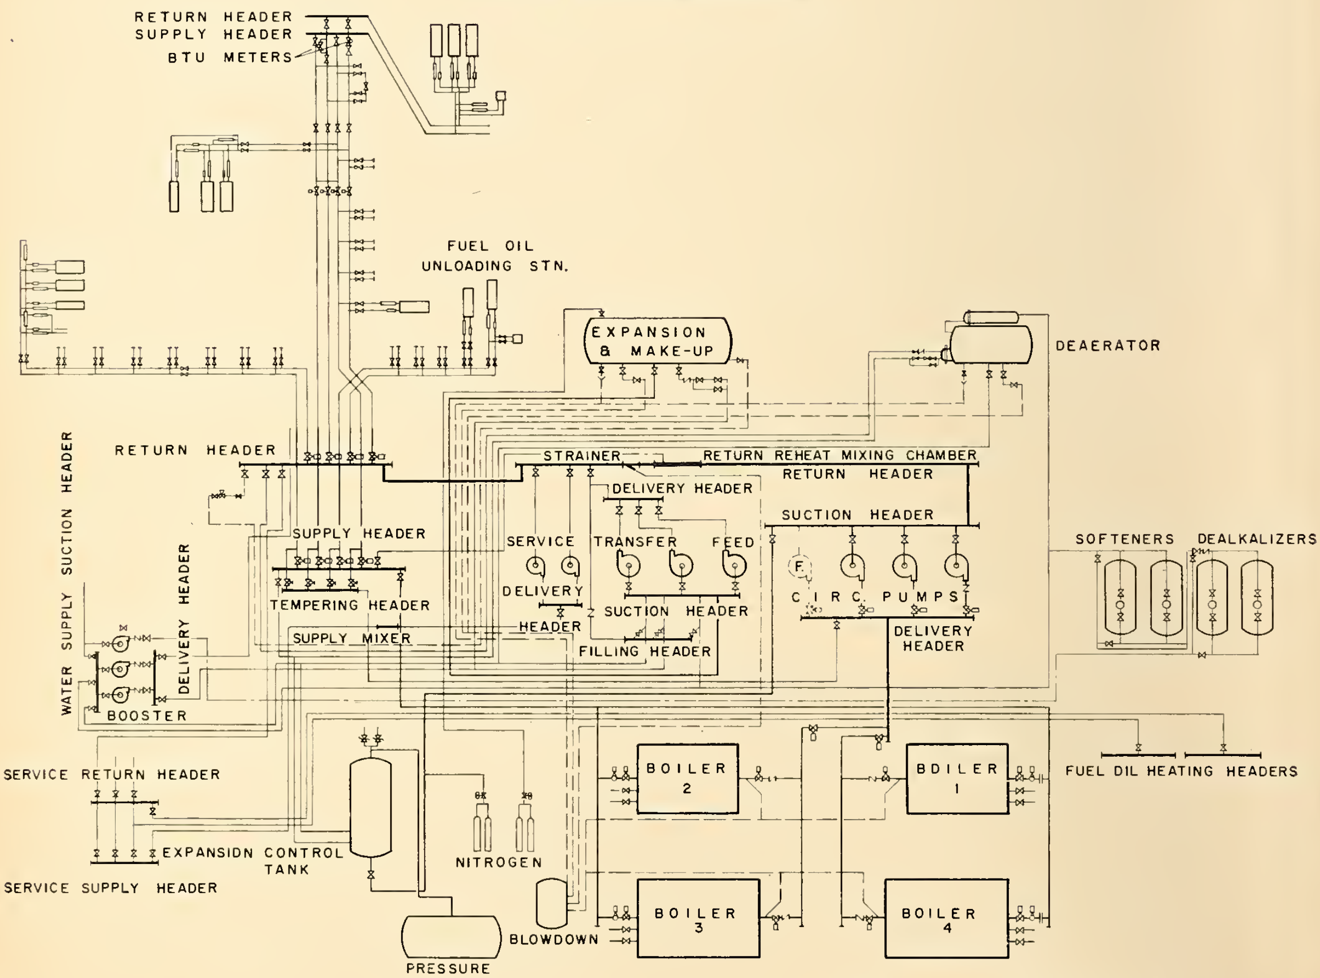
For these reasons the Department invited the major oil companies to participate in a common-usage hydrant system. Five companies expressed a willingness to make use of such a system and volunteered to supply the design and supervise the construction. The capital cost of the system was borne by the Department and ownership rests with the Crown.

The system is capable of dispensing three fuels; JP1, or kerosene; JP4, which is a wide cut distillation of kerosene; and aviation gasoline 115-145 grade. The first two turbine products can be delivered to the ramp at the rate of 2,000 igpm. which is sufficient to handle about three simultaneous refuellings. The aviation gas system will deliver 1,000 igpm. and will handle an equal or larger number of craft as the acceptance rate is lower than turbine powered aircraft. It is expected the usefulness of the third system to dispense gasoline will diminish within a few years. This third system will be used to supplement either of the existing turbine or be used for a third turbine fuel. This third fuel system can then be augmented with further pumping and attain a capacity of the two present turbine fuel systems.

The system may be divided into two distinct sections, the underground piping and the operating plant.

The under-ramp section (Fig. 3) consists generally of three 12 in. parallel pipes. Main lines from the plant and before loop supply is achieved are 16 in. At each gate, or parking position, an 8 in. lateral feeds the first hydrant and then diminishes to 6 in. for the hydrant farthest from the line. There are two groups of three outlets or hydrants at each position, each group being approximately under the wing of the aircraft. The hydrant valve is located in a 14 in. round box top of which is level with the apron. The box is covered when not in use. Within the box

Fig. 6. Central Heating System



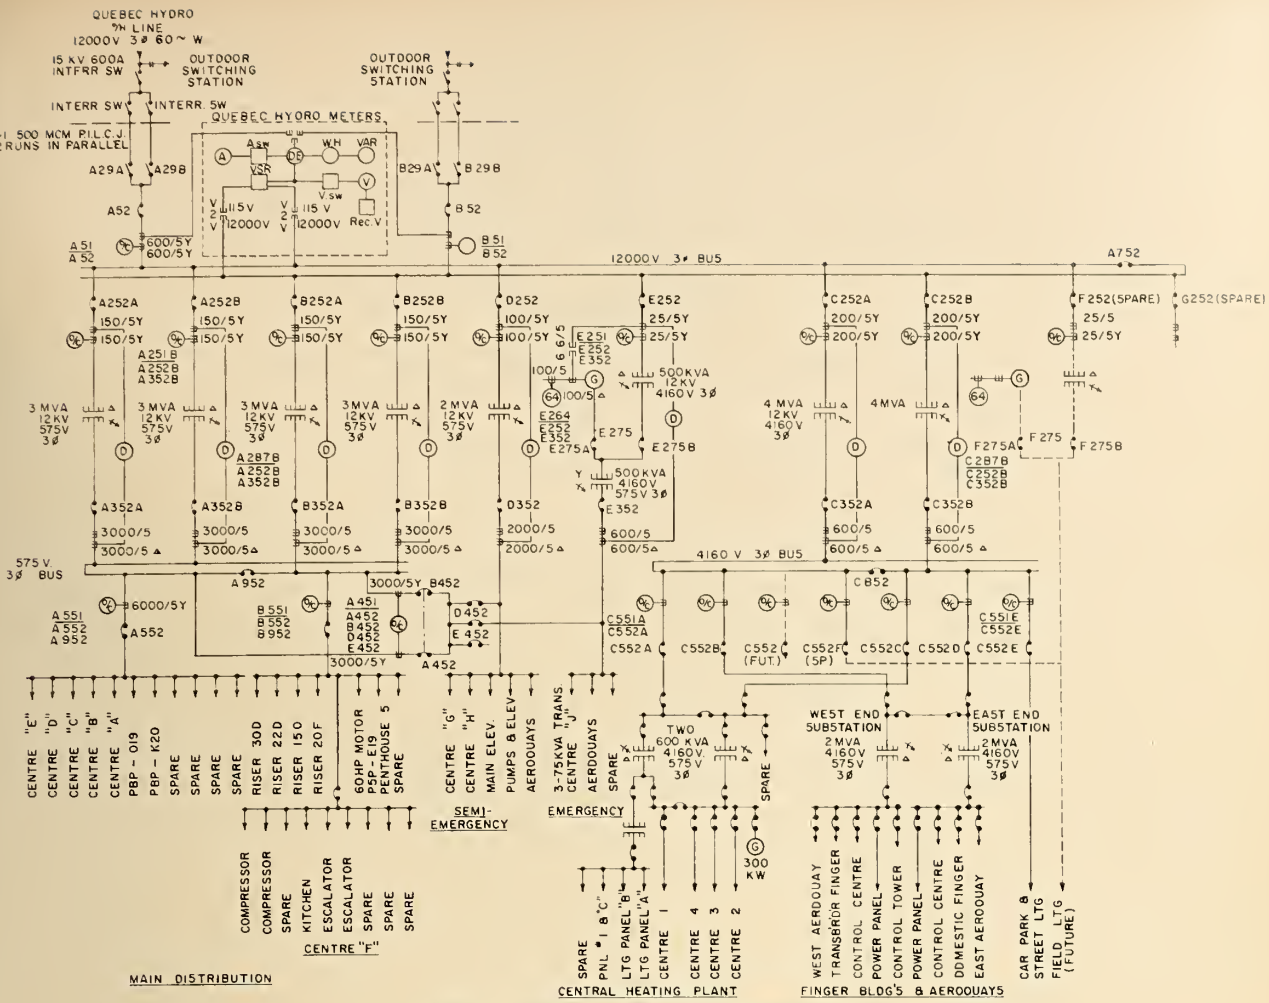


Fig. 7. Substation schematic diagram

there is a 4 in. hydrant valve, especially developed for this project. The largest size available prior to this development was 2½ in. The hydrant valve is operated by an air cylinder with remote "dead man" control which can be carried to the fuelling part of the plane by the operator. The valve has a bayonet-like top which will only accept hose of the correct hydrant cart and the dispensing hoses of the cart are similarly distinctive and can only be connected to a plane requiring that type of fuel.

Two hydrant carts are required for refuelling large jets of the DC8 or Boeing 707 type. These are positioned slightly forward of the leading edge of the wing. The hydrant cart is a short chassis truck and consists essentially of a filter, pressure relief valve, metres, piping and hoses. The 4 in. hose which connects to the hydrant is carried on a power operated reel on the truck. The 4 in. supply is then divided into two 2½ in. streams within the hydrant cart, each hose being connected to one of the two outlets in each wing. The 4 in. and 2½ in. end connectors on the hoses are self-sealing when disconnected, keeping the hydrant cart and hoses filled with fuel at all time.

A 4 in. butterfly isolation valve installed under each hydrant valve permits removal of any hydrant valve without interrupting service to any other hydrant.

All underground piping was wrapped with polyethylene tape and is cathodically protected with magnesium anodes. As the majority of the piping will be subject to full aircraft loading, backfilling was to 95% Proctor.

All laterals were graded downward to the mains and the mains are grated to low points, from which fuel can be removed by opening a valve on top of a vertical pipe or riser. This provision allows the removal of water or other contaminate. Minimum cover was set at 4 ft. at the hydrants, the balance of the piping is around 7-8 ft. deep and maximum cover is about 12 ft. Fluid flow will be about 3 f.p.s. at ultimate development of plant. Mains may be extended to serve additional gate positions should the aeroquay or fingers need additions.

The operating plant is located approximately 1,000 ft. from the terminal building. The plant (Fig. 4) is composed of unloading island, storage tanks, pumps and filtering equipment and a small operations building. The incoming fuel is removed from automotive tankers at the rate of 300 igpm. through a filter separator to a bank of settling tanks. Not less than 12 hours after the last delivery to the tank the fuel is transferred and again filtered to a bank of storage tanks. The fuel then is available for use. Fuel is removed from all tanks through floating suctions to insure cleanliness.

Once the fuel has entered the main pumping system it is under constant pressure (95 p.s.i. at the plant) out to the apron outlets. Withdrawal of fuel and the accompanying pressure drop actuates pumping. Rate of flow through instrumentation controls from one to four pumps (500 igpm. each) giving constant pressure over the entire range up to 2,000 igpm. in both ascending and descending order.

The plant can be expanded in any increment up to double its initial capacity with minimum interference to operations. The headers were designed so that any tank or pump can be connected to each of the three systems. EIC

Discussion

MORAN DAM AND THE FRASER RIVER

R. E. Potter, M.E.I.C.,
Consulting Engineer,
Victoria, B.C.
The Engineering Journal, December 1960, page 43.

Discussion by Mr. J. K. Sexton, M.E.I.C.

Mr. Potter is to be congratulated on having presented such a forceful picture of the "Fish versus Power" problem in British Columbia. It comes as a surprise to learn that almost 15 million kw out of an estimated total of 22 million kw of firm hydro potential will be lost to the Province if no power dams are allowed on salmon rivers.

(From the context it would appear that the term firm kw, indicates continuous kw of primary power.) This is indeed an enormous quantity of hydro potential to be eliminated from the nation's resources, and its loss will eventually attract widespread attention — even in a part of the country as well endowed with hydro resources as British Columbia. Surely a compromise must be found to permit the development of these resources to the best advantage of the community. Just as at Niagara where the conflict between power and aesthetic considerations has been so successfully solved, we must expect a solution to be found for the "Fish versus Power" problem of British Columbia.

As for the Fraser River, it is interesting to note that of the three alternative hydro schemes outlined by the Fraser River Board two contemplate the development of the total head by a number of dams of moderate height whereas one would combine several of these steps into a single dam at Moran with a record height of 720 feet. The company referred to by Mr. Potter has selected the Moran Dam alternative and raised its proposed height to 740 feet. This would result in a structure probably larger than any dam built to date, and the problem of financing such an undertaking to supply power to the Pacific Coast area would no doubt be very great. The time necessary for the construction of the project has not been mentioned by Mr. Potter but its size would indicate a period of say six to eight years. During all this time a large investment would be tied up. In 1956 Dr. J. L. Savage estimated the total cost at $512 million, and one wonders if this estimate made allowance for the interest charges that would be accumulated during such a long construction period.

There would also be the problem of finding a market big enough to absorb the output from the Moran Dam development after it were completed. Otherwise there would be a further accumulation of interest charges to add to capital costs, until the project could be fully utilized. Since the development would be one of the largest ever undertaken by private enterprise no doubt such financial considerations have received careful study, and it would be interesting to have Mr. Potter's comments on them.

Discussion by R. C. McMordie, M.E.I.C.

The author has outlined the problems facing early development of the power potential of the Fraser River in a manner compatible with maintaining existing anadromous fish runs. Based on the current status of fishery science, the author reaches the conclusion that, for early development, the river could support either fish or power, but not both. He supports the case for power.

Preliminary studies of potential hydro power sources in British Columbia indicate that, if the fish problem on the Fraser River System did not exist, the economic attractiveness of the power potential of this river is second only to that of the downstream benefits to be obtained by the development of Columbia River Storages. There can be little doubt that but for this fish problem, development of the Fraser sites would already be well under way, providing not only low cost power but also affording much needed flood protection.

With studies on some 11,000,000 kw of power potential already in progress on the Columbia, Clearwater, and Peace Rivers, none encumbered by fish problems, the development of the Fraser River sites, highly attractive as they are, could be deferred for some time. In the meantime, current fishery study is gradually accumulating basic research data and developing methods for transporting fish runs over dams or providing possible alternative solutions. The problem is complicated by the international aspect of interference with existing fish runs.

British Columbia is a young province with a vast potential of undeveloped natural resources. It has not yet reached the stage in its industrial growth where a sufficient proportion of diversified secondary industries has been established. Also, labour costs in the presently predominant primary industries are high relative to those in the rest of Canada. The availability of vast reserves of low cost power judiciously programmed, will do much to alleviate this imbalance which could tend to retard British Columbia's future expansion.

As a river with one of the largest remaining undeveloped power potentials on the continent, the Fraser must play an important role in the future of the province.

This paper serves to further focus attention on the unique power situation in British Columbia. It forcibly

Automation and Control Engineering in Canada

Conversion of the Jim Gray Hydro-Electric Plant

P. Kubilius, M.E.I.C.
Montreal Engineering Co. Ltd., Montreal

THE JIM GRAY hydro-electric plant was commissioned in 1953 as a manually-operated 60,000 kva. station of the system of Price Brothers and Company, Limited. In June, 1960, it became the first hydro-electric station in Quebec Province to be converted from manual to automatic radio control. It now is completely a remotely-operated station. It takes its commands from, and sends its conditions and information to a control centre in Kenogami, some 20 miles to the south. The transmission of the operating and telemetering data is accomplished by means of VHF broad band radio signals.

Four hydro-electric plants are owned and operated by Price Brothers and Company on the Shipshaw River in Central Quebec. They are the Jim Gray, the Adam Cunningham (7,500 kva.), Chute - aux - Galets (10,000 kva.), and Murdock-Wilson (70,000 kva.). Jim Gray is a double-unit plant, with each 30,000 kva. unit generating at 13.8 kv. 60 cycles and running at 277 r.p.m. under a head of 338 ft. The turbine is a Francis type waterwheel with a Woodward "A3" governor. The generator is equipped with a type "BJ" voltage regulator.

Chute-aux-Galets, the oldest of the three other plants, was commissioned as a manually-controlled plant in 1921 and still is operated manually. In 1953 the Adam Cunningham plant was built some three miles from Chute-aux-Galets and is under supervisory remote control from Chute-aux-Galets. Transmission of data is via a telephone cable. The Murdock-Wilson plant was added in 1957 and is under supervisory remote control from Kenogami with transmission via telephone cable. (Fig. 1).

Early in 1959 engineers began investigating the possibilities of converting the Jim Gray station from manual to remote automatic control. Two alternatives were studied for the power link between Jim Gray and Kenogami: power line carrier and VHF radio. The studies indicated that for equivalent installed cost, the VHF space radio with broad band capacities yielded a system which was more flexible, and which lent itself to more additional channels than the carrier. It was decided, therefore, that, if feasible, VHF space radio would be the means of communication. In April 1959, field tests proved the radio link was practical for remote control and telemetering. Following the tests it was decided the program would be started, with the Jim Gray plant as the first to be converted.

Economic Considerations

The plant was converted to reduce its operating cost. It was operated manually by eight men, two per shift. One man was the switchboard operator whose duties were confined mainly to the control room and generator floor. His helper operated the auxiliary equipment and supervised the operation of the mechanical equipment. Even though this plant was essentially manual, certain functions, such as synchronization, speed control, and centralization of some alarms were done automatically. This partial automation had already reduced the per-shift operating staff from three to two.

Price Brothers has a "roving" operator who visits the remote controlled plants for routine inspection. This "roving" operator now includes the Jim Gray in his rounds. The effect of total automation was the reduction in plant staff from eight to nil.

At a nominal $5,000 per annum per man, the operating cost will be reduced by about $40,000, with a capital expenditure of $80,000. The $40,000 annual saving is somewhat of a simplification. Plant operation costs such as housing, especially in remote areas, might easily exceed the actual labor cost. However, the initiation of such a program requires the upgrading and training of present personnel. There will be added costs involved in personnel turn-over to replace the existing staff, and to train new recruits. The likelihood of a costlier man/year is evident because of the need for men with increased technical abilities.

Automatic Controls and Protection

The main components to be controlled in the Jim Gray plant are shown in Fig. 2. To facilitate the remote control it was necessary to re-arrange the control and protection schemes. So the right maintenance personnel can be alerted in case of trouble, and so they can be provided with the necessary intelligence with a minimum number of indications, several protective functions are grouped for a single indication. (Fig. 3). The groups are:

- Non-lockout shutdown — Generator 1 & 2
- Lockout shutdown — Generator 1 & 2
- Transformer breaker trip 1 & 2
- Transformer alarms 1 & 2
- Urgent alarms
- Non-urgent alarms

The schematic drawing in Fig. 3 shows all protective gear and tripping and alarm points. The protective devices are shown in Fig. 2 and are described in Fig. 3. It was necessary to add a generator automatic control board consisting of three free standing panels complete with annunciator, speed matcher and auxiliary relays for automatic remote control of generators and associated equipment.

Supervisory, Signalling and Telemetering Equipment

The generators and auxiliary equipment are operated remotely under normal conditions but may be transferred to "local automatic" or "local manual" control by a transfer switch. There is one transfer switch for each unit and one for the station service and auxiliaries. The operator can call for: 1. generator start, stop; 2. close and trip the breakers (synchronizing is done automatically); 3. adjust loading; 4. raise, lower voltage.

In addition to the alarms shown on Fig. 3, the operator at the remote control centre is provided with indications of all breaker and butterfly valve positions, governor load limit, governor load, voltage adjustment rheostat travel limits, as well as master transfer switch position indications.

Circuitry

The remote control system used for this plant is of the frequency code type. Individual push buttons are provided for the necessary operations. Operate sequencies are transmitted and received by frequency shift equipment. When an operation is called for, the signal divider will operate the selected relays which key the frequency shift transmitter and an operating sequence of four radio tones is transmitted to the remote station. At the remote station, these tones are in turn detected by the frequency shift receivers. The sequence selector relay contacts energize the interposing relays. The latter contacts close and operate the device selected.

Immediate indications confirming operations such as air circuit breaker's closure while the push button is depressed, are obtained by transmitting a signal according to the position of the device. At the control centre, the decoding relays connected to the output of the frequency shift receiver operates the lamp selective relay. Contacts on the latter change the lamp configuration and confirm the completion of the operation.

The alarms at the remote station initiate an indication check cycle. During this cycle the position of each supervised device is checked and the control panel lamps are illuminated accordingly. For each alarm there is an interposing relay. A contact on these relays initiates driving of the stepping switch and keys the frequency shift transmitter. A signal is transmitted for each step. At the control centre this signal is decoded by the frequency shift receiver, which in turn drives the stepping switch and also picks up and drops out the interposing relays, controlling lamps. When an indication check cycle reports a trouble, it calls the attention of the operator by:

1. Illumination of a lamp.
2. Sounding of an alarm.
3. A change of lamp on the appropriate escutcheon.

A lamp will indicate which device operated to initiate the check (alarm). A push-button also is provided at the control centre for the supervisory station check.

Frequency shift equipment is used for the transmission of supervisory control impulses and telemetering signals over the VHF space radio. The transmitters located at the control centre are keyed by relays and a sequence of audio tones is transmitted. At the remote station these tones are detected by the frequency shift receivers and operate the designated relays.

The following operating frequencies for frequency shift equipment are used:

2295) CPS — signalling transmitter for supervisory control at Kenogami
and
2465) CPS — signalling receiver for supervisory control at Jim Gray
2635 CPS — Signalling receiver for indications at Kenogami
2635) CPS — Signalling transmitter for indications at Jim Gray
2805) CPS — Signalling receiver for telemetering at Kenogami
2975) CPS — and
3145) CPS — Signalling transmitter for telemetering at Jim Gray.

Fig. 1

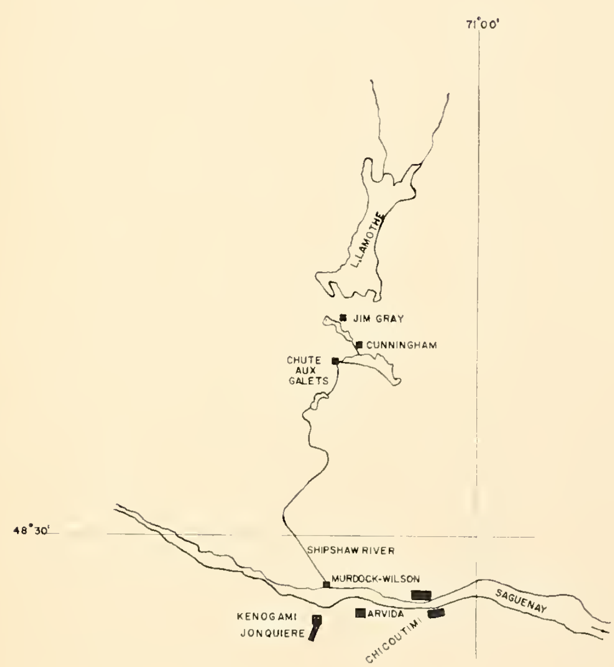

Fig. 2 (right)

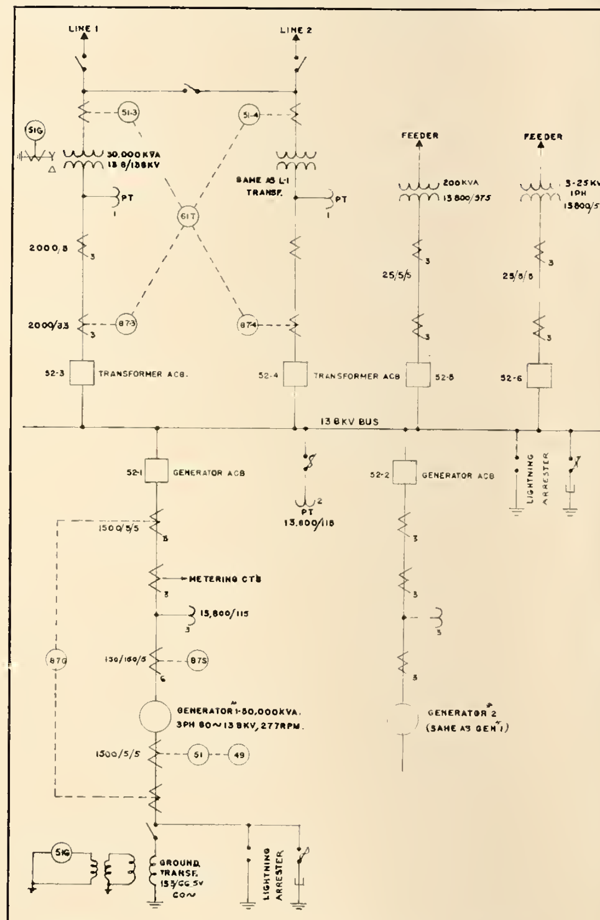

Telemetering is of time-ratio principle. The transmitter converts the electrical values being measured into evenly spaced signals, the duration of which depends upon quantity to be measured. These signals are transmitted at the rate of 300 impulses per minute. They key the frequency shift transmitter and at the control centre this intelligence is detected by the frequency shift receiver which in turn operates the telemeter receiver. The telemeter receivers decode this intelligence, convert it into a direct current which varies in magnitude from zero to one ma., according to the signal duration. The receiver is connected to a standard 0-1 MA DC instrument. The receivers indicate 99% of full scale readings in less than 3 seconds.

Megawatts are transmitted continuously for each generator. Ten "as called for" telemeter functions are provided:

governor gate position (unit 1 & 2)
governor gate limit (unit 1 & 2)
exciter field current (unit 1 & 2)
megavars (unit 1 & 2)
forbay elevation and bus voltage.

Synchronizing

With the transfer switch in the "manual" position, the breakers will be closed from the plant, after synchronizing across them. With the transfer switch in the "local automatic" or "remote automatic" position the operator may call for either of the two generator breakers to close in any order. The breakers will close only if the generator is running at speed-no-load and preset voltage. The closing of the breaker(s) will take place under control of the automatic synchronizer in conjunction with speed matcher as well as synchronizing check and voltage selecting relays. The synchronizer will be bypassed when either or both sides of breaker(s) is/are dead. An interlocking system has been arranged so that only one breaker can be synchronized at a time.

Closure of the generator breaker will cause the governor partial shutdown solenoid to be energized through auxiliary contacts on the generator breaker. This will allow the gates to open beyond the "speed-no-load" position, thus the unit can take on load. It should be noted that when the generator breaker is tripped, the governor partial shut-down solenoid will be de-energized thus causing the wicket gates to be brought back to the "speed-no-load" position.

Radio and ancillaries

The radio relay transmitter is used for transmission of control, indication and telemetering signals between the Jim Gray plant and the control centre at Kenogami. The radio is a FM unit for operation on frequencies 162.09 MC to Jim Gray and 168.75 MC to Kenogami. It uses eight tubes with 12 tuned circuits. The r-f output of this unit is 40 W. minimum, continuous duty. However, the Department of Transport has asked for reduction to 20 W. The radio relay receiver is for FM reception on frequencies 168.75 MC from Kenogami and 162.09 MC from Jim Gray, with 19 tuned circuits.

The 45 ft. antenna structures have been erected at the Kenogami site and Jim Gray generating plant, complete with six element yagi antennae, one for operation on each of the following frequencies — 168.75 MC & 162.09 MC.

Because the station service voltage varies between 110 and 104 v. depending on the system loading, it was necessary to supply two constant voltage transformers, giving single phase output voltage within plus or minus 1% of 118 v. when operating under exacting conditions.

An automatic change-over panel was supplied to provide a stand-by power for the VHF radio equipment when the 115 v. lph 60 cycle station service power fails. A DC convertor, driven from the supervisory lead battery, will supply the emergency AC power to the radio.

Governor pressure system and auxiliaries

Originally the governor was operated manually. It had only one solenoid which when de-energized initiated a complete shut-down of the unit. To allow full automation it was necessary to add:

speed matching (load adjusting) motor
gate limit motor
gate position switches
speed switches
creep signal transmitter
generator brake valves and control.

Also it was necessary to add a partial shut-down solenoid which when de-energized closes the gates to a partial gate opening. To start the unit, the master control relay energizes the complete shut-down solenoid (provided the butterfly valve is completely open), allowing the wicket gates to open to a limit set by the partial shut-down solenoid. As the unit comes to speed-no-load, the breaker closes and its auxiliary contact energizes the partial shut-down solenoid, allowing load to be picked up on the unit.

To ensure that the governor pressure system is in operating condition it was necessary to add oil level switches for alarms and low pressure switch for tripping of the unit.

Butterfly valve control

The butterfly valve was manually operated. Due to the wear on the waterwheel wicket gates, the water leakage was sufficient to maintain a unit speed too high for continuous brake application. The valve closure was made automatic with each shutdown and the leakage was reduced, thus permitting the generator brake application at a lower speed. The field tests have shown that the butterfly valves will open against full unbalanced penstock pressure. Therefore, it was not necessary to motorize their by-pass valves. The opening of the butterfly valve is incorporated in

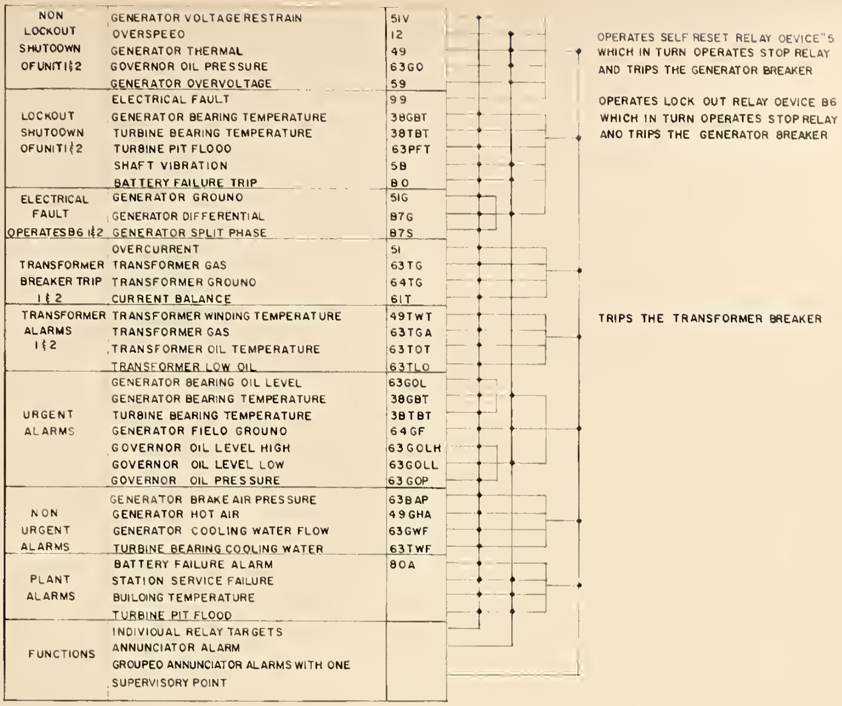

Fig. 3

the automatic starting sequence and is initiated by the master control relay.

Battery and charger

In addition to the existing lead acid, 60-cell control battery in the plant, a second lead acid supervisory 60-cell battery was supplied, complete with an automatic battery charger. Normally this battery supplies power to the supervisory equipment. In an emergency case it will supply the AC power for the VHF radio equipment through a DC-AC convertor.

Generator braking

Each generator has been supplied with a set of compressed air operated brakes. The brakes were applied manually, by means of a valve located on the generator floor. An additional electrically operated valve, timer and auxiliary relay have been supplied for each unit to provide an automatic braking cycle. The brakes will stop the generator in approximately 40 seconds with the gates closed and hold the rotor against turning. It is assumed that the field is left excited and utilizing the core loss and windage to reduce the speed to 25% of synchronous speed before the brakes are applied. Experience has shown that continuous application of the brakes at low speeds is more effective and causes less wear on the brake shoes and track than intermittent application at higher speeds. It was decided to apply brakes at 77 r.p.m. In case of emergency it might be desirable to apply the brakes continuously until the generator stops. But even then the length of time will not be considerably prolonged if the brakes are applied at 15% or 25% of synchronous speed. The continuous brake application simplified the brake control scheme. It was sufficient to add time delay and auxiliary relays to provide the required sequence. (Fig. 4). During the normal operation (the unit is running), auxiliary relay 20TX is energized and its contact 1-2 is closed. The transfer switch is on "automatic". As soon as the unit reaches 25% of synchronous speed, zero gate position (33-1 closes) and the generator breaker trips (52-b closes), the braking cycle commences. After a preset time interval, say 5 min., the time delay relay is de-energized and subsequently the auxiliary relay drops, thus the braking cycle is complete (solenoid 20 is de-energized).

After the generator has been stopped by the brakes, the oil film gradually squeezes out from between the rotating member of the thrust bearing and its stationary elements. After, say, 5 min. the brakes are released, since the friction exerted by the pressure on the thrust bearing is up to five times that obtained from the brakes. It is worthy of note that when the brakes were applied manually some smoke was produced (it means that the operator, though applying the brakes intermittently, commenced to apply them at too high speed). On the automatic brake application, the units were stopped very smoothly, without a trace of smoke.

Field Experience

Because of the already existing remote controlled hydro-electric plants in their system, Price Brothers was fortunate to have adequately trained personnel ready to take over the problems of Jim Gray. Some of their men were given special technical training which included technical courses, visits to various manufacturers to witness fabrication and testing of the various components.

The revision of all wiring diagrams and the programming of the change-over was carried out in the field by the staff of Price Brothers with the assistance of a field engineer from the consultants.

It is worthy to note that the company engineers showed a great interest in this automation and the technicians devoted most of their time (working a seven-day week) and energy in performing the installation and wiring of the additional equipment.

The conversion to automatic took three months of the field work, starting in March, 1960. The modification of some 50 drawings, redrawing and preparation of interconnection diagrams took two months. The installation of all additional equipment and wiring, some of which had to be done while the units were stopped (scheduled weekend shut-down) took the additional month. There were four technicians on the job and four tradesmen available on a "call basis" who installed some 8,000 ft. of single conductor cable and made approximately 5,000 connections. When all additional equipment was installed and wired and all interconnections made the actual change-over from manual to remote automatic control was done during two weekends and involved no loss of production.

It is fully expected, that as time goes on more experience is gained in the operation and maintenance of remotely controlled plants, the Price Brothers system will eventually become fully controlled from the control centre in Kenogami. The ultimate phase, would, of course, be the installation of an automatic dispatching system. This system would control generation to match demand and select the combination of generators and the capacities at which they should operate to result in the most economical generation and transmission.

Canadian Developments

The Department of Public Works is making increasing use of hydraulic models as a planning aid for construction work on harbors and rivers. Models eliminate guess work in such construction and their use results in large financial savings and in increased efficiency of the installations. This article, prepared by Major-General H. A. Young, Deputy Minister of Public Works, outlines briefly the history of hydraulic models and the use being made by the Department of these studies.

Some 25 years ago in Rangoon, Burma, a huge sandbar was being formed by the movement of tides across the harbor mouth and threatening to block navigation. The British Government was about to spend several million pounds to have the sandbar removed, but decided before doing so to set up a miniature hydraulic model of the harbor to study the causes of the disturbance. Engineers found that the model showed that the same winds and tides which had caused the sandbar to form would also cause it to disappear in a few years. They decided on a period of "masterful inactivity" during which the sandbar disappeared as predicted, resulting in a great saving in public funds.

This example has become a bit of a classic to engineers of the Department of Public Works involved in hydraulic model studies which, in the past few years, have saved the country millions of dollars in dredging and other maintenance and construction costs.

The hydraulic scale models in the laboratory reproduce in miniature the harbor channels and river beds as they exist in nature. Then the water is allowed to flow and the waves are generated artificially with the result that years are telescoped into hours and miles reduced to inches. The behavior of a mighty river at full flow and shoal conditions far in the future can be predicted. Many complicated questions involving the action of water can be answered. The hydraulic model has become an accepted and necessary part of marine developments.

One of the largest models to be used by the Department is the model of the Fraser River-Delta below New Westminster, B.C. Between 1949 and 1954, the cost of maintaining the navigation channel through the Delta was running between $700,000 and $900,000 per year. In the last few years, expenditures have not been above $500,000 per year and have been as low as $300,000. The model has also made savings possible in the cost of work other than dredging. It has assisted in making improvements such as in the design and location of protection walls and other marine structures.

The first and largest model study of a harbor construction project undertaken by the Department, was begun in 1955 for Port aux Basques, Nfld. Port aux Basques is situated at the southwestern tip of Newfoundland and is the island terminus of the C.N.R.'s connecting service maintained by ferry between there and North Sydney, N.S. Following the Confederation with Canada in 1949, a larger ferry than was used previously, was built and new harbor structures were erected. With the completion of the ship and harbor terminal, it was found necessary to provide additional protection for the berthing area. Even moored at the quay side the big ships would pitch and toss dangerously during stormy weather. A reduction in the residual waves at the ferry dock was necessary. These waves resulted from frequent and severe storm action outside the harbor and, since there was no natural protection, the waves caused extremely rough water at quay side.

A further consideration was that the protecting structures had to be built so as not to affect the old terminal still being used by smaller ships. Also, the positioning of the breakwaters had to be such as to leave an approach channel for the ferry, the "William Carson".

Facing these problems, the Department of Public Works had a complete model of the harbor, to a scale of 1 to 128, built by the Hydraulic Dynamics Section of the National Research Council in Ottawa. An exact prototype of the ferry vessel was built to the same scale as the model. Many miniature breakwaters were tried out in different locations until it was found which offered the best protection. This was done by

Model of Chandler harbor on the southeast coast of Gaspé Bay. Various types of breakwaters are tested to provide protection for structures against rough water.

subjecting the various proposals to simulated gale and storm conditions of various intensities in the laboratory.

As a result, the Department in 1959 completed the construction of breakwaters which fulfilled all the predictions of the model and provided the inner harbor at Port aux Basques with good protection. The model study for Port aux Basques was the key to the solution of this most difficult harbor problem, and the right answers were found, thanks to a scale model half the size of a hockey rink.

Public Works engineers are most enthusiastic about a hydraulic model study carried out in co-operation with the National Research Council for the harbor at Dingwall, N.S. A model was designed which in effect, did its own maintenance dredging — the miniature breakwaters and other structures were so designed that the resulting action of the water kept the harbor model free of sand and silt. If the harbor is built according to the model and if the predictions turn out to be accurate, the saving to the taxpayer will be considerable. In the past five years, maintenance dredging for Dingwall has cost the Department an average of $55,000 a year in addition to large dredging expenditures by private firms.

The Department hopes to bring about more savings as the result of a new model on which construction is just beginning at Queen's University in Kingston. It is a model of the harbor and approaches at Cobourg, Ont. It can easily be redesigned into a miniature of other ports on Lake Ontario or Lake Erie. It is hoped the new model will form the basis of a study which will enable marine structures to be designed to greatly reduce siltation problems which are affecting the ports and harbors of the two lakes.

A study was made of the harbor at Chandler, Que., on the south-east coast of the Gaspe peninsula. This location was exposed to wave action from the open sea and there was inadequate protection for existing harbour structures. At Glace Bay, N.S., another harbor problem was studied by the Hydraulic Dynamics Section of the National Research Council for the Department of Public Works. Glace Bay harbor is used largely for fishing and the problem is to cut down the action of waves in the inner harbor.

Another study was carried out for the port of Baie Comeau on the north shore of the St. Lawrence in Quebec. Baie Comeau is one of the rapidly growing North Shore industrial communities, which taken as a whole, represents one of Canada's more important industrial developments. The harbor problem there involved a study of several miles of shoreline, which was necessary for the planning of extensions to harbor facilities.

Other studies undertaken were for small harbors at Etang du Cap, Que., Ingall's Head, N.B., Lunenburg, N.S., Kingsville, Ont., and Lockesport, N.S.

A model study now under construction by the National Research Council for the Department of Public Works is of a different nature. The problem is at Rustico, P.E.I. where consideration is being given to construction of a bridge over Rustico Bay as part of the Gulf Shore Road. The main problem here is to prevent damages by beach erosion to sections of the highway and the approaches to the bridge. The Gulf Shore Road runs through P.E.I. National Park where highway construction is entirely a Federal responsibility.

The use of hydraulic models is exerting a continuous and growing influence on harbours and rivers construction work in Canada. This is as it should be, because there is no doubt that the influence is a good one. Before the introduction of model studies, the design of structures was based more on trial and error, and in harbor projects which are often large, even minor errors can be expensive. Studies in the laboratory, and the intelligent use of the research data they reveal have made possible improvements in design and location with the result that our harbor and river works more efficiently serve the purpose for which they were built. EIC

Errata

An article in the November issue concerning Montreal's Place Ville Marie project contained erroneous figures for some of the construction and excavation work. An up-to-date report on construction highlights, released by Webb & Knapp (Canada) Ltd., lists the following figures. Amount of concrete poured, 59,528 cu. yd. Structural steel erected, up to and including Dec. 1, 1960, 17,206 tons. Excavation, 257,866 cu. yd.

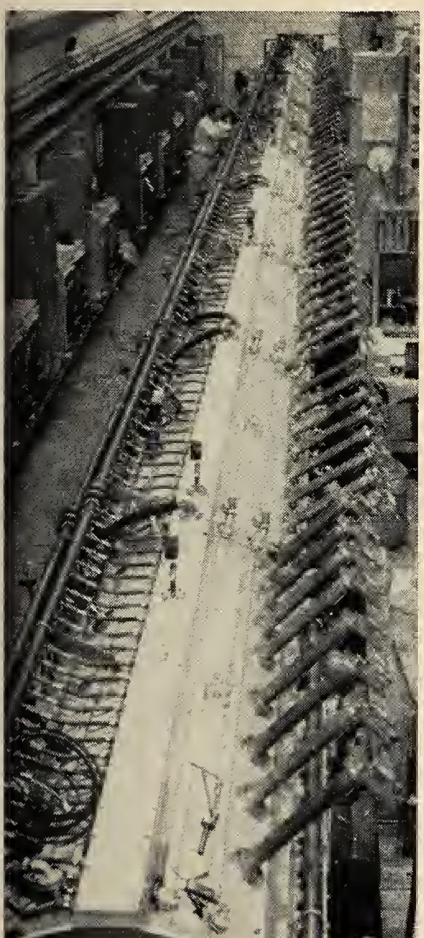
International News

World's Most Powerful Atom Smasher

A new atom smasher, the largest ever built in the United States, was recently put into operation at Brookhaven National Laboratory near New York City. One hour after its start-up, the big doughnut-shaped machine developed 30 billion electron volts of energy, setting a world record for power and accelerating nuclear particles to almost the speed of light, 186,000 miles per sec. The big device, known as an Alternating Gradient Synchrotron (AGS) is expected to attain even greater power levels, which will be used for investigations that are expected to yield new knowledge of the universe.

The Brookhaven synchroton will be used for several specific types of research; identification of the nuclear particles that make up atoms of ordinary matter; mass-production of little-understood particles such as mesons, hyperons, anti-protons and anti-neutrons; a search for hitherto undiscovered "strange particles" that physicists believe are in existence.

The 110-ft. long linac, composed of eleven 10-ft. sections coupled together, develops 50 million electron volts.

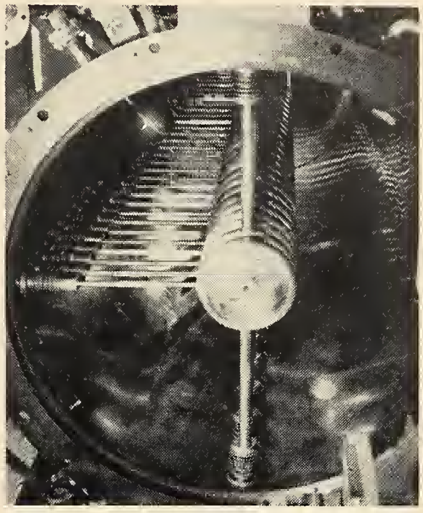


A good way to describe the operation of the synchrotron is to show how the machine increases the velocity of protons more than 30 times, to less than 0.1% of the speed of light.

The protons for use in the AGS are derived from hydrogen atoms, the lightest of the elements. The protons are acquired in a small chamber where an electrical arc tears away the electrons that revolve around protons. The resulting hydrogen nuclei are protons with positive charges. After the protons are made available, they are accelerated in three stages. First they pass through a Cockcroft-Walton generator, where they are accelerated to 750,000 electron volts. Next, the speeding particles are "shot" into a 110-ft.-long linear accelerator, called a linac, where they pick up 50 million volts of energy.

The final stage of acceleration is accomplished in the AGS, an "atomic racecourse" one half-mile in circumference and enclosed in a tunnel beneath 10 ft. of earth. The synchrotron is a vastly complex device. It consists essentially of a vacuum tube, which is a hoop of copper tubing about 7 in. wide and 3 in. high extending completely around the "racetrack" inside the circular tunnel. The copper tubing is contained by a circle of 240 magnets weighing 4,000 tons. As protons pass from the linac into the copper vacuum tube, the powerful magnets sweep them into a circular path. The magnet assembly is so arranged that it applies strong focusing forces to keep the protons in orbit and to prevent them from striking the walls of the vacuum tube.

The magnets do not increase the speed of the proton beam. This is done by 12 radiofrequency accelerating stations spaced at regular intervals around the circular vacuum tube. Each time the beam passes one of the stations, the protons are accelerated by 8,000 volts, which results in a total gain of 100,000 electron volts each time the beam completes its circular path. To reach the energy of more than 30 billion electron volts attained during the first trial of the synchrotron, the beam completes 300,000 revolutions, or 160,000 miles. The time required for this number of revolutions is only one second.



Interior of the linac showing drift tubes (centre) and vertical and horizontal supports inside tank. The proton beam enters the accelerator through the small hole in the centre of the first drift tube.

As the proton beam speeds around in the synchrontron, it passes through a target building constructed astride the "atomic racecourse". It is in this building that Brookhaven physicists will use the proton beam for experiments. By directing the beam at other atoms, reactions are produced which can be studied by means of emitted radiation. Many of the particles produced by atomic collisions exist for only a fraction of a millionth of a second before they decay into other particles or are converted into energy. These brief lifetimes, however, are long enough for the particles to be detected and recorded by instruments — counters, bubble chambers and photographic emulsions. A study of the records reveals the particles produced in the collisions.

Ultimately, it is planned to deflect the proton beam out of the AGS vacuum tube, which will enhance the usefulness of the machine by making possible many simultaneous experiments along the path of the beam. An 80 in. bubble chamber is now under construction for use with

(Continued on page 97)

Month to Month

Executive Committee Meeting

The Executive Committee of the E.I.C. Council met Nov. 19 in the Royal York Hotel, Toronto. President Dick was chairman. The following highlights of the meeting were taken from the minutes.

Oakville Branch Formed

Oakville, Ont., officially became the Institute's 51st Branch on the approval by the Executive Committee of a petition by Oakville Members. The Branch's charter will be presented by Dr. Dick during an official inauguration ceremony in February. Following are the officers of the Branch:

Chairman—A. A. Swinnerton
Vice-Chairman—H. J. Bexon
Secretary—J. W. Kirk
Committeemen—A. G. Ackerman, Program; C. F. Gross, Membership
Councillor—A. H. Thompson

Tariff Item 180 (e)

The General Secretary reported that the Committee appointed by Council Oct. 29, 1960, to receive the opinions of Council regarding the proposed amendment to Tariff Item 180 (e) was actively at work, and that councillors had been reminded to submit their opinions and the opinions of the Branches at the earliest opportunity.

Past President Tupper asked whether the text of the Institute's submission to the Tariff Board would be provided to Council. The General Secretary assured the meeting this would be done as soon as it has been prepared. He also reassured the meeting that consultations were being held with the Canadian Council of Professional Engineers regarding this matter.

Student Section at Loyola College

The Executive Committee heartily approved an application for permission to form a Student Section at Loyola College, Montreal. Loyola thus became the ninth Student Section, joining Assumption University, University of British Columbia, University of Manitoba, Ontario Agricultural College, Queen's University, University of Saskatchewan, University of Sherbrooke, and Waterloo University.

National Vocational Training Advisory Council

The General Secretary reported he attended a meeting of the National Vocational Training Advisory Council of the Federal Department of Labour in Ottawa, Nov. 3, 1960. He said he was present as liaison representative of the Labour Department's Advisory Committee on Professional Manpower, of which he has been a member for 15 years.

At this meeting Labour Minister Starr said there now is considerable unemployment in certain areas of the labour force. At the same time, Mr. Starr said, there are many vacant jobs which go unfilled because the required supply of technicians and workers with higher skills are not available. He noted the alarming drop-out rate from secondary schools, and urged an accelerated building and training program for the labor force.

The General Secretary reported that, in discussion during the meeting, he had stressed the importance of an adequate supply of technicians for industry, and for assisting the engineering profession in the performance of this work. A study will be made early in 1961 to attempt to find some general standard for technician training and related matters.

Canadian Conference on Education

The General Secretary reported that he participated in the Nov. 10 meeting in Ottawa of the National Committee of the Canadian Conference of Education. The Conference, sponsored by 64 national organizations, is planning the Second Canadian Conference on Education in Toronto, Feb. 18-22, 1962.

The objects of the Conference are to:

a. Focus the sentiments of citizens on the importance of education, and the need to take decisive action
b. Inform the public concerning the present state of education
c. State and examine new ideas about education

At this meeting the General Secretary had observed for the record and for the guidance of the program committee regarding the many technological developments which affect our lives and jobs have a definite impact on the aims, methods and scope of education. These, he said, should be considered when planning the program.

It was resolved that the General Sec-

Twenty-one Institute Members served as delegates or alternate delegates at the Sixth Congress of the Union Panamericana de Asociaciones de Ingeieros at Buenos Aires, Argentina, Sept. 18-22. One group is shown after its arrival in Buenos Aires. They are, from the left: Prof. Carson Morrison; Nicholas Fodor; W. N. Papove; A. T. Hurter; R. M. P. Hamilton; R. A. Frigon; Dr. James A. Vance; Paul Pelletier; C. C. Huston; G. R. Adams; W. H. Beaton; C. A. Dagenais; G. C. Hatch. Canadian participants not included in the photograph were: Dean H. G. Conn; Dean R. R. McLaughlin; Dr. K. F. Tupper; Leo Scharry; C. R. Vegh Garzon; Frank Athey; Harold Wright; H. B. Tafelmacher.

retary be instructed to keep the Engineering Education Division of the E.I.C.'s Committee on Technical Operations fully advised of the details of this Conference, so the Institute will be prepared to make a significant and appropriate contribution to the Second Canadian Conference on Education.

Relationships with provincial and territorial Associations and Corporation of Professional Engineers

President Dick reported that after numerous branch visits, and informal discussions with senior officers of several provincial associations, it has become evident to him that a relationship between the groups which will help attain what is best for all Canadian engineers must be achieved. With this common objective, there should be no effort wasted on competitive activities.

Past President Grant urged most strongly that the E.I.C. retain its identity at the branch level in advancing the well-being of engineers, with increased emphasis by the Institute on technical activities. Colonel Grant said serious problems would arise if, at the local level, non-members are able to obtain the same E.I.C. services as E.I.C. members. He said he could not reconcile himself to the Institute financing these services, or, in fact, to E.I.C. Branches retaining their charters under such circumstances. He also foresaw that E.I.C. Branches may lose their identity entirely if combined with local groups of provincial associations. He said he is opposed to the principle of confederation, and does not want to see the Institute lose its identity, prestige and functions by default.

Dr. Dick said the large majority of E.I.C. Branch officers concerned are intensely loyal to the Institute. But they now are faced with new conditions about which something constructive must be done in the best interests of the individual engineers in the localities concerned. He said the E.I.C. cannot instruct its branches not to co-operate with local groups of provincial associations if this appears an appropriate course of action at the local level; and that an organization which is not prepared to change its policies to meet changing circumstances will not flourish.

Past President Tupper suggested that the Institute should maintain a cordial relationship with the provincial associations, but should recognize them only as licensing bodies.

Vice-President Lawton said he was encouraged by the discussion. He emphasized the necessity for the E.I.C. to maintain a strong, virile and alert organization; to adhere to its objectives; and to render the types of service it should to its members. Mr. Lawton noted that steps were taken in the summer of 1960 to overcome long-standing problems vis-a-vis membership, and also to render all possible assistance to branch operations without detracting from the autonomy of the branches. He said many successful joint technical meetings have been held with sister societies. While there are many advantages of meeting jointly, he insisted the E.I.C. must not lose its own identity.

After considerable further discussion it was resolved that the following statement of policy be accepted by the meeting:

1. E.I.C. Branches must retain their identity and adhere to the approved system on government of the Institute.
2. The E.I.C. recognizes the associations and corporation of professional engineers in the provinces and territories of Canada as the sole licensing bodies of professional engineers in the respective provinces and territories of Canada.
3. E.I.C. Branches have the right to participate jointly in activities of mutual interest with any learned society or engineering organization, in conformity with the By-Laws of the Institute.

Committee on Membership

The first meeting of the Committee on Membership was held in Toronto Nov. 19 to chart a fresh and active course in E.I.C. membership promotion. Attendance of eight of the 11 committee members indicated the keen reaction to the work of the group. The extreme travel distances involved was responsible for the absence of the three other members.

With Fredericton Councillor Stan Cassidy as Chairman, the committee devoted most of the day to an examination of all phases of the Institute's organization and operation. Everything that might affect the attitudes of engineers — both members and non-members of the Institute — toward the E.I.C. was discussed with complete frankness. The best of the ideas and suggestions exchanged will be distributed to all concerned.

Included among the important conclusions reached at the meeting are:

A change is necessary in many of the former concepts concerning the running of the Institute. The Institute must be able to adapt to rapidly-changing times.

There is no substitute for personal contact, which creates interest on the individual level.

In many cases Branch organizations need overhauling, with new men put to work.

Large city Branches should consider dividing themselves into smaller Branches.

Many good customs and ideas to increase attendance at meetings and build interest can be adopted from other successful organizations.

Members of the committee will do all they can to assist Branches through personal contact.

In general terms, a three-point program emerged from the committee's discussions:

(Continued overleaf)

President's Column

BRANCH visits by the President during November included Hamilton, Ont., where more than 400 Engineers and wives gathered for their annual Ladies Night and Presidential Visit. Subsequent visits were made to Kitchener, Niagara, and Chatham. The latter included members and their wives from London, Sarnia, Border Cities and vicinity. At all these places, enthusiastic meetings were held.

The President also visited the Ontario Agricultural College at Guelph and Waterloo University at Waterloo, Ont. At both institutions the facilities for the teaching of engineering were inspected and suitable words of encouragement given to the students. There are active student groups at both institutions suitably sponsored by local E.I.C. Branches.

The Engineering Institute of Canada was officially represented by the President and Mrs. Dick at the "Bal du Genie" held by the Alumni and Students Association of Ecole Polytechnique in the Queen Elizabeth Hotel, Montreal on Saturday, November 26th.

A meeting of the Executive Committee of Council was held in Toronto on Saturday, November 19th when a number of Councillors from the Western Ontario area were also present. Concurrent with this event was a meeting of Council's Committee on Membership presided over by Councillor Stan Cassidy.

The Committee on Technical Operations is actively pursuing the development of increasing technical interest among all members, with particular accent on appropriate technical content of branch meetings.

A new Committee on Branch Operations has been appointed to study how branches operate, and to recommend to Council and the Branches regarding possible aids or techniques whereby the membership at large may benefit more widely from branch activities.

As the new year opens, may I take this opportunity to express, on behalf of the Institute, the very best wishes for 1961. This is the time when we should all take stock of our accomplishments during the year just closed, and suitably adjust our sights for the year that lies ahead. Our New Year's resolutions should include a sincere desire to improve our individual ability by some suitable augmentation of our technical knowledge, so that collectively we may enhance the technical accomplishments and ability of Canada's engineering fraternity, with the resultant improvement in Canada's national economy. EIC

1. To find from the Branches their membership problems.
2. To provide the Branches with as much guidance and assistance as possible.
3. To follow this with personal visits to the Branches.

The Engineers Confederation Commission

The third plenary meeting of the Engineers' Confederation Commission was held in Toronto, Nov. 25, 26 and 27, 1960.

The following delegates were present:

Newfoundland: J. B. Angel
Prince Edward Island: W. R. Brennan
Nova Scotia: G. F. Vail and G. F. Bennett
New Brunswick: T. C. Higginson and J. O. Dineen
Quebec: E. D. Gray-Donald, J. Lemieux, H. Gaudefroy and H. Cimon
Ontario: T. Foulkes, D. D. Whitson, C. T. Carson and L. D. Dougan
Manitoba: T. E. Storey and N. S. Bubbis
Saskatchewan: J. C. Traynor and J. B. Mantle
Alberta: J. McMillan and J. F. McDougall
British Columbia: F. A. Forward
Joint Secretaries: L. M. Nadeau and G. T. Page

John Clary, legal advisor of the Commission was also present during part of the meeting. W. K. Gwyer from British Columbia and E. W. King from the Yukon Territory had asked to be excused.

The meeting was under the chairmanship of John H. Fox, Chairman of the Engineers' Confederation Commission and Vice-Chairman J. E. L. Roy was also in attendance.

The Commission received for consideration the complete text of a proposed charter and proposed by-laws for a new national body combining the existing Canadian Council of Professional Engineers and the Engineering Institute of Canada as required under the Terms of Reference of the Commission, and preliminary proposals for the financing of this proposed body. Written legal opinions relative to these documents and to the procedure which would have to be followed for their implementation were tabled and the solicitor of the Commission attended part of the meeting to explain various legal aspects of the problems involved.

This, in effect was the culmination of a tremendous amount of work and study by a representative group of 25 engineers from all parts of Canada who have been given the responsibility, by their profession, of drafting a complete and detailed proposal for the confederation and unification of the engineering profession in Canada.

Since October, 1959, when the Commission and its eight committees became operative, a total of 68 recorded formal meetings and a large number of informal meetings were held, during which some 8,000 man-hours were spent by the 25 delegates who had to travel collectively an estimated total of 300,000 miles to attend these meetings.

After 13 months, during which each important aspect of the plan was carefully studied, both individually and in relation with other aspects, the Commission was finally in a position to consider a complete project and, as a result, several important decisions were taken although many details remain to be worked out.

Since the Commission is responsible and must report to the Councils of the Engineering Institute of Canada and the Canadian Council of Professional Engineers, it adopted as a policy that information relative to details of its work should not be made public until it was ready to take firm and definite decisions. The Commission is now in a position to release information on a number of points but feels that other aspects which have to be studied further before final decisions are taken should not be dealt with publicly at this time.

The major points concerning which the Commission has taken firm decisions may be outlined as follows:

1. Charter

After careful consideration of all possible alternatives and giving due consideration to the legal problems involved for all concerned, the Commission will recommend that the Charter of the Engineering Institute of Canada be used as a basis, with the necessary modifications to adapt it to the needs of the new organization.

2. Objects

In line with the terms of reference of the Commission, it was finally agreed to recommend that the objects of the new organization be as follows: (these

Miss Maudie Abraham was honored by officers and staff of the EIC on the occasion of her retirement from the staff after 41 years' service. Gifts were presented from the Montreal Branch and from Institute headquarters following a staff dinner. Madame Jacques Benoit, wife of the Chairman of Montreal Branch, is shown giving one of the gifts to Maudie. Looking on is EIC President Dr. Dick.

Engineers are the chancellors of four Canadian universities. This unique situation was marked recently in Montreal when a group of engineering friends honored them with a luncheon. From the left, they are: Dr. C. J. Mackenzie of Ottawa, Chancellor of Carleton University; Dr. R. E. Powell of Montreal, Chancellor of McGill; Dr. J. B. Stirling of Montreal, Chancellor of Queen's University; the Right Hon. C. D. Howe of Montreal, Chancellor of Dalhousie.

objects are incorporated in the proposed Charter):

(a) To develop and maintain high standards in the engineering profession.
(b) To facilitate the acquirement and interchange of professional knowledge among its members.
(c) To advance the professional, social and economic welfare of its members.
(d) To assist in the development throughout Canada of uniform registration requirements and examination standards for the engineering profession.
(e) To act in an advisory capacity in connection with legislative matters common to professional engineering bodies throughout Canada.
(f) To promote a knowledge and appreciation of engineering and of the engineering profession and to enhance the usefulness of the profession to the general public.
(g) To collaborate with universities and other educational institutions in the advancement of engineering education; to encourage original research and the study, development and conservation of the resources of Canada.
(h) To establish and maintain a bond between associations recognized by the Canadian Institute as Participating Associations and to promote the welfare of the engineering profession in Canada.
(i) To provide a forum for the discussion of problems common to all engineering bodies.
(j) To publish a national journal and such other technical and professional papers and transactions as may be of assistance to its members.
(k) To promote intercourse between engineers and members of allied professions.
(l) To co-operate with other societies for the advancement of mutual or national interests.
(m) To act as a national voice speaking on behalf of all the professional engineers of Canada.

3. Name

It will be recommended that the name of the organization be Canadian Institute of Professional Engineers and in French, Institut Canadien des Ingénieurs Professionnels.

4. Membership

The Commission will recommend that admission to membership in the Canadian Institute of Professional Engineers be obtained through registration as a Professional Engineer in a provincial or territorial association or corporation of professional engineers. Provision will also be made for admission to the proper grade of membership of engineers-in-training, junior professional engineers and students registered or recorded by these same bodies.

It will also be recommended that continuing membership in the proper grades be provided for all the present members of the Engineering Institute of Canada.

The Commission will recommend that there be five grades of membership as follows:

Fellow: This will be the highest grade of membership and will be used to recognize outstanding contributions to the engineering profession in technical or professional practice or in the fields of administration and teaching. It will be restricted to Members and the number of Fellows will be strictly limited.

Member: Will include only professional engineers registered in Canada.

Junior: Will be limited to engineers-in-training or junior professional engineers registered or recorded by the provincial associations.

Student: This grade will include only students recorded as such by the provincial associations.

Honorary Member: This grade will be used to honour persons who have attained eminence or have achieved great distinction in fields of endeavour allied to or asociated with the engineering profession, but who are not professional engineers registered in Canada. The number of Honorary Members will be very restricted.

• MONTH TO MONTH

5. Management

It will be recommended that the Canadian Institute be governed by a Council composed of the President, two Vice-Presidents, the immediate past President, one Councillor appointed by the Council of each of the provincial Associations and Councillors elected by the membership of the provincial Associations.

The number of elected Councillors shall be determined as follows: Associations with 301 to 5,000 members shall elect one Councillor. Those with 5,001 to 10,000 members shall elect two Councillors and those with over 10,000 members shall elect three Councillors.

The Commission further recommends that two Boards and four Standing Committees be formed under the Council as follows:

Board on Professional Interests — This Board will be composed of all the Councillors appointed by the provincial associations and will be responsible for the activities of the Canadian Institute in the field of professional interests including the co-ordination of the activities of the Associations in this field.

Board on Technical Services — This Board shall be responsible for the activities of the Canadian Institute in the field of technical services and for the co-ordination of the activities of the provincial associations in this field.

Committee on Finance
Committee on Branches
Committee on Publications
Committee on Honours and Awards

Provision will be made that under the administration of the two respective Boards, any number of committees may be established to allow for the implementation of the objects of the Canadian Institute of Professional Engineers.

6. Branches

Details of a program to provide the membership with an expanded program of branch activities are being developed. It is proposed that this program will make provision for the professional and technical aspects of the profession.

7. Student Chapters

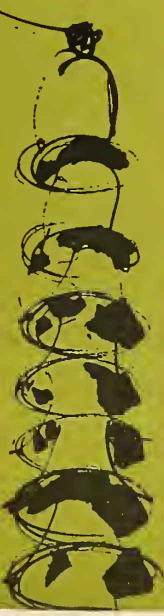
Provision will be made for an expanded program of student activities.

8. Membership Participation

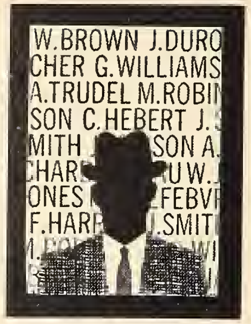
To provide for direct participation by each individual member in the basic activities of the Canadian Institute, it is proposed that at both the branch and national levels, members may participate in the activities of one or more technical and functional divisions. Each division will be concerned with a major area of technical or professional interest of the engineering profession.

9. Advance Schedule

It is hoped that at its next meeting scheduled for February, the Commission will be able to prepare a complete report for a submission to the Engineering Institute of Canada and the Canadian Council of Professional Engineers in advance of their 1961 annual meetings.

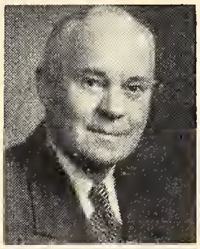


Personals



Dr. Richard L. Hearn, M.E.I.C. (Toronto '13), has been appointed President and a Director of C.B.A. Engineering Ltd., Vancouver, B.C. Dr. Hearn was General Manager and Chief Engineer, Hydro-Electric Power Commission 1947-55, and Chairman 1955-56.

R. L. Hearn, Hon. M.E.I.C.

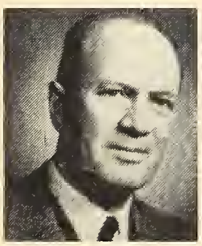


Dr. O. Holden, M.E.I.C.

Dr. Otto Holden, M.E.I.C. (Toronto '13), recently retired Chief Engineer of Ontario Hydro, was presented with a silver medal by the Engineering Alumni at the University of Toronto. The medal is awarded for outstanding achievements in the field of engineering.

Karl O. Elderkin, M.E.I.C. (McGill '20), has retired as President of Bowaters Engineering and Development Inc., in Calhoun, Tennessee. Mr. Elderkin joined the Bowater organization in 1952 and has been in charge of the design and construction of many of their mills.

W. J. W. Reid, M.E.I.C. (Toronto '24), has been appointed Senior Vice-President of the Otis Elevator Company, New York. Mr. Reid has also been elected a member of the Board of Directors.



W. J. W. Reid, M.E.I.C.

D. A. Barnum, M.E.I.C.

D. A. Barnum, M.E.I.C. (Michigan '29), was recently appointed Vice-President and Manager, engineering and sales, Corba Industries Inc., Quebec City.

Elzear N. Gougeon, M.E.I.C. (Mass. Inst. of Tech. '30), has been appointed Assistant Chief of the technical services division (Montreal area) of the Industrial Expansion Bureau of the Trade and Commerce Department.

Thomas A. Marshall, JR.E.I.C. (Georgia School of Tech. '32), has been appointed Executive Secretary of the American Society For Testing Materials, Philadelphia. Mr. Marshall was previously Senior Assistant Secretary of the ASME.

J. E. Laframboise, JR.E.I.C., an Athlone Fellow, has been studying at the Imperial College of Science and Technology, London, England where he was doing research work on flame quenching and flame traps operation. Mr. Laframboise is now working for Computing Devices of Canada, Valcartier, Que.

G. E. K. Dudman, M.E.I.C. (Alberta '54), has been appointed Chief Engineer for the Alberta Branch of the Dominion Bridge Company Limited. **A. Baxter,** M.E.I.C., has been appointed Manager, Mechanical Products of the same Branch.

G. E. Dudman, M.E.I.C.

D. Buckley, M.E.I.C.

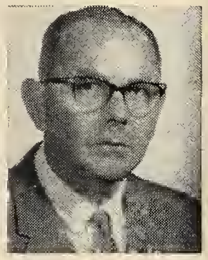
Donald C. Buckley, M.E.I.C. (McGill '49), was recently appointed assistant chief engineer in Wix Corporation Limited, Toronto, manufacturers and filtration specialists.

John W. Demcoe, M.E.I.C. (Manitoba '39), previously Acting General Manager of central region, Toronto, has been made General Manager of Canadian National Railways Atlantic region. Mr. Demcoe joined Canadian National in 1939.

A. C. Ridgers, M.E.I.C., has become chief design engineer in the engineering division of The Consolidated Mining and Smelting Company, B.C. Mr. Ridgers has been with the company since 1924.

R. T. Harland M.E.I.C. (Manitoba '38), formerly Chief Engineer, has been promoted Assistant General Manager of the City of Winnipeg Hydro-Electric System. **J. H. Benditt,** M.E.I.C. (Manitoba '27), succeeds Mr. Harland as Chief Engineer. Mr. Benditt joined the Winnipeg Hydro in 1927 and was previously General Superintendent of Distribution.

R. T. Harland, M.E.I.C.



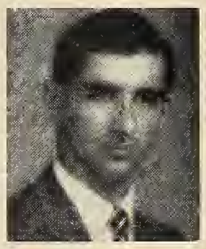
J. H. Benditt, M.E.I.C.

Alexander Baptist, M.E.I.C. (New Brunswick '47), has been appointed City Manager of Pointe Claire, Que. Mr. Baptist was formerly Town Manager and Industrial Commissioner of Hawkesbury, Ont.

Glen C. Riteey, M.E.I.C. (McGill '48), has been appointed Vice-President and General Manager of Rader Pneumatics (Eastern) Limited in eastern Canada. Mr. Ritcey was formerly Assistant Manager Pembroke division of Consolidated Paper Corporation, Pembroke, Ont.

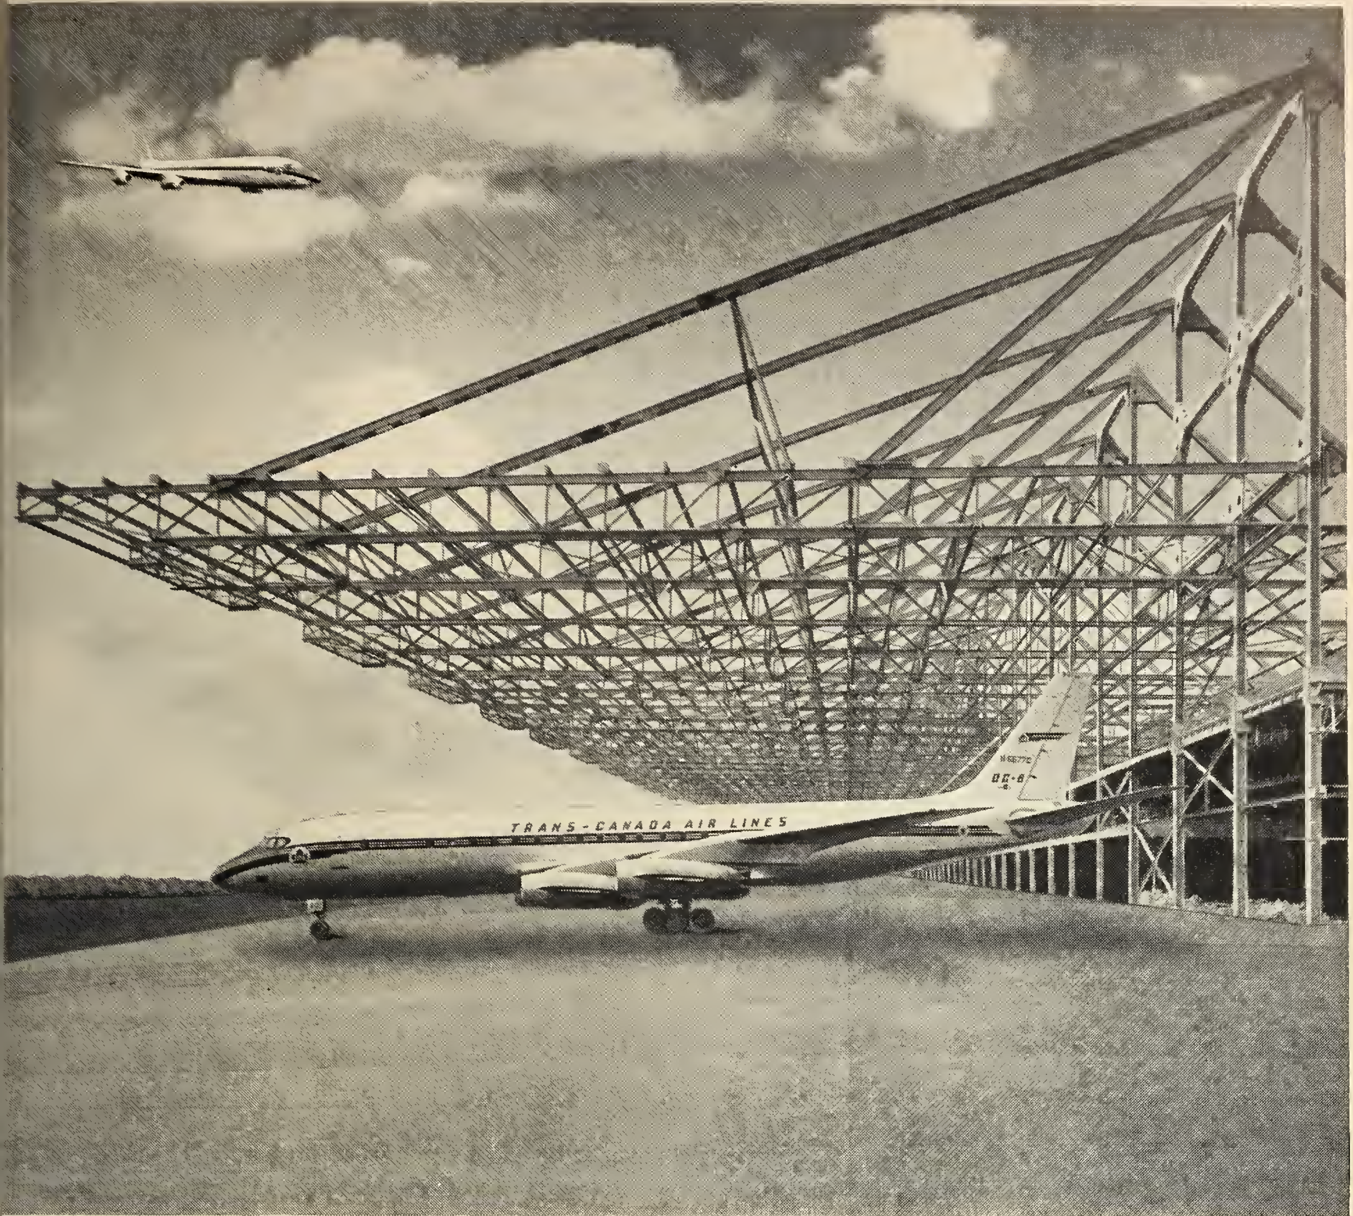
K. R. Fulton, M.E.I.C. (New Brunswick '48), has been appointed Vice-President (construction) of Canadian Engineering and Contracting Co. Ltd., Hamilton.

K. R. Fulton, M.E.I.C.



C. J. Gauvin, M.E.I.C.

C. Jacques Gauvin, JR.E.I.C. (Polytechnique '54), has been promoted to chief geologist for Steep Rock Iron Mines Limited, Steep Rock Lake, Ont.



Room to swing a jet

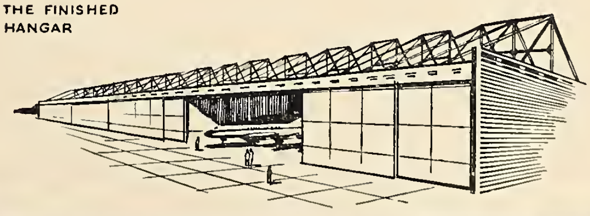
This huge steel frame is the backbone of a hangar for jetliners. It belongs to Trans-Canada Air Lines and is part of their new multimillion dollar base near Montreal designed solely for the maintenance of turbine aircraft.

Because of the size of modern aircraft vast covered areas free of all vertical supports are necessary to permit planes to manoeuver freely. In this building, structural steel, fabricated and erected by Dominion Bridge, is used to create the largest cantilever roof of its kind in North America. It projects 175 feet for a length of 836 feet and provides a post free area larger than two football fields.

The roof structure is suspended by diagonal members from anchored and braced steel columns. The design permits unobstructed entrance through 50 ft. high sliding doors for the whole length of the building. Five DC-8 jetliners can be accommodated. Architects and engineers were Ross, Fish, Duschenes and Barrett of Montreal and E. W. Sellors of T.C.A., and the general contractors, Pigott Construction Ltd.

This is an example of Dominion Bridge at work—five divisions—Structural, Mechanical, Platework, Boiler, Warehouse Steel. Fifteen plants coast-to-coast.

THE FINISHED HANGAR



44

DOMINION BRIDGE

T. E. Harris, M.E.I.C. (McGill '50), has been elected chairman of the Montreal section of the Standards Engineers Society. Mr. Harris is Mechanical Engineer, Power Crane and Shovel Division, Dominion Engineering Works.

W. H. R. Gibney, JR. M.E.I.C. (British Columbia '50), has been appointed Planning Engineer, Mines Division at The Consolidated Mining and Smelting Company's Sullivan Mine at Kimberley, B.C.

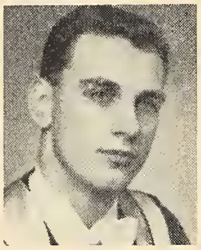
J. H. White, M.E.I.C. (New Brunswick '54) has been appointed Secretary, Gifco Limited, Moncton, N.B. Mr. White was previously Sales Engineer, Armco Drainage and Metal Products for Nova Scotia.

B. B. Kubow, JR.E.I.C. (McGill '56), has been promoted from Junior Engineer to Electrical Engineer in Southern Canada Power Co. Ltd., Montreal.

Lionel Simard, JR.E.I.C. (Ecole Polytech. '58), has been nominated Chief Engineer for the City of Jonquiere, Que. Mr. Simard was formerly employed by the City of St. Lambert, Que. as City Engineer.

S. D. Robertson, JR.E.I.C. (Queens '58), an Athlone Fellow, has returned from England where he studied at the Imperial College of Science and Technology, London, in the control systems field. Mr. Robertson has now taken a post at the University of Toronto as a Research Associate.

Louis Donolo, JR.E.I.C. (McGill '58, Harvard '60), has been appointed director and administrative assistant of Louis Donolo Inc.



R. Avery, JR.E.I.C.

Roland Avery, JR.E.I.C. (N.S.T.C. '60) is now junior design engineer for Foundation of Canada Engineering Corporation Limited.

John H. Duerksen, JR.E.I.C., has joined Atomic Energy of Canada, Limited as a Junior Research Officer in the Chemistry and Metallurgy Division. He has returned to Canada after two years of studying in Europe on an Athlone Fellowship. His first year was spent with W. J. Fraser & Co. Ltd., chemical contractors, as a graduate trainee, and in his second year he studied Nuclear Technology (Chemical) at the Imperial College of Science and Technology.

T. H. Welch JR.E.I.C. (Saskatchewan '60), has joined D. R. Rowe Engineering Services Limited and is now operating in the Tisdale, Sask. office.

Obituaries

Colonel William Herbert Magwood, M.E.I.C. (Royal Military College), former town engineer and building inspector of Cornwall, Ont., died Nov. 18. He was 91. Colonel Magwood was former commanding officer of the Stormont, Dundas and Glengarry Highlanders. He joined the Institute as an associate member in 1905, became a member in 1919 and was made a life member in 1947.

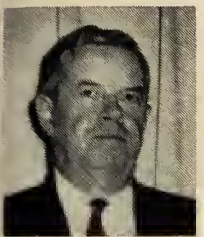
T. Dowsley Kennedy, M.E.I.C. (Berlin '05), past President of William Kennedy and Sons Ltd., died Nov. 9, at Owen Sound, Ont. He was 75. Mr. Kennedy entered the family firm in 1909 and became President in 1940. He joined the Institute as an affiliate member in 1911 and became a member in 1940.

Wesley Blaine Redfern, M.E.I.C. (Toronto '09), a partner in Proctor and Redfern, consulting engineers, Toronto, died September 17. He was 73. He was born and educated in Owen Sound, Ont. Mr. Redfern joined the Institute in 1920 as an affiliate member and became a life member in 1955.

(Continued on page 85)

(Continued from page 82)

Aubrey H. Perry, M.E.I.C. (Toronto '30), an internationally recognized authority on water and pollution problems, died Oct. 11, after a short illness. He was 54. Mr. Perry was with the Public Health Engineering Division, Department of National Health and Welfare, Vancouver. He became an affiliate member of the Institute in 1935 and a member in 1940.



A. H. Perry, M.E.I.C.

E. J. Blandford

E. J. (Ted) Blandford, Publication and Advertising Manager of the Engineering Institute of Canada, died Dec. 7, at the age of 59. Mr. Blandford was born in Kent, England and received his early education at the Colchester Grammar School. He served his apprenticeship in marine engineering on the Clyde. His first job was with the Dutch Shell Oil Company in Venezuela, where he spent three years. After settling in Montreal in 1927 Mr. Blandford worked as a space salesman for the publishing houses of Hugh C. MacLean and for Maclean-Hunter. He then worked for Vickers Shipbuilding, after which he opened his own business, Home Film Studios. Mr. Blandford became public relations manager for National Breweries Ltd. During part of his Second World War services with the R.C.N.V.R., he helped establish shipbuilding bases in the Maritimes. He ended his naval service with the rank of Lieutenant Commander. About 13 years ago he began working for the Institute and rendered excellent service throughout his association with the E.I.C. Mr. Blandford channelled his tremendous vitality into service and professional clubs and into his hobbies of painting, music, woodworking and photography. Survivors include his widow, the former Margaret Forrester, and sons John and George.

John E. Warner, M.E.I.C. (McGill '12), a prominent engineer in the paper industry, died Oct. 17, New York City. He was 69. Mr. Warner retired as chief plant engineer for the Robert Gair Paper Company, a subsidiary of the Continental Can Company, in 1957 after 21 years with the firm. He became an affiliate member of the Institute in 1920 and a member in 1940. He was made a life member in 1955.

Sheldon Byrne Clement, M.E.I.C. (McGill '01), Sarnia, Ont., died recently. Mr. Clement joined Ontario Northland Railway in 1906 and was made Chief Engineer in 1909. He retired in 1946. Mr. Clement joined the Institute as a student member in 1899, he became a member in 1911 and was made a life member in 1947.

Robert White, M.E.I.C., 76 yrs., a retired chief engineer of Williams and Wilson, Montreal, died Nov. 22. Mr. White emigrated from Scotland in 1911 and was in the employ of Canadian Pacific Railway for some years. He was associated for more than 35 years with Williams and Wilson, retiring in 1954. He joined the Institute as a Junior member in 1912 and became a member in 1940. He was made a life member in 1950.

Romeo Morrissette, M.E.I.C., former mayor of Cap-de-la-Madeleine, Que., has died. Mr. Morissette was 83. He joined the Institute in 1945 and became a life member in 1958.

T. H. Kirby, M.E.I.C. (McGill '13), chairman of the Winnipeg branch of the Institute in 1944, died Oct. 17. Mr. Kirby was 69. He was President of Filer-Smith Machinery Co. Ltd., Winnipeg, and had previously been with the Manitoba Power Commission. He joined the Institute as an associate member in 1919, transferring to member in 1940. He became a life member in 1954.

Other Societies

American Institute of Chemical Engineers

The 53rd Annual Meeting of the Society was held in Washington, D.C., Dec. 4-7. Thirty-four technical sessions were held and 11 plant trips arranged. Among the speakers were Fred Singer, University of Maryland, who spoke on "Scientific Exploration of Space", and Wallace Brode, Former Science Advisor, U.S. Department of State, who talked on "Scientific and Engineering Planning". Delegates also heard from the Dynamic Objectives Committee which has been working on a report on the future of chemical engineering.

Society for Experimental Stress Analysis

The second technical meeting of the season of the Hamilton Section of the S.E.S.A. was held Nov. 29. "Modern Strain Bridges, Scanners and Readouts" was the subject for the evening. George Kelk, President, George Kelk Limited, was the speaker.

Institute of Radio Engineers

The Toronto Section of the society visited Trans Canada Telemeter, Dec. 5. Following a description of the system, there was a conducted tour of the studios and facilities, from which programs are originated for the first pay-TV system in Canada.

The Society of Naval Architects and Marine Engineers

At the 68th Annual Meeting at New York, Nov. 19, John Rogers Newell was elected President for a two-year term. Mr. Newell succeeds Rear Admiral Albert G. Mumma.

American Society of Tool and Manufacturing Engineers

The A.S.T.M.E. held a meeting in Montreal, Nov. 16. Ed. Hanna, Chief Engineer, Landis Machine Company, gave an informative talk on "Thread Rolling".

American Society for Testing Materials

The Society has published their 1960 Annual Report of the Board of Directors. Of special significance in the report is mention of the creation of committees in new fields — sampling and analysis of metallic ores, the study of skid resistance of traffic surfaces, the standardization work in the field of ceramics for electronics, and the exploration of sensory testing.

The American Society of Mechanical Engineers

The Winter Annual Meeting of the A.S.M.E. was held in New York City Nov. 28-Dec. 2. Walker L. Cisler, President, headed the meeting during which more than 300 papers were presented at 123 sessions. Several outstanding engineers, executives and educators were honored through presentation of Society awards for their achievements. Among these was Henry Heald, President of the Ford Foundation, who was made an Honorary Member of the Society. The 1960 Power Show was held concurrently with the conference. Displayed was a variety of new equipment designed to supply the expanding power needs of all phases of American life.

Papers presented during the week included reports on such topics as aviation, management, railroad improvements, safety, professional practices, solar energy heating and atomic energy innovations.

The first day started with great excitement when delegates were told that May 4, 1964 might well be the day when a space capsule sets off to Mars. Some theories on the accomplishment of the mission were presented by Harold Brown of the Flight Propulsion Laboratory Dept., General Electric Company. The space ship would be powered by low-thrust electrical propulsion, a system some engineers are advocating as a lower weight substitute for chemically powered engines. Also featured that morning was a discussion by a Federal Flight Test Inspector on problems faced by pilots of new commercial jets. Charles L. Blake and Eric R. Woods, both of the Convair Corp., presented a paper in which they suggested a method by which passenger aircrafts could be checked and overhauled more quickly. They said that a computer, an electronic brain, built into each aircraft would permit the jet to be under constant check in the air and would enable quicker service to be carried out on the ground.

Paul C. Aebersold, Director of Isotopes Development for the U.S. Atomic Energy Commission, gave an interesting and informative paper about the radioisotope, on Tuesday. These radioactive forms of different chemicals, often man made, are "truly the success story of atomic energy," he said. He described the numerous uses they are being put to, including assisting in the discovery of cheaper fuels, processing food, keeping manufacturing processes at a standard tolerance and traeing oil in pipelines. At the same session, J. R. Mason, reviewed safety and regulatory controls for radioisotopes. Staying in the nuclear field, two engineers told a session about a new plant under consideration that uses sulphur to carry heat to the steam generator. Preliminary studies indicate that such a plant may be cheaper to construct and to operate than more conventional systems.

One of America's leading experts on solar energy, John I. Yellot, summarized sun-power developments during 1960. Another paper described experiments on solar-heated homes. An interesting discussion was held about photographic methods of studying combustion in rocket chambers.

(Continued on page 88)

The Associations and Corporation

The establishment of a province-wide network of chapters has been approved by the Executive Council of the Association of Professional Engineers of Ontario. The move is designed to bring about an improved system of communications between the Association and its membership. "Chapters will be formed in every large centre in Ontario in order that every member will be able to attend regular meetings without having to travel a great distance", says the President, Dwight S. Simmons. He added that between 35 and 40 chapters would be formed.

Included in Thursday's papers were observations by William M. Keller, Vice President of the Association of American Railroads, on his study trip to the U.S.S.R. At the same session, three other engineers supplied comments on mechanical engineering progress in other countries abroad.

During the last day of the meeting, Friday, William van der Sluys, Associate Director of Research for the Pullman Company, described a new train that can run with the locomotive at the back. Another railroad engineer described how railroads can compete successfully with trucks over the same route by means of a new train-truck car, a 'railvan'. Also among the highlights of the meeting was a paper presented by Charles M. Loucks, Consulting Chemist, Materials and Methods, Inc., on chemical cleaning of plant equipment.

Professional Survey

The Department of Labour's annual Survey of Scientific and Technical Professions is being carried out in the first quarter of this year with questionnaires being sent to some 25,000 engineers and scientists. This survey program provides the only comprehensive set of statistics covering all engineering and scientific groups. It is carried out with the co-operation of the principal professional associations.

Summaries of the results are sent to all who answer the survey. More detailed statistical reports are published by the Department as part of its professional manpower series. The present survey will provide employment and earnings data for 1960. In addition, for the first time, the Department is planning to publish data on salary rates to meet the demand from employers of professional personnel for this type of information.

The following taken from the 1959 survey, gives the median earnings in the main professional groups, with comparisons for 1958:

Field	1959	1958
Agriculture	$6,400	$5,900
Engineering	8,100	7,900
Forestry	6,900	6,700
Natural Science	7,650	7,400
Veterinary Medicine	7,350	7,000

Coming Events

54th Annual Meeting, The Canadian Institute of Surveying, Chateau Laurier, Ottawa, Feb. 8, 9, 10.

Winter meeting, The National Society of Professional Engineers, Des Moines, Iowa, Feb. 9-11.

Solid State Circuits Conference, Institute of Radio Engineers, American Institute of Electrical Engineers, Philadelphia, Feb. 15-17.

57th Annual Convention, American Concrete Institute, St. Louis, Feb. 20-23.

Annual Meeting, American Institute of Mining, Metallurgical and Petroleum Engineers Inc., St. Louis, Feb. 26-March 2. EIC

News of the Branches

Belleville

A. G. Tooth, M.E.I.C.
Correspondent

The atomic reactor installation in Bombay, India, was the subject of an address given the Branch at its Nov. 14 smorgasbord. Guest speaker at the meeting held at Tweed was G. R. Adams, Vice-President and General Manager, Foundation Overseas, Ltd. With the aid of excellent color slides, Mr. Adams outlined the difficulties of construction. These difficulties apparently were minor compared with the red tape which hampered operations with the Indian Government. Canada supplied all the material while India contributed the labor and the foundations. E. A. Cross, Regional Vice-President of the Institute, gave a short, excellent talk on the history of engineering.

Border Cities

Wallace A. Macdonald, JR.E.I.C.
Correspondent

Members of the Border Cities Branch, including Assumption University's student section, spent a constructive and enjoyable evening during the combined meeting of the Sarnia and London Branches at Chatham during the Nov. 18 visit by Institute President, Dr. G. McK. Dick. In the afternoon the executives of the three branches met with Dr. Dick and many interesting problems were discussed. This session was found very informative by the executives and it produced much incentive for future programs. In the evening, members and their ladies met for a reception and dinner. E.I.C. General Secretary Garnet T. Page outlined present and future plans and activities of the Institute. Dr. Dick, the speaker of the evening, discussed the importance of an engineer's wife's role in his life and duties. He continued his talk concerning the necessity of Canadian engineers' ingenuity. The Canadian engineer must continue his education after graduation, Dr. Dick said. Technical programs must be promoted to enable Canada and Canadian engineers to be recognized. In summarizing, the President advised engineers to raise their standards and to "keep on going."

The speakers were thanked by Art Worth of the Sarnia Branch.

Central B.C.

A. F. Joplin, M.E.I.C.
Correspondent

The annual meeting for presentation of reports and election of officers of the Central B.C. Branch took the form of a dinner get-together at Vernon, Nov. 25. Retiring Branch Chairman H. A. Price, Division Engineer for the C.P.R. at Penticton, presented his annual report summarizing the activities of the Branch during 1960. Mr. Price accepted the position of Branch member of the National Nominating Committee. Reports from Branch secretary W. M. Owen and the auditor's report received favorable consideration. Also discussed during the meeting were Tariff items 180 (e) and 180 (f) regarding the importation of engineering plans and specifications. Support was recorded for Council's action. Endorsed was the report by the Sub-Committee on Water Pollution which is of vital interest in the Okanagan. The following members were chosen to the executive: Branch Chairman—J. W. Nelson, Kamloops; Vice-Chairman—B. S. Harvey, Kelowna; Branch Councillors—T. Berger, Vernon; R. Wannop, Kelowna; M. Elston, Kamloops.

Special guests at the meeting were W. McKenzie, mining engineer and past president of Okanagan Helicopters, and G. Warren, mining engineer recently returned from five years in Peru.

Chalk River

R. O. Sochaski, JR.E.I.C.
Correspondent

Members of the Chalk River Branch participated in a field trip Nov. 19, to observe the NPD-2 nuclear power station. The three-hour tour was arranged by personnel of Ontario Hydro and Canadian General Electric and covered the complete power station. Items inspected included turbo-alternators, boilers, pumping stations, instrument panels, fuel assembly and storage bays, condensers, ventilation and electrical switch gear. The station is hoped to become critical late this year.

Kootenay

Ian Waterlow, M.E.I.C.
Correspondent

George Small, chief instrument engineer, Instrument Department, Cominco, discussed automation in process industries at the Branch's Oct. 24 meeting. After outlining the history and definition of automation, Mr. Small described a simple manual operation using instrumentation terms for the sequences. He then told how each of these sequences would be automated. Finally he touched briefly on computers, audio storage units, and taped sequences.

Loyola College

Richard Kind

The first meeting of the Loyola College Student Section was held Dec. 2. The formation of a student section had been approved at the Institute Headquarters less than two weeks previous to the meeting. The officers of the new section are: Chairman—Peter Mayers; Vice-Chairman—Ross Deegan; Sec. Treasurer—Richard Kind.

The speaker at the meeting was H. J. Racey, Vice-President, Racey, MacCallum and Associates Ltd., who gave a talk on "Microwave Construction in the Yukon". Mr. Racey's talk dealt mainly with the problems of constructing access roads from the Alaska Highway to the sites of microwave towers. His talk introduced the student members to some of the engineering problems encountered in the North, and was illustrated by slides.

University of Manitoba

Brian Grover, S.E.I.C.
Correspondent

Professor E. Kuiper, Hydraulics Professor at University of Manitoba, discussed harbor works in Harling, Holland, at the Nov. 24 meeting. Prof. Kuiper presented films showing the construction of the harbor dam in all stages, with emphasis on the protection of the slope of the dyke facing the sea by using asphaltic materials. He described the entire project and methods of construction with the aid of his own films. After his presentation, Prof. Kuiper answered questions from the audience of about 200 students.

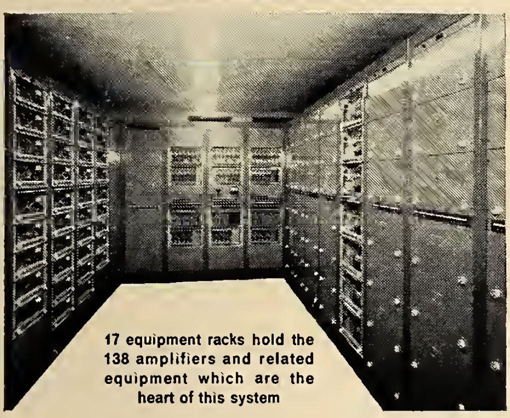
AIR TERMINAL BUILDING, DORVAL, P.Q.

Owner: Department of Transport
Chief Architect: W. A. Ramsay, Ottawa, Ont.
Associate Architects: Archibald, Illsley & Templeton, Montreal, P.Q.
Larose & Larose, Montreal, P.Q.
General Contractor: Foundation Company of Canada Limited, Montreal, Que.
National Distributor: General Sound and Theatre Equipment Limited, Montreal, P.Q.
Paging System Engineered & Installed by: National Electronics Limited, Montreal, P.Q.
Consulting Engineers: Leblanc & Montpetit, Montreal, P.Q.



17 equipment racks hold the 138 amplifiers and related equipment which are the heart of this system

1,735 speakers will carry messages like this through the new Dorval Air Terminal Building, 24 hours a day, every day of the year. This will be one of the world's hardest working public address systems, and it has been designed for maximum clarity in speech and music reproduction.

Working to basic specifications laid down by the Department of Transport, Northern Electric Company Limited designed the overall system and manufactured its major components. The installation of the Northern Electric system was engineered by National Electronics Company of Montreal.

Northern Electric is proud indeed to have participated in the new Dorval Air Terminal Building.

Northern Electric
COMPANY LIMITED

SERVES YOU BEST

was to have addressed the Ottawa Branch, Oct. 20. Due to illness, Mr. Danel's address was presented by Ernest Pariset of Montreal's LaSalle Hydraulic Laboratories. The advancement of hydraulic turbine development during the last 50 years as to efficiency and specific speeds was illustrated by slides. This was followed by details of different developments with which the author had been connected. The last part of the lecture was devoted to the feasibility of developing hydro power from tidal effects.

The Nov. 17 meeting heard Raymond Brunet of Ed. Brunet and Sons, General Contractors, Hull, Que., discuss construction and employment. Mr. Brunet had served as advisor to the Unemployment Insurance Commission and to the Canadian Construction Association, and thus was able to present both sides of the present unemployment problem. Statistics he employed emphasized the importance of the construction industry to the whole Canadian economy.

Peterborough

R. C. Johnston, JR.E.I.C.
Correspondent

A Northern Electric Company tape recording concerning Communism was heard at the Branch's Nov. 30 meeting. At the same meeting, 10 members were nominated for the Branch's 1961 executive. The Annual Gala Ball is scheduled for Jan. 29. This event has become one of Peterborough's main social functions.

Vancouver

D. R. Bakewell, M.E.I.C.
Correspondent

The erection of steel bridges was the topic of an address given the Branch's civil-structural group Oct. 18 by R. C. Harris, Construction Manager for Dominion Bridge Company. Mr. Harris illustrated his talk with excellent slides of bridges in various stages of construction, both in North America and Europe. Seventy-five members were present. French hydraulics expert Pierre Danel, President of SOGREAH, addressed a joint meeting of the Vancouver Branches of the Institute and of the Professional Engineers of British Columbia. Mr. Danel traced the evolution of the turbine, and discussed hydraulic problems in canal and harbor works. About 100 engineers attended the address which was illustrated with slides and films. Seventy-five couples enjoyed a smorgasbord dinner and dance at the annual Ladies' Night, Nov. 5.

Vancouver Island

W. N. Tivy, M.E.I.C.
Correspondent

Pierre Danel, President annd General Director of SOGREAH, Grenoble, France, addressed the Oct. 26 meeting on the subject of hydraulic turbines and hydraulic structure laboratory practice. His talk covered hydraulic turbine manufacture and turbine efficiencies,

harbor layout and tidal energy. Also discussed was the design of the relatively new bulb type turbine unit.

Winnipeg

P. M. Abel, JR.E.I.C.
Correspondent

Pierre Danel, President and General Manager of SOGREAH, Grenoble, France, discussed hydraulic turbines and hydraulic structure laboratory practice at the Branch's Nov. 1 meeting. He was introduced by V. L. Dutton, professor of Civil Engineering at University of Manitoba, and was thanked by Ed Kuiper, also a Civil Engineering professor at U of M. The talk was aided by slides and a short documentary film. A lively question and answer period was enjoyed by the large audience.

Yukon

Capt. J. P. MacGowan, M.E.I.C.
Correspondent

Howard Truman, resident engineer for the Department of Public Works at Dawson City, described the Flat Creek Road at the Branch's Nov. 26 meeting. Mr. Truman summarized the construction practices, techniques and intentions of the Flat Creek Road by the use of slides and tape-recorded interviews with the general foreman and other men. The Flat Creek Road starts near Dawson City and is planned to terminate at Eagle Plains. During the past two seasons, construction has proceeded to approximately Mile 62, Chapman Lake, with 35.5 miles being constructed during the 1960 season. Because of the scarcity of road building materials on the hillsides, initial plans have been revised and building is being done in the river valleys. This is particularly the case in the Blackstone River area where gravel fill material was obtained from the river bottom. An area of scenic grandeur and a potential oil reservoir will be opened by this road.

Engineers' Wives

The Engineers' Wives' Associations, Clubs and Auxiliaries are continuing their active programs from St. John's, Nfld., to Victoria. These programs, which include social and sports events, lectures and industrial tours, are a valuable part of the Branch activities. The following wives' groups have mapped comprehensive plans for the current season: Border Cities; Calgary; Cape Breton; Corner Brook, Edmonton; Halifax and Area; Hamilton; Kingston; Kitchener, Waterloo, Galt and Preston; Lakehead; Lethbridge; London; Moncton; Montreal; Niagara Peninsula; Nipissing and Upper Ottawa; Ottawa; Peterborough; Port Hope and Cobourg; Regina and Area; St. John's, Nfld., Sarnia; Saskatoon; Sault Ste. Marie; Toronto; Vancouver and Lower Mainland; Victoria; Winnipeg.

• DISCUSSION

(Continued from page 66)

points out the importance and urgency of continuing fishery research to resolve fish problems before the potential of economic power on non-fish rivers has been exhausted.

Discussion by G. Douglas Sauer, M.E.I.C.

Mr. Potter is to be complimented for his paper on a highly controversial subject — power vs. fish. His approach and conclusion — that the only answer is a choice between them — is somewhat novel and will no doubt arouse considerable discussion from both sides of the picture.

However, I believe there is still room for compromise and would like to suggest an approach to this.

Mr. Potter has noted that Moran Dam itself will not affect the Adams River run of Sockeye salmon, since it is located on the main stem of the Fraser above the confluence with the Thompson. As the Adams River run contributes by far the greatest percentage of Sockeyes, particularly during the so-called Adams River run, it is apparent that Moran would have little effect on the overall production of this valuable species of salmon.

It would therefore seem practical to proceed with further thoughts about Moran.

On the Columbia River at McNary Dam, an interesting experiment has been in process for the past three years and is still continuing. An artificial spawning station has been constructed downstream from the dam in an effort to explore the feasibility of diverting adult Chinook salmon from returning to their home spawning beds. Like the Sockeyes, the Chinooks are predominately a 4-year cycle fish, and it is not yet possible to determine the success of this experiment.

Many other experimental and research investigations have taken place in regard to determining the effect of stream blockage on migrant fish. One of the most interesting outlines is contained in the investigations at Baker Dam by the International Pacific Salmon Fisheries Commission by Messrs. J. A. R. Hamilton and F. J. Andrew in 1954. The results are quite devastating — about 63.5% of those which passed through the spillway over the dam and about 37% of those which went through the turbines were lost. The head is about 250 feet. The report also states that the subsequent reduction in catch

This large loss certainly suggests is roughly proportional to the mortality.
that the fisheries interests have a large stake in the problem of stream blocking by power or other interests.

On the other hand, the delay in development of the large hydro-electric power sites in these streams, particularly the more economical ones located relatively close to large load centers, is most frustrating and a wasting of a natural resource whose commercial value far outweighs that of the fish.

It is therefore recommended that the experimental work at McNary Dam be closely watched, and when possible, similar or related research be carried on or continued to achieve a compromise answer, rather than an aye or nay to the choice presented by Mr. Potter.

This need not delay Moran.

Discussion by J. H. Steede

I note that the figures you have used regarding the production of salmon from the Fraser River are taken from recent reports which include two very good years for the Adams River Run, at a time when salmon was bringing a very good price on the local market.

Your comments on the economic advantages of the large block of low-cost power which might be available if it should be feasible to dam the Fraser River are provocative.

We are watching with interest the efforts of the Canadian and American fisheries people to increase the productivity of barren streams below potential hydroelectric sites. If these experiments meet with the success which is hoped for, the whole economic picture of salmon production may be due for a change.

Author's reply

The time to construct the Moran Dam was calculated at five years. The financing was apparently going to be one of the easier phases even though over $42 million had to be included for interest during construction. The Company had plans worked out for a load of some two million horsepower when the plant was completed. This included exporting power to the United States. The Company believed it would be possible to arrange this with the Canadian Government although no agreements had been made.

Mr. McMordie points out the great amount of power available in the Columbia, Clearwater and Peace Rivers all unencumbered by fish.

These sources are all five mill to twelve mill power at the present load centre of British Columbia and not in the low cost primary power field that the Moran Development Company could reach.

The hope of the commentators seems to lie in fisheries research coming up with a solution. The development of artificial spawning beds below the dams at fish farms would appear to offer some hope. To the fisheries people this appears not as an alternative but as an adjunct to their resource.

With such a colossal amount of power at stake it would appear reasonable to be spending vast sums of money on research and experimentation to find the answers. The sums being spent are less than insignificant.

the synchrotron. Until it is completed the 6 smaller bubble chambers at Brookhaven will be used for AGS research.

This new Brookhaven synchrotron represents an important advance toward the long-range goal of world physicists—discovery of the ultimate indivisible piece of matter. This machine is expected to reveal new basic knowledge since it can probe more deeply than other accelerators. However, it may pose new problems, as its predecessors have, that will require more powerful accelerators. Plans for such machines are already being made in the United States and other countries. To aid in their development, Brookhaven physicists will reveal the results of their research and will cooperate with interested physicists in other countries.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*ELEMENTARE SCHALENSTATIK, 3rd. ed.

An introductory treatise on the statics of shells. Originally published as a textbook, the new edition has been enlarged and revised so as to be useful to the practicing engineer as well. After a brief explanation of the shell concept, the author discusses in detail the membrane theory of rotation shells, the bending theory of rotation shells, and specifically, the membrane theory of cylindrical shells. There are also notes on the states of stress and a tabular summary of membrane theory solutions for shells of various forms. (Alf. Pflüger. Berlin, Springer-Verlag, 1960. 112p., DM 19.50.)

*CONSTRUCTION CONTRACTING.

This book discusses the five basic management functions of organizing, staffing, directing, planning, and controlling, as they are applied to the conduct of a construction contracting business. Each area is developed from fundamentals. Typical topics covered are construction insurance, contract bonds, labor legislation, business forms, personnel and labor relations, fiscal records, safety, and bidding and estimating. (R. H. Clough. New York, Wiley, 1960. 382p., $9.75.)

*SYMPOSIUM ON AIR POLLUTION CONTROL

At the Third Pacific Area National Meeting of the ASTM in San Francisco, October, 1959, the following papers were presented and here are published:— Air pollution potential of California coastal climate; Wind and weather summaries for chemical plant design and air pollution control; Fluorescent dyes as airborne tracer materials; Colorimetric determination of formaldehyde and methanol from combustion source; determination of gaseous and particulate inorganic fluorides in the atmosphere. (Philadelphia, American Society for Testing Materials, 1960. 44p., $1.50. s.t.p. no. 281.)

*TRANSPORT PHENOMENA

An introduction to the field of transport phenomena for students of engineering and applied science. It is a parallel, systematic treatment of the three transport processes: momentum transport, or viscous flow; energy transport, or heat conduction, convection, and radiation; and mass transport, or diffusion. The media in which transport phenomena are occurring are regarded as continua, and very little is said about the molecular explanation of these processes, the continuum approach being considered by the authors as of more immediate interest to engineering students. (R. B. Bird and others. New York, Wiley, 1960. 780p., $13.75.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

*INDUSTRIAL ARCHITECTURE.

This book is an attempt to capture the essence of the modern factory. Particular emphasis has been placed on current practice in the U.S., Great Britain, and Germany. The four major types of industry — heavy, light, utility, and process — are analysed in terms of the various ways in which the units for each are enclosed, serviced, and operated. Also included is a study of industrial parks, estates and districts. The text is amply illustrated by photographs, line drawings and sketches. (J. F. Munce. New York, Dodge, 1960. 232p., $14.75.)

*MATERIALS IN NUCLEAR APPLICATIONS.

This volume contains papers presented at four symposia held during the Third Pacific Area National Meeting ASTM in San Francisco, October 1959, and a literature survey of the title subject — "Radiation effects in steels." The symposia fields are: radiation effects and dosimetry (14 papers); postirradiation effects in polymers (5 papers); technical developments in the handling and utilization of water and industrial waste water; industrial water for reactor use (2 papers); ceramics in nuclear energy (6 papers). (Philadelphia, American Society for Testing Materials, 1960. 344p., $8.25. s.t.p. no. 276.)

*SYMPOSIUM ON BITUMINOUS WATERPROOFING AND ROOFING MATERIALS.

Eight papers presented at the Third Pacific Area National Meeting of ASTM at San Francisco, October, 1959, plus a paper on weatherometer data on coating-grade asphalts from a June meeting in Atlantic City. Five of the eight papers cover aspects of manufacture, inspection, applications and service requirements of asphalt and coal tar materials; the remaining three are of specialized experimental or theoretical interest. (Philadelphia, American Society for Testing Materials, 1960. 81p., $2.50. s.t.p. no. 280.)

*PRINCIPLES OF GEOCHEMICAL PROSPECTING.

Hydrochemical, biogeochemical, and geobotanical methods of prospecting for the various kinds of ore deposits in igneous, metamorphic, and sedimentary rock, and in surficial (residual) blankets, are discussed, preceded by a history of the development and a generalized treatment of the principles of geochemical indicators. Two chapters are devoted to haloes and other anomalies in overburden and soils. There is a lengthy bibliography, mainly Russian publications. (I. I. Ginsburg. New York, Pergamon Press, 1960. 311p., $10.00.)

*FROM THEORY TO PRACTICE IN SOIL MECHANICS; SELECTIONS FROM THE WRITING OF KARL TERZAGHI.

A detailed account of the personality, professional achievements and method of working of Karl Terzaghi, composed mainly of his own words through selection from his writings, with some explanatory comment. Clearly demonstrated in this manner is the way in which he established the fundamental principles of soil mechanics and then used them as powerful tools in his engineering practice. Also included is a bibliography, and contributions describ-

ing his life, achievements, and their significance. (L. Bjerrum and others. New York, Wiley, 1960. 425p., $12.00.)

*KRANKHEITEN ELEKTRISCHER MASCHINEN, TRANSFORMATOREN UND APPARATE, 2nd. ed.

The need for collected information on electrical plant troubles has inspired this German treatise on causes, results, cure and prevention of faults and failures in heavy current machines, apparatus, and plant. The book covers installation and operational faults of electrical machines, transformers and auxiliary apparatus, with particular reference to the materials employed and the troubles directly resulting from them. (R. Spieser. Berlin, Springer-Verlag, 1960. 376p., DM 48.00.)

*GRUNDBAU-DYNAMIK.

A treatise on foundation dynamics intended both for the student in civil engineering and for the practicing or research engineer. After a general introduction, vibrating systems with concentrated masses are considered, introducing the civil engineer to the theory of forced oscillation. A chapter devoted to homogenous systems follows, and the final chapter goes into the fairly unknown area of the dynamics of soil. There is a bibliography of 115 German and English references. (Hans Lorenz. Berlin, Springer-Verlag, 1960. 308p., DM 46.50.)

*STATISTICAL THEORY AND METHODOLOGY IN SCIENCE AND ENGINEERING.

An elementary text involving simple college algebra and little calculus, with the balance between theory and practice weighed towards the understanding of principles. Topic selection for inclusion was made on the basis of the "interesting and useful", and length limitations imposed by the number of course hours available. Among those selected are binomial, multinomial, hypergeometric, Poisson, and bivarite normal distributions; variance analysis and tests; nonparametric tests; linear regression; hierarchial situations; and design of experiments. (K. A. Brownlee. New York, Wiley, 1960. 570p., $16.75.)

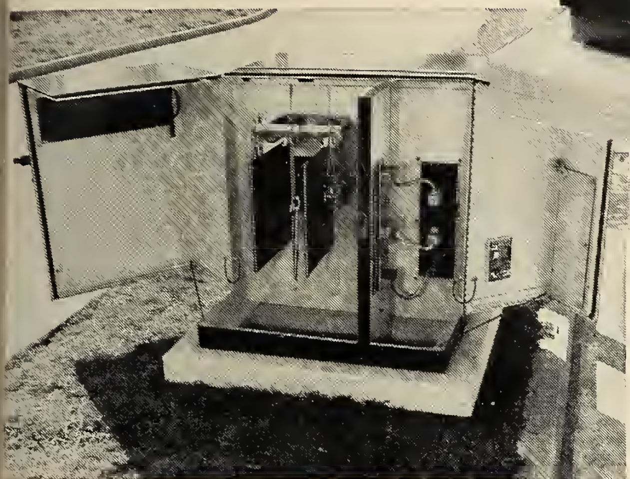
*COUPLED MODE AND PARAMETRIC ELECTRONICS.

This introduction to the theory of coupled modes shows how the use of the theory simplifies the study of coupled systems. From this point of view, it also presents a unified theory of travelling, wave tubes, backward wave oscillators, and similar microwave devices, and discusses the theory of parametric amplifiers, oscillators, and frequency converters. (W. H. Louissell. New York, Wiley, 1960. 268p., $11.50.)

*ELECTRICAL DESIGN DETAILS.

This book was developed as a quick and practical reference file of ideas for electrical design. The diagrammatic material, adapted from the magazine "Electrical Construction and Maintenance", represents all phases of electrical distribution and circuitry in industrial plants, commercial building including airports, tunnels, bridges, streets, and highways, and residential elements including private houses, farms, hotels and trailer parks. (J. F. McPartland and W. J. Novak. Toronto, McGraw-Hill, 1960. 231p., $9.75.)

For residential underground systems



- TAMPERPROOF but ACCESSIBLE
- COMPACT but SPACIOUS
- STANDARDIZED but VERSATILE
- QUIET and EFFICIENT

INSTITUTION OF STRUCTURAL ENGINEERS, FIFTIETH ANNIVERSARY CONFERENCE, 1958. PROCEEDINGS.

The Institution marked its golden jubilee by holding a conference, which covered the whole field of structural engineering, and was attended by delegates from all over the world.

There were ten technical sessions, at most of which four or five papers were discussed. The themes of the sessions were: the production of electric power; bridge design; composite construction, flat slabs and skin structures; various phases of structural engineering research; structural analysis; light-weight structures; precast concrete and lift slab construction; foundations and site engineering; airports and docks; mine structures, moving buildings; reinforced plastics, concrete testing, and structural engineering in the U.S. The discussion which took place on each paper is also included. (London, Institution of Structural Engineers, 1960. 404p., £5.)

***REINFORCED CONCRETE COLUMN TABLES.**

These tables have been specially prepared for practising structural engineers, architects, and designers. Special features include the extreme range of values for each column design, the wide range of rectangular column sizes, and the inclusion of values for eccentrically loaded columns both with reinforcing on all four faces and with extra reinforcing on the tension face alone. The tables are arranged in two groups — rectangular tied columns, covering 63 sizes, and spirally reinforced round columns, covering 12 sizes. (H. F. Fenlon. New York, Dodge, 1960. Various pagings, $15.00.)

ENGLISH-POLISH DICTIONARY OF BUILDING AND CIVIL ENGINEERING.

The dictionary contains over 37,000 British and American terms, with their Polish equivalents. The English terms have been taken from recent books, encyclopedias and periodicals, and cover engineering materials, architecture, town planning, all phases of civil engineering, hydraulic engineering, timber, and management. A list of English abbreviations is included, as is an index of Polish terms, keyed to the English terms, so that this volume can also be used as a Polish-English dictionary. (Ed. by A. Zboinski. Warsaw, Panstwowe Wydawnictwa Techniczne, 1959. 833p.)

ENGLISH-POLISH DICTIONARY OF MECHANICAL ENGINEERING.

There are over 38,000 technical terms in this dictionary, compiled from British and U.S. sources. The terms cover mechanics, metallurgy, foundry practice, welding, metal cutting, machine tools, automation, power, refrigeration, materials handling, transportation, missiles, etc. A list of common abbreviations is included, but there is no index of Polish terms, as there is in the previous dictionary. (Ed. by S. Czerni. Warsaw, Panstwowe Wydawnictwa Techniczne, 1960. 606p.)

NORTHERN ELECTRIC COMPANY LIMITED WINNING INSERT

The above illustration is a reduction, to a small scale, of the 4-page, 2-colour advertisement which fifty readers selected, from the viewpoints of ACCURACY-INFORMATION and ATTRACTION as the "best" in the October issue. The original advertisement, on pages 33, 34, 35 & 36 of the issue was printed in black and orange on heavy white stock.

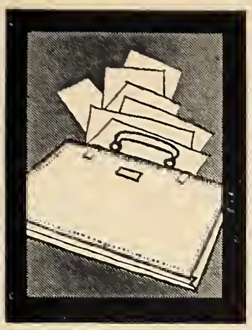
E.I.C. CERTIFICATE OF ADVERTISING MERIT

Northern Electric Company Limited has won the E.I.C. Certificate of Advertising Merit for the third time since the inauguration of the certificates in January 1959. The winning advertisement appeared in the October issue. It is a 4-page, two-colour, insert, black and orange, titled "OVERHEAD AND UNDERGROUND MATERIAL FOR COMMUNICATION AND POWER LINES DISTRIBUTED BY NORTHERN ELECTRIC".

The insert covers a variety of services and products made available to engineers through the company and lists some of the firms Northern Electric represents. The advertisement occupies pages 33, 34, 35 & 36.

Mr. E. H. Woodley is the Advertising Manager of Northern Electric Company Limited and the Montreal office of Foster Advertising Limited (Account Executive Frank Thompson) placed the business with us.

The selection, as usual, was made by 50 readers of The Engineering Journal who were asked to evaluate the advertisements in the issue from the viewpoints of ACCURACY-INFORMATION and ATTRACTION.



Business and Industrial Briefs

Appointments and Transfers

James N. Landis, Vice President of the Bechtel Corporation of San Francisco, has been elected President of the Engineers Joint Council, New York.

J. **Hector LeBlanc** has been named President of Freezmart Co. Ltd., Toronto. In addition to his new duties, he will continue to manage the packinghouse design division of the corporation. Bertrand **England** has been promoted from Senior Sales Engineer to Vice-President in charge of engineering, development and design.

The Canadian Fairbanks-Morse Co., Ltd., Montreal, have announced the appointment of **L. A. Weom** as Assistant to the President.

E. Jack Sheare, formerly General Manager of Taylor Instrument Companies of Canada Limited, has recently been elected President of the Company.

New appointments in the Chemicals Division of Canadian Industries Limited, Montreal, include the promotion of **Dr. R. W. Allgood** to Production Manager and **J. D. Crichton** as Specialty Chemicals Sales Manager.

The new Vice President of the Shell Oil Company of Canada, Limited is **Paul L. Kartzke.**

The appointments of **George Ditchfield** to the field sales staff of the Central Ontario District and **John E. Hales** to the Montreal District have been announced by Leland Electric Company Limited.

Canadian Ingersoll-Rand Co. Limited have appointed **George J. Prew** Manager, Merchandising Division with headquarters in Montreal.

The two companies Farrington Manufacturing Company Limited and Bradma of Canada Limited recently merged to form the organization now known as Farrington-Bradma Limited, Toronto. **V. B. Gale** is the Executive Vice President and General Manager of the new company.

The Canada Cement Company Limited have changed the address of their Toronto District Sales Office to The Manufacturer's Life Building, 200 Bloor St. E., Toronto 5.

K. W. Brown, who has been Vice President and General Manager of Avro Aircraft Limited during the past year, has returned to the Boeing Airplane Company in a senior executive capacity.

Dr. R. F. Knott has been appointed research manager of the explosives division of Canadian Industries Limited. He succeeds **Dr. J. F. C. Dixon** who is now technical manager of C-I-L's chemicals division.

A. C. Martinsen has been appointed Executive Vice President and General Manager of Catalytic Construction of Canada, Limited, Sarnia, Ont.

R. B. **Lanskail** has been appointed Manager, Technical Products Marketing, RCA Victor Company, Ltd. In his new position Mr. Lanskail will be based in Calgary.

Leon Simard succeeds the late J. Edouard Simard as a director of Sicard Inc., Montreal.

Developments

Information contained in this section has been obtained from press releases. Mention of products and services does not imply endorsement by the Institute.

HYDRAULIC RESEARCH in the United States, has been published for the United States National Bureau of Standards. This publication, the latest in a series of annual publications dating back to 1951, contains reports on hydraulic research conducted within the past year by various hydraulic and hydrologic laboratories in the United States and Canada. Nearly 200 subjects in the field are covered.

ULTRASONIC WELDING is the title of a new booklet published by the American Welding Society. It contains 38 pages and 29 illustrations and is designed to meet a growing demand for authoritative technical literature on new developments in the welding industry.

THE BOARD OF DIRECTORS of the Shawinigan Water and Power Company has declared a dividend of 20 cents a share on the no par value common shares of the Company for the quarter which ended September 30, payable November 25 to shareholders of record October 14. A quarterly dividend of 33⅓ cents a share also was declared on the Company's Class "A" common shares, payable November 15 to shareholders of record October 19.

ATLAS COPCO AB, of Stockholm, has announced the purchase of Svenska Diamantberg Borrnings AB, a company specializing in drilling operations for testing soil, rock strata, mines and ore deposits. Svenska Diamantberg, with headquarters in Stockholm is an international company with operations in many parts of the world. Atlas Corpo, the international firm of compressed air engineers with interests in 90 countries, manufactures rock drills, air compressors, mine loaders, pumps, hoists, pneumatic tools and similar equipment.

ULTRA-THIN stainless steel now is being bonded to a variety of back-up materials which can be used in anything from skyscrapers to a homemade shower stall. Stainless steel has been bonded to various materials in the past, but it has never been done in such light gauges. Costs are cut in some cases more than half by using the new product. Much of the secret of the success of the new product lies in the bonding agent.

TWO LIVE STEAM REHEATERS to be built by the Dominion Bridge Company Limited will be employed in Canada's first large scale nuclear power plant, now being built at Douglas Point on Lake Huron. The reactor-boiler produces saturated steam at 560 p.s.i. In order to reduce the moisture content of the steam in the late stages of the turbine the steam cycle equipment includes moisture separators and live steam reheaters between the high pressure and low pressure cylinders of the turbine. Because of limited application of live steam reheaters in central power plants anywhere, no precedents or standards were available to guide bidders.

TIRE NEGLECT costs Canadian truckers thousands of dollars a year and endangers the lives of drivers, warns the Canadian Highway Safety Council. The Rubber Association of Canada reports a major cause of premature tire failure is overloading. Although the weight placed on an automobile tire is important to the motorist, too, the heavier weights and greater variations of load on trucks makes overloading a much more serious problem for truckers.

A BOOKLET has been prepared by Imperial Oil Limited to put into proper perspective statements made about Canadian oil policy and about a major oil pipeline from Edmonton to Montreal. The booklet outlines what the company feels is a sound national oil policy — one which is in the best interests of all phases of this major industry — marketing, manufacturing, transportation and production.

A FURTHER PRICE REDUCTION in the price of copper has been announced by The International Nickel Company of Canada, Limited. The new price is 28.5 cents Canadian per pound delivered Toronto. Its price had been reduced Aug. 30 to 30 from 31 cents per pound.

A NEW PLANT to manufacture PETN, an explosive material with the chemical name "pentaerythritrol tetranitrate" has been completed by Canadian Industries Limited at its Beloeil, Que. works and now is in production. The $500,000 plant consists of two detached buildings somewhat resembling sod-covered pyramids.

SCREW THREAD STANDARDS have been given a common denominator of comparison in a volume published recently. More than 2,000 standards are listed. These cover the 33 countries which have National Standards for screw threads. There are 108 illustrations of screw thread forms, together with self-tapping screws.

ABSTRACTS have been published of 188 theses accepted for the Doctor's degree at the Massachusetts Institute of Technology in the 1958-59 academic year. The 288-page paper-bound book also lists the titles of theses presented for Engineer's and Master's degrees during the year.

PLASTIC BOATS primarily for export to the United States will be made by a subsidiary formed recently by Albin Motor AB, Sweden, large manufacturers of boat engines. The new plant is scheduled to go into operation early in the spring. Concentration in the first stage will be on building sailing craft with auxiliary engines.

AN ECONOMIC ATLAS of the Soviet Union has been published by the University of Michigan Press. The atlas, by George Kish, is the first of its type published in the Western world. Based on primary sources, the 60 colored maps picture the structure of Soviet economy in terms of its 15 major regions.

THE HEILAND DIVISION of Honeywell Controls Limited has introduced a low-cost direct recording oscillograph designed for use in normal laboratory testing and evaluation. Known as the 1406 Visicorder, the new model produces instantly readable records of up to six channels of scientific and test data simultaneously. It is the fourth member of the firm's Visicorder family of direct recording oscillographs. Previously introduced models have recording capacities of 14, 24 and 36 channels.

PROPERTIES, APPLICATIONS AND STORAGE of ultra-high purity gases are discussed in a new 16-page booklet offered by Union Carbide Canada Limited, Linde Gases Division. In addition to information about several gases the booklet contains charts and graphs showing the results of extensive testing including the areas of heat conductivity, excitation potentials, and discharge characteristics.

THE NEW LONDON WORKS of Northern Electric Company Limited were formally opened this autumn. The London Works will be an entirely self-contained manufacturing operation, producing telephone and outside plant apparatus all the way from raw materials to the finished product.

THE DIVISION OF BUILDING RESEARCH of the National Research Council has started a new series of mimeographed publications in order to make publicity available in finished form the results of its fire research work. The first of these studies describes the fire research furnaces that have been installed in the fire research building which was open for use in October, 1958. The furnaces were commissioned some time ago and now are in regular operation. They will be used primarily for research purposes, but since they are the only such furnaces in Canada a limited amount of actual test work for manufacturers also will be carried out.

CONSTRUCTION has started on a new, 40,000 sq. ft. plant near Toronto for Canadian Broomwade Ltd., specialists in the manufacture and distribution of compressed air and allied equipment. The parent company is Broom & Wade of High Wycombe, Buckinghamshire, England, established in 1898.

THE BRISTOL COMPANY now is offering a single-case time-program recorder-controller in its series 500 instrument line. The incorporation of the recorder and controller into a single unit affords a 50 per cent reduction in panel-space requirements.

A PRODUCTION LINE is being moved to Saskatchewan to facilitate building part of the South Saskatchewan Dam power project. At a cost of $250,000, Sparling Tank & Mfg. Co., of Oakville, Ont., is setting up a temporary shop to make penstock liners for the Coteau Creek electric power and irrigation project of the Saskatchewan Power Commission. The plant will be dismantled after the company contract has been filled late this year.

A SERIES OF split-body valves interchangeable on a "mix and match" basis with other valves and actuators it now produces, has been introduced by Honeywell Controls Limited. The company said the addition of the new valve as well as a cylinder actuator to its product line "makes possible an intermix of diaphragm and cylinder actuators with split bodies and globe bodies to match specific applications at the lowest possible combination price."

HIGH-PRECISION deep hole drilling by a revolutionary method has been introduced to Canada by Montreal Locomotive Works, Limited. MLW says it is the first and only heavy equipment manufacturer in Canada to use a tape-controlled automatic target drill. Company officials say the new installation offers outstanding advantages over the conventional method, the most important of which are precision, reliability and repeatability.

NODULAR IRON ROLLS (type 80-60-03) manufactured for the first time in Canada, are being supplied to two of Canada's major steel companies for their galvanizing lines. The rolls were made by Canada Iron Foundries, Ltd. Diameters in inches were 60, 48, 36, and 27, with widths from 58 in. to 72 in. The rolls are normalized and stress relived with a surface finish of 16 micro.

A NEW BULLETIN concerning air line oilers is available from Gardner-Denver Company. It gives operational and specification data on oilers with half pint to five gallon capacities. Bulletin LO-2 describes the company's various size oiler models and lists the data on care and operation of pipe lines, hoses and lubrication.

FASTER ASSEMBLY of structural steel, both in shop fabrication and field connections, is made possible by a new structural bolt now produced by the Steel Company of Canada, Limited. This bolt has been designated the Stelco Heavy Hex Structural (High-Strength) Bolt, conforming to A.S.T.M. Specification A 325.

TRIPLE CAPACITY of its iron ore recovery plant at Copper Cliff, Ont., will result from an expansion program announced by the International Nickel Company of Canada, Limited. Board Chairman Henry S. Wingate said that "using a process invented by the company's research staff and successfully established in its existing iron ore recovery unit, the expanded plant will treat 1,200,000 short tons per year of nickeliferous pyrrhotite high in iron content."

THE "CENTRI-PRIME" motorpump is the newest addition to Canadian Ingersoll-Rand's line of centrifugals. This unique pump combines the lifting capabilities of a self-priming pump and the high efficiency of a standard centrifugal pump. The "centri-prime" is a compact, single-stage, single-suction, centrifugal pump with a built-in positive displacement type priming unit.

IMPROVED PERFORMANCE and uprated capacity are featured in a new four-way solenoid controlled, pilot operated directional valve announced recently by Vickers-Sperry of Canada, Ltd., a division of Vickers Incorporated. Although price and envelope size have remained virtually the same, the valve's nominal capacity of 30 gpm is 50 per cent greater than that of previous models.

IMMEDIATE AVAILABILITY of 11 new, lighter-weight, wide flange steel sections has been announced by Bethlehem Steel Export Co., Canada. The new sections are the result of a continuing experimental and research program designed to provide the construction industry with better products.

TWO BLOWERS, each capable of delivering more than 8,000 c.f.m. at a pressure of 4 p.s.i.g., have been shipped recently to the British American Oil Company gas processing plant at Rimbey, Alta. They were the first blowers produced in Canada by James Howden & Co., of Canada Ltd., at the firm's plant in Scarborough, Ont.

A $500,000 Formation-Finishing plant for the Hart Battery Company Limited has been opened in suburban Toronto. Eventually the plant, which can be expanded to triple capacity, will not only finish and to store batteries, but also will manufacture the company's complete line from the automotive to the custom-made industrial battery.

UNION CARBIDE Canada Limited has opened its new head office building in Toronto. The 11-storey building is built in two sections with a main structure and an elevator tower in the rear. It will serve as head office for the company and its six divisions — Bakelite, Chemicals and Plastics, Consumer Products, Linde Gases, Metals and Carbon, and Visking.

THE 1960 SERIES of addresses on industrial relations has been published by the University of Michigan. This is a collection of 17 talks on personnel and industrial problems ranging in subjects from employee compensation to supervisory training.

THE 10TH EDITION, completely revised, of the Diesel Engineering Handbook, now is available. This is a comprehensive reference work on diesel, dual fuel, gas-burning engines, components, accessories and maintenance procedures. EIC

Beaver Bill says —

Dear Jim,

We were pleased to receive your letter last week and to hear the new job is going so well. You must find it different after the big city, but it's like meeting an old friend though, isn't it, to find a Branch of the Institute near at hand? Remember, Jim, wherever you are, the objects of the Institute are the same.

In a nut shell, the prime object of the Institute is to develop and maintain high standards in the engineering profession. It's there to advance the professional, social and economic welfare of our members, and to enhance the usefulness of the profession to the public.

The Institute makes it easier for members to acquire professional knowledge, and to exchange it. One way this is done is to work with universities and other educational institutions to advance engineering education.

Engineers should mingle with other professionals and with members of other technical societies—and the Institute helps here too.

Another point, and this is basic, is the encouragement of original research, and the study, development and conservation of Canada's resources.

Best of luck to you and the family. Write again soon.

Sincerely,

• LIBRARY NOTES

(Continued from page 102)

*PHOTOGRAMMETRY AND PHOTO-INTERPRETATION, 2ND. ED.

This is the second edition of "Aerial Photographs in Forestry," the title change indicating broadening of the scope to serve all who can use aerial photographs as a professional tool — geologists, soil scientists, botanists, geographers and engineers, as well as foresters. The five parts of the book discuss in detail aerial photographs, photogrammetry, mapping, photo-interpretation, and finally the special applications in forestry. (S. H. Spurr. New York, Ronald Press, 1960. 472p., $12.00.)

DESIGN AND CONSTRUCTION OF SANITARY AND STORM SEWERS.

The latest of the A.S.C.E. Manuals of Engineering Practice, this volume was prepared by a joint committee of the A.S.C.E. and the Water Pollution Control Federation. It covers all phases of the subject, commencing with a chapter on the organization and administration of sewer projects. Other topics covered are preliminary surveys, calculation of the quantities of sanitary sewage and storm water to be handled, hydraulics, special structures, design of sewer systems, structural requirements, materials, construction plans, specifications and methods, and sewage and storm water pumping stations. Useful bibliographies are included. (B. H. Swab, Committee Chairman. New York, American Society of Civil Engineers, 1960. 283p., $7.00.)

*DIGITAL COMPUTERS AND NUCLEAR REACTOR CALCULATIONS.

A primary objective of this book is to present to the nuclear engineer or scientist an introduction to high-speed nuclear-reactor calculations. One small reactor calculation is discussed thoroughly and a number of representative types of calculations is considered briefly. The first four chapters deal with an introduction to reactor problems, digital computers, programming, and numerical analysis, and the last four with considerations involved in actual reactor calculations. (W. C. Sangren. New York, Wiley, 1960. 208p., $8.50.)

*THE SURFACE CHEMISTRY OF METALS AND SEMI-CONDUCTORS.

This volume contains the papers presented at the 1959 symposium co-sponsored by the Electrochemical Society and the Office of Naval Research. Contributors from France, Germany, Australia and the U.S. are represented. All twenty-two papers are in English. The material is grouped in five parts — chemistry and physics of surfaces; imperfections and surface behaviour; electrode behaviour of metals and semiconductors; surface reactions in liquid media; and, surface reactions in gaseous media. (Ed. by H. C. Gatos, New York, Wiley, 1960. 526p., $12.50.)

*THERMOELECTRICITY.

Much of the material in this book is from the 1958 Conference on Thermoelectricity sponsored by the U.S. Naval Research Laboratory. Section two deals with basic parameters, examining the physics of the properties which determine thermoelectric performance and discussing thermal conduction and electronic transport in terms applicable to thermoelectric materials. Section three studies the chemical and physical properties of materials at high temperatures. Section four discusses the measurement of material properties, emphasizing high temperatures, and examining the relative merits of static and transient methods of measuring thermal conductivity. (Ed. by P. H. Egli. New York, Wiley, 1960. 407p., $10.00.)

CONTENTS

IN THIS ISSUE

Test Buildings in Building Research is discussed with authority by two executive staff engineers of the National Research Council's Division of Building Research. Dr. **Neil B. Hutcheon,** M.E.I.C., is Assistant Director of the Division in Ottawa. **G. O. Handegord,** M.E.I.C., is Officer in Charge of the Division's Prairie Regional Station. Both are Saskatchewan natives. Dr. Hutcheon was born in Rosetown and received his Bachelor's and Master's degrees from University of Saskatchewan and his Ph.D. from University of London. Mr. Handegord was raised in Regina. After receiving his B.Sc. in Mechanical Engineering from University of Saskatchewan he went on to University of Illinois where he earned his Master's degree. In their paper they point out that test buildings are by no means a consistently good approach in research into building problems. Certain phases of performance studies are investigated with profit by test buildings, but many difficulties are encountered.

William B. Rice, M.E.I.C., Associate Professor in the Department of Mechanical Engineering at Queen's University, presents the results of an experimental investigation in his paper, *The Formation of Continuous Chips in Metal Cutting.* Described is a mechanism, quite different from those assumed in the classical analyses, which was observed during orthogonal cutting. Mr. Rice obtained his B.Sc. from Sir George Williams College, Montreal, in 1950 and four years later received his B.Eng. from McGill. He earned post graduate degrees from McGill and l'Ecole Polytechnique in Montreal.

Carson Templeton, M.E.I.C., is the senior partner of a Winnipeg consulting engineering firm which conducted studies for a Royal Commission on Flood Cost Benefits. The Commission was established by the Manitoba government to assess which of a number of flood protection schemes proposed for the province were economically feasible. It is on that work that his paper, *Benefit-Cost Analysis of the Greater Winnipeg Floodway,* is based. Mr. Templeton, a graduate of University of Alberta, had extensive experience in similar work before establishing his own consulting firm in 1955.

A life line vital to the economic well-being of northern Ontario is being provided by a bridge which will link the twin cities of Sault Ste. Marie, Ont., with Sault Ste. Marie, Mich. *Sault Ste. Marie Bridge Design* is described with authority by **Carl H. Gronquist,** a partner in the New York consulting engineering firm of Steinman, Boynton, Gronquist and London. A native New Yorker, Mr. Gronquist received his graduate and post-graduate education in engineering at Rutgers University. He has extensive experience as a project engineer in charge of design and construction, and in charge of preliminary design and report on numerous bridges. In his paper, Mr. Gronquist deals not only with the design of the Sault Ste. Marie Bridge. He also puts the entire project in its proper perspective with details concerning need, history, geography and services.

Glacial-lake clay deposits in some areas of the Great Lakes were, at one time, up to 100 feet thicker than they now are. **G. T. Hughes,** M.E.I.C., explains this in his paper, *Glacial-Lake Deposits — the determination of their original depth in the Great Lakes region.* Mr. Hughes is an Associate Professor of Civil Engineering at the Royal Military College of Canada, Kingston. After graduating from University of Alberta where he obtained his M.Sc. in 1953 he taught at University of Saskatchewan. Mr. Hughes then worked in British Columbia for a firm of consulting engineers in soil mechanics and foundation engineering, and four years ago joined the R.M.C. staff.

H. R. Wright, M.E.I.C., points out that in most instances the cost of power in an industrial operation is not a major part of the total product cost. *Economic Aspects of Industrial Power Plants* deals with the alternatives of investing capital in a generating plant or of buying power from an outside source. Mr. Wright, a graduate of University of British Columbia, brings 29 years of experience to bear on the problem. He started as a design engineer on hydroelectric plant construction and now is Vice-President of Swanson Wright & Co., Engineers Ltd. — a consulting firm in Vancouver.

The purpose of *Trends in Electrical Engineering Education* is to collate some of the current trends in one place and under one title. **Dr. B. R. Myers,** M.E.I.C., has attempted to give the situation a useful perspective in guiding the engineering educator's thinking in matters of curriculum planning. Dr. Myers is Professor and Chairman, Department of Electrical Engineering, University of Waterloo. He previously was a member of the technical staff of Bell Telephone Laboratories, Inc., Murray Hill, N.J., and was with the Circuit Theory Research Group, Electrical Research Laboratory, University of Illinois.

Robert F. Legget, M.E.I.C., in his paper, *Early Ottawa and Engineering,* treats with nostalgia and admiration the emergence of an early construction camp to the bustling community of Bytown, and finally to the proud capital of Canada. Engineering played a vital role in the growth of Ottawa, and Mr. Legget expresses disappointment that some of these engineering landmarks soon may vanish. Mr. Legget earned an M.Sc. in Civil Engineering at University of Liverpool in 1925, and four years later came to Canada. After serving on the staff of Queen's University and University of Toronto he moved to Ottawa where he started the Division of Building Research of the National Research Council. He has been Division Director since 1947.

Beaver Bill appears this month on pages 98 and 134. **Stan Cassidy** has a membership reminder on page 118.

The raising of the flag marks the placing of the last beam in the thirty-four storey CIL House, at present Montreal's tallest building. The beam weighs two tons and is forty-two feet long.

Test Buildings in BUILDING RESEARCH

G. O. Handegord, M.E.I.C.,
Research Officer, Prairie Regional Station, Division of Building Research, National Research Council, Saskatoon.

N. B. Hutcheon, M.E.I.C.,
Assistant Director, Division of Building Research, National Research Council, Ottawa.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

THE USE of test buildings is by no means a consistently good approach in research into building problems. Test buildings may be useful for certain phases of performance studies, but as in most experiments, the difficulties in arriving at sound and useful conclusions increase with the number of variables introduced. The kinds of building research studies for which test buildings are most useful are discussed, and examples given. Test buildings used in various projects of the Division of Building Research are described.

Many people conceive a building research program as requiring full-scale test buildings, specially designed and instrumented for experimental purposes. In the housing field particularly, the concept of the "research house" appeals to the layman. He is likely to regard this as being at once the minimum and the maximum experiment required to prove a point. He is unlikely to differentiate between the use of an individual house, incorporating a variety of new materials and ideas, and the more realistic use of groups of houses incorporating certain specific variations. The common view appears to be that investigation of actual houses under actual conditions is a useful method of obtaining practical answers in a short period of time.

The scientist has never found this approach fully acceptable, preferring to conduct laboratory experiments under controlled conditions, followed by field application and observation. This apparent obsession of the scientist with controlled experiment is often difficult for the layman to understand, particularly in such a practical field as building. This paper suggests reasons for this attitude and discusses the philosophy of test buildings on the basis of experience gained in the building research field over the past ten years. Particular reference will be made to the Canadian use of test buildings and to the approach followed by the Division of Building Research of the National Research Council in the use of small test huts.

Tests on Full-Scale Houses

A full-scale house is, by itself, a complex arrangement of materials and components that can be described accurately only by means of a set of fairly detailed plans and specifications. The possible differences that may exist between houses, in materials, structural details, window arrangements, over-all shape and size, to name but a few variables, are almost without limit. Some of these differences may have little or no influence on the particular performance features to be investigated, but even if some factors can be ruled out on this basis, the number of features having possible influence on the result to be studied will still be large.

The variables inherent in house construction are only part of the problem; the complex effects of the exterior environment must also be considered. Wind, temperature, humidity, radiation, precipitation, and other factors that make up the weather, are all uncontrolled variables, acting sometimes separately and sometimes in combination. Some features of house performance may be related to one particular factor, but more often the combined effects of two or three factors are significant. Daily average values of outside temperature, for example, may represent a primary variable in one instance, but if freeze-thaw action is involved the related fluctuations of temperature and solar radiation become important. On the one hand the transient behaviour of weather factors may affect performance; in other cases the cyclical aspects over longer time intervals may be the important influence. Even annual weather cycles may change significantly at any one location, requiring a study to be continued over a period of several years. The weather thus not only increases the number of variables involved, but may introduce a time factor which requires the duration of studies on actual buildings extended to cover long periods, with corresponding increased cost.

There is yet another characteristic of full-scale house testing that complicates the situation, the question of occupancy. Occupants are normally necessary, both to simulate the actual case and for economic reasons. Although it is conceivable that the influence of the occupants on the interior environment could be duplicated artificially for certain studies, to do so in all other respects would be difficult and costly. Certainly from the economic point of view, the use of unoccupied houses in large numbers can seldom be justified. In any case, the variables introduced must still be contended with and in the majority of cases using real occupants, the differences between the various families involved must be recognized.

Two examples will serve to illustrate the marked influence which differences in the habits of occupants can have on studies in actual houses. An attempt to compare the summer comfort conditions in two occupied houses of widely different constructions failed because the differences attributable to the houses themselves were effectively masked by the uncontrolled opening and closing of

Fig. 1. Early test hut in Norway.

windows. In another case two houses were fitted with aluminum windows and frames on an experimental basis and were to be observed over one winter. The tenants in one house reported no difficulties with the windows. They did, however, ventilate the house extensively by opening windows, and dried all washing outdoors, so that the indoor humidity in winter was so low as to cause no condensation on the aluminum frames. The tenants in the second house said the windows were satisfactory but on examination after a period of cold weather a coating of as much as one inch of ice had accumulated on the warm side of the window sills, a condition that would have been quite unacceptable to many tenants. These tenants never opened windows in winter and dried washing indoors, thus maintaining a high moisture condition in the house.

Very few planned, large-scale house performance studies have been carried out in Canada. There have been, and probably will continue to be, studies on groups of a few "experimental" houses designed to demonstrate or evaluate some specific characteristics, but the results from such experiments are often of limited value. This approach was tried initially by the Division of Building Research in its early formative years, before its laboratory and other research facilities were available.

Two similar houses were built in 1947 at the Montreal Road site, as part of a staff rental housing program. These houses incorporated a variety of new materials and equipment, as well as involving one or two departures from conventional structural features. The observations made and the reports of the tenants were interesting and informative, but any conclusions that could be drawn had very limited application. Many of the features could have been studied to greater advantage in the laboratory had such facilities been available at the time. Perhaps the most significant results were to be found in the experience gained by the research workers involved.

On rare occasions an opportunity is provided in which the number of variables within a group of buildings may be reduced so as to make possible a designed experiment with a small number of samples. When such situations are recognized by interested people, useful results may be obtained with a minimum of expense. A notable example in Canada was the work of F. L. Lawton at Arvida, Quebec, in 1930 to 1935.[1, 2] The main study conducted by Lawton involved eight houses of identical plan and construction in which different insulation arrangements were employed. The houses were electrically heated, with the energy input metered accurately; the householders were co-operative to the extent of maintaining records of interior conditions. The nature of the experiment permitted the author to draw some fairly definite conclusions regarding the comparative thermal performance of the houses and to relate these to previous, less complete, investigations in a roughly quantitative manner. Even with close similarities within a group of houses, however, there were still many variable factors to complicate the analysis.

Fig. 2. Outdoor test station at Saskatoon showing the service building, six wood-frame test huts constructed over a service tunnel, and a standard hut on the left.

The need for statistically sound evidence from a large number of houses, under the wide range of climatic conditions and with the large number of variables to be contended with, is normally recognized by manufacturers of building products. Development departments in such organizations are continually producing new materials that must be tested to determine their suitability for use in houses across Canada. These products are tried out on a field basis in as many cases as the manufacturer can afford. When their performance has been tentatively established, they are released for sale. They therefore come to be used in a large number of houses across the country with their expected performance being confirmed or questioned through the medium of reports to the supplier. The manufacturer inevitably experiments to some degree with his customers in this way, using the information he gains to improve the performance of his product in future production.

This is the only economic method that he can utilize for no matter how much money is available for testing, it is not enough to enable him to cover all conditions to which his product will be exposed. The manufacturer's problem is really the same as the research worker's problem — he must do what it is possible to do, having in mind the requirements of the situation. The manufacturer, like the researcher, utilizes the scientific method. Observations of the performance of the product, isolation of the factors causing the effect, the development of hypothesis explaining the effect, and subsequent testing to confirm the hypothesis, summarises the procedure followed. The objective is the accurate prediction of performance, achieved through synthesis of the available information and experience.

The Use of Small Test Huts

Apart from the broad, all-inclusive field observation approach used by the manufacturer and the costly, planned statistical study of groups of experimental houses, there is another research technique that has been used with considerable success. This method involves the use of small, simple test buildings exposed to actual weather conditions. It has been used occasionally in studies of the thermal and moisture performance of building sections in North America and in the Scandinavian countries.

The first use of small test buildings for thermal studies on walls occurred in Canada in the period from 1920 to 1925, and in Norway at about the same time. Professor A. R. Greig, at the University of Saskatchewan in Saskatoon[3] compared the heating requirements of several huts of identical size, constructed of different materials. Initial measurements of electrical heat input were made, with interior conditions under manual control, but the following year automatic control was utilized. Because of the simplicity of the hut construction, not only were relative thermal values obtained but reasonable estimates of thermal coefficients of walls were possible.

Dr. Andreas Bugge[4] utilized the same basic approach at Trondheim, Norway (Fig. 1), with over 27 test huts of different construction. He later employed a technique similar in principle to the guarded hot box, which permitted the evaluation of the thermal properties of individual walls or roofs in these test structures.

Small test huts have the obvious advantage over full-scale test buildings of low cost, permitting a much larger number of units to be considered in an experiment. They need not conform to any particular shape or configuration, and may be as simple in construction as is possible while still in keeping with the design of the experiment. The variables associated with occupancy are eliminated and the restrictions imposed by the safety and health requirements of building codes are not applicable. Changes in construction features are more readily made to suit the changing demands of the experiment. Simpler structures permit simpler instrumentation. Measurement of mass and energy flow are more readily obtained and can be more easily analyzed than in complex, occupied buildings. Simpler, standardized shapes may considerably reduce the complications associated with wind and other weather phenomena.

Studies involving variations in construction, where the behaviour of individual panels under predictable exposure conditions alone is of interest, may be adequately handled in multi-panel test buildings. The test building in this case can be a simple single structure with exterior walls, roof, or floor, made up of different components or combinations of materials. The various panels are subjected to the same indoor and outdoor environment when similarly orientated and direct comparison becomes possible. Certain advantages of the "separate hut" approach in the heat and moisture flow aspect are lost, but a great deal is gained by the ease of panel removal for observation and measurement. The multiple panel test building has been used very successfully in the United States, notably at Pennsylvania State College and at the National Bureau of Standards. The method has particular advantages in the moisture performance field, representing a materials exposure approach, the test building serving only as an enclosure in which representative conditions may be maintained.

The smaller test huts are not without their disadvantages and limitations. Important characteristics of the simulated full-scale buildings are lost in size reduction. Aerodynamic simulation is impossible under actual conditions and over-all thermal and moisture storage capacity cannot be duplicated. In many fields the small test building is entirely unsuitable, such as in heating system performance studies, structural testing, foundation performance, and architectural planning, to name a few. In the materials field, however, particularly in the performance of building enclosures, the test hut has great potential, the basic problems with the method being in the selection of exposure conditions, internal and external, and in the instrumentation and processing of results.

The Use of Test Huts by the Division of Building Research

Test huts for studies in the field of thermal performance of walls were first erected by the Division of Building Research in 1950 in Ottawa and Saskatoon. At that time the Division had no laboratory facilities for thermal testing of walls and there was need for some information on the performance of newly developed materials and wall designs. In Ontario, insulated masonry construction was being proposed, and in the Prairie Provinces various new types of insulation and insulation arrangement for wood-frame construction were being introduced.

Preliminary planning for a test hut installation had been underway at Saskatoon by the University of Saskatchewan. This work led to the establishment of the Prairie Regional Station of the Division in Saskatoon, and the design and construction of an Outdoor Test Station on the campus of the university there (Fig. 2). This outdoor test facility provided an underground tunnel to permit access to six individual test huts from below (Fig. 3).

The thinking of the Saskatoon group influenced the design of the huts in Ottawa in so far as instrumentation and basic design were concerned. The huts were heated electrically to maintain constant interior air temperatures, with air circulation maintained using a fan. Initially, control of temperature only was employed, but in subsequent studies controlled humidification was added. In all cases the total energy input was measured on a daily basis and became the primary parameter of performance.

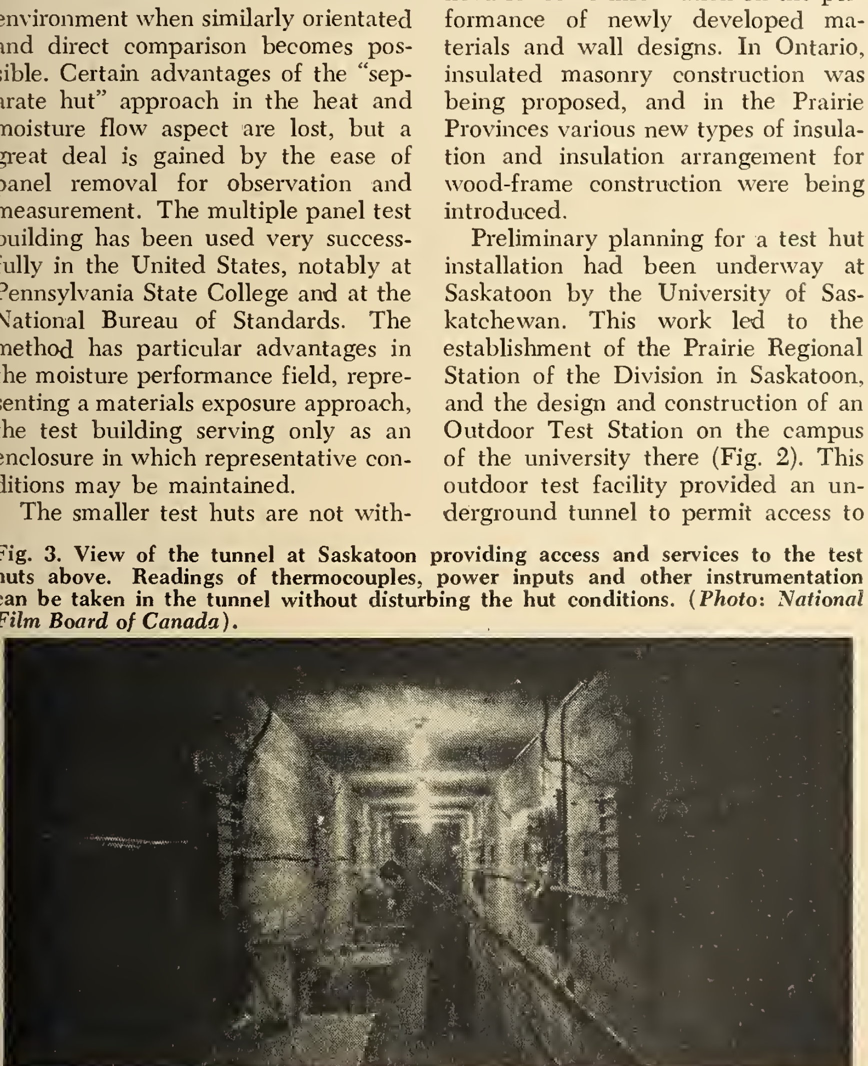
The Ottawa huts, involving unit masonry walls and incorporating variations having more significance from the moisture point of view, came to be regarded with somewhat different emphasis than those in Saskatoon. The influence of rain water absorption by masonry, coupled with the temperature-induced migration of moisture, led to studies which overshadowed the original relative thermal performance concept. Ottawa huts came to be regarded, quite naturally, as providing a means for exposure of walls to climatic conditions of Central Canada.

The Saskatoon installation had been specifically designed for thermal performance studies of variously insulated wood-frame walls. It had been anticipated that, in addition to overall thermal comparison between huts, correlations between heating requirements per unit temperature difference and wind velocity, as well as solar radiation, would be attempted. The north and south walls of each hut were also well instrumented for temperature and moisture content measurement in preparation for studies of transient conditions and solar radiation effects.

Enthusiasm for the test hut approach within the Division led to another development, that of using a "standard hut" as a type of calorimeter to be used in establishing climatic differences between various regions (Fig. 4). The thought was that the heat input to the test hut would be a measure of the combined effects of wind, outside temperature and solar gain on a small structure and, as such, would be indicative of the heating requirements for a particular area. Four such standard huts were erected, one at Saskatoon, Fort Churchill, Manitoba, Ottawa and State College, Pennsylvania. These huts were of insulated frame construction raised above grade level on a light metal stand, and heated electrically to maintain a constant inside air temperature (Figs. 2 and 4).

A useful comparison of the huts at Fort Churchill and Saskatoon was

Fig. 3. View of the tunnel at Saskatoon providing access and services to the test huts above. Readings of thermocouples, power inputs and other instrumentation can be taken in the tunnel without disturbing the hut conditions. (*Photo: National Film Board of Canada*).



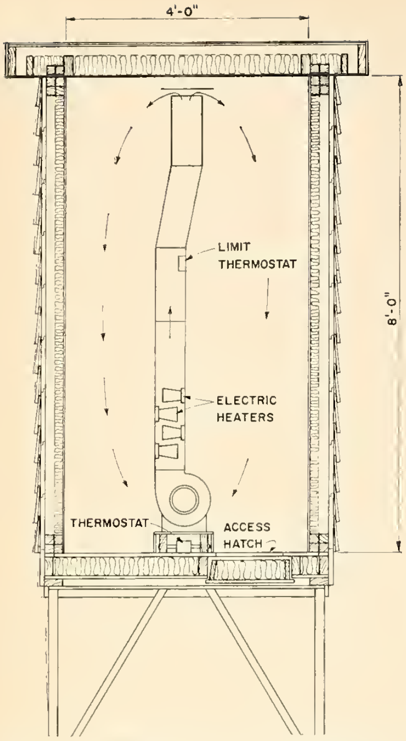


Fig. 4. Cross-section of the standard hut of the type exposed at Saskatoon, Churchill, Pennsylvania State College, and Ottawa.

made during the first year of operation in 1951, and interest was stimulated by the correlation found of heat input with wind velocity. A similar analysis of records from the six Saskatoon huts was undertaken but yielded rather disturbing results. It became apparent that the Saskatoon-Churchill hut agreement was largely fortuitous, and that the effects of variable air leakage between huts made useful comparison quite difficult. Correlation of daily heating requirements with wind velocity showed not only discrepancies between huts, but for the same hut from season to season. Disturbing though this was, the magnitude of the effect on average seasonal values for the individual huts was small.

Attempts were made to determine the air leakage characteristics of the huts directly, using a pressurization technique, and later employing tracer gas methods. These tests, admittedly incomplete, failed to establish any definite relation between measured leakage and heat input versus wind characteristics. It could be concluded only that the leakage of the individual huts changed with time and resulted in a thermal loss dependent on wind direction, velocity, and temperature difference.

The gradual development of laboratory facilities for steady-state thermal studies on built-up wall sections, both in Saskatoon and Ottawa, brought the test hut approach into new perspective. At best, it appeared that the hut technique offered only relative evaluation of wall thermal properties, and this only after a considerable time. A proper average value was obtained only after one year's operation; verification might require one to two more years of operation. It thus became clear to those concerned that the huts were of value in two particular fields:

(1) Studies of the performance of components under weather conditions that could not be easily reproduced or defined in the laboratory; and

(2) Performance studies involving periodic effects, dependent as to source and cycle on natural weather conditions and seasonal frequency.

These principles guided subsequent work at the two test locations. Studies at Saskatoon concentrated on the thermal effects produced by natural ventilation of the wall cavity. The investigations in Ottawa, concerned with cyclical effects, were concentrated on the summer-winter moisture migration reversal in insulated masonry construction.

Discussion

Test buildings for use in building research may range from existing structures, built for the usual purposes without thought for research, to small simple enclosures designed for the exposure to the weather, of building materials or components. Between these two extremes there may be individual houses of unique design, groups of buildings having certain similarities, intentional or unintentional, full-scale houses differing in some singular predetermined respect, or unoccupied huts designed to obtain information on one particular aspect of performance. The main difference in each case lies in the number of variables essential in evaluating the results obtained.

The vast number of existing houses that have been built in recent years provide a statistical "population" which can be "sampled" to obtain information describing the conditions of exposure of building materials and components. Records of temperature and humidity conditions indoors, fuel consumption, and foundation measurements can usually be accumulated with simple instrumentation and with the co-operation of the homeowner. In some cases, more detailed observations can be made. This information, obtained on an organized basis, can be used to define the conditions or to determine procedures for studies with small test buildings so that they may simulate the actual cases. Significant results can then be obtained with only a limited number of samples.

The utilization of these two types of "test" buildings, complementing each other, relegates the use of full-scale experimental houses to a few special cases only. It is indeed fortunate that this possibility exists, for the limited-number, full-scale experimental-house approach exhibits the disadvantages of both extremes. Almost as many of the primary variables as are involved in actual houses must be accounted for with only a token number of samples. The instrumentation and analytical techniques must be far more complex than with small-scale huts. Much more careful and extensive experimental design procedures must be followed, with little chance of subsequent changes being made except at considerable cost.

The concept of using actual buildings in conjunction with small test buildings and laboratory studies is not new, since the three progressive steps — from laboratory to pilot scale to full scale—have long been recognized as desirable in the development of industrial processes. The application to buildings is not, however, always so straightforward as in industry because of the number and complexity of the variables entering into the full-scale building situation, thus complicating the full-scale experiment.

Information relating to actual exposure conditions and to the performance of materials may be discovered either by design or by accident, in both actual buildings and in test structures. In the latter case, certain unexpected factors come to light more frequently because of concentrated and repeated observation, but information obtained through reports of problems from the field are still of great value.

Contrary to popular view, an experimental building is not always particularly useful in building research. For some purposes a building may represent but a single case from which little can be learned. In certain other cases a complete building may be the most suitable means for establishing realistically the conditions desired for study, but will seldom provide by itself an entirely satisfactory basis for experiment. Most problems can at some stage be handled best in the laboratory. There is a continuing challenge in building research to learn how best to combine laboratory and full-scale experiments in the solution of particular building problems.

THE FORMATION OF
Continuous Chips in Metal Cutting

Results of experimental investigations into the formation of continuous chips in metal cutting are presented. Observation of these chips using high speed photography is also described.

W. B. Rice, M.E.I.C.,

Associate Professor, Department of Mechanical Engineering, Queen's University, Kingston, Ontario.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

CLASSICAL ANALYSES of chip formation are based on the assumption that a continuous chip is formed by a process of simple shear.[1, 2] In general the results of these analyses cannot be justified experimentally.[3, 4] The suspicion that the assumption of a process of simple shear represented an oversimplification prompted the experimental investigation reported here.

The results showed clearly that, in general, the process is quite different from that usually assumed. Further, the mechanism of chip formation observed provides an explanation for two important phenomena which could not be satisfactorily explained in terms of a process of simple shear. These phenomena are:

Chip curl, and
Cratering wear.

Orthogonal Cutting: The investigation was limited to the case of orthogonal cutting, that is, to the case of a straight-edged cutting tool moving relative to the workpiece in a direction perpendicular to the cutting edge. Experiments disclosed that the lateral flow is negligible. That is, the process is essentially two-dimensional. It is emphasized that the chip is not peeled off, as the chip thickness is usually greater than the depth of cut.

Chip Classification—Ernst

Ernst[5] described three fundamental types of chip which he observed in orthogonal cutting. Shown above, they are:

- Type 1—Discontinuous;
- Type 2—Continuous (ribbon-like);
- Type 3—Continuous with built-up edge. That is, with a more-or-less stable deposit of workpiece material on the tool tip.

The author is responsible for the extra designation "ribbon-like" for the Type 2 chip. The reasons are presented below.

Classical analyses of Chip Formation

Merchant[1] proceeded to a mathematical analysis of the mechanics of formation of the Type 2 chip. He assumed that the process was one of simple shear characterized by a shear plane extending from the tool tip to the intersection of the free surfaces of the chip and workpiece. To illustrate the process Merchant devised a simple model, the progressive displacement of cards in a stack. As shown in Fig. 2 the cards are inclined at an angle, ϕ, called the shear angle, to the workpiece surface.

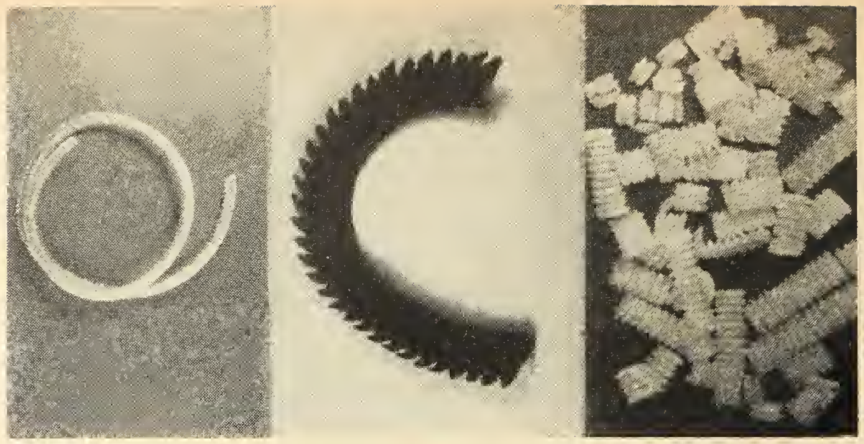

Fig. 4. "Segmented" Continuous Chips — Aluminum, Steel, and Wax.

Using this model, and invoking the minimum energy principle, Merchant obtained an expession for the shear angle in terms of

α = the rake angle

β = the *nominal* friction angle at the tool-chip interface, and

τ = the *nominal* shear stress on the shear plane

namely $\phi = (\pi/4) - (\beta/2) + (\alpha/2)$

Lee and Shaffer[2] argued that the solution for the shear angle is found in the configuration which gives:

1. Minimum machining force, *and*
2. Satisfactory stress distribution. Stresses induced within the chip are considered *satisfactory* as long as the yield stress is not exceeded.

The analysis is based on the assumption that the process may be represented by a *particular*, extremely simple, uniform stress field.

They concluded that Merchant's expression for ϕ is satisfactory when the rake angle α is greater than the friction angle β; but that in the reverse situation, which is more common

$$\phi = (\pi/4) - \beta + \alpha$$

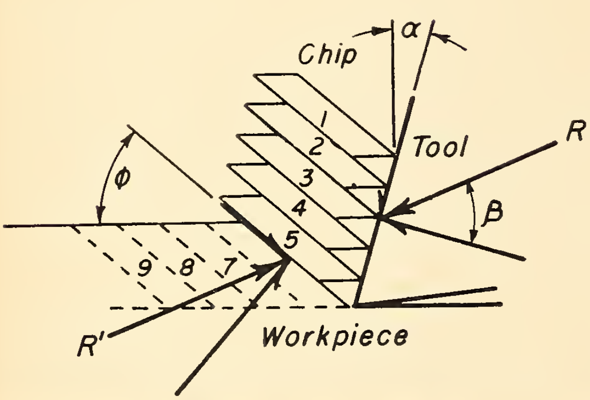

Fig. 2. (left) Schematic Representation of Cutting Process — Merchant.

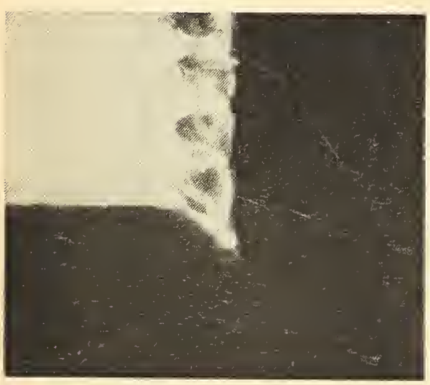
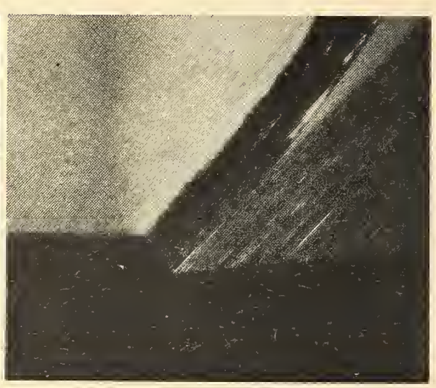


α = 0 degrees



α = 45 degrees

Fig. 3. (below) "Segmented" and "Ribbon-like" Continuous Chips.

They recognized that for small values of α or large values of β, ϕ could be zero or negative — an impossibility. They noted that under these conditions a built-up-edge may be observed. For these conditions they assumed that *another* simple stress field represents the process, and deduced the expression

$$\phi = (\pi/4) - \beta + \alpha + \Theta$$

where Θ is a measure of the built-up edge.

Experimental Results

The fact that in general these expressions cannot be substantiated experimentally led to the suspicion that the classical model represented an over-simplification, and prompted the experimental investigation utilizing high-speed photography as the major research tool.

The workpiece was specially extruded 26 ST Aluminum, and the tools were 18:4:1 high speed steel.

Ribbon-like and Segmented Continuous Chips: As shown in Fig 3, two types of *continuous* chips were observed. These were the Type 2 chip of the classical analyses, herein designated "Ribbon-like" to distinguish it from a new type of continuous chip consisting of definite segments firmly attached together, hence designated "Segmented".

Fig. 4 consists of photos of continuous segmented aluminum, steel and wax chips. The similarity of chips despite the dissimilarity of materials indicates the generality of the conclusions drawn from the data for 26 ST Aluminum.

Segmented Chip Formation: Fig. 5 illustrates the mode of segment formation.

Each segment was formed in less than .0004 second. Thus with the apparatus available, it was impossible to obtain a sequence of pictures of the same segment at various stages in its development. However, pictures were taken under the same conditions: their similarity justifies their use and necessitates this remark.

Fig. 5(b) is a sketch derived from the photographs of Fig. 5(a) to facilitate the explanation of segmented chip formation.

1) The material is compressed in front of the tool, bulging upward, as shown at the left of Fig. 5(b), until rupture occurs.

2) Rupture occurs when the slip-line field has the appropriate configuration. That is, it occurs when a) the direction of the maximum shearing *stress*, b) the direction of the minimum area subjected to shearing stress, and c) the direction of minimum shearing *strength* of the material are optimum.

3) As the segment is being displaced along the rupture surface, the formation of the next segment begins.

4) Subsequently, the newly formed segment, and the rest of the chip, consisting of previously formed segments, are forced upwards by the bulging of the material of the segment being formed.

Transition from Segmented to Ribbon-like: For smaller values of rake angle, the chips are segmented whereas for larger values they are ribbon-like.

The upper part of Fig. 6 illustrates the fact that the frictional force necessary to prevent a wedge from moving up an inclined surface increases as the incline decreases, that is, as the angle α increases. At the same time the normal force between the wedge and the inclined surface decreases, and consequently the frictional force decreases, and, eventually, the wedge will slip.

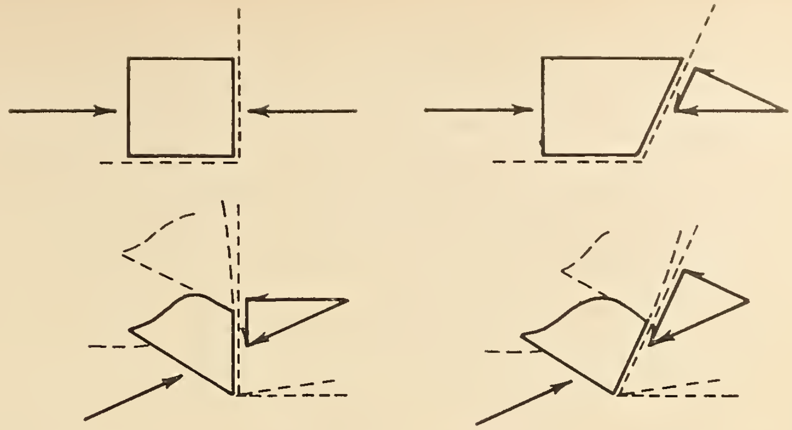


Fig. 6. Illustration of Effect of Rake Angle Upon Frictional Force.

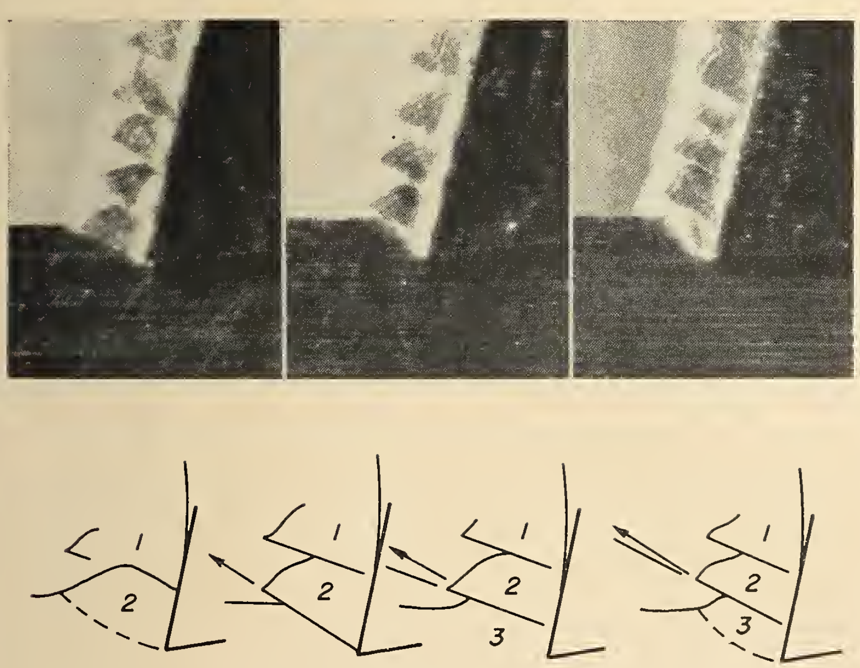
The lower part of Fig. 6 illustrates comparable conditions in chip formation. Therefore it is not surprising that at large rake angles the chip is radically different from that obtained at smaller rake angles. Thus, it appears that the ribbon-like or Type 2 chip is a limiting case of the segmented.

Fig. 5. Illustration of "Segment" Formation in a "Segmented" Chip. Material — 26S Aluminum; rake angle — 14½°; cutting speed — 228 f.p.m.; feed — 0.018 in. per revolution; chip width — 0.125 in.



Explanation of Chip-Curl Phenomena

In interrupted cutting under steady state conditions a sequence of similar spiral chips is produced. The chips are tightly curled at the beginning of the chips, and become less curled eventually reaching a more-or-less uniform curvature.

Hahn[6] conducted an ingenious experimental investigation of this transient chip-curl phenomenon. A tube was cut orthogonally as shown in Fig. 7. The cylinder was advanced when the tool was opposite the "window" and retracted when the tool was again opposite the "window". Thus only one uniformly deep cut was made in one revolution of the cylinder.

In order to get a comparison between chips which were formed at the beginning of cutting and those which were formed when equilibrium was established, an interruption in the form of a narrow strip of workpiece material was inserted in the cylinder approximately 20% of the distance from the "start".

A variable reluctance type dynamometer was used to detect tool forces. The data obtained from a tool-work thermocouple were considered as representative of the tool-chip interface temperature.

He discovered the same spiralling effect in both chips.

He rejected interface temperature as a controlling factor because the distance necessary to establish temperature equilibrium was small compared to that necessary for chip-curl equilibrium. He also rejected the effect of built-up-edge in that there was evidence of it in the first chip only after temperature equilibrium was established, but there was evidence of it throughout the *whole* of the second chip. There was no change

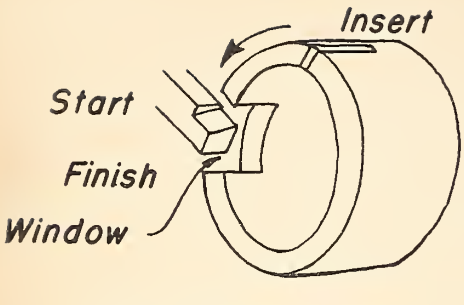


Fig. 7. Chip Curvature—Hahn.

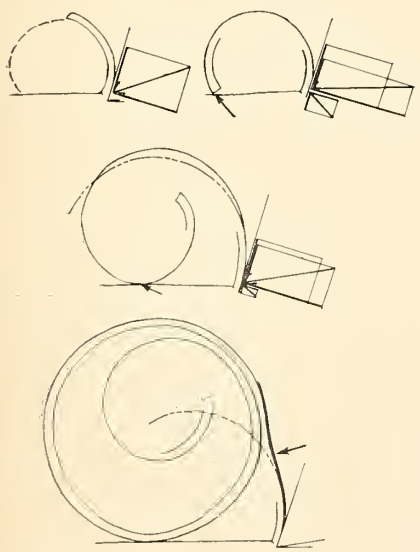
in temperature or tool forces at the insert yet the spiralling effect was the same in both chips. This led Hahn to conclude that the chip-curl phenomena are associated with the shear region, or as he so aptly phrased it, the chip is "born curled".

The mechanism of chip formation described in this paper provides an explanation of: 1) why the chip is "born curled", and 2) why successive coils are similar.

1) From the schematic representation of segmented chip formation, Fig. 5(a), it is evident that the plastic deformation of the segment being formed rotates the previous segment counterclockwise imparting curvature to the chip. Thus, the chip is "born curled".

When the tool face is limited to a fraction of the depth of cut as shown in Fig. 8 the bulging of the segment being formed rotates the previous segment clockwise and the chip is curled in the opposite direction. The length of the tool face shown is extremely small, approximately equal to the width of the letters on this page.

Fig. 9. Illustration of Formation of Chip Coil.



2) In the case of orthogonal cutting the chip eventually comes into contact with the surface of the work, as shown in Fig. 9(b), causing the chip to bend, and consequently changing the curvature by:

a) Permanently deforming the chip which is at a high temperature and hence susceptible to permanent set; or by

b) Changing the pressure distribution at the tool-chip interface, thus changing the frictional force, and hence the mode of chip formation. Evidence of the latter phenomenon is shown in Fig. 10 where ribbon-like sections occur in an otherwise segmented chip.

Fig. 9 illustrates the probable action during formation of a coil.

The force due to the interference between the chip and the workpiece causes a reduction in the frictional force (as does an increase in the rake angle). As a result a ribbon-like section is produced. Almost immediately the chip assumes the configuration of Fig. 9(c) causing an increase in the frictional force, and as a result a reversion to segmented chip formation. When the chip assumes a configuration similar to that shown in Fig. 9(d), the radius of curvature as the chip is "born" is as shown by the broken line (- . -). The forces on the coil cause the chip to bend in the region indicated by the arrow, eventually causing the chip to snarl or break. Then the process is repeated. It is therefore not surprising that successive coils are similar.

Explanation of Cratering Wear

A characteristic of tool wear is the development of a crater which starts at some distance from the tool tip, and grows, weakening the tool until the tool tip breaks off.

This phenomenon may be explained in terms of the segment formation illustrated schematically in Fig. 5(b).

Just prior to rupture there appears to be no *sliding* of the segment being formed relative to the tool face. The friction in the region of the tool tip is *static*. The previously formed segment **does** move relative to the tool face at some distance from the tool tip. The friction in that region is *dynamic*. At rupture the friction is wholly dynamic. It is therefore apparent that most sliding between the chip and the work occurs at some distance from the tool tip. Wear is the inevitable consequence of sliding. Thus most wear occurs at some distance from the tool tip—hence cratering wear.

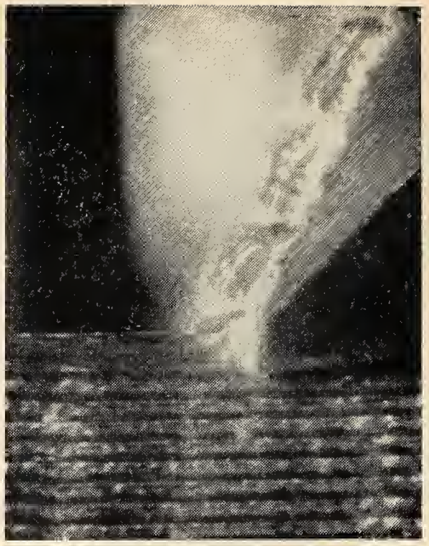


Fig. 8. Effect of Limited Tool Face on Chip Formation.

material — 26S aluminum
rake angle — 7½°
cutting speed — 211 f.p.m.
depth of cut — 0.17 in.
tool face length — .0210 in.

Apparatus

The general arrangement of the apparatus used in orthogonal machining experiments is shown in Fig. 11.

The principle components were a lathe, a tool force dynamometer and associated recording equipment, and the optical apparatus used to photograph the chip formation.

The dynamometer consisted of a tool holder clamped cantilever fashion in a supporting block. The tool holder had an offset square hole for the tool at the overhanging end, and a reduced rectangular measuring section between the overhanging end and the clamped section. Two strain gauges were attached to each of the faces of the measuring section. The gauges on the top and bottom faces formed a Wheatstone Bridge circuit for sensing vertical forces; while those on the sides formed a bridge for sensing horizontal forces. Each bridge was connected to a Universal Analyzer which in turn, was connected to a Two-channel Direct Writing Oscillograph.

The arrangement of the optical

apparatus is shown schematically in Fig. 12. An 83 mm. f 1.9 lens and a 35 mm. single-lens reflex camera and bellows were attached to opposite ends of a 19½ in. extension tube. A 45° prism was located between the lens and the subject. The image at the film was approximately 5 times actual size. The entire optical apparatus was carried on a camera support which rested on the ways of the lathe and was connected to, and thus moved with, the lathe saddle.

The brief exposure was obtained by flash illuminating the tool tip during the time that the camera shutter was open. The flash of 40 microseconds duration was produced by a Strobolume. The resulting blur in the photograph at a cutting speed of 228 f.p.m. was less than .002 in.

The Strobolume and Oscillograph Event Marker were both actuated by the opening of the camera shutter. Film used was Plus X and the lens opening was f6.

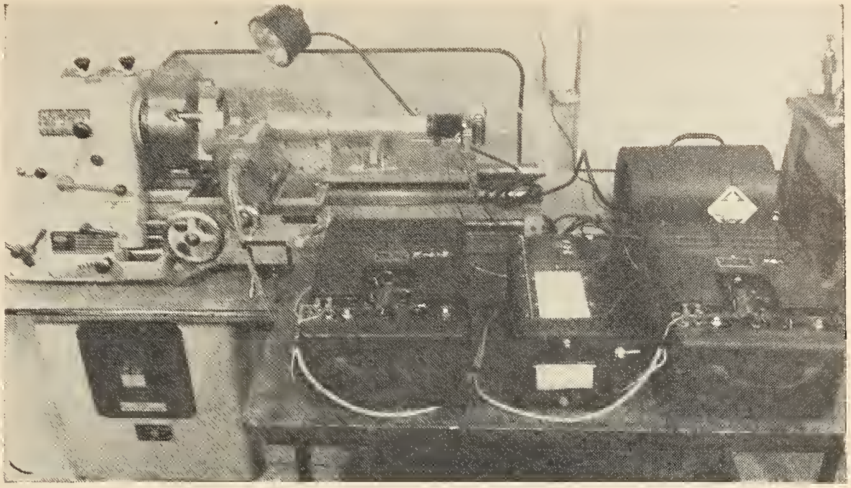

Fig. 11. General Arrangement of Apparatus.

Conclusions

The mechanism of *continuous* chip formation is quite different from those assumed in classical cutting analyses. It is a periodic process of plastic deformation and rupture in which, generally, a "segmented" chip is produced.

The Type 2 chip of Ernst's classification herein designated "ribbon-like" is a limiting case of the "segmented" chip. The transition from segmented to ribbon-like is the result of a reduction in frictional force with increase in rake angle.

The mechanism of segmented chip formation provides an explanation for chip-curl and cratering wear.

The rotation of the previously formed segment due to the plastic deformation of that being formed imparts curl to the chip. Interference between the chip and the workpiece, and the resultant changes in chip forces cause the chip to coil in a fashion peculiar to the cutting conditions.

Cratering wear occurs because most of the rubbing between the chip and the tool is at some distance from the tool tip.

GREATER WINNIPEG FLOODWAY

Carson Templeton, M.E.I.C.
Consulting Engineer, Winnipeg

Spring flooding in Winnipeg is a recurring problem. Some years the city escapes with negligible inconvenience; at other times damage approaches disaster proportions. This paper outlines a method of determining benefit-cost of a diversionary floodway.

TO ILLUSTRATE the method of making the analysis, let us follow through the studies of a Royal Commission which was set up by the Manitoba Government to determine what, if any, projects were economically feasible to reduce the flood hazard in Manitoba, or whether it would be cheaper to accept the damages as they occurred.

A benefit-cost analysis is the comparison of the dollar benefits which a project would produce for each and every year of the life of the project versus the dollar costs per year of the project. If everything is brought down to an average annual benefit versus an average annual cost, there is no problem in determining whether the project is economically feasible.

The history of flooding in Winnipeg is fairly well documented for 150 years. Most Canadians remember the 1950 flood. Although it was not as serious as it might have appeared in the newspapers, it was very close to being disastrous. As it was, it covered entire municipalities, some of which were mainly urban in character. It was only a few feet below the level of most of the houses in Greater Winnipeg where half of Manitoba's population lives. It was only a few feet below the level of the industries from where well over half the industrial taxation of the Province comes. It was only a few feet from closing off both major railways of Canada. Winnipeg has had floods before. In fact, in 1948, only two years before, there was some flooding which at that time was considered quite serious. It is easy to say that some of the low lying areas were improvidently settled — people should have known better, this is true. However, the whole area is almost flat. Thus when the river rises above the level of its banks, it is not very far below the buildings in the whole metropolitan area.

After the 1950 flood, steps were taken immediately to prevent such a recurrence. An immediate step was taken by the Dominion and Provincial Governments to construct a series of dykes along both sides of the rivers in Winnipeg to reduce a flood hazard. No attempt was made to contain the highest known flood, which is usually the prime requisite in designing any dyke or dam. The dykes were designed only to reduce the frequency of flooding. The reason for this emergency work was so the whole problem of flooding could be studied in detail without the governments being pressured into hasty action.

While the dykes were being built, the Dominion Government set up the Red River Basin Investigation, whose terms of reference included methods of flood protection for the whole Red River basin.

This investigation was under Mr. Gordon MacKenzie, who is now Director of the Prairie Farm Rehabilitation Administration. The Hydraulic studies were conducted under him by Mr. Robert Clarke, now Chief Hydraulic Engineer with the Water Resources Branch of the Department of Northern Affairs and National Resources. Mr. Clarke conducted the studies on the Red River and Mr. E. Kuiper who is now Professor at the University of Manitoba conducted the studies on the Assiniboine. In the course of the Commission's work, this report was reviewed in detail and found of particularly high calibre. It is well documented and thorough.

The Red River Basin Investigation compiled the history of flooding and computed discharges on the Red River and all of the Tributaries. It outlined a number of different methods of reducing the flood hazard. These methods included small and large dams, diversions, dyking and channel improvements comprising more than 20 different projects in all.

The Royal Commission on Flood Cost Benefit was set up to determine the most economically feasible combination of the projects.

When the Red River Basin Investigation was started, its first study was to determine the magnitude of past floods, which had been recorded in diaries, but never correlated to today's Geodetic datum. Incidentally, this study of determining the high water elevations proved to be a very interesting history of Winnipeg, and, in fact, most of the chronicles of various events were referenced to past floods. In 1880, Sir Sanford Fleming, who was then Chief Engineer of the C.P.R., wrote a very complete, well documented history of past floods. His information was obtained from the records and diaries of clergy, traders and other early settlers. The reason for making his complete study was that he was trying to have the C.P.R. crossing over the Red River put some 20 miles north of here, where there was no danger of flooding. However, as sometimes happens in the best engineered works, he did not have the final say, the crossing was put here and the City grew.

The 1950 flood did not materially disrupt the economic life of the City beyond the time that the flood was in process. The historic records, however, have proved very conclusively that in 1826, the water was some six ft. above the level of what it was in 1950. Such a flood would put the City out of commission completely and it is estimated that it would not be fully operative for over a year. In 1852, there was a flood 4 ft. higher than the 1950 flood and in 1861 it was 2 ft. higher than the 1950 flood. Between 1861 and 1950 there have been parts of Winnipeg flooded, but nothing of a very serious nature, except in 1916 and 1948 when things looked fairly serious, but these were soon forgotten when the 1950 flood occurred.

In the Red River Valley in the 1948, 1950, 1826 and 1852 floods, the whole valley was flooded and storage reservoirs would have had little use in preventing flooding. They would tremendously increase the flooded area above the dam to give limited protection below the dam. The lake formed in the 1826 flood would be about 25 miles wide.

Fig. 1 shows the area flooded in Greater Winnipeg. The Red flows North from bottom to top and the Assiniboine River comes in from the West. The darker colour indicates the probable extent of the 1826 flood and the lighter colours in the centre indicate lesser historic floods. This photograph covers the entire area of Metropolitan Winnipeg, except part of St. James and Charleswood, and Tuxedo. Thus, in a flood of the 1826 magnitude, of the present 400,000 population, some 370,000 would have been flooded out.

Fig. 2 shows the type of dyking which has been constructed throughout the Metropolitan Area. The dykes, as a rule, are 50 ft. wide and are used as regular streets, but the top of them is some 4 ft. below the level of the 1950 flood. It is possible, in an emergency, to build a temporary dyke on the river side as shown on the photograph. This emergency dyke would be built by equipment rather than sand-bags and would still leave room for two-way traffic on the land side. There are some 26 miles of dykes and line of flood defence in Greater Winnipeg.

Fig. 3 shows a diagrammatic view of a pumping station used to pump out the sewers in time of flood. The older sections of the City use combined sewers which have an outfall to the river. In times of flood, the river backs up these, into the basements and floods the low lying land behind the dykes. The sketch shows a cast iron gate, which closes off the sewer to prevent the river backing up. The pumps lift the water over the top of the dykes. There are some 25 of these stations in Greater Winnipeg with pumping capacities of between 35 c.f.s. and 275 c.f.s., depending on the size of the area protected.

Fig. 4 shows a Flood Frequency Curve. The dots on the curve all represent past floods and their frequencies computed. The curve itself was drawn by judgment. You will note that the 1950 flood has a frequency of once in 37 years, 1861 a frequency of once in 60 years and the 1826 flood a frequency of once in about 426 years. It should be remembered that floods do not occur at regular intervals. The climate follows cycles and so do floods. For example, the three largest floods in the last 150 years in Manitoba occurred during a 35 year period from 1826 to 1861.

Fig. 1. Areas flooded in 1950, 1852 and 1826 in the Greater Winnipeg area. (Legend: 1950-light area, 1852-grey and light areas, 1826-dark, grey and light areas.)

The second highest flood in the Fraser Valley was in 1948 and the third highest flood was only two years later in 1950.

Flood Protection Projects Considered

The main projects considered by the Red River Basin Investigation are:

(1) The Greater Winnipeg Floodways of a number of different sizes, varying from 20,000 c.f.s. to 145,000 c.f.s.

(2) Portage Diversions. Alternate routes are shown on each side of the City of Portage la Prairie.

(3) Russell Reservoir on the Assiniboine at Russell, Manitoba.

(4) A dam on the Pembina River.

(5) The Ste. Agathe Detention Basin.

(6) A diversion of the flood waters of the Rat, Rosseau and Seine Rivers and Joubert's Creek into an Eastern Tributaries Diversion.

(7) Omand's Creek Diversion.

(8) Dyking of the present river banks.

(9) Widening and deepening of the present channel.

Channel Improvements

When studying methods of flood prevention where the capacity of the river channel is not large enough, the logical solution would be to increase the channel capacity by widening and if possible, deepening. However, making it wider and deeper presents difficulties and tremendous expense in the heart of the City. When you consider that the present channel, filled right up to the top of the dyke, passes only 80,000 c.f.s. and the 1826 flood had 225,000 c.f.s., it can be seen that the channel needs to be 2 to 3 times its present size. Such an increase in size would mean complete revision of all the bridges and approaches and removal of streets, houses, industries, railways, etc.

A knotty problem would be the decision of whether to widen the river on the West side in the downtown area, thereby removing the C.N.R. Yards, coming right up to Portage & Main, or widen it on the East side and take out the St. Boniface Hospital. Such a scheme would have tremendous other costs in addition to cost of the removal of earth.

A floodway can do the same thing, but since it goes through undeveloped land, the costs are less and the excess earth can be placed alongside, rather than hauling it some distance.

An improved channel which would pass 140,000 c.f.s., which is about the same as the present channel plus a 60,000 floodway, would cost $120 million, a little over double the cost of the floodway.

Dyking

The conventional method of flood protection is to construct dykes up to at least the elevation of the highest known flood. However, they tend to give a sense of false security and if they fail for any reason, they cause a terrific rush of water which can cause a very serious loss of life and damages far beyond what they would have been had there not been any dykes.

Consider raising a street about 14

ft. and you could imagine the problems involved with intersecting streets, bridges, railways, buildings, etc., to say nothing of the threat of the wall of water if it should burst. In a City as old as Winnipeg, there are literally dozens of underground culverts, pipes and other structures of which there are no records. If one of these were to fail, it could cause the whole dyking system to fail. The present dykes are fine and are doing the job for which they were designed, which was providing a partial degree of protection, but to find more complete protection, a completely different scheme must be adopted.

The Ohman's Creek Diversion involved pumping of the flood waters over a height of land and then running it north by gravity to Lake Winnipeg. The pumping problem seemed insurmountable when one was talking about the intermittent use of pumps to handle, say 60,000 c.f.s.

The Ste. Agathe Detention Basin involved the placing of a dam across the Red River Valley which could give Greater Winnipeg a considerable help in levelling off the flood crests. It would have reduced the 1950 flood by about 4½ ft. in Winnipeg. Floods of larger magnitude would be reduced by lesser amounts and thus this scheme does not provide a satisfactory degree of protection.

Eastern Tributaries Diversion would provide less than a foot reduction in Winnipeg and thereby could not provide the protection needed for either the Red River Valley or Winnipeg.

Pembina Dam has substantial benefits in water supply and sewage dilution and if it could supply the Pembina Triangle with the potable water and irrigation water it needs, would be a very valuable project. However, to determine this value was considered beyond the terms of reference of the Commission and it computed the flood protection value and suggested further studies be made of the other benefits. The benefits of flood protection alone were not enough to justify the cost.

Russell Reservoir

The benefits of this are substantial in reducing the flooding between Portage and Winnipeg and in providing a more constant flow of water at Brandon, Portage and Winnipeg. This dry weather flow gives an adequate water supply and reduces the degree of sewage treatment. It has a Benefit-Cost Ratio of 6 and was recommended by the Commission.

The chief disadvantage of this project is that the dam is on a branch of a tributary considerably remote from Winnipeg, where most of the benefits are to be had. Its effect therefore is not as certain. For example, the whole Assiniboine flow in 1950 was 8,000 c.f.s. and therefore the Assiniboine projects alone would not have been much help. Ordinarily the flow would have been over double that amount.

Portage Diversion

In the location of the High Bluff Diversion with respect to the City of Portage la Prairie and Lake Manitoba there is some 25 ft. drop between the City and the lake, and in fact, the drainage for the City is to the lake rather than to the river.

This floodway would carry floodwaters from the Assiniboine to Lake Manitoba and would have a 25,000 c.f.s. capacity. It would not dry up the Assiniboine — it would only divert some water in flood time. Any of the water diverted would go out of the Red River drainage basin.

An interesting possibility would be the storage of the freshet waters from the Assiniboine in Lake Manitoba and then diverting them back into the Assiniboine farther east. In the late summer, this would dilute the sewage pollution in Winnipeg.

Greater Winnipeg Floodway

The location of the floodway around Greater Winnipeg would leave in the vicinity of St. Norbert and be about 26 miles long and would re-enter the river at Lockport. A floodway has a particular advantage in this location because immediately downstream from the City is Listers Rapids, where there is a fall of 10 ft. in 4 miles. Because of this drop, the backwater effects of the floodway re-entering the channel at Lockport are minimized. The channel is designed to have a 6 to 1 side slope on the southern section where the wet

Fig. 3. (right) Diagrammatic view of a pumping station used to pump out the sewers in time of flood.

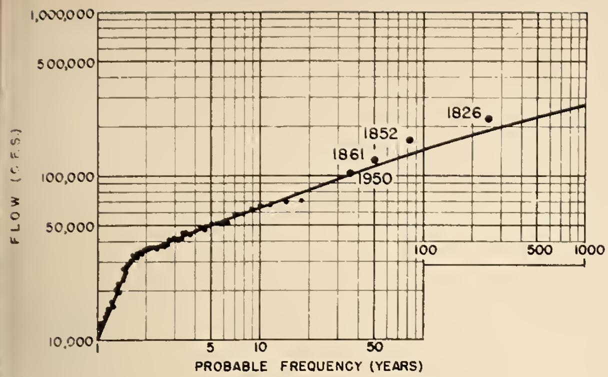

Fig. 4. Flood Frequency Curve

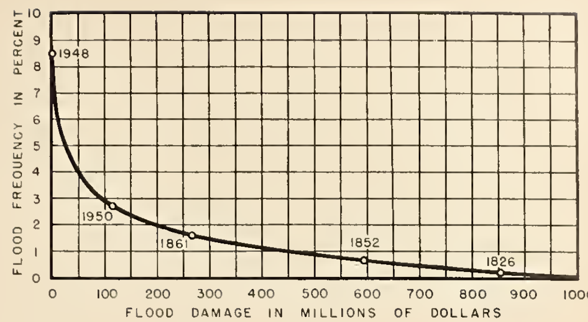

Fig. 5. Frequency Damage Curve

clay occurs and 3 to 1 side in the northern section where the soil is stiffer.

The control structure across the river downstream from the floodway intake would be used to control the flow in the river through the City in times of flood, thereby forcing more water down the floodway channel. (see Fig. 7.) The spoil from the excavation would be placed on each side. Floodwaters would enter the floodway channel on an average of every two years. Normal drainage from the East would be intercepted by the floodway which would carry it around the City.

Benefit—Cost Analysis

In making any benefit cost analysis, it is necessary to express the benefits and costs in terms of dollars per year. Benefits generally include flood protection, recreation, water supply, sewage dilution and any other applicable features. In this case, the Commission considered only the benefits of flood protection. Costs include not only capital costs, but amortization, interest on the money during the construction period before the project is useful, maintenance and repairs.

The entire study is to break these down to average annual benefits and average annual costs.

If a project has a benefit cost ratio of 2, it means that the average annual benefits are twice the average annual costs.

The balance of the study is to compute these annual benefits and costs.

Benefits

The benefits in these flood protection schemes are the reduction of damages that any project would bring about.

To find the average annual damage, it is necessary to estimate the damages which any flood would cause along with the frequency with which that flood would occur. For example, the losses caused by the 1950 flood amounted to some $110 millions. The frequency of this flood was once in 37 years or 2.7%. A flood of the 1826 magnitude in 1957 would have caused an estimated $850 million damages, but the frequency is only .2 and therefore, because of the infrequent nature, the average annual damage caused by the 1826 flood is about one half of the average annual damage of the 1950 flood.

To find the average annual damage, it is necessary to add together the damages from an infinite number of floods multiplied by their corresponding frequencies. This is most easily expressed by plotting a frequency-damage curve. The area beneath which gives the average annual damage for all floods.

Fig. 5 shows such a curve for Greater Winnipeg.

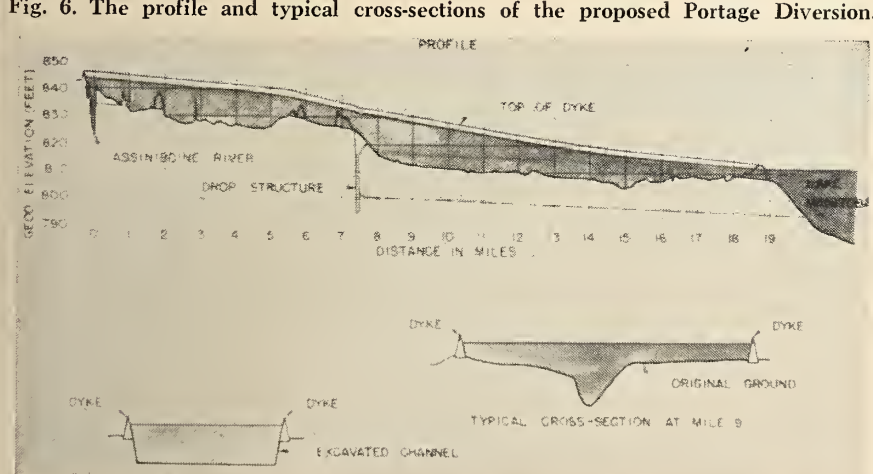
Damages

Fig. 8 shows the relationship of damages to the market values of a house as the flood waters rise. The records of the 1950 flood were used and it was found by observing several hundred of these, that the damage to the homes were related to the depth of water to which they were flooded. Immediately the water got over the main floor, which spoiled the floor and much of the furniture, the damages rose very rapidly.

The relationship between the market value of the home and the damages to the dwelling and personal property were related. The damage, once the water gets into the basements, starts at about 3.8% and rises only to about 7.3% until it gets over the main floor of the house. By the time it reaches 2 ft. above the main floor, the damages are about 42.7% of the value of the house. Having established this relationship, it was found necessary to obtain the elevation of each block in the city and put the market value of all the houses in that block on I.B.M. punch cards. Then, when each project was studied, it was only necessary to run the cards through the computer to determine the damages on that block for various heights of water.

To find the damages to commercial areas, a survey of the commercial buildings which were flooded in 1950 was conducted and the results tabulated on a sq. ft. basis for different types of commercial and industrial buildings. When industries are flooded out, there is a loss of income. In some cases, the workers are laid off without pay; in other cases salaried employees may continue on the payroll, whereby the loss is accepted by the employer rather than the employee. Nevertheless, there is a loss of income. In very major

Fig. 6. The profile and typical cross-sections of the proposed Portage Diversion.



floods, when the entire city would be inundated, most all industry and business would shut down for a time and would gradually open up again as their establishments were rehabilitated and their workers again had a place to live. For very major floods such as the 1826 flood, this amounts to a considerable amount of money because all bridges would be damaged or washed out and the main portion of the city would be disrupted. The loss of income was obtained from the Dominion Bureau of Statistics for income in Greater Winnipeg and this was correlated to the location in which the industries are situated.

In Fig. 9 these damages are totalled for all floods. The loss of income for a flood equal to the 1950 flood is fairly minor but for major floods, becomes increasingly significant.

From this chart you can read that the 1950 flood cost somewhere over $100 million, the 1861 flood would have cost $267 million, the 1852 flood would have cost $600 million and the 1826 flood would have cost $850 million. These are all direct costs — there is no allowance made in this study for intangibles such as the effect to the rest of Canada of cutting off the major railways. There is no allowance made for a possible loss of life. There is no value set on the effect of a flood threat hanging over the lives of people here, wondering if next spring there will be a flood. These and other intangibles were recognized by the Commission, but they were not taken into the computation of the damages.

Each project must be considered singly and in combination with other projects to find out what reduction in damages can be attributed to that project. To do so, the lowering of water levels for the various projects were calculated.

This has the same effect as reducing the frequency of all floods and thereby lowers the frequency damage curve. Thus, the area between the frequency damage curve under natural conditions and the newer frequency damage curve represents the average annual benefit.

Costs

The computation of the Costs are comparatively simple.

The capital costs are estimated in the usual way. However, since the floodway alone has close to 100 million cu. yd. of excavation in it, the unit prices are extremely significant. The Red River Basin, drawing on Mr. McKenzie's wide experience with the P.F.R.A., set a price of 30c per cu. yd. for common excavation. The Royal Commission studied this unit price in some detail. Local contractors thought that if anything, the price was too high. The Commission brought General La Rue, recently retired from the U.S. Army Corps of Engineers and who has a very wide experience in similar large projects, to discuss the problem. He thought the price of 30c was about right. The Commission also had a dredging company prepare a detailed cost estimate on the cost of excavation using floating suction dredges. Its estimate was 23c per cu. yd.

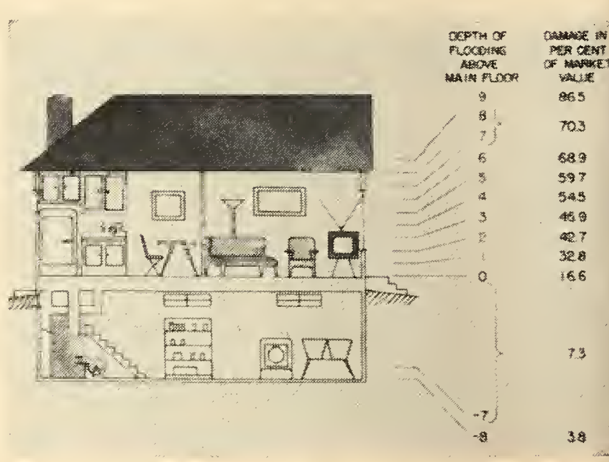
All things considered, the unit price for common excavation was left at 30c, but in its final report, the Commission inserted the sentences "There is some reason to believe that if the works were undertaken today, the actual cost might be less than the Commission used in its calculations. This would result in even more favourable benefit-cost ratios." This price may seem low to engineers from other parts of Canada, but Manitoba road jobs usually cost only 12-15c per cu. yd.

Table 1.
Estimated Cost of 60,000 c.f.s. Floodway

Right of Way	$ 3,520,000
Excavation	35,246,000
Aqueduct Crossing	260,000
Highway Bridges	5,639,000
Railway Bridges	6,762,000
Outlet Drop Structure	762,000
Control Structure and Dyke	4,537,000
Miscellaneous	635,000
Total	$57,361,000

Fig. 7. (left) An artist's sketch of the floodway as it leaves the river.

Fig. 8. (below) Flood damage to dwellings and personal property.



To illustrate the importance of this unit cost:

A difference of 1c in the cost of common excavation means a total difference in cost of $1,000,000.

In computing the average annual cost, it is necessary to amortize the capital cost over the life of the project. In this case, the life of the projects were assumed to be 50 years. One might say that the life of the projects should be more than this, but when the interest is taken into account, it makes little difference in the average annual cost whether a 50 or 60 year life is assumed.

In addition to the amortization is the interest charges. The Commission used an interest rate of 4%. In the light of today's high financing costs, one might argue that this figure is too low; however, the Commission studied interest rates over the past 50 years and came to the conclusion that in the next 50 years, an interest rate of 4% would be reasonable and conservative.

The maintenance of the floodway and the structures crossing it was also taken into the average annual cost. Maintenance included removal of silt deposited in low flows, side slope maintenance, mowing and weed control. Annual Bridge maintenance was taken as 1% of the capital cost.

The average annual costs of the three recommended projects amounted to $4 million. This figure is made up of $3,159,000 interest, $517,300 amortization and $325,500 maintenance.

In Fig. 10, the benefit cost ratio is shown diagrammatically. The floodway, with a benefit-cost ratio of 2.89, means that the benefits are 2.89 times the costs. The Portage Diversion benefits are 9.06 times the costs.

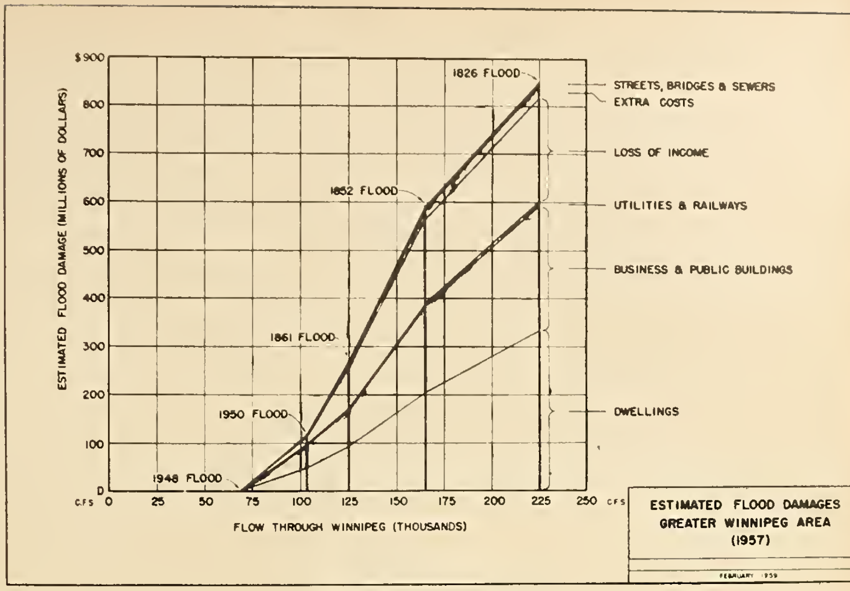


Fig. 9. Flood Damages

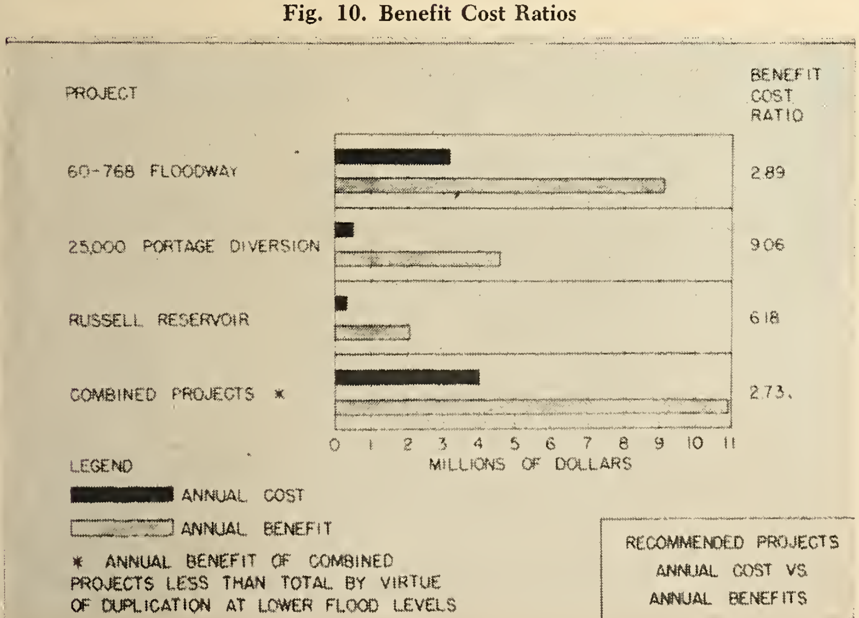
It should be noted that the benefit cost ratios of a combination of projects are less than any single project. The reason for this is because there is a duplication of protection for small floods. For all, except extreme floods, the floodway would prevent most of the damages from occurring and therefore the projects on the tributary would not be fully realized.

Even if an interest rate of 5% were used, the combination of projects would have a benefit cost ratio of 2.30.

These figures are computed on a 1957 Winnipeg. As the City grows larger, the benefits and costs will increase.

By 1981, it is estimated that the growth of the City will have increased by 71% and the damages of the various floods would be increased. The benefit-cost ratio of the three projects was estimated to be 4.1 in 1981.

Fig. 10. Benefit Cost Ratios



Comments

The Royal Commission on Flood-Cost Benefit contemplated trying to find out what degree of flood protection had been provided for other cities. In other words, should one try to provide flood protection against a 50 year flood, a 100 year flood, or 1,000 year flood. The Commission was not successful in determining the degree of the protection that other cities enjoyed. Not having a yardstick, it had to rely completely in the benefit-cost ratios.

No doubt the Greater Winnipeg Floodway will be an active issue again soon, as the Provincial Government is committed to building it and the Federal Government is committed to helping. This is a big project, but since the benefits are 2.7 times the costs, it is economically justified.

SAULT STE. MARIE BRIDGE DESIGN

C. H. Gronquist

Steinman, Boynton, Gronquist & London, Consulting Engineers, New York

A VEHICULAR BRIDGE to join the cities of Sault Ste. Marie, Mich., and Sault Ste. Marie, Ont., has for many years been a pressing need, for the continued growth and development of the region which depends on the construction of a span across the turbulent St. Marys River.

The St. Marys, which marks the International Boundary between Michigan and Ontario, drops between 18 and 24 ft. as it tumbles from Lake Superior into Lake Huron. The cities are divided by the river and the 100-year-old Soo locks and ship canals. These locks and canals, built to pass shipping around the falls, have been maintained and reconstructed as necessary during the intervening years so the waterway now is capable of handling the largest ships which can use the St. Lawrence Seaway.

Location

Sault Ste. Marie, Mich. is the northern terminus of U.S. Route 2, and the terminus of State Route 28 from the west, and State Route 129 from the south. U.S. Interstate Route 75 from Detroit will pass over the Mackinac Bridge, and, as a relocation of U.S. Route 2, will also have its northern terminus at Sault Ste. Marie. Portions of this interstate route are already under construction in both the Lower and the Upper Peninsulas of Michigan; the portion to be built at Sault Ste. Marie will connect directly with the Sault Ste. Marie International Bridge, and will be finished at the same time as the opening of the bridge.

The Canadian Pacific Railway, the Duluth, South Shore and Atlantic Railroad, and the Minneapolis, St. Paul and Sault Ste. Marie Railroad supply rail service to the city.

A low-level railroad bridge with swing and bascule openings has connected the twin cities, but the railroad swing span has recently been replaced with a new lift span bridge. The lift span was constructed in the raised position over the present railroad bridge, and now that the lift bridge is completed, the swing span, together with its supporting island in the south canal is being removed. Railway traffic was maintained during the construction of the new lift span.

Sault Ste. Marie, Ont. is reached from the east by King's Highway No. 17 which at present as part of the Trans-Canada Highway is being further extended northward and to the west around Lake Superior to Port Arthur and Fort William. This scenic highway should become a major tourist attraction. The Canadian Soo is served by the Canadian Pacific Railway and the Algoma Central and Hudson Bay Railway.

The Soo area has many important industries, including the Union Carbide Company on the Michigan side, the Algoma Steel Company and the Abitibi Power and Paper Company on the Canadian side, and extensive uranium mining installations which have been recently developed to the east in Ontario. The city ports handle a large amount of lake traffic in coal, limestone and lumber, and numerous firms dealing in these and other products have been established in the area.

In addition, the Soo is a popular recreation area, with excellent hunting, fishing and boating readily available.

With the recently completed Mackinac Bridge joining the Upper and Lower Peninsulas of Michigan, the proposed Sault Ste. Marie International Bridge will be the last link in the chain connecting the midwest and lower Michigan with the vast recreational and rapidly-growing industrial area of northwestern Ontario. Moreover, it has long been recognized that a vehicular bridge connecting the two cities of Sault Ste. Marie is needed for the continued growth of the twin cities, and that it is of prime importance for National Defence.

Legislation approving the construction of this bridge has been passed in the Michigan Legislature and the U.S. Congress, and in the Ontario Legislature and the Canadian Parliament.

The International Bridge Authority, an agency of the State of Michigan, is authorized to construct, maintain and operate the International Bridge. The St. Marys River Bridge Company is a corporate body created by the Senate of Canada in 1955 for a similar purpose. The rights and powers of the latter were assigned to the International Bridge Authority of Michigan to enable it to proceed with the financing and construction of the project.

Applications for approval of clearances and other details of the construction have been approved by the following agencies: U.S. Department of the Army, the Governor-in-Council of Canada, and the Canadian St. Lawrence Seaway Authority.

Conditions at Site

The St. Marys River drops approximately 21 ft. in the St. Marys Falls, and there is a similar difference in water level between the head and the foot of the several locks. At the head of the Falls a compensating works consisting of a series of sluice gates regulates the flow of water to maintain necessary depth of water in the power canals and for navigation in the ship canals. The United States power canal with the new powerhouse directly south of the Falls, delivers a maximum of 18,000 hp. of electrical energy. South of the U.S. power canal there are the two U.S. ship canals and their four locks through which pass the heaviest tonnage of shipping in the world, at a maximum rate of 75 ships a day. The Union Carbide Company power canal, Sault Ste. Marie, Mich., south of the ship canals, can deliver 40,000 hp. North of the Falls on the Canadian side, the Canadian ship canal and lock are located. The Great Lakes Power Company canal to the north of the ship canal delivers a maximum electrical energy of 27,500 hp.

The locks are ice-bound every winter for approximately three to four months, during which time navigation is suspended. The ice thickness varies from year to year to a maximum thickness of 30 in.

Bridge Location

This site, with its complex network of canals and various shipping requirements both above and below the locks, presents many problems in the determination of the most suitable location for a crossing. Numerous locations have been studied for the bridge crossing of the St. Marys River, as well as a proposed tunnel in the vicinity of Johnstone St. in the Michigan Soo and East St. in the Canadian Soo. It has been determined that the location which will meet all requirements at minimum cost is a line crossing the ship canals immediately east of the existing railroad bridge. The reasons are:

1. The recommended location will be the most economical that will satisfy all governing objectives. The bridge will have relatively short spans and will be located over shallow water and at shallow depth to rock;

2. The proposed location is as far above the locks as possible, to equate any hazard to the locks from the proposed bridge to that of the existing railroad bridge;

3. The bridge location is within the cities to best serve inter-city traffic in order to realize the maximum toll revenue for the project;

4. The bridge plazas are readily accessible to local traffic from either city;

5. The recommended location will connect directly with the proposed Interstate Highway System through Interstate Route 75 in Michigan which will be located at the west edge of the city and will have interchanges for connections to the city at Easterday Ave. near the toll plaza and at the south edge of Sault Ste. Marie, Mich. In Sault Ste. Marie, Ont. the bridge plaza at Huron St. will connect by one-way city streets to King's Highway No. 17 and the Trans-Canada Highway.

The recommended route runs just east of the railroads on both sides of the river and along the west edge of the Abitibi Power and Paper Company property on the Canadian side. The location will minimize any interference with the railroads or the Paper Company operations.

Construction Contracts

Except for the Michigan approach spans and the Easterday Ave. Inter-

Fig. 1. Highway Connections

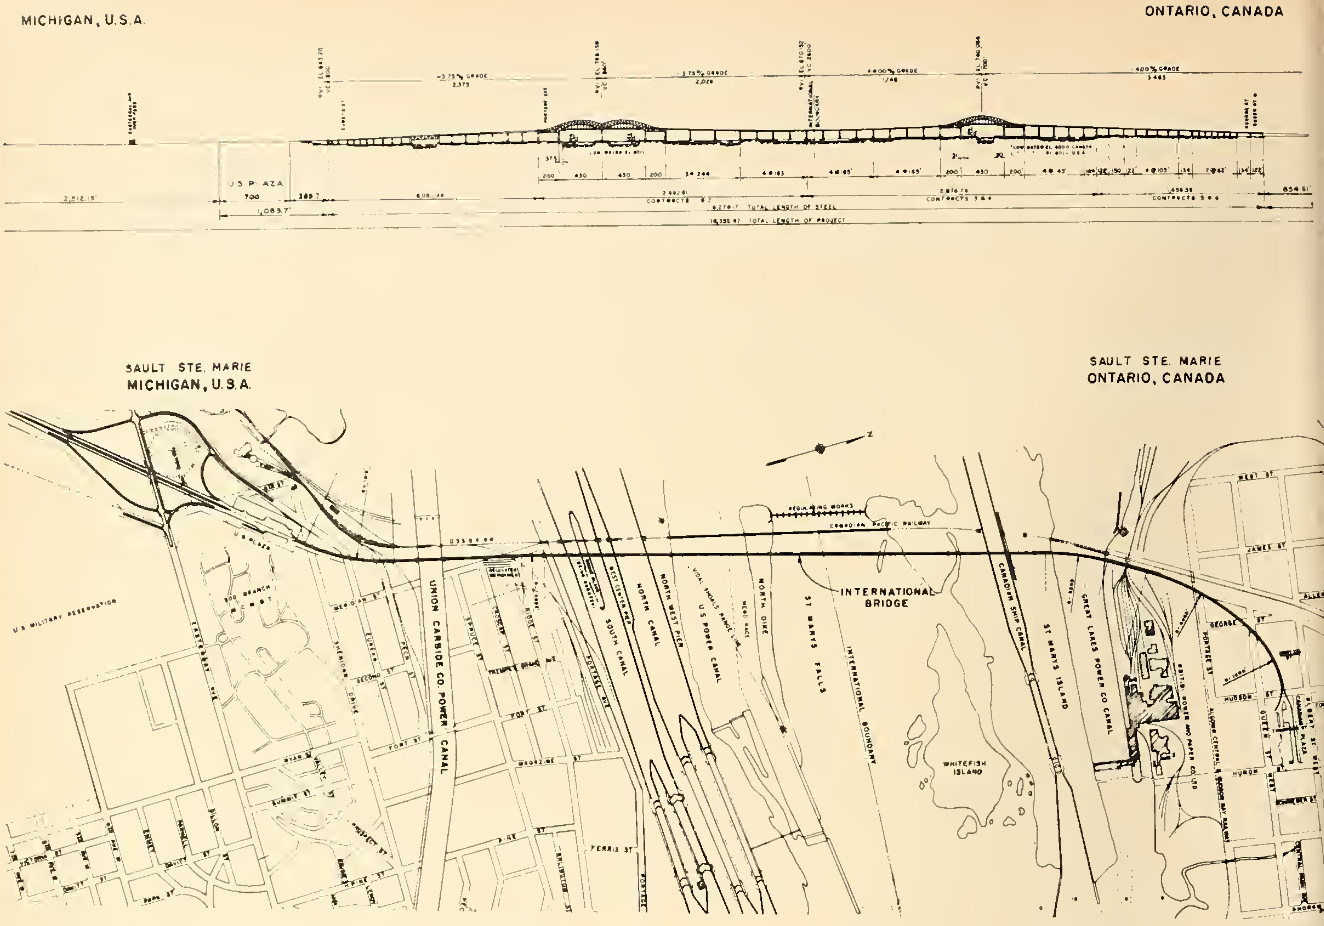

Fig. 2. General Plan and Elevation

change on Interstate Route 75, all of which will be built by the Michigan State Highway Department with the use of Federal funds, the American toll plaza and the remainder of the project from Portage Ave. near the south bank of the river in Sault Ste. Marie, Mich. to and including the plaza in Sault Ste. Marie, Ont. has been financed by the International Bridge Authority by means of a revenue bond program.

The Michigan approach spans will be constructed in two contracts, one for the substructure and one for the superstructure, including the deck and roadway lighting. South of the toll plaza on the Michigan side, the Easterday Ave. interchange consisting of a four-span bridge to carry Easterday Ave. over Interstate Route 75, together with a section of Route 75 and four interchange ramps, will be built under separate contract. The two-mile long section of Interstate Route 75 extending from the Easterday Ave. interchange to an interchange at the south edge of the city will be constructed by the Michigan Highway Department in conjunction with the bridge project, and will be opened to traffic on completion of the latter.

Bids were received in June 1960 by the International Bridge Authority on a total of six contracts for the substructure and steel superstructure for each of three divisions of the project, namely, the American river spans, the Canadian river spans and the Canadian approach spans. Contract drawings will be completed and bids will be received for the remainder of the work, including the concrete roadway, the lighting, and the plazas.

Subsurface Exploration

Borings along the proposed centre line of the bridge and approaches were made during September and October, 1958, and on the Michigan approach in the fall of 1959.

Rock was found generally at a shallow depth, ranging from 2 to 10 ft. below ground except in a few locations, mainly near the American plaza where rock was found to be 30 to 40 ft. below the surface. The overburden in general consists of sand, gravel and sandstone fragments. The rock is sandstone, with sand or clay seams in some locations.

The maximum foundation pressure on sandstone rock will be 6 tons per sq. ft. and the maximum foundation pressure on soil will be 3 tons per sq. ft.

Design of Bridge

The cost of construction of this project has been kept to a minimum consistent with adequate capacity, safety of traffic and conservative design. Structural details will facilitate fabrication and erection and will be conductive to economical maintenance.

The bridge geometric design is in compliance with the Interstate Standards of the U.S. Bureau of Public Roads.

The preliminary traffic study indicates that a two-lane highway bridge will have sufficient capacity for the anticipated traffic.

The above considerations have led to the adoption of an overall width of 28 ft. between curbs, providing 14-ft. lanes in each direction. In addition a 2-ft. emergency walkway is provided on each side of the bridge.

The roadway consists of a reinforced concrete slab with a 1½-in. asphalt wearing surface. The curb has been designed to facilitate snow removal and to permit snow to blow off the bridge.

Design Specifications

The specifications for materials, loads and permissible stresses which have been used as a basis for the design of the Sault Ste. Marie International Bridge follow general practice for modern structures of this type and magnitude.

The current specifications of the American Association of State Highway Officials have been followed, using the basic standard loading H20-S16-44 as generally applied to the design of bridges on major highways. The new vertical clearance of 16 ft. 3 ins. for structures overpassing Interstate Routes has been used throughout the project.

These specifications require design for a static wind pressure of 75 p.s.f. on the area of the structure as seen in elevation. This corresponds to a wind velocity of more than 100 m.p.h., far greater than any recorded velocity in that vicinity.

After careful consideration of the latest information on ice pressure on engineering structures, it was decided to adopt the very severe assumption of a transverse ice pressure for circular surfaces of 65,000 lb. per lineal ft. of pier width at the water line, similar to that used for the Mackinac Bridge. A longitudinal ice pressure of 5,750 lb. per linear ft. was taken simultaneously with the transverse pressure. The resulting forces are considerably greater than those generally assumed for engineering structures under comparable climatic conditions, and it is confidently expected that these forces are generously in excess of those to which the piers will ever be subjected.

General Description of Bridge

The bridge with its approaches is approximately 10,324 ft. long, exclusive of the bridge plazas, and the total length of structure is 9,280 ft. Including the plazas and the interchange south of the American plaza, the total length of project is 14,595 ft. or 2.76 miles. A 124-ft. minimum vertical clearance above low water is provided over the U.S. and Canadian ship canals, and the maximum grades are 3.75% on the U.S. side and 4% on the Canadian side.

The American plaza is located adjacent to Eureka St. between Easterday Ave. and Sheridan Drive for a distance of approximately 700 ft. South of the plaza the interchange between Interstate Route 75 and Easterday Ave. is located, including an overpass structure for Easterday Ave. The American approach runs north from the plaza to the River spans for a distance of approximately 2,471 ft., of which 2,081 ft. are on structure.

The River spans, comprising the two main structures over the American and Canadian ship canals and the crossings over the U.S. and Canadian power canals and rapids, have a total length of about 5,540 ft., of which the American spans are 2,663 ft. in length and the Canadian spans are 2,877 ft. long.

The Canadian approach, which is approximately 2,313 ft. in length, 1,659 ft. of which are on structure, extends north and east from the Canadian ship canal in a gentle curve to the Canadian plaza. This plaza lies between Queen St. W. and Albert St., and extends from Hudson St. to Huron St., a distance of approximately 660 ft.

TABLE I

Length of Project

Michigan State Highway Department		
Easterday Avenue Interchange......	2,911 ft.	
Roadway on Fill (North of Plaza)..	390	
Approach Spans.....	2,081	
Total............		5,382 ft.
International Bridge Authority		
American Side		
Toll Plaza........	700 ft.	
River Spans......	2,663	
Total............	3,363 ft.	
Canadian Side		
River Spans........	2,877 ft.	
Approach Spans.....	1,659	
Roadway on Fill....	654	
Plaza..............	660	
	5,850 ft.	
Total............		9,213 ft.
Total Length of Structure.........	9,280 ft.	
Total Length of Project..........		14,595 ft.

Substructure

The layout of the bridge including both approaches, provides for a total of 62 piers, of which 38 are two-legged bents having a single top strut. Eighteen are hammer-head piers for economy near the ends of the approaches where the pier heights are less. Six are pylon piers at the outer ends of the continuous truss units over the Ship canals and at the ends of the 275-ft. simple span truss over the Carbide Company power canal, in addition to the two abutments.

All the water piers are in relatively shallow water with a maximum depth of about 20 ft. in the U.S. power canal, 6 ft. in the rapids, and 17 ft. in the Great Lakes Power Company canal. Rock generally is close to the surface and all water pier footings will be founded in sandstone rock, placed as tremie concrete in steel sheet-pile cofferdams. The tremie seal footings in the rapids will be steel reinforced.

The piers in the U.S. power canal will be placed at a depth great enough to accommodate the widening of the canal for the future 20-ft. depth. The surrounding rock for an area of approximately 100 ft. by 100 ft. at each pier will also be excavated to this depth. The piers in this canal will be placed to align with the existing railroad bridge piers.

The truss span piers on the banks of the ship canals will be carried well into rock and will be constructed in the dry. Sealing of seams in the sandstone will be done as necessary to exclude water from the excavation, and to consolidate the seams.

The land piers also will be founded in sandstone rock except for the piers near the American abutment where the rock is fairly deep. These piers will bear on soil. The retaining walls and the Canadian abutment will also be founded on soil with a maximum soil pressure of 3 tons per square ft., and the American abutment will be founded on piles.

The total estimated volume of concrete in the substructure for the project, including the American approach spans, is 60,000 cu. yds.

Superstructure

The River spans include the American and Canadian main truss spans and the continuous girders spanning the U.S. Power canal and the St. Marys Falls.

The U.S. main truss spans consist of a four-span continuous truss unit with arch-form top and bottom chords and a suspended roadway over the American north and south ship canals. The two main spans are each 430 ft. long and the end spans are 200 ft. long. The design of the main spans has been planned to permit truss steel erection by cantilevering from the shore spans over the ship canals with materials being carried over the completed steel. The superstructure steel may be erected on either side of the west centre pier island by balanced cantilever erection about the pier and falsework bents on that pier island. With proper scheduling of construction operations it will be possible to avoid obstruction to navigation during the construction period.

A similar three-span continuous unit with arch-form top and bottom chords and a suspended roadway will span the Canadian ship canal. The main span is 430 ft. to permit construction of a future second canal, and the end spans are each 200 ft.

long, with the top chord at centre of main span 210 ft. above low water. The location of the north main pier has been placed on a line between the Canadian Pacific Railway swing bridge and the movable dam swing bridge, and 90 ft. north of the canal bank. Thus, when the bridges are swung, they will clear the pier, and sufficient space will be provided for pier construction.

Over both the U.S. power canal and the rapids, continuous girders are used. A three-span unit with equal 244-ft. spans is employed over the power canal, and three, four-span units with equal spans of 165 ft. are used over the rapids and south of the Canadian truss spans.

North of the Canadian truss spans, four 145-ft. simple span girders with one 124-ft. simple span girder are used on the horizontal curve over the Great Lakes Power Company canal.

Approach Spans

Since use of a pier in the Carbide Company power canal would have required widening of the canal for a considerable distance at substantial expense, a 275-ft. simple span deck truss will span this canal on the Michigan side.

Multiple beam spans approximately 30 ft., 63 ft. and 90 ft. in length are used in the 2,081-ft. Michigan approach south of the Carbide Company power canal where the alignment is on a 3-degree horizontal curve. North of the power canal a four-span continuous girder unit is employed with equal spans of 132 ft. on tangent, and three simple span girders with equal spans of 150 ft. are used south of Portage Ave. where the alignment is on a slight curve.

The Canadian approach consists of 1,659 ft. of beam and girder spans. Continuous girders with spans of 122 ft., 150 ft. and 122 ft. are employed for the three-span unit along the west edge of the Abitibi Power and Paper Company property adjacent to the pulpwood stacker and north of the power canal. Multiple girders are used for the four 105-ft. simple spans and for the two 134-ft. simple spans over the Algoma Central and Hudson Bay Railway and over George St. A skew span with multiple girders varying in length from 110 to 140 ft. is used over Queen St. The remaining spans are beam spans of 64-ft. length.

Carbon structural steel is used throughout for the superstructure, except that certain highly stressed members of the truss spans will be of low-alloy steel in conformance with the A.S.T.M. 242 Specification. The truss members are in general built up of 15-in. channels and cover plates, and lacing is avoided for any member of the bridge for economy of construction and maintenance, as well as better appearance.

The continuous trusses were analyzed with the moments over the piers as the redundants. The influence line computations for the continuous girders were performed by electronic computer. The stresses from lateral wind on the continuous truss spans were computed considering the effect of the curved chords. Lateral participation in dead and live load chord stresses was included in computing total lateral stresses.

Riveted construction is employed throughout, except for the composite beam spans, but the use of high strength bolts in place of field rivets will be permitted at the option of the contractor.

Muliple girders are used for the simple span girders of 105 ft. to 134 ft. span, which vary in depth from 6.5 ft. to 7.5 ft. Pairs of girders are used for the continuous spans which are from 132 ft. to 244 ft. in length and from 7 ft. to 12 ft. in depth. Pairs of girders are also used for the 9½ ft. deep 145 ft. long simple span girders.

The beam spans are of composite construction, generally 36 in. deep and vary from an abutment span of 30 ft. to a maximum span of 90 ft. on the American approach.

The stringers for truss and girder spans are set on top of the floorbeams and will be continuous in length of from 114 ft. to 368 ft. in order to reduce the number of joints in the roadway slab. The floorbeams, which are from 25 ft. to 30 ft. apart, are indicated to be 36 in. wide flange beams, but the contractor may elect to substitute deeper built-up girders where available depth permits.

In general the roadway slab will be of 7 in. ordinary concrete, but in order to reduce weight in the main spans of the continuous trusses, a 6-in. slab of lightweight concrete will be used. Bituminous surfacing 1½ in. thick will be used on all roadway slabs.

A 3-in. high curb with open sidewalk and curb guard railings will be employed to permit the snow to blow readily off the bridge. Favorable results have been obtained with this type of railing construction on the suspended spans of the Mackinac Bridge, but where high concrete curbs were employed, it was found that snow collected for a distance out from the curb equal to 12 times the curb height.

The total estimated tonnage of structural steel in the project, including the American approach spans, is 11,000 tons. Beyond the abutments the roadway is placed on fill extending to the plazas for a distance of 390 ft. on the Michigan side and for a distance of 654 ft. on the Canadian side.

Toll and Inspection Plazas

The toll plaza is located on the U.S. side adjacent to Eureka St. and

Fig. 3. View of Canadian Canal Crossing

ies between Easterday Ave. and Sheridan Drive. It is convenient of access to city traffic via Easterday Ave. or Eureka St. and will be directly connected to the proposed limited access Interstate Route 75. Property values in this area are comparatively low. This plaza will contain the toll booths, the U.S. Customs and Immigration building and inspection booths, the administration building and the garage and maintenance building. Ample provision has been made for future expansion to accommodate increased traffic. The plaza is approximately 225 ft. wide by 700 ft. long and will be paved with concrete.

The Canadian plaza is located between Queen St. W. and Albert St. W. and extends from Huron St. to Hudson St., but it will be unnecessary to take the frontage along Albert St. W. The plaza has been located in the city for convenience to the local traffic, while still providing connections to the major route via one-way streets. It is in an area of comparatively low-cost property. The plaza will contain the Canadian Customs and Immigration building and inspection booths, as well as a bus terminal and examination warehouse building. The plaza dimensions are approximately 270 ft. wide by 660 ft. long, providing ample capacity for future expansion to accommodate increased traffic. Approval of this layout has been received from the Chief of Accommodation, Department of National Revenue, Customs and Excise Division, Ottawa.

Lighting

A mercury vapor lighting series system will be used for the lighting of the roadway of the bridge. The roadway lights will be spaced 150 ft. apart, staggered about the centre line of the roadway, and will be at a maximum elevation over the ship canals of about 160 ft. above low water. This will greatly minimize, if it does not eliminate, the possibility of confusion between the much-lower existing lights of the canal area and the lights of the proposed bridge. However, it will be possible to use special shielded roadway lights to reduce glare and to confine the light to the bridge roadway.

Electric power will be supplied separately to each end of the project. Substations will be provided at each plaza and at other points to furnish power to the bridge, and emergency power for operation of toll recording equipment will be available in case of power failure at one of the stations. A telephone system will be provided on the bridge for maintenance and emergency use.

Estimated Cost of Construction

The estimated cost of construction of the project is $3.3 million for the Michigan approach, including the Easterday Ave. interchange; $5.8 million for the American plaza and American river spans; and $6.4 million for the Canadian river spans, Canadian approach and Canadian plaza; for a total of $15.5 million.

Construction Schedule

Financing was completed in September 1960. Assuming that all Right-of-Way for approaches can be obtained by March 1961, the following schedule of construction can be met. The construction of the foundations was started September 1, 1960, and based on the schedule below the bridge will be open for traffic on September 1, 1962.

Contracts for the substructure of the American and Canadian River Spans and for the American and Canadian Approach Spans were awarded September 13, 1960. Work was started September 13, 1960 and will be completed by November 1, 1961.

Contracts for fabrication and erection of superstructure steel for the American and Canadian River Spans were awarded September 13, 1960. Steel erection will begin June 1, 1961 and will be completed March 1, 1962. The contract for the American Approach Spans superstructure, including paving and lighting, was awarded in September 1960. Steel erection will start March 1, 1962, and all work will be completed October 1, 1962. The contract for the Canadian Approach Spans superstructure steel was awarded September 13, 1960. Steel erection will begin May 1, 1961 with completion January 1, 1962.

Paving operations will generally follow steel erection. Award deck paving contracts for the River Spans and for the Canadian Approach Spans April 1, 1961, begin paving August 1, 1961 and complete work August 1, 1962. Award Plazas and approach on fill contracts May 1, 1961, begin paving July 1, 1961 and complete work November 1, 1961.

Award contracts for the Easterday Avenue Interchange and American Approach on fill December 15, 1960, start work April 1, 1961 and complete work July 1, 1962.

Award Lighting and Electrical Contracts March 1, 1961 and complete this work by September 1, 1962.

Award Toll Booth Contract March 1, 1961. The erection of the booths would start on September 1, 1961 and all work would be completed by July 1, 1962.

Award Plaza Building Contracts April 1, 1961, start construction by May 1, 1961 and complete the buildings and Inspection Booths by July 1, 1962. EIC

Fig. 4. View of American Canals Crossing

GLACIAL LAKE CLAY DEPOSITS

Determination of their Original Depth in the Great Lakes Region

G. T. Hughes, M.E.I.C.
Associate Professor,
Dept. of Civil Engineering,
Royal Military College of Canada,
Kingston

When the glaciers retreated following the last ice age, large glacial lakes were formed. Clay sediments settled on the bottom of these lakes, sometimes to great depths. The original depths are found by consideration of sedimentation and consolidation.

WHEN THE glaciers which occupied the Great Lakes region during the Peistocene period retreated to the north, large glacial lakes were formed. Sediments accumulated at the bottom of these lakes—or this lake—to depths equal to or much greater than what exists now.

Portions of these deposits have been eroded by various forces, some of which are still active. It is of valuable interest to the civil engineer and to the geologist to determine the maximum depth of the glacial lake deposits, and the depth which has been removed since their deposition.

In some parts of the Great Lakes the amount of these clay deposits which have been removed from their surface since deposition ranges from nil to 10 ft. However, in areas of Lake Ontario deposits of glacial lake clay have had great depths of soil removed from the existing surfaces. An example of this is found at Kingston where it has been estimated by the consolidation test that clay deposits at one time were as much as 100 ft. thicker than they are now.

The correlation of total depth of deposition of glacial lake clays in one region compared with another since a given time can be obtained. The original depth of the clay deposits can be determined from the process of sedimentation, and the analysis of consolidation.

Glacial-Lake Clay Deposits

During the Pleistocene period the whole Great Lakes area including certain portions to the south, was occupied by the glacier. This continental glacier disrupted the previous drainage of the region, carved new channels in some cases and left various types of surface and lake deposits to later erosional forces. The St. Lawrence valley was dammed early in the movements of the glacier. The ice dam forced water from the glaciers to rise until it found an outlet to the Mississippi or eastward through the Mohawk valley in New York State.[1]

As the glacial front retreated to the north a lake was formed. The glacial lake was deeper and covered a much greater area than the present lakes. For instance, the Lake Ontario basin was occupied by Lake Iroquois which left shore lines to the north of Lake Ontario, and on the south extended into the Finger Lakes and other areas.[6]

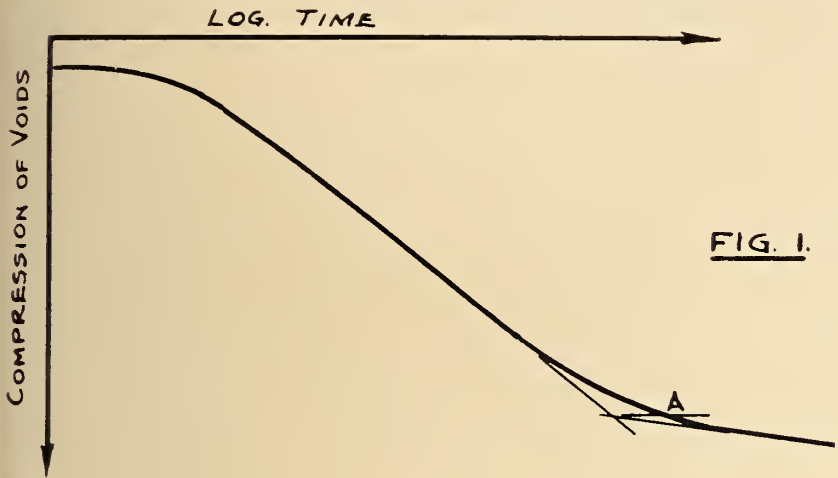
The formation of the lakes allowed the free seimentation of soil to the bottom of the lakes. The type of material deposited depended of course, on the type of material available in suspension and the season of the year. However, the net result was the formation of a clay deposit which in many cases is of a relatively weak nature.

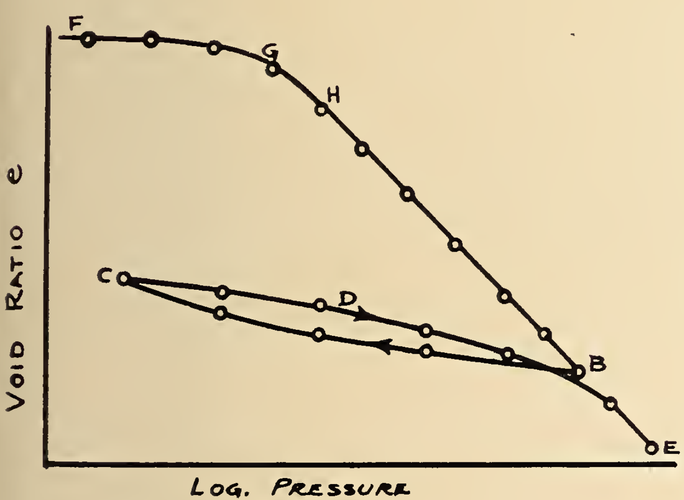
Glacial-lake deposits can be found today above the present water levels. Some of the deepest exposed deposits are found south of Lake Ontario. However, they have been almost completely removed from the higher lands on the north shore in Canada.

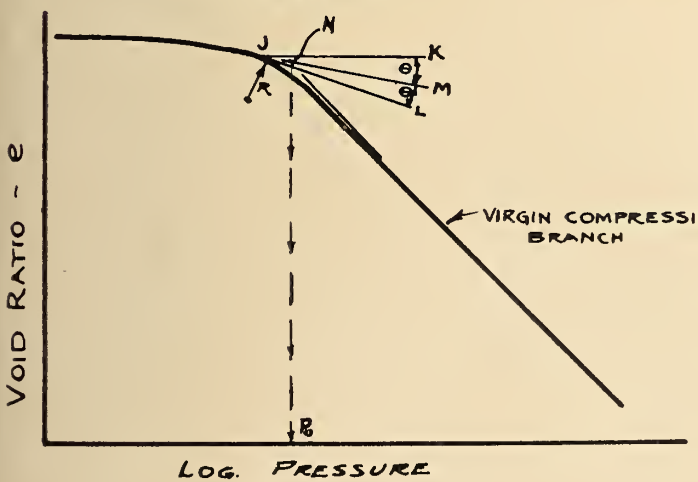
The seasonal variations which occurred in the pro-glacial lakes in the fresh, cold glacial water commonly experienced a summer and winter alternation in the type of material composing the glacial-lake clay deposits. In the summer relatively coarse, light grey material settled out in a layer, compared to a distinctly dark, finer grained layer deposited in winter. This alternate pair constitutes a varve. The transition from summer to winter is gradual, whereas that from the winter to summer is a sharply defined line or plane. The thicknesses of the varves vary with differences in melting rate in successive years. Therefore, it is possible to identify at different places the varve made in a particular year. When the unlike thicknesses of the varves for a series of years are plotted as an enlarged, jagged curve, the distinctive pattern of certain sequences is quite apparent. It has, therefore, been found possible to count thousands of years in succession where series of varve deposits permits the matching of such recognizable sequences from place to place. Together with this information, the determination of the maximum depth of glacial-lake deposits (even with undisturbed soil samples taken from drill holes) a correlation of total deposition in time in one locality compared with another, or with respect to surface elevation can be estimated.

As the glacier receded north, the St. Lawrence channel was reopened and the water level of Lake Iroquois was lowered to the present level of Lake Ontario which is 246.7 ft. above sea level.[2] The lowering of the water level caused the formation of streams in the Finger Lake and other regions which eroded channels in the glacial beds. One excellent example of this is the exposed varved clays at Mink Brook, Connecticut River Valley.

Figs. 1, 2, 3







Sedimentation or Consolidation

The formation of the glacial-lake clays is best described by the process of sedimentation and partly by consolidation. When the first seasonal or thickness of soil is deposited on the bottom of a lake it is considered to be normally loaded. It is exerted upon only by the forces of its own weight; that is, no greater forces have ever acted upon it in geological history. It is soft and any given volume of this deposit would consist of soil particles, which resemble a porous mass, with the pores completely filled with dater. The total load is taken by the soil skeleton. As another depth of soil or clay is deposited on the former layer, the former layer is not only subjected to the forces of its own weight but also the buoyant weight of the newly deposited layer of soil. As soon as this has occurred, the former layer begins to compress or consolidate under the new forces imposed upon it. The pore spaces, which can be referred to as voids, decrease under these loads. The compression or consolidation will continue until the load is no longer carried by the water phase but becomes completely supported by the soil skeleton. A characteristic curve for this process is shown in Fig. 1. When an additional layer of soil is deposited on the original soil layer, the original layer once again experiences the same pattern of consolidation as had occurred before. In each case the soil reaches 100% consolidation under the new load as represented by point A. However, it can be appreciated that the voids also have decreased during the successively larger loads to which it has been subjected.

The consolidation process which occurs in nature can be simulated in the laboratory by a consolidation test. Only the basic fundamentals of the test will be discussed here. However more details may be found elsewhere.[4] If the void ratio at A for each increment of load as indicated in Fig. 1, is plotted vs the log of the pressure due to the depth of soil, a definite characteristic type of curve is obtained as in Fig. 2. Each circle of the curve represents a point A of Fig. 1 for successively greater increments of load.

If we consider a soil sample from the glacial lake deposits which has been tested in the laboratory under increments of load which constitute the consolidation test, we will get the same type of result. However, let us load it to point B (Fig. 2) and then release the loads in small increments and in each case allow the soil sample to come to equilibrium before reducing the load further. Under these conditions we would obtain a curve BC. Then if we once again apply increments of load to the sample, and allow complete consolidation under each load, we will obtain the curve CDE. This curve represents a recompression branch of the consolidation or e log P curve. Point B represents what is called preconsolidation load point on the curve. The curve CDE is very similar to the original part of the e log P curve FGH. A point in the region of G represents a preconsolidation load in the same way as does point B. The preconsolidation load is the maximum load which has acted on the sample in its previous geological history; in our case the depth of overburdened or soil deposit.

The determinization of the location of G or the preconsolidation curve has a method which has been suggested by A. Casagrande. The graphical construction to locate the preconsolidation load is as follows. (See Fig. 3). Locate the shortest radius of curve in the region of the recompression curve as indicated by J. Next extend a horizontal line from this point and also construct a tangent to the curve at this point as represented by lines JK and JL respectively. Bisect the angle formed by KJL with a line JM. Next extend the tangent to the straight portion or the virgin compression branch of the curve until it intersects the line JM as represented by point N. Point N represents the preconsolidation load or maximum pressure that has acted on the sample of clay before in its geological history. The preconsolidation pressure is represented by pressure po. This pressure was caused in the case of our soil by the effective unit weight of the overburden multiplied times the depth of the deposit. The effective unit weight of the natural soil deposit is relatively simple to obtain and therefore the depth of deposit which existed over the sample in its geological history can be computed.

Fig. 4. Great Lakes Area

Maximum Depths of Overburden

A large percentage of the glacial lake clays in the Lake Superior, Lake Huron, Lake Michigan and Lake Erie areas are normally loaded. That is they have at present the greatest, or almost the greatest, overburden pressure acting on them that has acted on them in previous geological history. This is borne out by test results on glacial lake clays from Chicago. Sault Ste. Marie, Saginaw, Detroit Toledo, Fremont, Cleveland, as reported by others.[7,3] (Fig. 4). In some localities of these Great Lakes no overburden to a maximum of about 10 ft. has been removed in geological time.

However, in the Lake Ontario area, there are large deposits of glacial lake clays which indicate clearly that great depths of clay have been removed from the existing surfaces. An example of this occurs in the Kingston area. (Fig. 3). Consolidation tests performed on samples located below the present lake level indicate that at one time the soil had been subjected to pressures greater than those which exist today. These pressures were equivalent to a depth of about 100 ft of overburden greater than which exist today, or to an elevation of 347 ft. approximately.[8]

It is obvious that a similar case exists in such areas as the Finger Lakes and Mink Brook to the south and in other locations around the shores of Lake Ontario. With the determination of the age of a specific varve of glacial clay and the total pressure of depth of overburden in one locality compared with another it is possible to determine the respective amounts of total deposition or sedimentation in one area compared with another with respect to age or time.

Economic Aspects of
INDUSTRIAL POWER PLANTS

H. R. Wright, M.E.I.C.
Swanson Wright & Co. Engineers Ltd.,
Consulting Engineers, Vancouver.

The cost of power in industrial operations is generally a minor part of the total product cost. Even though the percentages are not high, a reduction or increase in the cost of power can be significant in maintaining adequate operating profit margins.

IT IS sometimes surprising to find that, with the possible exception of the metal refining industry, the cost of power in an industrial operation is not a major component of total product cost. It varies from about 1% in the lumber industry, 4% to 8% for pulp and paper, to 12% to 15% in some chemical plants. While these percentages do not appear to be high in themselves, a reduction or increase in cost of power can be a significant factor in maintaining satisfactory operating profit margins.

In the planning stages for a new plant or expansion of an existing plant, it is important to know whether or not serious consideration should be given to investment of capital in generating plant as opposed to purchase of power from an outside source.

Many of our pulp and paper and metallurgical plants obtain power from hydroelectric developments which are operated by the plant management or by wholly owned subsidiaries. The calculation of power costs is a relatively straightforward addition of fixed charges on capital, operating and maintenance labor and supplies, charges for water consumption, taxes and insurance. In certain cases it is possible to prorate some of the supervision and maintenance charges, and, where water is re-used for process, to prorate charges for water, but these are adjustments of secondary magnitude and calculations are similar in other respects to those for a separate hydro-electric utility system.

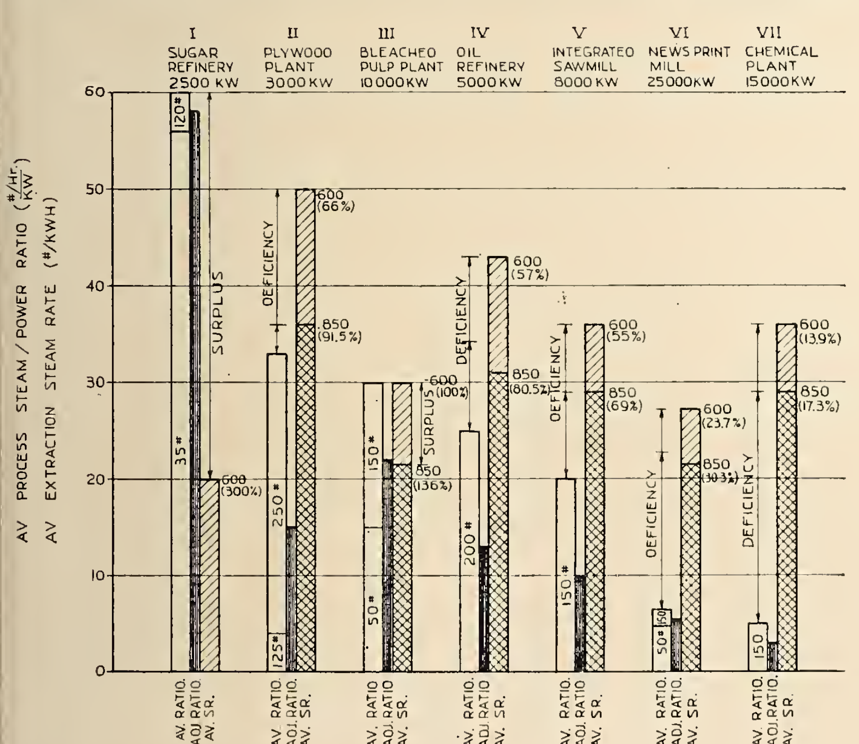
The calculation of power cost for a diesel electric plant is also comparatively straightforward except that prorated costs and possible credits for heat recovery may be of greater relative magnitude.

Steam electric plants, on the other hand, are often integrated closely into requirements for process steam, and the prorating of capital charges and operating costs can be complex.

It is of value in these cases to make rapid preliminary calculations of approximate cost. This paper has been prepared to provide a means of approximate determination of probable costs for steam power generation where the boiler plant is a necessary part of the process plant.

In general it can be stated that the diversion of capital for construction of an industrial steam power plant be-

Fig. 1. Variation in process steam/power ratios for a number of industrial plants.



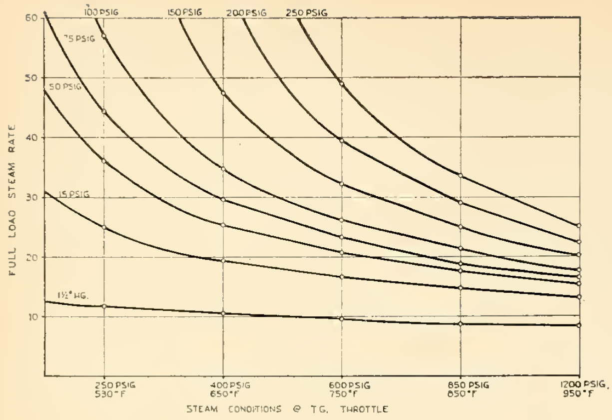


Fig. 2. Steam Rates for extraction turbines at different throttle and extraction pressures.

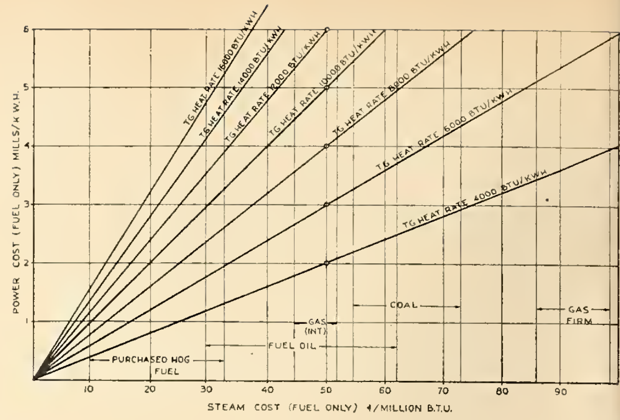

Fig. 3. Steam cost in cents/MKB against power costs in mills/kwh. for various turbogenerator heat rates.

comes increasingly attractive with: (a) an increase in the ratio of process steam demand to process power demand; (b) a decrease in the process steam pressure; (c) an increase in required power plant rating; (d) an increase in plant load factor; (e) a decrease in fuel cost.

Fig. 1. is a vertical bar diagram in which the first illustrates the wide variation in process steam/power ratios for a number of representative industrial plants.

For the sugar refinery the ratio is 60/1 with the greater part of the process steam requirements at 30 psig.

For the plywood plant the ratio is 33/1 and the main process pressure 250 psig. For the bleached pulp mill the ratio is 30/1 and the process flow divided equally between 50 psig and 150 psig. Similarly for the integrated sawmill the ratio is 20/1; for the newsprint mill, 6.6/1; for the chemical plant, 5.7/1, and for the oil refinery the ratio is .7/1.

These ratios may vary for specific plants in the same industry but can be taken as typical of the wide variation between industries.

The second bar in the chart shows the relative steam/power ratios after adjustment to a common 30 psig level by multiplying by the ratio of extraction steam rates from a common high-pressure base. The relative positions of the plywood plant and the bleached pulp mill are reversed by this adjustment.

The third bar in the chart shows the weighted average extraction steam rates for high-pressure steam conditions of 600 psig, 750° F., and 850 psig, 850° F., and the approximate surplus or deficiency of potential power generation from process steam in each case.

When the surplus is large, as in the case of the sugar refinery, and the variation in steam and power demands relatively small, it is possible to operate the plant without using a turbine condensing section. When the margin is small or where there is a deficiency, it is necessary to provide a condensing section, a separate condensing turbogenerator, or the equivalent in an outside power connection for frequency stabilization.

Fig. 2. is a chart showing aproximate steam rates for extraction turbines at different throttle and extraction pressures. The steam rates shown are full-load rates for a 5000 kw. unit and require adjustment for turbine rating and for part-load and extraction losses.

From the steam/power ratio in Fig. 1. and the curves in Fig. 2., the percentage of total process power which can be generated from process steam can be calculated for standard throttle steam conditions. Using this percentage the average turbine heat rate can be read from the chart in Fig. 8.

When the cost of fuel and the probable boiler plant efficiency is known, the calculation of the fuel component of process power cost component can be completed by reference to the chart in Fig. 3., which plots steam costs (fuel only) in cents/MKB against power costs (fuel only) in mills/kwh. for various turbogenerator heat rates.

The calculation of capital and operating cost components is more complex.

In most industrial plants where

**Oil at 50 cents/MKB and Wood at 20 cents/MKB as steam.

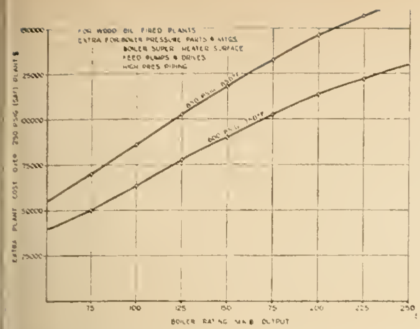

Fig. 4. Approximate additional cost of changing boiler plant steam conditions.

steam is required for the process in relatively large amounts, it is usual to assume that the capital investment required for generation of this steam is a basic charge against process equipment and only the additional cost due to increased operating pressure, increased boiler capacity, increased fuel storage, additional operating and maintenance charges, etc., are chargeable to the cost of power generation. Sometimes the segregation of these costs is a difficult task. For preliminary studies the charts which follow may be used with some discretion, bearing in mind that adjustments should be made throughout the preliminary calculation phase for any specific set of circumstances.

Fig. 4. shows the approximate additional cost of changing boiler plant steam conditions from 250 psig saturated to 600 psig, 750° F., and to 850 psig, 850° F. Costs include the extra for boiler pressure parts and super-heater, feed pump and drive, and high pressure piping, plus a moderate increase in boiler rating for plants where the majority of process power can be produced from process steam.

Fig. 5. gives preliminary estimating figures for the basic turbogenerator plant for non-condensing and extraction-condensing operation. It follows that any plant which shows a heat rate greater than 4000 B.t.u./kwh. must include the extraction-condensing turbogenerator or its equivalent unless an external source of power is available to make up the difference between non-condensing turbine output and plant demand.

In Fig. 6. the costs taken from Fig. 4. and 5. are combined to show the total capital cost in dollars chargeable to power generation and this same cost on a basis of dollars/kw. of plant capacity.

For extraction-condensing operation where there is more than minimum flow to the turbine condenser, it is necessary to add to the capital costs shown in Fig. 6. to reflect the cost of the necessary increase in boiler plant capacity. The amount of this adjustment can be obtained from the curves of incremental cost in Fig. 9.

The curves in Fig. 7. show approximate unit values of fixed charges corresponding to capital costs in the preceding curves for plant load factors of 50, 70, and 90%.

The slope of the preceding curves indicates why it is often difficult to justify power generation for smaller industrial plants even when fuel has a negligible or even a negative value, and at this point it is possible in many cases to form an opinion of feasibility without further study.

Typical unit costs for the plants listed in Fig. 1. are tabulated for comparison in Table 1. Charges include operating labour and supplies, and maintenance labour and materials, as incremental to those required for process steam generation alone. Fuel

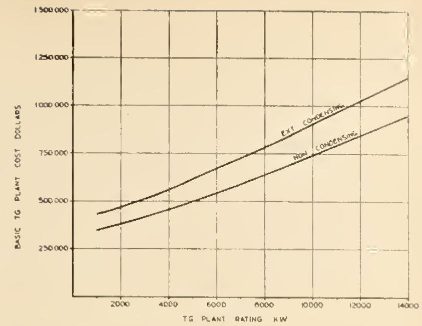

Fig. 5. Preliminary estimating figures for the basic turbogenerator plant.

charges are also based on incremental fuel values so that power generation in the wood/oil-fired plant is charged with the higher cost fuel. The totals are representative of costs actually experienced in similar plants.

As suggested, the principal value of the charts and the comment in the foregoing is to permit a fast preliminary appraisal of the economic feasibility of a project and to point out the areas which justify further detailed analysis, and for this reason they have been found to be a useful addition to engineering reference files.

As may have been gathered from the subject matter of this paper, one of the author's principal interests is in the study of power generation in the forest products industries.

In the lower mainland of British Columbia there is available an annual surplus of 600,000 units of hogged wood waste. In spite of conversion of most or all suitable solid waste to pulp chips, and diversion of some bark to production of bark extractives, the total surplus increases each year due to increased mill production. In urban areas where operation of burners is prohibited by air pollution by-laws,

Fig. 6. Costs from Fig. 4 and Fig. 5 combined to show total capital cost.

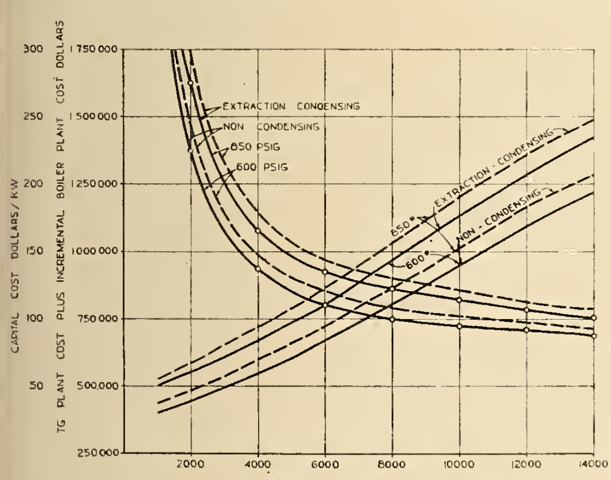

Fig. 7. Unit values of fixed charges corresponding to capital costs in the preceding curves for varying plant load factors.

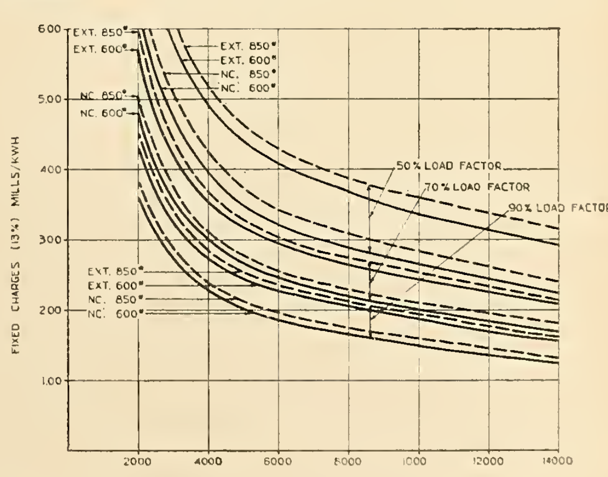

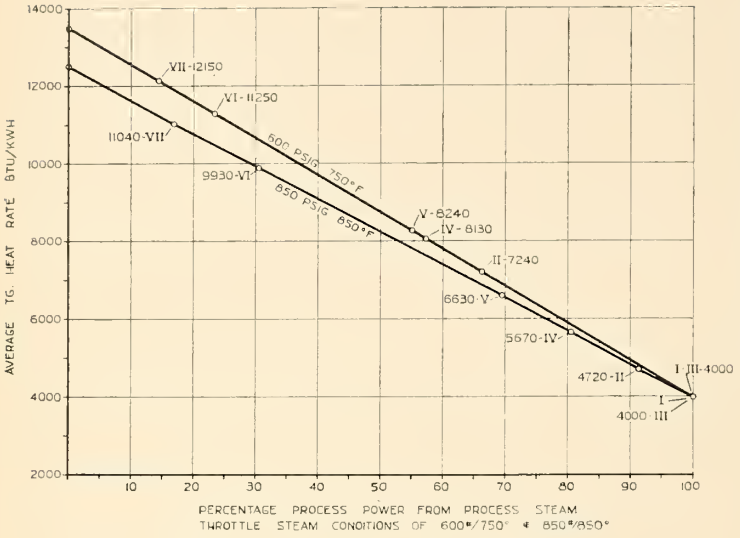

Fig. 8. Average Turbine Heat Rate

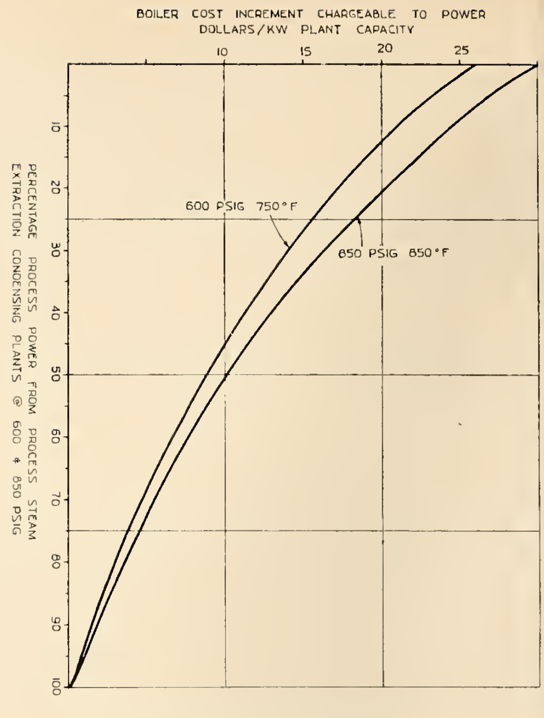

Fig. 9. Curves of Incremental Cost

disposal expense is a very real problem to mill operators.

Some time ago a study was made to determine the feasibility of construction and operation of a 150 MW, 60% load factor, utility type steam power plant to provide an outlet for disposal.

This study indicated that the industrial type power plant where the power plant is combined with process steam plant, as outlined here, is possibly a more profitable method of utilizing the available wood waste. This is especially true if the waste originates in the same plant, and the power plant fuel system is integrated with the mill waste system.

Consideration of the power generation project is prompted by necessity for replacement or expansion of existing power steam generating plant, by pressure from air pollution authorities, by a sudden increase in rates for purchased power, or by a combination of these factors, and where the power load is appreciable, the generation of power can show a satisfactory return from savings in purchased power and reduction in waste disposal expense.

In the selection of equipment for such a plant the specification for the boiler is a major item for thorough study.

The term 'hogged wood waste', or 'hog fuel', does not describe fuel characteristics any more than the term 'coal' describes the characteristics of lignite or bug dust. The range of variation is in some ways similar to coal. For comparison, coals vary in moisture content from under 5% to possibly 30% (or a ratio of 6/1), with higher heating values varying from under 8000 B.t.u./# to over 13,000, a ratio of 1.6/1. Wood waste may vary from 10% moisture content for plywood plant sander dust to over 60% moisture content for hemlock bark, a ratio of 6/1, and higher heating values from 7150 B.t.u./# for the true firs to over 10,150 for Douglas fir bark, a range of 1.42/1. The variation in fuel quality during actual operation is also probably greater and more rapid than in any coal-fired plant. Many operating problems are due to this sudden change from wet to dry fuel and back again to wet.

In recent years most of the large wood-fired boilers have been designed for pulp mill use to burn wet bark and refuse from the woodroom, augmented usually with oil, coal or gas fuels, or in a few cases by solid wood waste from outside sawmills: a somewhat different application from the normal sawmill or plywood plant application.

It may be of interest to examine some boiler designs offered recently for sawmill, plywood or shingle mill application.

These include a unit for pile burning of wood waste in a grateless cell at the bottom of a furnace designed for supplementary coal or oil fuel; a unit for optional thin bed or low pile burning of sawmill/shingle mill waste; and a somewhat larger unit for thin bed or pile burning of sawmill/plywood waste.

Each of these units provides for air preheating to approximately 500° F. to improve furnace stability with wet and variable moisture fuels and to improve boiler efficiency for possible future firing of purchased fuels; a baffle-free boiler bank to minimize erosion; from 20 to 50% of preheated high-pressure overfire air for increased furnace turbulence, to burn out light fuel particles; and a cinder return system using spent gas as a conveying medium to reduce fire hazard in collector hoppers. Sander dust where available is introduced with a minimum of conveying air below the feed spouts.

Incorporating improvements of this kind, a power plant just commissioned will replace two old HRT dutch oven process steam plants, and generate approximately 8000 kw. of process power requirements.

Our industrial plant management groups are continually striving for increased uitlization of raw materials and reduction of even minor items of operating expense. Where power generation can be shown to provide a satisfactory return on investment, there is little hesitation in providing necessary capital for quality equipment. The engineer can be of real value to these groups in preparation of feasibility studies, design, and in the solution of the many problems which accompany the development project. EIC

TRENDS IN ELECTRICAL ENGINEERING EDUCATION

B. R. Myers, M.E.I.C.

Professor of Electrical Engineering and Chairman of the Department, The University of Waterloo, Waterloo, Ontario.

In this age of rapid development it is recognized that many of the professions, engineering included, require instruction in greater depth than now is available during a four year course at university. Traditional teaching concepts must be revised.

THE SCOPE and procedures of engineering education are in a state of rapid evolution. More and more, it is being recognized that engineering as the other professions—requires education well beyond the bachelor's degree, and that a period of internship is required before a truly professional status is attained.

The traditional concepts of engineering education are therefore fast disappearing. Predominant in this trend is abandonment of the teaching of detailed engineering practice. The "know-how" type of course has been relegated from the university to either on-the-job training in industry after graduation or to the vocational school or technical institute, whose job it is to train rather than educate. In particular, non-technical courses on such matters as industrial processes, industrial management, which at one time, and not too long ago, were found in every engineering curriculum—no longer have a place in the university, since they tend to be descriptive and qualitative in nature and contribute little or nothing to the analytical and philosophical education of the individual. Similarly, the course content and teaching procedures of the technical courses are changing. The emphasis is towards more scientific disciplines, and away from practical engineering skills and manipulative procedures.

In short, the function of a university engineering curriculum is no longer to match the graduate to the industrial job market, but rather to give him a potential for creative activity in his chosen field. The onus for acquainting him with the clutteria of practical engineering procedures and the industrial climate must rest with industry in his internship after graduation, at the same time recognizing the potential which he has accrued in his university years and which he must be given the opportunity to develop further in his professional career.

The reasons for these trends are not hard to find. In contrast with earlier times, the spectrum of technological activity which now falls under the aegis of the professional engineer is almost without bound. Practising engineers are constantly confronted with problems for which their past training and experience is inadequate. Thus, training for a specific job is neither possible nor desirable. One manifestation of the trend in the last decade has been the vast increase in the industrial demand for engineers with advanced degrees. Another manifestation has been the introduction of post-graduate training programs by many large industrial organizations, offering purely academic courses of the type given in university graduate schools. Still another manifestation has been in the converse direction—the tendency for new graduate engineers to seek employment in the larger industrial organizations which can afford to offer further education and which also encourage research activity and scholarly pursuits.

These trends are particularly true in electrical engineering. Electrical engineering education is moving away from the traditional concepts of engineering more rapidly than any of the other disciplines*. The traditional simplifications formerly used in the teaching of many subjects are now clumsy and both practically and philosophically inadequate. Electronic devices are appearing, particularly semiconductor devices, which cannot be treated by classical physics; classical circuit theory is inadequate at frequencies which are now common; the teaching of "heavy" electrical engineering—heavy rotating electromechanical machinery courses and electric power systems analysis—and which used to occupy a major portion of the electrical engineering curriculum—now occupies but a small part of the academic spectrum. Indeed, modern electromechanical problems have become much more so-

*The author includes those electrical engineering subjects which are taught in Canada under the guise of "Engineering Physics"; for example, much of electromagnetic engineering, control system work, and so on.

phisticated—extending, for instance, into the subject of magneto-hydro-dynamics.

By virtue of the unique inter-disciplinary nature of electrical engineering, electrical engineers are rapidly assuming a dominant role in such fields as physiology and psychology —fields which are diverse in their pursuits. Experimental psychology in particular might almost be regarded today as a branch of electrical engineering which has sprung up on the wrong side of the campus. Another field in which electrical engineers have played a significant lead is that of information theory, due to the obvious connotation with signal communication theory. The electrical engineer finds himself intimately able to contribute in these various fields because he is disciplined in circuit theory, communication systems and control systems. These disciplines find ready application in physiology in studying neural responses and biological control systems; and in experimental psychology in studying muscular responses to electrical impulse trains, i.e. an application of data processing techniques—the analysis, storing and processing of digital data.

Reactions to these trends in different educational institutions have been many and varied. In fact, the academic scene is in a turbulent state of flux, not only in North America, but also in most other countries. A quick survey of existing curricula is enough to reveal that there is no such thing as a "typical" curriculum. Some curricula (particularly some of those offered as "Engineering Physics" in Canadian institutions) have a predominantly theoretical and scientific content; at the other extreme, some schools still offer a traditional curriculum, with a heavy content of classical rotating machinery, power, and industrial engineering courses.

The only significant common factor seems to be the turbulence and activity which exists in academic circles. Educators are searching for an optimal curriculum. An indication of this activity is the increasing number of conferences and meetings being held in North America for the specific purpose of discussing electrical engineering education. Some particularly well-attended meetings were the Summer 1957 Curriculum Workshop held at the Massachusetts Institute of Technology, the 1958 Sagamore Conference on Electrical Engineering Education, the Symposium on Electrical Energy Conversion and Control held at M.I.T. during the summer of 1958, the Spring 1959 Laboratory Workshop at Syracuse University, and the Conference at the Case Institute of Technology in 1959 which was devoted to the place of materials in the curriculum.

The purpose of the present article is to collate some of the current aspects of technical trends in one place and under one title, and thus give the situation a perspective which may be useful in guiding the electrical engineering educator's thinking in matters of curriculum planning. No pretense is made in the article of presenting, or even suggesting, a solution to the problem of optimizing a curriculum. Such a solution can only come after considerable deliberation and mutual exchange and assimilation of ideas over the years; even then it must be one of compromise.

Selected topics will be considered one at a time, and attention will be confined primarily with the undergraduate curriculum in mind.

The Basic Science Content of the Curriculum

The demand for more scientifically mature engineers has lead to a re-examination of the physics, mathematics and chemistry content of the engineering curricula. Although the reader can no doubt think of many others, some of the more popular questions being asked are:

Should classical physics precede the teaching of modern physics?

At what level, i.e. in which year, should modern physics be introduced?

Is enough mathematical preparation given to ensure an adequately quantitative level of presentation of the physics material in early years?

Might not some of the early mathematics and classical physics be better taught by members of the engineering faculty?

What provision should be made for advanced courses in physics and mathematics?

Should physical chemistry be a required course for engineers?

To what extent can numerical analysis, probability and statistics be introduced into the curriculum?

In physics, the main topics required in the freshman and sophomore years are Mechanics, Modern Physics, Electricity and Magnetism. In addition, there is usually some coverage of Heat and Light.

There is little doubt that these topics must be retained in the early part of the curriculum since they are basic to engineering. Mechanics is the most basic of all, and should be a substantial course spread over a whole academic year in order to permit assimilation of the material. It should be taught in the freshman year in order not to retard the rest of the curriculum. This brings up an important difficulty, however: namely, that the freshman is normally only just being exposed to the calculus which the mechanics course really requires. To postpone the mechanics course to sophomore year, that is until after freshman calculus has been completed, does not seem to be the answer because the same difficulty would arise in connection with whatever physics course was given in place of mechanics in first year.

The most tenable answer to the problem at the present time seems merely to require that the freshman physics instructor be made fully aware of it and hence prepare his lectures carefully to make up for the students' deficiency in mathematics at this stage. Hopefully, it may eventually be possible to enhance the level of preparation in high school prior to entering university, and thus eliminate the problem.

A similar difficulty is encountered with the modern physics course. If given at an early level, the student's mathematical maturity is inadequate to permit other than a qualitative survey course. Nevertheless, it is generally believed that it should indeed be given prior to the professional courses, to lay the groundwork for such courses as semiconductor electronics and a modern presentation of the properties of materials in the professional part of the curriculum.

Should the engineering faculty teach the early classical physics and mathematics courses? This is a debatable question, and one which has not yet been resolved. One school of thought is adamant in their "physics-by-the-physicists" and "mathematics-by-the-mathematicians" beliefs. Another school of thought believes that it would make for a better academic whole to have the engineers teach these early courses. Thus there would be less unnecessary duplication of material in the later professional courses, and the psychological effect on the student would be to improve, or even eliminate, his attitude to these early courses. This attitude now is generally one of intolerance and impatience due simply to the fact that the courses are given outside of the engineering departments.

As to what provision can be made for advanced courses in physics and mathematics in the later part of the curriculum, this is very much a local matter, depending on the size and facilities of the particular institution.

Presumably the most convenient method is to offer such courses as technical electives in the professional years; for example, a selection from courses in atomic and solid-state physics, experimental nuclear physics, quantum mechanics, physical chemistry, group theory, the calculus of matrices, advanced complex variable function theory, and so on, in addition to the more conventional sequence of electives in engineering. Thus, the full spectrum of student ability and engineering could safely be accommodated within a single curriculum, and much of what is taught in Canada under the title of "Engineering Physics" would be moved into the engineering curricula proper—which is where, in this author's opinion, it belongs. While there was a need many years ago for curricula which, as it were, bridged the gap between engineering and physics, that bridge has now been crossed by the engineers so that "Engineering Physics" as a title is rapidly becoming obsolescent.

Incidentally, it may be noted that physical chemistry was listed above as a possible advanced or elective course. This essentially answers an earlier question as to whether physical chemistry should be a required course. It seems to be generally agreed that it is not a necessary part of the curriculum for electrical engineering.

How about the last of the questions listed earlier—to what extent can numerical analysis, probability and statistics be introduced into the curriculum? Here, some definitive answers have cemented in the last two or three years. Due to the increasing complexity of modern technological systems, these topics have become essential to the training of the engineer. The increasing number of variables and the magnitude of the problems which he now has to solve calls for formal education in the methods of numerical analysis—leading in his professional years into the use of digital computers. The increasing complexity of modern systems and the continual tightening of performance margins, calls for some training in probability and statistics.

It is therefore felt that these topics should be seeped down into the undergraduate curriculum. *Numerical methods* and *numerical analysis* should be given in each of the professional years. Furthermore, they should be given by the mathematics department, since the mathematicians are best able to separate the problems and techniques into classes and thus maintain an orderly perspective which the professor of engineering may not have. Ultimately, in senior year, a course in digital computer programming may be given as an elective by the mathematics department. Computer aspects proper are dealt with in a later section of this article. Suffice it to say that numerical methods and numerical analysis courses are essential to the preparation and support of the computery work which the engineer will get in his professional courses.

The situation with *probability* and *statistics* is not quite so definitive. Past practice has been for the engineers to teach this material as and when they need it, in communication theory courses, for instance, rather than run it as a separate entity given by the mathematics curriculum. Since engineers are usually well-versed in the applications of probability theory it might be as well, in these days of crowding curricula, to continue the existing pattern.

So much for the basic sciences in the engineering curriculum. While the venue of this article is directed specifically towards the *electrical* engineering curriculum, many of the remarks made in this section apply also, of course, to the other engineering disciplines such as mechanical, civil and chemical.

Field Theory

All naturally-occurring electrical phenomena are basically three-dimensional. They are explainable in terms of field theory. The seemingly logical approach to the electrical engineer's professional education would therefore be to start with field theory. It might be said that this is in fact done to some extent in the early physics courses, when fields of force and other phenomena are studied. In the professional courses, however, it is an unfortunate fact that electrical engineering has traditionally relegated field theory to the background.

The reason for the traditional approach is not hard to find. Phenomena have been handled in the guise of circuits, with the circuit parameters defined on the basis of mathematical, not physical, concepts. The field concepts involved in the definition of circuit parameters have been given very little attention; for example, the convenient mathematical description of lumped resistance, capacitance and inductance is well approximated by the physical behavior of practical elements in the frequency ranges which have been in common use in the earlier development of electrical technology. The extension of frequency usage into the microwave region and beyond brought courses in electromagnetic engineering which were simply tacked on to the curriculum in the senior undergraduate years. Much of the associated theory merely extended the undimensional, linear, low-frequency concepts.

This approach does not always serve modern needs, however. Electrical engineering research activity in recent years has been directed in areas such as molecular engineering, microwave computers, cryogenic devices, solid-state devices, magnetohydrodynamics, parametric devices, scatter propagation, plasmas, beta-ray spectroscopy, nuclear blast simulation, biological computers, neurology studies—an infinity of applications requiring a more fundamental understanding of basic phenomena. These researches have made, and are still making, their impact on industrial technology. It is therefore becoming increasingly important that the undergraduate student be prepared, at least psychologically, to contribute in these areas if called upon to do so in his professional activities after graduation.

Many schools are doing this by giving an electrical science course immediately following the early physics courses, in which an engineering interpretation of basic field phenomena is developed and in which a thorough appraisal of field concepts is involved in defining circuit parameters. In addition, the early properties of materials courses are now being treated as much from their internal microstructure as from their handling and external working properties. In the solid-state area, modern electronic courses now include appreciable solid-state theory. In electromagnetic engineering, there is a welcome tendency to introduce elementary waveguide and antenna theory more thoroughly into the curriculum.

All this has been made possible by elimination of what used to be traditional courses such as economics and industrial processes, as well as by more efficient use of the time available in those courses which have been retained. Even so, there still is a tendency in many institutions to leave field theory until the later years, rather than seeping it down throughout the curriculum in conceptual and other forms. The issue is one which is constantly being evaluated by electrical engineering educators in searching for a well-balanced modern curriculum.

Circuit Theory

It is difficult to divorce circuit theory entirely from field theory in talking about the curriculum since the two disciplines are fundamentally inter-related and the ideal curriculum would presumably develop the two aspects simultaneously. There are, however, some distinct trends in the presentation of circuit theory, per se, which are worthy of note.

First and foremost, tradition has developed a large body of circuit *analysis* for strictly *linear* systems. The pattern has been to first introduce the student to elementary steady-rate analysis of simple passive circuits in his early physics electricity and magnetism course. This pattern continued in the electrical engineering courses with sinusoidal and cisoidal analysis of linear circuits. No attention was paid to non-linear and time-variant circuits. The pattern has changed considerably in the last few years, however, in that pole-zero concepts are now fairly general and the Laplace transformation has been almost exclusively adopted. The emphasis is more towards pulse techniques, and away from the old sinusoidal and steady-state influence. One manifestation has been that it is no longer philosophically desirable to have the student introduced to circuit theory from the sinusoidal steady-state point of view in the early physics course. Another manifestation is that certain aspects of network *synthesis* material are creeping into the undergraduate curriculum.

A more significant trend has been the incorporation of *signal theory* into what used to be exclusively circuit theory courses. The feeling is that signals and circuits cannot justifiably be divorced. A particularly important philosophical aspect is that this joint pattern lays a sound basis for bringing in some non-linear and time-variant circuit theory, by virtue of the student's introduction to integral transformations. In addition, it has become obligatory for the student to be exposed to the theory of functions of a complex variable—though many schools still teach this within the engineering courses proper, as and when they need it, rather than having a separate course in the subject given by the mathematics department.

Another function of the circuit theory courses is, of course, to generate the disciplines on which most servomechanism and control system theory depends. In this age of automation, it is highly desirable that the student of electrical engineering be required to take one course or another in control or servo systems in his senior year. This is rapidly becoming the case in mechanical engineering as well.

Energy Conversion

One of the most active areas of academic interest, that which used to be called "electrical machinery", is being redefined. The modern aim is to provide the students with a unified treatment of the theory of electrical machinery by approaching it from the standpoint of the underlying principles of electromechanical energy conversion. The steady-state performance of machines has traditionally been studied by phasor and equivalent-circuit methods. More attention is now being paid to transient analysis by generalization of the impedances through impedance transformations. Laplace transform methods are finding favour over the conventional use of Heaviside's calculus.

Thus, the modern approach to machinery exactly parallels that in circuit theory and communication. In conjunction with a more rigorous alliance to basic field phenomena, "machinery" thus presents the area of most radical change. It is extending even into magnetohydrodynamic conversion studies (the motion of an electrically conducting fluid in the presence of a magnetic field).

In short, energy conversion is appearing as the most important concept in electrical engineering education; it facilitates the cohesion of circuit theory, field theory, linear and non-linear systems. It presents the greatest threat to the older pattern of curriculum, which involved rotating machinery and power system courses.

System Analysis

One of the distinctive features in engineering which distinguishes it from other fields is the emergence of the *system concept*—the engineer's interest in whole systems, as opposed to the lone and separated components which comprise a particular system. Examples include transmission systems, electronic systems and control systems. The behavior of a vacuum tube, for instance, is of little interest as a physically isolated device; rather, it is its behavior when the device is embedded in its applicatory environment that is of most interest—specifically, the dynamic behavior of the system as a whole; for example, an electronic feedback amplifier is more properly viewed as a system, rather than as a collection of discrete components.

This systems-oriented bent, like the concept of the principle of energy conversion, has made a particular impact in very recent times on the rotating machinery area of the electrical engineering curriculum. The earliest electrical engineering curricula evolved primarily from a study of the theory, design and operation of rotating machines. The several types of machines were dealt with both separately and one at a time. Early courses dealt with the characteristics of each machine on its own.

With the advent of control systems and servomechanisms, however, a unification of curriculum planning has appeared possible. Just as with the vacuum tube in electronic applications, the rotating machine is now being treated as a component of an electromechanical system. This approach may well prove to be significant in achieving an optimal and efficient curriculum, in keeping with the increasing demands of the times.

Computery

The spectacular growth of technological achievement in recent years has been made possible primarily because of the even more spectacular growth of the computer field—a field which was not in existence twenty years ago. Both analogue and digital computers have become necessary tools of the practising engineer. The undergraduate student must therefore be exposed to their operation and use. While electrical engineers are interested in the design of computers as well as in their use, this section will be confined only to their use as a problem-solving tool.

The techniques needed to solve a problem on the *analogue* machine do not differ too greatly from those conventionally used in engineering analysis. Thus, little formal instruction is required for most educational purposes. One simple answer is to have a small analogue computer, for instance a desk-top machine, located permanently in each of the undergraduate laboratories. The machines should be accessible not only during their regularly scheduled laboratory sessions, but also at other times, to encourage the students to resort to them in solving homework problems as well as laboratory assignments. An alternative possibility to having a small analogue machine located in each laboratory would be to have a pool of several of them in a central location, with free access for students at all times.

The important thing is that it is of little use having computers available only at restricted times. Just like the slide rule or desk calculator, the computer must be available and ready for use essentially at the very instant that the individual requires it. This is particularly important so far as a student is concerned, since his time is limited by rigorous class schedules. If the computer is not available when he wants it, that is, when he is both free to use it and at the same time is motivated to do so, the danger is that he may never get to use it at all. This would constitute an educational failure for which the faculty would be, surely, as culpable as the student.

Concerning the *digital* computer, the common methods of solving engineering problems are no longer satisfactory. It calls for formal courses in numerical methods and some instruction in programming. These topics were discussed earlier in the section on the scope of the basic sciences in the engineering curriculum. Briefly, it was stated that numerical methods and analysis should be introduced and taught by the mathematics department in the professional years. A course entity in computer programming is not necessarily desirable, however, for programming is the professional prerogative of the mathematician.

Accordingly, it is believed that the best way to introduce the student to the digital computer as a problem-solving tool is through the medium of a small machine, to be used in regular course work rather than as a separate course on its own. Each electrical engineering department should have its own small digital computer, and program library. The students should be given enough instruction so that they can write elementary programs and gain some feeling for the potentiality of computery. It is not necessary that they be able to write the programs for all the problems which they may be called upon to solve by computer in their work. Library programs should be made available for the more complex problems.

A major objective in introducing computery into the undergraduate work is, of course, to eliminate the drudgery of long-hand computations. It is generally accepted that long-hand methods contribute almost nothing to the individual's education. In this day and age, no efficient engineering industry would fail to take advantage of computer facilities— either owned, rented or through a service bureau. Thus, most engineering graduates will have computers available for their work.

In addition to the small computer as a campus facility, there is also the question of establishing a large on-campus computing centre. Such a centre would house a large digital machine and would be staffed by professional full-time staff. Its function, however, would be more in the graduate and faculty research areas, rather than in undergraduate teaching. This author is firmly convinced that all universities should aim at establishing such a facility, though the question is not immediately germane to this article and will not therefore be discussed further.

Laboratories

Laboratory experience has always been, and still is, an essential ingredient of engineering education. With the increasing level of abstractness and unification of the classroom material, several questions arise in connection with the laboratory sessions.

First, is it now preferable to aim towards a more general type of laboratory, rather than the more prevalent fashion of running separate laboratories to accompany the corresponding lecture courses? Secondly, there is the impact of computery, discussed in the previous section, which permits more time for truly educational work by virtue of the elimination of long-hand and point-by-point computation.

These are probably the two main aspects, though the reader can no doubt think of many others. Suffice it to say that this is another of the most turbulent areas of interest. Some positive reorientation seems to have been effected at many schools. For example, the classical approach to heavy rotating machinery laboratories is disappearing in favour of the systems approach to machinery. It has finally been acknowledged in many areas that it is not necessary to employ huge, multi-horsepower machines; small, fractional-horsepower machines do the job just as well. Furthermore, the small machine is readily integrated into a control system, thus unifying the field and making for a better overall offering. In the electronics area, pulsed and digital experimentation is replacing a lot of the older sinusoidal work. Switching circuits are finding a place in the undergraduate laboratory — with an increasing element of logical design, rather than the more usual type of cut-and-dried experiment which had an accompanying set of purely manipulative instructions.

The basic problem in organizing a modern laboratory seems primarily one of faculty time available for preparation and supervision. It is much less time-consuming, and therefore also more economically feasible in terms of operating budget, to prepare and supervise the discrete, cut-and-dried type of experiment than the type of experiment involving design and interpretive work.

Concluding Remarks

The primary purpose of this article has been to list the major trends which are occurring in electrical engineering education and at the undergraduate level, and some of the reasons and manifestations associated with these trends.

Briefly, present reorientation of the undergraduate curriculum is towards truly scientific fundamentals, with a strong, almost total, de-emphasis of current engineering practice in industry. Due to the increasing complexity and size of modern technological systems and the continually accelerating pace of technology, the function of a university engineering education is no longer to match the graduate engineer to the immediate industrial market; rather, it is to give him the analytical and philosophical depth which means that, after a subsequent period of internship in industry, he has the creative potential which the present day calls for, as well as the potential for professional leadership.

No attempt has been made in this article to present a solution to the problem of drawing up a composite curriculum. It is felt that it would be unreasonable and uninformative to do so; for not only does so much depend upon local conditions, but also the national and international academic scene is still one of turmoil and indecision in searching for common agreement on what should be done.

Robert F. Legget, M.E.I.C.,

Director, Division of Building Research, National Research Council, Ottawa.

Early Ottawa and Engineering

OTTAWA is a charming city. To both residents and visitors alike the nation's capital with its waterways, its parks and parkways, and its steadily growing collection of stately buildings crowned by the noble group of buildings on Parliament Hill, must often appear to be a perfectly located city, an expanding municipality utilizing an area specially chosen as a desirable site for a capital city. But all who know anything of the history of Ottawa know that this superficial impression of its beginnings is far from correct. The city does occupy a lovely location but the city of today stands where it does mainly because it occupies the site of an early construction camp, built on a clearing in the virgin forest, its location determined by the start of a military canal that is still a notable engineering undertaking. This is but one of the close links between early Ottawa and early engineering work. Today under the co-operative guidance of the National Capital Commission and local municipal councils it is slowly being transformed from a rather nondescript town into a capital district of which the nation may well be proud.

There are many major cities of the world located on the banks of one river, some at the junction of two. There are but few cities, however, that have the good fortune to have three important rivers within their bounds. If the residents of Hull and Gatineau Point will permit such a slight geographical inexactitude, for the purpose of this paper only, then it can be said of Ottawa that its immediate area does include the confluence of three important rivers, the Ottawa, the Rideau and the Gatineau, all of which have had their influence upon its development. First and foremost is the Ottawa, one of the truly historic waterways of North America, providing the main route to the interior of most of this continent for almost all of the early explorers.

It was in 1613 that Champlain saw and described the lovely falls of the Rideau River, as he approached the Chaudière, there to disembark and follow the two short portages on the north bank of the river, long used by the Indians. As the continent was explored, he was followed by a steadily increasing stream of travellers, the Ottawa being used in preference to the St. Lawrence as the more direct route to the upper lakes and to the north. Brûlé and Nicolet, Le Caron and Brébeuf, Radisson and Groseilliers, and LaSalle in the 17th century; Lavérendrye, Alexander Henry and Alexander Mackenzie in the 18th; and a great number, including David Thomson and Simon Fraser, as recently as the last century — all these pioneers came up the Ottawa and portaged to the Chaudière. And in the very early use of this famous portage, unknown voyageurs, anxious to make their traverse a little easier, constructed what can accurately be described as the first Ottawa engineering project — four or five sets of stone steps and a small stone causeway near the upstream end of the Second (or Little) Chaudière Portage. Largely through the efforts of the two Canadian Clubs of Ottawa, these historic relics have been preserved in place, as a national historic site, just as they were used through the years; they may be seen today near the east end of Brébeuf Park in Val Tétreau (in Hull). What Canadian, and in particular what Canadian engineer, can stand on these ancient steps — looking at the wonderful panorama presented by the modern city — without being moved by thoughts of all the pioneers who have trudged up and down that same portage path, by reflections upon the the inevitability of some sort of settlement being formed adjacent to the great falls, now harnessed so completely for modern convenience.

Philemon Wright, a shrewd and energetic Yankee from Woburn, Mass., saw this possibility on his third journey north of his border with the result that in February 1800 he left his home town with his family and some associates, arriving in March at the Chaudière, there to settle on the north bank, thus founding what is today the modern city of Hull. The first settlers in the Ottawa valley had come

Photograph in the article heading is of a Bartlett print, published in London in 1842, in the possession of the author. It shows the entrance locks of the Rideau Canal as they appeared in 1839.

in a few years before, starting in 1791, but they were still scattered and isolated when Wright, with the aid of his sons, set about clearing his land. His fame spread and so he was soon followed by other pioneers who were attracted by the possibilities of business at the portage, including the redoubtable Miss Dalmahoy of Edinburgh (whose story all engineers should know even though it can not be classified as engineering). Caleb Bellows was one such settler; it is recorded that in 1809 he built not only a store but also a small dock on the south side of the river at what soon came to be known as Bellows Landing, the location from which the Rideau Canal might have started had it not been for a strange chapter of accidents. Nearby, another pioneer (Ralph Smith) built, in addition to his cabin, a still which might thus be classed as the first industry of the area.

By 1826, Philemon Wright had cleared 3,000 acres; Hull was a thriving little community. The south side of the river, however, was still almost untouched virgin forest, magnificent stands of trees extending right to the water's edge as travellers' accounts of the time vividly record. In the whole of Nepean township there were only two stores, one stone building, three squared timber houses and a few small log cabins. Such was the site of the modern city, when early in September of that year, the Earl of Dalhousie, Governor-in-Chief, accompanied by a middle-aged officer of the Royal Engineers, and their aides, sailed up the river from Montreal, to be greeted warmly by Wright. They had come to select the site for the entrance to the Rideau Canal, the British Government having finally decided that this vital link in the alternative route between Montreal and the fortress of Kingston must be built, even though the government of Upper Canada had declared itself too poor to contribute to the cost. Fear of renewed war was in the air. Military authorities knew that, if hostilities did break out again with the United States, Kingston could not be supplied (as it had been throughout the war of 1812) by way of the St. Lawrence, since American ambushes along the international reach of the river would be a certainty. The Rideau River had to be canalized, the Rideau Lakes linked by navigable channels, and the Cataraqui River transformed from a rushing stream into a chain of navigable lakes in order to permit the passage of supply vessels from Montreal, up the Ottawa and so to Kingston.

The Engineer officer was Lieut. Col. John By, selected almost certainly by the Duke of Wellington himself to be the Superintending Engineer on this great work. By and the Earl of Dalhousie inspected the site proposed by the Governor for the canal entrance, and agreed upon the first steps to be taken towards construction. Before they left to return to Montreal, the Governor wrote and gave to By a letter which was, in effect, the charter of Ottawa for in it he said: "I take the opportunity of meeting you here to place in your hands a sketch Plan of several lots of land, which I thought it advantageous to purchase for the use of Government. . . . These not only contain the site for the head locks, but they offer a valuable locality for a considerable village or town for the lodging of Artificers, and other necessary assistants in so great a work . . ." the letter proceeding to explain how some of the land was to be subdivided, even going so far as to detail how buildings should be located on the lots — the start of local town planning. One year later, the "corner stone" for the locks was laid by the Countess of Dalhousie in a small but pleasant ceremony held on Sept. 29, 1827. Less than five years later, on May 29, 1832, Colonel By now accompanied by his wife and two daughters and fellow officers came back to the same spot, but this time on board the little steamer *Pumper*, (renamed *Rideau* for the occasion) at the conclusion of the first voyage through the completed canal, starting at Kingston Mills. The achievements of John By during those five years, in design, construction and in local administration, constitute an epic of North American engineering.

Faithfully indeed did the Superintending Engineer carry out his assigned tasks — and the citizens of today benefit therefrom in innumerable ways. He reserved for the use of government the site now known as Parliament Hill. He laid out unusually broad streets, with the co-operation of Nicholas Sparks; Wellington and Rideau Streets are the legacy. He aided the establishment of local churches; he initiated local education; he started essential municipal services. His construction work is seen in the canal of today, with its flight of entrance locks and those at Hartwells and at Hog's Back, where By's great dam is now the core of the modern structure. He flooded Dow's great swamp in a singularly bold piece of engineering, thus bequeathing to the modern city the pleasure of Dow's Lake, constructing one of the first large earth dams in North America for this purpose, a dam still to be seen to the east side of Colonel By Drive. One of his construction buildings still stands, most fortunately, a fine example of old masonry work now happily used by the Ottawa His-

Fig. 2. Entrance Locks to the Rideau Canal as they appeared in 1860; the Sappers' Bridge is on the extreme right, the arch obscured by the wooden sidewalk; the Chateau Laurier now occupies the cleared area on the far side of the Canal, originally used as the construction work yard for the Canal (From a photograph by S. McLoughlin in the Public Archives of Canada; reproduced by permission).

torical Society and maintained by them as the Bytown Museum. Containing much interesting local historical material, it is so much under the shadow of the Chateau Laurier that all too few visitors (and citizens too) ever notice its existence. And on the site of his construction yard and main workshops stands the Chateau Laurier. Rarely has the construction of one engineering project been so directly responsible for the start of a city as was the Rideau Canal for Ottawa. It is good indeed to think that the Canal has become so central a feature of the city, that it has been so well maintained through the years, and that it has been so beautified by its surrounding gardens and parkways. Long may it remain so vital a part of this city.

Even before construction of the Canal was complete, the little construction camp had become a small town. At a dinner held in 1827, it had been suggested almost jocularly that the settlement, officially first called Rideau Canal, should be named Bytown. The name was quickly adopted for official use; as Bytown the city was incorporated and remained as such until 1855 when Ottawa was adopted as the new official name. Wharves and warehouses had been built on the River, adjacent to the canal entrance; these were very quickly put to full use. The canal did serve its intended purpose of conveying troops and military supplies, even though most fortunately these were not needed for actual warfare. But civilian traffic on the Canal increased rapidly; the merchants of Montreal were not slow to see the advantages of shipping their goods to Upper Canada by the new route, with the result that within a few years there was a regular and frequent service on what became known as the "Triangle Route" — Montreal, up the Ottawa, the Rideau Canal to Kingston, and back to Montreal down the St. Lawrence. Only when the first steamer reached Kingston by way of the finally completed St. Lawrence Canals, in 1855, did the Rideau route cease to be in fact, if not in name, the first St. Lawrence Seaway.

This canal traffic led not only to good business for Bytown but also to the erection of additional wharves, warehouses and service buildings, thus having an appreciable effect upon the physical development of Ottawa. So also did the corresponding traffic on the Ottawa River itself, between Montreal and Hull and Bytown. Towards the end of the century there was an express river passenger service by which it was possible to leave Ottawa at 7:30 in the morning and arrive in Montreal by 6:30 the same evening, making use of the once famous Carillon and Greenville Railway to circumvent the rapids below Hawkesbury without the delay of using the Ottawa River Canals. The first class fare for this splendid trip, including shooting the Lachine Rapids, was $2.50, meals being 50 cents each. The future of these picturesque and historic waterways, as old as the Rideau Canal, is now in grave doubt, in view of the start on the Carillon power project. Once before the old canals had been threatened, when the Georgian Bay Ship Canal project was under active consideration early in the present century. It was not built, but the Carillon project has already started. Some part of the old canals should be preserved.

Passengers on the Ottawa River steamers would see not only river traffic provided by other steamers and barges, but the special Ottawa River traffic consisting of rafts of squared timbers. The magnificent stands of white pine throughout the Ottawa Valley attracted early attention, to such an extent that they soon became a major source of supply for the British Navy in its great days of wooden warships. Philemon Wright was responsible for the first raft of timber to go down the Ottawa; it left Hull June 11, 1806. Almost a century later, June 18, 1904, the last raft made the same journey, the owner being another famous local figure—J. R. Booth. The rise and fall of this great industry within the hundred years is a fascinating story, the character of the Ottawa Valley being virtually transformed as the great trees were steadily cut down to be replaced — if at all — by smaller species. The great rafts were engineering structures of note, statically indeterminate without doubt, but sturdy and stable as built with all the skill of Ottawa rivermen, who became famous throughout the continent.

Rafts could not pass over the Chaudière and so had to be dismantled above, the timbers being passed down separately at first, to be re-assembled in the quiet water below the falls. Hardwood had actually to be carted around the falls, as much as 20 days being taken to transfer a full raft. It was no wonder, therefore, that during his first visit, in September 1826, Colonel By was approached for aid with this problem. He persuaded the Earl of Dalhousie to grant £2,000 for the dredging of a channel on the south side of the falls and this made some improvement. It was Ruggles Wright, Philemon's son, who first suggested the possibility of constructing timber slides as a solution to the continuing problem, following a visit he had paid to Sweden and Norway to study Scandinavian methods of handling large timber. The first slide was built in 1829; two more were soon added and competition became keen. They were most successful; rafts had merely to be disarticulated at the head of the falls, sent down the slide in sections, and re-assembled below.

Old photographs show clearly what an exciting venture was the "navigation" of a timber slide, but the river men were adept and sure of themselves, so sure indeed that when King Edward VII as the Prince of Wales visited Ottawa in 1860, he was taken down one of the slides on a small raft of squared timber, greatly to the concern of some in his entourage. One of the last "official" uses of the slides was in 1901 when the Duke and Duchess of Cornwall (later to be King George V and Queen Mary) were taken down during their Canadian visit of that year. The slides were splendid engineering structures, themselves solidly built of squared timbers. Remains of the slides are still to be seen, the upper part of the Wright slide within a stone's throw of the busy rue Principale of Hull, immediately behind the old Anglican Church of St. James. One, at least, of these old slides should be retained, restored and preserved as a reminder of one of the most colourful aspects of Ottawa's early history.

With the steady development of Bytown a local demand for sawn lumber arose, to meet which two firms established saw mills using water power derived from the use of a small amount of the water flowing over the Chaudière. Harris and Bronson, and Pattee and Perley, were proprietors of tow companies having original grants (issued in 1861) – names which include two well known in Ottawa in more recent years. Earlier, in 1851, Ezra Eddy of Vermont rented a small building in Hull and started to make wooden clothes pins, wash boards, bowls and pails, thus starting the great industry which occupies so dominant a place in the local economy today. John R. Booth came to the district shortly after from his home in the eastern townships; he worked at first for the Wrights but in 1858 rented a small shop of his own in Ottawa (with Robert Dollar) to manufacture split shingles. So started another great local industry, the development of which has involved so much plant engineering, as the power available at the Chaudière has been harnessed for use.

There were other mills in Bytown in those early days, the first a small one operated by the Bywash, a stream which ran down near what are now Cumberland and York Streets. The owner, Jean-Baptiste St-Louis, was leased a mill site at the Rideau Falls April 30, 1830; he was soon cutting wood along the Rideau for his new mill. Thomas McKay eventually came to own this mill; he had been operating a grist mill since 1833 on the other branch of the Rideau. W. C. Edwards and Company were later owners, operating the mills until the early years of this century. There is still a "mill" at the Rideau Falls, the National Research Council today operating a small water power plant, recently rebuilt in connection with the rehabilitation of Green Island, in which about 1,500 h.p. are generated. Small in comparison with developments at the Chaudière, the Rideau Falls mills and power plants provide an unbroken example of local engineering endeavour from the earliest days of settlement.

Thomas McKay

Thomas McKay's name is an honored one in Ottawa; the city owes much to him. A masonry contractor who had earned an enviable reputation in Montreal before the start of the Rideau Canals works, he was entrusted by Colonel By with the masonry work for the great entrance flight of locks, now so familiar a feature of the Ottawa scene. Testimony to the excellence of his workmanship can be obtained by going and looking at the masonry in the locks, so close to this hotel. Colonel By's satisfaction was shown by his gift to McKay, at the end of the work, of a silver loving cup, specially wrought in London. McKay was a successful as well as a capable contractor, with the result that he made a good profit on his Rideau contracts. Alone of all the major canal contractors, he chose to stay in Bytown, making this district his home for the rest of his life. Some of his money he invested in the mill already mentioned. Another use to which he put his profits was to build for himself a stone mansion, using the skilled Scottish masons he had employed on the locks. This great house was located so far from the centre of the settlement that it was called, derisively, McKay's Castle. McKay purchased the land on which he built, and 1,000 acres around, another act of folly in the view of the local inhabitants of the time. The 1,000 acres eventually included much of the village of Rockcliffe Park. McKay's Castle is known today as Rideau Hall, another legacy of engineering to the nation.

It was in 1868 that McKay's Castle, and 90 acres of land around it, were purchased by the nation (after being rented for two years) for the use of the Governor General of the newly-formed Dominion, after it had been decided not to build a new "Government House" on Nepean Point, as had been originally planned and strongly urged. Sir John A. Macdonald was overruled by his cabinet colleagues on this matter for he is reported to have said, at a later date: "I also wished to acquire all that property" (pointing to the direction of Nepean Point) "and to build Government House there; but some of my colleagues would not hear of it . . . the consequence is that . . . we have spent more money patching up Rideau Hall than a palace would have cost at Nepean Point." The patching up process still continues but the old house now has become such a national monument that any alternative to it as the Canadian home of Her Majesty and of her Canadian representative is unthinkable.

Parliament Buildings

An associated building must be briefly mentioned, even though engineers can claim no share in its design; its construction, however, was at the time an unprecedented feat of "engineering construction". This was the original block of Parliament Buildings, started as early as 1859. In 1860, the Prince of Wales made his special journey to the little settlement of Bytown in order to lay the foundation stone. The East and West Blocks of today give a good idea of what the original group of three

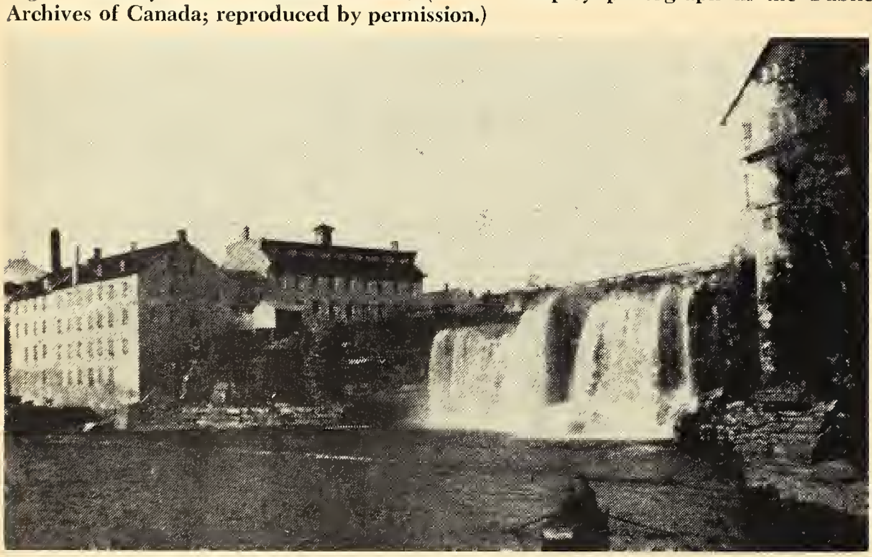
Fig. 3. Part of a timber raft going down one of the Chaudiere timber slides towards the end of the nineteenth century. (From a Tapley photograph in the Public Archives of Canada; reproduced by permission.)

buildings must have looked like. Destruction of the main building by fire in February, 1916 was a national tragedy, but the noble building replacing it after the war years now forms a most fitting centre to the lovely grouping on "The Hill". Writing in 1864 to John A. Macdonald, George Brown had this to say: "The buildings are magnificent; the style, the extent, the site, the workmanship are all surpassingly fine. But they are just 500 years in advance of the time. It will cost half the revenue of the province to light them and heat them and keep them clean. Such monstrous folly was not perpetrated in this world before. But we are in for it, I do think the idea of stopping short of completion is out of the question . . . I go in for such a superb folly that will bring visitors from all countries to see a work they can't see elsewhere. To say the truth, there is nothing in London, Paris, or Washington approaching it." Engineers can share with their architectural colleagues the pleasure which these old words may bring, even as they can share also in the responsibility for some of the interesting, if unusual, older buildings of the city such as the old "tin house" on Guigues Street at the corner of Dalhousie which shows how engineering skill, of a peculiar variety, can be applied to architecture.

An architectural friend suggests that the men capable of producing such work in the past were the predecessors of those who provide the air conditioning systems of today. Throughout the years, engineering and architecture have been closely linked in Ottawa. Today, it will take the united efforts of both professions, working with other citizens, to preserve for posterity at least some of the remaining links with the past.

Buildings are peripheral to engineering activity; bridges are not, their design being a major branch of civil engineering. The first major civil engineering undertaking in Canada west of Montreal was the construction of a bridge of which every Ottawa engineer may be justly proud, parts of which are still in daily use by heavy traffic, although unknown and unrecognized by all but the few. Reverting again to that busy visit to Hull in 1826 of The Earl of Dalhousie and Colonel By, the two men saw clearly that access from the north to the south bank of the Ottawa River would be an essential preliminary to the start of the Canal works. Another result of their short visit was therefore a decision that the river must be bridged, Colonel By noting that this could readily be done by a series of short bridges linking together the several islands that made the Chaudière a fall of such beauty. His Clerk of Works for the Canal, a Scot named John McTaggart, was therefore sent up from Montreal together with Thomas McKay, with instructions to get the bridge started; they arrived in Hull early in October, 1826. Undaunted by all the tales he had heard of the Canadian winter, McTaggart decided to build the first stone arch immediately; McKay loyally supported him, as his master mason. So started Canada's first winter construction job, a dry-stone arch with a span of 57 feet being completed by February, work proceeding through what must have been a particularly cold winter. McTaggart has left a graphic account, noting that he froze one of his hands one morning while shaving in an unheated room. It is this same arch that is still in use as an integral part of the modern Chaudière Bridge, located just north of the gateway to the Hull plant of the Gatineau Power Company but naturally unseen from automobiles; one has to be a humble pedestrian to see clearly this splendid piece of masonry work, still serving after 130 years.

Fig. 4. McKay's Mill at Rideau Falls. (From a Tapley photograph in the Public Archives of Canada; reproduced by permission.)



Work on the remaining arches proceeded throughout the early months of 1827; Colonel By himself is credited with the way in which connection was made across the Big Kettle, where a span of 200 feet had to be bridged. He had a small cannon brought to the edge of the gorge (probably borrowed from Philemon Wright for the occasion) and a shot was fired with a light cord attached across the rushing waters. This was used to pull successively heavy ropes over, until finally it was possible to haul across strong "iron cables" obtained for the purpose from the naval stores at Kingston. With this connection made, cables were strung from which was supported a remarkable 200-foot span wooden truss that can better be illustrated rather than described. The bridge was opened for use in 1827. It provided a 30-foot roadway and is said to have cost only £2,500. Appropriately named the Union Bridge, it was the first connection between Upper and Lower Canada, and served well throughout the busy Canal construction period. But in the spring of 1836 the truss collapsed, fortunately without loss of life.

A ferry service was quickly instituted. Operated by John Perkins, the main ferry boat was one of the early engineering wonders of the Valley for it was one horse power in fact, a horse walking in the boat on a treadle geared to a shaft on which were two paddle wheels. It was not until May 23, 1843 that the foundation stone for a replacement of the ill-fated timber truss was laid, a suspension bridge having been designed by Samuel Keefer under the supervision of H. H. Killaly, Chairman of the Board of Works of Upper and Lower Canada, predecessor of the Federal Department of Public Works. The new span of 243 ft. 6 in. was opened Sept. 17, 1844; it served for many years, until the construction of mills began to obscure the great falls from sight.

Colonel By was responsible for two other bridges, a small structure initially built of unpeeled logs to span a gully near the north end of the Union Bridge, dubbed "Pooley's Bridge" by Colonel By since it was constructed by one of his trusted assistants, Lieu-

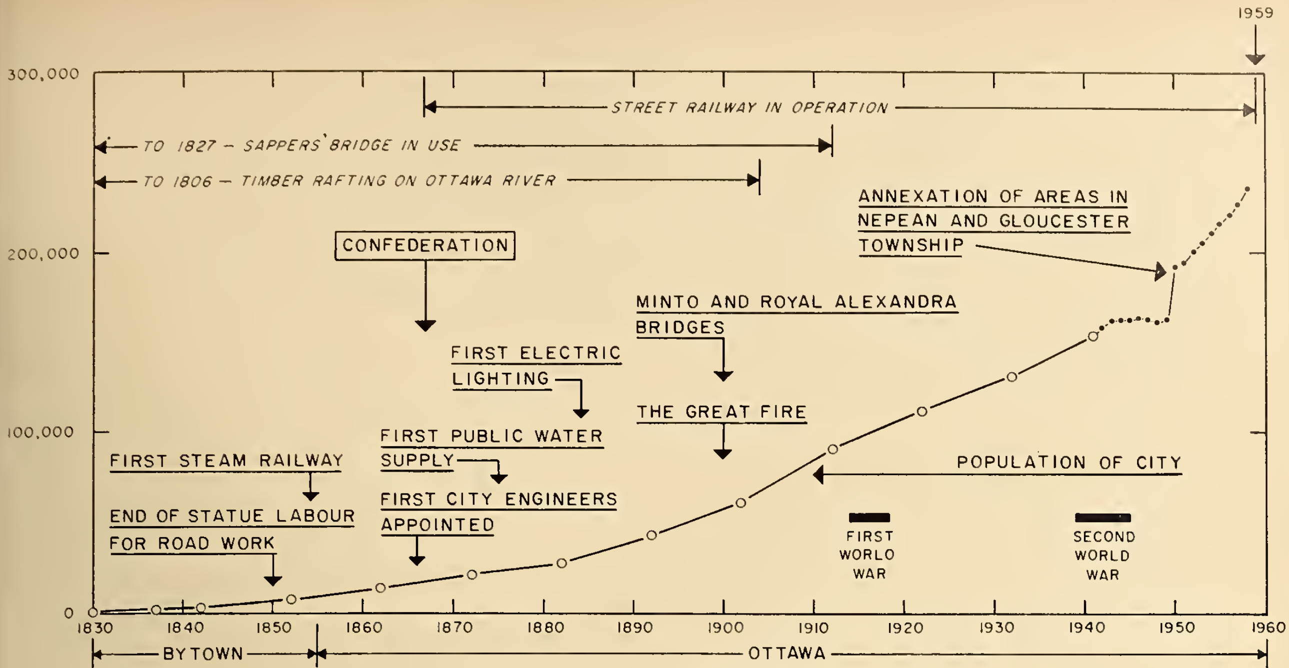


Fig. 5. The Growth of Ottawa.

tenant Pooley, R.E. Much more important, however, was the bridge necessary to span the valley in which the entrance locks were to be constructed. Clearly necessary if construction operations in the narrow valley were to be co-ordinated, it was the first major canal work to be undertaken under Colonel By's immediate direction by the Royal Sappers and Miners, two companies of which were raised in England in March, 1827 especially for service on the Canal. The bridge, known down the years as the "Sappers' Bridge", was a graceful arched structure occupying part of the site now used for the much larger Confederation Bridge. Built of cut limestone blocks, it was of such massive construction that its eventual demolition in 1912 was an unusually difficult operation, as older residents of Ottawa still recall. Although the bridge probably had to go in the march of progress, two stones from it were saved. They now form the monument in Major's Hill Park that marks the site of Colonel By's own residence (also destroyed), the stones fortunately still showing some of the carving with which the Sappers adorned this first piece of bridge building in the "wilderness".

It was not until the turn of the century that bridge building again became a major engineering activity in Ottawa. It was in 1900 that the still graceful Minto Bridges were built across the Rideau, and the great Interprovincial Bridge (more kindly named the Royal Alexandra Bridge) was opened Feb. 21, 1901. (Robert Surtess and Guy C. Dunn were the respective engineers.) Both structures were constructed by the Dominion Bridge Company, the Royal Alexandra Bridge (despite the horror with which it is now viewed by town planners) being still a notable structure and in its day the greatest bridge of the Dominion. Ottawa still has in use one of the first reinforced concrete bridges in Canada, this being the original Hurdman's Bridge built in 1906 by Emil Wahlberg. Engineers of the capital should keep a watchful eye on plans for the future of this interesting old structure. This gap in the history of bridge building in Ottawa is not surprising when one considers the slow growth of the little city throughout the nineteenth century. This is illustrated in an accompanying chart. It is true that railways had come to Bytown as early as 1854 but it was not until the twentieth century that they really displaced water transport.

It was on Christmas day, 1854 that a small train was pulled into the first railway station of Bytown, located in New Edinburgh through Thomas McKay's influence. The train ran on rails improvised from maple scantlings since there were no funds left to purchase iron rails. This was the northern terminal of the Bytown and Prescott Railway Company, for many years the only rail connection that Ottawa had. Until 1855, when the Rideau was bridged, passengers for Ottawa had to be taken across the river by boat after leaving their train. Walter Shanley was the engineer; his letters describing his work on the construction make fascinating reading. He found Bytown "a fast place (but) a snobbish town" too. He complained that he "was disturbed (in his office) half a dozen times one day by the President (of his Company) rushing in to try to force me to play cricket". It was not until the close of the century that the effects of the "railway mania" were seen in Ottawa. These were the years of the Quebec, Montreal and Occidental Railway; the Canada-Atlantic Railway; the Pontiac Pacific Railway Company and others with names almost as pretentious, but their development, construction and eventual incorporation into the C.N.R. and C.P.R. of today, with some disappearing completely, is a tale of this century.

The development of municipal engineering services was, correspondingly if surprisingly, also a feature of the later years of the last century. There is still so much to see of the origins of Ottawa that it is easy to forget that even when the Parliament Buildings were completed, Ottawa was still a rather grubby little town. The first road in the district had been built by Philemon Wright in 1818, from Hull to what is now Aylmer. It was operated for many years as the Aylmer toll road. Colonel By laid out some of the main streets of what is now the city and built a few other roads to give access to the canal works at Hartwells and Hog's Back. Statute labour was, however, still in use for road maintenance until 1850 so that it is perhaps not surprising that the streets of Bytown had the reputation of being impassable in the spring and fall because of mud, and in the summer on account of dust. It was not until 1862 that the city got permission to issue $40,000 worth of debentures for the drainage and macadamizing of its streets, the first city engineers being appointed in 1866. And it was not until 1895 that the first paving was laid, this being on Sparks Street, between the Canal and Bank Street, specially provided for the holding of a bicycle race. It is therefore not surprising that, in view of the slow development of good streets, Ottawa should have had one of the earliest street railway systems in Canada, the Ottawa City Passenger Railway Company being incorporated in 1866. It provided a service of one-man horse-drawn trams until its amalgamation with the newly formed Ottawa Electric Street Railway Company in 1893. The latter had operated its first electric streetcar in June, 1891. Residents of Ottawa saw the last operating streetcar May 1, 1959, electricity having had to give way here also to the claims of gasoline.

With abundant water power so close, it was natural that Ottawa should have been one of the first of Canadian cities to use electricity for lighting, even before it was used for power. It was first used for street lighting Nov. 4, 1884. Pembroke beat its neighbour city by merely a month and thus lays claim to be the first electrically-lit city in Canada. Oil lamps had been used for such public lighting from the earliest days, superseded by gas lamps about 1854. It is an interesting turn of the wheel of fortune to find gas again taking its place in the public service although now brought from the west and not made from coal, and used for heating rather than for light.

It will be surprising to many to find municipal engineering services relatively so recent a development in Ottawa. Nothing need be said about sanitary services, particularly with papers being given at this meeting about the design of Ottawa's first sewage treatment plant. But brief reference to the long and tangled story of Ottawa's public water supply must bring this record of early engineering in Ottawa to its conclusion. After the Royal Engineers had found it impossible to find well water on Parliament Hill, they initiated a system of carting water from the Ottawa River. Although some public pumps were provided at strategic points in the little town, water carriers soon came to be an important group in the local economy. So keen did competition between them become that in 1866 they had to be licensed. The first report recommending a proper public water supply was made to the City Council in July, 1859 by Thomas C. Keefer. Incredible though it may seem today, the lobbying of the water carriers was so successful that it was not until 1875 that the first City Water Commissioners were actually appointed. Perhaps the delay was fortunate since Keefer's original plan included the use of Parliament Hill as the location for a reservoir for a gravity supply. The first water was delivered in 1875, Thomas Keefer having been the engineer for a simple supply system that was the start of the fine public water service enjoyed by the citizens of today. As is so often the case, it took a tragedy — in this case the awful conflagration of 1900 — to bring home fully to the citizens of Ottawa the vital character of their water supply system. The legacy of the water-carriers' opposition to a public water supply certainly contributed to the great loss in that fire which in many ways marked a turning point in the history of the city.

Impersonal though such a summary record as this has had to be, it cannot conclude without brief tribute to the early engineers who were responsible for all the works described. John By will forever be honored as the founder-engineer of this city. His able young assistants were to make their names in many of the far places of the world, at least three becoming full Generals in the British Army. Many works were carried out by engineers whose names are lost, but Killaly, Shanley and Samuel Keefer have been mentioned even in this brief survey, as has also Thomas Coltrin Keefer, possibly Canada's greatest consulting engineer. He was the only man to hold office twice as President of the Canadian Society of Civil Engineers, the second time while he was President also of the American Society of Civil Engineers, the only Canadian (it is believed) ever to hold that high office. When the A.S.C.E. held the only meeting that it has held in Ottawa, in 1913, a highlight was a garden party reception in the lovely grounds of Thomas Keefer's home, the old gentleman — then in his ninety-second year — seated in the middle of his garden, receiving the greetings of his fellow engineers from all over the continent. He could then look back to a boyhod memory of seeing the first vessels sail up the original Welland Canal to mark its opening in 1829. There are living in Ottawa today engineers who have spoken with Thomas Keefer; thus can the whole history of engineering in Canada be bridged by two lifetimes. In one of the local hospitals lives a very old man who has told the writer that he can remember hearing from his grandmother how she stood on the banks of the Rideau River, watching Colonel By and his family go by in the *Pumper* on that memorable day in 1832. Thus can the engineering history of Ottawa be bridged by two lives.

It is a challenging history, a vital part of the warp and weft of the wonderful tapestry of the Ottawa story. Significant as have been many of the contributions of the engineer to the development of this capital city, let it also be remembered that some of his works have been a disfigurement of the local scene. This brief review started at the Chaudière; there must it come to its close — but with a glance at a "Chaudière" where one has to look hard between a conglomeration of singularly undistinguished buildings even to see the waters of the great river as they come over the falls. This used to be one of the beauty spots of the region, one of the focal points of local development. Should not engineers be in the van of those who have concern for the future of the Chaudière — for the restoration of what is left of at least one timber slide, for the marking and preservation of the arches of the old Union Bridge, for the restoration of some, at least, of the inherent natural beauty of these historic falls? Thus could honor be paid to the pioneers, service given to the citizens of today, and a further legacy provided for the citizens of tomorrow to remind them for all time of the vital connection between this capital of the North and its engineers.

Acknowledgments:

All who prepare such historical papers such as this record of Early Ottawa and Engineering are indebted to innumerable other writers and students who have rescued and recorded details of the past. It would, therefore, be invidious for the writer to attempt to record even those to whom he knows he is in debt in this way, but he does wish to acknowledge his indebtedness to his fellow members of the Advisory Historical Committee of the National Capital Commission (Anthony Adamson, Chairman) who have shared with him their interest in and expert knowledge of early Ottawa. Further information on the subjects touched upon in this paper may be obtained from the following books which the writer consulted freely in its preparation:

Brault, Lucien. **Ottawa Old and New**, 349 pp., ill., 1946, Ottawa.

Canadian Developments

One and a Half Million Dollar Fredericton Terminal Station

The recently constructed Fredericton Terminal Station has been built to accommodate 138 kv, 69 kv and 12.47 kv circuits with ease of interconnection between voltage levels. The layout is also suitable for future addition of circuits and transforming capacity. The new 138 kv network will in some instances parallel the existing 69 kv system. As part of the new grid, five terminal stations were designed with three already completed and in operation. Frank L. Newson, Design Engineer at The New Brunswick Electric Power Commission covers some of the major engineering features of the Station in his paper.

A modified one-and-a-half circuit breaker per element scheme was selected for the Station. It is modified because the tie transformers are part of the 69 kv and 138 kv buses. These transformers provide the interconnection between the buses. The first is a three-winding transformer connected star-delta-star. The Delta winding has sufficient capacity to connect a 10,000 kva capacitor bank in the future.

The protective equipment includes the grounding system, sky screening, lightning arresters, insulation levels, relay equipment and interlocking. Forty-three copper-covered grounding rods were driven to a depth of 16 ft. at a varying spacing of 30-60 ft. The ground rods are interconnected with a 500 mcm soft-drawn stranded copper conductor. The station steel, circuit breakers, switches, transformers, lightning arresters and steel buildings were connected to this grounding mat, in the majority of cases with 2/0 stranded copper conductor. The safety fence is grounded to a separate grounding-rod system which follows the fence line. Sky screening in the 69 kv section is achieved by raising the steel columns with steel rods to a height of 16 ft. above the nearest bus. The 138 kv section has sky wires that are 25 ft. above the bus to compensate for the greater spacing of the tower columns. Lightning arresters have been used at all voltage levels at power transformers with discharge counters on 69 kv and 138 kv levels.

The 138 kv-69 kv-12.47 kv tie transformer has standard gas relay protection, oil and winding temperature indications and expansion tank oil level alarm. The transformer has a percentage differential relay system with current transformers in the 12.47 kv tie transformer delta switchgear and in the 69 kv and 138 kv transformer bushings. The three-case relay equipment has harmonic-current restraint that keeps the tripping function inoperative during magnetizing inrush surges that are initiated by voltage changes on the power system. The arrangement of operating and biasing relay coils also keeps the relays inoperative during heavy through fault currents.

The distribution circuits, 12.47 kv 4-wire circuits supply unbalanced loads in the local areas around the Terminal Station. Each circuit has an inverse time overcurrent relay per phase with another in the residual circuit of the cur-

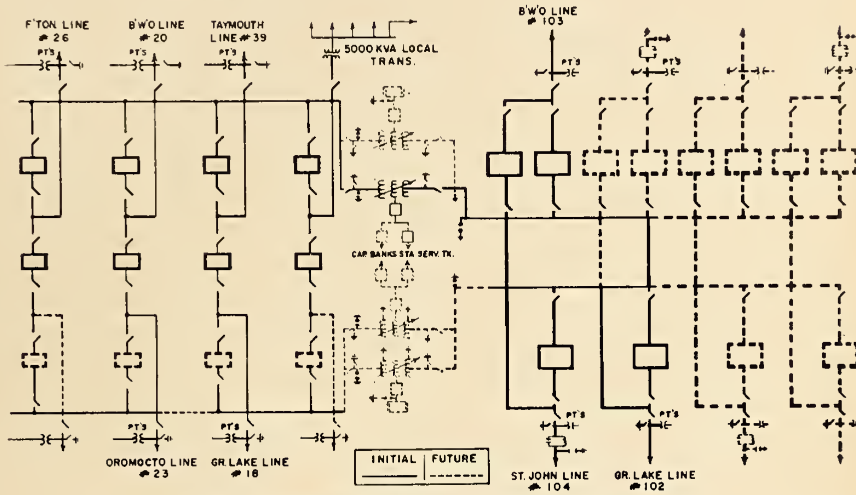

Fig. 1. One line diagram of primary equipment.

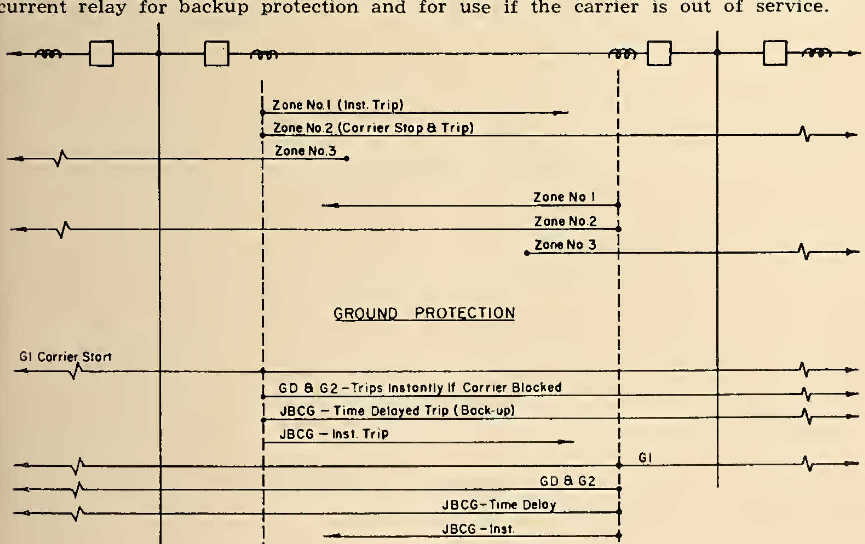
Fig. 2. 138 kv. Line Distance Impedance Relaying Phase Protection.

Zone 1 covers 90% of the distance of line section and trips instantly. **Zone 2** covers 125% of the line length and trips instantly if the carrier is blocked, otherwise 15-25 cycles. **Zone 3** covers adjacent line sections as backup and reaches further than Zone 2 from the remote opposite end of the line to act as a carrier starting device. Zone 3 trips in approximately 1 sec. G1 is a sensitive ground relay used to start the carrier only. GD plus G2 is a sensitive ground directional ground relaying used to stop the carrier and trip instantly if the carrier is blocked. JBCG is a ground directional overcurrent relay for backup protection and for use if the carrier is out of service.



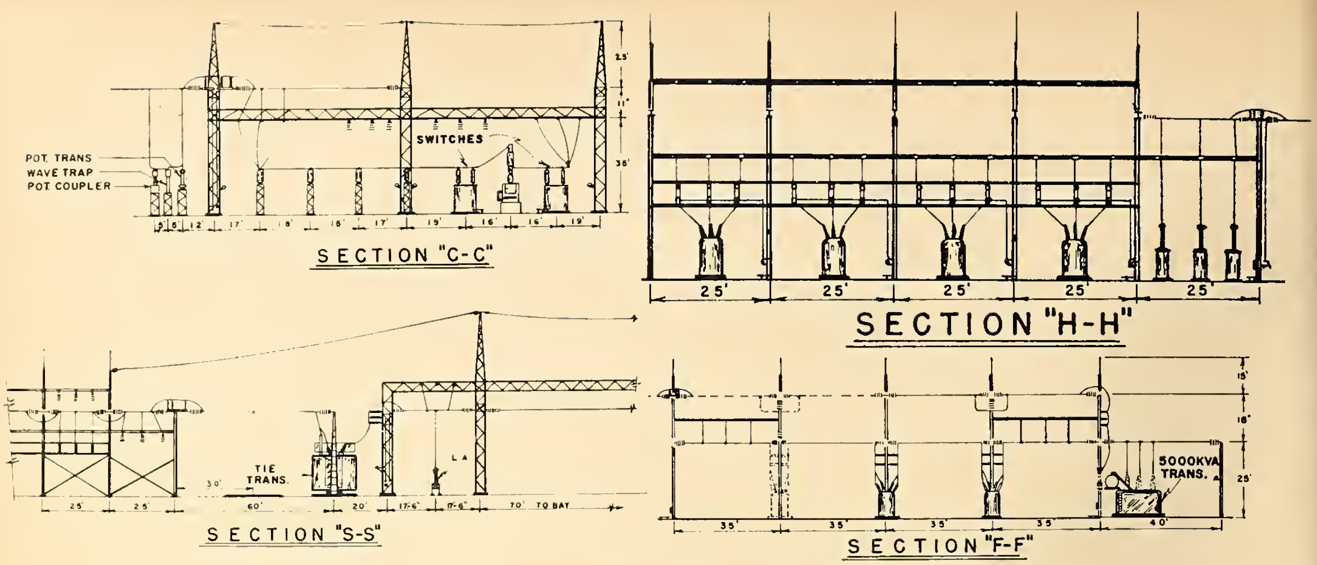


Fig. 3. Elevation sections of terminal plan view.

rent transformer system. There is a 12.47 kv ground fault back-up relay on the local transformer neutral. Each circuit breaker has a three shot reclosing relay.

The system operating center is a single story structure with basement and is electrically heated. The building has 10.4 kw of fluorescent lighting plus 3.75 kw of incandescent lighting in the control and shift dispatching section that is automatically switched to the station battery in an emergency.

The Moncton Terminal Station is to be remotely controlled from this Station over the power line carrier. Forty points are provided with seventeen to be operating initially. The supervisory equipment provides selective control and automatic indication of the remote terminal station. Continuous visual indication is provided for each supervised unit. The tap changer is controlled automatically from the 69 kv bus potential transformers, which keeps this bus at a fairly steady voltage level.

Each line has a single side band and audio shift carrier current equipment. Its primary function is to give the Commission its own telephone communication system and includes the Nova Scotia Utilities. Secondary functions are: remote supervisory control of generating switching and transforming stations, telemetered power quantities for system control for the dispatching centre and line relay control.

More and more the practice in Canada has moved to air blast circuit breakers for switching control of high voltage circuits. Oil circuit breakers are still being supplied but require special considerations when temperatures drop to 30-40° below zero. The 12.47 kv distribution oil circuit breakers are contained in a heated switchhouse supplied as a complete metal clad unit. The 69 kv and 138 kv ABCB's operate at different air pressures but have a common air storage system comprising 14-4.8 cu. ft. cylinders at 900 psi. The 69 kv circuit breakers have a conventional bulk oil circuit breaker appearance of the round tank design. Six interrupters are mounted in the single tank. The breaker is rated at 2500 mva. The 138 kv circuit breakers are a comparatively recent Canadian design particularly suitable for the high voltages and ratings that are developing in Canada. The interrupting capsule supplied has a rating of 5000 mva at an air operating pressure of 350 p.s.i. which surrounds the interrupting parts. Both these circuit breakers are a practical application of Paschen's law of gases, with the high pressure air preventing restriking of the arc and holding the contacts open. Series isolating switches are not required.

The ground fault current at the Station can be as high as 3 kv and, as additional generation is added to the system, this will increase. With a ground resistance of one ohm, a 3 ka ground potential rise will be reflected momentarily into the telephone circuits. The New Brunswick Telephone Company requires that neutralizing transformer equipment be applied if the ground potential should exceed 600 volts. The neutralizing transformer prevents the damage described and possible shock to telephone personnel and equipment.

The source of station service supply will be from the delta-tertiary 12.47 kv winding of the tie transformer, with an alternative supply from the distribution switchgear. This alternative supply will be transferred to the second tie transformer as soon as it is installed. The 12.47 kv source is transformed to 600 volts for the three-phase undergrounded delta system.

The 60 kv and 138 potential transformers are single phase to ground units of an oil minimum type. Three units are used on tie lines and bus potential requirements, and a single unit for radial feeders.

International News

£40,000,000 Nuclear Power Station for Scotland

The major portion of the civil engineering work on the two reactor structures and the turbine hall of the £40 million nuclear generating station at Hunterston, on the Ayrshire coast of Scotland, has now been completed. Around these main structures the various subsidiary buildings are now taking shape. The station is being built for the South of Scotland Electricity Board, and the first reactor is expected to be on load for the winter of 1962/63, the second towards the end of 1963. Concerned in the construction are the General Electric Company Ltd. and the Simon-Carves Atomic Energy Group, both of London.

The last sections of the concrete biological shield of the first reactor having been lifted into position, a start has been made on the erection of the structure to house the service machine. A "rehearsal" shaft for the charge-machine has been included in the first reactor structure. This will be able to test every function of the charge-machine and is expected to be used daily when the station is in operation.

The circumferential welding between the various courses of the reactor pressure vessel is nearly finished, and the welding in and non-destructive testing of the charge nozzles and control rod nozzles is progressing well. Therefore, the time for stress relief of the whole structure is approaching. Electrical resistance heating will be employed for this operation, which then will be followed by final installation work and a pneumatic pressure test. Closing in of the reactor structure, with precast concrete units which form the soffit of the roof biological shield, has begun.

If reactor performance is not to suffer, clean conditioning of the gas ducting, blowers and other plant directly in contact with the circulating cooling gas is necessary. Some of this cleaning is carried out on site, but the majority is performed in the works of the makers. The first gas circulator drive has undergone a satisfactory test of continuous running under load conditions and under simulated conditions of misalignment. A shock load test has also been successfully carried out.

The first steam-raising unit shell has been internally cleaned and is in position on its plinth, ready for the erection of the main gas ducts and installation of the internal tube banks. The shells of the other 15 steam-raising units, for both reactors, are in process of assembly.

Construction of the circulating waterworks is well advanced. The penstocks and all eight bandscreens inside the pumphouse have been erected, together with four of the six main circulating-water pumps and three of their 800 h.p. motors and associated pipework and valves.

Externally, the turbine hall, with transformers in their stone-filled bays on the north side, presents a finished appearance. Reinforced concrete blast walls have been constructed to prevent accidental damage to the cabling which will eventually be run over the pipe bridge linking each reactor to the turbine hall. The first of three 1,000 kw. emergency diesel generators is to be erected in the basement of the turbine hall. These sets will be used to supply the essential power station auxiliaries in the event of a failure of the incoming supply to the station.

The charge-machine maintenance building, to the south of the second reactor, is linked to both reactor structures by means of rail tracks, which serve to bring the charge-machines (which are at ground level) into the building for servicing.

Between the two reactors is the cartridge cooling pond. The capacity is such that the complete fuel charge of one reactor can be dumped into it in the case of emergency. The pond is divided into two unequal sections. Under normal conditions the larger section will store the discharged cartridges and the smaller one cartridges from channels in which a burst has occurred.

The weight of each reactor, including pressure vessel and contents, will be 80,000 tons. Preparation of the site has involved the excavation of 174,000 cu. yd. of rock.

An aerial view of Hunterston Nuclear Generating Station which is being built for the South of Scotland Electricity Board. The first steam-raising unit of reactor A can be seen on its plinth. The weight of each reactor will be 80,000 tons.

General Secretary

Garnet T. Page

Eastern Field Office

160 Eglinton Avenue E.,
Toronto 12, Ontario

Headquarters

2050 Mansfield Street,
Montreal, Quebec

Western Field Office

1177 W. 33rd Avenue,
Vancouver, B.C.

OFFICERS OF THE BRANCHES

AMHERST

Chairman, G. C. L. McEnery, 65 Bridge St., Sackville, N.B.
Secretary-Treasurer, G. B. Turnbull, 47½ Havelock St., Amherst, N.S.

BAIE COMEAU

Chairman, S. J. Simons, P.O. Box 1027, Baie Comeau, Que.
Secretary, L. A. G. Tellier, P.O. Box 575, Baie Comeau, Que.

BELLEVILLE

Chairman, H. T. Floyd, 16 MacDonald Gardens, Belleville, Ont.
Secretary-Treasurer, D. A. Law, 54 Montgomery Blvd., Belleville, Ont. Tel WO. 2-4511.

BORDER CITIES

Chairman, R. H. Darke, 3281 Everts Ave., Windsor, Ont. Bus. Tel. CL 6-2377, Res. Tel. YO 9-4863.

CHAIRMEN OF COMMITTEES

Standing Committees

Admissions:	P. W. Gooch, Montreal
Finance:	F. L. Lawton, Montreal
Legislation:	W. B. Pennock, Victoria
Library & House:	T. N. Davidson, Montreal
Publications:	R. A. Phillips, Montreal
Technical Operations:	B. G. Ballard, Ottawa

Divisions of Committee on Technical Operations:

Bridge & Structural Engineering:	T. Dembie, Toronto
Chemical Engineering:	Professor J. S. Hodgins, Hamilton
Civil Engineering:	R. M. Hardy, Edmonton
Electrical Engineering:	S. Sillitoe, Belleville
Engineering Education:	Dean Arthur Porter, Saskatoon
Geotechnical Engineering:	R. F. Legget, Ottawa
Hydro-Electric Engineering:	J. A. Thomas, Montreal
Management Engineering:	W. L. Hutchison, Toronto
Mechanical Engineering:	Professor J. S. Campbell, Kingston
Mining Engineering:	Chairman — to be announced.

Special Committees

Board of Examiners:	Professor J. L. DeStein, Montreal
Committee on Branch Operations	F. L. Lawton, Montreal
By-Laws:	J. S. Waddington, Brockville
Honors and Awards:	M. P. Whelen, Toronto
Professional Development Programs:	W. A. Dawson, Hamilton
Property:	T. N. Davidson, Montreal
Committee on Membership:	S. B. Cassidy, Fredericton
Seventy-Fifth Anniversary:	Dean H. Gaudefroy, Montreal
Student Policy:	C. G. Southmayd, Montreal

Trusts

Brace Bequest:	D. M. Stephens, Winnipeg
Harry F. Bennett Education Fund:	Otto Holden, Willowdale, Ont.

Secretary, R. L. Kennedy, 244 Esdras Place, Windsor, Ont.

BROCKVILLE
Chairman, J. R. Eastwood, DuPont of Canada Ltd., Brockville, Ont.
Secretary-Treasurer, W. E. Currie, 41 Bramshot Ave., Brockville, Ont.

CALGARY
Chairman, J. A. Webb, 78 Maliboo Rd., Calgary, Alta., Tel. AL. 5-6076.
Secretary, A. F. D. Shore, c/o Royalite Oil Co., 615-2nd St. S.W., Calgary, Alta., Tel. AM. 6-7021.

CAPE BRETON
Chairman, R. A. Bradley, 63 Archibald Ave., Sydney, N.S.
Secretary, L. R. Boutilier, 29 Royal Ave., Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, J. W. Nelson, 934 McMurdo Drive, Kamloops, B.C.
Secretary-Treasurer, W. J. M. Owen, 634 Eckhardt Ave., Penticton, B.C.

CHALK RIVER
Chairman, D. R. Page, 113 Algonquin St., Deep River, Ont.
Secretary-Treasurer, A. J. Kempe, 6 Troyes Ave., Deep River, Ont.

CORNER BROOK
Chairman, R. D. Herdman, 29 West Valley Road, Corner Brook, Nfld.
Secretary, H. A. Hinton, c/o Bowater's Nfld. Pulp & Paper Mill, Corner Brook, Nfld.

CORNWALL
Chairman, John M. Ferguson, Howard Smith Paper Mills Ltd., Cornwall, Ont.
Secretary-Treasurer, D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Chairman, Michel Normandin, 2055 Desrochers St., Sherbrooke, Que.
Secretary, H. A. MacLean, Moulton Hill Rd., Lennoxville, Que.

EDMONTON
Chairman, J. Longworth, 10828 - 67th Avenue, Edmonton, Alta. Tel. GE. 9-4951 loc. 248.
Secretary-Treasurer, George Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON
Chairman, M. P. Estey, P.O. Box 100, Fredericton, N.B.
Secretary, K. O. Bartlett, P.O. Box 44, Fredericton, N.B. Tel. GR. 5-6691.

HALIFAX
Chairman, J. G. Belliveau, 11 Ritchie Drive, Halifax, N.S.
Secretary-Treasurer, John Jay, P.O. Box 33, Halifax, N.S.

HAMILTON
Chairman, P. J. McNally, c/o S. S. McNally & Sons, 215 Superior St., Hamilton, Ont.
Secretary-Treasurer, David Friesen, 4 Piott Court, Stoney Creek, Ont.

HURONIA
Chairman, S. R. Walkinshaw, 311 Franklin St., Orillia, Ont.
Secretary-Treasurer, Louis Morgante, 36 Borland St. W., Orillia, Ont.

KINGSTON
Chairman, R. J. Kennedy, 2 Grenville Rd., Kingston, Ont. Tel. LI. 6-1731, loc. 361.
Secretary-Treasurer, L. C. Miller, 11 Durham St., Kingston, Ont. Tel. LI. 2-7311, loc. 318.

KITCHENER
Chairman, William Bobbie, B. F. Goodrich (Canada) Ltd., Kitchener, Ont.

(Continued overleaf)

President's Column

THE Presidential program for branch visits for 1960 concluded with meetings of the Cornwall, Kingston, Belleville and Port Hope Branches. Successful gatherings were held at each of these places. Opportunities were provided during the afternoon in each case for branch executives to meet the President.

The President and Mrs. Dick, accompanied by the General Secretary and Mrs. Page represented the Engineering Institute of Canada at the Annual Meeting of the American Society of Mechanical Engineers, recently held in New York City. The fine relationship which has existed between these two sister Societies was emphasized by both the retiring President, Walker Cisler, and the incoming President, William Byrne. Our A.S.M.E. friends did everything to make the visit pleasant for the Canadians, and the experience is one which will long be remembered.

To explore the possibilities of the numerous potentials of branch operation, a Committee has been set up with Mr. Fred L. Lawton, Montreal Vice-President, as Chairman to study this situation. Branch operation and its significance in the eyes of each member would appear to be one of the most important phases of the Institute's activities, and a thorough study of the branch situation is to be made to be sure that this contract is being suitably developed. It is also hoped that in the near future time will be available for the General Secretary to make even more branch visits, so that he may by personal contact with the present and future officers of the branches, be increasingly available to them for consultation and discussion of the types of programs most suitable for the various branches and for the development of technical activities wherever these can be fostered. While many branches continued to put on wonderfully successful programs, there are others which, by virtue of local circumstances and geographical restrictions, have problems in selecting program structures. It is felt that closer contact with the General Secretary in these cases may help the Branch Executives gain a fuller appreciation of what can be done.

In closing the President's column for this month we would like to pay tribute to a faithful member of the E.I.C. Staff who passed away suddenly early in December. We refer to Mr. E. J. Blandford who was for many years responsible for the advertising section of the Journal. Mr. Blandford worked well and faithfully for E.I.C. Deepest sympathy is extended to the bereaved wife and family. EIC

Secretary-Treasurer, C. G. E. Downing, c/o Ontario Agricultural College, Guelph, Ont. Tel. TA. 4-4120.

KOOTENAY

Chairman, L. S. Piper, 104 Kootenay Ave., Trail, B.C., Tel. 1652.

Secretary, I. Waterlow, Supt., Maintenance Refinery, Consolidated Mining & Smelting, Trail, B.C.

LAKEHEAD

Chairman, John A. Brown, M.E.I.C., c/o MacIntosh & Assoc., Radio Hall, Fort William, Ont.

Secretary-Treasurer, E. B. Ashton, J.E.I.C., 439 Heather Crescent, Fort William, Ont. Bus. address, P.O. Box 459, Fort William, Ont. Tel. MAyfair 3-9569.

LETHBRIDGE

Chairman, R. J. D. Gardner, 3006 10th Avenue S., Lethbridge, Alta.

Secretary-Treasurer, R. F. Smith, Street & Roadways Engineer, City Hall, Lethbridge, Alta.

LONDON

Chairman, George Hayman, c/o John Hayman & Sons, 432 Wellington St., London, Ont., Tel. GE. 2-5343.

Secretary-Treasurer, G. T. Fenwick, c/o Unifin Tube Company, P.O. Box 7, London, Ont. Tel. GL. 1-0230.

LOWER ST. LAWRENCE

Chairman, L. P. Dancose, c/o The Canada Gulf & Terminal Rly. Co., Mont-Joli, Que.

Secretary-Treasurer, Gerard Fournier, c/o Lower St. Lawrence Power Co., 6 St. Jean Street, Rimouski, Que.

MONCTON

Chairman, R. F. Weir, 165 Leonard St., Gunnigsville, N.B. Tel. EV. 2-0551 loc. 207.

Secretary-Treasurer, V. C. Blackett, 97 MacBeath Ave., Moncton, N.B.

MONTREAL

Chairman, H. A. Mullins, 3105 Glencoe Street, Town of Mount Royal 16, Que.

Secretary-Treasurer, Albert Deschamps, Jr., Deschamps & Belanger Ltee, 6931 Cote des Neiges Rd., Montreal, Que.

NEWFOUNDLAND

Chairman, J. P. Henderson, c/o Newfoundland Light & Power Co. Ltd., St. John's, Nfld.

Secretary, A. E. O'Reilly, c/o Newfoundland Light & Power Co. Ltd., P.O. Box 976, St. John's, Nfld.

NIAGARA PENINSULA

Chairman, F. R. Denham, P.O. Box 512, Fonthill, Ont., Tel. RE. 4-4525.

Secretary, Gordon G. Jacox, 8 Springhead Gardens, Welland, Ont.

NIPISSING and UPPER OTTAWA

Chairman, (Change of address) R. S. MacLennan, M.E.I.C., 442 Oak Street East, North Bay, Ont. Bus. Tel. GR 2-5250 — Res. Tel. GR 2-4976.

Secretary-Treasurer: Donald W. Briden, M.E.I.C., 734 Birchwood Rd., North Bay, Ont. Bus. Tel. GR 2-1300 — Res Tel. GR 2-1052.

NORTH EASTERN ONTARIO

Chairman, I. M. Foster, P.O. Box 672, Kapuskasing, Ont.

Secretary, J. W. Blakeman, c/o Spruce Falls Power & Paper Co. Ltd., Kapuskasing, Ont.

NORTHERN NEW BRUNSWICK

Chairman, George A. Bird, M.E.I.C., 51 Gerrard Street, Campbellton, N.B.

Secretary-Treasurer, M. B. Martin, Jr. E.I.C., 10 Andrew Street, Campbellton, N.B.

NORTHERN NOVA SCOTIA

Chairman, J. E. Clarke, 38 Maple Ave., New Glasgow, N.S.

NCRTH SHORE LOWER ST. LAWRENCE

Chairman, R. W. Pryer, 192 Cartier Avenue, Seven Islands, Que.

Secretary-Treasurer, L. E. Fischer, c/o Iron Ore Co. of Canada, Dock Terminal, Seven Islands, Que.

OAKVILLE BRANCH

Chairman, A. A. Swinnerton, 1087 Rebecca St., Oakville, Ont.

Secretary, J. W. Kirk, International Water Supply Ltd., Box 535, Oakville, Ont.

OTTAWA

Chairman, G. B. Williams, Chief Engineer, Development Engineering Branch, Department of Public Works, Room 174, Hunter Building, Ottawa, Ont.

Secretary, J. N. Prichard, 2234 McQuaig St., Ottawa 1, Ont., Bus. Tel. CE. 6-7531, Loc. 226.

PETERBOROUGH

Chairman, R. M. Allemang, 714 Walkerfield Ave., Peterborough, Ont., Bus. Tel. RI. 2-7711, Ext. 361.

Secretary-Treasurer, Peter Tuck, c/o Canadian General Electric Co., 107 Park St. North, Peterborough, Ont., Tel. RI. 2-7711, Ext. 471.

PORT HOPE

Chairman, J. L. Sylvester, 71 Walton St., Port Hope, Ont.

Secretary-Treasurer, D. A. Runciman, 49 Chapel St., Cobourg, Ont.

PRINCE EDWARD ISLAND

Chairman, William R. Brennan, Public Utilities Commission, Box 577, Charlottetown, P.E.I.

Secretary-Treasurer, E. S. Chandler, 242 North River Rd., R.R. 2, Charlottetown, P.E.I.

QUEBEC

Chairman, B. I. Burgess, c/o Canadian General Electric Co. Ltd., Industrial Centre 5, Quebec, Que., Tel. MU. 3-3431.

Secretary-Treasurer, Marc Bergeron, Concrete Repairs & Waterproofing Co., 520 Grand Allee East, Room 27, Quebec 4, Que.

SAGUENAY

Chairman, D. L. Aker, c/o Aluminum Co. of Canada, Avida, P.Q.

Secretary-Treasurer, J. R. Eason, 533 Normandie St., Arvida, Que.

SAINT JOHN

Chairman, P. W. Hastings, 56 Parks St. Extension, Saint John, N.B.

Secretary-Treasurer, Eldon D. Thompson, 62 Wright Street, Saint John, N.B. Bus. Tel. Oxford 2-8294.

SAINT MAURICE VALLEY

Chairman, J. I. Butcher, 1005-124th Street, Shawinigan, Que.

Secretary, J. E. Dunn, Box 951, Three Rivers, Que.

SARNIA

Chairman, H. V. Page, 541 Charlesworth Drive, Sarnia, Ont. Bus. Tel. ED 7-8282. Res. Tel. DI 4-4392.

Secretary, R. W. Hodgson, 885 Kemsley Drive, Sarnia, Ont., Tel. ED. 7-8221, Loc. 656.

SASKATCHEWAN

Chairman, L. T. Holmes, 3057 Retallack Street, Regina, Sask., Tel. Lakeside 3-7560.

Secretary-Treasurer, R. Bing-Wo, 2043 Cameron Street, Regina, Sask.

SASKATCHEWAN BRANCH SECTIONS

Regina

Chairman, L. W. Johnston, 3231 Whitmore, Regina, Sask.

Sec.-Treas., Reginald Bing-Wo, M.E.I.C., 2043 Cameron St., Regina, Sask.

Moose Jaw

Chairman, J. C. MacKay, M.E.I.C., 1270 Brown Street, N.W., Moose Jaw, Sask.

Sec.-Treas., T. L. Salmon, M.E.I.C., 1057 Henry Street, N.W., Moose Jaw, Sask.

Prince Albert

Chairman, William S. Paine, M.E.I.C., Assistant City Engineer, Department of Highways, City Hall, Prince Albert, Sask.

Sec.-Treas., R. Wayne Kyle, M.E.I.C., Assistant City Engineer, Engineering Department, City Hall, Prince Albert, Sask.

Estevan

Chairman: A. Guthrie, M.E.I.C., Box 1276, Estevan, Sask.

Sec.-Treas., Gerald R. Ursenbach, M.E.I.C., Producers Pipelines Ltd., Estevan, Sask.

Saskatoon

Chairman, R. C. Strayer, M.E.I.C., University of Saskatchewan, College of Engineering, Saskatoon, Sask.

Sec.-Treas., F. W. Catterall, M.E.I.C., Underwood, McLellan & Assoc., Box 539, Saskatoon, Sask.

Yorkton

Chairman, R. G. Brown, M.E.I.C., Box 579, Yorkton, Sask.

Sec-Treas., C. L. Slegel, M.E.I.C., 83 Elizabeth Avenue, Yorkton, Sask.

SAULT STE. MARIE

Chairman, K. I. Fletcher, 41 McCrae Street, Sault Ste. Marie, Ont.

Secretary-Treasurer, M. R. Wright, c/o Dominion Bridge Co. Ltd., P.O. Box 520, Sault Ste. Marie, Ont., Tel. AL. 6-5611.

SUDBURY

Chairman, R. P. Crawford, 218 College St., Sudbury, Ont.

Secretary-Treasurer, C. L. MacMillan, 1237 Woodbine Ave., Sudbury, Ont.

TORONTO

Chairman, W. L. Hutchison, Moffat's Ltd., Weston, Ont. Bus. Tel. CH 1-2611, Res. Tel. BE 3-7975.

Secretary-Treasurer, C. L. Thompson, c/o Honeywell Controls Ltd., Vanderhoof Ave., Leaside, Toronto, Ont., Tel. HU. 9-2151.

VANCOUVER

Chairman, John H. Swerdfeger, 928 Keith Rd., Hollyburn, West Vancouver, B.C.

Secretary-Treasurer, R. Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND

Chairman, E. T. Quirk, 5355 Parker Ave., R.R. 4, Victoria, B.C. Bus. Tel. Evergreen 3-4141.

Secretary-Treasurer, R. W. Lockie, 314 Cadillac Avenue, Victoria, B.C.

WINNIPEG

Chairman, W. L. Wardrop, 456 Notre Dame Ave., Winnipeg, Man.

Secretary-Treasurer, W. N. Isberg, 39 Turner Ave., Winnipeg 12, Man.

YUKON

Chairman, J. H. Reeves, c/o Northwest Hwy. Maintenance Est., Whitehorse, Yukon.

Secretary, J. P. MacGowan, c/o Northwest Hwy. Maintenance Est., Whitehorse, Yukon.

ONTARIO DIVISION

Chairman, H. G. Conn, Faculty of Applied Science, Queen's University, Kingston, Ont.

Secretary, A. C. Davidson, Dept. of Civil Engineering, University of Toronto, Toronto 5, Ont.

E.I.C.-C.I.S.S Committee

A national committee has been formed by the Engineering Institute of Canada and the Canadian Institute on Sewage and Sanitation who have joined forces to conduct a study of all phases of the use, conservation and pollution-control of Canada's water resources.

The official name of the committee is "E.I.C.-C.I.S.S. Committee on the Use, Conservation and Pollution-Control of Water Resources" consisting of 16 prominent engineers and scientists as follows:

Chairman—A. L. Van Luven, M.E.I.C., Montreal.

Members:—

J. S. Bates, M.E.I.C., Fredericton.
A. E. Berry, M.E.I.C., Toronto.
T. V. Berry, M.E.I.C., Vancouver.
P. H. Bouthillier, M.E.I.C., Edmonton.
N. S. Bubbis, M.E.I.C., Winnipeg.
R. L. Clark, Toronto.
J. D. Kline, M.E.I.C., Halifax.
J. F. MacLaren, M.E.I.C., Toronto.
A. D. Misener, M.E.I.C., Toronto.
L. Piche, Montreal.
J. G. Schaeffer, M.E.I.C., Regina.
J. B. Sprague, St. Andrews, N.B.
D. R. Stanley, M.E.I.C., Edmonton.
J. A. Vance, M.E.I.C., Woodstock, Ont.
W. L. Wardrop, M.E.I.C., Winnipeg.

All are recognized as leaders in the broad field of water resources, water conservation, and the treatment of domestic and industrial sewage.

The Committee will become familiar with the work now being done by many organizations that are concerned with water resources, and will solicit and analyze views of all Canadian organizations concerned. It will ask pertinent questions of the national executive of some 200 Canadian organizations including such groups as agriculturists, architects, business and industrialists, educationalits, engineers and scientists, game and conservationists, service groups, women's clubs and government organizations, as well as those interested in forestry, labour aspects, medical and legal aspects, political, civil and recreational aspects.

If justified by the factual data received from participating organizations, a report reflecting their collective reactions will be prepared and presented to governments and industry. It is hoped that useful information relating to such things as the need for a national research program will be obtained.

This report will provide the various governments and industry with an objective, scientific and unbiased analysis of the use, conservation and pollution-control of water resources in Canada which can be used by the federal and provincial governments as a comparison with their own work.

E.I.C. ELECTIONS AND TRANSFERS

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council on Dcember 20, 1960.

Member: E. A. Adamic, Windsor; L. F. Bolger, Calgary; G. V. Burgess, New York; R. J. Charlton, Cagary; D. H. Cockburn, Wilowdale; C. Csizmazia, Thompson, Man.; J. V. Findlay, Hamilton; A. G. Forrester, Vancouver; J. C. Hudspith, Toronto; J. Jablonsky, Toronto; S. M. Jones, Hamilton; K. R. Main, Vancouver; F. J. Parcher, Kingston; I. L. Smith, Toronto; W. J. Smith, Montreal.

Junior: L. J. De Boeck, Montreal; B. I. Howe, Baie Comeau; I. F. McIntosh, Winnipeg; W. J. Murray, Hamilton; F. E. Quon, Montreal; W. P. Robson, Trail; P. R. Yapp, Montreal.

Junior to Member: J. K. Abel, St. Catharines; G. M. Adamson, Montreal; A. P. Alexander, Montreal; D. H. Allison, Belleville; A. M. Anderson, Ottawa; W. R. Armour, Carleton Place; E. B. Ashton, Fort William; R. L. Baird, Montreal; K. J. Baker, Whitehorse; K. I. Bald, Toronto; D. E. Bastedo, Ottawa; D. S. Bate, Sarnia; C. J. Beaudoin, Quebec; C. M. Beck, Halifax; J. K. Belyea, Fredericton; M. M. Beraha, London; D. A. Bernard, Ottawa; R. E. Black, Montreal; H. T. Blake, Montreal; L. M. Bluteau, Montreal; J. C. Bodwell, Hamilton; E. H. Bowler, Ottawa; H. C. C. Briercliffe, Quebec; T. J. Briggs, Toronto; J. E. Brisson, Sherbrooke; M. J. Brisson, Montreal; S. H. Brown, Toronto; D. C. Buckley, Toronto; J. N. Buckley, London; C. H. Buehner, Hamilton; V. Burtnyk, Ottawa; J. S. Busby, Montreal; E. R. Bushfield, Ottawa; G. Campagnola, Kitchener; D. K. Campbell, Toronto; L. Carignan, Beauharnois; J. D. Carmichael, Montreal; J. Carpentier, Montreal; R. G. Chambers, Vancouver; J. P. Champagne, Sherbrooke; L. W. M. Churcher, Ottawa; A. F. Collings, Port Cartier; J. E. Cosgrove, Montreal; J. E. Cullen, Keswick; R. W. Cumming, Toronto; Z. J. Czaplinski, Montreal; R. A. Dahmer, Kitchener; P. Danciu, Hamilton; D. Danyluk, Nelson; M. D. Daunais, Calgary; G. R. Dawson, Vancouver; M. J. Dembinski, Montreal; J. L. Desautels, Ottawa; C. G. M. Dickson, Toronto; J. J. Dietrich, Ottawa; M. Dimentberg, Montreal; D. B. Downing, Ottawa; P. E. Drouin, Montreal; R. H. Drysdale, Winnipeg; H. H. Dubo, Hamilton; J. H. Dubuc, Montreal; J. M. Duff, Rexdale; R. A. Dugre, Asbestos; P. E. Dumont, Laval des Rapides; R. H. Dunn, Toronto; H. Dupuis, Montreal; J. E. Dykeman, Windsor; G. A. Dysart, Espanola; P. D. Eastcott, Peterborough; J. R. Eastwood, Calgary; K. C. Eaton, Kingston; R. W. Edmunds, Montreal; I. W. Edwards, Montreal; C. H. Eldt, Niagara Falls; C. R. Elliott, St. John's, Nfld.; F. E. Everett, Hull; C. W. Faessler, Toronto; R. M. Filiatrault, Queoec; C. A. Finnamore, Peterborough; L. C. Flett, Hamilton; H. Fligel, Montreal; K. S. Flitton, Toronto; D. R. Fonger, Winnipeg; J. Fox, Montreal; W. H. Fowler, Prescott; A. Fulton, Ottawa; R. R. Galpin, London; J. M. Gardner, Montreal; B. Geller, Montreal; W. H. R. Gibney, Kimberley; J. A. Gingrich, Toronto; E. F. Glass, Winnipeg; J. D. Goode, Toronto; T. E. Goodwin, Saskatoon; F. P. Gordon, Kemano; D. J. Gormley, Kamloops; M. G. Green, Deer Lake; H. F. Greenway, Cornwall; M. F. Grondin, Sherbrooke; W. H. Hall, Vancouver; M. E. Halladay, New Westminster; L. E. Hanley, Ottawa; L. H. Harper, Ottawa; D. W. Harvey, London; R. C. Hattie, Windsor, N.S.; W. L. Hatton, Ottawa; E. H. Hawley, Vancouver; E. G. Hazle, Toronto; G. I. Hector, Hamilton; P. J. J. Hemphill, Victoria; J. G. F. Henry, Toronto; C. W. Hitzroth, Washington; W. H. Hohn, Hamilton; A. E. Houghton, Venezuela; H. L. Howe, St. Bruno; B. M. Huffman, Edmonton; A. R. Irwin, Sarnia; M. J. Hutton, Montreal; G. C. Ireland, Ottawa; V. K. Jameson, Cornwall; R. E. Jeffrey, Montreal; H. C. L. Joe, St. Catharines; H. M. Johnson, Ste. Genevieve; H. E. Jones, Ottawa; R. A. Ross, Montreal; C. B. Joyce, Ajax; D. J. Kempster, England; J. E. Kennedy, Toronto; R. W. Kenny, Montreal; J. B. Kerby, Port Arthur; J. J. Kerr, Montreal; W. G. King, Montreal; C. J. Konzuk, Montreal; W. Koropatnick, Toronto; J. C. Lachance, Mont Rolland; P. E. Lafrance, Huntsville; C. H. Lamberton, Sarnia; D. H. Landells, Niagara Falls; M. R. Lang, Toronto; L. L. Langsner, Montreal; M. J. Larose, Thetford Mines; R. E. Lashley, Erindale; W. J. Laskaris, Banff; W. Law, Toronto; J. R. G. Leach, Hamilton; F. L. LeBlanc, Toronto; D. G. Leith, Toronto; P. F. The 55 ton capacity crane shown here is the largest ever built in Canada and one of the largest of its type in the world. A self-contained diesel electric unit drives nine motors, of which there is one each for the main hoist, auxiliary hoist and luffing drives, two for slewing, four for traveling.

Years of research, development and testing have made it possible for Provincial Engineering Ltd. to offer the most comprehensive selection of crane control systems available anywhere.

All crane controls manufactured and supplied by Provincial are full magnetic and operated by master switches or push buttons. Each control system being appropriate for specific purposes, a purchaser can select one which is most economically suited to speed regulation requirements. Purchasers of Provincial cranes have the option of specifying the manufacturer of the control components to aid plant standardization.

If you have a crane problem of any kind, or believe a crane would help in your operation, contact the nearest Provincial Engineering office listed below. One of our engineers will be glad to study your operation and make recommendations.

PROGRAM

11 A.M.—Registration

Noon—Men's Luncheon

1 P.M.—Keynote Address

2:15 P.M.—Technical Program

6 P.M.—Reception

7 P.M.—Conference Banquet

9 P.M.—Conference Ball

Keynote Address

— "The Challenge Facing the Engineer"
The Hon. Robert Winters, President,
Rio Tinto Mining Co. of Canada, Ltd.

Technical Program

2:15 p.m. — **The Big Bounce** — *Alec G. Lester, M.E.I.C., Vice-President, Engineering, the Bell Telephone Company of Canada.* Mr. Lester will describe, with the aid of a film, the use of satellites for intercontinental telephone calls. The film shows how the first such call was made using Echo I, a 100-foot balloon orbiting 1,000 miles above the earth.

2:15 p.m. — **Underwater Engineering** — *Rod Martin, Regional Manager, Western Division, International Underwater Contractors.* The training of divers for underwater construction work will be described with the aid of films. Mr. Martin will also describe important projects including surveys, soundings, concrete work, blasting, cutting operations, woodwork and raising sunken vessels.

3:15 p.m. — **Polystyrene Foam — Its Production and Applications** — *Brian Palmer, Technical Services Representative, Dow Chemical of Canada Ltd.* Outlined by Mr. Palmer will be techniques employed in producing Polystyrene, and some of its uses which include low temperature insulation, building material, prefabricated panel construction and buoyancy material.

3:15 p.m. — **Engineering as Training for Management** — *R. Ross Service, Director of Engineering, O'Keefe Brewing Company.* Mr. Service will analyze the various qualities required in management and will assess the extent to which they are developed through engineering.

4:15 p.m. — **Can Industry Generate Electric Power Economically?** — *E. W. Hill, Utility Sales Manager, Canadian Westinghouse Co. Ltd.* The increasing price of power has prompted many companies to consider generating their own power. Mr. Hill will discuss the important factors bearing on such a decision.

4:15 p.m. — **A New Look at Structural Steels** — *W. C. Kimball, Assistant Chief Metallurgist, Algoma Steel Corporation.* A review of the history and development of structural steels since 1920, with special emphasis on the first of a new series of steels C.S.A. G 40.8.

Ladies' Program

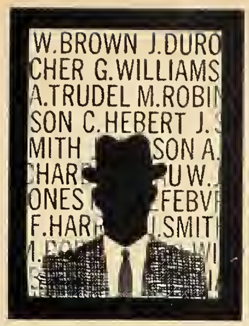
3:15 P.M.—Madame Tussaud's Waxworks

6 P.M.—Join the Men



Personals

Keith P. Gould, M.E.I.C. (McGill '48), has been appointed Hamilton District Manager of the Otis Elevator Company Limited. Mr. Gould joined the Company in 1948.

M. E. Stewart, M.E.I.C. (Alta. '47), has been appointed to the Board of Northwestern Utilities, Limited. Mr. Stewart is General Manager and has been with the gas company since 1949.

Dr. Donald Charles Rose, M.E.I.C. (Queens' '23), has been appointed Associate Director of the Division of Pure Physics, National Research Council of Canada, Ottawa. Dr. Rose will continue to head the cosmic ray section of the division and to represent Canada on various committees concerned with space research. He is chairman of the Associate Committee on Space Research and in 1959 was Chairman of the United Nations Technical Committee on outer space.

T. R. McLagan, M.E.I.C. (McGill '23) has been elected a director of the U.S. owned Sperry Gyroscope Company of Canada, Ltd. Mr. McLagan is leader of the Canadian Manufacturers Association and also President of Canada Steamship Lines Ltd.

W. E. Adkins, M.E.I.C. (Alta. '37), has been appointed Vice-President of Howard Smith Paper Mills Limited. He will continue to serve as Vice-President of Dominion Tar and Chemical Company, Limited.

W. E. Adkins, M.E.I.C.

C. B. Woodley, M.E.I.C.

C. B. Woodley, M.E.I.C., has been appointed Manager of Northern Electric Company's London works. Formerly chief engineer of the communications equipment division, Mr. Woodley is replacing **J. R. Houghton**, M.E.I.C., who has been appointed assistant general manager of the telephone contract division in Montreal.

W. D. Hurst, M.E.I.C. (Man. '30), has had Winnipeg's new 60 mpd. unattended automatic pumping station named after him by the Winnipeg City Council. Mr. Hurst is City Engineer and Commissioner of Buildings and played a predominant part in the success of the project.

R. E. Evans, M.E.I.C. (U.N.B. '45), is Manager of the newly formed Hydraulic and Thermal Power Department, Canadian Allis-Chalmers Limited. **J. R. Mainprize**, JR.E.I.C. (Toronto '50), is Chief Engineer of the new department.

L. J. Hammerschmid, M.E.I.C., (McGill '46), has been appointed Terminal Equipment Engineer with the Bell Telephone Company of Canada, Montreal.

J. F. Godsell, M.E.I.C.

C. K. Hurst, M.E.I.C.

Jack F. Godsell, M.E.I.C. (Cambridge '48), is one of three engineers who have received senior promotions in the Department of Public Works, Harbors and Rivers Engineering Branch. Mr. Godsell has been promoted from District Engineer at St. John, N.B., to Chief of the Marine Excavation Division in Ottawa. He replaces **Charles K. Hurst**, M.E.I.C. (Iowa '40), who becomes Chief of Maintenance and Operations Division. Mr. Hurst is replacing **John Eric Bright**, M.E.I.C. (Queens '38) who becomes Chief of the Planning and Construction Division.

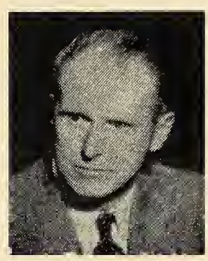
John R. Ogilvie, M.E.I.C. (McGill '54), has been appointed General Manager of Keele Buildings and Services Limited. This company has been established to service the industrial and commercial trades with warehousing and manufacturing buildings.

Jack Alton, M.E.I.C. has been named Bridge Engineer, Department of Highways, Victoria. Mr. Alton was formerly Assistant Bridge Engineer.

M. J. P. Gleeson, JR.E.I.C. (Queen's '51), has been appointed Manager, Sales Engineering, Canadian Locomotive Company Limited. This newly created position will consolidate administration of sales for all divisions of the company and includes development of new product lines.

Gordon Gracie, JR.E.I.C. (Toronto '52), has been elected Secretary-Treasurer of the Great Lakes Region of the American Society of Photogrammetry for 1961.

Stephen F. Angus, JR.E.I.C. (McGill '55), has been appointed Sales Engineer, Mechanical Division, Dominion Bridge Company Limited, Montreal. Mr. Angus has been a design engineer in the Mechanical Division since joining the Company five years ago.



J. E. Bright, M.E.I.C.

J. A. Pihlainen, M.E.I.C.

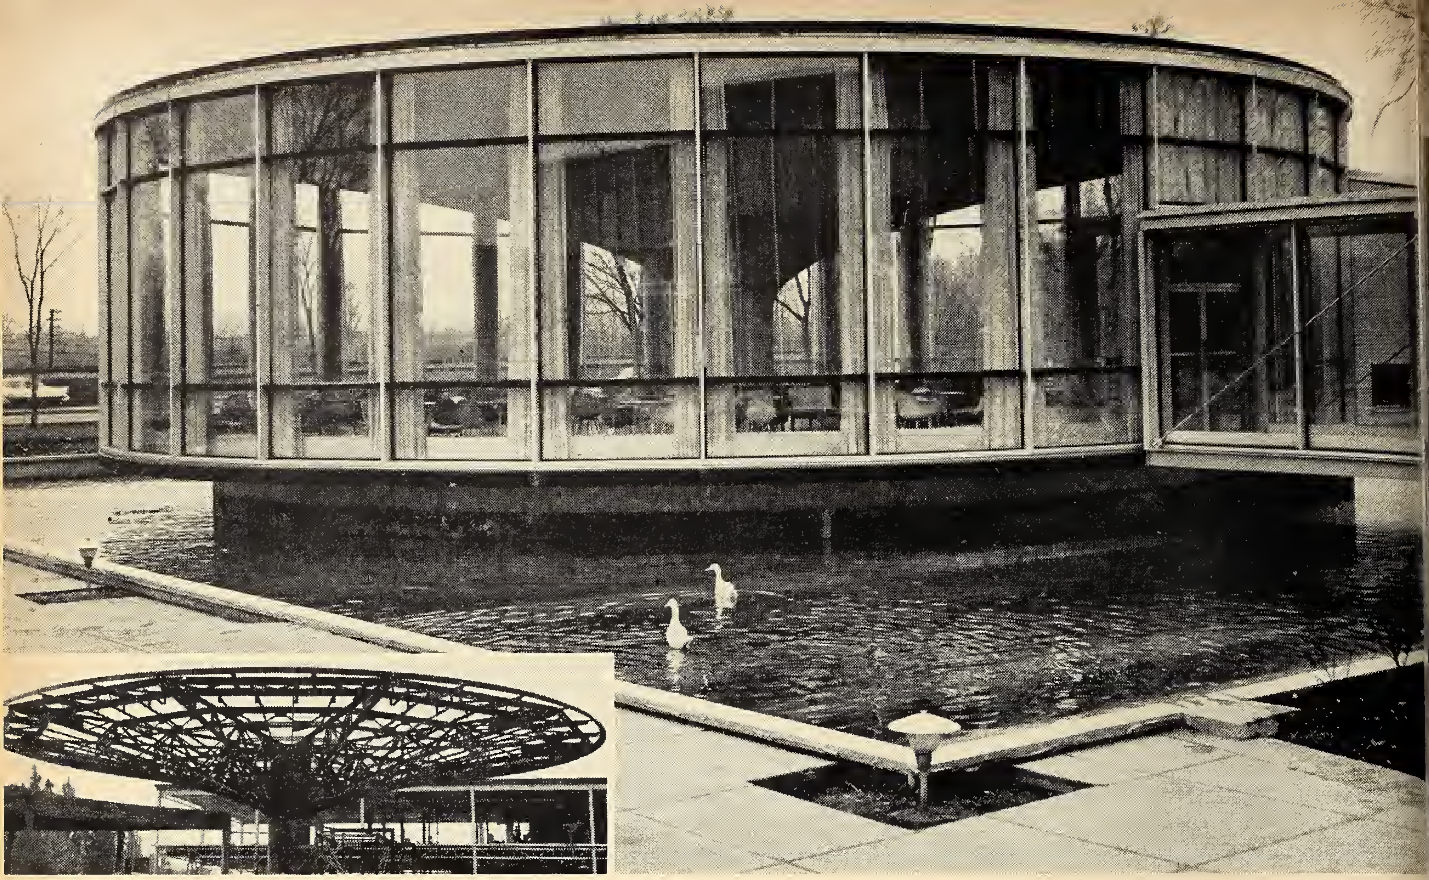
John A. Pihlainen, M.E.I.C. (McGill '50), has established an Arctic Consultant Service in Ottawa. Mr. Pihlainen also represents J. D. Mollard and Associates of Regina, Consulting Engineers specializing in air photo interpretation for civil engineering and geological purposes.

R. R. Real, JR.E.I.C. (Sask. '53), is one of four radio engineers of the National Research Council at Ottawa, who have won the 1959 Brabazon Award. The award was made by the British Institution of Radio Engineers, who offer it each year for the most outstanding paper on aircraft safety to be published in their journal.

Joseph H. G. Howard, JR. E.I.C. (R.M.C. '55, Queen's '56), has returned from Birmingham, England, where he was studying under an Athlone Fellowship and a N.R.C. scholarship. He is now with Pratt and Whitney Aircraft Co., Montreal.

Albert Hopkins, M.E.I.C., Hopkins Mining Consultants Ltd., Toronto, has been in-

(Continued on page 98)



Beauty—This striking cafeteria on the CIBA building employs a steel umbrella-like cantilever roof structure. (See inset). The characteristics of steel offer great scope to the imaginative architect.

Why you shoul

Better Economy—This merry-go-round building is the kindergarten of a new school in Regina. Close co-operation between the architect and the steel fabricator made the best use of materials and helped cut costs.

● PERSONALS

vestigating, surveying, and mapping trap rock deposits occuring on a chain of islands in the North Channel of Lake Huron, Ont. for Poly Ores Mining Co. Ltd. and Tough Rock Quarries Ltd.

John Douglas Fowler, M.E.I.C. (Queen's '55), has been appointed Development Engineer in the Marketing Division of Inland Cement Company Limited, Edmonton. In his new capacity, Mr. Fowler will provide up-to-date information and assistance on new uses of cement and concrete in the Prairies.

J. D. Fowler,
M.E.I.C.

R. L. Berggren,
M.E.I.C.

R. L. Berggren, JR.E.I.C. (U.N.B. '56), has been appointed Production Manager, Building Materials and Insulation Departments, Atlas Asbestos Co. Ltd., Montreal. Mr. Berggren was formerly Merchandising Manager, Building Materials Dept.

Obituaries

James Murdock Wyllie, M.E.I.C., 49, chief contractor of structural steel at Canadian Bridge Works, died Sept. 15. Mr. Wyllie had been with the company for 32 yrs. and played a prominent role in obtaining and processing such large contracts as the structural steel for the Rainbow Bridge, Niagara Falls; numerous bridges for the Department of Highways and local manufacturing plants. He was a resident of Riverside, Ont.

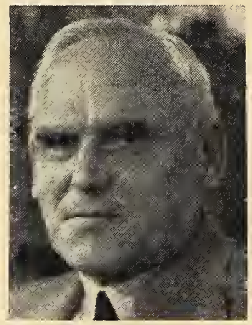
J. M. Wyllie,
M.E.I.C.

W. A. Mather,
HON. M.E.I.C.

William Allan Mather, HON. M.E.I.C. (McGill '08), Chairman and former President of the CPR, died Jan. 2. He was 75. Mr. Mather joined the company when he was 19 and was President from 1948 to 1955 when he became Chairman. Among the many honors which Mr. Mather received were an honorary degree of Doctor of Civil Law from Bishops University, 1951, Doctor of Laws University of Western Ontario and honorary degree of Doctor of Laws from McGill, 1956. He joined the Institute in 1911 as an associate member and became a member in 1920. He was made a life member in 1947 and in 1951 was awarded an honorary membership in the Institute.

Rt. Hon. C. D. Howe, HON. M.E.I.C. (M.I.T. '07) outstanding engineer and a major influence on government policy for a quarter of a century, died New Year's Eve at his Montreal home. He was 74. Mr. Howe held vital portfolios in the cabinet of Prime Ministers King and St. Laurent. He suffered personal defeat when the Liberals were swept from power in 1957.

His engineering skill brought Mr. Howe wealth and honors, including numerous honorary degrees from universities. Other recognition included the American Daniel Guggenheim Medal in 1954, and the Julian C. Smith Medal from the Engineering Institute of Canada in 1960. Mr. Howe, Chancellor of Dalhousie, was one of four engineers serving as Chancellor of a Canadian university



Rt. Hon. C. D. Howe,
HON. M.E.I.C.

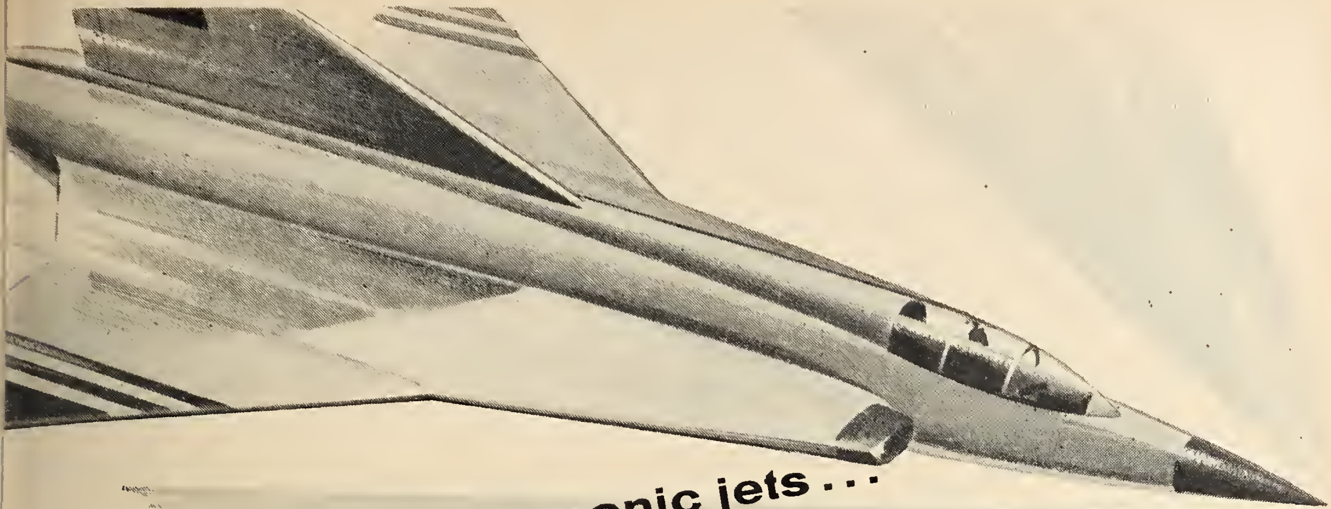
last year. He joined the Institute in 1922 and was made an honorary member in 1937. He became a life member in 1957.

Beaver Bill Says —

Dear Bob,

Well, you're out of University, with a sheepskin and a job.

One bit of counsel, if I may call it that, from an old friend. Graduation is just the start. If you're going to become a fine engineer, and I know you have it in you, you should continue broadening your outlook, enhancing your professional background and experience, and improving your ability to talk in public, all your life. How? Participate in the activities of the Engineering Institute of Canada, a university for life for engineers.



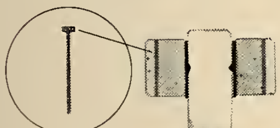
FIRST for supersonic jets . . .

NOW for industry . . .

"SCOTCH-WELD"
BRAND
STRUCTURAL ADHESIVES

This amazing new "chemical welding" process enables you to fabricate without welds or rivets, solve design problems, and reduce parts assembly costs

Adhesive bonding of thin metal aircraft skins, metal braces, stiffeners and other parts was pioneered by the aircraft industry to develop stronger yet lighter, faster, higher flying planes. Certainly, if "Scotch-weld" Structural Adhesives are used to advantage in assembling multi-million dollar high-speed aircraft, they can also be used to advantage in load-bearing applications in many other industries. This modern, high strength method of joining metals, reinforced plastics and other materials, permits improved design and production techniques, cuts costs and offers many unique benefits . . . smoother contours . . . lighter gauge materials . . . reduced inspection . . . unusual combinations of materials, and so forth. Already, "Scotch-weld" Structural Adhesives have solved design and production problems for manufacturers of appliances, metal shipping containers, pneumatic tools, pumps, motors, scaffolding and many other items. They may be able to do the same for you. Mail the coupon and let us show you how.



Adhesive bonding small pinion gears to rotor shafts provided savings of $56.37 per thousand by reducing rejects, and eliminating secondary operations and the necessity for 100% inspection.

A pump manufacturer reduced rejection rates from a high of 25% to nearly zero by adhesive bonding three separate die castings to form a single part.

National Association of Corrosion Engineers

New officers have been elected for 1961-62. E. C. Greco, senior research chemist for the United Gas Corp., Shreveport, La., has been elected President; Rolland McFarland, secretary and technical director of Hills-McCanna Co., Chicago, — vice-president; and G. G. Gribble, Jr., district manager for the Metal Goods Corp., Houston — re-elected treasurer. All officers are to be installed March 17, the last day of the Association's 17th Annual Conference and 1961 Corrosion Show, New York.

Canadian Institute of Steel Construction, Inc.

Structural steel draughting apprentices completing a twelve-week course at the provincial Institute of Trades were guests at a luncheon held at the Board of Trade Dec. 2, given by The Canadian Institute of Steel Construction, Inc. The course is Part I of a two-part six-month course which each apprentice takes during his three-year indentureship. The boys are sponsored by structural steel fabricating companies located in Ontario.

The C.I.S.C. has opened a new regional office in Winnipeg which is under the management of Hugh Krentz. He will service Manitoba, Saskatchewan and the Lakehead. This now puts C.I.S.C. regional facilities in Montreal, Winnipeg, Vancouver in addition to those available at the Toronto headquarters.

American Association of Cost Engineers

The "Soaring or Souring Sixties" was the subject of a talk given by Cecil H. Chilton to the Montreal Group of the American Association of Cost Engineers, Jan. 16.

Since 1956 when the Cost Engineers became organized into an international association, it has grown to a membership of more than a thousand. With so many active members in the Montreal area they are now feeling the need of a Regional Section.

Institute of Radio Engineers

The Toronto Section of the I.R.E. met Jan. 9 when C. J. McReynolds, Canadian Westinghouse Company Limited, presented a paper entitled "Ultrasonic Cleaning". He talked on the principles of ultrasonic cleaning, the systems available and their applications in industry.

The Chemical Institute of Canada

Dr. W. M. Campbell has been elected National Chairman of the Chemical Engineering Division, The Chemical Institute of Canada. Dr. Campbell, who is research director of the chemistry and metallurgy division, Atomic Energy of Canada Limited, takes over from Dr. W. H. Gauvin of the Pulp and Paper Research Institute of Canada and of McGill University. Other officers elected were: Viee-Chairman — Dr. J. W. Hodgins, McMaster University, Hamilton; Secretary-Treasurer — Dr. W. J. M. Douglas, McGill University.

The Society of Naval Architects and Marine Engineers

The Society has announced that it will continue, in 1961, the award of scholarships for undergraduate and graduate study. Accordingly, the Society is receiving, at this time, nominations for the four scholarships for graduate study which it has been offering each year in the past.

Society of Automotive Engineers, Inc.

The First International Congress and Exposition of Automotive Engineering, staged by the Society of Automotive Engineers, Inc., was held Jan. 9-13, Cobo Hall, Detroit. More than 100,000 engineers, including 25,000 SAE members from the United States and foreign countries had been invited.

At the Congress 70 sessions were held presenting more than 180 papers on topics ranging from new knock-testing methods, advances in truck tires, and equipment for clearing snow from jet runways, to vehicles for carrying explorers to the moon. More than 200 companies exhibited their latest developments in engines, materials, fasteners, mechanical components, hydraulic and pneumatic devices, and production equipment. The theme of the Science Pavilion was "Science Applied to Automotive Engineering". One area of the Pavilion depicted new powerplants such as the fuel cell, the rotating-combustion engine, the solar cell, and small nuclear reactors. Another area showed how physics and chemistry have provided clues to new materials and new ways to strengthen old ones. Committee meetings were held and work was done on

(Continued on page 104)

The Associations and Corporation

Ontario

Newly-elected President of the Association of Professional Engineers of Ontario is Lawrence C. Sentance, Manager, Defence Apparatus Division, Canadian Westinghouse Ltd., Hamilton. First vice-president — John W. Holmes, Niagara Falls, chief electrical engineer of H. G. Acres Co. Ltd.; 2nd vice-president — Robert L. Hicks, Toronto, who is with the Toronto Hydro-Electric System. Executive director of the Association is T. M. Medland; field secretary — T. C. Keefer; secretary-treasurer — David L. Turner, and field representative — Blake H. Goodings.

British Columbia

The annual meeting of the Association of Professional Engineers of B.C. was held in Vancouver, Dec. 9 and 10. William Hall, Victoria, was elected President of the Association and succeeds H. P. J. Moorhead. A. B. Sanderson was elected vice-president. The councillors elected, by classifications, were: R. H. Richmond — chemical; J. S. Kendrick — civil; H. R. Wright — electrical; P. N. Bland — mechanical; W. M. Armstrong — mining, geological and metallurgical.

Dr. O. M. Solandt, vice-president, research, Canadian National Railways, was the Guest Speaker at the annual luncheon. Dr. Solandt's topic was "Railway Research". Three members were granted Life Membership status. They were Dr. W. F. Sayer, C. C. Ryan and W. R. Curror. Another highlight of the meeting was the report of a special committee on Technical Education which stated that "there is a definite need for technical training facilities to fill the presently existing gap between vocational schools and the University". The meeting concluded with a banquet and a dance.

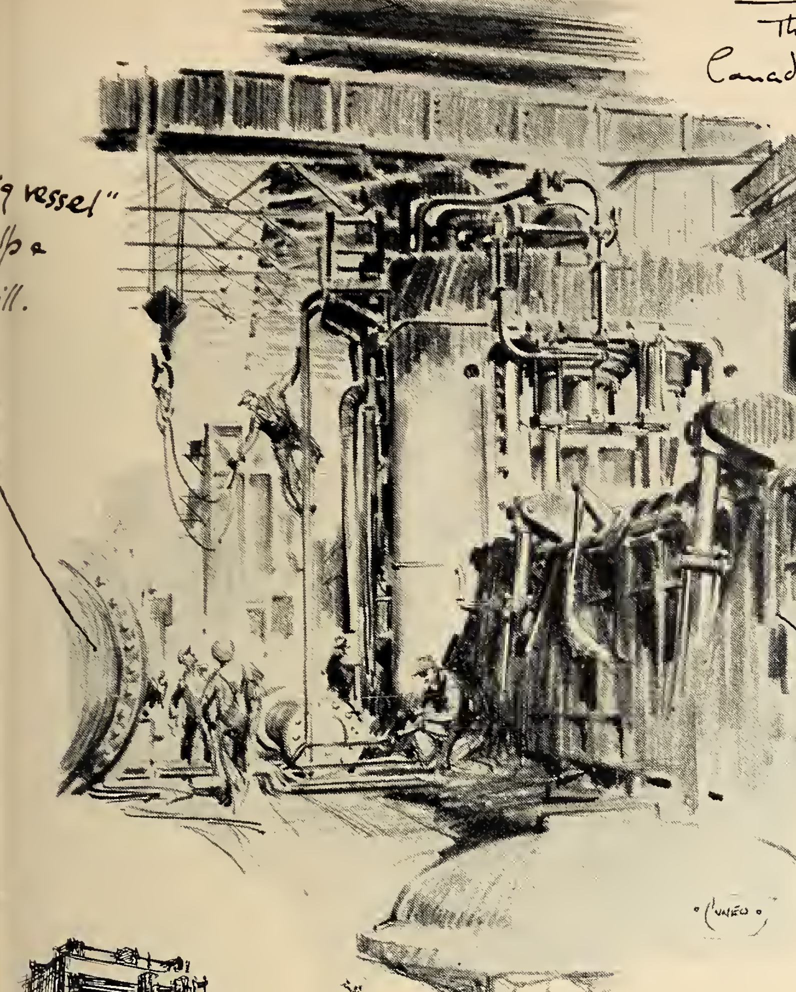
750 TON HYDRAULIC "SCRAP SHEAR"

This monster is to be installed in the Canadian National Railroad Yards, London Ontario. Its job is to crush, actually, bite up old steam locomotives. Its great guillotine blades can sever 6 inch steel with ease. For this I hate it. Yesterday I toured the C.P.R yards at St Luc, & saw the endless rows of proud rusty locomotives silently waiting their call to this modern madame Guillotine

"Vive le Progrès"



The hopper for loading.

Yesterday I was taken over a number of the locks of the St Lawrence Seaway & saw the massive gates that were made here in Canadian Vickers. Remarkable place this. It seems that they can take on anything from a ship to a "candy cooker".

This is a Vertical Boring Mill

It is turning a ball & socket expansion joint for the HUMBER RIVER SEWAGE TREATMENT PLANT (Romantic!) The reason for such a joint is to compensate for ground movement in the area. In other words the pipe may shift under the ground after its installation.

commission:-
ERT BOBY LTD.
ury St. Edmunds.

Overseas Companies make a vital contribution to the world-wide engineering resources of the Vickers Group. Whilst in Canada last year, Terence Cuneo paid a visit to Canadian Vickers Limited in Montreal, and these drawings give some idea of the part the company plays in Canada's shipbuilding and heavy engineering industries. The artist is shown in a typical sketching position

News of the Branches

Assumption University

Dean Morrison, M.E.I.C.,
Correspondent

A General Meeting was held Nov. 15 to present the budget for the school year 1960-61. The main position of the budget was delegated to subsidies. It was felt that this should be the main financial outlay since the students are not well off financially and were unable to attend some of the important functions of the Border Cities Branch. An example of results of this subsidy is the fact that 17 students were able to attend the Presidents Dinner Meeting in Chatham, Ont. The rest of the budget was set aside for current expenses.

Baie Comeau

G. W. Scott, M.E.I.C.,
Correspondent

The Annual General Meeting was held Dec. 1. S. J. Simons, Assistant Divisional Manager, Quebec North Shore Paper Company, was elected Chairman. In his report the retiring Chairman, G. W. Scott, gave a resume of the year's activities. Louise Tellier, Branch Secretary, stated that the Branch Membership was 59. There had been a slight decrease during the year resulting from the departure of engineers engaged on the Bersimis II Project at Labrieville but it was anticipated that membership would increase during 1961 with increased activity by Quebec Hydro on the Manicouagan River. The meeting concluded with the showing of the film "Quebec Winter Service" covering the winter navigation of the Lauritzen Line in the St. Lawrence River.

Corner Brook

Robert G. Scott, JR.E.I.C.,
Correspondent

The first meeting to be held in Newfoundland dealing specifically with prestressed concrete was held by the Corner Brook Branch Nov. 29. H. B. Carter, M.E.I.C., Assistant Resident Engineer, Bowater's Newfoundland Pulp and Paper Mills Limited, introduced the speakers, E. Leja, M.E.I.C., Managing Director, Lundrigan's Concrete Limited, and Harold Lundrigan, Jr. E.I.C., Manager, Lundrigan's Construction Limited.

Mr. Leja defined the title of their talk, "Prestressed Concrete", and went briefly into the history of this relatively new construction material. He discussed its advantages over reinforced concrete and its tremendous potential in the building field. He then gave a description of the various methods of actually producing prestressed concrete. Mr. Lundrigan followed up Mr. Leja's remarks by going into the theory of prestressed beams using actual numerical examples.

Liberal use was made of films, slides and scale models throughout the session. Especially interesting were films showing the actual making and placing of prestressed concrete on various projects throughout Newfoundland by Lundrigan's Concrete and Construction. Approximately 40 members and guests agreed that this was a most successful technical meeting. Refreshments were provided by the members of the Engineer's Wives Club. A vote of thanks was given by T. Rose, Jr. E.I.C., City Engineer.

An Executive Meeting was held Nov. 22 to draw up a schedule of winter activities. M. G. Green, M.E.I.C., Manager of Bowater Power Company Limited, Deer Lake, Nfld., was elected to the National Nominating Committee Headquarters.

A meeting was held Dec. 13 when P. Cupitts spoke on "Construction of Dokan Dam on the Lesser Zab River, Iraq". Mr. Cupitts is a Civil Engineer with Coode, Binnie and Preece, Consulting Firm.

Mr. Cupitts combined a film and lecture on the construction of the $40 million concrete arch dam. He noted that engineers from England, France, Austria and Germany took part in the project. For the design of the dam a new technique involving intensive mathematical and model experiments was developed at Imperial College, London University. From instruments incorporated in the dam structure it is eventually hoped to correlate theoretical and practical results. Shade temperatures ranging from 17° to 123° caused some difficulties. Artificial cooling means were employed before grouting contraction joints and after construction was complete to speed up removal of heat of hydration. Feature of the dam was one of the most extensive grout curtains ever constructed extending about one mile on either side of the dam itself. The film lasted some 20 min. and showed most of the important phases of construction. Following the film an interesting question and answer period was held and refreshments served.

Halifax

H. F. Peters,
Correspondent

The annual meeting was held Dec. 22 at the Nova Scotia Hotel. Refreshments and a light dinner preceeded the meeting. Attendance was below the usual number due to the imminent holiday season.

Committee chairmen reported on their activities during the year. The report of the representatives on the Committee on Confederation was received with great interest and was discussed at length.

Other reports at the meeting indicated success in the branch's policy of having monthly meetings, more social events and making the activities of the branch more widely known. Chairman of the recently-formed program committee, W. T. Windeler, reported on events arranged during the year and commented on the large attendance they attracted. Reports of the ballots for chairman and new members of the executive were received.

Hamitlon

Glyn T. Rees, M.E.I.C.,
Correspondent

The Eleventh Annual Professional Engineer's Ball was held Nov. 5 at Fischer's Hotel. Nearly 400 attended and President Dick was the guest of the night. President Dick spoke briefly to the engineers and their wives and stressed the importance of a high degree of technical proficiency in the engineering profession, in Canada, as a necessary adjunct to industrial growth and the development of the country's mineral resources. With this end in view the engineers present were urged to keep abreast of current advances in engineering technology and support professional development classes sponsored by the Hamilton Branch. Turning to the ladies, President Dick suggested that the engineers' wives had much to contribute to their husbands' careers, in some cases by encouragement, in others by advocating moderation.

Twenty Hamilton Branch engineers and their sons toured the City of Hamilton Water Purification Plant Nov. 26. The tour included the old "walking beam" type steam pump installed in 1856 which, although not now in service, is still preserved as a monument to those able engineers of 100 years ago.

Kitchener

A. R. LeFeuvre, M.E.I.C.,
Correspondent

A tour of engineering educational facilities at the University of Waterloo highlighted the visit of President Diek and General Secretary C. T. Page to the Kitchener area Nov. 6. During the visit at the University, the officials met with engineering faculty members and the student executive. In the evening the visitors were entertained by the executive members at a dinner meeting held at the Walper Hotel.

The meeting of Nov. 25 was held in the amphitheater of the University of Waterloo. It was the first time that the Institute had made use of these facilities. The members were welcomed to the University by Dr. D. T. Wright, Dean of Engineering. Cash prizes were awarded that evening to two engineering students at the University for technical essays submitted in a contest. These awards were presented by Vice-President Cross.

Professor J. W. Graham, Assistant Professor of Mathematics, was the guest speaker at this meeting and his talk was based on "The Anatomy of Modern Computers". Professor Graham illustrated his talk by means of slides and samples of computer components. He explained the fundamental logic and some of the circuitry of the computer, and made interesting analogies to the speed of these machines. A simple accounting procedure was used to illustrate the method of programming the computer.

Sixty-five members and student members were present and after the talk part of the audience asked Professor Graham to demonstrate the IBM 610 Computer, which the University is using at the present time.

Kootenay

I. Waterlow, M.E.I.C.,
Correspondent

At a meeting Dec. 12, Tom Brett, B.C. Telephone, Trail, B.C., gave a talk entitled "Canadian Microwave System". Mr. Brett described the Canadian microwave system with particular reference to the British Columbia section for which his company was responsible. He also showed the film "Waves of Sound", which described this construction.

Newfoundland

Anthony O. Nemec, JR.E.I.C.,
Correspondent

A meeting was held Dec. 12 in the auditorium of the Imperial Oil Building and was well attended by the members. A paper was given by Mr. Gordon MacDonald, M.E.I.C., Chief Highway Engineer, Dept. of Highways, Province of Nfld., entitled "Trans Canada Highway Construction in Newfoundland". This paper dealt with:

1. History of negotiotions having to do with Trans Canada Highway because of the special circumstances of New-

foundland becoming the 10th province of Canada.

2. The circumstances concerned with the general route and alignment problems.

3. The road system existing before confederation.

4. The special design specifications approved for Newfoundland.

5. The general construction methods employed in construction and problems presented by certain conditions in the field.

6. The paving program: a. specifications, b. plant and methods.

7. Soil conditions: a. geological areas, b. types of soils.

An extremely interesting question and answer period was held afterwards and coffee and sandwiches followed.

The Chief Bridge Engineer, Dr. E. Jacobsen is giving a paper on "Trans Canada Highway Bridges" at the next meeting.

Nipissing and Upper Ottawa

James W. Millar, M.E.I.C.,
Correspondent

Neil J. McMurtrie, Senior Design Engineer, Ontario Hydro Electric Commission, was the speaker at the Dec. 7 meeting. H. R. D. Graham, Manager, North Eastern Region, Ontario Hydro, introduced the speaker whose address was entitled "Research and Design Features of Extra High Voltage Transmission at Coldwater Project".

The Coldwater Project is a test facility near Waubaushene, Ont. It consists of two experimental transmission line sections each approx. ½ mile long with an instrument station between them. The purpose of the tests is to determine the minimum permissable conductor size for new EHV lines. Mr. McMurtrie stated that EHV transmission was not new, having been used in Western Europe, the United States and Russia but that sufficiently accurate data is not available to determine the size of the conductor with the exactness required by Hydro. It is proposed that eventually an EHV transmission line will extend from Abitibi Canyon into the Southern Ontario area involving ultimately two circuits over a distance of 450 miles. A slight reduction in the size of the conductor can mean tremendous reduction in cost.

Mr. McMurtrie said that with the completion of the St. Lawrence Seaway project the last big hydro development in Ontario was completed. The last remaining sources of hydro power in Ontario were being developed in the Northern part of the Province and it was in order to transmit this power over long distances that the EHV transmission lines were necessary. The lines will be designed to operate at 460,000 volts. The talk was accompanied by a film illustrating the construction and design features of the project.

L. E. Fischer, M.E.I.C.,
Correspondent

At a meeting Dec. 1 Mr. R. E. Grout, Vice-President Shawinigan Engineering Co., Montreal, gave his impressions of his recent visit to Russian hydro-electric stations. His talk was mainly based on a series of slides. Mr. Grout said that he was impressed by the size of some of their undertakings in this field which are now under construction. He was also impressed by the effort that was put into research.

At a meeting at Sept Iles, Que. Dec. 7, D. Sellick, M.E.I.C. gave a paper entitled "Basic Research in Blasting Cherty Metallic Iron Formations".

Oakville

J. W. Kirk, M.E.I.C.,
Secretary

An organizational meeting was held Nov. 28 and 20 members attended. The 1961 Executive was elected:

A. A. Swinnerton—Chairman
H. J. Bexon—Vice Chairman
J. W. Kirk—Secretary
A. H. Thompson—Councillor
A. G. Ackerman, C. F. Grass—Committee men

Bylaws were drawn up and adopted. Plans were also discussed for the President's visit on Feb. 8 when he is to present their charter.

Saskatoon

F. W. Fossey, M.E.I.C.,

Toronto Branch members were the guests of the Ontario Water Resources Commission for an afternoon and evening session on "Urban Environment and the Engineer", Dec. 1.

Dr. A. E. Berry, General Manager of OWRC welcomed the members of the Branch and he and his staff outlined the activities of the Commission. The second part of the afternoon session covered modern practices in sewage treatment. Dr. J. F. MacLaren, Consulting Engineer, Toronto, outlined the Humber sewage Treatment works as an example of a large, modern plant while D. S. Caverly of the OWRC staff used coloured slides to illustrate progress in small treatment plants. After an enjoyable dinner, the members toured the facilities of the newly completed OWRC labs.

The evening meeting took the form of a symposium on Air Pollution. A. H. Cowling, Chairman of the Select Committee of the Ontario Legislature on Air Pollution outlined the work and findings of his committee. The Toronto Program was outlined by R. L. Clark, Commissioner of Works for Metropolitan Toronto. The Hamilton Program was reviewed by Mr. D. H. Matheson, Director of Hamilton's Municipal Laboratories.

The session wound up with a discussion on "Urban Environment and the Engineer" led by a panel chaired by W. H. M. Laughlin.

Vancouver

D. R. Bakewell, M.E.I.C.,
Correspondent

J. S. Shakespeare, General Manager, and Mr. J. F. Pine, Chief Engineer, Peace River Power Development Co. Ltd., gave a talk on the "Peace River Hydro Development Including Some Engineering Aspects", Nov. 30. The talk was illustrated by colored slides. The speakers described their Company's findings and future plans in great detail. The respective role of the Peace River Development to the other existing and potential hydro developments in the Pacific Northwest was particularly enlightening.

On Nov. 17, the Civil-Structural Section heard a well prepared paper on "Fire in Buildings" by John Wheeler. Mr. Wheeler discussed all aspects of fire in buildings and covered protection, safety and fire statistics.

University of Waterloo

Carl Hamacher, M.E.I.C.,
Correspondent

The October-December quarter was highlighted by the presentation of awards to the winners of the technical paper contest sponsored by the Student Section. Mr. E. A. Cross, M.E.I.C, Vice President, presented the cash awards at a meeting of the Kitchener Branch, Nov. 25. Gordon Sterline, S.E.I.C., 3rd yr. Civil Eng., was awarded 1st prize for his paper "Open Stope Mining". Wallace Fletcher, S.E.I.C., Chemical Eng., was 2nd. with "Radiation Chemistry of Cycloherane; Iodine Mixtures".

A series of movies, courtesy of various industries, has been presented during the three month academic period and the films have been well received by the students.

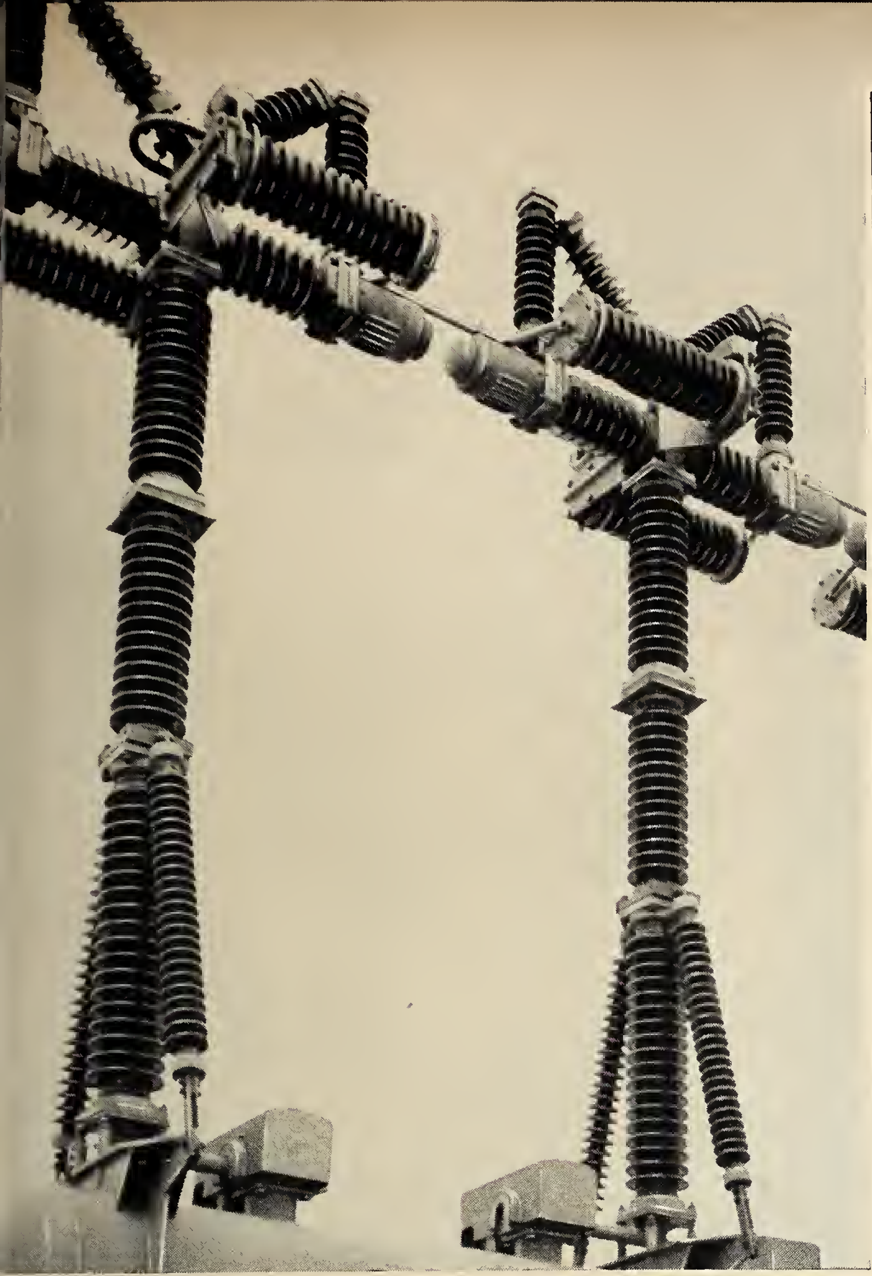
Fifty-five new student members have been enrolled, bringing the total student membership on Waterloo campus up to 125.

University of Western Ontario

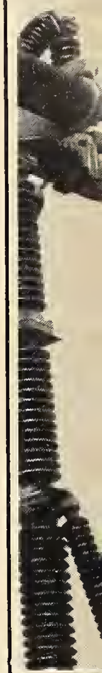
John Westeinde, S.E.I.C.,
Chairman

During the past years, the Undergraduate Engineering Society at The University of Western Ontario has undertaken to direct the cultural, social and athletic activities of the Engineering student body. A need was felt for the establishment of a professional engineering society for the technical betterment of the student. With this in mind an E.I.C. student branch was formed and an executive elected. Present membership is 70.

Events planned include a film meeting, a joint meeting with the London Branch, a joint U.E.S.-E.I.C. dinner meeting. EIC



BROWN BOVERI AIRBLAST CIRCUIT-BREAKERS IMPRESSIVE IN SEVERE LINE-DROPPING TESTS AT VOLTAGES UP TO 650 KV



Late in 1960, numerous field tests on Hydro-Québec's Bersimis Power Transmission System were made with Brown Boveri 300 KV Airblast Circuit-Breakers. Completely successful results were achieved in the following line-dropping operations:

- **44 Switchings at Bus voltages 400-500 KV**
- **16 Switchings equal to Bus voltages of 500-650 KV**

All operations were performed restrike free without over-voltages, and at a very steep rate of rise of recovery voltages.

The reasons behind the proven performance of
BROWN BOVERI AIRBLAST CIRCUIT-BREAKERS
are worth reviewing:

- Over 15 years operational experience and numerous successful field tests in many large power systems the world over.
- Design allowing complete interchangeability of breaker components.
- Simple mechanism assuring complete reliability and minimum maintenance even in extreme climatic conditions.

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*THEORY OF INERTIAL GUIDANCE.

This volume is devoted to a systematized development of the basic theory and elemental configuration of inertial systems as employed in stabilization, navigation, and guidance. The pertinent features of classical mechanics are reviewed through an evolutionary establishment of systematic configurations of Cartesian transformations, vector quantities, kinematic fundamentals, rigid body dynamics; gyrodynamics; and stabilized platforms. The author appraises the vertical coplanar dynamics of the levelling and indicating mechanisms, and then gives the spatial analytical description and simulation of inertial systems. (C. L. McClure. Englewood Cliffs, N.J., Prentice-Hall, 1960. 340p., $12.00.)

*BESTIMMUNGEN DES DEUTSCHEN AUSSCHUSSES FUR STAHLBETON, 7th. ed.

A compilation of German specifications and standards in the field of reinforced concrete covering materials, test methods, structural elements, and construction details. There is an extensive subject index. (Berlin, Verlag von Wilhelm Ernst & Sohn, 1960. 543p., DM 19.80.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

*THE TESTING OF ELECTRICAL MACHINES.

This book covers not only the actual techniques of testing, but also the purposes of the tests, the subsequent treatment of the data obtained, and the principles underlying the actions of the standard classes of machines concerned. Single-phase and three-phase commutator machines are not included. British testing practice and British Standard Specifications are referred to only. (L. H. A. Carr. London, England, Macdonald & Co., Ltd., 1960. 299p., 50/-.)

*ORGANIZATIONAL SYSTEMS AND ENGINEERING GROUPS.

The research here reported consisted of identifying and describing the organizational systems of each of two technical groups and of their individual parent companies, and then exploring and comparing the relationship between each system, and the background, behavior, performance, and satisfaction of each group's members. As well as reporting the findings of his research, the author indicates implifications the study may have for business administration and research in the behavioral sciences. (L. B. Barnes. Boston, Harvard Business School, Division of Research, 1960. 190p., $3.50.)

*THEORY OF MACHINES, 3rd. ed.

Intended for the engineering student, but also helpful for the draftsman and designer, this third edition has additional matter on gyroscopic motion, velocity and acceleration, toothed gearing, epicyclic trains, inertia forces in mechanisms, and vibrations. There are also chapters on balancing, dimensions, and dynamical similarity, governors, analysis of cams, and friction, including clutches. The analytical theory of five types of brakes is given, including brakes with external-contracting pivoted shoes; special attention has also been paid to the inertia effect of a connecting rod, to creep of belts, and to helical, spiral, and epicyclic gears. (B. B. Low. Toronto, Longmans, Green, 1958. 621p., $5.00.)

*SOILS ENGINEERING, 2nd. ed.

With a notable foreword by Karl Terzaghi, this is a practical introduction of the subject on the undergraduate level. It describes the origin, properties and classification of soils, all aspects of water, frost, and stress distribution in soil, and soil practice in connection with dams and levees, retaining walls, underground conduits, piles and pile-driving; and the consolidation and settlement of structures. This new edition incorporates improvements and additions reflecting advances in the science since 1951. (M. G. Spangler. Pennsylvania, International Textbook, 1960. 483p., no price given.)

*HEAT TRANSFER AND FLUID MECHANICS INSTITUTE—PROCEEDINGS, 1960.

This volume contains eighteen papers reporting completed investigations presented at the 13th meeting of the Institute, all American save for one from England and one from Belgium. The papers deal with research in vortex motion, boundary layer flows, origins of turbulence, flows not in thermodynamic equilibrium, separated flows, two phase flow systems, and thermal radiation problems in space technology. (Stanford, California, Stanford University Press, 1960. 259p., $8.75.)

*DICTIONARY OF AUTOMATIC CONTROL.

A unique feature of this book is an index arranged under the five major subject divisions the book covers—control theory and basic concepts, computers and data processing, industrial machine and process control, aircraft and missile control and telemetering, and control components and design features—which assists in the location of a particular term, as in a thesaurus. In the main text the terms are dealt with alphabetically by means of a brief discussion rather than just a definition. Extensive cross-referencing permits discussion of related terms or concepts under one heading in a unified essay, rather than in alphabetically-separated explanations. A chief engineer at Bulova Research Laboratories, Consulting Editor of the magazine "Automatic Control", and member of AIEE, IRE and AAS, the author has spent five years collecting, editing and interpolating the material. (R. J. Bibbero. New York, Reinhold Publ. Corp. 1960. 282p., $6.00.)

SAFE HIGHWAYS

*KINEMATICS AND DYNAMICS OF MACHINERY.

This text was developed for use in undergraduate machine design courses. The first ten chapters discuss kinematics, emphasizing acceleration analysis, comparing various methods of kinematic analysis, and demonstrating its role in the complete dynamics analysis of mechanisms. The next nine chapters cover static force analysis, and dynamic analysis; involving kinematic analysis as a tool, and covering in detail the speeds and static and dynamic balancing of rotating and reciprocating members, and forces imposed by gyroscopic effects. The final three chapters discuss cams, gearing and gear trains, using the principles of kinematics and dynamics in the process. (R. L. Maxwell. Englewood Cliffs, New Jersey, Prentice-Hall, 1960. 477p., $9.75.)

*MOTION AND TIME STUDY, 3rd. ed.

This edition reflects the extensive industrial applications made during the past five years, and includes new topics on work sampling and sampling standards, motion economy, statistical analysis and mathematical models, verified by first-hand observation in this and other countries. This is a practical book, presenting the basic principles of successful work and developing them through detailed description and extensive illustration from a wide variety of industry and types of work into the final time and motion study procedures. (M. E. Mundel. Englewood Cliffs, New Jersey, Prentice-Hall, 1960. 690p., $11.95.)

*THE RELAY PROTECTION OF HIGH VOLTAGE NETWORKS.

The English edition of a Russian work dealing with the theoretical aspects of the subject for specialists in the field. Relevant aspects of sequence networks, the vector locus method, symmetrical component filters, power directional devices, and the principles of construction and methods of theoretical analysis of systems of transmission line and bus-bar protection are discussed. Also included is consideration of the principles of auxiliary devices which serve for the selection of the faulty phase and for preventing the incorrect operation of protective gear during swings and for faulty conditions in the secondary windings of voltage transformers. (G. I. Atabekov. New York, Pergamon Press, 1960. 564p., $14.00.)

*THE NEW PRODUCT.

This guide to successful product development is presented from the point of view of general management. The basic concepts of top management planning and new product development are covered, as well as each major area of the business enterprise concerned with the successful development and marketing of a new product. Includes chapters on sources of new ideas, pricing, patenting, costing, and sales and advertising methods. (D. W. Karger. New York, Industrial Press, 1960. 234p., $5.00.)

*SYMPOSIUM ON HIGH-VOLTAGE CABLE INSULATION.

Three papers are included in this volume: "Paper for high-voltage cables"; "The Why and the How of Cable Oil Tests", and "The Utility Viewpoint on Cable Oils". (Philadelphia, American Society for Testing Materials, 1960. 39p., $1.50. s.t.p. no. 253.)

*THE CHEMISTRY OF PROPELLANTS.

The topics covered by papers in this volume include propellant sources and costs, liquid propellants, solid propellants, propellants for air-breathing engines, and basic studies on reactions during nozzle flow and jet engine deposits. High-energy propellants and basic propulsion problems are presented and discussed in five papers given at round table discussions. Papers are in French or English; some have extensive bibliographies. (S. S. Penner and J. Ducarme, eds. New York, Pergamon, 1960. 651p., $10.00.)

*SYMPOSIUM ON TREATED WOOD FOR MARINE USE.

This volume contains the seven papers presented at the Third Pacific Area National Meeting of ASTM in San Francisco, October, 1959. Topics covered include methods of evaluation of potential wood preservatives and of chemicals poisonous to the marine borer, the analysis of creosote, studies on wood piles in sea water, and tests on preservatives and specific woods used in piling. (Philadelphia, American Society for Testing Materials, 1960. 69p., $2.50. s.t.p. no. 275.)

*INTRODUCTION TO CONGESTION THEORY IN TELEPHONE SYSTEMS.

The purpose of this book is to present the study of stochastic processes describing the passage of telephone traffic through a switching system, and to introduce to telephone engineers recent mathematical developments in the general congestion theory applicable to telephone traffic. Strong emphasis is placed on the variety of the mathematical methods employed for the solution of congestion problems. Considerable use is made of such recent developments in general congestion theory as queueing theory, Markov chains, and renewal processes. (R. Syski. Toronto, Clarke Irwin, 1960. 742p., $23.00.)

*PROCESSES IN CRYOGENICS, VOLUME 2.

Volume 2 of the series summarizing articles on the whole field of low-temperature methods and techniques, as distinguished from low-temperature physics or chemistry. This volume presents papers on the storage and handling of cryogenic liquids; the gas refrigerating machine; bubble chambers; resistance thermometers; the three level solid state maser; methods of nuclear orientation; the 1958 scale of temperatures for the liquid Helium-4 region; and industrial low-temperature distillation for Deuterium. (Ed. by K. Mendelssohn. New York, Academic Press, 1960. 280p., $11.50.)

*PHYSICS OF THE UPPER ATMOSPHERE.

Eleven chapters of this book are detailed monographs on particular topics by specialists, all concerned with that part of the atmosphere above the height of 60 km. These deal with the thermosphere, the ionosphere, the properties and constitution of the upper atmosphere and its study by rockets and satellites, the airglow, general characteristics of auroras and their study by means of radar, interpretation of the auroral spectrum, and consideration of geomagnetism and meteors in the upper

*THE THEORY OF THIN ELASTIC SHELLS.

The proceedings of a symposium of the International Union of Theoretical and Applied Mechanics, held in Delft in 1959. The 23 papers presented at this symposium (5 in German, 1 in French) discuss two aspects of shell theory-non-linear theory and problems lacking axial symmetry. Frequently papers from two or more sources deal with the same topic, indicating simultaneous investigations in different countries, but these present different points of view and collectively, a broad perspective of each problem. (Ed. by W. T. Koiter. New York, Interscience Publishers, 1960. 496p., $9.00.)

*GRAPHITE AND ITS CRYSTAL COMPOUNDS.

This survey includes description of current lines of research without attempting definitive treatment where these are considered to be premature. It covers crystallographic models and structure of graphite, its physical, thermal, and electronic properties, and its crystal compounds and their electrical and chemical properties and chemical physics. The final two chapters discuss graphite oxide, and the chemical transformation of graphite to volatile products. There is a 28-page bibliography. (A. R. Ubbelohde and F. A. Lewis. Toronto, Oxford University Press, 1960. 217p., $5.25.)

CAREER OPPORTUNITY FOR MECHANI-CAL ENGINEER in New Alumina Plant. Harvey Aluminum, a dynamic, fast growing producer of primary aluminum and mill products is engineering a new alumina plant.. The following challenging position is now open: Senior mechanical engineer, minimum 4 years plant experience in the maintenance department of a Bayer ore process or alternatively, minimum 6 years' plant experience in the maintenance department of other extractive metallurgical or chemical processes. Candidates having experience with the operation of boilerhouses will enjoy preference. This permanent position offers excellent career opportunity with a strong growth company. Send complete resume of education to: Harvey Aluminum (Incorporated). Attention: Mr. Ron Howard, Director of Professional Personnel, 19200 South Western Avenue, Torrance, California. File No. 7210-V.

MISCELLANEOUS

ENGINEERS FOR SALES, PROJECT, design, research, development, control and management. Graduates of all types and ages required by clients of The Technical Service Council, a non-profit industry sponsored placement service. Write 2 Homewood Avenue, Toronto 5, for an application. There is no charge for work done on your behalf. File No. 6648-V.

TEACHING VACANCIES exist for undergraduate courses in Mechanics, Thermodynamics, Materials, in young Engineering Department. Minimum requirement — Masters Degree. Rank and salary dependent on qualifications. Write — Jack Bordan, Head, Department of Engineering, Sir George Williams University, Montreal 25, Canada. File No. 7180-V.

ENGINEER REQUIRED. Must be bilingual with 5 to 7 years' industrial experience in preferably production planning. To act as assistant to plant manager. Please apply directly to Mr. Jean Moreau, P.Eng., Eagle Pencil Co., Drummondville, Quebec. File No. 7187-V.

HYDRAULIC SYSTEMS DESIGN ENGINEER. A vacancy exists for a design engineer with North American experience in high pressure hydraulic systems and components for industrial applications. Apply Vice-President, Engineering, Jarry Hydraulics Limited, 4384 St. Denis St., Montreal 18, Quebec. File No. 7190-V.

A MOST UNUSUAL OPPORTUNITY for a competent technical man, thoroughly experienced in the complete operation of vertical stud Soderberg anode cells. The man selected must have an outstanding engineering record, a theoretical knowledge of this electro-chemical process, and extensive operational experience producing primary aluminum. Must be capable of quality inspection of actual operations. Excellent salary, major benefits. Detail your background and experience in strict confidence. File No. 7201-V.

WE REQUIRE TWO JUNIOR GRADUATE Engineers with from one to three years' experience. One mechanical or electrical engineer for our instrument department, preferably with some experience in automatic controls, and a mechanical engineer for general work in design and maintenance. Good opportunity for advancement with excellent salary and fringe benefits. File No. 7203-V.

ENGINEERING FIELD REPRESENTATIVES required to assume responsibilities for field operations in London, Ontario immediately and in Maritime Provinces. Maritime position opens only in June. Duties involve promotional work (not sales) with engineers, architects, contractors, and government officials, on an individual basis and through meetings with professional groups. Complete training in all aspects of the work will be provided. These positions are suitagle for recent engineering graduates interested in public relations work and limited structural design. Salary commensurate with qualifications and experience in $5,000 to $6,000 range. Reply in writing to Plywood Manufacturers Association of B.C., 27 Goulbourn Ave., Ottawa, Ontario. File No. 7207-V.

E.I.C. CERTIFICATE OF ADVERTISING MERIT

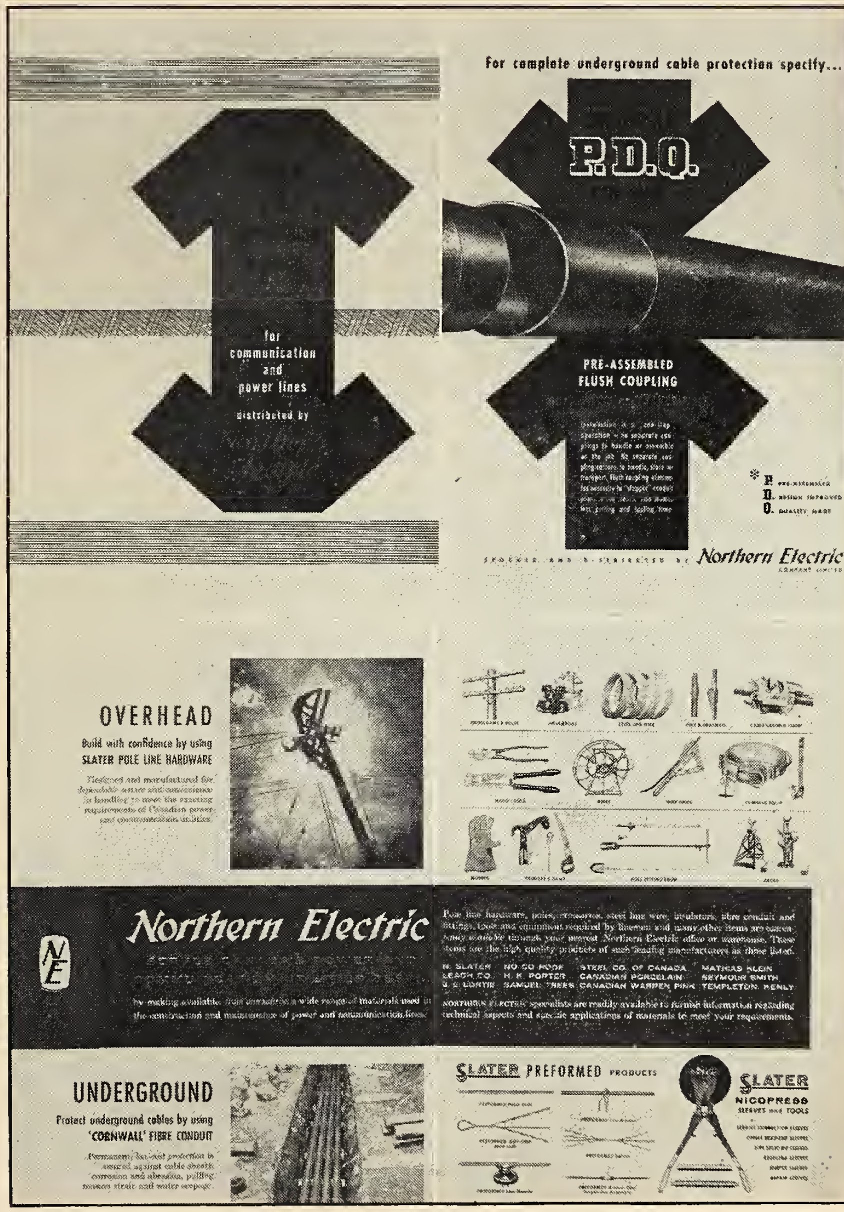
The E.I.C. Certificate of Advertising Merit for the month of November 1960 has been awarded to Northern Electric Company Limited. This is the fourth time, since the inauguration of the certificates in January 1959, that Northern Electric has been presented with this certificate. The winning advertisement appears on pages 33, 34, 35, & 36 of the November issue. It is a 4-page, two colour, insert, black and orange, titled "OVERHEAD AND UNDERGROUND MATERIAL FOR COMMUNICATION AND POWER LINES DISTRIBUTED BY NORTHERN ELECTRIC."

The insert covers a variety of services and products made available to engineers through the company and lists some of the firms Northern Electric represents. This same insert won the E.I.C. Certificate of Advertising Merit for the month of October.

Mr. E. H. Woodley is the Advertising Manager of Northern Electric Company Limited and the Montreal office of Foster Advertising Limited (Account Executive Frank Thompson) placed the business with us.

The judging of the advertisements was done by fifty readers of the "Journal" — five from each province — who made their selection from the viewpoints of ACCURACY — INFORMATION — ATTRACTION.

Front *Back*



Centre Spread

NORTHERN ELECTRIC COMPANY LIMITED WINNING INSERT

The above illustration is a reduction, to a small scale, of the 4-page, 2-colour advertisement which fifty readers selected, from the viewpoints of ACCURACY—INFORMATION and ATTRACTION as the "best" in the November issue. The original advertisement, on page 33, 34, 35 & 36 of the issue was printed in black and orange on heavy white stock.

Business and Industrial Briefs

Appointments and Transfers

The Foxboro Company, Foxboro, Mass., has formed a marketing division. Mr. C. **Schwarzler** has been appointed Vice-president of the new division.

Syntron (Canada) Limited has appointed **Walter O. Middleton** District Manager of British Columba and the Yukon Territory.

John J. Huggard, Assistant to the President of Continue-Flo Products Ltd., Hamilton, is spending one to two years in England. Mr. Huggard is assisting in the selling of the firm's products in the U.K. and Ireland. He will be in charge of sales and promotion co-ordination.

Otis Elevator Company Limited have appointed **Edmund M. Tuff** Construction Manager for Canada succeeding **George A. Thomas** who has retired.

R. Roy Ellis has joined The Indiana Steel Products Company, Ltd., Kitchener, Ont., as a sales engineer.

In addition to his duties as Executive Vice-President and General Manager of Howard Smith Paper Mills Ltd., **H. E. Mason** has been appointed Vice-president of Dominion Tar and Chemical Company, Ltd.

The Consolidated Mining and Smelting Company of Canada Limited has appointed **T. S. Campbell,** Mines Engineer, Benson Lake Property, Vancouver Island.

The appointment of **John F. Redmond** as Vice-President, exploration and production, has been announced by Shell Oil Company of Canada, Limited. Mr. Redmond will have his headquarters in Calgary.

G. J. Jackson has been appointed District Sales Manager, Dominion Structural Steel Limited, Toronto Division. Mr. Jackson was formerly Assistant Sales Manager, Montreal Division.

Canadian Petrofina Limited has appointed **J. C. Vezeau** Manager of asphalt sales. He will be organizing the marketing of asphalt products and co-ordinate the sales program with the refinery.

The A C and R Products Limited is to act as agents for the distribution of all Alco Valve Company products for air conditioning, refrigeration and industrial processing in Canada with the exclusion of British Columbia and Alberta. **W. G. Woodcock** is President and General Manager of A C and R Products Ltd.

Developments

Information contained in this section has been obtained from press releases. Mention of products and services does not imply endorsement by the Institute.

A MILLION DOLLAR carbon monoxide boiler and extraction steam turbine is being installed by British American Oil Company Limited at its Clarkson refinery, 20 miles west of Toronto. The boiler is designed to aid in heat recovery and disposal of waste gas by burning carbon monoxide and unburned hydrocarbons produced in the refinery's catalytic cracking operation. It will provide steam power for the recently completed alkylation unit and complement the high pressure steam boiler at present supplying the catalytic cracking unit. It will be capable of generating 165,000 lb. of steam per hr. at 600 p.s.i.g. at 750°F.

THE WATER RESOURCES BRANCH of the Department of Northern Affairs and National Resources has issued its annual review of current water power development throughout Canada, and of other construction pertaining to electric power supply and distribution. During 1960, a net total of 1,741,820 hp. of new hydro-electric capacity was added in Canada after allowing for 4,680 hp. which was dismantled or destroyed. Quebec's total of 1,176,500 hp. of new capacity installed during 1960 surpassed the combined total of the other provinces. The total installed capacity of new water power plants in Canada is now listed at 26,372,444 hp. New capacity to be added in Canada during 1961 is limited to about 243,000 hp.; however construction is proceeding at other developments where 4.5 million hp. are expected to be installed and where provision will be made for installation of an additional 1 million hp. in later years.

TO FAMILIARIZE the construction industry with shell roofs is the aim of a new booklet produced by Portland Cement Association, Chicago. The publication gives basic information on several aspects of shell design and construction. The lead article by a noted architect deals with some of the esthetic considerations encountered in this work. Also dealt with are characteristics of shells, including explanations of their action and suggestions for best realization of their potential plan layouts. The final article gives details on six American projects that illustrate the versatility of barrels, folded plates and hyperbolic paraboloids.

CONTRACT for design, manufacture and installation of the largest single solids contact water treatment plant in North America has been awarded to Graver Water Conditioning Co., Toronto, by St. Lawrence Corporation Limited. The plant, to be installed at St. Lawrence's Three Rivers, Que., newsprint plant, will provide clarified process water to ensure maximum brightness of paper. The plant will consist of an all steel reactivator 150 ft. diam. and 24 ft. high, chemical feeds and flow control equipment. Flow capacity will be 20,000 gal. per min. The plant is planned to be in operation by the end of March, 1961.

A NEW LINE of high intensity infrared heaters recently announced by Canadian General Electric Company Limited are claimed to eliminate snow removal problems. These heaters are installed so as to radiate heat over a particular area. The heat rays pass through the air without heating it, but warm objects which they strike. For the duration of a snow storm the heaters are switched on and the snow melts as it falls, thus eliminating snow removal chores.

A NEW ALLOY has been announced by Union Carbide Canada Limited, Metals and Carbon Division. The metal, "Haynes" alloy No. 56, is said to capitalize on the best characteristics of nickel, cobalt, chromium, molybdenum and iron. These ingredients are blended to give the alloy high-temperature strength and oxidation resistance. It is

(more Briefs on page 135)

• MORE BRIEFS

available in the form of sheet, plate, bar, wire and coated welding electrodes. Parts can also be produced by sand-, investment-, and resin shell-mould casting.

ULTRASONIC CLEANING SYSTEMS for industries, designed to clean any product from machine castings, gears and shafts to delicate instruments, have been introduced by Canadian Westinghouse. This method makes use of high-frequency sound waves to remove foreign matter from metals, plastics, ceramics and glass. A generator produces high-frequency electrical energy, which a transducer converts to high frequency sound waves that travel through the liquid cleaning agent. These waves cause "cavitation", the formation of countless microscopic bubbles that grow in size and then violently collapse, thus setting up a scrubbing action that blasts the contaminant from the substance being cleaned. The equipment is claimed to provide a fast, economical method of removing oil, grease, buffing compound, chips, dirt and foreign substances from recesses, small holes or crevices. It will also remove flux residue, scale formed on metal surfaces during heat treatment, and decontaminate radioactive parts.

A VISUAL SYSTEM for selecting tool steels has been created by Atlas Steels Limited. This company claims that the new system will enable users of high speed and tool steels to make correct specifying decisions based on their shop needs, without extensive metallurgical or engineering knowledge. The "Select-o-Graph" is made up of a wall chart with full-colour graphs that show at a glance the chief characteristics of 23 tool steels; and a brochure that repeats the graphs along with technical information.

WESTINGHOUSE ELECTRIC International Company has appointed Liquid Carbonic Canadian Corporation as exclusive Canadian distributors of its line of electric welding equipment.

THE FORMATION OF a subsidiary company to commercially develop an asbestos deposit at Coalinga, Calif., has been announced by Canadian Johns-Manville Co., Limited and The Kern County Land Company of San Francisco. The new operating compnay will be known as the Coalinga Asbestos Company. Johns-Manville Corporation owns a majority interest in it.

SMALL AIR COOLED ENGINE WELDERS with engine idler and self-starter, introduced by the Lincoln Electric Company of Canada Limited, are said to have added convenience and improved economy. The welder will accelerate to operating speed instantaneously when the arc is struck and slow to idling speed 8 to 10 sec. after the arc is broken. EIC

Technical Control of Ready Mixed Concrete by **M. F. Macnaughton,** M.E.I.C., covers some of the more important aspects of quality control. It also discusses some of the present problems relating to concrete quality — whether ready mixed or job mixed — and gives a brief review of some recent investigations which suggest at least a partial solution to some of these problems. Mr. Macnaughton, a native Montrealer, served overseas with the Canadian Expeditionary Force during the First World War after which he entered McGill University where he obtained a B.Sc. in Chemical Engineering. He received his master's degree from University of Michigan in 1924. After 28 years with Milton Hersey Co. Ltd., Montreal, Consulting Engineers and Inspectors, he joined Mount Royal Paving & Supplies Ltd., where he is Vice-President, Technical Control.

Harvey E. Martin, M.E.I.C., author of *The GM Portager Piggyback System*, joined General Motors Diesel Limited, London, Ont., 10 years ago as a Project Engineer. He was promoted successively to Supervisor of Project Engineering, Chief Project Engineer, and, in late 1960 to New Product Development Engineer. In his paper Mr. Martin outlines the rationale of piggyback systems and describes a different approach developed by his company. In the GM system the rubber-tired highway trailer rear tandems may be removed, and the trailer can be side loaded onto the rail vehicle. This allows a more simplified rail vehicle than now in general use for piggybacking. Mr. Martin was born in Napanee, Ont. After serving four years as an apprentice draftsman for Canadian General Electric Company he joined the Royal Canadian Navy. He obtained his B.Sc. degree from Queen's University in 1949.

Leo A. Leeyus, M.E.I.C., could call upon 12 years of experience in hydro electric projects for his paper, *Silver Falls Tunnel and Surge Tank Design.* Mr. Leeyus is a native Manitoban and received a degree in Civil Engineering from University of Manitoba in 1947. After graduation he joined the Hydro Electric Power Commission of Ontario where he now is Assistant Civil Design Engineer, Generation Design Department. Projects on which he has worked include Des Joachims, Niagara G.S. #2, Niagara River Remedial Works Control Structure, Pumping Generating Station (Niagara) and the Silver Falls project. Mr. Leeyus explains that the Silver Falls site is a typical example of an area where a hydraulic pressure tunnel is the most effective method of developing maximum power potential. The two basic requirements for the use of natural rock are that the topography lend itself to such an arrangement and that the rock be of satisfactory quality.

A tight schedule in the tunnel driving and concreting at Silver Falls made it necessary for the concrete operation to start while the tunnel driving was in progress. This is one of the problems outlined in *Concrete Tunnel Lining at Silver Falls Generating Station* written by **H. A. Jackson,** M.E.I.C., and **C. T. Bath.** The authors' qualifications include extensive experience in hydro electric projects. Mr. Jackson, Construction Manager for Northwestern Ontario of the Hydro Electric Power Commission of Ontario, joined the H.E.P.C. after obtaining a B.A.Sc. degree from University of Toronto in 1946. He has served as Construction Engineer at Otto Holden G.S. and as General Construction Superintendent at Manitou Falls G.S. Mr. Bath, a native Australian, came to Canada in 1953 and worked at the Kitimat and other hydro projects before joining Ontario Hydro in 1957. He now is Office Engineer of the Thunder Bay G.S. at Fort William. At Silver Falls, a 10,000 foot horizontal tunnel was driven between two lakes. Associated with the tunnel are two vertical shafts, and a surge tank joined to the tunnel by a reinforced concrete "T" section.

". . . for sheer presumptuousness at least, my title can hardly be surpassed," says **Dean J. W. Hodgins,** M.E.I.C., in his paper, *Technological Horizons*. The author, who is Dean of Engineering at McMaster University, Hamilton, first presented Technological Horizons as a talk before the Hamilton Association last year. Dean Hodgins points out that engineers spend their entire careers as custodians and purveyors of materials, energy, and information, "and that these three topics may very well serve as the basis for this discussion, for contemplation of them has suggested some rather strange inconsistencies." His thought-provoking paper reminds us of the past, reviews the present, and brings into sharp focus the responsibilities of the future.

A Study of *Winter Water Temperatures and Ice Prevention by Air Bubbling,* by **G. P. Williams,** M.E.I.C., presents water temperature data and the essential technical information that is available on air bubbling systems. Typical water temperature profiles under ice covers are given. Design considerations for air bubbling systems include a summary of design values which have been used at specific locations. The paper also reviews several experimental investigations on air bubbling techniques, both in the laboratory and under field conditions. Mr. Williams graduated in 1949 with a B.A.Sc. from University of British Columbia, and obtained an M.Sc. degree from Utah State University in 1951. He worked with P.F.R.A., Department of Agriculture, as field engineer on irrigations and drainage problems in British Columbia until 1952 when he joined the Aluminum Company of Canada as hydrology engineer at Arvida, Que. Three years later he joined the Division of Building Research of the National Research Council as a research officer with the Snow and Ice Section. During the past five years Mr. Williams has been involved in research projects involving the energy exchange from natural surfaces.

Beaver Bill appears this month on page 114, **Stan Cassidy** has a membership reminder on page 162.

Technical Control of Ready Mixed Concrete

About $5000 would cover the cost to a small operator of equipment required to take daily samples of ready-mix concrete he supplies. This paper is intended to present information from the point of view of the supplier, as well as the user, of ready-mix concrete.

M. F. Macnaughton, M.E.I.C.
Vice-President, Technical Control,
Mount Royal Paving & Supplies Limited, Montreal.

QUALITY CONTROL of concrete is a broad subject. To devote the space available to best advantage much detail pertaining to many of the essential requirements for the production of controlled concrete will be omitted. Cement and aggregates must conform to certain specific requirements as to physical and chemical quality, must be reasonably uniform as regards grading, and the equipment used in proportioning, mixing, and delivering the concrete must be accurate and efficient. Most of this will be ignored in this presentation.

In Montreal about 95% of all concrete used is premixed or transit mixed. Accordingly, this paper is intended to present information from the point of view of the supplier, as well as the user, of premixed or transit mixed concrete. At the same time much of the information developed is equally applicable to concrete mixed on the job.

Basic Test Facilities

In any ready mix operation it is desirable that the supplier be in a position to carry out systematic tests on concrete supplied. How extensive this schedule of testing should be depends on the size of the operation, the control over uniformity and quality of materials used, and whether the services of capable commercial test laboratories are available in the area.

The ready mix supplier may feel that he can dispense with this cost and rely on tests carried out by his customers to keep him advised of the quality of his concrete. Our experience has been that this is not the case. Quite frequently we have found that our own test results were in serious conflict with those of commercial testing laboratories. In dealing with such cases we have found our own laboratory testing to be of great worth. In a large number of cases the customer has accepted our results. In many other cases tests on cores taken from the structure indicated that the concrete was in accordance with the specified requirements, regardless of the adverse results reported by the commercial laboratory. In two cases, where the argument went to arbitration, the decision was in our favour and in no case did the complaint go to litigation.

Even the smallest ready mix company should be in a position to take daily samples of their product to check on performance. The equipment required for this is quite simple, and, for a small operator, costs about $5,000.

For a major supplier, something more is necessary. His technical control department should be in a position not only to test concrete, but to proportion mixtures to meet specification requirements with maximum efficiency and economy.

The text books, the hand compendiums, and the technical journals are full of presentations of methods of proportioning concrete. In this connection the term "method of proportioning" is preferable to the word "design".

Basic Principles

In the early days each author laid down hard and fast rules—the original Lewis Institute water/cement ratio theory[1] was an outstanding example of this school of thought—as to how concrete mixtures should be proportioned for specific results.

In addition to the water/cement ratio theory there were many other methods of proportioning suggested. A few of these were:

(1) Maximum density method of Fuller & Thompson[2]

(2) Fineness modulus method of the Lewis Institute[1]

(3) Surface area method of Edwards & Young[3]

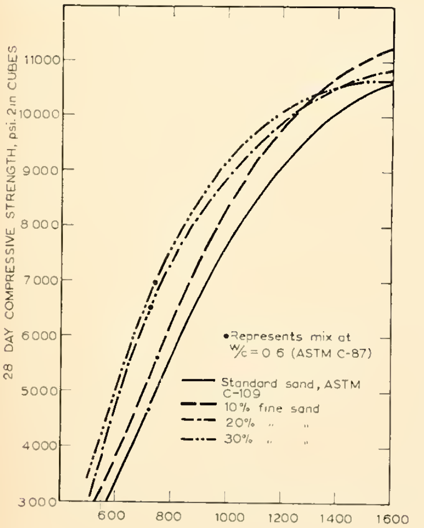
(4) Cement-space method of Talbot & Richart[4]

Other methods, as well as many variations of those mentioned, have been suggested.

In all cases the proponents of the various methods eventually retracted a large part of their pragmatic claims, and retreated behind a defence hedge with the suggestion that, prior to making any final decision as to the validity of the method presented for consideration, proof of the method would be desirable by actually making up trial mixtures with varying cement content, using the specific cement and the specific aggregates actually to be employed in the work, and subjecting test cylinders of the trial mixes to 28-day compressive strength tests before any concrete was delivered to the job.

Under these circumstances it seems useless to take you on a long review of the many methods of proportioning of concrete mixtures which have been suggested in the last 50 years. For a consideration of the situation as it was 27 years ago the reader is referred to an article published in the E.I.C. Journal for August, 1933, on "The Structure of Concrete Mixtures".[5] If you read this paper, please remember that, at that time, nothing was known about air entrainment in concrete mixtures, and very little about retarders. With these exceptions, the conclusions arrived at in this paper are still valid, and this method of determining optimum mixture proportions is again recommended.

Fig. 1—Results of compressive strength tests from cubes made with mortar of normal consistency.



Preliminary Studies

Prior to embarking on any considerable effort in the preparation of trial mixtures it is desirable to have some knowledge of the general problem, and a study of the literature on the subject will prove extremely beneficial.

In any such study the question of optimum grading is a matter of prime importance. While attainment of maximum density, per se, is not always beneficial in the overall problem of concrete mixture proportioning, as will be shown later, it exercises a considerable effect on the economical aspects of concrete proportioning in general. Therefore, prior to any attempt at proportioning concrete mixtures the grading of aggregates available for the work should be examined, to see if any improvement in this respect can be obtained.

Curiously, the classic work on grading of aggregates was carried out by a mining engineer, C. C. Furnas,[6] employed by the U.S. Bureau of Mines in Denver, Colorado. His problem was to develop gradings for rock mixtures used in backfilling mine stopes so as to minimize future shrinkage and settlement. His method of analysis was purely mathematical. It is interesting to note, that, while his analysis is mathematical, he had to determine, in advance, by trial, the density value of each individual aggregate size contained within the range of sizes.

It is interesting to note also, that, in this analysis, he had no particular interest in concrete mixtures, as such. However, a concrete technician, F. O. Anderegg,[7] adopted the grading methods outlined by Furnas, and adapted them to proportioning of concrete mixtures, with necessary adjustments because of the fact that the cement content was an added component, occupying space in the mixture as a binding material.

Shortly after this, C. A. G. Weymouth, working in California, published a report[8] covering optimum gradings for aggregates in concrete mixtures. He also submitted a mathematical formula for the optimum grading of aggregates for concrete. He also, like Furnas, had to rely for his basic constants, on results of tests for packing properties on individual sized aggregate fractions.

Furnas used calculus as a mathematical method in his analysis; Weymouth used analytical geometry in his approach. Both of them arrived at the same answer: that for proportioning of mixtures for maximum density the factor r, representing the quantity of each successively larger screen size, compared with the next smaller screen size, where the relation between screen sizes is 2.0 to 1.0, should be between 1.10 and 1.25, depending on the aggregate particle shape and packing properties.

Weymouth lays particular stress on avoiding "particle interference" in aggregate grading. His theory is that no particle size should be present in the mix in such proportion as to interfere with the free circulation of these particles in the matrix composed of all the constituents smaller than that size. If particle interference occurs the excessive amount of any single size interferes with the mobility of the mix, and with normal consolidation as the mixture sets and shrinks in volume.

Since the original work of Furnas and Weymouth the majority of searchers in the field of grading have accepted their conclusions, whether related to material for backfilling of mine stopes, fill for consolidation, Portland cement and bituminous concrete mixtures, as well as in many other fields.

Practical Application of Grading Studies

To the average producer of ready mixed concrete the grading of the coarse aggregate portions presents no great problem. The coarse aggregate, ranging in size from ¼ in. up, is delivered to the plant in shipments separate as to size, stored in separate bins, and weighed out in the required amounts.

The sand portion, usually ranging from ⅜ in. in size to -100 mesh, presents a greater problem. Here grading is perhaps even more important than in the coarse aggregate portion of the aggregate, and alteration of that basic grading presents more difficulties.

Theoretically, as cement content is increased from a minimum of, perhaps, 300 lb. per cu. yd. to a maximum of 900 lb. per cu. yd., very considerable changes should be made in the grading of the sand fraction to produce maximum economy in cement requirement.

For very lean mixtures, with low cement content, a high proportion of -100 mesh sand is desirable, in order to occupy space in the mixture, act as a void filler, and reduce the amount of mixing water required to induce plasticity. As the cement content is increased, with additional cement replacing water in the void spaces, the necessity for the presence of a part of the finest sand particles in the mix disappears, and they should be progressively eliminated as the cement increases in quantity. Finally, with very rich mixes, due to the void filling properties of the large amount of cement, only a small percentage of sand particles, below 50 mesh in size are required at all.

This means, of course, that, for optimum strength, for variable cement content, the supplier should be prepared to change the sand grading, as required, for the type of concrete to be produced. This is often done on large mass concrete projects, where a single, or a dual, class of concrete is desired, and where the grading of the sand fraction can be adjusted to that most suitable for the mix required.

For the average ready mix concrete operator such finesse is impossible. Unless he is prepared to install three bins in the plant to supply fine, medium and coarse sand in varying quantities, his only recourse is to arrange for a supply of sand of uniform median grading which will represent the optimum grading for mixtures between 2500 and 4000 p.s.i. in strength at 28 days. Mixtures leaner than 2500 p.s.i. in strength will tend to be harsh and unworkable. For these mixes air entrainment will assist greatly in remedying the effects of the too harsh sand. For mixes above 4000 p.s.i. in strength the use of dispersing agents will, to some extent, offset the disadvantageous sand grading, and increase the strength by 500 to 1000 p.s.i.

A limited amount of testing on mortar mixes, prior to general actual development of proportions for the concrete mixtures, can often afford useful information regarding the optimum grading of the sand fraction. As an illustration, in our Ottawa operations we use, as aggregate, sand and gravel from a deposit at Shawville, Que. The sand in this deposit, with an average F.M. of 3.10 for the fraction passing the 4 mesh sieve, is too coarse for optimum results in normal concrete mixtures, so it is blended with a proportion of fine sand, with a F.M. of about 1.60, obtained locally in the Ottawa area.

Since our Ottawa plants are equipped with only a single bin for batching fine aggregate, these two sands are pre-blended prior to depositing the mixture in the plant bin.

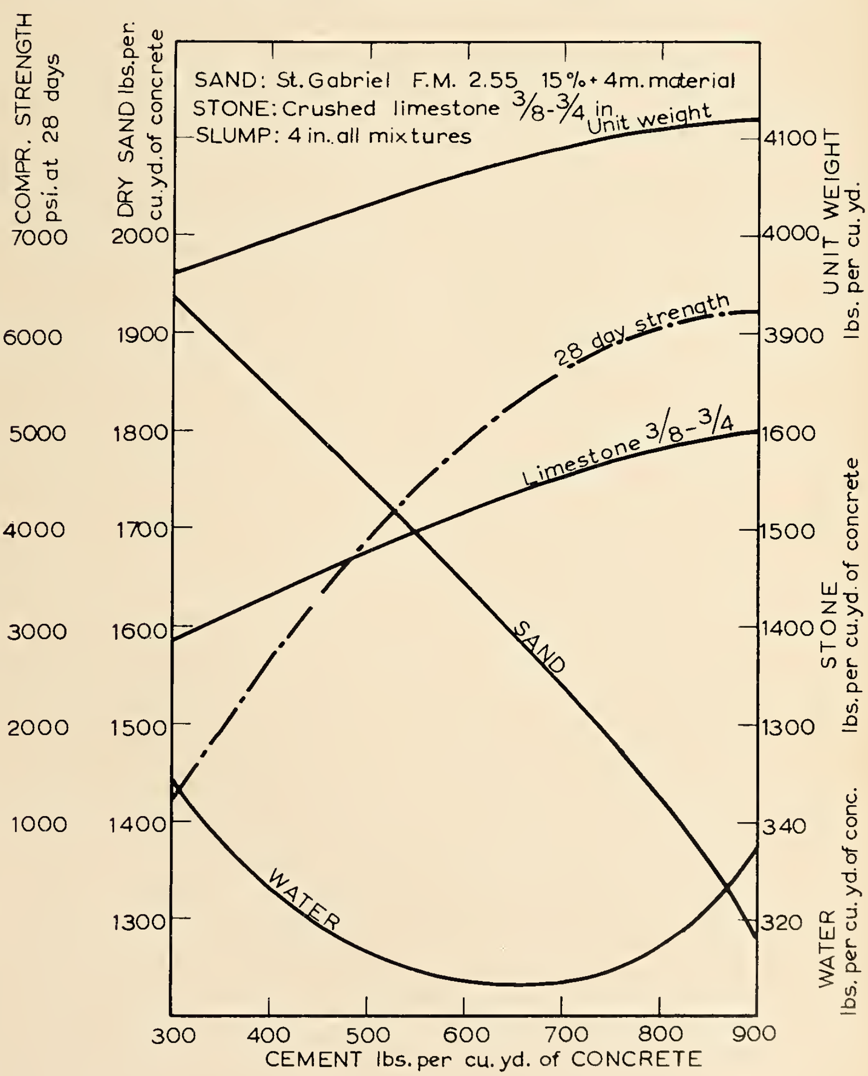
Fig. 1 shows the results of compressive strength tests obtained from 2 in. cubes at 28 days, on mortar mixtures of normal consistency, made in accordance with the method of A.S.T.M. Specification C87-58T, with a cement which is widely used in Ottawa. The specification calls for preparation and compressive strength tests of 2 in. cubes made from mixtures with a flow of 100±5 and a w/c ratio of 0.60. A comparison such as this leaves much to be desired, from the point of view of the concrete producer. The water requirements of different sands to produce a flow of 100±5 may be quite different, and the results obtained are not directly comparable, since the cement requirement, in pounds per cubic yard, is not taken into consideration. Cement is the most expensive ingredient in mortar or concrete, and the matter of cement cost per cubic yard is of vital importance to any concrete producer.

To obtain a broader view of the behaviour of different sands we make up four series of mortar mixes in the proportions 1:5, 1:3, 1:2 and 1:1.25 by weight, all with a flow of 100±5. The cement contents vary from about 480 to about 1450 lb. per cu. yd. The w/c ratios range from approximately 0.90 to approximately 0.30.

The information shown in Fig. 1 was derived from tests on such mixtures. The individual points designated on the curves indicate the results which would be obtained from mixtures with w/c ratios of 0.60.

The test results show quite clearly

Fig. 2—Typical graph covering proportions obtained from trial mixtures.



that the optimum percentage of the fine sand, over the greater range of normal mixtures, is about 20% to 30%. Accordingly, in our Ottawa plants, we are presently blending these sands in the proportion of 75% coarse and 25% fine.

Laboratory Trial Mixes

Once the problems relating to aggregate grading have been settled, the procedure then is to make up a series of trial mixes with the aggregates selected, and with cement factors of 300 to 900 lbs. per cu. yd. The exact proportions of fine and coarse aggregate are determined, on an empirical basis, by visual examination of the mixture.

A recommended method is to hold out, in the initial weighing, for the first mix, about 10% of each aggregate size, and make the final adjustment of aggregate quantities after visual inspection of the initial result. With an inexperienced operator this may mean undue delay and, perhaps, overmixing. The remedy, of course, is to discard this batch and make another under more uniform procedure.

The unit weight of the fresh concrete for each batch is determined, the slump and air content measured, and test cylinders cast from the batch. It is desirable to have at least six cylinders cast from each batch, three to be tested at 1, 3 and 7 days, two at 28 days, and one at 90 days.

The actual mix proportions, in pounds per cubic yard, are determined from the sum of the weights of the batch constituents, using the unit weight of the fresh concrete to determine yield.

Application of Basic Trial Mix Results

All of the information obtained from the trial mixes can be shown graphically, and Fig. 2 covers results of a series of trial mixes using a specific cement, coarse aggregate consisting of ¾-⅜ in. crushed limestone, and natural sand graded from ⅜ in. to -100 msh. All mixtures are made up with a slump of 4 in. It should be remembered that these are the quantities developed for the trial mixes. These should be increased by 1% because of some extra consolidation effect in truck mixer operation, as compared to laboratory trial mix tests, and by an additional 1% to compensate for shrinkage effects. For both weight adjustments, the required additional weight should be added to the aggregate weight only, without change in the cement or water proportion of the trial mixes.

The 28-day strength test results are plotted on the graph together with all of the rest of the information. With this it is a simple matter to develop mix proportions for concrete mixtures in this class for any specified strength.

Similar trial mix series can be made up for maximum aggregate sizes other than ¾ in. Our own schedule of standard mixes covers maximum nominal coarse aggregate sizes of ¼, ½, ¾, 1, and 1½ inches, as well as grouts, with no coarse aggregate at all.

We do not deliver concrete with aggregate coarser than 1½ in. nominal size, since handling aggregate larger than this presents some problems in operation, particularly in unloading the concrete from the trucks, and since, in normal ready mix operations, there is seldom any call for concrete with aggregate size larger than 1½ in.

Each test series represents a minimum of five samples of 6 cylinders each, or 30 test cylinders per series. With six aggregate sizes this represents 180 test cylinders. Extend this to several types of concrete, including plain, air-entrained, concrete with one or more types of dispersant material, concrete with retarders or accelerators, and the number of test cylinders required for even a preliminary look at the mix proportions will be between 1000 and 2000, for a single cement.

A.S.T.M. and A.C.I. both recommend proportioning for 15% above specified strength. We have decided, from our experience with variation in cement strength in the Montreal area, that this is not an adequate factor of safety, and we proportion for 20% above specified strength.

Since the strength-making property of the cement is probably the major source of variation in any well controlled ready mix operation, it is desirable to have fairly complete information about the properties of the cement used in making up the trial mixes.

For proper evaluation of the quality of the cement used in the trial mixes tests for mortar-making properties of the cement used should be carried out at the same time as the trial mixes are made. Then when the 28-day test results of the trial mixes become available the 28-day test results of the standard mortar mixes are also available for evaluation of the cement quality.

This, of course, does not help very much for the first series since there is no background of information about cement quality. However, after three or four sets of trial mixes the background will be available, and the operator will then know what factor of safety should be applied to this particular series of trial mixes in order to ensure that the required average safety factor will prevail.

Even from the same mill there will be fairly wide variations in the strength characteristics of the cement, and differences in the behaviour of cement from different sources may be even greater.

Fig. 3 gives an illustration of the variation of strength making properties of Type I Portland cement from the same mill, as well as results obtained from a different source. Here again, as in Fig. 1, test results obtained from a single mix of 1 part cement to 2.75 parts by weight of standard Ottawa sand, do not adequately disclose the behaviour of the cement over a wide range of mixtures. One might conclude, from the results of tests carried out on mixtures of 1 part cement to 2.75 parts of standard sand, that both cements from mill B were substantially the same. However, the results obtained from the two cements in rich, high strength mixtures are quite different.

Fig. 4 illustrates the variation in strength obtained from two series of trial mixtures, using similar aggregates together with cement delivered at different times from the same source. The two curves shown represent the highest and lowest strengths obtained from similar concrete trial mixes, using cement delivered from this source during the past three years. Between these curves could be shown 16 other curves occupying median positions which represent more closely the quality of the average cement delivered from this source.

Control of Concrete at Delivery Point

Having carried out the preliminary investigation it remains to see that the concrete delivered to the work meets the requirements. We check this by two methods:

(a) We have samplers who visit jobs to which we are delivering concrete. These men take periodic samples of concrete delivered to the work. These samples are taken to the nearest plant supplying concrete, where the test cylinders are cast, and later the cylinders are taken to the central control laboratory for storage and test.

(b) On work carried out by our own companies as prime contractors, and on some major projects carried out by other clients to whom we are delivering concrete, we have our own field inspectors on the job. These men run constant slump, weight and air content determinations on concrete supplied to the work, keep dispatch office and the central control laboratory advised of their findings, and also make adjustments to the concrete as required.

Limitation of Mixing Time

One of the greatest problems in the supply of ready mixed concrete, and particularly in the supply of pre-mixed concrete, is the matter of mixing time. All our Montreal plants are pre-mix plants, and we are more interested in the performance of this type of ready mixed concrete than in the so-called dry batch type, where the dry, or semi-dry, aggregate is loaded into the truck with the dry cement, and the truck is dispatched to the job, the driver adding water to the load either in transit or on arrival at the job site.

With a pre-mix plant more accurate control over slump is possible. The batcher can see the quality of the concrete that he produces; if it is slightly too wet or too dry he can adjust the next batch to correct the error and can orient himself for future batches. In a dry batch plant the operator does not have this advantage. He never sees the concrete that he is batching, and he might ship 10 loads to a job, either too wet or too dry, before any word got back from the job as to what the consistency was on arrival.

With all of our plants in Montreal pre-mix plants, we are interested only in pre-mixed concrete. Here the component parts of the mixture are weighed out, delivered to the pre-mixer, and finally, the mixed concrete is delivered to the truck. This concrete is completely mixed, except that it may have only about 90% of its potential air entrainment, if it is an air entrained concrete.

This concrete goes into the truck, and the truck proceeds to the job with the mixer revolving at agitation speed, or about 4 r.p.m. If the delivery interval between the plant and the job is 15-25 minutes the air content, on arrival, will be about the maximum.

On arrival at the site, if the job is not ready to take delivery of the concrete, the truck mixer is stopped, and the concrete in the truck allowed to remain quiescent. Every 30 minutes the truck mixer is turned over for 10-12 revolutions at full speed to overcome any mechanical segregation which may have occurred. No more mixing than this is required, or desirable.

It is obvious that, if mixing is 90% complete on discharge from the pre-mixer, any extended further mixing, even at agitation speed, might prove to be detrimental. In effect, with extended mixing time, the mixer operates as a grinding mill, degrading the aggregate particles, and producing more fines. Part of the energy input required to do this is translated into heat. This speeds up the chemical reaction and results in more rapid setting of the concrete. If air entrainment is specified, the increased production of fines, particularly if the aggregate materials are calcareous, results in a very rapid decrease in the air retention capacity of the mixture. Three effects are:

(1) Production of additional fine material;

(2) Development of additional heat;

(3) Elimination of air content.

These operate to make the mix drier and reduce the workability. It is obviously desirable to limit mixing time in the truck.

Even when delay in unloading has resulted in excessive loss of air means can be taken to correct this. All our trucks carry additional double strength A.E.A. in 5 oz. baby food cans. If part of the air content of the load has been lost the situation can be remedied by adding one or more cans of the A.E.A. and remixing the load. The drivers may not do this on their own initiative, but only on instructions from:

(a) One of our service inspectors;

(b) A representative of technical control;

(c) Central dispatch office, by radio.

Similarly, our drivers may add water only on direct instructions from some responsible person, either on our own staff, or on the staff of the customer. In all cases the person authorizing the addition of water has to sign the load ticket for the added water. In cases where the addition of water is requested verbally, and signature on the ticket is later refused, the driver has to state on the back of the ticket the circumstances relating to the case.

Temperature Rise

From past experience, winter or summer, we surmise that when concrete begins to set a significant increase in temperature is recorded. What this significant increase in temperature is we are not prepared to state, unequivocally, but, from some observations made it would seem that when a temperature increase of 6° to 8° F. is recorded in the concrete setting action is well in progress.

Consequently, when the temperature of the concrete in the truck has risen by this amount, the ultimate quality of that concrete is suspect unless it can be placed in position in the form within a few minutes. Depending upon individual conditions, a wide variation in behaviour of the concrete might result.

We periodically take samples of returned concrete which is to be dumped in order to have an adequate background of information about the behaviour of such concrete.

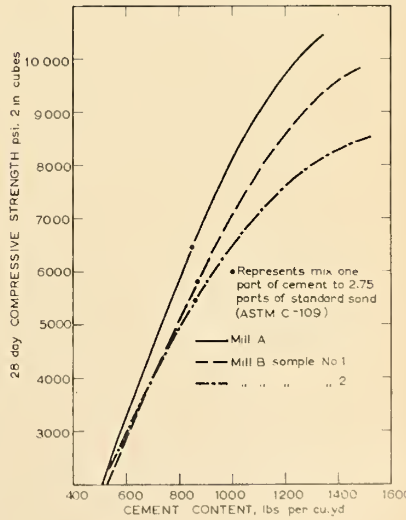
A very significant difference is noted between the behaviour of concrete in winter and in summer, as a result of basic differences in temperature conditions. In cold winter weather, with concrete leaving the plant at 60° to 70° F. we have had cases where the concrete was in the truck for up to five hours, with no significant temperature rise, only a slight decrease in slump, and no measurable loss in strength.

Use of Retarders

In winter in Montreal no problems are afforded by premature setting of our concrete. It is possible, by judicious control of aggregate temperature, to keep the temperature of the concrete loaded into the trucks between 60° and 70° F. No serious problems arise in connection with supply of concrete in winter except in relation to the customer who thinks that, because he specifies 2% calcium chloride in his concrete he can conveniently forget about heating and protecting his concrete in place in the form. This type of customer is becoming less numerous.

The situation is quite different in

Fig. 3—Compressive strength test results obtained from mortar mixtures (Flow 100±5) with different cements.



summer. Summer temperatures in Montreal reach a 90° to 100° F. maximum. With aggregates having an average temperature of 70° F., water at 65° F., and cement at 170° F., the temperature of a mix with a cement content of six Canadian bags per cu. yd., on discharge from the pre-mixer, will be 78.5° F. With eight bags per cu. yd. the temperature will be 81.5° F.

If the cement temperature is in the neighbourhood of 250° F., as was once the case, the temperature of the 6-bag mix, on delivery from the pre-mixer, will be 86° F., and the temperature of the 8-bag mix 92° F. With temperature conditions such as these the concrete sets while you look at it.

During the period of the "hot cement" frequent protests were made to the cement supplier, but to no avail. Precooling of aggregate materials and/or the use of ice in place of water was impractical, from both the mechanical and economic aspects. The only solution seemed to be in the use of a chemical retarder which would delay the setting action long enough to get the concrete to the job, unloaded, and placed in the forms.

During the winter of 1956-57 materials of this type, from a number of sources, were investigated. The majority of these were calcium lignosulphonates; by-products obtained in the manufacture of newspulp by the sulphite process. These materials varied very widely in their effect on concrete mixtures, but we were fortunate in finding several that reacted favourably with the cement and aggregates which we were using, and which we could use to control the rate of setting of our concrete. We have been using one of these for the past three years with very satisfactory results.

In addition to the tests with the lignosulphonates some tests were carried out with retarding agents of the hydroxylated carboxylic acid type. These also were satisfactory in their action, and, for some purposes, are probably better than lignosulphonates.

Overall Effect of Retarders

Before the trial tests had proceeded very far it became apparent that materials of both types produced results in concrete far beyond the immediate retardation effects which we were seeking. In addition to being retarders these materials were dispersants, reducing materially the amount of water required to induce plasticity. The lignosulphonates, in addition, possessed some air-entraining properties, in varying degree. The materials of the hydroxylated carboxylic acid type possessed no air entraining characteristics at all. In fact, they tended to act as densifiers. Whether the air-entraining retarders or the non air-entraining retarders are preferable depends, to a considerable degree, on the strength required for the concrete, as will be shown later.

The net result of all this was that in both cases, for equal cement content, the strengths of the mixtures in which the retarders were used were materially increased. Part of this increase in strength is derived, undoubtedly, from the decrease in water requirements; part of it is related, probably, in the leaner mixes at least, to the air-entraining properties of the admixtures; and part stems from the retardation effect itself.

It has long been known that the setting temperature of concrete greatly affects the ultimate strength. Prior tests have indicated that if the setting temperature is the normal 70° F., and the 28-day strength under these conditions is taken at 100%, concrete which is maintained at 40° F. for the first 24 hours after mixing may reach a strength of 120%, while concrete kept at 100° F. for the first 24 hours after mixing may reach only 80% of the normal strength. Chemical retarders apparently behave in similar manner, so that some part of the strength gain which is derived from the use of such additives is related directly to the retardation effect.

It is obvious that maximum benefit is derived from such admixtures in hot weather: in cold weather additional retardation, other than that afforded by the prevailing low temperatures, is likely to be undesirable. Even in warm weather, for special projects such as sliding form work, retardation may be undesirable.

Many commercial dispersants now on the market have integrated with them an accelerator to offset part, if not all, of the retardation effect. Where the accelerator is present in sufficient amount to completely offset the retardation effect, the benefits of retardation are lost, though the strength gain resulting from the dispersion and air-entraining effects may be retained.

Fig. 5 shows strength relationships for a number of series of trial mixes covering plain concrete, concrete with a retarder, concrete with a widely used air-entraining agent, and concrete in which both the retarder and the air-entraining agent were used. The wide differences exhibited by these mixtures, in relation to compressive strengths attained, will be referred to later.

Effect of Retarder on Retention Time

A comparison of the behaviour of similar mixtures, with and without a retarder, carried out in truck mixtures under normal summer conditions in Montreal, is shown in Fig. 6. Both mixtures contained, at the start of the tests, six Canadian bags (525 lb.) of Type I Portland cement per cu. yd., both were discharged from the pre-mixer to the truck with a slump of 4 in., both were subjected to similar temperature conditions and equal degree of additional mixing subsequent to their deposition in the trucks. The procedure, broadly, was as follows:

(1) After loading, the hatch was closed, and the mixer rotated at agitation speed for 25 minutes, to simulate the mixing operation in transit. Thirty minutes after the original mixing in the premixer a sample was drawn off, the slump, unit weight and air content of the concrete determined, and four cylinders were cast for determination of compressive strength.

(2) After the first sample was obtained the hatch was closed, and the mixer allowed to stand. After 40 minutes the load was remixed at agitation speed for one minute; the hatch was opened, and an estimate made of the slump of the concrete and the amount of water required to restore the concrete to the original slump. The estimated amount of water was then added, the load remixed, at full mixing speed for 12 revolutions in each direction, and another sample taken, 75 minutes after the original mixing.

(3) This procedure was repeated at two hours, and repeated at intervals of one hour thereafter until the completion of the test run seven hours after the original batching.

Fig. 6 shows the alteration in some of the characteristics of the concrete as a result of this treatment. The compressive strength is reduced with increase of retention time, and with the addition of water to maintain the original slump. The unit weight is decreased with increase of water. The temperature of the concrete rises with time, and, towards the end of the test, quite rapidly, indicating that setting action is well in progress.

Some of the results obtained appear to be inconsistent with the normal expected behaviour of concrete. This applies particularly to the results derived from the strengths obtained as compared to the original w/c ratios. After examining these

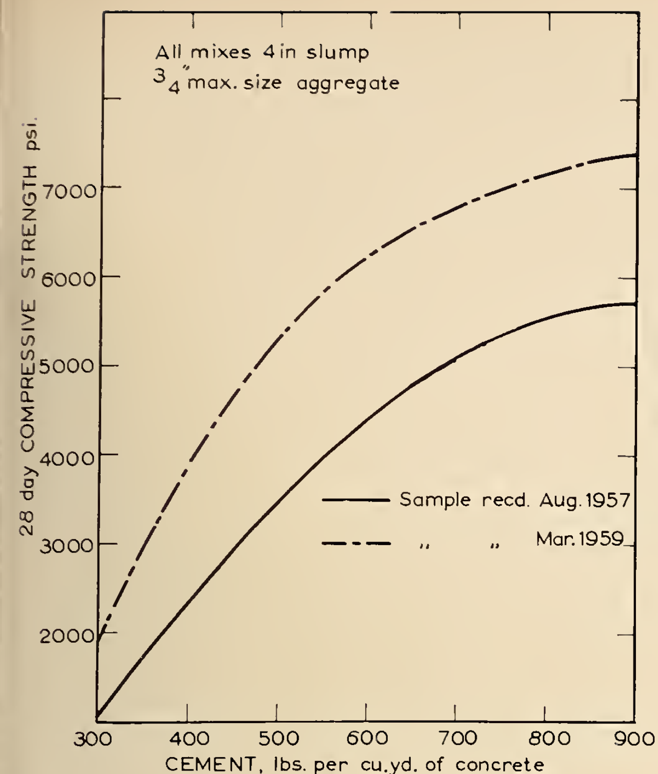


Fig. 4—Results from two typical series of trial mixes made with different samples of cement from the same mill.

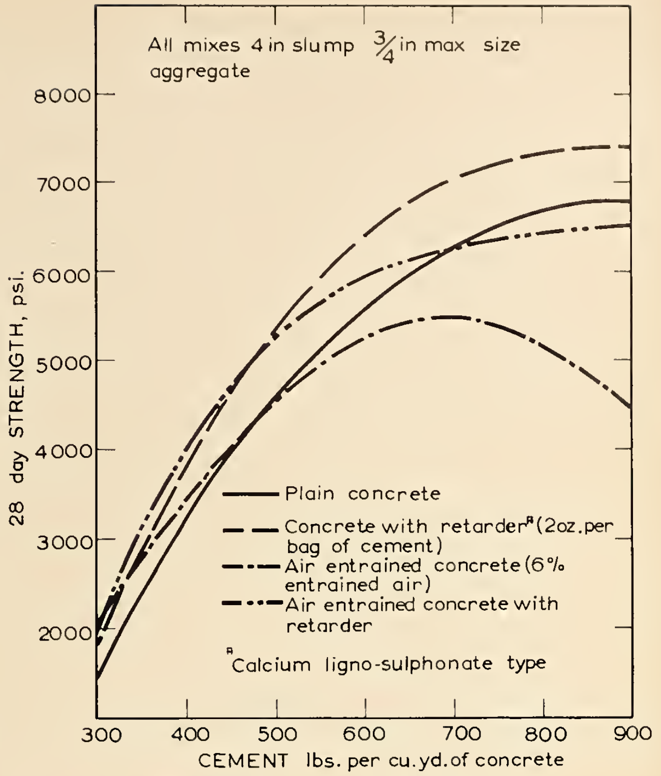

Fig. 5—Compressive strengths at 28 days obtained from trial mixes containing various admixtures.

closely it appeared that the true w/c ratio might be that existing in the concrete at the time it changed from a plastic mass to a solid.

Prior experience with the vacuum method of processing concrete,[9] where a large proportion of the original mixing water is removed by suction before the concrete sets, indicated that the true w/c ratio, affecting the compressive strength, was probably that represented by the relationship of water to cement in the mix after the excess water was removed.

Accordingly, density tests were carried out on samples of the concrete which had been moist cured in the damp room for seven days. In all cases the 7-day unit weights were appreciably higher than the wet weights for the corresponding mixtures. This would occur as a result of loss of water by bleeding, and subsequent shrinkage. From the unit weight determinations it was possible to calculate the apparent w/c ratio at the time of setting. Results of these calculations are shown in Fig. 7.

The surprising feature of this is the large difference between the w/c ratio of the wet concrete compared with the apparent w/c ratio of the same concrete at the time of setting. No explanation is readily apparent for the fact that, in both cases, the two pairs of curves cross. Some further exploration along these lines would seem to be desirable.

Revibration of Concrete

An interesting feature in the handling of concrete, which has recently returned to prominence, is the matter of revibration of the concrete some time after placing. In its present application it is closely associated with retardation.

A good illustration of this relationship is afforded by the practice followed in concreting some of the spandrel beams and deck spans of the Tappan-Zee Bridge on the New York Throughway, where a retarder of the hydroxylated carboxylic acid type was used to delay the set of the concrete in place until all of the concrete in the section in question had been placed, and settlement of the form, as a result of compression in the shoring, was complete. Then, while the concrete was still plastic it was revibrated to eliminate incipient internal strains and to minimize possibility of tension cracks. The method is described in an article,[10] "Setting Time of Concrete Controlled by the Use of Admixtures", by Raymond J. Schutz, in the Journal of the A.C.I., Vol. 55, January, 1959.

Nearer to home was the use of a lignosulphonate retarder for the concrete in the beams and slab of the reinforced concrete bridge supporting the steel cantilevers for the roof of the new T.C.A. hangar at Dorval Airport. Even though the work was done in winter time a retarder was used to delay the set for from six to seven hours until the first lift of concrete to the neutral axis of the beams was completed: a matter of about 350 cu. yd. This was revibrated with the concrete of the second lift, to the tops of the webs of the beams. At this stage there was a delay to permit as much settlement as possible to occur, and the concrete in the upper part of the webs was revibrated prior to placing the concrete for the roof slab. The work was successfully completed without development of shrinkage cracks.

Perhaps even more interesting was the information obtained from tests on samples of concrete representing the mix delivered for the construction of the base slab for a new test machine for Ecole Polytechnique in Montreal in September, 1958.

Here a high strength concrete was required. The slab was 59 x 20 x 4.5 ft. in dimension and required about 190 cu. yd. of concrete. Embedded in the concrete was a miscellany of steel anchorages for the holding down bolts. In addition, high tensile strength wire strands were carried in ducts for post compression of the slab in both horizontal directions, so as to develop maximum rigidity. Clearance between the various members embedded in the concrete was minimal, and it was decided to use a mix with a maximum aggregate size of ½ in., and a slump of 5 in., to facilitate placing of the concrete. A retarder of the hydroxylated carboxylic acid type was used to delay the set of the concrete in place for 10 to 12 hours, and the concrete in place was revibrated prior to setting. For very high strength concrete this type of retarder is preferable to the lignosulphonate type, since it entrains no air, and facilitates extrusion of surplus water while the concrete remains plastic.

The results were quite satisfactory. Compression tests on standard 6 x 12 in. cylinders, which were not vibrated, indicated an average strength at 28 days of 8300 p.s.i., and a strength at 18 months of 11,200 p.s.i.

Mr. B. A. Hesketh, in charge of the physical test laboratory at Ecole Polytechnique, carried out a fatigue test on a cylinder of this concrete at an age of 20 months. Details of the test were as follows:

Loading Range	*No. of Cycles*
1200-4500 psi	10,000,000
2200-5500 psi	10,000,000
3200-6500 psi	1,000,000
4200-7500 psi	40,000

After 40,000 cycles of test at 4200-7500 p.s.i. the test cylinder failed, exhibiting a normal double cone fracture.

The procedure followed in the three instances recorded will probably be used much more generally in the future.

Effect of Aggregate Size

Some of the questions that have developed as a result of observations of the behaviour of mixtures in which retarders have been used are rather puzzling. Some of the strength increases developed from the use of retarders are quite surprising. Some observers feel that these strength increases are brought about by the formation of a stronger gel as a result of the slowing down of the chemical reaction. Such a situation does develop in the case of the setting of some of the thermo-plastic resins, but the extension of this to the field of Portland cement chemistry is, possibly, a bit of wishful thinking.

Fortunately, some information developed from an investigation of an entirely different phase of concrete behaviour suggests a logical answer to this problem.

The classic water-cement ratio theory offered the premise that the strength of concrete is governed by the volume relationship of water and cement in the mix. Subsequent investigations have narrowed the application of this theory very materially, and it would seem that other investigations now in progress will narrow it still more.

For example, it has generally been accepted, as a corollary to the w/c ratio theory, that with increasing maximum aggregate size, for equal cement content and equal plasticity, the water requirement would be lower, and the compressive strength correspondingly higher.

Investigations carried out by Stanton Walker, Delmar Bloem and their associates in the National Ready Mixed Concrete Association,[11,12,13] and by our own Technical Control Laboratory in Montreal,[14] indicate that this is not the case, particularly in connection with high strength mixtures.

Fig. 8 shows compressive strength test results on three series of trial mixes using cement and aggregates from the same sources, but with varying maximum size of aggregate particles. The curves indicate that the theory of increasing strength with decreasing w/c ratio does not always hold good when aggregates of different maximum size are under consideration.

For a more direct comparison the data from which Fig. 8 was derived has been plotted in Fig. 9 to show the w/c ratio-strength curves for the three series of trial mixes in question. These show quite clearly that, for equal w/c ratio, the mixes with the smallest size aggregate, at least in the high strength range, are the strongest.

This was very puzzling, but a possible explanation was that the deleterious effects of water gain might be more pronounced with increasing

Fig. 6—Changes in properties of concrete resulting from long time retention in truck mixers

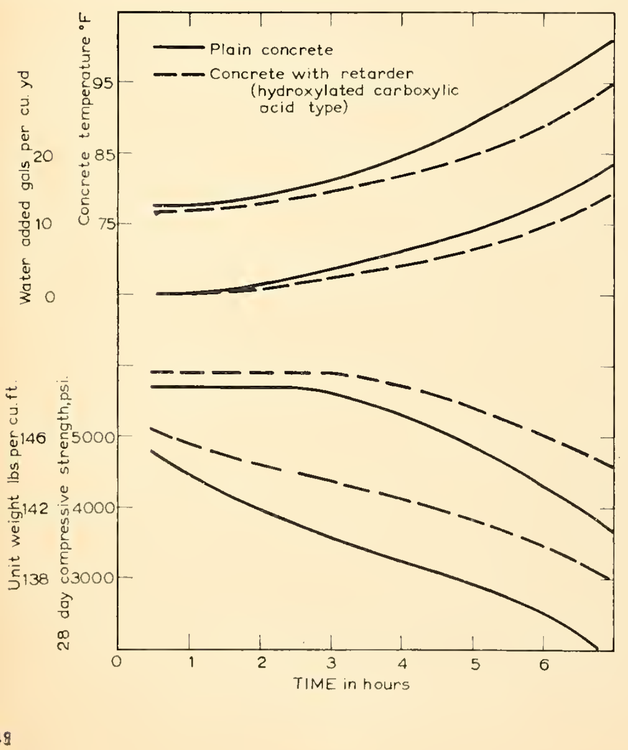

Fig. 7—W/C—Compressive strength relationship for mixtures shown in Fig. 6.

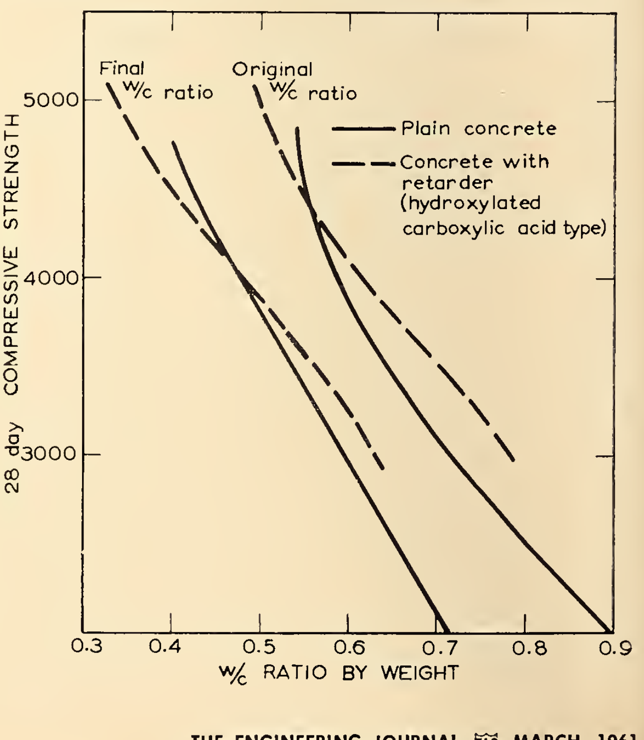

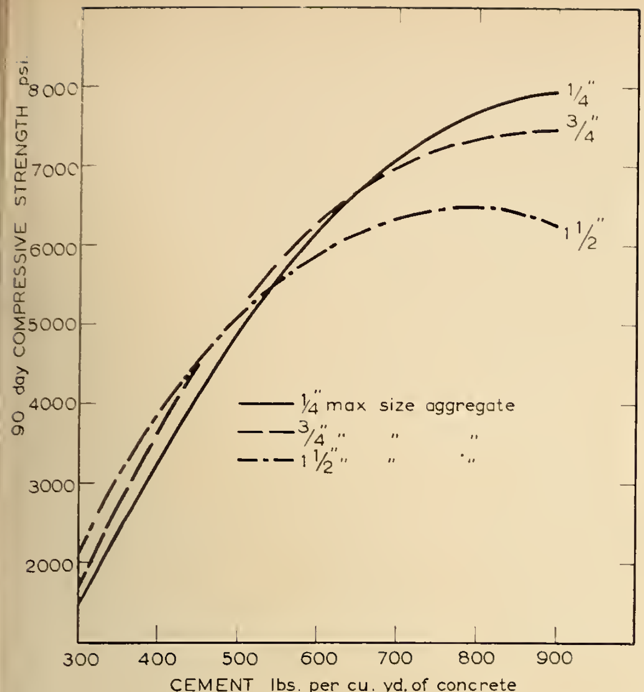

Fig. 8—Compressive strengths at 90 days from three series of trial mixtures with varying maximum size of aggregate.

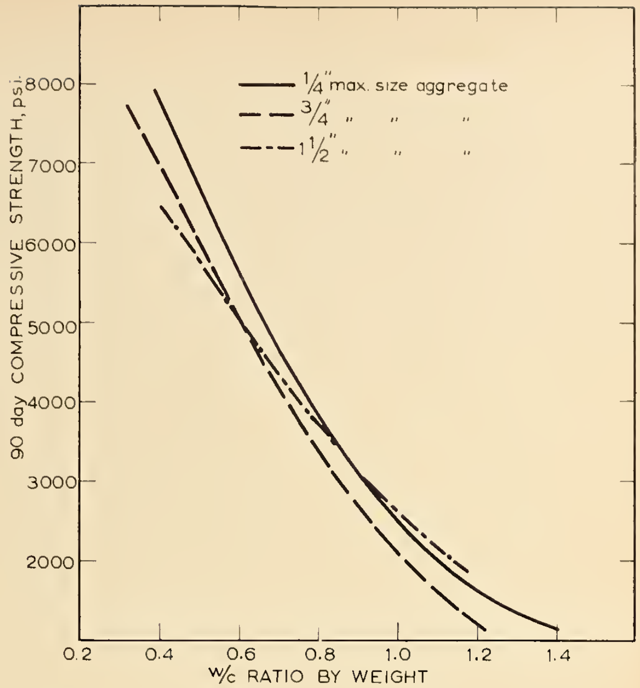

Fig. 9—W/C—90 day strength relationships for mixtures in Fig. 8.

size of aggregate, and the problem was dismissed without too much consideration.

Three years ago, when we began to carry out strength tests at very early ages—8 to 12 hours—to determine the effects of retardation, we found that this theory of water-gain being responsible for the lower strength of the concrete with the coarse aggregate was quite untenable. Water gain is, of course, complete as soon as the concrete begins to stiffen, and long before any measurable strength is developed. Yet the strengths at early ages, 24 hours or less, were quite normal, and did not exhibit any of the aberrations which develop at later ages, and which become more and more pronounced as the concrete ages and increases in strength.

Obviously, the cause of these effects is something which develops in the concrete after it passes from the plastic to the solid state, and it is equally obvious that the most logical explanation is internal shrinkage. Nearly all of the shrinkage which occurs in concrete develops in the cement-water phase, and the aggregate is comparatively unaffected. This applies, of course, to the samples under discussion here, which were kept in a saturated condition until tested. Where drying shrinkage also occurs a porous aggregate may contribute appreciably to the overall shrinkage of the concrete.[15]

While the concrete is still plastic, shrinkage of the cement-water phase will result in some movement of the aggregate particles, with subsequent shrinkage of the concrete as a whole. If we visualize a concrete consisting of only one size of coarse aggregate embedded in a matrix of cement-water paste, plastic shrinkage of the mixture as a whole may take place while the concrete is still plastic, as a result of extrusion of some of the water by gravity and evaporation effects. Once the matrix has set overall shrinkage of the concrete as a whole is no longer generally possible, but shrinkage of the cement water sandwiches between the aggregate particles still continues, and induces internal stresses which, in magnitude, are a function of the dimension of the aggregate particles.

The greater the proportion of cement and the greater the amount of water in the mix, the greater will be the ultimate shrinkage, and the greater will be the magnitude of the locked up stresses developed in the cement-paste sandwiches between the aggregate particles. Eventually, with very high cement content, and very large aggregate, these locked up stresses may become so great that the concrete may fail under the application of an external force which is actually less than that required to produce failure of a similar concrete made with

(a) Less cement per unit of volume, or,

(b) Smaller sized aggregate.

There is a very considerable volume of evidence being gathered to indicate that the above is probably the true explanation for some of the abnormalities observed in the behaviour of high strength concrete with varying sizes of aggregate.

Modulus of Rupture vs Compressive Strength

If there is any reason at all in the above argument we should expect that since shrinkage of the concrete after setting results in contraction of the cement-water phase, with development, generally, of internal tensile stresses, this tendency might be more apparent in modulus of rupture tests of the concrete, compared with compressive strength tests.

The modulus of rupture test, for concrete, determines the strength of the concrete in flexure, and to some degree is a measure of the tensile strength, since failure is induced by tension in the outermost fibres of the matrix at the lower face of the specimen.

In the compressive strength test, with shrinkage effects and stress development in all directions, some of the internal stresses, when the sample is loaded in compression, may cancel out. With the modulus of rupture test there is no possibility of relief of any of the internal stresses in that part of the beam which is being subjected to additional tensile stress, since all of the internal stresses, according to this theory, are originally in tension.

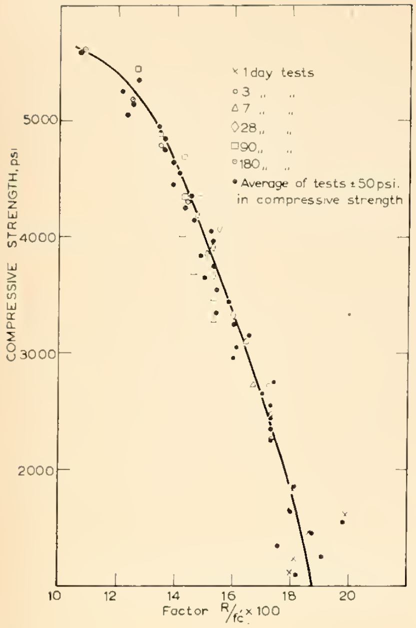

Fig. 10—Modulus of rupture—Compressive strength relationship derived from samples of concrete from Dorval Airport.

This is confirmed by a rather extensive investigation which was carried out in 1959 on samples from 135,000 cu. yd. of concrete which was used for the construction of a jet runway and accompanying taxi strips, for D.O.T. at Dorval Airport.

In this investigation samples were tested for compressive strengths and comparable modulus strengths, the two sets of samples being taken from the same batch, with test results determined at 1, 3, 7, 28, 90 and 180 days.

Mix proportions for this concrete were as follows:

		lb. per cu. yd.
Cement		475
Sand		1285
Crushed Limestone,	½ in.	600
	¾ in.	605
	1 in.	800
Water, (total)		250
Weight per cubic yard		4015
Slump		2½ in.
Air Content		4.0-6.0%

The sand contained 10% pea gravel between 4 mesh and ⅜ in size, which would be classed as coar. aggregate. The F.M. of the fraction passing the 4 mesh sieve was 2.60.

It was expected that as the concrete aged, the relationship between the strength of the concrete in compression, and the modulus of rupture test results, would change materially, depending on the age of the concrete.

A summary of the test results, covering 99 samples, of three cylinders and three beams each, is shown in Fig. 10. This shows quite clearly that age in time has nothing to do with the relationship $R/_{fc}{}^1$. The controlling factor in this relationship is the actual compressive strength of the concrete at the time of test, and, more probably, the extent of the internal shrinkage stresses which govern the strength of the concrete when tested, whether in compression or in tension. This, alone, determines what the flexural strength of the concrete shall be, for the specific aggregate and specific cement used, without regard to age of the concrete in terms of time.

As can be seen, test results at 1, 3, 7, 28, 90 and 180 days fall into a general pattern in which the value of $R/_{fc}{}^1$ decreases progressively as the compressive strength increases, regardless of the age of the sample. This would seem to support the premise that, as a result of internal shrinkage effects developed in the cement-water paste after the concrete hardens, internal tensile stresses are developed, and that these are reflected more vividly in modulus of rupture tests than in standard compression tests.

In Fig. 10 the results of all tests are plotted, firstly, as an average of results obtained from groups of three or more samples within a limited strength range for each age. These average results are identified by the legend. Secondly, all results, regardless of age of specimen, are segregated into groups with compressive strength falling within a range of ± 50 p.s.i. These are also plotted as single points on the graph. It is illuminating to note that the divergence from the mean, for the average result, regardless of age, is perhaps less than the divergence of the individual groups of test results at stated ages.

Special mention should be made of the results of the tests at 24 hours. These are all below 2000 p.s.i., and because of the difficulty of maintaining these samples under standard curing conditions in the field, little attention should be given to the comparatively wide scatter of results, compared with the results at later ages.

The graph shows quite clearly that the modulus of rupture strength of the concrete tested, and probably any other concrete, is a function of the compressive strength of the concrete, and varies with the compressive strength at any age.

Returning to the original premise, if increase in maximum size of aggregate is going to result in reduction of strength in flexure, which may occur before any indication of reduction in the compressive strength, it behooves the designers of pavements and airport runways, who are interested in the flexural strength rather than in the compressive strength of concrete, to consider the behaviour effects of aggregates of different maximum size in the concrete mixture. The Department of Transport, two years ago, reduced the maximum aggregate size in concrete, for paving on airfields, from 1½ in. to 1 in. Whether they did this as a result of prescience of these modern developments in the technology of concrete, or whether they adopted it as a result of the fact that, in many areas of Canada, aggregates coarser than 1" in size are difficult to obtain, will probably never be known. However, in adopting this attitude, they are anticipating current progress in concrete technology.

If we examine Fig. 10 closely it is apparent that, in the range of the lower compressive strengths, below 1000 p.s.i., which are of slight importance in any event, the factor $R/_{fc}{}^1$ x 100 may reach a value of 19.0 to 20.0. In the higher strength range the curve seems to be tending towards progressively lower values of the above relationship, and probably, with increase of cement content and compressive strength, will show even sharper reduction of values than indicated in this series of tests, which reached a maximum compressive strength of only about 5600 p.s.i. with a comparatively low cement factor of 475 lb. per. cu. yd.

At the maximum strength of 5600 p.s.i. obtained from this series of tests at 180 days the curve representing the relationship between the compressive strength and the modulus of rupture strength is veering sharply towards increasingly lower values of this relationship with increased compressive strength of the concrete. From an analysis of the results obtained it would seem that the modulus strength, even for this mix with comparatively low cement factor, and a maximum nominal aggregate size of only 1 in., reached a ceiling at a compressive strength of about 5000 p.s.i. Attainment of compressive strength greater than this, whether from the use of more cement in the mix, or increased aging of the concrete, probably will result in an actual decrease in the modulus strength.

It would be desirable to carry out further tests on high strength mixtures, with compressive strengths ranging up to 8,000 to 9,000 p.s.i. Perhaps, from the results of tests on such mixtures, with varying maximum size of aggregates, some interesting information might be developed.

Conclusions

If we now return to a consideration of the behaviour of retarders, applying the criteria outlined above, a reasonable explanation of the strength gains obtained as a result of their use is suggested. The retardation effect results in maintenance of the concrete for a longer period in a plastic or semi-plastic state. Extrusion of water, by evaporation or gravity effects, can be carried to a much greater extent. Post-vibration during this period may assist greatly in eliminating incipient strains in the semi-plastic mass by re-orienting the aggregate particles so as to fit more closely together. Consequently, if a greater part of the overall shrinkage in the concrete is effected while the concrete is still plastic and capable of adjusting itself, or being adjusted, to these shrinkage effects as they develop, the residual shrinkage which will take place in the cement-water paste after the concrete has changed to the solid state will be materially reduced. Internal stresses will also be reduced, and the strength ceiling of the concrete will be materially increased.

If we return to Fig. 5, and analyse the results shown in light of these later revelations, we can surmise, in relation to the A.E.A. mixtures, that they may exhibit, in high strength mixes, lower strengths because of greater internal shrinkage effects after setting. Such a condition is not only possible, but also highly probable.

One of the immediate effects of air entrainment, in fresh or old concrete, is to make the concrete less permeable. It is this characteristic, in fact, which affords A.E.A. concrete increased resistance against freezing effects. Obviously, if concrete resists entrance of water, because of the presence of multitudinous discrete air cells, it will also equally resist the loss of water, by gravity effects, evaporation or for any other reason.

Fig. 11—T.C.A. Maintenance Hangar, Dorval Airport, Montreal, where lignosulphonate retarder was used. *(photo Scherbi)*

For low strength concrete, air entrainment may be advantageous. For high strength concrete, where it is desirable to eliminate as much of the excess water as rapidly as possible before the concrete actually sets, it may prove to be an actual detriment towards the development of maximum strength in the concrete.

There is a very wide school of thought which feels that "bleeding" in concrete is undesirable, and that any appreciable degree of bleeding in a mix is conducive to segregation and possible loss in strength. For high strength mixes our test results indicate the direct opposite. For development of maximum strength in high strength mixes bleeding of concrete, provided it does not result from improperly graded aggregates, should be encouraged and assisted, by the use of suitable cements, suitable retarders and post vibration, if possible; and by the avoidance, as far as possible, of air-entraining agents in the mix.

These are some of the most interesting developments in concrete technology to-day, which offer very great promise in the production of materially better concrete in the near future.

Acknowledgement

The author wishes to record his deep feeling of gratitude to the late Mr. James Franceschini, who, as a result of his interest in modern developments, authorized and provided the facilities for carrying out these investigations.

Thanks are due also to Mr. R. A. Lapinas, Jr.E.I.C., concrete engineer for Mount Royal Paving & Supplies Limited, who organized and supervised the whole of the test programme.

GM Portager Piggyback System

H. E. Martin, M.E.I.C.,
New Product Development Engineer, General Motors Diesel Limited, London, Ont.

RAILROAD interest in *piggyback* stems from transportation competition which diverted premium, heavy-density traffic from the railways to the highways. Under certain conditions, highway transportation possesses flexibility which cannot be matched by conventional railway methods. The cost of conventional freight movement by rail is low between terminals, but relatively high at the terminal.

The costs are opposite on the highway: high between terminals but low at terminals compared with railroad operations. Piggyback, which combines the most efficient features of both highway and rail operations, has a vital role to play in the economy as a more economical method of transporting goods.

With new product development in mind, our company's representatives approached Canada's two major railroads regarding areas where available engineering talent might best be utilized. It was in answer to a transportation concept outlined by the Canadian Pacific Railway Company that a quite different side-loading piggyback rail vehicle was designed and developed.

A concentrated engineering effort was launched immediately to expedite this new product through its several phases. The following is a progress report on the development of the GM Portager which incorporates the advantages of containerization.

Current System

The CPR, one of the largest piggybackers in North America, is always striving to improve its system and equipment. Its current system involves the use of flat cars with special adaptions and railway terminal facilities consisting of ramps and walkways which allow highway trailers to be end-loaded "circus fashion". Trains are broken into modules of 10 to 15 cars for loading and unloading. A conventional highway tractor with elevating fifth wheel is utilized to move the trailers. After the trailer has been positioned, the retracted king pin pedestal on the flat car deck is elevated to secure the trailer king pin during transit.

This system, while it achieves the basic requirements of piggyback and produces satisfactory loading and unloading cycle times, has a number of shortcomings. Consideration of these shortcomings promoted investigation of other systems by the CPR and led to the conclusion that side-loading and its many apparent advantages should be fully explored. Prior to participation by our company, a side-loading rail vehicle was designed and constructed by the CPR from a conventional flat car. This confirmed certain principles and indicated that the design of a new system of side-loading should be pursued.

Side Loading

Side-loading offers advantages to both railroad and trucker.

The rubber-tired highway trailer rear tandems that are currently transported may be left behind at the terminal. This localizes licensing, maintenance and records and can reduce the number of tandems required in a trucking operation as none are "tied up" in transit.

The absence of the trailer tandem contributes to the over-the-railroad economy. A sizeable portion of dead weight is eliminated. The consequent lowering of the load provides a more favourable centre of gravity for stability and better tracking, brings the height within all system clearances and reduces train windage losses. As piggyback trains run at passenger train speeds, windage is a significant component of total train resistance.

The rail vehicle can be simplified. Aprons, guide rails, decking and other special requirements to provide a path on the rail vehicle for the highway trailer are no longer required.

The potential exists for shorter loading and unloading cycles with fewer manual operations to improve terminal economy and provide for faster delivery of goods to the customer.

The rail vehicle can be loaded and unloaded facing either way, from either side and in any order. This will eliminate some directional and sequential restrictions which exist with the current system.

Design Criteria

Other original design objectives of the side-loading rail vehicle were established:

1. The first cost of the vehicle should be significantly less than existing equipment;
2. Maintenance should be minimized;
3. The vehicle must be capable of running satisfactorily at speeds up to 75 m.p.h.;
4. The vertical and lateral accelerations to which the container is subject must be of the same order as those experienced in normal highway service. This defines the ride requirements;
5. Transmittal of railroad handling impacts to the container and lading must be such that no damage to either will occur;
6. Containers must have no attachments or modifications that would increase significantly the trucker's expense;
7. The vehicle must be compatible with existing railway equipment to the extent that it must run in the same train;
8. The vehicle should accommodate containers from 35 to 40 ft. long and should be able to carry a load of 60,000 lbs.

It should be noted that no restrictions or standardization of components with existing conventional car equipment were imposed on the design at this stage. This is contrary to the traditional approach and allows the design to be radical if it is necessary to best achieve the desired results.

Thus, the design of the side-loading system was started with a large degree of freedom but with quite stringent requirements. Early design considerations established a rail vehicle with a single centre sill member, single axle trucks and a container mounting that utilized the trailer king pin and rear guide angles. Trailers with these guide angles, which provide for tandem shifting or removal, are in common use. These sliding tandems are utilized by truckers to meet varied wheel base requirements of certain areas relative to axle loading. A concept of a loader to raise these containers from underneath was also established at this time.

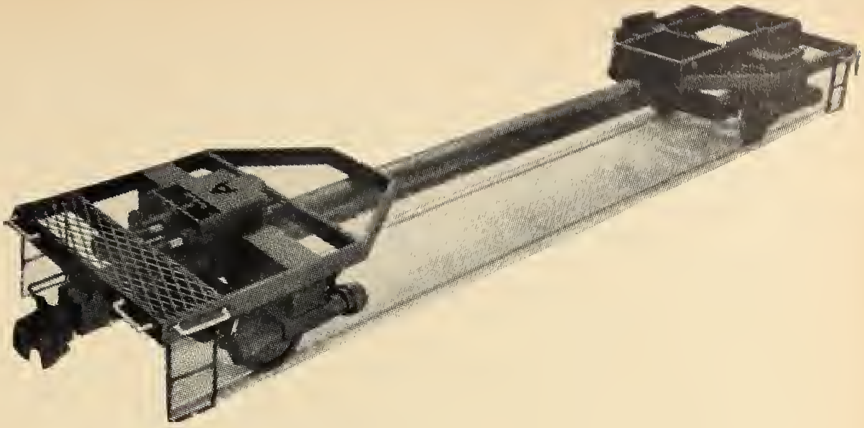

Fig. 1.

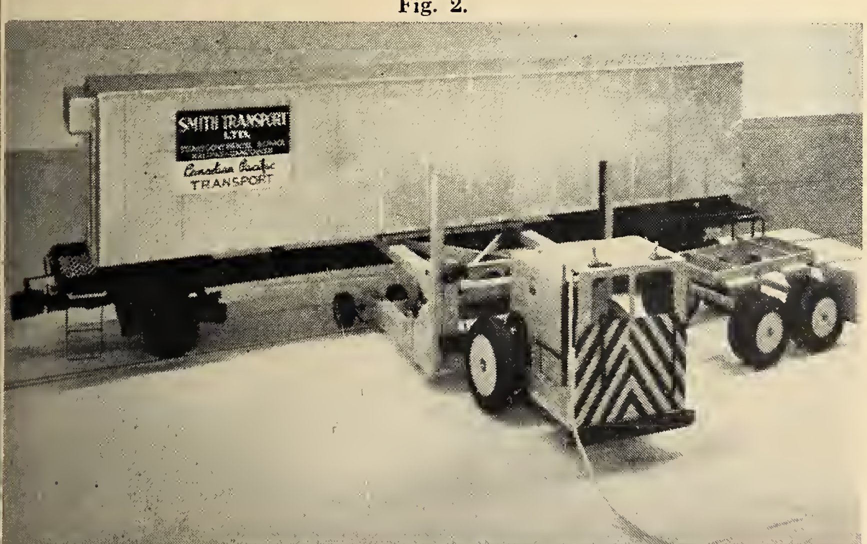
As soon as preliminary layouts were completed, ⅛ scale working models of the highway trailer, the loader and the rail vehicle were built. These models were of significant aid in visualizing improvements, overcoming restrictions and demonstrating the design of the new piggyback system. Fig. 1. shows the rail vehicle model and Fig. 2 shows the three models together.

Figs. 3a, 3b and 3c sketch three sequential positions of the equipment during a loading operation. Fig. 3a shows the highway trailer parked, ready for loading. In Fig. 3b, the loader has manoeuvered into position under the trailer, lifted the container off its rear tandem and is in transit with the load toward the vehicle. In Fig. 3c, the container has been positioned and lowered onto the rail vehicle. The rail vehicle's king pin hitch or fifth wheel has been locked on the king pin and the loader has departed. Unloading is accomplished by a similar procedure in reverse sequence.

The open centre section of the rail vehicle allows the loader table jack to be almost at the load centre to lessen the table structural requirements. The small diameter front wheels of the loader pass under the rail vehicle's centre sill eliminating any requirement for overhung counter balancing weight to provide stability when loaded. Quick and accurate spotting of the load can be achieved through four-wheel steering. Besides providing a short turning radius, four-wheel steering makes two additional loading manoeuvres possible. The loader can approach at an angle and aim the container king pin at the rail vehicle hitch. In other words, the loader can progress sideways while moving forward holding the container parallel to the rail vehicle. Furthermore, with the container king pin held in position over the hitch, four-wheel steering makes it possible for the container to be rotated about the king pin centre until its rear rails are lined up. These two manoeuvres eliminate the need for precise spotting and parallel locating requirements. The rail vehicle design allows a number of alternative loading methods.

Two prototype rail vehicles were built and tested to evaluate the unique features of the design. For identification, a model designation T-40 (Transporter for 40 ft. trailers) was assigned and the name "GM Portager" was added later. Progress on

Fig. 2.



some of the principal design features of the GM Portager components and their testing follows:

Underframe: A 16 in. diam. single tubular centre sill was selected to give high buff and drag strength and relatively low torsional resistance to keep all four wheels on the rails. No significant beam strength to support the vertical load of the container was required since it was supported directly above the trucks at each end. Rubber draft gears were used with standard couplers at each end of this sill member which, based on locomotive experience, had sufficient capacity to protect the GM Portager from road and yard railroad impacts. Air brake piping was routed through the centre sill tube. Other details of the underframe involved bolster structure for truck suspension, container mounting, air brake equipment mounting and the attachment of various other minor but essential equipment such as the uncoupling rods and the handbrake.

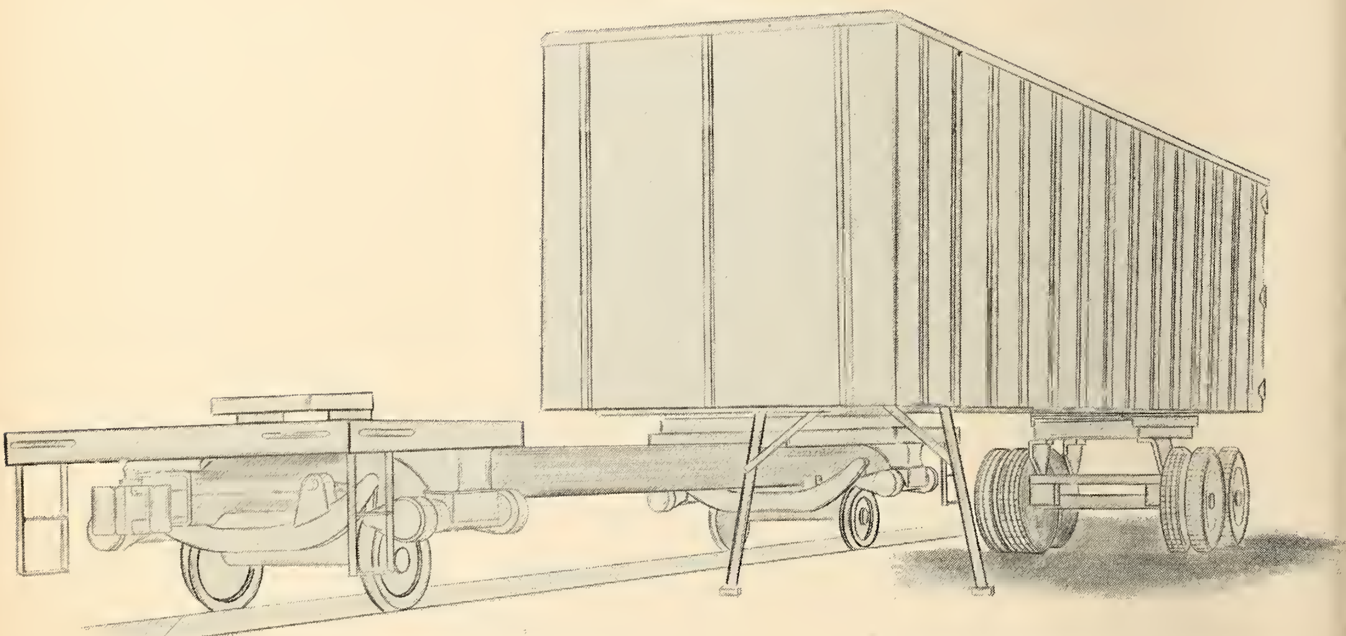
Truck Suspension: The two-wheeled design was selected because the maximum loading was within the capacity of four wheels per vehicle, using standard 33 in. diameter wheels. A swing hanger suspension was chosen to give easy lateral action—a requirement for high speed operation. A swing hanger length of 10 in. was selected arbitrarily. To develop high roll stability, a four-point swing link attachment to the underframe was used. The geometry for this arrangement was determined by calculations based on comparing the resistive force at the wheel flange against the rail to the maximum simultaneous overturning force that could be developed on a curve by a loaded vehicle. The four swing links were connected to the arms of the underframe mounted torsion springs. The flexible torsion-resisting elements of each spring consisted of two large preloaded rubber bushings. This spring design was chosen to provide a simple swing link connection and to act as a structural member, as well as giving a degree of vertical impact dampening. The idea of using rubber as a torsion spring element was conceived when, in an attempt to remove metal wearing bushings from a previously designed metal rod torsion spring design, it was found that the rubber bushings loaded in shear would provide most of the required torque reaction. The truck frame was fabricated, using two longitudinal box sections welded to a traverse flamecut member at each end. On one test vehicle, the axle was fixed and each wheel rotated on tapered roller bearings mounted in the wheel hub. This was done to assess any benefit that the differential action of free wheels might give to a four-wheel vehicle on a curve. The other test vehicle had wheels pressed on a rotating axle and inboard roller bearings. Other features of the truck were rubber-bushed stabilizing links to transmit braking and acceleration reactions to the underframe, automotive-type diaphragm single-acting brake cylinders and rubber-block bolster lateral stops mounted on an angle to also act as cushion seats in the event of the failure of any vertical suspension member.

Container Mounting: In order to use standard removable tandem trailers, the mountings on top of the underframe were designed to duplicate the manner in which this container is carried on a highway tractor and rear tandem. At the rear, support was provided by rails with the same spacing as highway tandem support rails which fit the container mounted tandem retaining angles. At the front, a highway tractor king pin hitch or fifth wheel was used. This hitch was conneeted to the underframe through a dual high-capacity rubber element arrestor gear. This gear allowed up to 10 in. of container "slosh" or restrained movement each way from centre to cushion the container and lading from railroad impacts. Frictional forces at the arrestor and rear rails add dampening capacity and prevent fore-and-aft jostling of the container in transit. Fig. 5 shows the king pin hitch mounting and the arrestor gear.

Testing and Evaluation

Structural Testing: Prior to vehicle assembly, the underframe was completely tested structurally. The method used involved the application of dynamic values of all loads separately and in combination, and measuring stress level at all critical locations with these loads applied to the structure. The results were analyzed graphically for fatigue using empirical formulae which have been proven by experience to yield reproducible and predictable results. This was accomplished by mounting the structure on a very rigid test fixture and applying the loads with hydraulic jacks. The fixture used for this test weighed

Fig. 3a.



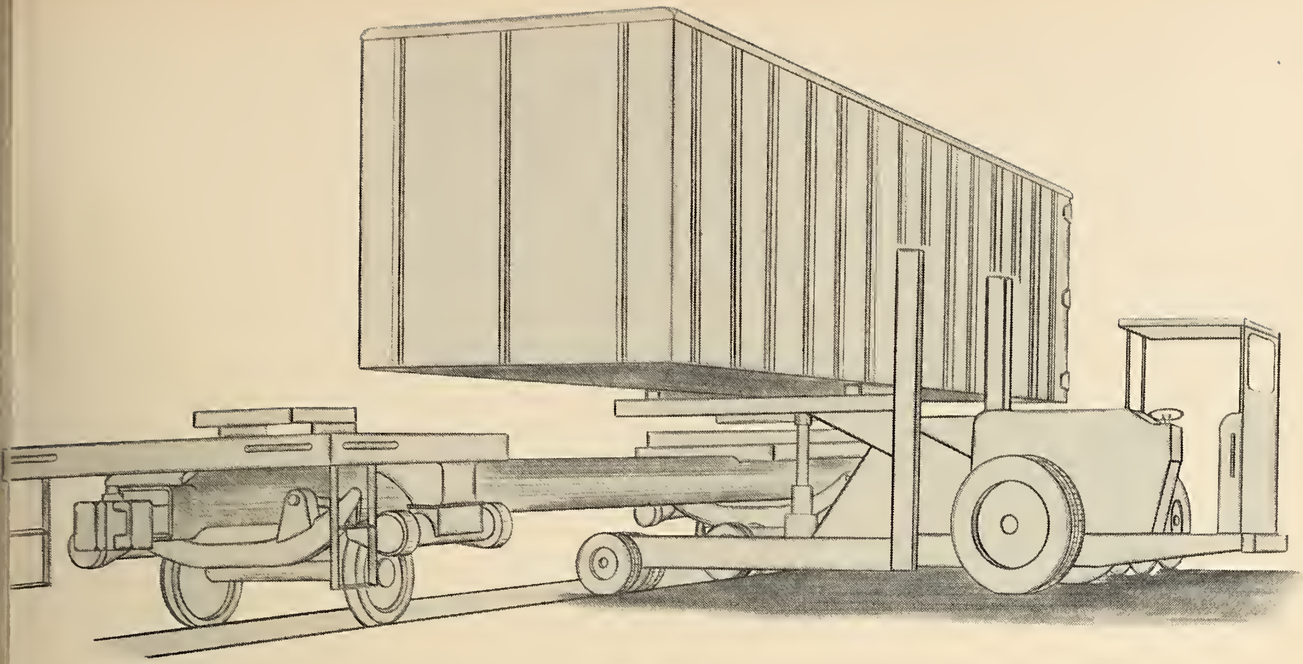


Fig. 3b.

ver 70,000 lb. The areas of high ress were generally known from the esign calculations. In order to precisely locate stress concentrations and ake certain none were missed, stress oat (a special paint that will "craze" areas of high stress) was applied the structure and loads were aplied. The locations for strain gauge pplication were thus established and nce the stress coat sensitivity was librated from samples the aproximate stress levels were also nown. Direct reading resistance wire rain gauges were then applied and ress values were measured for all esired load combinations.

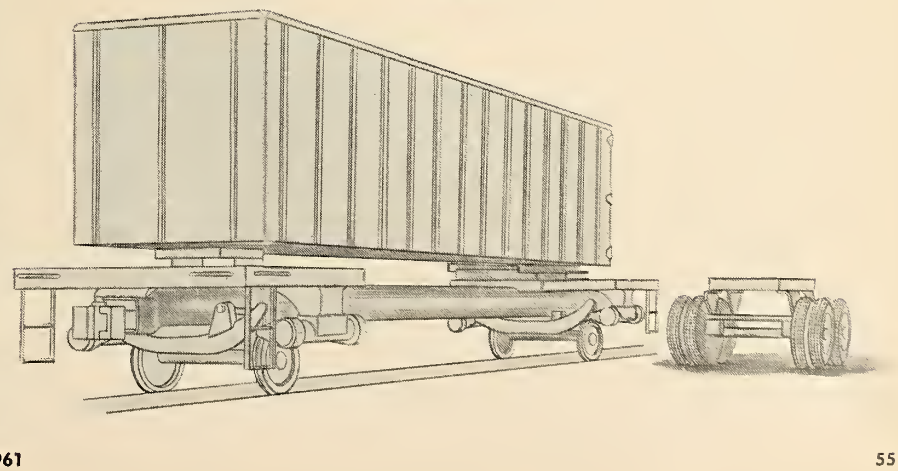
For this underframe test, 185 strain auges were used. Vertical, buff, impact at arrestor and twist loads were pplied separately and in desired ombinations. The results indicated ne area requiring major change due overstress and necessitated some inor revisions to eliminate localized resses. The underframe bolster section, that is the box section that ipports the outboard torsion springs, as overstressed in bending. Rebuildig to provide increased section and etesting was carried out and the ress level in these members was rought within acceptable limits. The visting test indicated an underframe exibility that, for a fully loaded ehicle, would allow one axle to be ver 2° out of parallel with the other xle with negligible underframe stress. was felt that this flexibility would ake a marked contribution to this ehicle's ability to "hold" the rail nder adverse conditions.

The frame for the truck was also ructurally tested in a similar manner using 50 strain gauges. No overstressed areas were found. Minor modifications were made to reduce two stress concentrations.

Running Tests: Railroad test runs were started on existing CPR piggyback rail vehicles before construction of the two prototype GM Portagers was complete. The total test program consisted of more than 300 different instrumented tests. Some of the variables were: four different railroad locations, three different vehicles, a number of loading variations, numerous running speeds up to 75 m.p.h. and vehicle modifications. Also included in these instrumented tests were impact tests at our London plant and tractor-trailer test runs on local highways using the same container and load as used on the railroad. Other tests and demonstrations involving only observation such as loader elevation and adverse buff conditions were also completed. In all, one prototype GM Portager accumulated over 11,000 test miles. All tests were prescribed and conducted jointly with Canadian Pacific's Mechanical Engineering, Piggyback and Research Departments. A caboose was provided by the CPR to be used as a test car. Power supply, instrumentation, communication equipment and signalling devices were installed in this vehicle.

The road testing instrumentation was selected to record ride accelerations, suspension and container movement, significant stresses and loadings and speed. Three four-channel ride recorders were used. Motions, stresses and loads were plotted by a multi-channel recording oscillograph. A recording calibrated tachometer maintained accurate speed records. Signalling pens on these recorders provided synchronization as well as a running record of such road conditions as curves, crossings, switches

Fig. 3c.



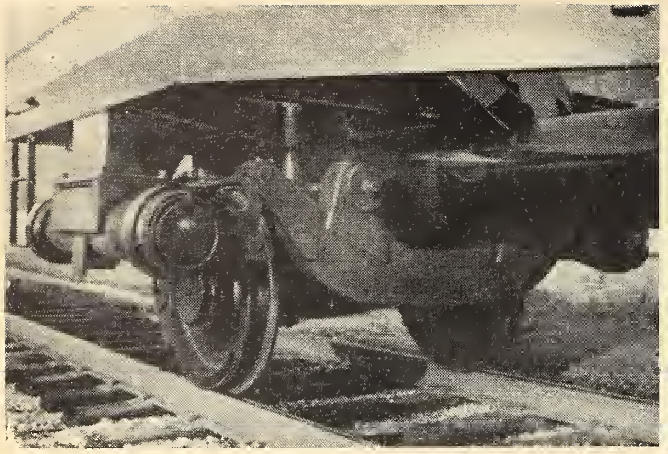


Fig. 4.

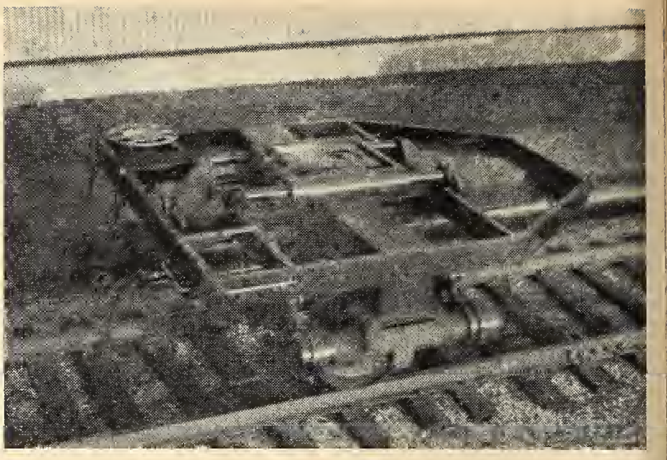

Fig. 5.

and bridges by using signalling keys operated by an observer in the test car cupola. Periodic observations and measurement provided records of wheel wear, torsion spring angular location, lading behaviour and other similar noteworthy conditions.

A base line for ride requirements was established from test runs on the highway using the same container and common lading in a conventional highway consist. Preliminary comparative records were established from railroad test runs and impact tests on a conventional "piggyback" loaded vehicle. This vehicle was included in the railroad test consist along with the prototype vehicles on a number of test runs for further direct comparison.

Prototype GM Portager evaluation started on a local branch line where light weight rail, sharp curves and the opportunity to aggravate the track conditions artificially were available. Trackability and general roadworthiness were assessed on this branch line. Then, higher speed runs were carried out on a section of mainline where curves were sharper and more numerous than normal. Final tests were conducted in revenue service in scheduled Toronto - Montreal CPR piggyback trains.

Impact Tests: Two series of impact tests were conducted. The first test consisted of impacting a conventional CPR piggyback car carrying a loaded trailer against several box cars with the brakes set. At 7½ m.p.h. the trailer king pin was pushed back about 6 in. with consequent structural damage to the trailer. This test indicated the necessity of accurate speed control, instrumentation and other aids to record stresses, deflections, relative movements, accelerations and speeds at impact in order to allow gradual impact increase to the point of damage and to provide a record of results. Consequently, an improved procedure was adopted when testing a loaded prototype GM Portager. A loaded coal car was coasted down an incline to impact against the test vehicle. Data was recorded on a multi-channel high-speed photographic type oscillograph and high-speed movies were taken. Motion, stress and speed transducers were engineered by our company and instrumentation, movie camera and technical assistance was provided by the National Research Council. Impacts were gradually increased to a value obtained from a fully-loaded coal car at 8 m.p h. at which speed the king pin hitch failed. The trailer was loaded with steel shot in 100 lb. bags to a gross weight of 49,000 lb.

Modifications: Prototype GM Portager modifications were made and evaluated during the test program as test results indicated their necessity in order to attain the design requirements. Noteworthy among these were:

(i) Lengthening of the truck suspension swing links to reduce both frequency and restoring force in order to slow down the lateral accelerations imposed on the container and lading:

(ii) Reduction of the rate of the torsion springs to reduce vertical accelerations;

(iii) Provision for secondary springing between the rail vehicle underframe and the container mounting to further reduce vertical accelerations. This was necessary because close limits on coupler heights did not allow enough primary spring deflection to achieve a sufficiently soft vertical ride for the container. Variable secondary springing to select the required spring rate was achieved by using a special test air suspension on which different air pressures and volumes could be selected;

(iv) Application of a different king pin hitch.

Test Results: The suspension proved to be very stable from the beginning. Roll was negligible, even after springing modifications, and with a heavy high centre of gravity load in the container. The modified suspensions achieved a vertical ride equivalent to that obtained on an average new highway. Excellent high speed trackability was obtained from the primary suspension. This suspension was *lively* in absorbing track irregularities without producing any tendency to sustained oscillation or vibration. The vehicle ran straight and true over the full range of load and speed conditions. Derailment did not occur under aggravated conditions. One test to evaluate track holding ability involved pushing a light vehicle without container on an 11½° curve with the full available starting tractive effort of four diesel-electric road locomotives. The combined shock absorption capacity of the draft gear and king pin hitch arrestor gear indicated a capability of protecting the GM Portager, the container and lading at impacts approaching 8 m.p.h.

Loader: A United States manufacturer has developed and built two prototype loaders for the CPR. These loaders were utilized in conjunction with the revenue test runs of the GM Portagers. Fig. 6 shows one of these loaders in the process of loading a container. The unit utilizes a standard highway tractor for motive power and achieves additional manoeuverability of the container by a hydraulically-actuated table shifting feature. A choice of fork spacing is an additional feature.

In Fig. 6, the container has been lifted clear of the tandem and moved into position over the GM Portager. The container has been elevated high enough for the landing gear to clear the centre sill of the GM Portager.

The forks, of course, pass above the centre sill while the wheels of the loader pass under it. Very encouraging loading and unloading times have been achieved.

If desired, the GM Portager can be moved from one track to another by lifting under the sill with the loader forks.

Conclusion

The foregoing has described the development of a container car to the completion of the test prototype stage. This program, although indicating a number of changes to improve standardization, reliability and adaptability, has proven the vehicle and the system to be sound. The accumulated experience has been used in the design of two production prototype GM Portagers. Standard wheels and axles with outboard bearings, reduced frame stresses, reduced manufacturing cost and a softer suspension, are the most significant changes from the test prototype design.

The differences between the test prototype and the production prototype cars have been evaluated. Structural tests confirm the increased strength and lower stress levels in the underframe. The truck changes have had no measurable detrimental effect on trackability. An improved vertical ride has been achieved due to the suspension modification.

A number of additional tests, mostly prescribed by the CPR, have been completed with satisfactory results utilizing the production prototype cars. One of these tests was the assessment of the derailing tendency of an unloaded GM Portager at the head end of a 3500 ton, 55-car freight train hauled by four road diesel units. Repeated pull and train "run-in" tests were conducted with this train on a railroad line which has grades up to 2% and curves up to 9°. "Run-ins" were produced by applying maximum dynamic brakes on all locomotive units with a stretched train. This produced an instantaneous head-end retarding force of 160,000 to 170,000 lb. at 20 to 25 m.p.h. and extremely severe impacts occurred due to the "run-in" of the train. This test relieved concern of possible derailment due to positioning of empty GM Portagers at the head end of trains. Signal tests determined a light, single GM Portager's ability to safely function all three types of signalling equipment — AC, DC and Coded (DC pulse).

Fig. 6.

During this series of tests two measurements were taken that are noteworthy:

(i) The maximum shocks due to normal "run-in" and "run-out" in high speed freight train operation were found to be in the order of 2½ m.p.h. impacts;

(ii) The dampening of the GM Portager rubber torsion springs was found to reduce peak road shocks by a factor of eight

In Fig. 7, a prototype GM Portager and a current piggyback car, carrying identical loads, are shown coupled together. The economics of complete GM Portager revenue trains are apparent although not determined. Because of weight reduction, less windage loss due to the lower, more streamlined profile and half as many wheels and bearings, significantly less horsepower will be required to pull these trains. It is felt that sizeable savings in loading and unloading man-hours can be realized. Potential savings also exist in the areas of rolling stock investment, trailer tandem investment and maintenance due to fewer wearing parts, stable high speed tracking and impact protection features.

Development efforts are continuing. However, the GM Portager has already demonstrated that it is a signicant step forward with resultant benefits to railroads, truckers and shippers alike.

SILVER FALLS

L. A. Leeyus, M.E.I.C.
Assistant Civil Design Engineer, Hydro Electric Power Commission of Ontario, Toronto

Tunnel and Surge Tank Design

At the Silver Falls site a pressure tunnel in natural rock was used to convey water to a powerhouse and surge tank situated to the best advantage at the surface. Discussed by Mr. Leeyus are considerations of design for both the tunnel and the surge tank.

IN AREAS favored with suitable rock conditions, the hydraulic pressure tunnel has often been found to be the most effective method of developing the maximum potential from a given hydro-electric site. Silver Falls is a typical example in this regard of the use of a pressure tunnel in natural rock for conveying water to a powerhouse and surge tank situated to best advantage on the surface.

Although pressure tunnels have been successfully used for this purpose in conjunction with both surface and underground hydro-electric schemes in a wide variety of different arrangements since the turn of the century, the last two decades in particular have witnessed an increasing emphasis on this mode of development. In some degree this is a natural consequence of the more favorable sites found as the pursuit for power progressively extends into more remote and rugged areas. The trend may, however, be more directly attributed to recent advances in tunnel driving and concreting techniques as reflected in lower costs and faster construction. Many projects which might otherwise have used surface conduits or some alternative form of installation have as a result found it more economical to use the pressure tunnel. In addition, improved methods of analysis and experience gained with successful installations have done much to increase the confidence of designers in the use of natural rock for structural purposes.

While the choice between a pressure tunnel and competitive surface alternatives can usually be resolved on the basis of economics, certain features of the former tend to make it the more attractive alternative. Among its advantages one might mention freedom from extremes of weather and climate, laek of foundation and anchorage problems, reduced maintenance requirements, flexibility of arrangement and year round construction possibilities. In special cases, the greater security of the underground installation from wilful damage, or the preservation of existing surface features may be considerations of significance.

The two basic requirements for the use of the natural rock for these purposes are firstly, that the topography lend itself to such an arrangement and secondly, that the rock be of satisfactory quality. Although the topography of Ontario is liberally endowed with good rock, its disposition relative to potential sites has rarely been suitable to the use of pressure tunnels. Excluding the twin 45 ft. diam. 5½ mile long water supply tunnels built at Niagara for Sir Adam Beck G.S. No. 2, the only pressure tunnel installation built by the Commission prior to Silver Falls was the Aguasabon development. Completed in 1948, this plant is located on the north shore of Lake Superior in the same general area as Silver Falls and, being very similar to it in tunnel size, arrangement and rock conditions, provided a number of useful design precedents.

A tunnel and a surge tank usually present a number of interesting problems not encountered in the design of conventional river plants. This paper will attempt in a general way to discuss some of the more significant considerations involved in the design of these items at Silver Falls. The term "tunnel" is used in an all inclusive sense and is assumed for purposes of this paper to include the entire pressure conduit from headworks to powerhouse, including both the intake and surge shafts as well as the steel lined section and penstock adjacent to the powerhouse. For information on other aspects of this project the reader might refer to companion papers on the tunnelling,[1] tunnel concreting,[2] and the project as a whole,[3] the last giving a general description and history of the project.

General Arrangement

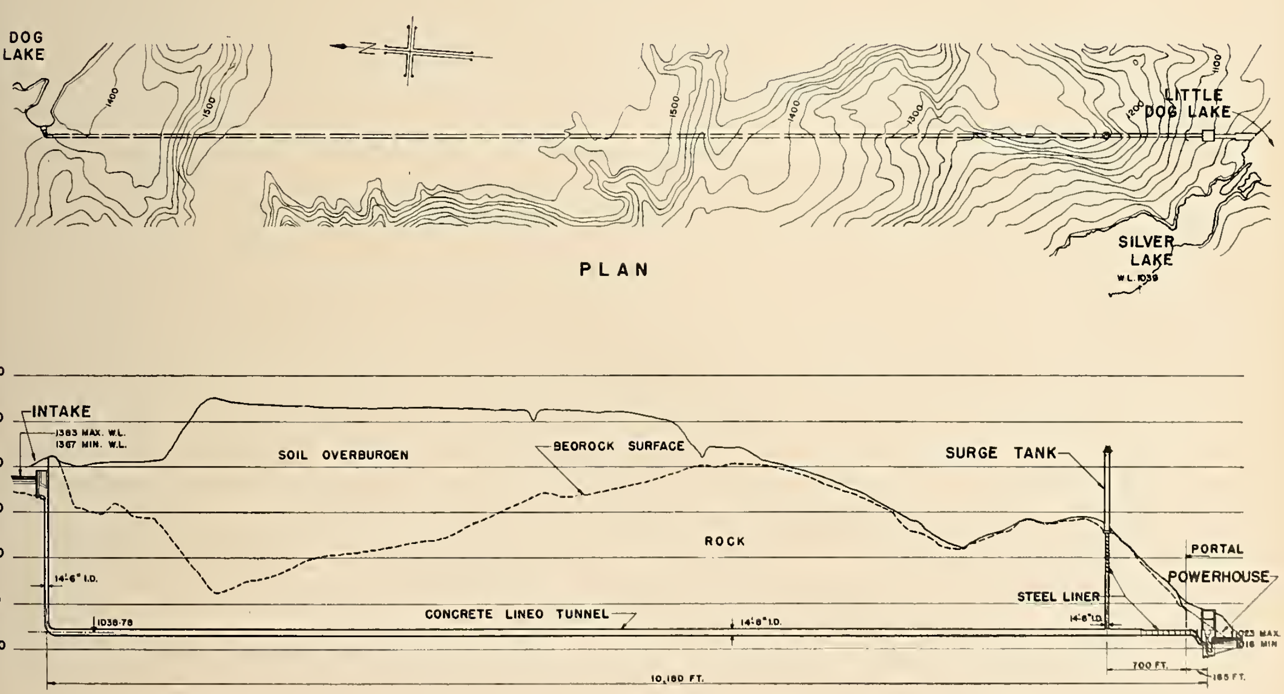
Preliminary studies encompassing multi-staged river plants, open-cut power canal and surface conduit alternatives had clearly established the economic superiority of a tunnel scheme. After site investigation had confirmed the existence of suitable rock conditions, further studies were required to determine the most advantageous final arrangement. From a fixed intake position on Dog Lake dictated by the nature of the bedrock, a number of tunnel alignments to different points downstream along the Kaministikia were possible, the two most promising being to outlets on either Silver Lake or a little farther downstream on Little Dog Lake.

An analysis of these indicated that the most favorable arrangement in either case would be a full length pressure tunnel running directly to a surge tank and powerhouse located on the surface at the downstream end. Despite a longer tunnel, the Little Dog Lake alternative was found to be economically preferable mainly because of its higher head. A further increase in head was possible by means of downstream river improvements which would lower the level of Little Dog Lake. This site in addition provided a steeper rock profile for improved surge tank and portal conditions as well as more favorable rock conditions for powerhouse and tailrace. The possibility of an underground installation was investigated, but did not prove to be economically attractive. A general idea of the topography encountered with this scheme may be obtained from Fig. 1.

A source of concern common to all the tunnel schemes was the problem of obtaining adequate roof cover for the tunnel at the bedrock depression near the intake. This took the form of a shallow saddle in the bedrock connecting the gently rounded rock knob centred on the intake with the ridge overlying the downstream part of the tunnel. The topography was such that a straight line alignment of tunnel from intake to powerhouse allowed maximum advantage to be taken of rock conditions in the powerhouse and surge tank area without appreciable sacrifice of roof cover at the depression. The need for adequate cover at this point, however, could not be satisfied without conflicting with tunnel grade and the elevation of the portal where it was desirable to keep the invert above high water levels in Little Dog Lake to avoid flooding during the construction period. This would later also permit drainage of the tunnel at all times without the necessity of pumping or of dewatering the powerhouse. Therefore, while it would have been desirable to provide a slight slope to facilitate tunnel drainage, a horizontal grade was used in conjunction with the raised portal elevation to retain the maximum possible cover at the depression.

A vertical shaft was used to connect from the intake structure to the tunnel proper in preference to a sloping shaft because it was felt that the maximum possible saving of approximately 250 ft. in length of conduit would not justify the additional costs and delays involved in changing equipment and methods to accommodate slope construction. With the intake shaft scheduled for excavation last, on the other hand, techniques

Fig. 1—Tunnel Profile (scale ratio 4:1).



used previously for the surge shaft could be used again to advantage, and the tunnelling could proceed uninterrupted on the horizontal grade already used of necessity along 80% of tunnel length.

At the surge shaft and portal, steel-lined sections are used through areas of diminishing rock cover where the conduit emerges to the surface. From the portal, the steel liner continues in the form of a sloping penstock down through an open rock cut to convey water the remainder of the distance down to a single unit powerhouse with a capacity of 60,000 hp. The final result, as shown in Fig. 1, is a rather conventional arrangement with a 10,000 ft. long tunnel developing the maximum possible head of approximately 350 ft. from the site.

Geological Factors

The bedrock of the Kaministikwia valley in the vicinity of the project is composed mainly of the massive paragneisses and granites typical of this portion of the Canadian Shield. This is covered except for scattered outcrops with varying depths of overburden consisting of terminal moraine and post glacial sedimentary deposits. The geological structure of the rock is rather complex, having resulted from a folding of the paragneisses by major intrusions of grey granite followed by faulting and numerous lesser intrusions of red granites and more basic rocks.

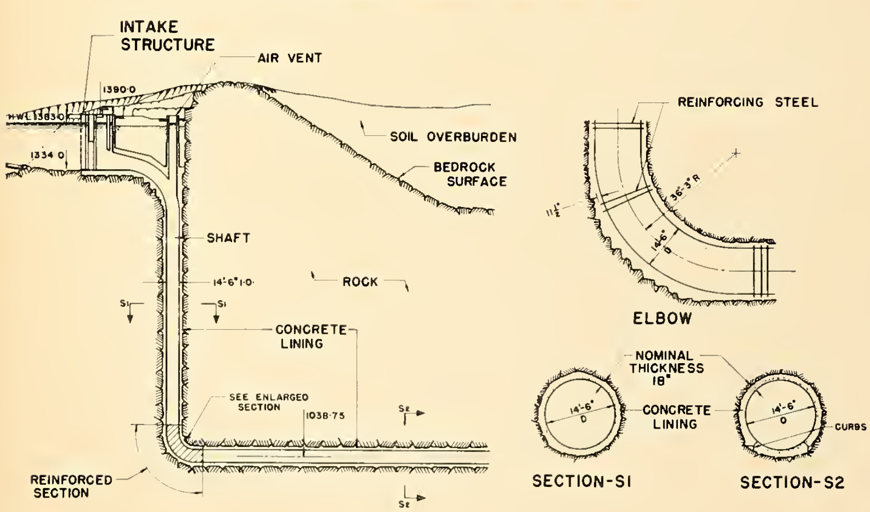
Metamorphic processes have healed most of the lines of primary weakness in the gneisses with the result that they are structurally sound at depth, and not unlike the granites in quality. Along its length, the tunnel passes through alternating areas of paragneiss and granite, the two constituents being encountered in about roughly equal proportions. The areas vary considerably in length, the alternations tending to become shorter and more frequent toward the depression and intake area. The rock structure in the intake area was particularly complex because of the numerous dikes and small intrusives of basic rocks in addition to the normal paragneiss and granite.

Slip planes and fractures were numerous throughout and rather irregular in pattern resulting in fairly prominent rock jointing. The majority of these were tight, however, and none appeared to be severe enough to have an appreciable effect on tunnel or liner safety. Sheared and brecciated zones which were found at the portal, near the depression and at the intake were found to be well cemented by secondary minerals and sound in character. The different rocks as a whole were hard and competent, and well suited for tunnelling and pressure conduit purposes. The specific gravity of the rock ranged from 2.63 for the granites to 2.78 for the paragneisses, suggesting an average value of approximately 2.7 or 170 lb. per cu. ft. for design purposes.

Tunnel diameter measurements which were made at various points following its excavation to determine rock squeeze showed only very small movements which ceased well before the pouring of the liner. While the measurements showed some variation, it was found that the major initial movements which were realized within the first 20 days, were all less than 0.10 in. Subsequent movements were all within the range of an additional 0.05 in. In addition to dispelling any concern about the effect of future rock squeeze on a liner, these measurements offered a general indication of the soundness and strength of the rock.

The material overlying the bedrock depression forms part of a ridge which acts as a natural dam separating Dog Lake from the Kaministikwia River. This consists of dense stratified layers of sand, gravel and boulders with bands and lenses of silt and clay, overlain by loosely packed surface deposits of sand, gravel and boulders. A zone of broken rock and gravel occurs at the bedrock surface. Continuous seepage from Dog Lake through the pervious strata has resulted in high ground water levels over the tunnel and in the existence of springs and erosion on the exposed downstream side of the slope. Owing to the presence of the silt and clay bands, however, it is possible that ground water pressures in underlying pervious strata close to the tunnel may vary considerably from a uniform gradient through lateral relief at the exposed slope. These conditions indicated the necessity of a tight tunnel in this area to prevent leakage which might alter ground water conditions to the detriment of the slope.

Fig. 2—Profile and sections intake shaft area.



Tunnel—Concrete—Lined Section

A concrete lining was adopted for the tunnel primarily on the basis of studies which indicated that the lined conduit would be less expensive than a larger unlined tunnel of equivalent hydraulic performance. The existence of certain blocky areas in the tunnel made it also desirable as a protection against possible rockfalls and the consequent expensive outages for repairs. It was further desirable in any case to have a liner in the depression area to reduce the possibility of tunnel leakage at this point in order to safeguard the stability of the natural ridge above. Losses due to leakage from an unlined tunnel nearly two miles long could easily be substantial even with careful grouting in the type of jointing present, whereas the lined tunnel would reduce this possibility and at the same time contribute further to the effectiveness of the grouting.

The final tunnel size was selected as a result of economic studies which indicated the optimum inside diameter to be 14 ft. 6 in., the circular cross-section being preferred for its hydraulic efficiency and its structural resistance to external pressures. The tunnel bore, however, was slightly out of round to accommodate the concrete curbs required on either side of the invert for construction purposes. Average flow velocities in the tunnel would reach a maximum of approximately 12 fps. under full discharge conditions.

The liner in the dewatered condition was assumed to act as thick-walled cylinder under the influence

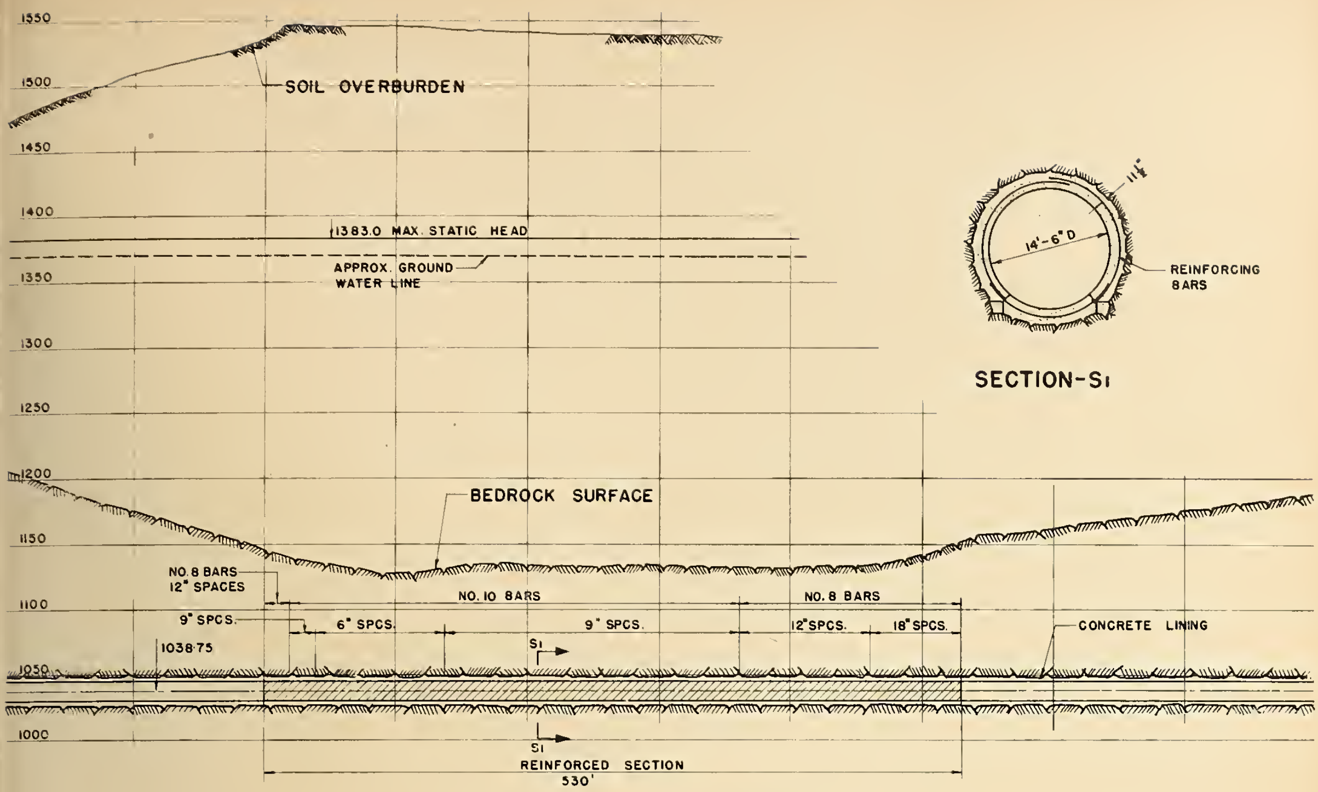


Fig. 3—Profile rock depression area.

of a uniform external ground water pressure. Where the surface profile fell below the internal pressure gradient, as when nearing the downstream end of the tunnel, the external pressure could reasonably be expected to conform to the usual assumption of being equivalent to the head to ground level. Tests conducted at Aguasabon had generally confirmed the validity of this approach. It also appeared reasonable where the ground profile was above the internal pressure gradient, to use the head to actual ground water level. While this condition prevailed over a considerable distance near the middle of the tunnel, the generally pervious nature of the overburden and the fact that the tunnel follows along the edge of the river valley suggested that the effective ground water levels would be considerably below surface grade. Under the circumstances it appeared probable that the external pressure would not exceed the internal pressure in the tunnel. This condition was known to occur at the intake by virtue of lake levels and by actual measurement of ground water levels at the depression area. An equivalent external pressure condition could occur at any point along the tunnel where the surrounding rock was tight enough to prevent relief of pressure resulting from long term seepage through the liner.

This assumption was accordingly used, resulting in the selection of an average liner thickness of 18 in., with a minimum allowable thickness of any point of 13 in. Average compressive stresses in the liner would be in the order of 1100 p.s.i. under the conditions assumed, reaching a possible maximum of approximately 1500 p.s.i. in the unlikely event of extreme ground water levels. A liner of this thickness would be adequate to carry any rock loads likely to result from local loosening of the rock at the soffit in severely jointed areas.[4]

This thickness agrees closely with existing tunnel installations of similar size and offered the prospect of convenient concrete placing. It also permitted the use of reasonable grouting pressures and appeared to provide sufficient depth for the installation of hoop reinforcing steel wherever required without unduly upsetting concreting methods, although later experience proved this expectation to be somewhat optimistic. Since the same considerations applied to virtually the entire length of tunnel, as well as the intake and surge shafts, it was convenient to use the same thickness throughout.

The plain concrete liner, while satisfactory for external pressures, could only be used where the depth of rock cover was adequate to fully resist internal tunnel pressures. The design of the tunnel for internal pressure was essentially a matter of assessing the degree to which the rock could be relied upon to fulfill this function.

Use of Cover—Theoretical Considerations

Various theories have been advanced over the years in an effort to explain the behavior of rock around open tunnels and pressure conduits under different conditions of loading. Recent trends in this respect which are described in a comprehensive survey by Jaeger[5] illustrate the increasing importance being attached to the state of stress naturally existing in the rock. Terzaghi and Richart[6], for example, have shown that the ratio between the vertical and horizontal compressive stresses which exist in the rock by virtue of its weight and geological origin have a major effect on the distribution of stresses around the empty tunnel opening. Their analysis indicates that where the natural horizontal stresses are less than 1/3 of the vertical in magnitude, tensile tangential stresses will be induced at the soffit.

A number of methods based on theoretical elasticity have been proposed for the analysis of rock behavior in conjunction with steel lined pressure conduits [7, 8, 9]. The generally favored approach consists of treating the rock surrounding a circular tunnel as a thick-walled cylinder concentric with the tunnel, its internal radius that of the bore and its outside radius equal to the shortest distance to rock surface. Hydraulic pressure inside the tunnel induces compressive radial and tensile tangential stresses in the surrounding rock which, according to theory, are a maximum and equal in magnitude to the pressure at the inside face, and which decrease radially in proportion to some function of their distance from the centre of the tunnel. These superimpose on the natural compressive stress field in the rock and its altered local distribution around the bore to establish the final stress pattern. This usually results in the existence of a tensile or "cracked" zone immediately around the opening, the extent of which is determined by the relative magnitude of the stresses involved.

Providing sufficient depth of cover is available, this zone will be enclosed within an area in which all stresses are compressive and which may be assumed to behave elastically as a thick-walled cylinder of somewhat increased internal radius.

Varying results are possible, depending on the ability of the rock to take tension. Rock tensile strengths are low, however, and frequently assumed to be nil because of jointing. In such cases its ability to take tension is limited to the amount of compressive prestress present. A plain concrete liner is commonly assumed to behave in the same manner as the rock by virtue of the similarity in their properties.

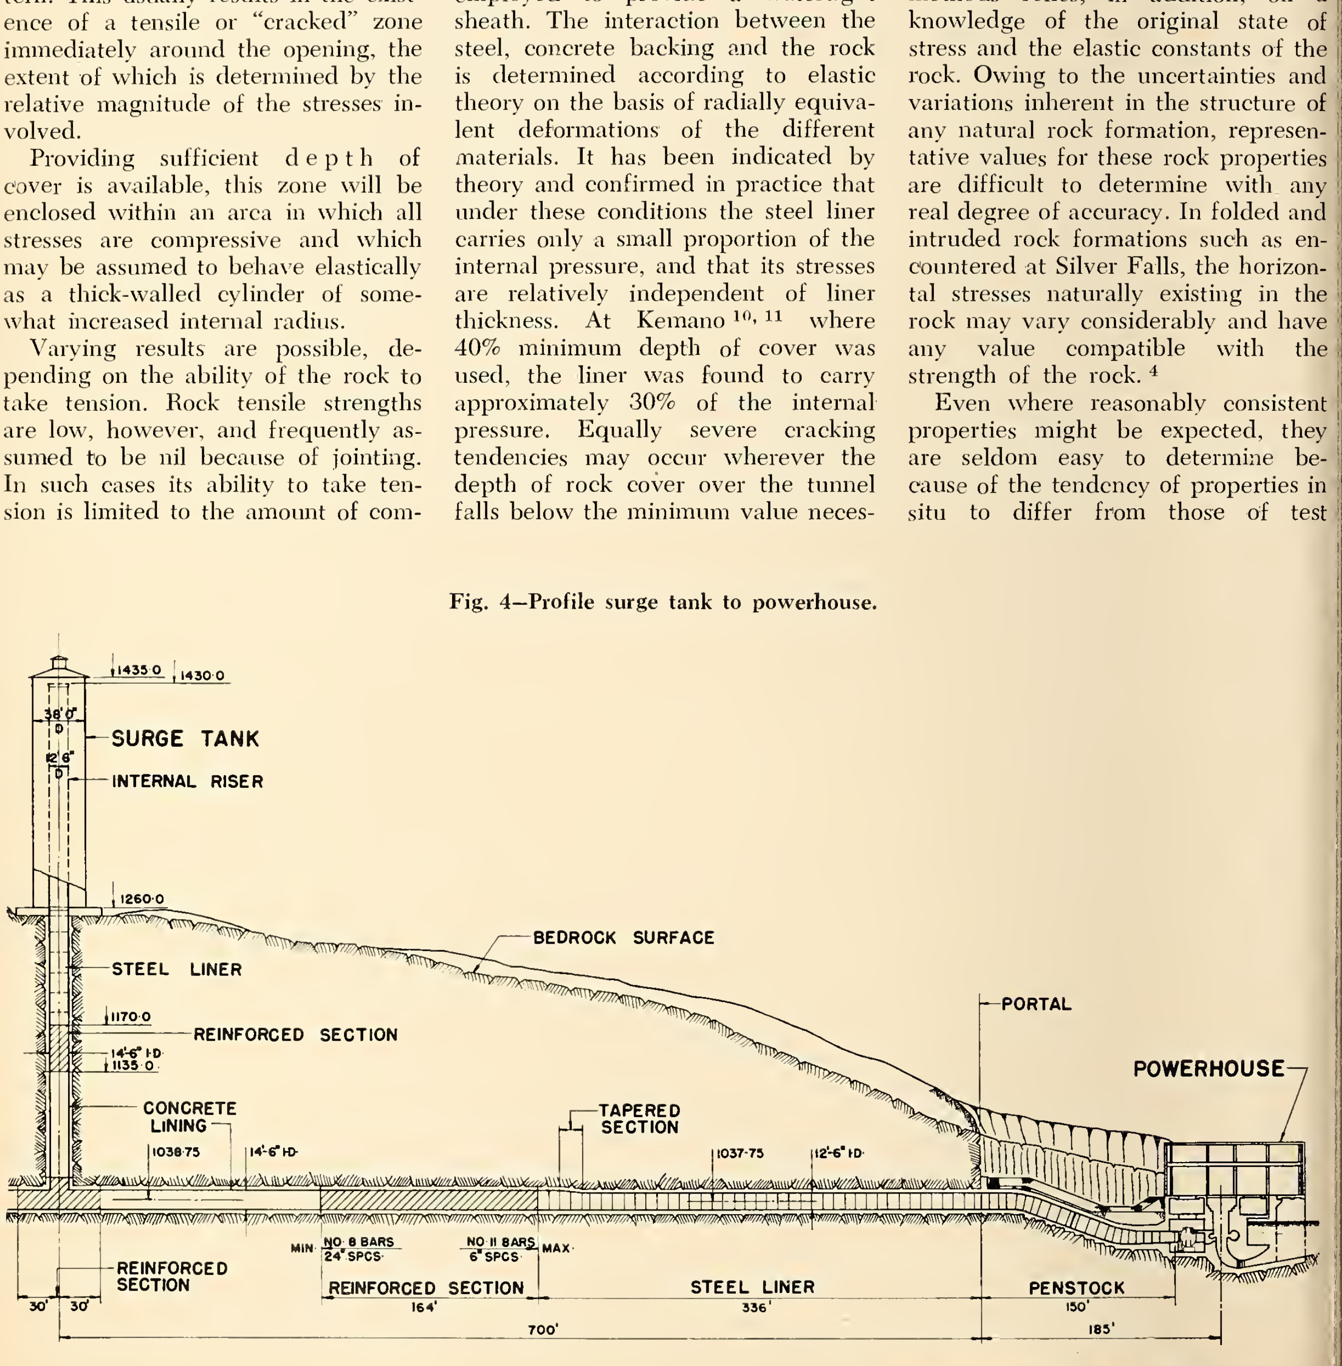
Where the resultant tangential stresses around the circumference of the tunnel are only slightly tensile or entirely compressive, and the rock is tight and otherwise of good quality, an unlined or plain concrete lined tunnel would appear to be satisfactory. With higher heads, however, even where adequate depth of cover to resist heave is present, the cracking tendency induced by the tensile stresses around the opening may be severe enough to warrant concern about leakage, particularly if the rock is of poorer quality or heavily jointed. In such cases a steel liner is usually employed to provide a watertight sheath. The interaction between the steel, concrete backing and the rock is determined according to elastic theory on the basis of radially equivalent deformations of the different materials. It has been indicated by theory and confirmed in practice that under these conditions the steel liner carries only a small proportion of the internal pressure, and that its stresses are relatively independent of liner thickness. At Kemano [10, 11] where 40% minimum depth of cover was used, the liner was found to carry approximately 30% of the internal pressure. Equally severe cracking tendencies may occur wherever the depth of rock cover over the tunnel falls below the minimum value necessary to prevent heaving. the steel liner in such cases being used to augment the strength of the rock as well as to prevent leakage. Assuming normal conditions wherein the natural horizontal stresses are usually less than the vertical stresses in the rock, the cracking tendency will be most pronounced at the tunnel roof.

While the theoretical methods are helpful in offering an improved understanding of rock behavior, there does not as yet appear to be sufficient knowledge available to accurately relate them to reliable safety factors in actual practice. There is reason to believe, for instance, that the cracking tendencies suggested by the theoretical tensile stresses might not be as critical as originally expected.

The successful application of these methods relies, in addition, on a knowledge of the original state of stress and the elastic constants of the rock. Owing to the uncertainties and variations inherent in the structure of any natural rock formation, representative values for these rock properties are difficult to determine with any real degree of accuracy. In folded and intruded rock formations such as encountered at Silver Falls, the horizontal stresses naturally existing in the rock may vary considerably and have any value compatible with the strength of the rock. [4]

Even where reasonably consistent properties might be expected, they are seldom easy to determine because of the tendency of properties in situ to differ from those of test

Fig. 4—Profile surge tank to powerhouse.



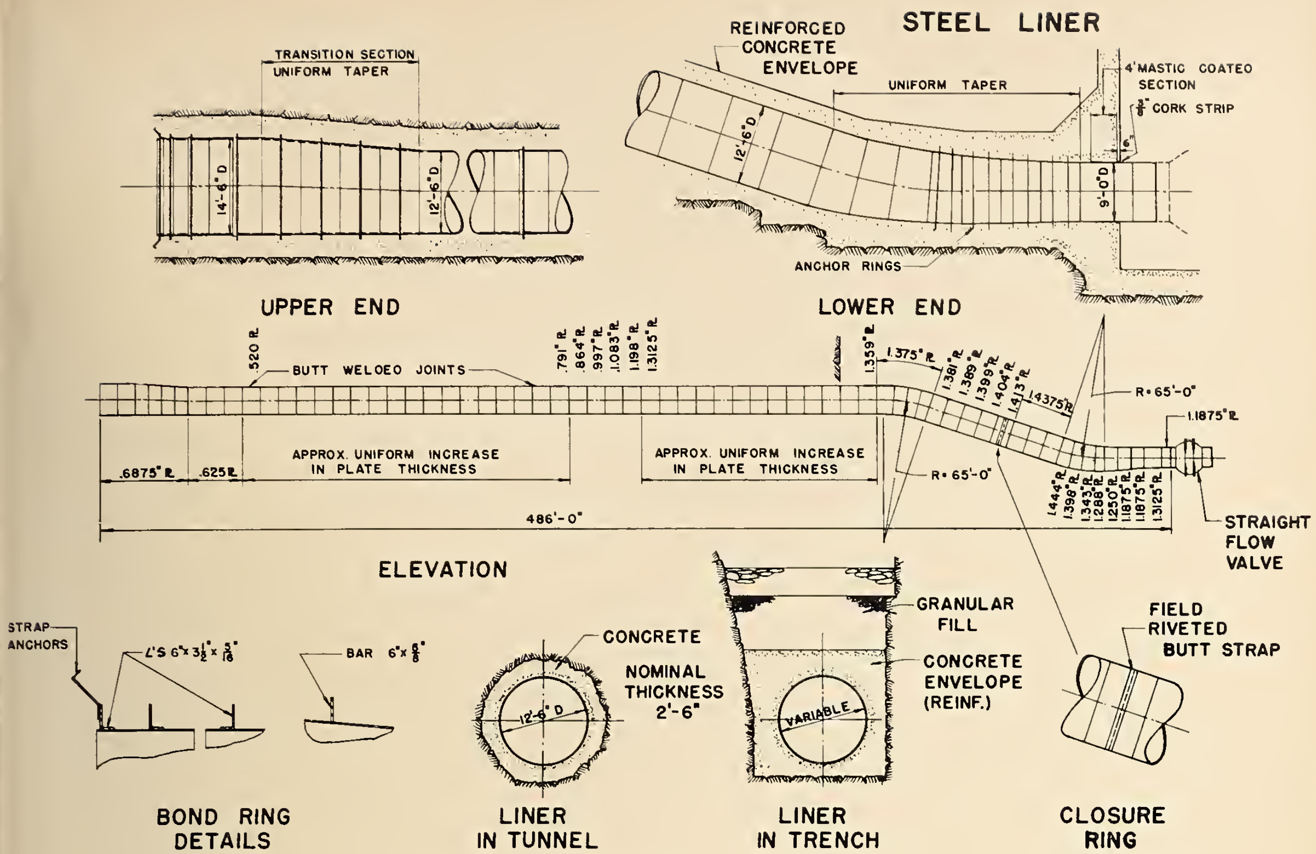


Fig. 5.

samples. The modulus of elasticity of rock in situ, for example, is invariably lower than that obtained from core tests, the elastic behavior usually also being preceded by a range of plastic deformation. These elastic properties can only be satisfactorily determined by conducting field tests in situ. A steel test cylinder or sphere grouted into an opening excavated at the desired test location is usually used for this purpose.

As a result of such limitations, it is usually necessary in tunnel design to resort to empirical rules and criteria derived from past experience. In addition to the scheduling difficulties which would have ensued, the use of elaborate test procedures were felt to be economically impractical for a project as small in scope as Silver Falls, particularly when directly comparable and proven empirical relationships were available from previous experience at the Aguasabon development.

Use of Cover—Empirical Methods

Values used for the minimum depth of cover necessary to safely resist internal pressures in unlined or plain concrete lined tunnels have shown a considerable variation in practice. One authority [12] recommends the general rule that the minimum depth of cover to ground surface should not be less than 70% of the maximum internal pressure head. Minimum cover of 50% has been frequently used, in some cases being assumed to apply to the combined depth of rock and overburden [13], and in others to the rock cover alone. In some instances even lower values have been used with success. [14]

It is generally agreed, however, that the depth of rock overlying the tunnel should be at least equal in weight to the maximum internal pressure. This is most commonly taken in the form of a vertical prism extending from the roof of the tunnel to the rock surface, its base equal to the tunnel bore in width. With this concept the shearing resistance offered by the rock at the sides of the prism is assumed to provide the necessary safety factor against rock heave. Variations of this have been obtained by flaring the sides of the prism outward to either side of vertical from the base. The minimum cover requirement at Aquasabon, for example, was established using a flare of 7°, and flare values as high as 30° are believed to have been successfully used in sound rock.

The depth of cover obtained by this means will vary with the amount of flare used, the specific gravity of the rock, and with such allowances as may be judged necessary by virtue of its character and quality. In view of the satisfactory results obtained using this method at Aguasabon under comparable conditions of rock, tunnel size and head, a similar approach appeared to be suitable for Silver Falls. Assuming an average weight of 170 lb. cu. ft. for the typical paragneiss and granite at Silver Falls, use of the vertical prism would result in a minimum cover requirement of 37%.

Concrete Lined Tunnel—Internal Pressure

When compared with existing pressure tunnel installations which range in head anywhere from an undetermined minimum to a maximum of 2600 ft., the 350 ft. head at Silver Falls may be considered to be fairly low. Although steel liners have been used with even lower heads, particularly in Europe, past experience with heads of this order has indicated that where a good quality of rock is available, a plain concrete liner is usually satisfactory. The plain concrete liner used at Aguasabon, for instance, has shown no sign of distress or leakage under similar conditions during its 12 years of service.

This would indicate that the theoretical tangential tensile stress of approximately 150 p.s.i. which would be induced at the inside face of the liner by an internal pressure of the same magnitude (max. static head), is not sufficient when taken in conjunction with the previously existing stresses to cause cracking severe enough to permit leakage of any consequence. This is no doubt due in part to the effect of pressure grouting which, in addition to applying an initial compressive pre-stress to the liner, also increases the modulus of elasticity of the surrounding rock, thereby reducing the radial deformations and cracking tendencies caused by internal pressure. The grouting would also help to counteract the formation of transverse cracks resulting from Poisson's ratio effect under internal pressure. With the use of proper grouting, there was little need to hesitate, therefore, in using the plain concrete liner to resist internal pressures wherever adequate depth of cover was available.

At the intake shaft and immediately adjacent sections of tunnel as shown in Fig. 2, external ground water pressures would likely be equal or nearly so to the internal pressure head at all times by reason of their position so close to the lake, barring the unlikely existence of local pervious or drainage zones in the rock which would provide relief. The conduit is, therefore, virtually in a state of hydraulic equilibrium with the rock stresses essentially those resulting from excavation of the opening. Ignoring the dewatered state, this condition is, in a sense, ideal for a hydraulic conduit since the internal pressure does not impose additional stresses on the rock, and the small differential between internal and external pressures gives little incentive for leakage.

The depth of rock cover along the tunnel is well in excess of the adopted minimum requirement of 37% except at the depression area and when approaching the portal. At the depression area, there was some concern that despite the generous amount of overburden, alternate filling and dewatering of the tunnel over a period of time might result in the formation of sufficient cracks and fissures in the liner and rock to create a leakage hazard, particularly in view of the low ground water levels possible at this point. The ability of the overburden to resist heave at its line of contact with the rock was likely to be uncertain due to local variations in the nature of the material and the very irregular nature of the rock surface. In order to protect against this possibility the liner was provided with reinforcing in the area where the rock cover fell below the minimum depth requirement as shown in Fig. 3. This was nominally proportioned to carry the balance of internal pressure remaining after deducting the weight of rock cover obtained with 7° flare from the maximum static pressure head. This rationalization resulted in a single layer of hoop steel varying in approximate inverse proportion to the amount of rock cover. The use of reinforcing at this point was felt to be preferable to a steel liner since it would not be subject to the same excessive external pressure requirements, and would be easier to install. While not watertight in the sense of a steel liner, it would reduce the amount of load carried by the rock and help to prevent leakage by resisting the tendency of the liner to form open tensile cracks under pressure. It could also be expected to increase the ability of the liner to resist point failure in small local areas of inadequate rock support.

As a result of the gentle bedrock slopes prevailing over the entire length of the tunnel, there was no need for concern about the depth of rock cover in directions other than vertical.

Tunnel—Steel Lined Section

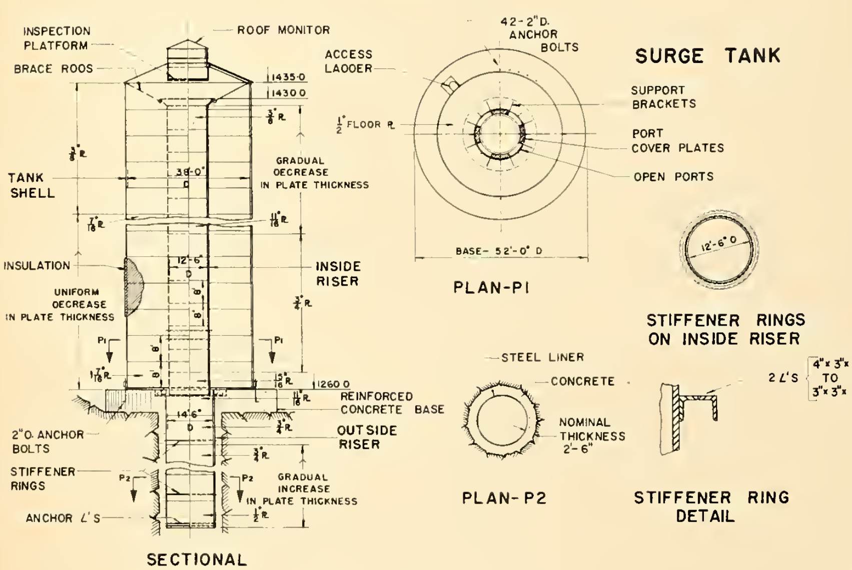
Where the diminishing rock cover approaching the portal fell below the minimum value estimated necessary to sustain full internal pressure, a welded steel liner was used in conjunction with hoop reinforcing to effect a progressive transition to the surface. In addition to carrying internal pressure loads, the liner serves as a waterproof membrane to prevent leakage through joints in the shallow cover near the portal, and for this reason alone, would be extended far enough into the tunnel to ensure fairly tight rock conditions. A liberal factor of safety was desirable in this area in order to avoid seepage which might have an unstabilizing effect on sidehill overburden adjacent to the powerhouse and transformer area.

There is some question as to the proper hydraulic load to use for the design of a pressure conduit in rock. It is felt in some quarters that because of the inertial effect of the rock cover, the pressure rise due to water hammer may be ignored in view of its short duration. This consideration would also apply, although with less justification, to the pressures resulting from mass oscillations of the surge system. The design in such cases would be based on the maximum sustained load represented by the maximum static head. Owing to the critical nature of the portal area, however it was decided to adopt the more conservative approach and to use the maximum internal pressure head including water hammer effect as shown on Fig. 7.

In the absence of reliable information on the elastic properties of the rock, the steel liner and reinforcing were proportioned on an empirical basis using normal working stresses in the steel. It was assumed that the reduced rock cover would contribute toward the support of internal pressure in proportion to its weight as determined by vertical prism, the steel being assumed to carry the balance.

No support was considered from the rock for the first 80 ft. upstream from the portal because of possible weakening effects from heavy blasting at the portal face. The steel liner

Fig. 6.



n this area was accordingly propor-ioned to carry the full internal pres-ure head. This was followed by a ransition zone 40 ft. long in which teel liner thickness could be de-reased in convenient increments to he value required after full allow-ance for rock support. From this point he internal pressure design head for he steel liner and reinforcing was ssumed to decrease in inverse pro-portion to the depth of cover, be-coming nil at the point where rock cover reached the 37% minimum lepth requirement of the concrete ined tunnel. The steel liner was ex-ended with decreasing thickness up o a point where buckling require-ments due to increasing external pres-ure began to dictate an increase, the xternal pressure head being taken equal to the head to ground surface. As the liner at this point had ex-ended into sound rock far enough to provide adequate seepage protection, hoop reinforcing steel was used in its place for the remainder of the dis-tance in order to avoid the additional requirements of external pressure. The resulting arrangement is shown n Fig. 4.

Using yield stresses and ignoring he pressure rise due to water ham-mer effect, the liner as determined would be capable of carrying the in-ernal pressure head due to mass oscillations of the surge system with-out assistance from rock cover in the area where it dropped below 37% of the assumed internal pressure head.

The liner was checked for buckling under external pressure in accordance with the revised theory of Amstutz,[15] assuming a gap between liner and concrete backing equal to three ten thousandths of the radius. For the 12 ft. 6 in. diameter of liner this would be equivalent to .022 in. The gap would occur initially as a result of the temperature and shrinkage effects due to concrete curing, and would be later increased by the cool-ing effect of the water on the liner and the subsequent plastic deforma-ion of the concrete and rock under oad.

While pressure relief drains, liner stiffeners, and anchors of various kinds have been used with thin plate iners to counteract the effects of external pressure, none of these alter-natives were felt to be particularly suitable for use at Silver Falls. Past experience with relief drains has shown them in many cases to be un-reliable, and the liner anchors and stiffeners invariably present difficul-ties during erection and concreting. Where the liner was not required for watertightness, therefore, the use of reinforcing appeared to be the most attractive alternative.

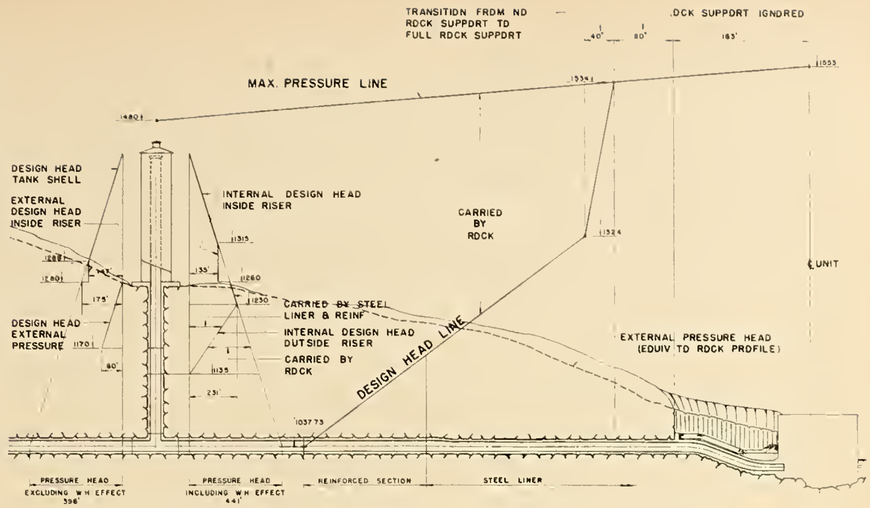


Fig. 7—Design Load assumptions; surge tank, tunnel liner, penstock.

The reinforcing was provided in a single layer of hoop steel in a manner similar to the depression area. This varied in spacing from a minimum of 6 in. at the liner to 24 in. at its termination. At the junction with the liner, fairly heavy longitudinal rein-forcement was used in conjunction with the hoop steel to provide a suit-able transition and overlap with the steel liner in order to reduce the danger of transverse cracking at this point. The steel for each hoop was provided in three lengths with lap splices on either side of the invert and at the crown.

Economic studies had resulted in the selection of a uniform 12 ft. 6 in. diameter for the steel liner and pen-stock. The change from the 14 ft. 6 in. diameter of the concrete lined tunnel to the 12 ft. 6 in. steel liner was accomplished by means of a tapered steel section incorporated into the upstream end of the liner, the in-vert being kept at the same level as that of the tunnel for drainage pur-poses as indicated on Fig. 5. The steel plate thickness varies from a maximum of 1.35 in. at the portal to a minimum thickness of .625 in. near the upstream end. Circumferential bond rings formed from 6 in. by 3 in. angles were located in the middle of each liner ring to provide better in-tegration of the liner with the 30 in. thick concrete backing. At the up-stream end, two anchor rings of similar material were attached to strengthen and anchor the end of the liner plate into the concrete assisted by strap anchors. Screw type counter-sunk plugs 2½ in. in diameter were provided at the crown in a pattern suitable for later use for pressure grouting.

Penstock

Being essentially a continuation of the steel liner in the tunnel, the pen-stock design was based on the same hydraulic requirements (Fig. 7) and was proportioned to resist the full maximum internal pressure at normal working stresses. As shown in Fig. 5, the uniform 12 ft. 6 in. diameter is continued from the portal around a 65 ft. radius upper elbow and down the slope to the beginning of a tapered lower elbow of the same radius, re-ducing to 9 ft. diameter at the up-stream wall of the powerhouse where connection is made to a straight flow valve of the same diameter. The tapered elbow was preferred because of its lower head losses and the im-proved flow characteristics which would be provided at the entry to the scroll case. Elbow radii were similarly selected with a view to minimizing hydraulic losses.

Since construction schedule require-ments dictated the erection of the penstock and liner from both ends toward the middle, a riveted closure section was provided in the sloping section to permit final adjustment of alignment and a stress-free final closure. This consisted of two sec-tions joined together by a butt strap which was field riveted after both sections had been welded to the ad-jacent sections of penstock.

At its downstream end the penstock is used to carry the full thrust result-ing from valve closure, a dresser coupling being used to provide the connection between the valve and the scroll case. This was preferable to transmitting valve forces into the scroll case because of the more favor-able combined stresses obtained by a tension connection. In addition to internal pressure and thrust loads, the penstock section immediately upstream of the valve was called upon to absorb residual eccentric forces from valve operating equipment which could not be completely absorbed by the anchor bolts securing the valve to its slip plate foundation. The effect of the thrust and eccentric loads due to valve operation was fortunately mitigated by the fact that the pressure rise which would result during its slow rate of closure would not be as severe as the maximum pressure rise resulting from rapid unit shut down shown on Fig. 7.

In the case either of valve operation, or of unit closure, the stresses resulting therefrom would be further aggravated by the behaviour of the penstock at its point of emergence from the concrete wall into the valve chamber. The tendency of the liner to expand upon release at the face induces additional stresses which often dictate the use of a thicker plate.[16] At Silver Falls, an effort was made to reduce the severity of this phenomenon by encouraging a more gradual or "two stage" transition from the fully confined to the unconfined state. This was done by coating a 4 ft. length of the penstock with a thickness of compressible ground cork mastic calculated to permit one half of the total expansion as illustrated on Fig. 5. A 6 in. cork band at the wall face was used both as a plug and a cushion to prevent failure and spalling of concrete at the face.

Stress analyses based on the foregoing resulted in the selection of a penstock section 1.312 in. thick extending a short distance upstream beyond the affected area. The remainder of the plate thicknesses in the penstock area range from a maximum of 1.444 in. to a minimum of 1.187 in. depending on variations in head and diameter. Anchor rings welded to the horizontal tapering penstock section downstream of the lower elbow were designed to transfer the maximum value of valve thrust into the surrounding concrete envelope, which in turn was longitudinally reinforced to recruit enough mass to prevent the possibility of movement.

The exposed penstock between the powerhouse and the portal was enclosed in a nominally reinforced concrete envelope following normal practice. In view of the possibility of rockfalls from the high vertical faces of the penstock trench and portal, the envelope was provided with a granular cover of 8 ft. minimum thickness designed to act as cushion against impact. At the downstream end this was fashioned in the form of a trap to prevent damage to the powerhouse from runaway boulders.

Surge Tank

Because of the length of the hydraulic conduit, it was essential to provide some means for the relief of excessive pressures which would result from sudden changes in load on the unit. While a pressure regulator might have served this purpose, the operating requirements of this station in the power network dictated the use of a differential surge tank which would allow full load rejection and full load demand based on an effective governor time of 4 sec. for both closure and opening over the full range of gate movement. With this type of arrangement, it was axiomatic that the surge tank should be as close to the powerhouse as possible in order to keep transient values of pressure rise in the turbine spiral casing and adjoining steel conduit down to a minimum.

Using preliminary tank dimensions obtained by Johnson's equations, economic comparisons were made of a range of tank positions taking into account the effect of consequent pressure rise changes on the steel liner and penstock. These comparisons indicated that optimum economic advantage of the various factors involved would be provided by a position 885 ft. upstream from the powerhouse as indicated on Fig. 4.

With the location fixed, final tank dimensions and operation were confirmed by the arithmetic integration method using an electronic computor. Design studies indicated that both the standpipe and elevated types of tank were equally feasible at this location. It appeared possible, however, that although the elevated tank would require a lesser quantity of steel than the standpipe, its greater complexity of fabrication and use of structural shapes might make it the more expensive alternative. This was later proved to be the case, the standpipe tank eventually being selected on the basis of its cost advantage.

The tank is an all welded structure and in its final form, as indicated on Figs. 4 and 6, has a 38 ft. diameter outer shell enclosing a 12 ft. 6 in. diameter inside riser. A 14 ft. 6 in. outside riser or steel liner extends 90 ft. down into the surge shaft. The tank bottom follows standard standpipe practice in the use of a 1 in. sand cushion under the ½ in. floor plate. This is enclosed around the outer edge by a ring of drypack which also serves to provide firm support for the tank shell.

The annular ring between the inside and outside risers provides a total port area equal to approximately 25% of conduit area which is divided into eight equal sections by the vertical steel plate brackets supporting the inside riser. The use of removable port covers in these sections permits any necessary adjustments of the port area. Initial computations indicated that a port area of approximately 14% was desirable.

A wind load of 35 p.s.f. was assumed to act on the projected area of the tank, but was not found to have a serious effect on stability. Around its perimeter the tank shell is anchored into the 7 ft. reinforced concrete base by anchor bolts attaching to brackets welded to the tank shell near the bottom. The entire weight of the inside riser is carried by the support brackets into the concrete base. A careful construction sequence was followed during erection to prevent damage to the final seal weld at the junction of the tank floor and the brackets. It was assumed that the rotational forces produced by bracket eccentricity would be fully carried by the bottom ring of the riser, vertical stiffener beams being provided on the inside opposite each bracket as additional reinforcement for this purpose.

The hydraulic loads used for the design of the tank are shown on Fig. 7. The inside riser is subjected to both internal and external loads as a result of the differential levels occurring during operation. Maximum differentials for both conditions were obtained assuming the worst combination of port area and operating sequence. In view of its high slenderness ratio of approximately 14:1 and the unknown effects of vibration encountered under certain conditions, somewhat higher differentials were arbitrarily assumed for design, and as an added safety factor, were assumed to occur from the top of the tank. As shown on Fig. 6, circular stiffeners were used along the riser to provide the necessary resistance to external pressures. The internal design head on the inside and outside risers included the effect of pressure rise due to water hammer which was assumed to diminish uniformly in its course along the conduit and up the surge shaft from a maximum at the unit to zero at the top of the tank.

The outside riser and reinforcing were extended 125 ft. down the shaft to El. 1135 where the weight of the rock cover would equal the internal pressure in order to reduce the possibility of rock uplift due to seepage. In view of the relatively flat slopes of the surrounding surface, it was estimated that, the rock below this point would be adequate to sustain the horizontal forces from internal pressure without assistance. Horizontal rock support was ignored for a distance of 30 ft. below tank bottom due to excavation effect in the more heavily jointed surface layers. Below this point the rock was assumed to contribute lateral support directly in proportion to its depth until wholly sustaining at the 1135 elevation. Reinforcing was substituted for the liner at the 90 ft. point where external pressure began to govern liner thickness. The junction of the surge shaft with the tunnel required substantial reinforcement against external pressure owing to its unsymmetrical shape.

Steel Design & Fabrication

The surge tank together with the steel liner and penstock were designed and fabricated to virtually identical requirements and specifications using ASTM A201 Grade A Flange Quality steel plate throughout for all load bearing plate surfaces. This steel was selected because of its ductility and good weld-ability as confirmed by satisfactory experience with previous penstock installations, and because of its favorable brittle fracture characteristics at low temperatures.

Normal working stresses of 15,000 p.s.i. in tension and 20,000 p.s.i. in compression were used for the plate, the former in conjunction with an allowable joint efficiency of 85% for all butt welded joints. A corrosion allowance of 1/16 in. was included in the thickness of all water containing plate except the floor plate of the tank and where stipulated minimum thickness values exceeded design requirements.

Welding in the field was carried out using the shielded metal arc process and in the shop by the automatic submerged arc process. Plates in excess of 1 in. thickness were preheated to 300-400° F before welding. All butt welded joints were stress relieved by the Linde Low Temperature stress relieving process and radiographed 100% to check for defects.

The penstock and liner and the surge tank outside and inside risers were shop welded into rings for shipment to the site, some rings of the inside riser also being shop welded together for shipment. The remainder of the joints were welded in the field. The 30 in. thickness of concrete backing in the steel lined sections of the tunnel and surge shaft originated mainly from the need to allow the necessary access for welding and radiographing of the circumferential joints.

Grouting

The grouting of the concrete-lined sections of the tunnel and shafts was carried out in two stages, the first being a low pressure operation at pressures up to 100 p.s.i. intended mainly to fill the voids left around the lining during concreting and the second later at higher pressures of 150 p.s.i. or over for the purpose of filling smaller voids and any fissures or cracks occurring in the rock and concrete liner.

The magnitude of the compressive stresses produced in the concrete lining by the final grouting will depend to some extent on the distribution of the grouting pressures around the outside of the liner and in particular on the amount of pressure release or drop following disconnection of the pump. The creep of the grout would also contribute to a reduction. It is usually considered therefore that final compressive stresses would be reduced to about 50% of those occurring during grouting. In the present case, ideal grouting at 150 p.s.i. would produce initial compressive stresses in the liner of approximately 900 p.s.i. which, according to this assumption, would provide final compressive stresses of approximately 400 p.s.i. This being considerably in excess of the theoretical tensile tangential stresses likely to be induced at the inside face of the liner, it may be concluded that the grouting pressures used would offer reasonable assurance against the possibility of tensile cracks in the liner.

In the steel lined section of the surge shaft as well as that of the tunnel, grouting behind the steel liner was carried out by means of the screw type plugs previously mentioned, using reduced pressures well below the buckling capacity of the liner. Grouting pressures in the surge shaft were further reduced approaching the surface to prevent uplift of surface layers of rock.

Conclusions

It is likely that pressure tunnel design will continue to rely heavily on empirical relationships from past experience until such time as some of the present obstacles in the way of more rigorous theoretical analysis are overcome. Due to the uncertainties involved in dealing with geological factors, the methods must of necessity be fairly conservative. The design at Silver Falls illustrates the application of one such approach to the conditions of a particular project site with satisfactory results.

AT SILVER FALLS GENERATING STATION

Concrete Tunnel Lining

Little Dog Lake and Big Dog Lake were connected by a 10,000 foot horizontal tunnel to take advantage of the elevation difference. Associated with the tunnel were two vertical shafts, and a surge shaft joined to the tunnel. Discussed are the concreting problems.

H. A. Jackson, M.E.I.C.,
Construction Manager, Thunder Bay Generating Station, Hydro-Electric Power Commission of Ontario, Fort William.

C. T. Bath,
Office Engineer, Thunder Bay G.S. Hydro-Electrical Power Commission of Ontario, Fort William.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

AT SILVER FALLS G.S. a 10,000 ft. horizontal tunnel was driven between Little Dog Lake and Big Dog Lake to by-pass a series of rapids and take advantage of the 350 ft. difference in the elevation of the two lakes in operating a 62,000 hp. turbine in a single unit powerhouse at Little Dog Lake. (Fig. 1).

Associated with the tunnel were two vertical shafts, (A) intake shaft approximately 300 ft. deep with a 90° elbow at the bottom and a 90° elbow and transition section at the top; and (B) surge shaft approximately 200 ft. deep and joined to the tunnel by a reinforced concrete "T" section.

The tunnel and shafts were concreted throughout. Variations from plain concrete were as follows: (Fig. 2.)

1) 336 lineal ft. of steel liner at the powerhouse or portal end, i.e., station 20+00 to 23+36.

2) 174 lineal ft. of reinforced concrete adjoining the steel liner, i.e., station 23+26 to 25+00.

3) 60 lineal ft. of reinforced concrete at the "T" junction with the surge shaft, i.e., station 26+70 to 27+30.

4) 530 lineal ft. of reinforced concrete at the "depression area" where there was rock cover of only 50 ft., i.e., station 100+70 to 106+00.

5) Reinforcing in intake shaft bottom elbow.

6) Reinforcing in intake shaft upper elbow.

7) Reinforcing in surge shaft.

8) 84 lineal ft. of steel liner in the

ɪp portion of the surge shaft.

The tunnel was driven to a nominal iameter of 17 ft. 6 in. and lined with 8 in. of concrete, providing a finhed diameter of 14 ft. 6 in.

The concreting operation was cared out in three distinct operations. ig. 3.)

1) Curbs—starting at the portal nd working in.

2) Invert—starting at the portal nd working in.

3) Arch—starting at the intake and orking out.

Because of the tight schedule in ne tunnel driving and concreting, was decided that the concrete opertion must start while the tunnel riving was in progress. The contruction schedule for the plain conrete allowed 12 weeks for pouring ne curbs, 6 weeks for the invert, and 0 weeks for the arch.

urbs

The work on the curbs started at ne portal when the tunnel driving ad reached the 8,200 ft. mark. The xcavation for the curbs was carried ut by a small gas driven rubber tire ackhoe, complete with scrubber, oading directly into muck cars, with he final cleaning being done by and. Re-usable plywood forms 18 n. in height and in 10 ft. lengths ith steel angle supports were set ccurately to line and grade along ither side of the tunnel. Irregularities between the bottom of the form nd the rock were filled in with in. x 6 in. lumber on end. Concrete was carried into the tunnel in two gasoline driven 8 cu. yd. mixers complete with catalytic scrubber, taken from transit mix trucks and mounted on specially constructed depressed rail cars. The concrete was chuted directly into place from the mixers. Screw anchors, later used to support the invert form, were set in the concrete at 5 ft. intervals and back 6 in. from the face of the curb. As this operation was carried out while the tunnel driving was in progress, concrete could only be poured during the drilling cycle. This meant that the operation extended over a longer period of time than would normally be required. The schedule called for the curb concrete to reach the intake shortly after the tunnel excavation was completed and before the intake shaft raising was complete. This would mean a minimum of lost time between the driving and the invert and arch concreting operations.

Passing tracks were left in position at this stage and gaps were left in the curbs at approximately every third car transfer slash left after the tunnel driving. These slashes were later used for switching cars during the invert clean-up operation.

When the curbs were poured, except in the previously reinforced sections and during the raising of the intake shaft, the "tights" left after the tunnel driving were marked. This was done by a frame moving along the curbs and fitted with radial spring steel feelers. Any tight spots were painted, drilled, and blasted, concurrent with the intake shaft excavation.

Fig. 1. Aerial view showing powerhouse with Big Dog Lake in background.

Invert Clean-up

During the tunnel driving there was approximately 18 in. of loose muck left in the bottom of the tunnel as a bed for the railway track. After the "tights" were removed and the intake shaft raised, the invert was cleaned, starting from the intake and working toward the portal. The rail track was lifted by mucking machine, ties were knocked off and the rails moved on to the curbs for use later in the concreting. A bulldozer was used to push up the muck and loose ties to the mucking machine which loaded this debris in the normal manner into the 6 cu. yd. mine cars. The direction of advance for this operation was opposed to the saw tooth effect caused by the flare of the bottom drills on the jumbo in drilling a 16 ft. round.

Due to ground water leakage and poor drainage created by the flat grade of the tunnel, the bulldozer was always working in a slurry of mud ahead of the final clean-up gang. Pneumatic air syphon pumps kept this to a minimum but at times it did hamper the operation of the bulldozer.

Final clean-up of the invert was done by men with a 2 in. diameter blow pipe working under a canopy. This canopy was on double flanged wheels and was moved by airtuggers along the rails set on the curbs. The canopy afforded protection for the bulldozer operator and those removing the rails. After the invert clean-up was completed and the tunnel meticulously washed, everything was ready to start the invert concrete.

Concreting Bridge

Both invert and arch concrete was placed by a pumpcrete machine. Consideration was given to using a pressweld machine but the engineers feared excess segregation if this method was used.

While the invert clean-up was in progress a mobile bridge was assembled outside the tunnel (Fig. 4) that would carry the two double 200 pumpcrete machines; (one as a spare) a conveyor belt to carry the concrete from the concrete cars to either pumpcrete machine and a passing track to handle full and empty cars. This bridge was 250 ft. long and was used for both invert and arch placing. It was supported on double flanged wheels running on the invert rails and plain wheels running on the concrete curbs. In addi-

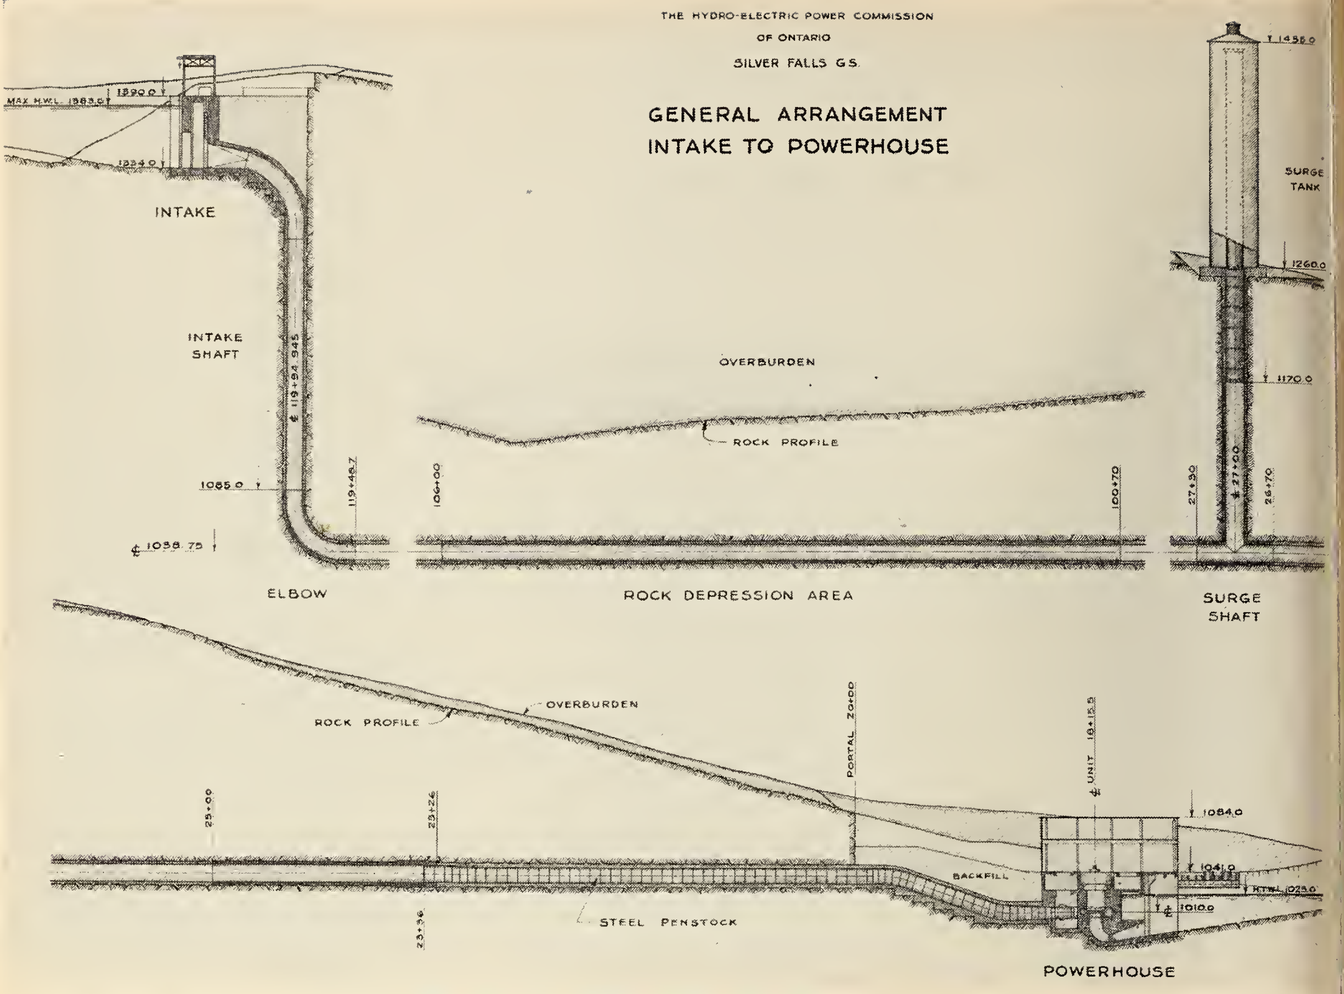

Fig. 2. Cross section of tunnel showing reinforced concrete sections.

tion to the pumpcrete machines the bridge was designed to carry a 15 ton locomotive hauling four 4 cu. yd. cars. The 12 in. diameter wheels were designed for a maximum loading of 24,000 lb. and were set 18 ft. apart. The wheels riding on the curbs were framed in two 12 in. channels, back to back, 20 ft. long. Eight inch wide flanged beams spaced at five ft. intervals along the channels formed a three span continuous support from curb to curb for the 85 lb. rail used on the bridge. An approach ramp, 50 ft. long, carried the trains up the 30 in. from the invert rails onto the bridge.

In placing the invert the concrete had to be pumped far enough ahead so that the concrete would be set up sufficiently hard to re-lay the rails on the poured invert and have them carry the weight of the pumpcrete bridge as it advanced. In order to obtain the scheduled advance of 600 ft. per day it was necessary to have a second bridge 600 ft. long ahead of the pumpcrete machines. (Fig. 5) The end nearest the machines ran on the invert rails while the leading end ran on the curb rails. This section of bridge carried the pumpcrete line and a light railway line and was high enough to clear both forms and screed as it moved along the tunnel. The steel invert forms, 200 lb. each, were removed from the curbs and with the aid of a small winch operated dolly, were loaded on the hand car. The car was then pushed to the forward end of the bridge and the forms man handled from there into their new location.

As the invert concrete hardened the rail was taken from the curb and placed on the invert on 4 in. x 6 in. ties with bevelled ends to fit the circular invert section. To make the transition of curb track loading to invert track loading, an inverted single Bailey bridge 40 ft. long was used. (Fig. 6.) The 30 ft. long rails were picked off the curb and moved into position on the invert under the Bailey bridge by means of small hand hoists attached to the Bailey.

Invert Concrete

The steel invert forms were bolted to the concrete curbs using preset screw anchors, giving a thickness of 15 in. on a radial joint between the edge of the curb and the finished 14 ft. 6 in. tunnel diameter. Twelve hundred lineal feet of forms were purchased (600 ft. each side) allowing them to remain in position 20 hours with four hours for re-positioning. The concrete was deposited in the invert by means of a swivel chute at the end of the pumpcrete line. Particular care had to be taken to ensure that the concrete was tight against the form. The invert was screeded by a 10 ft. long concrete screed riding on flanged wheels on the invert forms. It was found that the screed had to be loaded to a weight of about five tons to be sure it would not ride on top of the concrete free of the forms.

Following the steel screed were the two hand finishing platforms also running on rollers on the invert form. The invert was given a steel trowel finish. The hand finishers also placed screw anchors in the invert concrete 6 in. from the end of each 5 ft. panel, and 6 in. in from the edge. These anchors were used later to hold the arch form in place. Temporary sumps were located at 1,000 ft. intervals and where ground water seepage was occurring.

After the invert was hand finished fibre glass impregnated paper was placed on the centre section. This paper helped prevent droppings from the pumpcrete pipe and later concrete cars, from building up an objectionable roughness on the invert. Paper and droppings were removed during the final clean-up.

The complete bridge was moved ahead by an air operated hoist located at the front end of the bridge using a 1 in. two part line. A steel beam acting as a dead man was jammed between the curbs ahead of the invert forms. It was moved ahead as the work proceeded. The steel screed was either moved by a separate hoist or pulled ahead integral with the bridge. Pouring the plain concrete invert took 18 days with a maximum weekly advance of 3,660 ft.

The invert in the two reinforced sections had to be left out at this time because the reinforcing steel extended 3 ft. above the curb to provide the necessary bond length for the arch reinforcing. This reinforcing would not permit the bridge to advance. In these two sections of invert and the section at the portal where the steel liner was to be installed the rail track was cribbed up to the correct elevation.

Arch Concreting

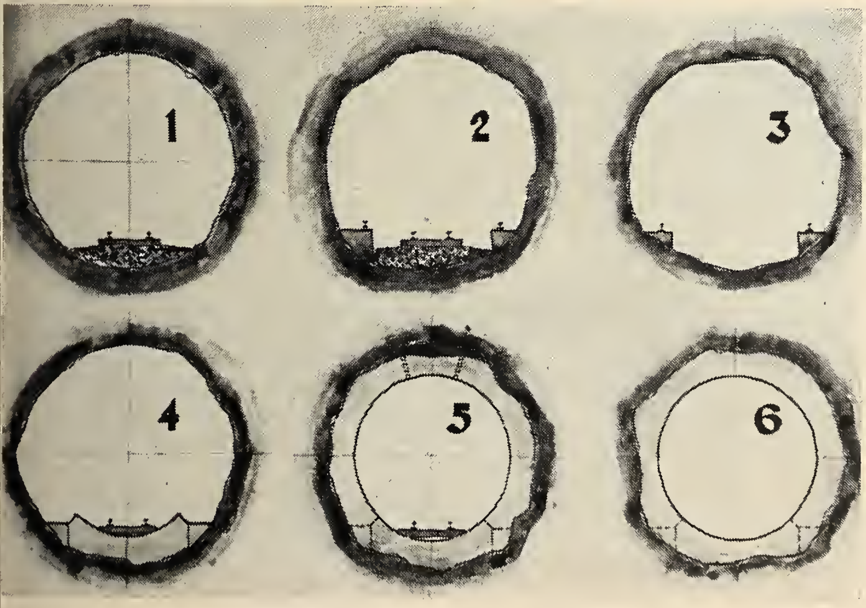
Knowing that we had to complete the arch pour in 10 weeks, a detailed engineering study was carried out to ascertain the method and type of form to be used to accomplish this in the most economical manner. The choice lay between the bulkhead method and the advancing face method. We were limited in our rate of pour to 50 cu. yd. per hour, this being the capacity of the pumpcrete machines.

In the bulkhead method pouring would be for 8 hours at 50 cu. yd. per hour producing an advance of 120 ft. down the tunnel. Steel pins in holes drilled around the rock circumference would brace the bulkhead. After the form was full the concrete would be allowed to set up for 12 hours, then the 120 ft. of form would be moved using a traveller running on the invert rails. The form would be in its new position ready for pouring before starting the next 24 hour period. This would give a daily advance of 120 ft., or 13 weeks to complete the plain concrete section. This method would mean the construction of 78 bulkheads and two shifts involved would only work 12 out of every 16 hours. This would mean paying the men's wages for four hours with very little return.

In the advancing face method, telescoping forms would be used and the pour would run continuously throughout the week with only a shutdown for Sundays. Based on the capacity of the pumps, we could attain a theoretical advance of 360 ft. per day and complete the arch in five weeks. Allowing the concrete to set up for 12 hours as in the bulkhead method, we would have to purchase 300 ft. of telescoping forms. Considering the economics and time allowed, the decision was made to use telescoping forms but only purchase 200 ft. and cut our rate of pour down to approximately 40 cu. yd. per hour.

On completion of the invert concrete, except the sections noted, the forward portion of the bridge ahead of the pumpcrete machine was taken out through the intake shaft and replaced with the arch forms and traveller.

Fig. 3. Tunnel sections showing concreting sequence.



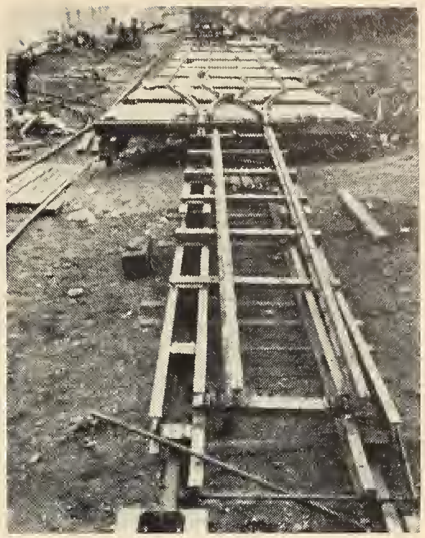


Fig. 4. Concreting bridge assembly showing approach ramp and passing tracks.

The steel arch forms were made up of panels 5 ft. wide with five panels bolted together to make a 25 ft. unit. The panels consisted of one-quarter inch skin plate on steel ribs hinged 6 ft. either side of the centre line so the units could be collapsed and telescoped through the others still in position. To allow for inspection of the sides, trap doors, 18 in. x 24 in. were located 4 ft. above the curb at 10 ft intervals on both sides of the form. To inspect the crown the trap doors were located on alternate sides of the centre line and at 5 ft. intervals. Provision was made in the panels for grout pipe connections.

The traveller used to move the 25 ft. units ran on the invert track and was fitted with vertical and side acting hydraulic rams for aligning the form to the 14 ft. 6 in. diameter circle. (Fig. 7). These rams were independently controlled from a consol incorporated in the front of the traveller. The hydraulic pump was electrically driven and the traveller pulled along the tunnel by an air operated winch. When the forms were correctly aligned they were bolted to the invert by means of the screw anchor bolts and also bolted to the preceding form. All bolting and unbolting was done with large pneumatic wrenches.

As only 200 ft. of form (eight units) had been purchased the concrete temperature and consistency were extremely critical in the placing of the arch. Too high a slump created segregation and made the concrete run too far so that all the forms were in use before the initial unit could be stripped and brought ahead to carry

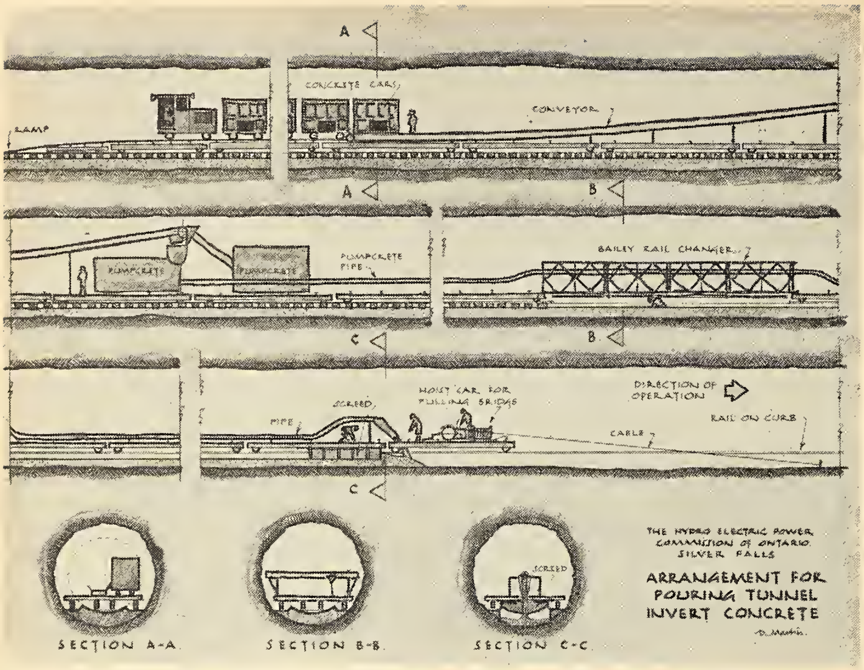

Fig. 5. Concrete bridge ahead of pumpcrete machines with hand car for moving invert forms.

on with the continuous pour. A very stiff mix, on the other hand, made it extremely difficult to force the concrete into all the irregularities of the shoulders and roof.

The pipe from the pumpcrete machine was carried on special cars high enough to support the pipe at a level between the arch form and the roof. (Fig. 8.) The last 250 ft. of line was made up of 8 in. pumpcrete pipe butt welded into a continuous length. This pipe, known as the "slick" line, is normally buried about 10 ft. in the concrete during placing. The arch concrete was started with a single slick line but was changed to a double slick line after the initial 1500 ft. had been poured. This meant there was a pumpcrete line coming off each side of the double 200 machine. Two slick lines afforded greater flexibility in filling voids and also keeping the face advancing uniformly on each side. When the pumpcrete began to labor the whole bridge was pulled ahead by the air operated hoist.

Specifications dictated that at the end of each week a bulkhead had to be set up on the end of the last form. As the arch pour progressed concrete test cylinders were made throughout the 24 hours. Results of these cylinders showed concrete strengths that would allow stripping earlier than the 12 hours specified. Setting up time was gradually decreased until eventually stripping was done after eight hours. Thus, although only 200 ft. of form was purchased, an advance of 300 ft. in 24 hours was ultimately achieved. Our average rate of production for all the plain concrete was 1,550 ft. per week. Once the organization and procedures were firmly established the most critical factor determining the rate of progress was the constant control of the concrete consistency.

The air and water lines used in driving the tunnel were supported on wall brackets and as the arch concrete progressed down the tunnel these services were re-laid on either side of the railway track on the invert. They were later required in the grouting operation.

At the start of the arch pouring we were using a seven bag mix. This produced an undesirable amount of hairline shrinkage cracks as the concrete set up. The mix was progressively dropped to a 6¼ bag, still keeping our stripping time at eight hours. The concrete for the arch left the mixing plant at an average of 64° F. Thermocouples buried 4 in. from the face showed a temperature rise after 24 hours to 90° F. for the 6¼ bag mix. In a further effort to minimize the cracking, fog nozzles were installed following the arch forms. This provided excellent curing for the freshly stripped forms at a lower cost than curing compounds. As the natural movement of air was along the tunnel and up the intake shaft the moisture laden air cured all the arch concrete previously poured.

Reinforced Concrete

After the arch was poured up to the start of the reinforced section in the depression area, 1500 ft. from the intake shaft, the bridge was pulled ahead over the cribbed section and the cribbing and rail track removed. Special slotted invert forms were set up in the same manner as previously described and the invert reinforcing steel placed. The ring steel varied from 1¼ in. diameter at 6 in. centres to ¾ in. diameter bars at 18 in. centres. The concrete bridge was positioned on the portal side of the depression area and the pumpcrete line extended as required to pour the invert. The steel screed was used as before and the invert hand finished.

When the invert concrete had set up, the reinforcing steel for the arch was installed. A complete circle of steel consisted of four bars with each joint having a lap of 30 diameters. As the steel was placed 11 in. back from the finished surface the slick line went between the form and the steel. The bridge remained stationary

Fig. 6. Bailey bridge rail changer.

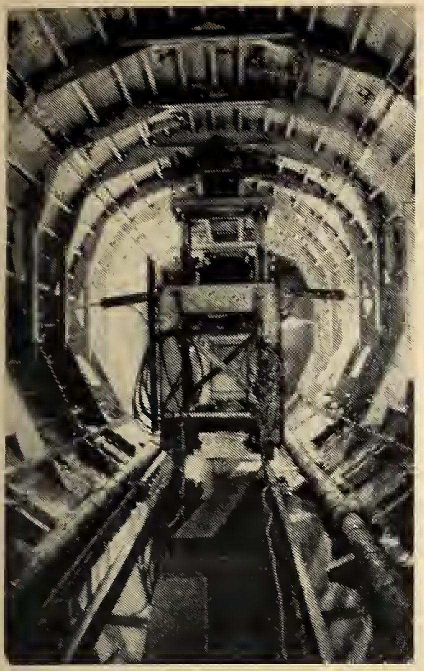

Fig. 7. Arch form and traveller.

for the arch pour in the depression area with the pumpcrete line being shortened as the arch advanced. To be sure that the concrete was forced behind the lapped sections of the reinforcing steel in the arch, a mix using ¾ in. stone was used and placed at a lower temperature. The lower temperature and elimination of the 1½ in. stone made it possible to force the concrete through the reinforcing steel and almost completely fill the arch before any setting up action occurred.

T Section

At the junction of the surge shaft there was a 60 ft. length of tunnel that was heavily reinforced in two layers. Bars, 1⅜ in. diameter, spaced from 6 in. to 15 in. centres and placed 45° to the vertical, formed the two circles; one 6 in. from the face of the form and the other 15 in. from the face. The tunnel in this "T" section was slashed out so that men could get in behind the reinforcing steel with vibrators.

After the reinforcing steel was in place in the invert and the invert poured using the same method as in the depression area, the reinforcing was set up for the arch. In addition to setting up the arch form, the steel forms for the bottom 10 ft. of the shaft had to be installed. These were attached at their top end to previously poured concrete in the shaft and the bottom end cut to intersect the arch forms. The two slick lines went through holes in these forms. As the concrete was poured in the arch the slick lines were withdrawn and the holes closed by sliding doors. Concrete was forced part way up the shaft forms by the slick lines and the remainder of the shaft topped off from doors in the shaft forms. With men in behind the reinforcing steel there was no problem in getting the crown and "T" section full.

Steel Penstock Liner

The steel tunnel liner was delivered to the site in rings 8 ft. long. These rings were assembled in a working area between the powerhouse and tunnel portal and welded together into sections having a maximum length of 70 ft. To move the liner into the tunnel, wheel brackets were welded to the sides of the sections. These were fitted so that the wheels ran on the rails set on the curbs. The sections, when rolled into the tunnel, were jacked into position, shimmed up and welded to the preceding section ready for concreting.

Each section was bulkheaded off 5 ft. from the free end and poured as a unit. The invert concrete was placed first, from one side of the liner, and the arch followed on before the concrete in the invert had a chance to set up and form a cold joint.

Shafts

The intake and surge shafts were concreted from the bottom upwards in 10 ft. lifts using two 5 ft. collapsible steel forms bolted together. The form was held in position by cables attached to rock anchors and aligned by anchors set in the previous pour, and raised to its new position by means of a mine hoist at the surface. In the surge shaft the concrete was placed by a 2 yd. bucket suspended from the hoist. The shaft was reinforced for its full length and in addition had a steel liner for the top 80 ft.

The intake shaft concrete was placed by an 8 in. pumpcrete pipe supported by a vertical cable and terminated in an enclosed hopper just above the forms. This method proved a quicker and safer method of placing. Both shafts were concreted at a rate of 10 ft. per day.

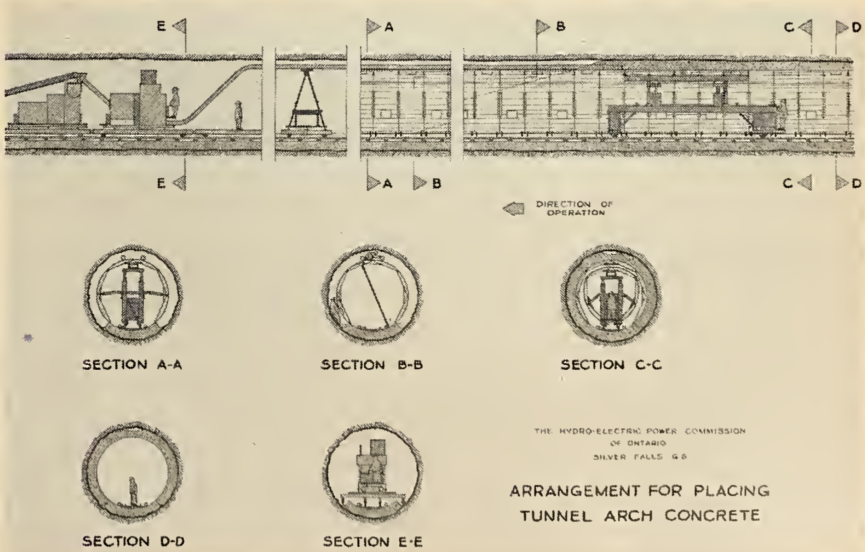
Grouting

The grouting pattern set up was to have one grout hole every 5 ft. throughout the length of the tunnel. The pattern for the holes was 36° to the left of the centre line, then 10° left of centre, next 10° right of centre line, then 36° right of centre, then back to 36° left of centre line and so on down the tunnel.

In the reinforced sections pipe sleeves were set in the concrete where grouting was required. These sleeves had tin cans over the ends next to the rock to prevent concrete from filling the sleeves. In the plain concrete sections, drilling for the grout holes followed as close as practical behind the arch placing. A muck car decked across the top was used as a drilling platform and the holes were drilled using stopper drills with air leg attachments. Grout holes were 1½ in. diameter throughout the tunnel and were drilled 6 in. into rock.

The grouting specifications called for the pressure grouting back of the tunnel lining to be done in two independent operations. The first was a low pressure operation up to 100 p.s.i. primarily to fill all voids around the concrete lining. The grouting could not be started until the concrete lining had been cured for 28 days. Grout mix for this operation was three bags cement, one bag fly ash, 5 cu. ft. sand and 22 gal. of water. The fly ash later was eliminated from this mix and replaced with cement. Connections were made to

Fig. 8. General arrangement drawing of arch placing.



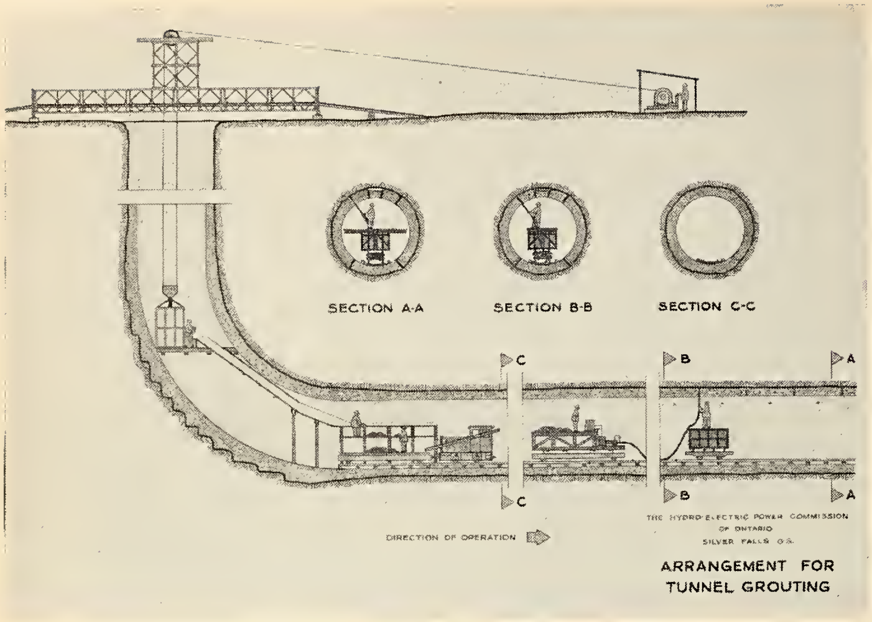


Fig. 9. General arrangement drawing of grouting operation.

all holes in the tunnel except those that vented grout freely within 20 ft. of the hole being pumped. The second operation was high pressure grouting at 150 p.s.i. This was required to fill all small voids remaining over the lining after the first operation. The holes used for low pressure grouting were drilled out and extended 3 ft. into rock. This ensured that any open seams or fractures in the rock were filled with grout. In all, over 14,000 lineal ft. of drilling was required for the grouting operation. No high pressure grouting could be started until the concrete had cured for 90 days. This requirement was later modified to 45 days. The mix used for the high pressure grouting was one bag of cement to 12 gal. of water.

To have the grouting sequence follow right behind the arch concrete it was necessary to lower all the grouting materials into the tunnel by way of the hoist at the intake shaft. (Fig. 9.) The fine sand taken from the blending sand stockpiled at the mixing plant was bagged and trucked to the intake. The sand, cement, and fly ash, all in bags, were man handled into a cage using roller conveyors and lowered onto a platform located at the bottom elbow of the shaft. A wooden chute dropped it down from this platform so that it could be piled on a flat car running on the invert rails. To cover the distance from the shaft to the grouting operation a locomotive was used to pull the loaded flat car. A small electrically operated conveyor was mounted on the side of the locomotive and conveyed the bagged ingredients from the flat car to the grouting platform's top deck.

The grouting equipment was located on a double platform car running on the 36 in. gauge invert track. The top platform had the mixers and material storage, while the lower platform carried the two grout pumps. The mixers fed by gravity into one or the other of the 6 in. pumps. One pump was a standby in case of a breakdown.

The grout was pumped ahead a maximum of 100 ft. through a 1 in. diameter hose and return line. This permitted continuous operation of the grout pump and a minimum of wasted grout while still maintaining a constant pressure. The specifications called for the pumps to have a minimum capacity of 50 gal. per minute at 100 p.s.i. pressure.

In the first 1500 ft. of the tunnel where only one slick line was used it was found that the quantity of low pressure grout required per lineal foot was over double that required per foot for the remainder of the tunnel where the two slick lines were used.

Total quantities used for low pressure grouting were 16,176 bags of sand, 11,411 bags of cement, and 1,574 bags of fly ash. In the high pressure grouting, 1,294 bags of cement were used. The low pressure grouting took 31 days triple shift, while the high pressure grouting took 14 days triple shift. A further pass of water testing was done in any area that accepted much high pressure grout. The same crew did all the operations consecutively. All holes drilled for grouting or testing had to be dry packed before the tunnel was flooded.

General

The concreting and grouting operations in the tunnel were under the supervision of a construction superintendent. He had a shift boss on each shift who was responsible for all operations. A concrete foreman was in charge of the placing and a grout foreman in charge of drilling, grouting and dry packing. Table 1 shows a list of shift personnel.

The safety record during the concreting and grouting of the tunnel, while not outstanding, did show that no serious injuries were sustained. A total of nine compensable accidents occurred, with the most serious being a dislocated shoulder sustained by a grouting foreman.

The co-operation received from the engineering staff on this work contributed greatly to the efficiency of the operations. The grouting inspectors particularly, gave us much valuable assistance.

TECHNOLOGICAL HORIZONS

J. W. Hodgins, M.E.I.C.,

Dean of Engineering, McMaster University, Hamilton.

From a talk presented at Hamilton, Ont., February 1960.

The horizons of technology stretch to the past and extend to the future. The vista is so great that it is difficult to set limits to such a discussion. Considered are three broad quests of man: for materials, for energy, and for a method of communication.

THE TITLE "Technological Horizons", may veer rather widely from the precision and terseness of definition which is supposed to be the hallmark of the scientist and engineer. Technological, of course, in the modern idiom, has the rather specific meaning of "applied science", and on definition of horizon is "limit of mental perception and experience". And since a horizon extends behind as well as ahead, for sheer presumptuousness at least, my title can hardly be surpassed.

Since it is probable that my audience represents a fairly broad spectrum of scientific sophistication, I must tread carefully between the Scylla of boring my technological colleagues with elementary science, and the Charybdis of losing students of the humanities in technical jargon, and this presents quite a problem. So I thought I would contemplate briefly the route along which we have come, and the elusive path which lies ahead as we proceed through our technological evolution. The difficulty with such a broad vista is to know where to start and in what direction to proceed. One is tempted to draw a poetic analogy about being lost at high noon in a forest. But here the analogy is false. For as one looks behind, the trees are increasingly sparse as the distance extends, while ahead their density increases almost exponentially. As engineers, we spend our entire careers as custodians and purveyors of materials, and energy, and information, and these three topics may very well serve as the basis for this discussion, for contemplation of them has suggested some rather strange inconsistencies. It is appropriate, too, to consider them in this order, for it was in this order that man's needs arose: first for materials to feed, clothe, and house him, then for energy to heat him, perform his work, and provide his transportation, and finally for a method of collating and communicating the vast store of knowledge which his active mind was discovering and inventing.

Man's quest for materials began far back in the mists of antiquity. Although our dental and digestive equipment are more appropriate to herbivorous diet, it is likely that our precursors on this planet took to eating flesh in times of drought. With his inadequate physical equipment, the first deliberate consideration of materials by the proto-man, was that of hand-weapons for killing of food. By the time the species had evolved into tool-makers, man was largely carnivorous—quantities of meat bones were associated with the remains of Pekin-man. His carnivorous habits were probably the cause of short-circuiting the extremely slow process of evolutionary bodily alteration in response to environmental change. By inventing extra-bodily equipment such as weapons, tools, shelter, and clothing which could be changed or discarded as circumstances dictated, man became the most adaptable of all creatures. The spread of tool-making skill, the ability to evolve, communicate, and perpetuate inventive ideas, and thus institute a tradition of manual skill and intellectual attainment has of course differentiated the development of our species from that of other animals whose power to evolve tradition is so limited. Whether or not this characteristic is the result of a series of random events of vanishingly small probability provides the basis for the current arguments raging on the possibility of intelligent animal life on the neighboring planets. Perhaps the argument will be settled within our generation.

The slow development of tools and weapons accounts for the passage of thousands of years in man's early history. Although a carnivore, he had not yet become a food producer, but remained a food hunter, and generation succeeded generation without any significant development in his methods. Everyone was a primitive tool artificer, a hunter, and a savage. There were, in other words, no specialists. In this sense, then, men have been savage for 95% of the lifespan of humanity. Only in the last 50 centuries has there been a division of activity by function—technology really dates from about 3000 B.C., when the idea of deliberate cultivation of food took hold. The first barbaric industry was born with the realization that a planned food surplus made life much easier and indeed, much more predictable. Since this surplus could support a full-time specialist who grew little food, but who would, for example, barter his primitive tools for it, the first differentiation of occupation had its beginning. Metal workers, specifically workers of copper were the first full-time industrial specialists.

Copper was the earliest useful metal, far more important than gold or silver. Its technology is an example of the enormous influence exerted by chemistry in moulding our lives, for although they did not know it, copper became useful in the late Neolithic Age because copper oxide has a rather low free energy of formation. Because of this, native copper could occasionally be found, and its malleability and ductility recommended it to the primitive metal workers. Moreover, the brilliantly-coloured oxides and sulfides of copper are easily roasted and reduced, and accidentally the annealing by heat was discovered.

And so the metal age started—some 20,000 tons of copper were produced between 1300 and 800 B.C., and alloys were fairly common (although usually an accident of the ore composition). Iron, whose oxide has a heat of formation nearly twice that of copper, was brought into use much later—about 1200 B.C. Its ores were widely distributed and the tools were cheaper and much more efficient than those of bronze. It made possible clearing of forests, drainage of marshes, and greatly improved cultivation. It was the democratic metal and greatly augmented man's arsenal of equipment for dealing with the forces of nature.

The materials used for man's dwellings have been profoundly influenced by both geography and geology, and it is thus impossible to treat the ancient world as a single unit. Large complex stone and brick structures were common in 3000 B.C. in Mesopotamia, some of them employing arch construction. Those of us who cope with that hallmark of suburbia, the septic tank, can contemplate the fact that 4000 years ago central sewers were fairly common in Persia. Some structural defects are surprising, particularly in Egypt, where without wheeled vehicles, they transported stone weighing over 2 million pounds regularly over large distances. They were most inconsistent in their foundation preparation, and frequently erected their gigantic structures on sand beds, or random rubble. And despite their great ingenuity at handling material the idea of squaring his stones before building, or even that geometrically prismatic blocks would be useful, seems to have eluded the early Egyptian stonemason.

The other material essential to any concentration of civilization is, of course, water, for irrigation, for human and animal consumption, and for sanitation, and great ingenuity was exhibited in earlier times to provide for the pumping, the storage, and transportation of water. The earliest engineered tunnels were engendered by the habit in Palestine and Arabia of creating an underground storage reservoir in the rock, connected to the citadel by stepped tunnels, often a half-mile long. But it was the conduction of water over long distances that brought civil engineering to a surprisingly advanced state 3000 years ago. The great aqueduct built by Sennacherib in 691 B.C. brought water from a tributary of the Greater Zab River to Ninevah, 50 miles distant. Wide as a highway, it was made of stone quarried near the beginning of the canal, and transported on wheels down the dry channel. The project, which involved the transportation of over 2 million blocks of limestone an average distance of at least 10 miles, was completed in 15 months. Obviously Sennacherib had better control of his labor force than any modern contractor. The bed of this canal showed considerable technical sophistication—concrete floated in bitumen, laid to a fall of 1/80 with astonishing accuracy which would put to shame some drain lines I have seen recently. In Rome at the time of Christ, Frontinus, the land surveyor, and water commissioner, recorded in splendid detail the engineering detail of the wonderful aqueduct system which daily conducted to Rome 300 million gallons—six times the average pumpage to this city.

By the time of Christ, then, the use of natural materials and the technology of building and elementary metallurgy were reasonably well developed. During the next 19 centuries, technology in the use of materials, in the production of alloys, and in the refinements of process metallurgy proceeded at an accelerated pace. But it is in this past half century – this minute 0.5% of our technological history, that materials have really come under our control. Since the turn of the century we have become increasingly the inventors, rather than the adapters, of materials. We are starting to have more than a glimmering of the chemistry and the physics of gases, liquids, and solids, and with the knowledge has come the ability to synthesize the properties we desire. This is what is different about this particular era in which we live—we are beginning to be able to produce a material to meet the requirements of a particular application, sometimes a material which never had a counterpart in nature.

Why are we so rapidly gaining confidence and sophistication with regard to the materials we need? Not merely because of the great wealth of information which increases almost exponentially. It is far less a random process than that. The main reason is that for the last two decades, science and technology have been combining their forces to answer the general question, "Why do materials behave as they do?" It is the realization that the properties of gases, solids and liquids are to be explained, in that microcosmic world of atomic structure, impurity content, crystal defects, and force fields. We are beginning to know why a material is viscous, or sticky, or hard, or shiny, why it does or does not conduct electricity or heat, how its properties will change with temperature, or electric field, or pressure.

The physical state which is simplest to explain and therefore elucidated earliest is the gas. A great deal was known about the behavior of gases 20 years ago. Since World War II (a time element amounting to 0.4% of our technological history) great attention has been focussed upon the next simplest physical state—the solid. Our solid state physicists, by applying the principles of quantum mechanics are providing a fundamental basis for our understanding of solids, and engineers have been quick to follow conception by technological application. Engineers unabashedly worry nowadays about what the atoms are doing. It is becoming commonplace for them to engage in what Professor von Hippel calls "molecular engineering". This gives the engineer a true spiritual connection to modern science—a partnership and a new freedom of action. He can conceive devices based upon ideal characteristics and then back in the laboratory inquire to what extent such properties can be made to order. It is symptomatic of these trends that new engineering curricula (such as that at McMaster University) have courses in "Properties of Materials", replacing the conventional metallurgy courses.

Probably the most spectacular solid state progress at present is in the field of semi conductors—a development of new and radical concepts. It truly has developed from nothing, for its genesis was the realization of the principles of the flow of holes in certain solids. The transistor is making possible striking reduction of power requirements and size, and spectacular improvements in the physical ruggedness of electronic equipment. The thermistor enables us to measure small temperature differences with startling sensitivity. New synthetic ferrites are revolutionizing the storage of information in computer cores or on tape. Crystals can now be grown artificially for optical, electrical, and cutting purposes. Polymer chemicals are developing plastics and elastomers as quickly as the requirement develops.

The scientist and the engineer are custodians of energy, and the next generation will become increasingly aware of this fact. As global society became more complex, so did the demand for energy increase—first to heat living space and to cook food, then to perform work for production and transportation. Since the first fire was kindled, our civilization has employed the legacy of energy emanating from our sun, and only a trivial fraction of our global energy supply has had any origin other than solar. For us, the most important chemical reaction in the world is the wonderful one:

$$CO_2 + H_2O \overset{h\nu}{\rightarrow} O_2 + C(H_2O)_n$$

This is the photosynthetic reaction, and represents the start of the synthesis of the food we eat, the fuel we burn, and the oxygen we breathe. After decades of research we are just starting to get a few glimmerings of the mechanism of this reaction. Its full elucidation may represent as important a technological renaissance as the utilization of the knowledge that matter and energy are related by a fairly simple mathematical equation. Why should such an innocent-looking chemical equation be so difficult to interpret? Why is its understanding so important? What applications might result from our ability to reproduce this reaction in the laboratory?

This short equation represents a monstrous simplification of the process involved when energy, in the form of sunlight, causes the combination of carbon dioxide in our atmosphere with water vapour, catalysed by the magnesium-organic constituent of green plants, chlorophyll. And what is wonderful about it is this:

Nature has found a way of storing pulses of energy until enough have accumulated to perform a chemical reaction. In order to cause carbon dioxide to combine to form one molecular weight of a simple sugar, 672 kilocalories of energy are required. Sunlight reaching the surface of the earth has an average energy equivalent only to about 312 kilocalories. And yet, wrapped up in the mystery of the chemistry of every blade of grass there is the ability to receive one burst of energy, then a second, and then even a third, and combine them to make available the little chemical reaction which makes it possible for us to continue living. This same reaction caused to grow the giant trees, which over geological time underwent chemical degradation, and stored the energy lavished millions of years ago as coal. Our petroleum came from a marine population whose life was sustained by sunlight's agency, which accumulated in the earth's wrinkles, in an endless rain through the silent ocean depths. It, too, is stored sunshine. Even our hydro-electric power, originates from water raised from one spot and deposited in another in probably our largest thermodynamic cycle—solar distillation.

Some of my engineering students will certainly have to cope with the problem of the source of energy as our irreplaceable fossil fuels become steadily more difficult to obtain economically.

One index of the development of a civilized society is the rate at which it consumes energy, and ours is gobbling up our reserves at a rate which is accelerating frighteningly. And the source of almost all of this energy is the fossil fuels—our irreplaceable legacy set aside over several million years of plant and sea animal growth, of anerobic oxidation, of conversion to complex hydrocarbon chemicals. It is hard to imagine at a period when gasoline is slightly cheaper than distilled water, that within the careers of my engineering students, world-wide study will have to be focussed on quite different patterns of energy distribution. The phrase which leaps to mind, of course, is "nuclear power" —which has developed from the first reasonable theory of the atom to those giant installations at Windscale and Calder Hall in a brief 40 years— 0.8% of our technological history. Surely from a development so spectacular, one can expect a practicable replacement for the energy we are so diligently dissipating as carbon dioxide into our urban atmospheres.

If the answer lies in power developed by the fission process—and this is at present the only practicable way to realize useful work from nuclear processes—there are two ancillary problems which loom very large indeed on our technological horizon, and to which great attention will have to be paid.

The first of these is the disposal of radioactive wastes from the power plant—already creating concern although nuclear power now supplies a negligible proportion of our requirement. If all of the electrical energy in the world were generated by nuclear fission it would be necessary to dispose of radioactivity equal to that resulting from the explosion of 200,000 medium sized atomic bombs per year! The second problem of major proportions is concerned with the distribution of the energy derived from nuclear reaction. It seems to be generally assumed that nuclear power will be distributed in the form of electricity—what other form of conduction is so convenient and rapid as that of the peripatetic electron? But it is all too infrequently pointed out that although we in Canada are fairly elaborately electrified, only about 15% of our total energy consumption is electrical! The other 85%, used for space heating, steam generation and surface transport is still derived from fossil fuels. If we do have to make a change, then, to complete electrification, an entirely new form of distribution grid would have to be devised —our present distribution network would be totally inadequate.

On our sun at a possible temperature of 50 million degrees Centigrade the fusion of hydrogen atoms proceeds, yielding helium and an attendant release of nuclear energy. One estimate is that 1000 billion pounds of hydrogen have been consumed this way every second since the beginning of time. It is inevitable that one of the most eagerly pursued researches of our era is the domesticating of the fusion reaction —the rendering docile of that awesome force which holds our populations in a state of trembling peace. The benign fusion reaction would have the great advantage that the problem of disposal of radioactive waste is negligible, and the supply of raw material is vast. Since the problem of distribution is difficult, but soluble, if the energy Utopia does arrive, it will probably be through the agency of atomic fusion. I still wistfully hope that the dark horse in the race will make a showing, that some quiet chemist will unravel the secret of the blade of grass, and learn how to store energy in a chemical system—upgrade it in potential, as it were. I hope he will learn to make an artificial chloroplast, so we may learn to collect and utilize the solar radiation which delivers more than 4000 horsepower to every sunny acre on our planet.

The third legacy of which we are all custodians and dispensers is information in its broadest sense, and in step with materials and energy, the accumulation, application, and processing of information have proceeded at a blinding pace. I am not going to quote statistics to prove how technical knowledge has proliferated; it has now become impossible for a single worker in certain fields to read all of the developments in his specialty, even if he ceased to be an active contributor and devoted all of his time to perusal of the literature. But this statement must not be construed to indicate that specialization must of necessity become more and more narrow. Far from it—great generalizations are beginning to appear in engineering which makes it draw closer to science—our engineer now must be more of a scientist than ever before. He must act as a translator, an inventor, and an expediter, ready to recognize the significance of modern scientific achievement, and apply it to the development of a process, a machine, or a structure.

It is entirely natural that the same ingenuity which provides this staggering wealth of scientific philosophy and technological data, has also developed elegant techniques for filing, and assembling, and processing these same data. In the trifling time of about a decade, it has become a commonplace in the laboratory to hear "I'll run it through the computer", or "See what the machine says". And we are becoming quite blase about hearing about aircraft, or distillation columns, or transformer, or control systems which have been designed by reference to some physical or electrical analogue device. Strangely enough, electronic computation demands not less, but more sophistication on the part of the engineer. The modern engineer must be a better mathematician than before, to realize both the striking advantages and the shortcomings of the electronic computer. He must be made aware that while a decade ago, his solutions of complex equations might grind to a halt because of the intractability of the mathematical expression, he now has a powerful tool for extracting answers from data which do not respond at all to traditional mathematical techniques. And he can solve problems, aided by the blinding speed which is a property of the electron, which hitherto were unattainable because of the limitations of time. This sudden burgeoning of electronic digital and analogue devices for solving of complex and tedious mathematical problems has, in one sense extended the imaginative horizons of our original thinkers, for they do not bog down in a morass of heartbreaking mathematical drudgery. They can see beyond, in the knowledge that the limitation is not physical or emotional stamina, but insight and ingenuity. But it has posed a problem for us academicians. In addition to bringing our engineers into the state of mind where mathematics is a friendly language and not a necessary evil, it has become our responsibility to make them at home in the field of applied mathematics. They must become aware at university of the total scope of the tools at their disposal, and numerical analysis is one of the most powerful. Our engineering schools in Canada are not, I think, sufficiently alert to this great opportunity, and indeed, it may be time to re-examine the entire mathematical program to assure ourselves that suitable balance is achieved between mathematical philosophy and our awareness of "mathematical hardware". I am aware that this can be misconstrued as a plea for less rigor and more empiricism, but can only repeat that the machine's excellence lies in its diligence, not its brilliance; it will always remain less intelligent than the man who directs its activities.

I have not presumed to demonstrate to those of you who are not scientists or engineers the fine philosophical development of our disciplines, for this has been done eloquently by far more qualified spokesmen. But the philosophy is there, and because of the technique of experiment which maintains balance between thought and action, is subject to checking at such frequency, that as Oppenheimer says, complacency can only be counted upon until the next issue of the journals. Nor do I want to pursue the discussion of the responsibility of the scientist for the sociological aftermaths of his discoveries. As Dr. Steacie once suggested, even the inventor of the milk bottle may be culpable, for a milk bottle does make a splendid weapon in hand-to-hand combat. But it may be worthwhile to ponder for a moment or two our horizons ahead, for the developments are going to continue to multiply as our understanding and control of our physical world becomes more and more sophisticated. Dr. Conant said, "Through many advances gained by science we may hope that as never before man may be free—free from want. But science alone, untempered by other knowledge can lead not to freedom but to slavery. At the root of the relation between science and society must lie a proper educational concept of the interconnection of our new scientific knowledge and our old humanistic studies."

It is in the adjustment of our society to our constantly changing background of technology that the inconsistencies I mentioned earlier seem so striking. Our human philosophies have lagged far, far behind our scientific ones, so that we stand confronted with one of the great ironies of history—the possibility, indeed the frantic hope that an agent of destruction will finally bring to us what thousands of years of philosophy have failed to do—global peace, ensured not by brotherhood, but by terror. Alfred Nobel's wish may finally be granted, that "A substance be produced of such frightful efficacy for wholesale destruction that it will make wars impossible." But whatever the reason, it allows room for the hope expressed by Oppenheimer for "a world to be united in law, in common understanding, in common humanity, before a common peril".

And so many other inconsistencies persist—much less basic than the threat to our survival, but strange in our modern scientific age, nonetheless. Our "way of life", replete with labour-saving gadgetry, has been achieved at a considerable cost in graciousness. It is indeed incongruous to contemplate our citizens in homes of consumate comfort, living in forests of overhead wiring, breathing atmospheres frequently polluted, unable to swim in the waters which lap the shores. Our insistence upon personal transportation has brought chaos to public transportation, and the leisure time created by extensive mechanization is causing a general relaxing of our sense of purpose and general propriety.

We are gathered on a campus where no amount of engineering ingenuity can now compensate for the losses incurred by a completely obsolete means of arriving at the price attached to the sale of labour services. The severe work stoppages on this continent have nullified millions of man-hours of engineering skill in the past year.

I wish to quote Mr. George F. Kennan, an historian and now at Princeton's Institute for Advanced Study, speaking about the United States, but his words ring fairly true for Canada as well:

"If you ask me—as an historian, let us say, whether a country in the state this country is in today; with no highly developed sense of national purpose, with the overwhelming accent of life on personal comfort and amusement, with a dearth of public services and a surfeit of privately sold gadgetry, with a chaotic transportation system, with its great urban area being gradually disintegrated by the switch to motor transportation, with an educational system where quality has been extensively sacrificed to quantity, and with insufficient social discipline even to keep its major industries functioning without grievous interruptions—if you ask me whether such a country has, over the long run, good chances of competing with a purposeful, serious, and disciplined society such as that of the Soviet Union, I must say the answer is 'no'."

I want to end by repeating one of my own effusions: "The scientist, the engineer, the historian, the sociologist, the psychologist and the economist must contribute as a team to the decisions of the future if we are to proceed rationally along this elusive path we tread. This presents a striking challenge to all of the disciplines, the challenge of re-establishing communication among the components of what was once a single philosophy." EIC

Winter Water Temperatures and Ice Prevention by Air Bubbling

G. P. Williams, M.E.I.C.
Research Officer, Division of Building Research,
National Research Council of Canada, Ottawa

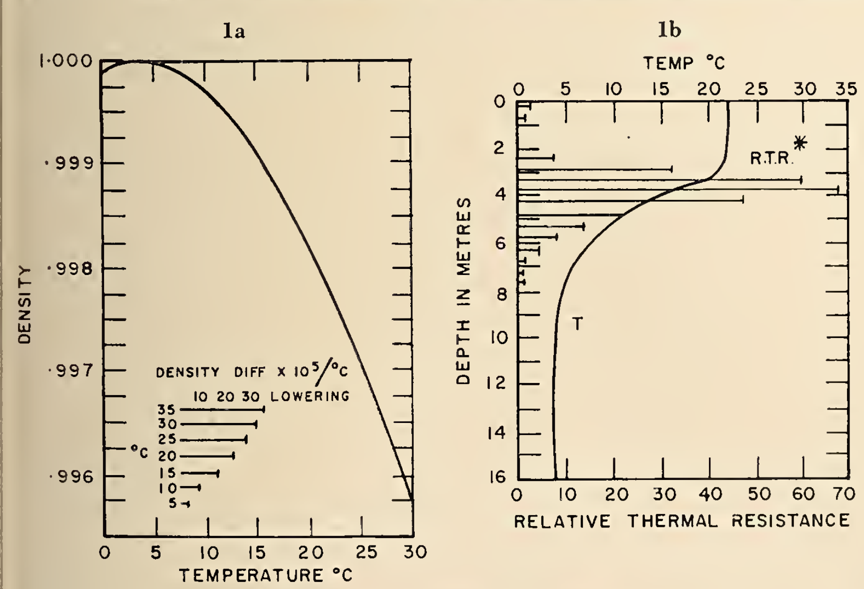
While much information is available concerning the prevention of ice formation by the use of an air bubbling system, apparently there has been no paper which summarizes this information. This report has been prepared primarily to be used by field engineers.

CONSIDERABLE interest has developed recently in Canada in the prevention of ice formation by the use of air bubbling systems. Although compressed air jets have been used to prevent ice formation for many years,[1] there has been apparently no paper which summarizes completely the information available. This report has therefore been prepared to present the essential technical information now available on air bubbling systems. It is designed primarily for field engineers, who are interested in the use of air bubbling systems but have not yet had an opportunity of investigating their application in detail.

Air bubbling systems depend on the fact that sub-surface warm water can be brought to the surface by rising air bubbles and thus used to prevent surface ice formation at specific locations. In order to plan an efficient air bubbling system, information is therefore required on the amount of heat available in a water mass. The amount of this thermal reserve can be estimated if water temperatures are known. Information on water temperatures and the factors which affect them are not generally available to Canadian engineers, so that it is a further purpose of this report to outline briefly the factors which govern water temperature, and to present some typical observations of water temperatures under winter conditions.

Fig. 1a. Density as a function of temperature and density difference per degree C lowering for distilled water.

Fig. 1b. A typical summer temperature profile and associated resistance to mixing.[2]



*1 R.T.R. = 8 x 10^{-6} i.e. the density difference between water at 5°C and 4°C for columns of water 0.5 metres long.

Water Temperatures in Lakes

The temperature of lake water is largely controlled by the process of convectional overturning of water from the surface to the bottom of the lake. The fact that fresh water has its maximum density at 39.2°F affects the circulation and the resulting temperature pattern markedly. Fig. 1a shows density as a function of temperature for distilled water as obtained from a recent paper by Vallentyne.[2] The density difference per degree centigrade change of temperature for water at different temperatures is shown in the lower part of Fig. 1a. Vallentyne stresses that in order to mix fluids physical work must be done and, other factors being constant, that the amount of work is proportional to the density gradient in the fluid. As an example he states that "Forty times as much work is required to mix layered water masses at 30° and 29° as the same masses at 5° and 4°, because the density difference is approximately forty times greater."

Vallentyne analyzed the typical lake temperature profile shown in Fig. 1b. He divided the temperature curve into ½ metre intervals and, from the dependence of the density on temperature, obtained the density at the top and bottom of each interval. He defined one unit of relative thermal resistance as the resistance to mixing offered by a ½ metre column of water with a temperature of 5°C at the top and 4°C at the bottom. By calculating the density differences between the top and the bottom of the ½

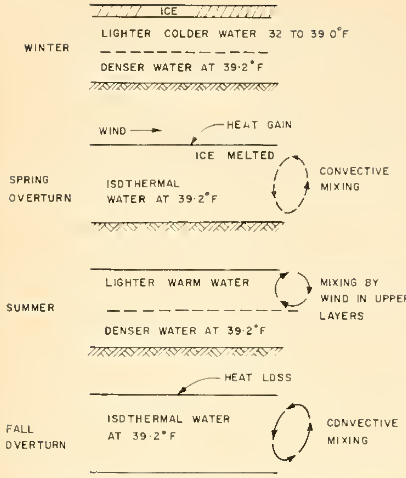


Fig. 2. Annual temperature cycle illustrated for a deep lake in the temperate zone.

metre intervals and comparing them with the standard, he then calculated for each interval the relative thermal resistance to mixing. The results of his calculations are shown in Fig. 1b. It may be seen that a slight increase in temperature difference in the warm water at the surface results in a large increase in the resistance to mixing.

Fig. 2 illustrates annual temperature changes in a typical deep lake. The water temperature of lakes is so markedly influenced by the process of convective heat transfer that it has been used as a basis of classification for fresh water lakes. Horton[3] divided lakes into three basic types:

(i) polar — surface temperature always below 39.2°F

(ii) temperate—surface temperature alternating above and below 39.2°F

(iii) tropical — never below 39.2°F.

He further divided the lakes into three classes according to depth: the first order 200 ft. and greater, second order 25 to 200 ft. and the third order 25 ft. and less.

In Canada most lakes of interest can be classed as temperate. In this type, with a first order lake, there are usually two turnover periods, in the spring and fall (Fig. 2). A second order lake, of depth 25 to 200 ft., also has two marked overturn periods in the fall and spring, but often in the summer there is complete mixing to the bottom, and in the winter the water on the bottom of the lake can cool below 39.2°F. A third order or shallow lake will have complete circulation at all seasons except when the surface is frozen. Brewer[4] indicates that water in a shallow lake at Barrow, Alaska, was essentially isothermal at any time during the ice free period. Fig. 3 illustrates the convective mixing of a shallow body of water during a period of cooling. These measurements made by the author illustrate that water remains essentially isothermal as long as the surface temperature is above 4.0°C (39.2°F).

Although water in third order lakes is generally isothermal during the ice free period, there are exceptions to this rule. Vallentyne[2] reports that, for a certain lake in Washington State, the density difference between the surface and bottom water is so great that the wind is unable to induce complete mixing, even though the lake is only three metres deep. The density difference is caused by large amounts of dissolved Epsom salts.

The importance of depth in studying the thermal regime of lakes cannot be overemphasized. Lebedev[5] states that "In the majority of cases the range of the lake heat budget is determined by the mean depth". In Sweden Melin[6] made some temperature measurements on Lake Kallsjön, which consists of three separate basins of different depths, connected by narrow shallow passages. He concluded that in thermal respects each basin could be classified as a separate lake. The shallow basin warmed more rapidly in the spring and cooled more rapidly in the fall, and the water temperature reached higher temperatures in the summer than in the other basins at corresponding depths.

In a lake considerable mixing can be caused by wind action. Brett[7] states that for Lakelse Lake, B.C., heavy winds tend to keep the greater part of the lake in circulation during the summer; and Kuenen[8] suggests that wind can keep an air hole open in a frozen lake by including a circulation in the water which brings warm water to the surface. He also suggests

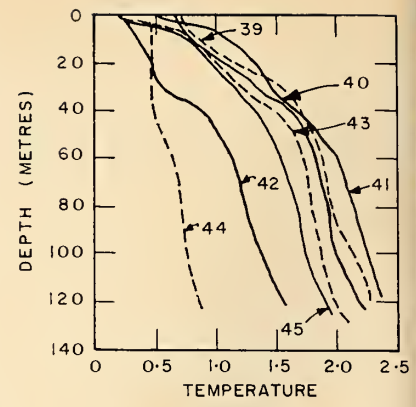

Fig. 4. Variations of water temperature with depth in the northernmost part of Lake Kallsjon, Sweden in March 1939 to 1945. Lowest water temperature observed during warm winter. Winter temperature of water in deep lakes is dependent on factors other than winter air temperature.[10]

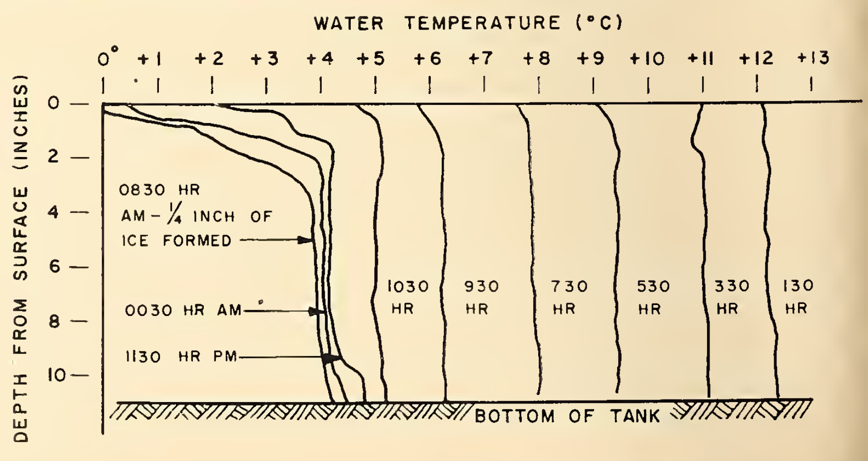
that in freezing weather an air hole can be made larger by wind circulation, as the edge of the ice melts when warmer water is brought to the surface by wind action.

One major factor in determining water temperature is the heat flowing into or out of a specified area because of different water currents. Rauson[9] in a study of water temperatures in Great Slave Lake indicates the variation in water temperatures that can be caused by inflow from a large river.

It is not always appreciated that the winter water temperature of a lake shows considerable variation when observations are taken at the same time in different years. Fig. 4 shows the variation of water temperature with depth in lake Kallsjön, Sweden, for different years. Melin[10] noted that the mean winter temperature of lake water did not necessarily depend on the mean air temperature. According to his report the coldest

Fig. 3. Temperature variations in shallow pool of water subject to cooling conditions. Feb. 17, 1959, Ottawa.



water temperatures were observed during a comparatively warm winter.

Fig. 5 illustrates the gradual water temperature changes underneath the ice cover of a small pond in the Ottawa area measured by the author during 1957-58. At this particular site, the water at the bottom of the pond did not reach its maximum density until mid-February, although it should be noted that in late December a mild spell reduced the thickness of ice cover and appeared to increase the water temperature appreciably.

Fig. 6 shows some water temperature profiles under ice covers in small lakes obtained by the author in the Ottawa area. These are more typical of conditions in this region and may be compared with water temperature profiles taken in several lakes in north Sweden by Melin.[10] The lakes in the Ottawa area may be classed as third order or shallow lakes, whereas the lakes in Sweden may be classed as second order lakes.

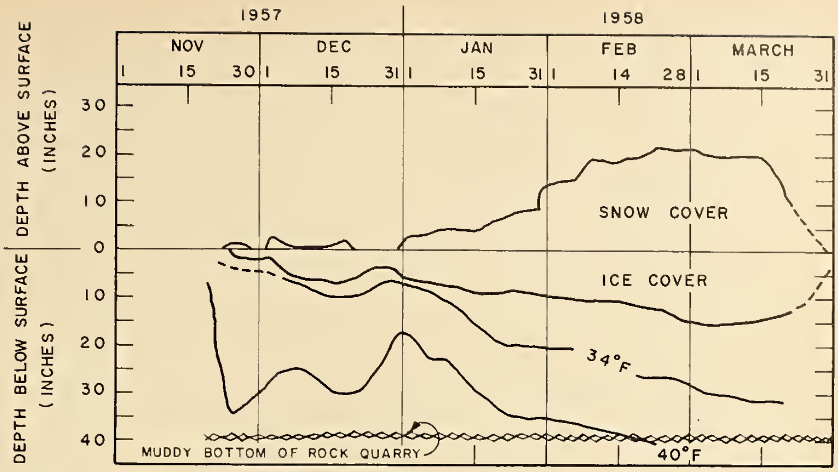


Fig. 5. Temperature variations under small ice covered pond — NRC grounds, Ottawa.

River Water Temperatures

In rivers the water mass is kept at nearly the same temperature by mixing. Thus an ice cover will not start to form until the temperature of the whole mass of river water is close to 32°F. Fig. 7 shows some typical water temperature profiles taken by the author in the Ottawa area in March, 1959. Even in Lake Temiskaming, a wide part of the Ottawa river where the flow velocities must be very low, there was sufficient mixing to prevent an appreciable temperature gradient from developing.

It is obvious that in rivers the heat inflow from upstream sources must have an important effect on the water temperatures at a particular site. For example, Cousineau[11] states that the water temperature at a particular section of Bersimis River never dropped to freezing point although this river is subject to fairly extreme winter cooling conditions.

TABLE 1

Summary of Air Bubbling Systems Reported in the Literature

Place	*Size of Hole*	*Spacing of Hole*	*Size of Line*	*Size of Compressor*	*Depth to Bottom*	*General*
Lake Mälaren Sweden	0.75 mm	10 metres	1½ in. I.D. anchored at 1-2 m from bottom	1.5m³/min. at 4 atmospheres	10-15 metres	Reference #14 approx. 900 metres length of area cleared of ice
Riddar Bay, Sweden	0.75 mm	5-7.5 metres	50 mm I.D. and 22 mm I.D.	8m³/min.	5–20 metres	Reference #14, variable success
Prescott, Ontario	1/32 in.	6-ft. intervals	3/4 in. anchored 1 ft. from bottom at 15-ft. centres	air pressure 40 p.s.i.	5-11 ft.	Reference #19
Celgar Ltd. B.C.	1/32 in.	40-ft. intervals	600′ 1-1.5 in. 2000′ of ¾ in.	125 c.f. per min.	15-20 ft.	Reference #20, 2-acre pond free of ice
Vernon Lake Narrows, Ont.	1/16 in.	10-ft. intervals	1.5 in. across 800-ft. channel			Reference #21, 200-ft. strip kept open
Kaministiquia River, Ft. William, Ont.			1¼-1½ in., 2000 ft. anchored 1 ft. from bottom			Reference #12, open water approx. 400 ft. x 15 ft. throughout winter
Slave Falls, Manitoba			1.5 in. iron pipe at 14 ft. along 1200-ft. dam			Reference #12
Mid-Finland District, Finland	0.8 mm	3-3.5 metres	1½-in. steel pipe also ¾ in. plastic hose	compressors at both banks of river		Reference #22, area 15 metres by 15 metres opened
Finland	0.75 in.	3.5 metres		Note: A 170-metre channel with an ice cover 60-70 cm thick required 43 compressor hours and 75 man hours to melt. Reference #23		
Safe Harbour, Maine			1-1½ steel pipe 1000 ft.	200 c.f. per min.	50 ft.	Reference #24

Sea-Water Temperatures

Although air bubbling systems have been used in sea water,[12] careful studies must be made of water temperature and salinity to ensure that ice can be removed or melted by this technique. The maximum density of sea water does not occur at 39.2°F and, therefore, convective mixing of the water may continue until ice forms at the surface. For air bubbling to be successful under these conditions, it is necessary that the water brought to the surface by the bubbles should have a salinity and temperature such that heat can be released for melting or preventing ice formation, that is the temperature of the salt water is higher than its freezing temperature. The freezing point of salt water decreases with increasing salt content. The action of wind and water currents is likely very important in determining water temperature profiles at a specific location. Fig. 8 shows the temperature gradients Tadashi[13] found under an ice cover in sea water.

No mention has been made of the subsurface flow resulting from variations in the amount of materials in suspension or horizontal variations in the amount of salt in sea water. The subsurface flows which result from these density differences are often referred to as "density currents" in engineering literature. For example, the upstream movement of salt water in open channels is attributed to the greater density of salt water compared with that of fresh water. The nature of such an intrusion is dependent upon the range of the tide and salinity of the sea water and the physical and hydraulic characteristics of the site. The effect of such intrusions are important in analyzing the thermal regime at those sites where salt water is mixing with fresh water or water of different salinity.

Design Considerations for Air Bubbling Systems

In any careful study of the feasibility of using an air bubbling technique to prevent ice formation, a thorough field investigation of the thermal regime of the particular site in question is an absolute necessity. An understanding of the heat losses to be expected from the surface and the lateral inflow of heat are also usually essential. In Sweden[14] a case was reported where an area 50 metres by 1.5 metres was kept free of ice when the mean water depth was only one to two metres. Conversely another instance was reported in the North Baltic where an installation in quite deep water was a failure because of supercooled water flowing into the area from a river source.

In the case of an open body of water under winter conditions, there can be very large heat losses from the surface. Fig. 9 compares various empirical formulae[15, 16 17] which give estimated heat losses for various air-water surface temperature differences. From these formulae it can be estimated that for a mean air-water surface temperature difference of 20°C (36°F), the total heat losses from an open water surface would be approximately 125 to 175 B.t.u. per sq. ft./hr.

Once an ice cover has formed, the rate of heat loss will be rapidly reduced because of the insulating value of the ice cover. For example, with an ice cover of 6 in. and a temperature gradient through it of 1.5°F/in., the heat loss is approximately 22 B.t.u./sq. ft./hr. If the ice cover is removed by air bubbling and the air-water surface temperature difference is approximately 20°C (36°F), then the heat loss would be 125 to 175 B.t.u. per sq. ft./hr.

If, for this example, the depth of the water was 20 ft. and the mean water temperature +33°F, then the thermal reserve would be 1250 B.t.u./sq.ft. of open water area. If the rate of heat loss was 125 B.t.u./sq.ft./hr. and no ice cover existed, the mass of the water would be cooled to 32°F within 10 hours. In the case where there is an ice cover and part of the ice is removed by air bubbling, the heat in the water

Fig. 6. Typical water temperature profiles under ice cover for small lakes in Ottawa area March 9-11, 1959.

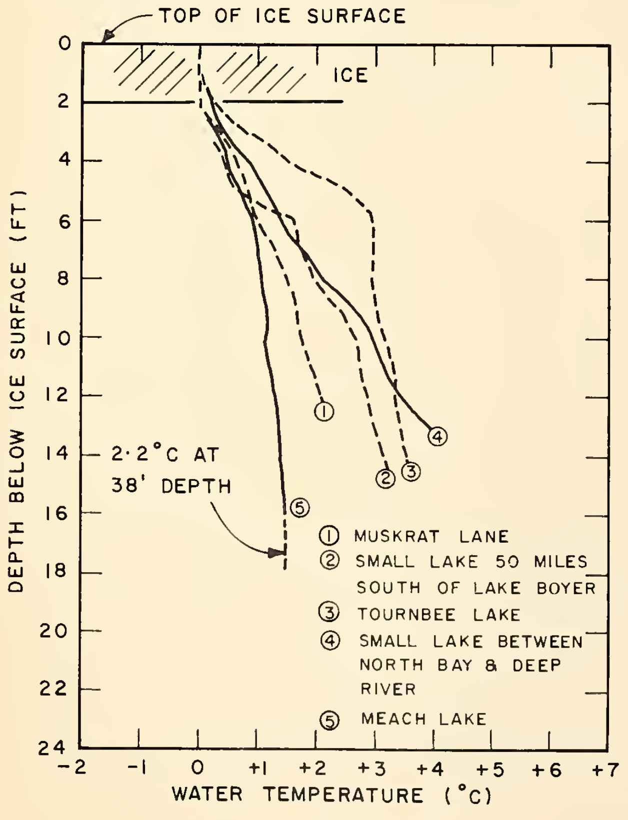

Fig. 7. Typical water temperature variation under ice sheet in flowing rivers, Ottawa area, March 1959. (Temp. gradient less than 0.1°C 10 feet.)

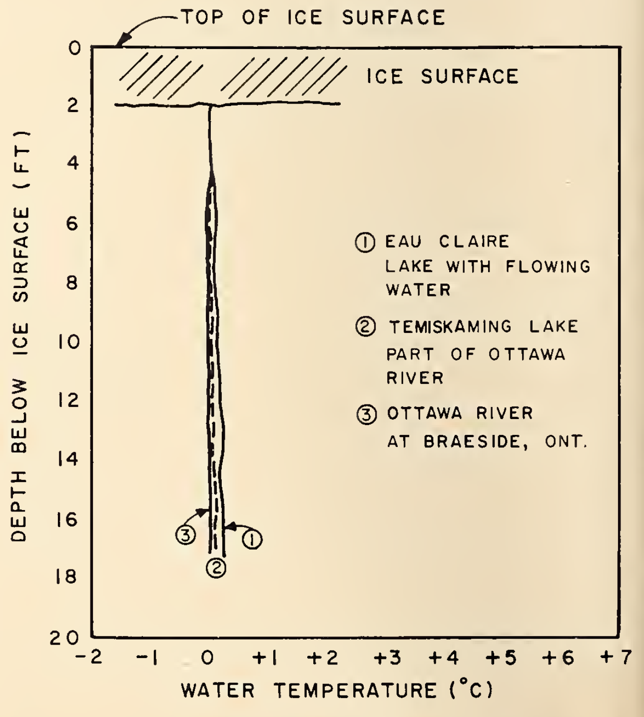

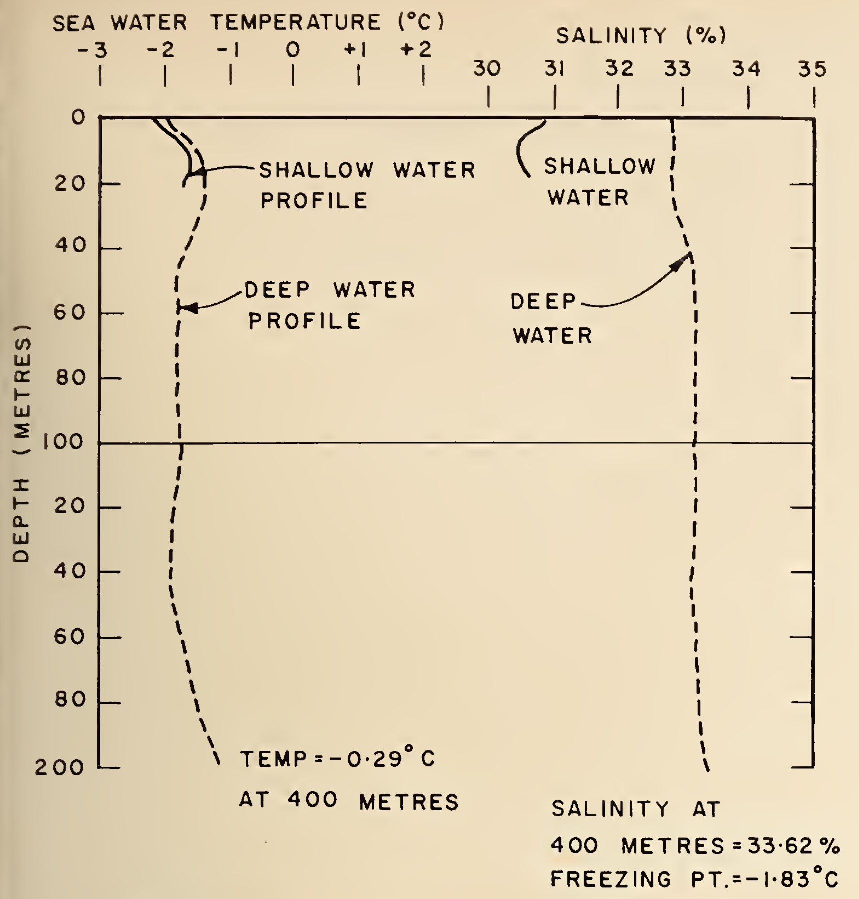

Fig. 8. Sea water temperature and salinity profiles at time of ice formation and under ice cover.[13]

for some distance surrounding the open area is available by advection for maintaining the water in the open area above 0°C.

Additional heat that can be supplied from the bottom of a lake or river is usually considered a minor factor. Nybrant[18] states that in latitude 50 to 60°N, the heat flow from the typical bottom material in October is approximately 1.8 B.t.u./sq. ft./hr; in December-January 1 to 1.8 B.t.u./sq. ft./hr, decreasing to almost negligible flow in April.

To plan the spacing and depth of air holes in a bubble system, information is required on the area of influence of a single air jet, on the size of air hole, and on the most efficient quantity of air to use. Since most studies on air bubbling systems appear to have been empirical, designed to give an answer for a specific location, there does not appear to be an engineering procedure for obtaining this design information. A summary of the various applications is outlined on Table I which gives the design values that have been reported in the literature. Although this table does not present a means of determining such things as air hole spacing, it does list the values which apparently have been satisfactory for the specific locations listed. In addition to the list of studies shown in Table I, there are a number of other cases reported where the technical information is so meagre as not to warrant inclusion in this table.

Experimental Investigations

Although most of the studies reported were empirical, there have been several experimental investigations on air bubbling techniques. Owen[25] in 1942 reported a detailed investigation of the flow pattern of various orifices studied in the development of an orifice to use for ice prevention at the Grand Coulee Dam. An orifice was developed which gave a balance between flow pattern, economy of operation, and non-freezing characteristics of the orifice.

One of the few other experiments in the laboratory on the flow of water induced by a rising column of air bubbles was recently completed by Baines and Hamilton.[26] They concluded that because the momentum of the vertical jet increases with distance from the source, other factors being equal, air bubbles increase in efficiency with depth. They indicated that the ratio of water discharge to air discharge increases with depth, but decreases with increasing air discharge. They also concluded that, with single orifices of 0.02 in. size or larger, flow is independent of size of orifice and depends only on the air discharge. They reported, finally, that further experiments might indicate that it is possible to apply scaling laws and thus have reliable model tests of air bubbling systems.

Clinch, Millman, Erickson[27] attempted to obtain some quantitative information on air bubbling systems under field conditions. Their calculated air-water flow ratios for a particular site varied over a wide range, but this they attributed to the inadequacy of field observations.

The area of influence of one air jet and the resulting water temperature distribution during air bubbling operation is a basic question which has not been answered satisfactorily. The only quantitative measurements on this problem of which the author is aware were made by Nybrant.[28] He noted that essentially the same water temperature was maintained throughout the whole body of water as far as 50 metres from the hose. He also noted that there did not seem to be a decrease in water temperature above the hose, as the mean temperature of the adjacent water was about the same. These observations suggest that, for this one application, the air bubbling system obtains very complete mixing of water within 50 metres of the hose. Although this one example is not sufficient to lead to a definite conclusion, it does suggest that the spacing of holes might be larger than is commonly used, as shown in Table I. In the Malar investigations[14] it was found that changing the spacing of the holes from 5 to 10 metres did not seem to change the area kept free from ice formation.

In what is perhaps the most detailed field investigation of air bubbles systems, Kaitera[29] made many observations of water temperature during air bubbling trials. He noticed that the temperature of the water did not fall as low as would be expected above the hose, though considerable heat was used to melt the ice and keep the area free of ice. He suggests that there must be considerable lateral movement of heat into the area near the air hose from the adjoining water mass.

Kaitera also investigated the dependence of ice melted on the volume of the compressed air used, the temperature of the water and the depth of the nozzle. Fig. 10 summarizes his findings. As might be expected, the higher the water temperature and the greater the depth of nozzle, the better the ice melting rate. His experiments provide some useful information on actual quantities of ice that can be melted under field conditions.

Conclusion

It is possible that much of the information available on air bubbling systems has not been made public. Judging from the reports that are available, however, considerable investigation is still needed before this technique can be so developed as to be the most efficient way of using the heat stored in water under ice cover to prevent ice formation.

Acknowledgements

This paper is a contribution of the Division of Building Research of the National Research Council of Canada, and is published with the approval of the Director of the Division. The author is indebted to several members of the Division, particularly to Mr. L. Gold, for helpful criticism of this report, and to Mr. R. Armour for help with some of the temperature measurements.

Discussion

ELECTRONIC COMPUTATION IN THE CHEMICAL INDUSTRY

R. N. Boyd, M.E.I.C.
Supervising Engineer, Design Services, Dupont of Canada Limited, Montreal.

V. J. Bakanowski, M.E.I.C.
Principal Computation Engineer, Dupont of Canada Limited, Montreal.

The Engineering Journal, December 1960, page 47

Discussion by D. A. Lamont, MEIC

The authors are to be congratulated on presenting a most interesting paper.

In particular, I would like to express my complete agreement with the point they have raised in connection with the need for good analytical engineers in industry to take full advantage of computer techniques and facilities. To my mind, computers have emphasized the need for mathematical and analytical engineers, the emphasis being on this ability more than on the particular branch of engineering in which they have received their formal training. I also believe that this change in requirements has brought about a need for a change in education programs. I would strongly suggest that industry and educators work closely together.

It would appear from the paper that all the authors' experience is in "off-line" general purpose computers, whereby the computer is used to calculate the set-points in operating the process; these set points being then manually set by the operators. I would like to ask the authors if they have had any experience or given any consideration to using "on-line" special purpose computers whereby the computer becomes permanently an integral part of the process control.

Discussion by D. C. Baxter

The authors of this paper are to be complimented on their lucid exposition of the application of computers to their chemical engineering field. Their paper underlines the fact that such devices are now an accepted engineering tool and are used in many engineering organizations on a routine basis.

The authors have put forward as the dominant feature of engineering computation the implementation of mathematical models in various phases of their work. Some further noteworthy applications are discussed below.

(1) The assistance which can be given to engineering or scientific testing, both in the design of experiments so that maximum information can be obtained from a given number of tests, and in the statistical analysis of test results so that the required casual relationships can be uncovered or the results presented in a more meaningful way. An important product of such analysis, which engineers often ignore, is the measure of how accurate or how meaningful is the answer obtained.

(2) With regard to testing techniques, electronic computation has opened up the use of random techniques by which tests can be carried out on operating plants or systems without the need for artificial intervention. Random or chance disturbances themselves provide the needed information when inputs and outputs are analyzed by correlation function methods.

(3) Another computer field of application is of course that of data logging and/or control. Analog devices have been performing this task for a number of years, and the simulation of a plant controller is illustrated in the authors' example. The logical ability of digital computer control has led to the appearance of several commercial, general purpose control computers in recent years.

(4) The application of digital control to an analog plant simulation leads to the need for combined or hybrid computer installations—an interesting extension of the authors' description of the particular advantages of analog and digital devices. In such a unit each contributes to a more versatile computation and simulation tool.

(5) In the product scheduling field the assignment of production outputs or the specification of input quantities is often determined by a computer calculation and the techniques of linear programming. The quantities are chosen from among the possible ones in such a way that cost is minimized or profit made a maximum.

The present discussor will not examine in detail the two examples given by the authors. They certainly represent every-day problems of the types handled by the two computers. The involved computational, arithmetic and logical aspects of the stress analysis computation contrast with the easy manipulation of variables, convenient recording, low accuracy and high speed requirement of the analog plant simulation.

Finally the desirability of "open-shop" operation of computers by engineers can be supported by this discussor's own experience. There certainly arise problems of sufficient complexity and length that closed-shop operation is an economic necessity (for digital computers at least). On the other hand there are many problems in research, design and operation where the engineer can best set up and run his own problem. Changes in plan can be made easily as the problem progresses, results obtained have more meaning to the engineer, and further possibilities offered by computers are more easily recognized. As the authors point out, in such an engineering operation the amount of red-tape involved in using the computers must be kept to a minimum and expert consulting advice should be on hand as needed. It has been the discussor's as well as the authors' good fortune to have both analog and digital machines

Canadian Developments

P.F.R.A. New Soil Mechanics Laboratory

One of the most recent building additions to the campus of the University of Saskatchewan was opened Dec. 14. The Soil Mechanics Laboratory of the Prairie Farm Rehabilitation Administration, Federal Department of Agriculture, is a three-storey building, of brick construction with a reinforced concrete frame costing approximately $430,000 to build. The function of the laboratory is for the testing and analysis of soils, concrete and other materials used in the construction of engineering works built by the organization in connection with its water development program. The Soils Mechanics Division was established in 1941 to provide the basic soils information required in the planning and design of the many water conservation projects that have been built under the P.F.R.A. These works have included structures from small individual farm sized dams to such large scale water conservation and development schemes as the St. Mary and Bow River Irrigation projects in Alberta and the South Saskatchewan River Dam currently under construction.

Science Postgraduates

The schools of graduate studies in Canadian universities have been expanding so rapidly since 1945 that the National Research Council of Canada has increased its allocation for grants and scholarships by thirty times. Highly trained scientists constitute one of the country's most important resources yet little information concerning them has been brought together and made known to those interested. The higher education of scientists and engineers presents a complexity of problems, it is becoming increasingly necessary for educators, legislators, administrators and employers to know more about the students who are engaged in graduate study and research in our universities. It is important to have the facts concerning the number of graduate research students, their fields of study, universities attended, expenditures made, financial support received, where they go when they graduate, who employs them, starting salary and relevant personal information. The National Research Council is constantly concerned with these questions and an article written by E. H. Stock and P. J. Beaulieu published in Canadian Public Administration, Dec. 1960, reports on general information collected annually by the N.R.C. and on two recent surveys that have been made on graduate science students in Canada.

A questionnaire sent out in the summer of 1959 to 2,196 graduate students showed that more than one-third were non-Canadians. They were distributed as follows; 148 from the U.K., 95 from Continental Europe, 58 from India, 70 from other Asiatic countries, 47 from the U.S.A., 18 from the British West Indies, 17 from Africa and 11 from Australia and New Zealand. Most full-time graduate students received financial support of some type, only seven per cent reported no support. More than one-third were getting their assistance through university funds, a quarter of them through the National Research Council and the remainder from various other sources which included government, industry, foundations and associations.

A survey completed last summer was designed to find out more about what happens to the new Ph.D. This survey was made of 385 graduate students in science and engineering who, in the Fall of 1959, were registered to obtain their doctorate during 1960. Twenty-six per cent indicated that they would not be able to complete their doctorate during 1960. Two hundred and twenty seven students reported that they had completed or expected to complete the requirements for a doctorate degree in 1960. Of these, 157 were Canadians; 113 to be employed (96 in Canada, 16 in the U.S.A. and one in India), and 44 to accept fellowships (13 in Canada, 16 in the U.K., 6 in the U.S.A. and 9 in other countries). Almost 70 per cent were leaving the country for further study, only 10 per cent were taking up employment in the U.S.A. Of the 70 non-Canadians 36 were remaining in Canada, 25 of them to be employed.

Among the 121 Canadians and non-Canadians who indicated that they were accepting employment in Canada, the universities attracted the greatest number (44) at the lowest average of the basic annual salaries reported ($6,210). The Federal Government was employing the next largest group (37) at the next lowest average salary ($6,490). Canadian industry was employing 22 new graduates at the highest average salary ($7,-620). The remaining 18 were being hired by (or returning to) various employers mostly under provincial government jurisdiction, at an average salary of $6,-990 per annum. Twenty-six doctors in science were to be employed in the U.S.A., almost half of these were being attracted to industry at the highest average of all salaries reported ($9,780).

Of the 63 graduates who were continuing their work by means of a postdoctoral fellowship, most would be doing so at the universities: 16 in Canada with an average stipend of $3,740, 10 in the U.S.A. ($4,910), 18 in the U.K. and 6 in other countries. Government and research institute fellowships have been accepted by 13, seven of them to study in Canada with National Research Council postdoctorate fellowships at stipends of $3,-700 for single and $4,500 for married fellows.

The National Research Council has also compiled a list of students registered in the graduate schools in physical sciences, engineering and biological sciences 1960-1961.

Montreal Science Fair

The first Montreal Science Fair is to be held April 7-8 at the Université de Montreal and is open to all secondary school students from greater Montreal. Organized by the Montreal sections of the Chemical Institute of Canada and the Engineering Institute of Canada, the Science Fair will provide unique opportunities for students who show an interest in some aspect of science and engineering to earn a university scholarship and at the same time bring recognition to their schools. Contestants are required to submit self-designed and assembled projects and prizes include $400 and $200 university scholarships. Groups of outstanding scientists, industrialists, educators and laymen are to perform the judging.

Science Fairs have been held with considerable success in other Canadian centres over the past few years and the following are to be held in 1961:

March 17-18—Kingston Fair, at Kingston; March 18—Richelieu Valley Fair at Beloeil, Que.; March 23-25 — Hamilton Fair at Hamilton; April 5-6 — Ontario Fair at Toronto; April 6-7 — Manitoba Fair at Winnipeg; April 7-8 — Montreal Fair at Montreal; April 22 — Vancouver Fair at Vancouver.

Use any reproduction process . . .

Your drawings reproduce sharper, clearer with Eagle Turquoise

TURQUOISE LEAD HOLDERS hold any TURQUOISE lead (5B to 9H).

TURQUOISE DRAWING PENCILS are made in 17 degrees, 6B to 9H.

TURQUOISE WITH ERASER, in grades 4B to 6H, is increasingly popular as a field tool.

Whatever the process, you'll get sharper, clearer prints if you use an Eagle TURQUOISE. Lines are more opaque and also blacker—because the graphite in TURQUOISE is finer-ground with denser-packed particles.

Get smoother, neater drafting, too! TURQUOISE glides effortlessly, evenly over paper, cloth, vellum, "Mylar"® And uniform grading means consistent peak performance.

So, no matter what you draw on, how you reproduce it, use Eagle TURQUOISE for superior results every time!

EAGLE

WANT A FREE SAMPLE? Write for a TURQUOISE pencil or lead, in the degree you'd like to test on your favourite drafting material. Eagle Pencil Company of Canada Ltd., 217 Bay St., Toronto 1.

International News

International Current Meter Group

Among the methods for metering large rates of flow accepted by the various national and international test codes, few have been longer established than the current-meter technique of flow measurement. In consequence the experience available is substantial, particularly on the Continent where this form of gauging is used almost exclusively in hydro-electric power-station measurements.

Certain aspects of current-meter performance and calibration procedure need further clarification. Researches to that effect have been in progress for a number of years in different countries and it was with the aim of co-ordinating these that the International Current Meter Group, ICMG, was founded in 1959. Under the Chairmanship of Professor Gerber of the Swiss Federal Institute of Technology, Zurich, representatives of seven countries drew up a complete research and development program and reached agreement on the distribution of effort. Members meet annually to review progress and to discuss the results obtained and these are published on behalf of the ICMG by the National Engineering Laboratory at East Kilbride, Scotland.

The ICMG is essentially a working group composed of experts in the field of flow measurement by means of current-meters, who are directly concerned with the problems under investigation. It is hoped that the formation of this group will, by resulting in a deeper understanding of the possibilites and limitations of a standard technique of flow measurement, give rise to the development of advanced methods and instrumentation. Delegates are interested in receiving information on current-meter performance or measurements of unusual interest. Contributions should be addressed to Dr. F. A. L. Winternitz, Secretary, ICMG, National Engineering Laboratory, East Kilbride, Glasgow, Scotland.

Another Nuclear Power Station for U.K.

Britain's latest nuclear power station is to be built at Sizewell, Suffolk for the Central Electricity Generating Board by the English Electric Co. Ltd., Babcock and Wilcox and the Taylor Woodrow Atomic Power Group. The contract is worth about £55 million. Supplying 580,000 kw to the national supergrid, the station will have the highest output and be the most compact of the seven commercial atomic stations now on order in the U.K.

The major new features of the design from which this compactness is derived are a new type of reactor building with both reactors under one roof; thick-walled, small pressure vessels, few high capacity boilers and the use of two large turbines to give a small turbine hall. In the reactor building, the two reactors are placed at either end of a single building, the space between them being used for common control, service and plant rooms. The concrete shield floor above the reactors extends from one to the other and allows simplification of reactor fueling and servicing machinery. Work begins at Sizewell in April and the station is planned to be in full operation in 1966.

EDUCATION

Israel Trains Nuclear Engineers

For the past four years the Technion, Israel Institute of Technology in Haifa, has been training a select number of engineering students in their senior undergraduate year in a special program in nuclear engineering. About two and a half years ago a special Department of Nuclear Science and Engineering was established at the Technion for this purpose, and a graduate program was added for the training of nuclear engineers. This program includes advanced study and a research thesis.

In addition to its teaching activities, a large proportion of the time and resources of the new Department is devoted to research activity in the field of applied nuclear science and engineering, especially in theoretical and experimental reactor physics, reactor control, nuclear chemical and reactor chemical problems, applied radiation and heat transfer.

The expanding demands of Israel's national nuclear program for peaceful atom work and the increased number of nuclear scientists and engineers which will be required, has led to the recent decision to expand and consolidate the Department of Nuclear Science and Engineering. At present the department has a teaching staff of 12 senior and junior members and is equipped with special physics laboratories, a laboratory for work with radioactive substances and a reactor simulator. Over 50 undergraduate students in different branches of engineering have received special training and six post-graduate students have completed their research work and have been granted higher degrees.

French Government Scholarships for Canadians

The French Government has established a "Service de Corporation Technique", in Paris to organize and coordinate foreign student's work in France, both in formal courses and in training positions in industry. It offers a grant of 750 new francs a month, free return trip from France to Canada, free travel relating to work while in France and comprehensive medical coverage.

Candidates are required to hold an engineering degree from a university of high standing, to have had some field experience for at least one year, a sufficient knowledge of French, and must present good references and a proposed plan of study. Particularly suitable for such scholarships are professional engineers and university professors who wish to supplement their knowledge in their specific fields.

International Course in Hydraulic Engineering

The Netherlands Universities Foundation for International Co-operation has published its prospectus for 1961-1962 International Course in Hydraulic Engineering to be held at the Technological University of Delft. The Technological University has the scientific potential at its disposal and NUFIC takes charge of the administrative side, concerning itself with the recruitment of the participants and with the provision of social facilities on their behalf. The course is organized under the guidance of a Board of Trustees, composed of representatives of both bodies.

Subjects given on the course include civil engineering, geodetical engineering, mining engineering, chemical engineering, naval engineering, aircraft engineering, metallurgical engineering and mathematical engineering. Three programs have been compiled from these subjects. These are: a. Tidal and Coastal Engineering (including harbors), b. Reclamation (including ground-water recovery), c. Rivers and Navigation Works. If, with a view to his future, a participant should prefer a combination of subjects other than that provided by one of these branches of study, he may submit a special program for approval. The course begins Oct. 19, 1961 and terminates Sept. 14, 1962.

The course is open to those who have received a thorough preliminary training in engineering. Practical experience in civil engineering is desirable in order to derive the maximum benefit from the course. A degree in civil engineering (or a related branch of study) of some university or other institution of higher learning is the minimum requirement for admission. Thorough knowledge of the fundamental principles of construction, applied mechanics and hydraulics and a good knowledge of calculus is essential. The course is given in English. Closing date for application July 31.

Summer Conferences at University of Michigan

Twenty-seven courses are scheduled for the 1961 Engineering Summer Conferences. Lectures are presented by outstanding men from industrial and governmental laboratories, as well as from universities. In addition to lectures, course time is assigned to discussion and work sessions, laboratory work and demonstrations.

These one and two week courses held during June, July and August are: Technical Writing, Recent Industrial Engineering Developments, Quality Control by Statistical Methods, Foundations and Tools for Operations Research and the Management Sciences, Recent Mathematical Advances in Operations Research, Modelling and Simulation in Operations Research, Advanced Data Processing Techniques, Introduction to Digital Computer Engineering, Theory of Computing Machine Design, Programming Concepts, Automata, and Adaptive Systems, Advanced Automatic Programming, Advanced Numerical Analysis, Intermediate Numerical Analysis, Analog Computer Solutions of Partial Differential Equations, Systems Engineering, Human Engineering Concepts and Theory, Signal Detectability and Sensor System Design, Random Processes, Semiconductor Theory and Technology, Advanced Topics on Solid State Masers, Fundamentals of Infrared Technology, Machinability of Metals, Applications of Stress Analysis to Design and Metallurgy, Mathematical Modeling for Metal Casting Processes, Flight Mechanics of Space and Re-Entry Vehicles, Elements of Nuclear Power Reactor Engineering, Underground Storage of Natural Gas.

Month to Month

Why Bother?

IT SEEMS that every week the mails bring another questionnaire or form to be filled out and returned promptly to the sender. Recently another was sent to you; this one from the Institute. Why bother to complete and return it promptly?

The fact that the form is a simple one —it takes only a minute to complete— really isn't sufficient reason to bother. What should concern you is the fact that the information received from this questionnaire will help the Institute improve its many services to you.

Frankly, no one has more than an educated guess as to what specific work Canada's tens of thousands of engineers are doing. We can find that so many received their degrees as, say, Civil, Mechanical or Electrical engineers. But this doesn't tell us into what fields they may have drifted, or what specific positions they have attained.

And so much depends on knowing. Technical programs and activities can be planned with greater confidence and for greater benefit if the interests of Canadian engineers are known in detail. The selection of technical papers in the Engineering Journal might be improved. The Institute Library and other headquarters services could be performed for greater total benefit if the staff knows exactly whom they are serving. Both Montreal and local technical programs will be tailored to best suit your interests.

An accurate record of the positions, nature of the employers and technical interests of the readers of the Engineering Journal also is essential, so that we may conform to the requirements of the circulation auditors of EIC publications. And, when we produce the new EIC membership list later this year, you will be listed accurately.

This is why we feel it is worth the bother to complete the questionnaire. A minute of your time will help us to help you.

Garnet Page

COMMITTEE ON TECHNICAL OPERATIONS

The Committee on Technical Operations was formed six years ago to carry through the Institute's increasingly heavy technical programs and activities. Its formation put on a streamlined and continuing basis the flow of technical information to Institute members.

The Institute has been a technical society since its inception. The organization and presentation of technical meetings has always been one of its primary objectives, as stated clearly in the founding Charter of the Canadian Society of Civil Engineers.

Engineering science has become increasingly complex since the CSCE was formed in 1887. By 1918 the all-embracing term "Civil" was inadequate to describe the many new interests of Canadian engineers and the society was renamed "The Engineering Institute of Canada."

While the objects of the Institute have remained the same, the machinery for effecting these objects has recently been brought up to date by the establishment of CJO.

This outline describes the technical activities of the Institute at all levels, national, regional and branch; how the CTO ties in with these activities; and the part played by individual members in the work of CTO and the Institute's many technical activities.

Organization

The Committee on Technical Operations is the national organization within the Institute through which the interests of all the Technical Divisions, which correspond to the major branches of engineering, are co-ordinated into national programs. CTO advises Council on matters of policy regarding technical activities, and is the national technical voice of the membership.

Objects

The following, taken from Section I of the By-Laws of the Institute, are the objects of CTO:

(a) To develop and maintain high standards in the engineering profession.

(b) To facilitate the acquirement and interchange of knowledge among its members.

(c) To collaborate with universities and other educational institutions in the advancement of engineering education.

(d) To promote intercourse between engineers and members of allied professions.

(e) To co-operate with other technical societies for the advancement of mutual interests.

(f) To encourage original research, and the study, development and conservation of the resources of Canada.

Terms of Reference

The terms of reference of CTO, as stated in the By-Laws, are:

"The Committee on Technical Operations shall consist of representatives of the several technical divisions of the profession. It shall keep all technical activities of the Institute under constant review."

"It shall recommend to Council the establishment of such divisions of the Committee on Technical Operations as necessary to carry out reviews of specific fields of technical activity and also such special or standing committees of the Institute as may appear warranted by developing needs in technical areas. It shall recommend to the Publications Committee particular papers for publication."

"The divisions of the Committee on Technical Operations shall encourage the formation of technical sections dealing with its area of engineering in the branches, assist such technical sections in their work, and co-ordinate all activities of such technical sections in the various branches."

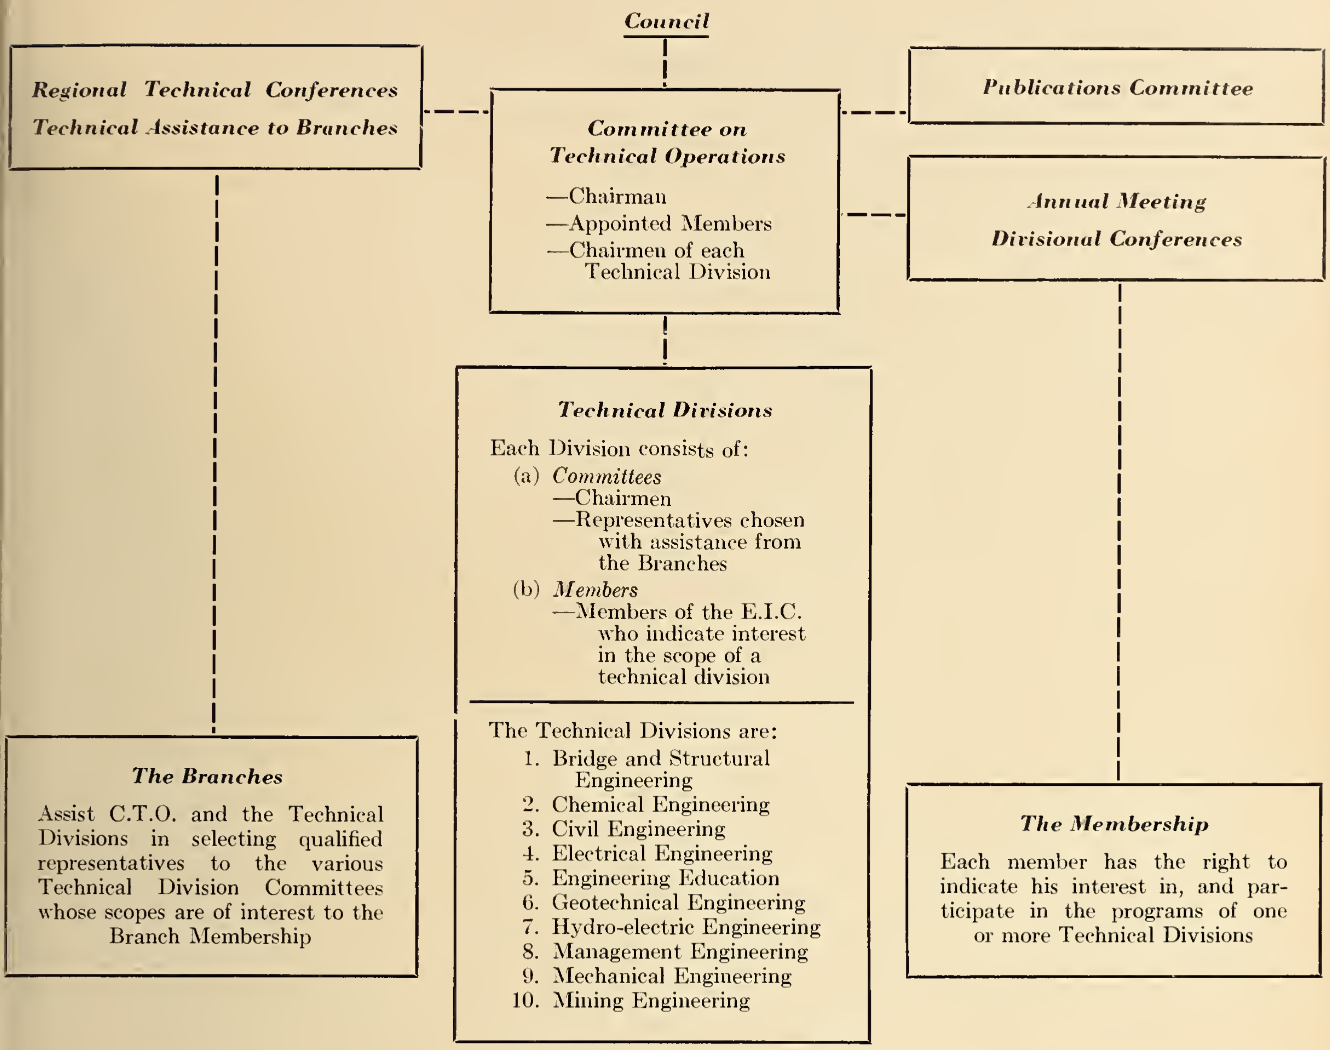
"It shall report quarterly to Council on technical activities of the Institute."

"That Council entrust responsibility for co-ordination of regional technical conferences and approval of requests for holding such meetings to the Committee on Technical Operations."

Composition

CTO is appointed by Council. It consists of a chairman, a number of appointed members, and the chairman of each of the Technical Divisions. At least two members of the Committee must be members of Council.

THE ENGINEERING INSTITUTE OF CANADA
TECHNICAL OPERATIONS



Organization

As is shown by the chart, CTO is a standing committee supported by the Institute's headquarters staff which provides secretarial and administrative assistance both to the national CTO and to the Technical Division Committees.

Each Technical Division Committee consists of representatives chosen with the assistance of the Institute's branches on the basis of technical eminence and geographic location. These representatives form the "grassroots" network through which reports of interesting activity are channelled to the national committee.

Operation

(a) General

Much of the responsibility for the successful operation of the technical divisions lies with the representatives who make up the Technical Division Committee.

The chairman of Technical Division Committees play key roles. It is incumbent upon them to evaluate correctly the material which they receive from many sources, and to develop ideas for technical papers and conferences and joint technical projects with other groups.

While the secretarial service of headquarters are available to division chairmen, it follows from the nature of their personal contact with their committee representatives that they are required to perform considerable administrative work.

The Technical Division Committees of CTO are in contact with practising engineers throughout Canada. Since the Committee represenatives are not obliged to attend meetings, there is no practical limit to the number of appointees.

(b) Annual Meetings

Each year CTO assigns to each Technical Division its quota of papers for the next Annual General and Technical Meeting. The technical division committee is responsible for the preparation of the best possible technical program for the division.

(c) Divisional Conferences

Divisional conferences are national in scope and deal exclusively with the specialized activities of one or more technical divisions. Such conferences call for the co-ordinated effort of all representatives on the committees of participating division or divisions, and for an extra effort on the part of those residing at the site of the meeting.

(d) Regional Technical Conferences

The part played by technical divisions in regional technical conferences is very much like that played at Annual General Meetings, except that a greater organizational responsibility usually rests on the divisional committee representatives resident at the site of the meeting. Strong, interesting and diversified technical programs are essential for regional technical conferences.

(e) Branches

Branch Executives are periodically asked for nominees as representatives to the Technical Division Committees and appointments are made by the Division chairman as required. As the technical division organization becomes more firmly established, it is anticipated that the representatives to division committees will become firmly involved with the organization of branch technical programs, so that branch activity will include the best possible technical programs and meetings in all parts of Canada.

(f) Co-operation with other groups

The technical divisions operate in specific branches of engineering, and are in a position to work closely with many specialized technical societies some of which operate branches or sections in Canada. Such co-operative efforts may be on either the national or local level.

CTO is so organized that new divisions may be formed by Council at will, the only requirement being evidence of a sufficient number of members who share a common interest in a generally recognized branch of the profession. Such members must be willing to devote time and effort to the development of new divisions, since the creation of a division merely provides a medium for the exchange of knowledge and ideas among members of the Institute.

As a general rule, specialized groups within the main branches of engineering should remain within the appropriate technical division as long as these members are able to obtain satisfactory service from it. This simplifies the administration of CTO, but does not preclude the creation of new divisions when a real need arises.

Descriptions and Scopes of the Technical Divisions

(a) Bridge and Structural Engineering Division

This division embraces the field of structural engineering, including new projects and techniques, new developments, research and application.

The entire field of structural engineering is covered, and the technical papers are concerned with bridge building, metal and steel construction of buildings, plastic design in steel, structural design in concrete, and new developments in the structural use of plastics and other synthetic materials.

The division represents the Institute as a member of the International Federation of Bridge and Structural Engineering, and as a participant in the activities of the Column Research Council.

It also co-operates closely with other divisions of CTO where there are overlapping interests, such as the civil engineering division and in the hydro-electric engineering division.

(b) Chemical Engineering Division

Through the Institute's international affiliations, the chemical engineering division has access to the programs and activities of the European Federation of Chemical Engineers. It co-operates closely with The Chemical Institute of Canada and with similar societies in other parts of the world.

(c) Civil Engineering Division

This division deals with all aspects of civil engineering not specifically covered by the Bridge and Structural Engineering Division and the Ceotechnical Engineering Division. It is concerned specifically with earth works, highways, hydrology, municipal engineering, transportation, marine works, and general construction.

There are few civil engineering projects of significance which are not now fully covered in the publications of the Institute, and the civil engineering division's attention is now largely concerned with the organization and sponsorship of technical meetings and conferences.

(e) Electrical Engineering Division

The electrical engineering division covers an extremely wide range of subject matter in the electrical field, with the only specific exception at the present time being in the field of Hydro-electric power which was made a separate division at the inception of the Committee on Technical Operations in recognition of the heavy emphasis on hydro-electric power in Canada.

The division now encompasses both power and electronics and is involved in all forms of electricity from direct current to the highest useable frequencies. Close co-operation is maintained with the Hydro-electric Engineering Division.

(f) Engineering Education Division

The reorganization of the Committee on Engineering Education to a division was made to facilitate general discussions at annual meetings, and to make it possible for interested members to present papers and to have them published in the literature.

Through the Institute's international contacts, this division is able to communicate and exchange ideas with other engineering educations organizations throughout the world.

(g) Geotechnical Engineering Division

This division, established in 1960, was organized to cover the technical requirements of the growing number of civil engineers who have become specialists in foundations and soils meehanics. The name was deliberately chosen to ensure complete coverage of this speeial field, which embraces the scientific applieation of man's knowledge of the earth's crust; since kindred subjects such as engineering seismology, and foundations in permafrost are dealt with by this group.

(h) Hydro-electric Engineering Division

Canadian engineers have an outstanding international reputation in hydro-electric work, and they are strongly represented at major world power conferences. The Hydro-electric Engineering Division plays a major part in fostering such partieipation, and in arranging for adequate representation and suitable papers to cover Canadian activity in this field.

Since hydro-eleetrical developments are usually joint civil-electrical-mechanical projects, this division works closely with these groups in the preparation of technical programs.

Specific subjects covered by the Hydro-Electric Engineering Division include rainfall studies, control of watersheds, design of penstocks, generators, turbines, control systems, surge tanks, floodways, load factors etc., and research into problems such as water hammer, cavitation, generator design, turbine design and control systems.

(i) Management Engineering Division

The management division was formed early in 1959 in recognition of the fact that large numbers of members are interested in the engineering aspects of modern business management. The main purpose is to foster and promote the exchange of ideas on scientific management at a level of the trained engineer-manager, but the division also embraces a number of related disciplines which apply to the operational level of management, such as industrial engineering, materials handling, quality control, and operations researeh.

The management division maintains close liasion with the Canada Management Council and is thus able to participate in the activities of the International Organization for Scientifie Management.

(j) Mechanical Engineering Division

The scope of this division's activity covers the major sub-divisions of mechanical engineering, including machine design, thermo-dynamics and fuels, prime novers and aeronautical engineering.

(k) Mining Engineering Division

Mining engineering was one of the first engineering subjects taught in Cana-

The Seventy-Fifth Annual General Meeting of the Engineering Institute of Canada will be held on Wednesday, May 31, 1961, at the Hotel Vancouver, Vancouver, British Columbia, between the hours of 9:00 a.m. and Noon. This meeting will receive the report of the official auditors, the Annual Report of Council, Committees, Representatives, and Branches, and such other business as may come before the meeting.

Garnet T. Page, M.E.I.C.

General Secretary

dian universities, and it is considered a very important branch of engineering in this country because of the importance of mineral resources in Canada's economic life.

This division is concerned with all aspects of mine operation and ore handling up to and including the concentrate stage. Its work involves both underground and open pit operations, so there is a close link with civil engineers. Activities in ore processing and concentrating call for close co-operation with the techniques of mechanical engineering and chemical engineering, and the mining engineering division works closely with both these divisions.

Branch Technical Activities

1. Objects

The Institute branches are the foundations from which grow the activity and the strength of its technical activities. The basis of these technical activities are the groups of members at the branch level who share common technical interests, and who engage in activities for their individual benefit and for the benefit of the profession as a whole. The reasons for the existence of the Institute are most simply and most dramatically illustrated at the branch level, because it is at the branch level that the Institute must provide the necessary organization to foster technical activities and services. This is the fundamental obligation of the Institute towards its members.

2. Organization

Branches are autonomous working within the overall scope of the Institute's Charter and By-Laws, and each is responsible to provide the organization best suited to the needs of the members in its area. Contacts are maintained through the technical divisions and the branch representatives on divisional committees, but a divisional committee may communicate directly with any branch, and is always ready to give advice and assistance to branches upon request.

3. Operation

One of the most effective media for the dissemination of knowledge at the branch level is the presentation of technical papers.

The planning, preparation and presentation of technical programs for branches is the major responsibility of the program committee of each branch. There are times, however, when they may require assistance and it is at these times that CTO and its divisions can provide useful services. Visiting speakers may be provided to deal with specific subjects of interest to the branch; advice and help in providing qualified panel members may be available; and the benefit of CTO's extensive experience in conducting symposia is always available.

In recent years CTO has advocated the organization of discussion groups for some of the smaller branches, to which it is difficult to attract good speakers of high repute.

It is stressed that the effective implementation of the Institute's agreement with the Institutions of the United Kingdom can come about only through branch action, and it is very much in the interests of all members to offer a satisfactory technical "home" to qualified members of these sister societies.

CTO and the Individual Member

This summary outlines the history, the purposes, and the organization of the Committee on Technical Operations of The Engineering Institute of Canada. It would be obtuse if it did not finally point out that the entire activity exists for the use and benefit of each individual member.

The world of engineering technology is vibrant and living; it requires the joint effort of all EIC members to keep it so, and it is to your personal advantage to give your professional talents in full measure, for you will receive much greater benefit than you give.

How can you participate? By serving the technical committees at the local level. By examining the technical programs made available at the local, regional, divisional, and national levels, and by making arrangements to attend meetings which interest you. Participate by questioning the speaker on points which may not be clarified adequately, and amplify his statements by your own experence if this is in order. Finally, participate by examining your own experience and trying objectively to decide whether or not you have some personal experience to offer to your profession in the form of a paper or address. Knowledge builds on knowledge, and one never knows the limit of a human idea, provided that idea is expressed to others who may be in a position to develop it. This is the very essence of the Institute's technical operations.

COUNCIL MEETING

The Council of the EIC met in Montreal, Saturday, Jan. 28, with President Dick as the Chairman. The following highlights are taken from the minutes of the meeting.

Budget

F. L. Lawton, Chairman of the Finance Committee, introduced the 1961 budget. Reviewing the Institute's activities of 1960 Mr. Lawton noted numerous areas in which marked progress was made. These included: more extensive coverage and higher quality technical papers at annual and regional meetings; 30 per cent more technical papers in the Journal; an active Membership Committee working on a national basis; the second largest increase in membership in the last 11 years; an active Committee on Branch Operations which already is achieving results; the completion of a long-term project which involved putting on a thoroughly sound basis the accounting practices of the Institute; the institution of the co-operative agreements with the United Kingdom Institutions and the initiation of discussions regarding co-operation with sister societies in France; the clarification of membership procedures; the streamlining of Council activities; the institution of procedures whereby the Vice-Presidents assume a share of the load carried previously by the President. A great deal of credit for these considerable achievements, Mr. Lawton said, rests with the President, Dr. Dick.

Mr. Lawton reported that a number of factors contributed to a 1960 deficit which was $38,572 higher than had been anticipated. These included a change in publications policy, which was discussed fully at every Council meeting from February to August, 1959, and which was announced too late in 1959 to achieve a maximum financial return in 1960. In addition, the cancellation of the members' subscription payment for the Journal decreased the revenue by some $58,000. Further, the regrettable death of the Publications Manager in 1960 caused the direct assumption of the responsibility for advertising sales by the Headquarters staff, with certain additional costs during the latter part of the year.

As a result there was a drop of about $17,000 in advertising revenue, a decrease of $58,000 in members' subscriptions and a large increase in printing and mailing costs due to a higher circulation than had been foreseen.

However, there are indications that the advertising sales revenue will increase in 1961 — the largest single sale of advertising space in the Journal's history just having been made. The Finance Committee has considered thoroughly the 1961 budget and is planning for a surplus of more than $22,000 in 1961.

Agreements with Provincial Associations

On the recommendation of the Finance Committee, the Council resolved that the President be authorized to name two members to represent the Institute on the Joint Finance Committee in Nova Scotia, thus reactivating the Joint Finance Committee in that province.

Notification was received from the Association of Professional Engineers of Alberta stating that "now that agreement has been reached to levy a charge of $1 against each Joint Member in Alberta to cover the administrative costs involved in the Joint Agreement, the A.P.E.A. Executive Committee has directed that the previous notice of termination of the Joint Agreement shall be withdrawn . . . "

On the recommendation of the Finance Committee, and recognizing that a number of problems are created by these agreements, it was resolved that the Institute should not now take action concerning these agreements, pending a decision with regard to Confederation.

Technical Operations

The Committee on Technical Operations has produced a draft E.I.C. Technical Operations Manual. A final version will be published soon. A summary of the manual appears in this month's Engineering Journal.

Also prepared is a draft Meeting and Conference Manual, and comments now are being received from previous Annual Meeting Committees.

A list of forthcoming technical meetings in 1961 was presented, as follows: EIC Annual Meeting, Vancouver, May 31 - June 2.

Joint Meetings

ASME-EIC Hydraulic Division Conference, Montreal, May 7-10

ASME (Co-sponsor EIC) Production Engineering Conference, Toronto, May 9-12

International Heat Transfer Conference, (Co-sponsor EIC) Boulder, Colorado, Aug. 28-Sept. 1

EIC-CIMM Regional Technical Conference, Newfoundland, November

Soil Mechanics Conference, Montreal, Nov. 9-11

Proposed Joint Meeting

CIC Chemical Engineering Division and EIC C.T.O. Chemical Engineering Division, November

EIC Regional Conferences

Southern Ontario Regional Conference, Niagara Falls, March 25

Montreal Regional Conference on Urban Transportation, Montreal, April 6-7

Northwestern Ontario Regional Conference, North Bay, May 6, tentatively

Quebec City Regional Conference, Quebec City, Nov. 2-4

75th Anniversary of EIC—1962

The 75th Anniversary Committee, with Dean H. Gaudefroy as chairman, presented its report which recommended projects, publications and special events to suitably mark this significant anniversary.

Branch Officers Conference

The Chairmen of the Committees on Branch Operations recommended that the nature of the Annual Branch Officers Conference at the 1961 Annual Meeting be altered. These changes would provide for demonstrations and illustrations of how branches may solve a number of problems, particularly regarding such things as membership promotion, attendance and support from senior executives in the area.

Policy Discussion

Council considered a letter sent by President Dick to members of Council in which he asked for opinions and suggestions concerning Institute membership and services. An ad hoc committee summarized the discussion, an abridgement of which follows.

EIC Image: There is a vital need to establish a clearer image of the Institute and this should be the major responsibility of the President as he visits Branches. A facet of this image should be a better realization of the many services available to E.I.C. members.

Communications: Apparently few members have sufficient knowledge of the Institute's activities beyond the Branch level. More liaison is needed between Branches and Council, and thus with the membership at large. There should be a militant effort made to promote better communications within the EIC and provide information to the membership. Every effort should be made to change the attitude of "What do I get out of the EIC?" to "What do I do for the EIC?" Increased effort should be made to inform non-members of the Institute. More attention should be given: improved communications between C.T.O. and Branch C.T.O. representatives; improved communications between the EIC and students; making good use of existing mailing facilities to assist in promoting the E.I.C. image and better communications; effective reporting of Branch and local engineering happenings to the Engineering Journal for publication.

Planning: There should be intelligent Branch planning of meetings and special care in the selection of officers. It may be dependent upon the Branch to obtain the maximum help from Headquarters in their planning. It should remain possible for as many members as feasible to take an active part in Branch affairs.

Sale of Advertising

Council noted that despite the pro forma nature of the Dec. 20, 1960, meeting of Council, it had been necessary to take immediate steps regarding the sale of advertising, due to the death of E. J. Blandford. Following careful discussion by the Finance Committee and other appropriate officers of the Institute it was agreed that the Institute assume sole responsibility for the sale of advertising in its publications. The advertising sales staff previously employed by the late Mr. Blandford have been employed by the Institute, and a Manager of Advertising Sales has been employed.

Activities of President and Vice-Presidents

Dr. Dick reported presidential visits had been made to the Ottawa and Quebec City Branches, that he attended the Annual Meeting of the Association of Professional Engineers of Ontario, and that he was to attend the Annual Meeting of the Montreal Branch. The President reiterated the necessity for the Institute to do for the Branches and the members what they particularly need, and these needs must be established and defined. Dr. Dick said the President will continue to visit Branches and that the General Secretary will make more separate visits to the Branches.

Vice-Presidents Cross, Antenbring, Higginson and Lawton reported on their activities and visits in their respective territories. The President said the Vice-Presidents have been extremely active, and suggested that their duties require more definition to assist in their expanding roles.

Tariff Item 180 (e)

The General Secretary said it had become obvious at the last minute that little good would be served if the Institute and the Canadian Council of Professional Engineers submitted to the Tariff Board a similar, but not precisely identical submission concerning Tariff Item 180 (e). Therefore, on the instruction of the President and subsequent ratification by the Chairman of the Institute's Special Committee on Tariff Item 180 (e), the EIC did not submit a separate detailed submission, but rather supported the proposals contained in the C.C.P.E. submission, Section 2, with reference to Number 128 — Engineers' and Architects' Plans, Drawings and Blueprints. The meeting accepted this report.

Report of Property Committee

T. N. Davidson, Chairman of the Property Committee summarized the Committee's report, which was ratified by Council. The report recommended no immediate action. The Chairman commented that the Headquarters buiding is inadequate as far as space requirements are concerned.

By-Law Amendments

J. S. Waddington, Chairman of the Committee on By-Laws, said the Committee, on receiving instructions, is prepared to submit proposed wording of By-Law amendments to Council prior to the 1961 Annual Meeting in time for circulation to membership as required by the By-Laws.

Action was deferred on revisions regarding the nomination and election of officers, Committee on Membership, Committee on Branch Operations and the Executive Committee. The Executive Committee will continue for a further year on a trial basis.

It was agreed that action should continue on proposed By-Laws changes concerning Honorary Members and Fellows and the title of General Secretary.

Canada's Centenary

On the suggestion of the Ottawa Branch, Council resolved that the Institute take the initiative at an early date in pressing for the establishment of a national museum of science and technology to mark Canada's Centenary, and in so doing, enlist the support of other technical societies in Canada, since a co-operative approach to the Government on this matter undoubtedly would be more effective.

Peterborough Branch

In discussion concerning a letter received from Peterborough Branch, Councillors agreed that engineers should be encouraged to participate in community life. It was the concensus that an engineer does not deserve to be supported in public service solely because he is an engineer, but that support should be on the basis of personal qualifications and qualities. In a resolution which incorporated this sympathy it was also stated that the name and crest of the Institute can not be used for any political pur-

Hydraulics Conference

Montreal
May 7-11

Queen Elizabeth Hotel

Technical Program

Monday, May 8

PRIME MOVERS I

1. "High Head Francis Turbines and Pressure Regulators — Mammoth Pool Project", *L. P. Brown.*
2. "High Head Penstock Design", *W. J. Smith.*
3. "The Quest for the Ultimate in the Interpretation of Experimental Data — An Engineering Challenge", *L. E. Jones.*

CAVITATION I

1. "Cavitation Tests of Hydrofoils Designed for Acceleration Flow Cascade — Report 1", *F. Numachi.*
2. "Problems of Predicting Cavitation Erosion from Accelerated Tests", *J. M. Hobbs.*
3. "On the Mechanism of Cavitation Damage", *C. F. Naude, A. T. Ellis.*
4. "Effect of High Velocity in Turbine Pitting", *F. L. Lawton, M. D. Lester.*

FLUID MECHANICS I

1. "A Flow Model for the Two-Phase Slug Flow in Horizontal Tubes", *E. S. Kordyban.*
2. "Adiabatic Flow of Flashing Liquids in Pipes", *M. Sajben.*
3. "Local Liquid Distribution and Pressure Drops in Annular Two-Phase Flow", *H. N. McManus.*

FLUID MECHANICS II

1. "A Preliminary Study of Turbulence Characteristics of Flow Along a Corner", *F. B. Gessner, J. B. Jones.*
2. "The Effect of Secondary Currents Upon the Capacity of a Straight Open Channel", *R. J. Kennedy, J. F. Fulton.*
3. "Theoretical and Experimental Investigation of Flow over Single and Double Backward Facing Steps", *D. E. Abbott, S. J. Kline.*

Tuesday, May 9

WATER HAMMER I

1. "Surges in Air Vents Adjacent to Emergency Gates", *I. W. McCaig, F. H. Jonker.*
2. "The Phase-Tank Topology of the Simple Surge Tank Equation", *A. V. Marris.*
3. "Complete Pump Characteristics and the Effect of Specific Speeds on Hydraulic Transients", *B. Donsky.*

COMPRESSORS I

1. "An Experimental Investigation of the Use of Supersonic Driving Jets for Ejector Pumps", *R. V. de Leo, R. Rose, R. S. Dart.*
2. "Characteristics of Helical Rotary, Positive Displacement Compressors", *K. E. Wichert.*
3. "A Correlation of Fan Performance for Solving Selection Problems", *N. J. Lipstein.*

JOINT PUMPS, PRIME MOVERS I

1. "Research Developments and Results Concerning Bulb Units Applications", S. X. *Casacci, J. P. Duport, R. F. Pariset.*
2. "Vibration of Vertical Pumps", A. *Kovatz.*
3. "Design Problems in Condenser Circulating Water Systems for Thermal Generating Stations", *J. T. Wieckowski.*

FLUID MECHANICS III

1. "Flow of Water Through a Force Field in a Soil Water System", *R. Yong, O. J. Frenkel.*
2. "Circulation in the Gulf of St. Lawrence and Subsequent Drift of the Ice", *G. E. Jarlan.*
3. "An Experimental Study of Vortex Chamber Flow", *J. P. Holman, G. D. Moore.*

Wednesday, May 10

JOINT COMPRESSORS—FLUID MECHANICS I

1. "Friction Drag on Bladed Discs in Housing as a Function of Reynolds Number, Axial and Radial Clearance and Blade Aspect Ratio and Solidity", *R. W. Mann, C. H. Marston.*
2. "Generalized Multi-Stage Compressor Characteristics", *G. L. Mellor.*

FLUID MECHANICS IV

1. "The Use of Wave Energy to Reduce Silt Deposition in a Harbour", *B. L. Mehaute, J. Cowley.*
2. "Moving Hydraulic Jumps in Fluidized Solids Systems", *R. W. Ansley, R. H. B. Hebbert.*
3. "The effect of Mass Transport of the onset of Turbulence at the Bed under Periodic Gravity Waves", *A. Brebner, J. I. Collins.*

FLUID MECHANICS V

1. "Parallelism of Open Channel and Gas Dynamics", *T. Blench.*
2. "Nonsteady Supercritical Discharge", *G. Rudinger.*
3. "Hydroelastic Vibrations of Flat Plates Related to Trailing Edge Geometry", *G. Toebes, P. Eagleson.*

HYDROLOGY AND ICE I

1. "On the Transfer of Heat from a River to an Ice Sheet", *W. D. Baines.*
2. "Measures of Value and Statistical Models in the Economic Analysis of Flood Control and Water Conservation Schemes", *D. J. Clough.*
3. "Formation and Destruction of Ice Covers on Rivers and Canals", *E. Pariset, R. Hausser.*

ADDED ATTRACTIONS

Sunday, May 7.	8 a.m. daily	"AUTHORS' BREAKFAST"
	5:00 p.m.	"EARLY BIRDS' SOCIAL"
Monday, May 8.	12:00 noon	HYDRO-ELECTRIC LUNCHEON
	5:00 p.m.	"DUTCH TREAT SOCIAL"
Tuesday, May 9.	12:00 noon	ASME-EIC LUNCHEON (Ladies Invited)
	5:30 p.m.	INSPECTION TOUR OF DOMINION ENGINEERING LIMITED PLANT
Wednesday, May 10.	8:30 p.m.	ST. LAWRENCE SEAWAY SYMPOSIUM—HIGHLIGHTS OF THE SEAWAY TOUR
Thursday, May 11.	10:00 a.m.	ST. LAWRENCE SEAWAY TOUR

LADIES' PROGRAM

Monday	9:00 a.m.	"COFFEE HOUR"
	12:00 noon	LUNCHEON AND TALK AT THE MUSEUM OF FINE ARTS
Wednesday	11:00 a.m.	LUNCHEON AT HELENE DE CHAMPLAIN RESTAURANT AND CITY TOUR

If you are interested in attending this Conference, Registration Forms and Advance Programs can be obtained from E I C Headquarters on request.

Mail to THE ENGINEERING INSTITUTE OF CANADA, 2050 MANSFIELD STREET, MONTREAL 2, QUE.

Please send me a registration form and an advance program concerning the ASME-EIC Hydraulics Conference to be held in Montreal May 7-11, 1961.

pose, and that EIC funds are not available for such purposes.

Sarnia Branch

Councillor J. E. Harris of the Sarnia Branch asked that Council recognize the newly-formed Lambton Institute of Professional Engineers as the official EIC Branch in the Sarnia area. After a full discussion it was the concensus that while Council is in sympathy with the desire of the Sarnia Branch to maintain the best possible local organization of engineers, it urged that at this time, when negotiations on the national level concerning Confederation are not yet complete, the EIC Sarnia Branch retain its identity. It was considered premature to change the title of the Branch now.

Engineers' Council for Professional Development

Council approved an amended Charter of the ECPD and the proposed amendments to the Rules of Procedure of ECPD as mailed to Council Jan. 11, 1961. Previously, the ECPD Executive Committee acted under authority granted by Council as follows: "Voted to approve the Charter as amended abd to refer it to the participating bodies for ratification." "Voted to approve the proposed amendments to the rules of procedure and to present them to Council for ratification, subject to the approval of the amendments to the Charter by the Participating Bodies."

President Elect

Bristow Guy Ballard was nominated for the presidency of the Engineering Institute of Canada for the year 1961. It was resolved unanimously, and by acclamation, that Dr. Ballard be named President for the year 1961-62, to take office at the 1961 Annual Meeting in Vancouver.

Membership

P. W. Gooch, Chairman of the Admissions Committee, tabled the procedures now being followed by the Admissions Committee. These procedures are to be considered at a future meeting of Council.

E.I.C. ELECTIONS AND TRANSFERS

A number of applications were presented for consideration and on the recommendation of the Admission Committee, the following elections and transfers were effected at a meeting of council on January 28, 1961.

Member: K. Brogaard, Vancouver; R. P. Byrnes, Montreal; W. S. Cramp, Montreal; J. H. DeBruyn, Toronto; K. Fiddy, Dartmouth; K. Giddings, Georgetown, Ont.; G. D. Howard, Montreal; G. A. Jeffs, Weston; T. J. Lynch, Montreal; L. R. Nash, Port Arthur; C. W. Ransome, Montreal; H. L. Schreiber, Hamilton; W. A. Thomann, Montreal.

Junior: R. D. Delaney, Chalk River; A. H. Lalonde, Three Rivers; A. J. Otter, Chalk River; J. A. M. van den Elshout, Montreal.

Junior to Member: H. T. Abbott, Port Credit; W. J. Adams, Winnipeg; J. C. Akerley, Boston; C. E. Alkerton, Hamilton; A. A. Albert, Rexton, N.B.; D. G. Allen, Toronto; G. E. Allen, St. Lambert; J. A. Allen, Sarnia; R. F. Allen, Whitehorse; W. L. Allen, Montreal; W. S. Amm, Hope, B.C.; G. J. Anderson, Papineauville; L. L. Anderson, Ottawa; S. S. Archer, Windsor; G. W. Argle, Revelstoke; B. T. W. Armishaw, Sydney; A. J. L. Aube, Buckingham; W. I. Aubin, Montreal; J. D. Baig, Halifax; M. E. Bailey, Kitchener; W. A. Ballantyne, Byron, Ont.; W. P. Banas, Montreal; G. L. Bancroft, Santa Ana, Cal.; G. Beauchemin, Montreal; R. F. Bell, Calgary; R. C. Bergey, Peterboro; H. Bily, Windsor; C. R. T. Bingley, Regina; D. R. Black, Montreal; C. C. Blackmore, Camlachie, Ont.; R. A. Booy, Temiskaming; J. Bourassa, Sherbrooke; J. P. Bourgon, Montreal; L. T. Brainerd, Montreal; F. M. Braybrooks, Vancouver; L. A. Broddy, Vancouver; D. A. Brooks, Montreal; D. S. Brown, Windsor; F. W. Brown, London, Eng.; J. A. Buchanan, Montreal; C. A. Buchholz, Sarnia; N. W. Bunn, Vancouver; F. G. Burchell, Copper Cliff; G. R. Burton, Coldbrook, N.B.; R. P. Cable, Edmonton; P. H. Cameron, Montreal; W. L. Canniff, Belleville; J. D. Cape, Kitchener; G. C. Cartwright, Winnipeg; J. L. Carveth, Calgary; J. R. Caza, St. Anicet, Que.; G. J. L. Chabot, Edmonton; W. S. Chick, Hamilton; R. Clarke, Montreal; T. H. Cooper, Scarboro; E. T. Cornell, Fort Frances; E. T. Cotton, N. Vancouver; M. A. Couse, Scarboro; J. S. Cummins, Brampton; J. W. S. Dalziel, Toronto; H. D. DeBeck, Kamloops; J. DeGuise, Montreal; W. G. Delahay, Scarboro; F. L. Delavigne, Scarboro; G. B. Delong, Agincourt; F. A. DeLory, Toronto; F. C. Desrochers, Montreal; L. Desrosiers, Montreal; G. Doin, Quebec; E. D.'Souza, Rimouski; H. H. Dofka, Toronto; T. E. Dolphin, Prince Albert; P. W. Douglas-Tourner, Kitimat; S. Dreluch, Montreal; P. A. Drouin, Riverbend, Que.; J. W. Drover, Isle Maligne; R. A. Ducker, Toronto; M. B. Duclos, Halifax; A. F. Dudek, Montreal; D. P. Duffey, North Bay; J. V. Y. Dupuis, Quebec; J. T. Dykes, Montreal; G. H. Eaton, Vancouver; D. H. Eckford, Kamloops; T. Elidoros, Montreal; V. G. Findlay, Montreal; G. W. Flewelling, Greenwood, N.S.; B. A. Foster, Montreal; D. R. Francis, Regina; E. C. Fraser, Montreal; J. B. Frederick, Kapuskasing; L. J. Frenette, Ottawa; D. Friesen, Hamilton; H. Furuya, Ottawa; F. E. H. Gardner, Toronto; C. A. Geddes, Burlington, Ont.; E. A. Gendron, Plattsburgh, N.Y.; D. H. Giauque, Vimy Ridge, Que.; K. R. Gillespie, Banff; E. H. Gilliatt, Roxboro; J. C. Gilmore, Port Arthur; W. F. Gilmore, Steep Rock; H. M. Gordon, Arvida; G. Gosselin, Montreal; J. W. Gouge, Vancouver; R. Gourdeau, Quebec; L. H. Groome, Montreal; G. K. Gunnarsson, Nanticoke, Md.; E. W. Halayko, Oakville; P. R. Hart, Brantford; F. C. Harvey, Edmonton; N. L. Harvey, Crofton, B.C.; D. W. Hawes, Montreal; N. J. Hawrysh, Toronto; H. R. Hayman, London; L. C. Hempsall, Port Mellon, B.C.; C. A. Hennigar, Kitchener; C. O. C. Henstridge, Montreal; S. E. Henwood, Toronto; R. Herdman, Corner Brook; H. S. Hicklin, Edmonton; J. C. Hickmore, Hamilton; J. L. A. Hogue, Gatineau; C. E. Holdway, Ottawa; W. G. Hollingsworth, Sault Ste. Marie; L. G. G. Holtby, Dartmouth; G. K. Hopper, Toronto; G. K. Hunter, Toronto; D. B. Imrie, Montreal; L. G. Jamieson, Montreal; A. P. Jesome, Ottawa; L. C. Johnson, Montreal; G. E. Johnston, Windsor; O. A. Juneau, Amos; K. E. Kansikas, Sault Ste. Marie; R. E. Kazan, Toronto; W. J. G. Kennedy, Vancouver; C. G. Kerr, Montreal; G. W. King, Santa Fe, N.M.; D. G. Kitson, Baie Comeau; E. N. Kolbeins, Vancouver; A. Koropatnick, Winnipeg; R. J. Kostick, Sarnia; M. Lajoie, Montreal; R. K. Lalor, Kingston; D. C. Lambert, Vancouver; J. M. Langevin, Quebec; M. L. Lapierre, Montreal; J. J. Lapointe, Montreal; A. R. Latham, Montreal; W. A. Laurin, Montreal; J. M. Lawrence, Clarkson, Ont.; G. L. Laycock, Trail; J. W. LeLacheur, Middle East; K. A. Le Mesurier, Ottawa; L. R. Letourneau, New Westminster; J. J. Leydon, Sarnia; E. E. Long, Vancouver; W. H. Lowry, Toronto; A. R. Luck, Nanaimo; C. F. Lund, Drummondville, C. N. Lund, Montreal; J. D. MacBride, Detroit; D. J. MacCandlish, Montreal; G. F. MacFarlane, Vancouver; I. C. MacFarlane, Ottawa; R. M. MacRae, Montreal; J. R. Mainprize, Montreal; J. E. Mainwaring, Windsor; L. Major, Chicoutimi; M. C. Malone, Toronto; D. G. Manzer, Baie Comeau; J. J. Marlow, Toronto; R. D. Marsh, Orillia; F. R. Marshall, North Bay; G. T. Marshall, Vancouver; A. P. Martinez, Los Angeles; M. H. Mayer, Detroit; D. A. McCammon, Toronto; R. D. McCargar, Hamilton; N. W. McDermid, Montreal; F. M. McGuire, Winnipeg; R. M. McIntosh, Winnipeg; D. J. McKinnon, Montreal; J. R. McMackin, North Bay; J. K. McMillan, Vancouver, W. L. McNamara, Fredericton; A. E. Meade, Fort William; A. O. Michaud, Sept Iles; S. L. Miller, St. John's, Nfld.; H. A. Mitchell, Plattsburgh; G. W. Morgan, Vancouver; L. Personals

Thomas W. Toovey, M.E.I.C., has been elected president of Sherbrooke Machineries Limited, Sherbrooke, Que. Mr. Toovey has been associated with the company since 1950 when he was serving as sales manager.

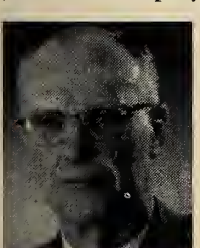
Penrose Melvin Sauder, HON. M.E.I.C. (Toronto '04), former general manager of the vast St. Mary-Milk Rivers Development in Southern Alberta, has retired. In accepting Mr. Sauder's retirement resignation, Hon. L. C. Halmrast, Alberta's minister of agriculture, paid tribute to him saying that his services as an engineer and advisor on all irrigation matters will be missed not only by Alberta, but by Canada as a whole. Mr. Sauder was awarded an honorary membership in the Agricultural Institute of Canada and the Julian C. Smith Medal for "achievement in the development of Canada" by the E.I.C. in 1947.

Leonard L. Youell, M.E.I.C. (Toronto '20), has retired as vice-president and general manager of Stone and Webster Canada Limited. Mr. Youell opened the company's first Canadian office in 1945.

Glenn H. Curtis, M.E.I.C. (Toronto '48), is succeeding Mr. Youell. Mr. Curtis joined the company in 1955 and was made vice-president in 1959.

A. Latreille, M.E.I.C. (Poly. '42), president of Alta Construction Co. Ltd., has been named director of the General Contractors' Section of the Montreal Builders' Exchange.

D. C. Crothers, M.E.I.C. (Queen's '37), has been appointed chief engineer, Compressor Sales, Canadian Ingersoll-Rand Co. Limited, Montreal. Mr. Crothers joined the company in 1937.



D. C. Crothers, M.E.I.C.

W. A. Devereaux, M.E.I.C.

William A. Devereaux, M.E.I.C. (Toronto '37), has been appointed general manager of the newly-organized Yarnall-Waring Company of Canada, Ltd., Guelph, Ont. This new Dominion-chartered company is a subsidiary of the Yarnall-Waring Company of Philadelphia.

Dr. G. G. Meyerhof, M.E.I.C. (London '38), has been elected Chairman of the Soils and Materials Committee of the Canadian Good Roads Association and member of the Advisory Council of the American Society for the History of Technology. He is Head of the Department of Civil Engineering of the Nova Scotia Technical College, Halifax.

Dr. G. G. Meyerhof, M.E.I.C.

J. L. Patterson, M.E.I.C.

James L. Patterson, M.E.I.C., has joined The Gas Machinery Company (Canada) Limited, Hamilton, as sales engineer. Mr. Patterson was formerly with Salem-Bresius Canada Ltd.

W. T. Hargreaves, M.E.I.C., has been named executive assistant to the minister and chief engineer, New Brunswick Dept. of Public Works. He has been associated with the department for the past 26 years.

R. E. Simpson, M.E.I.C. (Queen's '40), has been appointed general service manager The White Motor Co. of Canada, Ltd. Mr. Simpson joined the company at its Montreal factory in 1946 and in 1959 became assistant to the general service manager at head office, Toronto.

Marc Benoit, M.E.I.C. (Ecole Poly. '44) and **Fred J. Travers**, M.E.I.C. (Toronto '44), are managing partners of a recently formed consulting engineering firm — Benoit, Boucher, Simpson, Travers et Associes, Montreal. The firm plans to engage in general consulting engineering, providing comprehensive professional engineering services for hydro and thermal power developments, industrial plants and transportation.

William A. Wright, M.E.I.C. (Toronto '49), has been appointed manager, Electric Product Sales, Western District, Union Carbide Canada Limited, Linde Gases Division. Mr. Wright was formerly assistant to the sales manager, Electric Products.

W. A. Wright, M.E.I.C.

J. W. Hackney, M.E.I.C.

John W. Hackney, M.E.I.C., has been appointed vice-president Pan-American Management Ltd. Mr. Hackney will direct the technical staff services provided to corporations by Pan-American, from their offices in Montreal.

Louis Desrosiers, M.E.I.C. (Ecole Poly. '48), formerly with Gaspesia Sulphite Co., Chandler, Que., is now with Stadler Hurter and Company, Montreal. Mr. Desrosiers is spending a few months at their Paris office.

George N. Cater, JR.E.I.C. (U.N.B. '49), has been appointed assistant control superintendent at Anglo-Newfoundland Development Co. Ltd., Grand Falls, Nfld.

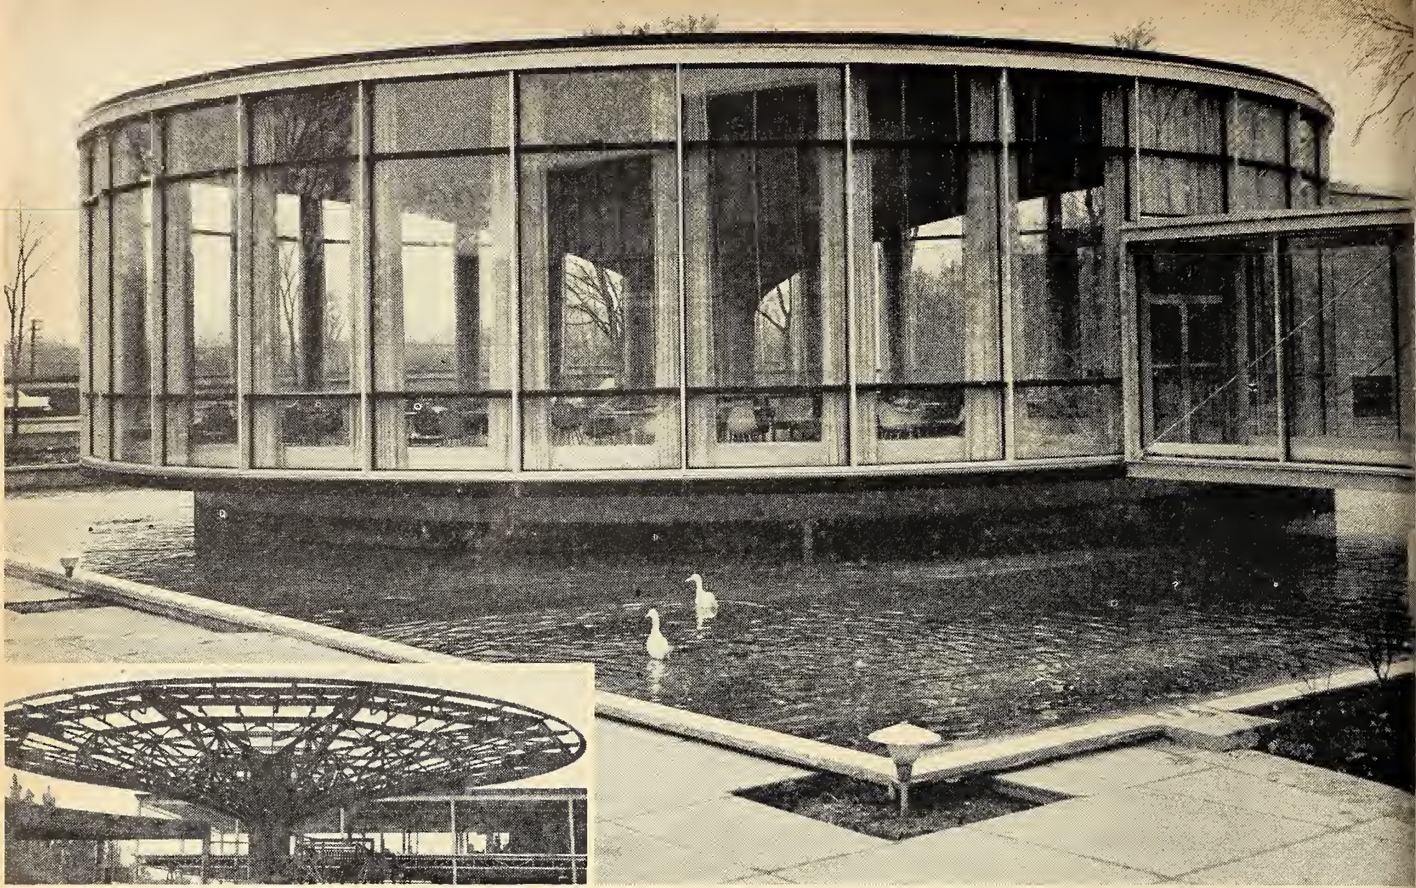
J. A. Smith, M.E.I.C.

M. A. Ward, S.E.I.C.

J. A. Smith, M.E.I.C. has been appointed vice-president of The Shawinigan Water and Power Company. Mr. Smith becomes vice-president, production and power operations.

Michael A. Ward, S.E.I.C. (Man. '59, a field representative in the Winnipeg Branch Office of The Master Builders Company, Ltd., has been awarded the Athlone fellowship from the U.K. government. Mr. Ward leaves for two years

(Continued on page 104)

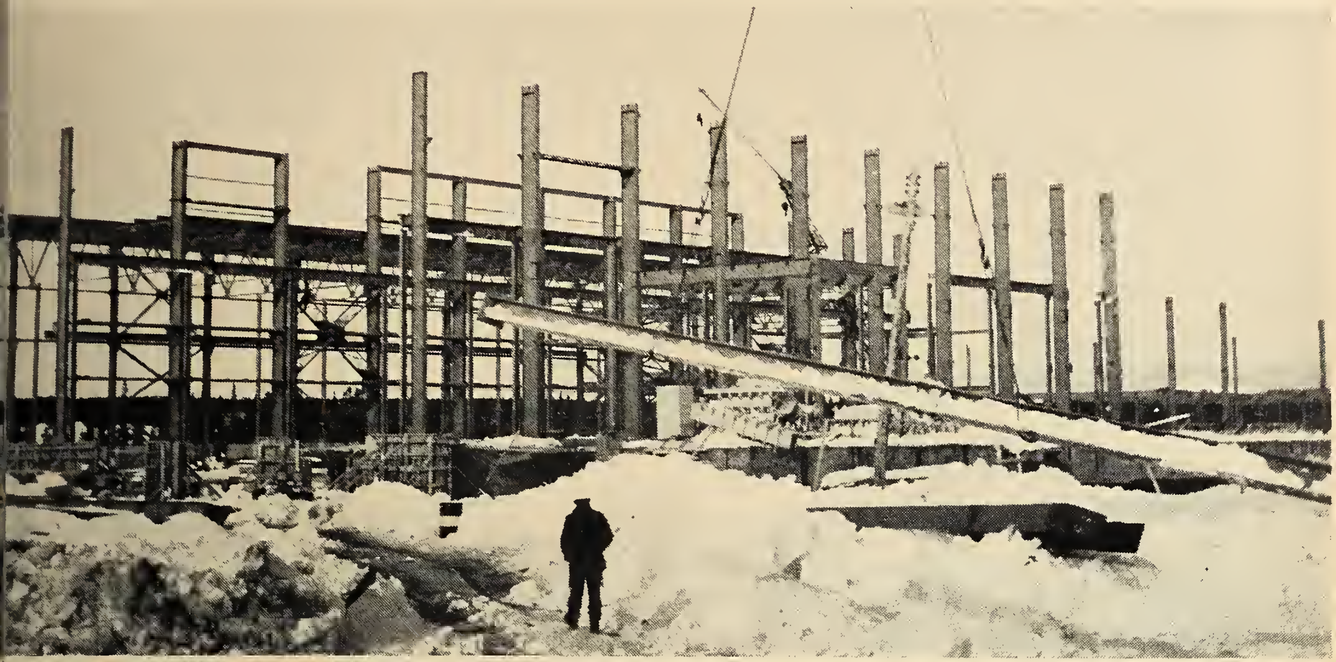


Beauty—This striking cafeteria on the CIBA building employs a steel umbrella-like cantilever roof structure. (See inset). The characteristics of steel offer great scope to the imaginative architect.

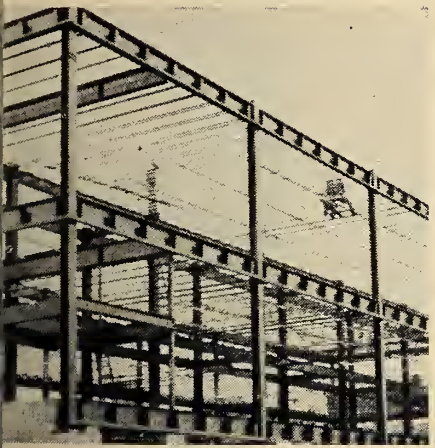
Why you shoul

Better Economy—This merry-go-round building is the kindergarten of a new school in Regina. Close co-operation between the architect and the steel fabricator made the best use of materials and helped cut costs.

Weather Construction—Steel goes up in any weather that men can work.
lding schedules are on time, no frosty weather delays.



esign and build in steel



e to the Future—A two-storey school
of steel that provides for the future
of a third storey. New columns and
an be weld-connected to this structure
e time comes.

FOR THE ARCHITECT it's design freedom. Structural steel is very versatile and can be made to take almost any architectural form. Its strength and lightness permit long spans to provide large column-free areas. The vertical supports that are necessary, take up minimum space and permit better use of basement areas.

FOR THE CONTRACTOR it's the ease and speed of erection. Steel arrives fabricated and goes up fast. High strength bolts speed the job and eliminate undue noise at the site. Steel is an all-weather building material and the job can go on no matter what the temperature. Schedules are easy to keep and sub-trades get in on time.

FOR THE OWNER it's early return on investment. Steel frame buildings go up fast, and start to pay off in the minimum time. Even a few weeks difference in completion dates can run into thousands of extra dollars. Steel is flexible too—changes and additions are easily made.

When you plan, consider carefully the merits of steel. Dominion Bridge maintain design, fabrication and erection facilities in most of the major cities. Their sales and engineering departments will assist you in any way they can. Have them show you what steel can do for your project.

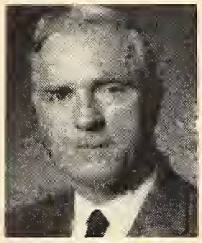
study and training in University and engineering firms in Britain.

J. M. Sharpe, M.E.I.C., has been appointed executive assistant, production and power operations. **Ralph F. Brooks,** M.E.I.C., has been named manager of the newly formed system operating department.



J. M. Sharpe, M.E.I.C.

R. F. Brooks, M.E.I.C.

K. Colin MacKenzie, JR.E.I.C. (McGill '56), has been appointed Manager, Capital Branch, Canadian Ice Machine Company Limited. Before his present appointment Mr. MacKenzie was CIMCO refrigeration sales engineer.

Charles Aquelina, JR. E.I.C. (London '57) at present working in the Structural Design Dept. of the Dominion Bridge Co., is returning to England shortly to further his studies in steel research at the Imperial College of Science and Technology, London.

Dean H. G. Conn, M.E.I.C. (Queen's '31), has left for New Delhi to carry out a survey under the Colombo plan auspices to help with India's third five-year plan. Together with **Dean R. R. McLaughlin** of the University of Toronto faculty of engineering, Dean Conn will survey the requirements in connection with India's regional engineering institutes which form part of their development program.

Obituaries

Archibald Gordon, M.E.I.C., 80, a retired civil engineer, died Nov. 26. Mr. Gordon was a resident of Moncton, N.B. He had previously worked with the Department of Public Works. He became a member of the Institute in 1942.

J. A. Heaman, M.E.I.C. (McGill '02), retired office engineer of the C.N.R., Montreal, died Nov. 9. After his retirement Mr. Heaman became a resident of Victoria. He started his engineering career with the Grand Trunk Railway as resident engineer in 1902 and in 1932 became office engineer in Montreal. He joined the Institute as a student member in 1901, became an affiliate member in 1909 and a member in 1916. He was made a life member in 1943.

Thomas P. Hutchinson, M.E.I.C. (McGill '44), a prominent figure in the industrial consultant and construction fields, died Montreal, Oct. 31. Mr. Hutchinson has been associated with several large Canadian firms on major projects and in 1958 he was appointed representative of INFILCO. He became a member of the Institute in 1950.

T. P. Hutchinson, M.E.I.C.

Alexander Peden, M.E.I.C., a retired standards engineer, died Montreal Nov. 20. Mr. Peden was an employee of the Dominion Bridge Company from 1901 until his retirement in 1952. He joined the Institute as a student member in 1903 and beeame a member in 1925. In 1947 he was made a life member.

D. Roland Webb, M.E.I.C., (U.N.B. '35), widely known consulting electric engineer, died Nov. 26. He was 47. Mr. Webb had been engineer in charge of electrical installations in many public and private buildings throughout the Maritime Provinces. He joined the institute as a student member in 1933 and became a member in 1942. EIC

Other Societies

Athlone Fellowship

The E.I.C. entertained members of the Boards of Selectors for the Athlone Fellowship at a luncheon Jan. 19 at the University Club, Montreal. United Kingdom Representatives present were: Dr. A. C. Monkhouse; Mr. E. O. Laird; Mr. Arnold Heckle. Representatives from l'Ecole Polytechnique were: Dr. H. Gaudefroy; Prof. J. Laurence; Prof. J. C. Bernier; Prof. R. Brais; Prof. P. P. Vinet. Representatives from McGill University were: Dean D. L. Mordell; Prof. W. Bruce; Dr. G. L. d'Ombrain; Prof. R. G. K. Morrison; Prof. R. E. Jamieson; Dr. I. R. Tait. E.I.C. members present were: President Dick; F. L. Lawton; E. D. Gray-Donald; C. G. Southmayd; L. A. Duchastel; Garnet T. Page.

Canadian Nuclear Association

The first annual meeting and conference of this newly formed Association is to be held in Toronto, May 16-17. On the agenda are prominent speakers from the United States and Canada who are engaged in the research, development or utilization of the peaceful uses of nuclear energy and radio isotopes. It is anticipated that approximately 250 members will be attending the conference.

The Association's membership is drawn from all parts of Canada from industry, commerce, education, government and private individuals whose participation in the new and rapidly developing field is widely diversified. I. F. McRae, Chairman of the Board, Canadian General Electric Co. Limited, is President and The Hon. Robert W. Macaulay, Ontario Minister of Energy Resources, is Vice-President.

Canadian Reasearch Institute

The new production plant and research laboratory has been opened in Don Mills, Ont. This building more than triples the space previously occupied, and will include office, warehouse, laboratories and manufacturing facilities.

The Chemical Institute of Canada

A Russian scientist, V. V. Tchebotarevski, of the Institute fo Scientific Research, U.S.S.R., was one of the speakers at the Conference of the Protective Coatings Division in Toronto Feb. 23 and in Montreal Feb. 24. The same technical program was featured in both cities.

Other speakers and their papers were: C. A. Kumins, Interchemical Corp., New York,—"Diffusion of Gases and Vapors through Unpigmented and Pigmented Vinyl Polymers—Glass Transition Effects"; Andrew Bowman, British Titan Products (Canada) Limited,—"Some Recent Trends and Developments in the Protective Coatings Field in the U.K."; L. E. Gast, Northern Regional Research Laboratory,—"Fatty Vinyl Ether Copolymers: Potential Materials for the Coatings Industry"; R. Spolski, Polymer Corp. Limited,—"Stereoregulated Elastomers".

The Society for Nondestructive Testing, Inc.

The first three lectures of the Society's educational clinic were given in Montreal Feb. 1, Feb. 8 and Feb. 15.

O. L. Burlone, L. E. Baxter Ltd., spoke on "Ultrasonic in a Simple Way" Feb. 1. He described basic elements of wave generation and propagation; ultrasonic sources; types of crystals and characteristics; different equipment and methods; application to testing, its uses and limitations.

The second lecture was given by T. W. McFarlan, Sperry Products Company, on Feb. 8. The title of Mr. McFarlan's lecture was "Theory of Ultrasonic Contact Testing". Covered in his talk were descriptions of various types of instruments; transducers, properties, design, uses, and limitations; effect of couplants; effects of size, shape and location of discontinuities; theory of transmission and reflection methods; interpretation of results; special tests and applications; personnel.

The third lecture was "Immersion Testing" by B. W. Smith, Curtiss-Wright Corp. The Feb. 22 lecture was given by F. C. Parker, Union Carbide Chemicals Company. He spoke on "The Inspection of Welded Structures" and described the effect of velocity of sound. Also covered in his lecture were refraction, attenuation, sensitivity, size, shape, orientation and type of discontinuities; transducers design, couplants, preparation of parts for inspection; standards; test blocs; interpretation of results; field inspection techniques; training and qualification of personnel; acceptance and rejection criteria; comparison with radiography.

Coming Events

- Annual Conference of Canadian Building Officials, Ottawa, April 5-7.
- 42nd Annual Convention and Welding Exposition, American Welding Society, New York, April 10-21.
- 39th Milan International Trade Fair, Milan, Italy, April 12-27.
- 63rd Annual General Meeting, Canadian Institute of Mining and Metallurgy, Quebec City, April 17-19.
- Muskeg Research Conference, McMaster University, April 18-19.
- VI^0 Salon International de la Chimie and the Conference Internationale des Arts Chimiques will now be held in Paris, France, April 25-May 4.
- 3rd Annual Meeting, Specification Writers Association of Canada, Montreal, April 28-29.
- Engineering, Marine, Welding and Atomic Energy Exhibition, London, England, April 20-May 4.
- Railway Modernization Conference, Institution of Civil Engineers, London, England, May 3-4.
- Symposium on Titrimethic Methods of Analysis, Chemical Institute of Canada, Cornwall, Ont. May 8-9.
- European Convention of Chemical Engineering, European Federation of Chemical Engineering, Frankfurt am Main, June 9-17.

The Associations and Corporation

Ontario

A total of 15 brief committee reports were presented at the 39th annual meeting by their respective chairmen. Noting changing trends in the technological nature of industry, the professional status committee said a philosophy must be developed and encouraged within the profession towards building an attitude of self-improvement in each member. By this means, true technical competence will be recognized within the profession as well as by industry, the report states.

T. W. Eadie, president of the Bell Telephone Co. of Canada was the guest speaker. In addition to Mr. Eadie's address, a report on the Colombo Plan was given by F. J. Lyle, Director, Trade and Industry branch, Ontario Dept. of Planning and Development.

G. W. Scott, M.E.I.C.,
Correspondent

Lloyd J. Severson, President of the Quebec Cartier Mining Company, gave a talk on "The Quebec Cartier Mining Project" at the Branch's Feb. 3 meeting. Mr. Severson was introduced by the Branch Chairman, S. J. Simons and his address covered a wide field in the geology and mining of iron ore. He described the nature of the various iron ore deposits throughout the world with particular reference to the Province of Quebec and Labrador. The geological surveys which led to the establishment of the Lac Jeannine project in Northern Quebec were explained in some detail as also were the features determining the nature of the sea and rail communications with the mining area. Mr. Severson explained the economic factors associated with the project which enabled the mining plant at Lac Jeannine, with an annual output of some 8 million tons of ore concentrate a year, to compete with the types of ore mined in the United States.

The actual description of the project, involving the construction of a deep sea harbour, a 192-mile railway, a mining plant and townsite was supplemented and vividly illustrated by an excellent film entitled "Accomplishment in Northern Quebec" recently produced by the Quebec Cartier Mining Company.

A vote of thanks was given by G. W. Scott of the Branch Executive at the conclusion of the discussion.

Border Cities

V. Corin, JR.E.I.C.,
Correspondent

The annual business meeting was held at the Prince Edward Hotel Dec. 14. Vice-President E. A. Cross gave an enlightening talk on the history of engineering organizations with particular emphasis on the Engineering Institute of Canada. Officers for the coming year were elected.

Forty-six members attended the annual "Smoker" on Jan. 25 at the Ridge Valley Golf and Country Club. A gambling night was featured in which prizes were awarded to winners.

Brockville

A. N. Campbell, M.E.I.C.,
Correspondent

John E. Brett, of Brett Oullette Blauer Associates, consulting structural engineers for Montreal's $80 million Place Ville Marie project, addressed the branch Jan. 17. Mr. Brett's topic was "Some Unusual Engineering Problems of Place Ville Marie Project". He described how special vibration pads were required for the steel columns of the 42-storey tower building, which were spaced between tracks. The pads are to absorb all vibrations eminating from the railroad. He also said how the presence of defective seams in the sedimentary rock which occupied the site area have no bearing capacity and make it difficult to find stable areas to place footings for steel columns, which required some footing levels to be at different depths.

Also discussed at the meeting was E.I.C. sponsorship of student "Science Fairs" and the possibility of their promotion in the area by the branch.

Cape Breton

Lloyd Boutilier, M.E.I.C.,
Correspondent

"Maintenance Metallurgy" was the title of a talk given by Frank Martin, Maintenance Metallurgist at Dosco's Sydney Works, at the Jan. 30 meeting. Mr. Martin discussed the causes of metal part failures, the factors influencing them, and methods of avoiding failures. He discussed non-destructive testing, splitting the subject up into five major divisions: penetration; radiation tests; ultrasonic tests; magnetic particle tests; electro-magnetic tests; liquid or dye penetrant tests. Slides were used to illustrate various points under discussion.

Mr. Martin was thanked by Bill Dodson.

Corner Brook

Robert G. Scott, JR.E.I.C.,
Correspondent

A meeting was held Jan. 10 and H. B. Carter, Assistant Resident Engineer, Bowater's Nfld. Pulp and Paper Mills Ltd., spoke on "Electric Motors in Industry". Robert Herdman, M.E.I.C., introduced the speaker.

Mr. Carter divided his lecture into two parts, a-c motors and d-c motors. Sub-dividing further into the various types he covered theory of operation, constructional features, typical uses, advantages and disadvantages of each. A large display of electrical motors in assembled and disassembled form were shown. These were provided by Bowater's Electrical Department. A lively question and answer period followed. The vote of thanks was given by Jack Fisher, M.E.I.C.

Loyola College

Richard Kind, S.E.I.C.,
Correspondent

A meeting was held Feb. 3 when John E. Brett of Brett, Ouellette Blauer Associates, discussed some of the problems met when designing the structure of the new Science Building erected at the College. An interesting question and answer period followed. The speaker was thanked by Ross Dugan, Chairman of the Student Section.

A une réunion du comité exécutif du Chapître tenue le 5 décembre dernier, le comité de nomination a annoncé le choix suivant des nouveaux officiers devant faire partie de l'exécutif du chapître pour l'année 1961:

Président: H. A. Mullins

Vice-président: C. G. Kingsmill

Membres du comité: G. H. Hoganson; M. S. Pappuis; M. E. P. Stephenson.

Durant les quelques années qui ont précédé son accession à la présidence, M. Mullins a rempli diverses fonctions et a été actif sur plusieurs des différents comités du chapître. Il a notamment été Président du comité des divertissements pour la période 1950-51-52, membre du comité exécutif durant 1953-54, représentant du Chapître au Conseil de l'Institut, et Président du comité des publications de l'Institut pour 1957-58, finalement, Vice-Président du comité exécutif et Président du comité de conduite et coordination pour l'année 1960.

M. Kingsmill a également apporté sa contribution aux activités de plusieurs des différents comités du Chapître et de l'Institut avant d'être nommé au poste de Vice-Président du Chapître. Messieurs Hoganson, Pappuis, et Stephenson ont également participé aux activités de plusieurs des différents comités du Chapître, avant leur nomination au comité exécutif pour l'année 1961.

At a regular meeting of the Branch Executive Committee held on December 5th, 1960, the Nominating Committee announced the following nominations as

Kodak
TRADEMARK

Kodak Industrial X-ray Film

Assures safe journey for airbound castings!

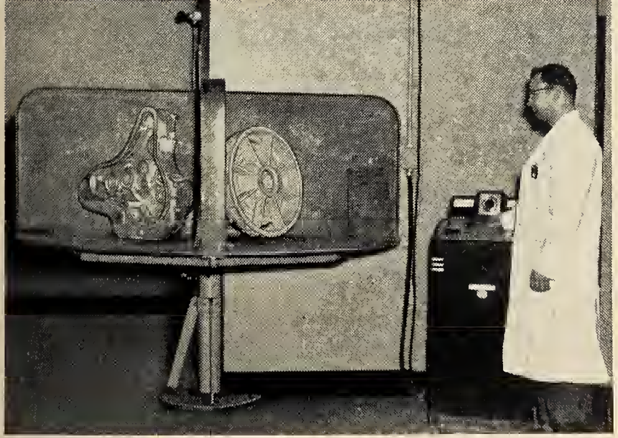
The air is no test ground for aeroplane castings. Radiography with Kodak Industrial X-ray Film finds any and every flaw first!

Light Alloys Ltd. of Haley, Ontario supplies castings to more than half a dozen manufacturers of aeroplanes and aeroplane engines. Everything from ski-clamps for commercial aircraft to gear boxes for helicopters is produced. And, almost every casting . . . whether it weighs 4 ounces or more than 120 pounds – is examined in the plant's radiography department. Only radiography gives proof that a casting is sound enough to withstand calculated design stresses!

"Radiography ensures that a casting meets the specifications", explains L. G. Day, plant manager. "Without industrial X-ray we would have no idea of metallurgical soundness. For example, a complex casting could have severe porosity and yet appear satisfactory to the eye. X-rays detect the flaws even in internal passages."

"All our machines are set for Kodak film", says Mr. Laporte, Chief Radiographer. "There is no tendency to fog or streak. Both the film and developing are so superior."

As at Light Alloys Ltd., Kodak Industrial X-ray Film can guarantee the right answers to your inspection problems. Contact your X-ray Dealer or Kodak Technical Representative for the full story. Or write: Canadian Kodak Co., Limited, Toronto 15, Ontario.



Light Alloys' Radiograph Dept. uses a revolving, 4-compartment "turntable" to speed its work. While castings are being radiographed in one compartment, other castings are set up in the other three ready to be radiographed. No time is lost between exposures of film!

CANADIAN KODAK CO., LIMITED
Toronto 15, Ontario

part of the new Executive for the coming year:

Chairman: H. A. Mullins
Vice Chairman: C. G. Kingsmill
Committeemen: G. H. Hoganson; S. Pappuis; E. P. Stephenson.

Prior to his accession to the chairmanship, Mr. Mullins served the Branch for a number of years in various capacities. He rose successively from Chairman of the Entertainment Committee during 1950-51-52, to member of the Executive Committee in 1953-54, and to Branch Representative on Council of the Institute and Chairman of the Institute Publications Committee in 1957-58. In 1960, Mr. Mullins was Vice-Chairman of the Executive Committee and also held the post of Chairman of the Policy and co-ordination Committee.

Mr. Kingsmill also served the Branch and the Institute in various positions prior to his nomination to the Vice Chairmanship. Messrs. Hoganson, Pappuis, and Stephenson, have likewise held a number of positions on several of the Branch Committees before becoming members of the Executive Committee for 1960.

L'assemblée générale annuelle du 30 janvier derner au cours de laquelle a eu lieu la mise en fonctions des nouveaux officiers de l'exécutif pour l'année 1961, a été rehaussé cette année de la présence du Président de l'Institut, le Dr. G. McK. Dick. Parmi les personalités éminentes présentes à cette cérémonie on notait: M. John Stirling ancien Président de l'Institut, M. Hugh Crombie ancien Président de Canadian Manufacturing Association, de même que messieurs Irving Tait, Ed. Smallhorn, Gury Martin et R. N. Coke, tous d'anciens Présidents du Chapître.

The Branch annual meeting which was held on January 30 last, and on the occasion of which took place the installation of the new Branch Officers was honored this year by the presence of Dr. G. McK. Dick, the President of the E.I.C. Among the several distinguished guests present were noted: Mr. John Stirling Past-President of the E.I.C., Mr. Hugh Crombie Past-Chairman of the Canadian Manufacturing Association and Messrs. Irving Tait, Ed. Smallhorn, Gerry Martin and R. N. Coke all Past-Chairmen of the Montreal Branch.

Professional Engineers' Wives Association, a voluntary organization formed about a year ago to promote friendship among the wives and widows of members of the Engineering profession has currently embarked on a drive to increase its membership. In this respect, approval was given for the group to make use of the Montreal Branch mailing list in its efforts to recruit new members.

Newfoundland

Anthony O. Nemec, JR.E.I.C.,
Correspondent

A dinner meeting was held Jan. 18 at the Newfoundland Hotel. John Henderson was Chairman. The speaker, David Straw, Assistant Chief Geologist, Canadian John's Manville Co., Ltd., was introduced by John Pike.

Mr. Straw spoke on "Asbestos Deposits in Baie Verte, Newfoundland" and outlined the geological features and extent of the deposits. The company has proven more than 35 million tons and believes that there is more to be located. A large processing plant and docking facilities for ocean vessels are now under construction. It was evident from Mr. Straws interesting talk that great progress is being made in the development of mining operations in that area of Newfoundland, which also has a large copper producing mine at Tilt Cove.

The meeting was attended by approximately 60 members and a vote of thanks was given by Mr. E. Ball from the Department of Highways. Mr. V. J. Southy, President of the local C.I.M.M. branch was a guest and was accompanied by a group from the C.I.M.M.

Nipissing and Upper Ottawa

J. W. Millar

A dinner meeting was held at the King Edward Hotel in Sturgeon Falls Jan. 11. R. S. McLennan presided and 20 members were present.

Following dinner, N. A. Burke of Temiskaming introduced the guest speaker, R. W. Bartholomew, resident engineer for Baily Meter Company Limited. The subject of his talk was "Modern Trends in Industrial Process Control."

Mr. Bartholomew said that measuring and controlling instruments were used most extensively in primary industries such as electrical utilities, water treatment plants, chemical and petroleum industry and pulp and paper mills. In the early days the steam-electrical and water treatment industry made the greatest use of industrial instrumentation. The major turning point in acceptance and subsequent development of modern metering and control equipment came with the industrial boom that accompanied World War II.

Since 1950 industrial instrumentation has experienced a fantastic expansion. In that year the gross sales in North

If you have recently had an APPOINTMENT or TRANSFER, let *The Engineering Journal's* editorial department know about it for a PERSONALS item. If you have a recent PHOTOGRAPH, send that too.

Beaver Bill says:

There are over 6,000 books on all phases of engineering in the E.I.C. library, and new books are listed each month in the Library Notes section of the Engineering Journal. E.I.C. members can borrow any of them. The library will compile a list of books on any particular subject on request.

America were about two billion dollars and in 1960 is likely to have exceeded seven billion. The trend towards automation is the reason for this and already there are fully automatic power stations, both hydraulic and thermal. Automation produces better and cheaper products but the application of automation is limited by cost, the superiority of human skills in some processes, loss of production due to failure of automated mechanisms and the need for further development of the controlling devices. Mr. Bartholomew said he believed automation is desirable and advantageous from both an economical and sociological point of view.

J. S. Cooper thanked the speaker and the chairman reported that the next meeting would be Students' night in North Bay Feb. 8.

Nova Scotia Technical College

J. H. Bethune, S.E.I.C.,

The Annual Ball was held Jan. 27 in the Commonwealth Room of the Nova Scotian Hotel, Halifax. Special guests included the Lieutenant-Governor of Nova Scotia and Mrs. Plow; the Hon. R. L. and Mrs. Stanfield; His Worship the Mayor of Halifax and Mrs. Lloyd; Mr. and Mrs. A. E. Cameron; Mr. and Mrs. J. G. Belliveau; Mr. and Mrs. B. N. Cain. The theme of this year's ball was "Remember When . . ." Each faculty entered an exhibit to coincide with the theme. The E.I.C. trophy, won by the Chemical Faculty, was presented by Lt.-Gov. Plow.

University of Manitoba

Brian Grover, S.E.I.C.,
Chairman, Student Section

At the Jan. 19 meeting Angus Laughlin, Chief Design Engineer of the Bridge Department of the City of Winnipeg Engineering Office, presented a program on "The Disraeli Freeway". After outlining the project Mr. Laughlin showed slides on all phases of the construction of the latest bridge over the Red River in Winnipeg. An interesting discussion developed and the program was greatly enjoyed by the 150 students in attendance.

The student papers competition commenced Jan. 26 with Allan Lansdowne presenting his paper on "A Sketch History of Bridges". An interesting film about suspension bridges followed.

Winnipeg

Peter M. Abel, JR.E.I.C.,
Correspondent

"The Electrical Consultant's Role in Lighting a Modern Building" was the title of a talk given by V. S. Buckler, chief electrical engineer of Green, Blankstein, Russell and Associates.

The guest speaker introduced his talk by covering the general background and technical knowledge which an illumination engineer must have, and the boundaries within which he must work to meet the requirements of the architect, the client, efficiency and economy. The main part of his talk dealt with specific buildings and their illumination problems. Mr. Buckler described in detail the installations in the Lorne Building, Ottawa, now housing the National Gallery, and the Norquay Building, Winnipeg, the new home for Manitoba Provincial Government Departments. This part of the talk was accompanied by slides of the two installations. He also discussed the use of natural sunlight in conjunction with artificial, modular systems, bubbles and combined heating and lighting systems in suspended ceilings. The active question and answer period following indicated that the members had gained a new insight into the illumination engineer's field.

The speaker was introduced by Prof. H. A. MacDiarmid and was thanked by Prof. S. G. Wicks, both of the Electrical Section of the Faculty of Engineering, University of Manitoba.

John E. Brett gave his talk "Some Unusual Engineering Problems of Place Ville Marie Project" at a meeting of the **FREDERICTON BRANCH** Jan. 26. **CHALK RIVER** held a joint E.I.C.-C.I.C. meeting Jan. 17 and heard an interesting talk given by Dr. D. C. Rose entitled "Upper Altitude Research in Canada". Members of the **CALGARY BRANCH** heard Ross Smyth of Trans Canada Air Lines, give an informative talk on "Air Transportation To-day and Tomorrow". Jan. 10. Professor H. M. Edwards, who is a traffic consultant for the City of Kingston, presented an illustrated lecture to the **KINGSTON BRANCH** Jan. 25, on traffic control problems. President Dick addressed **OTTAWA BRANCH** Jan. 12.

● DISCUSSION

(Continued from page 85)

available in the same location—another feature desirable to make these devices as useful as possible to engineers in their work.

Discussion by A. Porter, M.E.I.C.

During the past decade there have been increasing applications of high-speed computers in all branches of industry, but in few fields have these applications been more profitable than in the chemical and petrochemical industries. The authors are to be commended on presenting a well-balanced paper which indicates in specific ways how both analogue and digital computers can be used. Very rarely are both techniques considered in a single paper and for this reason alone the paper is a significant contribution to the literature. It is also encouraging to learn that "literally dozens of successful applications" have been recorded in spite of the fact that the computer techniques involved are still in their infancy—with the advent of highly reliable semi-conductor devices operating at ultra-high-speeds the future of computers in the chemical industry appears to be very bright.

A somewhat disquieting fact raised by the authors is that their company is obliged to organize classes in "advanced mathematics" for the benefit of their technical staff; because it should be expected that the universities would have handled this matter effectively. On the other hand, if "technical staff" implies non-professional personnel the establishment of the courses mentioned in the paper is a very encouraging sign. Professional engineers who have graduated during the past 20 years must surely have been given, at the universities, instruction in such topics as ordinary and partial differential equations, and the elements of probability and matrices. Indeed, instruction in the elements of the calculus, including elementary differential equations, is already common in many high schools of the Western World. And it is to be hoped that the universities will take very serious note of these deficiencies in their engineering graduates, if they still exist, and take urgent steps to correct them. The authors have contributed an important service to engineering education by bringing to light this most important matter.

Discussion by G. L. d'Ombrain

The further implications of this type of study are important. Management is being faced with the necessity of providing ever more expensive research tools for the appropriate extrapolation of its investigations and towards the further development of its research activities. For those who possess neither of these two valuable tools at the outset, there is the necessity to choose one or the other since economic considerations do not usually allow both to be purchased at the same time. The developments in analog computers while significant are nothing like so spectacular as those which are occurring every month in the field of digital computation. When engineering problems become complex, then really large-scale analog computers are required; the authors quote an example which uses the Pace computer and it is a computer with considerable ramifications which make it a costly instrument.

The interesting question, I think, would be whether the work which they did on the nitric acid plant could have been done on the digital machine. One of the complaints which many engineers have in regard to the use of digital machines is their feeling that they lose contact with the problem even if they themselves have been instrumental in programming the solution for their own problem. Having had some experience on working with analog computers, the idea that the analog computer gives a greater feel to the problem is in many cases an erroneous one if the problem is large and the analog computer has many operational amplifiers involved in the solution.

Another point that has to be remembered is that the authors use the analog computer to set up a differential equation which is subsequently solved by the computer; there is another approach which enables you to set part of the process as a direct analog, though on a different time scale which does certainly give one a greater feel of the problem, but this type of attack is usually only possible on special purpose computers. To illustrate what I mean by this, take the simple case of three cascaded, non-interacting (simple exponential lags) time lags having time constants T_1, T_2 and T_3, respectively. The output-input relationship for this is given by the following expression:—

$$\frac{\theta_0}{\theta_1}(S) = T_1T_2T_3S^3 + (T_1T_2 + T_2T_3 + T_1T_3)S^2 + (T_1 + T_2 + T_3)S + 1$$

From this it will be seen that if you wish to make an alteration in one of the time constants, for example the flow rate across a particular heat exchanger surface, you have to make three adjustments to the settings of the coefficient potentiometers of the analog computer. If the problem is more complicated as is normally the case, then a similar change would necessitate anything upward of 12 to 14 coefficient changes. In a special purpose computer, or in a general purpose computer arranged for this method of presentation, you represent each cascaded lag by its physical entity and therefore it is possible to go to one section of the computer and to mentally visualize this as the actual physical entity.

Now consider for a moment the problem placed on a digital machine. A program can be written in which the successive values of a particular time constant can be stored in appropriate locations, and the calculation carried out by the machine can successively call on the different values of this time constant to give appropriately different solutions. With the curve tracing attachments which can now be fitted to digital computers, the engineer can then be presented with a series of graphs showing the effect of the change of this, or any other, physical parameter of his problem. A disadvantage to this approach is that the individual separate solutions are obtained at the expense of a longer computation time than is the case with the analog computer. On the other hand, the engineer who is conducting the work is not necessarily tied to the computation machine in quite the way that he is tied when using the analog computer. The method of parameter variation on the digital machine also utilizes a considerable amount of computer memory and this was certainly a disadvantage with earlier types of computers, but with the ever increasing size of computers this disadvantage is disappearing. I would therefore ask both the authors whether they do not think that with the advent of high speed computers that the time may well be near when problems such as they put forward in their paper on the analog computer might not equally well be done on the digital machine; and I would further ask them that in view of the considerable advantage of digital machines for commercial transactions carried on within large companies whether it is also not likely that there will be an increasing tendency to buy large general purpose digital computers for engineering calculations which in the past have been done on analog computers.

In conclusion, I feel that there is a very definite field for the analog computer, but it is for the comparatively small scale analog computers which may be used as a handy laboratory tool rather than the very massive analog devices which are currently in use in certain organizations.

Authors' reply

D. A. Lamont: The authors have not had experience with "on line" computers, otherwise known as computer directed process control. The pioneering work being done in this field by others gives promise of effective optimizing control for chemical processes. The authors feel that training in mathematical analysis and in general purpose computer programming is mandatory for persons who are to design and operate the computer directed processes of the future.

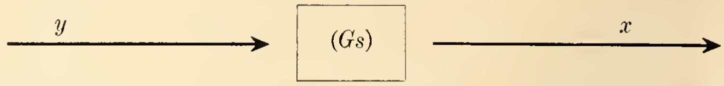
D. C. Baxter: The authors agree completely with the effectiveness of the other applications described. The use of random noise generators to provide input signals to general purpose analog computers opens up an important means of optimizing the design of systems or of individual components.

A. Porter: The training in "advanced mathematics" mentioned in the paper was given only to university graduates, over 80% of whom were professional engineers. While it must be remembered that many graduate engineers are employed in work not requiring mathematical skills, it is certain that the solution of engineering problems will increasingly depend on sound mathematical analysis. It is encouraging to note the growth in emphasis on analytical subjects in the curricula of Canadian engineering faculties.

G. L. D'Ombrain: If a large engineering or research organization were confronted with the need of buying either an analog or a digital computer, it is true that the latter might be selected largely on the basis of its data processing capabilities. These capabilities would be of great value for accounting work, and would undoubtedly contribute greatly to the justification of the computer. The point that must not be overlooked, however, is that digital and analog computers can be rented, at reasonable hourly rates, in the larger centres in Canada. Even a small organization can justify the rental charges, which are modest in relation to the results obtained, although the hourly rates may seem formidable.

The authors cannot agree with Dr. D'Ombrain's preference for digital computers for the simulation of processes and for dynamic analysis in general. While it may be an oversimplification, it has been their experience and that of others who have had experience with both types of machines that digital computers reign supreme for data processing and static design, and analog computers for simulation and dynamic design. The authors have frequently observed the reactions of design engineers and operating personnel to the simulation on an analog computer of one of their processes. Even with no previous exposure to analog methods, these people quickly develop a "feel" of the problem, and invariably increase their insight into the process being modelled.

The authors do not use the analog computer to set up differential equations. The equations are written in the form which best describes the physical system to be simulated and then the computer is used to solve the equations. Dr. D'Ombrain's example describing the simple case of three cascaded, non-interacting time lags is not normally programmed and solved in the way suggested. Therefore his comment regarding 12 to 14 coefficient changes is not necessarily applicable. One simple way to programme transfer functions is as follows:



(the input variable) (the transfer function) (the output variable)

$$\frac{x}{y} = \frac{a_1 s^n + a_2 s^{n-1} + \ldots + a_n s + a_0}{b_1 s^m + b_2 s^{m-1} + \ldots + b_m s + b_0} = G(s)$$

Procedure:

1. Cross multiply and divide by the highest power of s (the Laplace operator). (Assume $m > n$).
2. Re-arrange so as to define the output x in terms of the remaining factors, grouped in powers of $1/s$.
3. Synthesize the computer diagram by substituting

$$\frac{1}{s} = \int dt, \frac{1}{s^2} = \int\int dt\,dt, \text{ etc.}$$

With this approach the number of coefficient setting potentiometers which must be adjusted to change one time constant in the three capacity system described by Dr. D'Ombrain is 5 or 6, rather than 12 or 14 as his formula would suggest.

It should be stressed that a general purpose analog computer is adequate for the solution of even highly sophisticated programmes and special computers are not necessary.

RECENT ADVANCES IN EXPERIMENTAL STRESS ANALYSIS

J. B. Mantle, M.E.I.C.
Professor & Head, Mechanical Engineering Department,
University of Saskatchewan, Saskatoon
The Engineering Journal, January 1961, page 42

Discussion by C. M. Hovey

It is gratifying to note the active interest at the University of Saskatchewan in photoelasticity which, in my opinion, is one of the most powerful tools of experimental stress analysis.

Professor Mantle has given a good description of the characteristics of materials used for 3-dimensional hotoelasticity. However, the method of machining and slicing 3-dimen- ional models as well as the optical echniques used are just as important o accuracy as the selection of a roper material. It is felt that many vorkers in this field would have enefited from a description of the nethods used at Saskatchewan if hese had been included in the paper.

One also wonders whether or not he laborious iterative procedure for eparation of the principle stresses ias now been delegated to the com- outer.

The large number and variety of roblems being solved photoelasti- ally under Professor Mantle's direc- ive is impressive. In this connection, ie may be interested to learn of a olution for the design of a rein- orcement for a circular hole in a late under any condition of plain tress, which was derived by Pro- essor W. Bowes at Dalhousie Uni- ersity in 1951. This solution was hecked photoelastically at the Uni- ersity of Manitoba, but the check vas rather inadequate due to the dif- iculty of using 61-893. It would be nteresting to recheck the solution ising Hysol 6000.

In connection with Photostress, one s somewhat amazed at the advertised ensitivity of this method. It would e of value if a few figures were given, for example, as to the stress ensitivity and accuracy of this nethod for determining stresses in ull scale steel rigid frame structures.

The use of resistance strain gauges t high temperatures has always been f interest to manufacturers of gas nd steam turbines. I wonder if Pro- essor Mantle would care to comment n the reduction of data from such gauges. I have in mind the problem f determining the stress in a hot part which has experienced thermal ex- ansion by means of a gauge whose gauge factor has changed due to emperature, which is attached to a naterial whose value of E has changed with increase in temperature.

Discussion by John E. K. Foreman, M.E.I.C.

The Department of Engineering Science at the University of Western Ontario has been considering the purchase of this type of equipment, and the technique is thus still suf- ficiently new to us that I may be open to question in the following comment. However, it is my im- pression that the thickness of photo- elastic material attached to an actual structure has a considerable bear- ing on the accuracy of the results which are obtained when there is any bending present, in that the strains which are interpreted are average strains in the plastic, and not necessarily those at the surface of the structure. I understand that there are certain correction factors which can be applied to compensate for this (although probably only in circumstances where the curvature is known), but I have not as yet been able to elicit a satisfactory explanation from the manufacturers. I was therefore wondering if Prof. Mantle, in his experiments with this particular experimental stress analysis method, had been able to satisfactorily account for this discrepancy.

Author's reply

I am very appreciative of Mr. Hovey's remarks and questions.

Techniques for machining and slicing of three dimensional models at the University of Saskatchewan have been developed from recommendations in standard reference works, such as Frocht and Hendry. It is anticipated that our experiences in this regard will be detailed in subsequent papers dealing with specific projects.

The reader is referred to a recent paper by Thomson in the Proceedings of the Society for Experimental Stress Analysis (Vol. XVI, No. 1, 1959) in which an application of computers in photoelasticity is described. The digital computer was used to assist in separating principal stresses by the shear-difference method. So far as I have been able to determine computers do not lend themselves conveniently to speeding up the iterative process since the boundary conditions are usually quite irregular in stress analysis problems. Of course, the electrolytic tank method described in the Handbook of Experimental Stress Analysis is a form of analog computer that can be used to advantage in place of the iterative process.

As yet, my experience with "photostress" is rather limited but quite amazing accuracy is possible with the "photostress gauge" on steel. The tests that were made at the University of Saskatchewan indicated an accuracy of ±5 micro-inches per inch at strain levels up to 6000 micro-inches per inch using the unaided eye and numerical average of about five double readings.

The metal foil gauges are now being constructed so that they are self temperature compensating up to 1000°F and attempts are being made by the manufacturer to push this up towards 3000°F. These developments will simplify the reduction of data for the problem cited. In all probability one would have to choose an intermediate value of E to compensate for the change. Some research in this area might very well be undertaken.

In replying to Professor Foreman's question I cannot refer to our experiences because our work to date with "photostress" has been confined to cases where bending is not present. However, I concur with his belief that the equipment could be seriously in error if corrections are not applied. The manufacturer of course realizes this and has done considerable work on this. They have a report available entitled "Photostress Technical Report, April, 1958", by E. I. Riegner which deals with correction factors. Also the paper, "Reinforcing Effect of Birefringent Coatings" by Zandman, Redner and Riegner presented at the October 21, 1959, meeting of the Society for Experimental Stress Analysis treats the subject.

BRAKING OF HYDRO-ELECTRIC GENERATORS

H. O. Wilson, M.E.I.C.
Chief Engineer, Electrical Division, The Shawinigan Engineering Co. Ltd., Montreal
The Engineering Journal, January 1961, page 50

Discussion by Canadian Westinghouse Company Limited

The author of this paper is to be congratulated for focusing attention on the factors which need to be considered, relative to the satisfaetory braking of vertical water-wheel generators.

For the particular unit dealt with in the paper, it is quite reasonable that the initial brake application should commence at approx. 50 r.p.m. or 40% of rated speed. This takes full advantage of the natural braking from the turbine runner and the generator rotor, but yet allows for some possible gate leakage.

However, from tests made on a large, low speed Francis turbine driven generator, satisfactory braking has been achieved with the initial brake application at 27 r.p.m. or 28% of rated speed. In this case the deceleration curve was steeper than for the unit dealt with in the paper.

Again, for a large, high speed, impulse turbine-driven generator, it has been found that satisfactory brake life could not be obtained with initial brake application at speeds above 80 r.p.m., i.e. 25% of rated speed. In the case of this impulse turbine, no braking from the turbine runner was available, but only the friction and windage in the generator. Braking from an initial speed of 100 r.p.m. simply involved too much kinetic energy and severe warping and wear of the brake track resulted.

The above examples point out the variations that may be encountered between types of turbines, and of kinetic energy in the rotating parts, and of peripheral speeds at the brake track.

With the usual type of asbestos brake pad operating against steel brake segments, a co-efficient of friction of 0.40 at 350° is achieved at 50 p.s.i.

The maximum permissible pressure is taken at 150 p.s.i. but the operating pressure in general use is 100 p.s.i.

A rubbing speed of 80 f.p.s. is considered safe practice with a maximum temp. rise in the track of 200°F and the initial rate of heat input in the order of 40 BTU/ff^2 sec.

It is the practice of our Company to divide the brake track into segments which allows for replacement without dismantling the machine. But more important, gaps between the segments allow for expansion with heat.

The segments are designed and mounted to be as flexible as possible to reduce stresses from heating. Thick segments are avoided and the length and width are kept nearly equal.

Initial application of the brakes at reduced pressure will reduee the rate of heat input into the brakes. However, this extends the total braking time, and the total heat input will increase in the event of broken or leaky wieket gates.

The Paper considers only a normal automatic shut-down of the generator and under this eondition, the braking system must give long life of the brake track segments. Under emergeney shut-down conditions, the speed switch is sometimes bypassed and the brakes applied at high peripheral speeds. This may result in such permanent damage as to require replacement of brake tracks, as well as brake shoes, before starting up. If this is not acceptable under emergency conditions then the design would need to go to a very much oversized braking system, which would not only increase the cost but likely the overall dimensions of the generator.

Some more work remains to be done to establish closer parameters of good brake design and operating practice. It is to be hoped that the author in presenting this Paper will have encouraged the collection and study of operating data on this important subject of braking, from all designers and operators of hydroelectric generator stations.

Discussion by G. E. Ransom

I have read this paper with interest and agree with it whole-heartedly. Continuous braking has eliminated many of our troubles with brake tracks especially on the larger machines. Here also the selection of materials is critical to avoid surface cracking of the tracks.

The further refinement mentioned of building up pressure slowly as the units decelerate so that the rate of heat generation can be controlled has proven to be necessary. This is not as difficult as it sounds when one realizes that deceleration is proportional to time and to air pressure in a given volume building up through a given orifice is also proportional to time. Three devices connected in parallel have been used to accomplish the desired result: a needle valve and manifold adjusted to build up the pressure to maximum in the time required; a check valve in the direction to drain the system when releasing

(Continued on page 119)

• DISCUSSION

(Continued from page 116)

the brakes and a pressure reducing valve set at the minimum pressure required to lift the brake shoes onto the track. When the brake pressure air is applied the pressure immediately builds up to the minimum set by the reducing valve and then builds up to the maximum at a rate set by the proportions of the manifold and the size of the needle valve opening. By releasing the pressure, the brakes can be released through the check valve.

Discussion by J. B. Young, Jr.E.I.C.

In case of a serious emergency as for example in the event of a bearing failure or an earth fault in the alternator with the attendant risk of fire the brakes must be suitable for immediate application from full speed. It is therefore normal practice to design the brakes to bring the set to rest from full speed but in the interests of economy in brake shoe wear it is customary on a normal shut down to delay application of brakes till the speed has fallen to approximately half and the stored energy to quarter of its full speed value.

While it is true that for uniform rate of brake heating the pressure would require to be small at top speed and be gradually increased to maintain approximately constant the product of speed times pressure, this is an unnecessary complication.

It is more usual to design the brakes for constant pressure and of such dimensions that the average heat rate does not exceed ½ hp. p.s.i. of brake shoe surface. The diameter of piston in the brake cylinders and the number of cylinders is usually fixed to give a reasonable oil pressure (say 2,000 p.s.i.) when the pistons are required to jack up the rotating parts. Brake shoe linings (Ferodo in our case) can generally withstand a pressure of approximately 15 p.s.i. when jacking. The coefficient of friction of this material is of the order of 0.3.

Under earth fault conditions it is essential that the field be suppressed as quickly as possible in order to minimize damage to the stator core, under a normal shut down there is nothing to be gained by trying to maintain the field to obtain a slightly greater initial retarding effect as the field will have died away before the speed has dropped to 50% value.

While it is agreed that manual as well as automatic braking should be provided care must be taken to ensure that subsequent opening of the turbine gates automatically releases the brakes. Cases have been known where the turbine has run the alternator up to speed with brakes on with resultant damage to brake shoes and track. This can of course be avoided by suitable interlocking.

Most hydro sets are now equipped with permanent magnet governor generators whose voltage can be used as an indication of speed at which brakes are applied. A time delay relay is arranged with a 0 to 20 minute adjustment to release the brakes about 15 minutes after initiation of shut down.

In the event of failure of brake application the lubricating oil pumps continue to run for a short time to cover shut down time without brake application.

We (English Electric Company) have no actual test data of brake shoe temperatures but should expect these to be of the order of 300°C maximum.

Discussion by H. A. Janson

Mr. Wilson's suggestion that the turbine and generator manufacturers should collaborate closely for the best design of the braking system should be given every consideration. In practice, however, the customer himself or his consulting engineer might be in the best position to obtain the data

and provide the design specification required by the generator designer. Such a design specification should contain information concerning the retarding and driving torque on the set from a specified braking speed down to standstill. Information concerning the minimum braking torque desired would also be of value to the generator designer.

To the design considerations mentioned by Mr. Wilson, I would like to add one point which the designer, unfortunately, must not disregard. This is the possibility that, some time during the life of the machine, in spite of all safety measures, the brakes may be applied at full speed. The design should be such that any cracks and/or deformations which may appear due to such maloperation do not affect the strength and shape of the brake track to such an extent as to require immediate repairs.

In connection with the design considerations and design requirements raised by Mr. Wilson, a short description of ASEA's design of generator braking system may be of interest.

A fairly narrow braking track is machined on a main, wide brake plate having a radial depth equal to or greater than the depth of the rim. The brake plate is secured to the rim by all of its through bolts. Should the brake plate be in the form of segments, spigots are used in addition to the above bolts to ensure the greatest possible rigidity. The thickness of the brake plate is such that the temperature rise on the track surface will not exceed 200°C. Low carbon steel with good plastic qualities under heating and cooling cycles is used.

To counteract any waviness or unevenness of the brake track resulting from the rim stacking the final machining and polishing of the brake track is carried out on the assembled unit at a speed of 5-10% of the normal. While about one day is required for this operation, the design of the thrust bearings permits it.

The pad lining material used is of asbestos type without metallic particles or threads. The specific pressure is 20 to 30 p.s.i. and the co-efficient of friction not less than 0.3 at all speeds. The pad linings are designed for roughly three hundred complete brakings. The pads can be easily replaced by spare pads and the worn down ones provided with new linings by the station personnel.

Discussion by Douglas G. Berry

Intermittent operation of the brakes while the turbine is still absorbing power reduces the total heat production in the brake segments since a larger amount of the kinetic energy is dissipated by churning up the water in the draft tube.

Distortion of the brake segments is less with intermittent braking than with continuous braking. This is because, during the periods when the brakes are not operating, heat flows into the cooler parts of the segments and temperatures tend to equalise. It is obvious that with the intermittent braking the number of thermal cycles is increased but the severity of the additional cycles is not as great as during the initial operation.

The following observations apply to figure 1 in the paper:

1. The speed on curve 2, some 37½ seconds after synchronous speed, is 7% higher than on curve 1 and hence the rotating parts contain 14% more kinetic energy. This may be a result of changed tailwater level which could have a considerable influence on the retardation effect of churning up water in the draft tube. It would appear that the two retardation curves are not directly comparable.

2. On curve No. 2 it will be noted that the generator brakes are ap-

plied at 50% synchronous speed. At this speed the retardation effect caused by churning of water in the draft tube is very much greater than the retardation produced by application of the brakes. The effect of intermittent brake operation would be seen more clearly if the brakes were intermittently applied when the retardation effect of churning water in the draft tube was less.

3. In figure 1 the brakes are initially applied at 50% and 20% synchronous speed respectively and so a direct comparison cannot be made between the differences in performance. Direct comparison would have been facilitated by applying the brakes initially at the same speed.

Discussion by H. R. Sills, M.E.I.C.

Friction brakes are an excellent means of stopping and holding a generator at low speeds but, at high speeds, they have limitations:

(1) *The total energy to be absorbed*: Due to inertia alone, the energy in the form of heat that the brake surface must absorb varies as the square of the speed at which the brakes are applied. In addition, they must absorb energy due to gate leakage, which normally amounts to ½ to 2% of rated torque at standstill, to zero between 20 to 35% speed, and negative at higher speeds. At normal speed the braking effort of the turbine can vary from zero for an impulse turbine, to 6% for a high speed Francis turbine, to 20% for a low speed Francis turbine and to 80% for a propellor turbine. Thus, to limit the duty on the brakes, it is desirable to let the turbine absorb most of the energy of inertia at the top part of the speed range.

(2) *The rate at which heat can be absorbed*: Heat is absorbed into the brake plate at a rate determined by its thermal conductivity. The difference in temperature between the surface and the interior causes expansion on the outer surface. This is mitigated, by using a segmental brake surface, flexibly mounted, to provide for expansion; but if heat entry is too rapid the plates or their fastenings may be strained beyond their fatigue or elastic limits, resulting in cracking or possible failure. As the brake surface rotates from shoe to shoe, it is alternately heated and cooled, and rapidly expands and contracts. Should this cause the surface to exceed its limit of fatigue, it will develop hair line cracks, which may propagate. Heat also raises local spots which are subject to slightly higher pressure than adjacent areas and become progressively hotter and higher; they show up as spots of blue oxide, which fortunately is usually smooth and adherent; but, if too hot, the oxide flakes off and the surface roughens. Thus there is a limit to the rate at which heat may be safely absorbed, and this appears to be between 400 and 600 watts/sq. in. of brake shoe; by comparison, a stove elements operate at 40 watts/sq. in.

(3) *The number of brakes*: It is customary to design brakes to operate at 100 p.s.i. pressure, and corresponding shoe pressure of 40 p.s.i., to exert a friction force of 4 to 5% of rated torque, which is usually adequate to stop and hold a generator against gate leakage. More brakes would be worse for the brake surface; fewer would be inadequate.

(4) *The condition to be met*: The brakes are intended to be used to capacity mainly during the transition from idling speed to full stop. For a normal stop, the required rate of deceleration over this range is not usually a limiting factor. To get best utilization of the brake surface, the continuous capability should be assessed and not exceeded except, perhaps, in an emergency. If the heat transfer rate is limited to 400 w./sq.-in. most of the other factors are safe.

At 40 p.s.i. shoe pressure (100 p.s.i. air), a velocity of 1800 r.p.m. will produce 400 Watts/sq. in. and any appreciable operation above this speed may initiate hair line cracking. If the normal idling speed is less than this, brakes may be applied at full pressure. This speed is, usually less than half speed for most units. In Mr. Wilson's illustration, the brake surface speed at generator rated speed is 7900 f.p.m., and only reaches 1800 ft. at 23% speed, somewhat below the normal idling speed shown in his curves. But, in this case, the initial overload would not be serious, as the brakes would be cold and the rate of deceleration fast enough to reduce the overload before strains can develop; but the duty on the brakes can be made easier by always letting the generator idle for a minute or so after reaching 40% speed to assure it will be at minimum idling speed when brakes are applied.

Large machines have been built with brake surface speeds of 11500 ft./min. at rated speeds, and even larger ones with higher speeds are contemplated. On these it is desirable to initiate the braking sequence at 50% speed at low pressure, and to gradually increase the pressure as the machine decelerates. By this means the rate of heat input can be kept below 200 watts/sq. in. which is desirable to prevent charring and rapid wear.

One of the potentially dangerous hazards of generator brakes is the possibility of their being applied when the generator is on load. This has happened to my knowledge, twice on machines with automatic brake sequences, and several times by accidental hand operation. Fortunately, in none of these cases, did the brake surface break loose from the rotor, but they were badly cracked and had to be replaced. Thus I concurr with Mr. Wilson in recommending brake limit switches, a practice now gaining favour, to insure that the brakes are down when the generator is started and running. I agree heartily that intermittent braking should be discontinued. The origin of this practice is lost but I suspect it was initiated by operators to blow out the flames on the original maple brake shoes now not necessary.

Another survival which I suggest should be liquidated is the invariable specification requirement that "The brakes shall be capable of bringing the generator to a stop in five minutes against a gate leakage of two percent". Mr. Wilson, in his paper, has pointed out that the condition of 2% gate leakage torque is a fact only at standstill. I have shown why the five minute period should be modified so that the brake system of large units may endure as well as meet the stopping requirements. As the most desirable stopping sequence and time varies with the size and type of turbine, it is not easy to get a pat successor to this clause, but if the essential function is clearly specified, the brake designer can then be invited to describe his method of attaining it within the known limitations.

Author's reply

This paper was presented with the expectation that the discussion would be of value both to the manfacturers and the utilities, and I think that this has been accomplished.

With reference to Canadian Westinghouse remarks, it is never safe to generalize on a topic such as this and application of brakes at 40% rated speed should be taken as representative but each case must be considered individually.

From Mr. Berry's remarks it can be seen that this is a controversial subject. We agree that the two curves in Figure 1 strictly speaking are not directly comparable but we think that they serve to indicate in a general way that there is no advantage in our past practice of applying brakes intermittently at 50% speed and then continuously after a few intermittent applications as compared to applying the brakes continuously at approximately 40% rated speed. EIC

You and the Institute

THE ENGINEERING INSTITUTE OF CANADA means different things to different people. It may even mean different things to the same person at different times. Each member is constantly writing and rewriting his own definition; and it is the sum of these definitions that charts the course and progress of the Institute from year to year.

One concept of the E.I.C. is becoming more and more fixed. It is something like this:

"E.I.C. is a family of professional men engaged in related endeavours. Through participation in E.I.C., they create and grow and advance together".

As participating members of the Institute, they find ways to express and develop almost every individual talent they may have — through that expression, they gain much satisfaction for their creative desires.

By the nature of these opportunities, E.I.C. is most rewarding to those who use it as a facility for giving of themselves for the benefit of others.

It is also in the nature of these opportunities to be timeless. They have been the sturdy foundation of E.I.C. progress through almost 75 years. And as they are increasingly grasped, they will become the motive power of E.I.C.'s rise to new heights in the 75 years immediately ahead.

Why join the Institute?

No one can live in a vacuum — least of all an engineer. His professional world is growing and changing constantly. Unless he is content to be merely a time-server, he must always continue his own education and growth. In the strictly technical sense, he must keep up with new developments in his profession, through meetings and discussions, publications and personal contacts. The easy — and only — access to all of these in all fields of engineering in Canada is the E.I.C.

Further, through the strength of its history, record of service and numbers, the E.I.C. has a respected voice with which to speak for its members when needed. Joining the E.I.C. will add to this strength which is used for the benefit of the profession and the nation.

Becoming a member of the E.I.C. will not guarantee a promotion or a salary increase (although salary surveys show that members of technical societies generally earn more than non-members, and that management regards participation in technical society activities as important). What an engineer will get out of E.I.C. is really what he puts in. The Institute is not an abstraction, it is a collection of engineers. What it accomplishes is the sum of what its individual members do for themselves.

Most members of the E.I.C. can talk generally about why they belong and the benefits of membership, but this is rarely sufficiently detailed to convince a non-member engineer why he too should belong.

A Member's Check List

There are probably as many good reasons for being a member of the Institute as there are members. This following brief check list includes some of the more obvious advantages enjoyed by every member.

1. He can participate in Branch and Section activities at any one or more communities.
2. He can participate in preparation and presentation of engineering papers in his field.
3. He can participate in discussion of engineering papers.
4. He can participate in Annual and Regional meetings and Special Conferences on the same basis as leading Canadian engineers and industrialists.
5. He can participate in technical activities sponsored by any one or more of the Engineering Divisions:
   - Bridge and Structural Engineering
   - Chemical Engineering
   - Civil Engineering
   - Electrical Engineering
   - Engineering Education
   - Geotechnical Engineering
   - Hydro-electric Engineering
   - Management
   - Mechanical Engineering
   - Mining Engineering
6. He can receive The Engineering Journal and Transactions, the outstanding media for Canadian engineering papers.
7. He can have the benefits of the finest engineering library service in Canada.

8. He can have the benefits of an experienced employment service.
9. He can associate with his fellow engineers in life-long participation in Canada's outstanding engineering "University" — the E.I.C. — and enhance his stature as an engineer.
10. He can serve on Branch and National Committee activities, thereby improving his capability as an engineer and administrator.
11. He can become eligible for outstanding Institute awards and prizes.
12. He is welcomed, as an E.I.C. member, at general meetings of many leading cognate Commonwealth and U.S.A. founder societies in which he wishes to participate, on the same basis as their members.
13. He will benefit from the prestige of membership in the Institute.
14. He benefits from the collective technical activities of his professional co-workers.
15. He may use after his name the legally authorized letters indicating his membership: Member, M.E.I.C.; Junior, Jr.E.I.C.; Student, S.E.I.C.

LIBRARY

Access to the Institute's library is one of the many advantages of membership. The library belongs to the members of the Institute, and although it is located at headquarters in Montreal, its services are available to all members, wherever they may live.

The Institute's predecessor, The Canadian Society of Civil Engineers, was founded in 1887 and the first library catalogue was printed 1892. This continuous existence of nearly 70 years means that not only is the latest information available in the library, but that the collection contains much unique historical material, especially valuable for research purposes.

The library contains more than 7,000 books covering all branches of engineering and allied subjects. The prestige of the Institute is such that many publishers send us their new books for review in The Engineering Journal, and these volumes are added to the library's loan collection. More than 500 periodicals from over 30 countries are currently received. Complete files of many of these are kept, from Volume I, Number I.

Reading Room

Anyone may use the Reading Room, but only members may borrow books. A trained staff is available to answer queries and to direct the reader to the best sources of information. The Reading Room is open from 9 to 5 on week days, and 9 to 12 on Saturdays in the winter.

Telephone Service

Queries will be answered over the telephone whenever possible, but members requiring detailed information will probably find it more satisfactory to send their requests in writing if they cannot visit the library in person. It is not usually practical to give such information as formulae and specifications over the telephone.

Borrowing

Any item in the library may be borrowed by members, with the exception of some reference books. It has also been found impractical to send bound volumes of certain periodicals through the mail, and photo-copies of articles from these will be sent to members living outside Montreal.

Two books, periodicals or pamphlets (or more at the discretion of the librarian) may be borrowed at one time. The normal loan period is two weeks, which may be extended on application for another two weeks. Additional time is added to the loan period when books are sent by mail.

There is no rental charge for items borrowed from the library. Books sent out of Montreal are usually mailed at a special rate, and members are not required to pay postal charges.

Searches

The library staff is always glad to recommend books on a particular topic.

Bibliographies of books and periodical articles will be compiled on request. These are compiled from many sources and indices, and although the items may not all be available in the Institute library, they can be borrowed elsewhere, or photo-copies obtained. It is regretted that bibliographies cannot be compiled for students writing theses, as this is considered an integral part of the work. However, sources of possible information will gladly be recommended.

Other

The library provides a photo-copying service and makes a nominal charge of 25 cents a page. The library does not maintain its own translation service, but has access to translations prepared by other organizations. The charge for these varies.

A very active co-operation exists among technical libraries in the Montreal area and across Canada, and it is usually possible to borrow any item not in the Institute collection, or to obtain a photo-copy.

Members may subscribe to the periodical publications of other engineering societies at greatly reduced rates. A complete list of these will be sent on request.

THE PRESIDENT'S LETTER

On January 6, 1961, the President wrote members of Council asking certain specific questions which were designed to result in answers which would help Council assess how it could best enhance member satisfaction with the operation of the Institute.

Obviously, the returns to a questionnaire of the nature involved cover a range of situations. They cannot be reduced to specific percentages without qualification. Nevertheless, most useful guides to the thinking of membership can be derived. From this, recommendations for action can be framed.

The following includes some of the highlights of the tabulation of replies.

Councillors and the Branches

At Branch level what should Council do to make members satisfied? Answers to this varied widely, but from them three recommendations were made.

1. Pursue with all possible speed the plans of the Committee on Branch Operations.
2. Use the Engineering Journal to convey vital messages on optimum Branch activity.
3. Use Councillors more effectively than in the past in Branch Executive deliberations.

Members and Council Activity

What should Council do to make members satisfied with Council activity? Again there was a wide range of opinion, from which the four following recommendations could be made.

1. Take steps to achieve optimum performance by Councillors as the channel of communication between Council and Branches.
2. Make the Executive Committee a permanent feature as soon after the expiration of the additional trial period, in January, 1962, as possible, so that Council can deal with development of policy.
3. Provide, as soon as possible (1962 fiscal year), for payment of travelling expenses by Councillors to four meetings of Council per year devoted to policy deliberation.
4. Run a well-written story on the role of Council and the function of Councillors.

Members and Headquarters

Following are three recommendations made on the basis of replies to the question, "What should Council do to make members satisfied with Headquarters' Operations?"

1. The Committee on Branch Operations should examine what can be done about visiting speakers and engineers, to establish a policy and outlines of practice, for execution by Headquarters and publicity in the Engineering Journal.
2. The Committee on Branch Operations should investigate what can be done to provide more effective results from the Branch News correspondents.
3. The annual financial report can be developed to emphasize the reasons for the cost of Headquarters Operations.

Members and Vice-Presidents

Aside from four "no comment" replies, the Branches consider Vice-Presidents should play a much more active role than hitherto, and that an encouraging start has been made. Two recommendations arose from replies to the question, "What should Council do to make Members satisfied with Vice-Presidential assignments?"

1. Select the right men, willing to work and capable of travelling.
2. Pursue a policy of Vice-Presidents attending at least one Branch Executive Committee meeting for each Branch in his Zone. This should be done without waiting for an invitation. Advise Branches of proposed itinerary and ascertain if agreeable.

Members and the President

Councillors were asked: "What should Council do to make members satisfied with their relationship with their President?" In this connection, replies stressed the importance of the Presidential visit and early scheduling. It should be annual. Branches should be informed of Presidential visits to nearby Branches. Finally, the President should speak on an inspirational tone, free from the connotations of operational aspects of Institute activities.

The only recommendation which appears to be inherent in the replies on this question is the separation of visits by the President and by the General Secretary.

Members and the Journal

The question, "What should Council do to make members satisfied with The Engineering Journal?", again evoked a wide range of replies. From these, four recommendations could be made.

1. Draw to attention of Publications Committee.
2. Have General Secretary look into situation as regards delivery of Journal to Students.
3. Provide explanation of Journal financial aspects in Annual Report of Finance Committee.
4. Draw attention of CTO to coverage of chemical, metallurgical and mining fields.

Members and Transactions

A question similar to the one asked regarding the Journal also was asked concerning Transactions. From the replies, no recommendation appears in order beyond:

1. Continuance of Transactions.
2. Look into the possibility of shifting some papers from the Journal to Transactions.

CODE OF ETHICS

Adopted at the Annual Meeting, January 27th, 1925

(1) The engineer shall carry on his professional work in a spirit of fairness to employees and contractors, fidelity to clients and employers, and devotion to ideals of courtesy and personal honour.

(2) He shall refrain from associating himself with or allowing the use of his name by an enterprise of questionable character.

(3) He shall advertise only in a dignified manner, being careful to avoid misleading statements.

(4) He shall regard as confidential any information imparted to him as such as to the business affairs and technical methods or processes of a client or employer.

(5) He shall inform his client or employer of any business connections, interests, or circumstances which may be deemed as influencing his judgment or the quality of his services to his client or employer.

(6) He shall avoid attempting to obtain employment or professional engagement or advancement by competitive underbidding, by unjustly criticizing other engineers, or by other improper or questionable methods.

(7) He shall accept compensation, financial or otherwise, for a particular service from one source only, except with the full knowledge and consent of all interested parties.

(8) He shall discourage the practice of free engineering designing and advice by manufacturers and contractors.

(9) He shall not review the work of another engineer for the same client or employer, except with the knowledge of such engineer, or unless the connection of such engineer with the work has been terminated.

(10) He shall co-operate in upbuilding the engineering profession by exchanging general information and experience with his fellow engineers and students of engineering, and also by contributing to the work of engineering societies, schools of applied science and the technical press.

Beaver Bill says:

Did you realize Canada, with several sister nations of the Commonwealth of Nations, is singularly fortunate in its facilities for the education and professional development of engineers?

It is indeed unique, because Canada has a great Engineering University with 59 branches and sections serving our country on a regional basis, from St. John's to Victoria, from Hamilton to the Yukon. Of course, some of the branches are very large, some quite small, depending on the population served.

But each one of them has at its disposal the services of 10 faculties, covering every field of engineering. These faculties, or Engineering Divisions of the Committee on Technical Operations, are staffed with keen engineers anxious to provide you with the basis for a lifetime of improvement of your professional stature as an engineer, and your professional ability to serve Canada better.

This great Engineering University is the Engineering Institute of Canada, whose membership rolls proudly proclaim most of the great engineers who have played such a vital role in the development of Canada. Who are these men? Just a few —

Thomas Coltrin Keefer	***John Galbraith***
Sir Casimir Gzowski	***Col. R. W. Leonard***
Sir John Kennedy	***Julian C. Smith***
Henry J. Bovey	***George J. Desbarats***

This great Engineering University celebrates its Seventy-Fifth Anniversary in 1962.

Want to join? How much does it cost? Just 40 cents a week! The price of a package of cigarettes! But what a difference!

Sincerely,

Library Notes

Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

*FREQUENCY-POWER FORMULAS.

This monograph is a report on an attempt to find necessary and sufficient conditions for a physical system to obey the frequency-power formulas. In part one are described various energy function methods, and four types of frequency-power formulas, including the Manley-Rowe formulas. These four are also tabulated, along with other important information, in the appendices. In part two specific systems are considered—lumped dissipative, lumped reactive, and distributed systems. The final part discusses rotating machine applications and communications applications. (P. Penfield, Jr. New York, Wiley, 1960. 168p., $4.00.)

*ATOMIC THEORY FOR STUDENTS OF METALLURGY.

The third edition of a monograph first published in 1946 for advanced metallurgy students, to describe the general ideas on which the electron theories of metals and alloys are based. No attempt is made to deal with mathematical technique. The six parts of the book deal with general background theories; the structure of the free atom; the nature of the interatomic forces involved in the formation of solids, liquids and compound molecules; the free-electron theory of metals; the Brillouin-zone theory of metals; and finally specific metals are discussed from this standpoint. The crystal structure of the metallic elements is given in an appendix. (W. Hume-Rothery. London, England, The Institute of Metals. 427p., $7.50.)

*IP STANDARDS FOR PETROLEUM AND ITS PRODUCTS, PART IV: METHODS FOR SAMPLING, 19th. ed.

Beginning with 1960, the Institute's "Standard methods for testing petroleum and its products" will be issued in four separate sections—methods for analysis and testing; methods for rating fuels—engine tests; methods for assessing performance of crankcase lubricating oils—engine tests; and methods for sampling. Part 4 is the first to be received, and is a revised version of IP no. 51. The sampling techniques and apparatus described are technically equivalent to those in the ASTM 1957 manual. Minor differences in terminology persist through reluctance to change established nomenclature. (London, England, Institute of Petroleum, 1960. 44p., 10/-.)

*AN INTRODUCTION TO ASTRODYNAMICS.

An undergraduate-level text which relates the theory and techniques of celestial mechanics directly to contemporary space vehicle problems. There are two broad divisions in the text: "Fundamentals" includes discussions of general laws, minor planets, comets, geometry, and the astrodynamic constants; "More Detailed Analysis" covers such topics as orbit-determination, orbit computation, n-body problem, nongravitational forces, observation theory, and applications to interplanetary orbits. (R. M. L. Baker, and M. W. Makemson. New York, Academic Press, 1960. 358p., $7.50.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time, for a period of two weeks, excluding time in transit.

Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 2050 Mansfield Street, Montreal.

*THE PHYSICS OF FLOW THROUGH POROUS MEDIA, 2nd. ed.

This monograph continues the purpose of its first edition—to collect and coordinate information on the physical principles of hydrodynamics in porous media. The volume of material available made selection imperative, and this has been made on the basis of emphasizing general physical aspects and theory rather than particular cases and experimental aspects, and by presenting only one solution for basic differential equations where there may be many available. This present edition retains the material of the first, adding accounts of developments up to the summer of 1959. The major revision has been expansion of the treatment of multiple phase flow to three chapters—elementary displacement theory, immiscible displacement, and miscible displacement. The author is with Imperial Oil Ltd. in Calgary. (A. E. Scheidegger. Toronto, University Press, 313p., $16.50.)

*THE MECHANICS OF VIBRATION.

As the aim of this book is to present ideas rather than to describe applications, most of the discussion is in terms of "academic" systems—spring-connected rigid masses, taut strings, and uniform elastic bodies—although chapter 5 does discuss the extent to which real systems may be analyzed in terms of these ideal systems. The first three chapters discuss analysis of simple, complex and multi-freedom systems, and contain a progressive exposition of the receptance concept. The remaining chapters discuss vibration systems in shafts, bars and beams, systems with damping, and the excitation of a system by transient forces. (R. E. D. Bishop. Toronto, Macmillan, 1960. 592p., $20.50.)

*PHYSICS OF THE UPPER ATMOSPHERE.

Eleven chapters of this book are detailed monographs on particular topics by specialists, all concerned with that part of the atmosphere above the height of 60 km. These deal with the thermosphere, the ionosphere, the properties and constitution of the upper atmosphere and its study by rockets and satellites, the airglow, general characteristics of auroras and their study by means of radar, interpretation of the auroral spectrum, and consideration of geomagnetism and meteors in the upper atmosphere. The final chapter contains brief comment on advances during the IGY 1957/58 in each field, written by the author of the relevant chapter of this book. (Ed. by J. A. Ratcliffe. New York, Academic Press, 1960. 586p., $14.50.)

systems, and Fourier analysis. Some of the topics covered include circuits, impedance, dipoles, network theory, resonance, oscillating circuits, resistance, condensers, and inductance. There are useful bibliographies which include many references in English, at the end of each chapter.

It is planned that each volume will be complete in itself, and will give the reader enough basic information to enable him to read advanced texts and periodicals. (P. Grivet and R. Legros. Paris, Masson, 1960. 553p., 90 NF.)

TRAITE THEORETIQUE ET PRATIQUE DES ENGRENAGES, 3. ed.

Various changes and corrections have been made in this third edition to bring it up to date, and new tables and diagrams included. This first volume deals with theory and technology, and covers basic theory, surfaces of different types of gears, helicoidal and worm gears, teeth, pitch calculation, shafts, materials used, wear, train of gears, etc.

The author, a well-known university professor, is at present preparing a third edition of the second volume of this work, which is a study of material and equipment. (G. Henriot. Paris, Dunod, 1960. 443p., 64 NF.)

STANDARDS RECEIVED

ASTM standards. American Society for Testing Materials, 1916 Race Street; Philadelphia 3, Pa.

Bituminous materials for highway construction, waterproofing, and roofing (with related information). 8th ed., 1960. $5.50.

Mineral aggregates and concrete (with selected highway materials). 9th ed., 1960. $5.75.

Petroleum products and lubricants (with related information). vol. 1, 37th ed., 1960. $9.50.

Steel piping materials. 17th ed., 1960. $7.00.

CSA standards. Canadian Standards Association, 235 Montreal Road, Ottawa 2.

A23 — 1960 — Standards for concrete and reinforced concrete. $2.50.

A119.1 — 1960 — Code for split-barrel sampling of soils. $1.00.

A119.2 — 1960 — Code for thin-walled tube sampling of soils. $1.00.

C22.2 No. 5 — 1960 — Construction and test of service-entrance and branch-circuit breakers. 3rd ed. $1.25.

C105 — 1960 — Specification for indoor high-potential full-load air interrupter switches. $1.75.

G40.8 — 1960 — Specification for structural steels with improved resistance to brittle fracture. 35c.

0132.3 — 1960 — Specification for wood doublehung prefit window units. $1.00.

Z69 — 1960 — Specification for a radiation symbol. $1.00.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Beams and girders.

Buckling tests on plate girders, by Konrad Basler and Bruno Thurlimann. Stockholm, International Association for Bridge and Structural Engineering, 1960. 14p.

Effect of tensile properties of reinforcement on the flexural characteristics of beams, by R. G. Mathey and David Watstein. New York, American Iron and Steel Institute, 1960. 21p.

Breakwaters. Pneumatic.

A laboratory study of pneumatic breakwaters, by T. M. Dick and A. Brebner. Kingston, Ont., Queen's University Civil Engineering Dept., 1960. 31p. (C.E. Research Report no. 12).

Canada. National Research Council. Division of Building Research.

Canadian building digests.

Condensation between panes of double windows, by A. G. Wilson. Ottawa, 1960. 4p.

Rain penetration of walls of unit masonry, by T. Ritchie. Ottawa, 1960. 4p.

Technical papers.

Permafrost aspects of Hudson Bay Railroad, by J. L. Charles. Ottawa, 1960. 11p. (Technical paper no. 94). 25c.

Canadian Good Roads Association, 41st Convention, Toronto, 1960.

The behaviour of subgrades under repetitive loadings, by V. E. Vaughan.

Bridge location in relation to highway planning, by L. C. Johnson.

Can we save the cities from the stranglehold of traffic? by C. T. Brunner.

Evaluating highway-railway grade crossing treatments, by W. A. McLaughlin.

Landscaping for highway improvement, by A. K. Hay.

Problems in grouting prestressing cables, by T. Lamb.

The role of the resident engineer in construction control, by W. J. Malone.

Rural municipal road markings, by D. L. Lawrysyn.

Some aspects of traffic theories, by J. L. Vardon.

The study of the economic impact of urban expressways upon adjacent areas, by F. J. McGilly.

The use of chemicals in winter maintenance, by D. R. Brohm and H. M. Edwards.

Cement.

Long-time study of cement performance in concrete: Chapter 12, concrete exposed to sea water and fresh water, by I. L. Tyler. 1960. 12p.

Coal.

Possibilities of using nuclear energy for gasifying coal, by J. P. McGee and Sidney Katell. 1960. 11p. (U.S. Bureau of Mines information circular 7965).

Concrete. Prestressing.

Notes on fire tests of prestressed concrete. Chicago, Portland Cement Association, 1960. 13p.

Electrical engineering.
Electrical Research Association.

Technical reports.

A/T153 — Effect of heat ageing on the electrical and mechanical properties of varnished terylene fabric. 1958. 12/6.

A/T155 — Grips for tensile tests on very extensible tapes, by A. G. Day. 1959. 4/6.

D/T109 — Pressure piling in compartmented enclosures. I. Effects of bore and length of connecting tube in explosions of pentane/air mixtures, by T. J. A. Brown. 1959. 12/6.

J/T172 — The creep and rupture properties of 2¼% chromium, 1% molybdenum quality steel. A summary of British data (1% strain and rupture).

Appointments and Transfers

Atlas Copco AB has appointed Harry Grevby as managing director of Atlas Copco Canada, Ltd. Mr. Grevby succeeds **H. Sommerfeldt Jacobsen** who has been appointed managing director of the international Swedish Diamond Drilling Company, parent company of the Craelius organization, acquired by Atlas Copco in 1960.

Nik Cavell, recently High Commissioner to Ceylon, and from 1950-1958 administrator of Canada's Colombo Plan Aid, has been appointed a director of Balfour, Beatty and Co. (Canada) Limited.

Edwards of Canada Limited has announced the appointment of **Earland M. Dawson** as chief engineer.

The appointment of three managers within the North American Division of Atlas Steels Limited, has been announced. **George C. Olson** as works manager will be responsible for all manufacturing operations. **Bruce M. Hamilton** as manager of metallurgy will direct all divisional metallurgical functions. A. V. Orr as manager of marketing will be in charge of sales.

Atlas Copco Canada Ltd. has appointed **A. R. Belanger** district manager of the company's Vancouver branch.

Claude Clermont has been appointed district manager, British Oxygen Canada Limited at Montreal.

The Civil Service Commission has appointed **Arnold M. Tedford** director of the Commodities Branch, Department of Trade and Commerce. He succeeds **Denis Harvey**, who was appointed assistant deputy minister in July.

For the third consecutive year **M. S. Greene** of Montreal has been elected chairman of the Associated Equipment Distributors advertising committee. Mr. Greene acted as moderator for the business session on advertising at the A.E.D. annual meeting in February in California. He is sales promotion manager of Construction Equipment Co. Limited.

The appointment of **John Getgood** as president of Pacific Petroleums Ltd., Calgary, has been announced. Mr. Getgood succeeds **George L. McMahon** who has been appointed vice chairman of the board.

F. I. Morrissey has been appointed to the newly created post of superintendent of the engineering division, Canadian Club distillery, Hiram Walker and Sons Limited.

Recently elected to the Board of Directors of Union Carbide Canada Limited is **Allen T. Lambert.** Mr. Lambert is president of the Toronto-Dominion Bank and a director of a number of other companies.

Developments

Information contained in this section has been obtained from press releases. Mention of products and services does not imply endorsement by the Institute.

THE ANNUAL REPORT for 1959 of the European Federation of Corrosion now is available. The report is in three parts: the report of the General Secretariat with an account of activities within the Federation; reports from member societies on their technical work in the corrosion field; and a survey of institutes and research centres in individual countries which are concerned with problems of corrosion and the protection of construction materials.

COMPLETE PAINT finishing systems and component units for such systems is the subject of a new, 12-page technical bulletin released by Ross Engineering of Canada, Ltd. Data includes typical schematic layouts of finishing systems, illustrations and materials on such items as metal preparation units, spray booths, flow coat units, dry-offs, ovens, air heaters, conveyors and air make-up units.

A DEFICIT of $218,930 for the year ended March 31, 1960, was noted in the annual report of the British Columbia Power Commission. Gross revenues increased 11.4% to $19,077,564. The deficit, which was charged to reserves, was caused largely by increased fixed expenses, interests and depreciation, on capital works which had been put into service during the year and which had not yet been fully utilized in normal production.

MONTREAL LOCOMOTIVE WORKS, LIMITED, has been awarded a major contract for subway cars by the Toronto Transit Commission. Thirty-six cars are to be purchased by the TTC. The current move marks an important step in the Company's diversification program.

A NON-CONTACT CONTROL which is claimed to anticipate material breakage and to automatically stop a strip being rolled to prevent excessive material damage is announced by Canadian Allis-Chalmers. Anticipation of strip breakage is achieved by using magnetic amplifier static switching circuits in conjunction with an indicating tensiometer.

A "DO-IT-YOURSELF" self-curing kit has been introduced by Dominion Rubber Company which enables industrial users to make permanent repairs to conveyor belting and other products without special equipment, highly skilled personnel or the heat sources generally required for such operations. The kit, marketed under the name Holdtite Self-Vulcanizing Products, consists of various styles and sizes of repair components (rubber and fabric reinforced patches, sheet material, putties and cements,) the simple tools required to do most repair jobs and an instruction manual. The sealing and patching materials are self-vulcanizing compounds that cure quickly to a touch, resilient rubber at room temperatures.

AN OUTLAY OF $7½ MILLION is involved in an extensive electric generating plant expansion program scheduled by Canadian Utilities, Limited. Major item is a $4.4 million extension to the Company's Battle River plant south of Forestburg. Another $2.8 million is earmarked for extensions to the 17,500 kw. plant at Vermilion and almost $300,000 is set aside for the removal of the 8,500 kw. turbine from Vermilion to the Company's Sturgeon plant in northwestern Alberta.

Disc-webbed, roller bearing crankshaft and tunnel housing

Maybach industrial diesel engines — from 300 to 1,800 hp — can achieve 16,000 hours between major overhauls

Bristol Siddeley Engines Limited produce Maybach* diesel engines. Covering a power range from 300 to 1,800 hp, Maybach diesels are amazingly reliable and have shown that they can achieve major overhaul lives of between 12,000 and 16,000 hours.

The *proven* basic design features of the whole range (straight 4 to 16-cylinder V) are the same, and each unit can be turbo-charged, or turbo-charged and intercooled. The range operates up to 1,600 rpm and *combines the best performance and design qualities of high, medium and low-speed diesel engines:* light weight and compactness; excellent thermal efficiency; and extremely long life.

Advanced design features

The pistons are pressure-oil cooled. This gives very efficient heat dissipation and reduces liner and gas ring wear to a minimum. The roller bearing, disc-webbed crankshaft is exceptionally rigid within its tunnel housing, and in practice withdrawal is not normally necessary before 12,000 hours running. So low is big end bearing wear that in some cases the protective lead flash has been found intact when examined after 15,000 hours running!

Since the cylinder bore and stroke, and the majority of components, are identical in all models, spares stocks are considerably reduced. And during servicing semi-skilled labour can be used because great thought has been given to easy accessibility and removal of components.

World-wide application

Bristol Siddeley Maybach diesel engines are designed for a wide variety of industrial applications, from stationary and mobile light and power generator sets to oil-drilling rigs and pumping stations. Maybach diesel engines are in service all over the world and have built up an unrivalled record for reliable and economic operation.

For further information please write to: Bristol Aero-Industries Limited, 10210 Pie IX Blvd., Montreal North, P.Q.

BRISTOL SIDDELEY ENGINES LIMITED

HIGH-LEVEL MANPOWER IN OVERSEAS SUBSIDIARIES.

Foreign investment and management have always played an important role in industrial development throughout the world. This study considers the problems United States corporations operating abroad face in selecting and developing high-level manpower. The study is based on the experiences of American companies in Mexico and Brazil, but the conclusions are equally applicable to other parts of the world.

The topics covered in the study include: operation in a foreign country; relationship between the parent organization and overseas subsidiaries; the cost of imported manpower; dependence on Americans abroad; the selection and utilization of both imported and domestic manpower. A useful bibliography is included. (J. C. Shearer. Princeton, University, Industrial Relations Section, 1960. 159p., $3.00.)

CENTENARY OF THE BIRTH OF NIKOLA TESLA, 1856-1956.

Nikola Tesla was a Yugoslav physicist and electrical inventor who went to the United States in 1884, dying there in 1943. He was one of the first to convert electricity into mechanical energy, and in 1888 patented the induction motor, and designed new forms of dynamos, transformers, condensers, arc and incandescent lamps, etc. He also invented a means of controlling a torpedo boat from land.

This volume contains the papers presented at a Congress held in 1956 in Belgrade in his honour. The papers cover various aspects of his work and contribution to the advancement of electrical engineering, including one on his power system and the role it played in the success of the first power plant at Niagara. (Belgrade, Nikola Tesla Museum, New York, Heinman, 1959. 240p., $5.00.)

*ELEMENTS OF FLIGHT PROPULSION.

Written for students and practicing engineers, this book is used in undergraduate and first-year graduate courses, and requires a working knowledge of elementary calculus. It gives equal attention to both steady and non-steady propulsive flows, and is concerned more with broad views than rigorous analytical treatment. Specific classes of thrust generators are discussed merely as illustrations of general methods and ideas, in the final two chapters. The earlier chapters discuss basic laws and concepts, one-dimensional approximations, one dimensional steady and non-steady flow, non-uniform flows, diffusers, nozzles, dynamic flow machines, pressure exchange, combustion chambers, thrust, and drag. (J. V. Foa. New York, Wiley, 1960. 445p., $12.50.)

*DIGITAL APPLICATIONS OF MAGNETIC DEVICES.

Both a text and a reference handbook, this book describes the theory, electrical design, and logical design necessary for the development of digital systems using the magnetic core as the basic circuit element. Attention is concentrated on core-diode circuits, but transistor-magnetic core combinations and other specialized data-handling circuits also are discussed. Specifically excluded are memories employing magnetic tapes and drums, other electro-mechanical devices involving magnetic phenomena, and standard magnetic amplifiers. (Ed. by A. J. Meyerhoff. New York, Wiley, 1960. 604p., $14.00.)

*THE CONTROL OF MULTIVARIABLE SYSTEMS.

This monograph presents the results of the author's work while visiting professor at MIT, in the development of a theory of control for multivariable systems. The first part of the book is devoted to the most important property specific to such systems: interaction. It discusses the black box problem, the significance of indeterminancy in interrelations, representation of interrelated systems by P-canonical and V-canonical structures and the problem of decoupling, the strength of interrelations defined in terms of output, and a measure for strength for purposes of systems comparison. In part two the synthesis of control systems is dealt with through the development, study, and expansion of the representation of systems by binary operations. (M. D. Mesarovic. New York, Wiley, 1960. 112p., $3.50.)

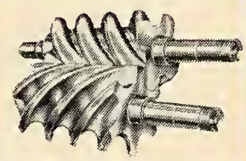
HOLMAN *Rotair* 150

Portable Rotary Screw Compressor



The rolling engagement of the rotors within the stator casing provides pulsation-free delivery of compressed air. Positive clearances prevent metal-to-metol contact, resulting in negligible weor and literally no maintenonce.

Now the proven performance of the Rotair rotary screw compressor is available in a compact model that delivers 150 c.f.m. at 100 p.s.i.—*enough power to operate three Holman heavy breakers simultaneously*. The Holman Rotair 150 is the *only compressor of its type* that can make this claim.

You can cut your costs with the new Rotair 150, too. Low initial cost, high capacity and particularly low maintenance costs make its price per cubic foot of air much lower than any competitive equipment.

The power unit is the well tested Ford Industrial Diesel engine, and like all other Rotair models the compressor is a single stage helical gear type, distinguished by its simplicity of design and minimal wear to its few moving parts. Write for information.

● LIBRARY NOTES

***PROGRESS IN METALLURGICAL TECHNOLOGY.**

Four lectures delivered at the 13th Annual Refresher Course of the Institution of Metallurgists, held in Scarborough, 1959. The papers cover modern developments in iron and steel production, extrusion and refining of non-ferrous metals, and melting and casting of both ferrous and non-ferrous metals. (Published for the Institution of Metallurgists by Iliffe, London, Toronto, British Book Service, 1960. 147p., $7.50.)

***OFF-THE-ROAD LOCOMOTION.**

General in treatment, this book serves as an addendum to the author's "Theory of land locomotion," (1956), in discussing subsequent developments and outlining the present state of the art of "terramechanics." Here, the author describes important developments since 1956 in industry and education, discusses soil and snow mechanics, tracks, wheels, tires and the making of predictions of vehicle performance and design parameters, all relevant to the vehicle treated as a unit in physical relationship to the soil over which it moves—other than the conventional roads and highways. (M. G. Bekker. Ann Arbor, University of Michigan Press, 1960. 220p., $10.00.)

***AMERICAN POWER CONFERENCE, PROCEEDINGS, 1960.**

The annual American Power Conference is concerned with practice rather than theory, and a broad overall view of problems of interest to the power industry and associated groups. Six topical sessions were held at the 1960 meeting. Papers presented at the General Sessions deal with national considerations such as American economic power, national strategy, nuclear propulsion in the Navy, and the challenge of new power sources such as magnetohydrodynamic generation, isotopic heat and power, and space vehicle propulsion. Nuclear power plants are discussed in the nuclear power sessions papers; steam generators and turbines, peaking and central station power plants and auxiliaries, condensers, fuels, industrial plants, traction vehicle power and space heating in the mechanical sessions papers; turbine-generators, high-voltage systems, switching, distribution, communications and protection control, computers and network analysers, and system planning and operation in the electrical sessions papers. The final two sessions dealt with hydroelectric power-rates, revenues, and new project financial and water technology-analysis and pollution control in industrial waters, and sea water conversion. (Chicago, Illinois Institute of Technology, 1960. 869p., $10.00.)

***STRESSES IN SHELLS.**

Written for practising engineers and research workers, this book contains a unified presentation of the basic facts of shell theory, and solutions in sufficient detail to make them readily applicable to design work. The level of the mathematical tools employed has been kept as low as compatible with the needs of the subject matter. Familiarity with linear differential equations is necessary, and with partial differential equations would be useful. Chapter one contains introductory matter, chapters 2-4 cover membrane theory, chapters 5-6 are devoted to the bending theory of the circular cylinder and the general shell of revolution, and the final chapter is concerned with the stability of shells. The appendix contains a compilation of formulas concerning forces and deformations in circular rings. (Wilhelm Flugge. Berlin, Springer-Verlag, 1960. 499p., DM 58.80.)

***STATISTICAL THEORY OF COMMUNICATION.**

This college-level introduction covers essentially all the basic elements of linear systems in the statistical theory of communications. Discussion in the final two chapters of orthonormal functions and the orthonormal representation of linear systems, important in the statistical theory of optimum nonlinear systems, is the only inclusion of nonlinear aspects. The text covers harmonic analysis, probability, random variables, ensembles, distributions, averages, densities, correlation functions, sampling theory, the fundamental relations of a linear system, and optimum linear systems, filtering, and prediction. (Y. W. Lee. New York, Wiley, 1960. 509p., $16.75.)

TECHNIQUES OF PLANT MAINTENANCE AND ENGINEERING, 1960.

This report of the eleventh Plant Maintenance and Engineering Conference is, as usual, divided into two sections. The first section contains the thirty-three papers presented at the Conference together with the discussions and questions on them. The topics covered include: the control of maintenance; training; air and water pollution; maintenance problems in small plants; sanitation control; maintenance costs, and work scheduling; planning to combat disaster by floods and tornadoes; preventive maintenance, etc.

The second section contains the proceedings of the round table discussions on maintenance in various types of plant: chemical; food processing; foundries; metalworking; petroleum processing; pilot; rubber; pulp and paper; steel and textile mills. (New York, Clapp and Poliak, 1960. 341p., $10.00.)

VIDEO TAPE RECORDING.

A basic treatment of the techniques, mechanics and circuitry used in video tape recording, based on lectures given by the author. Introductory chapters deal with the waveforms and signals used, and with electronic photography, followed by chapters on the mechanics of recording, the electronics of tape recording, and video recording. The rest of the volume is more advanced, and covers servo systems, the video system, colour correction circuits and servo and video circuits. A final chapter deals with machine and tape operations, and the Ampex and RCA control panels. There are many diagrams and illustrations. (J. L. Bernstein. New York, Rider, 1960. 268p., $8.95.)

PHYSIQUE DES CIRCUITS.

The first of a projected series of volumes giving a complete course in electronics, this text covers basic theories, and is limited to sinusoidal

E.I.C. CERTIFICATE OF ADVERTISING MERIT

Phillips Electrical Company has been awarded the E.I.C. Certificate of Advertising Merit for their full colour, full page "bleed" advertisement which appeared on page 101 of The Journal in December, 1960. Short, factual copy and the use of almost two-thirds of the page for a striking, natural colour action photo of two men handling the product —a bright yellow butyl rubber covered cable—undoubtedly contributed to the selection of this advertisement as the winner.

Each month a different panel of fifty readers of The Journal—five from each province—is asked to select the award-winning ad of their choice from the viewpoints of ACCURACY — INFORMATION — ATTRACTION.

The advertising Manager of Phillips Electrical Company Limited, Brockville, Ontario, is Mr. A. M. Antliff. The advertising agency which prepared and placed the advertisement is Heggie Advertising Company, Toronto. Jack Heggie is the Account Executive.

• MORE BRIEFS

EXCLUSIVE SALES AGENT for Pentachlorophenol manufactured by Naugatuck Chemicals, Division of Dominion Rubber Company Limited, is the Dominion Tar and Chemical Company Limited, the two firms announced.

THE CHEMICALS DIVISION of Canadian Industries Limited has announced the establishment of a polyurethane rigid foam technical service laboratory at Toronto. Facilities are available for the demonstration and application of techniques for foaming-in-place by both spraying and dispensing (pouring). Development of new techniques and uses of rigid foams is also planned.

WORLD WIDE SERVICE now is provided by the Steel Company of Canada, Limited, for high tensile steel bolts and nuts produced to the latest standards of the International Metric System. An increasing demand has been noted for metric threaded fasteners, not only from countries where the metric system is standard, but through the growing markets created in North America for servicing European-made automobiles and machinery.

THE PRODUCTS DATA GUIDE issued by the Master Builders Company, Ltd., provides information covering the use of all Master Builders products for improving concrete and other masonry products. The company calls it an indispensable guide to regular users of concrete admixtures, iron-armoured floor products, grouting and waterproofing material and other related products.

A LOW-COST system of photo-recording highway surfaces has been announced by Canadian Aero Service Limited, Ottawa. Called Sur/Fax, the system includes a precise strip camera, a specially-equipped truck, a film projector and a reader-printer. Sur-Fax film records are an objective, detailed record, obtained at a fraction of the cost and time of inventories made by walking or driving the area and noting or sketching defects.

A TRAMP METAL DETECTOR that is claimed to indicate tramp metal in practically any kind of material is available from Canadian ASEA Electric Limited, Montreal. This detector is sensitive to magnetic and non-magnetic metals alike. It consists of a search coil and a detector box that can be mounted separately. This equipment is designed for connection to a single phase, 115 or 230 v., 60 cycles supply and comes in a water-tight enclosure. A wide range of search coils is available for different kinds of materials and conveyances. The "Adset" is being operated in mines, ore handling plants, quarries, chemical plants, sawmills and the food and tobacco industries.

AN EIGHT-PAGE catalogue describing the features of the "Super 30" Fabricator has been prepared by Strippit Tool and Machine Company, Brampton, Ont. The publication explains in details how precision micrometric gauging enables the operator to position work quickly and accurately on this single-station metal-working machine. The catalogue also describes some of the special production-tested accessories.

METHODS FOR GROUTING the different types of heavy industrial equipment are described in a seven-page Master Builders Company publication, EPMG-2A. Non-shrink Embeco premixed grout is used to explain preferred grouting methods and techniques. The preparatory steps, forming selecting materials, mixing and placing the grout are seen in diagrams, charts and photographs.

OPERATION OVERTHRUST is the name of a geological study of the 372,-000 sq. miles of the Precambrian Shield that has been carried out by Hunting Survey Corporation Limited. This geological compilation consists of 500 individual photo mosaic sheets, each covering an area of approximately 720 sq. miles and with a separate transparent overlay showing all geological data and pertinent geophysical interpretation. All sheets are individual and have a scale of 1 in. to 1 mile, each covering ½ degree of latitude and ½ degree of longitude.

A SYSTEM to generate impulses for the operation of demand meters, totalizing relays, and data counting and printing has been developed by General Electric's Meter Department, Somersworth, New Hampshire. This impulse generator, designated type D-41, is applicable to large consumer billing, tie-line metering between utilities, electric generation, load survey and kilowatt demand load control systems. It is claimed that the device can be used where conditions of oscillation or float of in-out power occur with no impairment of accuracy. The machine is rated to operate from a power supply of 120 v. a-c and at temperature ranges from −25°F. to 150°F.

AN EMERGENCY lighting unit, which is claimed to operate automatically and instantaneously upon failure of normal power and also to automatically prepare itself for the next blackout, is marketed by Exide Industrial Division of The Electric Storage Battery Company (Canada) Limited, Toronto. The Lightguard Model "A" is designed for installation on posts or walls and is available as auxiliary lighting equipment for plug-in connection to 115 v., 60 cycle alternating current power sources. The equipment is powered by 3-COE-7 Exide-Tytex batteries and only requires additional water two or three times a year.

ASSOCIATED TUBE INDUSTRIES (Coldwater) Limited, has entered the welded stainless steel tubing and pipe field. This company has purchased the assets of Tri-Bay Industries which has been engaged in the manufacture of welded stainless steel tubing at Coldwater, Ont. It is directly associated with Oakton Products Limited whose name has been changed to Associated Tube Industries (Toronto) Limited. The A.T.I. (Toronto) has been manufacturing welded nickel alloy tubing up to ½ in. O.D. Both companies will be referred to as Associated Tube Industries (A.T.I.) for commercial purposes. The Coldwater plant will manufacture welded stainless steel pressure tubing in diameters ½ in. O.D. up to and including 2½ in. O.D.

THE FAIRFIELD Shipbuilding and Engineering Company Limited, Glasgow, Scotland, has produced a handsomely bound volume to mark its shipbuilding centenary. Colorfully illustrated the book tells of how the company which, in recent years has built some of the biggest naval and passenger ships in the world, began in 1834 as a little engine shop sixty feet by forty. Its first order was worth sixpence. By 1852 the company entered the marine engine industry and by 1860 built its first ship, the MacGregor Laird. Since then the company has been building battleships, battle cruisers, aircraft carriers, destroyers, submarines, passenger ships and tankers. Its subsidiary at Chepstow, Monmouthshire, specializes in welded constructional steelwork and recent contracts have included many bridges, steel framed buildings, crane girders and dock gates. EIC

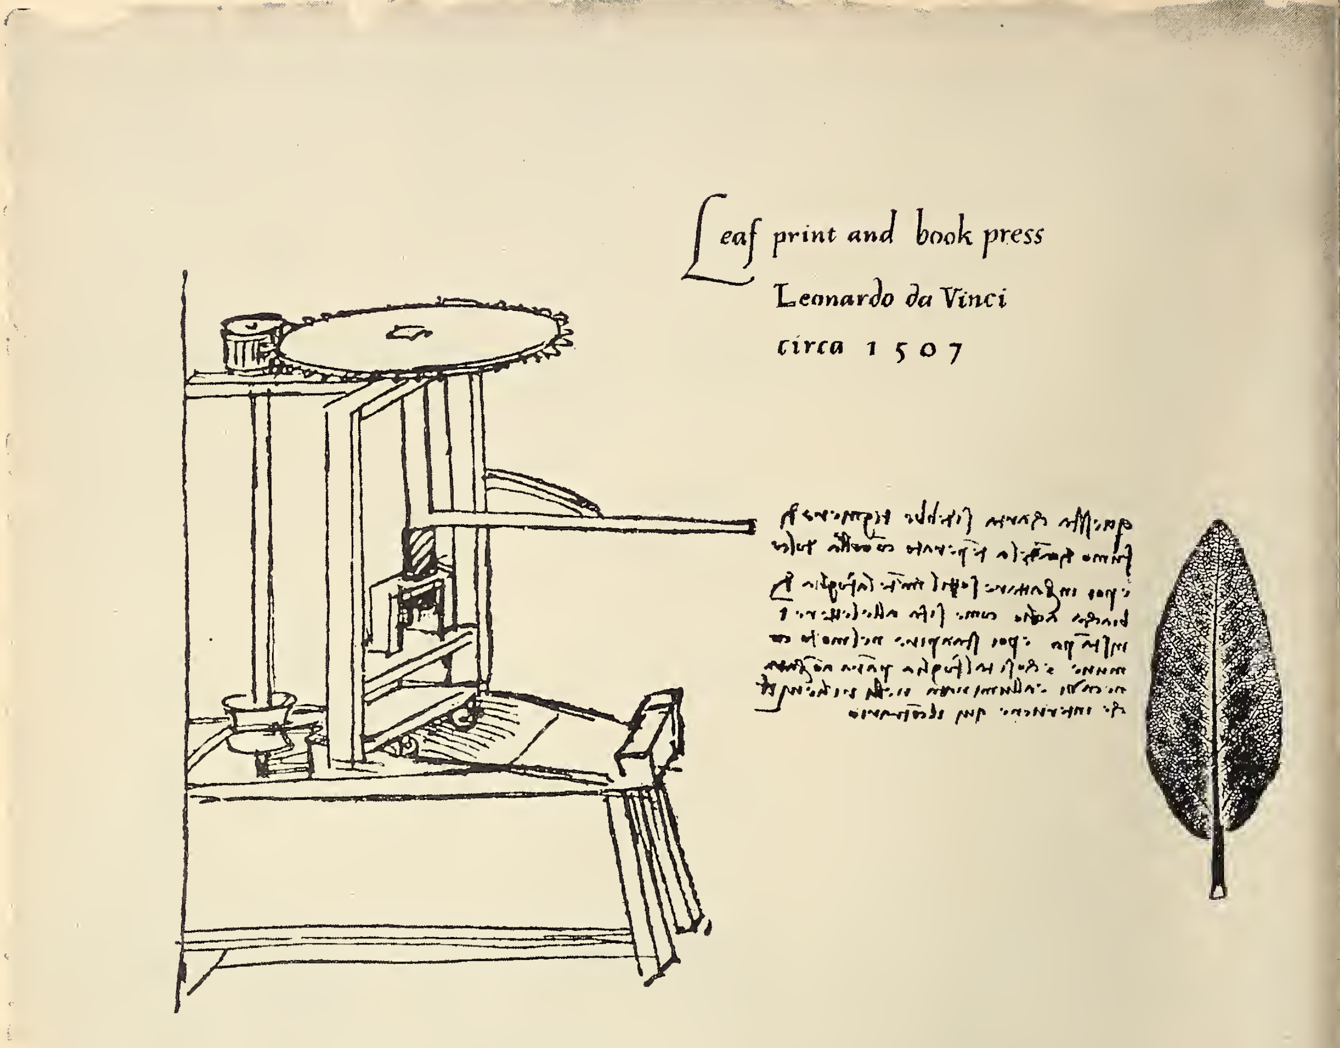
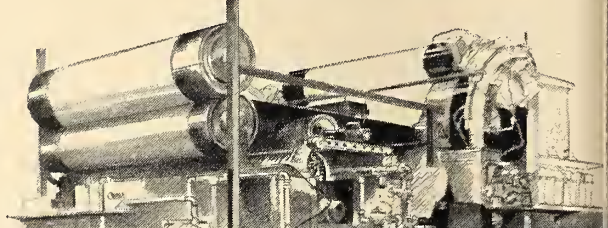
CONTENTS



LEONARDO DA VINCI, *artist, engineer, inventor, was one of the truly creative men of all time. Reproduced here are original sketches of a leaf, printed by a process of his own, and a press used in this printing operation.*



IN THIS ISSUE

A *High-Speed Gearbox* discusses the problems of high speed gear design for Canada which centre upon the correct compromise between large diameter gears with conservative tooth loading, and heavily loaded smaller gears permitting better lubrication conditions in consequence of their lower peripheral speed. The author, C. E. Gay, is in the Gear Engineering Department, Associated Electrical Industries Limited, Toronto. During a period of many years, the experience of AEI in this field has been wide, and in this paper the author describes the approaches to the problems encountered in the design of a recent gear drive with a tooth speed of 315 m.p.h.

Karl H. **Zement** brings 15 years of experience to bear on his paper, *Planning of Radio Relay Systems.* Since coming to Canada in 1951 he has worked mainly in electronic fields such as feed-back-control systems (servomechanisms) and communications. He has been associated with the Quebec Telephone Company at Rimouski, Que., since 1955. Mr. Zement explains that the ever-increasing requirements for long distance telephone and television circuits in the last few years, and the development of high grade FM radio systems designed to meet these needs, have contributed to a large amount of research done on radio propogation and radio system performance in recent years. His paper, which should be useful as a handy reference for evaluating a radio network, is a synthesis of information taken from a number of sources discussing different aspects of system engineering.

The high cost of modern construction has resulted in smaller operating rooms which require pulsed air for their ventilation, **Dr. Victorien Fredette** says in his paper, *Problemes de Bacteriologie dans la Ventilation des Salles d'Operation.* If no adequate filter is used in such ventilating plants, bacteria from the outside air may accumulate inside the operating rooms and may represent a source of potential danger. Dr. Fredette, eminently qualified to discuss such problems, earned a Bachelor of Pharmacy degree from University of Montreal. He later received degree in Chemistry and in Biology from the same university, and eventually earned a Doctor of Science degree from the Sorbonne in Paris. His present responsibilities include teaching at University of Montreal, and serving as assistant director of the University's l'Institute de Microbiologie et d'Hygiene.

The South Saskatchewan River project will provide extensive benefits in several broad areas. The project is discussed in *Hydrologic Investigations for the South Saskatchewan River Project* by **W. M. Berry**, M.E.I.C., **E. F. Durrant**, M.E.I.C., and **Casper Booy**. Mr. Berry received a B.Sc. degree from University of Manitoba in 1944, and an S.M. degree from the Massachusetts Institute of Technology in 1947 following studies in water resources development. In May, 1959, he became Chief Design Engineer for the Prairie Farm Rehabilitation Administration. Mr. Durant was born in Ladner, B.C., and was raised in Moose Jaw, Sask. He graduated from University of Saskatchewan in 1947 after following a course in Engineering Physics and two years later returned for supplementary courses in Civil Engineering. After four years as District Engineer with the Water Development Branch, P.F.R.A., he joined the staff of the Hydrology Division where he is now Chief. Mr. Booy, Design Engineer for the South Saskatchewan River Project was educated and trained in his native Holland. He joined the P.F.R.A. in Winnipeg in 1951.

Built-in extinguishing systems to protect rotating electrical equipment utilize either water or carbon dioxide. **J. H. Ingham**, M.E.I.C., discusses the relative merits of both types in *Fire Protection for Rotating Electrical Equipment.* Attention is paid to the speed of extinguishing, extinguishing power, economics, and intangibles. Mr. Ingham clearly indicates the preferences of both manufacturers and operators. The author joined the Dominion Bridge Company at Lachine, Que., after graduating from McGill in 1935. Mr. Ingham has been associated with Walter Kidde & Company of Canada Ltd., Toronto since 1941. He was Factory Manager until 1946 and Contract Engineer and Assistant to the Managing Director until 1953 when he was appointed Manager, Toronto District Office.

The Crisis in Measurement has long been an absorbing topic for **Dr. Leslie E. Howlett**. In his paper, Dr. Howlett explains that much of man's developments has depended upon his ability to measure the multitudes of phenomena. Measurement qualifies as a keystone to civilization. Lack of conformity of measurement systems constitutes a very real crisis. Dr. Howlett, a native of London, England, graduated from the University of British Columbia in 1927 with a B.A. in Mathematics and Physics. In 1928 he received an M.A. in Physics from University of Toronto and three years later a Ph.D. from McGill. Dr. Howlett joined the National Research Council in 1931 and culminated a series of promotions in 1955 by being appointed Director of the newly-established Division of Applied Physics. He was named President of the Advisory Committee for the Definition of the Metre in 1956, and Vice-President of the International Committee on Weights and Measures in 1960. In 1943 he was awarded the M.B.E. for his service in developing the optical instrument industry in Canada during the Second World War.

The main features of design and construction of the graceful Hugh John Flemming Bridge are described in the paper, *Concrete Arch Bridge at Hartland, New Brunswick,* by **E. van Walsum**, JR.E.I.C., and **T. J. Sluymer**, JR.E.I.C. The bridge consists of seven reinforced concrete arches with spans ranging from 250 feet to 280 feet. The structure was completed in 1960. Both authors are graduates of the University of Delft, Holland. Mr. Sluymer graduated in 1951 and joined the Heavy Engineering Section of the Foundation of Canada Engineering Corporation Limited in 1957 as Design Engineer. Mr. van Walsum graduated in 1952 and joined FENCO in 1955. He now is Project Engineer.

Two-Way Slabs and their Supporting Beams gives a brief, non-mathematical discussion of stress distribution. The more scientific approach used in advance literature is not sufficiently useful for those who have not made a special study of two-slab theory and have too little time available to do so when a problem is encountered. The author, **E. M. Rensaa**, M.E.I.C., was a member of the revision committee which decided to adopt the Marcus theory for the new edition of the National Building Code. He points out, however, that the opinions expressed are his own and may not in every detail be shared by other committee members. Mr. Rensaa received his B.Sc. Civil from University of Manitoba in 1933. After obtaining his M.Sc., Mr. Rensaa worked with the C.N.R. and the Federal Department of Public Works in Winnipeg. He then returned to his native Norway for nine years and started his own designing and consulting practice. Since 1947 he has been a partner in the Edmonton firm of Rensaa and Minsos, Architects and Consulting Engineers.

HIGH SPEED GEARBOX

C. E. Gay, Gear Engineering Department, Heavy Plant Division of Associated Electrical Industries

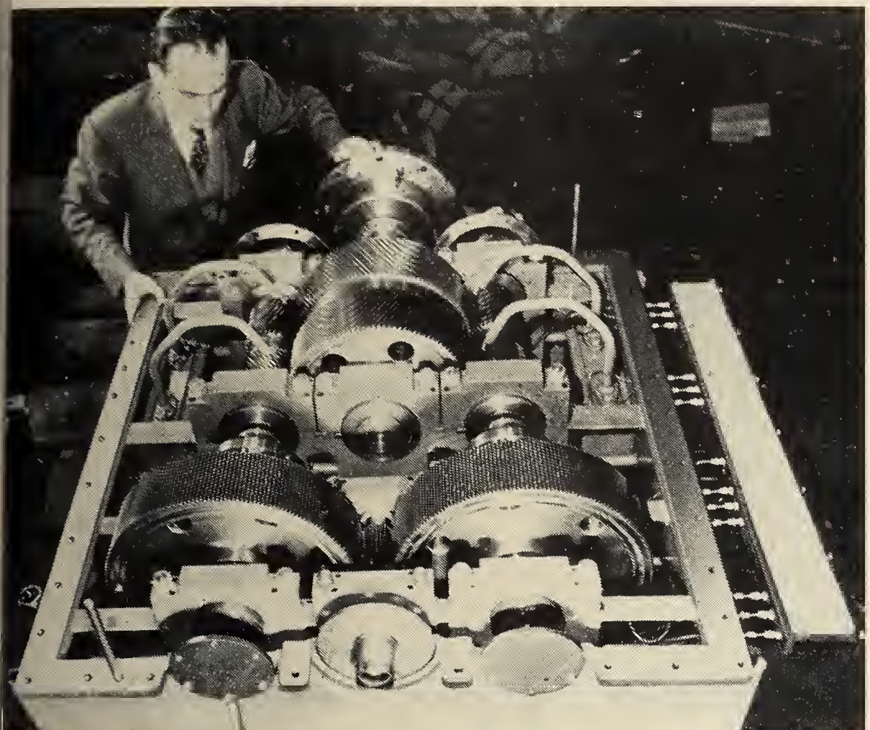

Fig. 1—The gearbox viewed from high-speed end with top cover removed.

THE PROBLEMS of high speed gear design centre upon the correct compromise between large diameter gears with conservative tooth loading, and heavily loaded smaller gears permitting better lubrication conditions in consequence of their lower peripheral speed. Over a period of many years, the experience of AEI in this field has been wide, and in this article the author describes the approaches to the problems encountered in the design of a recent gear drive with a tooth speed of 315 m.p.h.

A high-speed gearbox was recently supplied by the Heavy Plant Division of our company to an aircraft firm, for use in driving a gas-turbine test rig. The gearbox was delivered within five months from the receipt of the order.

The schematic arrangement of the rig is shown in Fig. 2. The gearbox has a variable speed input from 2000 hp. driving motor through a eddy-current coupling. It is designed to transmit 220 lb. ft. torque at speeds up to a maximum of 45,000 r.p.m. corresponding to a speed of 1700 r.p.m. input and, by simple changes of gear ratio, speeds between 20,000 and 55,000 r.p.m. may be obtained for values of torque of 525 lb. ft. and 175 lb. ft. respectively.

The operational characteristics are shown in Fig. 3, from which it will be evident that the major problems confronting the designer were resultant from the combination of high power and high speed. A design had to be adopted which would incorporate gears sufficiently large to meet the limitations of Hertzian and root bending stresses in the gear teeth, yet not be of such size that rotational hoop stresses would exceed limits of safety, nor that the special problems associated with lubrication and peripheral speed could not be solved. For these reasons the double increasing locked train design shown in the sectional view Fig. 4 was chosen, thereby dividing the torque equally between two layshafts and providing two mesh points each at half-load on the input and output gears. By this means the maximum pitch line speed was limited to 460 ft./sec.

As previously mentioned the design provides for speed and torque changes beyond the scope of the set of gears supplied, by the substitution of alternative gears. These changes involve only the output train. The factors which influenced this choice in preference to the low-speed train were:

(1) considerations of surface stress on gear teeth;

(2) cost — the low-speed gears would be considerably wider than the high-speed, the pinions would be hollow, and either an extra input coupling would have been required with each set of gears supplied or alternatively its removal and transference would have been necessary for each gear ratio;

(3) the simplicity of manufacture and accuracy of measurement of the spur output gears referred to later.

Tooth Loading

The curves of 'K-factor', root stress and pitch line speed given in Fig. 3 assume that an infinite number of output train gear ratios would be used to cover the output torque/speed envelope, that all points on the output torque curve therefore correspond to a maximum output speed, and that for any particular maximum speed the corresponding output torque value would not be exceeded. Since each of the machines to be tested with the rig have a torque characteristic which varies as the square of the speed, and that the number of machines to be tested is restricted, it will be seen that the above limitations are no embarrassment to the operator. The K-factor curves are related to Hertzian compressive stress in the gear teeth. This is the surface stress resultant from load per unit length of tooth and the relative radii of curvature of the teeth in mesh, and is one of the contributory factors giving rise to the phenomenon of pitting. K-factor varies directly with load and as the square of the Hertzian stress for any particular set of gears. In full consideration of the duties of the gearbox, the required life, and the economics of the design, the limits of K were fixed at a maximum of 150 for the low-speed train and 130 for the high-speed output gears. The economy of the design is illustrated in Fig. 3 by the proximity of the torque curves for these values of K, to the curve of output torque requirements. In line with the fact that Hertzian stress is proportional to load and that the ratio of the input train is never varied, it will be seen that the curves of horsepower and input train K-factor are proportional to each other. The gearbox is protected from overload by a torque meter on the output shaft controlling the excitation of the eddy current coupling. The input coupling is of the shear pin

gear type and serves as further protection.

Gear Materials

Further economies in the size of the gears could have been made by the use of hardened gears with higher surface stress factors and certain advantages obtained in reduced pitch line speed and centrifugal hoop stress. However, all known methods of hardening gears produce some tooth distortion which, for high-speed gears, must be ground away after the hardening process to avoid destructive vibration. Had hardened and ground gears been used, the saving in size would have been little, due to the dictates of shaft diameters and the proximity of bearings, and the cost may have been a little more than that of the design chosen. After consultation with the Research Department on questions of metallurgy and machinability, high-tensile chrome molybdenum steel was used for each pinion, and carbon steel approximating to EN 9 was used for the three gearwheels. All gears were hobbed in a temperature-controlled cubicle to limits of accuracy approximately conforming to BS. 1807, Class A 1.

Axial Location of Gears

It is common knowledge that helical gears provide for quieter running than straight spur gears, so that a double helical train was designed for the low speed. However, since double helical gears are subject to axial oscillation at tooth contact frequency due to inherent minute axial pitch errors, and since for the high-speed output train this frequency would be of the order of 20,000 cycles per second, it was recognized as damaging to attempt to allow the inertias of the high-speed rotating parts to be accelerated in accordance with the dictates of these errors. In consideration of the use of single helical gears in the output train, the magnitude of thrust would have necessitated a thrust bearing collar diameter larger than centrifugal hoop stress would permit, and the use of such a bearing at 55,000 r.p.m. is beyond the experience of design. A straight spur high-speed train was therefore chosen recognizing that, for most of its service, tooth contact noise would be beyond the audible range. In consequence, the design had to provide for the axial location of all gears with the exception of the low-speed pinions. These had to be allowed complete axial freedom to follow the input gearwheel, so that a gear-type coupling was introduced into each layshaft.

Load distribution

The locked train system requires a means for adjustment whereby even distribution of the load between the layshafts can be achieved, since small differences in backlash between gear teeth at corresponding mesh points at each side of the train can be of considerable consequence. This adjustment is provided at the ends of the two low-speed pinions by taper bore couplings fitted by an oil injection method, and should some small error still be present after adjustment, the torsional flexibility of the layshafts through the hollow low speed pinions is designed to cater for it.

Bearings

Plain bearings are fitted throughout the gearbox to meet the high speed and high load conditions, and special consideration had to be given the oil supply pressure and journal clearance of the output pinion, which has a journal speed of 300 f.p.s. Consistent with maximum reliability, bearing pressures were designed to be a little higher than for most applications, to offset the power losses applicable to large bearings at high speeds. The temperatures of all bearing shells adjacent to the bearing metal are measured with thermocouples taken to a special instrument which simultaneously records the temperature of any bearing selected by a multi-position switch, and constantly scans all bearings to sound an alarm should any one of them exceed a preset temperature figure.

Tooth pitch and accuracy

Careful attention had to be given to the choice of tooth pitches, since while a coarse pitch minimizes tooth root bending stress, greater accuracy and a lesser liability for gears to scuff are obtained from the use of a fine pitch. It should be appreciated that, for a locked train system with all gears on the same horizontal centre line, the loads on the bearings of the central gears, i.e. the input and output gears, are purely gravitational since tooth load from one side of the train is counteracted by that from the other side. The weight of the output pinion is of the order of only 20 lb. so that, had not extreme accuracy been obtained, dynamic forces due to tooth pitch error would have been of considerably greater magnitude than the weight, causing instability of the pinion and destruction of the bearing metal. While it is true that, had the pinion centre line been raised or lowered with respect to the high-speed wheels, a positive pinion bearing load could have been obtained, the pinion would not have remained equidistant between the two gearwheels within the limits of bearing clearance. Consistent with safe root tooth stresses therefore, fine pitches were used. Addendum correction was introduced to improve further the conditions of tooth sliding velocity, for it is this factor, unaccompanied by a similar or larger value of tooth rolling, which is largely responsible for scuffing disorders.

High-speed coupling

For physical reasons associated with the driven machine, the high-speed coupling is required to project at least 12 in. from the gearbox, and calculation of whirling speeds indicated that this coupling should be of a minimum weight and diameter. To meet these conditions a hollow quill gear-type coupling is used having less weight and greater torque carrying capacity per unit diameter than other types of flexible coupling. The quill member has external teeth and is free to float axially; the two internal toothed members are mounted to the adjacent shafts. For the further avoidance of whirling speeds and also journal instability, out of balance was removed from the high-speed pinion to an accuracy of 0.003 lb. in. A similar high degree of balance related to speed was ensured for each of the other rotating members.

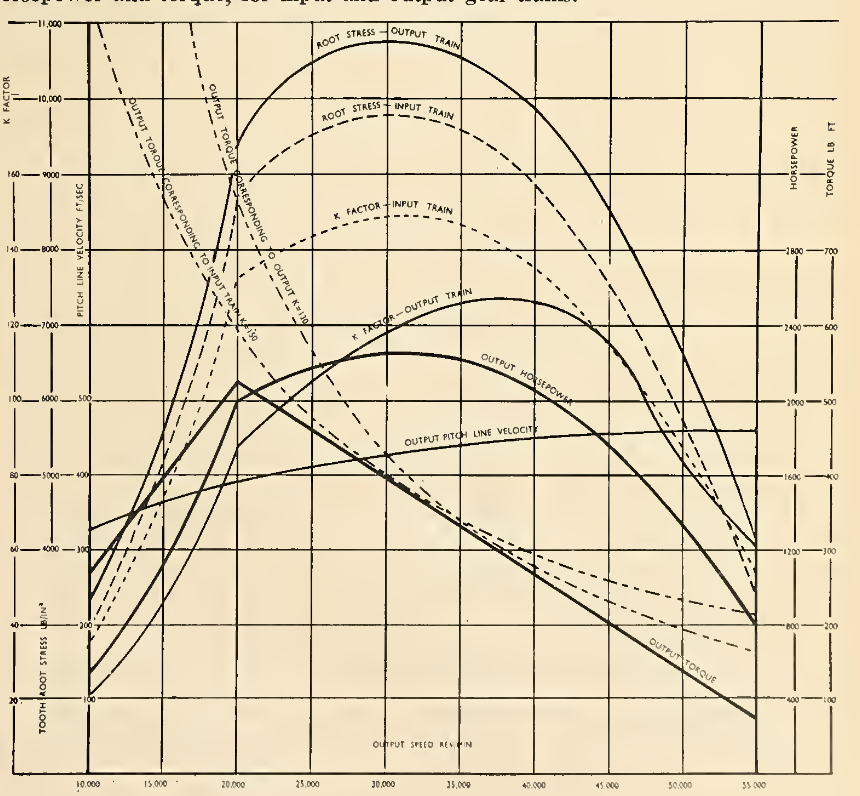
Lubrication

One of the major problems concerning the operation of gears at high pitch line speed is that of the lubrication of the teeth and the removal of the heat energy from the mesh. Even at relatively low speeds it will be found by simple calculation that the teeth move away from particles of oil supplied at pressure at a rate which does not permit them to penetrate to the full tooth depth, and that the position is further aggravated by windage. However, experiments show that, having established an oil film on gear teeth, it is very difficult to destroy it so long as the teeth are kept adequately cool. Provided that oil can penetrate the windage film, heat will be conducted away from the teeth satisfactorily whilst maintaining sufficient oil between them for lubricating purposes. At very high speeds the windage barrier is of considerable consequence. Oil must be delivered at pressure in a continuous jet and at right-angles to the air stream to prevent atomisation. That oil which does not reach the gears forms a medium of high density with the air, and becomes not only a more effective barrier to the supply, but a source of considerable power loss. A means for breaking the windage barrier in the vicinity of the supply jets is provided together with adequate capacity within the gearcase for hot oil to move away from the gears. Special attention had to be given to the choice of lubricating oil. Gears normally require heavy oil, particularly at high loads, to ensure that lubrication is hydrodynamic, but the viscous friction of heavy oil is contributory to power loss. A compromise solution was found.

Automatic controls

Referring again to Fig. 2, it will be noted that the entire rig together with all auxiliary equipment is housed within an enclosed cubicle. This is for safety reasons and necessitates remote control of all aspects of operation and testing. In order that the tester need

Fig. 3—Performance curves, showing K-factor, tooth root stress, pitch line speed, horsepower and torque, for input and output gear trains.



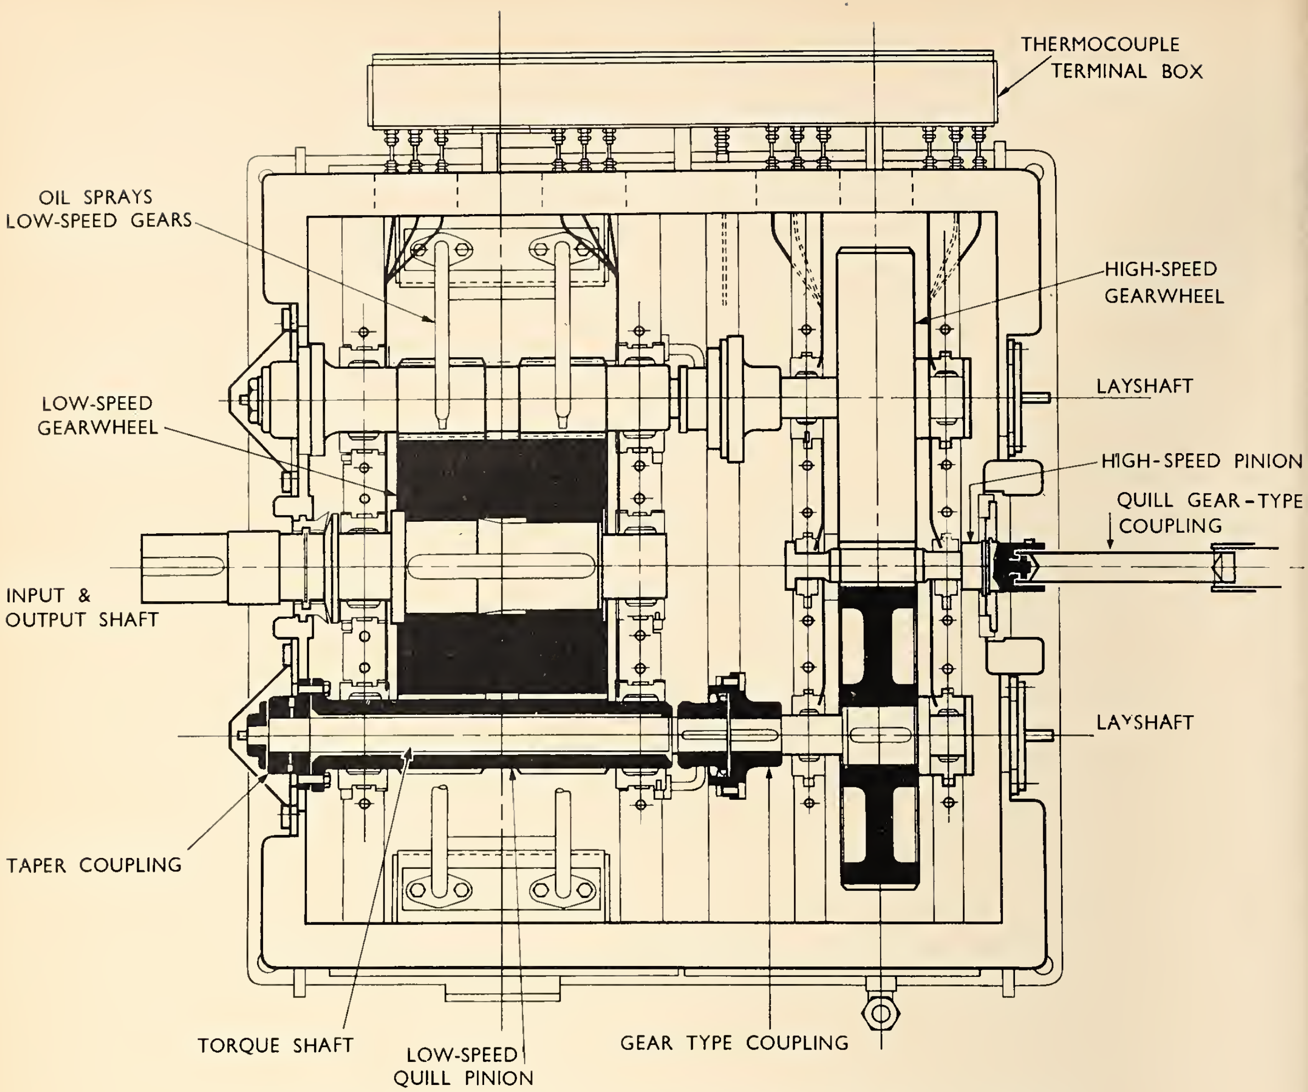


Fig. 4—Sectional view of gearbox, showing arrangement of layshafts and couplings.

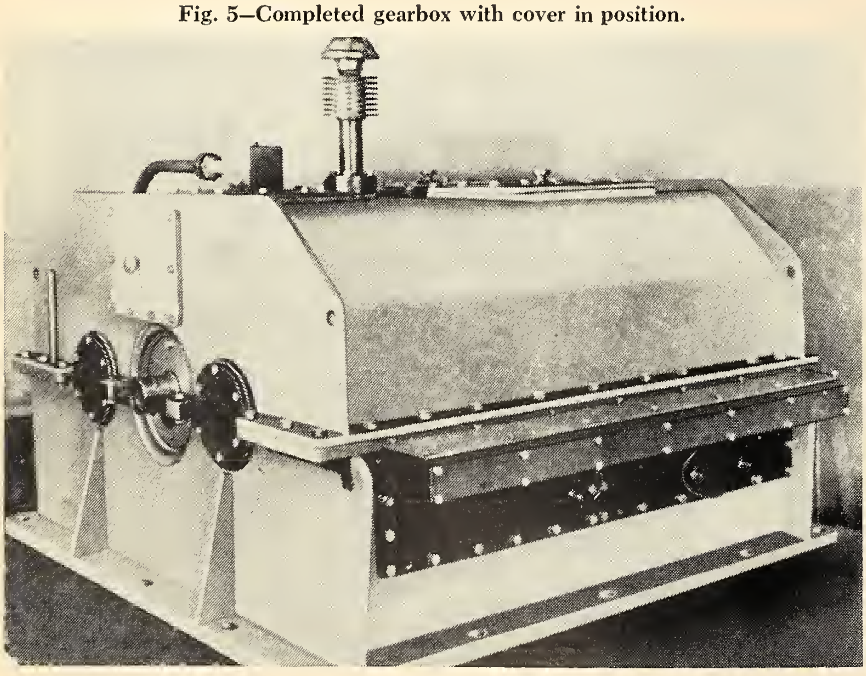
give little attention to the operation of the rig, many controls have been made fully automatic. It will be observed that the oil inlet temperature is kept within a preset range by automatic control of cooling water, and similarly if there is a fall in oil pressure, then the air driven auxiliary pump will start automatically, Careful attention is paid to filtration by the provision of suction and delivery strainers, a magnetic filter and a chip detector, as the blockage of an oil spray or the failure of a high speed bearing could have serious consequences.

Fig. 5—Completed gearbox with cover in position.



Successful tests

Extensive testing of the gearbox, occupying a total running time of approximately 24 hours, was carried out before despatch. Much valuable information was obtained concerning the behaviour of both gears and journal bearings at high speeds. This data correlates effects of oil pressure and flow, bearing temperature, and power losses. The quietness of running during test was quite remarkable and the maximum value of acceleration obtained from vibration readings was 244 in./sec.^{2} at full speed. The gearbox has been in successful operation at Montreal since February, 1960. EIC

PLANNING OF RADIO RELAY SYSTEMS

Karl Zement,

Quebec Telephone Engineering Department, Rimouski, P.Q.

THE ever-increasing requirements for long distance telephone and television circuits in the last few years, and the development of high grade FM radio systems designed to meet these needs, have contributed towards a large amount of the research done on radio propagation and radio system performance in recent years. Much information is presently available in the technical literature for engineering FM radio systems operating in the UHF and SHF bands and assessing the performance and reliability of such systems.

This paper is a synthesis of information taken from a number of sources discussing different aspects of system engineering. It should be useful as a handy reference for evaluating a radio network. The text will give the basic formulæ. Derivation of these formulæ with graphs and monograms will be given in the Appendix. A single hop system will be analysed as an example of the application of the above formulæ. Finally measured values of performance will be given and compared with calculated value for a 74A–I Lenkurt radio equipment operating at a frequency of 6000 mc. This model of equipment was the first to be installed in Canada.

General

Radio waves in the UHF, SHF range behave similarly to light waves in that they travel approximately in a straight line and are consequently subject to normal reflection and refraction phenomena.[12]

Refraction is a bending of the radio wave caused by changes in the dielectric constant of the atmosphere. The dielectric constant depends of course upon the temperature, pressure and humidity. Due to the fact that in a standard atmosphere the refraction decrease linearly with increasing height, the upper portion of the wavefront travels at a higher velocity than that portion near the earth and as a result, the radio wave follows the curvature of the earth. The amount of curving of the radio beam depends on the gradient of the refraction index of the atmosphere.

Since both the earth's surface and the beam are curved, trigonometric calculations of such a path become extremely difficult. These calculations may be simplified by assuming that the radio beam is travelling in a straight line, and that the earth's radius is changing in accordance with changes in the atmospheric density. The earth's radius can therefore be multiplied by a constant "k" the value of which will depend on the rate of change of the refraction index of the air with altitude. The value of "k" may vary between 0.5 and 3.0 with a value of 4/3 generally in agreement with the conditions normally found to exist in the atmosphere. However, where a radio system is designed with a high degree of reliability, "k" = 2/3 must also be considered.

To find the relationship to be expected between the geographical characteristics and the radio beam it is necessary to draw the profile between the proposed sites. This can be readily accomplished by the use of contour maps.

As an example, assume that site "X" and "Y" have been chosen. Ground elevations, i.e., clearance above hills, trees, buildings or other obstacles should be determined by plotting the profile of the land along the transmitting path on 2/3 and 4/3 earth's radius profile paper. If suitable profile paper is not available, a 4/3, 3/3 or 2/3 curve can quickly be drawn on rectangular coordinate graph paper using the following formulæ:

$h = 0.5\ DD_1$ for 4/3 earth's radius

$h = 0.67 DD_1$ for 3/3 earth's radius

$h = DD_1$ for 2/3 earth's radius

Where "h" = height in feet to be added to elevation obtained from contour maps at distance of "D" miles from site X, and "D_1" miles from site Y.

Having completed the profiles for values of "k" = 4/3 and 2/3 we must now determine whether the sites are satisfactory, and if so, the required tower heights.

The signal strength at the receiving antenna depends on the refractive condition of the path. If the waves arrive in phase, a maximum signal will be received. However, if the waves arrive in antiphase a minimum signal will be obtained. Since the distance traveled by each of the rays in a function of the relative altitudes of the transmitting and receiving antennas and the point at which refraction occurs, the signal will pass through a series of maxima and minima as the clearance above this point is increased. This phenomenon is discussed in the Appendix under "Fresnel Zones".

Reference is made to Fig. 1 and 2, showing a typical ground profile between two sites at values of "k" equal to 4/3 and 2/3 respectively. It can be seen that with the antennas at ground elevation at point D and E, a clear line of sight is obtained with $k = 4/3$ (Fig. 1) whereas, on the very same path peak C constitutes an obstruction with $k = 2/3$ (Fig. 2). Since it is usual to design microwave paths in such a manner as to obtain a clearance of at least 0.6 of the first Fresnel zone at $k = 4/3$ condition, and 0.33 first Fresnel zone at $k = 2/3$ condition, it is necessary in the case of peak C to elevate the antennas at each end of the path. Thus the antenna heights AD and BE are obtained.

As stated before, it is of primary importance that a prospective microwave station be capable of providing an unobstructed view of the adjacent station with which it must work, and that adequate clearance exist between the line-of-sight and the intermediate terrain. However, if transmission considerations alone were allowed to govern the choice of sites, some of the locations selected would undoubtedly turn out to be in elevated areas difficult to reach. Consequently in selecting possible sites for a radio system, it is well to keep in mind from the beginning that power must be made available at the site, and that access to the site will be highly desirable.

When a satisfactory path, with alternate station sites, has been selected on the topographic maps, a field inspection should be made to determine the probable accessibility of the various ocations.

Furthermore, it may be desirable to check the actual profile along the paths to make certain that the clearance indicated by the map elevations actually exist in the field. There are several ways of making these field checks to prove actual sighting between locations such as a signal lamp viewed through a transit or theodolite by night, or by using a heliograph signal by day, altimeter survey of the path, etc. However, these methods will not provide any information concerning the radio transmission conditions along the path. More complete data concerning the path may be obtained by making path testing with radio equipment. This method would be of great value on questionable paths, especially on those involving high towers and greater transmission distance. The result of these measurements will provide, together with all the physical data of the path the actual required tower heights.

Once the mechanics of drawing the path profiles between radio sites and of determining antenna heights are understood, it is essential that the transmission objectives of the projected radio system be set, so that in turn the various factors affecting the quality of the intelligence received be controlled during the system design period. The choice of the path lengths between sites, antenna type and size, type and quality of transmitters and receivers will depend on the amount of noise and signal-to-noise ratios acceptable at the receiving end.

Transmission and Noise Objectives on a Radio System

Toll telephone transmission objectives have been covered in detail in several papers.[1,2] They are usually presented under the headings "Long Haul" or "Medium and Short Haul" toll telephone objectives.

Long Haul System Noise Objectives

Multihop radio system carrying circuits over a distance of more than 1000 miles are placed under "Long Haul Systems". The noise level measured at the receiving terminal at a Zero Transmission Level Point (OTPL) with FIA weighting should not exceed 38 dba under normal conditions on a 4000 miles system. For systems less than 4000 miles in length the noise objective should be improved by a ratio of 10 log (4000/system mileage). The minimum for a system irrespective of length is 31 dba at OTLP. Details and definitions of Noise Quantities on Telephone Circuits are given as part of the Appendix.

Medium and Short Haul Noise Objectives

The noise objectives established for this type of system, i.e. up to 1000 miles in length, is 31 dba under normal conditions. For systems which have only one or two repeaters, an additional 3 db of margin should be provided in the noise objective (net 28 dba) to reduce the effects of nominal fading associated with the day to day operational characteristics of radio paths.

Contributing Noise Components

The main sources of noise are[3]:

(a) Thermal noise consisting mainly of noise introduced by first stages of receivers at repeater and terminal stations. This noise varies with the r.f. input frequency of the receiver, i.e. with the propagation conditions, but is independent of the speech content of the transmitted multichannel signal.

(b) Intermodulation noise is caused by non-linearity in the system, and may be divided into two parts of noise sources :

(i) Equipment noise sources which are intermodulation noise caused when multiplex signals give rise to harmonics or other distortion products. Such noise is dependent on the frequency distribution and the level of the transmitted multichannel signal. It is amplitude distortion in the terminal modulator, demodulator and amplifiers bandling the base band signals. Another source of equipment noise is phase distortion, i.e. group delay distortion in circuits handling r.f. and i.f. frequency modulated signals as well as nonuniform amplitude-frequency characteristics in such circuits. The latter may affect the relative sideband amplitude by causing distortion of the modulating signal. Some noise may also add by imperfect limiting at the demodulator. Normally, however, amplitude modulation introduced by the modulator and transmission system should be adequately suppressed by well designed limiters.

(ii) Feeder noise sources will be caused by mismatches in antenna feeder systems or other long i.f. or r.f. connections. A long i.f. cable, connecting a receiver to a transmitter at a repeater station for example, will produce a form of phase distortion, which may result in some noise contribution. Another undesirable effect which may be placed under Feeder Noise Sources are radio frequency echo signals, i.e. signals arriving at the receiver via an indirect path. These are normally high-level echoes as distinct from feeder reflections which are low level echoes having a relatively long delay.

(c) Multiplex noise contribution to the total noise on a radio system consists especially of "Residual Equipment Noise", "Interchannel Crosstalk" and or "Non Linear Noise".

Total Noise in the Radio System

The distribution of noise contributed by the thermal, intermodulation and multiplex sources are shown in Fig. 3 and 4, where a total objective of 28 dba is assumed in example No. 1 and 31 dba in example No. 2.[1,2,10]

If more than one hop is used in a

Fig. 1. Ground profile between two imaginary radio sites based on 4/3 earth's radius.

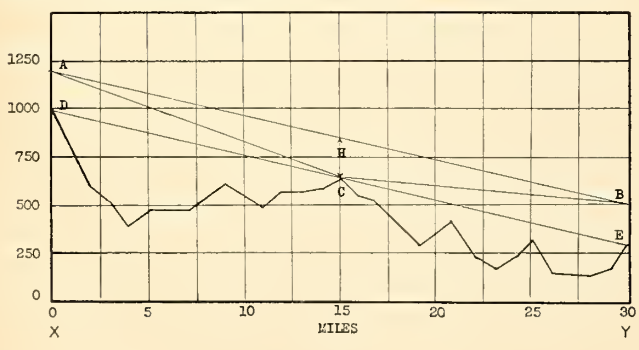


Fig. 2. Ground profile between two imaginary radio sites based on 2/3 earth's radius.

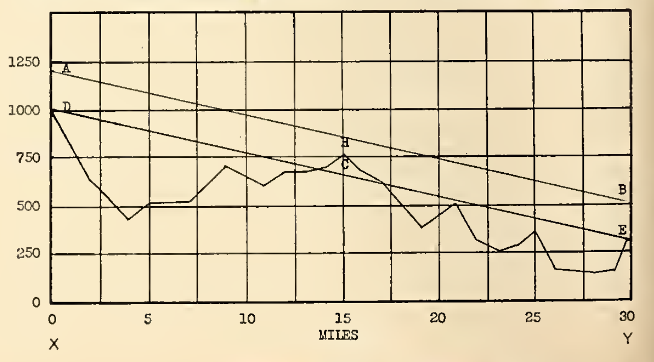

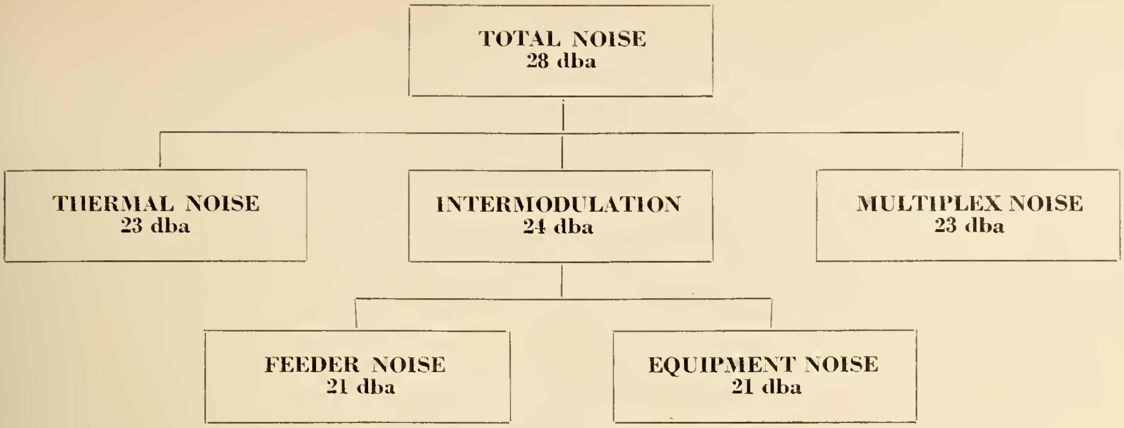

Fig. 3. Contribution of noise components with a total noise objective of 28 dba.

system, the signal, to noise ratio of the complete system may be found by using formula :

$$\text{Total Signal to Noise Ratio of the System} = 10 \log [1/\text{antilog}\,(db_1/10) + 1/\text{antilog}\,(db_2/10) + \ldots]$$

Where db_1 is the signal to noise ratio in db of repeater No. 1 and db_2 the signal to noise ratio of the repeater No. 2 . . . and so on. If it is desired to convert noise power given or calculated in dbm into picowatts (10-12 watt) or visa versa, Fig. 5 of the appendix can be used.

Some times it is convenient to convert the noise objective given in dba (FIA) or *dbRN* (144 wtg.) into a signal-to-noise ratio. With reference to the example given in this paper which is considering a single hop radio system, assume that the proposed total objective of noise falling in a 3 Kc bandwidth of a voice channel is 28 dba. Then from Fig. 3 we note, that for a total noise objective of 28 dba the maximum thermal noise should not exceed 23 dba under normal transmission condition.

From Table 2, column 3 (Part of the Appendix) we note, that the corresponding signal to noise ratio for 23 dba is 59 db flat weighting at OTLP. This ratio represents the signal to noise ratio comparing a 1000 cycles test tone with the flat noise power in the bandwidth of the voice channel.

Calculation of Thermal Noise

Basic Formula: It will be shown that fluctuation noise falling in a single 3 kc voice channel bandwidth is approximately determined by the following expression :

$$\frac{\text{Channel Signal Power}}{\text{Channel Noise Power}}\ (S/N)$$

$$S/N = 10 \log B/b + 20 \log \Delta f/mf + 10 \log (C/N) \qquad \text{(A)}$$

where

B = i.f. bandwidth in cycles
b = voice channel bandwidth in cycles
Δf = R.M.S. deviation in cycles
mf = mean frequency of worst channel in cycles
C/N = carrier to noise ratio at the receiver input (C/ENI)

Carrier - to - Noise Ratio (C/N)*:* It should be mentioned that the (C/N) carrier-to-noise ratio for a radio system can be calculated, providing the following basic system parameters are known :

P_t = transmitter power output (in db)
G_t = gain of transmitting antenna (in db)
G_r = gain of receiving antenna (in db)
L_p = path loss in db, relative to isotropic radiators
ENI = equivalent noise input power of receiver
L_m = misc. losses

G_t and G_r for simple parabolic antennas may be found by using formula (1)

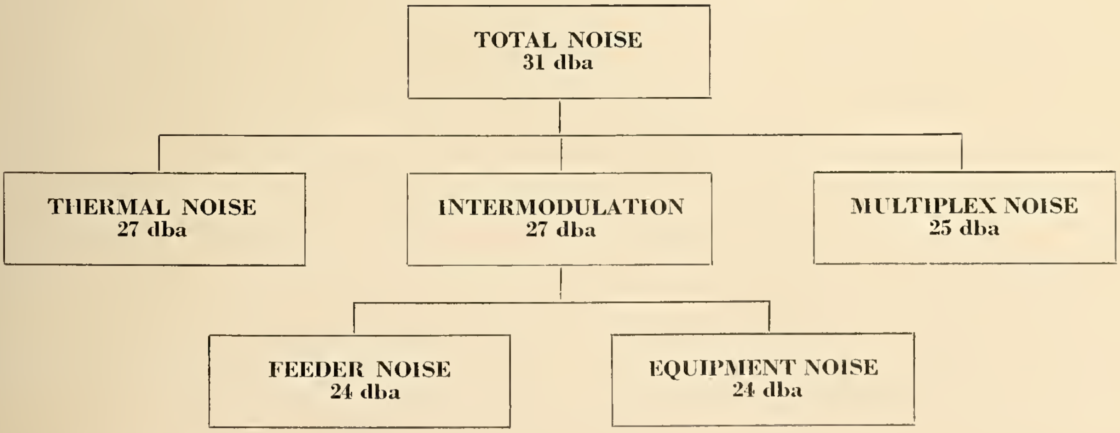
$$G_t \text{ or } G_r = 10 \log 4K(\pi R/\lambda)^2 \qquad (1)$$

where K is the illumination factor (usually taken for 55%)
R is the radius of the antenna mouth
λ is wavelength.

The same unit length must be used for R and λ. (For simplicity Fig. 6 may be used).

When the path length is known, the path loss between isotropic radiators may be found by using formula :

Fig. 4. Contribution of noise components with a total noise objective of 31 dba.



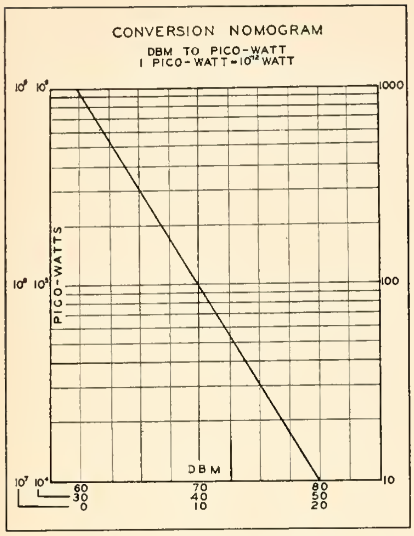


Fig. 5. Conversation Nomogram dbm vs. picowatts.

$$L_p = 10 \log 4543 f^2 D^2 \qquad (2)$$

where f is the frequency in megacycles,

D is the distance between the antennas in miles,

L_p is the path loss between isotropic radiators.'

The path loss can also be evaluated graphically by the use of Fig. 7.

The received r.f. carrier level or power defined as "P" may now be found.

$$P_c = P_t + G_t + G_r - L_r - L_m \quad \text{(or gains } - \text{ losses)} \qquad (3)$$

It should be noted that the value of "P_t" is normally determined from the specification of the equipment to be used.

The ENI or equivalent noise input of a receiver is the thermal noise of the receiver KTB times a noise factor, the value of which depends on the operating frequency and the type of mixer used in the receiver. For ease of calculation RETMA has proposed an empirical relation "$10f^{2/3}$", as a safe noise factor, where f is the frequency in Kmc/s.

From this we can find an approximate noise figure

$$N_f = 10 \log 10 f^{1/2} \text{ or } 10(1 + 2/3 \log f)$$

where N_f is expressed in db.

The thermal noise is "KTB", where "K" is the Boltzmann's constant, "T" is the temperature in degree Kelvin and "B" is the receiver bandwidth.[10,12] This may be shown as follows:

Suppose a noise source impedance of R ohms equal to the input impedance of the receiver. In considering the noise power, the internal impedance of the receiver is neglected as a noise source since it is accounted for the receiver noise figure. The maximum noise power that can be delivered by a generator of resistance R is, using equation (5)

Thermal Noise Power (p)

$$P = E^2/4R = KTB \text{ (watt)}$$

or in terms of db

$$P = 10 \log KTB \times 10^3 \text{ (db)} \qquad (5)$$

Combining equation (4) with equation (5), the ENI or equivalent noise input of the receiver is:

$$ENI = 10 \log (KTB \times 10)^3 + 10(1 + 2/3 \log f) \qquad (6)$$

The ENI can also be evaluated from Fig. 8.

It should be noted that:

(a) The ENI may also be obtained with greater accuracy by finding KTB and adding the known receiver noise figure usually given in the equipment specifications.

(b) The noise figure of a receiver is defined as the ratio (expressed in db) between the noise power output of the receiver and the noise power output of a hypothetical perfect receiver of the same bandwidth and measured at equal level points.

The receiver noise figure "N_f", equivalent noise power generated within the receiver "p" and noise power in a perfect receiver "P_h" are related as follows:

$$N_f = P - Ph,$$

where P_h is the noise power of a perfect receiver taken as KTB.

(c) In some equipment specifications the threshold level may be given. The receiver threshold level is usually defined as that level at which an incoming signal is 10 db greater than the receiver i.f. noise power referred to the input.[11] The knowledge of the detection threshold is important since this characteristic defines the signal level below which the system becomes inoperative.

The value for the received carrier power (equation No. 3) may now be compared with the equivalent noise input of the receiver ENI (equation No. 6) in order to obtain the carrier to noise ratio (C/N) at the input of the receiver.

$$C/N = P_c - ENI, \qquad (7)$$

where P_c and ENI are expressed in dbm.

Improvement factor for FM or Ph.M as compared to AM (expression $20 \log \Delta f/mf$): The thermal noise is uniformly distributed with frequency and in the case of AM the noise is uniformly distributed throughout the demodulated baseband. In FM, the uniformly distributed noise at the input of the frequency discriminator is changed to a triangular distribution at the discriminator output. This is fully explained in the Appendix under the paragraph "Demonstration of FM improvement factor".

$$\text{Improvement factor} = 20 \log \Delta f/mf$$

where Δf = R.M.S. deviation in cycles

mf = mean frequency of worst channels in cycles

Fig. 9 may be used for evaluating this improvement.

Bandwidth Improvement Factor (expression $10 \log B/b$ *of equation A):* The receiver noise in equation No. 6 was evaluated for a bandwidth "B" consisting of the total bandwidth of the i.f., usually taken between 3 db points. However, only the noise falling in a voice channel, taken as 3000 cycles wide for normal telephone operation, should be considered. The channel signal power/channel noise ratio for a voice channel is therefore improved by $10 \log B/b$ where "B" is the i.f. bandwidth between 3 db points and "b" is the voice channel bandwidth. Fig. 10 may be used to evaluate this factor.

Pre-emphasis Improvement: In a multi-

TABLE I

1000 cycles Test Power into 2B Test Set

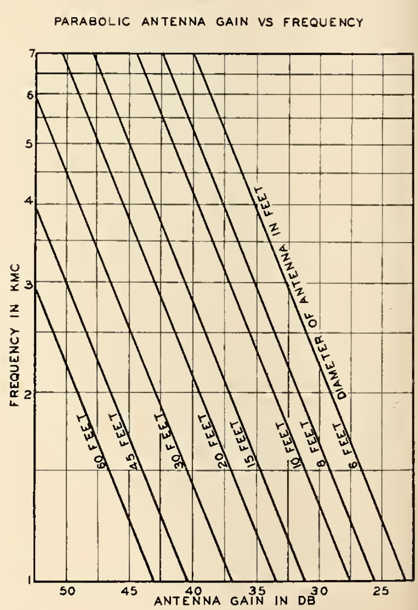
Fig. 6.



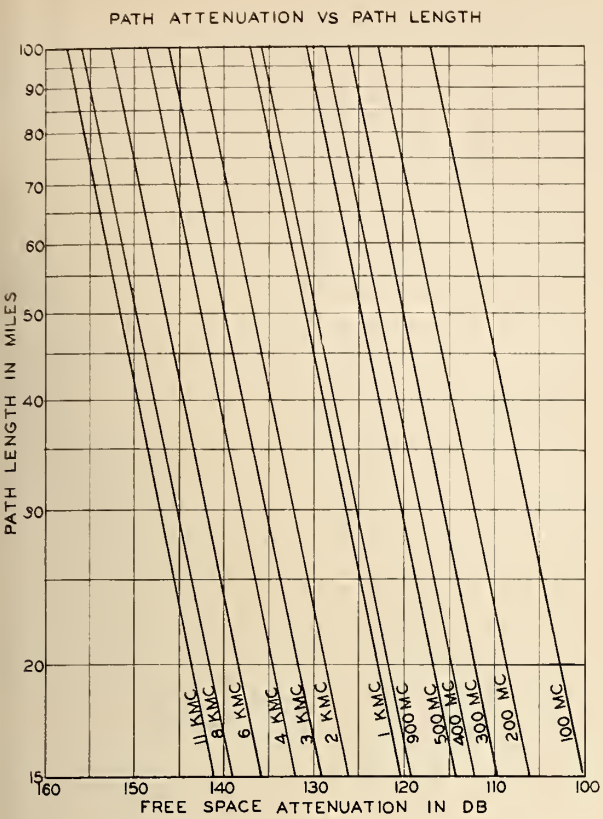


FIG. 7

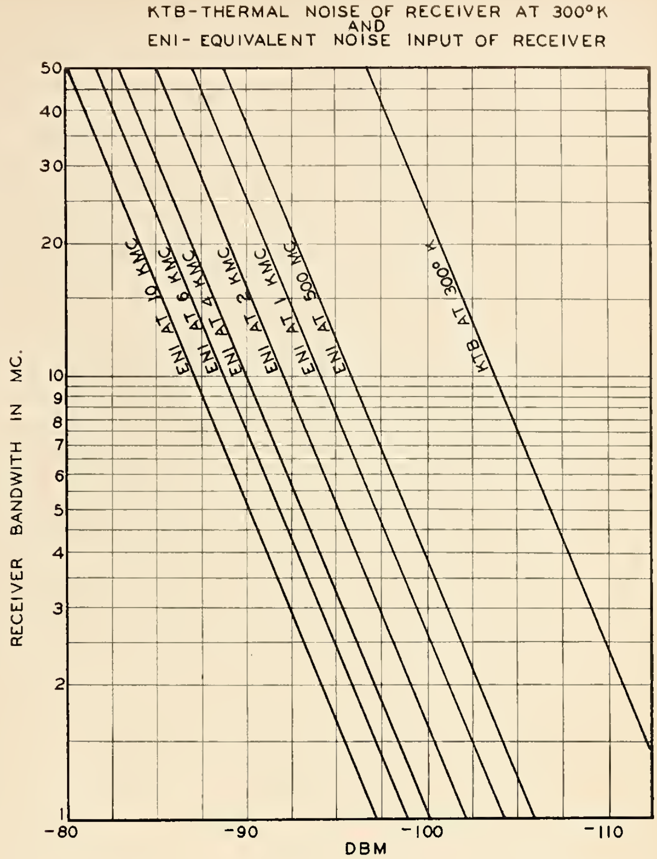

FIG. 8

channel FM radio receiver the output noise has a triangular distribution with frequency and therefore the top channel will have the poorest signal-to-noise ratio. By inserting a pre-emphasis network with an output increasing proportionally with frequency at the transmitter input, the output signal voltage will also be triangular. By passing the discriminator output voltage through a reciprocal network, the signal-to-noise ratio at the receiver can be reduced to a constant value, independent of frequency.

The degree of improvement expected from pre-emphasis, de-emphasis and correcting networks will depend on the circuit capacity and the pre-emphasis characteristics of the system. It is essentially a receiver design problem, and information with regard to this improvement are usually given in manufacturers' equipment specifications.

Multiplex Loading Factor: The signal-to-noise ratio derived above considers a radio system modulated by only one voice channel. Since more than one channel is used simultaneously on the radio system, the level of each voice channel must be reduced accordingly, to prevent overloading of the system. This reduction in level depends on the complex addition of individual amplitudes and phases of each voice channel. Also the number of simultaneously active channels must be considered in determining the level reduction. The multiplex loading factor has been subject of a thorough investigation by Holbrook and Dixon of the Bell Labs.[4]

Calculated and Measured Values for a Single Hop 74A1 Lenkurt Radio System

Suppose that the radio path characteristics are known. Furthermore, the total noise objective is set at 28 dba, as discussed previously. Then with reference to Fig. 3, the allowed thermal noise should not exceed 23 dba. This corresponds to 59 db signal-to-noise ratio in the worst channel.

The Lenkurt 74A1 radio equipment is now analysed in order to check if it meets the noise objectives. In the following system study, figures measured on a working 74A1 system operating between Grosses Roches and Matane in the Quebec-Telephone territory are given in order that the amount of error between calculated and measured values may be compared.

Known Parameters

$*P_t$ =	Transmitter output power	+27 dbm
$**G_t$ =	Gain of transmitting antenna	38.5 db
$**G_r$ =	Gain of receiving antenna	38.5 db
$*B$ =	i.f. bandwidth	8 mc between 3 db points
$*mf$ =	top frequency occupied by the multiplex on the baseband (12 kc to 1.2 mc)	1,080 kc = 1.08 mc
$*\Delta f$ =	Peak deviation	plus or minus 2 mc
$*N_f$ =	Noise figure of receiver	14 db
***	Path length in miles	18.4 miles
	Operating frequency	

* Parameters taken from 74A Lenkurt Equipment Specifications.
** The gain of antennas may be found from Fig. 6 of the Appendix. 38.5 db gain represents the gain of a 6 feet parabolic type antenna at 6,000 mc with 55% assumed illumination.
*** The profile below the transmitting path is shown in Fig. 11 and Fig. 12.

Gains

P_t =	Transmitter output power	+27 dbm
G_t =	Transmitter antenna gain	38.5 db
G_r =	Rec. antenna gain	38.5 db
Total gain		104.0 db
Losses		
L_p =	Path loss for 18.4 miles at 6000 mc	−137.5 db
L_m =	Misc. losses (waveguide, filters, etc.)	− 6.5 db
Total losses		−144.0 db

Received r.f. Carrier Level		
$P_c = P_t + G_t + G_r - L_p - L_m$		
or Gains − Losses		−40 dbm (−40 dbm meas.)
Noise Calculations		
KTB or thermal noise	−105.0 dbm	
N_f or noise figure	14.0 db	
$ENI = KTB + N_f$	91.0 db	
Threshold =	− 81.0 db	(−77 db meas.)

KTB is taken from Fig. 8 for 8 mc. i.f. bandwidth at 300° Kelvin. If the noise figure of the receiver is known, ENI may be found with more accuracy by using the relation $ENI = KTB + N_f$. If however, the noise figure is not known, ENI (approx.) may be found from Fig. 8.

Carrier-to-Noise Ratio (C/N)

$$C/N = P_0 - ENI$$
$$C/N = -40 - (-91) = 51 \text{ db}$$

where P_c is received r.f. carrier level. ENI is equivalent noise input power of receiver.

The threshold level equalt $ENI + 10$. This is based on the assumption that the noise peaks are 10 db above R.M.S. level. Therefore, if it is desired to find the signal-to-noise ratio at threshold the following equation may be used :

$$C/N_t = C/N - 10$$
$$C/N_t = 51 - 10 = 41 \text{ db}$$

Improvement Factor for FM as compared to AM (20 log $\Delta F/mf$)

When frequency of phase modulation is employed, large improvements in signal-to-noise ratios are possible due to the triangular noise distribution.

According to the equipment specification, Δf is 2×10^6 cycles per second and mf is 1.08×10^6 cycles per second for 240 voice channels.

$$\Delta f/mf = 2 \times 10^6/1.08 \times 10^6 = 1.85$$

From Fig. 9, we find for a $\Delta f/mf$ ratio of 1.85 an improvement of 5.5 db. The improved C/N ratio is therefore

$$C/N = C/N + 5.5$$
$$C/N = 51 + 5.5 = 56.5 \text{ db}$$

Bandwidth Factor (10 log B/b)

In KTB the noise has been considere for an 8 mc bandwidth. To convert tl noise level in a 8 mc bandwidth to tha in a 3 kc voice channel bandwidth, th noise level should be decreased by factor 10 log B/b where "B" is the i. bandwidth between 3 db points an "b" the voice channel bandwidth. Fror Fig. 10, we note that, the noise fallin in a 3 kc voice channel bandwidth i nearly 35 db less than that noise foun in the i.f. bandwidth of 8 mc. Thus th voice channel signal to noise ratio, S/N is therefore

$$S/N = C/N + 10 \log B/b$$
$$S/B = 56.5 + 35 = 91.5 \text{ db}$$

Pre-emphasis Improvement

The degree of improvement expectec from pre-emphasis, de-emphasis and cor recting networks depends on the circui capacity and the characteristic of the equipment in question. Since the exac value for this improvement is not available for the equipment involved, ar improvement of 2.5 db is assumed Therefore, the improved signal-to-noise ratio S/N in a voice channel bandwidth becomes.

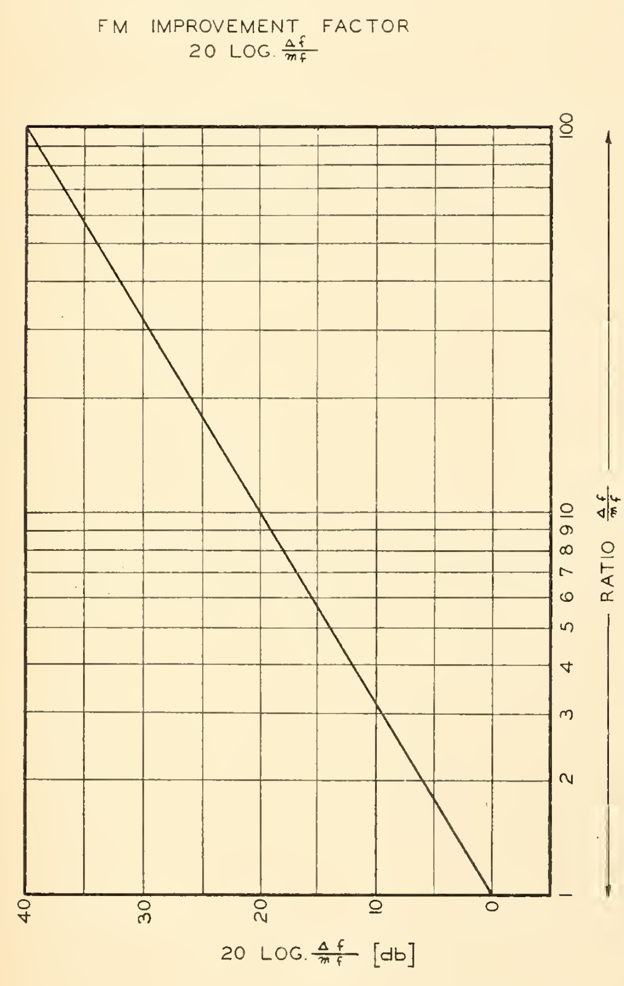

FIG. 9

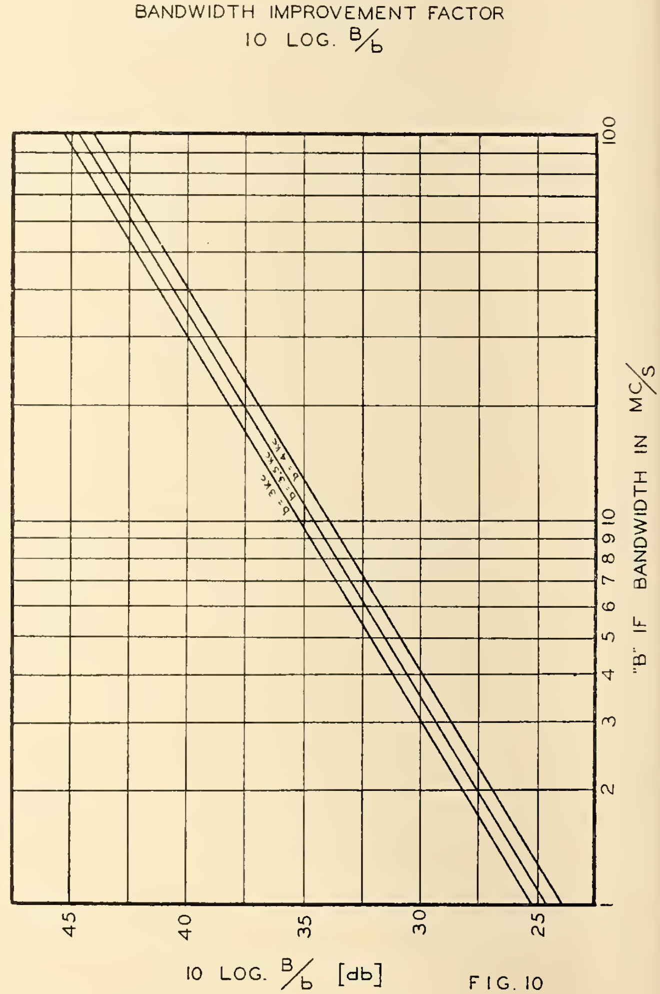

FIG. 10

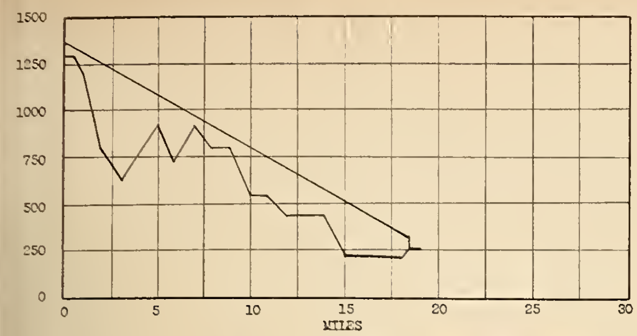

Fig. 11. Ground profile between Grosses Roches and Matane, Que. based on 4/3 earth's radius.

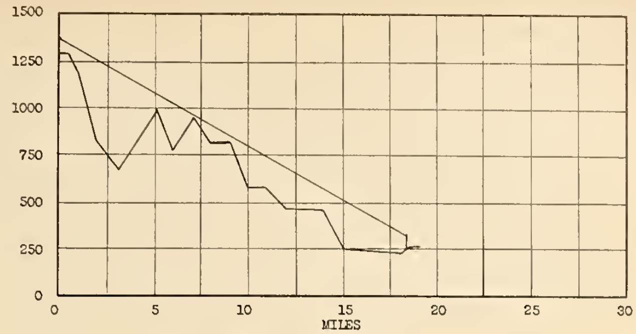

Fig. 12. Ground profile between Grosses Roches and Matane, Que. based on 2/3 earth's radius.

$S/N = S/N$ + Pre-emphasis improvement

$S/N = 91.5 + 2.5 = 94$ db

Multiplex Loading Factor

In a multiplex carrier system each channel must be reduced to prevent overloading or over-deviation of the modulator. The single multiplex channel input level to the transmitter, recommended by the manufacturer for 240 channels, is 18 db below the level producing 100% deviation. With reference to this, the voice channel signal-to-noise ratio must be reduced accordingly.

$S/N_{240\text{ channels}} = S/N - 18$

$S/N_{240\text{ channels}} = 94 - 18 = 76$ db

Noise in Terms of dba, F1A wtg.

As it has been stated above, the absolute value of signal-to-noise falling in a 3 kc voice channel bandwidth is 76 db.

Noise power may be measured on a Noise Measuring Test Set such as the W.E. 2B in terms of dba F1A wtg. With thermal noise uniformly distributed in a 3 kc band, −82 dbm flat wtg. corresponds to 0 dba F1A wtg. Therefore, the noise falling in the voice channel bandwidth is 82 − 76 = 6 dba F1A wtg.

Actual performance figures obtained for the radio system, as shown beween brackets (. . . meas.) in the system calculation are values as measured or based on measured values found in the field.

Measurements of Idle Noise

In practice, the noise contribution of the r.f. and i.f. stages of the receiver, as calculated above, are small compared to the noise produced by the modulator, demodulator, and other equipment with normal or high r.f. input levels. It is practically impossible to calculate the total noise without modulation, usually called idle noise, contributed by these other sources. Measurements of idle noise are therefore required if a complete picture of the equipment characteristics is desired.

Such measurements were taken on the 74A-1 radio system with an HP623B Signal Generator used as r.f. signal source. The results obtained are plotted in Fig. 13. The curves shown are average values of idle noise in dba F1A wtg. versus receiver input level in dbm.

The distant transmitter was then used as a signal source. The average idle noise level measured in the 26 kc slot with a median received signal of −40 dbm was found to be 23 dba. Average idle noise in a 550 kc slot was in the order of 17.5 dba, and finally in a 1200 kc slot, 16.3 dba.

Measurement of Intermodulation Noise

A typical arrangement of the test equipment for measuring the intermodulation noise of a radio system is shown in Fig. 14. The test consist of illuminating the baseband at the transmitting end with white noise between 50 kc and 1100 kc at a level 10 db above test tone input level for 240 channel loading. At the receiving end, the noise falling in a 26 kc and a 1200 kc slot of 3 kc bandwidth are measured.

Average values obtained for the 74A-1 equipment are shown in Fig. 13. The worst intermodulation noise figures obtained in a 24 kc and 1200 kc slots were 27.5 dba and 24 dba respectively.

The methods used for the above measurements are very similar to those described by E. V. Hird and R. A. March of the Lenkurt Co. of Canada Ltd.,[5] in a paper which also gives detailed information on the characteristic and performance of the 74A-1 radio equipment.

The measurements were made directly following a recent equipment modification and complete re-alignment by Lenkurt personnel.

APPENDIX

Diffraction of Radio Waves

The propagation of a radio wave in free space has been explained and it is possible to evaluate the strength of the energy at the receiving point if the distance to the transmitter is known. However, along an actual path the energy can seldom be considered to travel in a free space condition, since there is usually a finite distance between the direct ray and the earth contour between transmitter and receiver. The received energy can be greater or smaller than the free space value depending on the relative height of the diffraction point or obstruction.

The amount of attenuation due to diffraction can be calculated if we apply the diffraction theory of electromagnetic energy propagation as proposed by Christian Huygens, and Fresnel[1,6,12]

Fresnel Zones

Fresnel zones are circular areas surrounding the direct line of sight path between transmitting and receiving antennas at a radius that will make the distance from the perimeter a multiple of one-half wavelength longer than the direct line-of-sight path.

Let us consider then a transmitting path *"TOR"* of Fig. 16. At a distance *"d_1"* from the transmitter, and *"d_2"* from the receiver, an elevation along the path at point *"C"* can be taken as the diffraction point. The antenna heights at both ends can be chosen such that the diffraction point be one Fresnel zone below the direct ray. This means that, according to the above description of the Fresnel zone, the distance *"TCR"* will be one-half wavelength longer than the distance *"TOR"*. The radius of the first Fresnel zone can now be computed by simple geometry as follows.

Let *"H"* be the radius of the first Fresnel zone.

Let *"TC"* be longer by x_1 than d_1, and *"RC"* be longer by x_2 than d_2. Then by definition,

$$x_1 + x_2 = \lambda/2 \qquad (1)$$

By simple geometry

$$H^2 = (d_1 + x_1)^2 - d_1^2,$$

$$= 2d_1x_1 + x_1^2,$$

$$= x_1(2d_1 + x_1),$$

in all practical cases,

$$d_1 \gg x_1, \quad \text{and} \quad H_1^2 = 2d_1x_1 \qquad (2)$$

Similarly $\quad H^2 = 2d_2x_2 \qquad (3)$

Replacing x_1 of equation (2) by its value in equation (1) we obtain

$$H^2 = 2d_1\lambda/2 - 2d_1x_2 \qquad (4)$$

Subtracting equation (3) from equation (4)

$$2d_1\lambda/2 - 2d_1x_2 - 2d_2x_2 = 0$$

$$2x_2(d_1 + d_2) = d_1\lambda$$

$$x_2 = \frac{d_1\lambda}{2(d_1 - d_2)}$$

Substituting x_2 in equation (3)

$$H^2 = \frac{2\lambda d_2 d_1}{2(d_1 + d_2)} \text{ and } H = \sqrt{\frac{\lambda d_1 d_2}{d_1 + d_2}}$$

where H, λ, d_1, and d_2 are in the same units.

Practical forms of this same equation are given as:

$$H = 13.15\sqrt{\frac{\lambda d_1 d_2}{d_1 + d_2}}$$

or

$$H = 2280\sqrt{\frac{d_1 d_2}{f(d_1 + d_2)}}$$

Where H is given in feet,
λ is given in cm.,
f is given in mc,
d_1 and d_2 are given in miles.

Similarly it can be shown that the radius of the second, third, . . . Fresnel zones may be obtained by multiplying the above formulæ by $\sqrt{2}$, $\sqrt{3}$, ...

Effect of Fresnel Zone Diffraction

According to Huygens, every small element of the train of electromagnetic waves originating from the transmitter can be considered as a secondary energy source, sending out wavelets always away from the transmitter. This means that every point along the plane "*COD*" is an energy source radiating towards *R*.

Consider an instant at which the phase "*R*" of the wave "*T*" is zero. The energy from a point "*a*", slightly below "0", we arrive at "*R*" at a very short instant after the direct ray and add vectorially with it. The energy from all the points between "0" and "*C*" will act similarly, until at "*C*", the ray will be π radian, or half a wavelength behind the direct ray. The vectorial sum of all these points from the first Fresnel zone will produce an energy vector lagging the direct ray by $\pi/2$, and the total diffracted energy will be better than the free space value.

If point "*C*" were located such that it be two Fresnel zones below the direct ray, then the points along "*OC*" would radiate towards "*R*" with ever increasing phase difference, until at "*C*", the ray would be 2π radians or one wavelength behind the direct ray. The vectorial sum of all the energy sources along "*OC*" would then produce at "*R*" a total diffraction energy less than the free space value.

This diffraction theory also explains why energy can still be received when the direct line of sight path between "*T*" and "*R*" is completely obstructed.

Reference may be made to Fig. 15 which shows the effect of clearance on radio transmission.

Reflection

When dealing with wave propagation over surfaces such as water, desert or salt flats which can act as mirrors for some of the energy travelling between the transmitter and the receiver, it is usually preferable to consider the possibility that the total energy at the receiver may consist of energy arriving directly from the transmitter and also energy arriving after reflection on the intervening ground surfaces.

It is convenient to express the energy relations of the incident and reflected waves by a ratio called the coefficient of reflection. The coefficient of reflection (R) is defined as the square root of a power ratio, and is found by dividing the reflected energy per second leaving a reflecting surface by the energy per second incident to the same surface. If the two energies are of equal magnitude ($R = 1$), we have perfect reflection. If the reflected energy is smaller than the incident energy, the difference is either dissipated at the reflecting surface, or partially dissipated at the surface and partially passed through the surface as a refracted ray. In fact, when a radio wave encounters any medium whose electromagnetic properties differ from those of the previous medium, reflection and refraction take place simultaneously.

When a radio wave is incident upon the earth's surface it is not actually reflected from a point on the surface, but from a sizeable area. This reflection area may be large enough to include several Fresnel zones, or it may be in the form of a ridge or peak including only a part of the first Fresnel zone. For the case where the wave is incident upon a plane surface, the resulting Fresnel zones formed on the reflecting surface are elliptical zones and are similar to those which would be formed on an oblique

plane placed between a transmitting source and a receiver in free-space. Therefore, the earth-reflected Fresnel zones are simply a projected image of the free-space Fresnel zones at the plane of reflection and may be determined by the same geometry as that used for the free space Fresnel zones.

The significance of the ground reflected Fresnel zones is similar to that mentioned for the free-space zones. However, as radio waves are reflected from the earth's surface, they are generally changed in phase depending upon the wave polarisation and the angle of incidence. For horizontally polarized waves at the frequencies in the UHF, SHF range, such waves reflected from the earth's surface are shifted by about 180°, effectively changing the electrical path length by half a wavelength. On the other hand, for vertically polarized waves, a considerable variation in the phase angle will be found to exist for different angles of the incidence and reflection coefficients, and will vary between 0° and 180° lag depending upon ground conditions.[12] For horizontally polarized waves, therefore (and in some cases for vertically polarized waves) if the area of the reflecting surface is large enough to include the total area of any odd-numbered Fresnel zones, the resulting wave reflection will arrive out of phase at the receiving antenna with the direct wave and cause destructive interference.

In general, reflections occur at a number of points along the radio path and it is necessary to select the antenna height at which the reflected waves will not cause severe interference under varying propagation conditions. Where strong ground reflections are prevalent such as occur over salt flats, over-water or desert paths, one method of minimizing the effect of reflection is to provide clearances such that under normal propagation conditions the received signal level lies in the middle of a broad hump. (See Fig. 15). Another method consists in choosing the transmitter or receiver location such that the unwanted or destructive reflected rays are blocked by intervening hills or other obstacles.[7]

Noise Quantities on Telephone Circuits

The performance of a particular channel of a multiplex system for speech transmission involves many parameters which are in direct relation to the transmission quality.[8]

One of these parameters is the transmission impairment caused by the amplitude frequency characteristic of noise existing on the telephone circuit.

Because the different methods are difficult to interpret, this part of the paper proposes to compare noise quantities and to explain terms currently used.

In general two different types of instruments are used for noise measurements.

(a) The Western Electric 2B Noise Measuring Set,
(b) The 12A Transmission Measuring Set, manufactured by the Daven Company.

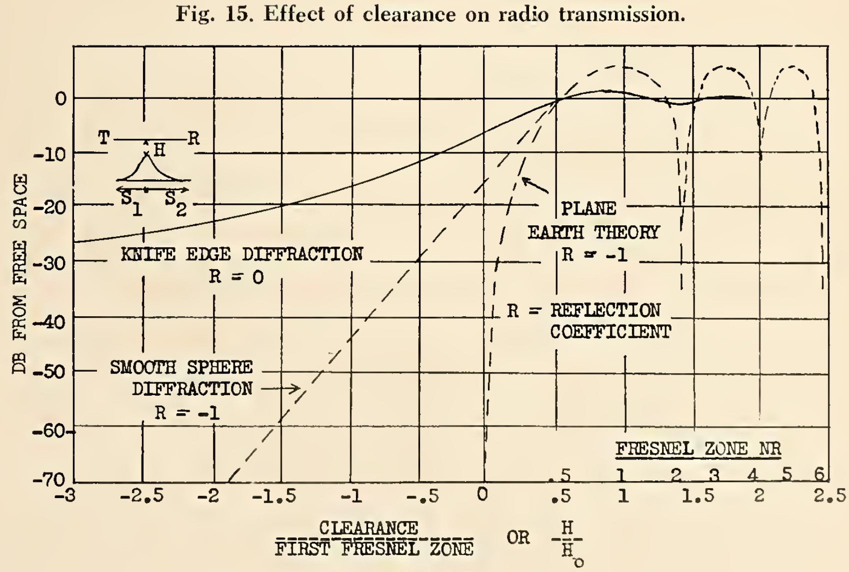
Both are used for noise measurements on voice frequency circuits and have comparable characteristics. However, they are calibrated to entirely different references.

The reference for reading dba (db adjusted) is obtained by making an adjustment to 10^{-12} watt reference, for equal transmission impairment due to the noise for the two different types of telephone sets.

The reference for reading dbRN (db above reference noise) is a 1000 cycle calibrating point at 10^{-12} watt or 90 db below 1 mw.

The terms 144 weighting and F1A

Fig. 15. Effect of clearance on radio transmission.



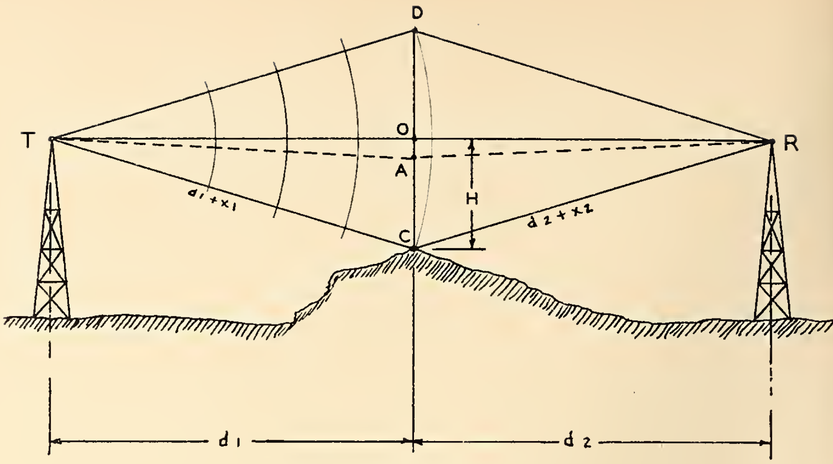
weighting take into account the relative interferring effects of different noise frequencies on a telephone line equipped with a telephone set using either a 144 type or a HA-1 type telephone receiver.

The comparison of the quantities measured with the two types of instruments, where a test power of 1000 cycles per second is applied to the input of each test set, is shown in Table I. The magnitude of the test signal is expressed in dbm, i.e. db with reference to 1 mw.

Table II compares the readings obtained from the two types of measuring sets when thermal type noise, flat over a 3 kc band, is applied to the test sets with different weighting conditions.

With reference to Fig. 17, it is also clear that with noise of types other than a 1000 cycles sine wave or a 3 kc band of thermal noise, the relations between the readings with different weightings would necessarily be different from those shown in Table I or II. In other words, a 500 cycle noise would read about 14 db greater on flat weighting than it would with 144 weighting or about 9 db greater with flat weighting than it would with F1A weighting. This is true whether the measuring set is a 2B set or a 12A.

The signal-to-noise ratio is obtained from two measurements, one of the signal and the other of noise. As a general rule, if the readings of signal and noise differ by more than 10 db, the magnitude of the signal can be considered the true value for practical purposes. However, in cases where these readings differ by less than 10 db, the magnitude of the signal will be considerably masked by noise and will require correction in order to ascertain the magnitude of the signal alone. This correction given in db can be found in Table III.



FIRST FRESNEL ZONE.

Fig. 16.

Demonstration of FM Improvement Factor

Consider a thermal noise component of frequency r.f.$_0$ This may be demodulated in a mixer to produce a frequency i.f. Such a noise component produces no output at the frequency discriminator assuming the discriminator is tuned to i.f. since the output depends upon the deviation from i.f.$_0$ Similarly a thermal noise component of r.f.$_0 + X$ cycles produces an output proportional to i.f.$_0 + X$ cycles and one at r.f.$_0 + Y$ proportional to i.f.$_0 + Y$ cycles. Assuming the discriminator curve is linear, a plot of noise output amplitude versus frequency will show a triangular distribution.

The improvement signal-to-noise ratio of a frequency modulated carrier compared with that of an equal amplitude modulated carrier when modulated by a single frequency is approximately 20 log D. However, where a single channel is transmitted with frequency modulation and the greater portion of the band is occupied, as for example, the transmission of TV signals, the improvement for the band as a whole becomes 5+20 log D. The derivation of the FM noise improvement over AM, i.e. the output signal-to-noise ratio of a FM carrier as compared to that of an AM carrier, assuming that the modulation by a single frequency is of equal amplitude, may be approached as follows. Equal signal outputs at full modulation and perfect limiting are assumed.

f_n = frequency of noise component
OH = modulated baseband
OB = Δf, r.m.s. swing of carrier (only 1/2 of the detector output is shown)
JH = top channel bandwidth
$OHED$ = represents the noise in an AM system
$OHGO$ = represents the noise in the FM system
f_h = (mf) = mean frequency of worst channel on the baseband occupied by multiplex
D = OB/f_h = Δf/mf = deviation ratio.

Consider the whole baseband as one channel as for TV signals for example.

N_{pa} = Noise power in amplitude modulated system
N_{pf} = Noise power in frequency modulated system

$$\frac{N_{pa}}{N_{pf}} = \frac{\text{Area } OHED \text{ (ordinates)}^2}{\text{Area } OGH \text{ (ordinates)}^2}$$

$$= \frac{(OD)^2 OH}{\int_0^H a^2 dfn}$$

$$\frac{a}{f_n} = \frac{AB}{OB} = \frac{KJ}{OB}$$

Solving a in terms of "fn"

$$a^2 = \frac{fn^2 (KJ)^2}{(OB)^2}$$

TABLE II

Thermal Noise in a 3 kc Band

Noise dbm	*2B Test Set* *dba*	*dbRN*	*Signal-to-Noise Ratio db 2B Test Set or TMS* *F1A wtg.*	*144 wtg.*	*Flat wtg.*
0	82	82	3	8	0

−40	42	42	43	48	40
−50	32	32	53	58	50
−60	22	22	63	68	60
−70	12	12	73	78	70
−80	2	2	83	88	80
−90	−8	−8	93	98	90

Note: With thermal type noise uniformly distributed in a 3 kc band applied to the input of the test set, this table shows the relation between corrected values in dba or dbRN measured with a 2B Noise Measuring Set.

$$\frac{N_{pa}}{N_{pf}} = \frac{(OD)^2 OH}{\frac{(KJ)^2}{(OB)^2}\int_0^H fn^2 dfn} = \frac{(OD)^2 OH}{\frac{(KJ)^2}{(OB)^2}\frac{f_h^3}{3}}$$

since

$$f_0 = 0 \qquad (OD) = (KJ) \qquad (OH) = (f_h)$$

$$\frac{N_{pa}}{N_{pf}} = \frac{3(KJ)^2(OB)^2 OH}{(KJ)^2(OH)^2} = \frac{3(OB)^2}{(OH)^2}$$

but OB = maximum swing of carrier
f_h = maximum frequency of channel $f_h = (OH)$

and

$$\frac{(OB)^2}{(f_h)^2} = (\text{deviation ratio})^2$$

or

$$D^2 = \frac{(\Delta f)^2}{(\mathrm{mf})^2}$$

$$\frac{N_{pa}}{N_{pf}} = \frac{3(OB)^2}{(f_h)^2} = 3D^2$$

If N_a = amplitude modulated noise voltage

N_f = frequency modulation noise voltage

$$\frac{N_a}{N_f}\sqrt{\frac{N_{pa}}{N_{pf}}} = \sqrt{3}\frac{(OB)}{(f_h)} = \sqrt{3}D$$

Assuming that the signal level input for AM "S_a" equals the signal input for FM "S_f", i.e. $S_a = S_f$, then

$$\frac{S_a/N_a}{S_f/N_f} = \frac{1/\sqrt{3}D}{1/1} = 1/\sqrt{3}D$$

and in terms of logs $= 20 \log 1/\sqrt{3D}$

$20 \log 1/\sqrt{3}D = -4.7 - 20 \log D$ (db),

i.e. very nearly $-5 - 20 \log D$ (db)

$$\frac{S_f/N_f}{S_a/N_a} = 5 + 20 \log D$$

TABLE III

Signal in the Presents of Noise

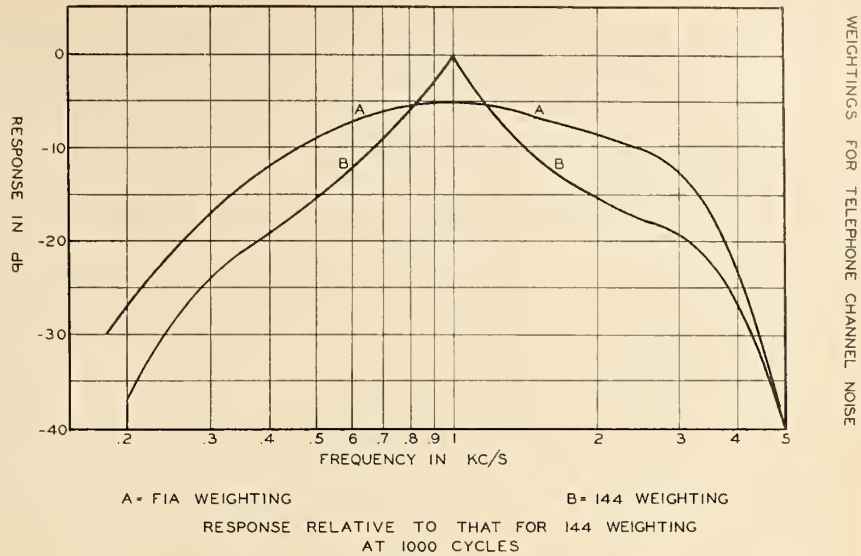

Fig. 17. Weightings for telephone channel noise.

FM noise improvement over

$$\text{AM} = 5 + 20 \log D$$

If multichannel transmission is used, we would be interested in the FM noise improvement over AM in the worst channel (top channel) of the base band. Assume that the baseband of both the AM and FM systems is represented by "OH". Then the AM noise power "N_{pa}" is again $(OD)^2 f_h$ while the FM noise power "N_{pf}" is again $\int_0^H a^2 dfn$.

Consider the noise in the top channel which is shown as "JH", i.e. $f_h - f_j$

$$\frac{N_{pa}}{N_{pf}} = \frac{\text{Noise in the top channel of AM}}{\text{Noise in the top channel of FM}}$$

$$= \frac{\text{Area } KJHE \text{ (ordinates)}^2}{\text{Area } LGHJ \text{ (ordinates)}^2}$$

$$= \frac{(KJ)^2(f_h - f_j)}{\int_0^H a^2 dfn}$$

$$\frac{N_{pa}}{N_{pf}} = \frac{(KJ)^2(f_h - f_j)}{\frac{(KJ)^2}{(OB)^2}\int_j^H f_n^2 dfn}$$

$$= \frac{(KJ)^2(f_h - f_j)}{\frac{(KJ)^2}{(OB)^2}\left(\frac{f_h^3 - f_j^3}{3}\right)}$$

$$= \frac{(KJ)^2(f_h - f_j)}{\frac{(KJ)^2(f_h^3 - f_j^3)}{3(OB)}}$$

$$= \frac{3(OB)^2(KJ)^2(f_h - f_j)}{(KJ)^2(f_h - f_j)(f_h^2 + f_h f_j + f_j)}$$

Performing the cancellation and noting that f_h is very nearly f_j, we have

$$\frac{3(OB)^2}{(f_h^2 f_h f_j f_j^2)} = \frac{3(OB)^2}{3(f_h)^2} = D^2$$

or in decibels $= 20 \log D$. FM noise power improvement over AM on top channel $20 \log D$ or $20 \log \Delta f/\mathrm{mf}$.

Acknowledgement

The author would like to thank Mr. F. C. Doak, Vice President and Chief Engineer of Quebec Telephone, for permission to publish, Mr. J. R. Tennet for his helpful suggestions, and Mr. J. C. Hurtubise for his help in preparing the manuscript.

Problèmes de Bactériologie dans la Ventilation des Salles d'Opération

V. Fredette, B.PH., D.SC., FCIC, FAAAS, *Directeur-adjoint de l'Institut de Microbiologie et d'Hygiène de l'Université de Montréal, Professeur agrégé de Bactériologie à la Faculté de Médecine.*

Conférence prononcée devant "The Engineering Institute of Canada", chapitre de Montréal, le 10 février 1960

The high cost of modern construction has resulted in smaller operating-rooms which require pulsed air for their ventilation. If no adequate filter is used in the ventilating plant, bacteria from the outside air may accumulate inside the operating-room and may constitute a source of potential danger. Reports from abroad have repeatedly described fatal accidents of this nature.

A simple technique is described for the bacteriological examination of sterile rooms and ventilating plants. It consists in looking for the perfringens bacillus. Such a technique may be used to control the installation and operation of similar devices.

From the knowledge obtained from the literature as well as through the personal examination of some twenty rooms (filling, operating, etc.) in six local institutions, requirements for the design and operation of ventilating plants in hospitals and drug manufacturers are fully described. Standards are still lacking, however, and only additional research can supply the necessary information.

LE COUT ELEVE de la construction moderne et l'impérieuse nécessité d'enfouir les salles d'opération dans le sol afin de parer aux accidents de la guerre atomique, biologique et chimique, contraignent les hôpitaux à restreindre les dimensions de ces pièces, d'ailleurs de plus en plus nombreuses, avec le résultat que la ventilation de celles-ci à l'aile d'air pulsé crée des problèmes nouveaux auxquels les chirurgiens et les ingénieurs font face depuis quelques années déjà.

En effet, lorsque les systèmes de ventilation ne comportent pas de filtres susceptibles d'arrêter de manière efficace et continue les bactéries de l'air extérieur, on risque des accidents spectaculaires comme les épidémies de tétanos post-opératoire rapportées en Angleterre depuis 1946, ou encore les cas de gangrène gazeuse comme celui rapporté en 1955 par un hôpital montréalais.

Ces redoutables agents microbiens, bacille tétanique et bacille perfringens, sont des hôtes normaux de l'intestin de l'homme et des animaux; on les retrouve nécessairement dans les matières fécales et le fumier, et partant, dans le sol enrichi avec ces excréments. De ce dernier habitat, ils passent facilement dans l'air avec l'aide du vent, surtout quand le sol est découvert.

Tant que ces hôtes microscopiques demeurent dans leur habitat naturel, ils se comportent comme de véritables bactéries saprophytes, i.e. qu'ils sont inoffensifs. Parviennent-ils à se retrouver *en nombre suffisant* dans une trouver plaie traumatique, surtout au niveau des grandes masses musculaires pour ce qui est de l'agent de la gangrène gazeuse, aussitôt ils deviennent les grands seigneurs de la pathologie infectieuse en déclenchant des processus graves dont la mortalité excède 50% dan la plupart des cas, même en présence de l'arsenal thérapeutique le plus approprié. Il devient évident qu'il importe avant tout *d'éviter* ces accidents.

Examinons donc à la lueur des acquisitions les plus récentes la situation actuelle et les moyens d'y remédier s'il y a lieu.

Technique d'analyse bacteriologique

Plusieurs techniques bactériologiques peuvent être utilisées pour rechercher la présence de germes dangereux dans les salles l'opération. Celle qui a été utilisée pour le présent travail est à fois simple et rapide: elle consiste en la recherche et caractérisation du seul bacille perfringens, l'agent le plus fréquent et le plus meurtrier dans la gangrène gaseuse chez l'homme.

Pour ce faire, des échantillons de poussière sont prélevés à l'aide d'écouvillons que l'on introduit aussitôt dans des tubes de bouillon à la viande cuite, fraîchement régénéré; ces tubes sont portés le plus rapidement possible à l'étuve réglée à 37°C. Si les bacilles perfringens sont présents, ils se multiplient si rapidement que déjà, au bout de 12 heures, ils forment un trouble homogène abondant agité par des bulles de gaz à odeur acide. Examinées au microscope, ces cultures montrent de gros bâtonnets trapus et immobiles, mesurant environ 1 micron de largeur par 2-3 microns de longeur (photos 1 et 2); transférées dans des tubes de lait scellés ensuite sous vide, ces cultures provoquent une coagulation alvéolaire en 8 heures. Mais c'est l'injection de ces mêmes cultures au cobaye qui demeure le test crucial pour l'identification certaine de ce germe: déjà en 4-6 heures après l'injection dans le muscle de la cuisse, un oedème volumineux occupe celle-ci et progresse rapidement pour envahir l'abdomen en 12 heures; l'animal meurt, enfin, en moins de 24 heures avec une grande destruction des tissus musculaires (photos 3 et 4).

Resultats

Ce jeu de détective bactériologique, pratiqué comme il vient d'être indiqué, fut répété dans une vingtaine de salles d'opération ou de remplissage dans 6 institutions locales differentes, avec le résultat net que le système de ventilation fut mis directement en cause dans tous les cas où le bacille perfringens fut retrouvé. Il faut signaler ici que plusieurs institutions, hôpitaux et autres, ont effectué des changements radicaux depuis cette époque.

Les résultats obtenus sont consignés dans la série de tableaux ci-joints.

A l'hôpital No 1, on peut voir qu'à la surprise générale, le bacille perfringens a été retrouvé pratiquement partout, même sur la lampe que l'on bascule au-dessus des plaies pendant les opérations. Bien qu'il ait été présent dans la bouche d'arrivée d'air et sur la grille de la bouche d'évacuation, le bacille perfringens n'a pas été retrouvé dans les interstices des fenêtres ni sur les murs. Dès lors, le système de ventilation devint l'objet de tous les soupçons.

Dans l'hôpital No 2, on note la présence du bacille perfringens régulièrement dans la bouche d'évacuation, plus rarement dans la bouche d'arrivée et sur le scialytique; ici, rien sur le plancher. Le système de ventilation semble donc encore en cause.

Au troisième hôpital, 6 salles ont été examinées dont 4 après nettoyage habituel, une sans nettoyage, et la dernière pendant une opération pour appendicite. On y voit que le bacille perfringens a été retrouvé dans 4 bouches d'évacuation puisqu'il a tué le cobaye en 22 heures; on le trouve aussi quelquefois dans la bouche d'arrivée, et une fois seulement sur le plancher. Ici encore, tout semble indiquer le système de ventilation.

L'hôpital No 4, enfin, a fourni deux fois sur trois du bacille perfringens dans la bouche d'évacuation; le plancher et le scialytique sont indemnes dans cet hôpital.

En conclusion de cette étude rapide, il semblait bien que le système de ventilation fût toujours en cause. Aussi, était-il urgent de vérifier si les installations étaient adéquates.

A l'aide de la même technique, toujours, des prélèvements aux endroits indiqués sur le schéma ci-joint permirent de poursuivre le bacille perfringens depuis la prise d'air à l'extérieur jusqu'à la salle d'opération, en passant à travers les divers grillages et filtres, y compris les jets d'eau. Le tableau suivant résume l'ensemble des trouvailles pour les 4 hôpitaux déjà mentionnés.

WINDOW	B. perfringes

On note d'abord qu'à l'hôpital No 1 le bacille perfringens a été retrouvé des deux côtés des deux filtres constitués, en l'occurrence, de laine d'acier imbibée d'huile.

A l'hôpital No 2, qui ne possédait pas de filtre central à l'époque, uniquement des filtres individuels à l'entrée de chaque salle, le bacille perfringens a également été retrouvé tout le long des canalisations.

Quant à l'hôpital No 3, il possède un filtre rotatif, à l'huile également; les résultats exposés ici montrent que ce type de filtre n'est guère plus satisfaisant que les autres.

L'hôpital No 4, enfin, voit ses filtres changés tous les 15 jours par le fabricant, ce qui devrait assurer, semble-t-il, le meilleur rendement; or, ici encore, le bacille perfringens a été retrouvé partout dans la canalisation.

En somme, aucun de ces 4 hôpitaux ne possédait alors un filtre convenable pour ces germes.

D'un autre côté comme ce problème de la stérilisation de l'air est primordial également chez les fabricants de médicaments injectables, il a semblé intéressant de comparer leurs installations à celles des hôpitaux déjà examinés. A cette époque, une seule fabrique possédait un type de filtre différent de ceux rencontrés dans les hôpitaux. Il s'agit d'un filtre électrostatique, doublé d'un filtre en laine de verre; il semble qu'il donne la plus entière satisfaction puisque, des 8 pièces alimentées par cette installation, une seule a fourni le bacille perfringens dans de la poussière accumulée derrière un meuble avant l'installation du filtre; partout ailleurs dans ces pièces, planchers, crevasses dans les fenêtres et cloisons, dessus de tables, on n'a pas pu trouver de germes, pas même le bacille subtil, alors qu'à la surface extérieure de la prise d'air, située d'ailleurs face à une écurie, 4 espèces différentes d'anaérobies sporulées ont été isolées. Or, ce filtre n'avait pas été nettoyé depuis un mois.

En résumé, on voit donc qu'une technique relativement simple peut fournir rapidement des renseignements précieux concernant le fonctionnement des systèmes de ventilation dans les salles d'opération et les salles stériles ou de remplissage. Cette technique a le seul inconvénient de coûter cher en animaux de laboratoire.

Bien entendu, plusieurs autres techniques ont été proposées pour faire cette étude bactériologique de de l'air; le seul ennui à l'heure actuelle réside dans le fait que les bactériologistes eux-mêmes ne sont pas d'accord sur la valeur de celles-ci Ce qui revient à dire que des standards bactériologiques restent encore à être formulés pour la direction des ingénieurs et des chirurgiens. Il semble justement que la situation, parce, qu'elle est récente, ressemble énormément à celle de l'analyse bactériologique de l'eau au début du siècle; des études nombreuses dans divers pays du monde ont permis eventuellement d'établir une technique officielle et des standards qui règlent efficacement la question de l'eau d'alimentation. Il devrait en être de même pour la bactériologie de l'air. Aussi, est-il opportun d'examiner, à la lueur du bacille perfringens, toujours, ce qui peut être réalisé à l'heure actuelle en fait d'installation susceptible de donner une certaine tranquillité d'esprit à tous ceux que la question concerne.

AIR INLET	No growth
AIR OUTLET	Cloudiness, gas; numerous Gram + cocci, few Gram + rods; stormy fermentation of milk; guinea-pig died from generalized gas gangrenc.
LAMP	Slight cloudiness
FLOOR	Slight cloudiness

Recommendations

Prise d'air au-dessus du sol: Bien que l'on sache depuis le début du siècle que le bacille perfringens habite normalement le sol, des installations que se prétendent modernes placent encore leur prise d'air au niveau de celui-ci; c'est risquer énormément et inutilement. En effet, pour la simple raison que l'on trouve de 3 à 10 fois moins de bacille perfringens dans l'air que dans le sol, tous les bactériologistes sont d'accord pour recommander que la prise d'air soit placée au-dessus du troit de l'hôpital ou de l'édifice concerné. Encore faut-il tenir compte le facteurs locaux comme la densité du traffic automobile dans la région, la prédominance des vents, etc.

Filtration bactériologique: Malgré les précautions recommandées ci-dessus, on trouve encore le bacille perfringens comme principal pathogène humain dans l'air extérieur, même au niveau du 11ième étage. Il est alors évident qu'un filtre bactériologique efficace doit être placé dans la canalisation pour empêcher ce bacille d'aller se concentrer soit sur le scialytique, soit sur les grilles des bouches de sortie. D'autre part, comme le bacille perfringens est une grosse bactérie, bien d'autres germes dangereux passeront également si on le laisse filtrer.

Plusieurs types de filtres satisfaisants se trouvent aujourd'hui dans le commerce: filtres électrostatiques, filtres en fibres de verre ou de cellulose, etc. Toutefois, seule une analyse bactériologique permet d'en déterminer l'efficacité sur place.

Souvent on soulève ici la question le l'emploi des rayons ultra-violets pour la stérilisation de l'air. Or, un comité spécial de l'American Medical Association a conclu, il y a plus de dix ans que: "they are not satisfactory for moving air". Par exemple, dans une école de l'état de New York, on a rapporté avoir obtenu une diminution de seulement 42% des bactéries en suspension lans l'air. Disons donc tout de suite qu'ils ne sont pas pratiques. En effet, pour stériliser 5,000 mètres cubes d'air à l'heure, il faut 22 lampes germicides de 25 watts chacune que l'on doit nettoyer régulièrement à l'alcool, et, enfin, remplacer dès que leur énergie atteint 60% de la puissance initiale.

Arrivée d'air filtre au niveau du plafond: Afin d'éviter de soulever les bactéries apportées par les pieds et les vêtements du personnel, on conseille de faire arriver l'air filtré à hauteur du plafond et de diriger le courant vers le bas. Cette disposition a pour but d'empêcher la formation de tourbillons et la création d'un point mort au-dessus de la table d'opération.

Pression positive dans la salle d'opération: Depuis le début du siècle, les ingénieurs anglais ont prôné le "plenum" system, i.e., l'air pulsé, pour la ventilation des salles d'opération. Or on voit encore de véritables égoûts aériens créés par les systèmes qui consistent à aspirer l'air des corridors environnants vers la salle l'opération; inutile de dire qu'il n'y a rien d'autre à faire qu'à supprimer radicalement de telles installations.

L'emploi d'air pulsé devient obligatoire avec les dimensions réduites des salles modernes. Or, la création d'une pression positive à l'intérieur de ces pièces entraîne automatiquement l'obligation de prévoir des écluses pneumatiques pour l'introduction du patient et du personnel ainsi que du matériel sans risquer la perte de cette pression positive qui constitue en quelque sorte un rempart contre les bactéries qui guettent aux interstices des portes et des ouvertures.

Sorties munies de soupapes pneumatiques: Comme nous l'avons vu, les bactéries introduites par le système de ventilation ont tendance à s'accumuler sur les grilles des bouches l'évacuation. Non seulement celles-ci doivent-elles disparaître, on doit les remplacer par des soupapes pneumatiques qui empêcheront les retours offensifs d'air extérieur quand le système est en arrêt soit pour nettoyage, soit en panne. De même l'ouverture d'une porte ne peut provoquer la chute de la pression positive si les bouches d'évacuation sont ainsi décorées.

Vingt changements d'air par heure: Ce minimum est nécessaire non seulement pour l'élimination des vapeurs explosives, et au contrôle de l'humidité et de la température, mais aussi à la dilution des bactéries apportées par les humains dans la salle d'opération. Des études classiques en Angleterre ont démontré que ces nombres microbiens augmentent avec l'activité déployée dans la salle, en particulier au début et à la fin de l'opération.

Evacuation à l'extérieur de l'air usé: Bien que la question de chauffage soit onéreuse, il n'est pas recommandé à l'heure actuelle de re-circuler une partie le l'air usé. En outre, à cause de sa teneur élevée en germes, cet air usé doit être éliminé aussi loin que possible de la prise d'air, et non côte à côte dans une même canalisation séparée par une cloison médiane, comme je l'ai vu dans une installation locale.

Nonobstant toutes ces recommandations, la seule façon d'être absolument certain qu'une installation est adéquate, c'est d'en faire l'épreuve sur place à l'aide de l'une ou le l'autre des nombreuses méthodes actuellement proposées dans la littérature mondiale. Tout comme le pharmacien grossiste ne livre pas une bouteille de médicament injectable sans y pratiquer une épreuve dite de stérilité, ainsi que l'exige la Loi des Aliments et des Drogues du Canada, l'ingénieur ne doit pas livrer et le chirurgien ne doit pas accepter un système de ventilation sans quelques épreuves bactériologiques qui donnent entière satisfaction quant à l'installation et au fonctionnement. D'autre part, seul le bactériologiste peut, à l'aide d'épreuves pratiquées à des intervalles réguliers, dicter le moment de nettoyer ou de remplacer les filtres proprement dits.

Un autre problème bactériologique qui semble loin d'être résolu bientôt, c'est la stérilisation des canalisations de faible diamètre maintenant possible de nos jours à cause des grandes vélocités utilisées. En effet, pendant les travaux de construction, les poussières et les germes s'accumulent dant ces tuyauteries, et, seule, une désinfection bien conduite peut mettre un système en état de fonctionner convenablement. Il n'est plus possible de faire nettoyer manuellement par des nains ou autrement ces tuyaux de faible diamètre; ou ne peut plus se contenter, non plus, de faire fonctionner le système pendant un temps plus ou moins bien défini dans l'espoir qu'il se nettoiera spontanément: les cannelures des tuyauteries modernes s'y opposent. Il faut donc désinfecter, et, ici encore, seule une analyse bactériologique peut déterminer si celle-ci a été efficace.

Standards

La question des standards bactériologiques pour les salles d'opération commence à s'agiter, comme je le signalais au début de cet entretien. Elle est à l'étude à l'heure actuelle et nous pouvons espérer que bientôt les ingénieurs et les chirurgiens auront des spécifications précises comme guide.

Les rares tentatives publiées jusqu'ici sont basées sur l'évaluation totale de la population bactérienne au sein d'une enceinte; aussi n'est-on pas surpris de voir des recommandations qui varient du simple au décuple (transparent). Il faudra probablement en arriver au choix d'un indicateur de pollution tout comme il en existe actuellement pour l'eau et le lait. La recherche du bacille perfringens peut servir ces fins, ainsi que l'expérience rapportée ici en fait foi.

De toute façon, on peut quand même énoncer déjà le principe suivant en guise de standard: "Il faut que la teneur en germes de l'air intérieur soit inférieure à celle de l'air extérieur". Autrement, mieux vaudrait en revenir à l'ancienne pratique de construire de grandes salles au dernier étage et d'y ouvrir de larges fenêtres pour diluer l'air intérieur avec l'air extrérieur.

Conclusion

En guise de conclusion, laissons la parole au Dr. Lowbury du Birmingham Accident Hospital en Angleterre qui écrivait: "More collaboration of surgeons, bacteriologists, architects, engineers and administrators would help to overcome these troubles, and there is also plenty of research to be done." HYDROLOGIC INVESTIGATIONS for the South Saskatchewan River Project

Presented at the 74th EIC Annual General Meeting, Winnipeg, May 1960.

THE SOUTH Saskatchewan River Projeet is a large multi-purpose water conservation project, providing for the use of the available water resources through river control, power supply, urban water supply, recreation and irrigation developments.

The projeet requires the creation of a reservoir 140 miles long having a flooded area of about 180 square miles. The reservoir will impound 8 million aere-feet of water. The main dam, situated 20 miles south of the town of Outlook, Sask., will be a rolled earth fill about 205 ft. high with a length of about 17,000 ft. involving the movement of about 50 million cu. yd. of material. A secondary dam is required in the Qu'Appelle River Valley which will be about 100 ft. high.

The project,[1] when completed, will irrigate approximately 500,000 acres in an area which has experieneed severe losses from drought conditions and it will stabilize agriculture in an area several times as large. It will make possible the construction of a large hydro eleetric power development in an area where hydro electric power possibilities are otherwise limited. It will provide unlimited water supply for urban centers in southern Saskatchewan which have no other visible source of supply. It will provide flood control along a 400-mile reaeh of the South Saskatchewan River and it will create valuable reereational facilities within reasonable access for a large portion of the population of Saskatchewan.

Description of the Drainage Basin

The South Saskatchewan River rises in Alberta and Montana, flows into the Province of Saskatchewan, merges with the North Saskatchewan River and proceeds as the Saskatchewan River into Lake Winnipeg in Manitoba. From there its waters reach the Hudson Bay through the Nelson River system. The drainage area above the dam site can be divided into three distinct parts which contribute to the flow characteristics of the river. The first part consists of the eastern slopes of the Rocky Mountains. Although this portion comprises only a small percentage of the total drainage basin of 48,800 sq. miles, it contributes a relatively large volume of runoff during the summer when the snow melts. The second part consists of the foothills east of the mountains. This part is a major contributor to the runoff: from snow melt in the spring and also from rainfall in the spring and summer. Together, the eastern slopes and the foothills produce approximately 92% of the average annual flow at the damsite. The third and the largest part consists of the relatively arid prairies, roughly east of a line through Calgary and Lethbridge. East from this line the average precipitation decreases considerably and in addition, there is generally a large moisture deficiency. As drainage in this large area is poorly developed the average runoff is usually low.

As a result of these conditions, the annual runoff usually follows a distinct pattern. From a relatively low winter flow, the river rises in the early spring due to snow melt in the Prairies and the foothills and reaches a spring peak usually sometime in April. After this peak has passed the river drops, and starts to rise again in May and June when the snow runoff from the mountains comes down. After the summer flood has subsided the river normally drops to relatively low flows in August and September until it reaches a fairly constant base flow which is maintained during the winter. Superimposed on this basic pattern are flood peaks eaused by heavy rainfalls in the foothills and mountains.

The variation in volume and peak flow from year to year is considerable. The primary factor that determines the total amount of runoff is usually the amount of snow available in the mountains. The rate of summer runoff, however, is affected by the rate at which the temperature rises in the mountains, and the timing and intensity of June-July rainstorms. The spring runoff from the foothills and the Prairies also shows large fluctuations due to the variations in extent of snow cover, rise in temperature, moisture conditions of soil, and coinciding rainfall. The summer peak is usually the larger of the two. Extreme floods on the river occur when a rapid melt in the mountains coincides with the occurrence of major rainstorms in the foothills.

Floods

After reviewing the factors related to the safety of the dam, it was decided that the spillway and related features should be designed to pass the following two floods:

Spillway Design Flood which is defined for purposes of this project as a large flood which has a probability of occurrence not greater than 0.1% (that is the chance of occurrence in any one year should be less than one in one thousand).

Probable Maximum Flood which is defined for purposes of this project as the largest flood that ever could reasonably be expected to occur at this site. This was to be obtained by a rational consideration of the chances of simultaneous occurrence of the maximum of the several conditions which contribute to a flood.

Further, it was decided that the spillway and related features should be designed (1) to pass the Spillway Design Flood with ample allowances provided for freeboard on the main dam and for hydraulic performance of the spillway structures, and (2) to pass Probable Maximum Flood with nominal allowances for freeboard and hydraulic performance.

Historical Floods

Flood peaks on the South Saskatchewan River at Saskatoon, a few miles downstream from the damsite, are the integrated result of several merging flood peaks contributed by the major tributaries. Rivers such as the Belly, Waterton, St. Mary, Oldman, Bow and Red Deer produce frequent floods individually due to two things—heavy accumulation of snow in their mountain headwaters, and early summer rainstorms on the foothill and mountain slopes. When the snow pack is heavy in this region, a heavy rainfall causes large flood peaks on these tributary streams. These peaks can coincide. The resultant flood crest then flows down the South Saskatchewan River with its peak being gradually decreased in magnitude due to valley storage.

The highest discharge recorded at Saskatoon during the period 1911-1959 was 147,500 c.f.s. on June 15, 1953. The second highest occurred on June 6, 1923 when a flow of 131,000 c.f.s. was recorded. Large floods are known to have occurred in 1908, 1902 and 1897. It is estimated that the flood in 1897 reached a peak of about 178,000 c.f.s. at Saskatoon. The flood of 1948 is worthy of mention since it is the only major spring flood which has occurred during the period of record. In that year a heavy snow cover on the Prairies and foothills, combined with a rapid warm-up produced a flood peak of almost 100,000 c.f.s.

General: The procedure followed in obtaining the probable maximum flood may be summed briefly: a very large rainstorm was assumed, the surface runoff from this storm was deduced for the various tributaries, and the tributary floods were then combined and routed down to the reservoir. A fuller description of each major step in the procedure follows:

Rainstorm: The first step in computing the probable maximum flood was to determine a storm that would be close to the maximum possible rainstorm. No attempt was made to derive this storm from air-mass analysis. This would have required a considerable amount of detailed information on recorded storms that was not available at that time. The following procedure was therefore used to obtain the design rainstorm. Isohyetals were drawn for all recorded 48-hour storms that had occurred on or near the basin. The most severe storm, (June, 1944) was then transposed to the center of the basin. In order to ensure better coverage and thus compensate for possible lack of optimum moisture content and storm efficiency, the shape of the isohyetals was modified somewhat without radically changing the total volume of rain. Care was taken, however, not to change the shape beyond that which was considered possible on account of the shape of other recorded major storms. The resultant isohyetal pattern of the design storm is shown on Fig. 1. A rainstorm with a greater total volume would probably be possible but the severity of the additional assumptions on the location, the shape and the distribution was assumed to compensate for that possibility.

Runoff from Rainstorm: The second step was to determine the runoff that would result from this rainstorm. For the foothill and mountain streams it was assumed that the soil would be soaked by heavy rain during the preceding months. The losses due to such factors as retention and infiltration were therefore assumed to be equal to the smallest values that occurred in the past during runoff due to the major recorded rainstorms. To determine these losses the hydrographs of the tributaries resulting from these rainstorms was studied. The runoff due to snow melt and base flow was separated by inspection taking into consideration the shape of the hydrographs and the variations in temperature at the mountains. The losses on the remaining part of the drainage basin were arbitrarily assumed to be a certain percentage of the rainfall. Those parts of the prairie that have a low average rainfall were assumed to have a relatively low runoff.

Total Runoff: The third step in determining the maximum probable flood was to estimate a major snow runoff. The severity of the snow runoff depends mainly on the extent of the snow cover in the mountains

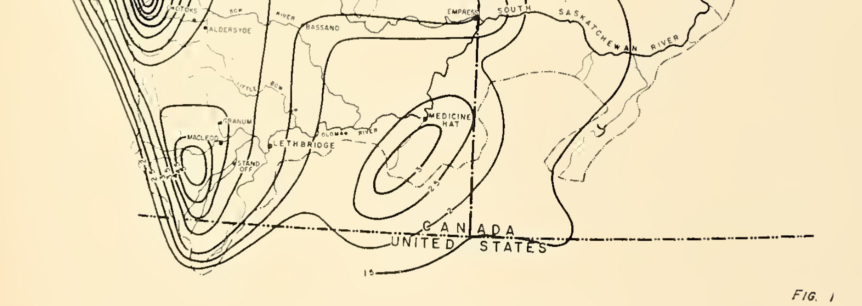

FIG. 1

TABLE I

Summary of Flood Studies

Stream	Gauge station or reach	Estimated drainage area	Recorded peak flow	Spillway Design Flood: Rainfall	Spillway Design Flood: Surface runoff & snow-melt	Spillway Design Flood: Base flow from local area	Spillway Design Flood: Peak at down-stream end of reach	Probable Maximum Flood: Rainfall	Probable Maximum Flood: Surface runoff	Probable Maximum Flood: Base flow & snow-melt from tributaries	Probable Maximum Flood: Peak at down-stream end of reach
		sq. miles	C.F.S.	inches	inches	C.F.S.	C.F.S.	inches	inches	C.F.S.	C.F.S.

* Total Tributary Area above Damsite

and on the temperature. To investigate these factors the accumulated runoff at a given gauging station may be plotted against the accumulated degree-days above 32°F. It was found that the curves thus obtained would first show a gradually increasing runoff per degree-day. After some time the curve would remain fairly straight and then it would show a gradual decreasing runoff per degree-day. Rainfall during the melting period would disturb the regularity but its effect could be estimated. Evidently the maximum runoff would occur when a warm period coincides with the time indicated by the flat portion of the curve. The maximum rate of discharge per degree-day varies for different years. It was therefore assumed that a major snow runoff could be obtained by combining the maximum recorded rate of runoff per degree-day with the assumption of a very warm period of several days. This procedure was followed for the Bow River at Seebe and for the Highwood River at Aldersyde. It was then found that even under those conditions the contribution of snow melt, including base flow, was of secondary importance compared to rainfall. Because of the large amount of work involved in this type of analysis and especially because of the scarcity of reliable data, the major snow runoff was estimated rather arbitrarily for the other tributaries.

Tributary Floods: To obtain the distribution of the runoff from rainfall for each tributary, 24-hour distribution graphs were obtained for each of these streams. The method followed in each case was essentially the method outlined on page 148 of "Engineering for Dams" by Creager, Justin and Hinds. Since, however, it has been observed that distribution graphs derived from ordinary floods generally have peak ordinates that are too small when used to calculate floods of extraordinary size, it was decided to arbitrarily increase these peak ordinates. The rule followed in getting the final distribution graph for each tributary was to use the larger value for the peak ordinate obtained from either (a) increasing the peak of the average distribution graph 15%, or (b) increasing the peak of the largest distribution graph by 7.5%.

The tributary floods then were obtained by applying the distribution graphs to the volume of rainfall runoff and adding the contribution from snow melt and base flow.

Routing: Routing of the tributary floods was done in steps governed by the location of the available gauging stations. Thus the Bow, Elbow, Highwood and Sheep tributaries were routed and combined at Bassano on the Bow River, while the Oldman, Willow, Waterton, St. Mary and Belly tributaries were combined at Lethbridge on the Oldman River. The Lethbridge and Bassano floods were then routed to Medicine Hat.

In each case the general method of discharge relationships was used. Stream flow records were analysed to discover the manner in which previous great floods had combined, including a determination of whether a flattening of the tributary peaks was required and to what extent the effect of the peak's time-lag must be considered. Having determined the manner in which the flood hydrographs combined, assumptions as to the amount and form of the inflow from the ungauged areas above the downstream gauging station were made, based on studies of similar inflows during past floods. Such inflow was added directly to the previously found flood hydrograph.

The question of time-lag, or time-of-travel, of peaks deserves special consideration. The worst condition for the final flood would be obtained if the peaks of all the tributaries coincided. It was found that in certain cases where a uniform storm occurred over neighboring tributaries, the resulting peaks did not coincide by a day or more. It was thought that in some cases these peaks could be made to coincide if it was proved feasible to assume the storm moving in such a way as to cause this coincidence. With this in mind a study was made of the direction and time-of-travel of past storms to determine limitations to storm movements over this area. The only case where it proved desirable to utilize this study of storm movements was in providing for the coincidence of the Red Deer and South Saskatchewan River peaks at Empress.

The review of past floods indicated that considerable flattening of flood peaks occurred in the reach of the South Saskatchewan River between

Medicine Hat and Saskatoon. For this reason it became particularly important and to correctly choose the point on the river at which to determine the spillway inflow hydrograph. This point is near the upstream end of the resorvoir at South Saskatchewan Landing because the effect of a large flood at the upper end of a reservoir is felt almost immediately at the lower end.

Results: As a result of the foregoing procedures, it was found that the probable maximum flood would have a peak flow of about 650,000 c.f.s. and a total flood volume of about 7 million acre-feet. (Fig. 2)

Flood	Peak @ Dam (cfs)	Peak @ Saskatoon	Apparent Probability of Occurrence
Spillway Design Flood	400,000	350,000	0.07%
Probable Maximum Flood	650,000	560,000	< 0.01%

Spillway Design Flood: The spillway design flood was obtained by following essentially the same method used to obtain the maximum probabe flood. The method differed only in the assumptions regarding the size and distribution of the rainstorm and the losses applied to it. Table I summarizes these assumptions. This study indicated that the spillway design flood should have a peak flow of about 400,000 c.f.s. and a total flood volume of about 4,000,000 acre-feet. (Fig. 2)

Check with Enveloping Curve: A plot was made of the maximum peak discharge per square mile of drainage area against the drainage area for streams of varying sizes rising on the eastern slopes of the Rocky Mountains north of latitude 44°. Since all the plotted points represent the greatest flood on record for each stream represented, an enveloping curve should indicate roughly the worth of the results. As may be seen from the graph (Fig. 3), the results appear reasonable.

Check with Frequency Curve: A frequency curve of peak discharge at Saskatoon was determined for the period 1908-1953. Plotting positions were obtained by Gumbel's equation. The frequency curve was drawn by eye, and a supplmentary curve for momentary peak flows was obtained by Fuller's formula. (Fig. 4) This frequency curve indicates that the results obtained are not unreasonable.

Discussion

Peak-Volume Alternatives: For any given reservoir and spillway, a flood having a smaller peak and larger volume may cause a larger spillway discharge than another flood having a larger peak and smaller volume. In this particular case, the actual shape of the flood hydrograph on the main stem will depend on the magnitude of the flood peaks on the tributaries and on the degree of coincidence of these peaks. In other words, every storm will cause a differently shaped hydrograph. To assess this complication it was decided to assume an arbitrary shape for the inflow hydrographs that would be both realistic and convenient for reservoir routing purposes: the well known Gaussian probability function was found suitable in this respect. This assumption made it possible to determine analytically a series of curves defining the maximum spillway discharge as a function of the magnitude of the peak and the total flood volume of the inflow hydrograph. The curves are shown on Fig. 5 and are based on the assumption that the reservoir is full at the start and that the outflow is kept equal to the inflow until the spillway gates are entirely opened.

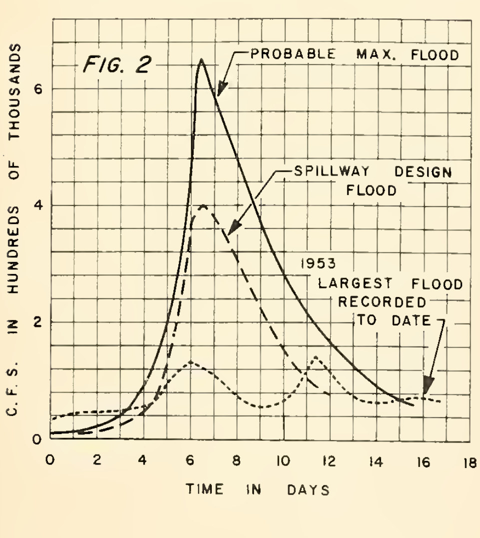
By plotting on the graph the appropriate points representing the two great floods derived herein, one may make one's own assessment of this aspect of the safety of the dam.

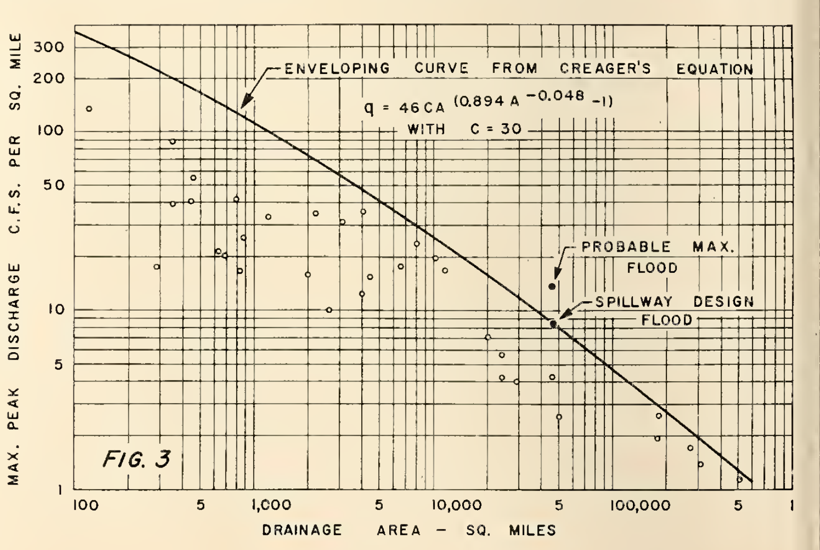
Spillway: Since a description of the spillway design and its hydraulic features is not properly a function of this paper, it will suffice to summarize the results of routing the floods through the reservoir and spillway.

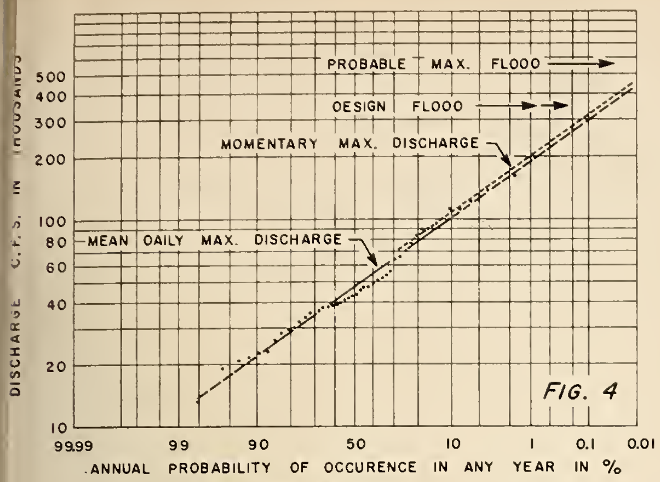
Spillway Design Flood	
—inflow	400,000 c.f.s.
—outflow	265,000 c.f.s.
Probable Maximum Flood	
—inflow	650,000 c.f.s.
—outflow	400,000 c.f.s.
Full Supply Level	1827.0 elevation
Maximum Water Level During	
—spillway design flood	1832.0 elevation
—probable maximum flood	1841.0 elevation
Top of Dam	1845.0 elevation
Minimum Freeboard During	
—spillway design flood	13.0 ft.
—probable maximum flood	4.0 ft.

Water Supply and Water Use

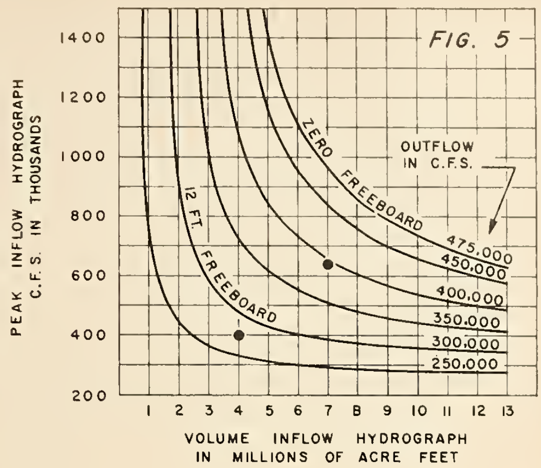
During the planning of any project, the ability of the river flow to satisfy the project demands must be studied. For this project an investigation was carried out in six phases. First, the recorded flows at several points in the basin were assembled and missing data were estimated; second, historical uses were estimated; third, the recorded flows were adjusted to nullify the effects of historical uses thereby obtaining natural flows; fourth, the water requirements under "full development" conditions in Alberta were estimated, (see Table 3); fifth, the residual flows, after deducting full development demands, were routed through the South Saskatchewan reservoir assuming all phases of this project were fully de-







FLOOD PEAK PROBABILITIES AT SASKATOON



veloped; and sixth, the effect of full development on flows downstream from the dam was studied.

Water Supply: Table 2 summarizes the natural flows at various points in the watershed for the period of record 1911 to 1956.

Uses of Water: Irrigation in Western Canada began in 1878 when John Glen constructed a ditch to water his haylands from Fish Creek south of Calgary. In the early years of this century, irrigation grew rapidly under the auspices of several irrigation companies. Since then, irrigation growth has been fairly constant and continuous (Fig. 7). At the present time, 856,400 acres have been developed for irrigation in the South Saskatchewan River basin, and completion of the projects listed in Table 3 will raise this total to 1,717,035 acres. In most areas where irrigation has developed, the land without water will support cattle grazing if there are 20 to 40 acres per head. Under irrigation and with mechanical grazing techniques, the same land will support cattle grazing with 0.5 acres per head. Also, the agricultural economy becomes more versatile under irrigation, with forage crops, sugar beets, truck garden crops and oil seed crops.

Municipal uses in the river system are also important. Edmonton, Calgary, Lethbridge, Red Deer, Drumheller, Medicine Hat, Regina, Moose Jaw, Saskatoon, North Battleford and Prince Albert—all the major centres on the Prairies except for Winnipeg—rely on the Saskatchewan River and its tributaries for their water supply. The growth of these centres and small communities along the river will place growing demands on the available water supply. At the present time, an urban population of about 1,000,000 is served from the river at an average rate of 120 gallons per person per day.

Industrial use of water has been increasing rapidly in the last few years. Large deposits of coal are available on the Prairies and for some time to come the generation of steam electric power will be economically feasible. Other industrial users, such as fertilizer, petro-chemical, mineral recovery, pulp and paper plants and others will be placing increasing demands on the flow of the river. Most industrial uses are recirculating. Although the actual consumption of water is low, a large flow of water must be on hand to satisfy the diversion requirements. Increasing industrial use may lead to stream pollution at some points but this is not now a problem.

TABLE 2

All figures in acre-feet

	For the Period 1911 to 1956		
	Minimum Annual Flow	Maximum Annual Flow	Mean Annual Flow
North Sask. R. @ Edmonton	3,922,000	9,287,000	5,673,000
North Sask. R. @ Prince Albert	3,494,000	10,501,000	6,345,000
South Sask. R. @ Alta-Sask. Bdry.	4,144,000	13,386,000	7,760,000
South Sask. R. @ Saskatoon	4,129,000	14,594,000	7,950,000
Sask. R. @ The Pas	10,776,000	30,176,000	18,200,000

Historical Background

Any attempt to discuss the relationship of water use to the water supply available would not be complete without a discussion of the various treaties and agreements which place restrictions on the present and future use of water. In 1909, Great Britain and the United States signed the Boundary Waters Treaty. Under Article VI of that treaty, Montana was given the right to use approximately 50% of the St. Mary and Milk River waters. Ultimately, this will mean an average annual depletion of 258,000 acre-feet before the St. Mary River enters Canada.

The transactions of the Prairie Provinces Water Board are also of interest. This Board has its origin in the British North American Act which gave the provinces the ownership of natural resources. In 1894, the Irrigation Act replaced the Riparian Doctrine on the prairies with an appropriate doctrine for water law. This act was administered by the Federal Government until 1930. Then the provinces assumed the administration of their water resources and each passed a Water Rights Act based on the Irrigation Act. Now it would appear that the Crown in the right of each province has ownership of the waters of the South Saskatchewan system within its boundaries. Some aspects of this situation are unworkable and the Prairie Provinces Water Board (P.P.W.B.) was established in 1948, "to recommend the best use to be made of interprovincial waters in relation to associated resources in Manitoba, Saskatchewan and Alberta and to recommend the allocation of water as between each such province of streams flowing from one province

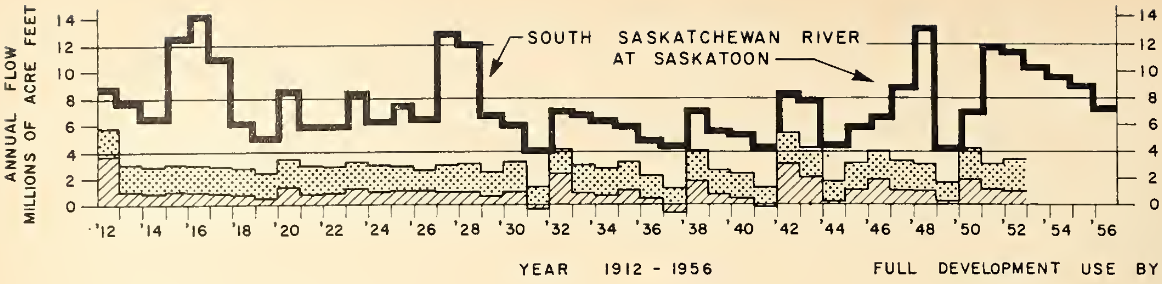


FIG. 6

into another province".

In carrying out its duties, the P.P.W.B. recommended the allocation of water for several projects, one of which is the South Saskatchewan Project. Before recommending that allocation, the Board carried out, in co-operation with P.F.R.A., a detailed water supply study. The object of this study was to ascertain whether there would be sufficient water for the project after allowing for the full development of allocations in Alberta (some 2.3 million acre-feet annually). The effects of future Alberta and Saskatchewan depletions of the flow into Manitoba was also studied.

As a result of these studies, the P.P.W.B., in October, 1953, adopted a resolution, subsequently ratified by the governments of Alberta, Saskatchewan, Manitoba and Canada, which follows:

1. The allocations already made by the Board and confirmed by the parties to the Agreement have assured an adequate water supply for the full development of each project.
2. There is sufficient water in the South Saskatchewan River and its tributaries to permit the full development, not only of existing projects but also of certain proposed projects, including the South Saskatchewan River Project and the proposed Red Deer Project.
3. The natural flow remaining in the river after water consumptive uses has been diverted will provide for the full water storage requirements for the purpose of all proposed projects, including the South Saskatchewan River Project.
4. The estimated amounts of hydro electric power to be produced by the South Saskatchewan River Project have been based on the estimated flows available after all consumptive uses of existing and projected upstream developments have been provided for.

Water Studies made by the P.P.W.B. Prior to the 1953 Resolution

Computation of Natural Flow: At several points along the main stem of the South Saskatchewan and North Saskatchewan Rivers and for most of the major tributaries, stream flow records are available for the period 1911 to the present. However, throughout this period water has been diverted from the river system for irrigation in Montana, for irrigation in Alberta and for the generation of hydro power by the Calgary Power Company.

The first step of the water supply study was to reconstruct these historical diversions and add them to recorded flows to obtain natural flows. From this study, a growth curve of irrigation in Alberta was prepared which may be of general interest to the readers. (Fig. 7)

Throughout the study, average monthly flows were used. Since it takes about two weeks under normal flow conditions for water to move from Calgary to Saskatoon and another 10 days to reach The Pas, it was necessary to adjust all flows for time-lag.

Future Water Requirements: Present irrigation diversions in Alberta are only about one-third of the estimated diversion when full development of existing allocations is reached. To assess the ability of the stream to supply future water requirements in Alberta and Saskatchewan, it was necessary to estimate the month-by-month requirement under full development conditions. Full development in this context refers to the irrigable areas shown in Table 3.

It was obvious from the flow records that the most critical water supply period would be during the 1930s and so the period 1923 to 1948 was chosen for study. Monthly diversions for that period were then estimated for the irrigation projects listed in Table 3.

The operations of the Calgary Power Company on the Bow River tend to convert summer flows into winter flows. It was, therefore, necessary to make an allowance for their future operations because of the importance of summer flows in meeting irrigation requirements.

These estimated diversions were deducted from the computed natural flow to obtain the surplus or balance of water which would be discharged from Alberta to Saskatchewan when full development is reached.

TABLE 3

Irrigation Development Upstream from the Dam

	Acres now under irrigation	Assumed for "Full Development Studies"
Western Irrigation District	50,000	50,000
Eastern Irrigation District	200,000	281,000
Bow River Project	131,000	240,000
Lethbridge Northern Irrigation District	96,100	96,135
United Irrigation District	34,000	34,000
Mountain View Irrigation District	3,600	3,600
Aetna Irrigation District	8,000	7,300
St. Mary, Milk River Project	318,200	495,000
Red Deer Project		350,000
MacLeod Irrigation District	3,500	5,000
Carmangay, MacLeod Extension, etc.		64,000
Swift Current Irrigation Project	7,000	21,000
Private Projects	5,000	70,000
	856,400	1,717,035

Water Requirements

Before the adequacy of the water supply can be studied, it is necessary, of course, to determine the requirements of the South Saskatchewan River Project. This was done by making due allowance for reservoir losses (seepage and evaporation) diversion to the Qu'Appelle basin, irrigation diversion, and water to generate power for irrigation pumping. The balance was assumed to be available for generating commercial power.

Irrigation Diversion: On the basis of plane table topography, gathered over a six-year period and a preliminary soil survey, it was assumed that 455,000 acres could be irrigated from the reservoir. After a study of Alberta projects, with similar climate and soils, a duty of water of 18 in. was assumed with an irrigation factor of 80% and gross conveyance losses of 30%. This annual demand was broken into monthly demands using percentages derived from measured diversions to projects in Southern Alberta. The gross demand was reduced for years of above normal rainfall.

Irrigation Pumping Water: Since 35% of the irrigable area would be served by gravity irrigation, the balance would have to be lifted from 15 to 120 ft. The energy for pumping this water was assumed to be derived from the power house at the project.

Qu'Appelle Diversion: For irrigation, municipal water supplies, truck farming and recreation, the Qu'Appelle Valley will require a firm water supply. Adequate water supply for the above purposes could be provided by a release from the reservoir of 200 c.f.s. during the seven summer months (April to October) although this would not be needed every year. The 24,000 acres of irrigation potential in the Qu'Appelle Valley were included in the figure given for total project acreage.

Reservoir Seepage: A constant seepage loss of 100 c.f.s. was assumed: 25 c.f.s. through the main dam and the balance through the Qu'Appelle dam and elsewhere.

Reservoir Evaporation: An annual allowance of 24 in. of net evaporation (evaporation minus precipitation) from the ever-changing reservoir surface area, was assumed.

Reservoir Operation: The purpose of the study was to assess the ability of the reservoir and the water supply to serve the project, rather than to develop operation rules for the reservoir. Basically, the method of computation was to supply the consumptive requirements listed in the foregoing section, and use the balance of the water to operate a hydro plant with an assumed efficiency of 80%.

It was assumed that the plant would be operated to produce the same amount of firm energy each year. The monthly output was assumed to vary from a low of 4.5% of the annual energy production in July to 14.0% in December.

By trial and error it was found that 325,000,000 kwh. could be produced each year. It was realized that if interconnection with other plants having reserve capacity were assumed, a different picture of the potential would be produced, but for the particular purpose of this study it was unnecessary. A capacity of 150,000 kw. was sufficient to produce this firm commercial energy, to produce an additional 125,000,000 kwh. per year of secondary energy and to provide all the energy required for pumping the irrigation water. Any installation greater than 150,000 kw. would generate still greater amounts of energy. Present indications are that ultimately the site may be developed to a capacity of 300,000 kw.

The over-all effect of "full development" on the average flows in the system are shown on Fig. 6.

Effects on Downstream Power Potential

There are several power sites in the Saskatchewan-Nelson River system downstream from the South Saskatchewan River Dam, three of which are under construction. On the South Saskatchewan there are the proposed plants at Batoche and Coxby. Below the junction with the North Saskatchewan River, plants have been proposed at Fort a la Corne and Nipawin. The hydro developments at Squaw Rapids and Grand Rapids are under construction. On the Nelson River there is a gross power potential of about 3,000,000 hp., with one plant (Kelsey) already in operation.

Although stream flow depletions in Alberta and Saskatchewan will average 3,050,000 acre-feet annually, the operation of the South Saskatchewan River Dam will increase downstream power potential (except on the Nelson River) over natural conditions because of the firm winter flows to be derived from storage.

The proposed Nelson River plants will derive their flows from the Lake Winnipeg watershed. About 20% of the inflow to this lake is contributed by the Saskatchewan River. It was found from an approximate analysis that "full development" depletions in Alberta and Saskatchewan would reduce this Nelson River power potential by about 3% to 4%.

Recent Developments

The changing concepts and needs of a water-hungry economy are variables which cannot be evaluated permanently but which need a continuing review. Since these water supply studies were completed in 1953, several major changes in the basic assumptions have occurred. Three important ones have been described to illustrate this problem.

Red Deer Project: (William Pearce Scheme) For the Water Board studies, 350,000 acres were assumed irrigable. On the basis of recent soils surveys, only 250,000 acres are considered suitable for irrigation (excluding the extension of this project into Saskatchewan). Recent proposals suggest that one of the main functions of this project would be to supply stockwater and municipal water by gravity to most of east central Alberta and west central Saskatchewan.

However, should economic concepts change and favor the development of sprinkler irrigation, the original acreage and more could be considered irrigable.

Municipal Water in Saskatchewan: Recently (December 1959) Saskatchewan recorded with the Prairie Province Water Board a proposal to supply by pipelines, 30,000 acre-feet of water annually from the North and South Saskatchewan Rivers for municipal purposes. At the moment, development appears costly, approximately double the cost of existing systems, but eventually, it will provide the only solution to expanding municipal requirements. Looking far into the future one can see pipeline systems of this sort leading to expanded industrial use, specialty irrigation, and even more municipal water to serve a stimulated population growth.

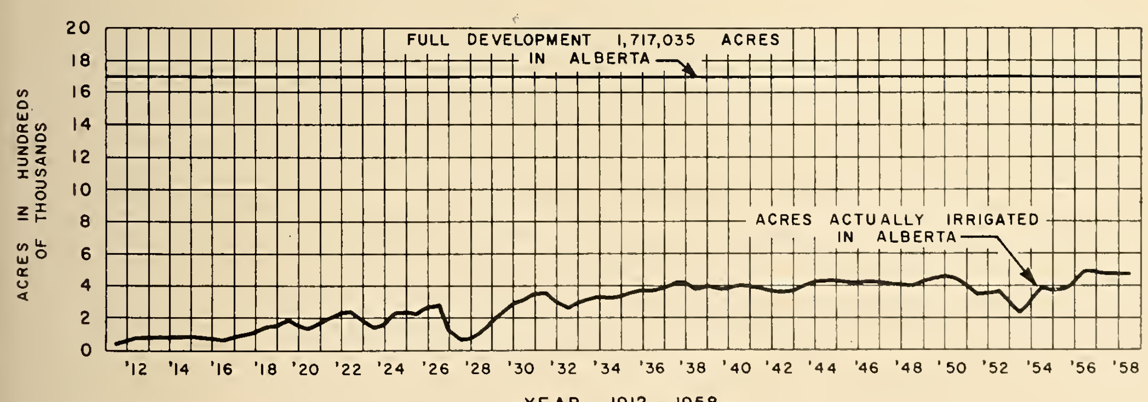

FIG. 7

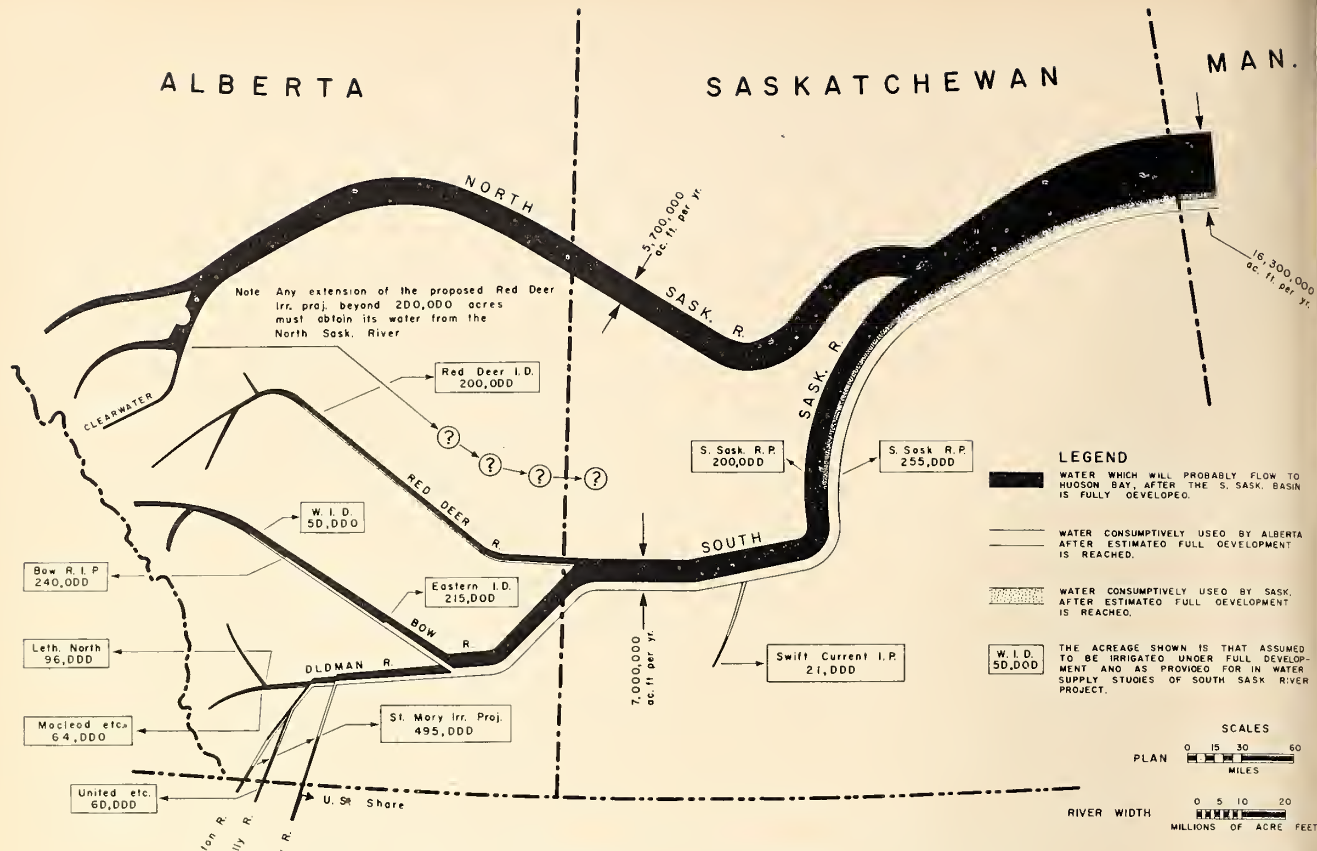

EFFECT OF "FULL DEVELOPMENT" ON SASKATCHEWAN RIVER SYSTEM

FIG. 8

Recent Power Developments: Until three years ago, hydro power in the Saskatchewan basin was limited to 320,000 kw. on the Bow River system operated by Calgary Power Company. In the balance of the watershed, electrical loads were served by coal, oil, and gas-fired steam plants, which can be expanded in small increments. However, as loads increase, the possibility of absorbing the capacity of a large hydro plant increases, and the construction of each plant, with associated storage and regulation enhances the power potential at all downstream sites.

The inter-related effects of power regulation and other storages which will probably be built over the next 20 years have not yet been studied. However, three general observations may be made; (i) as river regulation increases, better use can be made of the water resources, (ii) as river regulation increases, power potential increases and the water supply picture, particularly in the winter, will improve, (iii) moderate floods on the river will be fully controlled, although major floods will be less affected.

Review

Flood Inflow Hydrographs: The flood potential of the South Saskatchewan River is such that the spillway proposed for the South Saskatchewan River Dam will have to be capable of handling floods having inflow peaks of up to 650,000 c.f.s.

Water Supply: The South Saskatchewan River system after meeting existing municipal and industrial water requirements, and after watering 1.7 million acres of irrigation in Alberta, is capable of irrigating 450,000 acres from the South Saskatchewan River reservoir and generating a minimum of 325 million kwh. annually of firm commercial energy.

In Times to Come

In 1878 the irrigation phase of development in this huge watershed was begun. This development is continuing. Until now, the river flows have been adequate to supply this phase of water development. We now are on the brink of a rapidly expanding hydro power development. This phase will probably dominate the development scene for the next 20 years. However, thoughts of even the following phase have been expressed by some who like to peer into the future: municipal and domestic water distributed in pipeline transmission networks to areas far removed from the river; industrial growth placing large demands on the river for process water with attendant pollution problems; changes in agricultural science which lead to intensified irrigation and which justify high water rates. Although this tertiary phase cannot be clearly defined at the moment, it is safe to say that within the lifespan of some of us, the Saskatchewan River will be completely harnessed to supply the ever-expanding needs of a burgeoning population. When that day arrives, the South Saskatchewan River Project, with its 8 million acre-feet of storage will play a vital part in serving those needs.

FIRE PROTECTION for Rotating Electrical Equipment

Jason H. Ingham, M.E.I.C.
Walter Kidde & Company of Canada Ltd., Toronto

FIRE losses in Canada during 1959 amounted to $30 million. This covers only property damage. The loss of life and the loss attributed to reduced hours of production and other disruptions cannot be properly assessed. These indeterminates must be shared by the employer, the employee, and the general public.

Startling as is this figure, it doesn't tell us how much greater the cost would have been without the benefit afforded by built-in protection systems which went into action to prevent or control many other fires. It is true that when water sprinkler systems operate there is damage other than that attributed to fire. However, the cost of such damage is infinitely small compared with that caused by fire uncontrolled for any extended period of time. It is equally true that in certain applications, the loss due to water damage can be eliminated by the use of carbon dioxide as the extinguishant. It is of interest, therefore, to compare water and carbon dioxide as extinguishants for one important application of fire protection, the protection of rotating electrical equipment. This paper outlines the characteristics of the two media, and indicates some of the preferences expressed in favour of one or the other. It is an attempt to summarize in an objective manner the results of many conferences, interviews, and discussions, covering the overall problem.

Fires in rotating electrical machines vary in character. At one extreme there is the mere threat of fire which reveals itself in the operation of differential relays, thermostats, or other indicators of operational irregularities. At the other extreme is the fire so complete, so intense, that the copper components of the machine are fused. In such extreme cases, steel components of the machine warp, crack, and twist, particularly if water is applied to extinguish the fire or to control its spread to other parts.

In the field of hydro generators, it has been estimated that fire and the threat of fire cause shutdowns equal to 2% of the working hours of a machine. The shutdown period covers inspections, tests, repairs, and replacement of components. As with all other forms of combustibles, fire will occur in rotating electrical machines if there is:

(1) a source of ignition;

(2) oxygen (or air) to support combustion;

(3) a flammable material present.

The usual sources of ignition are sparks from short-circuits, overheated bearings, and friction heat from metal components that have suffered misalignment. The flammable materials may be deposits of dust or an oil film on the windings, lacquer or varnish used in the splicing of wiring, or the bonding material used in laminated components of the machine. The insulating material used in the windings may not burn readily but it decomposes under intense heat causing further short circuits, thereby intensifying the heat generation as well as creating a source of ignition.

Good fire protection requires prompt detection of the fire through the use of automatic detection equipment. Once the fire is detected, a built-in fire extinguishing system should discharge automatically to control the fire and hold the damage to a minimum. Simultaneously the machine should be de-energized and brought to rest as quickly as possible to reduce the spread of fire through wind currents caused by the moving rotor, and to permit access to the internal parts of the equipment.

The requirements for an effective extinguishing system may be summarized as follows:

(1) The system should extinguish the fire as quickly as possible to minimize fire damage;

(2) The system should prevent reignition until the rotor can be brought to rest and access gained to the internal parts;

(3 The agent used should not contribute to the damage incurred;

(4) The agent should contribute to the cooling of heated parts that would induce reignition.

The total damage may be broken down into two categories: first, the actual repair cost; and secondly, the revenue loss because of decreased system capacity or higher cost of power to replace that supplied by the damaged equipment.

The discussion to this point has concentrated on circumstances surrounding actual fires. It is important to consider also the situation where abnormal heat conditions in the equipment either necessitate a decision with regard to operation, or cause premature discharge of an automatic system.

Abnormal heating which develops in rotating electrical machines may be caused by internal shorts or by external faults caused by electrical storms or malfunctioning of control equipment. This abnormal condition may be detected through operation of differential relays, use of fixed temperature thermostats, or employment of smoke detection equipment.

Under automatic operation, there is immediate initiation of the fire-prevention system. If the condition is one which would ultimately lead to fire, damage is minimized by actuation of the system. If, however, the condition is due to equipment malfunction or is merely transient, the automatic feature of the system should be such that resulting costs caused by the employment of the agent, the inspection of equipment, and the interruption of service, should be kept to a minimum.

Under manual operation, these unnecessary costs are avoidable but another formidable problem is presented. Now the responsibility for an error initiating the operation of the system, is placed squarely on the shoulders of operating personnel, with the possibility of further damage while the operation of the system is delayed in order to ascertain that there is actually a fire condition.

Before analyzing protective systems in the light of the foregoing considerations, it is appropriate to review the basic extinguishing system. It has five components:

(1) a supply of extinguishing agent;

(2) piping to conduct the agent to desired point of application;

(3) a source of energy to move the agent from storage to the scene of use;

(4) suitable nozzles and other components to apply the agent in the manner desired;

(5) a method of initiating and shut-off, either manual or automatic.

In the carbon dioxide system, illustrated in Fig. 1, the agent, in a partially liquid state, is stored in cylinders at 850 p.s.i. This pressure, on release, causes the extinguishant to flow through the piping system to the discharge nozzles, and further, it can be used to initiate controls and protective equipment.

With water systems, pressure is provided by pumps, storage tanks pressure systems, or, in the case of hydro electric generators, by the penstock operating head itself. Here again a piping system is required but the discharge means is usually limited to the provision of a perforated pipe located within the machine to direct water on as great an area as possible of both rotor and stator windings.

Although total enclosure of a machine is desirable, it is not mandatory when a built-in water extinguishing system is installed, while it is a necessary requirement with a built-in CO_2 extinguishing system. However, where there is dirt or a flammable moisture-laden atmosphere, total enclosure of rotating electrical equipment is good insurance against fire risk. In addition, maintenance costs are reduced substantially because the internal working parts are kept cleaner.

It is readily apparent from the above brief outline of a system's components that the physical characteristics of the two available alternatives are not radically different. Any indication of superiority must be found in the characteristics of the extinguishing agents and the actual methods in which they are used.

Carbon Dioxide Systems

With respect to the speed of extinguishment, experience with carbon dioxide has been favourable. Although carbon dioxide has a lesser cooling effect than water, it has the advantage that as a gas it penetrates to portions of the wiring that water cannot reach.

To ensure immediate control of the fire and to maintain control during the period of rotor deceleration, carbon dioxide systems are so designed that gas is injected into enclosed rotating machinery through two independent discharge systems. The initial injection of carbon dioxide from the first piping system lasts for about two minutes and creates an oxygen-deficient atmosphere which extinguishes any fire that may have flashed. Also, with a fire condition imminent, the carbon dioxide, when released by differential relay actuation, establishes an oxygen-starved atmosphere that will not support combustion, thus preventing an outbreak of fire.

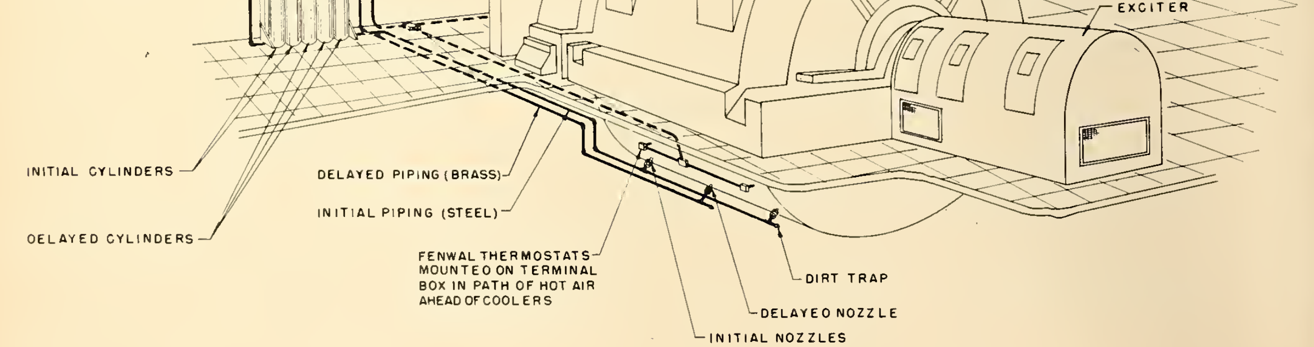
The second piping system is designed with an extended time of discharge so that the oxygen-deficient atmosphere is maintained throughout the period of deceleration. It is, of course, necessary to know the time of deceleration of the machine protected. Adequate data exist and accepted standards, such as are outlined in pamphlet 12 of the National Fire Protection Association, make this procedure reliable. Further, actual extinguishment of many fires in rotating electrical machines has proven conclusively the effectiveness of carbon dioxide in fires of this type, with complete extinguishment taking place either immediately following the discharge of the carbon dioxide system or within a few minutes after the machine has been brought to rest.

That carbon dioxide is non-damaging follows a consideration of the characteristics of the material. Although stored as a liquid, the rapid expansion which occurs at the discharge nozzles causes it to be discharged as a mixture of carbon

Fig. 1. Typical installation diagram of built-in carbon dioxide fire extinguishing system protecting a turbine generator.

NOTE
WHEN MORE THAN ONE GENERATOR IS PROTECTED BY THE SAME BATTERY OF CYLINDERS, DIRECTIONAL VALVES ARE INSTALLED TO ROUTE THE CARBON DIOXIDE TO THE GENERATOR AFIRE. THESE VALVES ARE AUTOMATICALLY OPENED BY THEMOSTATS IN THE GENERATOR THEY PROTECT.

INITIAL AND DELAYED CYLINDERS ARE RELEASED SIMULTANEOUSLY. INITIAL CYLINDERS PROVIDE FOR RAPID INJECTION OF CARBON DIOXIDE TO IMMEDIATELY BUILD UP AN INERT ATMOSPHERE. DELAYED CYLINDERS ARE SLOWLY DISCHARGED INTO GENERATOR TO MAINTAIN INERT ATMOSPHERE.



ioxide snow and gas. The snow asifies without passing through the iquid state so that neither wetting ction nor the depositing of moisture ccurs. Since carbon dioxide is dry, t neither damages the equipment nor nakes necessary a clean-up or dry-out after discharge. Because of its non-conductivity, carbon dioxide does ot provide a path for short circuits hrough partially decomposed insulation. It can be stored indefinitely vithout deterioration and when discharged neither corrodes nor damages nachines or parts, no matter how lelicate.

Under conditions of abnormal heating or equipment malfunction, carbon lioxide once again exhibits desirable characteristics, in that it has no ill effects on the equipment protected. If there is no fire in the machine at time of discharge, the carbon dioxide serves to prevent an outbreak should conditions develop which would favour combustion.

Again, in the event of an equipment malfunction or a temporary heat condition, which, on detection, is readily controlled, the equipment quickly can be brought back into operation. This is highly advantageous since short shut-downs can usually be handled without extensive re-routing or delays, whereas in the case of extended shut-down the load must be dropped for the duration of the time the machine is down and during that time replacement power or equipment must be paid for at emergency rates.

This characteristic of short shut-down permits carefree operation of a carbon dioxide system in time of doubt, since the only cost to the operator is the gas expended, while the potential saving is very great.

Water Systems

With one qualification, it is apparent that water systems are capable of quickly extinguishing a fire. However, since water extinguishes by cooling, fire in internal unexposed wirings can be controlled only by the relatively slow process of conducting water-chilled currents to the internal burning area. Water, being a liquid, can go only where driven by pressure.

It is also readily apparent that a water system will ordinarily prevent re-ignition during the deceleration period. The disadvantage of the water system lies in the damage chargeable to its use. It is in the evaluation of this damage that the greatest source of disagreement lies. Since the damage caused by the water used to extinguish the fire is absorbed in the cost of putting the machine back into service, it follows that there are no dependable cost figures for water damage alone. To recondition water soaked equipment, it is reasonable to assume the following operations:

Dry the rotor and stator either by removing the stator or by running under reduced load for the required period;

If damage is extensive, repairs and replacements must be made, followed by operation tests, under reduced load, for assurance of complete dry-out of insulation.

In addition to the actual cost of doing that portion of the above work which can be directly attributed to water damage, it is necessary to assess the added shut-down time caused and the resulting cost of this lost production time.

While the added costs resulting from the use of water rather than carbon dioxide may be hard to assess under conditions of actual fire, the delineation is more obvious under conditions of abnormal heating and equipment malfunction.

It is significant that most built-in water systems are manually controlled in an attempt to prevent premature operation. Furthermore, manual operation is restricted. Some operators have a firm rule that water systems will be operated only as a last resort after a fire has reached such proportions that the machine will be a total loss. Others instruct operating personnel that the water extinguishing valve must not be opened unless there is positive evidence of fire by the presence of smoke, excessive heat, or both. This fear of the adverse effect of water on rotating electrical equipment was responsible in at least one instance for unusually extensive damage because at the inception of fire in a machine the operators did not discharge the water for fear of creating unnecessary damage.

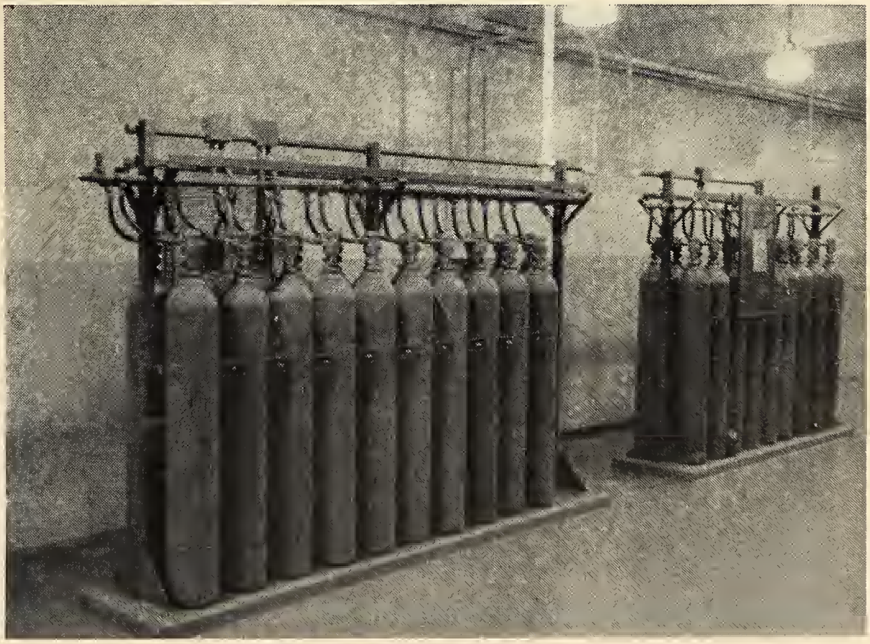
There is considerable difference of opinion with regard to the exposure of rotating electrical equipment to water. Many hydro-generator operators dislike any wetting and drying of their machines. They say there is substantial evidence to support the view that repeated wetting and drying of coils causes a break-down of the insulation, thereby shortening the life of the machine and increasing the risk of fire.

It has been argued that drying is relatively simple because facilities are always present to achieve it. At the time of installation, formal delivery requires that after erection and just before the acceptance test, the machine must be dried. Heat for drying is applied by shorting the windings. In some locations the use of permanently installed auxiliary heating equipment is a requirement, since there may be present in the machine, in addition to moisture, flammable solvents used in the field splicing of coils.

Generally, operators and manufacturers disagree on the need for care in any further drying operations following the acceptance tests. Operators, however, generally exercise the same care whenever the machine is exposed to moisture as is used at the time of the original drying operation.

Further, operators emphasize that water damage is not limited to the effect on the wiring. The machine must be carefully examined to ensure

Fig. 2. Carbon dioxide cylinders. The initial bank is in the foreground, the reserve bank in the background.



that bearing and machined metal surfaces are free of rust and other foreign matter. These operations all take time, with a resulting extension of the shut-down period and an increase in the indirect costs due to lost capacity.

Operators' Opinions

Many operators favour carbon dioxide to water, because they feel that automatic operation of the extinguishing system is mandatory to control the spread of fire within the windings. They consider the introduction of water undesirable, particularly if automatic actuation is provided.

For machines of 20,000 kva. or more, automatic systems are preferred. For small machines, the carbon dioxide can be applied using portable or wheeled extinguishers, or by manually-operated carbon dioxide hose-reel systems. The preference for automatic systems has extended to the point of reworking open-type or semi-enclosed equipment with forced ventilation, into closed systems, so that automatic-flooding carbon dioxide systems may be installed.

One usually forgotten advantage, operators point out, is the reduced insurance cost, which in the long run compensates for increased initial outlay. Insurance Underwriter make the following provision in their schedules for generating stations:

(A) Reduced premium rates when fixed steam systems are installed, or where the interior of the machine is accessible, when approved portable extinguishers are provided in quantity as required by the rating authority.

(B) Additional reductions when internal water spray or manually-operated carbon dioxide fire extinguishing systems are installed.

(C) Further reductions when automatically-actuated carbon dioxide systems are installed.

Thus the owner who installs approved built-in fire extinguishing systems enjoys an advantage as he negotiates his insurance rates from year to year as well as continuous peace of mind.

Water vs. Carbon Dioxide

Disadvantages of Water:

1. Only manual operation is normally furnished;

2. Generally, operators will discharge a water extinguishing system only when they are positive that there is fire which cannot be otherwise extinguished and only after the machine has been de-energized and there is no risk of the electrically conductive water causing a further short. Such delay increases the spread of fire;

3. Extensive cost (a) incurred in putting the machine back in operation after discharge of the system and (b) through interruption production during the shut-down;

4. No basic system design data. Water is discharged until operating or fire-control personnel judge that the outbreak is under control;

5. Water cannot penetrate windings to reach fire in interior coils, hence complete extinguishment depends on the cooling effect of externally applied water;

6. For modern, remotely controlled generating stations, any automatically operated water system would require automatic shut-off, since otherwise the deluge system would have to be shut off by someone lacking positive knowledge as to whether the fire is under control;

7. Repeated wetting and drying of machine windings is objectionable. Therefore it is not desirable to run proof tests, either after completion of installation or at periodical intervals thereafter. Consequently the effectiveness of any system is established only after it has been used to extinguish a fire.

Advantages of Water System:

1. There is usually a continuous, inexhaustable supply of extinguishant except where the supply is restricted to a water storage tank which must supply water for other service in the plant, or where the water supply is dependent on motor driven pumps that draw their power from a generator involved in the fire;

2. Total enclosure of the machine is not required;

3. Water will ordinarily extinguish and prevent re-ignition during the deceleration of the machine, provided that the fire is confined to exposed windings;

4 Almost unlimited cooling effect.

Disadvantages of Carbon Dioxide:

1. Requires total enclosure of the machine, for automatic built-in protection;

2. The quantity of carbon dioxide is limited to the available stored supply based on established design requirements;

A connected reserve bank can be furnished and is usually specified for multiple hazard protection;

3. Cooling effect is less than water.

Advantages of Carbon Dioxide:

1. Adequate design data is available based on proof tests and on results of positive extinguishment of fires in rotating electrical machines;

2. System can be discharged automatically;

3. If system is discharged automatically by differential relay actuation due to momentary power surge but no fire, no harm is done;

4. Non-damaging, i.e. no wetting action, no corrosive action, and no moisture deposits on delicate parts of machine.

5. Wind currents created by rotor in motion, help to distribute the carbon dioxide gas to insure complete penetration of all windings;

6. Decreased shut-down time after a fire or threat of a fire;

7. Complete discharge tests to verify that the fire extinguishing system is in perfect operating condition, can be run periodically without extended shut-down, since cleaning and drying are unnecessary after use;

8. Concentration tests can be run after installation to check distribution of carbon dioxide and verify that the desired dilution of air is achieved throughout the machine;

9. Carbon dioxide is stored under pressure ready for use. Pumps or other mechanical equipment are not required to pressurize the discharge system;

10. Carbon dioxide is a non-conductor of electricity, hence it is not necessary to de-energize the machine before carbon dioxide is discharged within it;

11. Carbon dioxide can be stored indefinitely without deterioration.

Costs

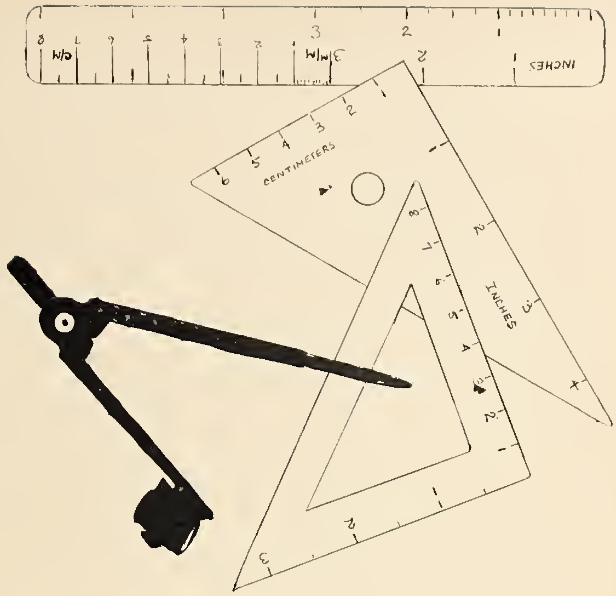
No paper of this type would be complete without data on comparative costs. A study of a recent project revealed that, based on protecting a bank of five generators each of 40,000 kva. and valued at $450,000 per machine, the cost of equipment for a water installation with automatic actuation (but no automatic shut-off after extinguishment) would be in the neighbourhood of $2,200 per machine. The cost of equipment for a built-in automatic carbon dioxide system having a main and reserve bank would be $2,600 per machine.

Conclusion

This paper has attempted to establish that, in the possibility of a serious fire when discharge of a *manually* operated system is delayed, the carbon dioxide system has the advantage in that it prevents or greatly reduces damage from possible ignition and permits immediate operation after inspection.

Finally, because of the costs inherent in drying after discharge, water system are usualy manually controlled. This introduces an intangible factor in the form of human error. As with all intangibles, the assessment and control of this factor are almost impossible.

THE *CRISIS* IN MEASUREMENT



L. E. Howlett
Director, Division of Applied Physics,
National Research Council, Ottawa.

Many of man's developments depend upon his ability to measure — and to corelate these measurements. Measurement qualifies as a keystone of man's civilization. Lack of conformity is a crisis.

EVEN superficial consideration of man's history suggests that his degree of civilization is directly proportional to his understanding and command of the world around him and that these accomplishments depend on his ability to measure the phenomena that he observes, and subsequently to relate them. Thus, measurement qualifies as one of the keystones of civilization. This conclusion makes it of considerable interest to take a survey of the history of measurement, analyze the philosophical principles involved and make an appraisal of where we stand today in such a fundamental field.

The urgent importance to make measurements in every field of human endeavor is probably the principal reason why the human race has developed through the ages such a startling hodge podge of units, standards and methods of measurement. Contradictory and unrelated units have grown everywhere to meet special and local needs in various activities because the devising of some sort of reference frame for measurement is essential before development can take place. Thus we had goldsmiths developing a number of systems of weights and measures; farmers developed others for their produce; surveyors were not to be outdone. The list is endless. Local borders, as well as national ones, have compounded the confusion. Even science itself has not been blameless. With the passage of time a large number of these variegated systems have become firmly entrenched in sentiment, tradition and familiarity. Some of these arbitrary units were at a later stage sometimes related to each other by direct measurement but this could not overcome the complexity and inconvenience of their use and manipulation which resulted from the way they were established in the first place. Once a system is well established in a particular area of human activity those who use it always howl rage and shock at the thought of change, quoting the cost and inconvenience involved without a thought for the future and the further compounding of confusion and waste.

It seems completely reasonable to us now that length, volume and area should be related in a simple way and very little extra thought shows the advantages of relating mass with length through volume. Nevertheless it is surprising to find that before the French Revolution it was only in ancient Egypt that these simple thoughts were grasped and practised. The Egyptians defined a cubic cubit of water as a talent of mass because they had observed by experiment that the cubic cubit of water always had the same mass. They ignored, it is true, the temperature effect because their methods of measurement were still too crude, but for this reason the effect to them was unimportant. Many of our own measurements — perhaps all — suffer from parallel limitations. Thus it could be said that within their limits of knowledge the ancient Egyptians had a consistent logical and simple system of measurement for mass, length, area and volume.

Having lost the simple Egyptian answer the world had to wait for the fresh, eager approach to reason and rationality, born in the French Revolution and in the logic of the French mind, to produce the metric system, consisting of the metre, the kilogramme, simple multiples and submultiples of these units and a relationship between the metre and the kilogramme through water. There was also an attempt to relate the unit of length to an unchanging natural constant. This failed because of experimental difficulties but was attained last October at the XI Conference on Weights and Measures held at Paris. The standard for the metre was not, however, related, as its founders hoped, to the circumference of the earth but to a particular wavelength of light emitted by an unperturbed atom of Krypton 86.

The metric system as proposed initially was, by today's standards, not a satisfactorily comprehensive system of measurement. It coped quite conveniently with length, area, volume, mass and any quantity which was a combination of these quantities, but not so conveniently with quantities such as force, electricity, temperature, brightness, and velocity. It was English scientists in the early 18th century who made the first desirable extension of the metric system by including another unit, the second, and so created the widely used centimeter, gram, second, system. They preferred to use centimeters and grams instead of meters and kilogrammes for reasons that seemed good and sufficient to them but this deviation is insignificant compared with the concept of introducing an extra unit of time to permit convenient measurement of a greater variety of phenomena including force, velocity, and momentum. At that time England could have gone over wholly to this extended metric system, at minimum economic cost and with great benefit to the budding industrial revolution and the development of engineering. However, England was proudly developing as a world power and this naturally did nothing to reduce her pride in and her attachment for her traditional national units. Further, the memory of the recent long and costly war with Napoleonic France did little to make generally popular anything of French origin. Therefore in spite of considerations of logic, simplicity and convenience the ancient systems of English measure continued not only to maintain their position in the everyday world but to improve and consolidate it.

In 1875, France called a very important international meeting in Paris that had as its aim the unification of international measurements and the promotion of the use of the metric system. The culmination was the signing of the Convention du Mètre. Among other things this treaty provided for a meeting of an international conference on weights and measures in Paris every six years, an international laboratory — the International Bureau of Weights and Measures, at Sèvres — and an executive — the International Committee on Weights and Measures — to direct international metrological activities between general conferences. This Convention is in force to this day and has been the greatest single influence in unifying measurement both in science and at the practical level. Initially the Convention covered only length and mass but was revised in 1921 to include electricity, photometry, thermometry and the establishment of physical constants needed for improving the accuracy and precision of the measurement standards. The Convention will probably be revised again in the near future to include fundamental units and standards for x-rays and nuclear radiations.

It is interesting to note that in the United States, from the American Revolution onwards, there was always a significant interest in the use of the metric system. The principal obstacle to its adoption in early days may well have been some question as to whether it might not ultimately disappear with other inovations of the French Revolution. In the last days of the 19th century this interest had developed to the point where the demand for a change-over to the metric system had become very great. By 1902 it was admitted by even the opponents of this step that a Bill then before the Congress, sponsored by Congressman Southard of Ohio to replace the English system by the metric system, would pass with a large majority. At the last moment, to the surprise of all, he withdrew the Bill. His later explanation was that he wished to persuade opponents rather than force a minority to an undesired action. However, the opportunity once lost was lost for many years because America was at that time industralizing rapidly and with each step the change became more costly and opposition to change became correspondingly greater.

This very brief historical account suggests how confused and arbitrary has been the approach to measurement throughout most of human history. We have already suggested that the very importance of measurement almost ensured such a condition in the absence of rapid means of communication. Be that as it may it is certainly only during the last 75 years that there has developed a degree of international agreement not only on common units but also as to what comprises a logical philosophical approach to the design of a system of measurement in order that we may have the simplest and most convenient framework on which to hang all our measurements. Clearly the closer we come to such an ideal the easier and more convenient it will be to make progress in scientific research or, for that matter, in any human endeavor.

We will now leave the history of the measurement muddle and take a look at the problem from what we may call a modern viewpoint. We shall try to build what we want from first principles without prejudice, if that is possible, from what has gone before. The Italian physicist Georgi did this at the beginning of the century.

We are confronted in the world about us by a great variety of quantities which must be measured if we are to develop a framework of physical laws. These are quantities such as length, time, mass, force, velocity, momentum, electric current, brightness, temperature, and radiation. We can call these quantities dimensions. We could obviously define an independent unit of measurement for all these dimensions but we would be reluctant to do so. The system would be too cumbersome. On the other hand we could base a system of measurement on only one dimension but we would reject this also as being rather inconvenient and artificial. In the light of the very distinguishable physical phenomena involved we would rather have for convenience, or perhaps for reasons largely of common sense, an adequate but minimum number of dimensions for which to establish measurement units with which we could, in combination with the laws of physics, measure any desired dimension. These chosen basic dimensions should be ones for which we have developed measuring techniques of the highest percentage precision and accuracy in order to keep our whole fabric of measurement as precise and accurate as we can.

Thus, it is apparent in the modern view that the reasons for selecting a group of dimensions to form the basis of a general measuring system are entirely pragmatic. This concept has not by any means always been clearly recognized. There have been interminable arguments that some dimensions are more fundamental in some sort of absolute sense than others. Arguments have at times bordered on the realm of mysticism rather than physical science. Preoccupation with the conservation of energy and the very successful development of generalized mechanics during the 19th century created a desire on the part of some physicists to attribute a special fundamental significance to the dimensions, length, mass and time. This outlook was probably largely responsible for the fact that when the theory of electricity was worked out there seemed to be no inclination to add an electrical dimension to the basic dimensions of length, mass and time for the same reason that English scientists had earlier added the dimension of time to the two original metric dimensions. Instead, electrical units were awkwardly expressed in terms of the three so-called fundamental dimensions length, mass and time. It also seemed to escape the notice of some hat the awkward fractional indices which appeared in electrical dimensional equations were no more than a natural result of using an awkward number of basic dimensions for the measuring system. Similar natural but somewhat startling results come from other choices. The astronomers, for good and sufficient reasons of their own, have used a measuring system in which the basic units are L and T with G the gravitational constant made equal to 1. This leads to mass being expressed as L^3T^{-2} which suggests the interesting possibility of measuring mass as cubic miles per hour per hour.

Such results are hardly justification for the philosophical discussions that at times have surrounded the choice and significance of the primary dimensions of a system. When the Italian physicist Giorgi introduced this modern approach to the problem he ended the 19th century's exclusive preoccupation with L.M.&T. He suggested that, because electricity presented a new group of physical phenomena quite distinguishable in intrinsic character from those of mechanics, it was sensible and convenient to add an electrical dimension to the length, mass and time group. He further indicated that the particular choice of electrical dimension was not important except for the usual reasons that should govern the choice of a basic dimension. The significance and value of his proposal was quickly recognized but physicists discussed it for nearly 50 years during which time it was further suggested that for the same reasons that the electrical dimension and the time dimension were added to length and mass two more basic dimensions were required to cover the distinguishable phenomena of temperature and photometry. Finally in 1954, the 10th International Conference of Weights and Measures meeting at Paris chose the dimensions, length, mass, time, current, temperature and luminous intensity to be the basis of an international measurement system called the International System of Units.

At the same time that the 10th International Conference chose these basic dimensions it also established units of measurement for each. These were and, of course, still are metre, kilogramme, second, ampere, degree Kelvin and candela. To establish the value of these units and to ensure their preservation standards for each were also defined. The metre is defined in terms of a special wavelength of Krypton 86. The kilogram is preserved by a platinum iridium mass held in the vaults of the International Bureau of Weights and Measures at Sèvres, France. The ampere was defined theoretically in terms of the force between two parallel infinitely long wires carrying an ampere. The degree Kelvin was defined by assigning a thermodynamic temperature of 273.16°K to the triple point of water. The unit of luminous intensity, the candela, was established by defining the brightness of a black body at the temperature of melting platinum as 60 candela per sq. cm. This system is a natural development from and a very material improvement over the metric system of the French Revolution.

At this stage of our discussion it might be pointed out that the Procès-Verbaux of the International Conferences on Weights and Measures, the meetings of the International Committee on Weights and Measures and those of the Consultative Committees of the latter provide a very rich source of information on measurement units, standards and the wealth of research that has gone into this field. Unfortunately these references are not too familiar to a great many physicists and engineers.

One more point about the international system of units should be mentioned. When Giorgi first proposed the addition of an electrical dimension he pointed out that if for example electric current were the chosen dimension, its unit — the absolute ampere — defined in terms of a force expressed in metres, kilogrammes and seconds, was very closely equal to the practical unit, the International ampere, which had been well established for some time on an arbitrary basis. Thus the unit of current could be placed on a fundamental basis instead of an arbitrary one without significant loss of continuity in the ampere. The absolute ampere as well as the candela were adopted officially by the Ninth International Conference on Weights and Measures in 1948.

The measurement system of Giorgi is often called the M.K.S.A. system or, more briefly, the M.K.S. system. Since there is literature on the subject which is misleading it is well to point out here that the two distinguishing marks of the M.K.S. system are

(1) the use of length, mass, time and an electric dimension as basic dimensions and

(2) the use of metre, kilogramme, second and ampere as units.

There is no necessary connection between the M.K.S. system and rationalization — an arithmetic artifice which changes the positions of 4π in the electromagnetic equations. The M.K.S. system like any other system can be rationalized or not depending on whether the user considers rationalization a simplification, as do most, or unnecessary as some still do.

Although the International System of Units is accepted without regard to national barriers by the scientific world the same is not true in the every-day world. Since the beginning of industrialization the ordinary industrial and commercial world has hardened into two camps, the English-speaking countries and their dependencies with the English system of measurement on one hand, and the majority of the other countries with the metric system on the other. Because of the industrial power and foreign trade of the English speaking countries the English system has to date much more than held its own in spite of the fact that it is awkward, inconvenient and illogical. On occasion groups in the English speaking world have pushed for the adoption of the metric system but they have generally been laughed out of court as longhairs who did not understand the economic facts of life and the tremendous cost that they were proposing for industry on the basis of what seemed to the industrialist a collection of scientific and academic niceties. In other words industrial strength overwhelmed logic, simplicity and convenience and none of the movements for change either in the United Kingdom or the United States have to date been able to get off the ground. The world of 1961, however, is a very different one and is likely to become more so very quickly. A real crisis confronts the users of the English system.

Today, the English speaking world using the English system of measurement is becoming proportionately a smaller and smaller island in a growing sea of metric system. The industrial development of metric Russia has changed immeasurable the influence of metric Europe in the last 40 years. India has just adopted the metric system and it became obligatory in Japan in 1959. Red China is using the metric system and will no doubt in the near future join the Convention du Mètre. These changes in the balance between the users of the English and metric systems are very formidable and cannot but affect world trade. To these accomplished facts can be added that it is only reasonable to suppose that the new countries of Africa and Asia, as they rise from colonial status, will adopt the elegant metric system in the absence of prejudice coming from economic or sentimental reasons. In the case of those developing from the colonies of European metric countries the metric system already has roots. Therefore it requires no crystal ball to see that what might be called the unfair dominance of the English system through trading and industrial capacity is rapidly becoming a thing of the past. It seems unbelievable that the new countries starting out on a basis of the metric system will wish indefinitely to introduce confusion into their developing economies by the acquisition of capital and other goods based on a system of measurement in conflict with their own when there will be substantial sources of similar goods in the metric area of the world either on this side or the other of the political boundaries between the East and West.

The undercurrent of strength which the trend to the metric system possesses at the present time, despite all the deep-rooted prejudices that still exist, can be detected in a recent development within the area using the English measure. The American yard and pound have been related to the metre and kilogramme since 1893 by equivalence ratios. There have been no particular physical standards which could be pointed out as the legal American yard and pound. In England it was otherwise — the physical entities, the Imperial yard and Imperial pound, were the standards. In 1893 these physical standards were identical to the American yard and pound defined by ratios. Since then, however, the Imperial pound and the Imperial yard, following the way of most flesh, changed in size so that small but industrially significant discrepancies developed between the United Kingdom units and American units. In Canada in 1951, the Canadian yard and Canadian pound were legally related by ratios to the metre and the kilogramme thus displacing the previous physical standards, the so-called Parliamentary copies of the Imperial standards of the United Kingdom. In 1959 the Commonwealth countries and the United States decided to remove discrepancies between their units to do away with troublesome industrial problems. They agreed on a definition for an International yard and an International pound which tied these units by ratios to the metre and the kilogramme. These units will be used for all commercial and industrial purposes in the Commonwealth (except metric India) and the United States. Thus the whole world now derives its units of measurement of length and mass from the metre and kilogramme prototypes held at Sèvres. The peculiarity of the Commonwealth and the United States is their current insistence on working with units established from these by ratios that are not simple; they then compound the folly by using multiples and submultiples that are also inconvenient. One thing, however, is now simple— one inch is exactly 2.54 cm! The displacement of the physical Imperial yard and Imperial pound as the basis of the English system in the United Kingdom would have been unthinkable in the heyday of the English system because of the loss of prestige by the tacit acknowledgment of the superior permanence of the metric standards, but the need for uniformity in precise measurements for international trade can be no longer ignored.

Trading nations using the English system of measurement already have grounds for very serious thought. The United Kingdom and the United States are already giving such thought to the problem. On this occasion it is not the longhairs who are concerned but the legislators, the industrialists and the traders. The study has been going on intensively in the United Kingdom for some 10 years. A Committee of the British Parliament reported favorably in the early fifties on a changeover to metric units to take place over several decades. Currently the British Association for the Advancement of Science, in co-operation with British industry, is endeavouring to count the cost of a change-over. In the United States the American Association for the Advancement of Science is undertaking similar enquiries and more recently steps have been taken to set up an investigating committee under the authority of the Congress to the same end. This committee is to report within four years. These various activities may not as yet foreshadow early action on a change-over but they do emphasize an entirely different attitude to the whole problem than that which has existed at any previous time. Fear is in the air about ability to maintain indefinitely foreign markets when using an archaic measurement system when the rest of the world has gone metric. Such fear of financial loss can be very effective in clearing prejudices. Sentimental attachment to a historical and traditional system can quickly take second place to expediency when financial loss is involved.

If a change-over to the metric system is to be dictated by the need to survive in international trade there are clearly many complex problems involved. They need ample study to minimize cost and confusion. It is a matter of grave concern that such studies are not being conducted in Canada as they are in the United Kingdom and the United States. It is a study that must be made by very diversified groups that constitute a cross section of our economy and its interests. If I may venture to say so the Engineering Institute of Canada, representing as it does both management and engineering, would seem one very appropriate body to set up a committee to make a twofold study to (1) keep closely abreast of the results and the thinking in the similar investigations going on in the United Kingdom and the United States and (2) uncover and study any problems that may be peculiar to Canada in any eventual change-over. With the unfavorable export balance that Canada possesses at the present time it would seem that any factor bearing on foreign trade is of great importance and deserves the closest study. The measurement problem is soon likely to be of greater significance rather than less.

There is another factor which justifies early consideration. A final legal change-over would probably have to be done concurrently with the Commonwealth and the United States. This leaves the ultimate initiative to the more powerful members of the measurement block. However, the problems of the coming years may not necessarily involve an all-or-nothing solution. If there were revealed by investigation any evidence that Canadian export trade in a particular area could profit by the use of the metric system it would be only sensible to start employment of it immediately. The metric system has been legal in Canada since 1871, so in this respect there are no impediments. Even in an ultimate complete change-over it is inevitable that both systems would have to exist side by side for a number of years. There may very well be a great many areas where we could do something parallel to that done by the manufacturers of scales in the metric countries of Japan and Germany. They sell us scales calibrated in the English system on one side and the metric on the other.

I hope very much that this brief and very incomplete presentation of a few of the aspects of this crisis in measurement will do a little to stimulate serious studies of where we are going as a nation in this fundamentally important area, what problems we will meet, what we can do about them, and when. EIC

CONCRETE ARCH BRIDGE AT HARTLAND, NEW BRUNSWICK

E. van Walsum, Jr., M.E.I.C.
Project Engineer, Foundation of Canada Engineering Corporation Limited, Montreal

T. J. Sluymer, Jr., M.E.I.C.
Design Engineer, Foundation of Canada Engineering Corporation Limited

A RATHER striking looking series of reinforced concrete arches near Hartland, N.B., was completed in the early summer of 1960 as part of the Trans-Canada Highway program.

The Department of Public Works of New Brunswick retained our company in June 1956 to make engineering studies for a proposed bridge carrying the Trans-Canada Highway over the Saint John River at Hartland.

Design Criteria

The design was governed by the Department's specifications which required a roadway of 26 ft. width, with safety curbs 9 in. high and 2 ft. wide on each side of the road. The structure was to be designed for H20-S16 truck loading or the CSA U-100 uniform live loading, whichever was governing.

Site

The location of the proposed bridge was chosen by the Department of Public Works of New Brunswick, some 3,500 ft. upstream from the longest covered bridge in the world, crossing the Saint John River at Hartland. The proximity of this famous old bridge was a challenge to create an attractive modern structure.

The Saint John River at Hartland is closed in by steep banks on both sides. The old road followed the curves of the river close to the river banks. The new alignment of the Trans-Canada Highway, however, was chosen to run through the hills. The centreline of the bridge, as established by the New Brunswick Highways Department, was virtually perpendicular to the main channel of the river and passed between two wooded islands, one just upstream and the other just downstream of the site.

Since the Trans-Canada Highway was projected to run through the hills on both east and west banks, the road level of the bridge was to be approximately 100 ft. above the average river bed. The deck was to have a grade of 1%, sloping up to the east. On the east side of the river, the structure was to pass over a single CPR track and N.B. Highway No. 2.

Hydrography

River flows in the Saint John River near Hartland vary between 5,000 and 245,000 c.f.s. Normally, the depth of water in the river averages about 3 ft. during two 3-month periods of the year, i.e., during Janauary, February and March, and during July, August and September.

During October, November and December, work in the river is possible although difficult due to increased flow. During April, May and June, work in the river is virtually impossible. The water levels fluctuate between an extreme low of 126 ft. and an extreme high of 157 ft.

Soil Investigation

A soil investigation, carried out during October and November 1956, showed foundation conditions to be excellent. Either bedrock or a dense grey till bearing stratum was present at depths of 5 to 45 ft. under the river bed. The overburden on these bearing strata consisted of a 5 to 10 ft. layer of loose to compact silty sand and gravel and for the remaining depth of compact silty sand.

Preliminary Design

Under the given conditions, a great number of alternative solutions would have been possible. The two alternatives which were most closely examined were a scheme of concrete arches (Fig. 1), and a scheme of steel deck truss spans (Fig. 2). According to preliminary estimates, the initial cost of the steel scheme would have been slightly less than that of the concrete arch scheme. Notwithstanding this difference in cost, the more expensive concrete scheme was recommended primarily on the basis of availability in the area of an abundant supply of labour, lumber, sand, gravel, reinforcing steel and cement. Good sand and gravel was present right at the bridge site. Other factors in favour of the concrete scheme were appearance and maintenance.

The recommendation to build the bridge as a series of concrete arches was accepted, so we proceeded with this scheme.

Due to the favourable soil conditions, the design of the substructure was relatively simple. The layers of sand and gravel and of compact silty sand which covered the bearing strata had N values varying between 10 and 160. In order to penetrate the very dense layers in this overburden, it was decided to use steel H bearing piles. The main features of a typical pier are illustrated in Fig. 3. The wide base of the piers was kept underground for aesthetic reasons. This base was made of Prepakt concrete placed within a steel sheet pile cofferdam. Piers 2 and 4 were made extra strong to withstand large horizontal thrusts during construction as will be discussed in more detail later. The main features of piers 2 and 4 are shown in Fig. 4.

When designing a series of concrete arches, it would seem logical to make all arches identical. In the case at hand, however, the roadway was to have a 1% grade. For aesthetic reasons it was decided to let the crown of all arches follow the 1% grade of the roadway, and to keep the spring lines of all arches in the same horizontal level. Thus all arches had different heights, spans and height-to-span ratios, but all arches were cut from the same parabola (Fig. 5). By cutting the various arches from the same parabolic shape, a great deal of re-use of forms and scaffolds was made possible and the computations were simplified.

Another basically important factor which had to be considered was whether the arches should be rigid or hinged, and, if hinged, to what degree.

A point in favour of hinges is that they make computations simple. To a certain extent hinges even make the computations more reliable in that they give the designer the advantage of knowing that the moments at hinges are zero or at least negligible.

From a construction point of view, hinges can be highly advantageous in certain cases if such hinges allow the use of precasting techniques. At this site, and with the size of arches under consideration, precasting of the arches was not practical. The use of hinges would therefore have no advantages from a construction point of view, while it would have the disadvantage of requiring some complicated details. It was therefore concluded that construction would be simplified by the elimination of hinges.

From a design point of view, it should be noted that a statically indeterminate structure has a great deal of reserve strength. Each hinge which might have been put in the arches would have reduced this reserve strength. This, therefore, is another reason for eliminating as many hinges as possible.

In certain cases, hinges may be used to advantage to relieve stresses, caused by such conditions as settlement of foundations, and temperature changes. Due to the excellent foundation conditions in this instance, however, settlements of appreciable magnitude will not occur. The magnitude of temperature-, shrinkage- and creep-stresses was limited by giving the arches a slender shape; rather than using two arch ribs per span, one slender arch barrel was used for each arch.

It was therefore concluded that the arches were to be fully fixed.

Serious consideration was still given to the possibility of using a *temporary hinge* at the crown of the arches. By placing some hydraulic jacks in the crown of the arches, it would have been possible to adjust the thrusts and moments throughout the arches. It was found, however, that the use of such jacks would have altered the stress condition at one point to advantage, but to equal disadvantage elsewhere in the arch. This was ample reason to eliminate this refinement.

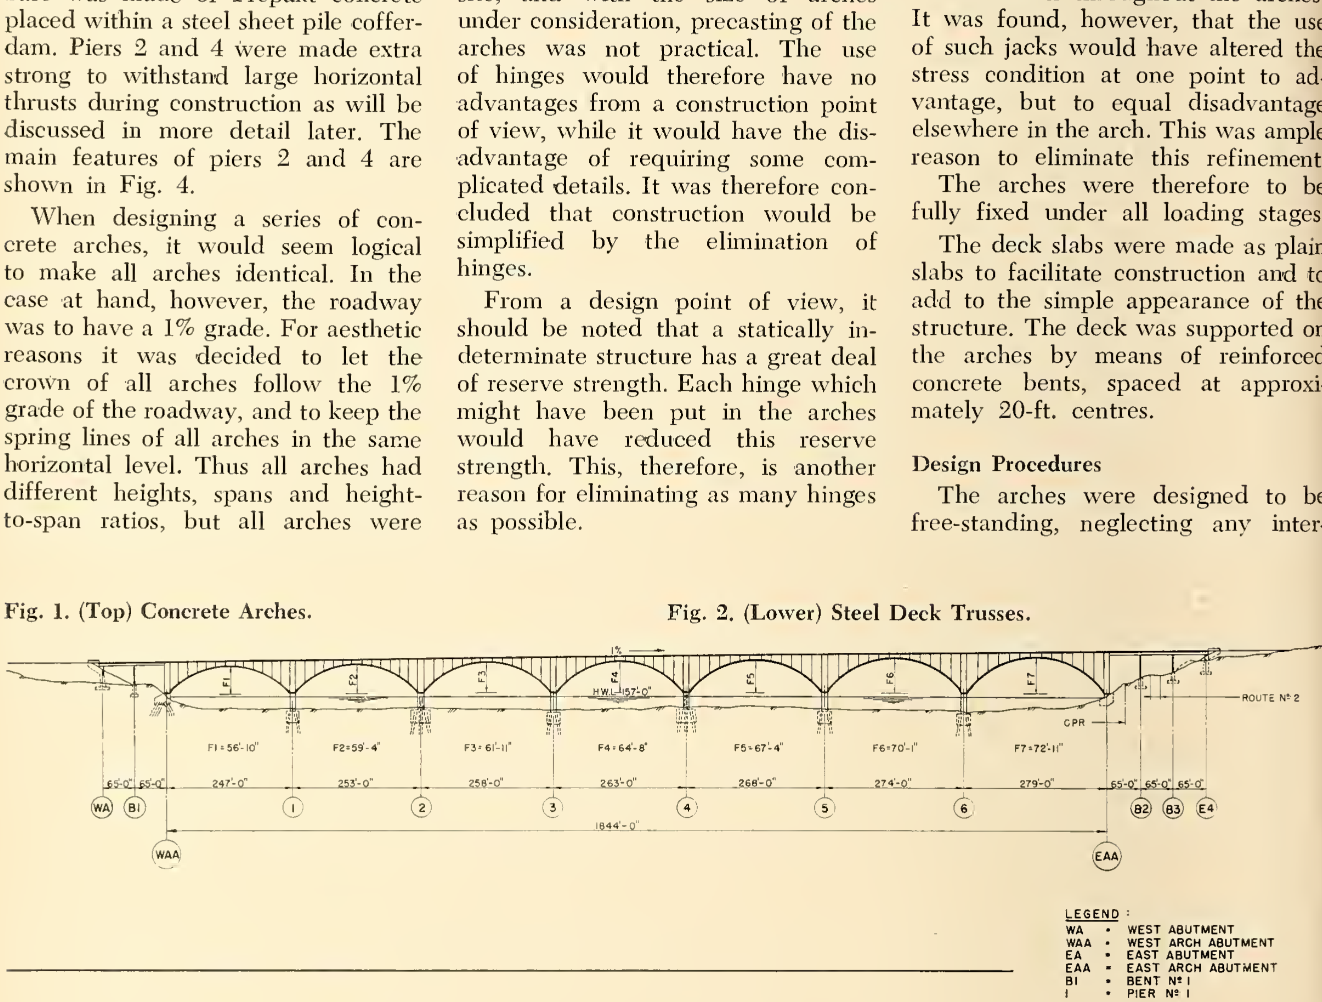
The arches were therefore to be fully fixed under all loading stages.

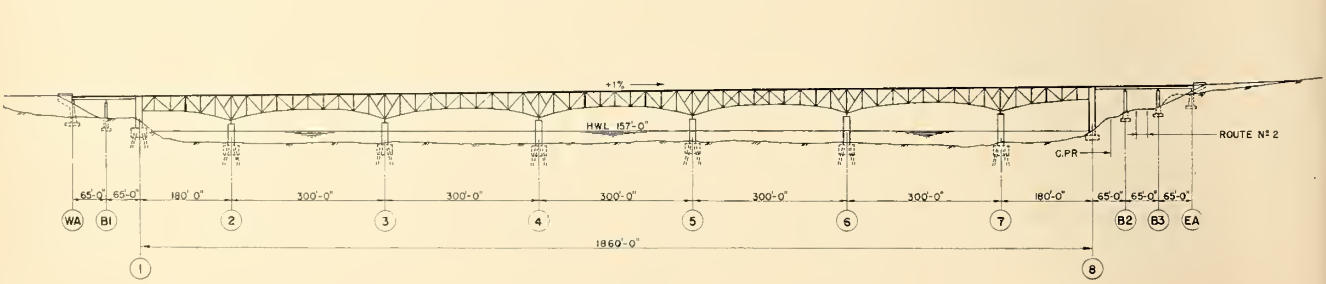
The deck slabs were made as plain slabs to facilitate construction and to add to the simple appearance of the structure. The deck was supported on the arches by means of reinforced concrete bents, spaced at approximately 20-ft. centres.

Design Procedures

The arches were designed to be free-standing, neglecting any inter-

Fig. 1. (Top) Concrete Arches. **Fig. 2. (Lower) Steel Deck Trusses.**





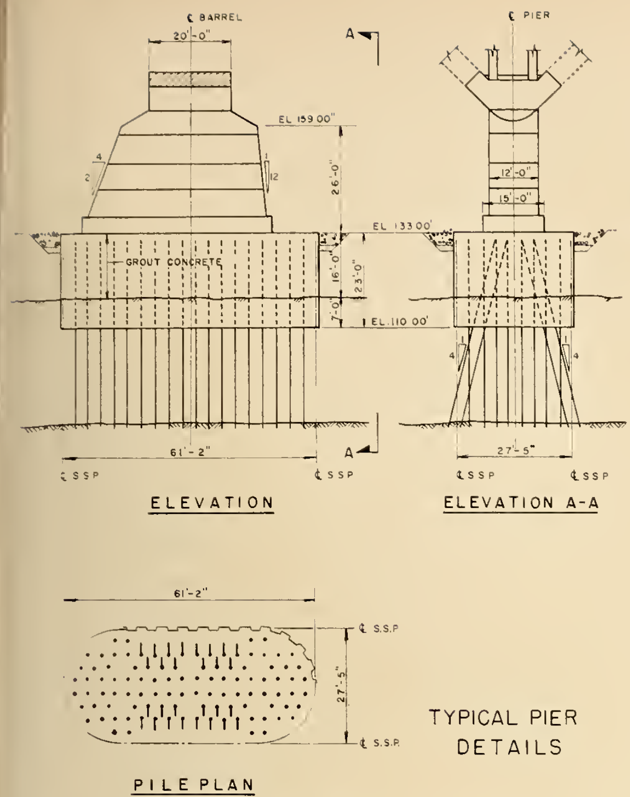


Fig. 3. Typical Pier (Piers 1, 3, 5 and 6).

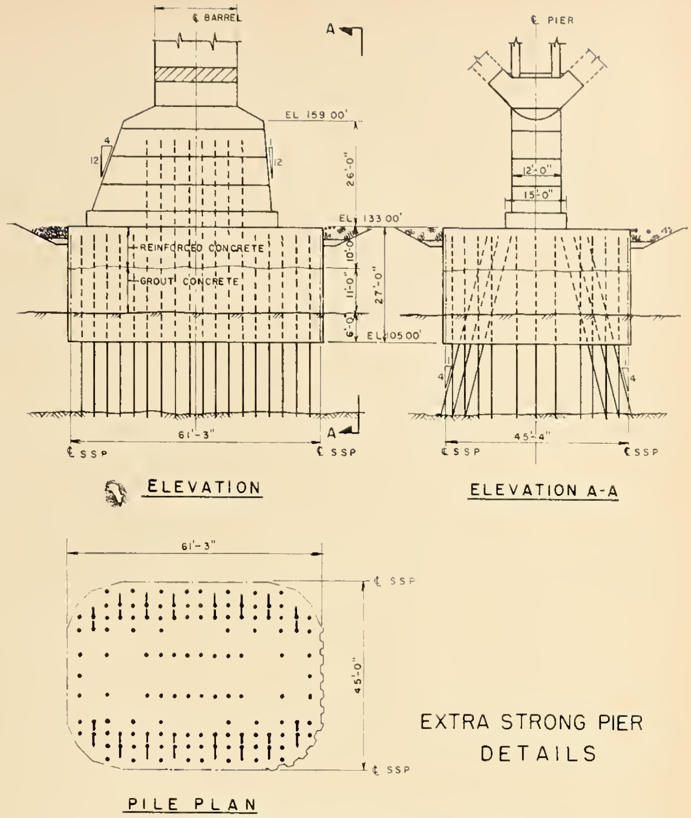

Fig. 4. Extra Strong Pier (Piers 2 and 4).

action between arch and deck. Neglecting this interaction was justified since the stiffness of the deck is about 1/30th that of the arches at the crown. Moreover, the most unfavourable loading of the arches occurred during construction, when the concrete bents were in place and the decks were being poured. During this governing stage it was impossible to count on the deck for stiffness.

The cross section of the arches varies so that the vertical projection of the arch thickness is constant at 3 ft.-6 in. (Fig. 6). The weight of the arches was reduced by approximately 20% by the use of cylindrical voids (Fig. 7).

The expansion of the deck was provided for by expansion joints in the deck above each pier.

Basic Formulae

The free-standing arch as adopted for this design is three times statically indeterminate. The three indeterminates were chosen at the elastic centre as shown in Fig. 8. From these basic formulae the stress distributions under different loading conditions were derived. The above formulae are based on deflections of the arches, due to bending only.

The normal forces in the arches cause a shortening of the arches. The M, N and V resulting from the arch shortening were computed separately. The influence on the stress distribution of deformations due to shear was neglected. This simplification is justified in this type of arch design since the line of compression of the arches follows more or less the parabolic centre line of the arches. The shear forces are therefore small under all conditions of loading and no appreciable forces are induced due to shear deformations.

Dead Load

Any deviation from the design dimensions of a structure will affect the dead load distribution. Since a contractor cannot build without certain tolerances, the actual weight distribution of a concrete structure is never the same as that assumed in the design. Usually there is no allowance made in a reinforced concrete design for variations in the dead load caused by inaccuracies during construction. This is due to the fact that in most instances a slight deviation from the design dimensions causes only very small additional stresses.

This situation is different, however, with arches. A uniform load on the arches causes no moments at all. Any change in a uniform load distribution, whether it is an increase or a decrease, will cause moments to develop in the arch.

A slight inaccuracy during construction will increase the moments in the arch appreciably. It was therefore assumed in the design that any part of the arch might in reality be 5% heavier than called for on the plans. This additional dead load was referred to as "moving dead load". This "moving dead load" was placed in different positions so as to create the worst stress condition in any one section.

In building the structure, the contractor was restricted to a certain construction procedure which was analyzed in the design. The restrictions which were imposed on the contractor will be discussed later.

Live Load

The CSA U-100 uniform live loading or H20-S16 truck loading was used, whichever was governing. This means that in the design of the arches the CSA U-100 live loading was used, and in the design of the deck the H20-S16 truck loading.

The arches were designed for eight construction stages and the final stage with live load. For each stage the influences of temperature,

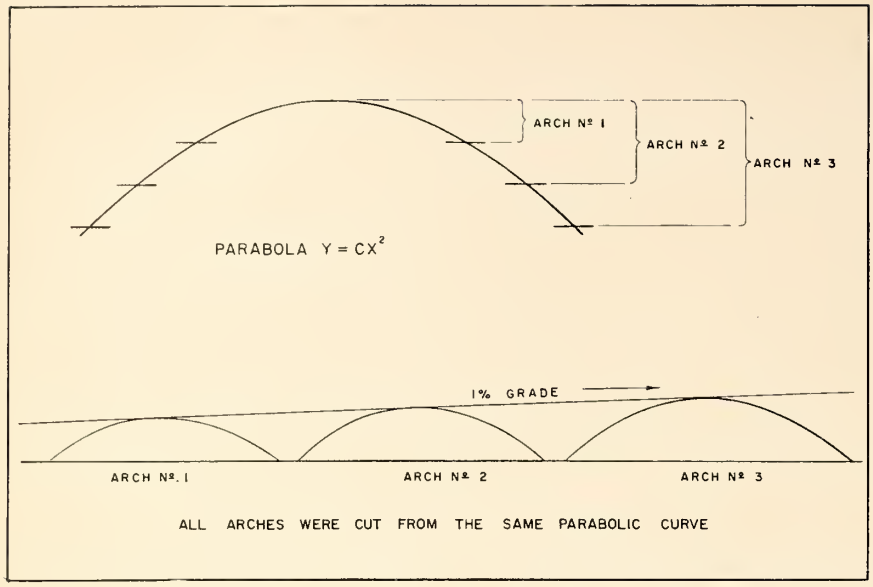

Fig. 5. All arches were cut from the same parabolic shape.

shrinkage, elastic deformation, plastic deformation, wind and assumed foundation settlement were analyzed. Also the stability of the arches was analyzed for each of the above stages of construction. The following assumptions formed the basis of these analyses.

Temperature and Shrinkage

Seasonal temperature rise of 35°F.

Seasonal temperature drop of 55°F.

Daily temperature variation of 20°F difference in temperature between top and bottom of barrel.

For the reinforced concrete of the arches a shrinkage strain of .0003 was assumed.

Elastic and Plastic Deformations

The instantaneous modulus of elasticity of the concrete was assumed to be 4×10^6 p.s.i., referred to as E_1. The creep was assumed to be 2.5 times as large as the instantaneous, elastic deformation. In other words, the modulus of "elasticity" for long time loadings was assumed to be

$$\frac{4 \times 10^6}{3.5} = 1.14 \times 10^6 \text{ p.s.i., referred}$$

to as E_2.

The arch deformation due to the dead load of the structure was computed using E_2, the modulus of elasticity for long time loading. The arch deformation due to live loading was computed using the instantaneous modulus of elasticity E_1. In computing the moments, shears and normal forces which result from these arch deformations, the same variations in the modulus of elasticity were adopted.

The moments, shears and normal forces resulting from arch shortening due to shrinkage were computed using the modulus of elasticity for long time loading E_2. Arch deformations due to daily temperature changes were analyzed using the instantaneous modulus of elasticity E_1.

In computing the moments, shears and normal forces which result from seasonal temperature changes, a third modulus of elasticity E_3 was used. The value assumed for E_3 was 2.7×10^6 p.s.i.

Wind

The wind forces which were assumed in this design were 50 p.s.f. This wind force was assumed to act parallel to the centre line of the structure on twice the area as seen in this direction and perpendicular to the centre line of the structure on 1½ times the area seen in that direction.

Settlement of Foundations

Horizontal, vertical and rotational movements of the foundations were considered. The foundation settlements which were taken into account were computed from the elastic deformations of the foundation piles, assuming that these piles were driven to unyielding rock and neglecting the support which the glacial till provides directly to the structure. Vertical differential foundation settlements have very little effect on the stresses in the arches. However, rotations and movements due to lateral thrust may induce considerable stresses.

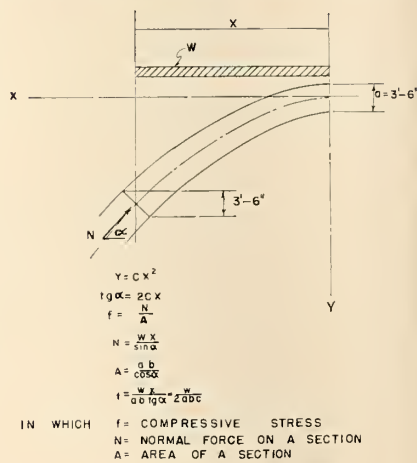
Secondary Stresses

In computing stresses caused by the several factors as discussed above, the arches were assumed to maintain a truly parabolic shape. In reality, however, the arches will deflect and therefore deviate from the parabolic shape. The deflection in any one point of an arch times the thrust at such point results in a moment. Such moments are to be corrected for the influence of the redundant reactions. After this first cycle in the computation of the secondary stresses is completed, the deflections caused by these newly established moments can be computed again and a second cycle of computations of the secondary stresses can be made. This can be repeated until the increase in moments between two successive cycles becomes negligible, in which case the series of successive secondary moments is convergent, which is also proof that the arch is stable. In case it is found that the series of successively computed secondary moments is divergent, the arch is unstable and the proportions of the arch have to be revised.

Stability of the Arches

When working on some early trial sections of the arches, it was found that successively computed secondary moments were divergent, which indicated that the arches which were being studied at that time were unstable. To improve the stability, the size of the arches was increased thus increasing not only the stiffness but also the weight. The advantages gained by the increased stiffness were to a great extent lost due to the increased thrusts. To overcome this problem, circular voids, 2 to 3 ft. in diameter, were introduced in the arch cross section, to reduce the weight and therefore the thrusts, without appreciably reducing the stiffness of the arches. The use of these voids is illustrated in Fig. 9. As a final check, the German Specifications "Massive Brücken, Berechnungsgrundlagen",[9] were applied to the arch section

Fig. 6. Vertical projection of the depth of the arches is constant, resulting in uniform stresses under uniform load.



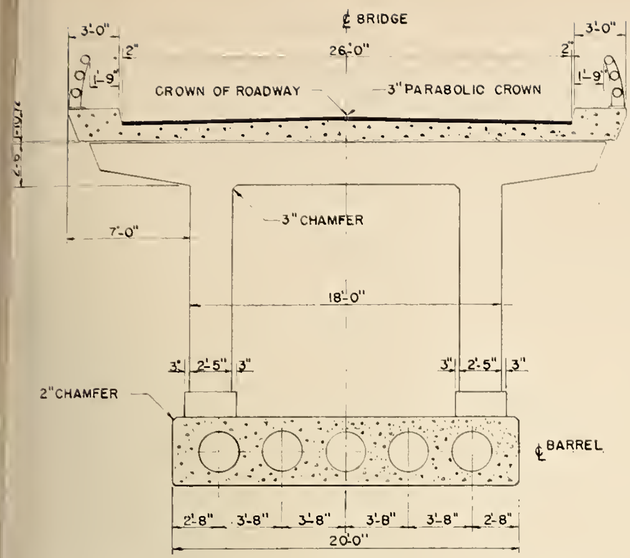


Fig. 7. Typical Cross Section throughout Arch and Deck.

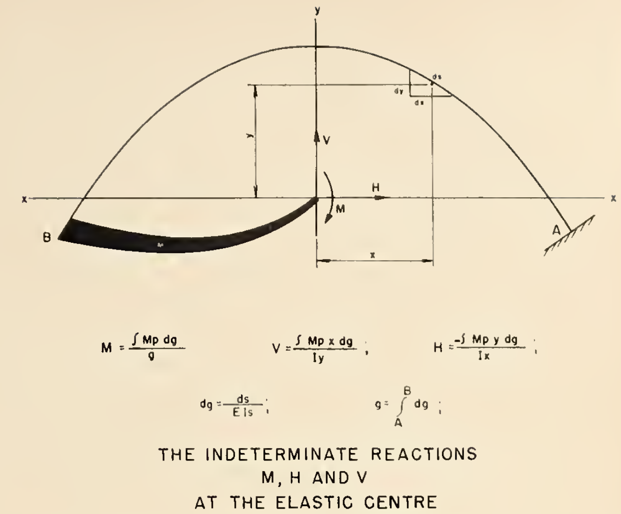

Fig. 8. The indeterminate reactions M, H and V at the elastic centre.

adopted.

Design of the Piers

In the completed structure, the resultant of all forces acting on a pier is virtually a vertical force. The horizontal thrusts from two arches on a pier counteract each other. During construction, however, some of the piers were loaded by an arch barrel from one side only.

One arch exerts, due to its own weight, a horizontal thrust of approximately 800 tons. Our first idea for dealing with such unbalanced forces was to tie the arches back to the west arch abutment by means of cables. Each pier was to be fitted with anchorages for these cables so that any one of the piers could be tied back at any time. This had the advantage that the substructure would not restrict the order in which the arches were to be built.

The disadvantages of the use of cables were that they would be in the way of the contractor and that their stress would have to be checked and adjusted as long as they were in place. There was also the danger that a heavy ice run would result in an ice jam, which might endanger the cables. This last consideration was decisive in abandoning the idea of using cables.

Instead of using cables, piers 2 and 4 were reinforced to resist the unbalanced thrust on their own.

The bases of these piers below ground level were widened from the standard 27 ft.-6 in. to 45 ft.-3 in. (Fig. 4). The steel piles supporting these piers were spread out accordingly and in order to reinforce the shafts of these piers, some of the bearing piles were extended into the shafts. With this arrangement the contractor was required to organize the stripping of the falsework in such a manner that only piers 2 and 4 would at any one time be exposed to unbalanced horizontal thrusts. This also placed on the contractor the requirement of using at least three sets of falsework.

Construction

The construction of this bridge was divided into two contracts:

a) Contract No. 1, for the construction of the complete substructure and the approach spans, and
b) Contract No. 2, for the construction of the arches.

The first contract was awarded in February, 1958, preparations started for the construction in March, 1958.

A concrete plant with two one-half yard mixers was ereeted on sloping terrain on the west bank. The capacity of the plant was at the very best 20 cu. yd. per hour, which was rather low for this type of job. The biggest pours in the first contract were 334 cu. yd. which took approximately 17 hours.

The contractor excavated his sand and gravel by scraper from the river bed and hauled it up the west bank, where it was separated into sand (sizes below ⅜ in.), gravel from ⅜ in. to ¾ in., gravel from ¾ in. to 1½ in. and coarse gravel of 1½ in. and bigger. The coarse gravel was used for grout concrete in the bases of the piers. The fine sand which is required for grout concrete was hauled in separately. The sand and the two remaining gravel sizes were used for reinforced concrete.

The contractor planned to build all piers from causeways. This in itself was a logical decision, since the river bed is very shallow for the better part of the year. The summer of 1958 proved, however, to be extremely wet, so that the contractor had great difficulty to keep the causeways above water.

The progress of the substructure construction in July, 1958, is shown in Fig. 10. On April 4, 1959, all piers were completed except for the last few cu. yd. of pier 6. This pour had to be interrupted on that day due to the rising water level of the Saint John River. The second contract, for the construction of the superstructure, was awarded to the same company whieh started work in July, 1958.

From the unit price bids which were received for this contract, it was clear that the governing factor determining who was to be the successful contractor was the unit price for the falsework.

The bidding highlights for the second contract (superstructure) compare as follows:

	Total bid	*Falsework*	*Total bid less Falsework*
Contractor #1	$1,310,000	$220,000	$1,090,000
Contractor #2	$1,400,000	$340,000	$1,060,000
Contractor #3	$1,570,000	$480,000	$1,090,000

This comparison shows that the differences in the various bids result directly from the differences in cost of the various types of falsework.

The successful contractor had devised a scheme by which the falsework consisted of braced bents at 20 ft. centres. The bents rested on wood piles. The 20 ft. span between bents was bridged by means of a series of plywood box girders. The bents were made up of five verticals of 10 x 10 spruce, with hardwood caps and sills. The plywood box girders consisted of two plywood webs which were glued to the sides of a timber frame. The timber frame was made up of 6 x 6 spruce top and bottom chords interconnected with 6 x 6 spruce verticals. The webs consisted of ½ in. and ⅝ in. plywood. The plywood, glued and nailed to the timber frame, provided the only connection between the members of the frame.

The presence of two "strong piers", piers 2 and 4 as described previously, governed the construction schedule for the arches proper. By November 30, 1958, arch No. 1 was virtually completed. In planning his operations, the contractor had to take into account that the ice could move out as early as the middle of March, 1959. By that time all falsework had to be out of the river and whatever arches were built would have to be able to stand on their own. Only piers 2 and 4 were capable of resisting unbalanced horizontal thrusts from free-standing arches. This meant that by the middle of March, 1959 the construction of the arches had to be completed up to either pier 2 or 4. Therefore the contractor had the choice of building arches 1 and 2, or all of arches 1, 2, 3 and 4 before the freshet.

Due to the slow progress of the substructure, it was considered too much of a risk to try and build the arches up to pier 4 before the freshet. The contractor therefore concentrated on the completion of the substructure during the winter months. When the 1959 spring freshet came on April 4, arches 1 and 2 were completed, all falsework was removed from the river and the substructure was virtually completed. On May 25, 1959, following the freshet, the contractor moved back into the river. During the summer of 1959 all operations went smoothly and efficiently. Progress of the work in June, July and October, 1959 is shown in Figs. 11, 12 and 13 respectively.

The decks on arches 1 and 2 were poured in August, 1959. To avoid unbalanced horizontal forces on pier 1, the deck pours on arches 1 and 2 proceeded symmetrically about pier 1, and to eliminate excessive bending moments in the arches, the pours on each arch proceeded symmetrically about the centre line of each arch as well. The contractor was therefore forced to pour his decks in a rather complicated pattern which, however, did not cause undue difficulties. For supporting the deck forms, the contractor used "span-alls" which proved quite successful.

All concrete work on the structure was completed just before Christmas, 1959. Patching of the holes left by form ties, asphalt paving and installation of railing was done in the early summer of 1960.

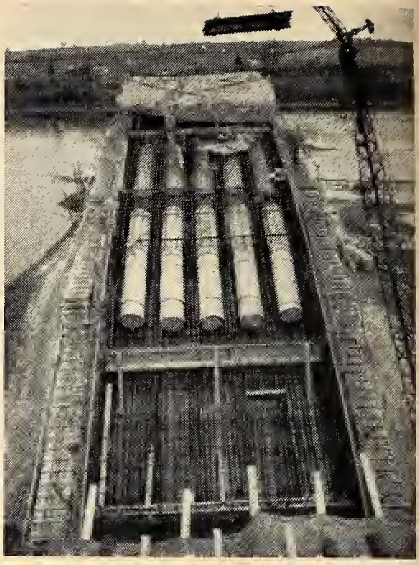

Fig. 9. The arches were made hollow by means of timber barrels. The diameter of the barrels varied from 2 ft. to 3 ft.

Acknowledgments

The Province of New Brunswick, in all matters concerning this structure, was represented by the Hon. J. Stewart Brooks, Minister of Public Works; Mr. R. Palmer, Deputy Minister of Public Works; Mr. B. H. Hagerman, Chief Bridge Engineer.

The Development Engineering Branch of the Department of Public Works in Ottawa was represented by Col. V. S. Thompson, then Chief—Structures Division, and by Messrs. G. D. Reid and H. A. Nason, Supervising Engineers, Trans-Canada Highway, during the early and later phases of construction respectively.

Mr. V. Landriault, Atlas Construction Company Limited, was the Project Manager.

This structure was designed in FENCO's Montreal Office through the joint efforts of Mr. Per Hall, President, Mr. D. F. Murphy, Chief Structural Engineer, Mr. T. J. Sluymer, Design Engineer, and E. van Walsum as Project Engineer.

Fig. 10. Construction of Substructure, July 1958. From foreground to rear, cofferdams of piers 1, 2 and 3. The piles protruding from the cofferdam of pier 2 were later incorporated in the shaft of this pier.

TWO-WAY SLABS and their Supporting Beams

E. M. Rensaa, M.E.I.C.
Rensaa & Minsos, Architects & Consulting Engineers, Edmonton

THE OBJECT of this paper is to give a brief non-mathematical discussion of stress distribution in two-way slabs and their supporting beams. Tables of bending moment coefficients, collected or adapted from other sources, are given. These tables are based on the equations developed by Dr. H. Marcus. A somewhat different form of tables, also based on the equations by Dr. Marcus, are included in the 1960 issue of the National Building Code. This paper is otherwise intended for clarification of that section of the Code and as a brief survey of two-way slab problems. There seems to be a scarcity of literature of this kind. The more scientific approach used in advanced literature is not sufficiently useful for those who have not made a special study of two-way slab theory and have too little time available to do so when a problem is encountered.

The writer was a member of the revision committee who decided to adopt the Marcus theory for the new edition of the National Building Code. It should be pointed out, however, that the responsibility for statements and opinions expressed in this paper are the writer's own and that the opinions may not in every detail be shared by other committee members.

Introduction

The mathematical theory of stress distribution in two-way slabs is quite complex even for a simply supported slab. When, in addition, such slabs are more or less continuous and of variable span ratios, an exact calculation of bending moments and stresses becomes impracticable for design purposes. Many of the most able engineers in Europe beginning with Lagrange in 1813 have worked on these problems and obtained correct solutions for specific cases. Valuable contributions to the theory and its practical application have also been given by North American engineers particularly during the last decades. Among these contributors may be mentioned H. M. Westergaard,[1] S. D. Lash,[2] N. M. Newmark,[3] C. P. Siess,[4] and others. A bibliography on two-way slab publications has been collected by the Department of Civil Engineering, University of Illinois.

An exact mathematical solution generally involves integration of a partial differential equation of the 4th order. Usable particular solutions may also be obtained by dividing the slabs into narrow strips in two directions and writing an equation for each point of intersection of these strips. Since deformation at these intersections are interdependent, a statically indeterminate system will result requiring the solution of a large number of simultaneous equations.

For those who are interested in the study of the mathematical theory of two-way slabs, reference is given to the books by S. Timoshenko and S. Woinowsky-Krieger,[5] H. Marcus,[6] and K. Girkman.[7]

To obtain mathematically correct values of bending moments and shears by means of the theory of elasticity is both difficult and time absorbing. Many attempts have, therefore, been made to work out approximate methods of solution. In order to be usable, such methods should give stresses in substantial agreement with actual ones and should not have too limited applicability. Several such approximate methods have been proposed and used.

Load Distribution from Equal Deflection

An early method of calculating bending moments in two-way slabs was based on the fact that when two centrally located slab strips cross each other, the deflection at the point of intersection must be the same for both strips. Fig. 1 a), b), and c) shows details of this method and formulae for load distribution coefficients for different fixities of supports.

Actual Conditions

The above equal deflection method assumes that the load on each strip is uniform along its complete length. That is not true, however. The load carried by the strip decreases in some manner from the full slab load at the support to a minimum load somewhere near the centre of the span. It is clear that under these circumstances the actual deflection of a slab cannot generally be found by means of an assumed uniform loading along the complete length of the strip. The method gives, however, bending moments that err on the safe side for the ordinary span length ratios of 1 to 2.

The bending moment does not necessarily depend on the actual deflection, but more on the curvature of bending at the section in question. In a very long slab we may have a considerable deflection at the centre of the long span strip, but there will be little or no longitudinal bending moment at the centre of span if there is little or no curvature of bending at that point in the longitudinal direction such as is indicated on Fig. 2. If there is no curvature of bending, there is evidently no longitudinal loading along such part of a strip and this indicates that the complete load on this centre portion is carried by the strip spanning in the transverse direction. However, even in such a case where there may be no two-way slab action at the centre portion of slab, such action will occur near both ends of the long span and the slab will still need reinforcement on these portions. The approximate value of such bending moments is indicated on Fig. 2. The maximum positive bending moment in the longtiudinal direction for a long slab is, according to Dischinger,[8] located at a distance of about lx/4 from the support regardless of support restraint. For a slab with ly/1x = 2 simply supported, Marcus[6] gives the location of maximum positive bending moment from the support as lx/2. This location will likely apply also to slabs with lesser span ratios than 2.

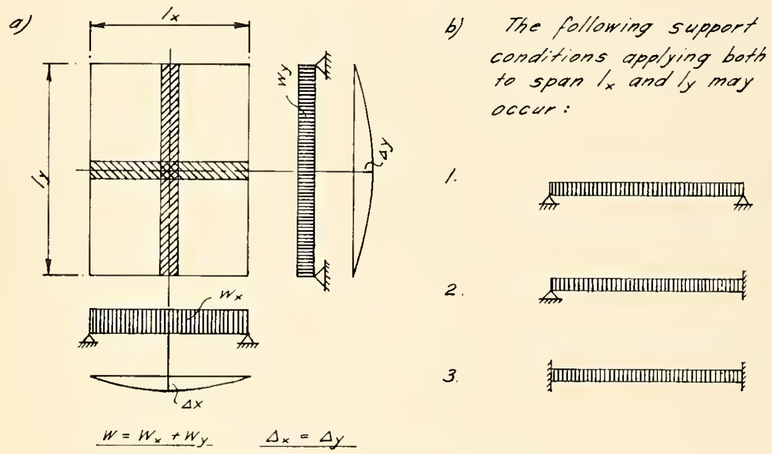
Both the exact and approximate theories assume the material to be homogeneous and the slab to have the same moment of inertia in both directions. This assumption is not correct for reinforced concrete. The moments of inertia are influenced by the extent of cracking of concrete in the tension zone and by the amount and location of reinforcement. These properties are of necessity different even for square slabs because the steel in one layer is placed on top of the reinforcement placed in the opposite direction.

We usually determine the amount of reinforcing steel in each direction on basis of the bending moments and allowable steel stresses. This is not generally correct for two-way slabs. We can only get the calculated stress if the curvature of bending and the effective depth correspond to the assumed steel stress. The angular curvature of bending is generally less in the long direction and the steel stress cannot, therefore, simultaneously reach the same value as in the short direction. It can only reach working stress intensity after the short span steel has been stressed to a higher value. The ultimate strength of the slab may not, however, be greatly affected by this condition. The reason for this is that the reinforcement having the least stress will receive additional load after the most highly stressed reinforcement has started to yield.

Plastic deformation of concrete, being approximately proportional to the compressive stress, will also tend to transfer stress to the least stressed reinforcement. This plastic deformation is also beneficial in other respect. It makes it unnecessary to reinforce for the absolute maximum positive and negative bending moments, but allows the use of a more average bending moment on a certain width of slab. This is a condition utilized in some code provisions for stipulation of bending moment coefficients.

In the case of a slab continuous over supports we have the additional condition of variable torsional resistance of the beams supporting the slab. Near the intersection of two beams or at a column the torsional resistance will be largest and will decrease towards the centre of the beam span. This will influence the effect of uneven loading on adjacent slab panels and the assumption of knife edge support is in most cases even less true than for one-way sla[illegible] In general it may be said th[illegible] influence of uneven loading is [illegible] a two-way slab system th[illegible] way slabs because of th[illegible] of loading in two directions.

It should be mentioned that the Poisson ratio of transverse deformation has an effect on the magnitude of bending moments. There is some uncertainty what the Poisson ratio is for concrete as this will depend to a certain extent on concrete strength and stress intensity. Figures of $\frac{1}{5}$ to $\frac{1}{8}$ are sometimes given. Assuming a ratio $\frac{1}{6}$ and a square panel simply supported, the effect would increase the bending moment as derived from Table I from $wL^2/27.4$ to $wL^2/23.4$. For steel with a Poisson ratio of 0.3 the corresponding bending moment would be $wL^2/21.1$. In cases where very accurate stress analysis is required it may be advisable to investigate the effect of the Poisson ratio. A study of such problems has been made by F. Czerny and other.[9] Considering the beneficial effect of plastic deformation and of torsional resistance of supporting beams, it is probably sufficiently safe in most cases of building construction to assume the Poisson ratio equal to zero. Furthermore, it is also usual to design for an average bending moment in a panel strip instead of the absolute maximum value of the bending moment. Most of the published tables of coefficients are based on Poisson's ratio being zero and this simplification also applies to the tables given in this paper.



Maximum bending moments and deflections for uniform loading will be as follows for the above support conditions:

Span l_x:

1. $M_x = \frac{w_x l_x^2}{8}$ $\quad \Delta_x = \frac{5 w_x l_x^4}{384 EI}$

2. $M_x = \frac{9 w_x l_x^2}{128}$ $\quad \Delta_x = \frac{2 w_x l_x^4}{384 EI}$

3. $M_x = \frac{w_x l_x^2}{24}$ $\quad \Delta_x = \frac{w_x l_x^4}{384 EI}$

Equations for M_y and Δ_y can be obtained in a similar manner.

c) When deflections for spans l_x and l_y are equated we get: $w_x = C\,w$ and $w_y = (1-c)\,w$.

C may be obtained from the following table:

Support Condition	1	2	3	4	5	6	7	8	9
C	$\frac{l_y^4}{l_x^4+l_y^4}$	$\frac{5l_y^4}{2l_x^4+5l_y^4}$	$\frac{2l_y^4}{5l_x^4+2l_y^4}$	$\frac{l_y^4}{l_x^4+l_y^4}$	$\frac{5l_y^4}{l_x^4+5l_y^4}$	$\frac{l_y^4}{5l_x^4+l_y^4}$	$\frac{2l_y^4}{l_x^4+2l_y^4}$	$\frac{l_y^4}{2l_x^4+l_y^4}$	$\frac{l_y^4}{l_x^4+l_y^4}$

Fig. 1.

The Effect of Torsion

The principal source of error in the "Equal Deflection Method" is the neglect of the influence of torsional resistance of the slab against deflection. If we assume a strip of a certain width located in a position away from the centre line of slab, it is clear that the deflection on both sides of the strip is not the same excepting at its supports. The reason for this is the inter-connection with the adjacent strips which do not have an equal deflection. The deflection at any point must correspond to the general curvature of deformation of the slab in a transverse direction, but the deflection on each side of a strip will in general not be equal excepting at a valley of deflection and at an unflexed support. This applies, of course, only if the strip ends are

$+M = \frac{1}{21.1} wl^2$

$R_b = +1.2375 \frac{W}{4}$

$R_c = -0.2375 \frac{W}{4}$

$R_b + R_c = \frac{W}{4}$

W = Total Load

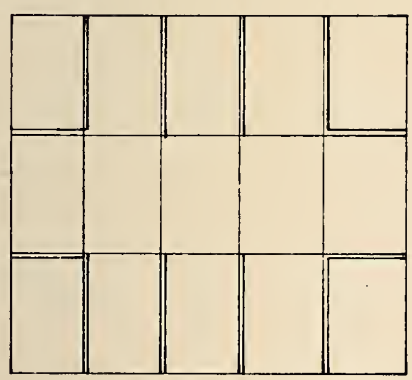

Fig. 5

fastened to the supports in such a manner that they cannot rotate freely, but are forced to follow the same elevation as the supporting beam. Fig. 3 illustrates this condition.

The result is that in most locations each strip in addition to longitudinal bending is also subject to torsion. The sum of torsional resistance of the slab strips will decrease the total deflection and consequently also decrease the bending moment in the slab. This reduction is sometimes very considerable. For instance, in the case of a square slab simply supported, the load distribution is equal in both directions. If we disregard the effect of torsion, the maximum bending moment for uniform loading would then be: $M = wL^2/16$. The effect of torsion, however, with Poisson's ratio equal to zero reduces the bending moment to $wL^2/27.4$. This torsional effect is greatest for simply supported slabs and decreases for continuous construction due to a much smaller total deflection and consequently a smaller angular rotation. The effect of torsion on a square slab uniformly loaded and with simple supports (Case 1) is to reduce the bending moment by about 49% while in a case with built-in edges (Case 9) the maximum positive bending moment reduces from $wL_x^2/48$ to $wL_x^2/55.7$ or only about 15%.

It will be understood from the above discussion that it is not practicable to carry out exact calculations of bending moments in two-way slabs for design purposes. The best we can do is to obtain by some approximate method design figures which are fairly realistic and which will give about equal safety factors for different cases of span proportions and support restraints. Several attempts have been made to work out acceptable approximate methods. Some such have proven to be fairly accurate but rather work absorbing. That applies for instance to Method I of the American Concrete Institute Building Code (A.C.I. 318-56). Method II of the same code is easier to apply but is not very satisfactory as far as accuracy is concerned. Method II which was used in the National Building Code of 1953 will, therefore, not be included in the 1960 edition of that code.

The Marcus Method

Dr. H. Marcus has made an extensive study of two-way slab problems and published a number of papers on the subject. In a book first published in 1924 and in revised form in 1932[6] he outlines the mathematical theory and gives his own particular method for solving such problems. A paper published by him in 1924 contained approximate methods for solving two-way slab problems.[10] This method was adopted for the German reinforced concrete code of 1925 and is still in use in that country. An outline of the method was given in the September 1944 issue of the Journal of the American Concrete Institute.

The approximate equations by Dr. Marcus were used to work out tables of coefficients for different span ratios and support conditions. Such tables may for instance be found in the German "Beton-Kalender."[11] The tables there are made up for six support conditions. This makes it necessary to reverse some cases of span proportions which increases the possibility of making mistakes. It is much more convenient to use nine support conditions and that has been done for the tables contained in the new reinforced concrete specifications of the 1960 National Building Code. The tables contained in that code are based on the Marcus theory and have been supplied by Mr. Paul Rogers, Member of the American Concrete Institute.

Tables of coefficients based on the more mathematically exact theory by Kirchhoff have been worked out by F. Czerny and may be found in the 1959 edition of the "Beton-Kalender". The figures, even though more accurate, do not seem to differ materially from those found by the more approximate Marcus theory.

Dr. F. Dischinger published in 1942 a very thorough discussion of load intensity and distribution on supports for two-way slabs.[12] He also included new tables of coefficients for slab moments based on the Marcus theory. These tables are set up in a somewhat different form from those in the National Building Code and are worked out for much closer intervals so that interpolation becomes unnecessary. The coefficients for bending moments in both directions are made a function of the short span only and that makes it necessary to square one length only when calculating bending moments. The coefficients in the Dischinger tables are divisors which contain only one decimal figure and for that reason appear to be best suited for ordinary slide rule calculations. Tables 1 and 4 have been adopted from Dischinger's work. The tabulated coefficients in Table 3 are for calculation of negative bending moments across the supporting beams. This table has been worked out by the writer from the basic equations for negative bending moments in Table 5.

It should be mentioned that the negative bending moments from the Marcus equations do not represent maximum theoretical values but are more like an average on the middle strip over the supports. The decrease from the maximum value is about 15%. The positive bending moments represent, however, maximum values for zero Poisson's ratio. Considering the middle strip as a whole, there is about an average balance of moment at support and some average over-design at the centre of span. Such an adjustment in bending moments is considered to be quite in order.

Table 2 contains coefficients for live load positive bending moments. The condition for such bending moments is checkerboard loading on adjacent spans and knife edge supports are generally assumed. These load and support conditions are not very likely to occur, so the coefficients should only be considered as approximate. This table has been worked out by the writer on basis of the corresponding table 4.5.5.C contained in the National Building Code, but has been changed into the same form as used by Dischinger. All bending moments are functions of the short span only and intervals have been determined from graphs.

The resulting bending moments found by means of all the tables should be in a substantial agreement with those obtained by using the Rogers tables. It might be pointed out that the coefficients contained in these tables need adjustment if adjacent spans differ much in length.

Table 5 gives equations for both positive and negative bending moments in accordance with the approximate Marcus theory.

Table 4 shows dead load bending moment coefficients for four support conditions. These apply where there are one or more free corners which are not fixed to the supports in such a manner that the existing bending moment in the slab can be taken and where the slab is not securely held down to prevent uplift of the corner. There may be cases where omission of such reinforcement is most convenient. Corner cracks, are, however, likely to occur under such conditions. The coefficients in Table 4 can be derived from the general equations in Table 5 as follows. The parts of the equations inside the brackets represent the torsional effect which we may call T. To get the coefficients in Table 4 substitute a new function $(1 + T)/2$ instead of T. In the case of a so-called waffle slab, these terms should be assumed as $T = 1$, since such a slab cannot be assumed to have an equal torsional resistance to a solid slab.

The Code allows concrete joists with fillers of hollow concrete units or clay tile with or without concrete top slabs and concrete joists with top slabs placed monolithically with the joists to be treated the same as solid slabs in calculating bending moments. The writer does not consider this to be justified, because such hollow slabs will evidently have far less torsional rigidity than solid slabs. It would seem advisable in such cases to neglect the effect of torsion.

Conditions at Free Corners

Bending conditions at corners would seem to justify some detailed explanation. Fig. 4 indicates how the bending moment acts along a diagonal. M_1 is the bending moment in a transverse direction to the diagonal. It is a positive bending moment giving tension in the bottom of the slab. M_2 is a negative bending moment in the direction of the diagonal giving tension on top of the slab at or near the corner. At centre of slab, both M_1 and M_2 are positive and of equal magnitude to the positive bending moment parallel to the sides of slab. It should be noted that both M_1 and M_2 are of the same magnitude but with opposite signs at the slab corner. From there M_1 increases slowly towards the centre of slab while M_2 decreases until it reaches a point of inflection from which it becomes positive. Unless sufficient reinforcement exists in the slab both at bottom and top to resist M_1 and M_2 cracking may result which will destroy the lever action of the corner and this will result in an increased positive bending moment at the centre of slab. The same will occur in case the corner is not held securely to the marginal beam and, therefore, can lift free off the beam. It may be noted that M_1 remains relatively large all the way to the corner and will generally require more positive reinforcement near this than what corresponds to a bending moment parallel and close to a marginal support.

The Code states that "where the slab is not securely attached to the supporting beams or walls, special reinforcement shall be provided at exterior corners in both the bottom and top of the slab". It would appear that this clause is somewhat unclear. It is in the writer's opinion not sufficient to attach the slab to its support unless the support has a sufficient torsional resistance to provide a near fixity against rotation in the vicinity of the corner. That is not always the case if the slab is supported on a steel beam or on a brick wall. In the case of concrete beams of ordinary proportions, we will in most cases have near fixity at a corner against rotation. The code provision will then, as a rule, suffice provided, of course, that there is a sufficient amount of positive and negative reinforcement present on top and bottom and of slab. Fig. 6 will illustrate why the corner reinforcement is so important. The contours of deflection will not be parallel to the sides, but follow a circular pattern near the corners. The slab here is quite rigid in a direction transversely to the diagonal because the slab span here is short. A kind of "beam" will, therefore, form across the slab at and near the corner. This "beam" will not only carry its own direct load, but will also receive load from the central portion of slab. Furthermore, since the slab corner generally is held down, it will, in addition, load the "beam" by adding a negative bending moment parallel to the diagonal.

The negative bending moment may be thought of as a force couple of which the innermost force will be a direct load on the "beam". This load condition creates the bending moment shown on Fig. 4 as M_2. If there is insufficient reinforcement at the bottom of slab, a diagonal crack may form, the slab will settle and M_2 will disappear since there is no longer a "beam" to carry the load mentioned above. If on the other hand there is sufficient steel at the bottom of slab but none at the top, a crack may form there perpendicular to the diagonal. The "beam" would still carry some load but there would be no reduction of positive bending moment at the centre from the destroyed force couple equal to M_2.

The Code requires an amount of negative reinforcement equal to ¾ of that for the positive bending moment along discontinuous edges. This relatively high requirement would not appear to be necessary for the centre strip unless the support has an unusual torsional rigidity and we want to avoid a visible crack between slab and beam. It is the writer's opinion that such cracks should be avoided but it is difficult to give a definite rule how much reinforcement is necessary for that purpose. For the centre strip of half the slab width one-half of the positive reinforcing should suffice in most cases. It is a different case with the side strips. Here the three-quarter reinforcement for negative bending moment is not too high as is evident from an inspection of the bending moment diagrams on Fig. 4. The high bending moment at free corners cannot evidently be taken proper care of without addition of extra corner reinforcement. In doubtful cases of support restraint it would seem ad-

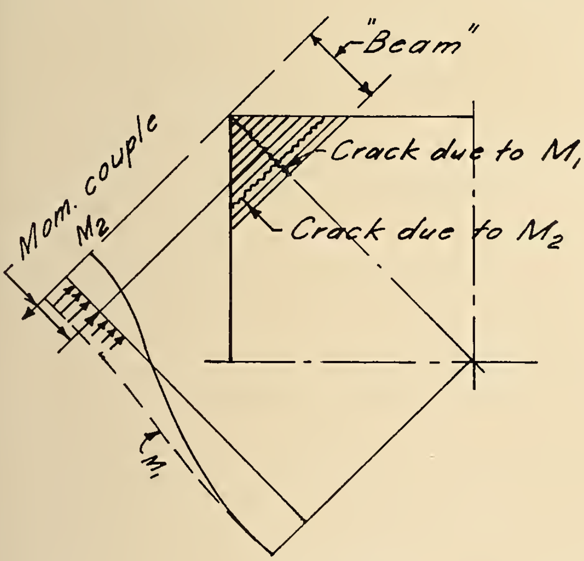

Fig. 6

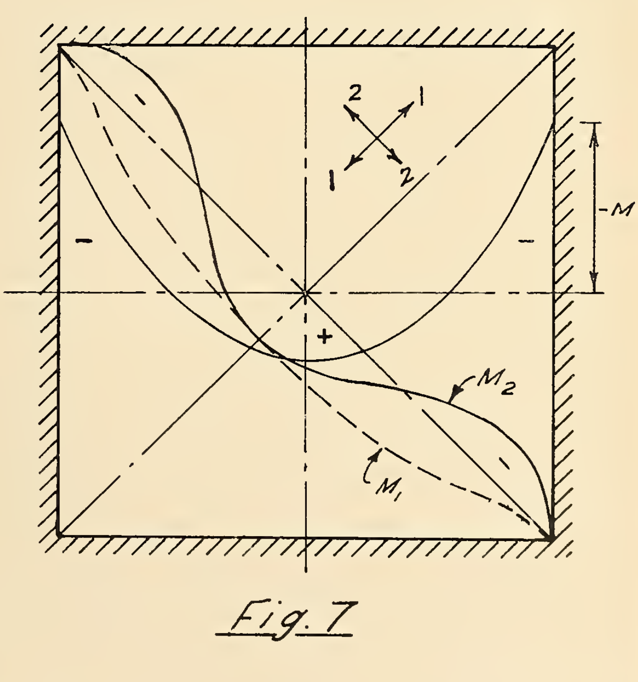

Fig. 7

visable to use Table 4 for calculation of positive bending moments.

It might be of interest to compare the freely supported slab with a square slab fixed against rotation along all edges and loaded uniformly. The bending moments along a diagonal and transversely to this are shown on Fig. 7. It may be noted that both M_1 and M_2 are zero at the corner. M_1 increases slowly from the zero value at the corner and can be taken care of by the ordinary negative reinforcement. There is no problem in this case with the slab lifting free of its support.

Concentrated Loads on Two-Way Slabs

The exact mathematical analysis of two-way slabs with concentrated loads is far more difficult than an analysis for uniform loading. Neither is there, as far as the writer knows, any approximate method of analysis comparable in accuracy to the Marcus equations for uniform loading. There is, of course, no real point loads but rather loaded areas of variable extent and shape. One special type is the line loading such as may be caused by partition walls in a building.

The problem of stress analysis due to concentrated loading is of considerable importance in connection with design of bridge decks and a great deal of analytical work has been done in this connection. Since it is not possible to express bending

moments explicitly in formulae, a complete analysis has to be made for any particular load position. From a series of such analyses, it is possible to draw area influence contour lines for bending moments at significant points of slab. Several such influence area diagrams have been worked out and published. Of such publications might be mentioned that by Pucher.[13] (See also Reference 5 Chapter 10.)

For ordinary building design an exact analysis of bending moments in two-way slabs due to concentrated loading would be too time absorbing, but it is necessary even here to get some idea of the bending moments and shearing stresses. The writer thinks that in the case of walls this might be done about in the same manner as outlined on Fig. 1 for uniform loading. Two strips perpendicular to each other can be assumed to carry the load. There is considerable uncertainty how wide a strip parallel to a wall can be considered as effective. Perhaps a reasonable assumption is a width of one-third the span length on each side of the wall plus the thickness of the wall itself. Transversely to the wall the effective width would, of course, be the length of the wall. One strip would then have a uniform load and the other a concentrated load. By equating the deflection at the point of intersection the approximate load distribution could be found. If in addition we disregard the effect of torsion, the result should err on the safe side.

It is evidently impracticable in most cases to obtain an accurate analysis of partition wall loading. The walls, even if of tile or other kinds of masonry, will not follow the floor slab completely if the slab deflects either due to live loading or due to long time plastic deformation. It is not unusual to see the floor deflect free of the base of wall for a compartively long stretch. This bridging effect may

TABLE 2: COEFFICIENTS FOR LIVE LOAD POSITIVE MOMENTS.

continue until a crack forms in the wall and that occurs particularly at door openings. A lot of cracking has been experienced in this connection with two-way slabs because of too great flexibility. Since the compressive strength of the concrete can be utilized in two directions there is a tendency to make such slabs too thin. The ultimate strength of a properly designed two-way slab will, therefore, almost always depend on the strength of the steel reinforcement.

Another problem encountered is to find the bending moment from load concentrations such as file cabinets and accounting machinery. A somewhat similar method to that proposed for distribution of wall load might be used. The effective slab strips can, according to some code rules, be assumed as either the width of the load plus two-thirds the span length, or alternatively as twice the distance from the load centre to the closest support in the direction of span. The smallest of these values to be used. Solving equations for equal deflection of two perpendicular slab strips will then give the load distribution between the two strips. Any great accuracy by such a method can hardly be expected but the result will likely be safe.

Beam Loading From Two-Way Slabs

The load distribution obtained from the equations in Fig. 1 was used for some time to obtain the loading on the supporting beams. The result was not bad as far as the beams in the long direction were concerned. For the short span beams the uniform loading found by this load distribution method was far from correct and the corresponding bending moment in the beams might only be a small fraction of the true values. A better division is to assume load distribution to each beam from the tributary areas of the panel bounded by the intersection of 45° lines from the corners with the median line of the panel parallel to the long side. This is an approximate load distribution used in most building codes. Even this method is not accurate especially for the short span beams. The method makes the loading of the short span beam independent of the slab length and that is not quite correct. The actual conditions are as follows:

We have found that the effect of torsion is to reduce the bending moment in the slab greatly. However, this effect is not obtained without some extra loading of the supporting beams. Considering Fig. 3 it is clear that in addition to the direct load from the slab each slab strip superimposes a torsional effect on the beams. This effect tends to transfer the reaction of each strip in the same direction as the slab twists, that is, towards the centre of span. Each strip presses down at one edge of its support and has an uplift effect at the other edge. The total effect of twisting of all the slab strips is to transfer the load on the beam to some extent towards its centre. This effect is, of course, only present where there is a torsional effect and would, for instance, not be of any importance on the central portion of a long slab such as is shown on Fig. 2. The shifting of load towards the centre of beam will, of course, increase the bending moment in the beam.

In the case of a rectangular slab simply supported it can be proven that there is a force creating uplift at the corner and there must, therefore, be a corresponding increase in the downward reaction of the slab on the beam since the algebraic sum of all the loads and forces acting on the beam must be equal to the weight of slab and its superimposed load. This can only be the case when the load on the beam, apart from the corner force, is greater than the gravity load. The loads shown in connection with Fig. 4 have been taken from Dischinger's work. An elementary consideration of Fig. 6 will also make it clear that the central loading must be greater than the gravity loading.

It should be noted that the corner force indicated on Fig. 4 is not present at continuous corners and we do not, therefore, have the same increase in beam loading where the slab is continuous. Even with continuous slabs there may be some shifting of load towards the centre caused by torsion, but the effect is generally small due to less deflection.

The correct way of calculating the bending moment in a beam would be analyze the slab panel with the parallel supporting beams as a unit. The bending moment carried by the slab in that direction would then be subtracted from the total bending moment in order to find how much of the total bending moment the beams have to carry. Such analyses have been made by Dr. Dischinger. They show that the triangular and trapezoid loadings as contained in the codes will give substantially correct results for interior panels of two-way slab systems but should be corrected for exterior panels. Referring to Fig. 5 Dr. Dischinger proposed that the beams marked with double lines should have the bending moments increased as follows:

In the X-direction for Ly Lx = 1

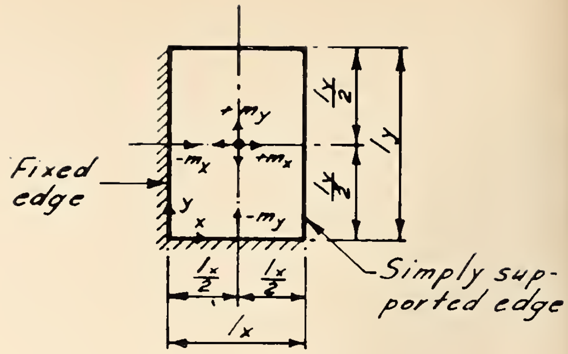
TABLE 5: EQUATIONS BY H. MARCUS FOR BENDING MOMENTS IN TWO-WAY SLABS CARRYING A UNIFORMLY DISTRIBUTED LOAD.

Note: The equations are based upon Poisson's ratio being equal to zero.



$$\varepsilon = \frac{l_y}{l_x}$$

TYPE OF SLAB	MAXIMUM BENDING MOMENTS			
	POSITIVE BENDING MOMENTS		NEGATIVE BENDING MOMENTS	
	$+m_x$	$+m_y$	$-m_x$	$-m_y$
1	$\frac{1}{8}\cdot\frac{\varepsilon^4}{1+\varepsilon^4}\left(1-\frac{5}{6}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	$\frac{1}{8}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\left(1-\frac{5}{6}\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	—	—
2	$\frac{45}{128}\cdot\frac{\varepsilon^4}{2+5\varepsilon^4}\left(1-\frac{75}{32}\frac{\varepsilon^2}{2+5\varepsilon^4}\right)wl_x^2$	$\frac{1}{4}\cdot\frac{\varepsilon^2}{2+5\varepsilon^4}\left(1-\frac{5}{3}\frac{\varepsilon^2}{2+5\varepsilon^4}\right)wl_x^2$	$-\frac{5}{8}\cdot\frac{\varepsilon^4}{2+5\varepsilon^4}wl_x^2$	—
3	$\frac{1}{4}\cdot\frac{\varepsilon^4}{5+2\varepsilon^4}\left(1-\frac{5}{3}\frac{\varepsilon^2}{5+2\varepsilon^4}\right)wl_x^2$	$\frac{45}{128}\cdot\frac{\varepsilon^2}{5+2\varepsilon^4}\left(1-\frac{75}{32}\frac{\varepsilon^2}{5+2\varepsilon^4}\right)wl_x^2$	—	$-\frac{5}{8}\cdot\frac{\varepsilon^2}{5+2\varepsilon^4}wl_x^2$
4	$\frac{9}{128}\cdot\frac{\varepsilon^4}{1+\varepsilon^4}\left(1-\frac{15}{32}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	$\frac{9}{128}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\left(1-\frac{15}{32}\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	$-\frac{1}{8}\cdot\frac{\varepsilon^4}{1+\varepsilon^4}wl_x^2$	$-\frac{1}{8}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}wl_x^2$
5	$\frac{5}{24}\cdot\frac{\varepsilon^4}{1+5\varepsilon^4}\left(1-\frac{25}{18}\cdot\frac{\varepsilon^2}{1+5\varepsilon^4}\right)wl_x^2$	$\frac{1}{8}\cdot\frac{\varepsilon^2}{1+5\varepsilon^4}\left(1-\frac{5}{6}\frac{\varepsilon^2}{1+5\varepsilon^4}\right)wl_x^2$	$-\frac{5}{12}\cdot\frac{\varepsilon^4}{1+5\varepsilon^4}wl_x^2$	—
6	$\frac{1}{8}\cdot\frac{\varepsilon^4}{5+\varepsilon^4}\left(1-\frac{5}{6}\frac{\varepsilon^2}{5+\varepsilon^4}\right)wl_x^2$	$\frac{5}{24}\cdot\frac{\varepsilon^2}{5+\varepsilon^4}\left(1-\frac{25}{18}\frac{\varepsilon^2}{5+\varepsilon^4}\right)wl_x^2$	—	$-\frac{5}{12}\cdot\frac{\varepsilon^2}{5+\varepsilon^4}wl_x^2$
7	$\frac{1}{12}\cdot\frac{\varepsilon^4}{1+2\varepsilon^4}\left(1-\frac{5}{9}\frac{\varepsilon^2}{1+2\varepsilon^4}\right)wl_x^2$	$\frac{9}{128}\cdot\frac{\varepsilon^2}{1+2\varepsilon^4}\left(1-\frac{15}{32}\frac{\varepsilon^2}{1+2\varepsilon^4}\right)wl_x^2$	$-\frac{1}{6}\cdot\frac{\varepsilon^4}{1+2\varepsilon^4}wl_x^2$	$-\frac{1}{8}\cdot\frac{\varepsilon^2}{1+2\varepsilon^4}wl_x^2$
8	$\frac{9}{128}\cdot\frac{\varepsilon^4}{2+\varepsilon^4}\left(1-\frac{15}{32}\cdot\frac{\varepsilon^2}{2+\varepsilon^4}\right)wl_x^2$	$\frac{1}{12}\cdot\frac{\varepsilon^2}{2+\varepsilon^4}\left(1-\frac{5}{9}\frac{\varepsilon^2}{2+\varepsilon^4}\right)wl_x^2$	$-\frac{1}{8}\cdot\frac{\varepsilon^4}{2+\varepsilon^4}wl_x^2$	$-\frac{1}{6}\cdot\frac{\varepsilon^2}{2+\varepsilon^4}wl_x^2$
9	$\frac{1}{24}\cdot\frac{\varepsilon^4}{1+\varepsilon^4}\left(1-\frac{5}{18}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	$\frac{1}{24}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\left(1-\frac{5}{18}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}\right)wl_x^2$	$-\frac{1}{12}\cdot\frac{\varepsilon^4}{1+\varepsilon^4}wl_x^2$	$-\frac{1}{12}\cdot\frac{\varepsilon^2}{1+\varepsilon^4}wl_x^2$

Increase by 25%
for Ly/Lx = 2 Increase by 35%
In the Y-direction for Ly/Lx = 1 Increase by 25%
for Ly/Lx = 2 Increase by 0
For values between these limits obtain the percentage increase by interpolation.

Since the actual loading on the beam in certain cases is greater than the gravity loading and generally greater than the load triangle on the short span beams, it follows that the shear in such beams is correspondingly higher. It is, therefore, recommended that the shear reinforcement be increased corresponding to the greater loading.

Discussion

FORMATION OF CONTINUOUS CHIPS IN METAL CUTTING

W. B. Rice, M.E.I.C.
Assoc. Prof., Dept. of Mechanical Engineering, Queen's University, Kingston

The Engineering Journal, February 1961, page 41.

Discussion by J. C. Millson

Although considerable work has been done in the metal cutting field in the U.S.A. and elsewhere, there has been little or none done in Canada and, having in mind its importance to all our industry, this is a rather surprising state of affairs. Your work is interesting both from the standpoint of the material used, aluminium, and the fact that it adds considerably to our knowledge of metal cutting behaviour.

I would like to ask if you would care to expand on your conclusion that "the chip is not peeled off" under orthogonal cutting conditions, since it has been found that the chip thickness is usually greater than the depth of the cut. It seems to me that it might be possible for the upsetting occurring in the chip as a result of the friction force applied to a relatively plastic material to give rise to sufficient thickening to account for this condition and still make it possible for the chip to literally "peel off." Is not the "ribbon-like chip" an example of this?

When considering the formation of this ribbon-like and segmented continuous chips, the statement was made that similarity of chips was apparent when working with a variety of materials, including aluminium-steel and wax. Although this represents a very wide range in properties, I hope it will be possible to expand your work to include materials which demonstrate a distinct variation in shearing yield strength to shearing ultimate strength, as well as work hardening rate. If materials such as aluminium, specifically one of the aluminium magnesium class, were compared with steel, the difference in mechanical properties could be evaluated systematically by the usual mechanical tests. In the case of the aluminium-magnesium alloy, with its high work hardening rate and high yield to tensile strength ratio, the plastic behaviour should show a marked difference to that of mild steel, with its low yield to tensile strength ratio and lower rate of work hardening. Differences in shearing strength could also be taken into account when comparing machining behaviour.

I expect the difficulty is not only to find time for such extensions of this programme, but also to sort out the many interesting avenues of investigation.

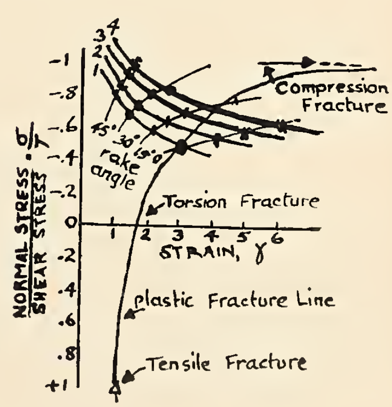
Discussion by N. H. Cook

There is little doubt that many of our commercial cutting operations produce segmented chips as described by the author. However, I believe that the author's conclusions are much too general to be supported by the experimental evidence shown.

In concluding that the transition from "segmented" to ribbon-like" chips is the result of a decrease in frietional force with increase in rake angle, the author presented a "black and white" solution for a situation which at best is a very muddled gray! Cook, Finnie and Shaw* have shown that the initiations of fracture in the cutting process is in good agreement with the initiation of fracture in tensile, torsion, and compressive tests. Correlation is made on the basis that the maximum plastic strain a material may undergo before fracture varies with the hydrostatic stress component, i.e., the position of the center of the Mohr's stress circle. Because strain hardening varies the size of the Mohr's stress circle, the ratio of the hydrostatic stress component to the maximum shear stress is taken as the quantity which will control the amount of plastic deformation before fracture. Figure 1 is a plot of plastic shear strain versus this stress ratio. Tensile fracture, torsion fracture, and compression fracture are used to fair in a curve representing plastic fracture for the material used (B1112) at room temperature. Also shown are cutting data points representing 4 rake angles and 4 fluids (1—CCl_4; 2—Ethanol; 3—dry; 4—benzene). The points to the left of the line represent continuous (ribbon-like) chips while the x's to the right represent segmented chips. Any change in material properties can shift the plastic fracture line. For instance, an increase in workpiece temperature generally moves the line to the right and results in more continuous chips. Thus, although the reduction of the friction force with increased rake angle is one of the factors affecting chip type, there are many other factors to be considered.

In segmented chips, the chip curl mechanism described can be influential, but is not the entire answer. For instance, the application of effective cutting fluids such as carbon tetrachloride, or ethanol, will reduce the friction force, reduce the degree (if any) of "segmentism" but will increase the chip curl.

Fig. 1. Correlation of Data with Materials Tests. (Trans. ASME, Feb. 1954)



*"Discontinuous Chip Formation." N. H. Cook, I. Finnie, M. C. Shaw, Trans. ASME, February 1954.

The mechanism of crater wear has previously been based upon the interacting effects of chip curl and the tool-chip interface temperature distribution. The author's mechanism is an interesting addition. If the crater occurs within the contact zone between the first segment (the static friction segment) and the tool, the proposed mechanism can be effective. However, if the crater occurs further away from the tool tip, under the second segment, for instance, it is difficult to see how this mechanism could function. The state of "static friction" under high pressure is conclusive to substantial welding between chip and tool which will result in severe wear when rupture occurs and the segment slides up the tool face. The second, third, fourth, etc., segments cannot bear as strongly upon the tool—particularly if they are being rotated away from the tool by the chip-curl mechanism described.

Discussion by John Convey

The paper serves to acquaint engineers with one facet of the research that is increasingly engaging the attention of universities and research institutions and which has to do with the machineability of metals. During World War II the speed of machining greatly advanced through applying new metals in cutting tools, such as tungsten carbide. How much greater are the needs of today with the advent of automation and the space-age requirements in high-temperature and high-strength metals! On the one hand there is need for better understanding of the mechanism of cutting and on the other hand for the metallurgist to know the factors of composition and structure that contribute to good machineability of metal.

The present contribution of Professor Rice gives engineers only a very brief summary of some phenomena of cutting action observed by him and he offers explanation for the mechanisms that he concludes are applicable in the formation of continuous chips in metal cutting. His distinction in this field of research arises from the doctoral theses which he presented to the Université de Montreal and it will be noted that his research has been supported in part by a grant of the Defence Research Board of Canada. It will be highly advantageous to have more such research conducted in Canadian universities and Professor Rice is to be commended for his design of equipment, including instrumentation and photographic methods that have made his observations possible despite a limited budget.

Professor Rice has shown initiative and resourcefulness and has given much greater study to the science of metal cutting than is indicated by the short list of references annotated from his extensive bibliography of the work of other researchers. He can be of assistance to engineers seeking information in this field and his research equipment should arouse considerable interest. It has been impossible for him in such a brief paper to do more than highlight some of his observations and conclusions in a field of research that is open to much controversy. It is good to have a Canadian professor add his theories to the melting pot, for it is from design of research equipment, careful observation of experiment, and publication of observations and theories, that science moves forward and practicable results are achieved.

It is hoped that Professor Rice in future work will be able to give consideration to microstructure of metals in relation to the bearing of structure on the mechanism of cutting.

Author's reply

The author wishes to express his appreciation to Mr. Millson, Professor Cook, and Dr. Convey.

The author visualized the "ribbon-like" chip as a "segmented" chip consisting of very small segments, the segment size and shape corresponding to the configuration of the stress field for values of the frictional force less than the critical value associated with transition from "segmented" to "ribbon-like" chips. However it may be, as Mr. Millson and one of the author's colleagues Mr. Salmon suggest, that the "ribbon-like" chip is "peeled off" and that the upsetting of the chip due to the frictional force accounts for the slight increase in the chip thickness. Indeed Kronenberg[1] focussed attention upon this upsetting force in a recent paper.

As suggested by Mr. Millson, Dr. Convey and by Professor Alexander the program is being extended to include other materials and to investigate the effect of microstructure upon chip formation.

The author feels that there is no real conflict between his concept of the mechanism of chip formation and that of Cook, Finnie, and Shaw. The author contends that he decrease in frictional force with increase in rake angle is a major factor in determining the nature of the stress field, and thus the ratio of the hydrostatic stress component to the maximum shear stress on the shear surface. Other factors such as temperature cannot be overlooked thus the author agrees with Professor Cook that a completely "black-and-white" solution is a simplification.

In a recent paper Shaw[2] pointed out that while carbon tetrachloride apparently gives relatively high friction in sliding experiments it gives very low values of cutting energy in cutting experiments. Carbon tetrachloride most likely affects the tool face friction (how, must await further experiments) which in turn affects the stress field, the ratio of the hydrostatic stress component to maximum shear stress, and the degree of curl.

With the dynamometer used in this work the interaction or "cross-talk" between horizontal and vertical components was indiscernible. According to calculations made in connection with a recent study of the force variation during the production of single "segments" the dynamometer is adequate for force variations of frequencies of less than 150 cycles per second. The design or selection of a dynamometer is a difficult task thus the author intends to gain access to Professor Cochkanoff's data. (Research project at Nova Scotia Technical College.)

Plan of Fort York, Upper Canada (showing its state in 1816) reproduced on new Kodagraph Contact Film, Estar Base. Original in Public Archives of Canada, Ottawa.

New way to restore old drawings!

New Kodagraph Contact Film, Estar Base, transforms old, soiled, or weak-lined drawings into top-quality intermediates which will stand up under punishment in print-making machines and on drafting boards.

Bound to be a favorite in darkroom as well as drafting room, this new Kodagraph Contact Film lets you produce same-size intermediates with new convenience. Simply expose with low-cost paper negative (or film negative) in standard contact printer. Process with either paper or litho developer. Exceptionally wide latitude — in exposure and development—all but ends make-overs.

See this new Kodagraph Film — and the others in the new Estar Base line: Kodagraph Autopositive Film, Kodagraph Projection Film.

All combine reliable Kodak emulsions on the new Estar Base — highly translucent, durable, and dimensionally stable, with excellent matte surface on both sides for easy drafting. Available in standard drawing sheet sizes and in rolls up to 52 inches wide. Call your local Kodagraph Dealer, or write Canadian Kodak Co., Limited, Toronto 15, Ontario.

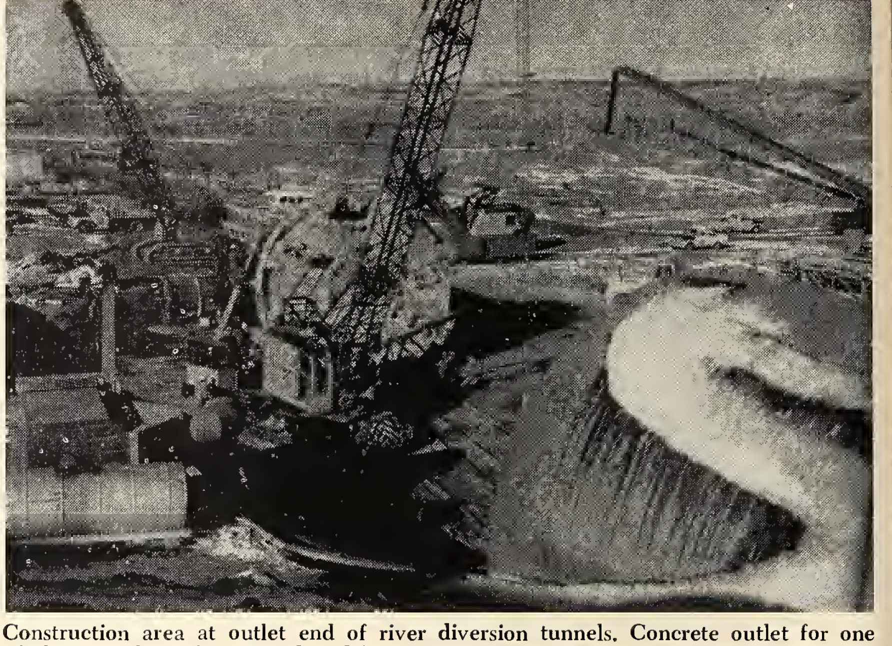
Canadian Developments

South Saskatchewan River Dam Progress

When Professor H. Y. Hind recommended a dam for the elbow of the Saskatchewan River more than 100 years ago, he could not have forseen the vast amount of equipment and manpower that would be used to build the structure. Professor Hind's proposed dam was 85 ft. high and 800 yd. long. The dam presently under construction will rise 210 ft. above the riverbed and will extend across the valley for a distance of about three miles. Five diversion tunnels of reinforced concrete construction are being built running through the west abutment of the dam. Over 19 million cu. yd. of earth have been excavated at the main damsite and 10 million of the 45 million cu. yd. of material have been placed on certain contract sites. By 1962-63 employment is expected to rise to a 1,500 peak at the damsite.



Construction area at outlet end of river diversion tunnels. Concrete outlet for one of the tunnels in foreground and Mole equipment in centre for drilling operations.

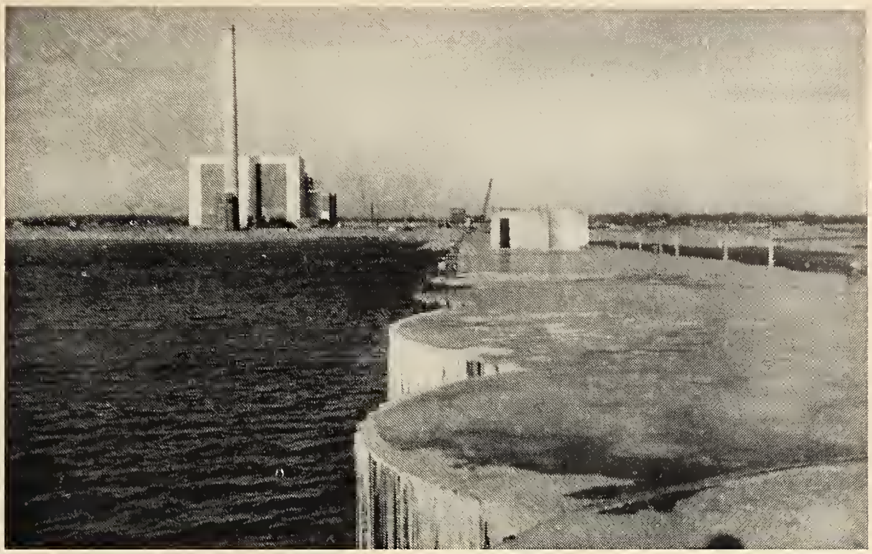
Work on the present tunnelling contract, which involves the driving and reinforcing with concrete of 10,000 ft. of 20 ft. diameter tunnel, the installation of steel lining in tunnels, and construction of outlet structures for the five diversion tunnels, has been primarily concerned to date with the batching and placing of concrete for the outlet structures. With this work now completed, the contractor can proceed with the actual tunnelling operations, says the Prairie Farm Rehabilitation Administration. The tunnels will carry the flow of the river after closure of the river channel has been made.

Lowering Mole by cable into tunnel entrance.

Recently the "Mole" equipment, which will be used to drive the river diversion tunnels in the downstream section of the dam was moved into place. Every available piece of machinery on the job had to be brought into use to anchor and control the descent of the 200-ton drill as it was gradually lowered by cable into the tunnel entrance. In operation, the massive electrically powered cutting head of the machine rotates slowly, grooving and pulverizing the shale face of the tunnel before it; the crushed material dropping into metal buckets that elevate and dump the material by way of a continuous conveyor belt, into awaiting cars for disposal. The over-all diameter of the cutting head, adapted for use on the South Saskatchewan River Dam, is 25 ft.

This particular unit is owned and was previously used by Peter Kiewit and Sons on the Oahe Dam Project of the Missouri River in South Dakota. Modification to the design of the machine was carried out by a firm in Brandon, Man., to meet the specific requirement of this contract. Although not the first time the machine has been used in Canada, this will be by far the largest construction job on which a Mole has been employed in this country.

As the tunnelling goes forward, steel ring beams, presently stockpiled at the site, will be installed as reinforcing in the tunnel along the connecting steel supports and wire mesh. This will then be covered with blown Cunite, to prevent shale walls in the tunnel from drying.



Looking toward shore from the lake end of a 1000 ft. long cellular dock built to serve the Ontario Hydro Lakeview Generating Station nearing completion.

Cellular Dock for Ontario Hydro Lakeview Generating Station

A cullular dock jutting 1600 ft. out into Lake Ontario has recently been completed by Dravo of Canada Limited, Toronto. The dock is to serve the new $250 million Ontario Hydro Lakeview Generating Station, scheduled to go into service this year. Located about 10 miles southwest of Toronto, the station will have an ultimate generating capacity of 1.8 million kw.

The dock consists of 21 steel sheet pile cells, interconnected with steel sheet pile arcs. They stand in water ranging from 10 to 35 ft. in depth. The 1,000 ft. long dock is an extension of a 600 ft. long, 40 ft. wide rock causeway. The causeway projects from a new shoreline, created by reclaiming a 600 ft. wide strip of lakefront with fill taken from the excavation for the generating station.

Each of the dock's 21 cells is 44 ft. in diameter and is filled with crushed limestone into which grout has been intruded to form a solid concrete core inside the sheet piling. Approximately 45,000 cu. yds. of intruded aggregate were used. Mass concrete was poured over the intruded base to form caps for the cells and a 16 ft. wide, 8 ft. high conveyor tunnel, which extends along the top of the dock 750 ft. from the end of the causeway. Required were 10,600 cu. yd. of ready-mix concrete, placed by pumpcrete methods, and 150 tons of reinforcing steel.

Galbraith Building

The University of Toronto's new engineering building, named after former Dean John Galbraith, was officially opened March 7. Special ceremonies marking the occasion began March 6 with a Convocation, at which honorary degrees were presented to four outstanding members of the engineering profession. These were: William Percy Dobson, Hon. M.E.I.C., director of research for the Ontario Hydro-Electric Power Commission until his retirement in 1955; Henri Gaudefroy, M.E.I.C., Dean of Ecole Polytechnique since 1953; John Hamilton Parkin, director of the Division of Mechanical Engineering, N.R.C., since 1937, and since 1951 director of the National Aeronautical Establishment; and John Bertram Stirling, Hon. M.E.I.C., president of E. G. M. Cape and Company, engineers and contractors, and a past president of the EIC. The Convocation address was given by Paul G. Hoffman who received the honorary degree of Doctor of Laws. Mr. Hoffman is the first managing director of the United Nations Special Fund, a U.N. special agency designed to aid investment in underdeveloped countries.

On Tuesday morning three special scientific lectures were delivered by Robert F. Legget, M.E.I.C., J. R. Pierce and Dr. G. V. Bull. Their respective papers were "Civil Engineering—Yesterday, To-day and Tomorrow", "The Many Problems of Communication Satellites", and "Hypervelocity Re-entry Studies at Canadian Armament Research and Development Establishment, Defence Research Board".

In the afternoon the Lieutenant-Governor of Ontario, the Honourable J. Keiller Mackay, opened the Galbraith Building. The building houses civil, electrical and aeronautical engineering and the administrative offices for the Faculty of Applied Science and Engineering. The University allocated $7 million for its construction and equipment and for renovation of existing buildings for applied science and engineering. In addition to modern expanded office and teaching space, departments now have much greater facilities for research. Civil engineering facilities include a one million pounds universal testing machine and a modern photostress laboratory. The building brings together sections of the civil engineering department previously spread over three buildings. New electrical engineering facilities include an antenna laboratory in a penthouse and a computer area housing both a digital and an analog computer.

Dean Galbraith was Ontario's first Professor of Engineering in 1878, first Principal of the School of Practical Science and, after that body became part of the University of Toronto in 1906, first Dean of the Faculty of Applied Science and Engineering. He died after guiding the growth of Ontario engineering education for 36 years.

University of Toronto's new engineering building, named after Dean John Galbraith.

International News

International Prize

The Association des Ingénieurs de la Faculté Polytechnique de Mons is to offer an international prize of fifty thousand Belgian francs which will be awarded for the first time in 1965. The prize is to be entitled "Prix International de l'Association des Ingénieurs de la Faculté Polytechnique de Mons" and will be quinquennial. It is to be awarded to the author of an outstanding and original work on the art of engineering. The jury will be composed of five members chosen by the Board of Directors of the Association. The jury may call upon specialists, who will be requested to make their reports on the papers that are submitted.

Engineers holding diplomas from universities and from recognized schools on university level are eligible for the prize. Only work submitted during the period of five years preceding the first assembly of the jury, before Sept. 1, 1965, will be accepted. The title of "Laureat du Prix International de L'Association des Ingénieurs de la Faculté Polytechnique de mons (A.I.MS)" will be conferred upon laureates. Work should be submitted in either French, Dutch, English or German. It should be typewritten in four copies and should bear a pseudonym signature. It should be sent to Monsieur le President de l'Association des Ingénieurs de la Faculté Polytechnique de Mons, 9 rue de Houdain, Mons, Belgium.

European Symposium on Space Technology

The British Interplanetary Society is organising the First European Symposium on Space Technology. It will be held in London June 26-28. The purpose of the Symposium is primarily to bring together engineers and scientists from Western Europe to discuss the possibility of formulating a joint program of space research.

The Symposium will be open to participation by countries in Western Europe, particularly those who belong to the Organization for European Economic Co-operation. It is also envisaged that Commonwealth countries, particularly Australia and Canada, will be concerned in any future program. The Conference will have heavy industrial overtones and will discuss the most fruitful lines of approach, bearing in mind the resources in men and materials available for participating nations.

Besides consideration of technical projects, there will be matters of finance and organisation to be dealt with, leading eventually to final decisions and recommendations for future consideration. It is hoped that this may lead to an expanding program of space exploration undertaken on the widest possible international basis and the closest possible collaboration with America and, if possible, the Soviet Union.

Sweden's Prefab Underwater Tunnel

A concrete underwater tunnel, 407 ft. long, was lowered in Stockholm recently. Claimed to be the world's first uninsulated and prestressed monolith of this type, the tunnel was built in two separate sections, 86 and 38 metres each. The tunnel was joined at a site nearby its destination.

The lowering of the tunnel on its site took place in stages. The monolith was suspended in four wire stays, one end of the tunnel being lowered 12.5 cm. at a time. Before the tunnel was finally positioned, two steel rollers were drawn along the entire length of the lake bottom to ensure that the bed was free from stones or other obstacles. In order to keep the tunnel submerged some 60 concrete slabs of a total weight of 1,700 tons were gradually placed on the tunnel roof. At the same time water was pumped into built-in tanks and into likewise built-in water mains with a diameter of 1.2m.

The tunnel rests on concrete plinths at both ends, the bottom being 14 metres below water level. Intermediate plinths will later be provided by pouring concrete through open shafts on both sides of the tunnel in its central part, thus casting pillars which will securely lock the monolith to the rock bottom. The connecting of the tunnel to both shores, where dams have been built, is estimated to take several months.

Israeli Tracking Station

A satellite tracking station is to be set up on the roof of the Aeronautical Engineering Building at the Technion, Israel Institute of Technology. The apparatus is on hand, the staff to man the station is now being trained and it is planned to start operations in April.

The program has been planned by the Haifa members of the Israel Astronautical Society and the operations will be directed by Jerome Shafer, Senior Lecturer in aeronautical engineering at the Technion.

The station will be one in a series ringing the world, operated in conjunction with the Astro-Physical Observatory of the Smithsonian Institution, Cambridge, Mass. Information on the paths of satellites crossing Israel or within the range of the telescopes is transmitted to the Cambridge laboratory. There it is coordinated with similar reports from other stations, and a full picture is obtained on trajectories and other data of interest to the scientists. The Smithsonian Institution makes this information available to any scientific body or agency concerned which may request it.

All stations in the network are manned by volunteers. The setting up of the Haifa station was made possible by a gift received from a friend of the Technion, Mr. Sam Sklar, and an additional gift from the Haifa Municipality.

CF-104 multi-mission Super Starfighter in its first flight. In an international production program involving Germany, Canada, The Netherlands, Belgium, Italy and Japan — more than 1000 Super Starfighters are programmed for manufacture. Canada is scheduled to produce, under Lockheed licence, 8 squadrons for integration into R.C.A.F.'s European Air Division supporting NATO units in Europe. These are being manufactured by Canadair Ltd. First production is scheduled to fly April.

Month to Month

Vancouver, City of Opportunity

As you will see, the emphasis in this issue of the Journal is on your Annual General and Professional Meeting which will be held in Vancouver from May 31 until June 2. If you have not already made plans to attend, perhaps we can interest you in so doing.

Those of you who have attended past Annual Meetings are aware they consist of two broad activities. One is the annual general meeting of the Institute with attendant business meetings of various committees. This is your opportunity to investigate the workings of the Institute in person, to see what has been accomplished in the past year, and to learn what programs your Institute plans to foster with vigor next year.

Your presence and voice are not only welcome; they are essential if the Institute is to continue its strong upward growth.

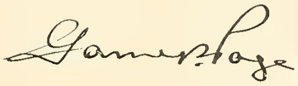
The technical program comprises the other broad phase of the meeting. More than 60 papers covering all phases of engineering will be presented during the three-day meeting. As an engineer you owe it to yourself and to your profession to keep abreast.

Personal contacts made at such meetings are both valuable and numerous. At least we can attest to the number of opportunities: last year more than 1,000 persons attended the Annual Meeting at Winnipeg.

The Annual Meeting is held each year in a different part of Canada to permit as many of our far-flung members as possible to participate actively in the work of the Institute. This year, Vancouver is the City of Opportunity. Western members should be able to attend with relative ease.

The ladies, too, should be delighted with the time and place of the meeting. We know Vancouver to be a visitor's delight. And we have been informed, in some confidence, that the city plans to be at its loveliest late this Spring.

Why not plan a few days off this Spring? Help the Institute help you. Be in Vancouver and combine pleasure with opportunity.



Executive Committee Meeting

The Executive Committee of Council met Feb. 25 at Headquarters in Montreal. President Dick was chairman. The following are highlights of the meeting.

Life Members Fund

Finance Committee Chairman F. L. Lawton reported that it has been agreed that a simple statement of practice governing the operation of the Life Members Fund should be adopted, as follows: (i) The Life Members Committee submits a report of its activities to Council annually. (ii) The funds paid into the Life Members Fund shall be within the care of Council but designated as a special fund separate from the general funds of the Institute. (iii) The disbursal of funds from the Life Members Fund for the purposes recommended by the Life Members Committee is authorized by vouchers signed by two members of the Life Members Committee.

Technical Operations Manual

It was noted that the Technical Operaitons Manual now is in final form for publication and the Executive Committee was pleased to authorize its immediate publication.

Technical Program — 1961 Annual Meeting

It was agreed that the Civil Engineering Division program for Friday Afternoon June 2, 1961, be devoted to a visit to the University of British Columbia to inspect the Fraser River Model.

Branch Operations

Mr. Lawton presented an analysis of replies to President Dick's policy letter to Councillors of Jan. 6, and it was resolved that recommendations contained therein be adopted and appropriate action taken to implement them.

Port Credit Branch

A petition was granted to form a Branch of the Institute at Port Credit, Ont., and that an initial rebate of $50. be made to this new Branch pending the establishment of the regular rebate. President Dick presented the Chapter to the Branch on March 24.

University of Western Ontario

A petition to form a Student Section of the E.I.C. at the University of Western Ontario was granted.

Branch Achievement Awards

Subject to the approval of Council at its April 22 meeting, two awards are to be established to be known as "The George McKinstry Diek Branch Achievement Award". They are to be presented annually to one large and one small Branch. Branehes will be judged on overall operations, membership growth and technical activities.

Interpretation of Procedures followed by Admissions Committee and Board of Examiners

An ad hoc committee is to be established to investigate present policy and practices of the Board of Examiners and to recommend to Council regarding desirable policy and practices to be followed by the Board of Examiners when dealing with applications for membership referred to it by the Admissions Committee.

The Engineering Journal

A regular editorial poliey is to be adopted regarding the insertion of four pages of a tinted stock in each issue of the Journal to be devoted to Presidential views, Council, activities, reports and contributions of the Committee on Technical Operations, the Committee on Membership, the Committee on Branch Operations and other vital contributions concerning the activities of the E.I.C. at all levels.

Membership Directory, 1961

The 1961 E.I.C. Directory is to be published in two sections. The first section is to contain a complete list of names in alphabetical order, with the member's branch indieated by number, a numerical code is to be established for all branches. The second section is to contain details about each member, with the names listed alphabetically under each branch. The present grade of membership and field of technical interest will be given.

1961 Annual General Meeting

It was agreed that the Annual General Meeting will commenee at 9.00 a.m., Wednesday, May 31, rather than at 10.00 a.m., and will adjourn at 12.00 noon. The extra hour will be devoted to the subjeet of Confederation. The Executive Committee approved the pub-

(Continued on page 105)

75th ANNUAL GENERAL AND PROFESSIONAL MEETING of

THE ENGINEERING INSTITUTE OF CANADA

May 31, June 1—2, 1961 Hotel Vancouver, Vancouver, B.C.

Registration

Advance registration through E.I.C. Headquarters closes May 20th.
Registration opens at 12 noon Tuesday May 30th, at the Hotel Vancouver.

Accommodation

The Hotel Vancouver is headquarters for the meetings and other events, but alternate accommodation will also be available at other hotels and motels in the area.

Technical Program

The technical program is listed on the following 2 pages.

Ladies Program

Early plans for this include the following:

2:30 p.m. Wednesday, Tea followed by a tour of the Japanese Gardens at U.B.C.

10:00 a.m. Thursday, Engineers Wives Association Meeting

12:30 p.m. Thursday, Luncheon, Royal Vancouver Yacht Club, followed by a tour of Marine Drive.

Friday evening — the Annual Banquet and Dance

Vancouver Diary

The events for all four days at the Hotel Vancouver are listed on the back of this program.

Committee

Chairman: Dean D. M. Myers, M.E.I.C.
Vice Chairman: Professor W. Heslop, M.E.I.C.
Secretary: F. M. Cazalet, M.E.I.C.

TECHNICAL PROGRAM Wednesday, Thursday, Frid

Wednesday, May 31

Mechanical

Side Tipping Log Barges
T. A. McLaren, M.E.I.C.

The Factors Involved in the Design of a Canadian Gangsaw
E. N. Parker, M.E.I.C.

Douglas Fir Plywood Manufacture
J. S. Abel

Bridge and Structural

Revision of the Reinforced Concrete Section of the National Building Code
M. W. Huggins, M.E.I.C. and W. G. Plewes, M.E.I.C.

Current CSA Specifications on Engineering Design in Timber
J. W. Wynand

Commentary on CSA Standard S16-1961
W. G. Mitchell, M.E.I.C. and D. L. Tarlton

Hydro-Electric

Outlook on the Relationship between Load-Frequency Control and Turbine Governors on Interconnected Power Systems
L. O. Long

EIC 1961 Annual Meeting

Use of an Electronic Analog Computer for Determining Optimum Settings of Speed Governors for Hydro Generating Stations
L. M. Hovey, M.E.I.C.

Economic Development of Hydro-Quebec Power Resources—System Studies Utilizing an IBM 704 Computer
J. Bourbeau, M.E.I.C., F. H. Jonker and J. G. S. Thomson

Civil

Sewage Lagoon for City of Saskatoon
D. R. Stanley, M.E.I.C. and E. Cole, M.E.I.C.

The Hydraulic Capacity of Large Corrugated Metal Culverts
C. R. Neill, M.E.I.C.

Marine Waste Disposal
E. A. Pearson

Electrical

Electronic Aids in Canadian Mapping
J. T. Henderson, M.E.I.C.

The D.R.B. Topside Sounder Satellite
R. C. Langille

Design Considerations for Large Radio Telescopes
J. L. Locke

Thursday, June 1

Mechanical

The Combustion of Gasoline during Engine Starting at Low Temperature
F. D. Hamblin, M.E.I.C.

An Evaluation of Plywoods and Plastics in Boat Construction
J. Brandlmayr, M.E.I.C.

The Thermal Wedge Effect in Hydrodynamic Lubrication
J. Young

The N.A.E. Five Foot Supersonic Wind Tunnel
K. F. Tupper, M.E.I.C., P. B. Dilworth, M.E.I.C. and L. A. Jenkins

Bridge and Structural

Weaknesses of the Theory of Plastic Design
A. Hrennikoff, M.E.I.C.

Unique Design in Glulam
B. Madsen

The Limit Design of Reinforced Concrete Continuous Beams
C. Berwanger, JR.E.I.C.

The Champlain Bridge—Steel and Prestressed Concrete Crossing of the Saint Lawrence River
B. A. Hesketh, M.E.I.C.

The Inspection, Repair & Maintenance of Highway Bridges in the City of London, Ontario
R. M. Dillon, M.E.I.C. and P. H. D. Edwards

Design of the Superstructure of the Port Mann Bridge
G. Hardenberg

Chemical

The Behaviour of Rarified Gases
D. S. Scott

The Production, Handling & Uses of Tonnage Oxygen by Cominco
C. H. Simpkinson

Hydro Electric

Engineering Research on the Fish and Power Problem
E. Ruus, and J. F. M. Muir, M.E.I.C.

The Beechwood Fish Hoist
J. D. Denovan, M.E.I.C.

Watershed Resource Value — The Associated Development of Fish and Power
V. Gwyther, M.E.I.C.

Geotechnical

Landslides in Over-Consolidated Clays
R. M. Hardy, M.E.I.C. and E. W. Brooker, M.E.I.C.

Carillon Foundation Studies
C. H. Pigot, M.E.I.C. and I. D. MacKenzie, M.E.I.C.

The Planning of Avalanche Defence at Rogers Pass
P. Schaerer, M.E.I.C.

TECHNICAL PROGRAM

Management

The Saskatoon Productivity Program
I. S. Evans, M.E.I.C.

The Economic Advantage of a Systematic Mapping Program of Outside Facilities to a Public Utility
J. S. G. Shotwell, M.E.I.C., W. C. Fisher, M.E.I.C. and V. J. Feeney

Effects of Changing Technology on Labor and Employment
W. Bruce, M.E.I.C.

NRC-EIC Symposium on Automatic Control

The Optimization of the Performance of an Ore Bridge, An Analogue Computer Study
J. A. Field, JR.E.I.C.

The Determination of Linear Multivariable Models for Complex Processes
R. J. Kavanagh, M.E.I.C.

Economic Performance Criteria for Optimizing Control Systems
J. H. Milsum

A Continuously Acting Adaptive Analog Computer for Determining the Impulse Response of Control Systems with Gaussian Signals
E. V. Bohn

The Control System of an Automatic Stereo Mapping Machine
J. M. Ham and G. L. Hobrough

Process Loop Optimization Through Valve Characterization Techniques
G. L. d'Ombrain and S. M. Lyle

The Optimal Gain of Manually Controlled Machines
C. B. Gibbs

Reliable Networks from Unreliable Components
Miss O. Boshko, G. S. Glinski, M.E.I.C. and J. Therrien

Friday, June 2

Joint Chemical-Mechanical-Management

Non Linear Control for Distillation Columns
G. A. McNeill

Some Engineering Applications of Analog Computors
P. N. Nikiforuk, and T. W. McDonald

The Need for Research in Planning Mechanization
J. C. Clapham

The Pipeline Transport of Solid-Liquid Mixtures
G. W. Govier, M.E.I.C.

Forced Variation During the Formation of Continuous Segmented Chips in Metal Cutting
R. Salmon, JR.E.I.C.

A Simulation of the Economy of British Columbia — A Guide to Industrial Development
R. E. Boston, JR.E.I.C.

Hydro-Electric

Speed Regulation for Hydraulic Turbines
J. L. Gordon, JR.E.I.C. and W. J. Smith, M.E.I.C.

On the Treatment of Stochastic Variables in Engineering Design
J. H. Milsum

Joint Engineering Education — Civil

Some Reflections on Trends in Engineering Training
A. Porter, M.E.I.C.

Urgent Tasks in Engineering Education
D. M. Myers, M.E.I.C.

Modern Techniques Solve Unusual Log Driving Problem
D. M. Foulds, M.E.I.C. and C. E. Davidge

Civil Engineering Education
S. D. Lash, M.E.I.C.

Have We a Problem in Engineering Education?
W. F. McMullen

A Research Viewpoint on Engineering Education
B. G. Ballard, M.E.I.C.

Civil

Three-Dimensional Photoelastic Analysis of a Diamond Head Buttress Dam
C. R. Jones and J. B. Mantle, M.E.I.C.

EIC Vancouver, May 31, June 1-2

The Structural Design of the Tunnels for the South Saskatchewan River Dam
C. Booy

Geology of the South Saskatchewan River Project
D. H. Pollock, M.E.I.C.

Electrical

New Uses for Ceramic Materials in Microwave Tubes
G. B. Walker

Rearward Communications for BMEWS
L. J. Hammerschmid, M.E.I.C.

Some Problems Encountered in Underwater Sound Research
H. H. A. Davidson

Electrical Installations in Modern Jet Aircraft
R. W. Farren

The Hows, Whys and Wherefores of EHV Transmission
C. M. Stairs

Concepts and Economics of Extra Long Distance Direct Current Transmission and System Interconnections
H. L. Briggs, M.E.I.C.

ANNUAL MEETING

Monday, May 29

Annual Meeting of Council	8:00 p.m.

Tuesday, May 30

Committee on Branch Operations	9:00 a.m.
Joint Luncheon, all conferences	12:30 p.m.
Continuation of Annual Meeting of Council	2:00 p.m.
Continuation of Committee on Branch Operations	2:00 p.m.
Press Conference	4:30 p.m.
Informal reception, all visitors welcome	8:30 p.m.

Wednesday, May 31

Authors' Breakfast	7:45 a.m.
Annual General Meeting	9:00 a.m.
Muriel's Room	12:00 noon
Opening Luncheon	12:30 p.m.
Students' Conference — opening session	2:00 p.m.
Muriel's Room	6:30 p.m.
Informal Dinner, Address by President Dick	7:00 p.m.
Social evening — informal	9:00 p.m.

Thursday, June 1

Authors' Breakfast	7:45 a.m.
Consulting Engineers — Directors' meeting	9:00 a.m.
New Council Meeting	10:00 a.m.
Muriel's Room	12:00 noon
Honours and Awards Luncheon	12:30 p.m.
Students' Conference — second session	2:30 p.m.
E.I.C. Committee on Membership	2:30 p.m.
Association of Consulting Engineers — Annual Meeting	2:30 p.m.
Association of Consulting Engineers — Annual Dinner	7:00 p.m.
Panel Discussion on Automatic Control	8:00 to 10:00 p.m.
Evening cruise by steamer "Princess Patricia"	9:00 p.m.

Friday, June 2

Authors' Breakfast	7:45 a.m.
Joint A.S.M.E.-E.I.C. International Council	9:00 a.m.
Students' Conference—final session	2:00 p.m.
Muriel's Room	6:30 p.m.
Annual Banquet	7:30 p.m.
Annual Dance	10:00 p.m.

EIC

the Engineering Institute of Canada

MONTH TO MONTH

(Continued from page 100)

cation of the Meeting and Conference Ianual which has been prepared by the aff, with the valuable assistance of revious Annual Meeting Committees.

Open House"

The proposal that E.I.C. Branches hold n "Open House" for graduating engieers was adopted. It is to be implemented by the Committee on Branch perations and the Student Policy Committee.

dministration

President Dick has visited the Monteal Branch on two occasions since the ast meeting, for its Annual Meeting an. 30 and for its Ladies' Night Feb. 7. On Feb. 8 he presented the new Dakville Branch with its Charter and isited the Toronto Branch and the University of Toronto Feb. 9. Vice-President Lawton will visit the Ottawa Branch, he St. Maurice Valley Branch and the Quebec Branch. Vice-President Higginon will be making visits to Branches in he Maritime Provinces during April and May. Vice-President Miller has received encouraging reports from the North Shore-Lower St. Lawrnece and Lower St. Lawrence Branches. The General Secretary recently visited the Halifax, Moncton and Prince Edward Island Branches and had extremely useful meetings, not only with members of the Branches concerned but with representatives from other Branches in the area. Mr. Luke visited the Border Cities and Peterborough Branches.

A luncheon was held for the President of the Institution of Civil Engineers and his lady when they visited Montreal March 28.

International Agreements

An ad hoc committee is to be established to recommend regarding an overall policy for the E.I.C. concerning cooperative agreements with other engineering societies.

Mr. Luke presented a report on the 1961 Annual Meeting of the International Association for the Exchange of Students for Technical Experience. He stated that between 50 and 60 students now are interested in participating in the exchange this year. Dr. W. B. Lewis of Atomic Energy of Canada Limited, Chalk River, Ont., has been nominated for the Neils Bohr International Gold Medal.

Faculty Advisor—The University of Alberta

Professor H. R. McArthur is to be appointed E.I.C. faculty advisor for the University of Alberta's engineering student body in Calgary. EIC

Have you played your part as a member of the Membership Committee?

Stan Cassidy

DUCTILE IRON

the **versatile** cast iron that can be bent

- **good ductility**
- **high strength**
- **good machinability**
- **controlled hardness**
- **wear resistance**
- **good castability**

Ductile iron shows its versatility in many ways, not only with outstanding mechanical and physical properties but also with the process advantages of grey cast iron; it can be cast into intricate shapes.

Alloyed grades of ductile iron containing nickel provide increased strength and yield, along with controlled hardness through heavy sections.

Write for a copy of the "Buyers Guide" containing a list of licensed producers.

Personals

Dr. Otto Holden, HON. M.E.I.C. (Toronto '13), was presented with an Honorary Membership Certificate by President Dick at a Dinner held by the Toronto Branch Feb. 9. The Council of the EIC elected Dr. Holden to Honorary Membership at its meeting April 30, 1960, but Dr. Holden was unable to be at Winnipeg to receive it at the Annual Meeting, May 26. The honour was an acknowledgment of Dr. Holden's achievements in the field of learning and of the steadiness which he has exhibited in times of stress in engineering affairs.

Formerly Ontario Hydro's Chief Engineer, Dr. Holden is a man whose record of achievement in the field of hydraulic engineering has brought distinction not only to himself but it has served to enhance the world-wide renown of the organization he has served since 1913. In helping to carry out Ontario Hydro's tremendous post-war expansion program Dr. Holden had a major part in further harnessing the waters of the Ottawa River through the completion of three important generating stations — Des Joachims, Chenaux, and the LaCave plant, the latter renamed in his honour, the Otto Holden Generating Station. Dr. Holden's services were enlisted in examining and reporting on plans for the construction of a hydro-electric project in the Snowy Mountains in southeastern Australia. He joined the Institute as an associate member in 1921 and has been a life member since 1956.

T. H. Dickson, M.E.I.C. (N.S.T.C. '22), former electrical engineer of the CNR's Atlantic region has retired after 35 years with the railroad. Mr. Dickson's last major project was the installation of the power distribution system and floodlights in the railroad's $15 million automatic classification yard.

C. W. E. Locke, M.E.I.C. (British Columbia '30), has been appointed vice president in charge of Asian operations of Sandwell International Limited, Vancouver. Mr. Locke recently returned from Asia and will be based at the company's Vancouver office.

Gordon A. Dysart, M.E.I.C. (McGill '51), has been appointed electrical superintendent of the KVP Company Limited, Espanola, Ont.

Allan Jackson, S.E.I.C. (Queen's '59), has been appointed Township Engineer of Tarentorus. Mr. Jackson has been with the Department of Highways since his graduation, connected with the MacNamara contract on Highway 17N.

Obituaries

Francis Caldwell Ball, M.E.I.C. (Toronto '23), chief sewer engineer of the London, Ont., city works died Jan. 15. He was 64. Mr. Ball has been an engineer with the City of London for the past 37 years. He joined the Institute as student member in 1920 and became a member in 1940. He was made a life member this year.

Thomas Arthur Barnett, M.E.I.C. died Dec. 12, Niagara Falls, Ont. He was 86. Mr. Barnett, a civil engineer, worked on construction jobs across Canada with such firms as the Hydro Electric Power Commission of Ontario, Foundation Company of Canada, International Nickel Co. of Canada Ltd. and the Wallburg Construction Company. He joined the Institute in 1922 as an associate Member and became a life member in 1952.

Robert Jones Bethune, M.E.I.C. (Dalhousie '07), well known civil engineer died Jan. 9, New Glasgow, N.S. He was 75. Mr. Bethune began his career in railway construetion work. He joined the Nova Scotia Highways Department in 1914 and was appointed division engineer for Guysborough, Antigonish and Pictou counties. He retired in 1952. He joined the Institute in 1940 and became a life member in 1957.

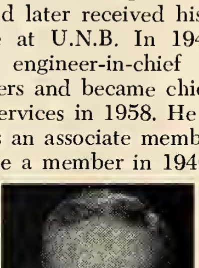
Edward Lancelot Cousins, M.E.I.C. (Toronto '07), died Feb. 9. He was 77. In 1912 he played an important part in the development of Toronto's harbour and waterfront. Mr. Cousins became general manager for the Harbour Commissioners in 1935. After his retirement in 1946 he continued as consultant. He joined the Institute as a student member in 1907 and became a life member in 1961.

Nathan L. Engel, M.E.I.C. (McGill '07), prominent electrical engineer, died Dec. 31, 1960. He was 77. Mr. Engel was born and educated in Montreal and began his career in the electrical power industry in 1907. He was manager of Hydro-Quebec's Industrial Department when he retired in 1949. He joined the Institute as an Associate Member in 1921 and became a life member in 1954.

G. E. Smith, M.E.I.C.

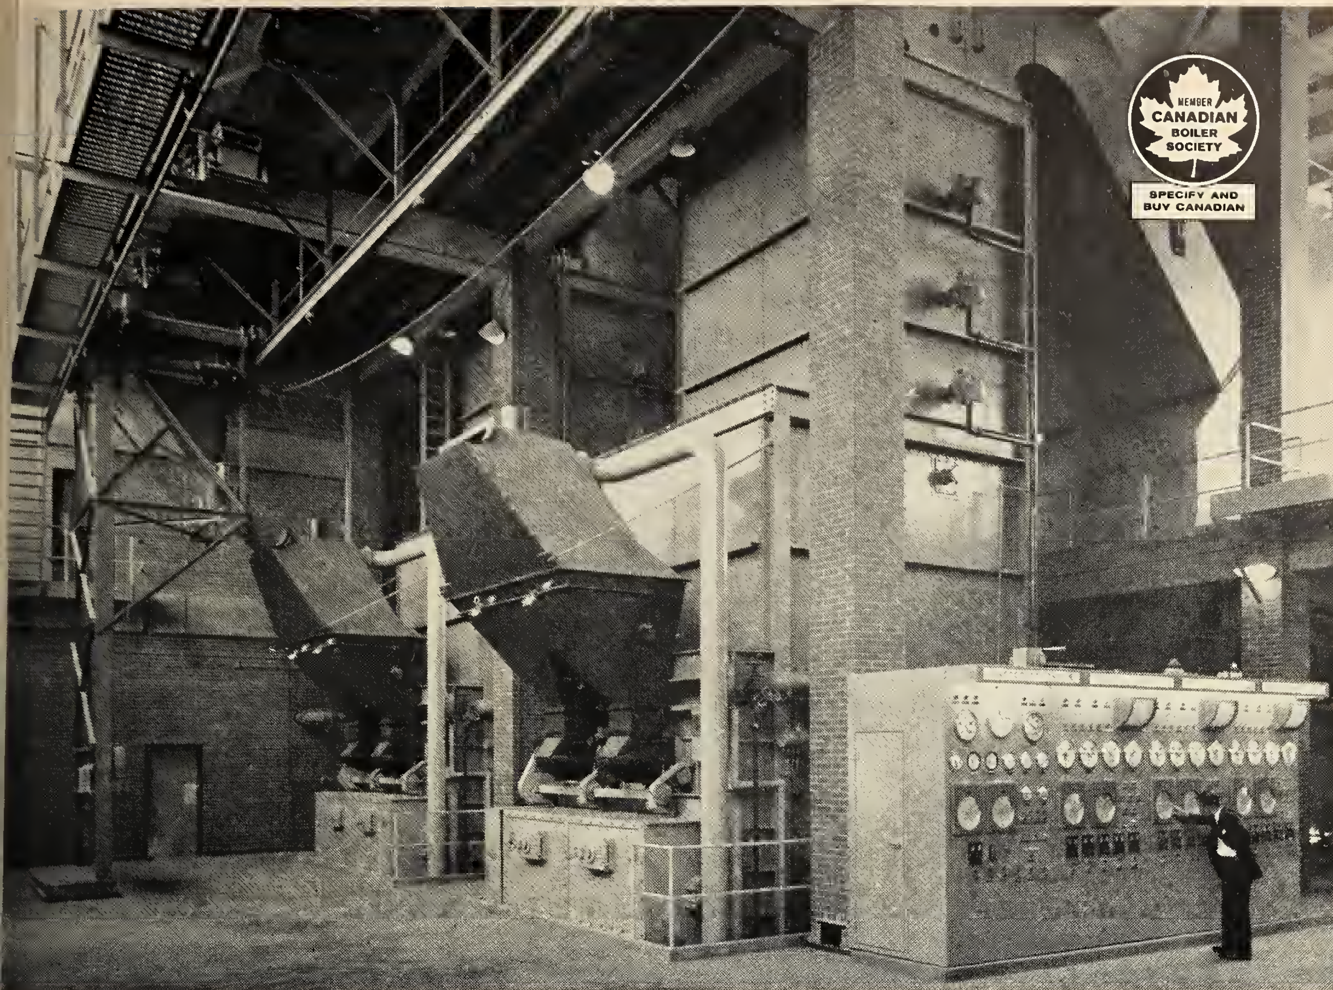
George Ellis Smith, M.E.I.C. (New Brunswick '12), civil engineer, died Jan. 28, Moncton, N.B. He was 71. In 1919 Mr. Smith joined the Canadian National Railways, and in 1951 became regional manager of the Real Estate Department for the Atlantic Region. He held this position until his retirement in 1954. He joined the Institute as an associate member in 1921 and in 1956 he became a life member.

Rear-Admiral Brian Roff Spencer, M.E.I.C., chief of naval technical services at Naval Headquarters, died Jan. 22, Rockcliffe, Ont. He was 54. Rear-Admiral Spencer entered the Royal Canadian Naval College at Halifax as a cadet and later received his engineering degree at U.N.B. In 1946 he was appointed engineer-in-chief at Naval Headquarters and became chief of naval technical services in 1958. He joined the Institute as an associate member in 1939 and became a member in 1940.



W. Taylor-Bailey, M.E.I.C.

Frank Whitham Taylor-Bailey, M.E.I.C. (McGill '16), director and former president of Dominion Bridge Ltd., died Feb. 28. He was 69. While overseas with the Canadian Engineers and Royal Air Force, he was awarded the Military Cross. In 1919 he joined the sales staff of Dominion Bridge Ltd. Mr. Taylor-Bailey was appointed president and managing director in 1951. He became chairman of the board in 1958. He joined the Institute as a student member in 1915 and became a life member in 1955.



H.T.W. system supplies ten separate buildings...

Three Dominion Bridge 40 million B.T.U. high temperature water boilers are being used in Ottawa to supply heat to ten large Department of Public Works buildings spread over several acres.

In applications of this kind, where heat must be distributed over a wide area, H.T.W. offers very definite advantages. These are evident in lower overall costs due largely to the absence of corrosion, elimination of condensate traps and separators, and the fact that mains may be laid with minimum regard for levels or grades. Because of the high thermal storage of the system a smaller capacity plant is possible thus reducing fluctuation in the firing rate to give better overall efficiency. Capital costs are comparable with H.P.S. installations.

The new plant, located on Riverside Drive, operates at 350°F. and 200 psig with an inlet water temperature of 220°F. One and a half inch drainable tube circuits are arranged for continuous upward flow and the water is distributed, according to the heat absorption capacity of the circuits, through stainless steel metering orifices. The boilers are coal fired and equipped with continuous discharge spreaders. Consulting engineers were J. Klassen and Associates, Ottawa.

Dominion Bridge design and manufacture water tube and fire tube boilers for a wide variety of applications. Assess 'Canadian-Made' first—call the Boiler Products Division at any of its offices across the country. Their experience is at your service.

Boiler Products Division **DOMINION BRIDGE**

DOMINION BRIDGE COMPANY LIMITED - FIFTEEN PLANTS COAST-TO-COAST

Other Societies

The American Society of Mechanical Engineers

The Production Engineering Division of the ASME will be conducting its annual division conference in Toronto, May 9-12 under the theme "International Co-operations for Productivity". The EIC is a co-sponsor of this conference. It will be held concurrently with the National Industrial Production Show of Canada.

In addition to the general production engineering and metal processing program, there will be two international panel sessions. The Wednesday afternoon, May 10, session will include discussions on machine and tool programming data preparation, problems evaluation and requirements of machine data for use in self controlling machines. The development of new concepts and schemes in the field of metal cutting, will also be discussed. On Thursday afternoon, unification of instruction media for production machines will be the topic under discussion.

Canadian Aeronautical Institute

The mid-season meeting was held Feb. 27-28 at the Marlborough Hotel, Winnipeg. The first session was devoted to Landing Engineering and included papers on "The Long and the Short of Runways", "Review of the Present and Future Aircraft Brake" and "A Review of Landing Gear on the Caribou Aeroplane". Monday's afternoon session was on Runways—Prepared and Otherwise. Two papers were presented, "R.C.A.F. Snow Removal and Ice Control" and "Operation of Wheel Equipped Fixed Wing Aircraft on Unprepared Land and Snow Surfaces in the Arctic Islands". On Tuesday, Feb. 28 Air Traffic and Flight Control was the theme. Three papers were presented, "Airspace Management in High Density Areas", "An Evolutionary Approach to Instrument Flare Out and Landing", and "The Pilot and Air Traffic Control". The final session Tuesday afternoon was a panel discussion on Training by Simulation.

Canadian Construction Association

Twenty-five senior members of the architectural profession in Ontario joined thirty-five sales managers and top personnel from the building products industry in a special two-day seminar at Scarborough, Ont., Jan 9-10. The meeting was designed to focus attention on mutual problems affecting architects and suppliers. The convention chairman was Dr. Thomas Howarth, Director of the School of Architecture, University of Toronto, and a stimulating keynote address was given by Robert F. Legget, Director, Division of Building Research, National Research Council.

The Canadian Institute of Steel Construction Inc.

The Institute maintains a library of 16 mm. color, sound films of interest to architects, engineers and contractors. Films include "Adventure in Steel", portraying the operations at the modern steel mills of Algoma Steel Corporation Ltd.; "Fury of the Winds"; "Men, Steel and Earthquakes"; "Skyway to the Future" (Burlington, Ontario Skyway) and "History of American Architecture".

International Institute of Welding

For the first time in the 13-year history of the International Institute of Welding the Annual Congress is being held outside Europe. In 1961 the American Council of the I.I.W. in conjunction with the American Welding Society, will sponsor the Annual Congress in New York.

On April 20 the Canadian Council is sponsoring a one-day industrial tour in the Welland-St. Catharines area. Delegates will be flown from New York to Niagara Falls, N.Y., where they will be met by buses supplied for the day by the Ontario Hydro Commission. In the morning the delegates will visit Ontario Hydro's Sir Adam Beck Power plant and in the afternoon they will tour local industries.

Society for Experimental Stress Analysis

Dr. C. B. Craig gave a talk on "Plastic Deformation" at a meeting held March 14 at the University of Toronto. Dr. Craig described the production of metal crystals, the basic mechanism involved in plastic flow, why the elastic theory is not applicable in the plastic range, and other associated subjects.

The Institution of Mechanical Engineers

The Council of The Institution of Mechanical Engineers, London, England, has awarded the 1961 James Watt International Medal to Professor Dr. Theodore van Karman, Ph.D., in recognition of his important contributions to the advancement of mechanical engineering science, which have extended the frontiers of engineering knowledge particularly in the field of aeronautics.

The nomination of Professor van Karman for this award was sponsored by the A.S.C.E. The James Watt International Medal was founded to commemorate the bi-century of the birth of James Watt, which took place Jan. 19, 1736.

Second International Heat Transfer Conference

The five day International Heat Transfer Conference is to be held Aug.

(Continued on page 113)

The Associations and Corporation

Prime Minister Diefenbaker, P.C., Q.C., is to address members of the Corporation of Professional Engineers of Quebec and their wives at the closing banquet of the 41st Annual General Meeting in Montreal, April 8.

The Committee on Professional Training has recommended to Council to sponsor the organization of a banquet where graduating engineering students would be presented with their certificates of membership in the Corporation. The banquet is planned for May 29 and it is the intention of the Committee to have a prominent engineer as guest speaker.

Ontario

The February journal of the Association of Professional Engineers of the Province of Ontario reports on Canadian Council's seventh survey of annual rate of remuneration of Canadian professional engineers. Table I shows a comparison of annual earnings across Canada as of December 1, 1960. Table II offers a comparison of the Dec. 1, 1960 survey with the one made in 1959.

▸ OTHER SOCIETIES

28-Sept. 1 at Boulder, Colorado. The conference, sponsored by four engineering societies, two American and two British, with participation by eight others, will be held on the campus of the University of Colorado. Great Britain is represented by the Institution of Mechanical Engineers and the Institution of Chemical Engineers. Sponsors and co-hosts of the conference in the United States are The American Society of Mechanical Engineers and American Institute of Chemical Engineers. Also participating are the American Society of Refrigerating and Air Conditioning Engineers, Chemical Institute of Canada, the Engineering Institute of Canada, the Institute of Aerospace Sciences, the Society of Automotive Engineers and the University of Colorado.

Papers have been submitted by engineers from the United States, Canada, England, U.S.S.R., Japan, Poland, Australia, France, Switzerland, Scotland, Sweden, Germany, and Yugoslavia. More than 100 papers on recent original work and new applications in heat transfer theory and practice have been accepted. To afford the opportunity for a full discussion of these papers, there will be no individual presentation by authors, but groups of related papers will be reviewed by special reporters and then followed by general discussions. Full opportunity to study the papers before the conference will be provided by supplying advance registrants with a bound copy of all the papers, well ahead of the meeting.

A special feature of the conference will be talks by four visiting lecturers who will review and synthesize the most recent developments in research and application.

The EIC representative on the organizing Committee is Professor J. W. Stachiewicz, M.E.I.C. and further information can be obtained by writing to him c/o Dept. of Mechanical Engineering, McGill University, Montreal 2.

National Industrial Production Show of Canada

The Hon. George H. Hees, Minister of Trade and Commerce is to open the third biennial National Industrial Production Show of Canada, to be held May 8-12 in the Industry and Coliseum Buildings, Toronto.

The Exhibition is in line with Federal Government decision to establish a National Productivity Council, which will co-operate with secondary industries to promote productivity and thus increase employment. The show will provide an opportunity for plant managers and owners, technicians, engineers, supervisors and executives to examine in one place the latest improvements in industrial production equipment, study methods and techniques, and select what they can use to improve their own production. There will be approximately 400 exhibits of production equipment, in different branches.

Royal Architectural Institute of Canada

The 1961 Convention of the Royal Architectural Institute of Canada will be held May 17-20, Chateau Frontenac, Quebec City. The 1961 convention theme is "The Building Community" and keynote luncheon speaker will be Philip Will, Chicago, President of the American Institute of Architects. A feature of the Assembly will be a special panel discussion covering the "Building Community" theme with prominent members of the Canadian building industry taking part. A post-convention tour of five European countries will follow.

National Electrical Day

Delegates from across Canada met at Halifax Feb. 6 to observe Canada's Electrical Day commemorating the birth of Thomas Alva Edison at Milan, Ohio, Feb. 11, 1847. Delegates were flown from Charlottetown, Moncton and Fredericton for the Luncheon attended by 257 at the Nova Scotian Hotel.

The luncheon was under the joint sponsorship of Canadian Electrical Council and the Power Committee of the Atlantic Provinces' Economic Council. The main address was given by J. W. Kerr, President, Canadian Electrical Manufacturers Association. Before the Luncheon a reception was given to the delegates through the courtesy of Nova Scotia Light and Power Company.

Coming Events

British Columbia International Trade Fair, Exhibition Park, Vancouver, May 3-13.

Hydraulic Conference, ASME-EIC, Montreal, May 7-11.

Symposium on Titrimetric Methods, The Chemical Institute of Canada, Analytical Division, Cornwall, Ont., May 8-9.

National Industrial Production Show of Canada, Industry and Coliseum Buildings, Toronto, May 8-12.

Annual Division Conference, Production Engineering Division ASME, Toronto, May 9-12.

ASME Production Engineering Conference, Toronto, May 10-12.

First Eastern Regional Convention, Society for Nondestructive Testing, Montreal, May 17-19.

17th Canadian Regional Conference, Illuminating Engineering Society, Montreal, May 14-16.

1961 Convention of the Royal Architectural Institute of Canada, Quebec City, May 17-20.

75th Annual General and Professional Meeting, Engineering Institute of Canada, Vancouver, May 31-June 2.

Canadian International Conference and Exhibit, Instrument Society of America, Toronto, June 6-8.

27th Annual Meeting, The National Society of Professional Engineers, Seattle, Wash., July 4-7.

44th Canadian Chemical Conference and Exhibition of the Chemical Institute of Canada, Montreal August 3-5.

News of the Branches

Chalk River

R. O. Sochaski, M.E.I.C.
Correspondent

Approximately 40 members, wives and guests attended the dinner meeting Feb. 14. Vice-President E. A. Cross was present and R. D. Blake of CARDE was the main speaker.

Vice-President Cross reviewed technical societies and their growth through the early days to the present, pointing out that the EIC is one that engulfs every branch of the engineering profession across Canada. He also mentioned that the Branch's members, being in contact with the atomic industry, should be in an ideal position for teaching other engineers about this expanding and important field.

Mr. Blake spoke on rockets. His talk was based on the Black Brant I and II rockets, which are manufactured at CARDE by the Canadian Government. Both these rockets consist of one motor, a nose cone, three fins and the necessary instrumentation. Mr. Blake described the process by which fuel is loaded into the engine casing and how these engines are tested on the 1,000,000 pound thrust test bed. The Black Brant I was designed for testing of solid propellant while the Black Brant II was designed as a research vehicle.

The meeting ended with a film on rockets.

"Corrosion costs United States and Canada $5.5 billion a year", said Mr. E. C. Halawell, Corrosion Maintenance Supervisor, Trans Mountain Oil Pipeline Company, at a joint meeting of the Central B.C. Branch of the Engineering Institute of Canada and the Association of professional Engineers, at the Round Up in Vernon Feb. 10.

Since joining Trans Mountain Mr. Halawell has devoted himself to the study of pipeline protection, a field of study as yet not fully explored, although a method of galvanic cathode protection for the British Navy's iron and steel ships was first advanced by Sir Humphry Davies about 100 years ago. In addition to galvanic cathodes, pipelines are also protected by special coatings and electrolitic cathodic protection by outside source of dc. current. The methods of applying this protection to oil pipelines with particular reference to the Trans Mountain Pipeline were explained in some detail. A lengthy question period followed.

Members attending from the major centres in the Okanagan as well as Revelstoke and Kamloops also heard this years Chairman, J. Nelson, M.E.I.C., City Engineer of the City of Kamloops, outline the years program which will include a visit to the smelter city of Trail, April 17., a meeting with the President of the EIC in Kelowna, May 26, and meetings at Kamloops Sept. 8, Penticton Oct. 6, and Vernon, Nov. 7. Western Field Secretary of the EIC, Cmdr. A. C. M. Davy was present at the meeting.

At a meeting held Feb. 7, John Fordham, Resident Engineer, Foundation of Canada Limited, gave a talk "Wharf Construction". The speaker was introduced by R. Goosney, JR.E.I.C., Project Engineer, Bowater's Newfoundland Pulp and Paper Mills Limited.

Mr. Fordham first discussed the factors which must be taken into account in the design of wharves in general. He then covered the four main types of wharf construction: trestle, sheet piling and fill, floating structure and coffer dam. Materials used, field of application and step-by-step building methods, received attention in each case. Throughout his talk the speaker made extensive use of diagrams and at its conclusion showed excellent coloured slides of wharves in construction at sites throughout eastern Canada.

The 11th annual meeting was held Jan. 27 and members heard Howard Smith, President of Dryden and Smith Planning Consultants, give an interesting talk on "Community Planning in Waterloo Township, Past, Present and Future". Mr. Smith outlined the need for increased community plannng based on the large influx of people expected in the next twenty years. With the aid of wall chart maps, he outlined some of the early planning of the township with regard to land use, roadways and parklands. In conclusion Mr. Smith appealed to engineers for ideas and assistance in future planning. L. Irwin Walle of Homar B. R. (Canada) Ltd. gave a talk at a meeting March 3. Mr. Walle's paper was entitled "Pneumatic Systems". He presented an interesting talk on applications and control of power pneumatic systems. He compared hydraulic and pneumatic methods of machine control. The short run Canadian operation favoured pneumatics because of low first cost. The speaker demonstrated a method of simplifying pneumatic installations by actuating a series of valves by a timed cam.

At this meeting the student executive was introduced to members. The executive for the winter-summer terms at the University of Waterloo are: President—John Rooroa, Vice-President—Mervyn Lumley, Sec. Treas.—Rodney McMurray.

Kootenay

I. Waterlow, M.E.I.C.
Correspondent

Mr. M. Phillips, Research Engineer at Cominco, gave a talk entitled "Cathodic Protection" to members Jan. 23.

Mr. Phillips described general principles of cathodic protection including the cathodic scale of metals. The suitability of various metals for cathodic protection was also described as well as the uses of zinc as a cathodic protective anode. Mr. Phillips completed his talk by showing slides of installations of zinc for this purpose in Port Coquitlan docking facilities.

Loyola Student Section

Richard Kind, S.E.I.C.

The section held its first annual dinner and stag Feb. 23 which was very successful. Approximately 65 members tended the dinner at which there ere three guest-speakers. J. C. Brodeur, . Johnson Company of Canada Ltd., poke briefly on civil engineering; . E. J. Layton, T. Pringle and Sons td., spoke on mechanical engineering nd W. J. Riley, chief engineer at perry Gyroscope Company of Canada td., spoke on electrical engineering.

Following the dinner there was an nformal gathering at which members ere able to meet and talk with guests nd professors.

Viagara Peninsula

"Nuclear Power Plants" was the title f a talk given by J. E. Holt, Canalian General Electric Company, Feb. 16. The speaker presented an excellent ddress on nuclear power plants with particular emphasis on the ones now being built in Ontario. Slides were shown and samples of uranium in various stages of processing were passed round. Mr. Holt was introduced by W. O'Reilly, JR.E.I.C. and thanked by R. McKimmie, M.E.I.C.

Newfoundland

Anthony O. Nemac, JR.E.I.C.
Correspondent

The Branch held a joint banquet with the student engineering society of Memorial University of Newfoundland Feb. 28. The guest speaker was T. J. Hobson, project engineer for Twin Falls hydro electric project in Labrador. Mr. Hobson gave an interesting and informative talk on the work in progress at Twin Falls and described the project as it would be when completed. The Twin Falls Hydro-electric operation is designed for an output of 120,000 h.p. which is expected to supply the needs of Labrador. Mr. Hobson also described the larger project of the Hamilton River development which is planned to have a continuous output of 4,000,000 h.p. The talk was accompanied by a showing of slides which vividly illustrated the magnitude of these projects. Mr. Hobson also displayed a scale model of the Hamilton River power project.

The banquet was attended by 80 persons—40 students and 40 members.

Nipissing and Upper Ottawa Branch

J. W. Millar, M.E.I.C.
Correspondent

A dinner meeting was held Feb. 10 to entertain students in the upper grades at local secondary schools who had shown an interest in becoming engineers. Each member sponsored a student for the evening, including the dinner. The guest speaker was W. G. Mann, president of W. G. Mann Associates, personnel advisers and consultants in Montreal.

Mr. Mann emphasized the importance of communicating with employers and employees, stressing the part the ability to communicate efficiently plays in a career. He used examples and anecdotes to illustrate his point. He recommended that students not making 75 per cent in high school think hard before entering engineering because such a student will have a hard time at university. Other requirements to make a good engineer, he said, are, to have some abstract reasoning ability and be good at space relations. The speaker was introduced by H. R. D. Graham, Northeastern regional manager, Ontario Hydro and was thanked by J. W. Millar.

Victoria

W. Tivy, M.E.I.C.

A. H. Paget, Comptroller of Water Rights of B.C. gave a talk Jan. 31 about his recent tour of Japanese hydro-electric projects and dams, which was in connection with the annual executive meeting of the International Committee on Large Dams in Tokyo.

Mr. Paget was impressed by the great activity in dam construction in the country. Earth-fill dams have been in use for well over a thousand years but the application of new techniques and use of new materials has brought a tremendous surge of heavy construction activity. Between 1950 and 1958, no fewer than 40 dams over 200 ft. high were constructed; since 1958, about the same number have been built or are under construction. Several of these dams are between 500 and 600 ft. high—among the highest in the world. It was evident from photographs shown by Mr. Paget, that modern methods of construction are prevalent in Japan. The experience and hard work of Japan's engineers and contractors has shown that they are capable of undertaking many of the world's large construction projects once the basic needs of their own country have been met.

Vancouver

The Branch started 1961 with the theme "Tuesday Night is Engineering Night". A program of specialized technical meetings under the Chairmanship of Alan Kay, M.E.I.C., has been very successful. Civil-Structural, Management, Natural Resources Development and Mechanical Sections have meetings on the first, second, third and fourth Tuesdays, respectively. The meetings have been well attended and appear to be filling a need for more technical rather than general meetings.

Civil-Structural Section—Jan. 10. Panel discussion on glulam structures entitled "New Horizons in Timber Structures". John McKenzie, Regional Officer, Canadian Institute of Timber Construction, was moderator. Feb. 7. Charles F. Ripley M.E.I.C., Consulting Civil Engineer, gave a talk on "Glimpses of Civil Engineering in Japan".

Management Section—Jan 17. Richard A. Mahoney, Management Consultant, spoke on "Management and the Facets Relating to Objectives, Policy and Control". Feb. 14. Conrad M. Lamond, Management Consultant, gave a talk entitled "Selection and Development of Personnel".

Natural Resources Development—Jan. 24. C. Riley, Consulting Geologist, spoke on "Potentialities of Natural Resources in British Columbia". Feb. 21. L. Edgeworth, of the Federal Dept. of Fisheries, gave a talk "The Salmon's Struggle for Survival."

Mechanical Section—Jan. 31. Dr. H. M. Ellis of I.P.E.C. gave a talk entitled "Electrical Utilities in the U.S.S.R." Feb. 28 W. B. Weston, Marine Superintendent, B.C. Toll and Highways Authority, spoke on "The Proposed 1,000 Complement Provincial Government Ferry."

The Professional Development Course has enrolled 45 members. The lectures started Feb. 8 and run throughout March. The theme for the 1961 course is "The Canadian Economy".

The annual meeting was held Feb. 16. The Sec.-Treas., W. N. Isberg, gave a report on the past season's activities and the auditor's report of Branch finances was presented. Prof. V. L. Dutton, M.E.I.C. was the guest speaker and gave a talk entitled "Thin Shell Structures".

Prof. Dutton gave a general discussion on the relative advantages and disadvantages of the use of thin shells for building construction, dealing first with theoretical considerations and a description of hyperboloids and hyperbolic paraboloids. The talk was profusely illustrated with slides of diagrams and photographs of many buildings under construction and those already completed. The talk was concluded with a description and illustration of two projects carried out by students of the Faculty of Architecture on the University campus grounds: one a thin shell concrete hyperbolic parabloid, and the other a timber hyperboloid.

The speaker was introduced by Prof. H. E. T. North of the University of Manitoba Engineering Faculty, and was thanked by R. Drysdale of the Manitoba Department of Industry and Commerce. A question and answer period followed the address. Also on display were a number of models and drawings executed by architecture students, and printed literature and pamphlets on the subject of thin shells.

The **BELLEVILLE BRANCH** heard T. V. J. Cudbird, Manager, Anti Corrosion Division, Canadian Hanson and Van Winkle Company Ltd., speak on "Corrosion and Materials of Construction", Feb. 12. This talk was illustrated by a 16 mm sound film. The **BORDER CITIES BRANCH** held a joint dinner meeting with local members of the A.P.E.O. Feb. 15. Approximately 85 attended dinner. Guests included L. C. Sentance, President of the A.P.E.O.,

E. C. Luke, M.E.I.C., E.I.C. Headquarters staff, and P. Ryan, A.P.E.O. Headquarters staff. Ladies Night at the **BROCKVILLE BRANCH** took place Feb. 6. A dinner and dance was held at the Prescott Golf Club. Garnet T. Page, M.E.I.C., General Secretary of E.I.C., gave an illustrated talk on his visit to Russia. A meeting held Feb. 9 was sponsored jointly by the **HAMILTON BRANCH** and the Student Engineering Society. Dr. W. W. Sawyer presented a most practical and interesting talk on "Maths for Engineering". The **KINGSTON BRANCH** held a meeting Feb. 22. This was 'Students Papers Night' and four papers were presented. The **UNIVERSITY OF MANITOBA STUDENT SECTION** has been holding meetings since January, connected with the student paper competition. The **UNIVERSITY OF ALBERTA STUDENTS SECTION** heard an address Feb. 21 by Murray Stewart, General Manager, Northwestern Utilities. Mr. Stewart gave a talk entitled "The Poor Benighted Engineer" and dealt with the role of an engineer in the community and as a manager.

Engineers' Wives Associations

The Annual Business and Dinner meeting of the **Border Cities Auxiliary** was held Jan. 30. Sixty members were present when the new executive took office. Mr. A. J. Gervais gave a talk on "Purchase and Care of Furs".

The recently formed **Corner Brook Club** met Jan. 16. Mrs. Murley and Mrs. Langens, described their recent European tour and illustrated their talk with slides. Public Speaking was the main topic for the February meeting.

The Hamilton Association heard an enlightening talk on Africa at their February meeting. Mrs. Glen Dawson illustrated her talk with slides taken on a recent trip.

A dinner meeting was held in Waterloo in January by the **K.W.G.P. Association.** Plans are being made for the Annual Meeting in May.

The second meeting of the **Kingston Auxiliary** was held Jan. 31. This was a successful evening with eight bridge tables playing.

The **Lethbridge** Association held an interesting gathering in January. The group toured Automotive Electric Canada Ltd., a firm engaged in assembling telephones for export.

The membership of the **London Association** has now reached approximately 200. It has been divided into eight sections and each section is responsible for the complete planning of one program during the year. The Annual Dinner Meeting was held in January with guests from Woodstock present. In March the Spring Tea was held at the London Art Gallery.

In January a Smorgasbord Supper was held by the **Regina and Area Association.** Its Annual Meeting was held March 14.

The **Sault Ste. Marie Club** held a supper Dance Feb. 17 which was well attended. It was held in the Officers' Mess of the Armouries. Mrs. Lillian Robertson of the Toronto Office was a guest.

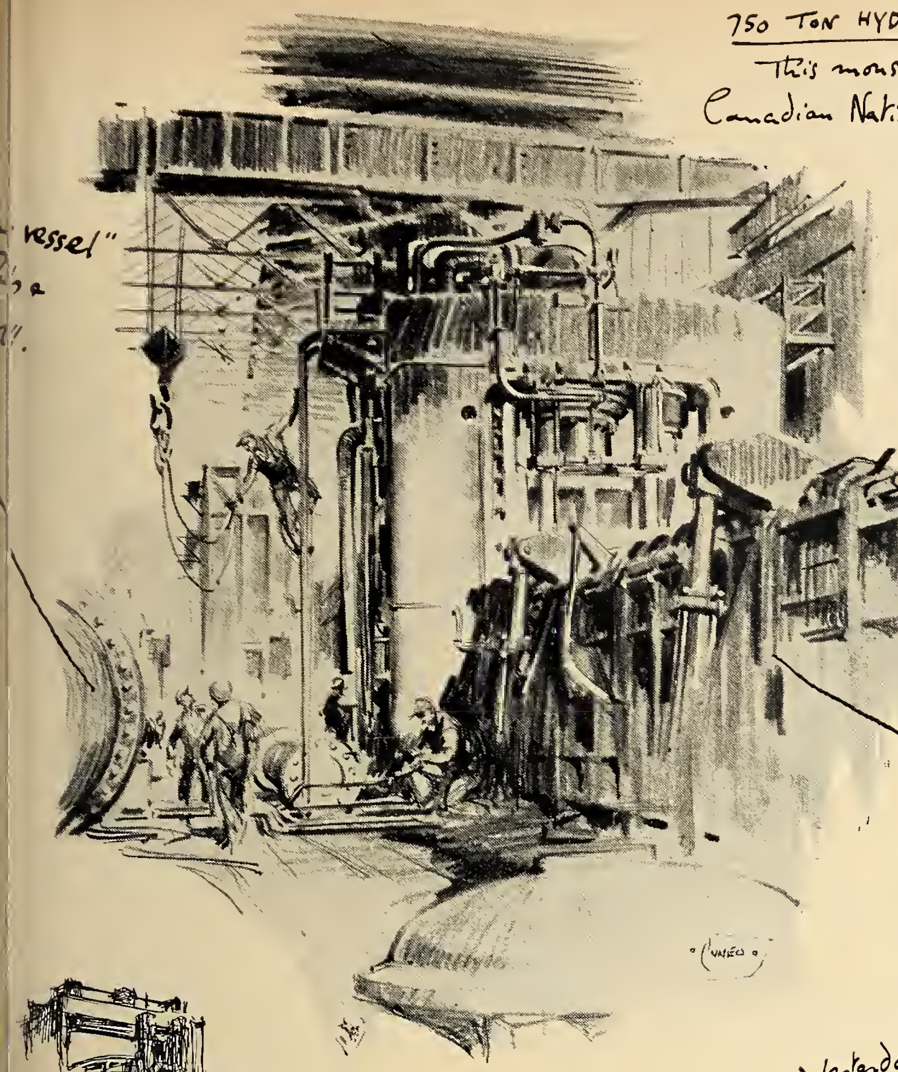
Plans are being made for the Spring Tea to be held by the **Sarnia Association.**

The Annual Meeting and Luncheon of the **Toronto Auxiliary** was held Jan. 11. The Auxiliary is making a $1,000. donation to the new Engineering Building at the University of Toronto. They have purchased curtains and an oil painting. Representatives from the Royal Doulton Company showed a film and explained the processing of this fine china. The Executive entertained Mrs. G. McK. Dick and Mrs. G. T. Page at luncheon Feb. 9. The Spring luncheon was held March 1 at the Granite Club with displays of costumes from the Stratford Festival.

The **St. John's Club** held a 'Musical Evening' in February and presented $100. scholarship to a student at Memorial University. A Dance and Bridge tournament was held in March.

The **Victoria Association** visited the Growers' Wine Company in February. This was followed by a luncheon.

A luncheon was held by the **Vancouver and Lower Mainland Association** in February. In March a Bridge and Tea was held at the Point Grey Golf and Country Club. The Annual Meeting and Luncheon is being held May 25. EIC



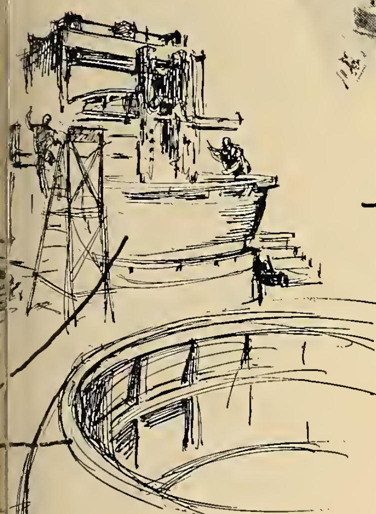
750 TON HYDRAULIC "SCRAP SHEAR"

This monster is to be installed in the Canadian National Railroad Yards, London Ontario. Its job is to crush, actually, bite up old steam locomotives. Its great guillotine blades can sever 6 inch steel with ease. For this I hate it. Yesterday I toured the C.P.R yards at St Luc, & saw the endless rows of proud rusty locomotives silently waiting their call to this modern madame Guillotine

"Vive le Progrès"

The hopper for loading.

" vessel"



This is a Vertical Boring Mill

It is turning a ball & socket expansion joint for the HUMBER RIVER SEWAGE TREATMENT PLANT (Romantic!) The reason for such a joint is to compensate for ground movement in the area. In other words the pipe may shift under the ground after its installation.

Yesterday I was taken over a number of the locks of the St Lawrence Seaway & saw the massive gates that were made here in Canadian Vickers, Remarkable place this. It seems that they can take on anything from a ship to a "candy cooker".

commission:-
RT BOBY LTD.,
ury St. Edmunds.

Overseas Companies make a vital contribution to the world-wide engineering resources of the Vickers Group. Whilst in Canada last year, Terence Cuneo paid a visit to Canadian Vickers Limited in Montreal, and these drawings give some idea of the part the company plays in Canada's shipbuilding and heavy engineering industries. The artist is shown in a typical sketching position.

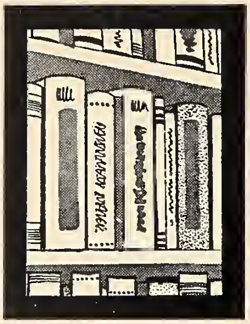
Library Notes



Prepared by the Library, The Engineering Institute of Canada

Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

RECTIFICATION, SUPERFINITION.

Of interest to all those engaged in metal working and finishing, the larger part of this volume is concerned with various methods of metal finishing and grinding. It covers the various types of abrasives used, the different types of grinding machines, and their manufacture and testing, different methods of machining, and safety precautions. A final chapter discusses methods of obtaining a superfine finish. Many useful illustrations and diagrams are included. (F. Henry and H. Pouret. Paris, Eyrolles, 1960. 146p., 23 NF.)

LA COMMANDE HYDRAULIQUE, 2. ed.

Although the field of application of hydraulic control is vast, its basic principles are the same, and the author presents these principles in his introductory chapters, which also include a comparison between electric and hydraulic control. The various machines and systems available are considered, and their application in regulators, controls and servomechanisms. The final chapters cover the use of hydraulic control equipment in aircraft, vehicles, vessels, presses, machine tools, etc. (C. R. Himmler. Paris, Dunod, 1960. 424p., 68 NF.)

***1301 REVIEW PROBLEMS.**

The purpose of this book is to provide an intensive practical review for persons planning to take the PE registration examination and the prerequisite EIT (Engineer-in-Training) exam which follows graduation and generally precedes practical experience. Individual problems selected from actual state registration exams form the basis of the review, and are arranged in two sections, corresponding to the two parts of the EIT exams. The "General" section (Chapters 1-11) covers such subjects as mathematics, chemistry, statics, thermodynamics, fluid mechanics, electricity, engineering economy, ethics, and contracts. The "Applied Engineering" section (Chapters 12-19) covers aeronautical, chemical, civil, mechanical, electrical, industrial and mining engineering, and surveying. The remainder of the book (Chapter 20), contains nine complete typical state examinations. Appendices give answers, symbols and abbreviations, addresses of state Registration Boards, and recommended reference books. (R. C. Brinker and others. Scranton, International, 1960. 388p., $7.50.)

***BIBLIOGRAPHY AND ABSTRACTS ON ELECTRICAL CONTACTS, 1959 SUPPLEMENT.**

The seventh annual supplement to a bibliography which now covers published material on the subject from 1835 through 1959 (STP's 56-G to 56-N inclusive). All include subject and author indexes, and annotated, fully-cited items arranged chronologically by date of publication. The effects which take place in the operation of electrical contacts are very complicated, involving the microphysics of the electric arc, the metallurgy of the contact materials, the mechanics of the operating mechanism, the physical and chemical properties of all materials and the ambient conditions. Limitations of ranges of titles and subject matter is a practical necessity, but all references of reasonable connection with the subject have been included. (Philadelphia, American Society for Testing Materials, 1960. 63p., $3.50 s.t.p. 56-N.)

***REPORT ON THE ELEVATED-TEMPERATURE PROPERTIES OF ALUMINUM AND MAGNESIUM ALLOYS.**

Contains data compiled by the ASTM-ASME Joint Committee on Effect of Temperature on the Properties of Metals. Summarized are elevated temperature, tensile and creep rupture properties of current commercially established aluminum and magnesium alloys. Both wrought and cast alloys are covered in various forms including rolled, forged or extended rod, plate, sheet and castings, both sand and permanent molds, and some data on alclad aluminum alloys. Data is given for each alloy in the form of a title sheet, giving its designation, chemical composition and specifications; while data sheets give a description of the material, the strength values for the mechanical properties, and tables and graphs of physical properties. By spotcheck, the top test temperature for which data is given appears to be 1000°F. (Philadelphia, American Society for Testing Materials, 1960. 308p., $7.00 s.t.p. no. 291.)

***SYMPOSIUM ON SPECTROSCOPIC EXCITATION.**

At the 62nd Annual Meeting of ASTM in Atlantic City, June 1959, this Symposium considered some of the parameters involved in obtaining reproducibility and accuracy in spectroscopy. The three papers included here discuss the matrix effect in excitation, the effects of gaseous atmospheres on excitation, and some properties of excitation sources such as flames and electric discharges, including hydrocarbon flames, plasma jets, and high-frequency, interrupted, continuous, and fluid-controlled arcs. (Philadelphia, American Society for Testing Materials, 1960. 62p., $2.50. s.t.p. no. 259.)

DESIGN OF CONCRETE PAVEMENTS FOR AIRPORTS.

This manual is intended for engineers responsible for the structural design of concrete pavements for airports, and presents the design criteria and practices already in use. The topics covered include: design criteria; subgrade and drainage; pavement thickness; joints; reinforcement design; construction practices; welded wire fabric steel reinforcement. (Washington, Wire Reinforcement Institute, 1960. 96p., $3.00.)

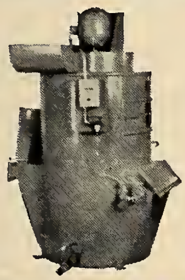
THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these notes are now available in the Library, and may be borrowed by members of the Institute. Two items may be borrowed at one time for a period of two weeks, excluding time in transit.

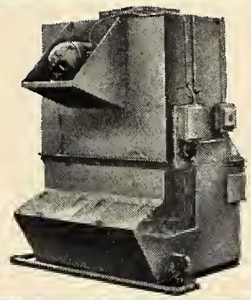
Library hours are: Monday to Friday: 9 a.m. to 5 p.m.; Saturdays: 9 a.m. to 12 noon. All requests and enquiries should be addressed to the Librarian at 1050 Mansfield Street, Montreal.

DeVilbiss FINEST WET TYPE DUST COLLECTORS IN CANADA!

DE VILBISS ARE THE ONLY SINGLE-SOURCE MANUFACTURER OF COMPLETE FINISHING SYSTEMS IN CANADA

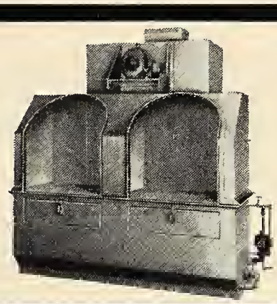


Uni—Wash Junior—500 to 2500 CFM.



Uni—Wash Senior—5000 to 50000 CFM.

Uni—Wash Shake out booth—5000 to 25000 CFM.



Uni—Wash down draft bench dust collector—
two positions,
Uni—Wash type illustrated—2500 to 7500 CFM.

As specialists on complete finishing systems, DeVilbiss have designed dust collectors that render maximum service and assure maximum safety.

Complete systems can be built to your specifications, or furnished in standard units. Detailed information is readily available. Please write for Technical Bulletin 1301.

FOR BETTER SERVICE, BUY
DeVilbiss

TECHNICAL BULLETINS & PAMPHLETS RECEIVED

Space limitations do not enable us to record these in the Library Notes. A mimeographed list of the Bulletins and Pamphlets received during the last month is available free on request to the librarian.

*SYMPOSIUM ON ROAD AND PAVING MATERIALS-1959.

The first section of this book contains a comprehensive progress report, and two papers discussing results of extensive tests on asphalt, including the microfilm durability test, all relating to research work carried out on the Zaca-Wigmore Experimental Test Road, a project of the California Division of Highways and Pacific Coast asphalt producers, begun in 1954. The second section contains four papers which discuss the prediction of performance of asphalt in terms of chemical composition, the flexibility characteristics of asphaltic paving mixtures as influenced by temperature, and degradation of aggregates employed in asphalt pavement structures. (Philadelphia, American Society for Testing Materials, 1960. 126p., $3.50. s.t.p. no. 277.)

GEORGE AND ROBERT STEPHENSON: THE RAILWAY REVOLUTION.

Deeply interested in tthe history of the Industrial Revolution, Mr. Rolt has already published biographies of two engineers connected with that period, Brunel and Telford. He has now written the story of the two Stephensons, father and son, and of the birth of the railway. Robert was also the designer of many famous bridges. Although most of their work was done in England Robert Stephenson worked for a time at the mines of Santa Ana in Columbia, and it was he who was the Engineer-in-Chief for the construction of the first, tubular, Victoria Bridge at Montreal. The book is illustrated with contemporary drawings. (L. T. C. Rolt. Toronto, Longmans, 1960. 356p., $6.00.)

A.R.R.L. ANTENNA BOOK.

This revised edition contains the information required by amateur radio operators on the theory and practice of antennas. It includes information on wave propagation, longwire and multiband antennas, rotary beams, antennas for very high frequencies, and mobile antennas. A useful bibliography is included. (West Hartford, Conn., American Radio Relay League, 1960. 320p., $2.25.)

HEAT TREATMENT OF METALS.

A practical text by a well-known author, giving in simple terms basic information on annealing, hardening and tempering. The first volume gives definitions of the various processes, and discusses grain size, the heat treating of aluminum and other non-ferrous alloys, steel treating and tempering, and case hardening. The second volume covers hardenability, isothermal transformation, heating for manufacturing processes, the choice and treatment of tool steels, heating and cooling, furnace types, and the design of components for heat treatment. (P. S. Houghton. Toronto, General, 1960. 2 vols., $3.75 each.)

BROACHING.

A discussion of a method of machining which now ranks as a major production process, showing the working of modern broaching machines, and giving details of the specialized cutting tools used, for both internal and surface broaching. The author has illustrated his text with examples of the practice found in modern factories. The various types of machine are illustrated, and there is a bibliography. (C. Monday. Toronto, General, 1960. 162p., $3.75.)

SPARK-MACHINING.

Much of the information in this volume previously appeared in the British periodical Machinery, and has been supplemented with that supplied by the manufacturers of spark-machining equipment. This method of finishing has developed rapidly over the past eight years, and much of that development has taken place in the U.S.S.R. The three chapters in the book cover basic principles, equipment and operation. (Toronto, General, 1960. 72p., $1.00.)

DIE-SINKING AND ENGRAVING MACHINES.

Machining by automatic duplication has now superseded hand methods, and has led to greater accuracy and increased production. This book covers the various die-sinking and engraving machines available, the electrical and electronic control of die-sinking, and hydraulic control. A final chapter discusses pantograph machines and their uses, including optical control. (H. C. Town. Toronto, General, 1960. 70p., $1.00.)

DISTRIBUTION SYSTEMS.

This most useful volume is intended primarily for the electric utility distribution engineer, but it will also be useful for all electric utility and industrial power systems engineers, as well as for students. It covers all aspects of distribution, including: load characteristics; substations; primary and secondary distribution; secondary network systems; distribution transformers; system voltage regulation; application of capacitors; voltage fluctuations on power systems; protective devices; metering; street lighting. Useful lists of references are included in each chapter.

This volume has been written by electric utility engineers of the Westinghouse Electric Corporation, and has grown out of the Corporation's Electrical Transmission and Distribution Reference Book, the first edition of which was published in 1942, which it is now planned to issue in three volumes, as an Electric Utility Engineering Reference Book. The other two volumes will cover system analysis and generation, and transmission and system protection. (Hamilton, Canadian Westinghouse, 1959. 567p., $15.00, $10.00 to students.)

MAGNETIC AMPLIFIERS; PRINCIPLES AND APPLICATIONS.

A presentation of the fundamentals of magnetic amplifiers intended for technicians and students, as well as a review of the subject for electrical engineers. Introductory chapters review the fields of magnetism, electromagnetism and magnetic circuitry necessary for an understanding of the subject. The author then discusses saturable reactors, self-starting and three-legged core magnetic amplifiers, compensating and polarized magnetic amplifiers, and variations of them. The text also covers amplifier gain, feedback, general uses and construction, maintenance, applications and circuitry. (P. Mali. New York, Rider, 1960. 101p., $2.45.)

THE CHORD OF STEEL.

The well-known novelist and historian has here written an interesting account of Alexander Graham Bell's early years in Brantford, where he made his great invention of the telephone, and where the first tests were carried out between Brantford and nearby Ontario towns. Mr. Costain was himself raised in Brantford, and thought that that city's connection with Bell should be more widely known. (Thomas Costain. Toronto, Doubleday, 1960. 238p., $3.95.)

THE DESIGN OF SEA DEFENCE WORKS.

Written by an expert, this is the first scientific treatment of a subject which has long been approached by a trial and error method. The author has included in his book both the results of research and his own experience, and points out that much research is still being carried on. The first chapter discusses tides and waves, and includes in an appendix a mathematical treatment of wave run-up on composite slopes, written by Thorndike Saville of the U.S. Beach Erosion Board. Other chapters cover natural sea defences, sea walls, estuary walls and counterwalls, hydraulic design of sea walls, and examples of sea, estuary and tidal river walls. Lists of references are included. (R. B. Thorn. Toronto, Butterworth, 1960. 106 p., $5.00.)

PULP AND PAPER MANUAL OF CANADA.

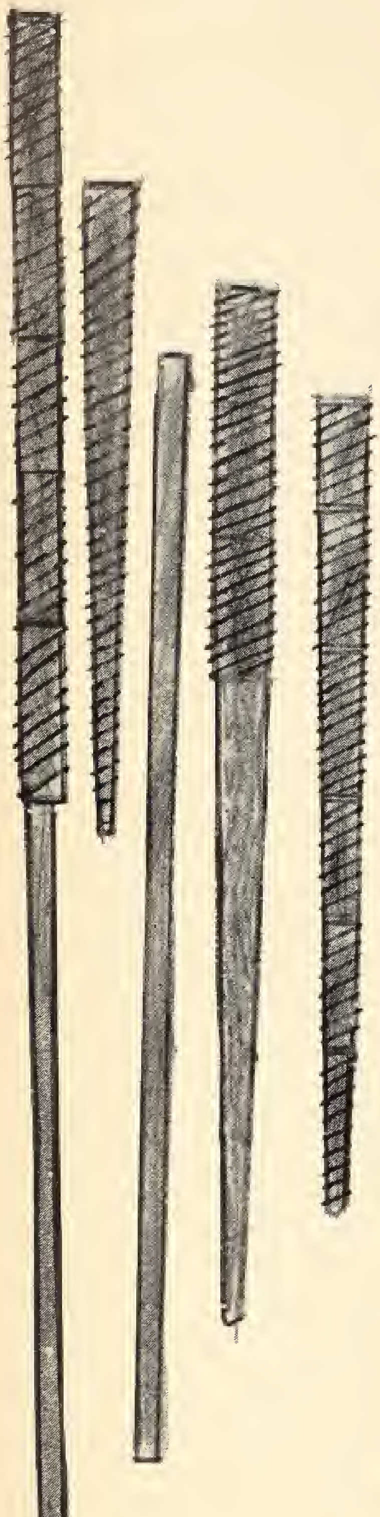
This twenty-eighth edition follows the pattern of earlier editions, being divided into four sections, General information, Operating information and techniques, Mill operating personnel and flow sheets, Service and suppliers listings. Several interesting papers, and useful statistics are included as usual. Anyone connected with the industry will find this Manual essential. (Ed. by J. N. Stephenson. Gardenvale, National Business Publications, 1960. 460p.)

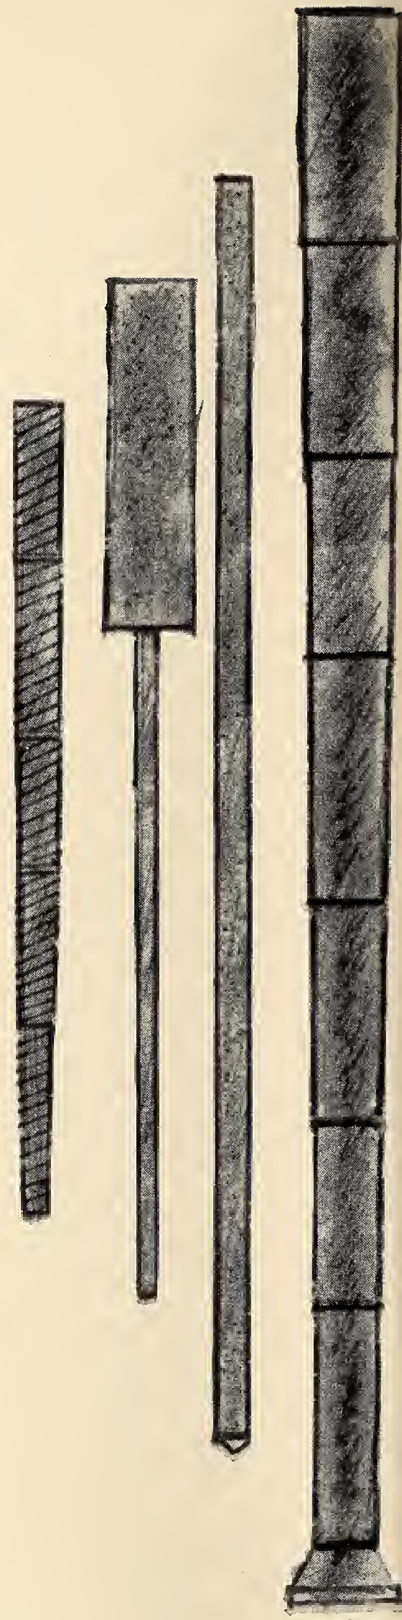
A CENTURY OF OIL AND GAS IN BOOKS.

It is fitting that the centennial of the oil industry in 1959 should be marked by the publication of this annotated bibliography of books written during the last 100 years, in English, on oil and gas. The compiler has personally examined almost all the 2000 items included, and has arranged the entries by subject, covering everything from prospecting to marketing. An author index is included. (Comp. by E. B. Swanson. Toronto, Saunders, 1960. 214p., $5.95.)

RADIOACTIVE WASTES: THEIR TREATMENT AND DISPOSAL.

The increasing use of radioisotopes in industry and medicine, and the growing number of nuclear power stations mean that the problem of the safe disposal of radioactive wastes must be solved now, and not be permitted to





assume the proportions that non-radioactive environmental pollution has.

This is a technical discussion of the problem and its solution by a group of British experts. The first half of the book explains the problems to be dealt with, the nature and sources of radioactive wastes, the hazards of radiation, the measurement of radioactivity. The second part deals with the treatment and disposal of liquid, solid and gaseous wastes. There is also a chapter on British law on radioactive wastes. (Ed. by J. C. Collins. London, Spon, 1960. 239p., 55/-.)

UNFIRED PRESSURE VESSELS.

This commentary on the A.S.M.E. Unfired Pressure Vessel Code, is now in its fourth edition, and it gives supplementary information intended to make easier the use of the Code. The book gives the history of the Code, methods of obtaining Code authorization, a description of the Code, basic causes of pressure vessel accident and failures. It also covers inspection and quality control, and welding requirement. A brief outline of Canadian pressure vessel requirements is also given. (Robert Chuse. New York, Dodge, 1960. 154p., $8.75.)

MACHINE DRAWING AND DESIGN, 7th ed.

Now in its seventh edition, and largely re-written, this text is intended for an intermediate course in machine drawing and design for mechanical engineering students. After an introductory chapter on the principles of projection, the following chapters cover the drawing and design of various components, etc., castings, fastenings, shafts, brakes, bearings gearing, valves, aircraft components, etc. Information is also given on factors influencing design, and toleranced dimensions. Exercises and examination questions are included. (W. Abbott. Glasgow, Blackie, 1960. 281p., 21/-.)

INFORMATION PROCESSING.

This volume contains the Proceedings of the International Conference on Information Processing organized by UNESCO in 1959. Some 2,000 delegates from 37 countries attended the meetings, at which more than seventy papers were read.

These papers have been grouped into seven sections, the first of which is concerned with methods of digital computing, and the uses of digital computers. The second section deals with a common language for computers, and the third contains seven papers on the automatic translation of languages. The next sections cover pattern and character recognition, and machine learning and thinking, and the logical design of computers. There was a special session on computer techniques of the future, and three symposia on the relation between analog and arithmetical calculation, error detection and correction, and the collection, storage and retrieval of information. All the papers are in French or English, and abstracts of each are given in English, French, German, Russian and Spanish. (Unesco. Toronto, Butterworth, 1960. 520p., $25.00.)

We need help. Get me Atlas.

ATLAS STEELS

Breakdowns are an industrial disease that can stop machines and shut down factories. When this happens, many companies call an Atlas Representative just as they would call a doctor to treat a human injury.
The man from Atlas knows his job. He is a member of the largest and best qualified specialty steel metallurgical team in Canada. Whenever a metal problem threatens your production schedule, call Atlas. Our man will be there promptly, with the right help. Your nearest representative is listed on the opposite page.

ATLAS STEELS LIMITED, WELLAND, ONTARIO. Warehouses: Montreal • Toronto • Hamilton • Windsor • Winnipeg • Vancouver. Representatives: London • St. Catharines • North Bay

RAPPORTS FINANCIERS DANS LES ENTERPRISES.

A French translation of the American Management Association publication, Reporting Financial Data to Top Management, this book covers the preparation of financial reports, with examples drawn from the experience of the authors. The topics covered include the organization of reports; reports on investment programmes, and economic situations; the financial report in a time of transition or organization, etc. (Paris, Dunod, 1960. 213p., 19 NF.)

***SYMPOSIUM ON NONDESTRUCTIVE TESTING IN THE MISSILE INDUSTRY.**

This volume contains seven of the eight papers presented at the Symposium, held in San Francisco on October 12, 1959. Included are papers on radiography of rocket motors, of weldments in motion, and in the 6-to 30-Mev range; ultrasonics in sandwich structures inspection, fluid-contaminating particle detection, and evaluation of missile materials and components; and mobile field inspection of missiles and aircraft. (Philadelphia, American Society for Testing Materials, 1960. 71p., $2.00 s.t.p. 278.)

COBALT MONOGRAPH.

Compiled primarily by staff members of the Battelle Memorial Institute, this monograph is a survey of the available literature on cobalt. In the chapters dealing with the mining, metallurgy, and physical, mechanical and chemical properties of cobalt, and with cobalt alloy systems, as much detailed information as possible is included. The second part of the volume considers the uses of cobalt in high-temperature materials, magnetic alloys, tool and die steels, cemented carbides, coatings, glass and ceramics, catalysts and pigments. Also covered are radioactive cobalt and its industrial applications, and medical and agricultural uses of cobalt. These chapters are less detailed, but extensive bibliographies refer the reader to sources of additional information. There is no index but a very detailed table of contents partially takes its place. (Brussels, Centre d'Information du Cobalt, 1960. 515p., 750 Belgian Francs.)

CORROSION PROBLEMS OF THE PETROLEUM INDUSTRY.

Nine papers presented at a 1959 symposium on this subject are published in this volume, together with the discussion on them. The papers cover: the corrosion of production equipment and gathering lines, and its prevention; corrosion problems in Lake Maracaibo; corrosion of tanker hulls; protection of storage tanks and pipelines; corrosion prevention in salt water cooling systems; non-destructive testing in the oil refinery; developments in corrosion-resistant materials, both metal and non-metal.

The Symposium was organized by the Society of Chemical Industry and the Institute of Petroleum. (London, Society of Chemical Industry, 1960. 235p., 30/-. S.C.I. Monograph no. 10.)

MODERN WORKSHOP TECHNOLOGY: PART II MACHINE TOOLS AND MANUFACTURING PROCESSES, 2nd. ed.

The many developments in the last ten years have led the editors to completely recast this work, which provides a survey of the principles and methods of modern mass production. The various chapters have been written by specialists.

The first two chapters cover the general principles common to all machine tools, and the theory of cutting. The remaining chapters discuss specific machine tools and techniques, turning; milling; broaching; grinding; presswork; measurement; inspection; lubrication; heat treatment; production planning, etc. New developments such as ultrasonic machining and spark erosion are discussed, there are many illustrations, and a useful bibliography.

The first part, already published, covered materials, and a third volume, now in preparation, will deal more extensively with production planning and automatic machines, thus completing a most useful series. (Ed. by H. W. Baker. London, Cleaver-Hume, 1960. 650p., 55/-.)

EXPERIMENTAL PLASTICS, 2nd. ed.

A practical undergraduate text, containing a variety of experiments in plastics technology, including all those which a student should have performed for the examinations of the Plastics Institute (London). The experiments are divided into four sections: the production of synthetic resins and polymers; the conversion of these into plastic materials; methods of fabrication by moulding, extruding, casting, etc.; the identification of plastics, and methods of testing. (C. A. Redfarn and J. Bedford. Toronto, British Book, 1960. 140p., $5.50.)

BASIC HUMAN FACTORS FOR ENGINEERS.

An introduction to the field of human engineering, in which the author discusses the design of systems and equipment for optimum human use, the organization of a human engineering department, task analysis, human-factors working forms, performance-test scoring and diagnosis, and personnel evaluation. A final chapter considers the part human engineering will play in astronautics.

The author, now resident in the U.S., formerly worked with the N.R.C. in Ottawa, and was a member of the E.I.C. (P. A. Verdier. New York, Exposition Press, 1960. 103p., $4.00.)

SPANNBETONBEAU, teil 1, 2. auf.

This text on prestressed concrete construction, intended for both practising engineers and students, commences with an historical introduction, followed by a brief section on theory. The remaining chapters cover materials, structural and fire tests performed in various countries, and detailed calculations for the design of prestressed concrete construction. In an appendix are lists of prestressed concrete bridges and buildings, giving for each the method of construction, and reference to any published descriptions. There is also a useful general bibliography, mostly of German publications.

This second edition has been brought up-to-date, and mention made of developments in different countries during the past four years. (W. Herberg. Leipzig, Teubner, 1960. 342p., 21.80 DM.)

DICTIONARY OF NUCLEAR PHYSICS.

A German-English, English-German dictionary containing some 5,000 words, giving both the U.S. and British terms where these differ. The terms included are used in uranium mining, reactors, nuclear fission and fusion, isotope research, and in other fields of nuclear physics. There is a useful list of English abbreviations, with their English and German meanings. (Hans Rau. Wiesbaden, Brandstetter Verlag, New York, Heinman, 1957. 247p., $5.00.)

PRAKTISCHE SCHALENSTATIK. Bd. 1 DIE ROTATIONSSCHALEN.

A mathematical treatment of the design of shells, intended for the design engineer. It covers the membrane theory of cylindrical, conical and spherical shells, and the deformation, bending

theory, heating and expansion of shells. The second section of the volume contains worked examples of the design of different shell structures. (J. Born. Berlin, Ernst, 1960. 218p., 50 DM.)

ORGANIZATION DES STRUCTURES DE DIRECTION.

Subtitled Top Management, this text presents the French theory of the organization of management. The first, theoretical, section of the book covers definitions of terms used, company structure, main and subsidiary operations of a company, staff functions and horizontal and vertical organization. The second part of the book discusses applications of the theories in various companies; electrical equipment manufacturing, chemical industry, ship yard, service station chain and a bank. (A. Vidal and J. Beaussier. Paris, Dunod, 1960. 144p., 11 Fr.)

NEW HOUSING IN GREAT BRITAIN.

A brief account of city planning, housing projects and suburban redevelopment in England during the last fifteen years. The text covers the growth of four "New Towns", all planned as a unit, and designed to be self-sufficient; residential areas designed as a unit; and individual blocks of flats and houses. The greater part of the book is a collection of plans, illustrating the points made in the text, which is in parallel columns in English and German. (H. Bruckmann and D. L. Lewis. Toronto, Burns and MacEachern, 1960. 131p., $9.50.)

REINFORCED CONCRETE PILING AND PILED STRUCTURES, 2nd. ed.

A description of current British practice in designing, manufacturing and driving reinforced concrete piles, with design data given in accordance with British Codes of Practice. Topics in this edition, for which new or additional material has been added, include the bearing capacity of piles; loading tests; pressures on sheet-pile retaining walls; stresses occurring during driving; the design of pile-caps for single piles and groups of piles and specifications and quantities. Other subjects covered are design, piled wharves and jetties, manufacture of piles, driving piles, piles cast in places. (F. E. Wentworth-Sheilds, W. S. Gray and H. W. Evans. London, Concrete, 1960. 149p., $4.00.)

***METHODS OF REGIONAL ANALYSIS.**

This volume presents some operational and some untested techniques for the analysis of geographical regions, as used in regional science. These techniques will supplement the general theory developed in the author's previous volume, "Location and Space Economy". Engineers will be interested chiefly in those operational techniques dealing with industrial location, land use, and urban structure, and such newly-developed bu untested techniques as interregiona linear programming, and gravity, poten tial and spatial models. (Walter Isarc New York Wiley, 1960. 784p., $9.50.)

HOW TO CHART DATA.

A guide to the use of charts in th areas of work measurement, plant sched uling and cost control. Six types of chart are covered, including straight-lin curves, monographs, two-way charts an multi-variable charts. The author dis cusses the different data required f each type of problem, and the cha best suited to the solution of the prob lem. This is a useful, entirely practica treatment of the subject by an autho who is outstanding in the field. (Ph Carroll. Toronto, McGraw-Hill, 196 260p., $8.75.)

ENGINEERING MECHANICS: STATICS.

The authors believe that the funda mental principles of engineering mech anics are best learned by studying th theory of each principle, and applying i to a practical problem. Consequently numerous problems and their solution are included in each chapter. The topic covered include equilibrium; coplana forces; plane framed structures; friction linkages; three-dimensional systems centre of gravity; moment of inertia fluid statics; virtual work; graphica solutions. (D. I. Cook and D. N. Pierce Scranton, Pa., International Textbook 1960. 227p., $6.25.)

TECHNIQUE ECONOMIQUE ET GESTION INDUSTRIELLE.

A study of economic techniques whicl can be used by businesses in their man agement. After a brief introduction t the subject of economic techniques, th book is divided into three parts, th first of which discusses the applicatio of economics to business, the differen types of sales, and demand theory. Th second part contains an analysis of pric structure, the relation between account ing and economics, depreciation. The las part considers stock regulation, opera tions research, linear programming, pric determination. Useful bibliographies ar included in which many of the article listed are in English. The author ha studied in the United States. (J. Le sourne. Paris, Dunod, 1960. 627p. 58 fr.)

LES CHOIX ECONOMIQUES: DECISIONS SEQUENTIELLES ET SIMULATION.

A bilingual volume, in which the first chapter is in both French and English and the remaining chapters are in either French or English, the latter being used when the material is taken from a study in that language. The topics covered include economic processes and sequential decisions; dynamic programming; Monte Carlo method; analogic simulation of air traffic control operations; simulation in logistics policy research; war games; application of games theory to company operation. Useful bibliographies are in-

MESSAGE FROM THE PRESIDENT

In the Annual Report which follows, you will note a record of a very active year in the history of the Institute. A considerable amount of study has been going on as to where the Institute is heading and what will be its requirements in these various possible directions.

No organization can remain stationary for very long. It must either be rising or it must be falling. Those leading the Institute this year have felt that we must put special emphasis on pushing the Institute into broader and more effective fields. More members, more branches, more technical activities, more publicity —all are necessary to help us on our upward path. New and active Committees of Council are implementing our targets. We are facing changing conditions on many of our engineering fronts. We must analyse these transitions and be prepared to meet them. We must render to our members, under all possible methods of operation, whatever they need to make them more capable than ever of raising the standard of technological activity in Canada. We must encourage our engineers, technicians and scientists to do their share in the pressing need for accelerated development of Canada's natural resources with which is so directly integrated the growth of Canada's natural economy.

Vous trouverez dans le rapport annuel de notre Institut toutes les raisons de qualifier d'année record celle qui vient de se terminer. Nos activités ont été très nombreuses et nous avons en particulier considéré l'avenir de l'Institut en explorant toutes les possibilités de son développement.

Une organization telle que la nôtre ne peut rester stationnaire longtemps. Il lui faut évoluer et dans cette évolution, si elle n'avance pas, elle recule. Les officiers de notre Institut sont convaincus que nos activités doivent devenir plus variées et s'étendre de façon efficace en maintes directions. Il nous faut plus de membres, plus de chapitres, plus de dynamisme dans nos activités, une meilleure reconnaissance au sein du public,—tout ceci est nécessaire à notre ascension vers de plus hauts sommets. Plusieurs nouveaux comités du conseil sont à l'oeuvre dans ce sens.

Nos conditions de vie se modifient de jour en jour, sur tous les fronts. Nous ne manquons pas d'analyser de façon précise cette période transitoire et de nous préparer à en tirer le meilleur profit. Nous devons assurer nos membres, dans quelque circonstance que ce soit, de toute notre aide en vue de rehausser la valeur de notre contribution à la vie scientifique, technique et industrielle du Canada. Notre Institut se doit d'encourager nos ingénieurs, nos techniciens, nos hommes de science, à participer de façon totale au développement et à la mise en valeur des ressources naturelles du Canada, base de la croissance de l'économie de notre pays.

George M. Dick

GEORGE MCK. DICK, D.SC., M.E.I.C.,
President, 1960-1961.

THE ENGINEERING INSTITUTE OF CANADA

annual report

for the year ended December 31 1960

REPORT OF COUNCIL

YOUR INSTITUTE IN 1960

Nineteen hundred and sixty was a year of real accomplishment for The Engineering Institute of Canada. This annual report lists the significant achievements of the past twelve months. Success does not just happen—it is the result of much careful planning and painstaking work by many officers, councillors, committees and individual members at all levels within the organization. The co-operation of many members made this progress possible, and the continuation and extension of this attitude will lend to even greater progress in 1961.

The continued growth of the Institute naturally has created some problems, and these are receiving diligent attention by the officers and staff. Prime among these problems is that of member communications and the need for every member to be aware of, and justly proud of, the fine record of achievement which is recorded each year in this series of annual reports.

In an organization as large and complex as The Engineering Institute of Canada, the report which follows does little more than highlight matters of importance. We trust that each member will derive much satisfaction from it, but at the same time will realize that much more remains to be done. It is through their efforts that 1961 will be an even better year.

Major targets for continuing concentrated effort are: to continue to improve BRANCH OPERATIONS, to increase MEMBERSHIP and to bring the best possible TECHNICAL PROGRAM to every member of the Institute. Many members are involved in the work of the Committee on Branch Operations and the Committee on Technical Operations, and EVERY MEMBER should consider himself an active worker on the Committee on Membership.

ACTIVITIES OF THE PRESIDENT

In the spring of 1960, Mr. J. J. Hanna completed his presidential visits to a large number of branches and student sections. During the summer, Dr. George McK. Dick visited engineers at work at The Canadian Armament Research and Development Establishment at Valcartier, Quebec, the laboratories of The National Research Council and The Bureau of Mines in Ottawa, and at The Ontario Research Foundation in Toronto.

Later in the year, Dr. Dick visited branches and student sections in the Atlantic Provinces and central Canada, and was honored by the bestowal of an Honorary Doctor of Science degree by the University of Sherbrooke in October. He represented the Institute at the annual meeting of The American Society of Mechanical Engineers in New York in December, and was host to a reception for Canadian engineers and their wives present at that meeting. He has held many meetings with senior officers of The Canadian Council of Professional Engineers and the provincial associations and corporation of professional engineers, in an effort to continue and further the best possible relationships between the Institute and these sister organizations.

INSTITUTE ADMINISTRATION

Major improvements in administration were made by the creation of an Executive Committee of Council on a trial basis to deal with administrative matters between Council meetings, thus allowing Council to spend more time on matters of basic policy. The Vice-Presidents have assumed a very active role in visiting and assisting branches and student sections in their territories, and the re-organization of headquarters' staff in functional groups parallel to the Institute's activities made 1960 a busy year indeed.

The By-Laws were amended by ballot of the membership to bring them in line with current practices and needs. The financial operations were transformed to an accrual system and purchasing, expenditures and other financial operations were put onto a system of close budgetary control after more than two years of intense work to bring this about.

The Committees and Representatives appointed by Council continued to make very important contributions to the efficiency of the Institute's operation. Not only do they study proposals which have been referred to them by Council, but each keeps in touch with situations and attitudes within its terms of reference and, when necessary, recommends considered action.

Among the staff changes during the year, Mr. J. H. Legere left to accept an appointment with the International Air Transport Association; Miss Maudie Abraham retired after the longest period of service of any employee in the Institute's history; and Mr. G. LaFontaine was appointed Associate Editor of EIC publications. Mr. T. R. Montgomery was appointed Controller and Office Manager and Mr. John Donovan was selected to serve as Manager of Advertising Sales following the sad passing of E. J. "Ted" Blandford, who had been our hard-working and popular Publications Manager for many years.

Both the Toronto Office, headed by Mrs. L. Robertson, and the Western Field Secretary, Commodore A. C. M. Davy, were kept extremely busy rendering on-the-spot service and assistance to the branches and individual members in the areas for which they are responsible.

The General Secretary has taken steps to increase the contact between branch executives and headquarters staff, by additional staff visits to all parts of the country. In addition, he and his personal staff, in co-operation with the secretariat of the CCPE, have devoted a great amount of time to the work of the Engineers Confederation Commission. In April he visited England to arrange final details of the co-operative agreements between the United Kingdom Institutions and the Institute, and had useful meetings with the Danish Institution of Civil Engineers and La Société des Ingenieurs Civils de France.

MEMBERSHIP

Institute policy with regard to membership was the subject of months of serious and intensive study during the year.

The program was undertaken in two stages. The first step was the creation of an ad hoc Committee on Membership Procedures. During the summer and early fall this committee made a thorough examination of all EIC membership policies and procedures. Many important changes were recommended and adopted by Council, all designed to increase membership and improve membership administration. Included in these measures, subject to By-Law ratification, are provisions to make transfer from Junior to Member automatic after five years, and to change the title Junior to Associate Member.

The second stage, started in the fall, was the activation of a national Committee on Membership, with representation from nearly all areas of the country. The object of this committee is to promote the growth of EIC membership by every possible means, with special emphasis on assisting and encouraging branch activity in this field. Council looks to this group for advice on membership development policy, and it acts as a co-ordinating centre for information and guidance.

The total enrolled membership at the end of 1960 stood at 21,536 which is a 7% increase over 1959. The detailed breakdown of this figure is given in the finance committee report.

In 1960 the Council examined several proposed methods for the preparation of a directory of members, and finally decided that a supply of a very economical form of directory should be published in 1961, for distribution to national and local officers and committees and for sale to interested members.

The policy regarding the provision of membership certificates was changed to provide for the free distribution of an improved form of membership certificate to all new members and to other members who request it.

Deceased Members

During the year 1960 the deaths of members of the Institute, including two Honorary Members, have been reported as follows:

Honorary Members: Angus, Robert W., Toronto; Killaly, A. Laurence, Peterborough.

Members: Adams, W. D., Grimsby, Ont.; Barnes, Charles T., Winnipeg; Bate, C. B., Sillery, Que.; Belanger, Alex. A., St. Antoine de Padoue, Que.; Bennett, J. E., Regina; Bolton, Fred S., Winnipeg; Branch, Alec. J., Lethbridge; Brydone-Jack, Ernest E., Joshua Tree, Calif.; Cochrane, M. F., Ottawa; Coward, George W., Cordoba, Argentine; Clement, Sheldon B., Sarnia; Cunha, S. H., Montreal; Dargie, A. H., Halifax; Darling, A. B., Montreal; Dobbin, W. L., Toronto; Edwards, C. P., Ottawa; Ford, J. W. H., Preville, Que.; Fraser, W. L., Cornwall; Gifford, F. D., Colborne, Ont.; Haffey, J. J., Valleyfield, Que.; Hammersley-Heenan, John, North Hollywood, Calif.; Hutchinson, T. P., Montreal; Jones, L. M., Islington, Ont.; Karn, H. C., Woodstock, Ont.; Kemp, J. Colin, Montreal; Kennedy, T. Dowsley, Owen Sound, Ont.; Kindersley, Charles St. B., Calgary; Kirby, Thomas H., Winnipeg; Lazier, Francis Stuart, Toronto; LeClair, Camille, Durham, England; Love, Alexander, Hamilton; MacKay, James J., Burlington, Ont.; MacKenzie, A., Winnipeg; MacKintosh, James, Toronto; MacLachlan, Wills, Maple, Ont.; Martin, Oskar, Kingston; Michell, H. G., Montreal; Miles, Harold R., Calgary; Milne, A. H., Montreal; Morrissette, Romeo, Cap de la Madeleine, Que.; Murphy, E. P., Ottawa; Newhall, Vivian B., Edmonton; Paulson, Frederick H., Warwick, R.I.; Pearce, K. K., Dewittville, Que.; Peden, Alexander, Montreal; Perry, A. H., Vancouver; Redfern, W. B., Toronto; Rice., J. Donald, Toronto; Riley, Thomas M., Evanston, Ill.; Serson, H. V., Ottawa; Smith, E. L., Edmonton; Steinman, D. B., New York, N.Y.; Stevenson, W. F., Edmonton; Stockton, Robert S., Spokane, Wash.; Swabey, H. W. B., Pointe Claire, Que.; Taylor, John, Hamilton; Treadgold, W. M., Toronto; Tremain, K. H., Montreal; Underwood, J. E., Saskatoon; Wakefield, William E., Ottawa; Warner, John E., Milford, Conn.; Watson, J. T., Lethbridge; White, Robert, Town of Mt. Royal, Que.; Wilson, Alexander, Montreal; Wilson, A. McD., Sault Ste. Marie; Wurtele, John S. H., Westmount, Que.; Wyatt, Digby, Toronto.

Junior: Hill, Ralph T., Kenilworth, Ont.

Students: Brosseau, Rejean, Granby, Que.; Cummings, G. E., Middleton, N.S.; Fortin, Gilles, Ottawa; Herbertson, Richard, Winnipeg; Stein, Lionel, Town of Mt. Royal, Que.

Affiliates: Annett, Fred A., New York, N.Y.; Baldry, G. E., Winnipeg; La Bissonierre, Alfred, Montreal.

ANNUAL AND REGIONAL MEETINGS

The 1960 Annual General and Professional Meeting held in Winnipeg was an outstanding success. Attendance was high, the local committee did a grand job, and the technical program arranged by the Committee on Technical Operations was judged to be one of the best in the Institute's history. The schedule of dates and places for future Annual Meetings is:

1961 Vancouver May 31-June 2 Hotel Vancouver
1962 Montreal June 13-June 15 Queen Elizabeth
1963 Quebec May 22-May 24 Chateau Frontenac
1964 Banff May 27-May 29 Banff Springs
1965 Toronto May 26-May 28 Royal York
1966 Winnipeg May 25-May 27 Royal Alexandra
1967 Montreal May 31-June 2 Queen Elizabeth
1968 Halifax

Since the completion of seventy-five years of service to the engineering profession will be the feature of the 1962 annual meeting in Montreal, a special committee was appointed to recommend regarding the nature of this event with Dean H. Gaudefroy as Chairman and members representative of all parts of Canada.

During the year regional technical meetings were held at Kingston, Ontario, and St. Andrews, N.B. (Maritime Professional Engineers Conference jointly with the Associations of Professional Engineers in the Atlantic Provinces). The Institute held a joint conference on Engineering Education with the A.S.M.E., and was host to the Annual Meeting of The Engineers Council for Professional Development.

Each of the regional technical meetings was arranged by a local committee, and engineers in neighbouring localities were invited to attend. The main attraction was a technical program which was in each case augmented by social events.

These meetings were well attended, and the concensus is that they serve a useful function in broadening the technical activities of the Institute by making it possible for larger numbers of members to attend a major meeting each year.

Plans have been initiated for the following conferences in 1961:

Joint Meetings

May 7-10	ASME-EIC Hydraulic Division Conference, Queen Elizabeth Hotel, Montreal, Que.
May 9-12	ASME (Co-sponsor EIC) Production Engineering Conference, Toronto, Ont.
Aug. 28-Sept 1	International Heat Transfer Conference, Boulder, Colorado (Co-sponsor EIC).
November,	EIC-CIMM Regional Technical Conference, Newfoundland.
November 9-11	Canadian Soil Mechanics Conference, Queen Elizabeth Hotel, Montreal, Que.

Regional Meetings

March 25	Third Southern Ontario Regional Conference, Sheraton Brock Hotel, Niagara Falls, Ont.
April 6-7	Montreal Regional Meeting, (Theme "Urban Transportation"), Mount Royal Hotel, Montreal, Que.
May 6	Northern Ontario Regional Conference, North Bay, Ont.
November 2-4	Quebec City Regional Conference, Chateau Frontenac, Quebec City, Que.

HONOURS, AWARDS, MEDALS AND PRIZES

These awards were presented during the 1960 annual meeting to those who could be present:

Honorary Memberships
Bristow Guy Ballard.
William Percy Dobson.
John Norison Finlayson.
Richard Lankaster Hearn.
Otto Holden.

Julian C. Smith Medals
Clarence Decatur Howe.
Hugh Andrew Young.

Plummer Medal
John Templeton Hugill

Leonard Medal
Victor Dolmage
J. W. Stewart

Duggan Medal and Prize
Alan Garnett Davenport

Robert W. Angus Medal
John James Traill

The following medals and prizes were not awarded in 1960: Gzowski Medal, Ross Medal, Sir George Nelson Award, Canadian Lumbermen's Association Prize, H. N. Ruttan Prize, John Galbraith Prize, Ernest Marceau Prize, Phelps Johnson Prize, Martin Murphy Prize.

BRANCH OPERATIONS

Another successful Branch Officers' Conference was held during the 1960 Annual Meeting in Winnipeg. In an effort to provide all possible assistance and information to branch executives, the Council authorized the formation of a Committee on Branch Operations in the latter part of the year. The manual of branch operations was again improved after another year of experience, and will be revised and re-issued early in 1961.

An interesting development was the action taken by the Toronto Branch to create a series of smaller branches in its territory but outside of Metropolitan Toronto. A new branch at Oakville was formed, and new branches are in process of formation at Port Credit and other centres. By this means local services will be made available to the many members who did not find it possible to participate in the activities of the Toronto Branch.

The officers, council and staff sincerely appreciate the great amount of voluntary work done by branch officers and committee members in rendering direct local services to the membership, and for their co-operation in supporting the many national and international projects which depend in large measure on branch support for their success.

CONFEDERATION

1960 was an extremely busy year for the Institute's representatives to The Engineers Confederation Commission and the Headquarters' staff concerned with serving the Commission. A large number of meetings were held ranging from full meetings of the Commission to the many committees and sub-committees engaged in making special studies and reports on behalf of the Commission.

During the year the Commission forwarded two progress reports to the Institute, the full texts of these reports are published on page 114 of the April 1960, and on pages 76, 77 and 78 of the January 1961 issues of The Engineering Journal. It is the stated intention of the Commission to present its final report to the C.C.P.E. and the E.I.C. prior to their 1961 annual general meetings, and a great deal is owed by all members to those whose unfailing work as participants in the work of the Commission will have made this possible.

CO-OPERATION WITH OTHER ENGINEERING AND SCIENTIFIC ORGANIZATIONS

In addition to the formal meetings between representatives of the member societies of such international organizations as U.P.A.D.I. and the Conference of Engineering Societies of the British Commonwealth, the Institute maintained regular and extremely cordial contacts with the Institutions in the United Kingdom, and other Commonwealth Societies, the founder Societies in the United States of America, the representative National engineering organizations in Europe, the Far East, and Latin America. These frequent exchanges of information and assistance have proven invaluable to the Canadian engineering profession.

At the national level, the Institute worked closely with The Canadian Council of Professional Engineers, The Canadian Aeronautical Institute, the Canadian Institute of Mining and Metallurgy, and the Chemical Institute of Canada, and others on a number of important government-sponsored or inter-society projects. There was no change in the agreements between the institute and seven provincial registering bodies in 1960.

An important activity in this area during 1960 was the signing of co-operative agreements between the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Electrical Engineers and The Engineering Institute of Canada. These reciprocal agreements provide members of any one of the participating bodies with the opportunity for participating in the technical activities while in the country of the host body, on payment of a nominal fee. In addition to providing a technical home for such members, full membership in the host society will be more readily sought after.

The Institute was pleased to learn that its invitation to hold the next Conference of Engineering Institutions of the British Commonwealth in Canada in 1962 had been accepted, and plans are being developed to make this important conference an outstanding success.

The Institute was fortunate in the presence of a large delegation of senior Canadian engineers in Buenos Aires at the time of the VI U.P.A.D.I. Congress. Led by Past-Presidents J. A. Vance and K. F. Tupper, the large EIC delegation made a significant contribution to the work of this important organization, which is unique in providing a forum between national engineering societies in all North, Central and South American countries.

Vice-President F. L. Lawton represented the Institute at the Centenary celebrations of La Société Royale Belge des Ingenieurs et des Industriels and presented the Institute's greetings.

The Institute was pleased to entertain representatives of Mexican engineering organizations for two weeks during October, and to assist representatives of the Argentine Society of Engineers while in Canada.

EMPLOYMENT SERVICE

The following statistical report compares the trend of activity in employment conditions over the past four years.

Jobs listed in 1960 in comparison to applicants seeking employment indicated a healthy supply and demand relationship. Eighty-six under-graduates registered for summer employment, and with a few exceptions these were satisfactorily placed.

To assist with expenses associated with the Employment Service, "Situations Vacant" advertisements are now sold to those wishing to advertise vacancies. As in the past, members may insert a "Situations Wanted" advertisement of up to sixty words without charge.

ENGINEERING EDUCATION

To enable more members to participate in and contribute to the development of the Institute's active interest in engineering education, the Committee on Engineering Education was transformed into a Technical Division Committee, within the structure of the Committee on Technical Operations.

The second national meeting of the Canadian Conference on Education will be held in Toronto in February 1962. The Institute is actively engaged in participating in the preparations for this important event.

The 1960 meeting of engineering educators, attended by over 70 deans and professors of engineering from every faculty of engineering in Canada, was held for two days at Queen's University in Kingston, during the Conferences of Learned Societies.

The Fourth Biennial ASME-EIC Conference on Engineering Education was held at Ecole Polytechnique in October. Delegates were also entertained by McGill University. This was very successful, and pointed out a basis for future meetings and the need for the preservation of the valuable material presented at such meetings.

The Institute was represented by Dean H. G. Conn and Dean R. R. McLaughlin at the First Pan-American Congress on Engineering Education, held in Buenos Aires, Argentina, in September.

On a continuing basis, the Institute maintains a close and effective relationship with universities, appropriate agencies of the federal and provincial governments, with the Canadian Education Association and the Canadian Teachers Federation.

GOVERNMENT LIAISON

In 1960 the Institute continued its close liaison with the Federal Government, working co-operatively with many agencies and departments on a day-to-day basis in the interests of Canadian engineering, and in

helping to solve problems referred to the Institute either directly or by virtue of the Institute's membership on committees and boards established by the government.

During the year the Council approved action leading to the presentation of briefs to the Royal Commission on Publications, the Senate Special Committee on Manpower and Employment, and to the Tariff Board regarding Tariff Item 180(e). Special attention was given to participation in the work of the Advisory Committee on Professional Manpower, the Canadian Vocational Training Advisory Council, and the Canadian National Commission for UNESCO.

LIBRARY AND FILM SERVICE

The statistics for 1960 indicate that use of the library has remained at approximately the same level as in previous year. On an average, the library staff handled 27.8 requests a day, but during the last three months of the year this rose to 31.5 a day.

Statistics of Library Use

	1960	1959
Mail enquiries	1817	1541
Telephone enquiries	2887	2932
Total	4704	4473
Persons using library	2656	2613
Borrowers registered	624	581
Circulation:		
Books	2557	2307
Periodicals	1122	1314
Pamphlets	186	221
Total	3865	3842
Books acquired	454	452
Value of books acquired	$4307	$4125

Increasing numbers of student members continue to use the library, both to request help in writing theses, and to supplement the book collections in their university libraries.

During the summer months a complete examination of the book and periodical collection was undertaken. Almost a thousand obsolete or little used books were discarded, and some collections of periodicals were discarded in toto, and only the most recent years of others retained. Much of this material was sold to book dealers.

Some four hundred books valued at over $4000 were added to the library collection, which now contains approximately 6100 volumes. Over five hundred periodicals are received regularly.

It was found uneconomical to care for the film collection adequately in the EIC library, and arrangements were made for the Canadian Film Institute to take over the distribution and servicing of the Institute's film collection. The branches have been notified of this change, and will be advised of new films of interest as they are issued. All members are invited to take advantage of the greatly extended service now made available by the Canadian Film Institute's large collection.

PROFESSIONAL DEVELOPMENT

In October, the Institute was host to over two hundred delegates to the 1960 Annual Meeting of The Engineers Council for Professional Development. Lasting three days, this meeting was devoted to an intensive and stimulating program, backed up by an efficient hard-working committee of members from the Montreal Branch.

The Institute was represented at all meetings of the Executive Committee and Council of E.C.P.D. during the year, and a further report appears on a following page.

At the Branch level, there is increasing interest in local P.D. courses in many parts of Canada, co-ordinated by the Institute's national Committee on Professional Development Programs.

PUBLICATIONS

With its terms of reference expanded and in more detail, the Publications Committee had an extremely busy year. The major effort was to ensure that the characteristics of the Institute's publications are in line with the objectives of the Institute and the needs of the membership.

In January 1960 the circulation of The Engineering Journal was expanded to include all practicing engineers in Canada whose names and addresses were known to the Institute at that time. By the end of the year, over 36,000 engineers were receiving the Journal. The reader response and financial results of this change are encouraging, particularly since the Journal was enabled to carry more technical papers in 1960 than in any other year in its history.

Late in 1960 the Institute was saddened by the death of its Publications Manager, Mr. E. J. Blandford, whose long and outstanding contribution to the Institute's publications were greatly appreciated. His passing necessitated a major reorganization of the advertising sales program of the EIC, which is now being conducted as a staff function.

"Transactions of the EIC" has continued to improve, and is now an accepted medium in which Canadian engineers publish the results of their fundamental research.

The fourth edition of "Engineering Careers in Canada" was distributed in December on a self-supporting basis. There has been a large demand for this publication from those interested in student guidance, and from students at high schools and universities. It is distributed free of charge on request.

A number of administrative publications were produced and are referred to elsewhere in this report.

SPEAKERS FOR BRANCHES

Speakers for Branches were arranged by Headquarters whenever feasible. Some difficulty is being experienced in the provision of good speakers for the smaller or more remote branches, and members agreeable to undertaking such assignments are urged to contact Headquarters. Approximately thirty-four speakers addressed a total of thirty-nine Branch meetings during the year under arrangements completed through Headquarters.

STUDENT AFFAIRS

Interest in the Institute continued at a high level in 1960 among Canadian engineering students. This enthusiasm is always given strong fillip by the Student Conference at the Annual Meeting, and the one held in Winnipeg in May was most successful. Through the co-operation and fine work of the Student Policy Committee, Faculty Advisers, and EIC student representatives, 1960 was another good undergraduate membership year. There are now nine EIC student sections on Canadian campuses, four having been established during the year at Assumption University, Loyola College, Ontario Agricultural College, and the University of Waterloo. More are under consideration.

Authorized annual grants were made to the Faculty Advisers, and to some branches in university centres. These funds were used in a wide variety of ways to promote and foster engineering student activities, according to local needs and ideas.

Institute material distributed through the universities during the year consisted of a new edition of the pamphlet "The EIC and You", the popular publication "Engineering Careers in Canada, 1960-1961", slide rule tie clips to every new student member, and hundreds of sample copies of The Engineering Journal.

The year also saw the appearance in printed form of the EIC Student Section Manual. This book was distributed for use to university student bodies, Faculty Advisers, and to secretaries of branches in university centres.

The EIC continued to lend its active support to the administration of the Athlone Fellowships during the year. It was of much assistance to Canadian Athlone Fellows during their time in the United Kingdom, by virtue of its close relationships with the Institutions of engineers in England.

The Institute continued active participation in and provided the secretariat for the International Association for the Exchange of Students for Technical Experience. The 1960 season completed the eighth year of Canadian support of the Association, and during the year the terms of reference of the Canadian IAESTE Committee were reviewed and brought up to date.

During the summer 107 foreign students visited Canada to work, and 24 Canadian students took advantage of job opportunities abroad. Financial difficulties are still the most important reason for the number of Canadian students to be below the incoming total. Further details will be found elsewhere in this report.

TECHNICAL OPERATIONS

National: The work of the Committee on Technical Operations was increasingly active during the year. A summary of its organization and method of operation appears on pages 127 to 130 of the March 1961 issue of The Engineering Journal. Action was taken to classify every member by his field of technical interest, so that the membership at large may participate more fully in the activities of the ten Technical Divisions. A manual of technical operations was prepared for the guidance of Technical Division Committee members, Branch Officers and staff.

Through this Committee, the Institute supports and assists many agencies of the government, and also co-operates with sister societies in Canada, on technical activities of major importance. Examples are the Committee on Wintertime Construction of the Canadian Construction Association, Committees of the Canadian Standards Association, the Canadian Radio Technical Planning Board, the Canadian Management Council, the Joint Committee on Renewable Resources and others.

An interesting new development, which promises to provide interesting and useful results, was the formation of a joint committee with The Canadian Institute on Sewage and Sanitation on the Use, Conservation and Pollution-Control of Canada's Water Resources.

International: The Institute actively participates in the sponsorship of programs of international technical organizations. Once again the Institute took an active part in the Sixth Nuclear Congress which was held in New York City early in the year.

The Institute representative to the International Heat Transfer Congress (1961) is actively promoting this work.

Other international activities include participation in the work of the ASME Committee on Air Pollution Controls, the Column Research Council, the International Association for Bridge & Structural Engineers, the International Federation of Chemical Engineers, the International Electrochemical Commission, the Society of Technical Writers and Publishers, and the Inter-Society Management Engineering Conference.

VOCATIONAL INFORMATION

Many of the branches continued their excellent work in the important field of vocational guidance. This consists mostly of speaking visits to students at junior colleges and secondary schools, and assistance to their staffs.

At Headquarters, guidance inquiries are usually in the form of written requests for literature, although a few interviews were held. Four pamphlets were in use during the year: "After High School What?", the French language piece "Science Genie", "Careers in Natural Science and Engineering", issued by the Department of Labour from Ottawa, and "Engineering, a Creative Profession" published by E.C.P.D. Many sample copies of the Engineering Journal were distributed as in previous years.

The very popular Institute publication "Engineering Careers in Canada" was again issued in 1960-1961. Its primary purpose is to serve the needs of first and final year engineering students at Canadian universities, to whom distribution is made without charge. This booklet is also sent free to all Canadian high school libraries, most public libraries, government departments and individuals, and to a growing list of interested recipients abroad.

The Institute co-operated with other national professional and technical bodies in sponsoring the Canadian Science Fairs Council, which co-ordinates the holding of science fairs at high schools in many parts of the country.

WIVES ORGANIZATIONS

Although not an official activity of the Institute, the E.I.C. attaches great importance to the activities of the engineers' wives associations. During 1960 the activities of the Engineers' Wives Associations increased all across Canada. The aim of all groups is to welcome newcomers to their centres and to promote cordiality and friendship among the wives of the members of the Institute, and in many cases, among the wives of all members of the profession. Membership figures range from twenty to over three hundred in different cities.

Respectfully submitted on behalf of the Council,

GEORGE MCK. DICK, D.SC., M.E.I.C.,
President

GARNET T. PAGE, M.E.I.C.,
General Secretary

AUDITORS' REPORT

We have examined the balance sheet of The Engineering Institute of Canada as of December 31, 1960 and the statement of revenue and expenditure for the year ended on that date and have obtained all the information and explanations we have required. Our examination included a general review of the accounting procedures and such tests of accounting records and other supporting evidence as we considered necessary in the circumstances.

During the year the Institute changed from the diminishing balance method of computing depreciation on furniture and equipment to the straight line method, and adopted the policy of setting up as an asset the inventory of miscellaneous supplies and other prepaid expenses, which in prior years had been written off in the year of expenditure. As a result of these changes the deficit for the year was approximately $4,800.00 less than it would have been under the previous methods.

In our opinion, and according to the best of our information and the explanations given to us and as shown by the books of the Institute, the accompanying balance sheet and statement of revenue and expenditure are properly drawn up so as to exhibit a true and correct view of the state of the affairs of the Institute at December 31, 1960 and the results of its operations for the year ended on that date, in accordance with generally accepted accounting principles which, except for the changes (of which we approve) described in the preceding paragraph, have been applied on a basis consistent with that of the preceding year.

PEAT, MARWICK, MITCHELL & CO.,
Chartered Accountants.

Montreal, P.Q., February 21, 1961.

TREASURER'S REPORT

Although the operations of the Institute for 1960 resulted in a deficit of $56,000 this was due to a combination of circumstances that will not recur, and we confidently expect that in 1961 we will operate at a surplus.

The decision taken by Council in 1959 to distribute the Journal free to all Engineers in Canada, starting with the first issue in 1960, resulted in a direct loss of revenue from Journal subscriptions of $54,000, which is approximately the deficit on the year's operations. The larger circulation of the Journal involved much greater printing and mailing cost, and although advertising rates were increased, advertising revenue could not be built up in such a short space of time to fully compensate for the loss in revenue and increased expense. Moreover, due to the death of Mr. Blandford, changes had to be made in our sales organization towards the end of the year.

The deficit was financed mainly by means of a bank loan of $40,000 guaranteed by securities owned by the Institute. It was decided that this method of financing would be preferable to liquidating investments, as it is expected that it will be possible to repay the loan out of revenue before too long.

As far as the regular expenses for administration and services of the Institute are concerned, a very close watch has been kept on all items. In spite of greatly increased activity, the total cost of administration and direct services has risen by only 1%, over 1959. This close control of all accounts is being continued and extended.

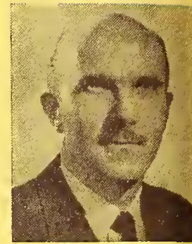
The Balance Sheet as at December 31, 1960 and 1959, the Statement of Revenue and Expenditure for the years 1960 and 1959, the Statement of Special Funds as at December 31, 1960, together with the Auditors' Report, are submitted herewith.

E. D. GRAY-DONALD, M.E.I.C.,
Treasurer.

REPORTS OF THE COMMITTEES

STANDING COMMITTEES

ADMISSIONS COMMITTEE



1. *Statistical Review*

During 1960, the Admissions Committee held eight regular meetings.

In all, 1145 candidates were considered:

Admitted for corporate membership		200	
Admitted for Affiliate		1	
Transferred from Junior to Member		870	
*Transferred from Student to Junior		11	
Transferred from Student to Member		1	
Special Cases		62	
(Referred to Board of Examiners	5		
(Rejected	28		
(Held for further investigation	29		
**Student Admissions		1813	
Total			2958
**Admissions and transfers through Provincial Associations:			
Admitted for corporate membership		137	
Transferred from Junior to Member		194	
Transferred from Student to Member		2	
*Transferred from Student to Junior		42	
Student Admissions		334	
Total			709
Grand Total			3,667

* Automatic transfers are not included in these figures.

** These figures are included for the sake of completeness, although these categories are not reviewed by the Admissions Committee.

The increase in the number of transfers from the grade of Junior to Member is due to the efforts of headquarters in encouraging those people to apply for full membership who had reached the limits as established by the by-laws.

2. *Procedures*

(a) The committee recommended to Council the reinstatement of the procedure of obtaining references in writing from all sponsors.

(b) The committee commenced the preparation for Council of a description of its complete operating procedures with reference to the by-laws under which it operates.

PETER GOOCH, M.E.I.C,
Chairman

FINANCE COMMITTEE

During the year your Finance Committee met 10 times, with much of its time devoted to the financial aspects of publications operations. Another feature of Institute financial problems which necessitated close attention was the changeover late in the year from a "cash basis" of accounting to an "accrued basis".

The financial outcome of the year's activities was a deficit of $55,772. This resulted from:

(1) Budgetary provision for a deficit of $18,100.

(2) The decrease of about $54,000 in income due to the remission of the Journal subscription charge.

(3) The late decision in 1959 to change the Journal distribution policy, so that the advertising sales staff could not secure the full increase in advertising sales anticipated.

(4) The necessity of a higher average press run than anticipated, in order to provide the guaranteed circulation, 34,000 copies as compared with 32,000.

Members will be pleased to know that the outcome for 1961, as anticipated in the budget, is a surplus, after allowing for extraordinary expenditures associated with the work of the Engineers Confederation Commission at $4,500, of $22,610.

The outlook for improved financial results from publication activities, essentially the Journal, looks reasonably good. It should be noted here that, with the demise late in the year of Mr. E. J. Blandford, the sales of advertising space were made a direct Institute responsibility with a suitable incentive provision in the remuneration of space-sales personnel.

With the completion of the 11 years ending December 31st, 1960, it is desirable that members have an opportunity of comparing financial and other vital Institute statistics.

Fig. 1 shows the growth in total membership over the past 50 years. On December 31st, 1960, total membership stood at:—

Hon. M.E.I.C.	42
M.E.I.C.	8,897
Jr.E.I.C.	5,576
S.E.I.C.	6,966
Affiliates	55
Total	21,536

Changes in composition of the membership, 1950-1960, are shown in Fig. 2. Growth in the proportion of students will

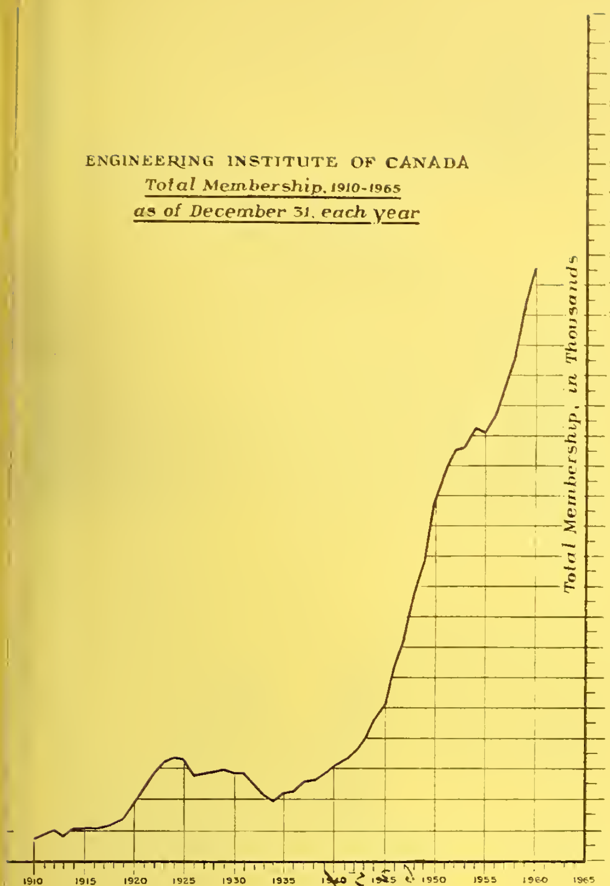


Fig. 1.

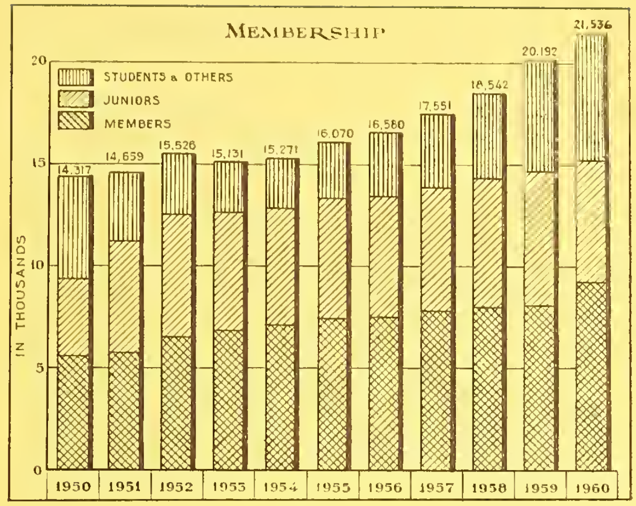

Fig. 2.

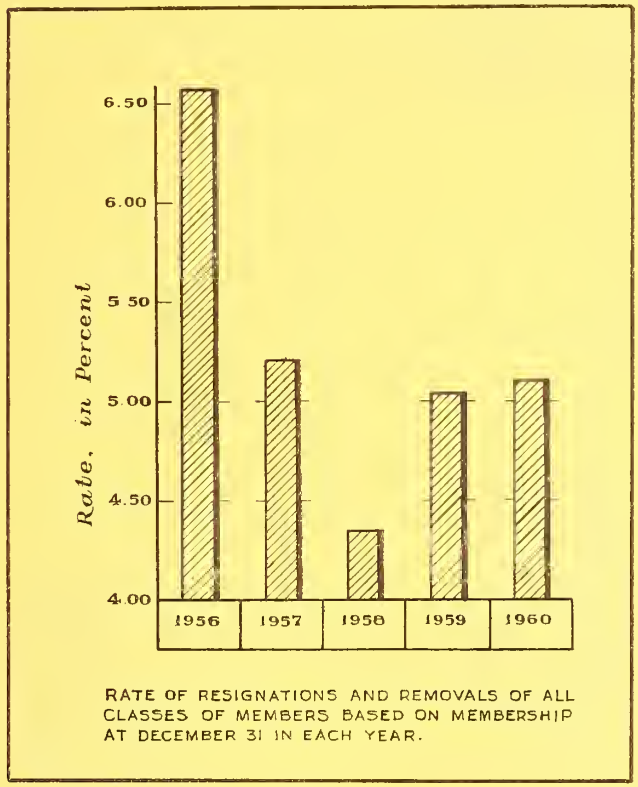

Fig. 3.

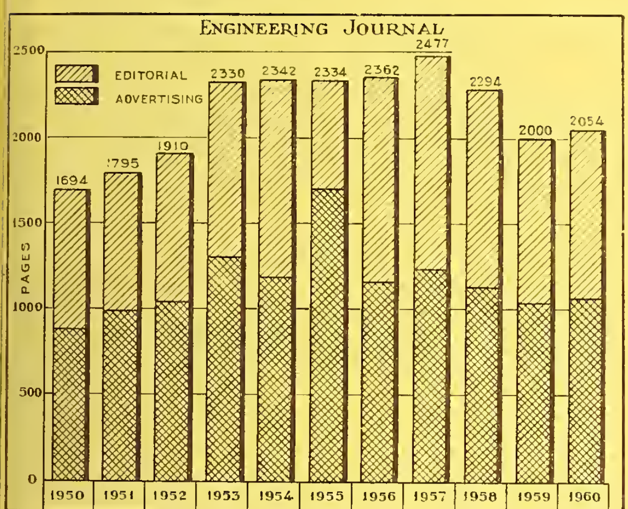

Fig. 4.

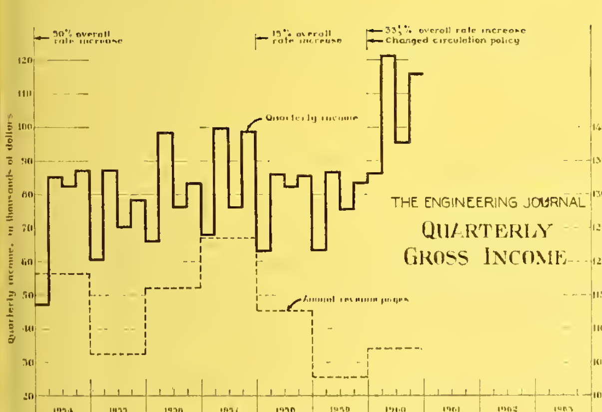

Fig. 5.

Fig. 6.

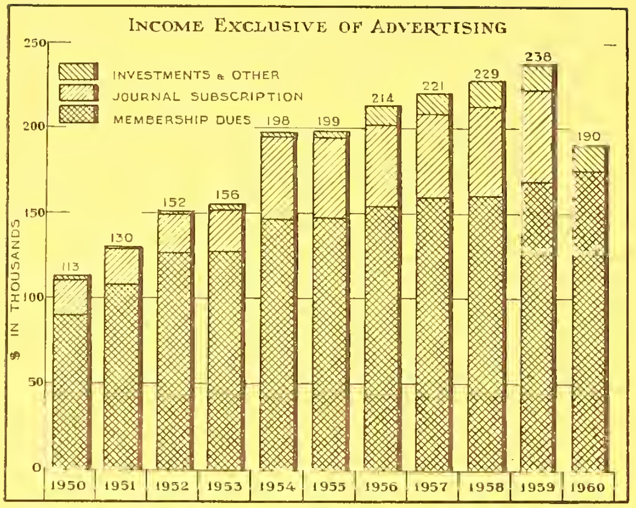

Fig. 7.

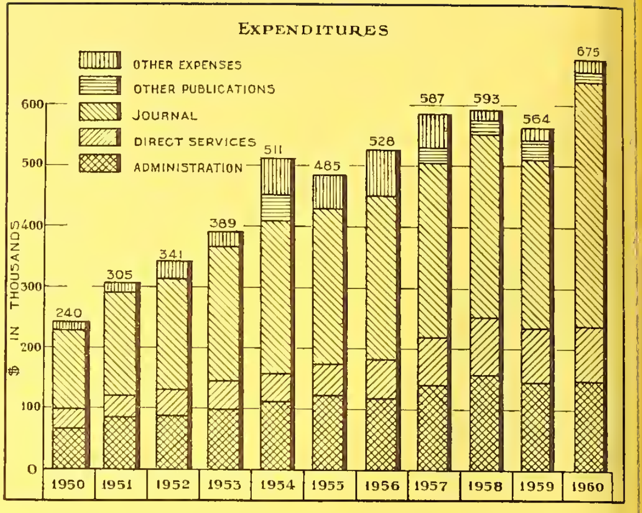

Fig. 8.

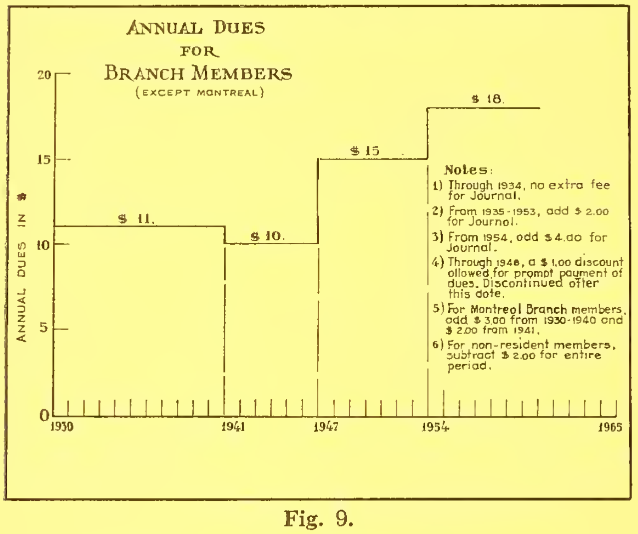

Fig. 9.

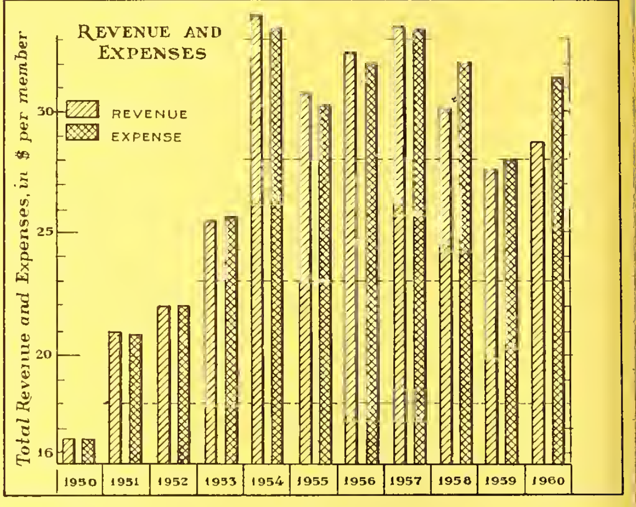

Fig. 10.

Fig. 11.

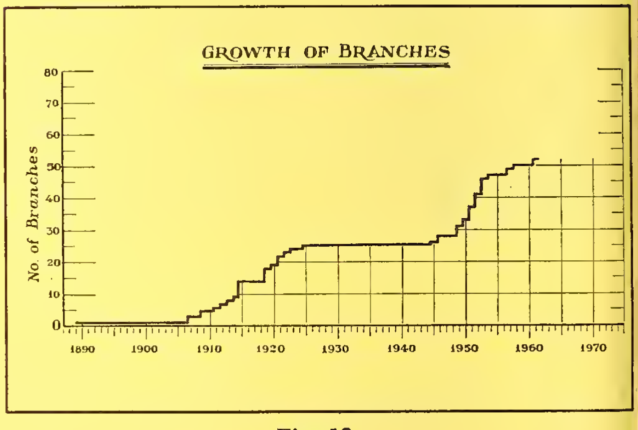

Fig. 12.

be noted. Fig. 3 indicates the rate of resignations and removals of all classes of members based on membership at December 31 in each year. It compares very favourably with the experience of sister societies. Nevertheless, its impact on E.I.C. activities should not be overlooked. An equal percentage of new membership is necessary to make up losses alone.

The Engineering Journal is influenced by general economic conditions, fluctuations in editorial and advertising content being displayed by Fig. 4. A comparison of advertising space and gross income for 1954-1960 is afforded by Fig. 5. The fluctuations in gross income appear to be characteristic; they play a substantial role in the Institute's cash position at any given time.

The trend in total income, from all sources, during 1950-1960, is shown by Fig. 6. Note the proportion of income from advertising. Breakdowns of income exclusive of advertising is illustrated by Fig. 7.

The breakdown of expenditures is clearly indicated by Fig. 8.

Changes in the basic membership dues over the period 1930-1960 are set out in Fig. 9.

In order to ascertain the real trend in income and costs, it is necessary to reduce them to a per-member basis. This has been done in Fig. 10.

A measure of the service afforded members is shown by Fig. 11. Numbers alone do not indicate quality. This, nevertheless, has been achieved in greater measures than ever, if many members' comments are valid.

An additional measure of the service afforded members is shown by Fig. 12, the increase in the number of Branches throughout Canada.

The Committee consists of the following:

J. M. BREEN, M.E.I.C.
J. H. BUDDEN, M.E.I.C
R. L. DUNSMORE, M.E.I.C.
T. W. EADIE, M.E.I.C.
R. A. EMERSON, M.E.I.C.
E. B. JUBIEN, M.E.I.C.
G. N. MARTIN, M.E.I.C.
E. D. GRAY-DONALD, M.E.I.C.
Treasurer, Vice-Chairman

F. L. LAWTON, M.E.I.C.
Chairman

COMMITTEE ON BRANCH OPERATIONS

On October 29th, 1960, Council decided on the establishment of a Committee on Branch Operations, "with the object of studying and recommending regarding Branch operations, and providing a focus of activity for rendering maximum assistance to Branches". Council, at the same time, noted the initial objective of the Committee would be the study of the over-all problem with the eventual purpose, if it is found necessary, of establishing a permanent committee with approved terms of reference.

A committee was promptly appointed. At the same time, consideration was given as to the best method of ascertaining that information relevant to Branch operations which the Committee required in order to carry out its assignment.

Subsequently, on December 20th, 1960, an extensive questionnaire was sent out to all Branches and Sections (6 Sections in Saskatchewan and one in Manitoba), with the request a meeting of Branch Executive Committees be called to consider the replies and that these be returned by February 15th, 1961.

At time of writing, returns to the questionnaire total 94.6%. They will be analyzed as promptly as possible and recommendations arising therefrom made known.

The following have agreed to participate in the work of the Committee:

G. M. Boissonneault, M.E.I.C.
F. M. Cazalet, M.E.I.C.
Edgar A. Cross, M.E.I.C.
George Desjardins, Jr.E.I.C.
Roger Desjardins, M.E.I.C.
J. R. Eason, M.E.I.C.
R. H. Stevenson, M.E.I.C.
C. L. Thompson, Jr.E.I.C.
G. F. Vail, M.E.I.C.
A. W. Wirth, M.E.I.C.

F. L. LAWTON, M.E.I.C.
Chairman

LIBRARY AND HOUSE COMMITTEE

Library

At the request of Council, the Committee studied retention of the Library versus arrangements to obtain similar services elsewhere. The recommendation adopted by Council and supported by the Branch Officers, was to retain the present facility and to increase its use by the members.

To this end, efforts were made to publicize the Library; the President contacted the Branches in this respect and inserts in the Journal were intiated to encourage increased usage. Corresponding members were added to the Committee to permit broader appreciation of servces which might be rendered.

An endeavour was made to lower the cost per unit of service. Progress was achieved in this direction by the effecting of a non-recurring saving accruing from the sale of an above average quantity of obsolete material and the elimination of the Film Library by a transfer of holdings to the Canadian Film Institute.

On the debit side, the staff has for some years been unable to keep up-to-date on cataloguing. This situation has reached serious proportions. It is attributable to staff problems, floor space shortages and the probable necessity for redefinition of Library policy. It is the intention of the Committee to review policy and make such recommendations to Council as are considered necessary.

House

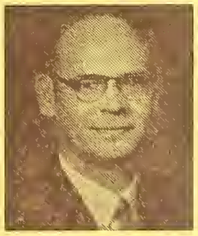
Demolition of the building to the north exposed the mitoyen wall. Although patched up by the adjacent owner, a recent inspection by the Committee disclosed hazardous conditions which were remedied on a split cost basis.

A wiring control panel and light fixture survey resulted in action which corrected overload conditions and resulted in improved lighting.

Further inroads on auditorium space for Headquarters office requirements is a distinct possibility. A report of immediate and short term space requirements will be made by the Committee to Council, shortly. The Committee indicated this situation would arise in the data it prepared for the longer term report on space submitted to Council by the Property Committee.

T. N. DAVIDSON, M.E.I.C.
Chairman

PUBLICATIONS COMMITTEE



The membership of the Committee for 1960-1961 was enlarged to include a representative of each of the nine technical divisions and, in addition, a vice-chairman. Geographical representation was provided as well with members residents of Toronto, Ottawa, Quebec and Montreal.

The first special task undertaken was to formulate terms of reference for the Committee. Revisions to the terms of reference, Section 49 of the Bylaws of the Institute appear desirable because of the growth of the Institute and its publications and because of changes in organization of the Institute. The new terms of reference, which were approved by Council in November 1960, assign specific responsibility to the Publications Committee for recommending to Council publication policies for technical journals, transactions, directories, books and related media in addition to the previously assigned responsibilities for approving articles for publication.

With the many people involved, either directly or indirectly, in the soliciting, approving, editing and publishing of Institute literature it is essential that policies be in writing if all concerned are to be expected to work to a common objective. With this in mind the Publications Committee has been working toward the establishment of a set of objectives for the Journal.

Concurrently with the study of objectives the Committee has made a study of the desirability of conducting a thorough survey of those receiving the Journal to ascertain what type of information is of greatest value to them.

The Journal competes with a multitude of other communication media for the time of its readers and therefore it stands to reason that the Journal should be as attractive and as easy to read as it can. With the objective of improving both its aesthetic and functional design a program of gradual change in the Journal has been undertaken commencing with the January 1961 issue.

R. A. PHILLIPS, M.E.I.C.
Chairman

SPECIAL COMMITTEES

75th ANNIVERSARY COMMITTEE

The Committee was appointed by Council in the spring of 1960 to make recommendations to Council regarding the planning of the annual meeting of 1962 which will mark the 75th Anniversary of the foundation of the Institute. The members of the Committee were appointed as follows:

F. M. Cazalet	Vancouver	S. B. Cassidy	Fredericton
A. C. Davidson	Toronto	P. Duchastel	Quebec
C. V. Antenbring	Winnipeg	E. T. W. Bailey	Hamilton

H. Gaudefroy, Chairman, Montreal

Due to the wide spread distribution of the membership of the Committee, it was not considered advisable to call a meeting of the group. Each member was requested to form a sub-committee in his own region to study the matter locally and to report to the Chairman in Montreal who himself operated with the support of a Montreal sub-committee. Through this action, we estimate that at least 40 members of the Institute have dealt with the matter. Ideas forwarded by one sub-committee to the Chairman were immediately dispatched to all sub-committees and discussed at large.

A great number of suggestions have thus been studied and those carrying the general support of all sub-committees were retained.

The report was handed to Council at its meeting of January 28, 1961. It was proposed that the program for 1962 be similar to that of other regular annual meetings and that emphasis in any possible way be put on the 75th Anniversary theme. Special ceremonies will be held subject to approval by Council.

The Committe has fulfilled its duties by reporting its findings to Council. It was discharged January, 1961.

HENRI GAUDEFROY, M.E.I.C.,
Chairman.

BOARD OF EXAMINERS

The Board of Examiners held two meetings during 1960, at which nineteen (19) candidates were considered.

Four (4) candidates were referred to Council with recommendation for acceptance as Members, after assessing and verifying their qualifications. One (1) candidate was referred back to the Admission Committee for acceptance Four (4) candidates were referred to the Corporation or provincial Associations of Professional Engineers for completion of their qualifications. One (1) candidate requested transfer to Member grade, but was not eligible. One (1) candidate has been given an oral examination and report is awaited. One (1) candidate is to be given an oral examination. Including these two candidates, at the end of 1960 nine (9) candidates were still under consideration.

J. L. DE STEIN, M.E.I.C.
Chairman

THE CANADIAN COMMITTEE OF THE INTERNATIONAL ASSOCIATION FOR THE EXCHANGE OF STUDENTS FOR TECHNICAL EXPERIENCE

So far as Canadian participation in the IAESTE plan is concerned 1960 is reported as a fairly normal year. 107 foreign students visited Canada, for work with 45 employers, and 24 Canadian students went abroad to 7 different European countries. The total exchange for Canada was therefore a 21% increase over 1959, which is a most encouraging result.

The only unusual item to report is that administrative trouble developed in attempting to place Canadian students in one European country, resulting in cancellation and disappointment for a considerable number of them, mostly at Ecole Polytechnique. This difficulty was traceable to our inability to consummate the exchanges concerned at the previous IAESTE Conference. Otherwise, Canadian student participation would have been at a record high.

Interest in IAESTE is increasing gradually throughout industry in Canada, particularly in the Eastern part of the country, and I am hopeful of growing participation. However, it was apparent during the late Fall months that general business conditions will have an adverse effect on prospects for 1961. Financial difficulties continue to provide the largest obstacle against wider participation by Canadian students.

N. S. Rogers and S. R. Whipple visited Canada during the summer as representatives of the IAESTE Committee in Great Britain.

L. A. DUCHASTEL, M.E.I.C.
Chairman

HONOURS AND AWARDS COMMITTEE

This committee was appointed in the fall of 1959 to review the rules governing the Institute honours, awards and prizes and to recommend any appropriate revisions or clarifications to Council. In our Interim Report forwarded to Council in November, we recommended that a National Committee for Prizes and Awards, preferably headed by the Immediate Past President, be established. This committee would be charged with the responsibility of recommending the appointment of the Chairmen of all individual Prizes and Awards Selection Committees for technical papers. It would also serve in an advisory capacity to the selection committees and would maintain a continuing study of areas where new prizes or awards are desirable. A prestige booklet covering all of the Institute's Prizes and Awards is recommended. Such a booklet could give biographical data about each individual in whose honour the award is made and would also serve to make these prizes and awards better known. The following members served on this committee:— Mr. V. A. McKillop of London, Mr. J. W. Dolphin of Kingston, and Mr. J. H. Legere of Headquarters Staff.

W. P. WHELEN, M.E.I.C.
Chairman

LEGISLATION COMMITTEE

No meetings of the Legislation Committee were held in 1960 and no matters have been referred to the committee. It is hoped that a meeting of the committee can be held during the opening day of the Annual Meeting in Vancouver and as a result of the meeting a report forwarded council for consideration.

W. B. PENNOCK, M.E.I.C.
Chairman

LIFE MEMBERS COMMITTEE

The committee is able to report another successful year. The annual contributions from members was substantial; the distribution of funds was much the same as for 1959; the committee was enlarged by the addition of four new members.

The year end total of Life Members was 760. There has been some confusion about numbers and an adjustment has been made recently so that the total membership appears to have been reduced, but such is not actually the case. During the year 54 died. A list of these is being sent to the Life Members along with a new list of all members with their addresses.

The membership is divided geographically this way. Canada 702; United States 43; Great Britain 18; Others 3. By branches Montreal has by far the greatest number — 173; Toronto has 99; Ottawa 77, Vancouver 39, Vancouver Island 39. Halifax and Winnipeg 25 each.

The funds are at a new high, now standing at $8,522.18. Contributions for 1960 amounted to $2,209.00. The Institute has made some suggestions recently as to projects that might be aided by the Life members which, if approved by the committee, would reduce the funds by about $5,000.00.

Again, the sum of $500.00 was donated towards theexpenses of delegates to the annual Students Conference. Towards student prizes the sum of $375.00 was made available, andcopies of the Institute's publication on the life of Sir Casimir Gzowski were purchased for distribution to those attending the Students Conference and to the libraries of the universities. In all, the total of expenditures was $1,133.39.

Early in 1960 the committee requested of the Council of the Institute that the funds of the Life Members be set aside from Institute funds and be clearly designated as a trust fund so there could be no possibility of confusion, and also that the interest earned by this money be credited to the account. Although it does not rightly belong in the report for 1960, the committee is able to report that early in 1961 Council agreed to the committee's request.

High on the list of possible projects for 1961 is a proposal to establish a memorial to one of Canada's most outstanding engineers. As well, consideration is being given to the projects proposed by Council and referred to earlier.

The personnel of the enlarged committee for 1961 is —

N. M. CAMPBELL
deGASPE BEAUBIEN
J. A. FREELAND, *Secretary*
P. S. GREGORY
HUET MASSUE
J. A. MCCRORY
C. K. MCLEOD, *Vice-Chairman*
BRIAN R. PERRY
J. B. STIRLING
I. R. TAIT
L. AUSTIN WRIGHT, *Chairman*

J. A. FREELAND, M.E.I.C.
Secretary

COMMITTEE ON MEMBERSHIP

During the fall of the year Council approved the re-activation of the Committee on Membership, on a broad new basis. Its principal functions are to promote the growth of E.I.C. membership, and to advise and assist Council on matters of membership policy. In the latter function it will continue the work started by the ad hoc committee on membership procedures during the summer of 1960.

The first meeting of the committee was held in Toronto on November 19th, with ten members attending, from widely separated parts of the country. It was recognized at the outset that membership promotion activity must take place essentially within the Branches, working with Headquarters' guidance and assistance. The discussions of the first meeting can be summed up in a three point program:

1. Obtain from the Branches details of their membership organization and problems;
2. Provide them with as much guidance and assistance as possible;
3. Follow this up through personal visits, and use of the Engineering Journal.

During December plans were developed for close co-ordination between the committee and Headquarters' staff, and the next meeting of the full committee was scheduled for early February.

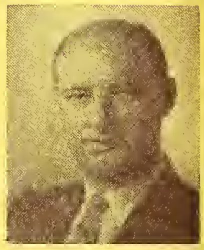
PROPERTY COMMITTEE



An enlarged Property Committee was established by Council on May 26th, 1960, with instructions to investigate and report on the provision of adequate accommodation for Headquarters, Publications, Library, Montreal Branch meetings and possibly those of sister societies. Council expanded the terms of reference to permit locations other than Montreal to be considered.

The report, prepared with the assistance of the Library and House Committee, was submitted to Council on October 29th, 1960. It was ratified January 28th, 1961 and was made available to the Engineers Confederation Commission at that body's request.

Aspects covered were real estate considerations, functional requirements, including consideration of club type facilities, projections of membership and of space requirements in detail for twenty years, joint use of building and services with other engineering societies, pros and cons of Ottawa and Montreal including reactions of Branch Executives in the two locations.

From this investigation, five major factors formed the basis for the Committee's recommendation. These are:

1. The future of the Institute is not clear (Confederation) therefore further consideration of relocation in another city is not warranted at the present time.

2. There is no particularly advantageous real estate situation to warrant sale of the 2050 Mansfield Street, Montreal property for monetary reasons.

3. The Montreal Branch prefers to continue to use facilities in the Headquarters building rather than to try to arrange meetings at hotels, universities, etc.

4. The Headquarters building is inadequate for Branch and Headquarters use, but the situation will not involve acquisition of additional rented space in the immediate future, although further inconvenience to the Branch is likely.

5. Sale of the present premises and temporary relocation in a good quality building in the downtown area would probably involve a net outlay increase of $20,000. to $30,000. per year over present rent plus return from investment of the capital realized by the sale.

The Committee's recommendation, therefore, is to take no action at present. Changes to the status of any of the factors enumerated above will necessitate reassessment of the situation.

T. N. DAVIDSON, M.E.I.C.
Chairman

STUDENT POLICY COMMITTEE

Your committee again organized a Student Conference, which was held in conjunction with the Annual Meeting in Winnipeg, where thirty-two (32) delegates from seventeen (17) universities discussed their problems and planned how the Institute might become a more vital force in the development of the engineering undergraduates.

At the close of the year our student membership was 6262, or almost 29% of the entire membership. This represents an increase of 72% over the last three years, during which time enrollment in the other membership grades increased by approximately 10%. The enthusiasm of our faculty advisers is a continuing source of satisfaction and this progress is a tribute to their efforts.

The committee has investigated several problems referred to it by Council and continues to explore ways and means whereby the Institute can work effectively at each campus.

C. G. SOUTHMAYD, M.E.I.C.
Chairman

COMMITTEE ON TECHNICAL OPERATIONS

The results of the EIC Annual Meeting in Winnipeg in 1960 have encouraged the Committee to continue the policy of making a careful selection from a broad survey of potential technical papers, and then providing full scope for discussion. The success of that meeting appears to have engendered a more active participation by members, and so many outstanding papers have become readily available for the 1961 Annual Meeting that the Committee felt compelled to increase the number of concurrent sessions. Arrangements have been made to accommodate at the Vancouver meeting the National Research Council Associate Committee on Automatic Control, and that Committee will conduct a symposium and present papers for open discussion by the EIC membership.

Two new technical divisions were approved by the EIC Council during the year—the Geotechnical Engineering Division under the Chairmanship of Mr. R. F. Legget, and the Engineering Education Division under the Chairmanship of Dr. Arthur Porter.

A joint EIC-CISS Committee on the Use, Conservation and Pollution Control of Water Resources has been created. This Committee has been very active and it is an excellent example of the manner in which the talents of the profession can be enlisted to serve our national interests. It is planned to enlarge the scope of this type of activity.

An increasing collaboration with other engineering societies has developed during the year. Arrangements have been made for a joint ASME/EIC Technical Conference on Hydraulics in May, 1961 in Montreal. A second joint conference with ASME is scheduled for the same month in Toronto on the subject of Production Engineering. A joint ASME/EIC Railroad Conference is planned for Toronto in 1962, and a Conference on Heat Transfer is under discussion for a later date.

Co-operative undertakings with our Sister Societies have not been confined to joint conferences. Agreements have been reached with the Institution of Civil Engineers, The Institution of Mechanical Engineers and The Institution of Electrical Engineers so that the members of those bodies residing in Canada may participate in our technical programs.

Throughout the year an effort has been made to interest the Branches in greater participation in our technical programs not only at Branch level, but at Regional and National level. Regional conferences have been scheduled for Niagara Falls and North Bay in March and May of this year. This is an encouraging development, and it is believed that the participation of Branch representatives in the technical activities of the Institute will result in increasingly important and stimulating contributions.

B. G. BALLARD, HON. M.E.I.C.
Chairman

TRUSTEES

JAMES H. BRACE BEQUEST COMMITTEE

The James H. Brace Bequest consists of the sum of $25,000., the income derived from this sum to be applied by the Institute for the benefit of unemployed and needy engineers. A committee to administer the fund has been appointed consisting of A. Deschamps, E. Mason, C. N. Murray, A. T. E. Smith, O. M. Solandt, and with D. M. Stephens as Chairman.

The principal sum of this bequest is $25,000. Interest has accrued in the amount of $1,920.34 to Dec. 31, 1959, plus $807.61 for the year 1960. The balance in the fund at Dec. 31, 1960, was $27,727.95. No disbursements have been made from the fund.

The main activity of the Committee during the year under review had to do with the enunciation of general principles which should govern the administration of the Brace Bequest. Progress was made toward this end and it is anticipated that a draft of the proposed "governing principles" will shortly be in shape for consideration by Council.

A further project contemplated by the Committee and to be undertaken as soon as "governing principles" have been established will have to do with the preparation of draft rules of procedure.

D. M. STEPHENS, M.E.I.C.
Chairman

HARRY F. BENNETT EDUCATIONAL FUND

During the year 1960 loans to a total of $2250.00 were made and repayments of $11,300.00 received. This along with a bank balance of $5,092.85 as of December 31st, 1959, resulted in a bank balance at the end of 1960, after allowing for outstanding cheques, of $14,069.16. This improvement in the cash position is due in most part to a reduction in the amount loaned and in the increase in repayments. This latter factor is most encouraging as it evidences the appreciation of those students receiving loans and of the benefit derived from their engineering education. The purpose of the fund is, it is felt, being accomplished by the assistance given.

It should be noted that on December 31st, 1959 the loans outstanding amounted to $27,709.50 whereas at December 31st, 1960 this figure stood at $18,718.96. One loan of $125.00 was written off due to death of the applicant and a voluntary subscription of $100.00 received. Interest on loans was received to the amount of $409.35 which was considerably more than the amount written off.

Very few of the loans now outstanding are of dates that would indicate that they will not be repaid and your trustees are of the opinion that the fund can be kept in a solvent position and with funds available for approved loans. While it is realized fully that the purpose of the fund is to make loans available to worthy students to assist them in acquiring an engineering education, it must be borne in mind that to keep this revolving fund available for future applicants every reasonable effort must be made to secure repayment where circumstances permit.

The trustees wish to express their appreciation of the efforts of the officers and staff of the Institute for their unfailing co-operation and sincere interest in the administration of the fund.

It has been a continuing source of pleasure and satisfaction to have had the opportunity of associating with my fellow trustees, Mr. Eric Smith and Dr. Jas. F. MacLaren and to them I tender my sincere thanks.

OTTO HOLDEN, HON. M.E.I.C.
Chairman

REPORTS OF REPRESENTATIVES

AMERICAN SOCIETY OF MECHANICAL ENGINEERS

The Council of the American Society of Mechanical Engineers

As the E.I.C. representative on the ASME Council I attended the series of Council Meetings held druing the ASME Annual Meeting in New York late in November, 1960.

The meetings were informative but there was no business of particular interest to the E.I.C. You will recall that there is reciprocal membership on the Councils of the two organizations though the E.I.C. representative does not have voting privileges on the ASME Council. At the present time this is not considered an important point, merely one with which you should be familiar.

H. G. CONN, M.E.I.C.
Representative

ASME-EIC International Council

During the year the Council met twice – in conjunction with the Annual Meetings of E.I.C. and A.S.M.E. respectively.

The Council considered a number of areas in which co-operation and co-ordination could be encouraged, including reciprocal representation on the respective Councils and certain technical divisions of each organization, joint meetings and conferences, interchange of technical papers, and student activities.

During the year, the ASME-EIC Biennial Conference on Engineering Education was held on the campus of Ecole Polytechnique on October 5 and 6, 1960, with an encouraging attendance. Continuation of this conference was discussed at length and the decision made that, in future, there would be no pre-determined designation of time or place, but the conference would be organized whenever either of the educational boards of the two organizations considered it to be appropriate.

Plans were reported for the holding of a Joint EIC-ASME Hydraulic Division meeting in Montreal in May, 1961.

As EIC is now a co-sponsor of the Inter-Society Engineering Management Conference, consideration was given to the possibility of holding the 1963 conference in Toronto.

In order that tenure of office for the Council may be brought into line with the latest regulations of the two bodies, the term of office for the current Councillors was extended to June, 1961.

While the activities of the Council itself are limited, it has observed in its meetings the progressive development of more complete understanding and co-operation between the two Societies.

L. C. SENTANCE, M.E.I.C.
Chairman, ASME-EIC International Council

Air Pollution Controls Committee

At the meeting of the above Committee was held in New York on December 1st, 1960, when the following matters were dealt with:—

(A) A report on Control Equipment, embodying a list of manufacturers of such equipment, was approved;
(B) No new list of instruments for measuring air pollution will be issued in 1961, as the present list is still up-to-date;
(C) A third edition of "Research Projects" will be ready in a few months;
(D) In future, the Air Pollution Control Committee will be aligned with the Power Department of the A.S.M.E.;
(E) An Inter-Society Co-ordinating Committee on Air Pollution will be established, to initiate and organise a symposium in which the existing state of knowledge and the need for additional knowledge will be discussed;
(F) A report was presented on the status of a revised Model Smoke Ordinance.

It may also be remarked that a meeting was held on Jan. 20, 1961, of the Sub-Committee on Air Pollution Control of the Canadian Standards Association. The Report of the Engineering Joint Committee, published in the "Engineering Journal", May 1951, was discussed as a possible basis for a Canadian Standard. Reports on this matter were considered and, after much discussion, a tentative form of report was agreed upon for further consideration at a later meeting.

A. E. ALLCUT, M.E.I.C.
Representative

CANADIAN GOOD ROADS ASSOCIATION JOINT COMMITTEE ON UNIFORM TRAFFIC CONTROL DEVICES

The preparation of the "Manual on Uniform Traffic Control Devices for Canada" has been a great task and a great accomplishment is beyond question. That its acceptance will be general has been assured by the fact that every Canadian authority concerned had the opportunity to express its views during the course of its many revisions, and before its final acceptance.

The great number of experts, members of the Joint Committee, who worked on its preparation, is a guarantee of its reliance as a true Canadian standard.

This masterpiece is the result of the endeavours of the Canadian Good Roads Association, but it is also that of others who have participated in its production, including the Engineering Institute of Canada.

A copy of the manual may be obtained from the Canadian Good Roads Association, 270 MacLaren Street, Ottawa.

J. O. MARTINEAU, HON. M.E.I.C.,
Representative

CANADIAN STANDARDS ASSOCIATION

Technical Committee

Since being appointed E.I.C. Representative to the Technical Council of the C.S.A. in April, 1960, I have endeavoured to obtain some background information as to the workings of this Council and to vote on the various proposed standards that are submitted from time to time to all the members of this Council.

On checking back through my files, I find that I voted in the affirmative on 24 separate standards and one vote in the negative. In addition, there was one standard on which I did not vote either way.

It is not always easy to make a decision in voting on these various proposed standards, as the range of subjects is very ide and one's knowledge is necessarily very limited. Consequently, I think it is only fair to state that had it not been for the services of a very competent staff in my own company it would not have been possible for me to vote intelligently on a great many of the proposed standards and changes to them.

In addition to the votes that were registered above, I find that there was correspondence with the Secretary of the Council on three proposed standards and that in each case, I received from the Chairman of the Committee concerned, very satisfactory replies to my questions.

E. B. JUBIEN, M.E.I.C.

COLUMN RESEARCH COUNCIL

The Column Research Council of the Engineering Foundation concerns itself with problems relating to the strength, design, and behaviour of columns and other compression elements in metal structures. A review of the work of the Council was given to the Annual Meeting of the Engineering Institute in Winnipeg in 1960.

Towards the end of 1960, the Column Research Council published a "Guide to Design Criteria for Metal Compression Members" incorporating the results of researches in North America and abroad over the past several years. The Guide provides an authoritative summary of knowledge on the field, and would be of use to specification writing bodies, and engineers in practice requiring special information on instability in metallic structures. Copies of the Guide may be obtained through the office of the General Secretary of the Engineering Institute in Montreal.

Following upon the publication of the "Guide", the research committees preparing material for publication have mostly been disbanded. In their place have been formed a number of "Task Groups" to undertake further new studies. Reports will be made on these from time to time as work progresses. It is perhaps interesting to note that the undersigned reported has been named Chairman of one of these new Groups.

REPORT OF THE LIAISON OFFICER FOR THE ENGINEERING INSTITUTE OF CANADA TO THE EMERGENCY MEASURES ORGANIZATION OF THE FEDERAL GOVERNMENT OF CANADA

Two separate projects were considered during the past year, both of which will be issued as specifications by the Canadian Government Specification Board.

The first project covered the development of a hydropneumatic pumping system for use with mobile emergency hospitals. Several meetings were held to discuss a desirable specification and this has now been completed and will be issued by the Canadian Government Specification Board under their No. 100-GP-1a.

This equipment is designed to be used in conjunction with portable power equipment for the supplying of potable water for emergency hospitals. It is to be capable of being used under a wide variety of conditions and types of water supply

The second project, which is still under consideration, covers the development of a lightweight 10 KW single phase internal combustion engine driven generator set for the supply of electric power to emergency hospitals. The factors involved in the design of this equipment are portability, reliability and capable of operating under a wide range of climatic conditions on an emergency basis.

The above equipment will be used in conjunction with hospital equipment which is being packaged and stored in strategic locations across Canada and will include everything from surgical equipment, X-ray equipment down to the water supply and power supply described above.

The specification for this plant will also be issued by the Canadian Government Specification Board on completion of the study.

ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

During the year 1960 the Engineering Institute of Canada, in addition to participating in the regular activities of the Engineers' Council for Professional Development, had the opportunity of acting as host in Montreal at the Annual Meeting of E.C.P.D. on October 3rd and 4th. The meeting was an excellent one, well attended, with good papers and all present, mostly from the U.S.A., were greatly pleased with the excellent arrangements made by the Institute for the meeting in the Queen Elizabeth Hotel. Amongst the other functions of the gathering was the Annual Dinner at which Colonel L. F. Grant had been chosen as the speaker, always a happy choice on any E.C.P.D. occasion. It will be recalled that Colonel Grant represented the E.I.C. on the Council of E.C.P.D. for a number of years, and for three years was its President. His unique qualities as a Canadian representing E.I.C. on E.C.P.D. has left an imprint that will remain for a long time. The Annual Meeting was a very profitable one and the representatives of the other constituent members of E.C.P.D. are always happy to share in Canadian hospitality.

The expansion of E.C.P.D. membership is a problem which has been under consideration for several years and during 1960 the Council of E.I.C. has approved of the applications of the Institute of Aeronautical Science (I.Ae.S.), the Institute of Radio Engineers, (I.R.E.), and the National Society of Professional Engineers (N.S.P.E. for admission to E.C.P.D. and the way has been cleared for appropriate action to be taken.

The Council of the Institute during the year also went on record as favouring the proposed amalgamation of E.C.P.D. and E.J.C. (Engineers Joint Council) and the necessary steps are being taken to bring this about.

E.C.P.D. was one of the sponsors of the U.P.A.D.I. (Pan-American) Conference on Engineering Education in Buenos Aires in September and the E.I.C. was represented by Dean H. G. Conn of Queen's University and Dean R. R. McLaughlin of the University of Toronto who presented papers dealing with some Canadian aspects of Engineering Education. Immediately following the Engineering Education Conference a regular U.P.A.D.I. meeting was held and quite a number of prominent members of E.I.C. attended.

Much of the activity of EI.C. in the work of E.C.P.D. centres in the work of the committees and therefore is never in the limelight and passes un-noticed. However, E.I.C. is represented on all E.C.P.D. standing Committees. Guy Savard of Montreal is Chairman of the Recognition Committee and J. C. H. Dessaulles also of Montreal is one of the members. Georges Demers of Quebec City serves on the Ethics Committee; Garnet Page is on the Information Committee and E. J. Muszinski of Montreal acts on the Student Development Committee. Dean H. G. Conn of Queen's University has become a member of the Education and Accreditation Committee and Roger Lessard of Montreal is on the Guidance Committee.

The Committee on Development of Young Engineers has three E.I.C. members, W. J. O'Reilly of Niagara Falls, W. E.

Lardner of Toronto and K. R. Crean of Hamilton. (The E.I.C. Young Engineers Development Program has progressed a long long way since Colonel Grant carried the spark from the E.C.P.D. Annual Meeting in Cleveland ten years or more ago that kindled the flame which has spread so widely through the E.I.C. Branches to the benefit of so many young engineers).

Dean Donald MacNeil of St. Francis Xavier University, Antigonish, Nova Scotia has joined Gordon R. Henderson of Sarnia and W. S. Wilson of Toronto to make up the three representatives of the Institute on the Council of E.C.P.D.

I believe that E.I.C. is assuming its full share of the work in carrying out the various activities of E.C.P.D. and that we are not shirking our responsibilities. On the other hand I am convinced that E.I.C. is well repaid for the support it affords E.C.P.D. as one of its constituent members.

W. S. WILSON, HON. M.E.I.C.
Representative on Executive Committee, E.C.P.D.

NATIONAL JOINT COMMITTEE ON WINTERTIME CONSTRUCTION

The C.C.A.-sponsored National Joint Committee on Wintertime Construction continued to function during 1960, its sixth year of operation. Full-fledged meetings were held in Construction House, Ottawa, on February 17th and September 9th. In addition, a brief, factual submission was made to the Senate Committee on Manpower and Employment. The first meeting of the Committee was deliberately held during the middle of the winter to assess the seasonal unemployment situation and the effectiveness of wintertime construction promotion activities.

Members recommended that the Federal Government make its announcement concerning any Municipal Winter Works Incentive Program for the 1960-61 winter at an earlier date in order to enable municipal officials to do the necessary planning for participation. It was also recommended that the municipal program be given wider coverage as to the type of project to be included. These recommendations were passed on to the Federal Government and it was most gratifying that the announcement was made on July 25th and that the effective date of the Program was set at October 15th rather than December 1st as in previous winters. Moreover, the Program was expanded in scope so as to include municipal buildings other than schools and hospitals and additional types of engineering construction. The response from the municipalities has increased appreciably. The Committee has advocated an extension of the incentive principle into the field of industrial and commercial construction.

Further discussions were held concerning the hours of work provisions on Federal Public Works projects which sometimes tended to reduce employment and earnings rather than increase wintertime employment. Subsequently, the Federal Government issued an Order-in-Council during the summer providing for greater flexibility in this field inasmuch as permits may now be granted allowing work to continue for more than eight hours a day if the weekly number of hours worked still does not exceed forty-four.

The National Joint Committee also devoted a good deal of its attention to the subject of publicity promoting more wintertime construction and employment. The National Research Council reported that it plans to prepare a new film covering wintertime construction of houses and smaller building projects which will serve as a companion piece to Wintertime Construction—It Can Be Done", which relates to larger buildings. Some smaller technical films are also being considered. The Canadian Construction Association has cooperated with the Department of Labour in furnishing textual material for an illustrated brochure on wintertime construction scheduled for use in 1961. The N.R.C. Division of Building Research Bulletin on Wintertime Construction has been revised and remains a "bestseller" for this type of technical note. The constituent national organizations of the N.J.C.W.C. have all been most cooperative in promoting wintertime construction in speeches, bulletins, briefs and other media. The seasonal unemployment problem in construction activity remains extremely serious in spite of substantial gains. All possible assistance by members of the Institute to reduce these seasonal swings would be most welcome.

SECOND INTERNATIONAL HEAT TRANSFER CONFERENCE

The 'Joint Committee on North American Participation' which is organizing the five day International Heat Transfer Conference to be held at Boulder, Colorado on August 28th to September 1st, 1961, consists of representatives of the two host societies (ASME and AIChE) and eight other co-sponsoring societies, including the Engineering Institute of Canada.

Most of the work of the Committee in 1960 was concerned with the selection of abstracts of proposed papers and subsequently with the revision of the papers submitted by those whose abstracts were accepted. Papers from thirteen countries were submitted and the final number accepted for the Conference will be about 130.

The work has progressed well and it is hoped that advanced programs should be available before the end of April 1961. It is also planned to have the pre-prints ready and distributed to pre-registrants well ahead of the Conference date.

CANADIAN RADIO TECHNICAL PLANNING BOARD

1960 was a year of accelerated activity in Canadian Radio Technical Planning Board affairs. The Board is a non-political, non-profit organization of users of radio communications and allied equipment, manufacturers, engineering and educational societies and other interested groups, and it continued investigations into the conservation and effective use of the radio frequency spectrum, acting as a technical advisory body to the Telecommunications and Electronics Branch, Department of Transport.

The Land Fixed and Mobile Committee gave priority consideration to split channel operation of 150 MC land mobile equipment and the Maritime Committee dealt wth D.O.T. Spec. 134 covering AM radiotelephone transmitters and receivers n the 1605-5000 Kc/s band.

Investigation of scatter techniques, interference, hazards, and frequency allocations was carried out by the Tropospheric Scatter Committee. The Television Committee completed its draft revision of D.O.T. Broadcast Procedure No. 5, Issue I: "Protection and Coverage Rules for V.H.F. Television". It also commented on other Specifications. The Railroad Frequency Allocation Plan recommending narrow channel Allocations, was circulated to sponsors. The Microwave Committee completed its recommendations on telephone channel parameters and microwave frequency allocations.

The Broadcast Committee commenced investigation of Spec. 150 and 151 covering AM broadcast transmitters and its Sterephonic Subcommittee held several meetings on stereophonic radio broadcast standards.

A suitable amortization period for non-type approved Ship Station Radio Equipments covered by Spec. 112 was investigated by the Amortization Committee. A sponsor vote by letter ballot approved the Committee's recommendations.

UPADI

The Union Panamericana De Asociaciones De Ingenieros continues to be active and it is my privilege, as your representative, to report to you at this time.

When UPADI was first organized in 1950, the purpose was to promote better understanding between the Engineers of the Western Hemisphere.

The 6th. Pan-American congress on education was held in Buenos Aires on September 12-17, 1960. It was followed by UPADI Convention September 19-22. Host to both meetings was the Union Argentina de Asociaciones de Ingenieros.

The Canadian delegation which included 15 Engineers, were also members of the Canadian Trade Mission to South America. We were well represented at all UPADI functions, including plenary sessions, round table conferences, committee meetings and the final meeting and banquet. The more important roles in this convention were taken by Past President Dr. K. F. Tupper and Professor Morrison of Toronto. The Canadians were well received at this conference. We met many old friends.

The representative of the Engineering Institute of Canada was again re-elected to the Board of Directors. Mr. Carols Vegh Garzon was again asked to represent us as an alternate.

A suitable occasion was arranged to pay tribute to the long and faithful services of Mr. Vegh Garzon on our behalf. This occasion was a reception held at the residence of Mr. C. A. Bissett, Commercial Consul of the Canadian Embassy in Buenos Aires, at which about 100 were present. The President's letter was read and a watch, with a suitable inscription, was presented to him by the Canadian Ambassador, Mr. R. P. Bower. This presentation was the highlight of the reception.

UPADI Fund Inc. also held a meeting. There was some change on the Board of Directors—Mr. George Browne of New York replaced Mr. James Todd of New Orleans, as President. The writer was re-elected as a member of the Board.

It was arranged that the next conference be held in Puerto Rico in 1962. The UPADI headquarters is to remain in Montevideo in the meantime.

There were discussions relating to interchange of students, the employment of students in Canada and scholarships. Many students attend convents and Junior Colleges in Canada.

In connection with these activities, it is recognized that few Canadians are well informed about UPADI affairs or Engineering, generally, in these countries, I would like to suggest that a committee be formed to keep the members of the Institute advised on UPADI matters and participation. Perhaps the E.I.C. would be interested in forming its own committee of International Relations at a later date to look after all Canadian Engineering activities in the International field.

In conclusion, may I say that I am very strongly in favour of our participation in UPADI activities, in financing these activities and encouraging Canadian Engneers to become interested in Latin-America. It is important, as it will provide opportunities for Canadian Engineers. It will help open the way for closer associations in a natural market for Canadian goods and services.

OFFICERS COMMITTEES & REPRESENTATIVES

OFFICERS 1960-1961

President

George McKinstry Dick, Sherbrooke, Quebec

Past-Presidents

C. M. Anson, Sidney — K. F. Tupper, Toronto — J. J. Hanna, Calgary

Vice-Presidents

Until June, 1962
Edgar A. Cross, Toronto
T. C. Higginson, Saint John
Charles Miller, Baie Comeau

Until May, 1961
C. V. Antenbring, Winnipeg
R. B. Chandler, Port Arthur
F. L. Lawton, Montreal

Treasurer

E. D. Gray-Donald

Councillors

Representing Sister Societies
B. Chappell, Winnipeg, Man.
W. F. Hayes, Prince Albert, Sask.
R. N. McManus, Edmonton, Alta.
Wm. J. Riley, Rosemere, Que.
C. G. Southmayd, Lachine, Que.
K. E. Whitman, Halifax, N.S.

Until June, 1963
Paul G. A. Brault, Montreal, Que.
A. C. Davidson, Downsview, Ont.
R. A. Phillips, Montreal, Que.
John S. Watt, Ottawa, Ont.

Until June, 1962
Frederick Alport, North Orillia, Ont.
N. S. Bubbis, Winnipeg, Man.
P. E. Buss, Thorold, Ont.
F. W. Buckley, Bathurst, N.B.
Hector Chaput, Ottawa, Ont.
C. V. Campbell, New Glasgow, N.S.
T. N. Davidson, St. Lambert, Que.
W. A. Dawson, Hamilton, Ont.
Georges Demers, Quebec, Que.
P. W. Gooch, Montreal, Que.
J. E. Harris, Sarnia, Ont.
W. G. Heslop, Vancouver, B.C.
W. M. Hogg, Sault Ste. Marie, Ont.

STANDING COMMITTEES

Admissions
Chairman: P. W. Gooch, Montreal; *Members:* W. Bruce, Montreal, W. G. Gauvin, Montreal, R. J. Harvey, Montreal, D. Laplante, Montreal.

Finance
Chairman: F. L Lawton, Montreal; *Treasurer and Vice-Chairman:* E. D. Gray-Donald, Montreal (Ex officio); *Members:* J. M. Breen, Montreal, J. H. Budden, Montreal, R. L. Dunsmore, Montreal, T. W. Eadie, Montreal, R. A. Emerson, Montreal, E. B. Jubien, Montreal, G. N. Martin, Montreal.

Legislation
Chairman: W. B. Pennock, Victoria; *Members:* P. N. Bland, Vancouver, S. Barkwell, Winnipeg, D. Cramer, Lethbridge.

Library & House
Chairman: T. N. Davidson, Montreal; *Members:* Jacques Benoit, Montreal, R. N. Boyd, Montreal, Col. W. A. Capelle, Ottawa, W. C. M. Luscombe, Montreal, J. E. Leo Roy, Montreal.
Corresponding Members: R. W. Underhill, Calgary, C. R. Elliott, St. John's, Newfoundland.

Publications
Chairman: R. A. Phillips, Montreal.
Vice-Chairman: Ben O. Baker, Ottawa.
Civil Engineering: N. B. Hutcheon, Ottawa.
Bridge & Structural Engineering: J. S. Walsh, Montreal.
Chemical Engineering: W. H. Gauvin, Montreal.
Electrical Engineering: D. J. McDonald, Montreal.
Geotechnical Engineering: I. D. Mackenzie, Montreal.
Hydro-Electric Engineering: P. Duchastel, Sillery, Que.
Mechanical Engineering: W. Bruce, Montreal.
Management Engineering: G. V. Meagher, Toronto.
Mining & Metallurgy Engineering: Paul Riverin, Montreal.
Chairman, Editorial Review Board, Transactions of EIC: A. Porter, Saskatoon (Ex officio).

Technical Operations
Chairman: B. G. Ballard, Ottawa.
Members: C. E. Frost, Montreal, R. M. Hardy, Edmonton, A. R. Harrington, Halifax, W. H. Paterson, Toronto.

Chairmen of Technical Divisions:
Bridge & Structural Engineering: T. Dembie, Toronto.
Chemical Engineering: Dean J. W. Hodgins, Hamilton.
Civil Engineering: R. M. Hardy, Edmonton.
Electrical Engineering: S. Sillitoe, Belleville.
Engineering Education: Dean Arthur Porter, Saskatoon.
Geotechnical Engineering: R. F. Legget, Ottawa.
Hydro-Electric Engineering: J. A.

omas, Montreal.
nagement Engineering: W. L. Hutchison, Toronto.
chanical Engineering: Professor J. S. Campbell, Kingston.
ning Engineering: No Appointee.

SPECIAL COMMITTEES

61 Annual Meeting Committee (Vancouver)

Executive:

airman: Dean D. M. Myers.
e-Chairman: Professor W. G. Heslop.
retary: F. M. Cazalet.
asurer: D. R. Bakewell.
ncouver Branch: J. H. Swerdferger.

Sub-Committee Chairmen:

blicity: Al Cronk. *Budget and Finance:* D. R. Bakewell. *chnical Papers:* C. Peter Jones. *Hotel Arrangements:* Ron Wilkins. *Registration:* R. F. Binnie. *Reception and Information:* C. F. Ripley. *Ladies:* Percy Bland. *Plant Visits and ansportation:* Ian Hamilton. *Muriel's Room and Entertainment:* Sydney Hogg. *Annual Dinner and Dance:* Howard R. ight. *Communication and Projection:* G. M. Ellis.

ard of Examiners
airman: J. L. DeStein, Montreal; *Members:* J. M. Cape, ontreal, J. E. Hurtubise, Montreal, M. V. MacDonald, ontreal.

mmittee on Branch Operations
airman: F. L. Lawton, Montreal; *Members:* G. M. Boismeault, Montreal, F. M. Cazalet, Vancouver, Edgar A. oss, Toronto, George Desjardins, Montreal, Roger Desjdins, Montreal, J. R. Eason, Arvida, J. R. Rettie, Winpeg, R. H. Stevenson, Hamilton, C. L. Thompson, Toronto, F. Vail, Halifax, A. W. Wirth, Sarnia.

mmittee on By-Laws
airman: J. S. Waddington, Brockville; *Members:* J. W. lphin, Kingston, A. D. Janitsch, Belleville.

nours and Awards Committee
airman: M. P. Whelen, Toronto; *Members:* J. W. Dolphin, ngston, V. A. McKillop, London.

nadian I.A.E.S.T.E. Committee
airman: L. A. Duchastel, Montreal.
dustrial Representatives: D. B. Best, Montreal, J. M. Cape, ontreal, E. A. Clark, Montreal, W. G. H. Holt, Montreal, E. Shaw, Montreal.
ciety Representatives: Douglas Jones, Montreal, C. Gerow, ontreal, T. H. G. Michael, Ottawa, D. M. Morrell, Montal, F. L. Lawton, Montreal, E. L. Mahoney, Ottawa.
niversity Representatives: G. A. Wallace, Montreal, Jean uay, Montreal, B. A. Howarth, Montreal.

mmittee on Membership
hairman: S. B. Cassidy, Fredericton; *Members:* R. Bingo, Regina, W. A. Capelle, Ottawa, Gaetan Cote, Sherooke, J. W. Dolphin, Kingston, C. L. Fisher, Winnipeg, on Hardy, Montreal, C. Peter Jones, Vancouver, R. J. ane, Montreal, Elsie MacGill, Toronto, G. F. Vail, Halifax.
x Officio Members: Vice Presidents, Hugh C. Brown, Ottwa.

ational Committee on Professional Development Programs
hairman: W. A. Dawson, Hamilton.

roperty Committee
hairman: T. N. Davidson, Montreal.
wo immediate Past-Presidents: J. J. Hanna, Calgary, K. F. upper, Toronto.
hairman, Finance Committee: F. L. Lawton, Montreal.
reasurer: E. D. Gray-Donald, Montreal.
hairman, Montreal Branch: H. A. Mullins, Montreal.
epresentative from Ontario: W. A. Capelle, Ottawa.
ecretary: Garnet T. Page, Montreal.

oint Committee of The Engineering Institute of Canada and he Canadian Institute on Sewage and Sanitation on the Use, onservation and Pollution-Control of Water Resources
hairman: A. L. Van Luven. *Members:* J. S. Bates, A. E. Berry, T. V. Berry, P. H. Bouthillier, N. S. Bubbis, R. L. Clark, J. D. Kline, J. F. MacLaren, A. D. Misener, L. Piché, J. G. Schaeffer, J. B. Sprague, D. R. Stanley, J. A. Vance, W. L. Wardrop.

Student Policy Committee
Chairman: C. G. Southmayd, Montreal; *Members:* J. Dubuc, Montreal, R. E. Jamieson, Montreal, J. Hahn, Montreal, E. J. Muszynski, Montreal, A. Pakalnins, Montreal, D. A. Young, Montreal.

BOARDS OF TRUSTEES

Harry F. Bennett Educational Fund
Chairman: Otto Holden, Willowdale; *Members:* J. F. MacLaren, Toronto, A. T. Eric Smith, Montreal.

Brace Bequest
Chairman: D. M. Stephens, Winnipeg; *Members:* Albert Deschamps, Montreal, Ernest Mason, Trail, C. N. Murray, Sydney, A. T. Eric Smith, Montreal, O. M. Solandt, Montreal.

REPRESENTATIVES

American Society of Mechanical Engineers:
Council: H. G. Conn, Kingston.
Air Pollution Control Committee: E. A. Allcut, Toronto.
ASME-EIC International Council: H. G. Conn, Kingston, L. C. Sentance, Hamilton, J. A. Thomas, Montreal, P. W. Gooch, Montreal, Georges Demers, Quebec City, (Alternate).

Canadian Construction Association:
Joint Committee on Wintertime Construction: W. B. Pennock.

Canadian Good Roads Association:
Joint Committee on Uniform Traffic Control Devices: J. O. Martineau, Quebec City.

Canadian Radio Technical Planning Board: E. H. Hayes, Ottawa.

Canadian Standards Association:
Technical Council: E. B. Jubien, Montreal.
Committee on Developing a National Code for Aluminum Pressure Piping: A. Brebner, Kingston.

Column Research Council: D. T. Wright, Waterloo, J. S. Ellis, Kingston.

Emergency Measures Organization:
Liaison Officer: R. E. Hayes, Ottawa.

Engineers' Council for Professional Development:
Council and Executive Committee: W. S. Wilson, Toronto.
Council: G. R. Henderson, Sarnia, D. J. MacNeil, Antigonish (also representing the Canadian Council of Professional Engineers).
Education and Accreditation Committee: H. G. Conn, Kingston (observer), C. H. R. Campling, Kingston, (Alternate observer).
Ethics Committee: Georges Demers, Quebec (also representing The Canadian Council of Professional Engineers).
Committee on the Development of Young Engineers: K. R. Crean, Hamilton, W. E. Lardner, Toronto, W. J. O'Reilly, Niagara Falls.
Guidance Committee: Roger Lessard, Montreal.
Information Committee: Garnet T. Page, Montreal.
Recognition Committee: J. C. H. Dessaulles, Montreal, Guy Savard, Montreal.
Student Development Committee: E. J. Muszynski, Montreal.

International Heat Transfer Conference, 1961: J. W. Stachiewicz, Montreal.

Sixth World Petroleum Congress, 1963 (Canadian National Committee): G. W. Govier, Edmonton.

Union Panamericana de Asociaciones de Ingerieros:
Directors: James A. Vance, Woodstock, Ont.
UPADI Fund Inc.: C. R. Vegh Carson, Montevideo, James A. Vance, Woodstock, Ont.

ENGINEERS CONFEDERATION COMMISSION

Chairman: John H. Fox, Toronto; *Vice-Chairman:* J. E. Leo Roy, Montreal.

EIC Provincial Representatives:
Alberta: J. McMillan, Calgary; *British Columbia:* W. K. Gwyer, Trail, B.C.; *Manitoba:* T. E. Storey, Winnipeg; *New Brunswick:* T. C. Higginson, Saint John, N.B.; *Newfoundland:* J. B. Angel, St. John's, Nfld. (Joint Representative); *Nova Scotia:* Professor G. F. Vail, Halifax; *Ontario:* T. Foulkes, Ottawa, D. D. Whitson, Toronto; *Prince Edward Island:* W. R. Brennan, Charlottetown (Joint Representative); *Quebec:* B. D. Gray-Donald, Montreal; J. Lemieux, Sherbrooke; *Saskatchewan:* J. C. Traynor, Regina; *Yukon:* E. W. King, Whitehorse (Joint Representative).

EIC FACULTY ADVISERS AT CANADIAN UNIVERSITIES

University.	*Faculty Adviser.*
Degree Granting:	
Assumption University of Windsor	Prof. R. G. Billinghurst, M.E.I.C.
Carleton University	Prof. S. G. Tackaberry, M.E.I.C.
Ecole Polytechnique	Prof. J. Dubuc, JR.E.I.C.
Laval University	Prof. Lionel Boulet, M.E.I.C.
McGill University	Dr. Andrejs Pakalnins, M.E.I.C.
McMaster University	Prof. W. R. Newcombe, JR.E.I.C.

• LIBRARY NOTES

(*Continued from page 134*)

cluded. (P. Rosenstiehl. Paris, Dunod, 1960. 355p., 47 fr.)

PRINCIPES DES CALCULATRICES NUMERIQUES AUTOMATIQUES, 2. ed.

The first part of this text discusses the principles of digital computers, binary systems, logical circuits, and actual computer operation and programming, with examples. The second part is a study of technology which is founded on the use of electronic tubes, transistors, germanium diodes, cryotrons, etc. (P. Naslin. Paris, Dunod, 1960. 243p., 13 fr.)

PHYSIQUE DES VIBRATIONS A L'USAGE DES INGENIEURS, 2. ed.

Developed from an undergraduate course given by the author, this text presents to the engineer an outline of the physics necessary for an understanding of the phenomena associated with vibrations. The first part includes a general study of vibration: oscillations; systems with one degree of liberty; shock and wave propagation. The second section deals with acoustics, sound, ultrasonics, and the application of acoustics. The third part covers optics, the nature and speed of light, diffraction, polarization, dispersion and spectroscopy. The last part discusses radiation, incandescence and photometry. Problems and their solutions are included. (A. Fouillé. Paris, Dunod, 1960. 552p., 64 fr.)

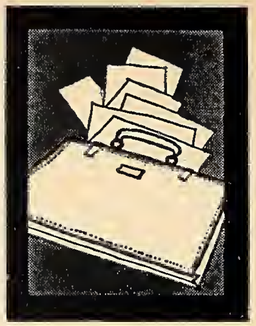
ELECTROTECHNIQUE A L'USAGE DES INGENIEURS. T. 2 MACHINES ELECTRIQUES, 5. ed.

Another text by this well-known author, this fifth edition of volume two has been revised to make use of the rationalized MKS system. It is concerned with the general theory of electric machines, particularly transformers, motors and generators. It covers such topics as flux, losses, static transformers, synchronous and asynchronous machines, direct current machines, and monophase and triphase motors. Bibliographies are included. Volume 1 is concerned with the principles of electrotechnics, and volume three with the applications of electrical energy. (A. Fouillé. Paris, Dunod, 1960. 439p., 18 fr.)

*SOLID PROPELLANT ROCKET RESEARCH.

This selection of technical papers, based mainly on a symposium of the American Rocket Society held at Princeton University in January 1960, forms the first volume of the Society's new series, "Progress in Astronautics and Rocketry". The next four volumes will appear in 1960-61. In this volume the papers are arranged in sections dealing with steady-state burning of composite propellants, combustion of metals, unstable burning in solid propellant rockets, ignition, and the mechanical properties of solid propellant grains. Most of the papers in each section deal with basic phenomena, but some papers on engineering aspects are included. (Ed. by Martin Summerfield. New York, Academic Press, 1960. 692p., $6.50.)

Business and Industrial Briefs



Appointments and Transfers

Atlas Copco Canada Ltd. has appointed **Burt Honeth** manager of the division for mining equipment sales. Mr. Honeth will make his headquarters at the company's head offic in Montreal.

J. B. Kelly has been appointed sales and technical representative of industrial films department of Du Pont of Canada. He was formerly in the marketing research division.

John R. Cann has been elected president of Raytheon-Canada Limited. He served formerly as executive vice president and general manager.

Union Carbide Canada Limited has appointed **R. S. Hughes** manager of production and engineering for the company's Chemicals and Plastics Division. Mr. Hughes has been a member of the organization since 1940, working in both Canada and the United States.

Canadian General Electric Company Limited has appointed **R. N. Fournier** a vice-president. Mr. Fournier is general manager of the company's wholesale department, with headquarters in Toronto.

J. A. Cross has been appointed vice-president of Dominion Structural Steel Limited. Mr. Cross was formerly associated with Dominion Structural Steel's parent organization.

Developments

Information contained in this section has been obtained from press releases. Mention of products and services does not imply endorsement by the Institute.

A LINE OF ELECTRO MAGNETIC bin vibrators introduced by Jeffrey Manufacturing Company Limited, Montreal, are claimed to ensure a steady flow of materials. A wide range of sizes and types are available to suit many types of materials and bin, hopper and chute thicknesses. These bin vibrators are entirely electrical. They are supplied with variable controls and the units are available for most electric frequencies.

THREE ENGINE DRIVEN WELDERS have recently been marketed by Air Reduction Canada Limited, Montreal. A 225 amp. ac-dc engine driven welder, powered by a Kohler engine can handle stick electrode welding, Heliwelding and Aircomatic welding. The power source supplies from 15 amp. to 265 amp. d-c and 25 to 320 amp. a-c. Two d-c diesel welders are recommended by the manufacturers for field welding. The "Yellow Jacket" welder has been designed in 300 and 400 amp. rated sizes and powered by a 4-cylinder, 4-cycle injection type diesel engine. The third welder, rated at 250 amp. and utilizing a 4-cycle, 3 cylinder direct injection type diesel engine, is available both as a d-c welder, a-c power plant or solely as an a-c welder.

A BULLETIN covering natural frequency vibrating feeders is available from United Steel Corporation Limited, Toronto. The company gives design data and dimensions on their range of "Grizzly" feeders. Used in applications where feeding is combined with separation of courses and fines this feeder is reported to offer many advantages over conventional equipment.

THERMAL ELECTRIC POWER GENERATING capability in Canada increased by 36.8% in 1960 over the 1959 figure, according to a country-wide power survey released by the apparatus department of Canadian General Electric Co. Ltd. The annual survey, based on Dominion government statistics, indicated that total power generating capability at the end of 1960, both hydro and thermal, was an estimated 30.5 million hp., an increase of 13% over that of 1959.

THREE WATER-COOLED silicon rectifiers built by Canadian Westinghouse have been placed in service at the Marathon Corporation Pulp Mill at Marathon, Ont. The rectifiers, each rated 12,767 amp. at 150 v. d-c, are used to supply power for the production of chlorine for bleaching pulp. The units have replaced mechanical rectifiers, and are energized from the original mechanical-rectifier transformers. Each rectifier is 10 ft. by 4 ft. by 7 ft.

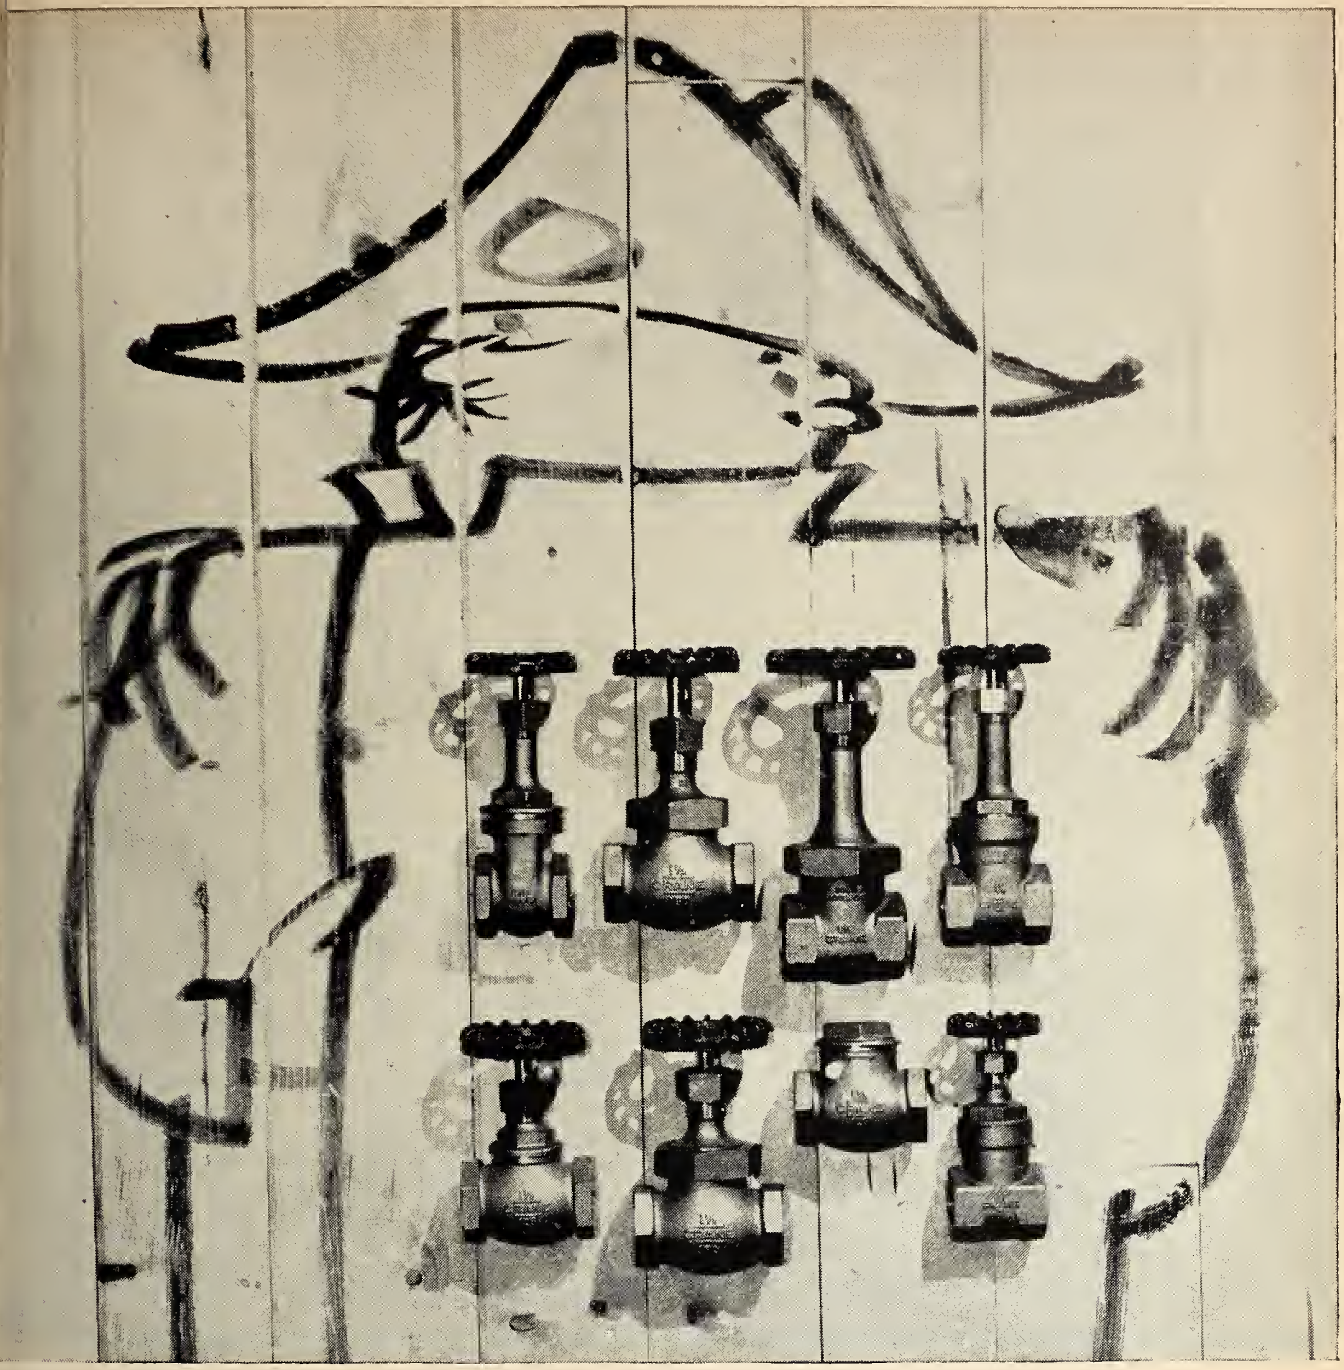
A PACKAGED AUTOMATIC FIRE-TUBE boiler is being marketed by Orr and Sembower (Canada) Ltd., Toronto. This boiler, the Powermaster Positive Flow Model, has burner and furnace located on the left side at the horizontal center line of the boiler. It is of three pass design with no tubes directly above or below the furnace. Aceording to the company, the side located furnace was found to provide the most efficient circulation of water of any feed injection and natural thermal circulation to augment eaeh other.

AN INCREASE of $500 in the Union Carbide Canada Limited's seholarships and fellowships has been announced. Henceforth the scholarships will be valued at $2,500 and the fellowships at $2,000. The company annually distributes 60 scholarships and four fellowships to students attending the 21 universities participating in the company's educational assistanee program.

AN ALUMINUM ALLOY is to be used for the first time in Canada in storage tank construction. Sparling Tank and Mfg. Co., Toronto, plans to use the alloy in building two fatty acid tanks for Polymer Corporation in Sarnia, Ont. This newly developed alloy, designated Alcan D54S, is expected to provide the optimum combination of strength, weldability and corrosion resistance for this application.

A SEVEN MILLION DOLLAR contract has been awarded British Insulated Callender's Cables Limited by the Magna Pipeline Company Limited, Vancouver, to manufacture, install and commission 53 miles of flexible submarine pipeline to transmit a supply of natural gas from the mainland of British Columbia to Vancouver Island. When completed this installation will constitute the world's longest flexible submarine gas pipeline. The laying operation of the Magna pipeline is planned to be carried out in 1963.

(More Briefs on page 184)



Top Brass: In the constant fight to maintain control over vital liquids, many a battle scar has resulted from faulty brass valves. Small wonder so many industry leaders "distinguish" their operations with Crane brass throughout. No matter how small, Crane won't sell a brass valve unless it exceeds industry-imposed standards by the widest of margins. Cheaper valves are sometimes available, but for those who won't risk valve failure for the sake of comparably meaningless first-cost savings, Crane is a "must". ■ With Crane, you not only save on operating costs. Unequalled local warehousing and fast deliveries cut storekeeping costs as well. You name the service—water, steam, oil, air, volatiles, low or high pressures, cold or hot—Crane has the brass. Screwed, flanged or solder joint ends; gate, globe and angle designs. All made in Canada . . . where a product *has* to be as good as its reputation. Crane Limited, 1170 Beaver Hall Square, Montreal, Quebec.

E.I.C CERTIFICATE

OF ADVERTISING MERIT

For the third time in 10 months, the Canada Cement Company Limited advertisement in THE ENGINEERING JOURNAL has been judged best from the viewpoints of accuracy, information and attraction, by a 50-reader jury selected from a geographical cross section of the publication's mailing list. The certificate winning advertisement was a 2-colour, double-page spread headed, "Spectacular! New! Functional! Concrete Roofs Made With Canada Cement".

Advertising Manager of Canada Cement Company Limited is Mr. John V. Tittley. The ad was prepared by Cockfield Brown & Company Limited (Montreal). The Account Executive is Mr. Bert Churchill.

CANADA CEMENT COMPANY, WINNING ADVERTISEMENT—JANUARY, 1961

• MORE BRIEFS

A TILTING-DISC VALVE intended for general service, has been designed by Dominion Engineering Company Limited, Montreal. This 'non-slam' valve, made of stainless steel, is a single piece body casting. It is being manufactured under the trade-mark "Uni-Tilt". Elimination of all flanges is claimed to make this valve one of the lowest priced, lightest and easiest to install check valves available. The disc, an aerodynamic section, is a precision casting. Since both the disc and body are of stainless steel, the need for separate seat rings has been eliminated. It is made in a complete range of pressures and sizes.

CASE HISTORIES of more than 200 bridge concreting problems and their solutions are studied in a 16 page bulletin published by the Master Builders Company, Ltd., Toronto. Stories of the variety of job and weather conditions common to bridge construction portray the part played by Pozzolith concrete in meeting these conditions. Also included are reports on concreting piers and bridge decks for highway and railway bridges, hot and cold weather concreting data, the use of lightweight aggregate in bridge work and placing and finishing problems encountered in bridge work.

"A GUIDE TO THE SELECTION of Electrical Equipment for Overhead Cranes" is the title of a booklet recently published by the Dominion Bridge Company Limited. This publication is intended to help the crane buyer analyze his proposed application and to obtain the required performance of the crane as well as the maximum value of his purchase.

FLAME-CUTTING MACHINES of the "Oxweld" type are described in a 28-page catalogue available from Union Carbide Canada Limited, Linde Gases Division. Machines described range from handy portable units to multi-torch shape-cutting machines capable of reproducing thousands of intricate shapes and patterns in steel. Also described is the LPT Photocell Tracer which is capable of reproducing complicated metal parts from exact size pencil or ink drawings. Included are specifications for each machine together with illustrations of typical installations and accessories.

a power proposal

...that may provide the solution to your generating requirements for peak loading, standby and remote locations. The free-piston/gas turbo-generator is a unique engineering concept proven in operation, combining the best features of the conventional diesel engine and of the gas turbine, at the same time eliminating the inherent disadvantages of both. Your inquiries will receive our prompt attention.

THE FREE-PISTON GASIFIERS ARE MANUFACTURED BY THE FREE-PISTON ENGINE COMPANY, UNDER LICENCE FROM PESCARA, S.E.P. AND MUNTZ

PEACOCK BROTHERS LIMITED P.O. BOX 1040, MONTREAL, P.Q.
SYDNEY, TORONTO, SUDBURY, WINNIPEG, EDMONTON, CALGARY, VANCOUVER

A SURVEYING INSTRUMENT that utilizes the micro-wave principle to measure distances is now being used by the Shell Oil Company of Canada. Distributed by the Telurometer (Canada) Co. Ltd., the tellurometer unit weighs about 30 lb. and is powered by a heavy duty battery. It is set up over a monument transmitting a series of micro-waves towards a receiver set up over a distant location. Steady impulses are received on the receiver unit circuit and transmitted back to the original sending unit. The interval of time required for the impulses to travel is indicated on the transmitter panel. The readings are converted into feet and decimals of feet. The units are interchangeable and either one may be used as a sender or receiver and readings may be made at either end of a line. The units are designed primarily for measurement of lines from 500 ft. up to 40 miles. Under ideal weather conditions, longer distances may be measured.

A RECENTLY DEVELOPED METHOD for joining aluminum to aluminum in a permanent bond has resulted in the formation of Piston Rebuilders Limited, Toronto. Applicable to any size of worn or burnt out aluminum piston, the repairing process is fully guaranteed by the company. A special alloy is bonded to the old piston body and then the piston is machined and ground. New ring grooves are cut to any specification. No spacers are required, new metal is machined to take new rings, as in a new piston. The company is also equipped to rebore liners within the size range 3.495 in. 7.550 in., and the rebuilt pistons can then be ground to precisely fit the rebored cylinder size. New rings and pins can be supplied, wrist pin bushings can be bored.

A CATALOGUE covering Fafnir miniature and instrument precision ball bearings is available from United Steel Corporation Limited. This 40-page publication contains dimensonal data as well as engineering and application information. Also contained is a full sized picture of each bearing.

A MAGNETIC THICKNESS GAUGE has been developed in Germany and is available in Canada from Frank Koch, Ottawa. The Mikrotest is a hand-instrument for measuring the thickness of protective surfaces on steel bases. It utilizes the attraction power of a permanent magnet through the layer to be measured, which depends on the thickness of this layer. The instrument requires no electrical power source. For measuring, the instrument is placed into the specimen to be measured with its pole resting on the surface after measuring dial has been adjusted to maximum thickness. The magnet resting on the non-magnetic surface is attracted by the ferro-magnetic base. By turning the measuring dial the spring is strained until the magnetic breaks and recoils into the housing: The accurate surface thickness can then be read on the measuring dial. *(More Briefs on page 193)*

...reduces weight...cuts cost

Continuing research and development by the steel industry now provides a lighter, stronger steel for buildings and bridges. The new A36 specification for structural sections, bars and plate provides 10% greater strength and a saving of 5% or more in weight, at less than 1% increase in cost ... by comparison with CSA G40.4 and ASTM A7 now in use. Design details are covered in the revised CSA S16-1960 specification. This is another achievement by the steel industry in its constant search for improved designs, materials and methods. To keep informed on steel developments write the Canadian Institute of Steel Construction.

LIBRARY NOTES

(*Continued from page 169*)

*MECHANICAL-ELECTRICAL EQUIPMENT HANDBOOK FOR SCHOOL BUILDINGS.

This handbook is devoted exclusively to the installation, care, and use of mechanical and electrical equipment in school buildings. It describes the necessary fundamental engineering aspects, but in a language understandable to a reader without technical education. The first five sections cover heating and ventilating, plumbing, sewage disposal, kitchen and cafeteria equipment, and illumination and electric wiring. In the final section and the appendix, fire prevention and first aid are discussed, and general information given on the contractor's guarantee, his responsibilities and administrative conduct relevant to school-building contracts, and on the selection and function of the consulting engineer. (Harry Terry. New York, Wiley, 1960. 412p., $9.50.)

ANTI-CORROSION MANUAL, 1960.

The third annual volume, this edition has been completely revised, and contains much new information. The first section covers industrial problems, including corrosion in the food and oil industries. Other sections cover resistant materials and their applications, both metallic and non-metallic, and including comprehensive preparatory treatment before applying protective coatings; protective coatings, including paints and primers, mastics, metals, plastics and vitreous enamel. Other articles cover spray painting, pipe coatings and tapes, protective packaging, cathodic proteetion, and water treatment for corrosion control. Bibliographies, as well as relevant British Standards are included, as is a buyer's guide. (London, Corrosion Prevention and Control, 1960. 404p., 60/-.)

ENGINEERING MANAGEMENT, 2nd. ed.

In this second edition, notice has been taken of the changes in industrial conditions since the first edition was published in 1948, the references brought up-to-date, and information on operations research and cybernetics included. The first section covers the "art" of management, and its application in an engineering manufacturing business. Under the "science" of management are discussed scientific method, the history of engineering, the structure of industry, legal aspects, and the development of scientific management. The third, and largest, section of the book covers the practical aspects of management: market research, production planning, estimating, budget, company organization, factory planning, personnel, production and control.

Intended as a textbook, this volume will be useful for both management and students. (S. A. Robertson. London, Blackie, 1960. 467p., 30/-.)

GEOLOGY FOR ENGINEERS, 4th. ed.

A textbook of geology, with the emphasis on engineering applications. New material added in this edition includes information on permafrost, tidal surges in the North Sea, the geology of the Kariba Dam site, and methods of site investigation. The topics covered include physical geology; rock forming minerals; igneous, sedimentary and metamorphic rocks; earth movements; structural geology; stratigraphy; geological maps; geology of water supply; the geology of reservoir and dam sites; cuttings and tunnels in various parts of the world. Although the majority of the examples given refer to the British Isles, the text is useful for all civil engineers. (F. G. H. Blyth. Toronto, Macmillan, 1960. 341p., $5.00.)

HOW TO GET THE MOST OUT OF YOUR TAPE RECORDER.

Written for the user of tape recorders, this book contains information on the type of tape recorder to buy, how the machines work, features of the machines, number of heads, and cost. Adjuncts to the recorder such as microphones and tape varieties are discussed, as are good operation, frequency response, distortion, signal to noise ratio, equalization, and stereo. (Herman Burstein. New York, Rider, 1960. 170p., $4.25.) EIC

• MORE BRIEFS

A HEAVY DUTY PUSH-BUTTON switch has been introduced by Joy Manufacturing Company (Canada) Limited, Galt, Ont. Known as the Flex-tite switch, the manufacturers recommend it for any 2-station push-button application. It fits all standard FS and FD boxes and flush mounting can be achieved on metal surfaces.

A FOLDER describing an established method of integrally water-proofing concrete by adding "Anti-Hydro" to the cement during mixing has been issued by Anti-Hydro of Canada Sales Ltd. The company claims that by treating concrete in this way it provides increased density, strength and hardness, acid and alkali resistance and non-dusting properties. It is also claimed to prevent freezing and to ensure cement hydration at temperatures down to 15°F. A table is included showing mixing proportions for various mixes.

THE BRITISH COLUMBIA Power Commission has announced that five Canadian firms of consulting engineers have been named to undertake major responsibilities in relation to the preparatory work being done in connection with the Columbia River development. The firms are Canadian Bureau of Allied Engineering Limited, Crippen Wright Engineering Limited, Montreal Engineering Company Limited and H. G. Acres and Company Limited.

A 22-MILLION-POUND-YEAR phthalic anhydride plant is planned by Dominion Tar and Chemical Company Limited. The plant will cost approximately $3.5 million and will be engineered and constructed by Canadian Badger Company Limited. It is to be built adjacent to the company's present facilities in Toronto. Phthalic anhydride is used principally in the manufacture of alkyd resins for paints, varnishes and lacquers, as well as in the moulding of glass-fibre reinforced plastic products. The new plant will use the fluid bed process, which permits lower engineering and operating costs, gives higher yields and produces a higher grade product. It is planned to be in operation early in 1962.

A STRIPPING TOOL that is said to cut stripping time by 60% is available from Pyrotenax of Canada Limited, Trenton, Ont. The company claims that the 'Sheathmaster' is easy to use and will strip 7,000 ft. or more of Pyrotenax mineral insulated cables without regrinding. The blade is made of precision ground high carbon steel. Spares and replacements are of low cost. The tool is available in two sizes, ⅜ in.-½ in. and ¾ in.-1 in.

A FULLY AUTOMATIC CIRCUIT and cable tester has been developed by Sperry Gyroscope Company of Canada Ltd. The scanner isolates the circuit or connection where the fault is to be found. Previous models isolated the fault down to a group of thirty pins, and the final isolation had to be made manually.

A SERIES OF REAMER BITS manufactured by Sandvik Canadian Ltd., are available from Atlas Copco Ltd. These reamers are primarily intended for use in drilling starting holes for burn cuts when drifting. They are carbide-tipped and of six-winged design. The advantages of this design are claimed to be longer life and a smoother, more even operation. The bits come in three diameter sizes, 1⅞ in., 2¼ and 2½ in.

AN EXPANDED LINE of Dryerpacs (dryer-dust collector combinations) has been announced by Barber-Greene Canada Ltd., Don Mills, Ont. The combinations include 27 capacity ranges in both portable and stationary models. It features drum diameters and lengths from 5 ft. by 20 ft. to 9 ft. by 30 ft., 3-12 cone dust collectors, and air flow capacities from 12,500 to 54,000 cu. ft. per min.

A DIESEL GENERATING PLANT that is claimed to be light enough to be carried on highway trailers yet powerful enough to supply the power needs of small towns is available from D. Napier and Son (Canada) Limited. The Deltic Compak is a complete diesel generating plant and has a specially designed high speed. It weighs 22 tons. Four models are available producing 1200 to 3000 kw. in single units.

THE THIRD VOLUME of the World Directory of Nuclear Reactors has been published by the International Atomic Energy Agency. The new volume is a supplement to Volume II published in Dec. 1959, and contains detailed information on 96 research, test and experimental reactors currently in operation or under construction in 21 countries. The reactors have been grouped into the following main categories: light water moderated, pool type (27); light water moderated, tank type (21); liquid homogeneous (6); solid homogeneous (19); heavy water moderated (13); graphite moderated (4); and fast research reactors (6). Full details are given for one representative reactor in each group and for reactors having little similarity with any other. For the remaining reactors, similar to those described in full detail, general information and major modifications are given.

A RESIDENCE for 130 students at Memorial University, St. John's, Nfld., is being sponsored by Bowater's Newfoundland Pulp and Paper Mills Ltd. A similar residence is being sponsored by Anglo-Newfoundland Development Company Ltd. Construction of Rothmere Hall is under way and Bowater Hall will start later this year.

A CONTRACT for two 84,000 h.p. hydraulic turbines has been awarded to the English Electric Division of John Inglis Co. Ltd., Toronto, by the Hydro Electric Power Commission of Ontario. Work will start immediately.

CONTENTS

IN THIS ISSUE

In *"The Behavior of Rarefied Gases"*, **D. S. Scott** defines a rarefied gas as one in which the molecular free path approaches some dimension of the containing equipment. Dr. Scott's paper covers two significant uses for rarefied gases in industry and discusses the kinetic behavior of these gases. The author is an Associate Professor of Chemical Engineering at the University of British Columbia. Born in Edmonton, he received most of his education in Alberta and graduated with a B.Sc. in Chemical Engineering from the University of Alberta in 1944. After a year as Petroleum Engineer with Imperial Oil Limited at the Norman Wells plant, N.W.T., he returned to the University of Alberta in 1945 and received his M.Sc. in 1946. In 1949 he received his Ph.D. in Chemical Engineering from the University of Illinois and has been associated with the University of British Columbia since that time.

"It is customary to think of a 'rarefied' gas as a phenomena encountered in the upper reaches of the atmosphere," Dr. Scott writes, "or in very high vacuum experiments carried out in laboratories. While this was true many years ago, industrial development of the last two decades have shown the desirability of high vacuum operation on an industrial scale." Dr. Scott explains that the phenomena of rarefied behavior are not a function of pressure alone, but are really dependent on the size of the container relative to the gas pressure. In his summary the author writes that it is believed "satisfactory flow equations exist for rarefied gas flow in circular channels. Equations applicable to many other shapes could be readily derived. Heat transfer processes in rarefied gases can be less readily and less exactly calculated, but adequate empirical correlations appear to be available to allow estimation of heat flow rates for a number of situations."

"Effects of Changing Technology on Labor and Employment" by Professor **William Bruce,** M.E.I.C., covers the reaction of industry to tremendous technological advances. The application of scientific knowledge to so many aspects of man's environment calls for significant changes and adaptations in the use of manpower. New materials, processes and methods have required changes in the education and composition of the labor force. At times workers have had to learn completely new skills or techniques. Flexibility, both in the organizational structure of industry and the composition of the labor force is imperative if industry is to keep pace with technological advances. The author is a Professor of Mechanical Engineering at McGill University and head of the department of Mechanical Engineering there. He is associated with the Economics and Research Branch of the Department of Labour, Ottawa, in studies of technological change in Canadian industry. Professor Bruce received his B.A.Sc. in 1941 and his M.A.Sc. in 1948 from the University of Toronto. He first became associated with McGill University in 1946 as Assistant Professor. Previous to that time he was an Assistant Research Engineer at the National Research Council's research program on gas producers for Motor Vehicles and was both instructor and lecturer in Mechanical Engineering at the University of Toronto.

In the conclusion of his paper Professor Bruce writes that economic history has demonstrated that the "advantages to be gained from the continuing application of science and technology to industry far outweigh the effects of any disruptions which result in the labor force. These effects can be minimized by foresight, careful planning and the use of some of gain to alleviate such personal hardships as may occur. The benefits accruing from improved technology are commonly considered to be those of increased profits on financial investment, higher wages, shorter working hours, greater availability at lower cost of a growing multitude of products, the freeing of human effort from exhausting physical labor and mental drudgery, and in general, a higher standard of living for all.

Author **B. H. Lloyd** explains that statistical quality control is a term that unfortunately indicates neither the general areas of applieation nor the principles upon which it is based. If anything, he says, the term has a tendency to create a misleading notion in the mind of management. For this reason, in his paper *"Statistical Quality Control as a Management Tool"*, he discusses at least briefly the place of statistical quality in the business world. Mr. Lloyd was born in Athabasca, Alta., in 1921 and completed his early education in Woodstock, Ont. He joined the staff of the Ontario Research Foundation as Research Engineer, specializing in industrial applications of mathematics and statistics. In 1948 he was a special lecturer in the Department of Engineering and Business at University of Toronto, concentrating on industrial management and industrial statistics. Mr. Floyd joined the Industrial Engineering Department of Canadian Industries Limited in 1949 where he worked as a staff engineer until 1954. Since then he has been in management consulting work where his background of industrial engineering and statistical methods has proved extremely useful. Mr. Lloyd is a Fellow and Founding Member of the American Society for Quality Control. He was a director of the Toronto Section of the Society and Chairman of the Montreal Section on three different occasions. He was Chairman of the Society's National Convention when it was held in Canada in 1956 and until recently was a member of its Editorial Board. In his paper Mr. Lloyd writes that the "term statistical quality control . . . connotes a basic concept qualified by the implications of the work 'quality' which designates a specific area of business activity. However, the concept is suitably applicable to other areas of business such as the management of inventories and costs. Therefore it is not uncommon to encounter the expressions 'statistical inventory control' and 'statistical cost control' both of which may be developments of the same concept as statistical quality control."

Plant reduces lubricants from 27 to 7...processing is improved

Multi-purpose Greases Cut Lube Costs

One plant in the basic chemicals industry has eliminated 20 lubricant specifications from its inventory. This was achieved by use of Texaco multi-purpose greases. Benefits of this system of lubrication include reduction of risk that operator will use wrong lubricant; less lubrication equipment required; reduction in time taken on lubrication rounds . . . with corresponding reduction of labor costs; saving in time in training lubrication crews; facilitates setting up of centralized lubrication system

ENGINEERING REVIEW 1960

General

Probably the most important development in Canada's economy during 1960 was the increased export situation. Some gains made last year may well be lost in 1961, and other advances will be difficult to maintain. Prospects for export expansion continue to exist, however, and the importance of exports appears to have engrained itself as an essential part of the economy.

From 1950 to 1953 the volume of exports increased 21%. A further 13% increase was noted in the next three years. But from 1956 until 1959 there was an increase of only 4%. An increase of between 7% and 8% was noted in the first three quarters of 1960 compared with the comparable period the previous year. A final quarter decline in exports wiped out some gains, but the overall increase during the year was one of the most impressive since 1950.

Europe's increasingly-healthy economy created a situation in which many supplies ran short. Canadian industry was able to fill many of these shortages. Steel exports, mainly to Europe, accounted for about one third of steel production during 1960. Until the close of navigation caused a slowing a high degree of steel production was maintained. Other segments of the Canadian economy had similar experiences.

Demand from the United States was below that of 1959, but overseas orders more than compensated. For the entire year, exports to the United States were about 3% below those of 1959. The fact that general exports increased despite a decline in shipments to the United States raised hopes of a better trade distribution.

While exports were growing, imports held to 1959 totals until late in the year. The main reason for this was that Canadian industry was producing more goods demanded by the local market. Also playing a part, of course, was the slackened pace of Canadian activity.

This year is expected to show somewhat of an inmprovement over 1960 in consumer expenditures. The increase in 1960 compared with 1959 is expected to be only in the nature of 1%. Canada's unemployment level adds a shade of caution to an otherwise encouraging forecast of consumer spending. The character of these expenditures is expected to show greater emphasis on non-durables rather than durables. Thus, purchase of such items as automobiles or major appliances will be deferred by many until general business conditions improve.

Displaced workers are being retrained at an accelerated pace as technical training programs are enlarged. For the most part, automation hysteria has dissipated.

Balanced against unemployment which is expected to affect about

(1) Averages of unadjusted data. (2) Percentage seasonally adjusted. (3) The data printed here are revised in accordance with the new definitions of "employment" and "unemployment" which came into effect in the September, 1960 issue of *The Labour Force*. (DBS Table).

10% of Canada's labor force was a 1.7% increase in employment over 1960. The increase in the labor force during the year was 2.8%.

Employment, Earnings and Hours Worked

For the fourth consecutive month the composite index of industrial employment declined in December 1960. This reflected decreases in many of its components. Manufacturing employment was off by nearly 1 per cent. However, average weekly wages and salaries, average hourly earnings and the average work week in manufacturing all were higher in December.

Labor Force

Little increase was shown in the total labor force in January of this year. Total employment was slightly above the December figure. On a seasonally adjusted basis, the rate of unemployment amounted to 7.7% of the labor force.

Capital Expenditure and Industrial Production

Total outlays of $8.3 billion in 1961 are involved in present plans for capital spending by all sectors of the Canadian economy. These figures are taken from the results of a recent survey covering business establishments, institutions and all levels of government. Estimates of expenditure for housing are included in the total estimates. Should this program be accomplished, total capital outlays in 1961 would exceed those of 1960 by more than $100 million. A larger construction program is responsible for the increase in total capital spending.

Capital expenditures for new construction are expected to be about 4% greater than those of 1960. Plans for the purchases of machinery and equipment, on the other hand, show a decline of about 2%. About 23% of Canada's gross national product would be devoted to expanding, modernising and renewing the

nation's productive facilities according to the capital program now planned. This is about the same proportion of gross national product that has been devoted for this purpose in the post-war period as a whole.

An advance of 0.3%, due to a 2.1% increase in mineral output, was shown in Canada's seasonally adjusted index of industrial production for January, 1961. Manufacturing, the electric power and gas utilities showed declines of 0.1%. The total index was 166.3, about 4% lower than the peak reached in January 1960.

In non-durable manufacturing a 1.3% advance was noted with increases in all but two of the eleven major groups. Declines were shown in tobacco products (3%,) and products of petroleum and coal (4%). A 5% decline in wood products was largely responsible for a 1.8% drop in durable manufacturing output. Declines also were reported in electrical apparatus and supplies (4%) and non-metallic mineral products (1%).

An increase of 1% was shown in non ferrous metal products while transportation equipment, reflecting increased motor vehicle production advanced 3%. Metal and fuel mining were up 2%, with non metal output advancing 6%, due largely to a similar advance in asbestos production. Increases also were recorded in iron ore (18%), zinc (2%), lead and other metals, including uranium (6%). An 8% decline was shown in nickel while gold and copper recorded smaller losses.

(DBS Table)

Major Industrial Areas

CHEMICAL

In common with other facets of the Canadian economy, the chemical industry failed to grow as rapidly in 1960 as forecast by economists in the spring of the year. However, relative to other economic areas, the chemical record was favorable, and in 1961 should continue to grow at a faster rate than the rest of the economy. In 1960, although the total value of sales of all of the manufacturing industries changed but little, the value of chemical shipments increased by 7%, and the physical volume increased by 12-15%. The increase in output was reflected in an increase in number of employees by 3-4% over 1959. Wholesale prices increased by 1%, and the total value of chemical materials produced and goods sold attained a new all-time record of more than $1.4 billion. This figure represents a growth of 130% based on 1949 production, compared with a growth in the other manufacturing industries of about 50% in the same time period. Trends in the various product divisions are indicated below:

(a) Acids, Alkalis and Salts: increased in value by about 5% over the 1959 figure of $307 million. A significant fraction of this gain was due to increase exports.

(b) Primary plastics, adhesives and rubber all recorded increases; the sharp declines in miscellaneous plastics exports were more than offset by

gains in exports of synthetic rubbers and related chemicals.

(c) Fertilizer sales were slightly higher, particularly influenced by the large production of mixed fertilizers.

(d) Paint and Varnishes: held up well, at about the 1959 level. The export market has little significance.

(e) Soaps, detergents, and toilet preparations lost considerable ground in the year.

In summary, then, the producers of chemicals for industrial uses showed considerably better progress than did the consumer chemical industries.

Indicative of the optimism of chemical management is the scale of new plant construction planned for 1961. Some idea of the scope of expansion of established product fields and invasion into new ones can be obtained from a coast-to-coast summary.

The following table illustrates the trend in capital spending in recent years in both current and constant (1949) dollars.

Year	Capital Expenditures						Capital Expenditures As Percentage of Gross National Product	
	Construction		Machinery and Equipment		Total			
	Current	Constant	Current	Constant	Current	Constant	Current	Constant
	Millions of Dollars						Per Cent	
1947[1]	1,397	1,671	1,043	1,245	2,440	2,919	18.5	18.9
1948[1]	1,824	1,905	1,263	1,343	3,087	3,248	20.4	20.6

1961	5,689	—	2,647	—	8.336	—	—	—

[1]Newfoundland not included in these years. (DBS Table)

Maritimes:

The largest new plant — the $50 million refinery of Irving Refining Limited started production in 1960, of a range of petroleum products (capacity 40,000 bbl./day). Significant addition to pulp capacity was made by Canadian International Paper, and Fraser Companies Limited, both in New Brunswick. At Wood's Harbour, N.S., seaweed chemicals were produced — alginates for use in foods. Linde Gas plans plants in Nova Scotia and New Brunswick, and Nova Scotia Pulp is constructing a $40 million plant at Point Tupper.

Quebec:

Twenty-three new chemical facilities were opened in 1960. Petrochemical production was increased (British American Oil, B.A. Shawinigan, Union Carbide) and petroleum facilities were expanded by 57,000 bbl./day (British Petroleum, Texaco, Shell). The first production in Canada of pentaerythritol tetranitrate (used in blasting explosives) was started by C.I.L. at Beloeil. New production of miscellaneous chemicals included lignin chemicals (Lignosol), maleic anhydride and polyvinyl chloride (Monsanto), and naphthalene (Record). Two new laboratories were opened (Ayerst, McKenna and Harrison, and Nichols Chemical Company). Planning is under way on a benzene plant (B.A. Oil), a new plant for titanium pigments (British Titan Products) and a plant for making columbium oxide concentrates (St. Lawrence Columbium and Metals Corpn.). C.I.L. is planning a threefold expansion of its central research laboratory ($3.5 million project).

Ontario:

Forty-four new chemical facilities began operation in Ontario, covering the whole spectrum of chemical endeavour. These included:

Atomic energy facilities: fuel test reactor, universal cell, and metallurgy "hot cave" A.E.C.L., Chalk River)

Petroleum expansion: Alkylate plant (B.A. Oil), Reformate (Regent)

Petrochemicals: Vinyl chloride (Dow), linear polyethylene (DuPont, Sarnia), ethyl chloride and ethylene dichloride (Ethyl Corpn., Sarnia), polyethylene masterbatch (Union Carbide)

Inorganic chemicals: Caustic potash (C.I.L., Cornwall), nitric acid (Cyanamid), chlorine dioxide (Marathon Corp. and Spruce Falls Paper Co.), aluminum chloride (St. Clair Chemical)

The largest chemical plant still under construction is that of Brockville Chemicals, at Maitland, to produce ammonia and hydrogen, starting with natural gas (anhydrous ammonia 200 tons/day, ammonium nitrate 150 tons/day, hydrogen 1,500,000 cu. ft/day).

Manitoba:

During the year, Border Chemical Company started to produce sulphuric acid at Winnipeg, and planning is well advanced on the Nuclear Research Centre (A.E.C.L.), and a particle board plant (Columbia Hardboard Co., Sprague).

Saskatchewan:

The major new facilities were the new refinery facilities of Consumer's Co-operative Refineries of Regina, the paint plant of International Paints (Canada) Ltd., Regina, and the commercial gas plant of Liquid Carbonic Canadian Corp., Regina.

Alberta:

Thirteen new plants commenced production, with the emphasis on petroleum products and petrochemicals. Petroleum products expansion was started by B.A. Oil Ltd., at Calgary (10,000 bbl./day of refined products) and at Rimbey (pipeline gas, propane, butane, natural gasoline, and sulphur). Canadian Oil added 7000 bbl./day capacity of natural gasoline and by-products, and Imperial Oil added to its asphalt production and opened its new alkylate plant at Edmonton. Inorganic facilities included carbon dioxide (Burns and Co., Calgary), cement (Inland Cement Co., Edmonton), and insulating wool (Fibreglas Canada, Edmonton).

Petrochemical expansion: Oxygen plant for Canadian Chemical Company, Edmonton

Sulphur plant: Canadian Fina, Windfall

Gas processing: Canadian Superiol Oil, Harmattan

Herbicides and Insecticides: Dominion Rubber Co., Edmonton

Amines, glycol, and pentachlorophenol: Dow Chemical, Fort Saskatchewan

Sulphur: Jefferson Lake Sulphur Co., Calgary, and Shell Oil Ltd., Pincher Creek

British Columbia:

The forest products industry was responsible for the largest addition to production, when the Celgar pulp mill opened, supplied with chlorine, caustic soda and caustic potash from the Cominco plant at Trail. Canadian Park and Tilford opened a new distillery at North Vancouver, and Phillips Petroleum Company completed a $5 million expansion of its refining facilities at Taylor.

Planning and construction underway testify to the great industrial activity in the province. These projects include:

Research laboratories: Columbia Cellulose Co., Prince Rupert

Iron and steel mill: Cominco, Kimberly

Phenol: Dow Chemical Co., Tilbury Island

Fluorspar: Rexspar Minerals and Chemicals Ltd.

Chemical Engineering Expansion at the Universities

Because the chemical industry in Canada is so aware of the necessity for continuous research and development, the enrolment in graduate schools continues to be heavy; the demand for chemical engineers at the baccalaureate level is high in the Spring of 1961.

Accordingly, chemical engineering teaching facilities are being expanded in several universities in Canada. A new chemical engineering department, headed by Dr. L. W. Shemilt has been announced at the University of New Brunswick, offering both undergraduate and graduate studies. New laboratory facilities are being added, too, at the University of Alberta, Essex College, University of British Columbia, and Laval.

Chemical Engineering Technical Meetings

Two chemical engineering conferences were held in Canada, both sponsored by the Chemical Institute of Canada. A total of 65 technical papers were presented, including about 15 invited papers. The first presentation was made of the R. S. Jane Award for outstanding accomplishment in the field of Chemical Engineering to E. R. Rowzee, President of Polymer Corporation. Joint meetings are scheduled with the A.I.Ch.E. in Cleveland, in May, 1961, and Boulder, Colorado, in August, 1961.

During the past year, the industry proceeded in a steady fashion with its expansion. The recognition of the importance of Canadian contributions to new technology is echoed in the opening of new research facilities right across the country; in this respect the chemical industry acknowledges the economic necessity of advanced technology to remain competitive.

This trend has resulted in the continued heavy enrolment in graduate schools, and in the stimulating activity in evidence at chemical engineering technical conferences.

The outlook for chemical industry in 1961, is that "the demand for chemicals will grow slightly faster than will total business activity, but chemical growth will be less than it was in 1960".

ELECTRICAL

This has been a year in which the "wraps" have been removed from a number of subject developments in varying degrees so that "now it can be told". As a result several papers in the forthcoming Annual Meeting will deal with subjects that have been under development for some time, but little has been published. In this category will be found papers on Electronic Aids in Canadian Mapping (Tellurometry); DRB Topside Sounder Satellite; Design Considerations for Large Radio Telescope; Telemetering Acoustic Data from a Floating Buoy to the Research Ship.

Then again, there are reports of recently accomplished achievements in the defence communications fields which is exemplified by the paper "Rearward Communications for BMEWS".

In the field of power transmission latest thinking on this subject will be covered by two papers: "The How's, Why's and Wherefore's of E.H.V. Transmission" and "Concepts and Economics of Extra Long Distance Direct Current Transmission and System Interconnection".

Two authors will give the results of their deliberations and research, one in the electronics field: "New Uses of Ceramic Materials in Microwave Tubes" and the other in the theory of Automation: "Treatment of Stockastic Variables in Engineering Design".

Few endeavours encompass as many phases of engineering as the aircraft industry and Trans Canada Airlines have always been in the forefront of developments in air transportation. In this important field there will be the paper "Electrical Installations on Modern Jet Aircraft".

To some extent the technical papers represent what has been going on or what has been accomplished in Canada in the past year. However there are perhaps three or more very important accomplishments which may be regarded as trends influencing the future of many Canadian developments. A number of large electrical companies are making important strides to develop their own products in Canada. Canadian General Electric developed and produced an Extra High Voltage Capacitor on a competitive basis in the world market for E.H.V. Transmission Line Components, and Northern Electric Company Limited did the research, design and production of a Parametric Amplifier in the one kilomegacycle Scatter field of Communications in competition with the world.

To meet competition of lower-wage-country producers the electrical industry knows it must put added emphasis on innovation. A good deal has been accomplished along these lines, but perhaps one of the major steps taken in this direction has been taken by Northern Electric Company Limited with the establishment of its Research and Development Laboratories in Ottawa. This major establishment could mean to Canada what Bell Telephone Laboratories has meant to the United States.

Electrical generation

HYDRO

The spiralling demand for power has led to the planning in recent years of hydro-electric schemes of a size which would have been ridiculed as impractical only a few years ago. Sites which are located within transmission distance of our more highly industrialized areas are being completely developed in a single stage of construction to capacities of millions of horsepower, and the ability of the larger power systems to absorb these blocks of power permits the realization of economies not available in other means of power production. This trend is typefied by hydro-electric activities during 1960.

In Quebec, construction commenced on the development of the Manicouagan and Outardes Rivers from which 6 million h.p. will ultimately be fed into the distribution system of the province. The main storage will be impounded behind a 700 ft. high multiple arch dam at the Manicouagan No. 5 site. Simultaneous development of the No. 2 site, farther down the river, will provide a source of power available at an earlier date than that from No. 5, but on which will utilize the benefits of the upper storage when it is brought into service.

Hydro-Quebec's Bersimis II plant was completed with an installed capacity of 900,000 hp. Beauharnois No. 3, with an installation of five 73,700 hp. units, also came on load. Work proceeded on the 720,000 hp. Carillon development on the Ottawa river. At the year's end, the first stage of construction was completed and a good start has been made on the second stage.

The Chute-des-Passes plant of the Aluminum Company of Canada, whose ultimate capacity will be one million hp. was completed with an initial installation of three 200,000 hp. units.

In British Columbia, studies of the Peace River development were concluded and a report was presented of schemes totalling 5 million hp. In January 1961, the Columbia River Treaty was signed culminating 16 years of study and negotiation.

Development of storage and power on the Columbia and its tributaries in Canada will yield some 4 million hp. of generation within the country and an estimated 1,750,000 hp. from the United States as downstream benefits.

High voltage transmission to enable larger blocks of power to be transmitted over greater distances continues to be the subject of very intensive study. The eventual success which will surely come from this study will make possible the economic development of huge schemes which are, at present, too far from large load centres for present day transmission capabilities.

Concurrently with the development of large hydro-electric plants, the demands of industry extending out into remote locations call for many smaller plants. Construction in Labrador, Northern Ontario and British Columbia continued at a high level.

Stations placed in operation during 1960 are listed below:

THERMAL

The bulk of the increase of thermal capacity in Canada during 1960 was in Ontario where new thermal capacity surpassed by a wide margin the amount of new hydro capacity installed. Nearly 300,000 kw. of new thermal capacity were brought into service in Ontario last year. Planned are facilities which will provide 1,136,000 kw. hydro and 2.6 million kw. thermal. Two more 200,000 kw. units were installed in Ontario's Richard L. Hearn thermal station at Toronto. When the final unit is installed this year the plant's total capacity of 1.2 million kw. will have been reached. The first 300,000 kw. unit at the Lakeview thermal station, which ultimately will have a capacity of 1.8 million kw., will be installed this year. A new thermal station near Fort William will have its first 100,000 kw. unit in service in 1961. An ultimate capacity of 1 million kw. is planned for this site.

The Manitoba Hydro-Electric Board has almost completed its Selkirk Steam Plant with one 66,000 kw. unit now in operation and the second about to go on power.

The Saskatchewan Power Corporation last year added a second 66,000 kw. steam unit to its boundary dam plant to double that unit's capacity.

Last year in Alberta new thermal capacity installed totalled 88,000 kw. Calgary Power Ltd. began installation of a 150,000 kw. steam turbine at its Wabamun plant. This plant now has two 66,000 kw. units operating. The capacity of the City of Edmonton Municipal plant was increased to 355,000 kw. with the addition of a new 75,000 kw. steam turbine.

Among major thermal projects in the Maritimes is a new steam plant at East Saint John, N.B. This plant will have an initial capacity of 50,000 kw. and an ultimate capacity of 250,000 kw. A 20,000 kw. unit was added to Nova Scotia Power Commission's Trenton steam plant to raise its capacity to 25,655 kw.

NUCLEAR

The major advance in the nuclear field last year was the beginning of work at the site of the 200,000 kw. Douglas Point Nuclear Power Station situated on the shores of Lake Huron between Kincardine and Port Elgin, Ont. The Ontario Hydro-Electric Power Commission, which is co-operating with Atomic Energy of Canada Ltd. in construction of the plant will operate Douglas Point when it goes on power in 1964.

Costs of the Douglas Point project is estimated at more than $80 million. Cost of power from the station is expected to be from 6 to 7 mills per kwh., compared with a cost of from 5 to 6 mills per kwh for power produced by coal-fired stations in Ontario.

Other projects included a 20,000 kw Nuclear Power Demonstration (NPD) station at Rolphton, Ont. where work now is nearly complete.

The relatively small size of the NPD station will not allow it to produce electricity at a competitive cost but it will serve as a prototype for full-scale power plants. Ontario Hydro also will operate this unit.

In Manitoba preliminary preparation of the site for the Whiteshell Nuclear Research Establishment began late in 1960. Canada's second research centre is expected to grow eventually to the size and importance of the research centre at Chalk River.

LISTS OF PLANTS UNDER CONSTRUCTION DURING 1960

		hp.
British Columbia	Kemano	150,000
Alberta	Brazeau	200,000
Saskatchewan	Squaw Rapids	276,000
	South Saskatchewan River Dam	255,000
Manitoba	Grand Rapids	450,000
Ontario	Otter Rapids	180,000
Quebec	Carillon	720,000
	Manicouagan No. 5	1,600,000 (ultimate)
Labrador	Twin Falls	120,000 (1st stage)
Nova Scotia	Sissiboo	8,000
	Weymouth	12,000

CAPACITY PLACED IN OPERATION DURING 1960

	Spray	62,000
Saskatchewan	Wellington Lake	3,300
Manitoba	Kelsey	210,000
Ontario	Red Rock Falls	26,500
Quebec	Beauharnois No. 3	368,500
	Bersimis II	360,000
	Chute-des-Passes	400,000
	Harte Jaune	66,000
Labrador	Menihek	13,500
Newfoundland	Heart's Content	3,200
North West Territories	Snow Falls	9,700

Construction

Put-in-place construction in Canada last year totalled about $7 billion. This was not regarded as an exceptional year and most authorities feel the 1961 total will be about the same.

Jack Soules, President of the Canadian Construction Association predicted a 1961 construction volume of $7 billion, roughly 20% of the Gross National Product.

Among the soft spots in construction last year was housing which showed a disturbing decline in 1960. Heavy engineering construction show-

(DBS Table)

ed strength in 1960 with awards being up more than 13%. Expenditure increases are forecast for road construction and gas and oil facilities. Water and sewage projects are expected to show considerable strength. A softening is anticipated in dams, power and communications, and marine facilities.

It is expected that industrial facilities will continue to show strength as they have since the 1958 recession. An indication of this continued strength is a 10% increase in awards. Institutional and commercial building during 1960 is expected to show a gain in the neighbourhood of 15%.

The Maritimes, Ontario and Western Canada are expected to show minor increases in construction last year while Quebec may be down slightly. A similar picture is expected to be shown in 1961.

Mineral Resources

GENERAL

The dollar value of Canada's mineral production in 1960 was the highest ever reported. Value of the output during the year increased 2.8% to nearly $2.5 billion. Physical volume of production was second only to 1959.

Substantial increases were shown by nickel ($55 million), copper ($31 million), zinc ($11 million), asbestos ($11 million), crude petroleum ($10 million), natural gas ($9 million) and gold ($6 million).

These increases offset serious declines in other minerals. The most serious decline was shown in uranium which was down $68 million. Iron ore declined $29 million and construction materials including cement, stone, brick and similar products were $10 million below the previous year's figures.

IRON ORE

While the unit value of iron ore shipped from most provinces increased during 1960 the general picture in the industry was one of decline. Producers shipped 19,203,378 long tons of iron ore last year, a drop of 12% from the record 1959 shipments.

Much of the softness resulted from conditions in the United States — Canada's principal iron ore market. On the basis of early predictions Canadian iron ore exports were brisk during the first half of the year, but a decline in United States steel production accounted for a sharp setback in iron ore receipts.

Conditions were more favourable in Canada's other major iron ore export markets – the United Kingdom, Western Europe and Japan. Exports to these markets remained at a high level through the shipping season and showed a total increase for the year.

Canada is experiencing increasingly stiff competition from other iron ore producing countries, particularly in South America and in Africa. This is causing extensive research on direct-shipping ores and the development of property for the production of high grade concentrates and agglomerates.

Newfoundland and Quebec continued to lead the provinces in iron ore production during 1960. Occupying lesser positions were Ontario and British Columbia.

NICKEL

An increase of more than 15% in nickel production during 1960 was responsible for a high annual record exceeding 250,000 tons. Increase in consumption of nickel in Europe was the major contributing factor to the record year. For the first time in many years North American consumption of nickel slipped below that of the rest of the free world.

Consumers of steel products in North America liquidated large inventories and retarded the production of stainless steel and nickel alloy steels during the second half of the year. This limited the consumption of nickel.

Distribution of nickel in the free world in 1960 showed Europe taking 43.5%, 0.5% more than the United States. Canada consumed 2.5% and others, 11%.

Producers of stainless steel showed the greatest increase in consumption in nickel in 1960. Another substantial increase was registered for the application of nickel in electro-plating, mainly as a result of the use by the automotive industry of improved techniques. These techniques permitted higher quality nickel plating.

Note: For detailed description of concepts, sources and methods see **D.B.S. Reference Paper (61-502) "Revised Index of Industrial Production, 1935-57."**

(1) The M.C.D. (months for cyclical dominance) measure indicates the number of months required, on average, for the emergence of the cyclical trend from the seasonally adjusted series. An M.C.D. of 4 implies that a four month moving average of the series (dated at the second month) is required in order to offset irregular movements and allow examination of the underlying cyclical trend. The series in this table are not adjusted for M.C.D. (DBS Table)

world continued to increase in 1960 and it is estimated that by the end of this year its annual productive capacity will be approximately 300,000 tons. A highlight in the Canadian nickel industry is International Nickel's new project at Thompson, Man. This project, rapidly nearing completion, will contribute substantially to the anticipated increase in the nickel production capacity of the free world.

The Thompson project, which will be the world's first fully integrated nickel producing operation, will have an annual production of approximately 75 million lbs.

It is anticipated that the free world's consumption of nickel will again be at a very high level this year despite the slowness in industrial pick-up in the United States.

ALUMINUM

Canada's aluminum industry in 1961 continued to be affected by the keen competition for international markets which first manifested itself strongly in 1957.

This competition, concurrent with a recession and the world's primary aluminum industry reaching a position of over-supply, continued to pose complex problems for Canada's aluminum industry.

Final figures for 1960 are expected to show sales and revenue at a high level but the main problem facing the industry is to continue to work toward expanding the market for aluminum throughout the world. Expanded markets would allow idle capacity to be re-activated with the attendant increase in employment opportunities.

During 1960 the Aluminum Company of Canada, Ltd., installed equipment in its Quebec and British Columbia smelters to produce metal in new forms. These include sheet ingot and extrusion billet which, while it does not increase the basic productive capacity, improves the company's competitive position.

Considerable attention is being given to the use of aluminum in new products, in building and construction, in automobiles, canning, railroad cars, packaging and in ship building.

ASBESTOS

The productive capacity of the asbestos industry was not fully employed during 1960, although most producers were operating at a high level at the end of the year. Prospects indicate a comparable level of production this year.

A major factor in the pace of asbestos production last year was the general feeling of business uncertainty in the United States. By compensation, export shipments improved to almost all overseas markets. Canadian producers improved their position in Western Europe—our second greatest market—despite keen competition from Russian asbestos. Exports to Japan were maintained at a record level and sales to other countries in Asia showed a gain over the previous year. There was no significant change in sales to South America.

Preliminary figures indicate that more than 60% of Canadian asbestos exports were in the asbestos-cement fibre range. Expansion of existing cement plants abroad and construction of new units continues and general market prospects appear favourable for some time to come. Short fibres continue to move moderately well and the prospects of using asbestos fibre in asphalt paving should provide a stimulus to this market.

Improved domestic demand for Canadian asbestos appears to be limited by the requirements of a market already amply provided for by existing plants. However, any change in the present domestic situation would result in the construction of expanded production facilities.

Exploration both in Canada and elsewhere continued on a modest scale, but apart from a prospect in far Northern Quebec, no discoveries of importance were reported. Asbestos property in the Baie Verte area of Newfoundland is to be developed and production is expected to start in 1963.

COAL

The year 1960 was a bleak one for coal. Among the factors contributing to a generally troubled industry were the ever-stiffening competition from other types of fuel and high production costs.

Coal production — nearly half from Nova Scotia mines — increased nearly 6% in 1960 from 1959. But 1959 was also a troubled year and production in 1960 was close to the lowest in the last 50 years. All coal-producing provinces except Alberta showed production gains in 1960.

Last year, natural gas from Western Canada began to hit the coal markets in central Canada with heavy impact. Residual oil at reduced prices was imported and became locked in a price struggle in the Montreal region with natural gas. Coal, of course, suffered as many of its long-established markets vanished. Canada's own oil refining capacity was increased both in the Maritimes and in the Montreal area, thus adding additional potential output of home-produced residual oil from imported crude.

Adverse geography, which imposes great distances between coal producing areas and potential markets, continued to trouble the industry.

On the other hand, 1960 was a year that saw stabilization in employment in the coal mining industry. This stabilization came after 10 years of steady decline during which nearly 1200 employees a year found themselves without jobs.

Contributing to this stabilization was the development of an export market in Japan for Canadian coal. Development of this market, however, may prove expensive in terms of assistance from public funds and the stabilization of employment may prove only temporary.

OIL

Output of crude oil in Canada during 1960 totaled more than 19 million barrels valued at $440 million. This represented an increase of about 3% from 1959. While this increase was not high a modifying effect was found in record production of butane and natural gasolines extracted from natural gas and sent to refineries.

This was the eighth consecutive year that crude oil led all minerals in value.

Bulk of the production came from Alberta (70%), and Saskatchewan (27%). While Albert's production was up only 2%, Saskatchewan increased its output by 10%, reflecting increased interest in medium gravity crudes. Saskatchewan's closer proximity to the big Eastern markets also enhanced its position.

Production of natural gas increased by more than 22% with daily production estimated at 1,380 million cu. ft. Of this Alberta supplied 76%, British Columbia 17% and Saskatchewan the remainder. Estimated value of total natural gas production was $45 million.

Domestic demand for refined petroleum products increased only slightly over the 1959 consumption 770,000 barrels a day. This was tempered by a decline in product imports of 26% to 79,000 barrels a day. At refineries, consumption of crude oil increased 5% indicating a greater reliance on Canada's refining industry to supply gasoline and fuel oils.

In the international market Canada enjoyed a fairly good year. Although imports of crude oil increased 4 million barrels to 120 million barrels in 1960, exports of crude oil increased by 20% to 42 million barrels. Completion of new refineries at Montreal and at Saint John, N.B., was responsible for most of the increase in imports.

Pipe-line activity was slow in 1960 but preparation work is well advanced toward a $300 million gas pipe-line program scheduled to start this year. Earnings reported during 1960 generally were higher than those of the previous year. These earnings reflected not only higher volumes handled but also the effect of measures taken to reduce costs and improve efficiency.

Less money was spent last year on land acquisition and survey work, while drilling footage increased both for exploration and development purposes. Exploration and development expenditures were estimated at $475 million, about 5% less than the previous year.

A favourable trend for 1961 is indicated by activity late in 1960. Increased demands for Canadian crude oil are anticipated in both the domestic and the export markets.

AUTOMOTIVE

The automotive industry in Canada enjoyed a relatively high level of business in 1960 and anticipates another favourable year in 1961. Last year, Canadians purchased more than half a million cars and trucks. Domestic production increased to an estimated 390,000 units compared to 368,000 the previous year.

Total exports were approximately 22,000 units, an increase of about 3,000 from 1959. Sale of small European cars also showed a gain, but the increase was smaller than it had been during the two previous years.

Each year a greater percentage of Canadians acquire automobiles and car owners are driving greater distances each year. These factors indicate a steady expansion of the market for cars in Canada.

Price increases on imported models could also contribute to an up-swing in Canadian production. The end of

the steel strike in the United States in late 1959 resulted in high production of automobiles early in 1960. It is not thought likely that employment in the Canadian automobile industry will reach that peak in 1961.

FARM MACHINERY

A trend towards larger farms in North America continued in 1960. This results in a demand for larger machinery, an increase in dieselization and emphasis on more business-like farm management. These trends reflect the farmer's desire to minimize labour costs and increase production.

A good crop year in 1961 would result in greater demand for more efficient farm machinery. A good crop year in 1960 gave farmers a higher cash income allowing them to invest in equipment.

A modest increase in domestic sales of farm equipment is forecast this year. Increased export sales to Germany and Australia largely offset reductions in several other countries.

SHIPBUILDING

While the Canadian ship building industry fared reasonably well in 1960 it faces a problem of reduced orders for work in the next few years.

During 1960 specialized service ships completed for the Government's fleet included a search and rescue vessel "Simon Fraser", a cargo-passenger ship "Hopedale", an icebreaker "John A. Macdonald", a sounding vessel "Beauport", a buoy vessel "Thomas Carleton", a ferry "John Guy", and three landing barges, all for the Department of Transport; a pipeline dredge, a motor launch and two scows for the Department of Public Works. Five Upper Lake type bulk freighters "John A. France", "Red Wing", "Murray Bay", "Carol Lake", "New Quedoc", with a total deadweight tonnage of 120,000, one 42,000 ton ocean-going tanker "Emerillon", two twin screw diesel passenger automobile ferries "Sidney" and "Tsawwassen", three tugs and fourteen barges were delivered to domestic commercial owners to serve differing modes of water transportation.

A general world wide slump in shipping which has persisted for several years reflected itself in the Canadian ship repairing service. Also affecting this service was the virtual disappearance of Canada's ocean going fleet. Foreign ships calling at Canadian ports continued to have only emergency repairs done in this country before returning to their home countries for major repairs.

Canada's navy has curtailed its production program although repair and conversion work on naval vessels continues to be important. There is a scarcity of commercial ships on order for domestic operators. The only orders on hand are for one tanker, one passage freighter and four bulk freighters, all scheduled for completion early this year.

LUMBERING

The general hesitant business trend in 1960 affected the Canadian lumber industry. However, at home and abroad the industry anticipates an improved market this year.

The main home bulk market for Eastern Canadian lumber is housing, and business last year failed to match expectations. Uncertain employment conditions caused many potential home buyers to postpone their decisions and surpluses of new homes were found in some metropolitan areas.

Toward the end of 1960 however a slight buoyancy was noted in the housing industry and it is anticipated a much larger number of housing starts will be made this year. It is anticipated that the number may be in excess of 120,000.

Outside the housing field construction maintained a satisfactory volume during 1960, and the outlet for lumber in these areas was sufficient to maintain inventories at a manageable level.

The export market for Canadian lumber also was satisfactory last year. A good portion of the strength resulted from increased demand for framing and construction lumber from the United Kingdom. The export market is expected to continue at an accelerated pace in 1961.

Management and Automation

One of the most misunderstood words being used in relation to our present economy is automation. The word conjures visions of offices and factories staffed only by rows of blinking machines.

Many employees fear that automation will cause widespread unemployment and attendant ills. Many experts believe, however, that while new machines may displace people, the displacement is only temporary. New equipment brings new industries and new procedures and offices and factories continue to absorb available workers although they may use them in a different fashion.

When many people think of automation they think of the large electronic computers. The cost of these computers is so high however, that their use is limited to large corporations. All offices employ automation to some degree, even if it involves only the use of a typewriter. Smaller offices will use bookkeeping machines, while in larger offices punched card equipment or magnetic tape electronic computers and data processing machines will be employed.

The growing volume of paper work has made many business firms increasingly aware of the benefits to be gained from improved methods and machines which handle such work.

Among the latest techniques in automation, still in the development stage, are magnetic ink character recognition and the optical character sensing machines. By means of these machines it will be possible to read mechanically directly from printed documents without the need of punched cards, magnetic tape or other intermediate equipment.

This is expected to open an entirely new approach to office operations. With machines that can interpret and process the written word, much of the drudgery of paper work

will be removed. This will release the eyes, brains and hands of employees for more intricate, important and interesting work.

In a nation faced with such strong competition commercially and industrially, efficient management may make the difference between success and failure. Correct management may be as important to engineering works as to any other field of endeavour.

Two Canadian universities, McGill and University of Toronto, now are offering diploma courses in management which are available to engineers.

In recent years there have emerged responsible business consultants operating on scientific and engineering principles.

Another burgeoning area is that of industrial engineering which in some instances has infused new life into industrial operation. This may be done with the help of industrial engineering consultants, maintained by industrial engineering departments permanently incorporated into an industrial organization, or by individuals trained in the principles of good management and good engineering.

Engineering Education and Scientific Research

EDUCATION

It is difficult for the undergraduate engineering curriculum to keep pace with the tremendous growth and advances in technology by dealing with engineering techniques peculiar to a given field or specialty. Particularly as these techniques are constantly changing and the specialties multiplying. If we attempted to do this we should now have course packages for training nuclear engineers, automation engineers, control engineers, electronics engineers a) vacuum, b) solid state, missile and rocket engineers, space engineers, human engineers. The list could be never ending. Change and obsolescence are almost daily occurrences in our recent technological history.

It is reported that one large company has recently been successful in putting the design of gears into a programmed form for the computer. Those familiar with gear design know that it is a high form of expression of the "art of engineering". It involves a rather subjective approach and a good engineer will come up with a design in about a day. The rate at which the computer will produce designs makes the engineer's effort in this area worth 84 cents a day. This is an extreme example but it is by no means fictitious. Three good men and a computer may be able to account for a lot of engineering effort.

Under such circumstances as these a realistic approach is being sought in the undergraduate curricula in some universities by placing emphasis upon the understanding and the use of mathematics, extending to quite high levels of complexity. For, by means of the more sophisticated mathematical techniques scientific principles and data can be assembled, and what is more important, consolidated into areas of applicable knowledge which are now referred to as engineering sciences—examples are fluid mechanics which embraces hydraulics, aerodynamics, supersonics and hypersonics; thermodynamics embracing combustion and heat transfer; kinematics; strength of materials; applied mechanics; circuit theory and systems analysis. The preoccupation of physicists with newer fields of knowledge has resulted in much of the later research developments in these areas being accomplished by engineers. This is particularly true in fluid mechanics, heat transfer and applied mechanics.

Through the formal application of mathematics common patterns and techniques of analysis and synthesis can be recognized. This provides the necessary basis (which the physicist has always used) for the orderly presentation and handling of a maze of scientific data. Our technical devices have become far more refined and intricate, new scientific facts are put to use almost immediately and others are vigorously sought out so that some desired transformation can be accomplished. As a result the engineer must encompass a much more diverse and complex body of knowledge than ever before. To make such a situation manageable the undergraduate curriculum is therefore attempting to develop an understanding of and an ability to use the common language, mathematics, in conjunction with basic scientific principles for the analysis of engineering problems and for the synthesis which is their solution. At the same time it tries to foster an appreciation of the art, of design, of the ingenuity and invention which are associated with the practice of engineering. It can not produce experts in any specialty but rather by laying a good basic foundation it develops potential engineering talent. In the light of such circumstances post-graduate study, formal and informal training, specialization and experience in industry, are major factors in the full development of the engineer.

Increased emphasis is being placed upon the need for a well balanced educational program. The strengthening of portions of the curriculum dealing with humanities and social sciences is recognized as very important to the fullest development of the engineer, although there is far from complete agreement that it can be successfully incorporated within an adequate technical program in the limited time available. Proposals have been made for a five-year course of study beyond senior matriculation, but these have been resisted due to the growing need for post-graduate study and later specialization. It has also resulted in a critical view being taken of the length of the academic year. It has been suggested that its length originated in the days when our economy was based primarily upon agriculture and young men were needed at seeding and harvest time back on the farm. However, we should not underrate the benefits to be gained by the student both professionally and financially from periods of exposure to engineering practice during his academic career. Furthermore, it should be remembered that learning is basically a physiological process and that there is a limit to the possible speed up of physiological processes. Time for the digestion and assimilation of knowledge is very necessary in educational processes and also for gaining confidence in the application of it. Some industrialists imbued with production concepts frequently suggest doubling the output with two alternating groups of students each year, and the staff working in some sort of round-robin manner. Put some efficiency into this education business they say. However, it must be remembered that both students and staff need time to reflect. Staff need time to further their personal development by study, research and practice. Students need the benefit of an integrated campus life within the university, which is more than just social events.

RESEARCH

The expansion of research in recent years has been much livelier than the growth rate in other areas of the economy. An estimated $350 million was spent on research in Canada last year. This is more than double the amount spent in 1955.

The federal government was responsible for most of the research spending—about $200 million.

The remainder was spent by industry on research and development. This increase reflects the general upsurge in the use of technology.

Growing international participation is one important aspect of Canadian science. In the past, scientists always crossed international borders with little or no concern for nationality but in recent years a number of arrangements have developed wherein Canada is supporting projects which are important in the international sense.

Canadian scientists played a substantial part in the Geneva Conferences in 1955 and 1958 concerning the peaceful uses of nuclear energy. In 1960 the Canada-India nuclear station was completed near Bombay to serve as a training centre for scientists of the Colombo plan nations of South East Asia. Our scientists are assisting in the work of the international atomic agency at Vienna, which is directed towards humanitarian uses of nuclear science. They are also taking part in a joint program of research with Euraton, an organization of European countries interested in nuclear development.

Canada also has been an able participant in the field of physical standards. Last year, the National Research Council took a leading part in the adoption of a new standard of length: the international metre is now to be defined in terms of wavelengths of light emitted from the element krypton.

Following the International Geophysical Year, to which Canadian scientists supplied valuable data, international programs of research are continuing under the same auspices that sponsored the IGY. One of these, COSPAR, is a committee for space research which includes members from both sides of the Iron Curtain. Canada is a member. She also has a representative on the technical panel of the United States Committee for the Control of Outer Space.

Canadian scientists serve on a large number of international committees. Several of these — in astronomy, radio science, pure and applied physics, pure and applied chemistry, geodesy and geophysics — are members of the International Council of Scientific Unions. Since 1956 world gatherings in six distinct fields of science have been held in Canada and two more conferences, in pure and applied chemistry and in microbiology are to be held soon in Montreal. EIC

THE BEHAVIOR OF RAREFIED GASES

D. S. Scott,

Department of Chemical Engineering,
University of British Columbia.

Paper to be presented at the 75th E.I.C. Annual General Meeting, Vancouver, May 1961.

IT IS customary to think of a "rarified" gas as a phenomena encountered in the upper reaches of the atmosphere, or in very high vacuum experiments carried out in laboratories. While this was true many years ago, industrial developments of the last two decades have shown the desirability of high vacuum operation on an industrial scale. As will be discussed later, the phenomena of rarefied behavior are not a function of pressure alone, but are really dependent on the size of the container relative to the gas pressure. Thus, if one is talking about channels of microscopic size, then rarefied gas behavior can occur at ordinary pressures. In fact, this leads to a natural division in the field of engineering application, between those cases involving containers of "normal" dimensions in which gases are handled at very low pressures, and those instances in which the space dimensions are minute, but pressures are normal. Nevertheless, it should be clearly understood that the principles involved are identical in the two cases, and any such division is rather unrealistic from the viewpoint of the basic theory required.

Industrial Importance

Uses of high vacuum technology have multiplied rapidly in recent years. The drying of heat sensitive biological compounds, such as blood plasma, or antibiotics, from the frozen solid state has been practised extensively. The concentration of milk, fruit juices and other foods by vacuum evaporation is an important industry. Metal winning (e.g. magnesium), and metal purification by vacuum melting are well established processes, which are, nevertheless, growing and changing rapidly at the present time. The techniques applied to the purification of fissionable metals are finding rapid acceptance in metallurgical processes in general. The process of vacuum metallizing, or coating, is in wide use, and the quality of the deposited metal films is improving as advances in technique occur. This particular field of vacuum metallurgy is certain to see even wider application for protective, reflective and decorative metal coverings.

The electronics industry has, of course, employed high vacuum techniques for many years. The wide use of the much larger cathode ray tubes which have been produced in the last decade, has required the production of increasingly higher vacuum in order to ensure a collision-free path for electron beams, as compared to the larger pressures which can be tolerated in the smaller receiving tubes.

Perhaps the metal industries will show the most rapid progress in vacuum technology in the next few years. Vacuum melted steels, alloys, copper, etc. have been found to have superior physical properties. The production of high melting and reactive metals such as titanium, zirconium and molybdenum requires vacuum melting as a standard technique. Heat treating, sintering and brazing of these and other metals under vacuum has become accepted procedure.

Finally, the vacuum drying of hermetically sealed moving machinery has been brought to standard practice for small refrigeration and air conditioning units in which easily clogged capillaries are used. The advantages of this technique are sure to be extended to units of larger size, and for different purposes.

Nature of Rarefied Gas

In a body of gas at normal conditions, molecules of the gas can be simply pictured as being in ceaseless random motion, with a high average velocity. This motion results in a very large number of collisions between molecules in short times, so that a given molecule travels only a short distance before it collides with another molecule. Obviously, some of the molecules, which happen to find themselves very close to the wall of the container, will strike the wall. The average distance travelled by molecules between collisions is called the "molecular mean free path", and its exact magnitude depends very much on the picture that one proposes for the mechanics of an intermolecular collision. In general, however, the mean free path will increase as the pressure decreases, and it will also increase at higher temperatures.

If the mean free path is very much smaller than the dimensions of the container (it has a value of about 10^{-5} cms. for air at normal temperatures and pressures), then there will be many intermolecular collisions for every wall collision, and the properties of the gas, such as viscosity, diffusivity, and thermal conductivity will be determined by these intermolecular collisions. However, if the container dimensions and the mean free path begin to be of the same order of magnitude (it is immaterial whether this occurs because the container dimensions are reduced, the pressure lowered, or the temperature raised), then the proportion of intermolecular collisions to wall collisions will become much less. Whereas at ordinary conditions one can ignore the wall collisions completely, under these circumstances what happens at the wall must be taken into account. In the final limit, where the mean free path becomes much greater than the container dimensions, a molecule will suffer many wall collisions before it strikes another molecule, and the gas properties will now depend entirely on the nature of these wall collisions. In this region, which is called the "Knudsen flow" region or "region of molecular streaming", each molecule behaves independently, the phenomena of viscosity disappears, and flow and diffusion are identical processes.

In general, the field of gas dynamics which has been described above is divided into three regions. This division is perhaps arbitrary to some extent, inasmuch as the transition is a smooth and gradual one, but it lends itself to the formulation of mathematical equations describing gas behavior. The first regime is that in which intermolecular collisions predominate and the gas can be treated as a fluid continuum. Gas flow is streamline in character in nearly all cases. The low densities or small flow channels result in low Reynolds numbers, which are well within the laminar region, and the Hagen-Poiseuille equation applies with good accuracy. Heat transfer and material transfer can be described by the correlations available for natural convection processes, and by the well known equations for heat conduction or for mutual diffusion.

Gas behavior in the second regime is usually characterized by the term "slip" flow. This term arises from the concept that a certain fraction of the gas volume adjacent to the container walls is now concerned with wall collisions only, and this volume is not a negligible fraction of the total. In flow, this results in the assumption of a velocity discontinuity at some distance from the wall (usually taken as 2/3 of one mean free path in length), or in other words, a "slip" occurs near the wall. This "slip" is responsible for the observed fact that flow rates in this region may be many hundreds or thousands of times as great as those predicted by the Hagen-Poiseuille law for the same conditions. This same discontinuity will exist also as a temperature discontinuity in heat transfer, and as a concentration jump in mass transfer. For these processes, this region is usually called the "transition" zone.

The third regime supposes that intermolecular collisions are virtually nonexistent, and all transfer processes occur by reason of molecular collisions with container walls. The mechanics of interchange of molecular momentum, and energy, or of molecules themselves with the walls or other surfaces of the vessel, now becomes the primary factor controlling the rates of any process in this region. In some cases (e.g. for flow and diffusion) sufficiently exact theoretical expressions exist for the calculation of the magnitude of these rates, but in other situations, empirical relationships must be used.

Overall rate equations covering all three regimes are frequently presented. In fact, the number and variety of equations involving varying degrees of empiricism, and applying within different limits, is one source of confusion for any person interested in this field of gas behavior.

The Functions of Vacuum Operation

In many instances the beneficial effects of low pressure operation are entirely analogous to those obtained by the use of high pressures. For example, chemical reactions can be influenced to proceed to a greater degree in the direction of increased molar volume. This effect is the one sought in such operations as the dissociation of some metal oxides and carbonates, or the reduction of these oxides by carbon.

In diffusional operations, such as drying, evaporation, distillation and desorption, the use of low pressure reduces the partial pressure of inert gases, and thereby increases the diffusional rate of the desired process. Heat transfer and fluid flow rates are increased because of the reduction in the number of intermolecular collisions. Some operations, especially those involving reactive or heat sensitive materials, must be carried out at lower temperatures, and these would be impractical if it were not for this increase in heat and mass transfer rates at lower pressures.

Apart from the carrying out of chemical reactions, or physical transfer processes, high vacuum provides a collision-free space which is required in radio and television tubes, and in particle accelerators. In vacuum metal coating, the surface which receives the coating is usually some distance from the metal source, and the condensation process requires an unimpeded molecular flow.

In general, high vacuum may be described as a process which operates to absolute pressures as low as 10^{-6} to 10^{-7} mm. of mercury, the lowest values employed in most modern commercial practice. However, ultra high vacuum of 10^{-10} to 10^{-14} mm. are now produced experimentally, and may be of future industrial importance.

Flow of Rarefied Gases

The two situations of greatest interest involving the flow of rarefied gases would seem to be those problems in which pipe-line flow in circular ducts is concerned, and the flow of gases through porous media of various kinds. The only difference in these two cases occurs because the geometrical shape and length of the channels in a porous solid are not usually known, and must be deduced indirectly or experimentally.

In the past the practice has been followed since Knudsen's original classic investigation[1] in 1909, of describing the flow of gases as it varied from laminar to free molecule flow in nature by means of an equation of the type,

$$G' = G/\Delta p = A\bar{p} + B \qquad (1)$$

where G is a molar flow rate, $\bar{p}$ is the mean total pressure, A is a constant for a given gas and duct describing the rate of Poiseuille flow, and B is another term, usually called a "slip" term, but in fact, being defined in different ways by various authors. One or more empirical constants were introduced in order to obtain equations which agreed well with experiment. Equation (1) suggests that the flow rate should vary linearly with the average total pressure in the system, but a flow minimum exists at low pressures in circular pipes, and some deviation from linearity also occurs at low pressures for many porous solids. Fortunately, these effects are not large, and equation (1) has served as a useful approximation, for example, as in the piping design charts presented by Brown et al,[2] or as a means of determining an equivalent circular pore radius by methods such as those proposed by Arnell.[3] Recently, however, Scott and Dullien[4] have proposed a new flow equation, one form of which can be written,

$$G' = (A\bar{p} + B)(1 - e^{-8K/\pi}) + Ce^{-8K/\pi} \qquad (2)$$

In this equation, A has the usual meaning, B is a slip flow term describing those molecules which undergo a single wall collision between intermolecular collisions, and C is the Knudsen flow term for those molecules involved in successive wall collisions. The quantity K is a dimensionless group defined as,

$$K = \frac{r\bar{p}}{\eta\bar{v}} \qquad (3)$$

where r is the pipe radius, η the viscosity and $\bar{v}$ the average molecular velocity. In equation (2), the constants A, B and C can all be determined directly from the kinetic equations given below. This flow equation was found to reproduce experimental results for pipe line flow, including the flow minimum, with an accuracy of a few percent over the entire range of pressures.

$$A = \frac{\pi r^4}{8\eta RTL} \qquad (4)$$

$$B = \frac{4\pi r^3}{3M\bar{v}L} \qquad (5)$$

$$C = \frac{16r^3}{3M\bar{v}L} \qquad (6)$$

In the above equation, R is the gas constant, T the absolute temperature, L the length of the pipe and M the molecular weight of the gas. The numerical constants given are derived from the kinetic theory of gas, and are not empirical.

A dimensionless form of equation (2), is of interest as an aid in design calculation. This can be written as,

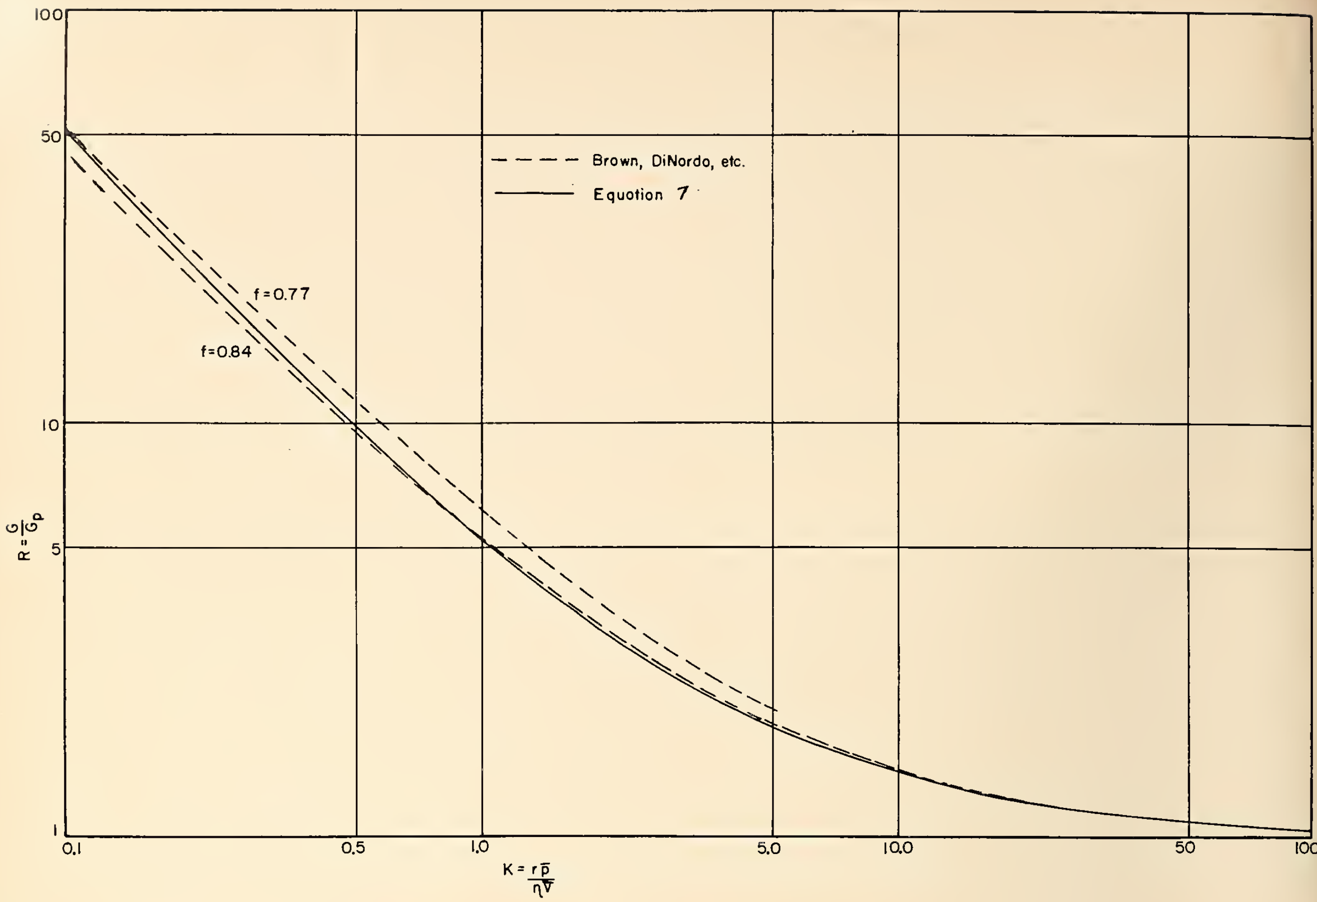

Fig. 1. Comparison of Flow Equation with earlier correlations.

$$\frac{G}{G_p} = e^{-8K/\pi}\left(\frac{1.144}{K} - 1\right) + \frac{4.189}{K} + 1 \qquad (7)$$

where G_p is the flow rate as given by the Poiseuille equation, that is,

$$G_p = \frac{\pi r^4 \bar{p} \Delta p}{8\eta RTL} = \frac{\pi r^4 (p_1^2 - p_2^2)}{16\eta RTL} \qquad (8)$$

A plot of this equation is shown in Fig. 1. It gives a satisfactory correlation of nearly all experimental data for flow in circular pipes over all three regions of flow described earlier.

It is of interest to consider the application of this equation to flow through powders or porous solids. If flow measurements are carried out as a function of pressure at pressures sufficiently high so that the term $e^{-8K/\pi}$ in equation (1) approaches zero, then a straight line is obtained. Extrapolation of this line to zero pressure gives a value for B, and the slope of the line gives the value of A. Then from equations (4) and (5)

$$\bar{r} = \frac{A}{B}\frac{4\pi\eta\bar{v}}{3} \qquad (9)$$

where r is now an equivalent radius. It has been shown[4] that the value of r so obtained agrees closely with the mercury penetration value. Further, it is possible to calculate a structural parameter for diffusion in a porous solid from these results. This "diffusion ratio", β, may be defined as the rate of diffusion which could occur in the geometric space occupied by the solid, to that which actually occurs through the pores of the solid. This ratio can be found from the expression,

$$\beta = \frac{16\pi A\eta A_s}{9B^2 ML_s} \qquad (10)$$

where A_s and L_s are the geometric cross sectional area and geometric length of the porous solid sample, respectively.

Further details of the application of equation (2) to the design of vacuum piping are discussed by Scott and Dullien.[4]

Heat Transfer in Rarefied Gases

At very low pressures, radiation may become an important factor in heat transfer. The reason for this lies in the absence of normal convection currents in the gas, and in the low rate of heat transfer by molecular conduction.

In general, for the region of laminar flow the ordinary heat transfer equations for natural convection can be used. In the slip flow and molecular flow regimes, however, the apparent thermal conductivity of the gas decreases with the pressure. Two approaches to this problem have been used, that based on an "accommodation" coefficient, due to Knudsen,[5] and one as described by Dushman,[6] suggested by Smoluchowski, which assumes a temperature discontinuity near the wall. The former assumes that when a molecule strikes a hot wall, a complete interchange of energy does not occur in a single collision, and therefore, the molecule leaves the wall with an energy somewhat less than that corresponding to the wall temperature. The accommodation coefficient is, in effect, the efficiency of the exchange process. For most substances its value lies between 0.8 and 1.0.

If a temperature discontinuity is assumed, then a trial and error solution is necessary to determine the temperature at the point of discontinuity. When this is known, the ordinary conduction or convection equations are applied to the balance of the gas. Equations for carrying out this procedure have been developed by Madden and Piret[7] and by Kyte, Madden and Piret.[8]

For heat transfer from spheres and vertical or horizontal cylinders, their equations give good agreement over very wide ranges. These equations take the form of 15 empirical correlations, each applying over a particular range, in terms of Grashof and Prandtl numbers for cases in which free molecule conductivity can be neglected (i.e. the temperature discontinuity can be neglected), but a simultaneous solution of two equations is required at low presures when free molecule conduction corresponding to the slip region of flow) begins to be of importance. While these equations appear to give good results, their use is rather laborious.

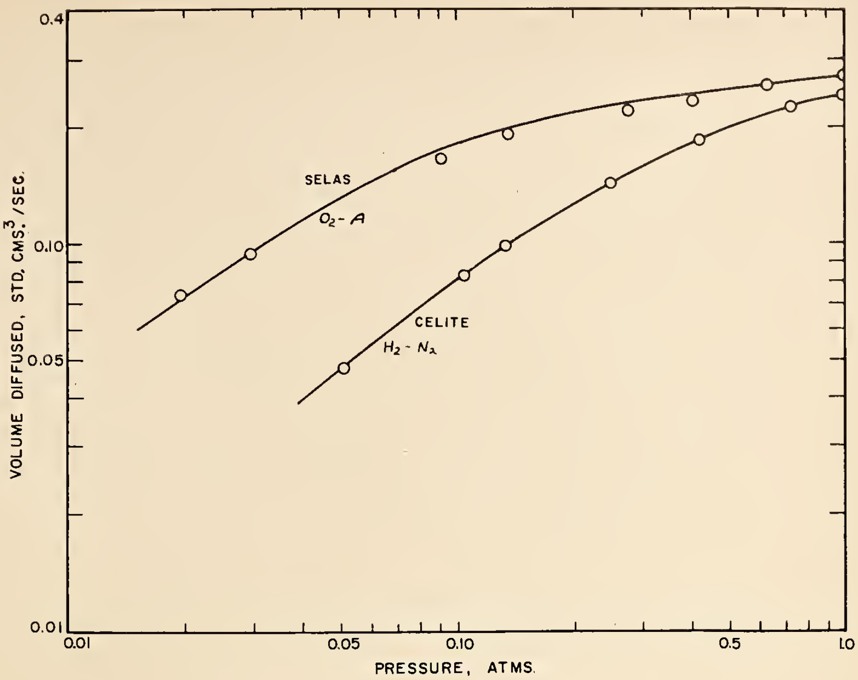

Fig. 2. Counter Diffusion of Gases through a Porous Solid at Constant Pressure.

O Experimental
— Calculated Eqn. 18

It is perhaps possible that a concept such as that used in developing equation (2) where three separate types of molecular collisions are considered, might give a single satisfactory procedure.

A brief outline of one fundamental approach due to Kennard,[9] is given below. It is well known that the apparent thermal conductivity of a gas decreases, when the mean free path length becomes an appreciable fraction of the length of the conduction path, or exceeds it. The apparent thermal conductivity k_g, can be assumed to be related to the ordinary thermal conductivity, $k_g°$, by an expression of the type

$$k_g = \frac{k_g°}{1 + (2j/L)} \quad (11)$$

where j is the distance over which the temperature discontinuity extends (i.e. the distance in which free molecule conductivity is assumed), and L is the length of the conduction path. From kinetic theory the distance, j, can be written,

$$j = \left(\frac{2-\alpha}{\alpha}\right)\left(\frac{2\gamma}{1+\gamma}\right)\left(\frac{kT}{\sqrt{2}\pi p\sigma^2 N_p}\right) \quad (12)$$

where α is the accommodation coefficient, γ is the specific heat ratio, σ is the molecular diameter and N_p is the ordinary Prandtl number of the gas.

Combining this with the previous equation,

$$k_g = \frac{k_g°}{1 + 5.08 \times 10^{-24}\left(\frac{2-\alpha}{\alpha}\right)\left(\frac{\gamma}{1+\gamma}\right)\left(\frac{T}{pL\sigma^2}\right) N_p} \quad (13)$$

This equation would apply for cases in which free molecule conduction and ordinary conduction occur. At low pressures it becomes the equation for free molecule conductivity. Inasmuch as the length of the conduction path, L, appears in the denominator of the ordinary conduction equation, that is,

$$q = kg \cdot A \frac{\Delta t}{L} \quad (14)$$

then it can be seen that for gases in the Knudsen flow range, the rate of heat transfer varies directly with the absolute pressure, and is independent of the length of the conduction path, in direct opposition to ordinary conduction.

If convection does occur in the gas space, then the more complex methods mentioned earlier must be used. On the basis of equation (13), Schotte[10] has proposed a method patterned after that of Deissler and Eian[11] for predicting rates of heat transfer in packed beds having void spaces of very small dimensions.

Some brief mention should also be made of the phenomena of "thermal transpiration" and "thermal diffusion". Thermal transpiration, also called thermomolecular flow, arises when two chambers at different temperatures are connected together. If these chambers are at low pressures and connected by tubing so that the tube diameter is about the same or smaller than the mean free path, then at equilibrium the pressures in two chambers A and B can be shown to be,

$$\frac{P_A}{P_B} = \sqrt{\frac{T_A}{T_B}} \quad (15)$$

As a consequence, this situation must be recognized when a pressure gauge held at one temperature is connected to a vacuum system at a different temperature. If the mean free path is much smaller than the tube diameter, than $P_A = P_B$. Empirical equations have been derived by Knudsen[5] for the transition region, but these are not entirely satisfactory, tending to give low answers.

Thermal diffusion is a process whereby in a gas mixture, there is a tendency for larger and heavier molecules to move to a cold surface, and for smaller and lighter molecules to move to a hot surface. In the steady state, the degree of separation resulting is determined by the mixing effect of ordinary diffusion, so that finally a concentration gradient will exist in the gas as a consequence of a temperature gradient. This process has been used on a continuous laboratory scale for the separation of isotopes, and a very considerable body of literature exists on the subject. A review of thermal diffusion is given by Dushman.[6]

Mass Transfer in Rarefied Gases

As the number of intermolecular collisions suffered by a molecule in travelling from some source to its destination is reduced, then its rate of transport will be increased. In the extreme case where the molecule can travel the entire length of the diffusion path without undergoing collision, the only limitation on the rate will be the rate of emission from the source. At higher pressures, ordinary diffusion equations will apply, and under molecular flow conditions, the equations due to Knudsen[1] or Langmuir[12] can be used. An expression for this rate of surface emission, as given by Sofer and Weingartner,[13] can be written,

$$G = P_v A_s \left(\frac{Mg_c}{2RT}\right)^{1/2} \quad (16)$$

where G is the mass rate of transfer, P_v is the vapor pressure of the solid or liquid in question and g_c is a constant, equal to the acceleration of gravity, relating force and mass units. Pressure units must be consistent throughout.

This equation gives a maximum rate of evaporation, and holds well for fresh or clean surfaces. If surface impurities are present very much lower rates will result, and it is therefore customary to include an emission coefficient in equation (16), which attempts to allow for this effect.

Little work has been done on more general expressions for mass transfer at low pressures which would include all three regimes of flow. Correlations have been attempted by Sherwood and Cooke[14] using the concept of an overall mass transfer resistance obtained by summing individual resistances, in the same manner as that employed for transfer processes at normal pressures. While a good correlation was presented, an error in the emission coefficient used has been pointed out recently by Madden.[15] It is interesting to note that this work, as well as results given by Littlewood and Rideal[16] tend to throw doubt on a great many values of emission coefficients reported in the literature. The possible error arises because the evaporating surface may have a temperature considerably different to that of the surroundings. If this temperature is not known, then the value of P_v used in equation (16) will be in error, with a corresponding error in the emission coefficient calculated.

Another problem associated with dilute gases occurs when diffusion is occurring between two chambers each at the same total pressure, but connected by small channels. A similar situation exists when the diffusion through a porous mass bathed in a flowing gas is considered. The diffusional process will be of the ordinary or mutual diffusion type when the ratio of channel radius to mean free path is large. The diffusion coefficient for this case may be calculated by means of the usual correlations, for example, those presented by Hirschfelder et al.[17] The ordinary diffusion coefficient varies inversely with the absolute pressure, and its temperature dependence is given reasonably well by $T^{1.75}$. In free molecule diffusion (which is identical with free molecule flow) the Knudsen diffusion coefficient, D_k, for a circular channel is

$$D_k = 2/3 r\bar{v} \qquad (17)$$

and hence is independent of the absolute pressure, depends on $T^{0.5}$ and varies directly as the channel radius. In the transition zone, a mixed type of diffusive behavior is observed, and the diffusion rate is not easily predictable. Empirical equations for this region have been proposed by Wheeler,[18] and recently Scott and Dullien[19] have developed e more exact expression for the constant pressure case. This equation is complicated to some degree by the fact that the steady state diffusion equations have a different functional form for the two limiting processes. The diffusion ratf for a binary mixture is given by the latter authors as,

$$G_A = \frac{D_B p}{RTL\alpha_A} \ln \left\{ \frac{1 - \alpha_A y_2 + D_B/D_K}{1 - \alpha_A y_1 + D_B/D_K} \right\} \qquad (18)$$

where G_A is the under rate of diffusion o gas A, D_B and D_E are the ordinary and Knudsen diffusion coefficients, respectively, y_2 and y_1 are the mole fractions of A at the two ends of the diffusion path of length L, and α_A is given by

$$\alpha_A = 1 + \left(\frac{M_A}{M_B}\right)^{1/2}$$

if A is the gas whose diffusion rate is being measured.

Scott and Dullien have also shown that, for all the modes of diffusion, at constant total pressure,

$$G_A/G_B = \left(\frac{M_B}{M_A}\right)^{1/2}$$

when a steady state diffusion process is occurring through small channels, or at low pressures. Results calculated from equation (18) are shown in Fig. 2, compared to experimental diffusion rates through a porous solid measured at varying total pressures. It can be seen that good agreement is obtained.

Summary

It is believed that satisfactory flow equations exist for rarefied gas flow in circular channels. Equations applicable to many other shapes could be readily derived. Heat transfer processes in rarefied gases can be less readily and less exactly calculated, but adequate empirical correlations appear to be available to allow estimation of heat flow rates for a number of situations. However, a good deal of experimental and theoretical development remains to be done before mass transfer rates can be calculated for a like number of cases.

Pumps capable of producing and maintaining low pressures in equipment of commercial size are now available in a variety of forms, and for a variety of conditions. Industrial use of high vacuum techniques is feasible, and is growing rapidly. It would be desirable, therefore, to develop adequate design procedures for transfer operations in rarefied gases, in order that this growth may be encouraged, and may have a firm basis on which to rest.

Nomenclature

A — Poiseuille flow constant given by equation (4)
A_s — Area of a solid, cm²
B — Slip flow constant given by equation (5)
C — Knudsen flow constant given by equation (6)
D_B — Ordinary binary diffusion coefficient, cm²/sec.
D_K — Knudsen diffusion coefficient, cm²/sec.
G — Molar flow rate, moles/sec.
G' — Specific flow rate, moles/(sec.) (unit pressure differential)
G_p — Molar flow rate calculated from the Poiseuille equation
j — Distance over which free molecule flow exists.
K — Dimensionless group in equation (2)
k — Boltzmann constant
k_g — Apparent thermal conductivity
$k_g°$ — Ordinary thermal conductivity
L — Length of a flow or conduction path
L_s — Length of a porous solid
M — Molecular weight
p — Absolute pressure
Δp — pressure differential
P_v — Vapor pressure
R — Gas constant
r — Radius of a circular pipe
r — Equivalent pore radius
T — Absolute temperature
$\bar{v}$ — Average molecular velocity
y — mole fraction (or volume fraction)
α — Accommodation coefficient
β — Diffusion ratio
γ — Specific heat ratio
η — Viscosity

EFFECTS OF CHANGING TECHNOLOGY ON LABOR AND EMPLOYMENT

William Bruce, M.E.I.C.,
Professor of Mechanical Engineering, McGill University

Paper to be presented at the 75th E.I.C. Annual General Meeting, Vancouver, May 1961.

IN RECENT times, the tremendous expansion in the application of scientific principles and knowledge to an ever-widening range of man's activities has been strikingly displayed in the growth and development of technology. The creation of a continuous stream of new materials, processes and methods, combined with the devising, building and maintaining of devices of increasing complexity and intricacy are resulting in significant changes in the contributions required from labor at all levels. The fact that man can now produce the basic food, clothing and shelter for his needs by a relatively small expenditure of his efforts and of natural resources is bringing about the development of a more complex form of society, but at the same time it also incurs the predominant necessity for a constant generation of much more artificial forms of employment. Part of the response to the need appears in a stimulated public desire and consumption of what might be called luxury goods and services. Another part is in the development and production of devices and equipment found to be necessary for purposes of military security, and still another, in the increasing of social capital through the construction of public buildings, parks, roads and highways, urban developments, and other forms of activity which contribute to the national welfare.

The attempt is to weave such actions into what will be a fairly stable economic pattern, yet one which is capable of fruitful expansion. The effects of these happenings are being reflected in the changing nature and composition of the labor force, in the educational and skill requirements involved, and in the employment opportunities which occur. There is a decided general trend in industrial operations to demand relatively higher educational qualifications of workers, extending even to the most menial of jobs. This is quite evident in an examination of personnel selection procedures over the years. Although the impact of changing technology is apparent throughout all areas of the economy it is particularly evident in the manufacturing or goods-producing industries and it is with this aspect that the following account is mainly concerned. However, it is relevant to consider first the general structure of the Canadian labor force as well as its proportionate distribution and growth characteristics. Also, the very marked depletion of manpower which has been occurring in agricultural occupations must be recognized.

The Canadian Labor Force

With the population of the country just over 18 million, the total Canadian labor force today is about 6.5 million persons, one quarter of them being female. During the past decade, while the labor force has grown at the average compounded rate of 1.9% per annum, total employment has expanded at the rate of 1.6%.[1] Although non-farm employment increased by 2.8% per annum, jobs in agriculture decreased by 4.5% per annum[1], and this industry dropped from the second largest employer of manpower to fourth position. Therefore in addition to the increase in jobs necessary to accommodate the growing labor force, new forms of occupation were required by a significant number of workers who had to transfer from agricultural activities to some other form of employment.

A further notable feature of the last 10 years is that the employment of women has risen by a percentage almost three times that of men[2]. This has meant a substantial increase in the employment of married women. In 1949, 28% of the females in the labor force were married, whereas today the figure is over 45% [3]. Women are entering the labor force in increasing numbers because of expanding employment opportunities for them, particularly in the trade, finance and service industries. It is estimated that within the service-producing group of industries (service, trade, finance, utilities and transportation) almost 40% of the job holders are women.

The manufacturing industry is the largest supplier of jobs and is the largest contributor to the gross domestic product. This industry presently accounts for more than one quarter of the total jobs available (25.7% in 1959). The services industry which consists in general of organizations, other than those listed below, producing a service rather than a product and including all levels of government, public administration, education, etc., is second, providing slightly less than one quarter of the total jobs (23.0%). These industries are followed by the wholesale and retail trades (providing about 16.0%), agriculture (12.0%), construction (7.6%), transportation, storage and communication (7.6%), finance and insurance (3.7%), mining and quarrying (about 1.6%), followed by the very minor contributors, forestry, public utilities, fishing and trapping[1].

During the past decade manufacturing operations have not managed to keep pace with the growing labor force in supplying the same proportion of jobs. Rates of employment growth have been lowest in the primary and secondary industry groups and highest in the service, trade, finance and public utilities operations. The average annual compounded rates of employment growth in the various industries running from lowest to highest have been estimated as follows[1]:—

	Percentage
Agriculture	−4.5
Mining, quarrying, oil wells (direct mining operations only)	+0.3
Manufacturing	1.3
Transportation, storage and communication	1.8
Forestry	2.2
Construction	3.1
Trade	3.6
Finance, insurance, real estate	4.0
Service	4.5
Public utilities	4.9

Within this period the gross domestic product has risen to such a value that the percentage contribution by agriculture was almost halved, and today this represents about one-fifth of that contributed by manufacturing operations. Employment has more than doubled in such activities as the mining of oil and natural gas, truck transportation, radio and television broadcasting (actually tripled), manufacturing of aircraft and parts (declining from a peak in 1957), and almost doubled in air transportation. The telephone industry shows a substantial increase but it too is declining from a peak in 1957. In transportation operations generally, the employment today is only about 5% more than the year 1949 due to significant manpower reductions in the railway, water and urban facilities. In mining operations overall the increase has amounted to about 23% but it also is declining from a peak in 1957. Employment in coal mining has dropped to less than half of that a decade ago [5].

However, the significant factors in the growth of the labor force versus employment opportunities appear to lie in the very large drop in the number of workers in agriculture, in the failure of manufacturing which is the largest employer of labor to increase, or even maintain its proportionate absorption of workers, in the relatively large increase in female employment in the service, trade and finanee industries, and in the substantial expansion that has and is still taking place in these latter industry groups. Also, an examination of the rates of growth of the broad occupational groups shows that the professional category has been increasing most rapidly, followed by the skilled and white-collar occupations. The semi-skilled and unskilled groups are growing at considerably slower rates while occupations in the primary industries are actually declining numerically. The fastest growing occupations are those requiring the greatest skill and knowledge, and consequently relatively high levels of education and training[1].

Agriculture

The character of jobs occurring in agriculture is noticeably different from the majority in other fields of labor. About 85% of the farm labor force consists of self-employed farm operators and unpaid members of farm families [6]. Although agricultural occupations accounted for over 45% of the jobs held by the Canadian labor force at the turn of the century, today they represent about 12% and the actual number of persons so employed is considerably less than it was then. While this rate of decline (an average of 4.5% per annum in the last 10 years) cannot continue indefinitely, a levelling off is not yet apparent. Despite such a reduction in manpower the output per man-hour in terms of the gross physical product has increased 2 1/3 times in the last 30 years, while the work force has been almost cut in half. Whereas in 1931 one agricultural worker achieved the food production for about nine persons of the population he now produces for about 25 persons with surpluses occurring in many foodstuffs. This has been accomplished through larger scale operations (amalgamation of smaller farms), by increased mechanization and the use of electric power on farms, as well as to improved methods in agronomy and animal husbandry, (and also to increasing amounts of imported fruit, vegetables and other foods). Farm tractors used in Canada increased from 160,000 in 1941 to 500,000 in 1956. In 1931 only 10% of the farms had electric power but 73% were using it in 1956 [6].

Due to greater concentration of activity at seeding and harvest times brought about by the emphasis on mechanization, seasonal employment is forming a larger portion of farm labor, but because of increasing competition from other industries, the relatively low wages offered for farm work, the longer working hours, the lack of fringe benefits and unemployment insurance, it is becoming more difficult to meet requirements. A recent survey by the Department of Labor indicates between 500,000 and 600,000 seasonal jobs in all industries with about 250,000 in agriculture [6].

The big shift of agricultural workers to other forms of employment draws attention to the probable methods of their absorption and to the difficulties encountered. Rural farm areas show about 30% of the population 14 years of age and over with nine or more years of schooling contrasted to 55% in urban areas.[6] In general, the educational patterns of rural areas are considerably below those of urban communities in the extent of formal schooling achieved by the majority of the population, and the worker transfers are likely to be to those jobs demanding little or no skill or experience.

The Manufacturing Industry

General Characteristics: An examination of Canadian manufacturing industries reveals that they have undergone considerable expansion since World War II, but that much of the operations are concerned with producing goods which have been conceived and designed, and are also made outside of the country. Consequently, if the Canadian-made goods cannot be produced more or as cheaply as elsewhere, or if they do not bear a preferred stamp of originality, quality or innovation, they are not likely to be sold in outside markets and the volume of production is limited to the national consumption. At the same time the great bulk of such things as machine tools, control systems and instrumentation, automatic equipment, computers and data processing machines, do not originate in Canada, yet the development and production of these devices involves the employment of considerable numbers of workers of high technical calibre, and the growing demand for this type of equipment is bound to ensure a dynamic and continuing activity in this most important area of modern technology. Automated systems both in production and administrative phases of industry, and the use of transfer machines and numerically controlled machine tools are beoming readily accepted forms of industrial operation. To survive, in an era which is experiencing economic competition of global proportions, an industry must absorb and preferably contribute to these fast and far-reaching developments. The Canadian contribution and participation in these recent technological innovations has been of very limited proportions, yet it is mandatory that it be increased if our manufacturing industries are to be self-sustaining, to retain a Canadian character of some stature, and to prosper.

The human desire and need for a multiplicity of gadgets of constantly changing specifications with a decided trend towards those of greater and greater intricacy and refinement means that the operations of conceiving, designing, producing and marketing of these devices are a continuing and growing form of employment. This is likely to remain so for a long time to come; until mankind is surfeit with material goods. Manufacturing operations employ a large number and great diversity of people with widely varying talents and skills. In recent years many occupations are being subjected to continuous and frequently rapid evolution while others are relegated to a state of obsolescence. This is much more so than in the harvesting of natural resources from mines, lands and seas, although even in these activities a great deal more is being accomplished with far less physical effort, through the applications of newly gained knowledge, of increased sources of energy and power, of ingenuity and improved organizational effort. However, it should be remembered that it is through the further processing of these reaped natural resources by the application of imagination, knowledge and skill in manufacturing desirable goods that jobs can be most effectively multiplied; rather than by the increased disposal of little- or non-processed materials to outside markets.

Engineering and Innovation: Change and obsolescence are almost daily occurrences in recent technological history: diesels for steam engines, jets for reciprocating aero-engines, automated systems for physical and mental manpower, micro-wave apparatus for telegraph, telephone, and long-wave radio signal propagation, transistors for electron tubes, guided missiles for jet fighter aircraft, synthetic for natural fibres, plastics and resins for metals and woods. In such an atmosphere of technological change and of increasing economic competition it is imperative to stimulate, foster and develop the human talents of creativity, ingenuity and organizational ability which can be applied to industrial activity. In the area of engineering design the use of the electronic computer as an aid in rapidly carrying out the necessary and previously laborious calculations is proving a great boon. It enables optimum designs to be achieved in a very short time with a very limited staff. Standard routine design problems which often arise in a repetitive manner are being successfully reduced to a computer program form which results in tremendous savings in time and effort. Such advantages are invaluable to any manufacturing industry engaged in a highly competitive field. Methods need to be found to stimulate and develop original engineering effort in Canadian industry, and to promote research and development work which will lead to the production of new products, processes and materials, to the conception and building of improved machines, to the reduction of costs and to increased productivity. Manufacturers should be encouraged to make greater contributions, if necessary with government assistance, in these areas which are so vital to a vigorous industrial growth.

The creation and establishment of new industries deserve all possible aid. It is essential that new businesses, making new products or rendering new services which will find a ready market come into being to replace others which fail because of product obsolescence, economic competition, or other causes. Business failures can result in much more labor displacement than that due to technological change. To further the evolution of new developments strong support, mainly financial, is needed for graduate study and research in universities, particularly in science and engineering, so necessary for advancing knowledge and technique, and for the advancement of scientific and technical personnel.

Technical and Skilled Manpower: The rapid growth of technology, both in diversity and complexity and in its application to industrial activity makes it most essential that engineering efforts be backed by a large, highly-skilled, well-qualified group of technicians who are specialists in particular technical lines. The growing need for specialized manpower can be seen from the fact that between 1931 and 1951 the professional worker component of the country's labour force increased by 21% from 4.8% to 5.8% (about twice the rate of increase of the total civilian labor force) and the skilled worker component increased by 36%, from 11% to 15% of the total labor force. By 1965 these values are expected to be 6.7% and 17.2% of the labor force, respectively [7]. University graduates in science, particularly at the doctorate level, are being employed in increasing numbers by industry, usually for research and development work. In 1901 there were fewer than three engineers for every 1000 non-farm workers, today there are more than eight [7].

Until recently in Canada a considerable gap in the technical manpower available existed between the tradesman and the engineer. This was clearly evidenced by the active recruiting outside of the country carried on by many companies during the last decade since many of the persons selected were of the technician category. For the five year period 1951-55 when immigration was at a high level the skilled labor force was increased through this means by almost 11% of the number reported in these occupations in the 1951 census. Between 1953-59 immigration provided more than five times the number of craft and technical workers that came from Canadian technical school programs [1]. In a survey of skilled tradesmen in Canadian industry during 1956, covering electronic technicians, senior draughtsmen, tool and die makers and floor moulders, it was found that the more highly skilled the trade or occupation the greater was the dependence placed upon immigration as a source of workers, which suggested that training facilities in Canada were unable to keep pace with the requirements for highly skilled manpower [8]. It has also been apparent that on the average the immigrant manpower has a much higher degree of formal vocational and technical training than is characteristic of native Canadians working in similar occupations. The quick and effective assimilation of these persons into Canadian industry is ample proof of the great need for personnel of this type. On-the-job experience and upgrading appear to have been the major means of developing skilled workers in Canada with immigration being the second largest source. The first method falls far short of the demands made by modern technology and cannot continue if a healthy industrial economy is to prevail.

The contribution in numbers of skilled workers produced by apprenticeship training since 1946 appears to have been about half of that due to immigration. This is a source of skilled workers which needs stimulation for the supply of new workers which can be provided by immigration is dwindling rapidly. Apprenticeship training is recognized, particularly by the metal working industries and by specialty groups such as in printing and weaving, as a valuable method of developing skills, but it seems to be carried out in a formal manner mainly by the larger companies. This appears to be due primarily to problems of organization and cost, and to the limitations set by union practices on the allowable ratio of apprentices to journeymen in any plant.

Candidates are selected from existing young employees and more commonly from technical, vocational and high school graduates. As a method of gaining basic skills and plant experience apprenticeship is used to develop personnel for future supervisory posts in shop operations and for other occupations in methods analysis, production planning, inspection and quality control, etc., as well as for producing versatile tradesmen. Available data indicates that between 1953-56 the proportion of manufacturing establishments with apprentice training increased from 16.6% to 22%, and the ratio of apprentices to non-office employees from 1:40 to 1:33 [7]. In 1956 the percentage of firms having apprenticeship training programs varied from a low of 6% in the petroleum industry to a high of 75% in printing and publishing. A large scale survey in 1959 throughout the mining, manufacturing, transportation and communications, and public utilities industries revealed that less than 2 out of every 100 workers were engaged in formally organized training programs for skilled workers which were provided by their employer [1]. It is significant to note that in view of the relatively high wage rates achieved for unskilled and semi-skilled labor through the actions of unions it is becoming necessary to offer incentives to younger workers to get them to enter apprentice training schemes which, of course, demand much greater personal effort than the average routine job. This usually takes the form of favourable wage rates while learning but it also will require recognition by both labour and management of the need for greater financial disparity among the unskilled, skilled and highly skilled categories in order to stimulate development of technical manpower.

While the emphasis on the need for the technician has arisen due to technological development, it is also due in many respects to the restrictive actions and the limited scope of the trades. The necessary attributes of the technician are, probably a greater intellectual capacity than the average tradesman, more formal training to higher levels which can enable him to gain a sound grasp of basic theoretical concepts, and the ability to adapt readily to changing technical conditions and new industrial requirements. He must encompass a fairly wide range of knowledge in a number of fields but his main concern is with the mastery of the latest industrial techniques in his specialty and in being able to keep pace with new developments. Recognition of this sphere of activity must be made technically, financially and socially by industry, government and the public in order to encourage the youth with ability to seek a career as a technician. A number of those who presently attempt to achieve a university education in engineering and are unable to meet the academic standards (as indicated by the large number of drop-outs) have talents well-suited for the activities of a technician and could very likely make a significant contribution and gain personal satisfaction in this field of endeavor. The existence of technical institutes with programs of education of some stature, capable of challenging the mind while providing up-to-date training in teehnology, are urgently needed. The attempt should be to make this pathway to a career in industry a valued one and graduates of such institutions should receive adequate recognition. The type of curricula employed should reflect an alertness to the latest industrial techniques and the necessity of complementing the university engineering courses of study, not emulating them.

In this way the engineering faculties of the universities will be able to concentrate on the development of more advanced forms of undergraduate curricula with a general upgrading in academic standards, and to increase their efforts in post-graduate study and research, and in the furtherance of engineering knowledge. The pattern in technology today is to attempt to put the most recently discovered scientific data to immediate practical use. In many areas of rapid development the pace is too great for the engineer who has received only a traditional engineering education. As a consequence, in such fields as the electronic, aero-dynamic, nuclear and chemical which are in the forefront of technological change, the graduates of science, at the doctorate level, are leading the way and playing a major role in many engineering activities. This, in conjunction with other factors, is bringing about a definite shift in engineering curricula to place the studies still more firmly upon the foundations of science and mathematics and to carry them to higher levels.

The recent action of the federal government in making funds available for the expansion of vocational and technical training and in its extension to higher levels is most commendable. It is certain to produce very desirable results. On the other hand, the very rapid evolution of machines, methods and processes means that in-plant training programs now conducted by industry must continue and undoubtedly expand in order to keep technical manpower abreast of new developments, and to provide the necessary flexibility in the frequently required transfers of labour from one area of activity to another. In 1959 it was determined that slightly over 9% of the workers who could be classified as technicians were in formal training courses offered by the employer [1].

Plant Operations and Labor Structure

That the productivity of the work force has greatly increased there is little doubt. It is evidenced both in the increased quantity and variety as well as the increased complexity of the goods produced. However, the effects of the greater application of mechanization and automation to industrial operations have produced several changing patterns in the structure of the labor force, and in the skills and eontribution required from it. The trends that are already evident will be continuous with some becoming more significant than others, depending upon the extent of industrial expansion, upon how modern technology evolves, and upon the rate at which advantage is taken of improved technological methods. More and more automatic machines and processes with higher production rates, and machines integrated as a single, eontinuous, operational unit by automatic work transfer systems are being used, and they require much less human assistance in their functioning.

In fact, machine operators are becoming machine tenders exercising little or no control upon the operations either in a qualitative or quantitative manner. Whereas previously a worker's pay was linked to his production rate over which he had certain control, now the trend is toward a fixed hourly wage since the rate is set by the machine and the man's functional ontribution to the production process is that of observer and attendant. The main requirements are for a pronounced sense of responsibility and a state of alertness to avoid such operational difficulties as machine jamming caused by careless loading or faulty operation which can result in a high scrap loss. Even in the toolroom, with the advent of greatly improved machines, many work procedures have been broken down into narrow specialties to such an extent that frequently a machine operator with limited skill can be employed instead of a highly skilled toolmaker of broad experience. The rapid developments that are taking place in the field of operational control of machine tools by numerical methods, using magnetic tape, punched tape or cards for programming, makes it almost certain that the above trends will be greatly accentuated in the near future. Numerical control of machine tools is a form of automation which is exceedingly flexible and can be readily adapted to custom work and small production schedules as well as to large scale efforts. It is therefore well-suited for Canadian conditions. Under such circumstances, with control programs prepared by methods analysts and production planners who are remote from the fabrication area, there will be a further de-emphasis on the skills and organizational abilities required in direct production operations.

Products of a more uniform quality are an outcome of the use of more automatic machines which leave little or no control in the hands of the operator. This has resulted in inspection methods shifting to statistical sampling procedures with quality control gained through close regulation of the fabrication process. The manpower required for inspection purposes is thus noticeably reduced. As products and processes become more complex and varied, methods analysis and production planning become increasingly important, and in general the responsibility for the quality of the product is transferred from the production worker to the planning, inspection and laboratory control groups.

While some progress has been made in mechanizing product assembly operations this is more difficult and costly to achieve, and the bulk of the direct production manpower still appears in such occupations. However, the breakdown of the work into sub-assemblies in which advantage can be taken of mechanized procedures and the extensive use of synchronized material conveyor systems to produce smooth flow patterns have done much to increase efficiency in this phase of manufacturing. In fact, the increased fabrication rates approaching steady flow conditions have emphasized the need for all materials handling operations to be mechanized and have brought about the general adoption of such methods. All of this has effectively reduced the labor content required in direct production, mainly of the unskilled and semi-skilled type. Most manufacturing operations particularly the mass production kind, reflect these trends. While they have a definite result in reducing employment opportunities in this type of work, there is a counteracting effect in the production of a greater variety of goods of greater intricacy in a greater number of establishments, which is contributing towards further employment.

In a highly mechanized production facility which represents a high capital investment and which requires a steady and continuous input-output condition for efficient operation, the importance of maintenance functions looms large. The integration of machines by mechanized and synchronized transfer systems and the use of more complex automatic equipment of all kinds means that even minor breakdowns can be costly since large portions of the plant may become idle. Because operations in such systems are based upon a continuous flow pattern and are performed on the work pieces in a simultaneous and sequential manner, work can not pile up at any station and be relieved later by overtime procedures. Therefore work stoppages must be kept to a minimum. If at all possible, troubles need to be anticipated and corrective procedures taken ahead of time. This need merges the maintenance features very closely with the direct production effort. Some of these needed actions can be taken by the machine tender on a routine operational schedule, some require the attention of more skilled and more specialized personnel. The setting-up, adjustment and repair of the newer automatic machines and systems is a much more difficult task than previously, requiring a much wider range of technical knowledge and competence.

The widespread use of electronically controlled equipment places great emphasis on the need for electronic maintenance skills. Elaborate control systems involving various combinations of mechanical, hydraulic, pneumatic, electrical and electronic circuits are used. A quick diagnosis of the cause of a breakdown, its location and rapid correction requires the services of one who is completely familiar with the equipment, who combines many of the talents and skills found in several standard trades and who is able to appreciate the basic theoretical principles which govern the operation of the system and to understand elaborate and often complex circuit diagrams; in other words, one of technician calibre. Eventually, as skill in the conception and design of these machines evolves, many will contain automatic indicators which will pinpoint possible sources of trouble permitting quick corrective measures to be taken. However, until such developments are generally forthcoming reliance must be placed upon the knowledge and skill of the maintenance worker. The need for such combined talents in one man is an area of frequent controversy between union and management interests regarding job classification and content, and restrictive trade practices. The alternative procedure of sending a repair crew, each member of limited capabilities, and of co-ordinating their activities, is usually a very inefficient method and is entirely inconsistent with the principles of advanced technology. There are numerous cases of this type which arise in production and in maintenance work and they create training problems as well as those of labor displacement. It is imperative that satisfactory solutions be found or technological progress can be hindered.

The extensive use of complex machines with intricate control systems means that much larger capital investments in equipment are being made and depreciation begins to rival labor as a major cost. A balance, which shifts only in the direction of higher capital investment, is likely to be struck in the rate at which this investment occurs depending upon the rate of rising labour costs. However, it is worth pointing out that all new inventions, methods or devices are conceived and brought into being not simply to save labor; many are associated with the development of entirely new products, the improvement of quality or the reduction of costs of existing products, or with the reduction of capital investment. While the rate of technological change depends upon the availability and the capabilities of the scientific and technical manpower, upon the availability of capital for investment, and upon the productivity related to market demand, human talents can be stimulated and their effectiveness increased, market demand can be influenced by adjustments in price structure and by improved quality and innovation of the products being sold, and new markets can be vigorously sought out. Technological advancement should not be hindered. It needs to progress with all possible speed in view of its vital importance to national welfare and security in both the economic and military sense.

Effects on Office and Clerical Work

In contrast to the decreasing proportion of workers engaged in direct production there are relatively increasing proportions of professional, clerical, and other so-called white collar workers appearing in other phases of industrial operations. Evidence of this trend appears in the growth of salaried compared with hourly rated personnel [9]. University graduates are now sought to fill numerous positions and many companies actively recruit those possessing higher degrees. While some of this is due to the creation of an increasing number of supervisory jobs reflecting greater control and a more highly developed form of industrial organization, the great bulk is due to the increase in general office employment associated with present-day methods in the manufacturing and marketing of goods. More information on operations and more data tabulation are necessary adjuncts of the industrial complex. Such things as unemployment insurance, hospitalization, pensions, and other fringe benefits, the union dues check-off system, income tax collection, data accumulation for governmental statistical and taxation purposes have all contributed to the growing load of office work. It is estimated that in 1900 clerical workers formed about 3% of the working population and today it is about 25%; some 30 years ago there was one clerical worker for 12 production workers whereas now the ratio is about one to four production workers[9].

Indeed the number of persons employed in office and clerical work has reached such top-heavy proportions it appears certain that mechanized and automated systems using electronic data processing and computing machines will be effectively applied to eliminate slow cumbersome methods, to streamline and speed up data handling operations, and to reduce costs. While unit production costs have been steadily decreasing office costs have been consistently rising. Also, this approach is the obvious complement to developments within the plant where the institution of continuous flow patterns and automatically accomplished work procedures are stressed. The end result which is being sought is an integrated establishment with all areas of activity operating along similar lines and at comparable rates, with the procuring of raw materials, manufacturing, warehousing, sales and distribution being effectively scheduled and closely controlled. In this way the most efficient use can be made of natural resources, capital, labor and management. Most clerical processes have basically common patterns and much of the routine tabulation, classification and handling of office data are readily adaptable to automatic processing. Occupations such as bookkeeping, filing, invoicing, some forms of accounting, and the routine handling of data connected with any of this work are most likely to be affected. Studies which have been made of possible consequences upon employment indicate the result as likely to be a decline in the rate of expansion of the labor force in this sector rather than a drastic reduction of employment. The effect, which may be expected to be gradual, is similar to those due to many technological changes which are occurring. During a period of economic expansion, while not markedly affecting the numbers of persons employed because of the possible transfer to other types of jobs, nevertheless, they are bound to be reflected in the rates at which new entrants to the labor force can be absorbed in these areas of industrial activity.

The following are some of the observations which have been made in a recent review of the effects of office automation[9]. While eliminating certain occupations office automation also introduces some new ones, but of course the numbers are of more limited proportions. Such jobs as project planner, systems analyst, program coding clerk, console operator, peripheral equipment operator, keypunch operator, data typist and tape librarian come into being. Only the first three positions require a good knowledge of business operations and computer techniques, all others can be mastered, after a short training period, by personnel who have no special skills. For most routine office work, coding operations can be simplified so that even programming can be carried out by one who has no special mathematical background but has an ability for logical analysis.

Though all office occupations will not be affected by automation to the same extent, some scarcely at all, the general tendency is towards a more marked division between executive or supervisory functions and subordinate positions concerned with machine operations. As a result, promotion up through the ranks to the supervisory level becomes less likely since many intermediary positions will have disappeared. Promotion to new jobs is through special training rather than by experience in other work. "The need for a certain background of technical information and a fresh malleable approach to problems of work organization which office automation demands of executives is likely to result in a higher proportion of younger professional men in managerial ranks."[9] In recent years the trend is towards the university graduate being utilized more exclusively in managerial and executive positions. Vocational training schools have been largely bypassed by the rapidity of developments and this has placed the burden for technical training on the manufacturers and users of electronic office equipment; this situation is likely to continue as long as the cost of such equipment prohibits its purchase for training purposes[9]. "The same can be said for most developments in automation which have appeared in factory operations." But perhaps of greater importance is the necessity of enlisting the co-operation of educational authorities at the secondary school and university levels in an effort to provide orientation for students towards the new job opportunities created by automation, with a broad background both in general knowledge and modern office organization which will enable them to assimilate rapidly the technical skills required".[9]

Labor Displacement and Unemployment

Because of increasing use of automatic systems and the greater productivity resulting from improved technology, "saved labor" undoubtedly occurs in many phases of industrial operation. While in periods of reduced economic activity this so-called "technological displacement" could cause some unemployment it should be remembered that new adoptions of technological developments, which are requiring increasingly higher capital investment, are much less likely to occur in periods of economic recession. In a dynamic economy which is producing an ever greater variety of products, supplying a continuously expanding market, this labor displacement usually has little effect in causing unemployment of a permanent nature. By reducing the intake of new employees, displaced labor can often be reabsorbed within the establishment, although worker transfers to other activities, even within the same organization, can involve re-training or at least periods of re-adjustment for gaining new job experience.

Due to their more limited contribution to work processes, the ability of unskilled and semi-skilled labor to switch to other forms of employment seems to be less affected by technological change than in the case of skilled labor where the problems are more acute. Frequently it is difficult for such skilled workers to obtain jobs either in the same plant or elsewhere at an equivalent level of skill or status. However, the number of skilled workers displaced by technological changes appears to be much smaller than in the case of the unskilled and semi-skilled types. The most effective employment of existing skilled labor and the re-absorption of those displaced will depend more and more upon the broadening and extension of their skills and on the increasing of their technical knowledge, particularly since the "bumping" procedures, which are the basis of the seniority employment system, do not favour narrow specialization.

Seniority recognition, which can have far-reaching effects in such labor disruptions, may conflict with the selection of personnel best-fitted for particular work assignments. The ability to adapt readily to a changing environment and to absorb new knowledge or technique varies considerably from person to person and is usually a characteristic of youth rather than of age and experience. Also, the matter of the growing size of the "fringe benefits" part of a worker's financial reward is serving to identify him still more closely with the company operations causing him to wait for re-call after a lay-off rather than seek new employment. Yet it is such limitations in the mobility of labor which present a serious handicap to the rate of adoption of new technology. Flexibility in the work force, both in disposition and kind, is a necessary requirement.

To gain full advantage of the benefits of modern technology the organizational structure of industry needs to keep pace with technical developments, however, at the same time, human values must receive foremost consideration. Fears of a threatened job loss and possible unemployment because of the introduction of new devices or methods can be a serious obstacle to industrial development and a major drawback to good union-management relations. More than ever before the responsibility rests with joint management and union action in careful and intelligent planing for proposed changes, so that the possibility of external displacement is minimized or removed entirely, and in providing just settlements for job evaluation and wage rate problems which arise due to internal displacement. Satisfactory solutions to such problems can be achieved only in an atmosphere of mutual respect and trust and with full recognition of common goals. In periods of economic recession, unemployment becomes a major responsibility of the government to provide some income to the unemployed, to help them find new jobs, to stimulate such areas of the general economy that are most likely to create additional jobs, and to make certain that facilities are available for the training for other possible forms of employment of such workers as are able to profit by it.

An examination of the recent pattern of unemployment increase shows that it tends to be concentrated among male workers and is highest in the young age group, below 25 years, tapering off above this age. This reflects the reduced employment opportunities in the goods-producing industries where the labor force is predominantly male, and the expanded openings for female workers in the more rapidly growing service, trade and finance industries. It also indicates the effect of union seniority regulations which result in those with the least years of service in an organization, usually the younger workers, being relegated to the unemployed ranks. The new entrants to the labor force and those seeking entry constitute a large proportion of the unemployed. Last year the percentage rate of unemployment showed highest for laborers and construction workers, followed by transportation and primary industry occupations, and was least for clerical workers. An analysis of the educational level of the unemployed at that time revealed that 44% had not finished primary school, while 26% had finished; 22% had had some secondary school education but only 8% had completed secondary school or higher.[1] The brunt of unemployment appears centred upon those who have a relatively low level of education and training. In general it would seem that the more highly educated persons can meet the requirements of a greater number of jobs, can adapt more readily to new conditions, and when necessary can achieve job transfers more successfully. Whether or not greater proportions of highly educated workers with improved skills and advanced training can be absorbed into our economy at faster rates is perhaps debatable. There seems to be little doubt however that it is in the areas which require such kinds of workers where the most rapid employment growth is occurring, and that it is mainly from such persons that new ideas, innovation and change emanate.

Conclusion

In the light of economic history the advantages to be gained from the continuing applications of science and technology to industry far outweigh the effects of any disruptions which result in the labor force. These effects can be minimized by foresight, careful planning and the use of some of the gain to alleviate such personal hardships as may occur. The benefits accruing from improved technology are commonly considered to be those of increased profits on financial investment, higher wages, shorter working hours, greater availability at lower cost of a growing multitude of products, the freeing of human effort from exhausting physical labor and mental drudgery, and in general, a higher material standard of living for all. It is important to remember that the benefits should and must appear in other diverse ways as well, such as the reducing of the manpower necessary for the production of goods and of food and so facilitating the enlargement of service occupations as found in education, medical care, travel, entertainment, printing and publishing, the repair and maintenance of personal effects; the increasing of social capital through the development of the arts, the improvement of government and other forms of social order, the growth of parks, planned urban communities, fine public buildings, highways; charitable aid to those segments of the world's population lacking in technical prowess to help them achieve greater self-sufficiency and better living conditions through the application of technology; and in total, in the greater economic strength and military security for the nation.

STATISTICAL QUALITY CONTROL AS A MANAGEMENT TOOL

B. H. Lloyd,
Director, Management Consulting Services,
Price Waterhouse & Co., Montreal.

The place of statistical quality control in the business world requires at least a brief explanation to overcome a misleading notion in the mind of management. The term does not indicate the general areas where it has applications, or its basic concepts.

Presented at the 74th E.I.C. Annual General Meeting, Winnipeg, May 1960.

STATISTICAL quality control is a term that unfortunately neither indicates the general areas of application nor the principles upon which it is based. If anything, the term has a tendency to create a misleading notion in the mind of management. For this reason in a paper entitled 'Statistical Quality Control As A Management Tool' one is obliged to discuss at least briefly the place of statistical quality in the business world.

Walter A. Shewhart, formerly of the Bell Telephone Laboratories, New York, is the acknowledged creator of the term *statistical quality control.*[1] It is important to understand that the statistical implication of Shewhart's development was that of statistical methods based on the theory of probability. In this sense statistics does not refer simply to the collection and presentation of numerical data, which is a more common interpretation of the term.

Shewhart envisaged that the quality of a physical substance could be described by various characteristics and that numbers could be used to measure the effect of the characteristics on the substance. The word *control* was not meant to imply that the technique would result in direct control in the usual sense but that the use of the method would assist management to gain a better understanding of the manufacturing process. Consequently the action taken by management would result in achieving the quality objective more frequently than if they had not used the technique.

The term statistical quality control, therefore, connotes a basic concept qualified by the implications of the work 'quality' which designates a specific area of business activity. However, the concept is suitably applicable to other areas of business such as the management of inventories and costs. Therefore it is not uncommon to encounter the expressions 'statistical inventory control' and 'statistical cost control' both of which may be developments of the same concept as statistical quality control.

It is because of the common concept that we find papers on such subjects as inventory management and cost control appearing in the quality control journals. Only because of the vigorous imagination of students seeking to find useful applications of a principle do we encounter the apparent confusion caused by the use of statistical quality control in areas other than quality control.

Application of the notion of statistical quality control was so successful and gained so much publicity it was not surprisingly that theorists became interested in this new development. Mathematical statisticians commenced to turn out so many statistical tools, some practicable others badly conceived or impractical, that Dr. Shewhart could well have identified himself with the mythical sorcerer's apprentice whose fortuitous scheme for reducing work resulted in far too much production.

The growth in use of statistical quality control over the past 20 years has been phenomenal. The American Society for Quality Control, organized in 1945, has now nearly 12,000 members of whom approximately 500 reside in Canada. However, not until about 1950 did Canadian management begin to realize that statistical quality control was a technique worthy of greater recognition. In this country it is still common to find manufacturing companies with waste and defective product as high as 50% using outdated quality control techniques.

Inspection Department

Many companies still maintain inspection departments for the purpose of screening the acceptable from the unacceptable product. They rely on the final inspection to assure the consumer of an acceptable level of quality regardless of the effect on cost. There are two outstanding weaknesses to this practice. First, the inspection of all items manufactured will not guarantee outgoing product of acceptable quality particularly where inspection is subject to human error. Secondly, sorting to obtain acceptable product is economically inferior to the method of statistical quality control. One finds it difficult to understand in these times, when cost reduction is such an important element in business administration, how management can ignore or overlook quality control as a potential source of increased profits. It seems that, if the sales demand is met and if the customer is satisfied, then quality obligations have been satisfactorily discharged. However, the modern manager cannot afford to accept the existing costs of waste, defects, product repair, inspection, product testing and customer dissatisfaction unless he has thoroughly investigated the advantages of scientific techniques such as statistical quality control.

Risks in Sampling

Before management can fully realize the potential of statistical methods it must recognize that when a decision is based on a limited amount of information, there is a chance that the decision will not produce the desired result. When the element of chance can be measured, the statistician can be of help. For example, the inspection of a sample of manufactured parts taken from a lot may be used to determine whether or not the lot is acceptable for shipment. There are two risks involved in this situation. First, the sample analysis may cause the shipment to be rejected when in fact it is acceptable. Secondly, the sample may have enough acceptable parts to cause the shipment to be accepted when it should have been turned down. Since these risks are present whether management wishes to recognize them or not, management can improve the precision of its judgment by basing the sampling plan on preassigned measures of risk. It is natural to want to keep the risk of making a wrong decision small. It is also to be expected that management will want to spend as little money as possible in collecting information upon which to base a decision, but these two criteria are conflicting. For practical reasons a 10% sample is commonly used for inspection of goods for shipment when a little larger sample might result in a lower net cost to the company. It is often found that management wishes to assume very small risks of making a wrong decision but the resulting sample is so large that the increased cost is prohibitive. This dilemma is one that management must resolve. It cannot be ignored without incurring greater net costs to the company.

Control Chart

The same underlying thinking applies in the use of the statistical quality control chart. As long as the measure of a quality characteristic is within the control limits, there is a risk that variations signify a real change in the quality of the product. However, should the measure fall outside of the limits, there is a relatively high probability that this indicates a significant change. The spread of the limits varies as the degree of risk. A narrow band means that some apparent out-of-control conditions might prove to be due to chance. Wider limits would increase the probability that quality changes would go unobserved. The two risks must be balanced with the affected costs if the application of the technique is to be successful.

Development of Management's Acceptance

One cannot expect members of management, other than perhaps those directly engaged in the management of the quality control function, to understaond or even to attempt to understand the methods of statistics. However, it is perhaps just criticism of a management that does not understand in general terms the principles of statistical quality control, if the technique is being successfully applied in the company.

Dr. L. R. Hafstad[2] contended that engineering management were indulging in self-flattery in thinking that they could avoid variability. He questioned that engineers could make things so uniform that they didn't have to worry about probability distributions. In short, variability is present whether the engineer manager wishes to recognize it or not and he probably will benefit from trying to understand it rather than to ignore it.

From the original concept produced by Dr. Shewhart, in the space of 36 years noteworthy developments in applications of statistical methods have taken place in 3 major areas, namely technical research, industrial processes and business administration.

The statistical quality control chart developed by Shewhart and the later introduction of acceptance sampling in inspection operations have now become the rule rather than the exception, but it cannot be maintained that these devices have universal application. Not every manufacturing process can save money through statistical quality control. Not every inspection operation can make use of statistical sampling. The greater successes have been achieved undoubtedly in mass manufacturing processes dependent upon few variables but some ingenious methods have been devised for short run manufacturing and complex processes.

The statistical quality control chart in shop applications functions directly as a tool of the shop operator. In addition, by periodic observance of the charts, operating management can soon learn to assess the immediate quality performance and to ensure that necessary corrective action has been taken before the weekly or monthly operating report is prepared.

Quality Summary Reports

Many manufacturing plants now have eliminated detailed quality summary reports and rely on a brief weekly meeting at which quality control and production personnel discuss each operation that has been out of control during the week. It is common for the quality control manager to refer to the quality control charts at this meeting explaining, where possible, the causes of significant deviations from acceptable standards of quality. If the offending quality condition has not been corrected, management may outline the corrective action to be taken and raise the point for discussion at a subsequent meeting. The meeting not only serves as a clearing house for quality problems but eliminates delay and clerical time in the preparation of quality reports and the attendant profusion of copies.

Statistical Sampling

Management to some extent still regards statistical quality control as a kind of hocus pocus. Since considerable mathematical training would be required to understand some of the techniques, particularly where the principles of statistical sampling are concerned, this attitude is understandable. Two examples may serve to illustrate this point. In excavation work surface formation is sometimes dislodged by arranging a series of detonations in time sequence with the explosive charges placed at scientifically determined depths. It is important that detonations occur in the proper order but the time interval is very small and variations in quality of the detonator disrupt the order of firing. In one instance a statistical sampling procedure was developed for the inspection of blasting caps that enabled management to predict field performance in terms of the probability of misfires. It was through this approach that a satisfactory quality control system was established. Because of destructive testing it was necessary to use a sampling procedure but statistical sampling provided the degree of precision that helped management set quality standards and assured satisfactory performance in the field. In this case some members of management, not fully comprehending the technique, could not help regarding the results with some degree of awe.

A second example, though not so dramatic, occurred in a dairy. For some time the company had been experiencing a net plant gain in milk. Although substantial plant losses were expected due to bottle breakages and other causes, statistical sampling soon demonstrated that, on the average, but underfilling the bottles only a few cubic centimetres, which was not only practical but allowable, resulted in a net book gain in product. It was possible using this statistical approach to estimate the gain, the losses and the resulting net production, which were reasonable reflections of the book figures. It was interesting to note that although responsible members of management realized that there was a gain, it had not occurred to them that this would compensate for controllable losses which represented an appreciable amount of money relative to the net profit. In addition to this, it was fairly simple to demonstrate using statistical sampling methods, not unlike the methods of work sampling, that an overloaded maintenance program was the cause of much of the trouble. Management were impressed by the results but it is doubtful that the technique would interest many at the management level particularly in small companies having few specialized personnel. In this sense therefore it is doubtful that statistics could be considered a tool of management, but in the sense that the methods are used to solve management problems the role of the technique is properly cast.

Relative Cost of Defective Conditions

Although statistical quality control as a plant activity basically serves as a technique for detecting significant variations in quality, this in itself is often not sufficient. For example, a 10% defective level in steel washers due to burrs may be less costly to the company than a 1% defective level in bronze bushings due to oversize drilling. It is customary in some companies to determine the relative cost of defective conditions as a measure of quality control performance. This approach is of value in determining machine maintenance and repair priority.

Some companies use summaries of lost revenue due to defect conditions as a means of emphasizing the importance of operating within specifications. Thus in one company a reduction of 50% was possible in lost revenue per product unit, as a result of statistical quality control, within one month from the beginning of the program. It should not be deduced from this that concerted management effort could not have achieved this without help from statistical quality control. Nevertheless, the technique not only dramatically isolated the source of difficulty but impressed on everyone the impact on company profits.

Statistical Methods and Business Administration

There is no doubt that the concept of statistical quality control has had wider application in product and process quality than in other areas of business activity. Nevertheless useful derivatives of the technique have appeared on the horizon in business administration, among which are the more impressive applications of statistical inventory management and statistical cost control. Inventory levels are of great interest to management because of their effect on costs and customer service. It is usually of vital importance to be able to fill customer orders on time and management would prefer that this be carried out at the smallest expense to the company.

It cannot be maintained that statistical techniques are essential in all inventory problems but statistics has been helpful, for example, in studying the frequency of orders to be filled. If it is possible to establish the nature of the frequency of demand, it is then possible to prediet the movement of units from inventory which must be known before base stocks and re-order points can be established at an economic level. The statistical quality control chart has been applied to the inventory turnover index for the purpose of bringing to the immediate attention of management changes in the movement of goods.

Charles Bicking has described statistical applications to control errors on stock cards, restocking orders and discrepancies between physical stocks and stocks card records.[3] The applications helped to improve the quality of the data being used in an inventory control study and are examples of the scientific approach to the improvement of clerical performance.

Statistics in Accounting

There is some evidence that the notions of statistics are gaining popularity in the accounting profession but the exactness of accounting work is a deterrent to development in this field. This is a condition not unlike that experienced in engineering. Frequently an accountant will react to the error phenomenon with great consternation, but an engineer will often attempt to rationalize a situation in which an error has occurred.

The accountant and the engineer have much in common, both having been established practitioners for many centuries. It is not surprising, therefore, that the accountant became aware of the value of statistical sampling at about the same time that Shewhart's technique was gaining acceptance. In 1933 L. A. Carman prepared a paper entitled 'The Efficacy of Tests' which was likely one of the earlier papers on the subject of statistical sampling as it applied to auditing work.[4] Since that time progress has been made in the use of statistical sampling by the accounting profession, but there has been noticeable resistance to the acceptance of the statistical principles. The apparent reluctance cannot be attributed entirely to the accountant so much as to the lack of attention on the part of the statistical designer to the basic accounting problem.

An excerpt from a treatise prepared by Dr. Edwards Deming,[5] renowned statistician, can perhaps serve to illustrate this point. Dr. Deming's reference is to a sample of records for July, 1953 chosen for study by a group of top executives in a specific industry to provide legal evidence in a case that threatened their industry. Dr. Deming remarked "Was this a sample? Of what? Of 1953? Not in my definition. Why Because I know of no way to place limits on the degree of uncertainty of any useful inferences that might be made from the study of July". In other words the sample was not planned to answer the question asked. What should they have done? Dr. Deming suggested that a stratified random sample of the records for the full year of 1953 would have been a much better plan for little additional cost.

Techniques to Fit Purpose

As in the case of engineering, sampling techniques must be designed carefully to suit the accounting purpose and straight application of methods from statistical texts will not be tolerated. A public accounting firm cannot be texpected to stake its reputation on any plan that does not fulfil the qualifications. The statistical approach will only be practicable when the aecountant and the statistician both understand the implications and consequences of the statistical reatment. For example, careful think-ng has gone into successful projects o reduce accounting work on inter-ine settlements for both air and rail ransportation companies. Briefly, the rrangement between two companies s to agree on specified risks that ettlements may be in error to the xtent of a fixed dollar amount. Settle-nents between companies for speci-ied periods of time are then based on amples. It has been demonstrated, to he satisfaction of the companies in-olved, that the clerical savings are ubstantially in excess of the revenue hat could be lost due to sampling rror.

nterpretation of Controllable Costs

Management has been greatly im-pressed by the effect of statistical nethods on the interpretation of con-trollable costs for the cost accounting activity. One of the advantages of a conventional standard cost system is that the accounting records will reveal variations from objective levels of costs. The periodic examination of de-viations from standard may be ex-tremely time consuming if there are many products under the system of control. Many of the cost deviations are difficult to trace and it is doubt-ful that a search for assignable causes would be rewarding. In other words, costs, as in the case of quality charac-teristics, are subject to the caprices of chance causes. Management can be saved a great deal of time if they are spared the task of attempting to ac-count for cost deviations that behave in a random manner. The statistical method has made it possible for the cost accountant to place limits on the objective cost level within which the actual costs are allowed to vary with-out particular concern on the part of management. Costs deviating by more than the limits are subjected to further examination since it is expected that significant reasons could be found for variations of this order.

In a company manufacturing chemi-cal products management was faced with the formidable task of reviewing 35,000 cost figures a month. It was not unreasonable to expect that unless outstanding disparities appeared on the cost sheets the review would be cursory and in many cases decisions would be based only on the reviewer's experience and judgment. In addition to the problem of reviewing a large number of figures, the analysis of the cost variations was complicated. Pro-duction volume varied considerably over the year with commensurate variations in production unit costs which contributed significantly to the total cost variance. Statistical control techniques were applied successfully to separate the factors affecting cost variances. Consequently the time re-quired by management to interpret the cost reports was reduced consider-ably and noticeable improvement re-sulted in the effectiveness of subse-quent decisions.

Application to Industrial Engineering

In the field of industrial engineering, statistics has been useful in devising sampling plans to estimate the produc-tion time lost because of various delays and to test the validity of work standards. The advantage of the sta-tistical approach in such cases is im-measurable since the cost of otherwise obtaining the desired information often would be prohibitive. The statistical background necessary for applications of this nature in industrial engineering is equivalent to that re-quired for statistical quality control and therefore is fully within the scope of engineering trained personnel.

Mathematical Probability

There is much evidence to support the contention that developments in the theory and application of mathe-matical probability will provide man-agement of the future with interesting and beneficial recourse. Dean Arthur Porter has recently given us an indi-cation of what to expect, in a report to the *Financial Post*.[6] Dean Porter foresees the development of a "think-ing machine" which will employ the concepts of probability to predict the future. One need not tax his imagina-tion a great deal to contemplate the meaning of such an instrument in the world of management. It might seem on the surface that less will be required of management with such equipment available and that they may not even require an understand-ing of high school arithmetic. Dr. Grant Butterbaugh[7] does not adhere to a policy of mathematical illiteracy for garduates of colleges of business administration, although he admits that in general there are tendencies in this direction. How can manage-ment be expected to understand the implications of advanced thinking if they are not equipped for it? The answer probably lies in the approach to teaching and course curricula in our educational institutions. It might be more realistic to expect that man-agement of the future will need to have a greater understanding of mathematical concepts and funda-mental scientific principles if they are to achieve the utmost benefit from developments in these areas. If this is not to be so, applied scientists and mathematicians will continue to find it difficult to sell management on the value of their endeavours.

AGM Paper #1

Some Reflections on Trends in Engineering Training

Arthur Porter, M.E.I.C.,
Dean of Engineering, University of Saskatchewan, Saskatoon.

In spite of the failure of academicians to recognize engineering as a true university discipline until the close of the 19th century, remarkable advances have taken place in engineering education during the past fifty years. Technological advance is essentially dynamic and the labile fringe of knowledge in the subject is necessarily highly activated because technology guards and guarantees both the economic advance and the military security of nations. This paper discusses some of the basic trends in engineering education with special reference to curricula, practical training, technological research, and the employment of professional engineers. As an example of these trends recent developments in the College of Engineering, University of Saskatchewan, are considered. A major contention is that, on account of the broad spectrum of ability of undergraduate students, two streams must be recognized and catered for in the engineering schools, there are, first the essentially technical stream, and second the engineering scientific stream. The tendency in some engineering schools, especially in departments of electrical engineering, to follow the lead of the M.I.T. experiments in electrical engineering education is considered to be an undesirable trend for reasons which are outlined.

The paper emphasizes the special importance of practical training and the part to be played by industry in establishing adequate apprenticeship schemes at all levels. Some consideration is given to the "sandwich courses" now in operation in Colleges of advanced Technology and in certain University Engineering Schools in the United Kingdom.

Technological research has gained in stature in the universities during the past few years and it is considered an essential requirement for teaching at the engineering scientist level. There is, however, some justification for the viewpoint that a high proportion of technological research may be more effectively executed in industry or in government-supported laboratories. The justification for and the nature of university technological research is considered with special reference to inter-disciplinary activities.

AGM Paper #2

Three-Dimensional Photoelastic Stress Analysis of a Diamond-Head Buttress Dam

C. R. Jones
Crippen Wright Engineering Ltd., Vancouver
J. B. Mantle, M.E.I.C.,
Head, Department of Mechanical Engineering,
University of Saskatchewan, Saskatoon

This paper elaborates on a three-dimensional photoelastic stress analysis project carried out at the University of Saskatchewan involving the diamond-head buttressess of the dam for the Squaw Rapids Power Development. The stress-freezing and slicing method was employed using one of the new three-dimensional photoelastic materials, Hysol 6000 OP. Of particular interest are the techniques used for model making by the cementing together of several machined parts and for loading the model by means of 14 Neg'ator clamps of various sizes adapted to act as compression springs. Typical calibration curves are given for these loading devices plotting force against clamp extension under operating conditions. Results provided include representative isochromatics with tangential stress distributions around the galleries and magnitudes and directions of principal stresses for the web.

AGM Paper #3

Watershed Resource Value—The Associated Development of Fish and Power

Val Gwyther
Val Gwyther & Co. Ltd., Consulting Engineers, Vancouver

The necessity to conserve the salmon resource, in the many watersheds of British Columbia has retarded the development of other resources (primarily hydro electric power) due only to present inability to ensure present production of salmon by natural spawning and rearing in fresh water. This condition exists today even though we are unable to affix a definite yearly value to salmon production due to variations in climate and other influences of nature. In order to conserve and increase production of the salmon resource in a watershed, from which we wish to obtain the benefits of power, we must provide means to protect these fish, in their entire fresh water life. This paper discusses matters vital to proper understanding of salmon production in large quantities jointly with power. With this joint development of watershed value, where large lake areas exist or are impounded, the value of the salmon resource may well exceed that of power.

AGM Paper #4

The Hydraulic Capacity of Large Corrugated-Metal Culverts

C. R. Neill, M.E.I.C.,
Hydraulic Engineer, Research Council of Alberta

In designing corrugated-metal culverts, engineers customarily use either the slope capacity charts published in the handbook of the leading manufacturer, or the head-capacity monographs issued by the U.S. Bureau of Public Roads. Both of these sources of design information have certain deficiencies, and are apt to be used indiscriminately for problems to which they are not really applicable. Believing that there was need for experimental checking of existing hydraulic design information and also for a more convenient form of presentation, the Bridge Branch of the Alberta Department of Highways recently initiated a research program into the problem, undertaken under the auspices of the Joint Highway Research Project in Alberta, which includes the Department of Highways of the province, the Research Council of Alberta, and the Civil Engineering Department of the University of Alberta as participating bodies. This paper describes the field experiments carried out to date, and the development of a method of analysis which enables head-capacity charts to be produced for all sizes, lengths, and slopes.

AGM Paper #5

Effects of Changing Technology on Labour and Employment

W. Bruce, M.E.I.C.,
Professor of Mechanical Engineering, McGill University

In recent times, the tremendous expansion in the application of scientific principles and knowledge to an ever-widening range of man's activities has been strikingly displayed in the growth and development of technology. This activity has provided a stimulation which has penetrated almost every phase of industry and its repercussions are being constantly felt. The creation of a continuous stream of new materials, processes and methods, combined with the devising, building and maintaining of devices of increasing variety and complexity are resulting in significant changes in the contributions required from labour at all levels. This is reflected in the altering nature and composition of the labour force, in the educational and skill requirements involved, and in the employment opportunities which occur.

In such an environment it is essential that man be able to adapt readily to rapid evolution and change in his working activities; to accept reduced or even complete elimination of skill or labour requirements in some areas, and in others, to exert greater work efforts in the sense of acquiring new knowledge or learning new skills and techniques. To gain full advantage of the benefits of modern technology the organizational structure of industry needs to keep pace with technical developments. Flexibility in the work forces both in disposition and in kind is a necessary requirement.

AGM Paper #6

Weaknesses of the Theory of Plastic Design

A. Hrennikoff, M.E.I.C.,
Professor of Civil Engineering,
University of British Columbia, Vancouver

As the advocates of the plastic theory of design of steel structures bring it more decisively into the field of practical application, its weaknesses become more conspicuous. While the basic or rigid plastic theory is quite simple and logical the situation changes on the appearance of buckling. Instability conditions are difficult to analyze even in the elastic range. The plastic theory, operating with loads magnified by the load factor, projects the stresses beyond the elastic limit where the problems of buckling become virtually intractable. This situation leads to the use of doubtful and inadequately substantiated formulae and procedures. Furthermore, some of the loading conditions used in the theory appear arbitrary, making the safety of design questionable.

AGM Paper #7

The Use of an Electronic Analog Computer for Determining Optimum Settings of Speed Governors for Hydro Generating Units

L. M. Hovey, M.E.I.C.,
Consulting Engineer,
The Manitoba Hydro-Electric Board, Winnipeg

The author describes the use of a small nine element electronic analog computer which can be used for analyzing dynamic problems encountered in power systems which involve the solution of differential equations. The general principles of the computer are described with examples of how the units are connected up to solve certain well known equations. The computer has been successfully used by The Manitoba Hydro-Electric Board for analyzing and demonstrating governor performance of a hydraulic turbine generator. This analysis involves the solution of three simultaneous differential equations. A description is given as to how the computer is connected up to solve these three equations and graphs will be included showing the effect on speed regulation when the parameters of the turbine and governor are varied.

AGM Paper #8

The DRB Topside Sounder Satellite

R. C. Langille,
Superintendent, Electronics Laboratory,
Defence Research Telecommunications Establishment, Ottawa

The Defence Research Telecommunications Establishment has studied the ionosphere over northern Canada for the past fourteen years in order to better understand the difficulties of high frequency radio communication in the auroral regions. The reflecting and absorbing properties of the ionosphere to high frequency radio waves prevents much knowledge from being obtained about the upper part of the ionosphere by radio soundings from the surface of the earth. Since a knowledge of the upper part of the ionosphere would be most useful in radio communication studies, it was decided to study the ionosphere from above by means of an earth satellite.

The Topside Sounder satellite will carry a sweep frequency ionospheric sounder somewhat like those used for sounding the ionosphere from the earth's surface. It will cover the frequency range 1.5 to 11.5 Mc/s and will telemeter the information to ground stations on a frequency of 136 Mc/s, which is not affected by the ionosphere. The satellite will be launched from the west coast of the USA early in 1962. It will be in an 80° inclination circular orbit at a height of about 650 miles. The design of the experiment and the construction of the 275 lb. satellite package will be described. The package is being designed and built in Canada, and will be placed in orbit by a rocket supplied by the National Aeronautics and Space Administration of the USA.

AGM Paper #9

Urgent Tasks in Engineering Education

D. M. Myers, M.E.I.C.
Dean, Faculty of Applied Science, University of British Columbia, Vancouver

Engineering education is at present in a state of flux. It is the subject of widespread discussion and recent years have brought forth a profusion of conflicting views. Some of these views are progressive and range from the mild to the extreme; others are conservative or reactionary. University engineers are now in the throes of making what are probably the most important decisions in the history of engineering education. The purpose of this paper is to stress that rigid and sometimes dogmatic adherence to what have hitherto been regarded as basic principles might very well lead to stagnation and even extinction of engineering as a profession.

The paper deals particularly with the requirements for *uniformity* and *breadth* in engineering education. The author examines these two factors and makes suggestions as to how to achieve adequacy without undue uniformity, and depth without undue sacrifice of breadth.

AGM Paper #10

The Factors Involved in the Design of a Canadian Gangsaw

E. N. Parker, M.E.I.C.,
North Vancouver, B.C.

Gangsaws are less well known than the other types of saws used in the production of lumber in Canada. They have been used in Europe for a considerable time and have also been employed extensively in North America under somewhat different operating conditions. These two types of operation are contrasted.

The various types of saws available are discussed and some of the factors affecting the user's choice of a saw are outlined. Service conditions affecting the overall design are covered and a description of the components and their function in a typical gangsaw is given.

The design considerations for the various parts of the saw are reviewed and the choice normally available concerning the selection of materials and the placement of components is outlined. Power sources and requirements for operating the saw are also mentioned.

AGM Paper #11

Current CSA Specifications on Engineering Design in Timber

J. W. Wynand
Chief Engineer, Timber Preserves Limited,
New Westminster, B.C.

During recent years, considerable improvements of design procedure and construction practice, based on intensified research and recognized engineering principles, have been achieved in the timber construction field. This development was not restricted to sawn timber construction only, but encompassed manufactured timber products, such as glued-laminated timber and structural building components made of plywood, foundation piling and pole frame construction, as well as wood preservation, timber fastenings and adhesives.

In order to make the results of this development work available to engineers and architects, it was necessary to establish new data covering materials and design procedure, in recognized specifications and codes. After presenting the complete list of CSA Specifications dealing with structural wood and wood products, a more detailed discussion of the changes and reasons for changes, of working stresses, grades, design procedures etc., follow.

AGM Paper #12

On the Treatment of Stochastic Variables in Engineering Design

J. H. Milsum,
Head, Analysis Seetion, Division of Mechanieal Engineering, National Research Couneil, Ottawa

In recent years it has become essential to consider stocrastic or random input variables in the design of many engineering systems, with consequent modification of classical design procedures which were based upon steady-state, sinusoidal or transient inputs.

Most natural signals affecting engineering systems are partially random at least. In control systems, the randomness is propagated around a closed loop. Analytic design is possible for linear system, but in the more realistic non-linear case approximate methods are required unless solution is made by computer. For engineering purposes there are two essential measures of stationary random signals — the amplitude probability density function (APD) and the power spectral density (PSD) or its Fourier transform, the autocorrelation function. Some commonly encountered APD's are presented in the paper, PSD's are introduced and the mathematical relation for filtering of PSD's by dynamic systems is discussed. The experimentally-determined characteristics of several natural signals are discussed.

AGM Paper #13

Engineering Research on the Fish and Power Problem

J. F. M. Muir, M.E.I.C.,
Head, Department of Civil Engineering, University of British Columbia, Vancouver.
Eugen Ruus,
Assistant Professor, Civil Engineering Dept., University of British Columbia.

Recent fisheries-engineering research in the United States and Canada on the safe passage of anodromous fish past dams of low and intermediate heads is described. The development of the great rivers of British Columbia for fish, power, and flood control is discussed. Fish passage facilities for a proposed dam and generating station of 700,000 horsepower near Spuzzum on the Frazer River are described. A fisheries-engineering research program is recommended.

AGM Paper #14

The Need for Research in Planning Mechanization

J. C. Clapham,
Head, Operating Researeh Section, British Columbia Researeh Council, University of British Columbia, Vancouver

Companies will be compelled to continue mechanizing because of pressure from competing companies and industries. Present methods of selecting mechanization projects normally involve the assessment of a small number of alternatives obtained by: (1) surveying latest examples in the industry (subjectively correcting for differences in application); (2) drawing parallels from other industry; (3) using creativity or ingenuity.

Operations-research overcomes the limitations of these methods by directing exploration and evaluation of alternatives in the following ways:

a) It makes possible a quantitative assessment of a proposed scheme in the particular circumstances to which it is to be applied.
b) By indicating the sensitivity to various factors, it can direct creativity by guiding its application to useful areas.
c) By a more systematic exploration of possibilities, it can arrive at near-optimum solutions.

Since many problems of mechanization are fundamental and complex, industry-wide support for research in this field is suggested.

AGM Paper #15

Unique Design in Glulam

B. Madsen,
Chief Engineer, Glulam Products Limited, New Westminster, B.C.

Potash is one of the major components of modern-day fertilizers. Until recently potash had to be imported from New Mexico and transportation constituted a great part of the cost. When Potash was discovered in Esterhazy, Sask., plans were started for development of the rich and important mine. The structures described in this paper are the Storage Buildings. The demand for fertilizer is highly seasonal and it is necessary to have storage facilities to accommodate several months production. The problem faced was to develop a design which would meet the speical requirements. The pile to be covered consisted of a 204 ft. diam. cylinder 16 ft. in height, located below the ground level. The potash would form a 62 ft. high cone on top of this. The structural frame would have to be entirely outside of this space. The paper describes the seletcion of the materials, the design, construction, testing and other pertinent factors.

AGM Paper #16

Douglas Fir Plywood Manufacture

John S. Abel,
Consulting Engineer, Taeoma, Washington

This paper gives an outline of the engineering phases of the plywood manufacturing process for Douglas Fir Plywood. It describes the general design of a plywood plant, type of buildings, steam and electrical supply, plant arrangement, and manufacturing equipment involved.

In addition to the engineering features it describes a number of the process steps with which the engineering is closely related. The manufacture of plywood involves block handling, peeling, transporting and handling green veneer through the tray system, clipping to size, storing green veneer, drying, sorting dry sheets, patching, gluing, pressing, trimming, sanding, patching and finishing. The nature of plywood manufacture is such that no two plywood plants are alike. To give a clear general picture the author has described a simple straightforward conventional plywood plant, a one lathe, one dryer, one press installation. The balancing of the stock throughout the operations will ordinarily make such simplicity impractical and this is commented on in the paper.

Moisture content of veneer and its behaviour in the make-up of plywood, and problems related to gluing panels, are mentioned. Press operation, which is the heart of the process, is treated at some length and the press is described in detail.

This paper is not intended primarily for those engaged in the business of plywood manufacture but is written to give to an engineer interested in plywood plan design an over-all idea of the technical requirements and problems involved in the design of a plant for the economical manufacture of Douglas Fir Plywood in British Columbia and the Pacific Northwest.

AGM Paper #17

The Limit Design of Reinforced Concrete Continuous Beams

C. Berwanger, JR.E.I.C.,
Assistant Professor, Dept. of Civil Engineering, University of Manitoba

The continuous beam is encountered with sufficient frequency in structural design to warrant special consideration of its solution. The most familiar of elastic solutions is the moment distribution method. However, the advantages of the more rational inelastic design methods have been established with the Plastic Design Theory for steel structures. The uniformity of safety factor leads to a more economical use of materials and the simpler methods to savings in the design office.

The inelastic or Limit Design method presented in the paper considers continuous beams to be made up of smaller segments or elements: propped cantilevers (exterior spans) and fixed beams (interior spans). A complete solution of these continuous beam elements for required moment and rotation capacities is presented for both concentrated and uniform distributed loading. The solutions are presented in graphical form to facilitate design.

The application of a safety factor to the required rotation capacity is recommended where the fixity at the continuous support is not that of a fixed end. Expressions for the moment and rotation capacities of reinforced concrete sections are presented. The use of equivalent loads replacing combinations of loading is demonstrated in a design example which also illustrates the proposed Limit Design method.

AGM Paper #18

The Beechwood Fish Hoist

J. D. Denovan, M.E.I.C.,
Assistant Office Engineer, Civil Division, The Shawinigan Engineering Company Limited

Among the rivers in New Brunswick utilized by the Atlantic salmon for spawning is the St. John River and its tributaries. When designing the Beechwood hydro electric power station on the St. John River, it was imperative that adequate fish handling facilities be provided to transfer fish from below the damp up to the forebay of the development. The elevator fish hoist selected for this purpose was developed in close co-operation with the Department of Fisheries and realized substantial economies in construction over the alternative facilities considered for the site.

This paper considers the general conditions affecting the selection of facilities and the factors establishing the criteria for design. It describes the fish handling facilities and in particular, the fish hoist, which were installed at the Beechwood Development, and relates some of the operating experience gathered since these facilities were placd in service. Modifications to the facilities resulting from this operating experience are also considered.

AGM Paper #19

Some Problems Encountered in Underwater Sound Propagation Research

H. H. A. Davidson,
Pacific Naval Laboratory, Esquimalt, B.C.

The Pacific Naval Laboratory was established by the Defence Research Board in 1948 to do research in marine physics in support of the national defence program. Early work was devoted entirely to underwater sound propagation. Echo studies with triplane and spherical targets were characterized by fluctuations of received signals over a wide dynamic range, necessitating the development of special logarithmic amplifiers for reception. In long range propagation experiments, the limiting factor was ambient noise at the receiving ship, originating both in ships' machinery and in wave action. To overcome this problem, hydrophones and pre-amplifying units were installed in a remote drifting buoy, with radio telemetering links to relay data to the receiving ship. The noise background then was found to be flow noise generated by motion of the hydrophones. Neutrally buoyant hydrophone assemblies were devised to reduce the flow noise to a minimum.

The handling of heavy targets, buoys, transmitting and receiving arrays at various depths and in rough seas presented formidable mechanical difficulties.

AGM Paper #20

Carillon Foundation Studies

C. H. Pigot, M.E.I.C.,
Assistant Chief Engineer, Power Development Division, Quebec Hydro-Electric Commission, Montreal
I. D. MacKenzie, M.E.I.C.,
Geologist, The Shawinigan Engineering Company Limited, Montreal

To verify assumptions used in the design of the Carillon Hydro-Electric Power Development, an in-situ shear test was carried out during the fall of 1960 on a particular shale bed which had been identified as the weakest in the area. This bed was located strategically some 10 to 20 ft. above the foundations of the sluiceways. A 36 in. diam. calyx drill, a wire saw, and hand labour were used so that the test blocks, five in all, could be exposed with a minimum of disturbance to the shale bed. A hydraulic jack assembly, consisting of a hand-operated jack, a ball and socket joint, and a roller path, was used, acting against a reaction beam, to apply predetermined vertical loads. The horizontal load was applied by large diameter twin hydraulic jacks arranged so that their extremely slow rate of travel was identical and independent of the resisting force encountered. In four out of five of the tests, primary consolidation was completed prior to the application of the shearing force; in Test 5, the horizontal load was applied immediately after application of the vertical load. This paper is not intended to be a profound discussion on the theories of soil mechanics or foundation design but rather a description of the methods used and the results obtained in performing in-situ shear tests on a particular altered shale bed in the bedrock at Carillon. It is hoped that this description of the tests will be of help to engineers confronted with similar problems at other locations even though the shear strength values obtained at Carillon may not necessarily be applicable.

AGM Paper #21

Side-Tipping Log Barges

T. A. McLaren, M.E.I.C.,
President and Managing Director, Allied Builders Ltd., Vancouver

The movement of logs over the exposed waters on the west coast of Vancouver Island and Queen Charlotte Island has presented a transportation difficulty. The latest development for handling these logs on exposed waters is the side-tipping log barge of which several units have been built in the past few years. The side-tipping log barge is essentially a quick turn around movement. An efficient logging camp can load approximately M'BM in 12 to 16 hours. The barge can be towed at a speed of 6½ to 7 knots loaded and about 8 knots light in fair to moderate weather. The time required for unloading varies from 10 to 30 minutes. It is not suggested that the side-tipping log barge, described in detail in the paper, is by any means the final development in log transportation. The side-tipping barge still has several disadvantages. However, the advantages gained have made other methods of transporting logs in exposed areas obsolete.

AGM Paper #22

The Production, Handling and Uses of Tonnage Oxygen by Cominco

C. H. Simpkinson,
Assistant Superintendent of Development Research
Chemicals and Fertilizers Division
The Consolidated Mining and Smelting Company of Canada Limited, Trail, B.C.

In the early thirties when The Consolidated Mining and Smelting Company of Canada Limited (Cominco) at Trail, B.C., first launched into the chemical fertilizer field the production of ammonia was a major concern. Consequently, an electrolytic plant was built for the generation of hydrogen from water and a Claude air liquefaction plant was installed to supply nitrogen from the air. The large volumes of by-product oxygen released posed a utilization problem. Transportation costs eliminated the possibility of sale to outside markets so in-plant uses were developed. These included the use of oxygen in sulphur dioxide reduction furnaces, its use as a chemical reagent in a cyclical sulphuric acid plant, oxygen-enriched air in suspension roasting of zinc sulphide concentrates, oxygen air blast in lead blast furnaces and in slag retreatment furnaces.

By far the largest tonnage of oxygen is produced from the hydrogen cells. Details of production, collection and distribution are given. Materials of construction, special operating problems and hazards are discussed. Oxygen is the breath of life if properly used, but there is danger in careless handling.

AGM Paper #23

The Inspection, Repair and Maintenance of Highway Bridges in the City of London, Ontario

R. M. Dillon, M.E.I.C.,
Dean, Faculty of Engineering Science,
University of Western Ontario, London, Ont.

P. H. D. Edwards,
Structural Design and Project Engineer,
M. M. Dillon & Company Ltd., London, Ont.

Increasingly, over the last few years, maintenance of existing concrete and steel bridges has become a major problem throughout Canada. While this is due in part to the natural aging of the large number of such bridges constructed in the 1930's, it is, however, evident that the use of de-icing salts in winter road maintenance is greatly accelerating the deterioration of these structures.

The City of London, Ontario maintains 10 major crossings of the Thames River and a number of subways, overheads and minor structures. A thorough inspection was carried out. This paper discusses certain problems and design faults encountered during this inspection and makes certain recommendations in connection with inspection routine and future new construction.

AGM Paper #24

Speed Regulation for Hydraulic Turbines

W. J. Smith, M.E.I.C.,
Chief Civil Engineer,
Montreal Engineering Co. Ltd.

J. L. Gordon, JR.E.I.C.,
Supervising Engineer, Civil Section,
Montreal Engineering Co. Ltd.

This paper outlines a procedure for determining the variations in frequency of hydro electric generating units operating in isolated systems resulting from sudden load changes. Data from tests which tend to confirm the accuracy of theoretical computations is presented.

Also, from experience gained through the installation of over forty hydro electric developments, and their subsequent performance, criteria are presented for the assessment of the inertia required in a generating unit, depending on the type of operation (base load or peak load) and on whether the unit is isolated or interconnected with a system.

AGM Paper #25

The Hows, Whys and Wherefores of EHV Transmission

C. M. Stairs,
Specialist — Power Systems Engineering, Systems Application Engineering, Apparatus Department,
Canadian General Electric Co. Ltd., Peterborough, Ontario

In this paper the general topic of Extra High Voltage Transmission is reviewed with particular emphasis being placed on its economic position in the power systems of the future, rather than on the technical struggles which have made its use possible. In order to outline the economic facts to all interested engineers the technical content is kept to an absolute minimum.

The main conclusion which is drawn from this analysis is that the advent of EHV will not, in the majority of cases, drastically influence the cost of power delivered to the ultimate user from a distant power site or over an interconnecting tie between neighbouring utilities. On the other hand the transmission line savings associated with the use of EHV can amount to many millions of dollars and therefore will fully justify a continuing research and development program.

AGM Paper #26

Commentary on CSA Standard S16-1961

W. G. Mitchell, M.E.I.C.
Chief Design Engineer Canadian Bridge Works, Dominion Steel and Coal Corp. Ltd., Riverside, Ont.
D. L. Tarlton
Development Engineer, Canadian Institute of Steel Construction, Inc., Toronto

The new Fifth Edition of CSA Standard S16, "Steel Structures for Buildings", contains several modifications and revisions when compared with the requirements of the Fourth Edition published in 1954. Technological progress in steelmaking and fabricating methods, as well as extensive research into the actual behaviour of steel members and connections, made the publication of an up-to-date specification imperative.

Rules and formulae which had been satisfactory when applied to the type of structural steel used almost exclusively heretofore had to be reviewed in the light of a trend toward improved mechanical properties and a greater number of readily available grades of steel. Of necessity, the size of the Specification had to be increased. Here the problem was to avoid giving the designer too little guidance, while at the same time trying to prevent the extension and elaboration of the specification material into a work of text-book proportions.

The treatment of unit stresses, the design of fasteners, and the incorporation of detailed requirements for plastic design all represent departures from the format of previous editions. It is the hope of the authors that this commentary may serve the structural designer by offering a logical analysis of the reasons for the major revisions and, in so doing, minimize the possibility of an incorrect interpretation of the specification requirements.

AGM Paper #27

An Evaluation of Plywoods and Plastics in Boat Construction

John Brandlmayr, M.E.I.C.,
President, John Brandlmayr Ltd., Vancouver.

This paper evaluates the place of plywoods and plastics in the construction of boats under 100 feet in length. All other hull construction materials including solid wood, and the various metals are first briefly considered. Then the physical and economic characteristics of plywood hulls are outlined and current construction practice is described. The same is done for plastic hulls which are nearly all of fiberglass reinforced polyester resin.

Manufacturing costs are compared for different materials and the results of a cost comparison study of 35′ sloops in wood compared to fiberglass construction are given in graphical form. Plywoods are displacing solid woods in power boat hulls and in the case of power boats over 20′ have a cost advantage over fiberglass. Fiberglass has become the dominant material for small power boats and for sailboats up to 40′. Further aims in boat building materials are discussed.

AGM Paper #28

Have We a Problem in Engineering Education?

W. F. McMullen
Engineering Personnel Manager, Canadian General Electric Company Limited

It has been said that the hardware, plumbing and wiring should be drastically reduced in today's undergraduate engineering curriculum. The student's time should not be wasted in teaching specialized techniques that are certain to become obsolete. Some engineering curricula in Canada are moving towards teaching only scientific and engineering fundamentals, with the expectation that industrial experience will do the rest. Is this a correct approach based on our present economy and current utilization of engineers? In Canada we are primarily concerned with building *things*, and our need is for engineers, not scientists.

For many reasons, one of which could be called geographical, the input into our engineering schools is made up of students with very little concept of what is involved in engineering or scientific work. Many students could be said to have "backed into" engineering simply because, since a University education is the thing, engineering looked as good a course as any. This appears to be compounding our problems of proper utilization.

AGM Paper #29

Revision of The Reinforced Concrete Section of the National Building Code

Mark W. Huggins, M.E.I.C.,
Professor, Department of Civil Engineering, University of Toronto
W. G. Plewes, M.E.I.C.,
Research Officer, Building Structures Section, Division of Building Research, National Research Council, Ottawa

When the Revision Committee on Concrete for the 1960 edition of the National Building Code of Canada began its work, a new Canadian Standards Association Specification on Concrete Materials was ready for publication and was considered satisfactory for the concrete materials portion of N.B.C. It was thought, however, that the C.S.A. Code on reinforced concrete was in need of revision to bring it up to date with the American Concrete Institute Standard Building Code 318-1956 and also to incorporate those changes in N.B.C. 1953 which had been issued as revision slips.

The most important changes in the Code may be listed under the headings of shear, bond and anchorage, and crack and deflection control. The section of N.B.C. 1960 dealing with shear, bond and anchorage has been considerably strengthened with a view to ensuring that there will be no repetitions of failures such as those which occured in United States Air Force warehouses in 1955 and 1956. With a view to minimizing cracking, the new Code requires more careful attention to the effects of shrinkage and temperature and to means of guarding against these effects. The Marcus method has been adopted for two-way slabs to replace the present A.C.I. method which occasionally result in designs with inadequate negative bending steel and consequent concrete cracking.

A table of permissible span to depth ratios for beams made with Standard aggregate concrete, as well as a means of adjusting for light weight concretes, has been included in the Code. The maximum permissible slenderness ratio for columns has been increased with the requirement that such increased ratios shall only be used where full allowance has been made for the effects of end conditions and shrinkage and plastic flow.

AGM Paper #30

The Port Mann Bridge Superstructure

G. Hardenberg
C.B.A. Engineering Ltd., Vancouver, B.C.

The Port Mann Bridge, now under construction, over the Fraser River is a major link in the Trans Canada Highway section between Vancouver and the Fraser Valley. The basic requirements for the design of this structure called for a four-lane, 54 ft. wide roadway with two 5 ft. sidewalks and a Main span of 1200 ft. with a vertical clearance of about 145 ft. Due to extremely poor soil conditions at the site — the foundations of the Main Piers reach about 200 ft. below ground elevation — all designs which would transmit appreciable horizontal loads to the foundations such as suspension bridges and stiff arches were accordingly ruled out.

Comparative studies indicated that a design incorporating an orthotropic steel deck was definitely more economical than any of the other types investigated. The main structure consisting of a Main span of 1200 ft. with flanking side spans of 360 ft. is a stiffened tied arch i.e. an arch designed only to sustain compression forces, the necessary stiffness and load distribution being provided by stiffening girders. The stiffened tied arch is well suited for use with an orthotropic plate, which acts as part of the Main girders (top flange of stiffening girders) in addition to its function as bridge deck. The arch ribs are riveted box sections of about 52 in. x 55 in.; the stiffening girders riveted box members with a depth of 12 ft. and the steel deck consists of a steel plate, maximum thickness of ½ in., longitudinally stiffened by box stiffeners spaced 2 ft. ctc and supported transversely by crossbeams spaced at 6 ft. 3 in. ctc. The deck panels, each about 65 ft. (the width of the bridge) by 25 ft. are completely shop welded. All field spliees except for the transverse deck splices are designed for high strength bolts. The latter will be countersunk riveted connections, in order to obtain a sufficiently flat base for the asphalt road surface. Extensive use is made of low alloy steel in the main load bearing members and for the welded deck a special notch ductile quality has been specified.

AGM Paper #31

The Behavior of Rarefied Gases

D. S. Scott
Associate Professor,
University of British Columbia, Vancouver

A rarefied gas is defined for the purpose of this article, as a gas in which the molecular mean free path approaches some dimension of the containing equipment. In general, two cases of industrial importance can arise, first, the design and functioning of high vacuum systems operating at low absolute pressures, and second, the flow and diffusion of gases in solids with a fine pore structure. In the first case, equipment dimensions are "normal" and the molecular mean free path is abnormally large, and in the second case, the container dimensions are very small. Freeze drying, vacuum distillations, and flow in porous reservoir rocks or porous catalytic solids are examples of practical importance.

The kinetic behavior of rarefied gases is discussed. Accepted flow and diffusion formulae for gases are presented for the limiting cases, and two new formulae for the "slip" flow and "transitional" diffusion range are presented. In the light of the above discussion of flow and diffusional behavior, the important correlations for heat and mass transfer processes in rarefied gases are presented and evaluated. Finally, some practical examples of possible industrial importance are given in which behavior as a rarefied gas might be expected to occur.

AGM Paper #32

New Uses for Ceramic Materials in Microwave Tubes

G. B. Walker,
Research Professor, University of British Columbia, Vancouver

At the present time low-loss ceramics, such as alumina, are extensively used in microwave tubes mainly as supports for electrodes and as vacuum windows through which the power generated may pass into an external waveguide system. The remarkable electrical and mechanical properties which can be obtained with recently developed ceramics holds some promise that these materials may find some applications in which the ceramic plays a more direct part in the operation of the tube.

At wavelengths in the centimetre and millimetre region it is necessary that the dimensions of the tube become comparable with the wavelength and this has lead to new principles of design, e.g. the klystron, the magnetron and the travelling wave tube. A large number of successful structures have been developed, but all suffer from certain disadvantages at U.H.F. operation, e.g. the size becomes minute raising constructional difficulties and cooling problems and moreover, metal losses increase with frequency so that efficiency is impaired.

Ceramics offer at least a partial solution to many of these problems, points of interest being simplicity of construction and electrical efficiency. Ceramic slow-wave structures also offer interesting possibilities for the design of high-energy electron linear aceelerators, but research in these fields is still at an experimental stage with many questions to be answered.

AGM Paper #33

Economic Development of Hydro-Quebec Power Resources—System Studies Utilizing an IBM 704 Computer

J. Bourbeau, M.E.I.C.,
Quebec Hydro Electric Commission.
F. H. Jonker and J. G. S. Thomson,
H. G. Acres & Company Limited

To facilitate the Quebec Hydro-Electric Commission's planning of the development of power sites, a model of the Commission's expanding system has been simulated on an IBM 704 computer. The nature and scope of the model, and the methods of analysis used, are described.

AGM Paper #34

Design Consideration for Large Radio Telescopes

J. L. Locke,
Officer in Charge, Dominion Radio Astrophysical Observatory,
Department of Technical Surveys, Penticton, B.C.

Recent observations of the radio emission from celestrial objects have provided the astronomer with much new information. But the observations have shown the need for radio telescopes having larger apertures than those now available. For centeimetre wavelengths the only suitable type of telescope appears to be one having a large reflecting surface, usually a paraboloid of revolution, which focusses the radiation on a small antenna. The design of telescopes of this type presents many engineering problems. The mount must allow the telescope to be pointed to any part of the sky with high precision and a drive system must be provided for the accurate tracking of celestrial objects. Severe tolerances are placed on the reflecting surface which must maintain its accuracy for all orientations.

The factors influencing the design of radio telescopes of various sizes for use at different wavelengths are discussed and the manner in which the problems have been solved in existing and planned telescopes is outline. The possibility of telescopes of extremely large aperture is discussed.

AGM Paper #35

Civil Engineering Education

S. D. Lash, M.E.I.C.,
Head, Department of Civil Engineering,
Queen's University, Kingston.

Civil engineering is a profession in which art and science are integral parts of a coherent discipline. The universities are training two groups of people, an élite — who will in due course become professional engineers, and a larger group whose activities will often be of a sub-professional or non-professional character. Undergraduate training must therefore consist of general education plus a broad programme of engineering studies, the latter consisting of applied science and technology. The heart of an engineering course is applied science and there is a danger of over-emphasizing the importance of basic science and mathematics and of under-emphasizing the humanities. There is room for variety in e technological content of civil engineering courses and me selection must be made. Although practical experience an essential part in the training of a civil engineer it is ot necessary that it be done in summer vacations and niversity courses might well be shortened for those who ish to get their degree first and their practical experience ter.

Graduate study is an increasingly important part of civil gineering education and at the Master's level greater mphasis is now being placed upon course work than ormerly. There is a danger that both Master's and Doctor's ograms may be extended over excessive periods of time.

AGM Paper #36

)utlook on the Relationship between Load-Frequency Conrol & Turbine Governors on Interconnected Power Systems.

.. O. Long

)esign Engineer with the Electrical Division, Shawinigan ngineering Company, Montreal

In view of the trend towards interconnection of power ystems for the many benefits derived therefrom, this paper eviews briefly the basic requirements of the mechanical-ydraulic turbine governors and automatic load-frequency ontrol. The basic principles of the electro-hydraulic turbine overnor are briefly outlined drawing attention to its adantages particularly with respect to area-wide load-frequency control.

Certain operating problems caused by inter-action beween governors and load-frequency control and between ontrol systems of interconnected utilities are described. ome suggestions are advanced to improve power regulation n interconnected systems.

AGM Paper #37

Non-Linear Control for Distillation Columns

G. A. McNeill,

Monsanto Chemical Company, Limited,

formerly with Canadian Chemical Company, Ltd.

A balanced distillation column has inherent non-linearity n its operation. This can be used to effect a simple optimizng controller which will optimize the separation. Only tandard control hardware is required which makes for implicity and reliability.

The method was specifically developed for use with a hromatograph analyzer but could also be adapted to conentional temperature measurement or other type of analyzers.

AGM Paper #38

Rearward Communications for BMEWS

Leo J. Hammerschmid, M.E.I.C.

Terminal Equipment Engineer, Toll Area,

The Bell Telephone Co. of Canada, Montreal

This paper deals with the communication aspects of the Ballistic Missile Early Warning System, which is designed to give the North American Air Defence Command the warning time necessary for retaliation, should an enemy ICBM attack be launched across the northern polar regions. A brief description is given of the BMEWS system, including the three Forward Detection Sites at Thule, Greenland; Clear, Alaska; and Fylingdales Moor in Yorkshire, England. This is followed by information on who is building the system, and how various Canadian communication companies are contributing. For the sake of completeness, the missile detection process is briefly described.

The Rearward Communication System, designed to convey information rapidly and accurately between the Detection Sites and the Display Facility is considered in more detail. The basic objectives are reviewed, new developments made necessary by the stringent communication requirements are mentioned, and the rearward routes from Thule and Clear are described. The route control concept is defined and the various types of circuits in each rearward "circuit package" are described. Details are given of the special Data Transmission System designed specifically for BMEWS, and include the Data Signal Format, the Triple Interleaved Parity method employed for error detection, the Operating Modes, and the Automatic Status Reporting System.

AGM Paper #39

Some Engineering Applications of Analog Computers

T. W. McDonald and P. N. Nikiforuk

Assistant Professors of Mechanical Engineering, University of Saskacthewan

This paper presents a discussion of some engineering applications of analog computers. In this paper analog computers are subdivided into two main groups: the special purpose machines, and the general purpose machines. As an introduction to the subject, a general description is first given of these two groups. Following this a detailed description is given, together with examples, of conducting sheet analogs, resistance-capacitance network analogs and d.c. electronic analog computers. These computers are compared consequently as far as accuracy, flexibility and maintenance are concerned. Some of the examples quoted are descriptions of work presently being done in the Mechanical Engineering Department at the University of Saskatchewan.

AGM Paper #40

The NAE Five Foot Supersonic Wind Tunnel

K. F. Tupper, M.E.I.C.

President, Ewbank & Partners, (Canada) Ltd., Toronto

P. B. Dilworth, M.E.I.C.

President, Dilworth, Secord, Meagher and Associates Limited, Toronto

L. A. Jenkins

Project Engineer, Dilworth, Secord, Meagher and Associates Limited, Toronto

The achievement of increasingly higher speeds in large scale conventional types of continuous operation wind tunnels entails an excessive premium in both capital and operating costs. Such wind tunnels also present serious technical problems in the design of compressors and drives suitable for operation over a wide range of operating speeds and air densities, and in the removal of the substantial quantities of heat generated during operation. As a result of these factors, a new generation of high speed wind tunnels have evolved during the past decade based on the principle of intermittent operation and "driven" by high pressure compressed air drawn from a large storage vessel. The new NAE five foot high speed wind tunnel now nearing completion at Uplands, Ottawa constitutes the latest and probably the most versatile of large wind tunnels of this type in North America. It will have a useful operating speed range from Mach 0.2 to 4.5 at stagnation pressures from 1.8 to 13.7 atmospheres. This paper presents a general description of the NAE High Speed Wind Tunnel facility and major wind tunnel components and discusses some of the basic technical problems entailed in its design.

AGM Paper #41

The Combustion of Gasoline during Engine Starting at Low Temperature

F. D. Hamblin, M.E.I.C.,
Special Lecturer in Mechanical Engineering, University of Saskatchewan, Saskatoon

The mechanical engineer with a specific interest in internal combustion engines, experiencing his first Canadian winter, finds his attention drawn to the effects of the low temperatures on engine performance. Fuel consumption of gasoline engines is increased during the winter months; yet a library study indicates that little work has been done in this field. The main part of the available information is concerned with lubrication problems, while the combustion of the fuel has been almost entirely ignored. The increased fuel consumption is no doubt partly due to the increased viscosity of the lubricants in the engine, transmission and rear axle. However, it does not seem credible that the magnitude of the increased can be attributed to lubrication alone; suggesting that poor combustion of the fuel might also be a contributing factor. The fuel consumption should be approximately constant during the running phase since the engine operates at about the same temperature in both winter and summer. Thus, the increase must occur during the starting and warm-up phases. Compared to summer temperatures, the starting phase may extend over a longer period and the warm-up phase is most definitely prolonged at low ambient temperatures.

An extensive research program, dealing with the combustion of gasoline during the starting and warm-up phases, has been started at the University of Saskatchewan. It seemed logical to consider the starting phase initially, with an extension into the warm-up phase in the light of the results of the starting tests. The initial investigation is now complete and the results are reported in this paper.

AGM Paper #42

The Thermal Wedge Effect in Hydrodynamic Lubrication

John Young
Assistant Professor, Department of Mechanical Engineering, The University of British Columbia, Vancouver

Thrust bearings composed of flat parallel surfaces can operate under fluid film conditions by the formation of a 'thermal wedge.' The general Reynolds equation and the energy equation which govern the thermal wedge mechanism are here solved in three ways, illustrating the effect of certain initial assumptions in the analysis.

The experimental results presented are shown to be in fair agreement with derived curves, showing that while the thermal wedge does exist, and is appreciable at low loads and high speeds, it cannot be depended upon to provide a load-carrying film in normal lubrication practice.

AGM Paper #43

Electrical Installations on Modern Jet Aircraft

R. W. Farren,
Electrical Systems Engineer, Trans Canada Airlines, Montreal

The intent of this paper is to cover in the fullest possible way within the limits allowed, an outline of the application of Electricity in its numerous forms on modern jet aircraft. The introduction covers briefly the historical aspects of the changeover from standard 28 volt D.C. systems to the A.C. Three Phase Constant Frequency systems now employed in jet aircraft; and a review of the environmental, climatic, chemical and physical factors which influence the design and selection of electrical and avionic equipment and systems.

An outline of the main electrical power installation is covered with special emphasis on the design and selection of the Constant Speed Drives and Alternator, in conjunction with regulating and protective systems employed. This includes such areas as Frequency and Voltage Control, Synchronising and Paralleling of multiplex systems, over and under frequency protection, reactive load sharing, under-voltage, overload and differential protection etc. The use of secondary aircraft power sources such as Rotary and Static Inverters and Emergency Battery Systems is also mentioned.

Many systems are briefly examined to illustrate the many electrical applications in use; including such systems as Engine Control, Flying Surface Control, Anti-Atmosphere, Pressurization and Air Conditioning, Instrument Systems, Galleys, Lighting and Avionic equipment for communication and navigation. In conclusion future trends for the electrification of the next generation of jet aircraft, now under construction, are examined.

AGM Paper #44

The Structural Design of the Tunnels for the South Saskatchewan River Dam

C. Booy
Design Engineer, Prairie Farm Rehabilitation Administration, Regina

Five tunnels, together 21,600 feet in length with an inside diameter of 20 feet, are required to handle the divertion flow for the South Saskatchewan River Dam. After completion of the Project the tunnels will be available for power.. The problems encountered in the design of these tunnels are discussed. The tunnels are depressed below river level in order to locate them in firm Bearpaw shale. The shale is a rather soft rock which can be excavated without blasting. It may exert a lateral pressure on the tunnel lining considerably in excess of the vertical pressure. Also, the shale shows a pronounced tendency to rebound after unloading, which complicates the design of the portal structures. During the construction period the shale is expected to behave as a rock so that the temporary ground support was designed for fall-out loads which are relatively independent of the depth of overburden. During the life of the project the shale is expeeted to behave more like a plastic material so that the concrete lining was designed for loads which are a function of the weight of overburden. Central control shafts surrounded over part of their height by steel shells will house the gates. Raised inlet structures are provided 500 feet downstream of the portals which permit the portal excavation to be backfilled. These will be used as power intake structures. The design of the portal structures and the control shafts is discussed briefly.

AGM Paper #45

Geology of the South Saskatchewan River Project

D. H. Pollock, M.E.I.C.,
Chief, Air Photo Analysis and Engineering Geology Division, Prairie Farm Rehabilitation Administration, Regina

This paper presents readers with an appreciation of geologic features and events that have exerted a significant influence on various phases of engineering of the South Saskatchewan River Project, such as the preliminary damsite-selection program, the floodplain and abutment investigation, the exploration for construction materials, and the design of the dams and their appurtenant works. The paper makes only limited reference to the significance and application of the geology as this subject matter would be better discussed under headings dealing in detail with project investigation, design and construction.

The project is a joint undertaking by Canada and Saskatchewan to utilize waters of the South Saskatchewan River for irrigation, generation of power and river regulation.

AGM Paper #46

The Saskatoon Productivity Program

I. S. Evans, M.E.I.C.,
Head, Division of Information Services, Saskatchewan Research Council, Saskatoon

The author's observations in Saskatchewan industry showed that the largest single problem facing it is to find some means of using its resources, i.e. buildings, plant, tools, raw materials and people more efficiently or increasing its productivity. Believing this to come within the sphere of competence and authority of the provincial research council nd the Technical Information Service of the National Research Council an attempt, officially a pilot experiment, was nade to examine the productivity techniques now used and o teach them to foremen and management.

The second phase of the experiment will be to see if hese conventional techniques need to and can be modified o suit Saskatchewan conditions better. This paper is an account of the activity in Saskatoon to date.

AGM Paper #47

A Simulation of the Economy of British Columbia—A Guide o Industrial Development

R. E. Boston, JR.E.I.C.,
Assistant Professor of Mechanical Engineering, University of British Columbia

This paper describes the concept of the Leontief Input-Output Analysis method as a predictive device for estimating the magnitude of changes in an economy. More specifically, the feasibility of using Input-Output Analysis is examined here as a means of evaluating a proposed industrial development program for the province of British Columbia.

Thus this presentation is to be viewed only as a first step toward the final goal of actually specifying an industrial development program over a definite time interval. Several industrial development questions are presented along with preliminary results to indicate the usefulness of the simulation. The details are to be the subject of another paper.

AGM Paper #48

Modern Techniques Solve Unusual Log Driving Problem

C. E. Davidge,
Assistant Hydraulic Model Engineer,
Hydro Electric Power Commission of Ontario, Toronto
D. M. Foulds, M.E.I.C.,
Hydraulic Model Engineer, Ontario Hydro.

This paper illustrates that techniques common to applied research work may be adapted to solve a complex log driving problem. An extension to the Cameron Falls Generating Station on the Nipigon river caused changes in the currents in the forebay, which affected the log driving operation of the Abitibi Power and Paper company. Large quantities of wood collected on the racks of the powerhouse and logs were jamming between the guide booms some distance away from the entrance to the log chute. The extent of the affected area was determined by a float survey which also indicated the magnitude and direction of the surface currents. By moving the booms so as to parallel the direction of movement, a moderate improvement was achieved, however it was evident that some additional force was required to keep the logs in motion. Flow developers were considered to offer the most promising solution but this was checked before field testing by constructing a 1:24 scale model of the headpond and of each developer. The solution derived from the model tests was verified by the field trials where one full season of operation has been successfully completed.

AGM Paper #49

Marine Waste Disposal

Erman A. Pearson,
Professor of Sanitary Engineering, University of California, Berkeley, Calif.

A marine waste dispersion system is a functional component of the total treatment facility and should receive appropriate attention in conception and design. The first step in the rational development of a waste disposal system is resolution of the beneficial uses of the receiving water and the water quality criteria necessary to protect the uses. Studies of the physical, chemical and biological characteristics as well as the waste assimilating capacity of the receiving water are necessary to locate properly the terminal facility, estimate performance and to design the dispersion system.

The significant oceanographic factors affecting the design of coastal dispersion systems are discussed, and particular attention is given quantitation of nearshore circulation systems, current structure, density-temperature structure, and eddy diffusivity coefficients.

A rational method is presented for computing the concentration of waste in waste-sea water dispersion plumes including the initial mixing as well as the subsequent eddy diffusion. Solutions to the classical diffusion equation considering both point and line sources and constant and variable diffusion coefficients are presented. Application of these equations perimts a quantitative appraisal of the cost and benefit of various degrees of waste treatment and corresponding outfall and diffuser systems for attainment of water quality criteria.

AGM Paper #50

The Champlain Bridge—Steel and Prestressed Concrete Crossing of the Saint Lawrence River

Boris A. Hesketh, M.E.I.C.,
Associate Professor of Structural Engineering,
Concrete and Structural Laboratories,
Ecole Polytechnique, Montreal

A general description of the Bridge is given and some of the methods of construction used in the building of the prestressed concrete sections examined.

The Champlain Bridge, when completed, will connect the Island of Montreal with the South Shore Communities of the Saint Lawrence River. It will constitute a greatly needed addition to the roadway traffic capacity of the three existing bridges—Jacques Cartier, Victoria and Honoré Mercier. A six-lane highway is provided for, along the entire length of the bridge, with a possibility of a seventh-lane addition between the Island of Montreal and Nuns' Island. The total length of the bridge, including the approaches, will be in excess of 4 miles and the cost is estimated as $35,000,000.

AGM Paper #51

Concepts and Economics of Extra Long Distance Direct Current Transmission and System Intereonnection

H. L. Briggs, M.E.I.C.,
Member, National Energy Board, Ottawa

This paper is an economic feasibility study relating to the place which high voltage direct current transmission would have in relation to the development of Canada's remote hydro power potential, if high capacity DC conversion and control equipment were developed for commercially dependable operation.

Studies of extra long distance (600 to 3000 mile) transmission systems indicate the need for very high annual load factor loadings of high value power if in an economic sense such a system is to be justifiable. A single line is not a consideration since its reliability is zero; on the other hand while good results can be obtained from a 2-circuit system, near optimum results are available from a 3-circuit parallel system, cross-switched at appropriate intervals. This development of DC transmission has not been proposed by others as far as is known, perhaps by reason of the lack of DC switchgear.

A conclusion reached by the author is of the real need which exists today for research into and development of direct current equipment such as will enable remote Canadian power resources to be transported to load centres, not via an all-purpose national grid, but on a point-to-point basis custom tailored for each specific project combination.

AGM Paper #52

Electronic Aids in Canadian Mapping

J. T. Henderson, M.E.I.C.,
Applied Physics Division,
National Research Council, Ottawa

A number of electronic systems, described briefly, are employed to expedite map making in this country. Their use has effected great economy of time and money. Conspicuous successes have been achieved in the case of distance measurements, as illustrated by the use made of Shoran, tellurometer and geodimeter. In an attempt to present an overall review other specialized equipment for use by the hydrographer and the photogrammetrist is also mentioned.

AGM Paper #53

Sewage Stabilization Ponds for the City of Saskatoon

D. R. Stanley, M.E.I.C.,
Consulting Engineer,
Stanley Grimble Roblin Ltd., Edmonton;
E. J. Cole, M.E.I.C.,
City Engineer, City of Saskatoon, Sask.

About twelve years ago, the State Health Department in North Dakota began approving the use of open ponds for the treatment of raw sewage and this practice has spread rapidly to many midwestern States in the United States and to Canada. These ponds have sufficient surface area to assure aerobic conditions but in the past two years, short detention ponds have been built to provide anaerobic biological treatment.

Sewage from the City of Saskatoon is discharged to the South Saskatchewan River with about 85% of the flow being comminuted prior to disposal and the rest going into the river raw. Some pressure has been exerted on the City to treat its sewage and a study of the problem has been made. The study considered the use of conventional primary treatment and aerobic and anaerobic stabilization ponds.

An analysis indicated that aerobie ponds would compare in cost to conventional primary treatment with anaerobic ponds being about one-half the cost of the other alternatives. It is feasible to construct small anaerobic ponds at a remote location to treat part of the sewage from the City and experience with the operation of these over the next few years should supply sufficient data to determine if this method can be used to treat all of the sewage from Saskatoon.

AGM Paper #54

Landslides in Over-Consolidated Clays

R. M. Hardy, M.E.I.C., *E. W. Brooker,* M.E.I.C. *and W. E. Curtis,* JR.E.I.C.

Many of the major rivers and streams in northern

Alberta, the Peace River block of British Columbia and the southern portion of the Yukon have cut through shale deposits which have been highly consolidated by the weight of glaciers many hundreds of feet thick. Engineering construction in these valleys frequently produces change in the stability conditions sufficient to precipitate major earth movements. Experience to date in the area has shown that it is very difficult to determine by conventional subsoil exploration methods where such instabilities will develop. Moreover, conventional methods of stability analysis are inadequate to accurately assess the stability of these slopes as they exist naturally or as they may be modified by engineering works.

In recent months very complete investigations have been undertaken at two locations where major instability has developed incidental to road and bridge construction. This paper describes for these two sites the conditions encountered and the investigations made; shows the inadequacies of conventional methods of stability analyses when applied to these conditions, and presents a modification to the conventional effective stress stability analysis which appears to permit a reasonably accurate assessment of the stability conditions to be made. The significance of the modified stability analysis in the design of corrective measures to improve the stability conditions is also discussed.

AGM Paper #55

The Planning of the Avalanche Defence for the Trans Canada Highway at Rogers Pass

P. A. Schaerer, M.E.I.C.,
Snow & Ice Section, Division of Building Research, National Research Council, Ottawa.

The Rogers Pass section of the Trans Canada Highway is threatened by numerous avalanches which are mainly the result of the heavy amount of snowfall and the steep, long mountainsides. In 1953, at the same time when the highway route was first studied, an avalanche survey was organized to obtain the information required for the formulation of an avalanche defence plan, for the design of avalanche defence structures and for the future avalanche warning service.

This paper describes the observations that were made and how they were used for the formulation of an avalanche defence plan. The various possible defence methods are discussed and the defence chosen for Rogers Pass is outlined.

AGM Paper #57

A Research Viewpoint on Engineering Education

B. G. Ballard, M.E.I.C.
Vice-President Scientific and Director
Radio and Electrical Engineering Division,
National Research Council, Ottawa

Canada's engineers have served her well in the development of her primary industries. Some came from Europe and some from the United States, but Canadian universities very early initiated engineering training, and many of the men who contributed so much to country's growth were born and trained in Canada. The universities discharged their responsibilities well.

The pattern has ehanged in recent years. Canada emerged from colonial status and almost overnight became an industrial nation in a highly competitive world. The future demands men with new ideas, men who are imaginative enough and creative enough to make the best possible use of our resources. They must also have adequate training and encouragement to develop their creative talents, and these requirements clearly delineate the role of the university.

No longer can the universities be content only to impart to students the accumulated knowledge of the past. They must lead the way in creating new design techniques and new processes. They must look upon research not as an extra-curricular luxury to be financed by some benevolent outside organization, but rather as an essential element of university life. We need schools to impart knowledge of the past, but we need universities to develop knowledge of the future.

AGM Paper #58

The Hyraulics of the Pipeline Flow of Solid—Liquid Mixtures

G. W. Govier, M.E.I.C.,
Professor of Chemical Engineering, Dean of the Faculty of Engineering, University of Alberta, Edmonton;
M. E. Charles,
Research Engineer, Research Council of Alberta, Edmonton

Solids may be transported with liquids in pipelines, depending upon the particle size, density and concentration, either as non-settling or as settling mixtures. The conditions which determine in which manner a mixture will behave are discussed. Non-settling mixtures frequently behave as non-Newtonian fluids and at high concentration approach Bingham plastic behavior. The pressure drop, flow rate relationships for Bingham plastics and pseudo plastics are reviewed.

Settling mixtures cannot be treated as single phase systems except under conditions of high turbulence. Experimental pressure drop, flow rate data and the durand empirical correlation are reviewed. The semi-theoretical equations of Newton et al are discussed and compared with actual data.

AGM Paper #59

Force Variation During the Formation of Continuous Segmented Chips in Metal Cutting

R. Salman, JR.E.I.C.,
Research Assistant, Queen's University, Kingston
W. B. Rice, M.E.I.C.,
Associate Professor in Mechanical Engineering Queen's University, Kingston.
L. T. Russell,
Naval Research Establishment, Defence Research Board of Canada, Dartmouth, N.S.

A recent paper (published in the Engineering Journal) described the mechanism of formation of segmented continuous chips, and presented an explanation of chip-curl and cratering wear. Some speculation concerning the cutting force variation during the formation of an individual segment was involved. The paper describes the method of measuring the force variation and corelating it with the phase of segment formation in chips of 26S aluminum in which the segments were completely formed in .006 seconds. The results and the limitations of the method are presented. The research upon which this paper is based is supported (in part) by the Defence Research Board of Canada, under Grant DRB 9535-03.

SUMMARIES OF PAPERS TO BE PRESENTED AT THE SYMPOSIUM ON AUTOMATIC CONTROL BY THE JOINT NATIONAL RESEARCH COUNCIL ASSOCIATE COMMITTEE ON AUTOMATIC CONTROL AND THE ENGINEERING INSTITUTE OF CANADA JUNE 1, 1961, IN VANCOUVER

Paper AC-1

The Optimization of the Performance of an Ore Bridge, An Analogue Computer Study

by J. A. Field, Department of Electrical Engineering, University of Toronto.

As with many other manually operated devices there is little information available concerning what the optimum performance of an ore bridge could be. This study of the optimum performance of the ore bridge yielded information that would be useful in determining the economic practicability of additional control equipment to improve performance, and would aid in future design of such bridges. An idealized bridge and a control circuit to replace the operator were simulated on an analogue computer and optimum conditions found by repeated trials. The equations of the idealized bridge are developed and the necessary computer approximations described.

Paper AC-2

The Determination of Linear Multivariable Models for Complex Processes

by R. J. Kavanagh, Department of Electrical Engineering, University of Toronto.

In order to design a control system for a process it is necessary to be able to describe the dynamic behaviour of the process in some way, e.g. by means of a transfer function. In many practical situations the use of special test inputs such as sine waves or steps to determine a transfer function is not suitable and the process is so complicated that a theoretical derivation of an appropriate process description is not feasible.

A method which is applicable to such situations and which is becoming widely studied is that of utilizing the statistical properties of the process inputs and outputs recorded while the process is in normal operation.

The paper develops the theory of this method for multivariable systems by first discussing the identification problem, which involves the determination of the transfer matrix of an active linear multivariable system by statistical analysis of the system inputs and outputs. It is shown that the exact solution is not applicable to practical processes and the paper then derives the transfer matrix for the optimum linear multivariable model in the minimum mean square error sense. The formulation of this model is identical to that of the optimum linear multivariable filter. The derivation given in the paper is original in that it is carried out in terms of matrix quantities thereby reducing the mathematical complexity. An interesting result is obtained concerning the correlation of the errors which result when the model is optimum.

The paper concludes with an assessment of the practicability of the method and a qualitative discussion of the various factors which govern the accuracy of the model transfer matrix. A bibliography listing papers relevant to the statistical method of estimating system dynamics is given in an Appendix.

Paper AC-3

Economic Performance Criteria for Optimizing Control Systems

by J. H. Milsum, Division of Mechanical Engineering, National Research Council, Ottawa.

The subject of economic performance criteria for optimization of control systems is considered after a brief review of conventional dynamic performance criteria, and the general concept of optimizing control. For economic optimization, the sum of operating costs is driven to a minimum value. These costs may be divided into "error penalty" costs and "power" costs which are functionally related to signals within the control loop, and which are "traded-off" against each other for a minimum. Examples illustrate the analogy of this method to that already used in engineering design and industrial management. Finally basic techniques are briefly reviewed for "hill-climbing" the performance criterion.

Paper AC-4

A Continuously Acting Adaptive Analog Computer for Determining the Impulse Response of Control Systems with Gaussian Signals.

by E. V. Bohn, Department of Electrical Engineering, University of British Columbia.

It is shown that the autocorrelation and cross-correlation functions of signals with a gaussian amplitude distribution can be determined from switched correlation functions. These are obtained by using the zero cross-overs of one signal to operate a gate which selects the positive or negative value of a second signal. A delay line for the zero cross-overs can be readily instrumented. Applications of this method to determine the impulse response of a feed-back control system are discussed. An analog computer is described which automatically adjusts itself to signal level and system bandwidth variations. Figures of merit and functionals of the error are easily determined at the output for adaptive control system optimization.

Paper AC-5

The Control System of an Automatic Stereo Mapping Machine

by J. M. Ham and G. L. Hobrough, Department of Electrical Engineering, University of Toronto and Hunting Associates Limited, Toronto, Ontario, respectively.

An automatic photogrammetric plotting instrument employing multiple-loop adaptive servos is described. The mechanical function of detecting and removing parallax from the stereo model is performed automatically by this instrument.

The detection of parallax between two images requires that corresponding points in the images be identified. In the Stereomat, a small area is scanned by a spot of light moving in a random pattern. Fluctuations in the light produced by the scanning spots crossing image boundaries are sensed by a separate photo-elcctric cell for each photograph. Signals from the two photo-electric cells are processed electronically to produce X and Y error voltages. The error voltages actuate servo motors which continuously adjust the geometry of the optical systems to reduce parallax to acceptably low values. The Y parallax nulling servo orients the projectors to correspond to the orientation of the serial cameras at the moment of exposure. The X parallax nulling servo effectively locates a reference point on the surface of the terrain in the servo model.

The magnitude and azimuth of terrain slope are computed by additional circuitry and steering signals are derived which enable the reference point to trace out constant height contours or paths of steepest descent. Both the size of the scanning pattern and the velocity of tracing are continuously optimized in response to image and terrain conditions.

Paper AC-6

Process Loop Optimization Through Valve Characterization Techniques

by G. L. d'Ombrain and S. M. Lyle, Department of Electrical Engineering, McGill University, Montreal, Que.

The performance of a linear process control system based on three cascaded first order lags controlled by a proportional-plus-integral controller and using both linear and exponential control elements is analysed and demonstrates the marked inferiority of the exponential valve for desired value system disturbances despite its beneficial effects for load value disturbances. An element which has two discrete gain values which are a function of its own output and of an incorporated dead space is then introduced into the forward loop between the controller and the control valve. It is shown that this arrangement gives improved results when based on the criterion of the minimum of the moment of the error squared for systems subjected to both load and desired value changes.

Paper AC-7

The Optimal Gain of Manually Controlled Machines.

by C. B. Gibbs, Defence Research Medical Laboratories, Toronto.

A spot of light on a CRT was controlled by a joy-stick, the operator's task being to effect uniform display movements with the highest possible speed, to a specified level of accuracy.

The thumb, hand and forearm were used in control and the extent of their movement was varied by altering the control gain. The speed of display movement was varied by introducing exponential lag between control and display. The effects of these variables were explored in positional and velocity control systems, and comparisons were based on the time taken for accurate display movements.

It was found that the optimal gain of the positional system depended on the lag; formulae were derived to express the relation. The optimal gain of the velocity system was independent of lag, and its value was computed.

In the positional system, control by the hand was superior to either thumb or forearm. With zero lag, increased gain (decreased limb movement) markedly reduced the accuracy of thumb control; there was much less deterioration with the longer limbs in these special conditions. Changes in gain had similar effects on all limbs in all the other experimental conditions, and in the velocity system.

It is concluded that rapid limb movements are continuously monitored and terminated by kineaesthetic feed-back from muscles and joints. Display movements in positional systems, however, must be terminated by visual cues, when exponential time lags are present. The same need arises in velocity systems with or without exponential delays, because of the phase lag between control and display movements.

The main theoretical issue is whether 'open-chain' or 'closed-loop' principles are used in controlling voluntary movements. The implications of this problem for current theories of learning and the transfer of skill are briefly discussed.

Paper AC-8

Relable Networks from Unreliable Components.

by Miss O. Boshko, G. S. Glinski, M.E.I.C., *and J. Therrien, Electrical Engineering Department, University of Ottawa.*

This paper is concerned with the study of the reliability of logical digital networks. It discusses how the reliability of such a network can be improved by properly interconnecting basically unreliable elements.

A given logical function can be represented by a suitable arrangement of components in a net. The theory of graphs can be used as a mathematical model for a study of the properties of such networks.

A summary of the work on logical nets is given with special emphasis on the work of von Neumann and Shannon, on the reliability of such nets. Although both come to the conclusion that a net can be made as reliable as desired by adding more elements, their methods differ in the redundancy required.

The introduction of the majority element greatly simplifies the structure of logical circuits. The work of McCulloch using these elements is discussed. He found that certain networks are "logically stable" under the effect of changes in the thresholds.

Experiments on logical nets are described. The first is a test on the "learning" ability of such network. An experiment on reliability is then described in which measurements are made of the changes in the "learning" properties of the network as some of its elements become defective.

Finally it is suggested that these studies should be extended to include pulse-rated asynchronous circuits, and should also be oriented toward the consideration of the proper balance between component and signal redundancy.

ANNUAL MEETING PREPRINTS

Preprints of all Annual General Meeting papers abstracted on the preceding pages will be available at the Meeting in Vancouver. They also can be obtained from The Engineering Institute of Canada, 2050 Mansfield St., Montreal 2, Que.

AUTOMATIC CONTROL PREPRINTS

Preprints of all papers to be presented at the Symposium on Automatic Control by the joint National Research Council Associate Committee on Automatic Control and The Engineering Institute of Canada also will be available both at the Meeting and from the E.I.C. The charge for these preprints will be announced at the Meeting and in the June issue of the Journal.

Canadian Developments

Studies in Air Pollution under way

An extensive research project has been put into operation in the fields of industrial hygiene and air pollution. This is part of a two-phase approach to the problems being taken by the Institute of Industrial Hygiene and Air Pollution of the University of Montreal.

The entire program is expected to take between seven and 10 years. Following the initial three-year phase the Institute will involve the provision of specialized personnel, laboratory space and equipment.

Assisting in the first phase were grants-in-aid given by the Department of National Health and Welfare, and grants from private sources.

At the University of Montreal a study of the pneumoconstriction effect of dust and on the pneumodilatation effect of certain aersols on the lungs is being undertaken by the Physiology Department. A grant to Dr. Hans Selye of the Institute of Experimental Medicine and Surgery of the University will assist his study of the mechanism of penetration of toxic substances through the skin.

These projects initiated by the Institute are considered extramural. A grant from the Department of National Health and Welfare will enable the Institute to study the insecticide problem in relation to health in the Province of Quebec. This is the Institute's first intramural project.

In the second phase research projects and teaching could be concentrated in the Institute where a congregation of specialists would permit a team approach to the many current industrial hygiene and air pollution problems requiring investigation. The consultants and an advisory committee would consider whether facilities existing in other University departments should be duplicated.

The Institute was established in May, 1960, and was approved by the Quebec Department of Health under a federal-provincial agreement.

Initially, a survey financed by the Department of National Health and Welfare was conducted in several countries where institutes devoted to the subject are operating. This survey followed extensive discussions between Dr. Kingsley Kay, Senior Scientific Consultant, Department of National Health and Welfare, and Dr. F. J. Tourangeau, Director of Industrial Hygiene, Quebec Department of Health.

The need for an institute in Montreal was indicated by the changing economic structure of Quebec. At the end of the Second World War, two-thirds of the province's population lived in rural areas. Now about two-thirds of the five million persons in Quebec live in urban areas.

Distinguished consultants from Europe and North America devoted their efforts in organizing the Institute's program.

The Institute staff now includes: Director Dr. Tourangeau who also is professor of Industrial Health and Air Pollution; Sarto Plamondon, Assistant Director who is Associate Professor of Industrial Hygiene; Dr. Kingsley Kay, Senior Consultant on a part-time honorary basis; and consultants in toxicology, physiology, physiological hygiene and industrial hygiene engineering. Other consultants will be secured in the fields of chemistry, physics, otology, ophthalmology and psychological hygiene.

The teaching program will be made subject of special study by organizational staff and consultants in collaboration with University authorities and appropriate professional organizations. It will be directed towards undergraduates and graduates in science, medicine, nursing, engineering and chemistry.

Self Sufficient Sewage Treatment Plant

The Iona Island Sewage Treatment Plant which is to be completed in late 1962 is designed to grow with the needs of Vancouver. Its peak flow will be 340 million gal. per day and will serve a population of 640,000. The plant will be a model of self-sufficient operation. Sludge gas produced from the plant's digestors will provide fuel for the engines that operate the plant. No more than 18 men will be needed for round-the-clock operation and maintenance.

The plant, for primary treatment of sewage, was designed to handle both sanitary and storm water flow particularly in wet weather peaks.

The operating cycle of the plant starts with the inflow of raw sewage through three 66 in. concrete siphons under the north arm of the Fraser River. The raw sewage is pre-chlorinated on entry to the plant and then goes to the pump building where screening and grinding takes place. Speed pumps lift the sewage to the grit chambers where the flow is slowed down so that coarse grit will drop out. This grit is carried away daily for use as on-site fill. From the grit channels the flow passes through five preaeration tanks. Air is blown through the flow to settle out the fine grit and aid in the sedimentation process. When the flow continues on through five sedimentation tanks it is maintained at a velocity low enough to get rid of organic material.

The two digestion tanks are the heart of the treatment process. They are 80 ft. in diameter, 35 ft. deep and each has a floating cover. Digestion is most effective when the sewage which has now become sludge is maintained at a temperature of 90° to 95°F. Circulation pumps constantly withdraw the sludge from the tanks and pump it through the adjoining sludge control building where it is heated, using waste heat from the engines which operate the plant.

The digesting process produces gas which makes possible the economical operation of the treatment plant. This gas, called sludge gas, is about 70% methane, and plays two roles in the plant operation. It is bubbled back through the digestors to assure intimate mixing of raw and digesting sludge. This improves the digestion process. Secondly, it is used to fire the main engines which generate power for the whole plant. This gas can be fed directly to the engines or compressed and stored for future use. Should there be any failure in the gas system, the engines automatically switch-over and would be operated on diesel fuel.

After a 30-day cycle in the digestion tanks the sludge is pumped to four sludge lagoons west of the Plant. The clarified effluent left enters a four-mile outfall channel which carries it out over Sturgeon Bank to mix with the tidal currents off the mouth of the Fraser River.

International News

Philippines Copper Plant

An integrated copper, zinc and ammonium sulphate plant to change ores into finished copper products is to be constructed in the Philippines at a cost of $23 million. Chemical leaching, gaseous reduction, and newly-developed rolling methods will turn low-grade ores into high quality copper powder without a melting step at any point in the process.

The capital cost of this installation to produce high purity copper should be 40% less than conventional smelting, refining and casting plants. The process to be used at Marinduque will make it possible to get high grade copper products from any starting material currently used by the copper industry. Complex ores such as copper zinc combinations can be handled more effectively than by conventional methods. Also, the capital cost of facilities to produce strip and tubing from copper powder will be at least 50% less than for conventional fabricating techniques starting from cake, ingot or billets.

The Export-Import Bank of Washington, D.C., has approved a $13 million loan to Marinduque Iron Mines Agents, Inc. for construction of the plant. This amount will be matched by Marinduque in pesos.

Jesus Cabarrus, president of Marinduque, said that the new plant will have important effects on future copper producing facilities and will produce immediate improvements in the economy of the Philippines. For the first time the new island republic will have an integrated copper industry capable of meeting all its copper requirements. Not only will the new plant produce approximately 14,000 tons per year of fabricated copper products, but it will also produce an estimated 100,000 tons per year of ammonium sulphate fertilizer. Fertilizer is badly needed in the Philippines for the production of sugar and rice. Zinc, at the rate of about 5,000 tons per year will be available either as zinc oxide or electrolytic zinc particularly for use in the galvanizing industry.

Output of this integrated copper-zinc-ammonium sulphate facility is estimated to yield, at current U.S. prices, an equivalent annual value of approximately $18.5 million for Marinduque. It could result, too, in a net annual saving of $10 million in foreign exchange for the Philippine economy.

Mr. Cabarrus feels that the establishment of this integrated primary industry would have other advantages for the Philippines. The new Marinduque plant will need 1,000 employees. Small manufacturing facilities to produce items such as air conditioning equipment, radiators, decorative metal products, weather stripping, hardware and electrical appliances would be established. A hydroelectric power plant program under way is aimed at increasing the living standard of the Philippines. The availability of domestic copper wire undoubtedly will be important to this program.

Every step or phase of the process has been proven in commercial operation in various North American installations. The ores from Marinduque mines have proved suitable to this type of operation.

Helicopter Completes Steel Tower

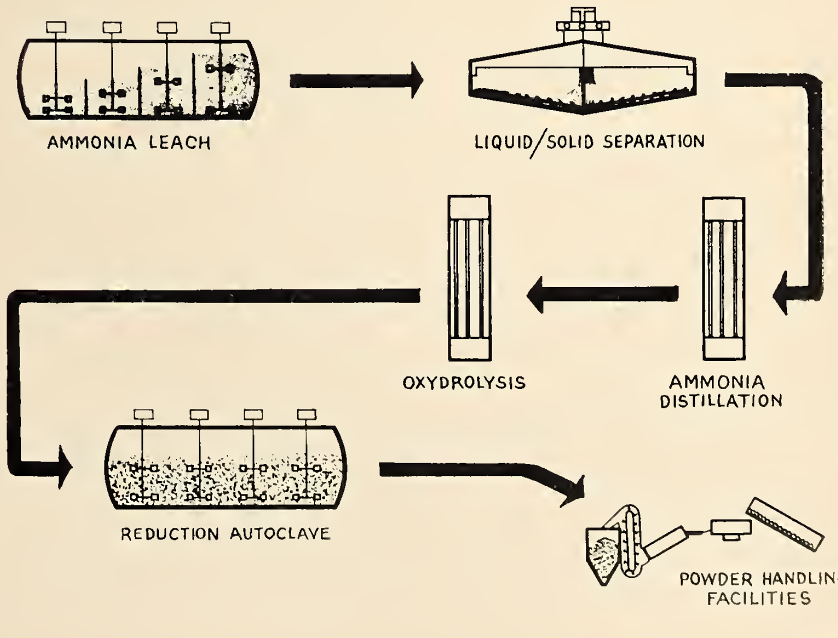
A steel transmission tower in Coos Bay, Oregon was completed by helicopter four days ahead of schedule.

A barge-mounted crane erected the lower 111 ft. of the 200 ft. tower on concrete footings. The remaining pre-built sections weighing between 500 and 1,200 lb. were laid out in order of assembly on the shore about 1,000 yd. from the tower. As the helicopter hovered low over the staging area, the ground team hooked each steel section to its cargo hook. Once above the tower, the helicopter hovered steadily with each steel section until signaled into position. When the assembly was bolted in place the pilot pressed the electrically controlled cargo hook release and flew back for another load.

Average time for each delivery round trip was under five minutes. Thirty structural assemblies plus insulators were delivered in this way.

The project, the first of two similar towers built to span 115,000 v. lines across ocean shipping channels in Coos Bay, is part of a four-mile powerline now under construction to serve a new paper mill.

This Simplified Diagram shows the major steps in the chemical process of producing pure copper powder from ores. With no melting steps anywhere in the process, the chemical method of refining offers great cost advantages from an equipment and operating standpoint.



Month to Month

Executive Committee

A meeting of the Executive Committee of Council was held in Montreal, April 8. President Dick was Chairman. Following are highlights of the meeting.

Financial Statement

F. L. Lawton, Chairman of the Finance Committee, presented the financial statements for February, 1961. He said the Finance Committee considered the statements to be satisfactory in the light of general economic conditions and that the Institute can be reasonably confident of its position. He noted that since the Institute's accounting system began operating on an accrual basis, the Finance Committee is able to maintain the closest possible supervision of financial operations.

Branch Officers Meeting

The General Secretary reported that the second of a series of meetings with regional groups of branch officers was held in Niagara Falls, March 24. This meeting was in line with an experimental policy of trying to utilize the General Secretary's travel time more effectively. The meeting was considered very successful and the branch officers were able to discuss matters which are not normally considered during more formal presidential visits.

Southern Ontario Conference

The General Secretary reported that the Third Southern Ontario Regional Conference, held in Niagara Falls March 25, had been very successful. Approximately 300 persons registered for the conference. A complete report will be available at a later date.

1962 Railroad Conference

It was reported that the Institute had informed the American Society of Mechanical Engineers that it was interested in becoming a co-sponsor of the ASME-AIEE Railroad Conference tentatively scheduled to be held in Toronto in April, 1962. This offer has been accepted.

Activities of Officers

President Dick reported that he had addressed the inaugural meeting of the Port Credit Branch March 24, the Third Southern Ontario Regional Conference March 25, and had visited the Sudbury Branch and Kirkland Lake region.

Vice-President Lawton said he was to visit Quebec City April 10 to address a joint meeting of the EIC and the AIEE.

Vice-President Cross said there is an excellent reaction from branches to visits from a Vice-President. He considered this practice well worth continuing. He reported on visits to the Chalk River, Orillia and Peterborough Branches, and student meetings at Hamilton and London. Before the season ends he plans to visit Cornwall, Sarnia and Kingston.

Public Relations

Following a discussion concerning the need of projecting the Institute's "image", and methods of accomplishing this, it was resolved that the President be empowered to appoint an ad hoc committee as soon as possible to study the proposed terms of reference of a Public Relations Committee. This ad hoc committee is to be requested to present its recommendations to Council at the Annual Meeting.

Relationship with A.P.E.O.

Following discussion concerning the Institute's relationship with the Association of Professional Engineers of Ontario it was decided that the E.I.C. publish a clear statement of policy regarding co-operation with A.P.E.O. This statement is to be published in the Journal, and distributed to Councillors and Branches in Ontario.

Career Development

The need for the Institute to investigate and improve its provision of vocational information was discussed. It was felt that a national E.I.C. Committee could provide valuable assistance to this end.

Following discussion it was resolved that a Committee be appointed to explore this field with a view to giving assistance to Branches and encouraging E.I.C. Branches in university centres to provide guidance to students. It was agreed that the Committee be known as the Committee on Career Development.

National Productivity Council

The General Secretary stated he had received comments from senior officers and members of the Institute concerning the fact that the Federal Government failed to appoint an engineer, primarily because of his engineering qualifications, to the National Productivity Council.

It was resolved that a letter be sent by the Institute to the Prime Minister expressing its regret and concern regarding the fact. The letter, addressed to Mr. Diefenbaker, follows:

Dear Sir:

National Productivity Council

The Engineering Institute of Canada notes with approval the principle of the Federal Government's constructive attitude toward the promotion of the efficient utilization of Canada's resources, manpower, and industrial efficiency; as expressed in the appointment of the National Productivity Council.

It is a matter of regret and concern to this Institute that the government apparently has failed to recognize the direct connection between all of the stated objectives of the National Productivity Council and the engineering profession in Canada.

'Productivity" implies the application of science and technology, and it is believed that the major concern of the Council will be engineering and technological problems, and their relationship to problems of labour management, and resources.

It is the opinion of The Engineering Institute of Canada that the membership of the National Productivity Council should include at least one appropriately qualified engineer, appointed primarily because of this qualification.

If future appointments are made to the Council, The Engineering Institute of Canada urges that an appropriately qualified engineer be appointed, in his capacity as an engineer.

Yours truly,
Garnet T. Page, M.E.I.C.
General Secretary

E.C.P.D.

The second term of Colonel W. S. Wilson as one of the E.I.C. representatives to the Engineer's Council for Professional Development expires next October. Colonel Wilson is not eligible for re-appointment. It was resolved that Mr. G. Demers be appointed to the E.C.P.D., replacing Colonel Wilson.

African Students

The General Secretary said McGill University students are required by the Faculty of Engineering to obtain six months of practical experience in Canada before a degree is granted them. A problem has been encountered with African students, many of whom are studying in Canada under Commonwealth aid sponsorship. Because they are not permanent residents of Canada, many companies do not offer them work as they are unlikely to be prospective permanent employees. McGill asked the Institute to assist the students in finding summer employment since this is a definite requirement if they are to obtain their degree. The Institute agreed to help these students in any way possible.

Technological Education

The Institute has been invited to be represented at the National Conference on Technological Training May 9-10, 1961, in Ottawa.

It was resolved that Dean D. M. Myers of the University of British Columbia represent the Institute at the Conference.

Striking Committee

On the recommendation of the President-elect it was resolved unanimously that Dr. K. F. Tupper be named Chairman of the Striking Committee for 1961.

UNESCO

The Institute has been appointed a Rotating Member of the Canadian National Committee for UNESCO for the period 1961-63. It was resolved that Dr. K. F. Tupper of Toronto be appointed E.I.C. representative, and the General Secretary be appointed E.I.C. alternate representative to the Canadian National Commission for UNESCO for this period.

Third Southern Ontario Regional Conference

Eight branches participated in the Regional Conference held at Niagara Falls, March 25. They were Border Cities, Hamilton, Kitchener-Waterloo, London, Niagara Falls, Oakville, Sarnia, and Toronto.

The keynote address was given by The Hon. Robert Winters, president, Rio Tinto Mining Co. of Canada. Mr. Winters outlined the challenge which engineers in Canada face today. He commented on the challenge to the technical and creative skills of the engineer which exist in our society. At the turn of the century, we had half a dozen or less branches of engineering which were recognized and broadly practised; now we have many times the number of acknowledged spheres of engineering endeavour. Mr. Winters concluded: "The engineer today, more than ever before, is meeting the challenge in making his training available in solving a wide spectrum of problems. The engineer plays his full role only when he accepts responsibility in these broader fields of administration and public service and when he is prepared even to run for public office."

The technical program included address by Alec G. Lester, M.E.I.C., Vice-President, Bell Telephone Company, in which he described, with the aid of a film, the use of satellites for intercontinental telephone calls. Rod Martin, Regional Manager, Western Division, International Underwater Contractors, gave a talk on "Underwater Engineering". Brian Palmer, Technical Services Representative, Dow Chemical of Canada, outlined the techniques employed in producing Polystyrene. R. Ross, Director of Engineering, O'Keefe Brewing Company gave an address on "Engineering as Training for Management". E. W. Hill, Utility Sales Manager, Canadian Westinghouse Co. Ltd. gave a talk entitled "Can Industry Generate Electric Power Economically?" W. C. Kimball, Assistant Chief Metallurgist, Algoma Steel Corporation, gave a review of the history and development of structural steels since 1920 entitled "A New Look at Structural Steels". Approximately 300 persons attended the meeting.

Shown at the highly-successful Third Southern Ontario Regional Conference are, from the left: Hon. Robert Winters, M.E.I.C., President, Rio Tinto Mining Company of Canada, Ltd.; Mr. R. Denham, Conference Chairman; President Dick.

Additional Report

The Report of the National Development Program Committee was not included in the 32-page Report of Council, Committees and Branches of the E.I.C. which appeared in the April issue of the Journal. Following is the report:

During the past year P.D.P. has served the needs of engineers in those centers where this movement has been organized, by providing non-technical programs to stimulate interest and understanding of the topics outside their chosen field of activity.

The effectiveness of the movement has been dependent on the receipt of reports from the Corresponding Members of each operating group.

Because of the national character of the Engineering Institute of Canada intercommunication has often been difficult to promote and maintain, however with the enthusiastic cooperation of the Corresponding Members the hope is cherished that the National Executive will continue to receive regular reports from the operating groups.

Saturday June 18, 1960 a Regional Conference was held at Hamilton when progress reports were received from Toronto, Sarnia, London, Brockville, Niagara Falls, Kitchener and Hamilton. The general concensus indicated that a high level of interest was being maintained in P.D. activities. In Western Canada enthusiastic groups are in operation at Vancouver, Kootenay, Calgary and Winnipeg. Inquiries have been received from other branches expressing their desire to organize P.D.P. groups, and in each case information has been disseminated by the National Committee to assist them.

The Hamilton group records the successful sponsorship of a course on Economics, as prepared by the Canadian Association of Adult Education. The feeling exists that this material can be used in the coming years with continued success. C.A.A.E. material covering several fields can be beneficially included in P.D.P. groups, especially in the smaller centers.

Non-technical training of engineers continues to be of utmost importance in developing citizens who can fulfill their responsibility in society.

E.I.C. ELECTIONS AND TRANSFERS

A number of applications were presented for consideration and on the recommendation of the Admission Committee, the following elections and transfers were effected at a meeting of council on February 25, 1961.

STUDENTS ADMITTED

University of Laval: R. Arcand, M. Arsenault, G. Beaulieu, H. Begin, A. Belanger, Y. Belanger, J. P. Bilodeau, L. A. Blouin, J. M. Boivin, H. Bonneau, A.

(Continued on page 132)

OFFICE OF THE PREMIER

PROVINCE OF BRITISH COLUMBIA

VICTORIA
1 9 6 1

April 7th

Mr. G. McK. Dick,
President,
Engineering Institute of Canada,
2050 Mansfield Street,
MONTREAL 2, QUEBEC.

Dear Mr. Dick:

Probably nowhere in Canada is the vital role of the professional engineer better appreciated than here in British Columbia, where we have seen in the years following World War II the greatest per-capita growth in the nation.

Development projects of international repute have marked almost every year of British Columbia's post-war history, and we are confident that the wonders of technological progress are just beginning for our province. One has only to consider, for example, the immense hydro-electric projects about to be undertaken on the Columbia and Peace Rivers to realize that the time-tested phrase, "Land of Opportunity", still has real meaning in British Columbia for all who believe that big dreams can be made big facts.

To the members of the Engineering Institute of Canada who join us, I know, in bringing these dreams to reality, I am accordingly most happy to extend the heartfelt welcome of the Government and people of British Columbia. We are confident that your 75th Annual Meeting opening May 31st in Vancouver will be an outstanding success, and we hope that you will take time from your deliberations to enjoy the hospitality which our province is eager to extend to you.

Most sincerely,

Premier

NEWLY ELECTED OFFICERS OF THE INSTITUTE

At the Annual Meeting, three vice-presidents and 34 councillors will take office and will serve with others whose terms of office continue. The complete list of council members will appear in the June issue.

Francis Mott Cazalet, M.E.I.C. was elected vice-president of the Institute for Zone "A" — the Western Provinces.

Mr. Cazalet is Gas Sales Engineer with the B.C. Electric Company Limited. Since becoming a member of the Institute in 1945 Mr. Cazalet has been active at all levels. He has served as Vice-chairman, Chairman and past Chairman of the Branch, as well as holding the office of Councillor.

The Western Vice-President's non-professional activities include the Toastmaster Club of which he is Area Governor. He is president of the Vancouver Y.M.C.A. swim team and is a director of the Vancouver Y.M.C.A.

F. M. Cazalet, M.E.I.C.

P. E. Buss, M.E.I.C.

Paul E. Buss, M.E.I.C., elected Vice-President for Zone "B", the Province of Ontario, joined the Institute as an associate member in 1927, 12 years after he graduated from the University of Michigan.

Mr. Buss, whose home is in Thorold, Ont., brings to the Vice-Presidency a history of long service to the Institute's Niagara Peninsula Branch. He served several terms as Councillor, the first in 1937, and was a member of the Board of Management, Ontario Division, 1956-61. He was Branch Chairman for one year and Secretary for one year.

Vice-President Buss was a member of the Thorold Town Council for 10 years and president of the Thorold Board of Trade for five years. He has served as Chairman of his local Red Cross organization and has assisted in the activities of such organizations as the V.O.N.

Mr. Buss was born in Three Rivers, Michigan, and during World War I served as a sergeant with the United States Army Engineers in France. He then was with Provincial Paper Limited at the Company's Head office in Toronto, then as engineer on construction of the first sulphite plant at the head of the lakes at Port Arthur.

He later was on the engineering staff of Dominion Engineering Works, and for a number of years was plant engineer at the Thorold Division of Provincial Paper Ltd. During 1932-33, he and his two brothers carried on experiments in developing the new process for producing rock wool by the spinning method, since adopted in part by the entire industry. At present he is President of Spun Rock Wools Limited, Thorold.

Gerald N. Martin, M.E.I.C., Vice-President for Zone "C", Quebec, graduated from Ecole Polytechnique 27 years ago.

Mr. Martin joined the Institute as a Junior in 1937 and in 1944 became a Member. In the Montreal Branch, he served with the junior section and as a committee member. In 1952 he was chosen Vice-Chairman and the following year — became Chairman.

Vice-President Martin served as Councillor from 1954-56, during part of which time he was chairman of the Publications Committee. He was Institute Treasurer in 1958 and has served two periods on the Finance Committee. He was active in the work on the A.S.M.E.-E.I.C. International Council and the Institute's Committee on Technical Operations. He was a C.P.E.Q. Councillor 1958-60.

Two papers written by Mr. Martin concerning combustion and boilers resulted in two Phelps-Johnson prizes.

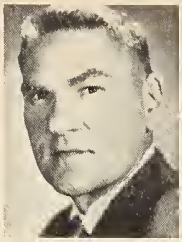
G. N. Martin, M.E.I.C.

T. A. Monti, M.E.I.C.

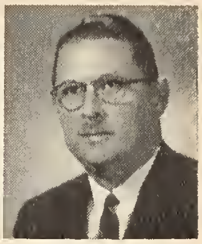
Thomas A. Monti, M.E.I.C. has been elected a Councillor representing Montreal Branch. Dr. Monti received his Civil Engineering degree in 1941 and 6 years later received his doctorate from University of Montreal. He was a member of the Montreal branch executive in 1950-51, was chairman of the branch's junior section and was president of the entertainment committee. He was vice-president of C.P.E.Q. in 1956 and was active in Corporation committee work. He is active in theatrical circles and with numerous charitable organizations. Prizes for papers written by Dr. Monti include the Ernest Marceau Prize, the Keifer Medal and the Duggan Medal.

Roger J. Harvey, M.E.I.C., was re-elected Councillor for Montreal. Mr. Harvey joined the Bell Telephone Company of Canada as an engineer in Montreal 15 years ago. He now is supervising engineer-Estimates and Design, Outside Plant Division, Engineering Department, Eastern Area. Mr. Harvey first became active in the Montreal Branch in 1949-50 when he served as Vice-Chairman of the Program Committee, then as Chairman of the Radio Communications Section. Subsequently he was Program Committee secretary, Secretary-Treasurer, ex-officio member of the Executive Council and Executive Committee member. In 1956 he became a member of the Admissions Committee.

Hugh Carey Brown, M.E.I.C. was elected Councillor for Ottawa. Mr. Brown graduated from McGill in 1926. He became active in Institute affairs following the war. He served as chairman of the Proceedings Committee of the Ottawa branch in 1956, was Treasurer in 1957-58, Vice-Chairman in 1959 and Chairman in 1960. He also was Chairman of the Joint Golf Committee in 1959. In 1960 Mr. Brown was Chairman of the Institute's Committee on Membership Procedures. He is a member of A.I.E.E. and the C.P.E.Q. During the war he was mentioned in dispatches when he was attached to the Signals Corps in Italy. Mr. Brown is a member of the Rideau Club and the Rivermead Golf Club.

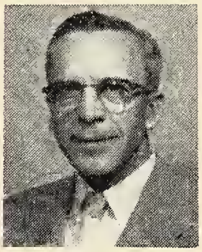


R. J. Harvey, M.E.I.C.

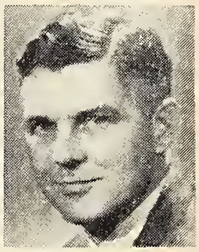


H. C. Brown, M.E.I.C.

Arthur M. Toye, M.E.I.C., elected Councillor for Toronto, is Bridge Engineer with the Ontario Department of Highways. Mr. Toye became a student member of the Institute while at University of Toronto, became a Junior in 1926 and a full Member in 1940. His activities with Toronto Branch include: member Branch Executive, 1957; Chairman Entertainment Committee, 1958; Branch Vice-Chairman and Chairman of the Papers and Meetings Committee, 1959; and Branch Chairman in 1960.



A. M. Toye, M.E.I.C.



C. Peter Jones, M.E.I.C.

C. Peter Jones M.E.I.C., elected Councillor for Vancouver is a partner in the consulting engineering firm of Read Jones Christoffersen. He received his B.A.Sc. degree from University of British Columbia in 1948, two years after he joined the Institute as a Student Member. He has served as Secretary, Vice-Chairman, and Chairman. He was Chairman of the Technical Papers sub-Committee of the Vancouver Committee for this year's Annual Meeting in Vancouver. He was also a member of the Institute's Committee on Membership. Active in local affairs, Mr. Jones was a member of the Board of School Trustees of North Vancouver, 1958-61 and served as Chairman last year. Other interests include skiing and swimming. He is a member of the Association of Professional Engineers of British Columbia.

L. C. Johnson, M.E.I.C., was chosen Councillor for Vancouver Island. Mr.

Johnson, Chief Bridge Design Engineer with the British Columbia Department of Highways graduated from U.B.C. in 1946. He served as a member of the Vaneouver Island Branch executive in 1957 and in 1958, was Vice-Chairman in 1959 and was Chairman in 1960.

L. C. Johnson, M.E.I.C.

J. Longworth, M.E.I.C.

Jack Longworth, M.E.I.C., Councillor for Edmonton, is an Associate Professor of Civil Engineering at University of Alberta and is a member of Consulting Structural Engineering, Kasten, Longworth and Associates Ltd. Mr. Longworth received his B.Sc. in Civil Engineering from the University of Alberta in 1945 and two years later received his M.Sc. degree from University of Illinois. He was an executive member of Edmonton Branch in 1957 and 1958, Young Engineers Committee Chairman, 1958, Branch Vice-Chairman and Chairman of the Program Committee in 1959. Mr. Longworth was elected Branch Chairman in 1960. He is member of Council of the Association of Professional Engineers of Alberta.

F. W. Catterall, M.E.I.C., Councillor for Saskatchewan, is Design Engineer with the Saskatoon firm of Underwood McLellan & Associates Ltd. Mr. Catterall was educated at the University of Saskatchewan where he joined the Institute as a Student Member in 1952. Four years later he became a full Member. He was Secretary of the Saskatoon Section 1959-61 and now is Chairman of that Section.

F. W. Catterall, M.E.I.C.

G. Flavell, M.E.I.C.

George Flavell, M.E.I.C., was elected Councillor for Winnipeg. Mr. Flavell, Sales Engineer, Apparatus Division of Canadian Westinghouse Co. Ltd. became a full Member of the Institute in 1956. In the Winnipeg Branch he has served as Papers Chairman and Vice-Chairman of the Electrical Section, and in 1958-59 as Chairman of the Electrical Section. He is a Councillor of the Association of Professional Engineers of Manitoba. He is a member of Toastmasters Skyliners. Other interests include photography and golf.

G. B. Starr, M.E.I.C., Councillor for Yukon branch is Territorial Engineer with the Yukon Territorial Government in Whitehorse. Mr. Starr graduated from the University of Manitoba in 1934 and before going to the Yukon was a member of the Vancouver Island, Vancouver, Central B.C., and Calgary Branches of the Institute. He was Chairman of the Yukon branch in 1959-60, and is Chairman of the Branch's Nominating Committee for 1961-62. He has been active in church, community, and professional affairs.

H. R. Hatfield, M.E.I.C., was re-elected Councillor for Central British Columbia. Mr. Hatfield graduated from U.B.C. in 1928 and two years later joined the Interior Contracting Company at Penticton. He worked with this company until 1958, by which time he had become President and Superintendent. He now is a consulting engineer. During World War II, Mr. Hatfield spent a year with the RCAF, and from 1941 until 1945 acted as Service and Works Engineer with the RCE at Petawawa, Barriefield and Chilliwack. Mr. Hatfield is a former Chairman of the Central British Columbia Branch.

Lloyd Williams, M.E.I.C., new Councillor for Kootenay, is Assistant Manager, Engineering Division, The Consolidated Mining and Smelting Company of Canada Limited at Trail. Mr. Williams has been an executive member of the Kootenay Branch for the past three years. He is a member of A.P.E.B.C. He is Reeve of the Municipality of Tadanac and is active in Chamber of Commerce affairs, and local sports activities. Mr. Williams has had several papers published on Cominco operations and practice.

L. Williams, M.E.I.C.

R. H. Wallace, M.E.I.C.

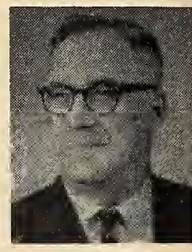
R. H. Wallaee, M.E.I.C., Councillor for Brockville, received his B.Sc. from McGill in 1926. He is Chief Engineer of the Canada Starch Co. Ltd. at Cardinal. Mr. Wallace has the distinction of serving as Chairman of both the Cornwall and Brockville Branches.

T. E. Flinn, M.E.I.C., Councillor for Belleville is an Operations Engineer with Ontario Hydro. Mr. Flinn was a member of the Branch executive 1953-58, served as Chairman of the Branch Professional Developments Committee 1954-56, and was Branch Chairman in 1958-59.

C. E. L. Hunt, JR.E.I.C., Councillor for Chalk River, is Loop Development Engineer for Atomic Energy of Canada Ltd., Mr. Hunt was Program Chairman of the Chalk River Branch 1958-59, and was Branch Chairman 1959-60.

S. D. Lash, M.E.I.C. was chosen Councillor for Kingston. Dr. Lash is Head of the Department of Civil Engineering at Queen's University. He reeeived his B.Sc. London in 1928, MSc. London 1929 and his Ph.D. from University of Birmingham in 1933. Dr. Lash was ehairman of the Kingston Branch in 1944, 1945. He is a member of the Bridge and Structural Sub-Committee of the Institute's Committee on Technical Operations. He is past Chairman of the City of Kingston Planning Board. Dr. Lash has had six papers published in the Engineering Journal and in 1941 was awarded the Gzowski Medal.

S. D. Lash, M.E.I.C.



D. B. McKillop, M.E.I.C.

D. B. MeKillop, M.E.I.C., who was re-elected Councillor for the Lakchead Branch is Area Engineer for the Canadian National Railways in Fort William. Mr. McKillop became a student member of the Institute in 1929, the year he graduated from Queen's University. He was Chairman of the Lakehead Branch in 1958 and was elected Councillor the following year. Mr. McKillop is a Commissioner of the Lakehead Harbour Commision, a member of the Fort William Library Board, and chairman of the Thunder Bay Field Naturalists.

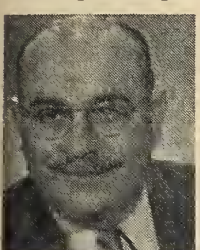
V. A. Ainsworth, M.E.I.C., Councillor for Newfoundland, is General Manager of Newfoundland Light and Power Co. Ltd., at St. John's. Mr. Ainsworth became a Member of the Institute 19 years ago.

A. S. Mitchell, M.E.I.C., re-elected Councillor for the Eastern Township, was born and educated in Montreal. He graduated from McGill University (Honours) Metallurgy, in 1938 and was awarded the A.S.M. Prize for Metallography and Thesis. Previous to joining The Union Screen Plate Company of Canada (Limited) Mr. Mitchell worked with International Nickel Company and Consolidated Mining & Smelting Company. Mr. Mitchell was plating engineer for Union Screen in 1941-42, General Superintendent in 1942-43, Works Manager, 1953-59, and was appointed Sales Manager in 1959. He has served as Treasurer of the Eastern Townships Branches of the E.I.C. and C.P.E.Q. and was elected member of Council for the town of Lennoxville.

S. B. Cassidy, M.E.I.C., was re-elected Councillor for Fredericton for a third successive term. Mr. Cassidy, a communications and electrical contractor, was born at Sussex, N.B. He received his B.Sc. degree from U.N.B. in 1933 and six years later earned his M.Sc. From 1933 until 1939 he was engaged in geophysical work with the New Brunswick Gas and Oil Field and was then appointed chief engineer with radio station C.F.N.B. In 1946 Mr. Cassidy entered his present business. Apart from his engineering work, Mr. Cassidy owns a restaurant, a hardware store and a service station. Last year Mr. Cassidy was appointed Chairman of the Institute's Committee on Membership.

J. F. Chantler, M.E.I.C., Councillor for Nipissing and Upper Ottawa, is Mill Manager for Canadian International Paper at Temiscaming, Que. Mr. Chantler was Branch Chairman in 1957-58.

Harry A. Gadd, M.E.I.C., re-elected Councillor for Port Hope, followed his engineering studies in England. This included an engineering course at Rugby College of Technology and mechanical apprenticeship at British Thompson-Houston Company, Rugby. Mr. Gadd came to the Canadian General Electric Company Limited in Toronto in 1923 and has been employed since then by C.G.E. His activities include manufacturing, sales and engineering assignments. He now is manager, plastics engineering, C.G.E. plastics plant at Cobourg.



H. A. Gadd, M.E.I.C.

W. B. Ibbotson, M.E.I.C.

W. B. Ibbotson, M.E.I.C., Councillor for Sudbury, received his B.Sc. from the University of Manitoba in 1925. He is Master Mechanic of Reduction Plants for the International Nickel Company of Canada Ltd. at Copper Cliff. Mr. Ibbotson was Chairman of Sudbury Branch in 1958-59, and has served as Chairman of the Education Committee and the Papers and Publicity Committee. Active in community affairs, Mr. Ibbotson has served as member of the Copper Cliff Library Board, the High School Board, and the Technical School Advisory Committee of Sudbury.

Emil Bodmer, M.E.I.C., re-elected Councillor for Baie Comeau, is Maintenance Engineer for the Quebec North Shore Paper Company. He received his degree in Mechanical Engineering from the University at Burgdorf, Switzerland in 1944. He graduated with distinction, earning the highest marks of all 1944 graduates. Mr. Bodmer was a founder of the Baie Comeau Branch and has served as Branch Secretary, Chairman, and as a member of the Organization Committee. He is active in local church affairs.

R. W. Pryer, M.E.I.C., Councillor for North Shore Lower St. Lawrence is Soils Engineer with Quebec North Shore and Labrador Railway at Sept-Iles. He received his Bachelors degree from McGill in 1950 and his Master's from Purdue in 1958. He served as Branch Chairman in 1960-61.

J. U. Moreau, M.E.I.C.

J. U. Moreau, M.E.I.C., Councillor for the St. Maurice Valley, is a principal in the Trois-Rivieres Consulting Engineers firm of J. U. Moreau and Associates. He became a Student Member of the Institute in 1947, the year before he graduated from McGill. He was Chairman of the Junior Section of the St. Maurice branch in 1951-52, and was Branch Chairman in 1956-57. He is a member of the Club Richelieu in Trois Rivieres and is a past Director of the Trois Rivieres Chamber of Commerce.

J. W. Wilson, M.E.I.C., Councillor for Amherst, is Branch Manager of Armco Drainage and Metal Products of Canada Limited at Sackville, N.B. Educated at University of Toronto Mr. Wilson became a full member of the Institute in 1956. He was Chairman of the Amherst District Branch in 1958. Mr. Wilson was President of the Sackville Board of Trade in 1960-61, and President of the Sackville Rotary Club in 1958-59.

J. W. Wilson, M.E.I.C.

J. W. G. Scott, M.E.I.C.

J. W. G. Scott, M.E.I.C., Councillor for Saint John, N.B., is employed by the Standard Dredging Co. Ltd., at Lancaster, N.B. He was educated at U.N.B. where he received his B.Sc. (Civil) in 1949. Mr. Scott served as Secretary-Treasurer of the Saint John Branch and was elected Chairman in 1959. He is a member of the A.P.E.N.B., of the Westfield Golf Club and of the Thistle Curling Club.

H. B. Carter, M.E.I.C., Councillor for Corner Brook, is Plant Engineer of Bowater's Newfoundland Pulp and Paper Mills, Ltd. A graduate of McGill, Mr. Carter served one term as Councillor and has been active in Branch activities. He is a past-President of the Association of Professional Engineers of Newfoundland and is Vice-Chairman of the Corner Brook Public School Board.

W. J. Phillips, M.E.I.C., Councillor for Halifax, is Electrical Engineer for the Nova Scotia Light and Power Company, Ltd. An N.S.T.C. graduate, Mr. Phillips joined the Institute as a Student Member in 1947. In Halifax Branch activities he served three years on the Professional Development Committee, one as Chairman, was a member of the executive for four years including one term as Vice-Chairman and another as Chairman. He is a member of the AP.E.N.S., and of the Bluenose Chapter of I.E.S. where he served one term as Chairman. Interests, besides his family, include photography, stamps, books and all sports.

J. R. Menard, M.E.I.C., re-elected Councillor for the Lower St. Lawrence, is a principal of the Rimouski Consulting Engineers firm of Menard and Marsan. He joined the Institute as a Student Member in 1942, the year before graduating from the University of Montreal. Mr. Menard was Secretary of the Lower St. Lawrence branch 1951-55 and was Chairman in 1956-57. He was National Director of the Junior Chamber of Commerce in 1954 and last year was

Why this power-operated diaphragm valve is so versatile...economical

The Grinnell double-acting air motor teams up with the Grinnell-Saunders* Diaphragm Valve to provide a power-operated valve that's versatile and economical! What's more, the "Grinnell" name on each part assures you of the highest quality throughout the completed unit. Available in a range of motor sizes for ½″ through 6″ valves. For details, write Grinnell Company of Canada Ltd. — Edmonton, Montreal, Toronto, Vancouver, Winnipeg.

You get a wide choice of accessories too!

- Handwheel closing device
- Positioner
- Adjustable travel stop
- Adjustable opening stop
- Position indicator
- Microswitches

'. E. P. Duncan, M.E.I.C. (Glasgow '13), ›neral manager subway construction ith the Toronto Transit commission, as retired. Mr. Duncan, who has been ith the TTC for 40 years, will, howver, still be connected with the onstruction of the subway. He has een appointed general consultant on ıe construction of the University Ave. ıbway and will see the first phase ırough to operational stage in 1963. W. [. Patterson, M.E.I.C. (Queen's '35), is) succeed Mr. Duncan. Mr. Patterson as been the Commission's chief engieer for the past 12 years.

:harles W. Nash, M.E.I.C. (Wash. State :oll. '23), has been elected president of he B.C. Natural Resources Conference. Ir. Nash is director of load developıent.

. E. Cranswick, M.E.I.C. (Man. '29), has een elected vice president, wholesale livision, Canadian Westinghouse Comany. The division is engaged in the narketing of a broad range of light lectrical apparatus products to power ıtilities, contractors and institutional ustomers.

George L. Macpherson, M.E.I.C. (Toonto '20), has retired from the Board of Directors of Imperial Oil Limited. Mr. Macpherson became a director in 1954 and was formerly general manager of Imperial's manufacturing department.

J. M. Paquet, M.E.I.C. (Poly. '34), has opened his office as consulting engineer, mechanical and electrical in Quebec City. The office operates under the name of Paquet and Dutil, Consulting Engineers.

Joseph D. Dexter, M.E.I.C. (MeGill '32), has been appointed chief engineer, Bowaters Mersey Paper Company Limited. In 1941 Mr. Dexter was commissioned as an aeronautieal engineer in the R.C.A.F. Following the war he was appointed senior engineer with the company and in 1950 was appointed assistant chief engineer.

Dr. Arthur Porter, M.E.I.C. (Manchester '34), Dean of the College of Engineering at the University of Saskatchewan, has been appointed First Professor of Industrial Engineering at the University of Toronto. Dr. Porter was head of the research department at Ferranti Electrical Company in 1949 and returned to England in 1955 to become professor of Light Electrical Engineering at the Imperial College of Science and Technology, University of London. He joined the University of Saskatchewan in 1958 and was responsible for the introduction of engineering science courses for students of superior intelligence. He has directed a program of research at the University concerned with studies of the learning process in man and machines, the collaboration between engineering and medical scientists.

J. S. Waddington, M.E.I.C.

J. S. Waddington, M.E.I.C. (Man. '34), has been appointed a vice-president, Phillips Electrical Company Limited. In this position Mr. Waddington will be responsble for the operation of the Brockville, Montreal and Vancouver divisions and for overall technical coordination. G. H. Gallimore, M.E.I.C. (Man. '36), has been appointed manager of the Montreal Division. He will be responsible for the manufacture of telephone and power cables by the Company's Montreal plant. Mr. Gallimore joined Phillips in 1939 as sales engineer.

R. E. Tweeddale, M.E.I.C. (U.N.B. '35), has been named "Electrical Man of the Year" for Canada. A plaque representing the National award was presented to Mr. Tweeddale Jan. 24, following the Canadian Electric Association's National Convention luncheon. Each year the plaque is donated by the electrical publications of Hugh C. MacLean Company to the man who, in the opinion of a Committee of Editors, has made the most notable contribution to the progress of the electrical industry in Canada. Mr. Tweeddale was nominated as being responsible for the creation of the Maritime grid linking the electric utilities of New Brunswick and Nova Scotia into one power pool.

Prof. C. G. E. Downing, M.E.I.C. (Sask. '40) and Prof. F. H. Theakston, M.E.I.C., recently attended the International Technical Congress on Agricultural machinery in Paris. Prof. Downing, head of the Ontario Agricultural College department of engineering science, presented a paper at the Congress and Prof. Theakston, director of the Canadian Farm Building Plans Service Centre, studied developments and design of structures and equipment.

David Blair, M.E.I.C. (U.N.B. '46), has been appointed chief engineer, Modern Construction Limited. Mr. Blair formerly spent nearly 15 years with Canadian National Railways, the last six being spent as senior officer in the company's Atlantic Region.

Dr. W. C. Leith, M.E.I.C. (U.B.C. '48, McGill '60), has joined Hydronautics Inc., consultants in hydrodynamics at Rockville, Maryland, where he is specializing in cavitation damage of metals. For the past eight years he was mechanical research engineer with Dominion Engineering Works, Montreal.

B. I. Maduke, M.E.I.C. (Sask. '48, '52, Harvard '52), has been appointed manager of R. M. Hardy and Associates Ltd., Edmonton. Mr. Maduke has had wide and varied experience in the field of soil mechanics and foundation engineering in Quebec, Ontario, British Columbia, the Prairie Provinces and Northern areas.

Douglas H. Cohoon, M.E.I.C. (McGill '49) has been appointed Vice-President and Managing Director of Fry-Cadbury Limited, Montreal.

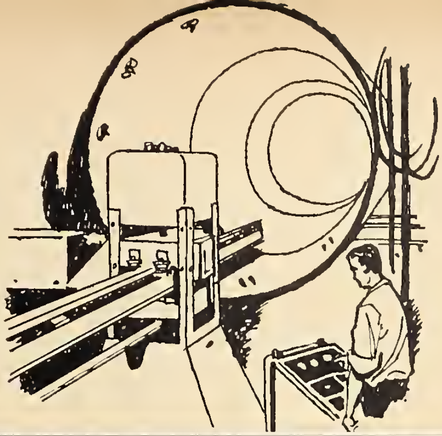
K. M. Mote, M.E.I.C. (Birmingham Central Tech. '49), has returned to Canada and is director and partner of F. and F. Tractor Equipment Limited. The company is at present serving the agricultural field but hopes shortly to cover the industrial field.

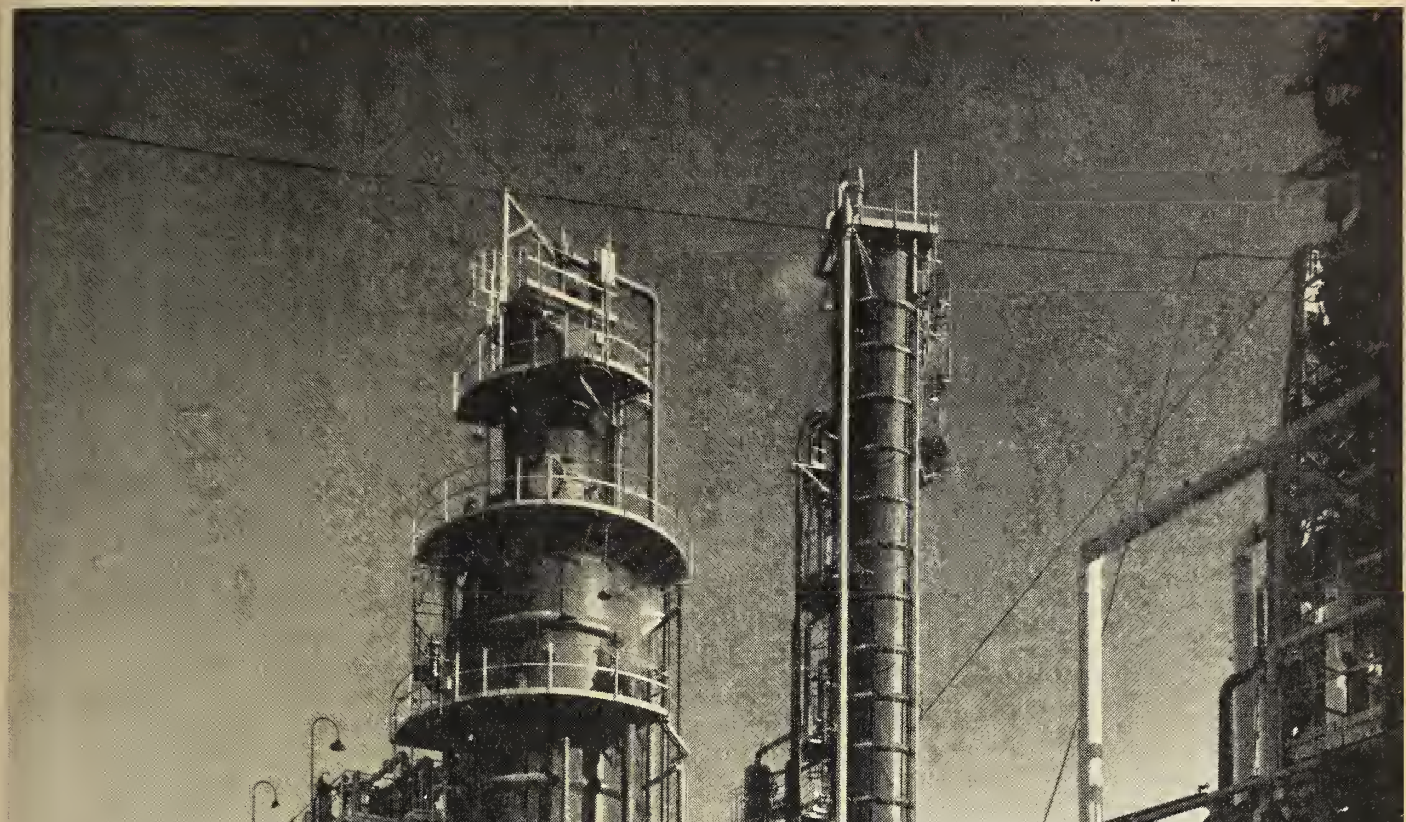
E. F. Holmgren, M.E.I.C. (Alta. '50), has been appointed manager of the Edmonton office of Materials Testing Laboratories Ltd. Mr. Holmgren has had wide experience in the field of concrete technology and concrete problems with ten years' experience in the field of ready mix concrete.

D. C. Cullingham, M.E.I.C. (Toronto '50), has a position with Parsons and Whittemore (France) in connection with the design of a sulphite disolving pulp

(Continued on page 94)

he Tough Ones...





Typical refinery towers. D.B. has a great deal of experience in the fabrication of vessels for the oil and chemical processing industry.

mill. Mr. Cullingham previously assisted in the start up of a pulp mill in Sitka, for the Alaska Lumber and Pulp Company.

Guy A. Hamel, M.E.I.C. (McGill '50), has been appointed technical services manager, Omark Industries Ltd., Guelph, Ont. Mr. Hamel will be in charge of the company's product service functions.

Robert Herdman, M.E.I.C., formerly Plant Engineer at Bowater's Newfoundland Pulp and Paper Mills Limited, has been transferred to Calhoun, Tennessee, where he will assume the position of Assistant to the Chief Engineer with Bowater's Engineering and Development Incorporated.

Jean-Louis Bourret, JR.E.I.C. (Poly. '52), has been elected president of the Quebec Concrete Products Association. Mr. Bourret is at present sales manager for Quebec Ready-Mix Inc. and is a director of the Association des Diplomes de Polytechnique.

E. H. Gilliatt, M.E.I.C. (N.S.T.C. '52), has been appointed assistant general superintendent, transportation, in charge of technical aspects, Great Lakes Region of the C.N.R. Mr. Gilliatt was formerly transportation engineer at Montreal headquarters.

W. Buryniuk, M.E.I.C.

Walter Buryniuk, M.E.I.C. (Sask. '53), is head of a consulting engineering firm in his name with his office in Port Arthur, Ont. Mr. Buryniuk previously worked as resident engineer with C. D. Howe Co. Limited and as assistant park engineer for the Civil Service of Canada in Banff.

R. Vanier, S.E.I.C. (Ecole Poly. '60), has been appointed Assistant City Engineer of City of Outremont.

G. H. Beuker, S.E.I.C. (Sask. '60), has been appointed lighting services supervisor, Saskatchewan Power Corporation, load development department. Mr. Beuker was formerly engineer in the electrical transmission design department.

Obituaries

Ira William Beverly, M.E.I.C. (McGill '18), electrical engineer, died March 5 at Winnipeg. Mr. Beverly was born in Kettle Falls, Washington, U.S.A., and received his education in Canada. He served as a pilot with the Royal Air Force in World War I. In 1926 he took up residence in Winnipeg where he later became Vice-President of Sangamo Company Limited. Mr. Beverly became an associate member in 1939 and became a life member in 1940.

H. H. Cantwell, M.E.I.C. (Union '07), a prominent figure in the pulp and paper industry, died Dec. 1. Mr. Cantwell came to Canada in 1916 and for more than 40 years served the pulp and paper industry in various executive positions. He joined the Institute in 1921 as an associate member and became a member in 1940. He was made a life member in 1957.

Frederick Harris-Lowe, M.E.I.C., died March 3, at St. Catharines, Ont. He was 59. Mr. Harris-Lowe was born in Kent, England and came to Canada in 1922. In 1941 he joined the Royal Canadian Engineers, and served for five years. He was employed by the Ontario Paper Company Limited in 1945, and later became manager of engineering. He held this position until the time of his death. Mr. Harris-Lowe became a member of the Institute in 1959.

Henning Jones Hermanson, M.E.I.C. (Sask. '25). Engineer for the Department of Highways, Province of Newfoundland, died Feb. 24 at St. John's, Nfld.

Mr. Hermanson was born Feb. 26, 1902, in the Parish of Hasjo, Province of Jamtland, Sweden. He received his B.A. and B.Sc. from the University of Saskatchewan.

Mr. Hermanson was employed as resident engineer with the Department of Highways in 1949. He supervised construction of various sections of the Trans Canada Highway between Gambo and Grand Falls, Nfld. He held the position of office engineer at the time of his death.

Mr. Hermanson was a registered engineer in the Province of Saskatchewan where he practiced engineering after his graduation. From 1923 until 1927 he was employed as resident engineer on various construction projects in that Province. From 1928 until 1930 he was a resident engineer on construction of Provincial highways, Province of Saskatchewan. He served as a district engineer for maintenance and constructio for the Saskatchewan Highway Depar ment from 1930 until 1945. Mr. Herman son then held the position of engine for the Campbell-Mannix Company Prince George, B.C. until that compan was dissolved in 1948. Mr. Hermanso then took charge of a reconnaissance su vey for the Department of Mines an Resources, Ottawa, in the Yukon territor between Whitehorse and Dawson City When this project was completed M Hermanson moved to Newfoundland an took a position with the Department o Highways.

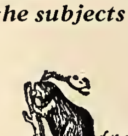
Mr. Hermanson was a charter membe of the Association of Professional Engineers of Newfoundland and a membe of the Association of Professional Engineers of Saskatchewan. He joined the Engineering Institute of Canada as associate member in 1938 and became a full member in 1940.

Colonel Redford Henry Mulock, M.E.I.C., awarded the DSO and bar a Dunkirk, in World War I, died Jan. 23 He was 76. Colonel Mulock was a Commander of the Order of the British Empire and a Chevalier of the Legion of Honor. In 1921 he joined the Canadian Air Force as air commodore. He retired in 1924. Colonel Mulock joined the Institute in 1905 and became an associate member in 1912, he was awarded a life membership in 1954.

Walter Laidlaw Saunders, M.E.I.C., died March 5. He was born in Goderich, Ont., and studied engineering at the University of Toronto. He served as a lieutenant with the 6th Battalion of Canadian Railway Troops in France from 1917 until 1919. He was employed as assistant engineer on construction and maintenance with the Canadian Pacific Railway in Saskatchewan. In 1922 he joined the Department of Highways of Ontario and later became Ottawa division engineer. In 1949 he was transferred to Owen Sound, Ont. as division engineer. Mr. Saunders joined the Institute in 1910 as a student, became a junior in 1913, an associate member in 1920 and was awarded a life membership in 1960. EIC

Beaver Bill says:

Films pep up a meeting! Films are valuable for training! If you are having trouble arranging a program, plan it around a film. The E.I.C. film collection is now being distributed by the Canadian Film Institute, 1762 Carling Avenue, Ottawa, which has a collection of hundreds of films. Write and ask for a list of films on the subjects in which you are interested.



Pyrotenax cables were used as feeds to all floors of the Berkley Towers Apartment Building in Vancouver.

"Pyrotenax" for an apartment building

WHY NOT?

Pyrotenax®

TYPE M.I. CABLES

PYROTENAX OF CANADA LIMITED
PLANT & EXECUTIVE OFFICES
TRENTON, ONTARIO
TEL. EXeter 2-6571

T.M. REG'D.

OFFICES & WAREHOUSES: TORONTO WINNIPEG VANCOUVER

Of course you'll find "Pyrotenax" in a well-planned apartment building, or for that matter, in any well-planned building. "Pyrotenax" is the cable you can install and forget—it comes in its own permanent, integral raceway. And it actually exceeds code requirements, yet costs no more than old fashioned wiring methods. Save time, save money, save worrying about the future—rely on Pyrotenax mineral insulated cables. You can install "Pyrotenax" indoors, outdoors, or buried directly in the ground, in hot or damp locations.

You don't wait for delivery . . . "Pyrotenax" is made in Canada!

The ASME Aviation Conference was held at Los Angeles, March 13-15. Highlights of the meeting included a talk by C. J. Dayle, Thompson Ramo Wooldridge, Inc., about a miniature power plant that works on the same principle as a commercial generating station but is small enough to tuck into an orbiting satellite. Called "Sunflower I", the unit uses the heat of the sun instead of fuel and is designed to power the radios and other equipment in satellites. John W. Marshall, project engineer at Edwards Air Force Base, pointed out in his paper that helium production, centered around Amarillo, Texas, is not expected to meet demand this year. One way to conserve supplies, he contended, was to avoid losses in shipment by supercooling the helium to 452 degrees below zero F. where it becomes a liquid. Helium gas is now shipped in tanks under heavy pressure. D. B. Mackay, research specialist, North American Aviation, Inc. gave a paper and explored several possible refrigeration systems on the moon and discussed their relative advantages and disadvantages. Another speaker at the conference, Robert Z. Snyder, Aviation Medical Acceleration Laboratory, told aviation specialists of the tests performed on a human centrifuge to make sure pilots could control a new U.S. Navy aircraft even if the plane should slip into a spin.

American Society for Testing Materials

A three-day symposium on materials and electron device processing was held April 5-7, in Philadelphia. Subjects covered in the 35 papers included control of ultraclean device assembly areas, new techniques for the detection of trace contaminants, advanced device cleaning processes and reports on the effects of such cleaning on device performance. Also included were discussions of the characterization and control of gaseous and vacuum processing ambients, as well as safe handling practices and uses of beryllia ceramics.

Canadian Construction Association

The Association presented a brief on behalf of the construction industry of Canada to Prime Minister Diefenbaker and Federal Cabinet members March 21. C.C.A. President Arthur G. Sullivan headed the delegation.

The submission was based on the Statement of Policy and Resolutions passed at the C.C.A.'s 43rd Annual Meeting and endorsed by 59 affiliated construction organizations. Recommendations were made on the many facets of importance and concern to the industry including bidding and contract procedures, labour relations, apprenticeship, housing, taxes and tariffs and wintertime construction. The brief also outlined the Association's National Highways Policy and acquainted the Cabinet with its proposals designed to increase employment.

The Chemical Institute of Canada

The C.I.C. has established a committee to implement its program to certify suitably qualified chemical technicians. While the Institute is providing the machinery for dealing with certification procedures, it is hoped that ultimately

The Associations and Corporation

C. P. E. Q.

The 42nd Annual General Meeting of the Corporation of Professional Engineers was held at the Queen Elizabeth Hotel in Montreal, April 8.

During the meeting, A. J. Groleau, Vice-President of the Bell Telephone Company of Canada, was elected President of the Corporation, succeeding Arthur Piche of Quebec City.

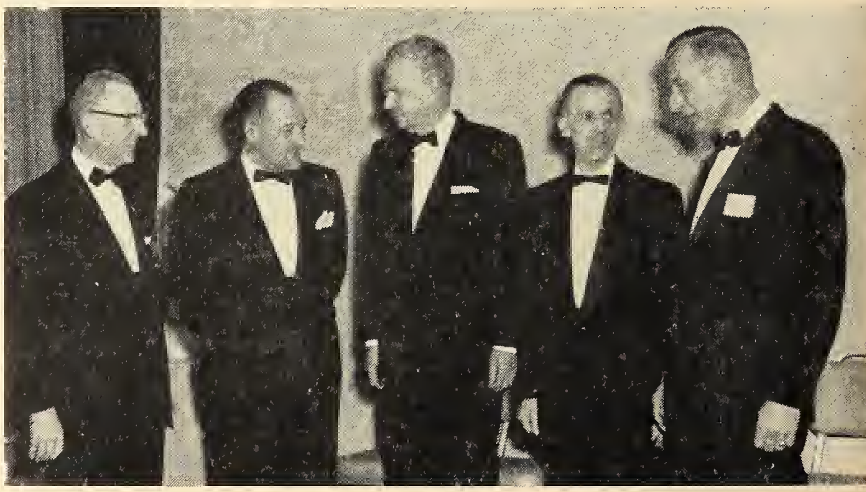
Gilles Sarault, consulting engineer of Quebec City, was elected Vice President, and H. J. Racey, consulting engineer of Montreal, was re-elected honorary Secretary-Treasurer of the Corporation.

R. A. Phillips of Montreal, Manager of Marketing for Canadian General Electric, was elected to Council. Mr. Phillips replaces W. J. Riley of Montreal who preceded Mr. Piche as Corporation President.

Prime Minister Diefenbaker, the guest speaker at the banquet, was presented with a certificate of honorary membership in the Corporation. This was only the third honorary membership awarded in the Corporation's history. The two others were the late Hon. C. D. Howe and the late Premier Maurice Duplessis.

Approximately 1,000 persons attended the banquet which followed the afternoon meeting which dealt with internal business.

Shown at the Annual Meeting of the C.P.E.Q. are, from the left: Dr. George McK. Dick, E.I.C. President; A. J. Groleau, C.P.E.Q. President-elect; Mr. Diefenbaker; Arthur Piche, C.P.E.Q. immediate past-President; L. C. Sentanee, A.P.E.O. President.



● OTHER SOCIETIES

the qualified technicians will assist in carrying on this program through an independent body.

Various governmental, industrial and educational groups have given warm support to this program which is designed to provide a method of uniformly assessing and grading the qualifications of technicians with widely diverse backgrounds. The Chairman of the committee is Dr. W. G. Hines.

Illuminating Engineering Society

The 17th Canadian Regional Conference is being held at the Queen Elizabeth Hotel, Montreal, May 14-16. The Society will focus on improvements and trends in office, home, school and industrial lighting techniques. The agenda will include papers dealing with "Municipal Lighting in Montreal", "Bridge Rail Lighting", "Economic Comparisons of Various Fluorescent Industrial Lighting Systems" and "Atmosphere Lighting in the New Vanguard Aircraft". The general chairman of the conference committee is J. P. Cristel, M.E.I.C., of the Shawinigan Water and Power Company.

The Institute of Radio Engineers

The Toronto Section held a meeting at the University of Toronto, April 3. Mr. G. W. Steck, Manager, Communications Product Sales, Westrex Corporation, New York, gave a talk "Command and Dispatch Consoles for Mobile and Point to Point Systems." Mr. Steck described the electrical and mechanical design and human engineering aspects of complex command and dispatch systems for single or multi-operator use in utility, police, fire or civil defence radio systems. At a meeting held April 2 L. Casciato, Traffic Research Corporation Limited, gave a talk entitled "Controlling Traffic in Metropolitan Toronto with an Electronic Computer".

Instrument Society of America

ISA is holding its first Canadian International Conference and Exhibit in Toronto June 5-8. Headquarters for the Conference June 5-8, will be the Royal York Hotel. The Exhibit, June 6-8, will be in the Queen Elizabeth Hall at Exhibition Park.

Twelve Conference sessions are planned with approximately 35 papers. Commencing Monday there will be a Management Day Program with two sessions planned on "Industrial Instrumentation — The Impact of Computers". Other sessions include Power Plant Instrumentation; Pulp and Paper; Underwater Instrumentation; Feedback Control Systems; Chemical and Petroleum; Analysis Instrumentation; Measurement and Control Data Handling and Computation. Over 100 exhibitors are expected. Featured will be a wide range of instrumentation, data handling and computation equipment.

Coming Events

- Annual Meeting, American Society of Tool and Manufacturing Engineers, New York, May 22-26.
- Annual Meeting, Canadian Society of Plant Physiologists, Ottawa, May 24-26.
- Annual General Meeting, Canadian Aeronautical Institute, Toronto, May 25-26.
- 75th Annual General and Professional Meeting, Engineering Institute of Canada, Vancouver, May 31-June 2.
- 11th Annual Meeting, Canadian Association of Geographers, Montreal, June 1-3.
- Summer Instrument Automation Conference and Exhibit, Instrument Society of America, Toronto, June 5-8.
- General Assembly, International Organization for Standardization, Helsinki, June 5-16.
- Summer Meeting of the Technical Section, Canadian Pulp and Paper Association, Saranac Lake, N.Y., June 7-9.
- Annual Meeting, Canadian Council of Professional Engineers, Edmonton, June 7-9.
- 16th Annual Congress, Canadian Association of Physicists, Montreal, June 7-10.
- Summer Annual Meeting, American Society of Mechanical Engineers, Los Angeles, June 11-15.
- Eighth International Nuclear Congress and Exhibition on Electronics and Atomic Energy, Rome, June 15-29.
- Annual Meeting, Canadian Electrical Association, Banff, Alta., June 26-28.
- Annual Meeting and Convention, Agricultural Institute of Canada, Regina, June 26-29. EIC

News of the Branches

At a meeting held Feb. 1 members heard an interesting talk on "Underwater Diving Operations". International Underwater Contractors Limited is the Canadian associate of the parent French oganization, Société Génerale de Travaux Maritimes et Fleveaux, or as it is better known, 'Sogetram'—the world's only international organization of professional frogmen. Representing International Underwater Contractors were F. Dreville, M.E.I.C., Montreal manager, and Tech. Diver Hervé Lallier.

Mr. Lallier briefly described the rigorous training and exacting requirements necessary in the make up of the professional frogman. The activities of the company were effectively illustrated by two color films entitled "White Island Lighthouse" and "Wreck Buster".

At a meeting held March 23, J. C. Dykes, M.E.I.C., Instrument Engineer, Dominion Tar and Chemical Company Ltd., gave a talk on "Instrumentation". In his address, illustrated by slides, Mr. Dykes described a typical flow process operation in the pulp and paper industry with a view to indicating the scope and responsibilities involved in the work of the instrumentation engineer towards establishing quantity and quality control. He also gave an outline of the prominent part the instrumentation engineer now has to play in establishing the design details in a new industrial plant particularly where the process is one involving continuous fluid flow. The extent to which instrumentation can be a major economic factor in plant work was shown by Mr. Dykes' observation that in the petrochemical industry instrumentation may amount to 12% of the total cost of the project.

Topic of a March 13 address by E. J. Jones, Aerial Survey Mapping Branch, Dept. of Mines and Technical Surveys, was "Air Survey and Mapping Work".

With the exception of two areas, all of Canada has been aerially photographed for map work and topographic maps are available in many scales. The two areas are to be photographed during the next few years. Oceanography staff are being trained and the number of staff is being increased. The Polar Continental Shelf is being investigated to determine natural resources as well as all mapping survey data. Mr. Jones was introduced by T. J. McQuaid and was thanked by W. Benger.

Fifteen senior Mechanical Engineering students from Nova Scotia Technical College with Professor Ahern of the Mechanical Engineering Faculty were guests at the March 17 meeting. Purpose of their visit was a tour of the Sydney works of the Dominion Steel & Coal Corp., Ltd. During the few hours they spent there they viewed various operations and departments including the blast furnace, open hearth furnace, heavy mills, rod and bar mill, wire and nail departments and the coke plant. Several of the guides were Branch members employed by DOSCO.

In the evening the visitors were guests at a smoker attended by 40 members. They were welcomed by Rod Bradlev, Branch Chairman, who expressed the hope that future Mechanical Engineering classes would be able to tour the plant. Following a buffet supper the film "The Dosco Story" was shown. Harry Leonard, spokesman for the student visitors, expressed their thanks to the Branch members.

"Instrument Engineering" was the title of a talk given by J. T. Dykes, M.E.I.C., at the March 2 meeting. Mr. Dykes introduced his subject by explaining the duties of an instrument engineer. He discussed instrument engineering in general, covering such subjects as circuitry and plant wide methods of indexing instrument components. The amount of instrumentation justified on a typical plant installation was thoroughly covered. The question and answer period was lively with questions centering on the relative merits of the various systems used to identify and index instrument components and systems.

Graduating engineers from the Nova Scotia Technical College were guests of the Branch at a reception and dinner held at the Jubilee Boat Club, March 7. Seventy-two members and 127 students participated. Highlight of the evening was a panel discussion on the theme of "What Industry Expects from the Engineering Graduates". Leading the discussion were F. Dean, Dominion Structural Steel, M. J. Magman, Imperial Oil, A. R. Harrington, Nova Scotia Light and Power, and H. C. McGee, Canadian General Electric. The Panel pointed out that graduating students were presumed to have a good technical knowledge; what the graduate lacked was knowledge of how to adapt and sell his training, training in personnel management, a knowledge of financing and a knowledge of markets. A knowledge of all these matters is essential before the graduate can realize his full potential in business life. The necessity for continued study to keep abreast of current technical and other developments was emphasized.

Hamilton

P. J. McNally, M.E.I.C.,
Chairman

A meeting was held with the McMaster University engineering society Feb. 9 with Dr. W. W. Sawyer as principal speaker. Dr. Sawyer spoke of the erroneous tendency to teach and learn by note rather than by illustration and simple reasoning. He gave mathematical examples of the two methods. However, it was clearly indicated that the improved methods could be applied equally to all branches of learning. Edgar A. Cross gave an interesting history of the growth of engineering, particularly of engineering societies.

At the March 9 meeting, Mr. Marsh

of the Aluminum Company of Canada, spoke to members at the Argyll and Sutherland Highlander's Officers Mess. Mr. Marsh talked of some recently appreciated structural properties of aluminum. His talk was illustrated with slides showing many new and engineered uses of aluminum sheets and structural shapes.

An "Industrial Problems Night" was featured at the March 15 meeting. Thirty-eight members and guests heard problems discussed by A. K. Sneddan, Aluminum Company of Canada, H. W. Legere, Du Pont of Canada and R. O. Moore, Canadian Industries Limited. Respective topics of discussion were "Examination of the Conditions of Extrusion Press Tie Rods", "Fire Hazard Considerations in the Use of Flammable Heat Transfer Mediums", and "Determination of Cause of Low Flow in Raw Water Intake Line".

Lower St. Lawrence

Marcel Carrier, M.E.I.C.,

Roger J. Paquin, Managing-Director of Quebec Terminal Limited was guest speaker at a meeting held Jan. 23. His topic was problems of winter navigation. At the March 21 meeting, Leslie Orr, Chief Chemist for the Imperial Oil Refineries, gave a talk on petroliferous operations and products extracted from crude oil. An interesting film illustrated his talk on various stages of oil refining.

The annual Memorial University of Newfoundland Engineering Student Speech Night was held March 27 at the auditorium of the Newfoundland Light and Power Company. This affair is conducted to award a $50 prize to the engineering student who gives the best speech as judged by the E.I.C. members in the audience. Three of the finalists of the University engineering seminar program were selected by the Engineering faculty to compete for the prize.

This year's winner was William W. Johnston, a second year engineering student who plans to take Civil Engineering at the University of Toronto. His speech, titled "A Metropolitan Dilemma" dealt with some of our local motor vehicle traffic problems as well as those faced by the major cities in Canada.

The runners-up were Leblan Davis who spoke on "The Decca Navigation System" and Rod Chafe whose talk was entitled "Exploration in Newfoundland for Peat Moss". Both are second year engineering students who plan to attend Nova Scotia Technical College after obtaining their engineering diplomas from Memorial.

The report of the nominating committee, presented at the conclusion of the meeting, was approved by the members.

Ottawa

M. Bozozuk, JR.E.I.C.,
Sec./Treas.

The Junior Section held their "Papers' Night", March 9. Forty engineers and students attended. The judges were Colonel W. A. Capelle, M.E.I.C., Department of National Defence, J. N. Pritchard, M.E.I.C., Waterworks Department of the City of Ottawa, and J. S. Watt, M.E.I.C., National Harbours Board.

Colonel Capelle summarized the papers presented and offered helpful criticisms to the speakers. G. B. Williams, M.E.I.C., Deputy Minister of the Department of Public Works, presented the prizes. First and second prize winners in the Junior Section were H. J. Thorburn and T. M. Dick, respectively. Of the students, G. Saunders and E. Edelson were awarded first and second prizes respectively.

At a joint meeting held with the Chemical Institute of Canada March 15, Dr. I. A. Johnson gave a talk on "Analog Computers". He dealt with the typical problems that are found in industry that can be solved using analog computers. Typical problems were discussed and a differential equation written for its solution. Dr. Johnson went on to outline how computers are programed. He concluded his talk by showing a short film.

Four technical meetings were held in March.

Dr. A. R. Anderson addressed the branch March 7. The subject of his talk was "Recent advances in Prestressed Concrete." Dr. Anderson is a co-founder of the Concrete Technology Corp. in Tacoma, Washington. This organization specializes in research technology, product development and the production of high strength concrete precast and prestressed structural members.

"Management Responsibility" was the subject of the speech given at the March 14 meeting. E. C. Roper who gave the talk is an Instructor at the Dept. of Commerce, U.B.C. He has a wide experience in management as he has been President of the Howe Sound Co., Manager of Britania Mining and Smelting Co. and is a past president of the Mining Association of B.C.

Two speakers, A. MacDougal and J. Carrigan, discussed "Cranberry Creek Hydro Electric Project, Revelstoke, B.C." at the March 21 meeting. This project, which has been recently completed is an excellent example of a small hydro electric facility specifically designed for local needs. The talks were illustrated with slides.

Heinz J. Heinrich came from Montreal especially to talk to the members on "Airline Maintenance in the Jet Age—An Economic Challenge for Technical Management". This address was the highlight of the March 28 meeting. Mr. Heinrich is Superintendent of Planning at Dorval for Trans-Canada Air Lines. He has been with this company for 17 years and has served as Chairman of International Air Transport Association of America, Production Planning Committees. Mr. Heinrich has spoken at various international management conferences and is the author of articles on Planning and Aviation. He is a Consultant to the aviation industry, The Royal Canadian Air Force, and the United States Air Force.

The annual Student Night was held March 16 at the Pembina Hotel, gave members the opportunity to the Student Section members from University of Manitoba. Chairman Dr. C. S. London.

Following dinner the program with presentation of Summer T Prizes of $10 and bronze me Dean A. E. Macdonald gave the i duction. Prof. W. F. Riddell pres James Cran, winner of the best Engineering thesis; Prof. J. P. C. Mc presented Garnet Ward, winner in Electric Department; Prof. R. E. C presented Rudy Kaethler, winner in Mechanical Department. Dean A. Macdonald then presented the A.S. book prizes and memberships to following: A. M. Lansdowne, J. A. C K. M. Postgate, W. H. Lehn and F Finlay.
